PPs *see* prepositional phrases (PPs)
pragmatics
and Chinese *ba*, I.376, I.417–32, I.451
and existential questions, V.392, V.406
Prague School, II.279
Prakrit, II.485
Predicate Agglutination, I.326
Predicate Argument Structure (PAS), IV.469, IV.472
predicate cleft (P-cleft), IV.450–1
predicate fronting, II.185
Predicate Internal Subject Hypothesis, IV.71, IV.72, IV.78
predicate movement, and Condition C, IV.78–84
predicate nominals, existential polarity items as, III.376–80
predicates
assertive, II.188–9
co-arguments, III.187, III.189
and middle formation, III.164
and reflexivity, I.266–9
see also complex predicates; depictive predicates; secondary predicates
predicate–argument relations, IV.40, IV.47, IV.59, IV.63, IV.69–72
predication, IV.181
dominance relations, II.75, II.122–3
restrictions, IV.331–3
Rothstein's theories, IV.216
Williams's theory, IV.215–16
see also secondary predication
Predication hypothesis, of inalienable possession, II.605–9
Predication Principle, I.292
predicational copular sentences
interpretive properties, IV.326–9
and specificational copular sentences compared, IV.311–29
syntactic properties, IV.311–26
typological issues, IV.296–304
predicative raising, in copular sentences, II.12–14, II.18–19
prelexical transformation, I.297, I.300–2
premise-conditionals *see* conditionals, factual
preposition drop, in topic structures in Chinese, V.163
preposition stranding, I.626, II.89, II.388, II.401, III.169, III.631–84
under A-movement, III.648, III.650, III.653–61

preposition stranding (*cont'd*)
under A'-movement, III.632–3, III.648, III.649–53
analyses of extraposition, II.154–8, II.241, II.251–3, II.263–5
Case-theoretic approach, III.638
D-to-P incorporation
analysis, III.645–61
lack, III.661–9
from specifier position, III.669–71
government-theoretic approach, III.640–5
lack of in Romance, III.632
possibilities, III.632–3
reanalysis approach, III.638–40
and sluicing, IV.274–6
syntactic constraints, III.633–7
syntax–morphology–interface condition, III.647–8
use of term, III.631–2
prepositional complementizers (P-complementizers), III.641–3, III.647–8
prepositional objects, c-command restriction, IV.221–2
prepositional phrase substitution (locative inversion), II.181, II.185
prepositional phrases (PPs)
pied-piping, III.603–5, IV.330–1, IV.369–70
in verb projection raising, V.281–4
prepositions
morphological relation to adverbs, I.86, I.88
and object shift blocking, III.397–401
and verb particle constructions, V.370–1
preverbal focus languages, Hungarian, II.276–8, II.282–3, II.287–8, II.290–1
preverbal pronoun restrictions, and complex inversion, IV.622–3
Prince, Alan, II.318, III.298, IV.687
Prince, Ellen F., II.279, IV.94–5, IV.310, IV.327, IV.351
Principense, serial verb constructions, IV.263
Principle A, II.147, II.246, II.565, III.187, III.215, IV.128
violations, IV.141–2
Principle B, II.147, II.155, II.246, II.565, IV.103, IV.104, IV.637
violations, IV.621, IV.636
Principle C, II.147, II.220, II.240, II.259, II.565, III.215, IV.364–5, IV.396
violations, IV.132, IV.636, IV.637
Principle of Unambiguous Domination (PUD), IV.437
Principles and Parameters Approach (PPA), II.624, III.281, III.282–3, III.307, III.575, III.707, III.710, III.713, III.714, IV.544, IV.545–6
assumptions, III.692–3
and case in Japanese, I.298, I.300, I.304, I.311, I.365
and clitic doubling, I.521
and copular sentences, II.14–16
and double object constructions, II.117, II.127
and ellipsis in NP, II.146
empty categories, II.146, II.155–69
existential sentences, II.211, II.216
no rule of passivization, I.167
and pied-piping, III.571
and reconstruction, IV.40, IV.59, IV.84, IV.86
and Superiority effects, III.296–8
theta positions, I.299, I.303
Prinzhorn, Martin, III.654, V.320, V.323
Prior, Arthur, V.96, V.123
PRO
in canonical binding theory (Chomsky 1981), I.270
generic or arbitrary construal, II.597
and passive SE unergatives, IV.160–1
and secondary predication, IV.213–14, IV.216–18, IV.219
as empty category in free relatives, II.348–9
as a null predicate, II.16–17, II.18
and subject clitics, IV.611–13
pro
empty VP in ellipsis, II.155
see also null subjects
pro heads, identification, III.601–3

Praise for *The Blackwell Companion to Syntax*, Volumes I–V

"When I first started studying linguistics in 1960 it was possible for an assiduous student to read almost everything in the field. The success of the discipline has meant that those happy days are, happily, gone forever. Syntax is now so big that no one can read even a fraction of what is on offer. There have been two unfortunate results: first, today's syntacticians keep rediscovering old facts, often reinventing eccentric wheels; second, they keep complaining that other linguists ignore their work. The usual excuses are that the material we ought to have referred to is distributed, seemingly at random, among hundreds of books and articles; life is finite; institutional pressures are unrelenting; and it is hard enough keeping up with work done in one's own framework on one's own area of special interest, without trying to see what rival theorists in adjacent areas might have had to say on the matter at hand, however relevant in the long term their contribution might be.

Such excuses will no longer do. *The Blackwell Companion to Syntax* provides a comprehensive overview of the progress and achievements made in syntax over the last 35 years. A galaxy of international stars under the leadership of two distinguished linguists, Martin Everaert and Henk van Riemsdijk, has constructed an unparalleled and monumental survey of empirical facts and theoretical insights covering the entire field. Whether you are interested in parasitic gaps, Icelandic logophors, or quantifier scope ambiguity, you will find here the essential background to your own contribution. This is a major achievement and the Companion will rapidly become essential reading for all serious linguists."

Neil Smith, University College London

"*The Blackwell Companion to Syntax*, unique in character and designed with great skill and care, is sure to be a rich source of high-quality information on critically important topics, and an invaluable research tool for the study of language."

Noam Chomsky, Massachusetts Institute of Technology

"For any serious researcher interested in theoretical linguistics, this incredible companion will remain an important and extremely useful source of reference for years to come."

Yukio Otsu, Keio University, Tokyo

"The flow of linguistic theory is shaped by the empirical puzzles of the rocks and the banks of the river bed. Any particular rock will have different effects at different points in the river. This Companion assembles the empirical puzzles and that is an enormously valuable service: it enables readers to understand why particular puzzles were of interest at particular stages in the development of theory and it assembles the puzzles into a compendium, in the belief that puzzles need solutions at every point in the development of theory, even if the shape of the solutions changes significantly at different stages of theoretical development.

The compendium of puzzles will be a great resource for young investigators, joining the river at some point and wanting to know what was upstream as they find their way downstream."

David Lightfoot, Directorate for Social, Behavioral and Economic Sciences, National Science Foundation, Arlington, VA

"Looking for a topic to work on? Grab *The Blackwell Companion to Syntax* and read some articles there. Or you may try to think of a topic not covered (if that is possible). Either way, this five-volume set should be within your reach if you want to be an active researcher."

Akira Watanabe, University of Tokyo

"In a rapidly moving field, it is essential to have an accessible repository of the empirical generalizations that fueled the theoretical debates. These generalizations have not only a historical value. It is often the case that the latest theoretical constructs tend to focus on the most recent empirical issues being discussed and ignore the previous ones. In this respect, this book provides a constant reminder of what needs to be incorporated in the current debate. It can be considered the empirical memory of the field."

Joseph Aoun, University of Southern California

"*The Blackwell Companion to Syntax* will be an indispensable source for theoretical, descriptive, and applied linguists alike. Much of the syntactic knowledge accumulated since the *Aspects* is not easily accessible and some of it may even be in the world of oblivion for many linguists. Younger scholars may have difficulties to understand some of the work done in a by now obsolete theoretical framework. Others may want to have easy access to the analytic knowledge of earlier work in their daily research activities. Since the knowledge presented in the Companion is largely independent of the various stages of syntactic theorizing, it can profitably be used by researchers working on syntactic problems whatever their theoretical background may be. The contributions of the present encyclopedia have been written by top scholars in the field covering practically all important issues addressed in syntax during the last forty years or so. It will certainly serve as an essential research tool for a great number of linguists for many years to come."

Ferenc Kiefer, Hungarian Academy of Sciences, Budapest

"*The Blackwell Companion to Syntax* is a very important accomplishment. Everaert and Van Riemsdijk have brought together a large group of internationally reputed researchers, each of whom analyzes a particular empirical domain that has played a central role in the development of syntactic theory. It is a valuable reference and pedagogical tool. I have no doubt that this work will benefit not only undergraduate and postgraduate students of linguistics but anyone interested in syntax and in the remarkable intellectual history of the field."

M. Carme Picallo, Universitat Autònoma de Barcelona

"This is the most impressive collective endeavor in the field of syntax ever attempted. It summarizes the (basic) descriptive results obtained for a great many syntactic phenomena in the last fifty years of research in generative grammar. It is an indispensable work of reference for students and researchers alike."

Guglielmo Cinque, University of Venice

"Since the beginnings of generative grammar, our knowledge of the syntactic aspects of the human language faculty has increased exponentially, with every investigation giving rise to ever deeper investigations and to cross-linguistic research. Every time I write a paper, prepare my lectures, or advise students on their research, I am confronted with the problem of accessing a vast body of syntactic knowledge. With 77 case studies written by leading syntacticians, *The Blackwell Companion to Syntax* is certain to help address this fundamental problem."

Christopher Collins, Cornell University and New York University

"The past 30 years have seen an explosion in the breadth and depth of linguistic research, as focused theoretical perspective has sharpened empirical investigations. The Companion is a time capsule for the results of empirically significant projects, ensuring that the results of the past are not lost in the future. Any scholar who opens the volumes will find there a wealth of wide-ranging, scholarly, and theoretically informed discussion of just about every syntactic phenomenon currently known to the field – from double nominatives to topicalization; from the spray/load alternation to SOV languages. The insightful and rich chapters come from some of the extraordinary researchers of the time period. If the next generation of scholars does not utilize this marvelous resource, it will not be the fault of the editors and authors, and they can be sure that current researchers will profit immediately from this outstanding project."

Jane Grimshaw, Rutgers University

The Blackwell Companion to Syntax

Volume II

Blackwell Handbooks in Linguistics

This outstanding multi-volume series covers all the major subdisciplines within linguistics today and, when complete, will offer a comprehensive survey of linguistics as a whole.

Already published:

The Handbook of Child Language
Edited by Paul Fletcher and Brian MacWhinney

The Handbook of Phonological Theory
Edited by John A. Goldsmith

The Handbook of Contemporary Semantic Theory
Edited by Shalom Lappin

The Handbook of Sociolinguistics
Edited by Florian Coulmas

The Handbook of Phonetic Sciences
Edited by William J. Hardcastle and John Laver

The Handbook of Morphology
Edited by Andrew Spencer and Arnold Zwicky

The Handbook of Japanese Linguistics
Edited by Natsuko Tsujimura

The Handbook of Linguistics
Edited by Mark Aronoff and Janie Rees-Miller

The Handbook of Contemporary Syntactic Theory
Edited by Mark Baltin and Chris Collins

The Handbook of Discourse Analysis
Edited by Deborah Schiffrin, Deborah Tannen, and Heidi E. Hamilton

The Handbook of Language Variation and Change
Edited by J. K. Chambers, Peter Trudgill, and Natalie Schilling-Estes

The Handbook of Historical Linguistics
Edited by Brian D. Joseph and Richard D. Janda

The Handbook of Language and Gender
Edited by Janet Holmes and Miriam Meyerhoff

The Handbook of Second Language Acquisition
Edited by Catherine J. Doughty and Michael H. Long

The Handbook of Bilingualism
Edited by Tej K. Bhatia and William C. Ritchie

The Handbook of Pragmatics
Edited by Laurence R. Horn and Gregory Ward

The Handbook of Applied Linguistics
Edited by Alan Davies and Catherine Elder

The Handbook of Speech Perception
Edited by David B. Pisoni and Robert E. Remez

The Blackwell Companion to Syntax, Volumes I–V
Edited by Martin Everaert and Henk van Riemsdijk

The Handbook of the History of English
Edited by Ans van Kemenade and Bettelou Los

Chapters Grouped by Author xiii

List of Contributors xvi

Preface xix

Acknowledgments xxv

Volume I

1 The Accusative Plus Infinitive Construction in English: Jeffrey T. Runner 1

2 Adjectival Passives: Joseph Emonds 16

3 Adjectives: Order within DP and Attributive APs: Daniel Valois 61

4 Adverb Classes and Adverb Placement: Denis Delfitto 83

5 Affectedness: Mona Anderson 121

6 Analytic Causatives: Maria Teresa Guasti 142

7 A-not-A Questions: Paul Hagstrom 173

8 Bare Plurals: Denis Delfitto 214

9 Binding Theory: Terms and Concepts: Eric Reuland 260

10 Bridge Phenomena: Nomi Erteschik-Shir 284

11 Case (with Special Reference to Japanese): Kazuko Inoue 295

12 Chinese *Ba*: Yen-Hui Audrey Li 374

13 Clitic Climbing: Reineke Bok-Bennema 469

14 Clitic Doubling: Elena Anagnostopoulou 519

15 Comparative Deletion and Subdeletion: Norbert Corver 582

16 Conditionals: Rajesh Bhatt and Roumyana Pancheva 638
17 Contraction: Grant Goodall 688

Index to all Volumes 705

Volume II

18 Copular Sentences: Andrea Moro 1
19 Derived Nominals: Bożena Rozwadowska 24
20 Double Nominatives in Japanese: Koichi Tateishi 56
21 Double Object Constructions: Joseph Emonds and Rosemarie Whitney 73
22 Ellipsis in DP: Anne Lobeck 145
23 Embedded Root Phenomena: Caroline Heycock 174
24 Existential Sentences and Expletive *There*: Andrea Moro 210
25 Extraposition: Mark Baltin 237
26 Focus Movement (with Special Reference to Hungarian): Kriszta Szendrői 272
27 Free Relatives: Henk van Riemsdijk 338
28 Freezing Effects: Norbert Corver 383
29 Gapping: Kyle Johnson 407
30 Gerundive Nominalizations: Gary Milsark 436
31 Grammatical Verbs (with Special Reference to Light Verbs): Tara Mohanan 459
32 Honorifics: Nobuko Hasegawa 493
33 Icelandic Logophoric Anaphora: Eric Reuland 544
34 Implicit Arguments: Rajesh Bhatt and Roumyana Pancheva 558
35 Inalienable Possession: Jacqueline Guéron 589
36 Inverse Linking: Robert May and Alan Bale 639
37 Left Dislocation (including CLLD): Artemis Alexiadou 668

Index to all Volumes 701

Volume III

38 Logophoricity: Eric Reuland 1

39	Long-Distance Binding in Asian Languages: Peter Cole, Gabriella Hermon, and C.-T. James Huang	21
40	Long-Distance Binding in Germanic Languages: Eric Reuland	85
41	Long NP-Movement: Howard Lasnik and Cedric Boeckx	109
42	Middles: Peter Ackema and Maaike Schoorlemmer	131
43	Mittelfeld Phenomena (Scrambling in Germanic): Hubert Haider	204
44	Multiple-*Wh*-Questions: Veneeta Dayal	275
45	*N*-Words and Negative Concord: Anastasia Giannakidou	327
46	Object Shift: Sten Vikner	392
47	Partial *Wh*-Movement: Gisbert Fanselow	437
48	(Past) Participle Agreement: Adriana Belletti	493
49	Phrasal Stress and Syntax: María Luisa Zubizarreta and Jean-Roger Vergnaud	522
50	Pied-Piping: Julia Horvath	569
51	Preposition Stranding: Paul Law	631
52	Properties of VOS Languages: Sandra Chung	685
Index to all Volumes		721

Volume IV

53	Quantifier Scope Ambiguities: Katalin É. Kiss	1
54	Reconstruction, Binding, and Scope: Dominique Sportiche	35
55	Resumption: James McCloskey	94
56	The SE-Anaphor and its Role in Argument Realization: Carmen Dobrovie-Sorin	118
57	Secondary Predicates in Australian Languages: Eva Schultze-Berndt	180
58	Secondary Predication: Susan Rothstein	209
59	Serial Verbs: Pieter Muysken and Tonjes Veenstra	234
60	Sluicing: Jason Merchant	271
61	Specificational Copular Sentences and Pseudoclefts: Marcel den Dikken	292
62	Split Topicalization: Hanneke van Hoof	410

Preface

Generative grammar has always set its aims high. From its inception in the 1950s, the ambition has been to go beyond observational and descriptive adequacy to reach explanatory bliss. Important work would be about 'conditions on transformations' rather than on 'some properties of *wh*-movement in English', about the 'transformational cycle' rather than on verb clusters.[1] This is what science should be like. And while earlier attempts at achieving a semblance of an explanatory theory were often clumsy and inadequate, these past forty or so years have shown that truly fundamental questions can now be asked and addressed.[2] This emphasis on theory has not, of course, altered the fact that linguistics is a thoroughly empirical science, but data and analyses are seen as what they are: tools to help us understand the structure and properties of the human language faculty. It is the fate of tools that when the product is finished they are put away. When some (as it turns out controversial) data from Italian had suggested that the notion of bounding node should be parameterized, we then forgot about the Italian data and happily proceeded with the idea of parameters.[3] Numerous other examples could be added.

More generally, the data and analyses that at some point in the history of generative grammar played an important, sometimes even a crucial, role have a tendency to fade into the background rather quickly.[4] This effect is particularly strong when the piece of theorizing they helped to establish becomes obsolete, but it is even true when the theoretical insight persists over time. As time went on, and as generative grammar (using the term in the broad sense, including all its theoretical diversity), in its explosive success, expanded to dozens of countries, hundreds of universities and colleges, and many hundreds of researchers, the muckheap of once useful but then discarded empirical material continued to grow. Old hands in the field may still be served by a good memory, helping them to dig out some of these rejects if they seem useful at some later stage, but successive new generations of young linguists simply don't have access to the wealth of data, generalizations, and analyses that might be terribly important to their research if only they knew about them.

But it is not only a problem for younger generations. Researchers who like to keep track of developments, particularly (but not only) in those subfields that are not directly related to their own research, or who work in closely related disciplines such as, for instance, psycholinguistics or sociolinguistics, find it increasingly difficult to keep track. Current handbooks are often concerned with current theorizing, but only marginally with the history of the various versions of the theory and even less with the empirical generalizations underlying those theories. As a consequence, an ever smaller percentage of the potentially useful empirical material is treated in standard textbooks, and hence the rest is not part of the knowledge that researchers and students in the field may be expected to possess.

It might be objected that the articles in which all this wisdom is stored are, after all, still around in the journals, in the books, in the libraries. But given their theoretical focus, the titles are often unrevealing as far as the empirical domain is concerned, keywords are notoriously absent or unreliable, relevant data are scattered over several articles, and, most importantly, the presentation of the data in these articles is subservient to the theoretical claims that are made and hence not presented in succinct, didactically useful ways.[5] So searching for the relevant materials, even if you know what to look for, is often hard. For young researchers, such a search task is doubly difficult because very often the descriptive generalizations are presented in a jargon and formalism that were characteristic of the theoretical framework at the time, sometimes decades ago. Who thinks to look up the term 'backward equi' when looking for data relevant to what we now call exceptional case marking (ECM)?[6]

Having a good, theoretically oriented mind is not enough. You cannot gain an understanding of the abstract properties of Universal Grammar without having any ideas about interesting empirical areas that might provide the crucial evidence (or counter-evidence) for your claims. But these flashes of empirical insight can only come if you have enough knowledge in your head to start the neurons firing away. And you can only have that knowledge if you have been taught about a certain range of phenomena in a variety of languages, or if you have had access to a repository of such materials to work through by yourself. The problem is that such courses are rarely taught, the reason being more often than not that the relevant data are not available in a form that is didactically usable.

This is the lacuna that we are hoping to fill with *The Blackwell Companion to Syntax*. In these five volumes, we offer you 77 case studies of syntactic phenomena that should, at least partly, fill the gap and constitute an important research tool for the working linguist and for teachers and students of syntax (and its interfaces). In bringing these chapters together, we were guided by a working definition of what a syntactic case study was supposed to be. The following properties were thought to be central: *a well-delimited empirical area (both as to the construction(s) involved and as to the languages in which the phenomena are found) whose analysis has, at one time or another in the history of generative grammar, played an important role in the theoretical debates at that time*. More often than not, we will find that such results are relatively robust in the sense that they will stand and

be interpretable regardless of various innovations or adaptations of the version of the theory in which they first saw the light.

The so-called 'verb-raising' construction in Continental-West Germanic languages (chapter 75) will serve as an example. Much has been published on this subject, a reasonable degree of consensus exists about the most important properties of the construction, its analyses have been frequently used to support theoretical proposals, etc. Nevertheless, the existence of this complex of facts is hardly known outside the small group of specialists in this field, the main properties cannot be presupposed as common knowledge, and no one in the field can be properly held responsible for ignoring the verb-raising construction. In a situation like that, the chapter's presentation will be oriented toward combining views and formulating them in such a way that they will be accessible to researchers from various approaches to the theory of grammar.

In addition, of course, the delimitation had to be such that the empirical subdomain in question could be treated in manageable chapters. It would have been unthinkable to include a case about relative clauses: even a thick monograph would not do such a topic justice. But the subtopic of free (headless) relative clauses (chapter 27), a topic that in the late 1970s and the 1980s generated a considerable literature, is a typical example of what we had in mind.

What about the theory? We wanted to make the empirical generalizations, the insights into the properties of constructions, the main focus of each chapter. But wherever useful and possible, of course, reference can be and is made to the theoretical issues that the phenomena in question were or even are relevant to. This introduces a certain bandwidth, and indeed some of our authors stress the empirical side more strongly while others swerve more easily into theoretical discussions. With a project this size it has been impractical to impose more uniformity than we have achieved here. It was, frankly, not always easy to convince our authors to take time away from their primary theoretical research to write the chapters we asked them to. And it was also on occasion hard to curb the attention that they tended to give to theoretical issues and their own role in those theoretical developments. More generally, wherever possible we suggested that theoretical issues be addressed in robust, sustainable ways, not in terms that would reflect the fads and the terminological peculiarities typical of a specific brief period in the short history of generative grammar.

It does not take a great deal of knowledge of the field to realize that an enterprise such as the present one is a highly open-ended affair. Even if we had achieved complete coverage at the time of appearance, new cases would soon present themselves. But complete coverage is unattainable in the first place. It is always possible to come up with other potential cases, not represented in the present work. Even now we already have a number of ideas about cases that might be added and which may at some point be added to the present collection. Nevertheless, we believe that the coverage that the present collection achieves is very considerable. So much ground is covered that already it seems doubtful that future graduate students of linguistics could be expected to work through all of this material. If a student manages part of it and has the rest at his or her disposal

as an encyclopedia of linguistic phenomena, we feel certain that his or her research will greatly benefit. As teachers we are frequently confronted by a big question mark in the faces of students or even fellow faculty members when we use terms like 'contraction', 'subdeletion', or 'freezing effect'. And when asked "Where can I read up on this?" we are often faced with our own bad memory and the virtual impossibility of pointing toward one representative text that will concisely and competently explain what kind of phenomena are hiding behind these terms. This, we feel sure, is now a problem of the past.

If, as we are convinced, this *Companion* will become an important research tool in linguistics, a pressing need will also be felt for additional case studies to be added. While it may well be possible to project further volumes in the future, or an updated or extended version of the present publication, it has been clear to us from the start that the best way to make this an incremental enterprise is to publish these cases electronically. This would allow the possibility of reviewing cases now published, adding new cases relatively easily, and allowing discussion fora, etc. When that happens, the way to expanded coverage of the field will be paved. For the moment we refer you to www.syntaxcompanion.org to keep you informed on developments in this area.

One point to make about the references: every individual chapter has a reference section; the consolidated reference list is in volume V, and in the XML CD version the links are to the consolidated list rather than to the end-of-chapter lists. So in the chapter references you may find entries with a, b, etc. after the date even if there is only entry with that author and date in that chapter, because there is more than one entry in the whole five volumes with the same author and date. For example, even if there's only one Chomsky 1995 cited in any one chapter, it will appear as Chomsky 1995a or 1995b or 1995c, because there are three Chomsky 1995 entries in the consolidated references for the whole five volumes, identified as a, b, and c.

As editors of this encyclopedia of case studies, we have had to make many choices. In doing so we were greatly helped by the project group at NIAS, the Netherlands Institute for Advanced Study in the Humanities and Social Sciences, at Wassenaar, in the dunes lining the Dutch coast, in 1996/1997. The definition of what we would consider a typical case study was intensively discussed and ultimately fixed by that group: Reineke Bok-Bennema, Norbert Corver, Denis Delfitto, Joe Emonds, Martin Haiden, Itziar Laka, Eric Reuland, Tim Stowell, Sten Vikner, and, to some extent, Ian Roberts. We were also fortunate to have good input and feedback from Hagit Borer, Jan Koster, and Edwin Williams, our special outside consultants. The original list of cases was also compiled by that group. First sample chapters were produced during that year. And we brainstormed a lot about who would be the ideal author for which chapter. Nevertheless, we accept full responsibility for all the choices that were made.

We do wish to emphasize, however, that it has never been our intention to suggest that the present collection could be interpreted as a kind of canon, in the literary sense of the word (to the extent that literary scholars are still prepared to advocate such a notion). What we say above about the open-ended character of

an enterprise such as this should underline the fact that nobody could pretend that it is at all possible to establish such a canon, even if one tried to.

The first plans for this project were made in 1993. That is when we decided to apply to NIAS to see if we could get together a team of colleagues with whom to discuss the scope, the objectives, and the realization of the present work. The application was approved. We gratefully acknowledge the generous support, financial, logistic, and otherwise, of NIAS and, in particular, Dick van de Kaa and Wouter Hugenholtz, respectively the rector and the director of the institute. The group convened in the splendid isolation of NIAS in the academic year 1996/1997. There, we were happy to be able to work together with the colleagues mentioned above. Ilke van den Ende joined us as a student trainee. We were also happy to be able to organize two workshops at NIAS during that year. A third was held in Los Angeles at USC with the help and support of Hagit Borer and Tim Stowell in 2001. We wish to thank the participants at these workshops for their contributions, and LOT (the Dutch National Graduate School of Linguistics) as well as NWO and KNAW (the Netherlands Organization for Scientific Research and the Dutch Royal Academy of Sciences respectively) for financial support for these workshops. We also wish to thank the BSGM Foundation for an additional grant to the NIAS group. Last but not least we wish to thank those who have assisted us with the administration and correspondence, with the copy-editing and the HTML-conversion and the maintenance of the website: Jenny Doetjes, Bart Hollebrandse, Rob Goedemans, and Hannah de Mulder. Without them we literally and figuratively could not have managed. Thanks are due to NWO and the Utrecht Institute of Linguistics OTS (Language in Use project) for grants that made this assistance possible.

Finally we would like to thank all those at Blackwell who, over the years, have helped us realize this project – Ada Brunstein, Philip Carpenter, Sarah Coleman, Tami Kaplan – and the copy-editing team – Fiona Sewell, Anna Oxbury, Peter Kahrel – for doing such a wonderful job.

Utrecht and Tilburg
Martin Everaert and Henk van Riemsdijk

NOTES

1 Cf. Chomsky (1973); Evers (1975b).
2 See, for example, Chomsky (2004).
3 Cf. Rizzi (1982b).
4 The reverse also holds true. Certain empirical domains have never figured prominently in theoretical debates, and remain, thus, uncharted territory from a descriptive point of view.
5 We should add that publications like *Linguistics Abstracts Online* will, in future, solve part of the problem we note.
6 Cf. Postal (1974).

  3.3 Rightward agreement in inverse copular sentences: pro as a null predicate
4 Conclusion

1 Introduction: what is a copular sentence?

Few concepts in the history of linguistics have received more attention than the concept of 'copula', which was first introduced in the field by Abelard in his *Dialectica*. In fact, the term 'copula' and the associated phrase 'copular sentences' are meant to refer to a variety of conceptually distinct objects; for example, copular sentences involve a special verb in Indo-European languages whereas they may involve a pronoun in Semitic languages. In fact, there is no 'standard' definition of the notion of 'copula'. Leaving discussions and full references for a brief history of the notion of copula to the appendix of Moro (1997), we can at least single out three distinct analytical traditions: first, stemming from Aristotle's own work in the field, the copula has been considered as the sign of tense,

or more generally of those inflectional features that are normally expressed syncretically on the verbal predicate; second, starting at least from Abelard, the copula has been considered as the sign of affirmation, and this meaning has been pursued by the Port Royal school, influencing many subsequent theories; third, ever since Frege's and Russell's works in the field, the copula has been considered as ambiguous between the sign of identity and that of predication. In this case study, we will concentrate on copular sentences from two Indo-European languages, English and Italian, that played a central role in the development of generative grammar and more generally of formal syntax in the twentieth century; for a general and in-depth source of studies of the verb *be* and its equivalent across languages see Verhaar (1967, 1968a, 1968b, 1969, 1972, 1973). It is nevertheless important to highlight the fact that copular sentences have always constituted and still constitute a challenging field for all grammatical models: the aim of this work is to illustrate both some well-understood and some rather murky aspects of these constructions, concentrating on the general consequences that the syntax of copular sentences has for the general design of grammar. Data will be mainly taken from English and Italian for three distinct reasons: first, these two languages do have verbal copulas (*be* and *essere*, respectively); second, most recent literature is based on analyses of these two languages (especially since current analyses of copular sentences are related to the analysis of expletives: see chapter 24); third, the two languages instantiate two opposite values of the pro-drop parameter, allowing us to extend our knowledge of the impact of this parameter on grammar.

Let us define 'copular sentences' as those sentences whose main verb is *be* (the copula) and its equivalents across languages. In English, such a verb can be followed by DPs, APs and PPs:

(1) a. John [$_{VP}$ is [$_{DP}$ the cause of the riot]]
    b. John [$_{VP}$ is [$_{AP}$ angry]]
    c. John [$_{VP}$ is [$_{PP}$ on the wall]]

In some languages, such as Italian, moreover, bare NPs can also follow the copula:

(2) Gianni [$_{VP}$ è [$_{NP}$ causa della rivolta]
    'Gianni is (the) cause of the riot.'

As for those cases where the copula is followed by a VP, such as in *John is coming here* or *John is to come here*, they are not generally labeled as 'copular sentences', since the verb *be* in these cases rather plays the role of an auxiliary or a modal respectively. *A priori*, there wouldn't be a reason to consider the sentences in (1) and (2) as special with respect to any other sentence of the kind [DP VP]. This expectation is generally borne out, with one exception: in fact, a particular subtype of copular sentence, i.e. sentences of the type [DP copula DP], does show surprising properties, with many consequences both theoretical and empirical. These properties have attracted the attention of linguists throughout the

development of the discipline, and their discussion has often reflected the debate within generative grammar.[1] In the next section, some of these properties will be reviewed.

2 The anomaly of copular sentences

Consider a sentence of the type [DP V DP] in an SVO language like Italian or English. For any choice of V we expect there to be a set of asymmetries distinguishing the two DPs from a syntactic point of view. For example, we expect the preverbal DP to trigger agreement on the verb, to c-command the postverbal DP asymmetrically, and to be subject to more restrictions with respect to movement transformation than the postverbal DP (e.g., *that*-trace effect in English, absence of cliticization from preverbal DPs, etc.). These asymmetries, which are frequently dubbed the 'subject–object' asymmetries, constitute some of the major empirical arguments for assuming an asymmetric representation of sentences in natural language syntax such as the following (cf. Chomsky 1986b: 62):

(3) [DP [$_{VP}$ [V DP]]]

Indeed, there is no *a priori* reason to expect the same asymmetric representation not to remain valid when a sentence of the type [DP V DP] is construed by choosing the copula as a V. But in fact, this expectation is not borne out.

2.1 Testing verbal agreement, wh*-movement, and cliticization on copular sentences of the type [DP V DP]*

Let us first of all consider a copular sentence like the following in English:

(4) [a picture of the wall] is [the cause of the riot]

It can be easily shown that verbal agreement yields exactly the same pattern as all sentences of the type [DP V DP], i.e. the verb agrees with the preverbal DPs, not with the postverbal one:

(5) [some pictures of the wall] are/*is [the cause of the riot]

Wh-movement of preverbal and postverbal DP, however, yields a first anomalous fact:

(6) a. [which picture of the wall] do you think (*that) t is the cause of the riot?
b. *[which wall] do you think that [a picture of t] is the cause of the riot?
c. [which riot] do you think that a picture of the wall is [the cause of t]?

d. *[which cause of the riot] do you think that a picture of the wall is t?
e. [what] do you think that a picture of the wall is t?

As far as *wh*-movement is concerned, the behavior of preverbal DPs in copular sentences indeed parallels the well-known behavior of non copular sentences: *wh*-movement *of* a preverbal DP is possible only across non-overt complementizers (6a) and *wh*-movement *from* a preverbal DP is not possible (6b). As for postverbal DPs, instead, the situation for copular sentences is different from that for non-copular sentences: *wh*-movement *from* a postcopular DP is possible as in non-copular sentences (6c), but if one tests movement *of* the whole postverbal DP in a sentence like (4), the result is that only *what* can be extracted (6e); the phrase headed by *which* is banned (6d).[2]

This anomaly with respect to *wh*-movement is not inherently related to this specific type of movement, though. If we turn to a language like Italian, which allows clitic movement, for example, similar patterns can be easily detected. Normally, a postverbal noun phrase in a sequence of the type [DP V DP] can be cliticized onto the verb or there can be cliticization of subparts of it onto the verb. *Prima facie*, copular sentences are not deviant. Consider the following examples:

(7) a. una foto del muro è la causa della rivolta
a picture of the wall is the cause of the riot
b. una foto del muro lo è t
a picture of the wall it is
c. una foto del muro ne è [la causa t]
a picture of the wall of-it is the cause

Yet there is an anomalous fact here: copular sentences are different from all other sentences of the type [DP V DP] in that the clitic replacing the postverbal DP is always the uninflected form *lo*, as opposed to the case with verbs other than the copula, where inflected clitics occur, such as *lo*, *la*, *le li* etc. (cf. Burzio 1986).

2.2 *Surprising anomalies of some copular sentences of the type [DP V DP]*

The result of movement tests changes dramatically if we now check a sentence like the following:

(8) [the cause of the riot] is [a picture of the wall]

A priori, there is no reason to expect this sentence to be different from its associate in (4). In fact, (8) is superficially identical to (4), i.e. it is a [DP V DP]-type sentence.

Agreement offers a first cross-linguistic contrast:

(9) a. the cause of the riot is/*are some pictures of the wall
b. la causa della rivolta sono/*è alcune foto del muro
the cause of the riot are/is some pictures of the wall

In Italian, the copula now agrees with the postverbal DP: notice that the sentence in (9b) is by no means to be considered as a typical case of rightward agreement with subject inversion, which is typical of pro-drop languages like Italian. Indeed such a case could exist, but it would correspond to the linear sequence [V DP DP] or to the one involving cliticization [clitic V DP]:

(10) a. [[sono la causa della rivolta] alcune foto del muro]
are the cause of the riot some pictures of the wall
b. [[lo sono t] alcune foto del muro]
it are some pictures of the wall

Rather, the sequence here is DP V DP; thus rightward agreement is totally unexpected, even in a null-subject language like Italian.

Let us now focus on the postverbal DP of the copular sentence of the type [DP V DP] in (8) and test movement from and of it in turn (cf. (6c)):

(11) *which wall do you think that the cause of the riot is [a picture of t]

Movement from the postverbal DP now yields the same violation as movement from the preverbal DP. As for movement of the postverbal DP, we have the following result (cf. (6d) and (6e)):

(12) a. *which picture of the wall do you think that the cause of the riot is t
b. what do you think that the cause of the riot is t

Movement involving a phrase headed by *which* gives an ungrammatical result whereas movement involving *what* does not. This contrast between *which* and *what* constitutes a sharp and apparently not immediately understandable departure from the general pattern concerning postverbal DPs. If we turn to cliticization in Italian we obtain similar unexpected results (cf. (7b–c)):

(13) a. *la causa della rivolta lo sono t
the cause of the riot it are
b. *la causa della rivolta ne è [una foto t]
the cause of the riot of-it is a picture

Cliticization of and from the postverbal DP is blocked here. There is no other sequence of the kind [DP V DP] in Italian that shows the same behavior (excluding, of course, those where the postverbal DP is an adverbial like *due volte* (twice), as in *Gianni ha letto il libro due volte* (Gianni has read the book twice)).

2.3 Testing infinitival copular sentences of the type [DP V DP]

We have so far collected some surprising facts concerning copular sentences by considering finite contexts; let us briefly consider copular sentences in infinitival sentences. Another unexected asymmetry can be easily detected. As a first step, consider the following sentence:

(14) John considers [a picture of the wall to be the cause of the riot]

It is a well-known fact that the copula can be omitted in these contexts:

(15) John considers [a picture of the wall the cause of the riot]

If we test the same fact with respect to the associated copular construction we have the following sharp contrast:

(16) a. John considers [the cause of the riot to be a picture of the wall]
b. *John considers [the cause of the riot a picture of the wall]

Summarizing, we have isolated a cluster of surprising facts concerning copular sentences of the type [DP V DP]. In certain sentences of this type, but crucially not in all sentences of this type: (a) there can be no *wh*-movement of and from the postverbal DP, unlike for all other choices of V; (b) *wh*-movement of the postverbal DP is limited to *what* and impossible for phrases headed by *which*; (c) in Italian, agreement anomalously goes with the postverbal DP and (d) cliticization of and from the postverbal DP is banned; (e) omission of the infinitival copula is impossible in English. Again, one must crucially observe that these restrictions do not occur for all instances of sentence of the kind [DP copula DP], but only for a subset of sentences. More specifically, referring to the pair we tested here, these restrictions occur for the sentence *the cause of the riot is a picture of the wall* but not for the associated sentence *a picture of the wall is the cause of the riot*. Since both sentences are [DP V DP] type, there can be hardly any doubt that the simple asymmetric representation in (3), i.e. [DP [V DP]], cannot be maintained for both sentences.

2.4 Further anomalies

In the final section we will present a sketchy illustration of a proposal that accounts for the observed anomalies within a principled framework. For now, let us proceed to illustrate the anomaly of copular sentences by considering some other challenging facts: let us focus first on Binding theoretical effects.

2.4.1 Binding theoretical effects and the unambiguous interpretation of the copula

It is a well-known fact that the Binding domain of an anaphor or a pronoun contained in a DP can be altered when it occurs with the copula. For example:

(17) a. $John_i$ met his_i cook
b. *$John_i$ is his_i cook

The pronoun cannot be bound by the subject of the sentence when the verb is the copula. These kinds of data have been observed by many authors as they challenged the definition of 'minimal binding domain', i.e. the domain where Binding principles must be satisfied. To account for data like (17), and many others, Giorgi and Longobardi (1991), for example, proposed that Chomsky's (1986b) definition of minimal domain as a Complete Functional Complex was to be refined in such a way that the predicative nature of the postverbal DP with copular sentences mattered. Accordingly, a domain is defined as complete with respect to a head whenever it exhausts either all theta-roles assigned by the head or all the grammatical functions pertaining to the same head. This could derive the cases in (17): *John* is within the functional complex of *cook* in (17b) only, since only in that case does *John* play the grammatical function of subject of *cook*; thus the minimal domain of Binding is the whole sentence in (17b), whereas it is the postverbal DP itself in (17a); this explains the observed contrast. However, other anomalous properties have been discovered which go uncaptured even within the more refined version of the definition of Complete Functional Complex. I will briefly illustrate them by relying again on Moro (1997).

Consider a case like the following:

(18) a. $[John and Mary]_i$ considered [these to be [each other's$_i$ best performances]]
b. $[John]_i$ believes [these to be [the best pictures of $himself_i$]]

In both cases, the anaphors contained in the postverbal DP can be bound by the subject of the matrix clause. If the domain of binding were defined as proposed by Chomsky 1986b (and refined by Giorgi and Longobardi 1991) this should not be possible, since the minimal domain where all grammatical functions pertaining to a head are exhausted in (18a–b) is the embedded clause where *these* plays the role of subject of predication.

Relying on observations of Binding theoretical effects, it is also possible to show that the nineteenth-century semantic view according to which the copula is ambiguous between identity and predication cannot be maintained in syntax. This view, which is traditionally attributed to Russell (1903), is standardly exemplified in the following sentence (which in fact goes back at least to Frege's works):

(19) [the morning star] is [the evening star]

Allegedly, the interpretation of this example has been considered as a sign that the copula is ambiguous: (19) is analyzed as though the copula was expressing identity between *the morning star* and *the evening star*, as opposed to cases like *Socrates is a man* where it is analyzed as a sign of predication. Empirical consideration involving Binding effects show that this conclusion cannot be maintained. Suppose we construct the following sentence, intending it to be an identity statement, that is, a sentence where both DPs are symmetrically referential:

(20) *[the morning star]$_i$ is [its$_i$ source of energy]

Clearly, there is no way for the pronoun to be bound by the subject. On the other hand, if a predicate indicating identity, say *one and the same as*, is explicitly expressed in the sentence, the result is totally different:

(21) [the morning star]$_i$ is one and the same as [its$_i$ source of energy]

Coreference is possible here on a par with pure transitive constructions which do not involve predicative nominals, such as:

(22) [the morning star]$_i$ lost [its$_i$ source of energy]

In (21), indeed, we do have a genuine identity predicate (the AP *one and the same as*) as opposed to the case of the bare copula in (20): neither DP is the predicate of the other, given that the local domain for binding is limited to the DP itself in each case. Notice also that if (19) is analyzed as an identity statement, the same should be said for the embedded sentence in a case like the following:

(23) I consider [[the morning star] [the evening star]]

Clearly, (23) does not contain any copula, but the relationship between the two DPs is the same as in (19), reinforcing the hypothesis that the copula is not a predicate (of identity).[3] Finally, it is important to notice that Russell unambiguously considered the copula as a sign of identity when it is followed by a noun phrase, and a sign of predication when it is followed by an adjective (the original examples are *Socrates is a man* vs. *Socrates is human*). This passage has often been neglected or misquoted, it appears; otherwise linguists who refer to Russell's thought should always analyze nominal copular sentences as identity statements, and they clearly do not. All in all, I would like to emphasize that what must be affirmed here is that identity is not predicated *by the copula* or equivalently that one of the two noun phrases involved in a copular sentence always plays the role of a predicate. Whether or not the notion of 'identity' is suitable to an understanding of the relation between the two noun phrases is a different matter that involve the semantics of DPs rather than the copula.

2.4.2 Backward reflexivization: a recalcitrant case

Naturally, we have not exhausted all empirical issues concerning Binding effects in copular sentences. Many interesting facts still call for an explanation. I will simply refer here to two of them: so-called 'backward reflexivization' and pseudo-extraction. Another interesting topic, namely specificational copular sentences and pseudocleft sentences, is treated separately in chapter 61. The first phenomenon, discovered by Ruwet (1975), can be simply illustrated via the following paradigm (reproduced from Moro 1997):

(24) a. le sue$_i$ lettere sono l'alibi di Gianni$_i$
the his letters are the alibi of Gianni
b. l'alibi di Gianni$_i$ sono le sue$_i$ lettere
the alibi of Gianni are the his letters
c. le lettere di Gianni$_i$ sono il suo$_i$ alibi
the letters of Gianni are the his alibi
d. *il suo$_i$ alibi sono le lettere di Gianni$_i$
the his alibi are the letters of Gianni

Only in one case can the pronoun not be bound by *Gianni*. As far as I know, no reason has been given to explain this recalcitrant fact: any simple application of Binding theory does not give the correct output.[4]

2.4.3 Pseudo-extraction

Copular sentences are anomalous even for Theta theoretical considerations. Consider the following pair (cited from Moro 1997: 79 ff):

(25) a. Beatrice è desiderata da Dante
Beatrix is desired by Dante
b. Beatrice è il desiderio di Dante
Beatrice is the desire of Dante

The first example is a simple case of a passive sentence: *Beatrice* is assigned its theta-role in the object position and promoted to the preverbal position, where it plays the role of a subject. *Prima facie*, the two sentences, which both involve *be*, should be analyzed in a parallel way. More specifically, the null hypothesis is that in both cases Beatrice is moved from a thematic position to the subject position. Although this simple solution is surely appealing, it cannot be maintained. The reason why this anaysis cannot be adopted lies in the fact that it involves extraction from a DP and would thus go against a rather well-established generalization, which owes its origin to an observation by Cinque (1980). This generalization states that a constituent can be extracted from a DP only if it can be possessivized (see Giorgi and Longobardi 1991 for an updated discussion and a new derivation of this phenomenon). Unfortunately, if we apply this to the DP under discussion, we actually obtain the opposite of the result we need to support an analysis involving extraction. Consider the following fragment:

(26) [il suo desiderio . . .]
the his desire

The pronoun *suo* can only be interpreted as the experiencer as in *il suo desiderio per Beatrice* (the his desire for Beatrice). Thus, the hypothesis that *Beatrice*, which is interpreted as the patient, be extracted from the predicative nominal in the corresponding copular sentence in (25b) cannot be maintained. The phenomenon exemplified in (25b) has been labeled 'pseudo-extraction', a term which at least has the merit of emphasizing – at one and the same time – both the similarities and the differences between this construction and the passives.

Although no solution has been offered to solve this puzzle concerning copular sentences, one can get some idea of the extension of such a phenomenon within the class of noun phrases occurring in copular sentences. Let us consider in particular a number of noun heads which are compatible with two arguments. It is easy to establish that like *desiderio*, other nouns such as *paura* (fear), *timore* (fear), *preoccupazione* (worry), *piacere* (pleasure) allow pseudo-extraction:

(27) a. l'inferno è la paura di Dante
the inferno is the fear of Dante
b. Virgilio conosce [la paura di Dante per l'inferno]
Virgil knows the fear of Dante for the inferno
c. la città di Dite è il timore di Dante
the city of Dite is the fear of Dante
d. Beatrice conosce [il timore di Dante per la città di Dite]
Beatrice knows the fear of Dante for the city of Dite
e. Cerbero è la preoccupazione di Dante
Cerbero is the worry of Dante
f. Maria conosce la preoccupazione di Dante per Cerbero
Maria knows the worry of Dante for Cerbero
g. la luce è il piacere di Dante
the light is the pleasure of Dante
h. Ulisse conosce il piacere di Dante per la luce
Ulisse knows the pleasure of Dante for light

On the other hand, by no means do all bi-argumental nouns allow pseudo-extraction: for example, *descrizione* (description), *racconto* (narration), *fotografia* (photograph), *apparizione* (apparition) yield ungrammatical sentences:

(28) a. *l'inferno è la descrizione di Dante
the inferno is the description of Dante
b. Virgilio conosce [la descrizione di Dante dell'inferno]
Virgil knows the description of Dante of-the inferno
c. *la città di Dite è il racconto di Dante
the city of Dite is the narration of Dante
d. Beatrice conosce [il racconto di Dante della città di Dite]
Beatrice knows the narration of Dante of-the city of Dite

e. *Cerbero è la foto di Dante
Cerbero is the photograph of Dante
f. Ulisse conosce [la foto di Dante di Cerbero]
Ulisse knows the photograph of Dante of Cerbero
g. *la luce è l'apparizione di Dante
the light is the apparition of Dante
h. Maria conosce [l'apparizione della luce a Dante]
Maria knows the apparition of-the light to Dante

A first rough generalization may now be formulated. It seems that pseudo-extraction is allowed only with those noun phrases which express psychological attitudes and not with those 'extensional' verbs which denote activities like describing, narrating, etc. Thus, borrowing the terminology proposed for certain class of verbs by Belletti and Rizzi (1988), it is tempting to call this class of noun phrases 'psych-nouns'. Accordingly, the following provisional generalization can tentatively be formulated:

(29) Only psych-nouns allow pseudo-extraction

Keeping the discussion on a descriptive level, we can push this generalization to the limit by asking whether it should be reformulated as an 'if-and-only-if' clause. In other words, we can try to establish whether all (and only) psych-nouns allow pseudo-extraction. It seems that the answer to this is negative. For example, there are cases like *cruccio* (worry) that surely are psych-nouns from a semantic point of view, which show a different pattern when compared to elements like *desiderio* (desire):

(30) a. Beatrice è il cruccio di Dante
Beatrice is the worry of Dante
b. Virgilio conosce [il cruccio di Dante (* per Beatrice)]
Virgil knows the worry of Dante for Beatrice

On the one hand, they allow constructions like (30a), namely *Beatrice è il cruccio di Dante* (Beatrice is the worry of Dante), which strongly resembles cases of pseudo-extraction (specifically, the theta-role assigned to *Beatrice* comes from the N^0). On the other, they are clearly not bi-argumental, as (30b) shows, and so the very idea of extraction has to be excluded in principle. This (together with other possible cases) suggests that the generalization presented above calls for a further refinement.

Summarizing, in this section we have highlighted some empirical reasons which make copular sentences anomalous. First, we observed that a subset of copular sentences of the kind [DP V DP] does not respect the usual subject–object asymmetry (specifically, in certain cases extraction of and from the postverbal DP cannot take place with both *wh*-phrases and clitics); second, some Binding theoretical anomalies have been presented which challenge the standard frameworks;

third, theta-role assignment in copular sentences appears to run against a well-known generalization, suggesting that passivization in DPs is not well understood. Of course, this review does not exhaust all the facts that concern copular sentences; nevertheless, the cluster of facts considered here is indicative of how this field of research has had a deep impact on the general theory of grammar. In the next section, I will present a unified theory of copular sentences that has generated some debate in the field by solving some of the problems illustrated here and raising further questions.

3 Inverse copular sentences

In the previous section, we observed a cluster of anomalies which concerned copular sentences and which involved movement. More specifically, we observed that in a subset of copular sentences of the kind [DP V DP], the postverbal DP does not allow movement from it and at the same time it cannot be moved, with respect to both *wh*-movement and clitic movement. The postverbal DP, rather, behaves like the preverbal subject of embedded sentences with an overt complementizer. Clearly, the structure in (3), namely [DP [V DP]], is not empirically adequate to explain the syntax of copular sentences exhaustively.

3.1 The raising of predicates

The first step toward a principle-based explanation of the anomalies of copular sentences came from Stowell's (1978) proposal that *be* is a raising verb. On this proposal, the structure in (3), repeated here as (31a), must be extended as indicated in (31b):

(31) a. [DP [V DP]
b. [DP [V [t DP]]

where the subject moves to preverbal position to be assigned case. Stowell's argument was crucially based on the assumption that the position held by the preverbal DP in a copular sentence can be occupied by a subject expletive such as English *there* or Italian *ci* (see existential sentences and *there* insertion, chapter 24, for a detailed illustration of these constructions). Clearly, taken on its own (31b) cannot solve the problems illustrated in the previous section concerning movement. Even if the structural 'space' between the two DPs is augmented, one cannot see any reason why the postverbal DP should behave anomalously *only in certain cases*. The solution that I will present here, proposed in Moro (1987, 1988) (and refined in Moro 1997), is based on a simple consideration. A traditional view stemming from Chomsky's work and further elaborated by Rothstein (1983) maintains that the preverbal DP 'saturates' the function expressed by the predicate, in 'roughly the Fregean sense' (Chomsky 1981: 116). This is generally true for verbal predicates, but what happens if the predicate is a noun phrase?

The key step is to assume that in such a case the preverbal position is accessible to the predicate provided that it belongs to the proper lexical type, namely a noun phrase. More specifically, the proposal is to abandon the 'Fregean' approach and assume that the only requirement for a preverbal position is that it hosts a DP. Accordingly, a structure like (31b) has the following 'mirror' counterpart:

(32) [DP [V [DP t]]

Such a structure, which was labeled 'inverse copular sentence' to contrast with the 'canonical copular sentence' in (31b), offers the possibility of construing a unified theory of copular sentences, one which on the basis of a principled framework explains the whole cluster of anomalies with respect to movement. Again, the only difference with respect to the standard theory of clause structure is to abandon the idea that the preverbal DP 'saturates' the function expressed by the predicate.[5] In what follows, I will sketch the essentials of the unified of theory of copular sentences by highlighting some of its empirical consequences and the paths of research it opens.[6]

As a preliminary, let us assign the two sentences we tested in the previous section two distinct structures, indicating that the preverbal DP is respectively moving from either the subject or postverbal position, and call them 'canonical' vs. 'inverse' sentences, respectively:[7]

(33) a. [a picture of the wall] is [t [cause of the riot]] (canonical sentence)
b. [the cause of the riot is [[a picture of the wall] t] (inverse sentence)

In such a case the two postverbal DPs appear in different contexts and play different grammatical roles. In the canonical sentence (33a), the postverbal DP plays the role of the predicate, while the subject of predication has been raised to the preverbal position; in the inverse sentence (33b), by contrast, the postverbal DP plays the role of the subject of predication, while the predicate has been raised to the preverbal position. In other words, the two sentences have the same lexical underlying structures and are transformationally related.[8] Before approaching the issue of locality of movement, let us immediately observe that this theory explains why the copula cannot be omitted in infinitival inverse copular sentences. Consider the relevant cases, reproduced here as (34):

(34) a. John considers [a picture of the wall (to be) the cause of the riot]
b. John considers [the cause of the riot *(to be) a picture of the wall]

If there were no infinitival copula in (34b), there would be no landing site below the matrix verb for the predicative noun phrase, so there would be no way of forming an 'inverse copular sentence'. On the other hand, the copula can be omitted in (34a), since the corresponding structure would simply be one where neither the subject nor the predicative DP has moved. Let us now briefly turn to the locality facts: relying on the unified theory of copular sentences presented

here, we can reformulate the question in a more precise way by asking why extraction of and from the subject (i.e. the postverbal DP) of an inverse copular sentence is prohibited.

3.2 Explaining locality restrictions on the subject of inverse copular sentences

Although we cannot go through a detailed analysis, I would like to suggest the major lines of reasoning.[9] The crucial fact to notice is that the postverbal subject of an inverse copular sentence is in fact in the same kind of situation as the preverbal subject is in, as far as locality is concerned. For the sake of simplicity, let us represent the two fragments as follows:

(35) a. . . . V^0 [DP . . .
b. . . . C^0 [DP . . .

In both cases, the subject is governed by a non-lexical head within a clause structure; the complementizer in (35a) and the copula in (35b). Taking the traditional view stemming from the Aristotelian tradition, we will consider the copula as a functional head expressing the inflectional feature of the clause. This allows us to understand the locality phenomena in a principled framework.

Let me synthetically anticipate the lines of reasoning. The central idea is that the absence of movement of and from the postcopular DP of an inverse copular sentence is related to two independent locality conditions that have been recognized since the early models within the Principles and Parameters framework: first, movement of a phrase can originate only in a context that is 'rich' enough to signal the origin of movement (ECP); second, movement cannot cross two arguments in a single step (Subjacency). These two notions have been variously implemented, although there is general agreement that they depend on two distinct grammatical features (although the two are not totally independent, of course): the ECP is related to agreement (cf. Chomsky 1981: 251; Rizzi 1990b) while the Subjacency condition is related to lexicality (cf. Chomsky 1986b; Cinque 1990c; Chomsky 2000: 117). Adopting this view, we can explain the extraction asymmetries as follows. Any version of the Subjacency condition based on L-marking would immediately exclude extraction *from* the postverbal noun phrase of an inverse copular sentence (cf. (35a)). Why is this? L-marking is a local relation between a head and a full phrase: the head marks the full phrase according to the information specified in the lexicon. Prototypically, a head would L-mark its complement; hence, V^0 L-marks the object, P^0 L-marks the noun phrase it precedes, etc.[10] In general, the local relation that counts for L-marking is the government relation.[11] The fact is that neither C^0 nor V^0 is able to L-mark the lower DP. Although they govern it, they do not select it; hence the DP counts as a barrier and it blocks movement from the noun phrase.

However, the absence of L-marking cannot be regarded as the reason why movement *of* the postverbal noun phrase of an inverse copular sentence is not

possible. In fact, movement of the noun phrase from this position is fully grammatical in canonical copular sentences. To understand why movement of the noun phrase is blocked, we can rely again on the fact that the subject of inverse copular sentences is in the same syntactic environment as a preverbal subject, i.e. that (35a) and (35b) are essentially analogous as regards locality conditions. Consider the structural condition that permits extraction of the preverbal subject. Since Rizzi (1990b), it has been assumed that such a movement can be performed by passing through the spec position of a governing head and activating agreement on it;[12] if that position is already occupied, say by a *wh*-phrase, there can be no extraction from the preverbal position (cf. *who do you know t* C^0 *t represented Heaven in this way t?* vs. **who do you know how* C^0 *t represented Heaven t?*). Thus, we can simply extend Rizzi's ECP-based analysis to the case of copular sentences: if the spec of the copula is hosting the raised predicate, the lower subject cannot be extracted from the small clause for ECP reasons. Thus, we can derive the facts of the previous section from principled reasons: the subject of an inverse sentence cannot be moved as a whole and there cannot be extraction from it, for ECP and Subjacency reasons respectively.[13]

The contrast between phrases headed by *which* and *what* in both canonical and inverse copular sentences is also explained. Consider again the relevant examples, reproduced here as (36):

(36) a. *which picture of the wall do you think that the cause of the riot is?
b. what do you think that the cause of the riot is?
c. *[which cause of the riot] do you think that a picture of the wall is t?
d. [what] do you think that a picture of the wall is t?

The fact that *which picture of the wall* cannot be extracted is explained regardless of the difference between canonical and inverse copular sentences, as we just said: the agreement features of the copula have already been activated by the chain of the predicate, witness the agreement on the verb: thus, movement of *which picture of the wall* yields an ECP violation in (36a). In fact, if *which picture of the wall* is to be extracted, this can only happen from a preverbal position such as *which picture of the wall do you think is the cause of the riot?* But why is it possible to move *what* in (36b)? If we maintain the theory presented here, the possibility of extracting *what* in (36b) forces us to assume that: first, (36b) is a canonical sentence where the extracted element is the predicate not the subject, i.e. (36b) is the interrogative counterpart of a sentence like *the cause of the riot is a very stupid event*; second, the trace of *what* is not governed by the agreement features contained in the copula – rather it is governed by an abstract head contained in the predicative DP it is extracted from. Notice that there is independent evidence that *what* is more embedded than *which* in the DP it is contained; witness contrasts like the following:

(37) a. *[which a girl] I met!
b. [what a girl] I met!

This contrast suggests that the proper internal structure of the *wh*-phrase is one where *what* is generated in a lower position than *a*, as if it were the *wh*-counterpart of an expression like *a wonderful girl*, whereas *which* competes for the same position as *a* and thus is excluded:

(38) [what [$_{D^0}$a] [. . . t . . .

Thus, the reason why (36b) and (36d) escape the ECP violation is that the trace has a different proper governor to rely on, arguably an abstract head belonging to the D^0 system which is not available to *which*.

3.3 Rightward agreement in inverse copular sentences: pro as a null predicate

Let us now turn to the contrast between English and Italian concerning agreement. Recall the relevant examples, reproduced here as (39):

(39) a. the cause of the riot is/*are some pictures of the wall
b. la causa della rivolta sono/*è alcune foto del muro
c. the cause of the riot are/is some pictures of the wall

Two assumptions must hold in explaining these facts: first, agreement in Italian cannot be the result of a spec–head relation between the copula and the subject because we independently know that the subject of an inverse copular sentence can never move; second, it would be highly desirable from a theoretical point of view if such a cross-linguistic distinction could be traced back to the presence of pro in Italian, since this contrast could then be immediately traced back to an independently motivated parametric distinction between the two languages concerning verbal agreement, i.e. the pro-drop parameter. These considerations lead to the following partial representation in Italian:

(40) [DP . . . pro copula [DP . . .

What triggers agreement on the copula in Italian is not the preverbal DP but rather pro, which indirectly agrees with the subject in situ: in other words, pro would play the role of a *null predicate* rather than of a *null subject*. Notice that the fact that pro can play the role of a null predicate along with that of a null subject is independently motivated by sentences like *sono io* 'am I', 'it's me', whose correct structure (41a) is the exact opposite of the one assigned by Chomsky (1981: 88, 289fn 14) (41b), where *io* (I) was considered to be the predicate while *pro* was considered to be the null subject:

(41) a. pro sono [io t]
b. pro sono [t io]

That (41) is an inverse copular sentence can be easily proved by noting that: first, *io* cannot be cliticized to yield *lo sono* (which incidentally is grammatical but

corresponds to the cliticization of the predicate in a canonical sentence like *sono stanco* 'am tired');[14] second, by no means can *sono io* be considered as similar to *telefono io* 'telephone I', namely as an instance of the inverted subject sentences typical of null-subject languages (cf. Chomsky 1981; Rizzi 1990b). In fact, *io telefono* is a well-formed sentence whereas **io sono* is ungrammatical. The reason why the latter sentence is not well-formed is due to the conspiracy of two independent factors: on the one hand, the copula must co-occur with a subject and a predicate (unlike *telefonare*, which can occur with only one DP); on the other hand, pro cannot be licensed in situ in the small clause; it can be licensed only in sufficiently rich morphological environments, such as the preverbal position. Thus, **io sono* is ungrammatical for the lack of a predicate and *sono io* is an inverse copular sentence.

Second, in which structural position is the preverbal DP? There are two possibilities here. Either the DP is in a spec position of the split Comp field in the sense of Rizzi (1997), or it is within the IP system higher than spec-AgrS (or any equivalent spec position which triggers agreement on the verb). That such a DP cannot be in the split CP field can be tested by activating the lower head position of such a split system, namely Fin^0. One possibility is to occupy Fin^0 by a verb, as in Aux-to-Comp constructions, and see where the DP is:

(42) a. . . . [essendo] [$_{IP}$ la causa della rivolta t le foto del muro . . .
being the cause of the riot the pictures of the wall
b. *. . . la causa della rivolta . . . [essendo] t le foto del muro . . .
'being the cause of the riot the pictures of the wall'

The preferred sequence is the one where the DP follows the auxiliary raised to Fin^0, offering a piece of evidence in favor of the idea that the preverbal DP in Italian inverse copular sentences is lower than the split Comp field. Interestingly, notice that if this analysis proves tenable, inverse copular sentences would offer a strong clue to children acquiring Italian, since they would be forced to assume that pro is obligatory in preverbal position with all verbs, unless one wants to assume the rather implausible hypothesis that pro is obligatory only with the copula and specifically only with inverse copular sentences.[15]

Third, why is pro coreferential with the overt DP? There is no explanation for this fact, but it must be observed that this is the very same phenomenon one observes in inverted subject constructions in a pro-drop language, as in *telefona Gianni* (pro *telephones Gianni*, 'Gianni telephones') where pro is forced to be coreferential with the postverbal DP *Gianni*.

4 Conclusion

Summarizing, the unified theory of copular sentences of the type [DP V DP] presented here crucially relies on the hypothesis that along with canonical copular sentences where the subject is raised to the preverbal position ([DP V [t DP]]),

there also exist inverse copular sentences where the predicative noun phrase is raised to the preverbal position, leaving the subject in situ ([DP V [DP t]). This allows us to derive the observed anomalies concerning movement in copular sentences. Specifically, it can be observed that the postverbal subject of an inverse copular sentence is in a local environment similar to that of the preverbal subject of an embedded sentence governed by an uninflected overt complementizer: there can be no movement of the subject (for ECP reasons) and there can be no movement from the subject (for Subjacency reasons). The distribution of the copula in infinitival copular sentences can be immediately interpreted, since it is only in inverse copular sentences that the copula cannot be omitted, i.e. it cannot be omitted when there would be no specifier position for the predicative DP to cross over the subject. As for the agreement facts, the unified theory allows us to assume a conservative analysis, suggesting that along with the role of the null subject, pro can also play the role of a null predicate, yielding non-trivial consequences for language acquisition.

Clearly, this unified theory of copular sentences is not able to solve all problems and questions raised by this type of construction. Nevertheless, this theory has provided promising tools for a progressive unification of other fields. A first example is existential sentences of the type *there copula DP*: this particular type of copular sentence has played a central role in the development of formal syntax since at least Jespersen (1924). I will simply refer here to chapter 24, where *there*-sentences are treated in detail. Another example is cleft and pseudocleft-sentences. Given that cleft and pseudo-cleft sentences are instances of copular sentences of the kind [DP V DP], the obvious question has been raised whether clefts and pseudo-clefts are instances of canonical or inverse copular sentences and, more importantly, whether this unified theory is helpful in understanding their syntax (see chapter 61).[16] A further question is raised by sentences of the kind *it copula CP*, such as *it's that John will not come here today*, as the answer to *what is is that bothers you?*: clearly, assuming the unified theory proposed here it would be hard to say that they are instances of canonical copular sentences, because this would amount to saying that the CP following the copula plays the role of a predicate – hardly a plausible assumption. Rather, the residual option allowed by the unified theory of copular sentences is more promising, since sentences of the kind *it copula CP* (like *What is it that bothers you?*, *It's that John left*) can be considered inverse copular sentences, where the CP plays the role of a subject and the preverbal DP (*it*) plays the role of the propredicate; i.e. [it is [CP t]] is their structure. Interestingly, this analysis of sentences of the type *it copula CP* raises an obvious question as to the structure of the type *it seems CP* (like *it seems that John left*), where the so-called 'quasi-copula' *seem* occurs. Indeed, in Moro (1997) a theory of *seem*-sentences was proposed that analyses *it seems CP* sentences as involving raising of a propredicative *it* out of an embedded clausal structure whose subject is a CP (namely, [it seems [CP t]]), paralleling inverse copular sentences of the type [it is [CP t]]. Other questions raised by the unified theory presented here involve the plausibility of predicative DP raising in other domains. Indeed, an extension of the analysis based on predicative raising has

been proposed by Kayne (1994), Dikken (1995b), Zamparelli (1995) and Bennis et al. (1998) in the field of noun phrases, interpreting, for example, cases like possessive constructions (*the car of John*) or epithets (*this idiot of (a) John*) as involving predicative raising across the subject, first proposed in the field of copular constructions.

We end the discussion here, concluding much as we have started, observing that copular sentences still constitute an open field of discussion and one that has very intricate relations with many other domains of grammar.

NOTES

1 For a quick list of references within generative grammar, one could see Ruwet (1975); Higgins (1979); Moro (1987, 1988, 1997); Stowell (1978); Longobardi (1985); Heggie (1988); Williams (1980); Heycock (1994b); Guéron (1992); Dikken (1998b); Heycock and Kroch (1999). For a full list of references in the field since Aristotle, instead, see the appendix of Moro (1997).

2 Higgins (1979), quoting Geach (1962), suggests that the impossibility of *wh*-moving a predicate headed by *which* is a semantic restriction called Buridan's Law: we will see that such an asymmetry can be traced back to the different syntactic nature of the two *wh*-words.

3 The fact that the two DPs in (23) can be inverted simply shows that in these cases there is no way to decide *a priori* which noun phrase is the subject and which one is the predicate, as was already clear in Jespersen (1924: 153 ff).

4 Although this is not the place to expand working intuitions, it may be noticed that the postverbal subject of (24d) is focused: this could be a hint to construe an explanation for backward reflexivization. See also Moro (1997: 274) for a critical discussion. For the role of Focus on Binding phenomena see also Heycock and Kroch (1999).

5 This type of structure is to be kept carefully distinct from cases of 'locative inversion.' Hoekstra and Mulder (1990), for example, suggested that unaccusatives can be analyzed as 'locative inversion' constructions where spec-IP is occupied by a PP (ia) on a par with copular constructions like those in (ib) (see Hoekstra and Mulder 1990: 28 ff):

(i) a. $[_{IP}\ [_{PP}$ into the room$]_i$ enters $[_{SC}$ a man $t_i]]$
b. $[_{IP}\ [_{PP}$ in the room$]_i$ is $[_{SC}$ a man $t_i]]$

This analysis, which explicitly subsumes the theory of *there*-sentences as inverse sentences proposed in Moro (1991) (cf. Hoekstra and Mulder 1990: 33 ff), cannot be maintained, for empirical reasons. Consider the following examples:

(ii) a. $[_{DP}$ the cause of the riot$]_i$ is $[_{SC}$ a man $t_i]$
b. $[_{DP}$ the cause of the riot$]_i$ is/*are $[_{SC}$ John and Mary $t_i]$
c. $[_{PP}$ in the room$]_i$ is $[_{SC}$ a man $t_i]$
d. $[_{PP}$ in the room$]_i$ are/*is $[_{SC}$ John and Mary $t_i]$

Assuming that agreement is invariantly established in spec-IP, it would be hard to assume that (ia) and (ib) instantiate the same type of structure. Rather, (ib), repeated

as (iic), is an instance of the topic constructions that have been analyzed by Cinque (1990c) and Rizzi (1997) involving some portion of the scattered CP layer (and movement of the verb to a higher functional head). This would explain why the equivalent of (ib) in Italian involves a locative clitic *ci* (iiia) which is not allowed in an inverse copular constructions (iiib):

(iii) a. $[_{IP}\ [_{PP}$ nella stanza$]_i$ *(c') era $[_{SC}$ un uomo $t_i]]$
b. $[_{IP}\ [_{DP}$ la causa della rivolta$]_i$ (*c') era $[_{SC}$ un uomo $t_i]]$

The status of *ci* with the copula is discussed in detail in a separate case study, chapter 24. As for the lack of *ci* in Italian unaccusatives (but not in many northern Italian dialects; see Burzio 1986 and Poletto 1993), see Moro (1997).

6 It should be noted that the idea that copular sentences always occur with one predicative and one referential DP (hence the idea that the preverbal noun phrase can be a predicate when the postverbal one is a subject) was first proposed by Jespersen (1924), and independently introduced in generative grammar by Longobardi (1985). Moro's contribution (in Moro 1987, 1988, and subsequent works) was to propose a *transformational* analysis relating the two surface structures.

7 I will not discuss here the reasons that drive DP movement to preverbal position. Whether it is Case, as generally assumed, or Dynamic Antisymmetry (as proposed in Moro 2000), is still under debate.

8 The fact that the two sentences share the same lexical structure does not imply that they are synonymous. In fact, in the inverse copular sentence the postverbal subject is inherently focused, as opposed to what occurs in canonical copular sentences. The nature of focus within VPs is quite an obscure issue; certainly one cannot simply assume that the focus-related position here is the same as the Focus position in the split-Comp field explored by Rizzi (1997); see Belletti (1999a) and Longobardi (1999) for extensive discussion of postverbal focus positions.

9 See Moro (1997) or the appendix of Moro (2000) and references cited there for a detailed proposal on the locality conditions applying on the subject of inverse copular sentences.

10 There are various ways of implementing the notion of L-marking relying, for example, on theta-relations (Chomsky 1986a) or selection (Cinque 1992). The latter appears to be empirically more adequate; a head X^0 L-marks a phrase YP if and only if X^0 governs YP and X^0 selects YP. It is interesting to note that the notion of L-marking endures even in the Minimalist framework. "Though varieties of govenment would be 'imperfections,' to be avoided if possible, the closer-to-primitive notion of L-marking should pass muster, hence also the notions of barrier that are based on nothing more than L-marking" (Chomsky 2000: 117).

As for the class of phrases to which L-marking applies, notice that when the predicate is left in situ, extraction is fully grammatical even if there is no L-marking. Hence, we should regard L-marking (hence barrierhood) as a specific condition on argumental noun phrases, not on predicative ones, which behave like verbal phrases much as in the original definitions of the Subjacency conditions (see Roberts 1988a for a critical discussion).

11 For the sake of clarity, let us assume government to be a local c-command relation: a head governs its complement, the head of its complement, and the spec of its complement. For a critical discussion of government see Giorgi and Longobardi (1991); Rizzi (1990b).

12 Agreement then turns out to be the element which performs the 'action at a distance' that the ECP is about, and it has been proposed that it can be generalized to virtually all cases in Moro (1993b). In fact this appears to be one possible implementation of a universal requirement that has long been recognized within generative grammar: "it is not unreasonable that Universal Grammar should require that the presence of an empty category be signalled in some manner by elements that are overtly present" (Chomsky 1981: 251).

13 For independent reasons for assuming a two-principle theory of locality, see chapter 24.

14 Notice that *chi sono* 'who am' cannot be considered as the counterpart of *sono io* 'am I'; first person pronouns can never be *wh*-moved (cf. *telefono io* 'telephone I' vs. * *chi telefono?* 'who telephone-first sing.'. This can be regarded as a further support to the idea that the subject of inverse sentences does not move.

15 Incidentally, notice that inverse copular sentences are not rare: they are extremely productive in Italian, even in child speech contexts.

16 Rightward agreement in Italian can be exploited as a diagnostic in these cases. In fact, in Italian cleft and pseudo-cleft sentences it is clearly the case that agreement goes to the right, as in *sono i libri che Gianni legge* 'it are books that Gianni reads' or *ciò che Gianni non gradisce sono i libri* 'what John doesn't like are books'. One can easily conclude that cleft and pseudo-cleft sentences are instances of inverse copular sentences.

9 Conclusion

1 Introduction

Derived nominals are nominal structures derived from other syntactic categories by means of derivational affixes. In modern linguistic tradition this term is associated with deverbal nominalizations denoting eventualities of various sorts (as opposed to, e.g., agentive *er* nominals). In the generative tradition the study of derived nominals thus understood dates back to Lees (1960). Since then, during subsequent stages of the development of the theory of grammar, and as a result

of the ever growing interest in nominalizations, various problems have been identified and their number keeps growing in view of the recent intensive cross-linguistic studies.

Cross-linguistically, derived nominals have a mixture of nominal and verbal properties. As categorial hybrids they constitute a challenge to the modern theory of grammar. Even in a single language such as English the range of derived nominal constructions is quite diversified with respect to their nominal and verbal properties: derived nominals such as *destruction*, nominal gerunds such as *the destroying of the city*, or verbal gerunds such as *destroying the city* (chapter 30). Different languages show different nominalization patterns and variations. Therefore it is very difficult to develop a theory that would provide a consistent account of all the varieties. There is no consensus as to the nature of the nominalization process and the relationship of the derived nominal to the base verb. Among derived nominals, action nominalizations (that is, those derived from Agent–Patient verbs like *destroy*) have been studied most extensively. They have usually constituted the basis for the development of various theories, which, on closer scrutiny, do not always work when confronted with derived nominals from other semantic classes, such as, for example, nominalizations of the notorious Experiencer verbs like *fear* or *amuse*. The mixed categorial nature of derived nominals, the inter-language and intra-language variations as well as the Experiencer problem have inspired research in this area, at the same time leading to a lot of controversy. Here we will be primarily concerned with the derived nominals proper, and not with gerundial constructions or nominal infinitives (chapter 30). The prototypical derived nominal is presented in (1):

(1) a. the enemy's destruction of the city
    b. the destruction of the city by the enemy
    c. the city's destruction by the enemy

Koptjevskaja-Tamm (1993), following the tradition represented earlier by Comrie (1976b) or Comrie and Thompson (1985), provides an exhaustive cross-linguistic and typological classification of languages with respect to action nominal constructions (ANCs). Typological studies reveal that languages vary as to the closeness of nominalizations to underived noun phrases or to verb phrases in respect of both semantic and syntactic properties. Their intermediate nature is unquestionable, though: they are indeed a mixed category rather than an independent category whose properties would be different from those of NPs or VPs. Although they have nominal external distribution, their internal syntax is often not unlike that of a verb phrase. The degree of their 'nouniness' and 'verbness' varies from the point of view of both intra-language and inter-language variation. All these facts remain problematic in view of the generally endocentric phrasal pattern encapsulated in the X-bar conventions and the prevailing generative conception of syntactic categories as discrete elements within a system of contrastive oppositions. In view of the universality of the noun–verb distinction (which is assumed in different linguistic traditions; cf. Sapir 1921: 117–19; Hopper

and Thompson 1985), the task of the linguistic theory is to provide an account of the categories which clearly show both nominal and verbal properties. The history of nominalization studies shows that at various points different aspects of the properties of derived nominal structures were discovered and emphasized. Particular theories focus either on what nominalizations share with verbs or on what makes them nominal. There is no single division line between various approaches, though some researchers try to simplify the issue and group the approaches into complementary pairs. Thus we can often encounter such binary divisions as transformationalist vs. lexicalist approach or syntactic vs. lexical derivation.

2 Transformationalist–lexicalist controversy

This binary contrast is assumed by Koptjevskaja-Tamm (1993), Borer (1991, 1993), and Fu (1994). The early transformational approach is represented by Chomsky (1957) and Lees (1960) and contrasted to the Lexicalist Hypothesis developed in Chomsky (1970). The transformationalist approach is to make the link between derived nominals and their corresponding verbs a matter of syntactic derivation; the lexicalist approach is to express the link in the lexicon. In the early stages of the development of generative grammar the only possibility of expressing the link between related structures was via a syntactic transformational process operating on sentences, which by its nature accounted for clausal properties of derived nominals. Chomsky's (1970) seminal paper "Remarks on Nominalization" was a reaction to the transformationalist hypothesis. He argued against a transformationalist analysis of derived nominals, illustrated further in (2) and having their sentential counterparts in (3):

(2) a. John's eagerness to please
    b. John's refusal of the offer
    c. John's criticism of the book

(3) a. John is eager to please.
    b. John has refused the offer.
    c. John criticized the book.

Chomsky (1970) pointed out that the following properties of derived nominals are problematic for the transformationalist approach:

- The productivity of derived nominals is restricted.
- The semantic relations between the associated proposition and the derived nominal are quite varied and idiosyncratic.
- The nominal has the internal structure of a noun phrase.
- Well-known transformations that apply to sentences (such as raising to object, raising to subject, or dative shift) are barred from nominalizations.

He provided an alternative account, the Lexicalist Hypothesis, according to which derived nominals constitute separate items in the lexicon. Building on an elaborated system of syntactic features introduced in Chomsky (1965), he proposed that the same selectional properties of verbs and related nominals should be captured by the same lexical entry with the same selectional requirements, but neutral with respect to the category. This gave rise to the X-bar theory, widely adopted in modern grammar and extended later on. In this way the link between a derived nominal and its corresponding verb was located in the lexicon, that component of the grammar where all the idiosyncracies are listed. This theoretical move took care of the problems enumerated above. Since then the consensus has been that nominalizations are base-generated in the lexicon rather than syntactically derived, but the question of the relationship between nouns and verbs has not been settled. Rather, it has become much more complex and now it occupies a central place in theoretical research. The dominating tendency in recent studies is to introduce mechanisms which would allow different derivations of different types of derived nominals. Both the lexical tradition and the syntactic tradition in nominalization studies have come to the point where it is necessary to recognize syntactically different, though morphologically identical deverbal derived nominals. There are various independent versions of what might be regarded as the neo-transformational approach. Differ as they may in initial assumptions and theoretically important details, they share the basic claim that the difference in interpretation and argument distribution corresponds either to the level at which a morphological operation takes place or to the functional layers that dominate the nominal head.

The point of departure for the various approaches is the argument distribution in nominals as compared to verbs. Only from the point of view of this single property it turns out that the debate cannot be reduced to the simple transformationalist–lexicalist controversy.

2.1 Configurational hypothesis

The lexicalist approach developed in various directions. One of its most recent versions is represented by Giorgi and Longobardi (1991), who develop Chomsky's (1970) assumption that the structure related to a verb is the same as that related to the corresponding noun. Accordingly, their thematic properties remain the same as well. To put it in simple words, both nouns and verbs have subjects and complements, and both nouns and verbs assign theta-roles to the respective positions in the same way. Furthermore, various rearrangements of arguments within the nominal and verbal projections are due to the same principles of grammar, such as 'Move α', which apply both in the domain of clauses and in the domain of noun phrases. Thus the well-known analogy illustrated in (4) and (5) below obtains:

(4) a. The barbarians destroyed the city.
    b. The city was destroyed by the barbarians.

(5) a. The barbarians' destruction of the city
b. The city's destruction by the barbarians

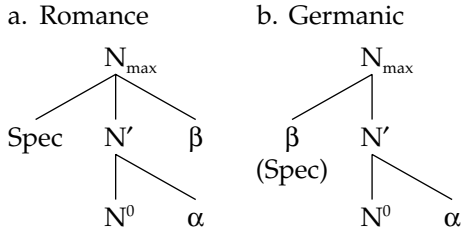
Under this approach (5a) and (5b) are transformationally related in the same sense in which (4a) and (4b) are, and the possessive phrases of (5) have the same prominence as the surface subjects of (4). These views are generalized into the Configurational Hypothesis, consisting of two clauses:

(6) **Configurational Hypothesis:**

- It is possible to identify, within NPs, definite theta- (and non-theta-) positions at various levels of hierarchical attachment: whenever an element of the N-frame appears in a position arguably different from the one where it should be projected at D-structure, its displacement must, then, be governed by the general conditions holding on antecedent–trace relationships created by 'Move α'; moreover, the binding of anaphors and pronouns in NPs obeys the same constraints as observed in clauses.
- The theta-structure of Ns (their theta-grid and the conditions on theta-assignment) strictly parallels that of Vs, so that the differences appearing on the surface must be due to the intervention of other modules of grammar which determine some systematic variation (Giorgi and Longobardi 1991: 2).

To accommodate the differences in the distribution of NP satellites between Germanic and Romance languages, Giorgi and Longobardi enrich the X-bar theory with the directionality parameters: 'Head–Complement' and 'Head–Subject'. Internal arguments are projected to the right of the head in Romance and in Germanic; external semantic functions are licensed at D-structure on the right in Romance but on the left in Germanic, as represented in a simplified way in (7):

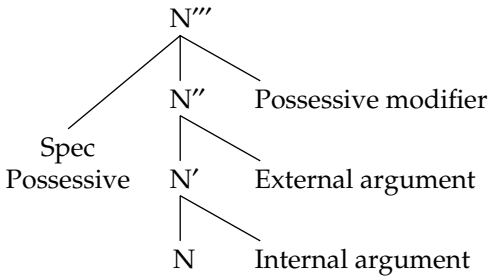
(7) **The Head–Subject Hypothesis:**



(β = subject, α = complement).

Next, on the grounds of binding evidence, Giorgi and Longobardi propose a three-layer structure for an Italian NP:

(8)



In Italian NPs, all the occurrences of arguments to the left of N are the result of movement to Spec (core case of movement), which together with the Possessivization Principle quoted in (9) is supposed to account for the distribution of arguments and for the binding facts in Italian:

(9) **Possessivization Principle:**
The unique phrase allowed to appear as a possessive is the hierarchically highest genitive argument of an NP (Giorgi and Longobardi 1991: 68).

Giorgi and Longobardi claim that the syntactic template of the NP determined by the parameters fully predicts the distribution of arguments in nominals. This is by virtue of the fact that the null assumption of the Configurational Hypothesis is that all the grammatical processes, including the theta-assignment conditions, are identical for verbs and nouns. On this approach no reference to lexical or semantic information is allowed, apart from recognizing the classic syntactic distinction between external and internal arguments (introduced by Williams 1981a) in the theta-grid of a lexical item, neutral with respect to the category. Given the syntactic template for the NP with canonical D-structure positions for the internal and external arguments of the theta-grid (which distinction is equivalent to the distinction between the object and the subject), the distribution of arguments is predicted. By its nature, configurational approach does not refer either to the content of thematic roles or to any other kind of lexical information.

Giorgi and Longobardi (1991) are primarily concerned with the structure of NP as such. They do not discuss complexities within the domain of derived nominals such as the result/process distinction. Nor do they provide any explanation for the failure of Agents of transitive actions to surface as subjects of NPs, which is attested in a number of languages (e.g., Romance, Slavic, Modern Greek), as opposed to Agents of result nominals (sometimes also referred to as material nouns).

2.2 Non-configurational thematic approaches

The configurational hypothesis assumes complete parallelism between verbs and nouns and, as described in the previous section, mapping principles are stated in syntactic terms. On closer investigation it turns out that the argument realization

in derived nominals depends on some semantic distinctions which the categorial view ignores. Those who recognize the distinctions differ in what they consider crucial for stating important generalizations.

The regular pattern in (1), which gave rise to the categorial lexicalist approach, is attested only for prototypical Agent–Patient predicates. English nominalizations from verbs with non-affected objects (chapter 5) do not have a passive nominal:

(10) a. John enjoys the movie.
b. The movie is enjoyed by John.
c. John's enjoyment of the movie
d. *the movie's enjoyment by John

Anderson (1984) proposes a constraint which prohibits movement of non-affected objects to the Specifier position of an English NP. In addition to cases like (10) we observe the non-existence of nominalizations derived from Object Experiencer verbs:

(11) a. *the book's amusement of the children
b. *the news' terror/horror of Mary
c. *his rude behaviour's disgust of Mary
d. *the book's delight of the public

The regularity of the patterns illustrated in (10) and (11) inspired lexicalist non-categorial thematic approaches to nominalization represented among others by Amritavalli (1980), Rappaport (1983), Hoekstra (1986a), and Rozwadowska (1988). Their essence is the claim that formal realization of arguments is determined by their thematic role with respect to the head. In other words, it is not the syntactic structure which is directly inherited from the verb by the nominal, but the thematic grid. The mapping rules are then formulated directly in terms of thematic relations assigned by a predicate. Moreover, verbal and nominal projections are treated separately, and accordingly, the mapping rules between theta-roles and structural positions for nominals are formulated separately from the corresponding verbal projections. The theta-grid itself can be shared by nominals and verbs, but the rules are independent.

Although the thematic generalizations formulated in various ways and using various thematic labels are observationally adequate, the explanatory value of thematic generalizations both with respect to nominalizations and with respect to other grammatical phenomena has been questioned. Thematic systems are notorious for the arbitrariness of their definitions and the multiplicity of their thematic labels. New thematic labels are often introduced as the need arises, and it is quite difficult to achieve a consensus on what and how many thematic relations do exist. The attempts to decompose the thematic labels into a small, finite set of features (such as, e.g., Rozwadowska 1992; Reinhart 1996) reduce the number of primitives and account for the substantial overlap among the

traditional atomic concepts but do not provide any more principled, motivated, or explanatory basis for the generalizations.

The next stage in the non-configurational lexical approach was the event-structure approach to derived nominals developed in Grimshaw (1990) and discussed in section 4. The event-structure approach is closely connected with the result/process ambiguity discussed in section 3. The Event Structure Theory of nominalization developed in Grimshaw (1990) can be placed in between the configurational (categorial) view and the thematic view. There are two important ingredients of this approach. First, it makes crucial use of the distinction between result nominals and process nominals, and second, it introduces a derived lexical level of argument structure, which determines both the argument distribution in nominalizations and the existence of a nominalization itself. The mapping rules do not refer directly to thematic roles, but to the lexical level of Argument Structure, which is derived from the Lexical-Conceptual Structure via a two-dimensional hierarchy, one dimension being thematic and the other aspectual. The aspectual hierarchy presupposes the existence of an event structure in the sense of Pustejovsky (1988). Thus, ultimately, nominalizations are analyzed in terms of event structure.

3 Result/process ambiguity

Significant ambiguities within the system of nominalization were discussed by Anderson (1984), Walinska de Hackbeil (1984), Grimshaw (1986, 1990), Lebeaux (1986), Roeper (1987b), Zubizarreta (1987), Malicka-Kleparska (1988), Picallo (1991), Bottari (1992), Schoorlemmer (1995, 1998a), Rozwadowska (1997), Engelhardt and Trugman (1998a, 1998b), Rappaport (1998), and Alexiadou (1999b), among others. Anderson (1984) distinguishes between concrete nouns, such as *store*, which take lexical possessives, and abstract nouns, such as *reliance*, where *'s* is inserted transformationally. A similar distinction between abstract and concrete nominals is the basis for Malicka-Kleparska's (1988) distinction between regular nominalizations and their irregular lexicalizations. Walinska de Hackbeil (1984) discusses a relation between clausal nominals with a full theta-grid, and the so called theta-nominals, where one of the argument positions is absorbed in the lexical process. The properties of the clausal nominals as contrasted to those of the theta-nominals are illustrated below:

(12) a. Possession *(of such knife) was her dream.
b. This is my favorite possession (*of such knife).

(13) a. Their acquisition by the museum was thoughtless.
b. *Their recent acquisitions are here. (ungrammatical on the passive interpretation)

(14) a. The doctor coldly observed this nervous crossing and uncrossing of legs.
b. This (*un)crossing on the Ave is dangerous.

In (12a) the clausal nominal requires the presence of the theme argument, which contrasts with (12b), where we have the corresponding theta-nominal with no argument possible. Examples in (13) illustrate a possibility of passivization within the clausal nominal and its impossibility in the case of the theta-nominal. This is claimed to be a consequence of the absence of the argument structure in the latter case. (14) illustrates the difference between the two kinds of nominals with respect to propositional negation. To summarize Walinska de Hackbeil's observations, the action/process nominals in the (a) examples above are clausal nominals because they share a number of properties with clauses, while the theta-nominals in the (b) examples lack such properties.

The distinction between process nominals (since Grimshaw 1990, these are often referred to as complex event nominals and abbreviated to CENs) and result nominals has been well documented cross-linguistically. Zubizarreta (1987) draws a similar distinction between result and event nominals and accounts for the difference between them with respect to argument realization, illustrated in (15) and (16) for Romance languages. The nominals in (16) have only the event interpretation as opposed to the result interpretation in (15):

(15) a. la descrizione degli avvenimenti di Gianni
the description of the facts of Gianni
'Giannni's description of the facts'
b. la description du paysage de Pierre (Fr.)
la descripcion del paisaje de Pedro (Sp.)
'Pierre's description of the landscape'
c. sa description du paysage (Fr.)
su descripcion del paisaje (Sp.)
'his description of the landscape'

(16) a. la description du paysage par Pierre (Fr.)
la descripcion del paisaje por Pedro (Sp.)
'the description of the landscape by Pierre'
b. l'interprétation des données par Pierre (Fr.)
la interpretacion de los datos por Pedro (Sp.)
'the interpretation of the data by Pierre'
c. la traduction de l'oeuvre de Balzac par Pierre (Fr.)
la traduccion de la obra de Balzac por Pedro (Sp.)
'the translation of Balzac's work by Pierre'
d. la démonstration du théorème de Pythagore par Pierre (Fr.)
la demonstracion del teorema de Pitagora por Pedro (Sp.)
'the proof of Pythagoras's theorem by Pierre'

The main difference between (15) and (16) is that the Agent is realized as the second post-nominal genitive (or a prenominal possessive pronoun) with result nominals but in the *par* phrase (the equivalent of the English *by* phrase) with event nominals. There is a clear complementary distribution between these two varieties.

Similar facts obtain in other languages. The clear difference between result nominals and process/event nominals in respect of both the internal and external distribution, including co-occurence with adjectives and adverbs, has been discussed recently for Italian in Bottari (1992); for Catalan in Picallo (1991); for Greek in Markantonatou (1995), Alexiadou (1999b), and numerous references therein; for Russian in Schoorlemmer (1995, 1998a, 1998b), Engelhardt and Trugman (1998a, 1998b), Rappaport (1998); for Polish in Rozwadowska (1997) and Willim (1999, 2000). It turns out that in addition to the distinctions similar to those identified for English, one of the salient and very clear properties of derived result nominals in Romance, Slavic, and Greek is the possibility of two adnominal genitives in the case of result nominals derived from transitive verbs. Such distribution is never possible with process/event readings. The latter may take only one adnominal genitive, always expressing the Theme (Patient) argument. The Agent must appear in an optional prepositional phrase or in the instrumental case (equivalents of the English *by* phrase). While the contrast is uncontroversial and widely recognized, the terminology and the views are not uniform. Thus, for instance, nominals with the *by* phrase are standardly referred to as passive nominalizations. In a non-standard way, Alexiadou (1999b) takes the single genitive restriction as the indication of the intransitivity and accordingly refers to them as intransitive nominals. Consistently, result nominals taking two adnominal genitives are treated by her as transitive nominals.

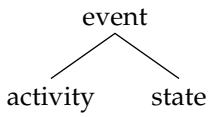
This obvious contrast has led to the development of various approaches concerning both the internal structure and the derivation of the respective subtypes of derived nominals. Zubizarreta (1987) attributes that difference to a universal distinction between *description*-type nominals and *destruction*-type nominals, the former being ambiguous between the result, non-argument taking nominal, and the event nominal with predicate–argument structure. Thus for Zubizarreta, in Romance nominals the adjunct genitive phrase (i.e., the external postnominal argument in Giorgi and Longobardi's 1991 theory), generated in the postnominal position immediately under the NP node, has two essential properties: it is lexically marked as +Poss and it is syntactically bound to the Specifier position. Zubizarreta defends the hypothesis that the nominals which denote an event cannot carry a Poss-variable, while the nominals which denote the result of a process can. This explains the contrast between the *destruction*-type and the *description*-type nominals: the event nominals in contrast to the result nominals cannot carry the Poss variable, and consequently the genitive adjunct *de NP* cannot receive an interpretation.

4 The event-structure theory of nominalizations

The result/event ambiguity was taken as the starting point for a more elaborated theory developed by Grimshaw (1990), who refers to that ambiguity as the result/process distinction and links the ambiguity with aspectual properties, arguing that the real distinction is between nouns that have an associated event

structure (the so called complex event nominals) and nouns that do not. The latter include both the result nominals discussed in section 3 and simple event nominals (abbreviated to SENs) such as, e.g., *examination* (=*exam*), *race*, *war*, *storm*, etc. An example of the internal event structure for an accomplishment, analyzed as consisting of two subevents, is given in (17):

(17)



For an event to count as complex, it does not need to be necessarily a branching event. This means that one of the branches may be empty. It is only crucial that it should be analyzable in terms of aspectual distinctions, i.e., that it has some temporal organization. Thus all kinds of Vendlerian events count as complex: activities, achievements, accomplishments, and also states (such as, for instance, *fear* or *love* in Grimshaw's analysis).

In Grimshaw's theory, argument structure is composed from the thematic and aspectual analyses of a predicate according to the respective hierarchies given in (18). She hypothesizes that any predicate lacking an aspectual analysis will also lack an argument structure and will never take any grammatical arguments at all:

(18) a. (Agent(Experiencer(Goal/Source/Location(Theme))))
b. (Cause(other(. . .)))

The prediction is that complements to complex event nominals will be obligatory (i.e., capable in principle of being obligatory but perhaps subject to lexical variation). Since derived nominals are often ambiguous, it is not always obvious how they behave with respect to their argument-taking properties. On closer investigation it turns out that only on their complex event interpretation can they take grammatical arguments. The result nominals take neither Agent nor Patient (or Theme). The complex event nominals do not pluralize, while the result or simple event nominals do. Moreover, the complex event nominals can be modified by aspectual adverbs. These contrasts are illustrated in (19):

(19) a. The assignments were long. (no a-structure)
b. the assignment *(of unsolvable problems) by the instructor
c. Only observation of the patient for several weeks can determine the most likely . . .
d. These observations are very interesting. (no a-structure)

The modifiers *frequent* and *constant* force the complex event reading of the noun and thus its a-structure must be satisfied. Therefore (20b) and (21b) are not grammatical:

(20) a. The expression is desirable.
b. *The frequent expression is desirable.
c. The frequent expression of one's feelings is desirable.
d. We express *(our feelings).

(21) a. The assignment is to be avoided.
b. *The constant assignment is to be avoided.
c. The constant assignment of unsolvable problems is to be avoided.
d. We constantly assign *(unsolvable problems).

According to Grimshaw, the process of nominalization consists in the suppression of the external argument, defined as the argument which is most prominent on both the thematic and the aspectual hierarchies quoted in (18) above. The non-existence of nominals in (22a–b) is explained as a consequence of the non-existence of the external argument in the case of Object Experiencer (OE) predicates: there is a conflict in prominence between the thematic and the aspectual dimensions, and thus there is no argument which could be most prominent on both dimensions, thus qualifying for being the external one. The nominals in (22c–e) are claimed to be result nominals without argument structure – their satellites are mere modifiers:

(22) a. *the event's embarrassment/humiliation of Mary
b. *the movie's (constant) amusement/entertainment of the children
c. Mary's embarrassment/humiliation
d. the embarrassment/humiliation of the bystanders
e. the amusement/entertainment of the children

The suppressed external argument can be realized in a *by* phrase, which is an argument-adjunct (a-adjunct) linked to it. As summarized in (23), the *by* phrase is licensed by the suppressed external argument and in nominals limited to Agents only:

(23) a. by, a-adjunct, external argument
b. by, a-adjunct, Agent

If there is no external argument, the nominalization does not exist, and the *by* phrase is not licensed. (23b), originally proposed by Rappaport (1983), is supposed to explain the impossibility of the Experiencer of a Subject Experiencer predicate being realized in the *by* phrase, as illustrated in (24):

(24) a. *Fear of flying by many people
b. *Dislike of flying by many people

With respect to argument distribution, the predictions of Grimshaw's theory can be summarized as follows: both the *by* phrase and the prenominal possessive are

argument-adjuncts linked to the external argument, lexically suppressed in the process of nominalization. Only complex events undergo the process of nominalization and only such complex event nominals have an argument structure. All the other nominals are either result nominals or simple event nominals, and the rule of the suppression of the external argument of a predicate does not apply to them.

Grimshaw's theory inspired a lot of cross-linguistic research and raised a lot of controversy. The division of nominals into three types (i.e., results, simple events, and complex events) has been generally accepted. What has been questioned or has become highly controversial is the suppression mechanism and the explanation for the distribution of the *by* phrase. This controversy is also closely related to the debate on whether derived nominals are instances of passive nominals or not (cf. Borer 1993; Engelhardt and Trugman 1998b; Rappaport 1998; Schoorlemmer 1998b; Alexiadou 1999b).

5 Neo-transformational account of nominalizations

Another line of current research is represented by Borer (1991, 1993), Hazout (1995), Picallo (1991), Fu (1994), Schoorlemmer (1995, 1998a, 1998b), Engelhardt and Trugman (1998a, 1998b), Van Hout and Roeper (1998), and Alexiadou (1999b). They argue for the syntactic derivation of process nominals in contrast to the lexical derivation of result nominals. Thus their approach can be treated as the revival of the early transformationalist approach within a much more sophisticated and refined syntactic theory, which offers mechanisms and solutions capable of overcoming the drawbacks of the early transformational account. Individual researchers differ in many points, but they all share the assumption that the environment for the morphological operation of combining the nominalizing suffix with the root may be regulated by the presence vs. absence of different functional projections and/or syntactic processes. The inspiration for this approach is the parallel morphology model developed by Borer (1991, 1993).

5.1 Parallel morphology and derived nominals

In contrast to the traditional view on the autonomy of the word-formation component, which assumes the linear ordering between morphology and syntax, Borer (1991, 1993) considers an alternative notion of autonomy which allows the interaction between the two modules in a parallel fashion. According to her, a module is autonomous if (a) it has a distinct set of primitives not found in other modules, and (b) it constitutes a coherent set of formal operations which are distinct from those found in other components. Given this notion of autonomy, there is no need to maintain that two autonomous modules interact with one another at a fixed unique point (like D-structure level in the standard approach). A word can be derived either in the lexicon, before the D-structure insertion, or later on, after D-structure. The post-D-structure word formation is novel as compared to the lexicalist approach. The relevant aspects of the output of each syntactic operation

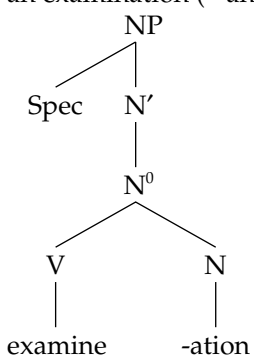
are available to the word-formation component, and likewise, the relevant aspects of the output of each word-formation operation are available to syntax.

A morphological word, an M-word, is the output of the autonomous morphological component with its independent restrictions and properties. Syntactic operations, such as the head-to-head movement, can create the environment in which such word formation can take place. In that case the word formation takes place after a syntactic operation. This process is referred to as the syntactic derivation as opposed to the lexical derivation, which takes place in the lexicon, without any prior syntactic processes. So the word $[YX]_X$, where X (the affix) is the head, can be derived either in the lexicon, prior to D-structure insertion, or in syntax, after D-structure. In the former case the properties of Y, the non-head (the root the affix attaches to), are opaque, whereas in the latter case the properties of the non-head are transparent, because it originates in a syntactic head position, and then is raised to adjoin to the affix. Parallel morphology attributes the transparency of a non-head of a word to the presence of a syntactic projection of that non-head. The transparent properties include both argument structure and adjunct phrases of the non-head. In this regard, parallel morphology differs from lexicalist approaches in assuming that the non-head is syntactically present in the structure.

A word inserted following D-structure, which is both an M-word and an X_0 with a complex syntactic structure, results in the impossibility of any semantic drift in that case. The dual representation as both M-word and X_0 with an internal structure ensures that such words will always have as a subpart of their meaning the semantic and selectional properties of the phrases embedded in them, or a violation of the Projection Principle would result. M-words which do not have a syntactic representation are not thus constrained. Some properties of the embedded morphemes may and will disappear, without any violation resulting.

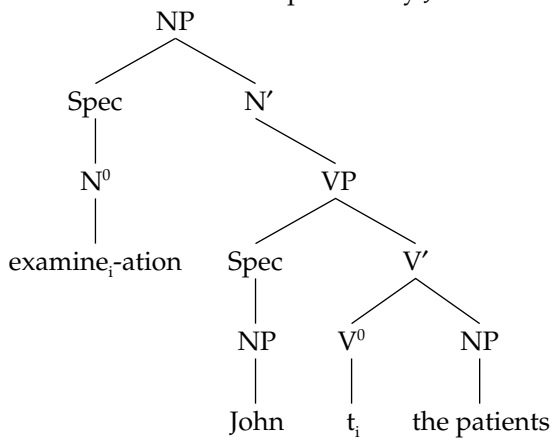
Parallel morphology (or its spirit) has been adopted in recent accounts of mixed categories, in particular nominalizations. Borer (1993) uses her model to account for the result/process ambiguity of derived nominals by attributing it to the presence of the VP constituent within the NP in the case of process nominals and its absence in the case of result nominals. A result nominal is formed in the lexicon and can be inserted at D-structure as an N_0, which then projects an NP like an ordinary noun:

(25) an examination (= an exam)



A process nominal, on the other hand, is inserted at S-structure. The environment for the respective morphological rule to apply is created by V-raising, which takes place to satisfy the morphological requirement of the N (*-ation*):

(26) The examination of the patients by John.



The parallel morphology approach directly accounts for the presence of argument structure in the case of process nominals (here attributed to the presence of the VP) and its lack in the case of result nominals. However, mere presence of the argument structure is not the most important criterion for the V-raising (neo-transformational) approach as such, because in lexical accounts the presence of the argument structure can be attributed to the inheritance of the theta-grid. Therefore further evidence has been brought up in defense of the V-raising structure for derived nominals. This has been done for various languages: Fu et al. (1995) argue for the presence of the VP in English derived nominals on the basis of their admitting certain adverbs and the *do-so* test. Hazout (1994, 1995) presents evidence for the presence of the VP constituent in the action nominalization constructions in Hebrew and Arabic, while Fu (1994) gives extensive support for the V-raising structure in Chinese derived nominals, at the same time modifying and extending Borer's original idea. Schoorlemmer (1995) and Engelhardt and Trugman (1998a, 1998b) adopt parallel morphology for Russian.

Fu (1994) admits that there remains a problem: if there is an underlying VP in derived nominals, then why is it that some VP-related elements such as verbal case-marked NPs and adverbs do not occur in derived nominals? What is the difference between VPs in derived nominals and other VPs? Borer (1993) and Fu (1994) propose that head licensing (Case and Adverbs) requires that the licensing head be dominated by its 'extended projection' in the sense of Grimshaw (1991). The absence of verbal case-marked NPs and adverb phrases is to be explained, then, by the absence of extended verbal projection in derived nominals. Fu proposes that nominalization structures may vary between an underlying VP and an underlying IP. Languages whose nominalization constructions admit verbal cases

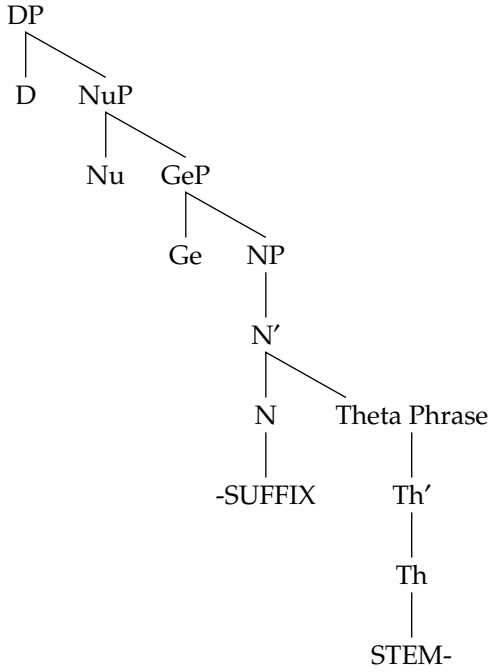
and adverbs have nominalizers which select for an IP rather than VP. It is the presence of an IP that makes the head licensing possible for verbal Cases and adverbs. Similar arguments are extensively discussed in Alexiadou (1999b).

5.2 Picallo's account

Similar ideas are presented in Picallo (1991). Unlike Borer, however, Picallo regards her proposal as the continuation of Chomsky's (1970) "Remarks on Nominalization." She supports the view that the thematic structure of Nouns parallels that of Verbs and adapts to the current theoretical framework (Chomsky 1986, 1989) the suggestion made in Chomsky (1970) that lexical elements may not be categorially marked in the lexicon.

Picallo attributes the difference in argument distribution between result nominals and event/process nominals in Catalan to the ambiguity of the nominalization suffixes: they are either inflectional elements or derivational ones. When the nominalization suffix is analyzed as an inflectional element, the DP will receive the event/process interpretation, and will have the structure in (27):

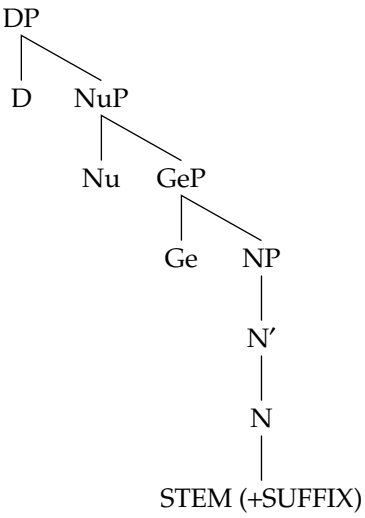
(27)



(DP = Determiner Phrase, NuP = Number Phrase, GeP = Gender Phrase)

The nominalization suffix can complementarily be analyzed as a derivational morpheme. The DP will then have the result interpretation with the structure in (28):

(28)



Non-deverbal nominals, which designate only objects and do not have the nominalization suffix, will be assigned structure (28), like result nominals. According to Picallo, the analysis of the nominalization affix as a functional category is what allows the event/process reading to obtain. Then she shows that in Catalan among monadic nominals, the intransitive unergative nominals (in contrast to the ergative ones) have only the result interpretation, as they do not take temporal modifiers. Picallo points out that a great number of intransitive nominals in Catalan do not take any of the Catalan nominalization suffixes (i.e., *-acio*, *-ada*, *-iment*, etc.). Therefore, she concludes that there are no syntactic nominalizations of intransitives in Catalan, and consequently, adjunct-subjects (i.e., *by* phrases) are impossible with intransitives:

(29) a. *el salt per part de l'atleta
'the jump on the part of the athlete'
b. *la lluita per part del gladiador
'the fight on the part of the gladiator'
c. *el xiscle per part del nen
'the scream on the part of the child'

The nominalization suffix is analyzed as a functional element which has the property of absorbing the external role. Consequently the external argument cannot be realized in argument position and its appearance as an adjunct is licensed.

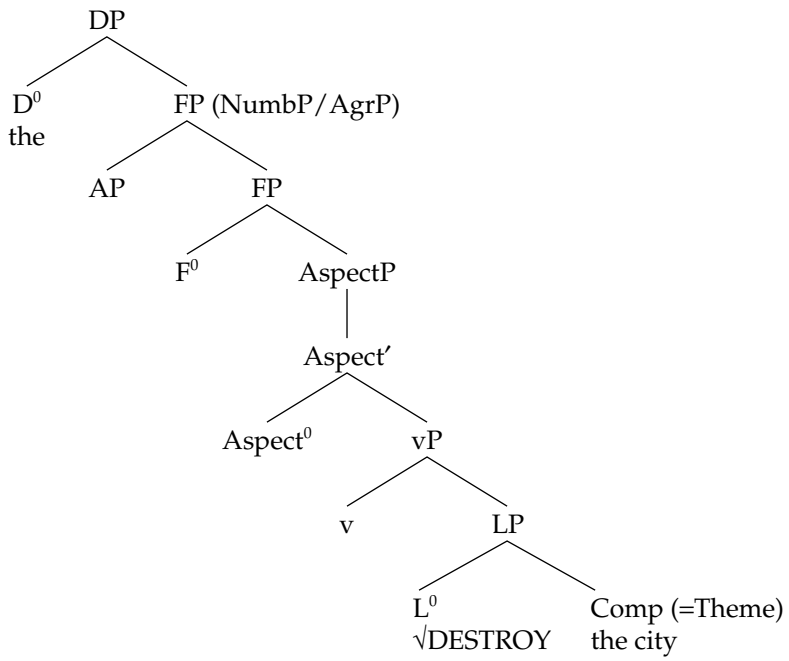
Borer explicitly states that her approach is in opposition to the lexicalist position and refers to it as the syntactic one. On the other hand, Picallo's proposal, similar in spirit to Borer's theory, though articulated in a different way, emerged as the continuation of the configurational approach advocated by Giorgi and

Longobardi (1991). Borer's and Picallo's theories converge and share the spirit of the neo-transformational approach in advocating the lexical–syntactic distinction, the presence of the syntactic projection in the syntactic nominal, and the V-raising (or theta-raising) operation allowing the creation of the nominal after D-structure. The difference between them is such that Picallo adheres to the category-neutral approach to lexical entries, while Borer assumes a category-changing morphological process.

5.3 Alexiadou's ergativity patterns of derived nominals

Another version of the structural account of the ambiguities attested in the domain of derived nominals is offered by Alexiadou (1999b). Alexiadou proposes that the differences between the two types of nominals should be explained in terms of different functional projections under which the respective nominals are embedded. She argues (like Borer 1993; Fu 1994; Schoorlemmer 1995, 1998a, 1998b; Van Hout and Roeper 1998) that result nominals are inserted directly under nominal projections, whereas the structure of process nominals includes (i) an Aspect Phrase (AspP) and (ii) a 'deficient' light v/Voice Phrase (vP) that does not license an external argument. Only vP and AspectP are present within process nominals (there is no Tense projection). The presence of AspP explains the aspectual properties of process nominals, whereas the presence of vP accounts for the eventive reading of these nominals. The structure for process nominals is presented in (30):

(30)



According to Alexiadou (1999b: 89), result nominals and process nominals are similar in the sense that both include the lexical node as their basic component, and hence both can take arguments. Process nominals are like verbs in the sense that their internal structure involves a Lexical Phrase embedded under vP and AspP. The difference between result and process nominals results from the absence of functional layers in the former, and does not reduce to a difference in the base (category neutral vs. nominal). Another important ingredient of Alexiadou's approach is that there is no process of passivization within nominals (contra Picallo, Borer, and Bottari). Schoorlemmer (1998b) argues for lack of passivization within nominals on the basis of Russian. Alexiadou claims that nominals are generally intransitive, i.e., they are ergative constructions. Furthermore, Alexiadou distinguishes between process and event nominals (i.e., those with durative and terminative interpretation respectively), whereas in previous accounts either those two labels were used interchangeably or the difference was unimportant.

All the current theories of derived nominals are concerned with the result/process ambiguity in the domain of action nominals. The debate cannot be reduced to the simple lexicalist–transformationalist controversy. First, drastically different accounts are advocated within what can be roughly referred to as the lexicalist position, and second, theories which essentially share the basic ideas (e.g., Borer's and Picallo's accounts) have been developed from different underlying assumptions with respect to the lexicalist–transformationalist controversy. All the theories presented above cover the same range of linguistic facts; namely, they account for the result/process ambiguity within the domain of action nominalizations. Moreover, only transitive actions are easily accommodated in all the above solutions. Intransitive derived nominals (i.e., nominals derived from unergative verbs) turn out to be non-existent.

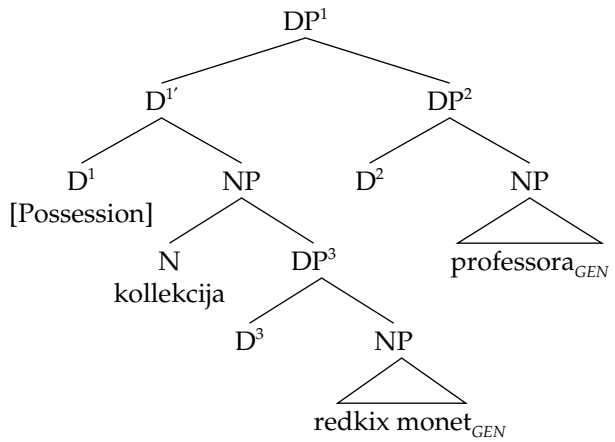
5.4 *Configurational accounts of the result/process distinctions in Slavic languages*

Purely syntactic accounts for the different syntax of action nominals and result nominals have also been attempted for Slavic languages such as Russian or Polish (Engelhardt and Trugman 1998a, 1998b; Rappaport 1998; Schoorlemmer 1998a, 1998b; Willim 2000). All these accounts are configurational, though often mutually incompatible. As mentioned above, the main difference between result nominals and process (action) nominals in Russian and Polish consists in the possibility of two adnominal genitives with result nominals and lack of the second genitive with process nominals. As reported in Engelhardt and Trugman (1998b), the common trend in the analyses of Russian NPs has been to view only the lexical head N as a possible source of Case for genitive DPs (cf. Babby 1992; Rappaport 1992; Schoorlemmer 1995). Under the standard assumptions those analyses were forced to treat all possessor elements as adjuncts, and did not explain why possessor adjuncts are ruled out in process nominals. Engelhardt

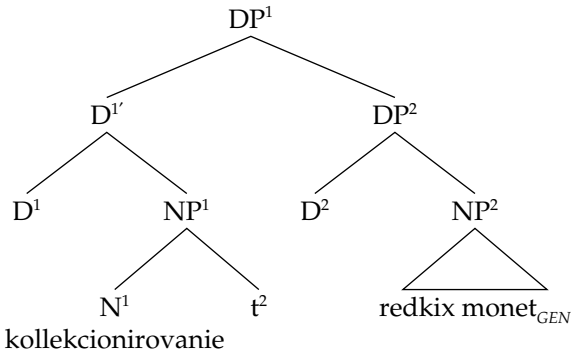
and Trugman (1998a) exploit the idea that genitive subjects in Russian are licensed by the functional head D. This is an extension of the account of subjects of nominal projections proposed for other languages (Abney 1987 for English; Szabolcsi 1987, 1994 for Hungarian; Engelhardt 1997 for Hebrew; Grosu 1988, 1994 for Rumanian). In addition to adopting the assumptions of parallel morphology, Engelhardt and Trugman assume that the Case licensed by functional and lexical heads in NPs is of a different nature (structural and inherent respectively). Inherent case is licensed by the lexical head N to its complement, whereas the structural case is licensed by the functional head D to the syntactic subject of the NP, i.e., the genitive DP occupying the specifier position. This mechanism, together with the assumption that all process nominals in Russian contain a passive VP-projection, rules out the possibility of double adnominal genitives in process nominals.

Rappaport (1998), following Engelhardt and Trugman (1998a), assumes the DP analysis and claims that the NP is selected by a functional category of Determiner. However, he proposes a different Case-system. He distinguishes the internal geometry of material NPs (equivalent to Grimshaw's results) and action nominal NPs, and elaborates a mechanism of licensing NP-internal case assignment. Assuming the distinction between inherent case licensed by selection (and accompanied by the assignment of a thematic role) and structural case licensed by the need to check uninterpretable features (and divorced from thematic role assignment), Rappaport distinguishes two Determiners. The content of one is the feature [possession]. This Determiner can select a material noun and assign inherent case to its external argument together with a thematic role of Possessor by the mechanism of selection. The other Determiner has no semantic content and an uninterpretable case feature, which entails that it assigns structural case, unrelated to thematic role assignment. This uninterpretable feature [~genitive] needs to be checked, and DP^2 can do so by permitting its case feature to raise to the position of D^1. The relevant configurations are presented in (31) and (32):

(31)



(32)



Rappaport's analysis does not require the assumption that all process nominals in Russian contain a passive VP-projection. Neither does it distinguish between lexical and syntactic derivations.

Willim (1999, 2000) deals with the syntax of Polish NPs and the mechanism of genitive Case-checking. She suggests that in object-denoting nominals involving two lexical genitives, the Possessor is an adjunct rather than an argument of the noun and that it is adjoined to the lexical projection of the noun. The genitive Case of the Possessor is not supported by the noun and consequently, the subject or object can surface in the genitive. Otherwise, Polish, Czech, and Russian disallow two lexical genitives. Assuming that in these languages only one genitive argument can occur in the nominal complex, Willim claims that the second relevant head is missing, i.e., there is no Determiner.

5.5 *Gerunds as nominalizations*

The binary distinction between syntactic and lexical nominalizations becomes even more complicated when confronted with gerunds (chapter 30). English *-ing* constructions pose a well-known problem in being three-way ambiguous and in exhibiting both verbal and nominal properties. The standard, traditional treatment recognizes three types of *-ing* structures: action nominals, gerunds, and *acc-ing* constructions, illustrated below (after Adger and Rhys 2000) in (33 a, b, and c) respectively:

(33) a. Jo's devouring of cakes
b. Jo's devouring cakes
c. Jo devouring cakes

Adger and Rhys (2000) argue that the constructions in (33b) and (33c) differ crucially from the construction in (33a). They propose a binary division between NGs (33a) and VGs (33b, c) and claim that the two classes could be distinguished by the representation of their argument structures: NGs have no argument

structure while VGs have argument structure. Then, following Borer (1984a) and assuming a modularized architecture for the morphology and syntax, they postulate a lexical combination for the affix and the root to derive NGs, but a syntactic combination of the root and the functional head *-ing* via head movement to derive VGs. As a result, there is a single lexical entry for the affix *-ing*, and different licensing conditions for complements depending on the presence vs. absence of argument structure. Such an account is incompatible with the approaches presented above, because it leaves no room for the explanation of the result/process ambiguity of derived nominals in terms of argument structure and the level of derivation (lexical vs. syntactic). Adger and Rhys's proposal presupposes that NGs are like derived nominals in having no argument structure.

6 Intransitive nominals

By intransitive nominals we will understand here nominals derived from intransitive verbs. (Note, however, that a different understanding of intransitivity is assumed in Alexiadou 1999b.) Basically, all the theories reported above cannot accommodate them in a consistent way. Grimshaw's *by*-phrase licensing rule in (23) predicts that if there are nominalizations from intransitive unergative verbs (that is, those that have an external argument available for suppression), then that suppressed external argument should appear in the *by* phrase.

Contrary to the predictions of the theories reported above, there are languages where complex event nominals derived from unergative intransitive verbs do exist (cf. Rozwadowska 1995b, 1997 for Polish, or Schoorlemmer 1995, 1998a, 1998b for Russian). As discussed in Rozwadowska (1995b, 1997), Polish intransitive nominals qualify as CENs, since they may take aspectual modifiers, allow control into purpose clauses (another test employed by Grimshaw to check the complex event status of a nominal), and exhibit the familiar event/result distinction. Moreover, Polish intransitive nominals appear in aspectual pairs. Polish one-participant events must have their only argument expressed as a possessive modifier, irrespective of the type of semantic predicate (whether unergative or unaccusative).

Schoorlemmer (1995: 297–300) recognizes the existence of intransitive complex event nominals in Russian and thus provides further evidence for their existence cross-linguistically. Schoorlemmer (1998a) demonstrates that Russian intransitive CENs, like the Polish ones, occur in eventive contexts, can take aspectual modification, and allow control into purpose clauses (if unergative). Both in Polish and in Russian, Agents of complex event nominals derived from intransitive verbs must appear as possessives and not in an Agentive phrase equivalent to the English *by* phrase. An example of a Polish intransitive nominal is presented in (34), whereas Russian intransitive nominals are illustrated (after Schoorlemmer 1998a) in (35):

(34) a. pływanie Janka w swoim własnym basenie przez godzinę
'John's swimming in his own swimming pool for an hour'

(35) a. My prisutstvovali pri Irinoj igre na skripke.
we were-present at Ira's play on violin
'We witnessed Ira playing the violin.'
b. My prisutstvovali pri ego izč eznovenii.
we were-present at his disappearance
'We witnessed his disappearance.'

The existence of intransitive CENs constitutes a challenge to the theories that do not admit them. The obligatory realization of their single participant as the possessor is a counter-argument to the suppression theories. While predicting the difference in argument distribution between non-argument-taking and argument-taking nominals in the domain of transitive actions, Grimshaw's (1990) theory (like Zubizarreta's 1987) fails to predict the failure of single participants of intransitive complex events to surface in the *przez/by* phrase. Borer's (1993) and Picallo's (1991) accounts do not admit intransitive complex event nominals either. Borer treats all syntactic nominalizations (corresponding to Grimshaw's CENs) as derived from passive verbs, so automatically intransitives are not considered at all. Picallo claims that among monadic nominals in Catalan only ergative nominals can designate events/processes, whereas the intransitives (i.e., unergatives) appear to be only able to have the result interpretation. Picallo observes that with respect to their morphological characteristics, ergative nominals, without exception, appear with a nominalization suffix (i.e., *-acio*, *-ada*, *-iment*, etc.), whereas a great number of intransitives consist of an NP stem with features for Gender and Number only, without a nominalization morpheme. Its lack accounts for the absence of the event/process reading. Similar implications can be found in Alexiadou (1999b) and Markantonatou (1995). Polish and Russian are different from English, Catalan, or Modern Greek in admitting complex event reading (i.e., abstract, non-concrete event/process interpretation) in the domain of intransitives. This is a challenge for all the available accounts referred to so far, which, despite significant theory-internal differences, all fail to accommodate single participants of unergative eventualities.

7 Psych nominals

Psych nominals are nominals derived from the so called Experiencer verbs, divided into Subject Experiencer verbs and Object Experiencer verbs. They are illustrated for English in (36) and (37):

(36) a. John's enjoyment of the film
b. *the film's enjoyment (by/of John)
c. John enjoys the film

(37) a. John's amusement at the books
b. *the book's amusement of John
c. The books amused John.

The contrast in the distribution of nominal satellites between the pattern in (36) and the pattern typical of action nominals illustrated in (1) was already noticed by Anderson (1984). Anderson accounts for this contrast in terms of a constraint on movement of "non-affected" objects inside NPs (chapter 5). Nominals such as those in (37) must then be treated as derived from adjectival passives rather than from verbs and are irrelevant for Anderson's constraint. For a critique of such an account see Amritavalli (1980) and Rozwadowska (1988).

Rappaport (1983) and Rozwadowska (1988) independently formulate different versions of thematic constraints responsible for the distribution of satellites in derived nominals. Rappaport introduces the thematic label *Experienced* and suggests within the framework of Lexical-Functional Grammar that Experienced is restricted from being assigned the Poss function. Then, quite separately, she mentions nominals such as those in (38) and refers to Anderson's (1984) constraint on the movement of non-affected objects to account for their ungrammaticality:

(38) a. *history's knowledge
b. *John's sight by Mary
c. *the event's recollection
d. *the problem's perception
e. *the picture's observation
f. *the novel's understanding

Rozwadowska (1988) introduces the feature-decomposition approach to thematic relations and formulates various thematic constraints on the distribution of satellites in deverbal nominals in terms of features. She argues that they are more consistent than all the previous theories, that they account for a wider range of facts, and that they capture the overlap among thematic relations. The relevant constraints are presented in (39):

(39) a. A [−change, −sentient] argument cannot appear in the specifier position of an English nominal.
b. If one of the two arguments of a transitive nominal is [+change], then this argument must be expressed in a single argument nominal.
c. Only [+change] arguments can be expressed as genitive complements of Polish transitive nominals.

Note that single-argument nominals are understood here as nominals taking one satellite but derived from transitive verbs:

(40) a. Rome's destruction
b. John's love
c. John's surprise

The constraint in (39b) is motivated by the contrast between (40) and (41):

(41) a. *the barbarians' destruction (where *the barbarians* = Agent)
b. *the books' love (cf. *John loves books*)
c. *her behavior's surprise (cf. *Her behavior surprises John*)

The constraint in (39c) is illustrated with the Polish data in (42–43):

(42) a. Jan podziwia Marię.
John-nom admires Mary-acc
'John admires Mary.'
b. podziw Jana dla Marii
admiration-nom John-gen for Mary-gen
'John's admiration for Mary'
c. *podziw Marii przez Jana
Admiration-nom Mary-gen by John-gen

(43) a. Dzieci zdumiewają rodziców.
children-nom amaze parents-acc
'Children amaze parents.'
b. zdumienie rodziców dziećmi
amazement-nom parents-gen children-instr
'parents' amazement at the children'
c. *zdumienie dzieci (przez) rodziców
amazement-nom children-gen (by) parents-gen
*'children's amazement of/by the parents'

All the above thematic constraints work consistently for both Object Experiencer and Subject Experiencer predicates, which is an argument in favor of the thematic constraints rather than syntactic solutions, since the two classes of predicates share thematic properties but differ in syntax.

As discussed in section 4, under Grimshaw's analysis psych nominals derived from Subject Experiencer verbs are stipulated to have both argument and aspectual structures, and the lack of the *by* phrase in them is attributed to the semantic restriction on the *by* phrase in nominals. Psych nominals derived from Object Experiencer verbs are claimed to be results with no argument structure.

In opposition to this view, Pesetsky (1995: 72) maintains that nouns derived from Object Experiencer verbs like *agitation*, *annoyance*, *amusement*, etc. are not result nominals but argument-taking nouns, hence true nominalizations, some of which have uses that refer to objects, but not results. Rozwadowska (1997), on the basis of Polish, develops further the idea that nominals related to both Subject Experiencer verbs and Object Experiencer verbs show all the ambiguities recognized in the action domain. Rozwadowska (1997: 44–48, 85–97) demonstrates that psych nominals display the same pattern as action nominalizations. The examination of the cluster of properties standardly assumed to be tests for

argumenthood reveals that psych nominals in general can be both argument-taking and non-argument-taking. In other words, they qualify as CENs. The predictions of the suppression theory, however, are not met then.

Markantonatou (1995) provides evidence from Modern Greek that many psychological predicates are related to some nominal. She shows that they take as many syntactic arguments as do the verbs they are related to and that they can be modified by the same durative adverbials:

(44) a. I agapi *(tu Yiani) *(yia tin Maria) dio hronia sto telos ton trelane.
the love the-gen Yianis-gen for the Maria for two years in-the end him made-crazy
'Yianis' love for Mary for two years made him crazy in the end.'
b. (O Yianis) agapuse *(tin Maria) epi dio hronia.
the Yianis loved the Maria for two years
'Yianis loved Maria for two years.'

Markantonatou concludes that nothing is suppressed here, contra to Grimshaw's claim. Markantonatou proposes a mechanism for the derivation of Modern Greek deverbal nominals which requires the existence of an 'internal' ([–r]) argument, i.e., the argument bearing a semantically unrestricted grammatical function. She claims that a small set of simple, unification-based operations within the framework of the Lexical Mapping Theory of LFG (Lexical Functional Grammar) provides a broader coverage than the suppression theory.

Rozwadowska (1997) suggests that the lack of the *by* phrase in intransitive and psych nominals can be related to their intransitivity at the event-structure level, where the number of event participants is crucial. Borrowing from Van Hout (1996) the idea that the number of event participants is a primitive at the level of event structure, Rozwadowska divides the domain of eventualities into external (i.e., non-psych) eventualities and internal (i.e., psych) eventualities. External eventualities can be either one-participant or two-participant eventualities, whereas internal eventualities are necessarily one-participant eventualities. Such division groups together intransitive actions and all psychological events. Then the distribution of the *by* phrase in derived nominals can be explained in terms of some version of Williams's (1987a) ergativity rule operating at the level of event structure.

8 More on aspectual properties of derived nominals

8.1 English derived nominals

The relevance of aspectual dimension for the analysis of derived nominals was recognized by Grimshaw (1990). Aspect is understood there in the sense of Vendlerian disctinctions, i.e., lexical differences between different types of predicates

(activities, accomplishments, achievements, and states). The fact that derived nominals co-occur with the same temporal adverbials as do the corresponding verbs, as well as their co-occurence with the adjectives *frequent* and *constant*, is taken as evidence for the presence of aspect in them.

Further studies of aspectual distinctions in derived nominals (e.g., Schoorlemmer 1998a, 1998b; Snyder 1998; Alexiadou 1999b; Rozwadowska 2000) show that the problem of the presence of aspect in derived nominals is much more complex and needs more attention. Snyder (1998) maintains that in English, active CENs derived from accomplishment verbs denote either the "development" (i.e., an "on-going process") or the "culmination" of an underlying event. The compatibility of the nominal with the verb *continue* is taken by Snyder as evidence for the "on-going process" reading, illustrated in (45a). On the other hand, Grimshaw's example in (45b) illustrates the "culmination" reading (though not labelled in this way by her). That this is not an isolated phenomenon is further illustrated (after Snyder) in (46):

(45) a. If the barbarians' destruction of the city continues for another week, little will remain.
b. The total destruction of the city in only two days appalled everyone.

(46) a. If the reorganization of the filing system continues, I'll never be able to find anything.
b. If the consumption of our food continues at this rate, we'll exhaust our supplies in a week.

Snyder's examples with *continue* are supposed to prove that on top of the accomplishment reading standardly recognized with CENs derived from accomplishment verbs, active CENs allow also a "development" reading, which passive nominals resist, as illustrated in (47):

(47) a. ??If the city's destruction (by the barbarians) continues for another week, little will remain.

Snyder claims that compatibility with *frequent* and *constant* is characteristic of propositional nominals and plural SENs, but not CENs or singular SENs. Passive nominals are incompatible with such modifiers, which suggests that they resist a propositional reading. However, Snyder claims that they receive a clear complex-event reading and can serve as the subject of *occur*. They are incompatible with *continue*, which leads to the conclusion that the passive nominalization of an accomplishment denotes the culmination of an underlying accomplishment event. Similar views are presented in Alexiadou (1999b). Alexiadou presents arguments against the result analysis of passive nominals. She introduces the distinction between events and processes, arguing that English passive nominals are generally event nominals, i.e., have a terminative interpretation.

8.2 Polish derived nominals

As shown in Rozwadowska (1995a, 1997), in Polish there are two types of derived nominals that qualify as CENs: derived nominals similar to those attested in other languages and the so-called verbal nouns. Polish verbal nouns are derived by means of the productive suffix *-nie/-cie* and appear in aspectual pairs (perfective vs. imperfective) distinguished morphologically in the same way as the corresponding aspectual pairs of verbs. Verbal nouns in Polish have more verbal properties than other derived nominals. However, they are unlike verbal gerunds or nominal infinitives (chapter 30) in not admitting accusative case on the object. It is also worth noticing that Polish is exceptional even when compared to other Slavic languages (e.g., Russian). The existence of the two types of CENs in Polish as contrasted to Russian led Schoorlemmer (1995) to emphasize that Russian derived nominals are sensitive to aspectuality and not aspect. Also it inspired Schoorlemmer's proposal that Polish verbal nouns contain an embedded IP whereas Russian and Polish derived nominals contain only an embedded VP. Such a proposal is consistent with the approaches presented in the preceding sections, most of which relate different types of derived nominals to different functional projections or different levels at which the morphological operation takes place. Rozwadowska (1997, 2000) presents more evidence that all the three types of derived nominals (i.e., object nominals and two kinds of CENs) exist in Polish both in the action domain and in the psych domain. Polish derived nominals (as opposed to verbal nouns) are aspectually neutral, i.e., they are ambiguous between the perfective and the imperfective reading or their aspectual interpretation is idiosyncratic. On the other hand, Polish verbal nouns in all semantic domains seem to appear in aspectual pairs.

The following facts should thus be highlighted:

(i) In Polish there are two types of nominals that meet the criteria for CENs: aspectually neutral derived nominals with argument structure on one hand, and *-nie/-cie* nominals which have grammatical aspect in addition to argument structure on the other hand.
(ii) Polish derived nominals (but not verbal nouns) and English derived nominals share essential properties, including the aspectual ambiguity, which in fact suggests the absence of aspect rather than its presence in them.
(iii) The ambiguity of the derived nominals coincides with the internal complexity of the event denoted by the nominal (i.e., it is possible only with accomplishment verbs).

8.3 Russian derived nominals

Engelhardt (1998) and Engelhardt and Trugman (1998b) propose a correlation between the level of nominalization and the aspectual properties of the derived nominal. They observe that Russian *-nie* nominals are syntactic and claim that the syntactic derivation triggers an imperfective viewpoint of the event, in the

sense of Smith (1991). They do not claim that syntactic derivation of process nominals preserves aspectual features of a base verb, but that, irrespective of the aspect of the verbal base, syntactic derivation will always result in an imperfective nominal. According to this view syntactic nominalization is thus an imperfective operator. As one piece of evidence for their hypothesis Engelhardt and Trugman (1998b) provide the distribution of modifiers such as Russian equivalents of *frequent* and *constant*, which have been found to be restricted to process nominals across languages. It turns out that in Russian the nominal derived from the imperfective base functions predominantly as a process nominal, whereas the one formed from the perfective base is preferred in the result interpretation. They also point out that perfective verbal bases stop giving rise to new *-nie* derivations.

9 Conclusion

Concluding this overview we can say that the current research agenda in the area of derived nominals goes in the direction of finding correlations between aspectual interpretation and syntax.

  6.1 Kuroda and Fukui's parametrization approach
  6.2 Case particles as functional heads
7 Conclusion

1 Introduction

The existence of the Double Nominative Construction as in (1) is one of the peculiarities that linguists working on the Japanese language have always paid attention to:

(1) Nihon -ga kokumin -no heikin jumyoo -ga mijika -i.
Japan NOM citizen GEN average lifespan NOM short PRES
'It is Japan whose citizen's average lifespan is short.'

This construction is taken to be peculiar because it has been considered that the subject position and the Nominative Case assignment which usually comes with it are unique per clause. Sometimes the non-uniqueness of the subject/Nominative has been taken as evidence that Japanese lacks the notion *subject* in formal terms, and, at other times, the existence of such a construction has been regarded as the basis of parametrization on the function of the syntactic categories *INFL/Tense/Agr/C(K)ase*, as they are all said to be relevant to the Nominative Case assignment/checking. Some people notice the focal characteristic of the 'outer' subject and investigate where it comes from. Because the Double Nominative Construction does not fit into the ordinary scheme of the clausal structure [S NP [VP V NP]] with a unique subject per clause, the analysis of this construction has enough power to affect the theory of the clausal structure per se.

This case study presents and reviews some previous work on this peculiar construction and sees what issue is at stake and what the construction can tell us about the theory of the clausal structure. Section 2 introduces types of Double Nominative/Subject Constructions that exist in a single language called Japanese. As Japanese has another topic/subject marker *-wa* alongside the ordinary Nominative *-ga*, we cannot avoid mentioning how *-wa* and *-ga* interact with each other. Section 3 discusses the focal characteristic of some Double Nominative sentences. In this context, the rule 'Subjectivization' as a kind of focalization rule will be introduced. Section 4 overviews analyses of other types of Double Subject sentences not derived by Subjectivization. Section 5 introduces views on Case assignment/checking in relation to the Double Nominative Construction. The non-uniqueness of the Nominative Assignment in this particular construction has been and is an important issue for the theory of grammatical Case. Section 6 reviews what kind of typology is possible to allow for Double-Nominative languages and Unique-Nominative languages. Section 7 summarizes the article.

2 Double Subject/Nominative Constructions

2.1 *The Double Nominative Double Subject Construction*

In a language like English, on the basis of which the theory of generative grammar has mainly developed, the position of the subject and the assignment/checking of the Nominative Case have been taken to be unique for a clause:

(2) a. John's uncle is a doctor.
b. *John uncle is a doctor.[1]

This is not the case in Japanese. In Japanese, having two or more Nominative Subjects is possible:

(3) a. Jon -ga isha -da.
John NOM doctor is
'John is a doctor.'
b. Jon -ga oji -ga isha -da.
John NOM uncle NOM doctor is
'It is John whose uncle is a doctor.'
c. Jon -ga oji -ga me -ga chikai.
John NOM uncle NOM eye NOM near
'It is John whose uncle is nearsighted.'

In the classical treatment of the Nominative Case, as in Chomsky (1981, 1986a), the Nominative Case of the subject is assigned by the subject's being governed by a category INFL(+ Tense/Agr), in the following structure:

(4) [IP NP [I' INFL(+Tense,AGR) VP]]
(NP assigned Nominative)

Due to the convention of the X-bar theory at that time, the number of the specifier (SPEC) of the phrase has been considered to be one, so the number of NPs with the Nominative Case is also considered to be one. Thus, the position of the subject has been regarded as unique. The existence of the Double Nominative Construction is peculiar in this context. Even though the position of the subject and the position of the Nominative Case (regarded as identical at that time) are taken to be unique, why do Japanese and some other languages allow for having two or more Nominative phrases per clause? We have five choices (or maybe more) to answer the question:

(5) a. The uniqueness requirement on the Nominative Case assignment is under parametrization, and, for languages like Japanese, **multiple** assignment of the Nominative Case feature is allowed.
b. The Nominative Case in languages like Japanese is **not assigned**. The existence of the Case particle (*-ga* in the case of Japanese) guarantees the Case feature. There is a requirement of uniqueness on Case assignment, but not on Case particles. This type of analysis is often connected with the fact that the Nominative in Japanese often expresses the discoursal focus.
c. The Nominative Case in Japanese and other double subject languages is not assigned by the functional category INFL(+Tense/Agr). It is **assigned to a particular lexical position**, such as Spec(VP). Because the lexical projection does not need to be and is not unique in any respect, we can have multiple subjects.
d. The Nominative Case in languages like Japanese is always licensed by some semantic relation, which is usually called **'aboutness'**. For example, the Nominative Case in (3b) is licensed by the fact that the uncle's being a doctor is 'about' John.

e. The Nominative Case Assignment and the requirement that the clause have a subject (the Extended Projection Principle (EPP)) can be satisfied by **separate structural relations**. For example, the EPP can be satisfied by the existence of Spec(IP), while the Nominative Case assignment can be satisfied by some other structural relations, allowing for seemingly double subjects.

These possible analyses do not necessarily contradict each other and researchers often take two or more positions at the same time. We will return to the previous analyses in later sections.

2.2 Topic and subject

The subject is not always with the Nominative Case in Japanese. In the following example, the Nominative Subject is preceded by the topic of the sentence:

(6) Hanako -wa Taroo -ga tazune -ta.
Hanako TOPIC Taro NOM visit PAST
Hanako, Taro visited.

In many such cases, we can easily find the non-topicalized version, in which the topic is with a grammatical relation other than the subject (object in the case of (6)):

(7) Taroo -ga Hanako -o tazune -ta.
Taro NOM Hanako ACC visit PAST
Taro visited Hanako.

However, there are cases where the topic cannot find the 'source':

(8) a. [NP Shinbun -o yomi -tai hito] -wa Asahi -ga koko -ni ari -masu.
newspaper OBJ read want person TOPIC The Asahi NOM here LOC exist PRES
'As for those who want to read newspapers, we have The Asahi here.'
b. *[NP Shinbun -o yomi -tai hito] -ga$_{NOM}$ Asahi -ga koko -ni ari -masu.
c. *[NP Shinbun -o yomi -tai hito] -o$_{ACC}$ Asahi -ga koko -ni ari -masu.
etc.

These 'pure' topics are associated with the sentence by some sort of 'aboutness' relation, as I indicate in the gloss. Once we take a view that the Double Nominative Construction is licensed by the semantic/pragmatic 'aboutness' relation, we need to distinguish the Double Nominative Construction and topics as in (8), and find the source(s) of the differences between the two constructions.

2.3 The Nominative Object Construction

The Nominative case is not always assigned to the semantic subject. In the following examples, the Nominative Case is assigned to those phrases which are regarded as objects in English and other languages:

(9) a. Taroo -ga eigo -ga hanas -e -ru.
Taro NOM English NOM speak can PRES
'Taro can speak English.'
b. Taroo -ga Hanako -ga suki -da.
Taro NOM Hanako NOM fond of PRES
'Taro likes Hanako.'
c. Watashi -ga mizu -ga hoshi -i.
I NOM water NOM want -PRES
'I want water.'

The fact that the Nominative Case can be given to the object in some constructions is often regarded as evidence that the Nominative Case assignment in Japanese is not structural. On the other hand, some researchers say that this is evidence that the Case assignment in Japanese is not unique, and that multiple Case assignment/checking is possible.

In sum, the existence of the Double Nominative Construction in Japanese is still under various interpretations. This is partly because the notions 'Double Subjects' and 'Double Nominatives' are not necessarily identical, as we have seen in the preceding two subsections.

3 Focus/exhaustive listing and Subjectivization

Kuno (1973c) points out that the main distinctive feature of the two seemingly subject-marking particles *-wa* and *-ga* in Japanese is in the discoursal informational status of noun phrases marked with them:

(10) a. ***-Wa***
-Wa is either *thematic* or *contrastive*.
i. Thematic
Jon -wa gakusei desu.
John TOPIC student PRES
'John is a student.'
ii. Contrastive
Ame -wa hut -tei -masu -ga . . .
rain CONTRAST fall PROG PRES but
'It is raining, but . . .'
b. ***-Ga***
-Ga marks the subject of the sentence in either *neutral description* or *exhaustive listing*.

i. Neutral description (only occurs with predicates representing an action, existence, or temporary state)
Jon -ga ki -ta.
John NOM come PAST
'John came.'

ii. Exhaustive listing (obligatory with predicates representing a stable state)
Jon -ga gakusei -desu.
John NOM student PRES
'John and only John is a student.'

(Kuno 1973c: 59–60; my arrangement)

Even though Kuno uses completely different terms for them, neutral description and exhaustive listing are both representations of the discoursal focus. The exhaustive listing *-ga* focalizes only the noun phrase marked with it, while the neutral description *-ga* focalizes a larger domain. What is important here is that *-ga* is not a mere Nominative marking particle, but also can mark a discoursal focus.[2] With a predicate representing a stable state, the *-ga*-marked phrase is interpreted as exhaustive listing.

This generalization about the distribution of exhaustive-listing *-ga* collapses in the following examples:

(11) a. Kono kurasu -wa dansei -ga yoku deki -ru.
this class TOP male NOM well able PRES
'Speaking of this class, the boys do well.'

b. Kono kurasu -wa Jon -ga yoku deki -ru.
John
'Speaking of this class, John does well.' (Kuno 1973c: 64 (10))

In (11a), even though the predicate *deki* 'able' expresses a permanent state, the noun phrase marked with *-ga*, namely *dansei-ga*, is ambiguous between neutral description and exhaustive listing. *Ga* with a stative predicate is not always interpreted as exhaustive listing. On the other hand, the noun phrase *Jon-ga* in (11b) is always interpreted as exhaustive listing.

To account for this fact, Kuno cites two other facts. First, (11a) has a corresponding non-topical sentence, where the sentence-initial phrase *kono kurasu-wa* is not topicalized but marked with the Nominative Case. On the other hand, (11b) does not have such a corresponding sentence:

(12) a. Kono kurasu -ga dansei -ga yoku deki -ru.
this class NOM male NOM well able PRES
'It is this class in which the boys do well.' (Kuno 1973c: 67 (16b))

b. *Kono kurasu -ga Jon -ga yoku deki -ru.
John
'It is this class in which John does well.' (Kuno 1973c: 68 (18b))

In (12a), it is *Kono kurasu-ga* but not *dansei-ga* which is interpreted as exhaustive listing. Thus, we can obtain the following generalization:

(13) The leftmost noun phrase marked with *-ga* in a sentence with a predicate which expresses permanent state must be interpreted as exhaustive listing.

In (12a), *kono kurasu-ga* must be an exhaustive-listing noun phrase because it is the leftmost phrase marked with *-ga*. As for (11a), there are two possibilities. First, (11a) can be (12a) with the first Nominative phrase *kono kurasu-ga* topicalized. In this case, the interpretation of *-ga*-marked phrases goes as in (12a), and *dansei-ga* is a neutral description phrase. The second possibility is that (11a) be (14) with the genitive phrase topicalized:

(14) Kono kurasu -no dansei -ga yoku deki -ru.
this class GEN male NOM well able PRES
'The boys in this class do well.' (Kuno 1973c: 68 (21))

In that case, it is the noun phrase *kono kurasu-no dansei-ga* which must be interpreted as exhaustive listing, because it is the only Nominative phrase in the sentence. The ambiguity of (11a) is thus accounted for.

Then the question is: why is such ambiguity impossible for (11b)? To account for this, Kuno cites another fact. It is possible to have a genitive source for (11b), as we show (14) corresponding to (11a), but the semantics of the genitive relations is different, according to Kuno:

(15) Kono kurasu -no Jon -ga yoku deki -ru.
this class GEN John NOM well able PRES
'John, who is in this class, does well.' (Kuno 1973c: 73 (33b))

In (14), the genitive relation is restrictive, while in (15), it is non-restrictive. Kuno suggests that this difference may be the reason why we cannot have (12b) (see Kuno 1973c: 73, fn. 8). On the basis of these observations, Kuno formalizes the following Subjectivization Rule:

(16) **Subjectivization:**
Change the sentence-initial NP-*no* (with some semantic relation; see the above observation (K.T.)) to NP-*ga*, and make it the new subject of the sentence.
(Kuno 1973c: 71 (28a))

Subjectivization, for example, shifts the structure (17a) to (17b):

(17) a. [S [NP [NP kono kurasu -no] dansei -ga] yoku deki -ru.] (= (14))
b. [S [NP kono kurasu -ga] [S [NP dansei -ga] yoku deki -ru.]] (= (12a))

(15) cannot undergo Subjectivization because the genitive relation in it, being non-restrictive, is not one of those semantic relation that can trigger Subjectivization. Thus, Kuno (1973c) has established the basis for the later works on the Double Nominative Construction.

4 After Subjectivization: analyses on Double (Nominative) Subjects

Kuno's Subjectivization approach to the Double Nominative Construction is certainly one example of a fine pure syntactic analysis of previously unknown grammatical facts. However, it gives rise to the following two problems:

(18) a. Is the genitive–head relation the only source of Subjectivization or the Double Nominative/Subject Construction? In other words, is the Double Nominative/Subject Construction always 'derived' by movement/adjunction?
b. How can we assign the Nominative Case to the 'derived' subjects?

(18b) will be dealt with in sections 5 and 6, where the mechanism of Nominative assignment is directly dealt with. This section will introduce approaches to (18a). It will be pointed out that derivation from the genitive position is not the only source of the Double Nominative Construction, but the Double Nominative Construction can also be licensed by what we call 'aboutness'. There are even scholars who say that 'aboutness' is the only distinctive feature of the Double Nominative Construction, and that there is no such rule as Subjectivization.

4.1 Kuroda on Major Subject

Taking up Kuno's ingenious analysis of the Double Nominative Construction, Kuroda (1986) points out that all Double Nominative sentences cannot be derived by 'Subjectivization':

(19) Tokyoo wan -no sakana -ga koozyoo haisui -ni -yoru
Tokyo bay GEN fish NOM factory drained water DAT by
kaisui -no osen -de moo sudeni sisha -ga san
sea water GEN pollution by already already dead person NOM three
-mei de -tei -ru.
persons come out PROG PRES
'It is fish of Tokyo Bay that due to the pollution of sea water by water drained from factories the death of three persons has already happened.'
(Kuroda 1986: (129))

(19) does not have the genitive source which Subjectivized sentences do:

(20) Tokyoo wan -no sakana -no koozyoo haisui -ni -yoru
Tokyo bay GEN fish GEN factory drained water DAT by
kaisui -no osen -de moo sudeni sisha -ga san
sea water GEN pollution by already already dead person NOM three
-mei de -tei -ru.
persons come out PROG PRES

Kuroda calls such an extra subject *Major Subject*.

Kuroda, on the basis of this and other examples, claims that the extra Nominatives (and topics) are licensed in the following structure:

(21) [S **NP** [S . . .]]

That is, provided that NP can hold a proper predication relation with the rest of the sentence, the extra subject can be semantically licensed.

In addition, Kuroda in his earlier work (1978) notes that there are two types in the predication relations held in the Double Nominative sentences derived by Subjectivization. Consider (22) and (23):

(22) [S Zoo -ga [S hana -ga naga -i]]
elephant NOM trunk NOM long -PRES
'It is elephants that have long trunks.' (Kuroda 1978: (64))

(23) [S kono hana -ga iro -ga kirei -da]
this flower NOM color NOM beautiful PRES
'It is this flower whose color is beautiful.' (Kuroda 1978: (65))

(22) is derived by Subjectivization from a sentence *zoo-no hana-ga naga-i* and the derived subject is Chomsky-adjoined to an S node. However, in (23), the extra subject is sister-adjoined. Kuroda distinguished between the two because, in (23), the predicate *kirei-da* is involved in two predication relations, namely that the color is beautiful and the flower is beautiful, but, in (22), the extra subject holds a predication relation with the rest of the sentence as a whole (the sentence does not imply that elephants are long). This type of distinction still must be reflected in the structural analysis of Double Nominative sentences.

Moreover, Kuroda (1986) points out that there are apparent topics which cannot alternate with *-ga*:

(24) Shinbun -o yomi -tai hito -wa koko -ni ari -masu.
newspaper ACC read want people TOP here LOC exist PRES
'Those who want to read newspapers, (you find) them here.'
(Kuroda 1986: (145))

(25) *Shinbun -o yomi -tai hito -ga koko -ni ari -masu.

Kuroda correctly points out *shinbun-o yomi-tai hito-wa* is not even a topic of the sentence in (24), because the sentence is not about those who want to read newspapers but about newspapers. Kuroda claims that this is the reason why (25) is impossible. The 'topic' phrase in (24) cannot hold any predication relation with the rest of the sentence.[3] So far, we need to distinguish at least four kinds of topics and subjects in Japanese structurally or semantically.

4.2 Pure Topic

Tateishi (1994) points out that, in addition to examples like (24) which Kuroda uses, there is a group of real topics which cannot alternate with *-ga*:

(26) a. Taroo$_i$ -wa Jiroo -ga Hanako -ni kare$_i$ -no musuko -o
Taro TOP Jiro NOM Hanako DAT he GEN son ACC
shookai -shi -ta.
introduce do PAST
'As for Taro, Jiro introduced his son to Hanako.'
b. Hannin -wa Saburoo -ga ayashi -i.
perpetrator TOP Saburo NOM suspicious
'As for the perpetrator, I suspect Saburo might be.'

As the glosses show, the two *-wa* phrases are topics of the sentence, and, in this sense, they can hold proper predication relations with the rest of the sentences. According to Kuroda's statement in the previous section, this may be enough for licensing the Nominative Case on such topics. However, topics in (26) cannot alternate with *-ga*:

(27) a. *Taroo$_i$ -ga Jiroo -ga Hanako -ni kare$_i$ -no musuko -o shookai -shi -ta.
b. *Hannin -ga Saburoo -ga ayashi -i.

These examples show that the domain of predication relations and the domain of Nominative assignment are not identical. We need to distinguish at least five types of Double/Multiple Subject Constructions:

(28) a. Subjectivization I: The derived subject holds a predication relation with the main predicate. (= (23))
b. Subjectivization II: The derived subject holds a predication relation with the rest of the sentence as a whole. (= (22))
c. Major Subject: No genitive origin. The extra subject holds a predication relation with the rest of the sentence as a whole. (= (19))
d. Pure Topic: No Nominative alternation. The extra topic holds a predication relation with the rest of the sentence as a whole. (= (26))

e. Non-Topical 'Topic': No Nominative alternation. No predication relation. (= (24))

If these distinctions must be stated in terms of structural distinctions, we need to have four clausal domains at least:

(29) a. The domain in which the subject can hold a predication relation with the main predicate. (*v*P?)
b. The domain in which the Nominative Case is assigned. (IP or TP)
c. The domain in which the predication relation is possible. (Somewhere between IP and CP)
d. The whole clausal domain. (CP)

4.3 Mihara on 'aboutness'

Mihara (1994), in his book on Japanese syntax, claims that all Double Nominative sentences are licensed in terms of the notion 'aboutness'. He claims that, provided that the sentence is 'about' the subject/topic, the Nominative assignment is licensed. Take the example in (19) from Kuroda (1986), which is repeated in what follows:

(30) Tokyoo wan -no sakana -ga koozyoo haisui -ni -yoru
Tokyo bay GEN fish NOM factory drained water DAT by
kaisui -no osen -de moo sudeni sisha -ga san
sea water GEN pollution by already already dead person NOM three
-mei de -tei -ru.
persons PROG PRES come out
'It is fish of Tokyo Bay that due to the pollution of sea water by water drained from factories the death of three persons has already happened.'
(Kuroda 1986: (129))

The meaning of (30) can be paraphrased as in (31):

(31) Fish of Tokyo Bay are such that the death of three persons by eating them has already come out due to the pollution of sea water by water drained from factories.

According to Mihara it is this "such that" relation which allows for the generation of an extra subject.

However, Mihara's claim cannot stand as is when we look at the Pure Topic. The Pure Topic sentence is also connected with the rest of the sentence by what Mihara calls an 'aboutness' relation, but the Pure Topic cannot be Nominative-marked. 'Aboutness' cannot explain everything about Double Nominatives, though it may be that Double Subjects/Topics are licensed by 'aboutness' or predication relations.[4]

4.4 Tateishi's non-movement analysis

Tateishi (1988) proposes an analysis of Subjectivization from a different point of view. He notices the fact that Subjectivization has a genitive origin. For Tateishi, for example, example (1), repeated here as (32), has the structure of (33):

(32) Nihon -ga kokumin -no heikin jumyoo -ga mijika -i.
Japan NOM citizen GEN average lifespan NOM short PRES
'It is Japan whose citizen's average lifespan is short.'

(33) [IP [NP Nihon -ga [NP kokumin -no heikin jumyoo -ga]] [VP mijika] -i]

For Tateishi, the extra Nominatives stays in situ in a Genitive position. The Nominative Case is assigned to the Genitive position by a kind of Case feature percolation. Thus, there is no movement involved in Subjectivization, according to Tateishi (1988).

Heycock (1993) criticizes Tateishi's analysis on the basis that an adverb can be inserted between the two Nominative phrases, casting doubt on the constituency of the two Nominative phrases as a whole:

(34) Nihon -ga zannen-nagara kokumin -no heikin jumyoo -ga
Japan NOM unfortunately citizen GEN average lifespan NOM
mijika -i.
short PRES
'It is Japan whose citizen's average lifespan is unfortunately short.'

However, we must say that it is still conceivable that movement seemingly involved in Subjectivization is a kind of Scrambling and that, if so, the Nominative assignment in situ is still a possibility. Independently of this, Tateishi (1994) points out that Scrambling of subjects in the Double Nominative Construction is possible. For example, (33) can undergo Scrambling and have the following word order:

(35) Kokumin -no heikin jumyoo -ga nihon -ga mijika -i.

Tateishi (1994) has refuted Tateishi's (1988) analysis on the basis of this fact on Scrambling, because it appears that, if (32) is the correct structure, (35) involves movement of a non-maximal constituent. However, once Scrambling of the subject is possible, we can derive (35) by moving the Nominative phrases twice:

(36) [NP t_j Kokumin -no heikin jumyoo -ga]$_i$ NP nihon -ga]$_j$ t_i mijika -i.

Thus, Tateishi's (1988) analysis still remains as a formal possibility.

5 Nominative assignment

This section and the next introduce studies trying to answer (18b), repeated here as (37):

(37) How can we assign the Nominative Case to the 'derived' subjects?

This section introduces those which propose mechanisms of Nominative assignment, and section 6 introduces studies which try to explain the existence of the Double Nominative Construction by parametrization of a part of language faculty.

5.1 Saito's analysis of Nominatives

Saito (1982, 1985) proposes that the Nominative Case *-ga* in Japanese is a kind of inherent Case. In Saito (1982), he appears to identify the trigger of this inherent Case to be a focus. As *-ga* is an inherent Case triggered to be generated by some kind of thematic or semantic relations, *-ga* phrases can be generated more than once, Saito states.

The most serious trouble with Saito's approach is that it is actually very hard to identify the triggering semantic relation for the Case particle *-ga*. As we have mentioned in section 3, it is true that *-ga* in the root context expresses a kind of focus, neutral description, or exhaustive listing. However, as Kuroda (1986) correctly points out, *-ga* is not always focal in the non-root context:

(38) [Moshi zoo -ga hana -ga mijika -kereba] dono yoo -ni
if elephant NOM trunk NOM short if how way DAT
shi -te banana -o tabe -ru -daroo.
do and banana ACC eat PRES Q
'If elephants had short trunks, how would they eat bananas?'
(Kuroda 1986: (106))

There is no indication of focus in the conditional clause in (38), as the focus of questioning here is on how elephants eat bananas. Thus, it is not clear what *-ga* expresses, except that *-ga* may be Nominative. There is no strong evidence which shows that *-ga* is inherent.

5.2 Multiple Nominative assignment

Takezawa (1987; Takezawa and Whitman 1998) proposes that the existence of the Double Nominative Construction in Japanese is due to the lexical characteristic of the category INFL in Japanese. In English, the number of Nominative-marked phrases in a tensed clause is one, because INFL requires a strictly one-to-one Case-assignment/checking relation with a noun phrase. On the other hand, according to Takezawa, Japanese allows for a single INFL assigning/checking

the Nominative Case with two or more noun phrases, allowing for Double Nominatives.

Such an analysis of Case assignment/checking works, and it may be advantageous given the fact that there is a distinction between a Double Subject Double Nominative construction and a Double Subject Topic construction (see section 4). Such a distinction may well be described in terms of the domain of Nominative assignment/checking. In fact, Ura (2000) recently proposes a view that Case feature checking may be parametrized between one-to-one and multiple for his analysis of Double Subject Constructions. The only flaw in this kind of account is that it is speculative and 'parametrization' of the lexical item INFL/Tense comes from nothing else. This is what the studies introduced in section 6 are exploring.

6 Functional categories and Double Nominatives

As we have seen in the previous section, there is a possibility that some kind of parametrization is involved in the existence/absence of the Double Nominative Construction. However, is it just a simple direct description of the fact? For example, is the parametrization in question of the form [+/− unique Nominative assignment/checking], as Takezawa (1987) and perhaps Ura (2000) argues for? Studies introduced in this section try to answer this question. They all claim that the peculiarity of the Double Nominative Construction comes from something deeper.

6.1 Kuroda and Fukui's parametrization approach

Fukui (1995) and Kuroda (1988) both try to derive a set of differences between languages like English and those like Japanese from a simple parametric difference which covers the very basic of clausal construction. For example:

(39)

Japanese	**English**
Lack of surface *wh*-movement	Obligatory *wh*-movement
Scrambling	No Scrambling
Stacks of Determiner-like elements	Unique Determiner per Noun Phrase
No grammatical plural form which triggers agreement	Number agreement required
Multiple Nominatives allowed	Unique Nominative per clause

Though they differ in the details of their formulation of the parameter in question, it can be stated as follows:

(40) English forces agreement, while Japanese does not force agreement or lacks agreement at all.

As agreement in the current syntactic theory is basically a feature-checking relation between the head and the Spec in the projection of functional categories

(Chomsky 1995c), the lack of agreement means the lack or inertness of functional projections. Thus, languages like Japanese must generate virtually everything in lexical projections, according to Fukui and Kuroda. The lexical projections are not under the control of feature checking and there are basically no bounds to the number of levels of projections in terms of X-bar theory or whatever replaces it (e.g., there are no bounds to the number of adjectives preceding and modifying a noun). Thus, in a language like Japanese where the subject is in the lexical projection on the surface, the multiple subjects are possible, so far as there can be a proper semantic relation between the subject and the rest of the sentence:

(41) [I′ [VP NP-ga [VP NP-ga [VP NP-ga . . .]]]]

Thus, the multiple Nominatives are possible, according to Fukui and Kuroda.

Then what is the Nominative Case? On this issue, Kuroda and Fukui differ. Kuroda claims that *-ga* is marked and licensed whenever a noun phrase is clause-initial. Kuroda views Case in Japanese as something assigned based on linear positions, not on structural relations. Fukui, on the other hand, claims that *-ga* and other Case particles are of a special syntactic category K(ase), and K is generated to Case-mark an NP in languages like Japanese where structural Case assignment/checking is not possible.

The major weak point of Fukui's and Kuroda's approach is that they cannot distinguish the types of Topics/Subjects introduced in section 4. However, their approach to Japanese grammar is worth exploring in that they try to derive numbers of differences in two types of languages from a single, simple parametric difference, which possibly simplifies the form of Universal Grammar drastically.

6.2 Case particles as functional heads

Whitman in Takezawa and Whitman (1998) shows a unique view on Japanese Case marking. He agrees with Fukui that the case particles in Japanese constitute independent syntactic categories and are not simply a marking on NP. He differs from Fukui in that Whitman considers case particles as fully projecting functional categories. For example, for Whitman, a simple transitive sentence in Japanese has the following structure:

(42) [IP Taroo [I′ [I -ga] [TrP Hanako [Tr′ [Tr -o] [VP shikatta]]]]]
Taro NOM Hanako ACC scolded
'Taro scolded Hanako.'

For Whitman, the Nominative Case particle *-ga* is an instance of a functional head INFL and the Accusative Case particle *-o* is an instance of another functional head Tr(ansitive) (or *v* or AgrO or whatever we call it), and the clausal structure in Japanese has full projections, just like English. Case marking/checking is done by the Spec–Head relations just as in English. Japanese is different

from English in that INFL lacks Tense/Agr features, basically following Fukui's and Kuroda's claims. Because Japanese INFL *-ga* lacks features, it can be multiplied in a single clause, according to Whitman:

(43) [IP Zoo [I′ [I -ga] [IP hana [I′ [I -ga] [AdjP nagai]]]]]
elephants NOM trunk NOM long
'It is elephants whose trunk is long.'

The two INFL *-ga*s are responsible for the two occasions of Nominative marking/checking.

The problem which immediately arises from Whitman's treatment of Japanese grammar is that we cannot conceive of a way to derive a sentence to which Scrambling of a noun phrase has applied, where a noun and a case particle appear to move together as if they constitute a constituent, as in (42):

(44) Hanako -o Taroo -ga shikatta.

A noun and a case particle following it always move together, and Whitman's grammar does not have a way to guarantee this. However, his way of analyzing Japanese clauses is worth exploring, because it may show another direction the theory of Universal Grammar may head in once parametrization of the characteristic of functional heads, as proposed by Fukui and Kuroda, can be accepted as something real.

7 Conclusion

This article has introduced theories and analyses of Japanese Double Subject/Nominative Constructions. It has been shown that this peculiar construction may be a guiding light for various branches of syntax, such as focus, the basic clausal structure, topic/subject distinction, and the role of functional heads in grammar. So far, there has not been any theory of this construction which covers all of the characteristics/distinctions that are introduced and reviewed in this article. Future studies on the Double Nominative Construction must be both theoretically intriguing and descriptively accurate, as almost all issues relating to this peculiar construction have been presented.

NOTES

1 Note that this is different from the Left-Dislocation Construction, as in (i):

(i) John, his uncle is a doctor.

2 Perhaps because it is non-topical.

3 Tateishi (1990, 1994) claims that the topic in (24) is base-generated in Spec(CP), on the basis that a sentence with this type of topic cannot allow for LF *wh*-extraction. Whether Tateishi's approach is correct or not, it is certain that this type of topic must be generated outside of ordinary domains of predication, S or IP(TP).
4 See also Fujii (2000), which argues that Subjectivization and Major Subject Construction must be distinguished, on the basis of other sets of data.

5 Conclusion: what we think we know

1 Introduction: empirical boundaries of the construction

1.1 Double objects in dative alternations

The representational status and proper derivation of double object constructions have long been a subject of debate in generative grammar. Most of the controversies stem from the fact that many languages from different families display a 'dative alternation', although complements to verbs in these languages normally follow a relatively fixed word order. That is, an indirect object may appear either as the object of a preposition or as one of two noun phrase objects of the verb, the other being the direct object. In the latter configuration, neither has any indication of oblique case or PP status.

Many studies have analyzed the English double object construction and its close relatives in other languages. This review will summarize and evaluate a number of these, beginning with Fillmore's (1965) classic study, continuing through some Relational Grammar studies and Government and Binding analyses such as those by Kayne (1981c) and Larson (1988b). Our comparative presentation and integrated conclusions crucially depend on accounts of dative and applicative alternations in several non-Indo-European languages. We terminate by covering some later analyses such as Den Dikken (1995c) and Pesetsky (1995).

However, our review of the massive literature on double objects doesn't pretend to be exhaustive. We regret that we could not include the most recent materials on the topic or a number of unpublished works. Nor do our short summaries really do justice to the many long and detailed studies. Rather we give a taste of each proposal, focusing as often as not on what we perceive as weaknesses rather than strengths, and try to extract certain cross-linguistic descriptive generalizations.

The sentences in (1) exemplify Fillmore's (1965) TO-dative alternation and those of (2) his FOR-dative pattern:[1]

(1) a. Mary sent a present to each family member.
b. Mary sent each family member a present.

(2) a. Carolyn baked that cake for my children.
b. Carolyn baked my children that cake.

It is important to observe that double object constructions encompass only patterns where neither of two NPs in a verb's complement system is a predicate nominal. That is, each object must stand in a different semantic relation with the verb (or be assigned different theta-roles). In traditional terms, the two NPs are direct object and indirect object (DO and IO). In contrast, the example in (3) does not contain double objects. Rather, it exemplifies secondary predication, where a predicate nominal follows and modifies the direct object. The syntax of predicate nominals differs greatly from object NPs; cf. Emonds (1985: ch. 6) for a discussion of seven differences:

(3) The Jets {called, considered, declared, judged, named} Officer Krupke a fink.

It has been often observed that head-initial SVO languages that lack a dative alternation, such as some well-studied Romance languages, nonetheless contain exact counterparts of (3). Oehrle (1976) proposes that the same phrase structure rule can generate both secondary predication and double objects. However, following the demise of language-particular phrase structure rules, most analysts agree that these two kinds of double NP constructions are related neither empirically nor theoretically. Consequently, we will not further analyze secondary predication or predicate nominals.

We will often crucially use some well-known studies published in English for double object constructions in head-initial languages other than English: Chung (1976) for Bahasa Indonesian; Kimenyi (1980) for Kinyarwanda (in the Bantu family); Aissen (1983) for Tzotzil (in the Mayan family); Haegeman (1985) for West Flemish; Baker (1988a) for many non-Indo-European languages; Baker (1988b) and Alsina and Mchombo (1990) for Chicheŵa (Bantu); Zhang (1990) and Den Dikken (1995c) for Chinese;[2] Den Dikken (1995c) for all the modern Germanic languages; and Holmberg and Platzack (1995) for Scandinavian languages.

The following typical examples of double object constructions alternating with DO-PP are respectively from Baker (1988a: ch. 5) and Chung (1976):

(4) **Chicheŵa:**
a. Mbidzi zi-na-perek-a msampha kwa nkhandwe.
zebras SP-PAST-hand-ASP trap to fox
'The zebras handed the trap to the fox.'
b. Mbidzi zi-na-perek-er-a nkhandwe msampha.
zebras SP-PAST-hand-APPL-ASP fox trap
'The zebras handed the fox the trap.'

(5) **Indonesian:**
a. Ali mem-beli telefisi untuk ibu- nja.
Ali TRN-buy television for mother-his
'Ali bought a television for his mother.'

b. Ali mem-beli- kan ibu- nja telefisi.
Ali TRN-buy- APPL mother- his television
'Ali bought his mother a television.'

In the (b), or double object, examples, the verb carries what is called an 'applicative suffix', a term borrowed from anthropological linguistics. This suffix marks the 'promotion' of an ordinarily oblique NP complement of an unmarked transitive verb to the direct object of that verb. Extending the terminology, it can be proposed that even verbs that are not overtly marked (English, Dutch, Mainland Scandinavian) can have null applicative inflections for indirect objects (section 2.5). Depending on whether the applicative suffix seems closer to a TO or a FOR dative, the literature usually refers to 'dative applicatives' (4) or 'benefactive applicatives' (5) respectively. We return briefly in section 3.4 to the structural position of this affix.

A dative alternation often occurs in SVO systems, but it can occur in V-final systems. Korean, a thoroughgoing head-final language, has speakers who accept a double accusative construction with an applicative auxiliary verb (Choe 1986). It thereby contrasts with its close syntactic cousin Japanese, also head-final, whose indirect objects must appear with a dative case marker. But with the exception of Korean and Dutch, it appears that almost all languages whose dative alternations have been scrutinized in widely available work are head-initial. Caseless double objects may thus have some affinity with head-initial systems, but we have not investigated this intriguing possibility.

Before turning to the more common SVO dative alternations, we summarize some results of two enlightening studies of double objects in the V-final system of Dutch, Haegeman (1985) for the West Flemish dialect and Den Dikken and Mulder (1991) for Standard Dutch. According to Haegeman, West Flemish treats double objects differently with two distinct verb classes, which are reminiscent of TO vs. FOR datives.[3] Unlike English and the many head-initial languages reviewed below, the indirect object of the TO dative can lack an overt P *aan* 'to' only if VP-internal (as one of two objects). Such an NP can neither passivize nor topicalize without P resurfacing. Consequently, she concludes "that the indirect object is a PP in all positions and that the prepositional head of the PP can be non-overt, . . . if and only if governed by a case-assigning verb" (1985: 285). If correct, this reinforces our suspicion that double objects involving truly bare indirect object NPs are limited to head-initial systems.

Den Dikken and Mulder's (1991) empirical arguments focus more on parasitic gaps and whether object scrambling in Dutch is an 'A movement' or an 'A' movement' (read 'A'' as 'A-bar'). Nonetheless, their structural conclusions about Dutch double objects are similar to Haegeman's. They argue that Dutch 'bare' indirect objects (those lacking an overt preposition) have the form $[_{PP}\ [_{P}\ \emptyset]$ – DP] and are syntactically related to preverbal phrases $[_{PP}\ [_{P}$ *aan*] – DP]. This 'covert prepositional dative' structure then accounts for why bare indirect objects do not freely bind parasitic gaps. Moreover, they echo Haegeman in noting that such PP

structure also accounts for an inability to passivize, in clear contrast to the bare indirect objects of verb-initial systems.[4]

Haegeman (1985) also examines an intriguing (though inexact) West Flemish counterpart to a FOR dative (with verbs such as *trekken* 'pull' and *beloven* 'promise'), which seems to involve a bare NP adjunct similar to what traditional grammar often calls a "dative of interest." She shows that these West Flemish NPs do clearly become nominative subjects of passive verbs, in contrast to Fillmore's observation about English FOR datives (see note 1). But she also argues that they originate outside the lowest verb phrase, that is, they are adjuncts of V'. If so, they again do not constitute an 'object' (i.e. a complement) in the sense focused on in this study.

As a review of existing treatments in the literature, the bulk of this chapter will necessarily concentrate on comparing those VO(O) systems which fail to distinguish their double objects either by case-marking or by an overt P. Our conclusions may or may not apply to double object constructions in head-final systems such as Dutch.

One descriptive generalization about such head-initial double object languages that has received little attention is that in every such language, the indirect object precedes the direct object if and only if subjects precede predicates. Typically, in well-studied SVO constructions, the indirect object must be first. But in Tzotzil, widely described as subject-final, the indirect object follows the direct (Aissen 1983: 286). This generalization suggests that, at some level, the indirect object may have a subject-like property. And although several analyses of double objects reviewed in section 4 treat indirect objects as deep subjects, it is not clear whether any of them can naturally express the apparent predicate–subject word order of Tzotzil double objects. For in order to do so, any subject-final word order would have to reflect a single factor, such as SPECIFIER position relative to a head. But concepts such as phrase-final specifiers are not discussed in these works.

1.2 Double objects not in dative alternations

A different sort of double object construction consists of co-occurring direct and oblique objects in languages with overt oblique morphological case(s), or 'm-case'. Holmberg and Platzack (1995) show that Icelandic has m-case. The largest class of Icelandic triadic verbs, including *give*, *send*, and *tell*, takes a direct object marked with accusative case ('A') and an indirect object marked with dative ('D'):

(6) Jón gaf Ólafi bókna.
John gave Olaf (D) a-book (A)
'John gave Olaf a book.'

Holmberg and Platzack carefully contrast double objects in Icelandic to double objects in Mainland Scandinavian, which lacks m-case. For example, Icelandic

give-type verbs cannot take dative *to*-constructions, they allow DO–IO order under some circumstances, and either object may be passivized as a nominative ('N'). These properties are almost the opposite of those found in Mainland Scandinavian and other systems that lack m-case, such as English:

(7) a. *Eg gaf bók til Jóns.
I gave book to John
'I gave a book to John.'
b. Jóns mun gefa bókina einhverju bókasafni.
John will give the-book some library
'John will give the book to some library.'
c. Jóni var gefin bókin.
John (D) was given the-book (N)
'John was given the book.'
d. Bókin var gefin Jóni.
the-book (N) was given John (D)
'The book was given to John.'

In our view, Holmberg and Platzack make a methodological error at the outset: they assume that Icelandic's m-case provides a key for determining how to assign abstract case in double object constructions without m-case. In particular, they assume that IOs rather than DOs must receive structural case by some extra mechanism. It seems more likely that both morphological case and the other properties of Icelandic double objects (e.g., freer word order, restrictions on benefactives, at least partial complementary distribution with overt P constructions, differences in passivization and impersonal passives) result from some deeper structural difference between Icelandic and Mainland Scandinavian. In fact, several of these properties suggest that IOs with m-case are structurally PPs.[5]

Taking this 'fault line' as crucial, we accordingly set empirical boundaries on this study as follows: except for subject and direct object argument NPs with so-called quirky case, we propose that object NPs with oblique case are generally PPs with null P. That is, the oblique m-cases of Icelandic, German, Latin, Slavic languages, and so on are morphological reflections of structural adpositions rather than reflexes of the dative alternation of section 1.1.

However, we do not claim that oblique m-case is an infallible indicator of PP status.[6] Obliquely case-marked object NPs that are not deep direct objects sometimes (but not typically) 'advance' to surface direct object position and hence may not be PPs in surface structure. According to Holmberg (1991b) such advancement occurs in Icelandic. In some languages an oblique case-marked NP may even be a deep direct object; for example, Faltz (1978) suggests that Walbiri dative-marked NPs can be structural direct objects. We thus claim only that NP arguments of Vs are base-generated as PPs, subjects or direct objects; there are no 'bare NP' indirect objects.

Reorderings and advancements of direct and oblique objects that are morphologically invariant – that is, that retain their m-cases or their overt Ps – are more

likely due to scrambling than to a dative alternation. Scrambling typically (but not only) operates in languages that overtly mark NP case. For example, Den Dikken (1995c: section 4.6), building on Müller's (1992) discussion of German, argues that the latter "features no genuine Dative Shift. What appears to be Dative Shift is actually A'-scrambling of a zero-headed dative PP."[7] We tentatively agree with this conclusion, although we cannot fully exclude that languages with overtly case-marked NPs could, upon investigation, reveal a non-scrambling dative alternation.

Den Dikken's argument is based on one line of thought in traditional grammar, to the effect that oblique cases other than genitive are alternative forms of PPs. We can state this as follows:

(8) **Structure-Dependent Case:**
Double object constructions in which one object is marked with productive, overt oblique case always involve at least one structural PP.[8]

An alternative view of case assignment, espoused for example by Zaenen et al. (1985, henceforth 'ZMT'), is that "Case can be assigned in (at least) three different ways": case can be semantic, idiosyncratic, or structural ('functional'). We might give this approach the name of 'autonomous case theory'.[9] Such a theory would be less restrictive in the types of underlying structures that could be proposed for double object constructions. In particular, no underlying PP would have to be present for case assignment.

In this chaper, we reject any source of case other than the four structural case-assigners V, P, I, and D. Moreover we hold that any category that can assign case can do so only once. We offer six arguments for preferring this structure-dependent case theory to autonomous case theory:

(i) Overt and null P parallelism. In 'four-case' languages such as Classical Greek, German, and Icelandic, structure-dependent case (8) predicts correctly that the case of a bare second object in double object constructions – what is usually called 'dative' – should be whichever case is ordinarily assigned by overt P.[10] An autonomous case theory, by simply defining the indirect object's case as 'dative', makes no prediction as to what case is expected with overt Ps.

(ii) Oblique case complements of nouns and adjectives. Indo-European case systems suggest the following generalizations: V regularly assigns accusative case and P regularly assigns oblique case; N and A do not assign case but receive case (Stowell, 1981); and when an NP does not receive case from its expected case-assigner, some P often assigns case to NP by default. These observations almost certainly hold independently even in autonomous case theory. Structure-dependent case consists simply of maintaining that these statements are exceptionless. Since bare oblique case NPs among multiple complements are exactly those lacking 'expected case-assigners', we hypothesize null Ps to assign them. They should occur with essentially the same distribution as other PPs.

Consequently, since Ns and As have PP complements but not direct objects in a wide range of languages, we expect that Ns and As can also have oblique but not accusative complements. This general asymmetric pattern, a mystery in a framework of autonomous case, is confirmed in many languages; for example, German in Van Riemsdijk (1983a).

(iii) Restrictions on combining oblique cases. Because the Icelandic dative can appear either as a (specially marked) direct object or as an empty-headed PP, Icelandic can have 'double datives', so this combination does not decide between structure-dependent and autonomous case theories. But in unstipulated constructions, structure-dependent case (8) defines accusative as the unique case assigned by V to a direct object and associates bare oblique case with PP structures. Consequently, it predicts the cross-linguistic absence of both double accusatives (outside of predicate nominal agreement) and double genitive complements. A theory of autonomous case cannot make any such prediction, as in fact its proponents admit: "Some other gaps remain unexplained, however; for example, nothing in our account of case would prevent Icelandic from having GEN GEN or ACC ACC combinations in postverbal position" (ZMT: 480).[11]

(iv) Syntactic patterning. If some syntactic restriction distinguishes between NP and PP, autonomous case theory predicts that any oblique case phrases should act as NPs. Under structure-dependent case, oblique NPs (except those arguably in unique subject and object positions) should pattern rather with PPs. Here are two examples:

(a) The French relative pronoun *qui* as an object of P refers only to animate antecedents, but otherwise is indifferent to the value of this feature. When *qui* follows the dative marker *à* 'to', it is animate, i.e., the oblique phrase *à qui* acts like a PP (C. Piera, p.c.).

(b) A small class of discourse markers such as *wa* 'topic' and *mo* 'too' in Japanese immediately follow maximal phrases of any type (Kuroda 1965). Phrase-final nominative and accusative case markers *ga* and *o* on NP must delete in the presence of these discourse markers, but head P such as *e* 'to' or *kara* 'from' do not. The dative case marker *ni*, like Ps but unlike NP case-markers, appears with these discourse markers.

In both these examples, a structure-dependent case theory makes correct predictions, but autonomous case theory does not.

(v) Quantifier floating. We are not aware of a systematic cross-linguistic study, but the literature variously indicates that quantifier floating off obliquely case-marked NPs is less acceptable. In our view, this tendency is explained because oblique NPs are embedded in PPs. Hence they do not c-command a modifying quantifier located outside the PP. See section 3.2.6.[12]

(vi) Undergoing NP movement. Structure-dependent case holds that an oblique case NP complement is usually a PP with an empty head. It then follows that except for direct objects with a 'quirky case' (as in Icelandic), oblique object NPs should not be able to structurally substitute for subject NPs; they should only topicalize like a deep PP. In confirmation of our hypothesis for oblique

objects, ZMT (sections 3–5) observes precisely this contrast: "Thus the same type of tests that show that oblique NPs can be grammatical subjects in Icelandic show that the German analogues cannot be analyzed as such" (ZMT: 478).

We thus take structure-dependent case as established in the rest of this study. Each V and P can assign only one case, whether or not the case is morphologically overt. V usually assigns accusative but sometimes can assign an oblique 'quirky' morphological case. Conversely, P assigns oblique case, but in marked situations P may assign a quirky morphological accusative (German *für* 'for' etc.). As we will see, this pairing of case assigners and NPs rules out a number of somewhat ad hoc analyses of dative alternations in double object constructions.

2 The first debate: lexical alternation vs. transformational 'promotion'

2.1 The dative movement rule

Much early transformational work assumed that the dative alternation resulted from a movement rule, based on the degree of regularity of its operation and the synonymy of the two alternating structures. Versions of the rule generally built the presence of a V into the structural description, since double object constructions exemplify a certain kind of verb complementation. Double object constructions appear only in those phrases which also permit prepositionless (= accusative) direct objects, suggesting that the V and perhaps also the direct object have an important role in licensing a double object construction.[13]

Herriman (1995: ch. 2) surveys earlier traditional and generative analyses of indirect objects. A typical treatment (in the introductory text of Akmajian and Heny 1975: 183–186, 220) proposes the following rule of Dative Movement:

(9)

Structural Description:	V	NP	{to, for}	NP	
	1	2	3	4	
Structural Change:	1+4	2	Ø	Ø	

However, compared with similar early transformational rules such as Passive Formation, the range of conditions on English Dative Movement suggests to many that it cannot be a regular syntactic formation. The dative alternation seems to display to some extent both the features of a transformational alternation and those of a non-productive lexical alternation. Under predominant assumptions in generative thinking, it does not lend itself straightforwardly to either type of analysis. Sentences (10a–b) illustrate one example of a lexical alternation. (Lexical alternations per se are not treated in this study.)

(10) a. Mary {supplied/donated/*positioned} a weapon to each member.
Mary {supplied/*donated/positioned} each member with a weapon.

b. Carolyn {fed/distributed/*nourished} that cake to my children.
Carolyn {fed/*distributed/nourished} my children with that cake.

As with a lexical alternation, the dative alternation does not apply across the board to all verb phrases meeting the structural description in (9). TO-datives are compatible with certain classes of 'transfer' verbs, for example those in (11), and only some of these can undergo the alternation:

(11) a. Dr. Smith {gave/sent/showed} the library his collection.
b. *Dr. Smith {donated/transferred/showed off} the library his collection.

Similarly, FOR-datives appear with characteristic verbs of preparation and creation, and again, only some of the latter permit the prepositionless variant:[14]

(12) a. Luisa {baked/fashioned/bought} the children some gingerbread houses.
b. *Luisa {invented/devised/dispatched} the children some new toys.

Moreover, while most English verb phrases containing a double NP complement are closely paraphrased by verb phrases containing NP and a *to* or *for* phrase, a disparate collection of verbs taking double objects does not permit such paraphrases {e.g. *allow*, *ask*, *bet*, *charge*, *cost*, *deny*, *envy*, *fine*, *forgive*, *pardon*, *spare*}:

(13) a. This watch cost Mary fifty dollars.
The manager denied the students a chance to explain.
b. *This watch cost fifty dollars {to/for} Mary.
*The manager denied a chance to explain {to/for} the students.

Additionally, several authors, such as Green (1974), Oehrle (1976), Pinker (1989), and Jackendoff (1990a), feel that the dative alternations, at least in English, are not really paraphrases. That is, they need not share truth values. Green (1974: 157) claims that learning necessarily occurs for using (14a) felicitously, but not for (14b). Similarly, Pinker (1989) claims that possession must change in (14c) but not in (14d):

(14) a. Mary taught John linguistics.
b. Mary taught linguistics to John.
c. John threw Bill the book.
d. John threw the book to Bill.

Emonds (1993: 227–228), in contrast, claims that such examples don't actually differ in truth values.[15] Rather, according to Anderson's (1971) study on constant semantic properties of direct objects, truth conditions are preserved in dative alternation pairs as in (1), (2), and (14), while meanings can contrast in pairs of lexical alternations such as (10); one member of some pairs can be true while the other is false.

Other authors have tried to distinguish the two versions of the dative alternation on pragmatic grounds. Erteschik-Shir (1979) claims that the indirect object in double object constructions tends to be definite (for her, "non-dominant") and Thompson (1995) that it is 'more topicworthy'. However, such claims seem concerned at most with language use rather than syntax. For example, if a speaker wishes to contest *That professor teaches in a sexist way*, a perfectly well-formed response can be *But nonetheless he always teaches girls the hardest parts of his theories*. Here the previously unmentioned indirect object is indefinite and the direct object definite. Syntactically, dative alternations are equally well-formed with definite or indefinite objects in either position.

In the longer perspective, what has finally offset doubts about the synonymy of the English dative alternation and strengthened the hand of transformationalists is a number of carefully argued analyses of double object constructions in a range of non-Indo-European languages. In many such languages, a semantic indirect object alternates freely between a PP and a direct object position; when in the latter position, the verb is regularly inflected as an applicative. Most generativist analyses of applicatives have claimed that this dative alternation is productive. For Chung (1976: 54–55), the only restriction in Indonesian is that "for a handful of verbs whose indirect objects have undergone Dative, the applicative affix may be irregular or covert." Baker (1988b) contrasts Chicheŵa's somewhat sporadically formed locative applicatives with the productivity of its benefactive applicatives. The advancement of indirect to direct object in Tzotzil, a Mayan language, also marked by a regular dative applicative verbal prefix, is not only productive but obligatory: Aissen (1983) concludes that "there are no sentences in which the indirect object has not advanced to direct object." Moreover she gives empirical arguments that the Tzotzil indirect object is not an 'initial 2' of RG (= a base direct object).

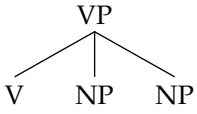
While productive relations involving applicative morphemes support a transformational account of dative alternations, they have been studied during a period when construction-specific transformations such as Dative Movement are seen as failing to capture generalizations. Thus, later proposals that the dative alternation derives from movement attempt to subsume it under Move α. These analyses, which will be reviewed in section 4, have tried to derive double object constructions from some combination of language-particular parameters and universal grammatical principles, rather than returning to a specific transformation such as (9).

2.2 *Lexicalist approaches to double object structures*

Some linguists have argued that the English double object structure is not derived by transformation because of its uncertain productivity in that language. Rather, double object structures are directly selected by lexical entries of verbs. The two NPs are then differently interpreted in a semantic component. Oehrle's (1976) dissertation is the first detailed argumentation that dative pairs result from a lexical alternation. Verbs like *give* and *send* subcategorize for two sets of

complements, NP PP and NP NP. The two sets are related through a 'lexical redundancy rule', a less narrowly defined mechanism than movement rules. He proposes that double objects have the 'flat' structure in (15), where both NPs are sisters to the verb:

(15)



Oehrle additionally argues that certain movement restrictions on dative NPs, which we review in section 3.1, arise from a general constraint on the accessibility of 'inner' NPs (those closest to the verb).

The theory of Lexical Functional Grammar (Kaplan and Bresnan 1982) proposes a similar 'surface' analysis for double object verbs. Two distinct sets of grammatical functions are assigned to the unified predicate argument structure of Agent, Theme, and Goal:

(16) a. V (SUBJ) (OBJ2) (OBJ)
b. V (SUBJ) (OBJ) (to OBJ)

These functions then map directly onto surface strings where OBJ2 is Oehrle's 'inner object' and the direct object is labelled OBJ. Thus, any systematic pairings of meanings in the double object construction are expressed directly only in predicate argument structures. As for any syntactic correspondences, the LFG system also "captures the systematic connection between NP–NP and NP-to-NP constructions by means of a lexical redundancy rule" (Kaplan and Bresnan 1982: 180).

Although Green's (1974) framework includes transformational relations, she bases her analysis of indirect objects rather on the semantic properties of relevant verbs. She groups verbs that license Dative Movement into different semantic classes, and relates these classes to different underlying structures, associating several verbs with the base structure (15) rather than a structure including a PP. For example, *pass* and *take* are in the '*bring*' category, *feed* is in the '*give*' category, *buy* and *save* in the '*selection*' group, and so on. She concludes that 'Dative Movement' should actually be divided into a series of interrelated processes that relate double object constructions and NP–PP sequences in either direction – from NP PP to NP NP or from NP NP to NP PP – according to those combinations of semantic features available for the verb in question. This approach is actually reminiscent of Harris's (1957) notion of transformational relations between sets of surface paradigms.

Pinker (1989) formulates a theory of lexicosemantic representation that attempts to make the semantic characteristics of 'dativizable' verbs more precise. His main concern is how children are able to learn the dative alternation without access to negative evidence. That is, the child must learn without being told which verbs are unavailable for the double object construction. For example,

how does the learner realize that *give* is acceptable in this context, but *donate* is (usually) not, although the two verbs have very similar meanings? (For a full discussion of this issue, see Pinker 1989: ch. 1.)

Pinker proposes a 'Grammatically Relevant Subsystem' hypothesis, arguing that "there is a set of semantic elements and relations that is much smaller than the set of cognitively available and culturally salient distinctions, and verb meanings are organized around them" (Pinker 1989: 166). Linguistic processes, including lexical alternations, are sensitive only to members of this set. He then develops a set of relevant verbal features and uses linking rules to map certain groupings of features onto certain syntactic structures. These features are detailed enough to distinguish between dativizable verbs and similar verbs that do not display the dative alternation. (See Pinker 1989: ch. 5.) Although Pinker's analysis is lexicalist in the sense that he assumes without argument that 'Dative Movement' is a lexical alternation, nothing in his theory precludes applying it to a transformational theory of datives. In fact, it might serve to weaken one of the main arguments against Dative Movement, that its application is not predictable.

Jackendoff (1990a) is another theorist who believes, like Oehrle, that a lack of full productivity in the dative alternation supports a purely lexical account of double objects. He reserves transformations for more transparently regular alternations such as passive. He elaborates on some of Green's ideas for verb classes, claiming that the semantic facts of double objects and their verbs militate against a transformational analysis, at least for English. For Jackendoff, generalizations about theta-roles do not explain the difference between verbs that allow double objects and those that do not. Unlike Pinker, he finds no plausible contrast between the roles assigned by *give* and *donate*, which both appear to assign 'beneficiary' and 'goal' roles to their complements. He feels rather that the inherent meanings of verbs determine whether there is a dative alternation.

For example, verbs of creation or preparation such as *sing* or *bake* allow double objects, while benefactive NPs with other verbs such as *copy* or *eat* occur only in *for*-phrases:

(17) a. Enrico {sang/copied} an aria for Luisa.
b. Enrico {sang/*copied} Luisa an aria.
c. Susan {baked/ate} some vegetables for her mother.
d. Susan {baked/*ate} her mother some vegetables.

But Jackendoff's analysis of this paradigm actually undermines his argument that dative alternations are lexical. He suggests that creation/preparation verbs take a *for*-phrase complement, whereas *for*-phrases with verbs like *eat* and *copy* are adjuncts. But if so, Move α cannot 'lower' an adjunct, presumably base-generated outside V^1, into direct object position. A transformational account therefore seems to explain precisely the contrast Jackendoff brings to bear against it.[16]

Along similar lines, Jackendoff (1990a: 449) favors a lexicalist account for a generalization of Pinker (1989), whereby motion verbs that "imply influence of

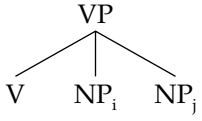
the Agent continuing throughout the Theme's trajectory" do not appear with double objects:

(18) a. He {dragged/moved/pushed} the material to Bill.
*He {dragged/moved/pushed} Bill the material.
b. He {dropped/kicked/threw} the material to Bill.
He {dropped/kicked/threw} Bill the material.

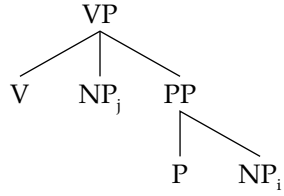
An adequate analysis should probably relate this distinction to whether the P indicates an actual spatial trajectory, as in (18a), or whether it simply introduces a third NP argument, as in (18b). We return to this distinction in section 2.5.

Lexical explanations for the dative alternation among Chomskyan theorists received a theory-internal boost in 1981. Chomsky's *Lectures on Government and Binding* does not argue against a movement derivation for double objects. However, his Projection Principle, a central tenet of Government-Binding theory, requires that the argument structure and thematic roles of complement phrases remain constant throughout a derivation. As it is used in that work, this principle rules out the possibility of a surface structure configuration like (19a) (where the complement phrase consists of two NPs) being transformationally derived from a deep structure (19b) (where the complement phrase consists of an NP and a PP):

(19) a.



b.

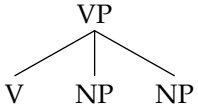


Thus, we understand why Czepluch (1982: 1) introduces a contemporaneous discussion of the dative alternation with the comment: "Nowadays it is widely held that the alternation between the prepositional IO and the prepositionless IO represents a lexical rather than a transformational relationship."

2.3 *Transformationalist objections to lexicalist approaches*

Generativists (e.g., Czepluch 1982: note 5) could nonetheless see that assuming Oehrle's (20) as the deep structure for double objects creates many problems for Government-Binding theory:

(20)



We enumerate five such problems with flat double object structures here:

(i) A flat deep structure for double objects precludes any straightforward syntactic account of the synonymous pairs in the dative alternation, including the pairings in the fairly transparent productive applicative systems of the Bantu languages, Indonesian, etc.[17]

(ii) A simple and hence optimal case theory states that case assigners (such as V and P) assign exactly one grammatical case to a single, adjacent NP (cf. Pesetsky 1995: 124). This is our Structure-Dependent Case theory in (8). In a flat structure, the assignment of case to the second NP of the double object construction in (20) becomes problematic. Chomsky (1981: ch. 3) assumes that the V in this situation assigns an additional 'inherent Case' to one of the objects and the usual structural case to the other. Thus one or the other type of case assignment applies over an adjacent NP only in this exceptional instance. As explained in a cross-linguistic study of passives (Åfarli 1992: section 3.1), such double assignment of case undercuts attempts at coherently characterizing 'case-absorption' in passives.

(iii) Work on double object applicative constructions in non-Indo-European languages, first in the framework of Relational Grammar (Chung 1976; Kimenyi 1980; Aissen 1983) and later in Government-Binding under the impetus of Marantz (1984) and Baker (1985a, 1988a), revealed many syntactic properties which demonstrate that prepositionless indirect objects function cross-linguistically as surface direct objects, while the deep direct objects they occur with do not. An additional paradigm using particles (Emonds 1972a) supports the same conclusion for English. This body of work taken together (see section 3.2) argues that the indirect object must be 'promoted' (using Relational Grammar terms) from a deep status of an 'initial 3' (a deep oblique complement) to a 'final 2' (a surface direct object) in the course of a derivation. Flat deep structures obscure this 'promotion'.

(iv) Whether or not one embeds a flat deep structure (20) into the Government-Binding framework, any explanation of the syntactic restrictions on double object constructions (discussed in section 3.2) based on some kind of structural 'inaccessibility' of an inner NP is too powerful. It incorrectly predicts that indirect object NPs cannot be passivized; see note 1. Whitney (1982, 1983) and Czepluch (1982) discuss in more detail the inadequacy of the structure (20) as a basis for explaining the grammatical relations and syntactic properties of double object constructions.

(v) The important and influential squib of Barss and Lasnik (1986) shows that several considerations based on binding of anaphors, weak crossover, quantifier-variable pairings, superiority, and negative polarity – the very cornerstones of Government-Binding theory – require that the indirect object in a double object construction, for example in (1b), (2b), and (14a, c), asymmetrically c-command the direct object to its right. (Cf. also Larson 1988b; Pesetsky 1995: 125–126.) As this influential piece is transparently written, easily accessible, and mercifully brief, we will not summarize it further, but simply accept their preliminary conclusion

as a basis for further discussion: "The problem now is to determine how it is that the first NP in a double-object VP asymmetrically c-commands the second NP, and this requires discussion of the phrase structure of these VPs" (Barss and Lasnik 1986: 350).[18]

A final logical weakness of lexicalist accounts of datives is the nature of their argument that, since non-alternating double objects (double object sentences without a *to-* or *for*-phrase paraphrase) occur anyway, a rule of dative movement is redundant. This reasoning is curious, since prosaic sentences resembling passive transforms (*John was killed by the riverside*) are never taken to argue for the redundancy of the passive transformation.[19]

Perhaps what is lacking from the lexicalist perspective is the ability to imagine a plausible derivation for these non-alternating sentences. Suppose that a double object verb such as *cost* or *deny* is lexically specified for two NP complements, as in *This watch cost Mary fifty dollars*. An obvious consequence of an optimal case theory such as (8) is that a V cannot have two object NP sisters, so that the most economical base structure that satisfies such a lexical specification is (21):

(21) This watch cost NP $[_{PP}\ [_{P}\ \emptyset]$ NP]

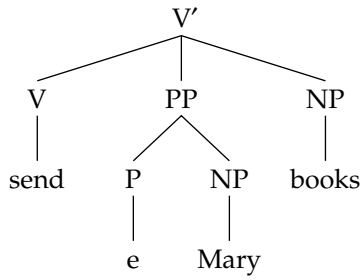
Herriman (1995: 204), citing several traditional grammarians, observes that the second complements of many non-alternating double objects are indeed akin to "NP adverbials." They are thus possibly PPs whose P is idiomatically zeroed either optionally (*envy, forgive*) or obligatorily (*fine*, *spare*). Other verbs with non-alternating double objects may fall under one of the analyses in section 2.5.

We conclude that non-alternating double objects, as in (13), do not bear on the issue of whether English or any other language exhibits transformational raising of indirect to direct objects.

2.4 Government-Binding attempts to save a lexicalist analysis

The tension resulting from the requirements of Government-Binding theory[20] and the need for a cross-linguistically convincing analysis for double objects stimulated a "datives industry" throughout the 1980s and early 1990s. Some linguists first attempted to reconcile a theory of base-generated double objects with Chomsky's Case theory by building in covert syntactic structure. In particular, Czepluch (1982) and Kayne (1984b) analyze the indirect object NP as a 'covert' PP with a P that remains empty throughout the derivation, as in (22). In both analyses, the direct object is case-marked by the verb, although not under the adjacency to V^0 required by Stowell (1981):

(22)



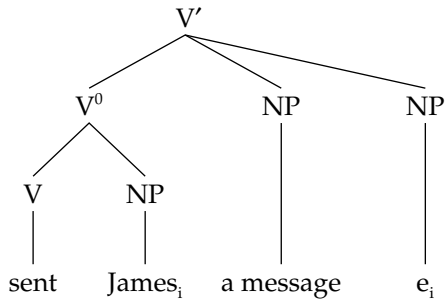
Czepluch (1982) proposes that ordering of the PP before the NP in (22) is determined by the requirements of case assignment and Chomsky's Empty Category Principle, which forces the dummy P to be properly governed. The empty P attaches to the verb through Reanalysis, allowing the verb to indirectly transmit case to the indirect object NP.

For Kayne (1984b: 195–196), "an empty preposition cannot be the source of Case," but can "transmit to its object an objective case received by percolation only if prepositions in that language normally assign objective case. Then objective case transmission by P_e is available in English, but not in French." Kayne's proposal is then that P assigns case differently in the two languages, although neither language has overt case morphology outside the pronoun system.[21] This treatment of the dative also "leads one to conclude that the [dative passive] is an instance of preposition stranding, . . . except that the stranded preposition is empty" (1984b: 196).

While we share with Zhang some uncertainty over exactly what Kayne and also Larson (1988b) actually imply in this regard, we agree that "under one possible interpretation, Kayne's and Larson's theory makes the following claim: Languages that do not permit P-stranding also do not permit Dative Shift" (Zhang 1990). Hoekstra (1995: 122) makes this explicit: "the English pattern of indirect object passivization is limited to languages allowing preposition stranding." Zhang's squib shows that Chinese contradicts any such claim, as do Indonesian and other non-Indo-European languages with dative applicatives. As observed in Van Riemsdijk (1978a), P-stranding is rare and probably limited to a subset of Germanic languages; hence it cannot be a precondition of a dative alternation.

Stowell (1981) analyzes the dative alternation in terms of movement, but upon closer inspection it is more a lexicalist than a 'Move α' solution. In his view, indirect object NPs incorporate into the verb (V^0) by means of a 'word formation rule', one which creates words of unlimited complexity, such as the bold sequence in *The girl* ***sent the man who had won huge sums of money at Monte Carlo*** *flowers*. The complex verb assigns case to the direct object NP and, rather problematically, the prepositionless indirect object also receives or 'absorbs' case from the adjacent verb. An indirect object is thus realized either as a lexical NP or an empty NP co-indexed with the incorporated NP, as in (23):

(23)



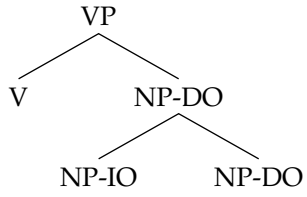
If a lexical indirect object NP is realized outside V^0, the P *to* is inserted adjacent to it as its case-assigner.

Stowell's solution to the non-productivity issue incorporates aspects of earlier lexicalist semantic proposals. He notes that obligatory double object verbs such as *cost* indicate a kind of possession of the direct object by the indirect. Presumably, the indirect object has a Possessor theta-role in these cases, but not the role of Goal. On the other hand, some indirect object NPs receive the role of Goal but not that of Possessor, as exemplified in *David sent a package to England*. Stowell proposes to attribute the dative alternation to an indirect object having the double role of Goal/Possessor (or Goal/Beneficiary in the case of FOR-datives). When a V allows a dual interpretation, the indirect object NP may incorporate into the V or not. If V assigns only the Possessor role, NP must incorporate; if V assigns only the role of Goal, incorporation is disallowed.

For Stowell, indirect objects receive theta-roles differently according to their structural position after Dative Movement. That is, if Possessor is something like a 'principal' theta-role, the NP must be inside V^0, while a Goal as a principal theta-role is incompatible with such an NP. However one formalizes this relation between word formation and theta-roles, it is the output of his Dative Movement that is playing the classical role of deep structure. That is, (23) represents the level relevant for theta-role interpretation, which is in turn input to a transformational derivation. But any rule that applies prior to deep structure in a Government-Binding framework is not a transformation but a lexical relation. Finally, then, Stowell's is a lexicalist solution.

Hellan (1991b) proposes the following covert structure to solve the case-marking problem (ii) of section 2.3. He adopts a right-branching base structure, as shown in (24):

(24)



The verb marks the topmost NP-DO for case, in accordance with Stowell's (1981) adjacency requirement. Case-marking then percolates down to the lower NP-DO. The indirect object is inherently case-marked by virtue of its position in the structure, similar to Chomsky's (1981) proposal for how an English possessive NP receives its case. Like the 'small clause' analyses we review later, one can say that Hellan's (24) straightforwardly expresses Stowell's idea that the indirect object 'possesses' the direct object in the double object construction. On the other hand, the notion of case being assigned without a case assigner contravenes the original concept of abstract case, which pairs case assigners with case-marked NPs. Moreover, as will be seen in section 4.4, the existence of a single constituent uniting both double objects is problematic.

The above four Government-Binding variants of base-generated double objects (Czepluch, Hellan, Kayne 1984b, and Stowell) do not provide an appropriate underlying structure for the asymmetrical c-command required by Barss and Lasnik (1986), or for explaining the derived direct object properties (iii) and (iv) of section 2.3. In addition, beyond one or two considerations that each author brings up in support of his idea, their modifications away from an optimal version of case theory, where case assigners assign only one kind of case to a single sister NP along the lines of Structure-Dependent Case (8), don't simplify or explain other areas of grammar.

Our conclusion is that, taken together, the arguments (i)–(v) against flat structures enumerated in section 2.3 settle the first debate. Lexicalist analyses, especially in the Government-Binding framework, have not solved the double case problem (ii). They do not address the compelling cross-linguistic regularities of applicative constructions (iii), summarized below in section 3.2. And they fail to provide the badly needed asymmetric c-command of the deep direct object by the bare indirect object (v). We thus take the position that a double object construction results from transformationally promoting to direct object a deep indirect object of a P, whose untransformed English spell-out is a *to* or *for* phrase. The still debated nature of this transformational process will occupy us in section 4.

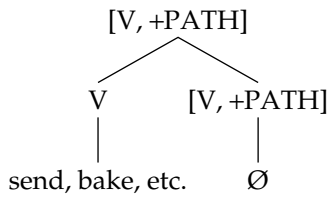
2.5 *Solving non-productivity*

The transformationalist accounts of productive non-Indo-European dative and benefactive applicative constructions have emboldened advocates of dative movement, but a more satisfactory account of its non-productivity in English is still needed. Some variant of Pesetsky's (1995: section 5.1.3) proposal to extend a type of applicative suffix to English (and perhaps other Germanic languages) may solve this problem.

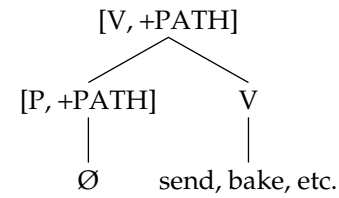
Suppose that English verbs in either TO-dative or FOR-dative alternations occur with a null affix of derivational morphology as in either (25a) or (25b). We leave aside discussion of its features and its role in licensing double objects until section 3.4. For the moment, we take this derivational formation to be 'right-hand headed' in the sense of Williams (1981b), as in either (25a) or (25b), and we

assume that this null affix shares a feature PATH with the directional P that it appears to replace:

(25) a.



b.



Under this analysis, English now conforms to a cross-linguistic generalization, which Den Dikken (1995c: ch. 5) refers to as the "systematic homophony of so-called applicative and causative affixes." He fully illustrates this phenomenon, based on parallel verb affixations in Indonesian, Nahuatl (Tuggy 1987), and Sanuma (Borgman 1989). Using Pesetsky's zero morpheme, we can say that English applicatives and English causatives for many base adjectives are also homophonous: they share a (non-productive) zero affix.[22]

On one level, this proposal just displaces the problem of non-productivity into the lexicon, but this is where both morpheme lists and null morphs are known to play a role (Pesetsky 1995: 128–129). For example, it allows for natural expression of a generalization about word formation that must haunt even the most devoted partisans of lexical unpredictability: namely, general classes of 'short' verbs in English enter into dative alternations productively.

In this regard, Fraser's (1974: 13–15) discussion of which verbs combine with postverbal particles is pertinent, for the same class of English verbs productively exhibits TO-dative and FOR-dative alternations. "Surprisingly enough, it is the phonological shape of a verb that determines to a large extent whether or not it can combine with a particle. . . . the majority of verbs occurring with particles are monosyllabic and the remainder are made up primarily of bi-syllabic words which are initially stressed." The English lexicon must thus contain the following restriction on 'null applicatives':

(26) **Restricted style:**
Verb stems whose only stress is initial combine productively with a null applicative affix.[23]

Once (26) is properly expressed as derivational morphology, relatively few double object verbs have to be listed separately as appearing either optionally or obligatorily with the null applicative affix. For the TO-dative alternation, the following verbs with some non-initial stress are listed in Herriman (1995: 61, 104): *accord*, *administer*, *advance*, *afford*, *allocate*, *allot*, *allow*, *apportion*, *assign*, *assure*, *award*, *begrudge*, *bequeath*, *concede*, *deliver*, *deny*, *extend*, *forbid*, *permit*, *prohibit*, *recommend*, *refund*, *refuse*, *reimburse*, *remit*, *repay*, *return*, *telegraph*, *telephone*, and *vouchsafe*. For the FOR-dative she lists (1995: 124, 146) *design*, *embroider*, *ensure*, *furnish*, *guarantee*, *occasion*, *prepare*, *prescribe*, *procure*, *provide*, *purchase*, *reserve*, and *secure*.

However, most of these 'exceptions' can be analyzed as containing a prefix and an initially stressed stem.[24]

In standard American speech, verbs that carry secondary or non-initial stress are usually incompatible with a dative alternation. However, (26) may be relaxed to a style (27) in which any singly stressed English verb can take double objects. This accounts for examples like the following, although they are still excluded in the restricted style: *We delivered Mary the package*; *Bill embroidered her a blouse*:

(27) **Relaxed style:**
Verb stems lacking secondary stress combine productively with a null applicative affix.

This change of style drastically shortens Herriman's list of exceptional double object verbs. In the other direction, some of the non-alternating double object verbs discussed in section 2.3 (e.g., *ask*, *bet*, *charge*, *cost*, *deny*) may be lexically listed as obligatorily requiring the null applicative affix; little would seem to turn on this.

Gropen et al. (1989: 243–245) list some verb classes that don't occur with double NPs even though they satisfy (26). Two types are "manner of speaking" verbs (*scream*, *whisper*, *yell*) and verbs of continuously caused motion (*drag*, *move*, *push*), exemplified in (18) in section 2.2. Indirect objects of such verbs are always expressed in *to*-phrases. In these cases, following Larson (1988b: section 5), it may well be that the P's independent theta-role assigning content causes it to be present throughout the derivation. In the terms of Emonds (1993), reviewed here in section 4.5, such Ps are lexicalized in deep structure, which blocks their object NP from advancing to direct object. Pesetsky (1995) and Den Dikken (1995c) propose a similar account in terms of a lexical P that assigns a theta-role characterized by "continuous imparting of force." As a reviewer notes, perhaps the term 'indirect object' is simply not appropriate for objects of these contentful Ps.

3 An emerging consensus: transformational raising of the indirect object to direct object position

3.1 Restrictions on promoted indirect objects

3.1.1 The Restriction on A'-extraction

In section 2.4, we concluded that a double object construction results from transformationally promoting to direct object a deep indirect object of a P, whose untransformed English spell-out is *to* or *for*. An anti-transformationalist counter might claim that the apparently 'promoted' italicized objects in (1b–2b) are simply parallel to the italicized deep objects with 'Goal' theta-roles in (28b):

(1) b. Mary sent *each family member* a present.

(2) b. Carolyn baked *my children* that cake.

(28) a. Mary provided a present to each family member.
Carolyn supplied that material to my children.
b. Mary provided *each family member* with a present.
Carolyn supplied *my children* with that material.

In addition to the telling semantic arguments of Anderson (1971) against this view, a cross-linguistic syntactic property also suggests that the surface objects in (1b–2b) have a different syntactic status from those in (28b). Generally, Goal direct objects can move freely, exactly like other direct objects, to any peripheral position (e.g., by *wh*-fronting or rightward Complex NP Shift). However:

(29) **Restriction on A′-extraction:**
Movement of a 'promoted' indirect object NP unmarked by a P or dative case to a non-argument position is ungrammatical.

This restriction on what Government and Binding calls 'A′-movements' holds for both Goals (*to*-datives) and Beneficiaries (*for*-datives):[25]

(30) a. ??Which sister$_i$ shall we send t_i a present?
??Who$_i$ did Carolyn bake t_i that cake?
b. *This is the friend$_i$ (that) {Mary sent t_i a present/Carolyn baked t_i that cake}.
c. *Kids$_i$ are always easy to {tell t_i a story/buy t_i presents}.
d. *Charlie {sent t_i a book/baked t_i that cake} [the girl who lives next door]$_i$.

For English, this restriction on *wh*-movement is first noted in Fillmore (1965). Ross (1986) observes that indirect objects without P cannot undergo rightward Complex NP Shift (30d) either. Further examples of (29) are presented and discussed in Oehrle (1976), Ziv and Sheintuch (1979), Hornstein and Weinberg (1981), Whitney (1982, 1983), Czepluch (1982), Barss and Lasnik (1986), Baker (1988a: section 5.4), and Hellan (1991b).

As Whitney (1982, 1984) observes for English, the restriction (29) generalizes to all Government and Binding 'A′-movements', that is, movements to non-argument positions, whether to the left or right, as in (30d).[26] This bi-directionality in itself excludes any account of (29) that depends on a left–right asymmetry, such as many theories of parsing and some syntactic theories. These movement restrictions apply even though the dative NP behaves like a direct object in other ways (see section 3.2) and is in a position (next to the verb) in which a base-generated direct object would be movable.

This descriptive generalization is no artifact of English. It holds cross-linguistically for applicative languages such as Chicheŵa (31) and Chamorro (32) (data reproduced from Baker 1988a: 291–292):[27]

(31) a. Atsikana a-na-perek-er-a mfumu chitseko.
girl SP-PAST-hand-APPL-ASP chief door
'The girl handed the chief the door.'
b. *Iyi ndi mfumu imene ndi-na-nen-a kuti atsikana
This is chief which 1sS-PAST-say-ASP that girl
a-na-perek-er-a chitseko
SP-PAST-hand-APPL-ASP door
'This is the chief which I said that the girl handed the door.'

(32) a. Hu tugi'-i i che'lu-hu ni kätta.
1sS-write-APPL the sibling-my OBL letter
'I wrote my brother the letter.'
b. *Hayi t-in-igi'-i-n-ñiha ni kätta?
who NOM-write-APPL-LK-their OBL letter
'Who did they write the letter (to)?'

(31b) contrasts with the permitted relativization of an ordinary direct object (Baker 1988a: 289):

(33) Iyi ndi mfumu imene ndi-ku-ganiz-a kuti a-na-on-a.
this is chief which 1sS-PRES-think-ASP that 3sS-PAST-see-ASP
'This is the chief that I think she saw.'

Before reviewing how authors have treated restriction (29) theoretically, it is important to appreciate that this kind of syntactic property strongly suggests that a promoted Goal phrase, even though it has the position and many other properties of a direct object, is not simply that. Even without a fully satisfactory account of the cross-linguistic paradigm (29), a promotion analysis at least distinguishes between (1–2) and (28b). Simply considering double object constructions to be base-generated provides no reason at all to expect different behavior under A'-movement.

3.1.2 Accounts of the Restriction on A'-extraction

Oehrle's (1976) base analysis includes the statement that inner NPs, that is, those followed by a direct object, are inaccessible to movement rules, but this basically only rephrases the problem posed by restriction (29). Moreover, Baker (1988a: 295) points out that explanations based on the inaccessibility of an inner NP (as defined by the simultaneous presence of an 'outer NP') encounter a further difficulty. In Chicheŵa and Chamorro, morphologically identifiable applicatives with promoted oblique NPs can be formed with certain classes of intransitive verbs. Extraction of the applied object in these cases is just as bad as extraction

of the inner object of a transitive verb. Accounts of (29) that depend on the presence of two NPs, rather than on the derivational status of the promoted NP, are thus inadequate.

Stowell's (1981) solution for the Restriction on A'-extraction (29) is somewhat more attractive. Recall that in his analysis (23), a bare English indirect object (of whatever length) is incorporated under the V by a 'word formation rule'. It then follows that the inner NP cannot be further moved, as syntactic rules never apply to parts of words. Larson (1988a) also invokes some type of inaccessibility restriction based on a verb forming a deep constituent with an indirect object.[28] Both Stowell and Larson circumvent the problem of the bare dative NPs' seeming ability to move (only) to A-positions by claiming that 'dative passives' (34) involve movement from an outer, non-promoted position directly to the subject position. Since the deep indirect objects then receive case after passivization, there is no need for an oblique *to* or *for* with a trace t_k:

(34) We_k might be given a book t_k.
A $woman_k$ was offered the job t_k.
The $guests_k$ were finally fixed an appropriate lunch t_k.

Once English dative passives are not derived directly from double object constructions, however, an important generalization is lost. Early generative analyses observed that English verbs which do not permit prepositionless double objects prohibit dative passives as well:

(35) *Our club might be {distributed/donated/suggested} some books.
*A woman was {demonstrated/outlined/revealed} the procedure.
*The guests were finally {concocted/designed/reordered} an appropriate lunch.

That is, dative passives appear to derive, in English at least, from double object constructions. Hoekstra (1995: section 3) provides two further arguments against passivizing indirect objects in their base position. Along the same lines, Romance languages lack dative passives because they lack bare double objects. Thus, the following descriptive generalization encompasses both English and Romance:

(36) **Dative passive Restriction:**
Passivization of indirect objects (unmarked by any dative case) results from moving NPs already promoted to direct object.

The Stowell and Larson accounts of dative passives contravene (36) and thus fail to predict data such as (35) naturally.

Czepluch (1982) takes a different approach to the restriction in (29). As seen in section 2.4, he analyzes bare datives in terms of a base-generated PP headed by an empty P. He rules out extraction of the bare dative NP through a constraint

on movement out of empty-headed phrases, which would leave a presumably unacceptable 'layered trace' under a PP. In order to nonetheless allow dative passives, Czepluch must extend case theory so that these layered traces are unacceptable only under the conditions of A'-movement. That is, a sentence like **Who did John give the book?* is ruled out because the trace of *who* cannot be either directly or indirectly case-marked.

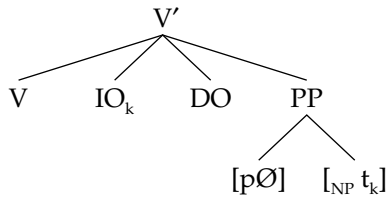
Den Dikken (1995c: section 4.2) provides a somewhat similar account of (29) that also involves the structure of a PP. Summarizing relevant data from a range of authors, he concludes that only "short" (clause-bound) *wh*-movement of promoted IOs can be grammatical, as in (30a), and this only in some languages, such as Dutch, Norwegian, and certain dialects of English. For these systems with grammatical "short" overt *wh*-movement of indirect objects, i.e., which seems to contravene (29), Den Dikken argues that an entire PP headed by an empty dative-assigning P is fronted.[29] In contrast, he claims that many A'-extractions, including at least those in (30b–c), involve Empty Operator Movement or more generally simple movement of an NP, and these are always excluded (1995: 188). Our formulation of (29) does not require P to be overt, and hence countenances Den Dikken's analysis or others which permit a fronting of an empty-headed PP.

Baker (1988a: 299) proposes a different refinement of Czepluch's approach, which he calls the Non-Oblique Trace Filter. This filter blocks any trace of an A'-operator lacking oblique case if its non-verbal governor incorporates into a higher verb. By stipulating the presence of an operator in the filter, he automatically exempts passive traces from it while still blocking A'-movements, or in other words the restriction stated as (29). It is doubtful whether this ad hoc device works empirically, since it also appears to wrongly rule out A'-movement of a passivized bare indirect object, which is cross-linguistically permitted (Alsina and Mchombo 1990: section 2).

Hellan (1991b) illustrates (29) for Mainland Scandinavian, arguing that the trace of an A'-movement of a bare indirect object is ill-formed, rather than movement itself. In his structure (24) for double objects, the verb governs just the direct object; the bare indirect object is licensed and receives a theta-role only by virtue of its structural position (akin to a possessive NP). Moreover, he claims that such lexical NPs do not need to receive an abstract case, whereas traces of *wh*-movement uniformly do require case. Hence, those NPs licensed by virtue of their structural position, and not by a lexical licenser, are precisely those which cannot undergo A'-movement (29). A virtue of this proposal is that it can account for why possessive NPs in English, for example, are not available for A'-movement either. However, it must be observed that extracting possessive NPs (the Left Branch Constraint of Ross 1986) is significantly less acceptable than violating (29).

Whitney (1982, 1983) proposes an account of (29) that does not require extending case theory or special restrictions on movement of the inner NP. Like Czepluch and Baker, she assumes that indirect objects are generated under a PP. They then move to their surface position next to the verb, leaving a trace in the usual way:

(37)



All further movements to an A′-position, including Complex NP Shift and other A′-movements (Whitney 1983, 1984), leave a trace that serves as a variable in LF. Further movement of indirect objects is then blocked by Chomsky's (1982: 31) principle that a variable "must be A-free in the domain of the operator that binds it." The variable in the position of IO_k is under the first branching node V′ over the original indirect object trace, therefore not A-free.[30]

This analysis correctly predicts that *wh*-movement, Complex NP Shift, and other movements of bare indirect objects to A′-positions are ruled out, while movements to an A-position, like passive, are acceptable. It also distinguishes base-generated NPs next to the verb, which are extractable, from indirect objects that have been promoted to direct object position, which are not.

Whatever the ultimate fate of these competing proposals for explaining the restriction (29), this robust cross-linguistic paradigm itself strongly suggests that bare indirect objects are not generated in the base as direct objects but rather move to their surface position. The restriction on their further movement, which base-generated direct objects are not subject to, can be satisfactorily accounted for only if their transformational history is distinct from that of direct objects.

3.1.3 Scope Freezing: confirmation of indirect object promotion

Some double object studies whose structural proposals we will review in section 4, e.g., Aoun and Li (1989) and Larson (1990), have brought out a property of double objects that confirms their status as a derived, non-base construction. In English at least, many quantified NP arguments may optionally take 'wide scope' over a higher one in base constructions:

(38) a. *Two new topics* might reinvigorate **every girl in the class**.
b. He assigned *two new topics* to **every girl in the class**.
c. It seemed to *every girl in the class* that **two new topics** were needed.

In (38a–b), the topics may vary as a function of the girls, i.e., the lower bold NPs may take wide scope over the higher italic NPs. In the other interpretation, the topics are fixed independent of every girl (i.e., the higher italic NPs take wide scope). Similarly in (38c), the lower bold NP may take either wide scope (the topics are fixed) or narrow scope (the topics vary with the girls).

But as Aoun and Li (1989, 1993b) point out, a prepositionless indirect object as in (39) seems to tolerate only wide scope. That is, (39) does not typically mean

that every girl had the same topics. Rather, the girl is fixed first (wide scope) and then the topics:

(39) He assigned *every girl in the class* **two new topics**.

What is of interest in this regard is that wide-scope readings of the higher italic NPs are also strongly favoured in structures derived by subject raising (40a), passive (40b), and, as pointed out by a reviewer, locative inversion (40c):

(40) a. *Two new topics* seemed to **every girl** to be unfair.
b. *Every girl in the class* might be reinvigorated by **two new topics**.
c. *On two big billboards* were (painted) **every party's slogans**.

The property illustrated in (39)–(40) is called 'Scope Freezing'. A plausible initial description of what is at stake involves movements into argument positions, which in a range of cases are apparently subject to (41):

(41) **English Scope Freezing:**
NPs moved into A-positions must take wide scope over NPs that they c-command.

We are often somewhat sceptical of the relevant acceptability judgments, and consequently find it difficult to use Scope Freezing to evaluate the merits of the rather complex structures and derivations proposed by various authors. What seems clearer and actually more to the point for our purposes is the fact that this phenomenon pretty clearly groups together promoted prepositionless indirect objects with other 'moved NPs' such as those raised to SPEC(IP) in (40). Thus, while it is easy to interpret the base-generated example *He talked with every girl in the class about two new topics* with wide scope on topics (there are only two), a parallel interpretation of (39) seems at best forced and unnatural.

From this perspective, whatever its ultimate structural analysis, it is plausible to conclude that Scope Freezing (41) constitutes a second diagnostic for the derived rather than base-generated status of bare indirect object NPs.

3.2 Direct object properties of promoted indirect objects (Relational Grammar 3 → 2)

Section 3.1.1 has highlighted an important syntactic property (29) of prepositionless indirect objects that 'betrays their origins': these objects differ from direct objects in resisting A'-movements. Deep direct objects with a Goal role are not subject to this restriction: *What did you spray with paint? Who did you approach on the street?* Provided promoted indirect objects leave a trace of some sort, an account of (29) in terms of a general condition on variable binding is in principle available.

A second restriction on promoted indirect objects is 'Scope Freezing', i.e., their inability to house (English) quantifiers with narrow scope, as discussed in section 3.1.3. Finally, a third restriction, observed in Baker (1988a: 278–279, 1988b), is that the head indirect object noun in benefactive applicatives cannot 'incorporate' into a governing verb (in contrast to a deep direct object noun). We thus have three independent reasons to believe that bare indirect objects are not simply structural deep objects with Goal theta-roles, but are somehow transformationally derived.

With respect to most other properties, however, dative shifted NPs behave like direct objects, whether or not a language has an overt applicative affix. In Relational Grammar (RG) studies such as Perlmutter and Postal (1983b), this change is described as '3 to 2 advancement', where 2 indicates a direct object. As a result of advancement, a deep or initial indirect object behaves like a direct object with respect to a whole battery of syntactic and morphological diagnostics for direct objects. A side effect of this advancement is that a deep or initial direct object NP is demoted to what RG calls 'chômeur' status. That is, a chômeur NP fails a number of these same diagnostic tests for surface direct object status.

In many languages with productive dative alternations, an overt 'applicative' verbal affix accompanies the advancement to direct object. Marantz (1982) proposes that this situation is typical: when verbs have supplementary overt morphology corresponding to an oblique argument NP, that NP and not the usual direct object behaves like a surface direct object. Baker (1988a: section 5.3.1) refers to this remarkable cross-linguistic pattern as Marantz's Generalization. However, as we see below, advancement is not invariably accompanied by an overt applicative suffix.

3.2.1 Indonesian

Chung (1976) is a thorough RG study of indirect objects in Indonesian (= Bahasa Indonesia), whose basic word order is S-V-O-(PP). "Dative permutes a direct object with an indirect object or benefactive, and deprives the indirect object/benefactive of its preposition. . . . Some form of the benefactive suffix . . . is typically added to the verb" (1976: 41). She emphasizes that P is omitted if and only if "the IO is moved between the DO and the verb," exactly as specified in the early transformational rule (9) for English:

(5) a. Ali mem-beli telefisi untuk ibu-nja.
Ali TRN-buy television for mother-his
'Ali bought a television for his mother.'

b. Ali mem-beli-kan ibu-nja telefisi.
Ali TRN-buy-APPL mother-his television
'Ali bought his mother a television.'

Chung then goes on to provide extensive and convincing arguments that an indirect object promoted by Dative behaves as a direct object in Indonesian. "The IO can, for instance, be passivized. . . . It can be replaced by the true reflexive, *diri* 'self'. . . . It can undergo Object Preposing, if the subject of the sentence is a

pronoun [the normal condition on this rule]. . . . And the original IO is subject to the major [deletion] strategy, with *jang*, for Relative Clause Formation . . . In contrast, [for any of these diagnostics] the underlying DO no longer behaves like a direct object after Dative has applied" (1976: 58–60).

3.2.2 Kinyarwanda

Kimenyi's (1980) analysis of Kinyarwanda advancement is another detailed RG study of double objects. We have used the succinct summary of this work in Poser (1982).

Kimenyi finds evidence for several transformational alternations of complement phrases in the language, and the various rules promoting oblique objects introduce applicative inflections on the verb. One of these rules promotes indirect objects to direct object status. His study enumerates an impressive number of corresponding operations distinguishing Kinyarwanda direct from oblique objects, which he refers to under the rubrics of Passive, Stativization, Object–Subject Reversal, Pronoun Incorporation, Reflexivization, Clefting, Pseudo-Clefting, Exclusive Insertion, and Existential Insertion. Using the same logic as Chung's study, he then shows that Kinyarwanda prepositionless indirect objects invariably act like direct objects with respect to these operations.

3.2.3 Tzotzil

Aissen's (1983) RG study of indirect objects in Tzotzil shows that arguments for advancement to direct object can be constructed even in the absence of a dative alternation. She specifically couches her analysis in terms of derivations: "While my conception of sentence structure follows that of relational grammar in its essentials, I assume that these levels of relational structure do constitute a derivation, roughly in the spirit of transformational grammar" (1983: 274).

A special characteristic of Tzotzil is that its lexicon lacks P morphemes whereby indirect objects can surface in PPs. "Two facts about Tzotzil obscure the existence of Indirect Object Advancement. First is the fact that [42] is the only way to say 'I sold pigs to Sun'. . . . Second, *čitom* 'pig' in [42] is, it will be claimed, the initial direct object, but not final direct object, this relation being held by *li Sune*. *Citom* is a final direct object chômeur" (1983: 272–273):

(42) ʔI-h-čon-be čitom li Sune.
ASP-ERG1-sell-APPL pig the Sun
'I sold the pigs to Sun.'

Aissen makes the case for advancement by isolating three tests for direct objecthood: direct objects agree with a verb in person and animate number (43a), and they are the only passivizable complements:

(43) a. Mič-a-mah-on?
Q ASP-ERG2-hit-ABS1
'Are you going to hit me?'

b. Mi mu š-a-čon-b-on l-a-čitome?
Q-NEG ASP-ERG2-sell-APPL-ABS1 the-your-pig
'Won't you sell me your pigs?'

She observes that in the double object construction "the verb agrees in person with the indirect object and not the direct object" (1983: 281), as exemplified by the obligatory first person object agreement in (43b). Similarly, the Tzotzil verb agrees in animate number with promoted indirect objects but not demoted direct objects. She concludes, "There are three kinds of evidence that the initial indirect object is the final subject of the passive sentence: evidence from person agreement, number agreement, and word order" (1983: 282–283).

A lexicalist response to Aissen might be to view Tzotzil Goal phrases as simple variants of direct objects. We reproduce two of her arguments against this position: (i) The verbal suffix *-be* in (42–43), which we gloss as applicative, may not occur with simple transitives. (ii) A different verbal suffixation with *-van*, which indicates a discourse-specified human direct object, "is quite regular and . . . there appear to be no lexical exceptions" (1983: 292). However, this *-van* apparently marks only *deep* direct objects, since it cannot replace a subject of an intransitive complement to a causative (44b). The fact that (fully productive) *-van* is equally ungrammatical with an indirect object signaled by *-be* (44c) confirms that the latter cannot be a deep structure direct object either:

(44) a. (causative with overt first person lower subject)
L-i-y-ak' lok'-ik-on.
ASP-ABS1-ERG3-let leave-INTR-ABS1
'He let me leave.'
b. (causative with discourse-specified human object)
*ʔI-ʔak'-van lok'-uk.
ASP-let-OBJ leave-INTR
'He let people leave.'
c. *Tas-čon-be-van čitom.
ASP-sell-APPL-OBJ pig
'He is selling people pigs.'

That is, while the bare indirect objects of Tzotzil are indeed surface direct objects, they are not deep direct objects but rather advance to that position in a derivation.

3.2.4 Chicheŵa

On the basis of his work with Sam Mchombo, Baker (1988b) describes a range of double object properties of the Bantu language Chicheŵa according to which bare indirect objects behave like direct objects, while the deep direct objects which follow them do not. Only the bare indirect object in Chicheŵa (i) must be adjacent to the verb (1988b: 370); (ii) undergoes passivization in all dialects (1988b: 386); (iii) "can be expressed by the object prefix on the verb" (1998b: 354); and (iv) cannot be relativized in accord with the restriction (29):

(31) a. Atsikana a-na-perek-er-a mfumu chitseko.
girl SP-PAST-hand-APPL-ASP chief door
b. *Iyi ndi mfumu imene ndi-na-nen-a kuti atsikana
This is chief which 1sS-PAST-say-ASP that girl
a-na-perek-er-a chitseko
SP-PAST-hand-APPL-ASP door

An additional property confirming the derived nature of the Chicheŵa bare indirect object is the fact that it may not undergo Baker's 'noun incorporation'; this possibility is reserved for nouns governed by the verb in deep structure (reminiscent of the Tzotzil suffix *-van*). Baker's structural explanation for these facts, while transformational, does not sanction any phrasal movement of NP within the VP, but rather employs 'P-incorporation' into the V; this incorporated P is the source of the Chicheŵa applicative suffix. We return to his analysis in section 4.1.

3.2.5 Scandinavian

Mainland Scandinavian languages, lacking overt oblique case, have a fairly productive dative alternation similar to English, described in Holmberg and Platzack (1995). The bare indirect objects act like their English counterparts: they must precede and asymmetrically c-command the deep direct object and they freely passivize in either periphrastic or synthetic passives, as seen in (45b–d). As in all Germanic languages, there is no overt applicative morphology on the verb. The following examples are Swedish:

(45) a. Johan visade mej en intressant bild
Johan showed me an interesting picture
b. (periphrastic passive)
Jag blev visad en intressant bild
I was shown an interesting picture
c. (synthetic passive)
Jag visades en intressant bild
I showed-PASS an interesting picture
d. Johan {blev förärad/ förärades} en medalj
Johan {was presented/ presented-PASS} a medal

The passive formed by moving the deep DO is apparently marginal in Swedish, but allowed with some verbs:

(46) a. (periphrastic passive)
?Bilden blev visad mej tre gånger
the-picture was shown me three times
b. (synthetic passive)
?Bilden visades mej tre gånger
the-picture showed-PASS me three times
c. Medaljen {förärades/ blev förärad} Johan
the-medal {presented-PASS/ was presented} Johan

An informant reports that in Norwegian, IO and DO passives are apparently equally good, while Danish is said not to accept passivising the deep direct object in a double object construction. The analysis of Holmberg and Platzack (1995) is reviewed here in section 4.3.4.

3.2.6 English

This language is poor in diagnostics that syntactically distinguish a surface direct object among bare NPs. However, some can be constructed; cf. note 1. Emonds (1972a) tests the PP-like nature of the direct object in a double object construction by its interaction with intransitive prepositions (particles). Intransitive prepositions can follow a direct object, as shown in (47a), but not a PP, as shown in (47b):

(47) a. The secretary sent a memo out to the committee.
Bill fixed a drink up for John at the party.
b. *The secretary sent a memo to the committee out.
*Bill fixed a drink for John up at the party.

For speakers who allow a particle at all within a double object construction (e.g., the authors), the first or promoted NP behaves like a direct object in (48a) while the second NP behaves like a PP, as seen by the ungrammaticality of the particles in (48b):

(48) a. The secretary sent the committee out a memo.
Bill fixed John up a drink at the party.
b. *The secretary sent the committee a memo out.
*Bill fixed John a drink up at the party.

The pattern is considered to have quite different implications in analyses that group double objects into small clauses, such as Kayne (1984c) and Den Dikken (1995c: ch. 3). We return to their reinterpretations of (47b) and (48b) in section 4.2.[31]

A second test distinguishing English derived direct objects from chômeur NPs involves shifted quantifiers. Chung (1976: 81–82) observes that in Indonesian, non-adjacent 'floated' quantifiers are fully acceptable as modifiers of subjects and direct objects, but not as modifiers of PPs or chômeurs. The same (admittedly rather weak) contrast holds in English, where the test concerns not quantifiers at the end of the clause as in Indonesian, but rather quantifiers shifted just to the right of the NP they modify. These NPs with floating modifiers can be either direct objects (49a) or promoted indirect objects (49b), but they cannot be PPs, as seen in (49c–d):

(49) a. We sent the books all {by mail/to that man}.
I fixed those drinks both {with ice/for Sue}.
b. Mary {brought/sent} the boys {each/both} a present.
c. We sent a refund to those men (??all) by mail.
d. I fixed those drinks for the girls (??both) with ice.

In certain analyses of section 4, a demoted or chômeur NP is embedded inside an additional surface XP. Hence, like an object of a P, such an NP fails to properly c-command shifted quantifiers, which seems to be the correct empirical result:

(50) We sent that man [$_{XP}$ [$_{NP}$ the books]] (??all) by mail.
I fixed Sue [$_{XP}$ [$_{NP}$ those drinks]] (??both) with ice.[32]

Summarizing, since an English quantifier can only shift to the right of an NP in direct object position, only the promoted NPs and not the chômeurs resulting from indirect object movement properly c-command these Q.

The diagnostics for surface objecthood from diverse languages, as reviewed throughout this section, seem to lead to an inescapable conclusion, reflecting Marantz's Generalization, that double object constructions (that is, those where neither object exhibits an overt oblique case) involve repositioning a deep indirect object in a derived direct object position:

(51) **Consensus on promotion:**
Where a language systematically allows two surface NP objects indistinct from accusatives to have different theta-roles, the thematic or deep indirect object is structurally the surface direct object.

3.3 The Barss and Lasnik Binding paradigms

As observed in section 2.3, Barss and Lasnik (1986) discuss six different paradigms, widely thought to be best accounted for in terms of Chomsky's (1981: ch. 3) Binding Theory and c-command at LF. These paradigms require that the English promoted indirect object in a double object construction asymmetrically c-command the demoted or chômeur NP. The constructions include antecedent/bound anaphor pairings (e.g., *send the two managers each other's foreman* vs. **send each other's manager the two foremen*), quantifier/bound singular pronoun pairing (e.g., *every man*, *his*), weak crossover paradigms, superiority restrictions on *wh*-extraction, and negative polarity pairings. It suffices to summarize here by observing that they are widely taken to establish the conclusion (52):

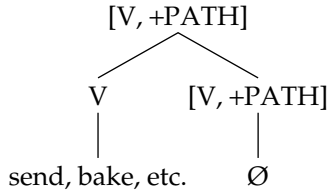
(52) **Consensus on superiority:**
A promoted indirect object surfaces as asymmetrically 'higher' than a deep direct object.

Thus, there has also emerged a consensus concerning whether double object constructions are transformationally derived. Many authors now agree that they are, and the indirect or applied object surfaces in a direct object position asymmetrically higher than the deep direct object, which is somehow 'demoted'. However, there is currently almost total disagreement as to how to best represent that demotion.

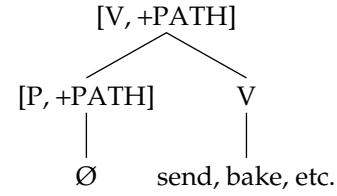
3.4 The position of the applicative affix

Provided we retain the right-hand headedness of English (and most other) morphology, there are only two possible structures (cf. section 2.5) for a null applicative affix on English double object verbs: a null grammatical head V, as proposed in Marantz (1993), or an incorporated P:

(25) a.



b.



We have seen throughout sections 1 and 3 that overt applicative affixes are generally suffixes across languages. Unsurprisingly then, Baker's (1988a–b), which derives them by head movement of P into V (cf. section 4.1), represents the incorporated applicative P as a suffix. However, in a clear majority of well-motivated head movements that give rise to single words, such as noun incorporation and V-raising, a moved head becomes a prefix. This discrepancy in morpheme order within a V then suggests the correctness of (25a) for representing applicatives.

Indeed, the morphemes for the benefactive applicatives in head-final Korean VPs (Choe 1986) and the dative applicatives in complement-final Chinese VPs (Huang 1991) can both alternatively appear as independent V glossed as 'give' in those languages. Moreover, the Korean applicative verb *cwu-* takes the full range of the morphology associated with that language's verbs. Thus, we do not hesitate to hypothesize that applicative suffixes, both overt and covert, are uniformly of category V, in accord with the expectations of Lieber's (1980) and Williams's (1981b) word-internal Right Hand Head Rules.

Assigning applicative suffixes to the category V additionally explains why languages fail to have parallel constructions in other types of phrasal projections; the complex V structure of (25a) but not the P-incorporation of (25b) accounts for the cross-linguistic impossibility of applicative nouns or applicative adjectives, for example.[33]

4 The ongoing debate: the position of the direct object in the presence of promotion

4.1 Double objects result from incorporation of a null Case-marker

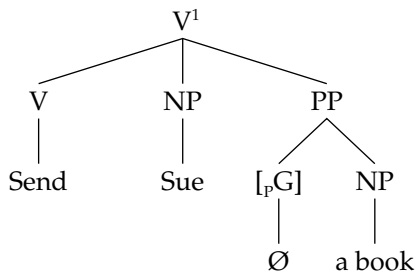
Most Relational Grammar analyses have consistently argued that an indirect object ('an initial 3') in applicative constructions simply replaces the direct object ('becomes a final 2'). From this it correctly follows that promoted indirect objects

act as direct objects with respect to later processes that depend on the final grammatical status of an NP, exactly as required by the considerations of section 3.2. Under this view, the (optional) fate of a deep or initial direct object in RG is to be demoted into the 'chômeur' (unemployed) status of Perlmutter and Postal (1983b), though still remaining vaguely associated with the main verb. In phrase structural terms, the demoted deep object NP remains somewhere in the deep VP.

However, both promotion and demotion within VP contravene Chomsky's (1981) Projection Principle, at least as it has been widely understood. Thus, the Relational Grammar conception of '3 to 2 advancement', translated into Government-Binding terms, violates the usual formulation of the Projection Principle twice.

One way to ensure that a promoted indirect object both acts as a direct object for several syntactic processes and at the same time asymmetrically c-commands an RG chômeur is to claim that the required surface relation of the double objects is simply their deep relation. That is, no NP movement or promotion occurs. This can be implemented by postulating that some empty (surface) P introduces the thematic direct object, as in (53):

(53)



This is Pesetsky's (1995: 125) proposal: "The second object of a double object construction . . . is [an NP] introduced by a null Case-assigning element G." This empty G selects an NP with a 'Theme' semantic role (i.e., a direct object) and "must move from its base position [in (53)] and affix . . . to the governing verb" (1995: 127). Pesetsky goes on to discuss various possibilities for fixing the category of G, and tentatively concludes that the best candidate is P.[34]

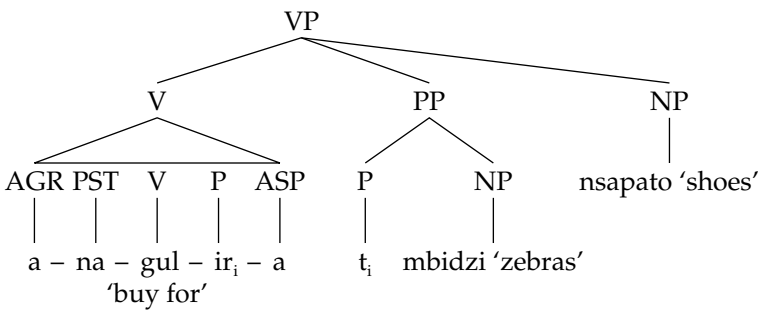
Pesetsky's hypothesis provides a simple theory of structure-dependent case-assignment (one case-assigner for each NP; section 1.2) as well as an explanation for the non-productivity of the English double object construction (section 2.5). Nonetheless, it reduces to a latter-day version of lexicalism, since the incorporation of P plays no structural role in either the syntax or the interpretation of the two NPs. Its disadvantages are consequently due to the fact that the bare indirect object has no transformationally derived character: (i) Anderson's (1971) general semantic properties of direct objects, which promoted indirect objects lack, become stipulated aspects of the item G (Pesetsky 1995: 179–180); (ii) the base structure (53) cannot explain the Restriction on A'-extraction (29); (iii) Aissen's

(1983) arguments against deep representations like (53) for Tzotzil go unanswered (section 3.2.3); (iv) there is no explanation for why promoted indirect object nouns exhibit 'Scope Freezing' (section 3.1.3) or cannot undergo the further step of incorporation in a language with that option (Baker 1988b).

In addition, overt applicative realizations of incorporated Ps are generally homophonous with Goal rather than Theme prepositions (e.g., Chinese *gei* 'to'; Zhang 1990); this tendency creates awkwardness for the structure (53).

Pesetsky's proposal is structurally similar to, but derivationally distinct from, an earlier, extremely influential proposal of Baker's (1988a, 1988b). Baker accounts for Marantz's Generalization by a variant of (53) in which a null surface P introduces the first (indirect) rather than the second (direct) object. Unlike Kayne's earlier proposal for an empty P which remains in situ, discussed above in section 2.4, Baker claims that a deep P transformationally incorporates into V, leaving a trace and surfacing as overt dative and benefactive applicative morphemes, as in the Chicheŵa illustration (54):

(54)



(Baker 1988a: 263)

According to Baker, an empty P cannot govern or assign case to its object, so this NP must receive case from some other source. He achieves this and explains many other derived direct object properties of RG's promoted indirect objects by utilizing his quite convincing and general Government Transparency Corollary (Baker 1988a: 64). According to this proposal, if a head Y (here P) adjoins to a higher head Z (here V), then a phrase otherwise governed by Y becomes governed by Z. Since the complex V (V + P) in (54) then governs the stranded NP, the latter is assigned accusative and treated as a direct object. Incorporation and Government Transparency thus together account for the fact that deep oblique NPs can behave as surface direct objects. To further ground this system empirically, Baker (1988a: ch. 5) surveys in detail several properties of applicative systems rather schematically reviewed in section 3.2 above.[35]

Baker's and Pesetsky's analyses of double object constructions have in common that they respect the standard interpretation of Chomsky's (1981) Projection Principle: neither analysis modifies the position of any complement NP in the course of a derivation, and consequently no single VP contains multiple links in a single argument chain. A further merit of Baker's framework is that

transformational P-incorporation (a subcase of head movement) accounts for the difference between the deep and surface status of the bare indirect object; this 'inner NP' is governed by P in deep structure and hence lacks properties of deep direct objects, but by V in surface structure, whereby it acquires direct object properties through Government Transparency.

Baker's 'transformationalist incorporation' (54) is supported by several intricate properties of the applicative systems he examines, and it escapes the criticisms we levelled against Pesetsky's 'lexicalist incorporation' analysis (53). Nonetheless, (54) appears to have two serious weaknesses. First, the asymmetric c-command required for the paradigms of Barss and Lasnik (1986) is exactly the opposite of that in (54), as observed in Emonds (1993), Marantz (1993), and Pesetsky (1995). Since the deep direct object asymmetrically c-commands the indirect object at the end of the derivation, the binding properties holding between double objects should be the opposite of what holds for English double objects, or at least the second 'outer' NP should act like it c-commands the first.

Second, Baker is left without a general device by which the deep or 'demoted' direct objects in (54) can acquire case, or at least pass the Case Filter. Consequently, he develops two alternatives in his section 5.3.4, one in terms of a highly stipulative extension of case theory and a second in terms of a rather abstract 'LF incorporation' of the thematic direct object (thus exempting it from the Case Filter in his system). The revised case theory not only subscribes to a non-explanatory notion of autonomous case (cf. section 1.2), but also extends the inherent vs. structural case dichotomy in several directions.[36] Pesetsky's (1995) variant on Baker's incorporation is in fact principally motivated by his explicitly less baroque view of case assignment.

Baker's second alternative for satisfying the Case Filter abandons assigning case to the second NP in a double object construction. Rather, he proposes 'N-incorporation in LF' for the chômeur of the dative alternation which would otherwise violate case theory. This sidestepping of the Case Filter seems to be pretty much an untestable hypothesis, though he tries to turn the obligatory incorporation of second objects in Southern Tiwa applicatives to his advantage.[37] It is hard not to conclude that such purely abstract use of incorporation has no effect other than rendering the incorporated constituents essentially exempt from any claims of grammatical theory.

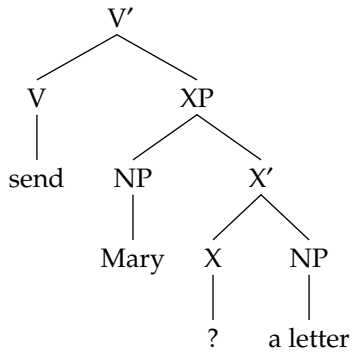
Finally, although Baker's structure (54) provides a means for formulating a 'Non-Oblique Trace Filter' to explain the Restriction on A'-extraction (29), the actual formulation and workings of his filter seem ad hoc (cf. section 3.1.2).

4.2 *Double objects are two arguments in small clauses*

Several Government and Binding authors have proposed that double object structures in Germanic languages are in fact grouped into single constituents. The indirect object and the direct object are then respectively taken to be the surface subject (or 'Specifier') and the object (or 'Complement') inside this constituent. Disputes concern the exact categorical nature of this putative phrase

and its head, which we can here call neutrally 'XP', as well as the issue of whether the surface position of the IO in (55) is base-generated or derived by movement:

(55)



Provided that the 'subject' IO is higher than the 'complement' DO in the surface form of XP, all these analyses can account for the consensus on superiority (52), i.e., the paradigms in Barss and Lasnik (1986), whether or not they predate that article. If an analysis utilizes the XP structure so as to move the indirect object to its surface position in (55), presumably into SPEC(XP), the analysis also has a good chance of capturing the ways the IO doesn't act like a deep direct object (51), as well as the further Restriction on A'-movement (29).

However, in all these analyses, the internal structures attributed to each author's categorial choice for the XP remain fairly problematic. It should be kept in mind that overt 'internal NP subjects' of categories other than IP and DP are actually never attested in English in diagnostic positions such as a focus in clefts or pseudo-clefts. These 'object phrase' analyses moreover typically require that V govern across the XP boundary into the SPEC position, not only for assigning case to the IO but also for the several other surface object properties brought out especially in Relational Grammar studies (cf. section 3.2). Few of these analyses make any attempt to either broadly justify or precisely define this kind of governance, exceptions being Kayne (1981c) and Den Dikken (1995c).

Especially when XP in a structure like (55) is not some projection of V, it is customary to refer to it as a 'small clause' (i.e., a clause-like structure lacking many – or nearly all – clausal properties). The choices for XP can be IP (formerly S) or PP, reviewed in this section, or NP/DP, reviewed in section 4.4. The choice of VP for XP ('Larsonian shells') is reviewed in section 4.3.

4.2.1 Some doubts about small clauses

Kayne (1981c) proposes that trees must be binary branching, which leads him to conclude that double objects form a constituent rather than each being a sister to V. As the binary branching hypothesis has been so influential, practically blinding the field in our opinion to any approach inconsistent with it, it is worth looking into the justifications given for it.

Kayne's (1981c) initial justification for binary branching is a purely formal exercise. A type of tree relation between antecedents and traces alluringly named an 'unambiguous path' is shown to be compatible only with binary branching trees.[38] However, as the article's first section indicates, there is nothing 'unambiguous' in binary trees about the actual location of an antecedent; in order to find an anaphor's antecedent, the direction 'up or down' in the tree must be specified independently at each dominating node. That is, specifying unambiguous paths to an antecedent is simply a formal equivalent to specifying c-command over strings of variable length.

Subsequently, Kayne (1984c) presents theoretical and empirical arguments to motivate binary branching and hence small clause structures for English double objects. We first treat in turn four considerations that seem to have impressed subsequent analysts: (i) an argument based on learnability, (ii) the relation of binary branching to Kayne's theory of 'connectedness', (iii) the way Kayne insulates small clause theory from disconfirmation, and (iv) argumentation based on coordinations. We delay until the next subsection his proposal for English paradigms with particles, (47–48) above, which bear more directly on double objects.[39]

(i) Learnability. Kayne (1984c: ix) remarks that binary branching "constitutes a step towards a solution to the learnability problem for phrase structure (How does the language learner know what tree representation, of all those available in theory, to associate with a given sentence?)." This remark has impressed later researchers, being echoed for example in Den Dikken (1995c: 27). But in fact binary branching does not reduce the set of grammars, since learned parts of grammars, probably the lexical entries of functional categories, actually contain no information about branching. Rather, as Kayne's cited rhetorical question indicates, binary branching can facilitate not acquisition but *processing*. It can (only) help associate *given sentences* with certain trees rather than others.

But to our knowledge, procedures that have been implemented for processing models invariably use the argument-taking devices of heads in a central way, whether these be thought of as argument structures, theta-grids, lexical conceptual structures, event structures, or subcategorization frames. In these procedures, an indispensable step in either producing or comprehending a sentence of any complexity is always (56):

(56) **Economy of representation:**
Match the lexical argument information of a head with a syntactic tree, using as little structure as possible.

If no structural economy were built into using argument information, arguments could be located anywhere – not even near the head in question.

Now binary branching suggests no way to eliminate or supplant (56). But given (56), there is no processing reason for associating arguments with a head by any means other than sisterhood; sisterhood is required whenever it is possible.

Of course, research has revealed many grammatical reasons for positing a non-sister relation between heads and their subjects, so-called 'external arguments', independently of any concerns here with double objects. However, has it found comparable reasons for any non-sister relation for 'internal arguments', which should be similarly justified? Our evaluations below of many proposals for such non-sister complement structures suggest rather that binary branching results in convoluted and inadequate analyses.

Consequently, not only is binary branching unrelated to language acquisition, in models of sentence processing it at best supplements economy of representation (56). We thus cannot agree with Den Dikken (1995c: 28), who claims that small clauses "are available at no cost whatsoever." We rather feel that their additional structure must be empirically justified by improved characterizations of paradigms involving double complements.[40]

(ii) Connectedness. In an impressive series of detailed analyses of extraction and movement phenomena, Kayne (1981a, 1981c, 1983) develops a theory of "connectedness" in trees which is designed to account for a number of paradigms involving extractions, parasitic gaps, multiple questions, etc. These papers do not discuss binary branching (or double objects), but it is true enough that researchers such as Den Dikken (1995c: 28) often conceptualize or explicate this theory in terms of binary branching trees.

Nonetheless, the connectedness results can be recast without binary branching, although to demonstrate this in detail would require a paper in itself. Informally, Kayne's final statement of connectedness (1983) requires the deepest variables bound by operators to be terminal right branches; nothing mentions a left branch, i.e., a subject of a small clause. An alternative formulation that Kayne (1981c: note 36) himself cites is the analysis of Koster (1978b: ch. 2); we are more familiar with a slightly different version in Koster (1978a), called there the Nesting Hypothesis.[41] We would reformulate the latter in terms of prohibiting material to the right of the most embedded bound category it applies to; such an approach to the material treated under the rubric of connectedness does not refer to branching at all. Thus, binary branching is not an intrinsic ingredient of connectedness or more generally of successful theories of movement and extraction.

(iii) Insulation. Binary branching depends very much on small clause ('SC') analyses for many double complement structures. Yet the following assumptions largely 'insulate' small clause theory from disconfirmation: "Taking small clauses to be maximal projections . . . , [they are] transparent to government only when the governor and the maximal projection are sisters" (Kayne 1984c: x) and "N cannot govern across a boundary" (1981c: section 3.2). Thus, if a small clause in its base position is a sister to V, it acts as though it isn't there (due to transparency). If it is anywhere else (moved or a sister to N or base-generated in some ungoverned position), it also acts as if it isn't there, because its subjects (at least those Kayne discusses) are in need of case, which they cannot get in any of these positions. Consequently, the general way to test for presence of a constituent in generative grammar, namely movement (Ross 1986), is rendered

inoperative. Even strong supporters of small clause structures agree with this observation (Den Dikken 1995c: 47, 61). So finally, a small clause ends up acting syntactically as if it isn't there; it plays no role in movement or in limiting movement.[42]

On this point, a referee correctly observes that normal clauses (IPs) also often act "as if they aren't there"; they don't move away from their introductory C and, when non-finite, are not barriers to case-marking from the outside. But these observations simply underscore the tenuous status of IP itself (as a binary branching daughter of a projection of C). This weakness doesn't argue for small clauses, but rather undercuts even Bresnan's (1970) binary division between C and IP. Nonetheless, she supported her division by noting that parentheticals can divide C and IP. *The Board will declare {that/whether}, during the past year, the company has been profitable*. Such parentheticals are unacceptable with small clauses: *??The Board will declare, during the past year, the company profitable*. This difference implies that there are no positive diagnostics for small clause constituency.

Of course, the question remains: is insulation from disconfirmation, achieved for SCs by Kayne's two cited theoretical stipulations, a good thing or a bad one? Several researchers seem to feel that it provides a kind of license for ubiquitous small clause structures. But insulation from disconfirmation cannot in itself constitute a reason to reject alternatives using ternary branching for representing double objects, which after all accords with a straightforward interpretation of economy of representation (56).

(iv) Coordination. Small clauses might be motivated by paradigms based on coordinations (or deletions) rather than movement. For example, authors sometimes cite coordinations as in (57) as support for small clause constituents:

(57) John [$_{VP}$ turned [$_{SC}$ [$_{SC}$ the heat up] and [$_{SC}$ the air conditioning down]]].

But these sequences are arguably reductions of coordinate VP or IP with an empty second V as in (58), parallel to similar coordinate sequences as in (59):

(58) John [$_{VP}$ [$_{VP}$ [$_{V}$ turned] [$_{NP}$ the heat] up] and [$_{VP}$ [$_{V}$ Ø] [$_{NP}$ the air conditioning] down]].

(59) He [$_{VP}$ [$_{VP}$ [$_{V}$ misses] [$_{NP}$ his wife] on Saturday] and [$_{VP}$ [$_{V}$ Ø] [$_{NP}$ his friends] on Sunday]].
John [$_{VP}$ [$_{VP}$ [$_{V}$ thought] of [$_{NP}$ Mary] mornings] and [$_{VP}$ [$_{V}$ Ø] of [$_{NP}$ Sara] at midnight]].

These latter can't be small clauses since the combinations *his wife on Saturday, Mary mornings*, etc. are not predications.

The possibility of replacing *and* in both (58) and (59) with *but*, as in (60a), is also telling. This is a possible clausal coordination pattern for root predications, as

in the structures in (58–59). However, a coordination of clausal complements as in (60b), whether they be SCs or of any other type, would require a *not* after *but*:

(60) a. John turned the heat up but the air conditioning down.
He avoids his wife on Saturday but his friends on Sunday.
John thought of Mary mornings but of Sara at midnight.
Mary should come inside but keep a coat on.
b. They should avoid coming inside {and/*but} keeping a coat on.
Permission to come inside {and/*but} to keep a coat on is rarely given.

Thus, more complete coordination paradigms reveal the inadequacy of SC analyses such as (57) and support rather an alternative in terms of coordinated VPs with an empty second V, as in (58).[43]

4.2.2 Sentence-based small clauses

Whatever one's theoretical predispositions with respect to small clauses, analyses using them must still be evaluated on their empirical merits. So let us now turn to the argumentation in Kayne (1981c, 1984c) for grouping English indirect and direct objects together as small clauses.

In Kayne's (1981c: sections 2.2–2.3) first proposal, the small clause XP over English IOs and DOs is an S. It neither is endocentric nor places the IO higher than the DO. In a second proposal (Kayne 1984b) (inferred from his note 5, "it now seems preferable to follow Stowell," and from his page xi), XP is apparently NP; the bold sequence in *send* $[_{NP}[_{PP}$ ***Mary]*** $[_{NP}$ ***Bill's book]]*** presumably has the curious form $[_{NP}[_{PP}[_{P}$ Ø] NP] – NP].

Kayne (1981c) makes a detailed argument for these SCs based on their being impossible in English nominalizations, crucially using his postulate that "N cannot govern across a boundary." Consequently, a prepositionless indirect object cannot properly receive case inside a nominalization because the small clause boundary insulates it from government. This argument could extend to other small clause analyses of double objects, as their proponents are doubtless aware. But in competing transformational accounts, any promotion of indirect objects in an NP domain will necessarily place them in a PP so that they can receive case. But then they will not c-command their base position, i.e., their traces will be improperly bound. Such considerations equally well explain the absence of double object constructions in NPs. So Kayne's influential nominalization argument in favor of double object small clauses is not definitive.[44]

As another argument for analyzing double objects as small clauses, Kayne (1983c) uses the ordering restriction illustrated in (61), according to which English intransitive $[_{PP}$ P] must precede $[_{PP}$ P – XP] (Emonds 1972a):

(61) a. The secretary sent a memo out to the committee.
They are trying to make John out a liar.
b. *The secretary sent a memo to the committee out.
*They are trying to make John a liar out.

Kayne excludes (61b) by means of 'recursive small clauses' as in *make* $[_{YP}\,[_{XP}\,[_{NP}$ *John]* $[_{X'}$ *a liar]]* $[_{Y}$ *out]]*. Since *make* is not a sister of XP, the latter's subject is ungoverned, hence not assigned case, hence ungrammatical. However, his discussion provides no indication of how this small clause structure contributes to meaning. Thus, the sharply different SCs for the synonymous pair (62) would apparently have no effect on meaning:

(62) a. send $[_{SC}$ a memo out] to the committee
b. send $[_{SC}\,[_{SC}$ the committee out] a memo]

Additionally, the fact that (62b) is good for many speakers, including the authors, disconfirms Kayne's account of (61b), since his proposal rules out (62b) on exactly the same grounds as (61b). Moreover, the very fact that these small clause structures seem scattered about with no specification of their distribution is highly suspect.

Finally, consider the secondary predication *bring John his food cold*. While recursive small clause structures (AP inside YP) might accommodate *bring* $[_{YP}$ *[John]* $[_{Y}$ *Ø]* $[_{AP}$ *[his food]* $[_{A}$ *cold]]]*, an identical bracketing could also tolerate **make John a liar out*. A solution might consist of imposing an ordering restriction on intransitive P as heads of SCs, thereby bringing us back to the starting point of Emonds (1972a). Consequently, the restriction evidenced in (61b) ends up providing no evidence of small clause structure.

There thus seem to be no real arguments for double object small clauses in Kayne (1984c), nor do the theoretical acquisition or connectedness considerations often advanced in their favor have any force. The structures themselves have significant drawbacks, as mentioned in the discussions of the SCs in (61) and (62). To these can be added the oddity of their internal structure, as seen in (62). The only consideration that remains in their favor is Kayne's (1981c) account of why they do not occur in English nominalizations, an account that we feel could be challenged along the lines indicated above.

4.2.3 PP-based small clauses

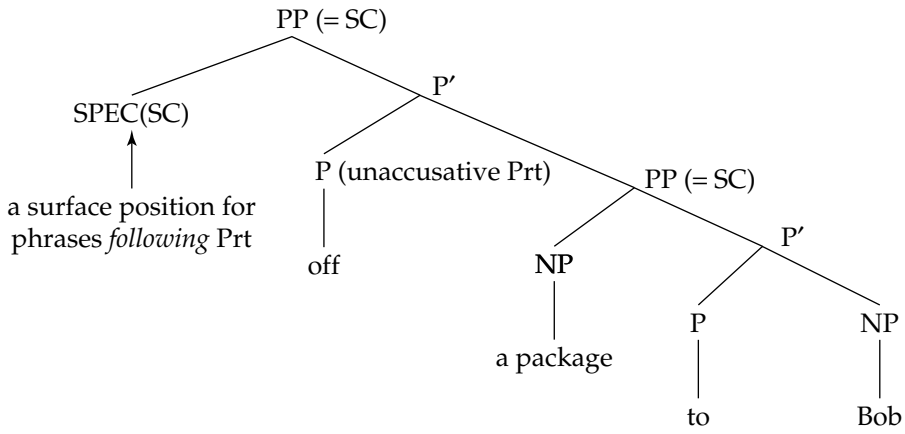
Den Dikken (1995c: ch. 3) provides a more carefully designed and defended SC analysis of English double objects as complex PPs, with special attention to their properties when they occur with particles ('Prt'), as in *John sent Bob off a package*.[45] By applying Baker's (1988a) Uniformity of Theta Assignment Hypothesis ('UTAH'), he defends his cross-linguistic proposals with argumentation based on Dutch and Chinese double object constructions as well. While the author explicitly bases his SC framework on the dubious theoretical motivations for small clauses (learnability, connectedness, and binary branching), his extensive argumentation does not entirely rest on them, and hence must be independently evaluated.

Aspects of Den Dikken's analysis derive from his assumptions that SCs (i) "are available at no cost whatsoever," (ii) "are the sole incarnation of subject predicate relationships," and hence (iii) "all share the semantic aspect of property

ascription"[46] (1995c: 24–25, 28). His resulting SC structures, which he considers costless, are in our view somewhat arbitrary, as per our section 4.2.1. That is, they don't satisfy movement diagnostics for PPs, and moreover the mechanisms for how predicates select them are not specified.

The center of his analysis is that English postverbal particles are 'unaccusative' P heads of SCs. Deep structure PPs for double objects with particles therefore contain two small clauses, as in (63):[47]

(63)

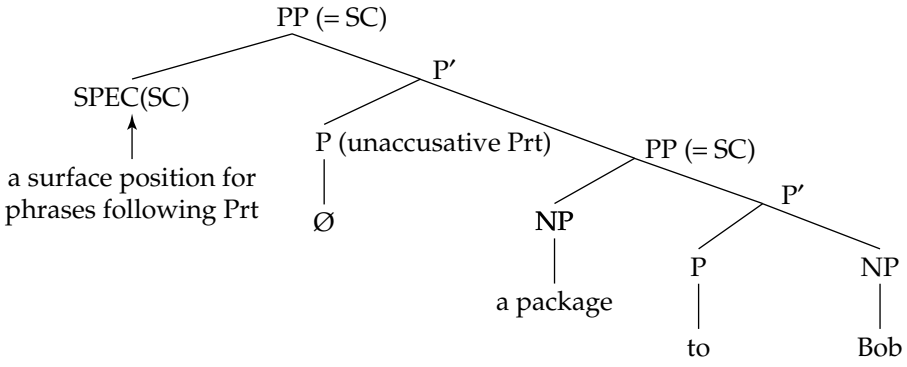


Den Dikken (1995c: sections 3.7–3.8) further claims that a third empty headed verbal small clause SC′ above (63) provides additional surface housing for a sequence NP + Prt, for theoretical reasons related to PPs but extraneous to the double object NPs.

By the time Den Dikken provides some motivation for all three of these small clauses and for the various mechanisms that finally ensure word orders and case-marking, his analysis becomes baroque; the biggest questions then concern whether all the various steps in his undeniably careful analysis really have independent justification or plausibility on the basis of other constructions. Two examples: (i) The direct object in *To Mary was given a book* receives nominative case through a sort of extended chain that involves a case-marked PP in subject position, its trace, and SPEC–HEAD agreement with this trace inside one of the small clauses (1995c: 119). (ii) Postverbal particles in structures such as *send off Bill a package* obligatorily incorporate into otherwise empty small clause verbal heads that follow the main verb.

Nonetheless, parts of Den Dikken's analysis seem convincing. For instance, he constructs some arguments based on Dutch and Chinese for an empty P even in deep structures for double objects without particles (1995c: sections 3.11–3.13). By cross-linguistic similarity (i.e., using Baker's Uniformity of Theta Asssignment Hypothesis), he concludes that a lexical Prt can also be null and thus that (64) (cf. his tree (63)) must be part of the general deep structure for English double object constructions:[48]

(64)



Let us examine his proposal that the top SC should be embedded in a third SC′ (actually a bare VP) which mediates between the lexical V and the Prt heads. A central motivation for this empty V head above SC in (63–64) is its role as a target for incorporating the lowest (case-assigning) Goal P, which then assigns case to the Theme NP in *send Bob off a package*, as illustrated in Den Dikken's (1995c: 133) final labeled bracketing for (63).[49] While the author's argument may be a legitimate use of Baker's (1988a) Government Transparency Corollary, if we stand back a bit the consequences seem bizarre. The implication is that a P heading a complement (the lower SC) *within* a clause (the upper SC) can, with enough gymnastics, move into the very head that selects that clause, analogous to operations on a sequence *make Bill blame the accident on Harry* by which the P *on* would finally incorporate into *make*, skipping over *blame*, and then assign case to *Bill*.

To us, these machinations bring up the following overriding issue: if Principles and Parameters systems permit such an analysis, with its extra abstract V predicate and attendant complex case-marking and chains of co-indexing, it seems likely that the systems themselves are underconstrained. Alternatively, one could set out to show that such incorporations (i.e., sidestepping of 'head to head' movement) are really needed in a range of other, possibly similar constructions – or that such incorporations are excluded in principle save in just the case under discussion. But only such wider justifications can dispel doubts about proposals as internally complex as Den Dikken's intricate case-marking for the Theme NP in a double object construction. We therefore are critical of the additional SC′ above the double object deep structure PP in (64).

One might try to eliminate this higher abstract V and retain only two SCs in Den Dikken's (63–64) by reworking his case assignment, perhaps by making particles 'optionally' unaccusative. Two reasons for not doing this is that the bolded *up the number* and *the number up* will then both be PPs in such classic examples as (65), and they must both be insulated against PP movement, which seems difficult. Small clauses are generally insulated from movement because their subject NP would lack a case-assigner, as discussed earlier; but the sequence *up the number* should be able to move if it were analyzed as a PP:

(65) John looked **up the number**.
John looked **the number up**.

A final doubt about an SC account of double objects concerns economy of representation as expressed in (56). If indeed a single PP small clause can encompass both a DO in its specifier, case-marked by a higher head, and an IO complement to its head (e.g., *to*), why should these two NP arguments of a V ever be realized inside some more complex structure which licenses bare IOs? This question seems to loom over Den Dikken's – and other – small clause analyses of double objects; any such structure that is more complex than a transitive verb with an indirect object marked by a P should be ruled out by Economy.

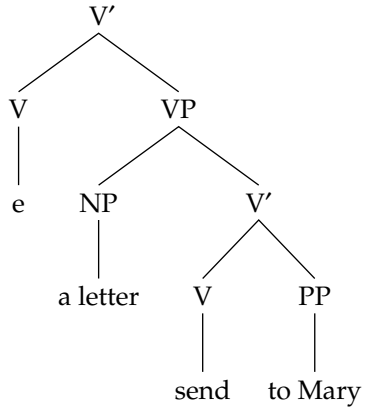
4.3 Double objects are two arguments in lower verb phrases

4.3.1 Larsonian shells

Working in a Government-Binding framework, Larson (1988b, 1990) makes a proposal for double object constructions now known as a 'Larsonian shell'. He agrees with Relational Grammar in promoting indirect objects to direct object status and demoting the original direct object, thereby expressing the asymmetric c-command required by the paradigms of Barss and Lasnik (1986).

The particularity of Larson's analysis is its deep structure; the double object construction is a deep VP complement to a higher empty V as in (66). In this complement (i) only the indirect object PP has complement status, (ii) a direct object begins in a deep VP Specifier position, and (iii) the empty head of a postulated higher VP is a landing site for an eventual V-raising. Larson considers the direct object of the double object construction the 'deep subject' of a lower VP. The latter cannot receive case in this position unless the lexical V raises to a position outside the lower VP where it governs and hence can case-mark the NP in this Specifier position:

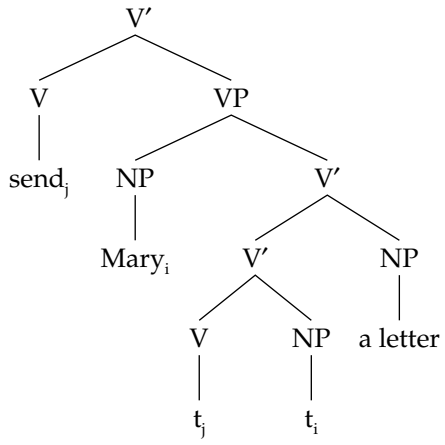
(66)



Larson derives the double object construction by what he claims to be a passive-like movement of the indirect object. A different execution of this basic idea is proposed in Aoun and Li (1989, 1993b), as reviewed in the next subsection.

In Government and Binding terms, the dative operation absorbs or withdraws case from the 'object' of the verb in (66) (that is, the indirect object) and suppresses the theta-role of the 'subject' (the direct object).[50] The deep direct object simultaneously becomes an adjunct of the V', partly parallel to the *by* phrase of passives. The indirect object can then move to the 'VP subject' position, analogous to a passivized subject:

(67)



When the indirect object moves up to the inner subject position, it asymmetrically c-commands the second NP, and receives case from the raised verb. The adjunct direct object is assigned case by the lowest V', which is curiously reanalyzed as a V even though it contains a phrasal trace. Den Dikken (1995c: section 3.2) scrutinizes the possible effects of Larson's reanalysis, and concludes that it especially faces problems with respect to the English paradigms in which particles combine with double objects.

A number of other oddities result from analyzing a direct object as an adjunct: (i) unlike other adjuncts, the direct object is often obligatory; (ii) it receives case from the head of its phrasal sister (unlike adjunct agent phrases in the standard passive, which require a P); (iii) it freely undergoes successive cyclic A'-movement, counter to a usual restriction on adjuncts (e.g., *What did Mary know how to send John?*). In contrast, Larson's derived position for a promoted indirect object is exactly that of a true deep direct object. Consequently, the IO in a double object construction should undergo A'-movement, contrary to the descriptive generalization (29). Larson does discuss some of these problems (1988b: section 3.3), but to our mind unpersuasively.

The widespread adoption of Larson's complex analysis may be largely due to its compatibility with other influential contemporary ideas. As observed above, Kayne (1981c, 1984c) has convinced most syntacticians to limit trees to binary

branching, yet his initial recasting of head-initial double object constructions in binary trees led to his rather problematic category labels for double object small clause structures (see section 4.2.2). Alternative binary structures like [[V – NP] – {NP/PP}], in which the surface direct object follows and asymmetrically c-commands the indirect object, would wreak havoc with the Barss and Lasnik (1986) paradigms.

Larson's structure (66) seems to remove these problems, thus clearing the way for binary structures via his structural 'Single Complement Condition'. This basis for binary branching seems like an independent advantage, although its proponents have not seriously addressed a host of other double complement constructions for which the Barss and Lasnik arguments would demand similar treatment. Their properties continue to challenge proponents of binary branching, whatever the correct analysis of double objects.[51]

Shell structures raise other questions not yet adequately addressed.[52] For example, why can't the lower VP complement of the empty V in (66) be replaced by an NP such as *good ideas*, deriving (via head movement of N substituting for the empty V) a word salad something like **John did(n't)*$[_{VP}$ *ideas*$_i$ $[_{NP}$ *good* $t_i]$]? Perhaps Larson (1990: 597–598) intends to answer this by the claim that if a V's arguments "can't be fitted into the minimal VP that it heads, this forces an upward branching of X-bar structure to secure an argument position for the agent." But then this stipulation, to the effect that a shell over an XP 'can be' of the same category XP, should be strengthened to 'must be'. Indeed, rather late in the presentation, Larson (1988b: sections 7.1–7.2) claims that an argument of α must always be realized within some (possibly higher but presumably adjacent) projection of α.

Additionally, one wonders if these are the only shells possible. That is, are there also cases of empty-headed APs over APs, etc? Along the same lines, nothing prevents lexical entries from multiplying the number of shells for single items. The Larsonian framework, far from limiting the number of a verb's complements (as is often inferred from his Single Complement Hypothesis), makes no claim about the maximal number of arguments for a single predicate.[53]

If *send* is truly an intransitive verb with an inanimate subject (Larson 1988b: 342), we should be seriously rethinking the nature of lexical entries, since apparently the frames of verbs are nothing like what they appear to be. But in fact, is there independent support for treating an indirect object as the sole deep complement of apparent di-transitive verbs? Larson's (1988b: 340–341) two arguments for such a V' constituent, based on idioms and a suggested closer semantic link between verbs and their indirect objects, are impressionistic and unconvincing (Emonds 1993: 220–221).[54]

Larson (1990: section 5.3) further argues for his constituent structure with a claim that both gapping and pseudo-gapping can delete a V' constituent which unites verbs and indirect objects in (66). However, finding contrasts in pairs like (68) that would support this claim is difficult; the (a) examples, in which V' deletes, don't seem to contrast with those in (b), in which V' is supposedly not available:

(68) a. ??He sends love letters to Mary and she $[_{V'}$ Ø] dessert recipes.
Bill fixes martinis for us more often than he {did/would}$[_{V'}$ Ø] manhattans.

b. ??He sends love letters to Mary and she to Bill.
Bill fixes martinis more often for us than he {did/would} for you.[55]

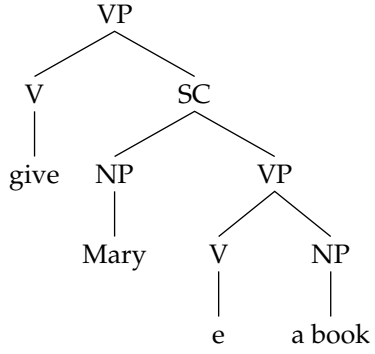
Finally, Larson's case theory is sui generis. He tacitly assumes that the demoted deep object cannot be within a PP, perhaps in deference to the widely shared view that the Projection Principle forbids lowering. Consequently, to explain how a single verb essentially assigns case twice, he assumes that a V assigns both an inherent and a structural objective case. A typical transitive verb is taken to assign both inherent and structural case to its direct object, in contrast to standard variants of case theory. Then, when a double object construction is present, the cases can be split: the indirect object receives structural objective case and the direct object inherent objective case. Within this rather elaborate framework, both cases are suppressed for passive formation, but only structural case for dative shift. Larson also claims that Infl (I) is required for the assignment of objective case, although participles and restructuring verbs (which can be transitive) can be argued to lack I (cf. note 53).

On the positive side, Larson's analysis accounts for the Barss-Lasnik paradigms in both the base and permuted versions of double object constructions. Moreover, in spite of the marginal role assigned to PP structures, Larson (1988b: section 5) provides a valuable discussion of the complementary roles of the contentful English Ps *to*, *of*, *from* vs. the applicative suffixes in other languages (the former typically blocking dative interchange and the latter licensing it). The virtues aside, we have not concealed the fact that we find much to question in this influential account. What seems strange is not the author's proposal, but the way in which, in spite of their many problematic aspects, Larsonian shells quickly became the standard basis for treating double objects.

4.3.2 Reversing Larson's order of arguments

As discussed in section 2.1, several authors claim that the double object construction indicates a kind of possession of the direct object by the indirect object, even though verbs such as *offer*, *sing*, and *read* make this doubtful. Partly to express this putative property, Aoun and Li (1989) propose that double object constructions are small clauses (SC) of indeterminate category, headed by an empty V of possession, as in (69):

(69)



How to determine the category label and distribution of this small clause structure is left vague; apparently all and only lexical entries for double object verbs stipulate this type of clausal complement with an SC subcategorization frame. However, the many verbs of transfer that do not allow double objects (section 2.5) will either have quite different complement structures, or the argument interchange in their SC complement (a counterpart to Larson's 'passive' account of dative movement) must be obligatory for such verbs.

Another problem with (69), which is base-generated for Aoun and Li, is that we would expect the indirect object to freely undergo A'-movement just as subjects of other supposed small clauses do (e.g., in *consider John foolish*, etc.). But as observed in the discussion of the Restriction on A'-extraction in section 3.1, this is not the case.

Further questions must be asked in order to evaluate the structure in (69). Why should an empty V be restricted to small clauses, when verbs generally occur in all types of clausal structures?[56] As with Larson's account, what restricts the number of shells contained within each other? Why does the passive form of $[_V$ e] mark its postposed subject with *to* or *for*, while other passive verbs induce *by*, and why is there no passive auxiliary in only this new type of passive?

In spite of these problems, the main proposal that Aoun and Li (1989) are arguing for is a theory of quantifiers that depends only on the configuration of dominance relations. Our many questions about the labels and provenance of their structures may therefore not seriously undermine their principal hypotheses, which concern the interpretation of quantifiers.

4.3.3 Lexical alternation in Larsonian shells

Bowers (1993: section 4) presents a critique of Larson's proposal to assimilate the dative alternation to that of passives, as well as a revised analysis that circumvents some of the attendant problems. This revised proposal uses a variant of shell structures to account for both the double object and the prepositional dative constructions, but considers the relation between them to be akin to a lexical causative alternation; that is, *give* with double objects realizes the structure of *make IO* ***own/have*** *DO*, with *give* raising from a lower to a higher V position. In comparison, the prepositional construction with *give* realizes *make IO* ***belong*** *to DO*, with the double object verb again raising to the V head of the higher VP shell.

Bowers's main innovation is to revise – in fact, expand – shell structures in terms of his study's general theory of predication, which posits (for small clause constructions as well) an alternating sequence of Pr(edicate)P and VP shells. This alternation is achieved by some phrase structure conditions (1993: 595), which force a sequence of dominance relations (70) in which each phrase's Specifier position houses an NP argument of the deep lexical verb. The lexical V starts from the lower V position and raises to the higher one, so as to provide case for the 'inner NP' whose surface position is the Spec of the higher VP. According to Bowers, NPs in the double object construction are positioned in the surface as follows, with their roles as subscripts:

(70) $[_{PrP}\ \mathbf{NP_{SUBJ}}\ \mathbf{Pr}\ [_{VP}\ \mathbf{NP_{IO}}\ V\ [_{PrP}\ t_{IO}\ Pr\ [_{VP}\ \mathbf{NP_{DO}}\ V]]]]$

The four bold nodes in (70) indicate overt morphemes for a simple sentence such as *We sent Mary books*.

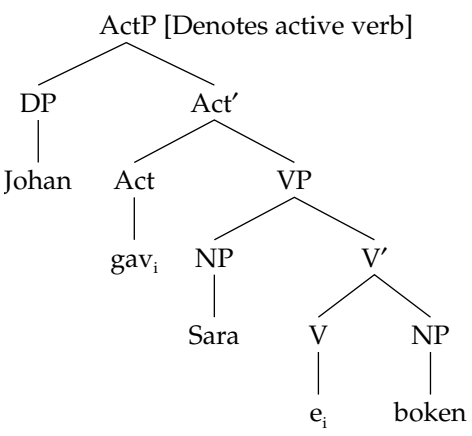
Bowers is naturally concerned to show that his analysis improves on that of Larson. Thus, he criticizes aspects of Larson's case-assignment mechanisms and the proposal that the DO in a double object construction is in a transformationally adjoined position; our criticisms of Larson concerning (67) above in this respect recapitulate his. For Bowers (1993: 598), Larson doesn't propose enough structure; rather, all three arguments in a double object construction have properties of underlying subjects (uniformly identified with SPEC positions), as expressed in (70). This structure permits all three to c-command (non-final) floating quantifiers (including crucially *We sent the boys all a book*; *?we sent John the books all in nice packages*; *we sent the books all to John*); but see note 32. It also permits the 'outer object' to be modified by secondary predication (*We sent John the food cold*), which is not ordinarily allowed for adjunct NPs.

While it does not come across as the author's main point, a lexicalist approach to double objects under any guise seems to us to fly in the face of the accumulated cross-linguistic arguments reviewed in section 3 in favor of accounting for the dative alternation transformationally. Moreover, while *give* may well paraphrase both *make own* and *make belong to*, we cannot carry the analogy much further: what pairs of causatives are paraphrased by double object verbs like *promise*, *sing*, *write*, *butter*, *carve*, *cook*, and *fix*? That is, in spite of its rather elaborate transformational raising and phrase structure, including a novel head category Pr uninstantiated in the lexicon, Bowers's analysis is lexicalist, by his own account (1993: 643–644).[57] Perhaps it is not inherently so, but as it stands it is.

4.3.4 Presence or absence of morphological case

For double objects in Mainland Scandinavian, Holmberg and Platzack (1995: 191) posit a deep structure similar to Larson's (1988b), raising the V during the derivation as follows:

(71)



They suggest (1995: 194) that double object constructions are base-generated and are unrelated to what they call '*to*-constructions'. This recourse to treating the alternation lexically would in itself seem to be a drawback.

Holmberg and Platzack's main purpose in discussing double objects is to demonstrate the effects of the presence or absence of 'm-case' (morphological case) in a language. They note that in Icelandic, which has m-case, double objects behave differently from those in Danish, Norwegian, Swedish, and English, languages that don't have m-case. Icelandic direct objects receive accusative case and indirect objects dative, while in the other languages, both NPs have the same ('accusative') case. They take the Icelandic facts as evidence that the case on indirect objects is generally not assigned structurally; a conclusion radically at odds with Baker's (1988a, 1988b) assimilating of promoted indirect objects to object position in applicative constructions. In their view, the fact that in Danish, Norwegian, and Swedish, the indirect object retains the same case even in passive and expletive sentences suggests that it is behaving in this respect like a PP.

The authors propose that dative case assignment in Icelandic is the result of a lexical selection feature on the verb. In Mainland Scandinavian, it is achieved by a structural case-licensing rule: "Accusative is licit in Spec-VP" (1995: section 7.4), which recalls a number of Government and Binding analyses which assign accusative case in a lower specifier. Their approach correctly predicts several differences between Icelandic and other Scandinavian languages, based on the presence or absence of this structural case-licensing, and their structures also account for the Barss and Lasnik paradigms. At the cost of an additional special projection 'ACTP' for agents, they in fact remove some of the uncertainty concerning multiple Larsonian shells brought out above. They further argue for their structure by proposing that the indirect object exhibits some specifier properties: for example it cannot be deleted or extracted to an A'-position, as expressed earlier in the Restriction in (29).[58]

The fact is, most of Holmberg and Platzack (1995) focuses on Icelandic double objects rather than on double objects without m-case. With respect to this contrast, we have been following Den Dikken's (1995c) conclusion, cited here in section 1.2, about the difference between German, with m-case, and English, without it; namely, double objects in an m-case system may require fundamentally different treatment from dative alternations in English and other languages. The largest class of Icelandic double objects, those that occur with *give*-type verbs, do not alternate with a *to*-construction, unlike English and Mainland Scandinavian. Moreover, the paradigms for movement with Icelandic double objects are almost the opposite of those in other languages. The two Icelandic objects may invert if the indirect object is a heavy NP (cf. notes 17 and 26 for the exclusion of this in Indonesian and English respectively), and either object may passivize under the same conditions. (Holmberg and Platzack suggest that the heavy NP's status as sentence focus substitutes for the lack of case marker in these sentences.) Any complete theory of indirect objects will, of course, have to account for these contrasts with m-case languages. But the point we developed in section 1.2 is that

the paradigms with m-case are so different from 'bare' double objects that they are unreliable as a basis for an adequate theory of double objects in languages that lack it.

Holmberg and Platzack's treatment is thus problematic because it is not so much an analysis of the dative alternation in Mainland Scandinavian (which they take to be lexical) as an argumentation for particular types of VP structures and case assignment. In their framework, the double object construction, which they assume does not include an underlying P, is an apparent problem for their claims. Like Larson, they use case assignment in lower Specifiers to explain the grammaticality of double objects in their framework. This contrasts with analyses that assign case to IOs structurally, by an overt or covert underlying P.

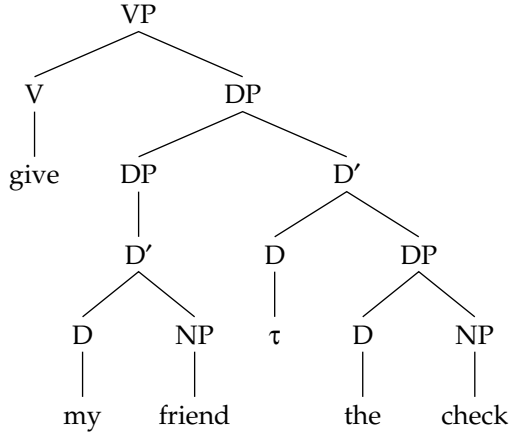
4.4 Double objects are two arguments in lower NP/DPs

Johnson (1991) proposes that double object constructions are a type of small clause, following Kayne (1984c), with the indirect object acting as the subject of the clause and the direct object acting as a complement. However, the housing of the small clause is a nominal projection, a DP. At least superficially, his structure for double objects and that of Hellan (1991b) are the same.

Johnson's analysis highlights an 'NP first' condition on complements, the requirement that complement NPs appear in English, with very few exceptions, immediately following the verb. He explains this requirement by claiming that main verbs in English move out of the VP they head. NP complements are forced to 'Object Shift' to a specifier of VP to receive accusative case. They must therefore come before PPs or other non-nominals in the VP complement.

The double object construction poses an apparent counter-example to Johnson's explanation of the 'NP first' rule because it does not explain how the second NP can receive case. To avoid this problem, he therefore suggests that the underlying complement structure for double objects contains a single DP, crucially invoking Abney's (1987) 'DP Hypothesis' for the structure of noun phrases:

(72)

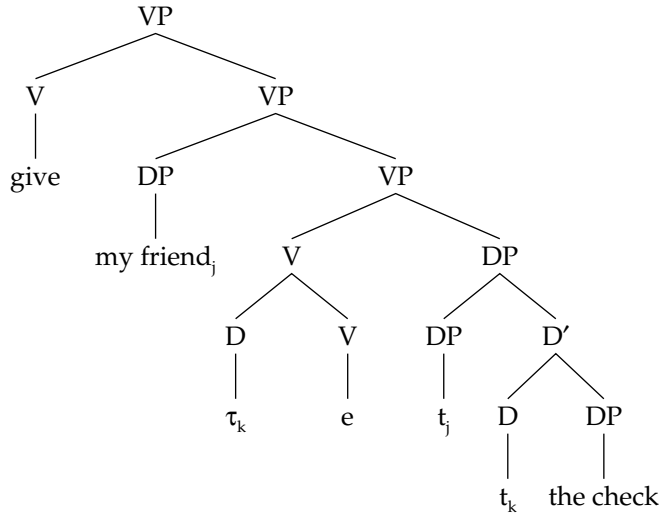


He further proposes that an abstract head τ of the encompassing DP is a case assigner, and thereby able to provide case to its complement (the seeming direct object *the check*).[59] The V then moves out of VP and the first (indirect) object moves to [Spec, VP] to receive case, as in (73) below, both typical moves in later Government and Binding analyses. This analysis predicts correctly that the first DP in a double object construction will have the position and behavior of a direct object. The structure (72) is also compatible with the Barss and Lasnik paradigms.

Johnson argues that his structure can also explain certain properties of Object Shift in Danish, noted in Vikner (1989): both objects may be shifted together or the first object may move, but the second may not. These movement possibilities are expected if both DP objects are part of a larger DP and if the higher inner DP is accessible to movement, much as a subject of a clause.

However, the structure (72) then incorrectly predicts that both objects may move together in English, yielding ungrammatical sentences like **Whom the check did you give?* and **My friend the check was given*. Den Dikken and Mulder (1991: section 5) carefully critique Johnson's analysis, enumerating paradigms they feel it fails to handle properly. Johnson's own approach to avoiding "double object movement" uses a variant of Baker's (1988a) argument that Noun Incorporation can sometimes substitute for case assignment. He incorporates the case assigner τ into the verb's D-structure position and then Object Shifts the first DP into [Spec, VP], as before. When this incorporation is blocked, the 'big DP' in (73), a simplified version of Johnson's proposed derived structure, must stay in its base position:

(73)



The larger DP cannot move in this situation because it contains the trace of τ and cannot move outside its scope without violating Chomsky's (1981: ch. 3) Empty Category Principle. This alternative correctly blocks the movement of both DPs in English, but it would incorrectly block it in Danish. Johnson's system then has to make τ-incorporation obligatory in English but not in Danish.[60]

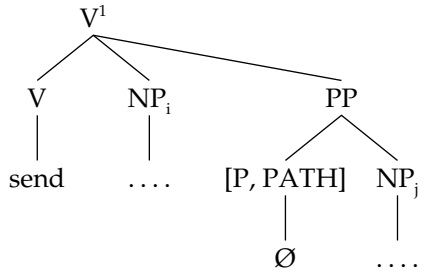
This analysis of double objects has a number of problems, besides the ad hoc properties of the D-head τ in an otherwise unattested type of deep structure DP. For example, it does not address the Restriction (29) on movement of dative NPs to A'-positions, though scenarios for banning A'-bound traces in SPEC might be invoked as in Holmberg and Platzack (1995). It is unclear how to relate Johnson's (72) to the applicative constructions of non-Indo-European languages surveyed in section 3, which share so many properties with English and Scandinavian double object constructions. Nor does (72) tell us why the latter are (close to) synonymous with constructions with overt *to*-phrases, whose head is unquestionably P (modification by *right*, stranding behavior, etc.). These problems taken together with those outlined in Den Dikken and Mulder (1991) seem to us to render this 'DP as small clause' approach at least in need of serious modification.

4.5 Double objects exchange positions

Given the twin needs imposed by the Relational Grammar arguments for indirect object advancement (section 3.2) and the Barss-Lasnik asymmetry requirements, Emonds (1993) reworks his (1972a) proposal that 'Dative Movement' is a structure-preserving transformational interchange of a direct and indirect object (i.e., '3 to 2 advancement' accompanied by demotion of the direct object). An appropriate Principles and Parameters reformulation of the original construction-specific rule requires that the interchange be sanctioned by UG, but licensed only in languages with some specific lexical property. His analysis uses a somewhat idiosyncratic understanding of the Projection Principle to predict that dative movement is the only possible type of argument interchange.

The proposed lexical property concerns licensing the empty Ps that are 'deleted' in classical dative shift (9), such as English *to* and *for*. Emonds (1993) claims that these lexical items enter derivations only in PF, and then only in the absence of any dative shift.[61] That is, in both the shifted and unshifted variants (1) and (2), the entire derivation of LF from Deep Structure contains an empty node [P, +PATH] as in (74), needed only for assigning case to the second NP:

(74)



The deep complement structure in (74) is selected by a frame +___NP^NP or +___NP (^NP). The Projection Principle is satisfied whenever a subcategorized YP 'constitutes' (= dominates all the lexical material under) a sister of X^0 at each

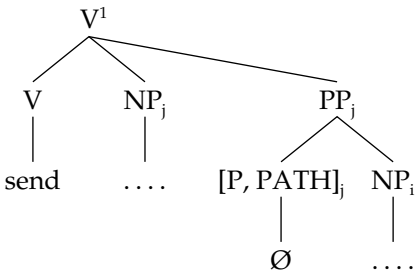
relevant level.[62] Like all variants of this Principle, this formulation excludes interchanging any complement with a subject or adjunct or introducing any new ZP under an X′, but it permits interchanging complement NPs (only) around an empty P. Emonds claims this is exactly the formulation that can capture the observed cross-linguistic variation in applicative constructions, which is due to how lexicons license this P.

This structure-preserving interchange of objects satisfies criteria (i)–(v) in section 2.3 for promoted indirect objects in a transformationalist analysis: (i) It accounts for the synonymy of the dative alternations and the cross-linguistic similarity between these alternations and applicative constructions. (ii) While the analysis doesn't decide issues about proper levels for case assignment, it provides two case assigners for two adjacent NPs. (iii) The analysis promotes indirect objects and thus constitutes a basis for explaining their direct object behavior in applicative constructions (section 3.2). (iv) Regarding the unavailability of the promoted NP for A′-movements (29), see below. (v) Finally, the PP structure in (74) provides asymmetric c-command of the second NP by the first, in both shifted and unshifted sequences, and thus accounts for the Barss and Lasnik (1986) paradigms.[63]

The underlying PP configuration in (74) is taken to universally define an indirect object, independently of a direct object and the category of the head. If grammatical relations and theta-roles are represented in LF, as is generally assumed, then Emonds's analysis requires that both deep direct and indirect objecthood and/or the corresponding theta-roles be somehow carried through a derivation. Depending on the design of the transformational computation, carrying such information through a derivation may be problematic.[64]

A late or PF insertion of Ps such as *to* and *for* in the unshifted version of (74) is obligatory because of a general prohibition against unlicensed empty categories.[65] Less straightforward is the obligatory licensing of an empty P in (74) in (only) a shifted or 'interchanged' derivation. Emonds suggests that an empty head, for example P in (74), is co-indexed with its sister in underlying structure. The structure-preserving *interchange* of NPs, while respecting his Projection Principle, then yields the derived configuration (75), where i is the index of the deep direct object and j of the deep indirect object. His claim is that no preposition can be inserted 'late' in this shifted derivation because a general condition on PF-insertion of a head requires non-distinct indices between heads and complements:[66]

(75)



The resulting co-indexed structure (75) then accounts for the crucial cross-linguistic Restriction on A'-extraction (29) of promoted indirect objects as follows. If the NP_j in (75) subsequently moves to an A'-position, *both* its trace *and* the empty-headed PP_j are bound by the same operator. This configuration violates Koopman and Sportiche's (1983) Bijection Principle prohibiting an A'-constituent from locally binding two empty categories (here NP_j and $[P, PATH]_j$).

A reviewer has observed that a structure-preserving interchange of double objects does not predict (i) the Scope Freezing of section 3.1.3, (ii) why some English speakers accept immediately postverbal particles with transitive V but not with ditransitive V, or (iii) why second or 'chômeur' NPs passivize in some but not all double object systems. However, it is our impression that, aside from ad hoc stipulations, the competing analyses reviewed here do no better in accounting for these three properties. In particular, as pointed out in section 3.1.3, English Scope Freezing seems to be a property of all 'A-movements', and is hence irrelevant for choosing among the various A-movement accounts.

Finally, the object interchange in (75), while a necessary condition in this analysis for licensing an empty P, must still not be *sufficient* to license it, for if it were, every language – including Romance languages – would allow dative movement. In order for $P = \alpha$ to be empty, Emonds proposes that the feature of P (here PATH) must additionally be 'alternatively realized' on a (possibly null) applicative affix β, as in Marantz's (1993) structure (25a). This possibility is allowed by what he claims is a general principle extending at least to morphology:

(76) **Alternative realization:**
Language-particular lexicons can alternatively realize a feature F of α on β only (i) when projections of α and β are sisters and (ii) when β is a closed class item, that is, one whose lexical entry includes no (open-class) semantic features.

Since V and PP are sisters in (75), a closed class affixal head of V (β) is a potential language-specific locus for an alternatively realized PATH feature of a P (α). Alternative realization by applicative affixes, as in Bantu languages, Chinese, Indonesian, etc., is thus a necessary part of this analysis of dative alternations. And as also proposed in Pesetsky (1995), Emonds's analysis requires further that the lexicons of Germanic languages without morphological case furnish null, non-productive applicative affixes for their dative-shift verbs.[67]

5 Conclusion: what we think we know

In this chapter, we have proceeded through a labyrinth of hypotheses which attempt to explicate an indirect object's transformationally regular 'promotion to object' in many languages without productive Case-marking, including English, Dutch, Mainland Scandinavian, and several non-Indo-European VO(O) languages. The generative market place, spanning three decades of debate on the

resulting 'double objects', indeed offers a rich choice of highly refined products for treating this challenging raw material. In our tour of this bazaar, we have not been sparing in our criticisms, just as the authors reviewed did not spare their predecessors. (In fact, we only barely mentioned some of these critiques, which can be quite telling.)

At the end, we venture to hold strong opinions about certain – we dare say established – cross-linguistic hypotheses, which would defy disconfirmation within even the broadest transformationalist framework. In particular, we are convinced that (i) a structure-dependent theory of abstract case-marking (8) provides superior accounts of double object constructions, and (ii) a null PATH affix akin to overt applicative affixes found outside Indo-European is a good basis for an account of English and Mainland Scandinavian 'double accusative objects'.[68]

We further agree with what we feel are presently four consensus positions:

(51) **Consensus on promotion:**
Where a language systematically allows two surface NP objects indistinct from accusatives to have different theta-roles, the thematic or deep indirect object is structurally the surface direct object.

(52) **Consensus on superiority:**
A promoted indirect object surfaces as asymmetrically 'higher' than a deep direct object.

(29) **Restriction on A′-extraction:**
Further movement of a 'promoted' indirect object NP unmarked by a P or dative case to a non-argument position is ungrammatical.

(36) **Dative passive Restriction:**
Passivization of indirect objects (unmarked by any dative case) results from moving NPs already promoted to direct object.

There is still some debate over whether indirect object 'promotion' results from transformational movement, but properties of promoted objects discussed in section 3.1, such as the restriction (29) and Scope Freezing, strongly suggest that it does. On the other hand, we have seen in section 4 that the field has not convincingly demonstrated the superiority of any particular account of how the direct object in a double object construction comes to be 'demoted'. That is, it has not been able to agree on a formal and yet non-ad hoc characterization of what Perlmutter and Postal (1983b) term in Relational Grammar a 'chômeur'.

NOTES

We thank two referees for close readings and careful commentaries and suggestions, which we have in almost all cases tried to incorporate. We also appreciate very much the computational expertise and assistance of Rob Goedemans.

1 Fillmore (1965) judges that both objects in the TO-dative double object construction can passivize, while in the FOR-dative neither can:

(i) I was given a book.

(ii) A book was given me.

(iii) *I was bought a hat.

(iv) *A hat was bought me.

Judgments vary widely on (ii) through (iv), especially when wider classes of verbs are considered. Langendoen et al. (1977), advocating the value of questionnaires for settling such disputes, conclude that (ii) is grammatical in some area dialects but ungrammatical in others. Similarly, Holmberg and Platzack (1995: 189) claim that the Norwegian counterpart of (ii) is acceptable but that the Danish is not. Our judgments suggest a generalization of the latter pattern, namely, the deep direct object can't be easily passivized in either type of dative:

(v) A woman was offered the job.

(vi) ?The job was offered a woman.

(vii) The guests were finally fixed a lunch.

(viii) ?A lunch was finally fixed the guests.

Because these facts are murky, theoretical studies have not progressed much in differentiating properties of TO- vs. FOR-datives in English.

The analyses of non-Indo-European double object "applicative" constructions discussed in this chapter all make it clear that indirect objects in double object constructions regularly undergo passivization.

2 Chinese resembles the other languages listed in that its Vs precede their NP complements, although in other ways the language is head-final. Since this study concerns V and its objects, we include Chinese.

3 Haegeman does not use these terms. Her main theoretical point is to motivate a specific reformulation of 'Burzio's Generalization', with which we take no issue.

4 For Den Dikken and Mulder (1991), Dutch indirect objects are not always related to PPs. They argue that only base-generated bare indirect objects can properly license certain *immediately adjacent* parasitic gap and secondary predication constructions. However, since the rather robust cross-linguistic results of section 3 here suggest PP sources for all indirect objects, they make us wonder whether this adjacency might license predications and parasitic gaps in some other way.

5 We return to Holmberg and Platzack's treatment of mainland Scandinavian in section 4.3.4. We note that they consider an Icelandic "inverted" double object construction (with IO in final position) to be "a *to*-construction without a preposition but with m-case and focus instead" (1995: 207); we agree. Our doubts are limited to their structural parallels between Icelandic and Mainland Scandinavian for the order IO–DO.

6 Zaenen et al. (1985: section 4) claim that certain Icelandic dative-marked objects that undergo the passive are likely to be direct objects. To account for this, they propose

a language-particular characterization for Icelandic direct objects: "an argument that either immediately follows the verb or is an accusative object." It would be preferable to maintain a universal definition, that a direct object is an NP sister to V. We can then say that this V characteristically assigns accusative but, in Icelandic, V can also assign quirky case to certain direct objects.

7 Den Dikken accepts Müller's claim that German indirect objects undergo A'-fronting but argues, contra Müller, that this movement should be considered Scrambling and not Dative Movement per se.

8 Structure-Dependent Case (8) does not imply that every NP complement overtly marked for oblique case must be in a PP. Single NP objects may be obliquely case-marked without any PP being present (so-called quirky case).

9 ZMT (note 13) attributes this trichotomy of case assignment to Hjelmslev and, within Government and Binding, to Babby (1980). Some traditional Latin grammar handbooks also reflect this line of thought.

10 The statement holds also for Latin's five-case system if its ablatives and datives, whose forms are in fact always identical in plurals, are analyzed as a single oblique case assigned by P. A theory of autonomous case lacks any basis for explaining this sort of pervasive case syncretism.

Under this view, the distinct dative singular suffixes in Latin are then oblique case allomorphs required when a governing P is both null and unmarked for the feature SOURCE. (Null Ps which are +SOURCE predictably take the ablative.) It then comes as no surprise that (i) overt Latin Ps can require any case *except* the dative, and (ii) locative DPs mysteriously surface as dative in a Latin poetic style in which locative Ps can 'drop'. Such consequences are accidental in a scheme of autonomous case.

11 Even more restrictively, when a language has no quirky dative direct objects, as in German for example, "there should be no DAT–DAT, DAT–GEN or GEN–GEN verbs in that language." ZMT (479) credits Czepluch (1982) with making this correct prediction within the GB framework.

12 As pointed out by a reviewer, Romance dative clitics on V are not clitics for PPs or Ps. They correspond rather to the DP or D object of an empty P located in an argument or adjunct position. Hence such clitics can have a floating quantifier, as in this French example: *Jean leur a tous donné des livres* 'John them has all given some books'.

13 Jackendoff (1973) argues that P may take two complements (NP + PP), as in the bold PP in *It was* ***down the street to Mary*** *that he tossed the ball*. It is doubtful that a double object of the type studied here could ever appear in a PP, for example, as **It was down Mary the street that he tossed the ball*. That is, the double objects under scrutiny in this study appear only inside XPs headed by V.

14 There seem to be competing styles with respect to the productivity of the English dative alternation. This study and most of the literature focuses on a more conservative style. However, several observers note a less standard style which allows a dative alternation for any verbs consistent with that style:

(i) Somebody with more sense better recommend those girls some different make-up.
He went and designed his parents a real nice family room.

By mixing a verb from academic style with the less standard style in (i), one can create sentences acceptable to no one:

(ii) *Could you reiterate the judge your story, please?
*She caramelized her parents a crème brûlée.

Advocates of treating the English dative alternation as an unpredictable lexical phenomenon sometimes contrast examples like (i), perhaps culled from some observed corpus, with unacceptable examples from the conservative style (ii). This confused methodology proves nothing, since the data are not from a single style of speech.

15 Den Dikken (1995c: 158–159) accepts the logical non-equivalence of pairs as in (14) but argues that this does not preclude a transformational relation between them; he suggests that the difference between members of a dative alternation concerns aspect, not theta-roles. Similarly, Hoekstra (1995: note 5) maintains that 'affectedness' rather than thematic role distinctions differentiates the pairs.

16 Larson (1990) notes that in examples like *Enrico sang Luisa an aria* the theme is "for the benefit of the beneficiary." Thus, this example implies a predication that the aria was for Luisa, but *Susan ate vegetables for her mother* does not imply that any vegetables were for her mother. Since a direct object NP c-commands a PP complement but not an adjunct, it is plausible that LF c-command of one complement by another directly represents a predication, while the non-c-command relation between an object and an adjunct is meaningless.

17 Chung (1976: 54–56) enumerates many properties of the Indonesian 'Dative' rule (i.e., empirical properties of that language's double object construction) which exactly mirror the English double object construction. Lexical accounts have not addressed the issue of expressing these cross-linguistic generalizations.

18 Jackendoff (1990a: 435), in supporting Oehrle's flat structure for English double objects, ascribes many properties of double object sequences simply to their surface order: "An account appealing to linear order generalizes with the greatest of ease."

But at least some Barss–Lasnik paradigms involve asymmetric c-command of the second object by the first independently of linear order, as shown in more detail in Emonds (1993). In (i), direct object antecedents correctly c-command anaphors, but in (ii) objects of a P fail to c-command the anaphor and hence don't qualify as antecedents:

(i) Mary described Bill and John to each other/themselves.
She told Bill and John about each other/themselves.
The company reimburses my brothers for each other's expenses.

(ii) *Mary talked about Bill and John to each other/themselves.
*He argued about John and Mary with each other/themselves.
*He argued with John and Mary about each other/themselves.
*Mary spoke of Bill and John to each other/themselves.
*The company relies on my brothers for each other's expenses.

Unlike the objects of P in (ii), objects of *to* and *from* can bind anaphors, perhaps because these latter PP structures are deleted in LF.

19 Logically, non-alternating double objects as in English (13) are a base construction or they are not. If they are, then dative movement can simply be a structure-preserving subcase of Move α, using the double NP structure as landing sites. If they are not a base construction, then their only plausible underlying source is indeed an NP–PP sequence, that is, exactly as in a transformational analysis of the dative alternation.

Consequently, in spite of their hold on lexicalist advocates, unpaired double object sentences are irrelevant to the whole debate.

20 These are the Projection Principle and the exclusion of complement positions as landing sites.

21 Hoekstra (1995: section 2) first broadly supports and then (sections 5–7) modifies Kayne's empty P proposal. He develops a system in which the empty P can have a different status in different Germanic languages, sometimes being only a sort of case-mark on the NP itself.

22 This null applicative affix effects what derivational morphology calls 'conversion', whereby a class of morphemes in one lexical category appears to occur in another (Walinska de Hackbeil 1983). For example, English lexical adjectives such as *brown*, *correct*, *erect*, *mature*, *narrow*, *obscure*, *open*, *quiet*, *round*, *secure*, *slow*, *smooth*, *steady*, and *sour* can "convert" to derived verbs by virtue of a null causative affix, akin to the overt causative suffixes *-en*, *-ify*, and *-ize*. (None of these affixes is productive.) Unlike these causativizers, applicative affixes do not change the stem category, but then adjectival *-ish* and many non-productive diminutive or gender suffixes on N do not change categories either.

23 Pesetsky (1995: 129) points out that "morphophonological restrictions on affixation are familiar, ranging . . . to syllable-counting restrictions like those on the English comparative." Thus (26) is formally akin to prosaic observations such as: the nominalization suffix *-al* combines only with final-stressed verbs (*arrive*, *betray*, *confer*, *construe*, *dismiss*, etc.); the causativization suffix *-en* combines only with monosyllables; and the comparative suffix *-er* is incompatible with non-initial stress or tri-syllabic A. The proposed applicative affix for English also recalls Keyser and Roeper's (1992) proposal that double objects involve a 'null abstract clitic'.

24 As pointed out by a reviewer, the null affix may combine with lexically 'inseparable' unstressed prefixes, which perhaps in Modern English have come to include *a(d)-*, *be-*, *con-*, *de-*, *en-*, *ex-*, *for-*, *per-*, *pro-*, and *ex-*. In other Germanic languages including Old English, such prefixes generally do not interfere with patterns of uniform initial stress. With this proviso, Herriman's lists of exceptions reduce to a handful of problematic cases: ??*telephone your friends an answer*, ??*guarantee that customer a year of service*, ??*secure the general the base perimeter*.

25 As seen in note 1, passivized indirect objects that are beneficiaries (i.e., Fillmore's *for*-datives under a movement analysis) are also marginally ungrammatical in some dialects (?*Mary was baked a cake*). This rarely discussed and poorly understood restriction plays no role in the following discussion.

26 Even though the unacceptabilities are not dramatic, many researchers, including those without commitments to a transformational component, repeatedly reproduce the relevant data in a wide range of English A'-constructions (e.g., Ziv and Sheintuch 1979; Herriman 1995). Herriman's massive empirical study refers to rightward extraposition as 'Position 3' and to fronting as 'Position 4' and concludes for indirect objects of her Class 1 verbs: "only two examples [of Position 3, extraposition] were found . . . preceded by the . . . object *it*" (1995: 87); "initial position in the clauses, is . . . of even more doubtful acceptability than position 3, discussed above. Many grammarians . . . exclude this position altogether, while others . . . note that it is highly unusual" (1995: 89). Then: "No examples were found of class 2 indirect objects in these positions [extraposition and fronted] in the corpora" (1995: 118); "none of the corpus examples of class 3 indirect objects occur in positions 3 and 4" (1995: 140); "No examples were found of class 4 indirect objects in positions 3 and 4 in the corpora" (1995: 157).

27 Nonetheless, the weak acceptability judgments supporting the generalization (29) are sometimes disputed for some languages or dialects. For example, Tuller (1984) indicates that the pattern of (32b) is grammatical in Hausa dative applicative constructions. Thus, the accounts proposed for (29) may have to contain a language-particular dimension.

28 Larson (1988b: section 2.3) argues that what Ross (1986) terms Complex NP Shift (blocked for prepositionless indirect objects) is not rightward movement of a heavy NP, but leftward movement of a V′ called 'Light Predicate Raising'. This term is misleading, as the V′ in these cases has no 'lightness' requirement: *John [repeatedly sent to the girl who had called] expensive gifts from Selfridge's.* The unanswered question is why unstressed direct objects block raising of V′, however light V′ may be: **John sent to her his.*

29 Den Dikken further argues that A′-extraction of PP with an empty P is always clause-bound.

30 Whitney's account assumes an early construction-specific formulation of dative movement, so that when the indirect object moves, the deep P of the indirect object in (37) also deletes. The first branching node over the deepest NP trace is then V′; consequently, this trace c-commands any 'intermediate trace' in the promoted IO position. Her account perhaps does not spell out clearly enough this role of the loss of P.

If movement of the indirect object does not lead to loss of a branching PP, perhaps the explanation for (29) is rather that *intermediate* traces always contravene Chomsky's cited principle, by binding potential LF variables in their base position. In fact, this eventuality may account for the exclusion of successive cyclic movement in many languages. Ever since Lasnik and Saito (1984), it seems likely that the only intermediate traces permitted are those that for special reasons delete in the derivation of LF.

31 As noted in Oehrle (1976), the order in (48b) can occur in two circumstances: if the IO is a pronoun or if the particle is *back*. Den Dikken (1995c: section 3.15.2) suggests that such a use of *back* is part of the DO Theme NP, rather than a head of a complement.

32 We do not agree with Bowers (1993), for whom it is acceptable to float quantifiers off second objects, as in ??*We sent John books all in nice packages*. See the discussion in section 4.3.3.

33 Although we adopt Marantz's (1993) structural representation (25a) of overt and covert applicative suffixes, his syntactic claims about the structure of double objects strike us as largely arbitrary. Despite the truth-value equivalence of the double object and 'oblique goal' constructions V-NP-PP, he derives them from entirely distinct base structures: "the double object constructions will contain two VPs while the oblique constructions contain only one" (1993: 120). His justification for distinct base structures in terms of two different 'event structures' is basically discursive rather than evidential. Such a proposal is undermined by the arguments in section 3.1 for the derived nature of the double object construction.

Marantz's different structures, in which the first NP asymmetrically c-commands the second, do account for the paradigms of Barss and Lasnik (1986). But does his analysis achieve anything beyond this? According to his own commentary (1993: 130–131), neither of these two distinct structures with the V between the two objects accounts for the surface word orders; rather, "the linear ordering of constituents is part of the S-structure (SS) to PF interface and not a property of SS." Nor is any explanation provided for the differing syntax of second objects in two groups of double object

languages; applicative verbs are said to govern the second NP differently in the two types, but no independent evidence is given for this stipulation other than the point of departure: when the second NPs passivize and undergo object agreement, the applicative verb governs in one way (as in Koopman 1984), and when they do not, the structurally identical applicative verb governs in another (as in Baker 1988a).

34 As he develops his treatment in his chapter 6, Pesetsky finds it advisable to thoroughly recast more familiar conceptions of phrase structure ('layered syntax') in terms of his general theory of 'Cascades', which lies outside the scope of this work. This development affects his conception of how to properly revise (53).

35 As further support for his approach, Baker points out that applicative constructions are impossible with verbs that cannot assign case, that is, with true intransitives. The only class of apparent Chicheŵa intransitives allowing applicative formation includes verbs like *sing* and *dance.* Verbs in this group often take 'cognate' objects, so presumably they can assign case. Rather than being truly intransitive, they may simply not require a direct object. For further discussion, see Alsina and Mchombo (1990).

36 Note 28 of Emonds (1993) claims that Baker's final version of case theory has eight stipulative properties. Even if two or three such properties succeed in accounting for cross-linguistic variation (e.g., with respect to when demoted direct objects may be passivized), the residue remains unattractive.

37 Overt syntactic incorporation of an argument N does indeed exempt it from the Case Filter, as Baker notes, since the latter is a requirement on surface NPs. Hence the obligatory overt incorporation of otherwise caseless second object in Southern Tiwa would actually seem to confirm the operation of the Case Filter, rather than supporting some kind of exemption from it.

38 Principle (3) from Kayne (1981c): "An anaphor that falls under the binding principles must be connected to an antecedent by an unambiguous path." To the extent that c-command mimics linear order, as is frequent in analyses using binary trees, imposing a requirement that antecedents are found on 'unambiguous paths' amounts simply to saying that an anaphor's antecedent 'precedes it' somewhere in the string.

39 Kayne (1984c) also suggests that Stowell's (perhaps English-particular) adjacency requirement on V-object case assignment can be derived from binary branching. He claims that '[V Adv] NP' is not possible if NP is to receive a theta-role and that "V [Adv NP] is impossible" as well. But such structures should then equally well be excluded for the PP complement in the idiomatic (and grammatical) *decide quickly on the boat.* This grammatical VP then requires either ternary branching or some other stipulation about theta-roles equivalent to (or less general than) Stowell's adjacency on case-marking. Clearly nothing has been gained; the adjacency condition has *not* been derived from binary branching.

40 Binary branching may well be a serviceable processing principle for projecting adjuncts, coordination structures, external arguments, or the X^0-internal structure of compounds. That is, it might function as a kind of 'Elsewhere Condition' for tree construction, whenever (56) is not available. But this review concerns precisely those structures for which (56) *is* available.

41 After briefly mentioning some facts of P stranding in Dutch, Koster (1978b) formulates his Nesting Hypothesis in terms of forbidding certain material on both the left and right of empty categories. The hypothesis can be better compared to Kayne's system by limiting it to forbidding material on the right of empty categories.

42 Small clauses are not needed for defining LF binding domains or for LF subjecthood. The locality imposed by Chomsky's (1981: ch. 3) Binding Principle A involves the

presence of a subject in LF. But subjects are generally defined by means of some c-command relation with a phrasal predicate, and make no reference to whether the node immediately dominating them is clausal or not; for example, a direct object c-commands a secondary predication and hence can be its LF subject.

43 Arguments against SC analyses of (57) can also be constructed in terms of gapping. The many studies of this construction in the 15 years following the initial generative study of Ross (1986 [original dissertation 1967]) came to a consensus: well-formed gapping constructions contain two remnant phrases as in (i), but not three as in (ii):

(i) Mary turned on the heat, and John [$_V$ Ø] the two TVs.
Mary turned on the heat in the morning, and John a bit later.
One thief stole [the TV upstairs] and another [a CD player in the hallway].

(ii) ??Mary turned on the heat in the morning, and John the two TVs a bit later.
??One mover put [the TV] upstairs, and another [a CD player] in the hallway.

Consequently, if SC constituents united direct objects and postverbal particles (or double object sequences), the following gapped clauses would have only two remnant phrases and should hence be well-formed:

(iii) ??Mary turned the heat {on/up}, and John the air conditioning {off/down}.
??Mary sent John *Hamlet*, and Sue Bill *Julius Caesar.*

From the marginal status of (iii), one can then only conclude that neither (57) nor double object constructions are best analyzed with single small clause complements.

44 The version of Koster's (1978a) Nesting Hypothesis noted in section 4.2.1 can account for the ungrammatical extractions from objects inside nominalizations that Kayne attributes to their status as small clause subjects. Unfortunately, a full comparison of possible alternative analyses of nominalizations is well outside the scope of this review.

45 From the perspective of small clause advocacy, Den Dikken (1995c: section 2.3) also provides a different sort of critique of Kayne's double object structures, especially those containing particles.

46 This requirement of Den Dikken's on small clauses, that they are actually interpreted as predications, seems to us minimal. Yet many small clause structures proposed by Kayne and other advocates, such as SC analyses proposed for the double complement constructions listed in note 51 below, do not fulfil even this basic criterion of semantic compositionality.

47 Cf. tree (52a) in Den Dikken (1995c: 132). For explicitness, we replace his SC and XP with PP and P′ in accord with his standard view that particles are P. Our use of P′ rather than PP is only for making clear the pairings between heads and projections.

48 We observe that the existence of an extra empty P in dative constructions, essentially teasing apart PATH P and PLACE P positions in Dutch, does not in itself justify an SC structure encompassing the two NPs.

49 The lower P travels further up to the head of SC′ after moving from inside the lowest P′ in (63). Den Dikken is careful to show how each step conforms to the theory of movement he adopts. He also offers a critique of Larson's (1988b) analysis for not conforming to restrictions on movement.

50 Larson treats the preposition *to* in (66) as a 'pure' Case marker without extra semantic content, which renders it susceptible to absorption. His account does not explain why overt P absorption after indirect object movement is obligatory (**They sent$_k$ John$_i$ [$_{VP}$ t$_k$ to t$_i$ a letter]*), even though a stranded P can remain after NP preposing in English passives (*John$_i$ was [$_{VP}$ spoken to t$_i$ by Bill]*).

51 The wide gamut of double complement structures, many already familiar from Chomsky (1965: ch. 2), includes those of *promise (Mary to behave yourself)*, *persuade (Bill it's raining)*, *strike (the children$_i$ as dangerous to them$_i$)*, *prevent (the girls from seeing each other)*, *say (to every student that he's brilliant)*, *speak (two languages to everybody)*, *seem (to John {that/like} it is raining)*, *remind (Mary of her duties)*, *rob (John of money)*, *take (3 hours to eat lunch)*, *taste (spoiled to John)*, etc. In light of the Barss-Lasnik paradigms, the binary branching hypothesis leads to the conclusion that all the preceding parenthesized strings are constituents, presumably small clauses. This conclusion strikes us as a reductio ad absurdum, but seems not to have deterred proponents of binary branching complementation.

52 One of the few discussions of some of these issues is Larson's (1990) response to Jackendoff (1990a); many authors assume shells as in (66) with no attempt to independently justify them.

53 The proposal of Roberts (1985) to the effect that any V must keep on raising until it gets to an I doesn't limit the number of shells; cf. Larson (1988b: 343). Moreover, in some fairly well-supported analyses, e.g., of English participles (Emonds 1985: ch. 2), no Is are paired with V heads.

54 Larson in both articles pursues a rather ingenious account of Heavy NP Shift, claiming the latter doesn't move; instead, his deep V' constituents, in (66) for example, substitute for a higher empty V *([$_{V'}$ send to John] any book you can find*). This V'-raising prima facie violates Chomsky's (1986) restriction against substituting phrases for heads; to avoid this Larson claims it involves 'reanalysis'.

His exclusion of a shifted indirect object (**send a book any woman who will accept one*) is at bottom a stipulation (1988b: 348). Moreover, other instances of Heavy NP Shift (*send John tomorrow any book you can find*) are unnaccounted for, as pointed out by Den Dikken (1995c: note 4).

55 Larson claims that pseudo-gapping can derive from a "V' constituent that is elided or replaced with *do*" (1990: 629). This seems inadequate, since the *do* of pseudo-gapping is in an I position, not a V position, as seen in (68).

56 It would be strange if a particular grammatical verb, say *get*, occurred only in one type of clause, say infinitives.

57 While Bowers does provide an account of the Restriction (29) on A'-extraction of the IO in a double object construction (and criticizes Larson's analysis on this count), he must nonetheless stipulate a condition on traces to do so.

58 This argument is actually double-edged, since if the authors use the same VP structure with a *to*-construction, the direct object will be a specifier of VP. But the latter does not exhibit the same specifier properties in the corresponding sentences; that is, it can be extracted to an A'-position. This problem leads Holmberg and Platzack to redefine the direct object so that it is actually a specialized kind of complement. Their proposal is that the direct object can be a complement of V if it is a sister of V' and V has not licensed case in V' (1995: 195). This rule works only if a P is present to assign case to the indirect object.

59 One has to hesitate about a D which assigns case to a DP complement. For example, definite articles and demonstratives never seem to assign case. While various authors

have proposed that quantifiers such as *all* and *both* have DP complements, such structures are unlike (72) because their specifiers cannot be overt DPs.

60 We must observe that determiners do not typically incorporate into V in the structures studied in Baker (1988a). One may wonder if Johnson's ideas might not be better served with P rather than D as the head of his single complement, along the lines of Den Dikken (1995c).

61 Emonds (1985: chs. 4 and 5, 1993) develops a theory of late or PF lexical insertion for both bound and free morphemes that do not contribute to LF.

62 The late insertion of *to* and *for* as heads of complements crucially uses the fact that the Projection Principle does not hold at the level of PF. These two P must differ by some feature, of course; plausibly, it is ±LOCATION.

63 Since a structure-preserving alternation is a permutation, it necessarily involves two NPs. This may explain why studies of dative and benefactive applicatives (Chung 1976; Aissen 1983: section 5.1; Baker 1988a: section 5.3.2) repeatedly find that indirect object advancement is allowed only with transitive verbs. Analyses such as Hellan's (1991b) and Den Dikken's (1995c), in which bare indirect objects appear only as 'part of' the following direct object, correctly predict this in a different way. Alsina and Mchombo (1990: section 3) dispute this generalization on the basis of examples like the following, in which (passivizable) benefactive applicatives seem based on intransitives:

(i) Yêsu a-ná-f-ér-a anthu ônse.
1-Jesus 1-PST-die-APPL-Ø 2-people 2-all
'Jesus died for all people.'

The examples given by these authors involve verbs that are plausibly 'unaccusative', *die* and *run*. If the construction (i) somehow involves an NP-trace in object position, the generalization can perhaps be maintained.

64 Emonds (1993) implicitly rejects the inevitability of a trace with every movement. His analysis is more compatible with theta-roles being assigned to complements 'phase by phase', as they are merged with a selecting head. Such interpreted complements are then present within X^1 throughout a derivation, including by traces if extracted from X^1. No additional restriction immobilizes them within X^1.

65 We can conclude from Aissen's (1983) treatment that the Tzotzil lexicon lacks an appropriate directional P, thus ruling out the unshifted version: "*ta* is the only preposition in Tzotzil and functions variously to introduce locative, temporal, and instrumental phrases" (1983: 287). And: "Any derivation in which the final level of structure contains an indirect object [i.e., an object of P] is ill-formed" (1983: 298).

66 It would be perhaps less stipulative to assimilate the empty co-indexed P_j in (75) to a sort of trace, in the sense that movement generally leaves behind co-indexed covert categories.

67 Another possible locus β for alternatively realizing PATH (α) is on a closed-class object of P. Certain grammatical Ds may be 'inherent dative pronouns' with an optional PATH feature, as in the dialectal *John gave it me* and *The book was sent me* (Cf. **The book was sent close friends*.) Such Ds could stand alone as bare IOs without undergoing dative movement. This may also explain the dialectal possibility allowing "short" *wh*-fronting of datives contravening (29), reported in Den Dikken (1995c: section 4.2).

68 As V-final languages, Standard Dutch and West Flemish may or may not fall under generalization (ii) in the text. Cf. section 1.1.

4 Ellipsis, proper government, and the Empty Category Principle
  4.1 Specifier government in NP
  4.2 Ellipsis in DP
  4.3 Licensing and identification in DP
5 Conclusion: current research directions

1 Introduction

The study of ellipsis in noun phrases originates as part of a broader investigation of ellipsis as *null anaphora*, where missing material is interpreted under identity with an antecedent in much the same way as a lexical pronoun. Some examples are given in (1–3) below, where in each, the ellipsis site is interpreted under identity with an antecedent in the previous discourse:

(1) The committee endorses every bill the president proposes but the advisors approve only a few [e].

(2) I really liked this book and I know you'll like these [e].

(3) The students went to the bookstore and each [e] bought a book by Chomsky.

Early analyses of ellipsis explore the hypothesis that null and lexical anaphors are constrained by the same universal principles. Indeed, in early work in generative syntax, ellipsis in English noun phrases (typically referred to as N' anaphora or

N' ellipsis) is analyzed as resulting from a deletion transformation, *one's* deletion, in which ellipsis results from deletion of a lexical proform. The status of the *one's* deletion transformation figures prominently in early debates between proponents of the 'deletion' approach to null anaphora and advocates of the 'interpretation' approach, where empty categories are base-generated and subject to rules of interpretation. Ellipis in noun phrases is subsequently analyzed within the Principles and Parameters framework as involving proper government of *pro*, an empty pronominal category, licensed by what is ultimately argued to be a functional category DET, the head of DP. This approach leads to in-depth, cross-linguistic analyses of the properties of the determiner and quantifier systems to determine the feature specifications of different functional heads, and the role those features play in licensing and identification. This research also explores connections between ellipsis in DP and substantive adjective and partitive constructions, in particular partitives which involve clitic *en* (French) and *ne* (Italian).

2 Ellipsis as null anaphora

Ross (1986; original dissertation 1967) is the first to investigate the parallels between ellipsis and lexical pronouns. His crucial insight is that ellipsis phenomena in general (VP ellipsis, sluicing, and ellipsis in NP) appear to violate the same cluster of constraints also violated by pronouns, that is, constraints respected by movement rules. Moreover, other phenomena involving 'missing' constituents, such as gapping and comparative deletion, do not exhibit this behavior, and thus appear to be distinct from ellipsis. Specifically, Ross observes that both pronouns and ellipsis obey the Backwards Anaphora Constraint (BAC) (see also Langacker 1966), but violate both the Complex NP Constraint (CNPC) and the Coordinate Structure Constraint (CSC). (See also Hankamer 1971.)

That ellipsis sites, like pronouns, obey the BAC is illustrated in (4–7), which show that both pronouns and ellipsis sites can precede their antecedents, but only when contained in subordinate but not coordinate clauses:

(4) a. John enjoys waking up early, and *he* likes to see the sunrise.
    b. **He* enjoys waking up early and *John* likes to see the sunrise.

(5) a. John enjoys waking up early because *he* likes to see the sunrise.
    b. Because *he* likes to see the sunrise, John enjoys waking up early.

(6) a. Each student woke up early and all [e] saw the sunrise.
    b. *All [e] saw the sunrise, and each student woke up early.

(7) a. Each student woke up early because all [e] wanted to see the sunrise.
    b. Because all [e] wanted to see the sunrise, each student woke up early.

(8) illustrates that both pronouns and ellipsis can be contained in NPs that do not also contain their antecedents. In Ross's terms, pronouns and ellipsis thus violate the CNPC:

(8) a. We heard that *Mary* likes [$_{NP}$ the man who talked to *her* at the party].
b. Most people liked Mary's *presentation*, but I also talked to [$_{NP}$ a number of people who didn't like Sue's [e]].

That pronouns and ellipsis violate the CSC is illustrated in (9), where the pronoun and ellipsis site are contained in coordinate clauses that do not also contain their antecedents:

(9) a. [John saw Mary] and [*she* said hello to *him*].
b. [John read Mary's book] and [she read his [e]].

In current terms, what we might view as null anaphors in ellipsis contexts seem to obey Principle B of the Binding Theory in (10), just like lexical pronouns. That is, like pronouns, ellipsis sites are free in their binding domain, which we can informally define here as the clause containing them. (This does not apply to Antecedent-Contained Ellipsis, which will not be discussed here.)

(10) **Binding Theory:**
A An anaphor must be bound in its binding domain.
B A pronoun must be free in its binding domain.
C An R-expression must be free.

Ross exploits this connection between ellipsis and pronominalization, proposing that the source of ellipsis in noun phrases is in fact the pronoun *one*, which is deleted by a transformational rule.

2.1 One's *deletion*

Ross proposes that *one's* deletion involves replacement of part of NP at deep structure by the pronoun *one*, as in (11b), and subsequent deletion of this pronoun by transformational rule, to derive the surface structure in (11c):

(11) a. Mary bought two books on astronomy, and she read [both books on astronomy] last night. (deep structure)
b. Mary bought two books on astronomy, and she read [both *ones*] last night. (*one* pronominalization)
c. Mary bought two books on astronomy, and she read [both] last night. (*one's* deletion)

Deriving ellipsis in noun phrases by *one's* deletion raises a number of questions that suggest that it can be the source of ellipsis only at a certain cost to the grammar. Investigation of the strengths and weaknesses of *one's* deletion lays important groundwork for discussions of *deletion* vs. *interpretation*, and whether it is in fact explanatory to derive elliptical constructions from deletion of lexical pronominal counterparts. *One's* deletion also raises questions about the internal structure of the noun phrase, and highlights the different distribution of pre-nominal elements that can successfully introduce the ellipted category in NP in English.

One immediate issue that arises in a *one's*-deletion approach to ellipsis is that it requires certain cases of ellipsis in noun phrases to derive from ungrammatical sources. Jackendoff (1971) points out, for example, that the sentence in (12a) must derive from the ungrammatical sentence in (12b) (see also Perlmutter 1970a; Sommerstein 1972). A *one's*-deletion analysis is therefore particularly problematic for deriving ellipsis in mass noun phrases:

(12) a. Max's wine was good but Bill's [e] was even better.
b. *Max's wine was good but Bill's *one* was even better.

Jackendoff (1977) circumvents the problem of *one's* deletion by proposing that ellipsis in noun phrases derives not from deletion, but rather from noun phrases with base-generated, empty pronominal (PRO) heads. Determiners preceding PRO undergo a 'substantivization' rule, given in (13):

(13) ART − PRO ⇒ 1 + substantive − 2
OBLIGATORY

This rule derives the ellipsis constructions in (14):

(14) John wanted to read the dossiers of famous linguists, and/but he succeeded in reading [Morris's/some/many/one/mine/three/none/these/every one PRO] NP

Substantivization has the additional effect of converting certain determiners into the appropriate phonological forms before PRO, as illustrated in (15):

(15) a. every + PRO = every one + PRO
b. no + PRO = none + PRO
c. my + PRO = mine + PRO

Jackendoff (see also Selkirk 1977) explicitly connects the syntax of ellipsis in noun phrases to that of partitive noun phrases, arguing that both dominate PRO heads, and that as a result, both undergo substantivization of a determiner or quantifier. The partitive noun phrase *each of the trees*, for example, has the internal structure in (16), and the ellipsis construction *each [e]* has the structure in (17):

(16) $[_{N'''}$ each $[_{N''}$ $[_{N'}$ PRO of $[_{N'''}$ the trees]]]]

(17) a. $[_{N'''}$ each $[_{N''}$ tree]]
b. $[_{N'''}$ each $[_{N''}$ PRO]]

In both (16) and (17b), PRO triggers substantivization of the quantifier *each*. Jackendoff predicts that both elliptical and partitive noun phrases will exhibit the same changes in phonological shape of the quantifier or determiner that precedes PRO. He therefore predicts that in ellipsis constructions, the quantifiers *every* and *no* are realized as *every one* and *none* before PRO, just as they are in partitives:

(18) a. every one of the men/*every PRO of the men
b. every one PRO/*every PRO

(19) a. none PRO/*no of the men
b. none PRO/*no PRO

Perlmutter (1970a) notes further problems with *one's* deletion, observing that although prenominal adjectives can introduce the N' pronominalized by *one*, *one's* deletion in these contexts is nevertheless ungrammatical. (See Baker 1978 and Hornstein and Lightfoot 1981 for arguments that *one* pronominalization replaces N'.)

(20) a. Svetlana has two red masks and Guido has a green ***(one)**.
b. Svetlana has two red masks and Guido has one too.
c. *Svetlana has two red masks and Guido has a one too.

Perlmutter explains these facts by proposing that there exist in English both a pronoun *one* and a numeral *one*, and further, that the English indefinite article is the unstressed counterpart of the numeral *one*. (See also Jackendoff 1977 for discussion of two possible derivations of *one*.) This proposal explains a set of recalcitrant ellipsis facts, in addition to those illustrated in (20).

Perlmutter argues that the phrase *a green one* in (20a) actually derives from the grammatical source in (21), where the numeral *one* is unstressed, and thus can reduce to *a*:

(21) one green one ⇒ a green one

To block the ungrammatical (20c), Perlmutter proposes that unstressed pronominal *one* is obligatorily deleted after a numeral. The source of (20c) is thus (22):

(22) Svetlana has two red masks and Guido has one one too.

Unstressed pronominal *one* in (22) will obligatorily delete, deriving the grammatical (23):

(23) Svetlana has two red masks and Guido has one too.

Further evidence for this claim is given in (24–25), where we see that pronominal *one* deletes only after numerals, but not after adjectives:

(24) Svetlana sells red masks and Guido sells green ones

(25) a. *Svetlana sold three masks and Guido sold four ones.
b. Svetlana sold three masks and Guido sold four.

An account in which *a* is the unstressed counterpart of the stressed full numeral *one* also explains the contrast illustrated in (26):

(26) a. *a village in Greece and a (an) in Yugoslavia.
b. a village in Greece and one in Yugoslavia.

According to Perlmutter, (26a) is ruled out because *a* is a proclitic with no host to which to attach. Under such conditions only the stressed full form of the article, namely the numeral *one*, can appear.

Though Perlmutter's analysis makes certain correct predictions about ellipsis in indefinite noun phrases (and a variety of other data involving the distribution of the indefinite article *a*), the analysis is unavoidably ad hoc, as it must stipulate that *one* obligatorily deletes after numerals, but not after adjectives. We are thus left without an explanation for the ungrammaticality of the (b) sentences in (27–28). In these sentences, unstressed *a* can cliticize to *new*, but ellipsis is nevertheless ungrammatical:

(27) a. Svetlana sells old masks and Guido sells new ones.
b. *Svetlana sells old masks and Guido sells new.

(28) a. Svetlana wants to sell an old mask and Guido wants to sell a new one.
b. *Svetlana wants to sell an old mask and Guido wants to sell a new.

In addition, as Perlmutter himself points out (fn. 6), it appears that certain determiners other than numerals trigger obligatory deletion of *one*:

(29) a. *my flag and hers one
b. my flag and hers

Again, it remains to explain why *one's* deletion is obligatory in (29b), but blocked after adjectives.

Other early approaches to *one's* deletion address the status of personal pronouns, such as *we*, *you*, *she*, etc. Postal (1969) argues that personal pronouns are

definite articles that derive from noun phrases in which they are followed by the pronoun *one. One* deletes by a late (and, Postal admits, ad hoc) rule deriving the forms in (30b) from the sources in (30a). The status of pronouns as determiners thus emerges early on in discussions of ellipsis in noun phrases:

(30) a. we ones/you one/she one
b. we/you/she

Sommerstein (1972) takes the opposite approach, claiming that the definite article *the* is a pronoun, replacing a full NP. He gives a number of arguments against Postal's analysis of pronouns as determiners, based on evidence from Greek, a language which allows constructions analogous to English *the in London* and *the loved by Rebecca*. He argues that in English count-noun phrases, *one* must be inserted after *the* in order to derive *the one in London* and *the one loved by Rebecca*. Thus, his approach includes an obligatory rule of *one* insertion, which inserts *one* in count-noun phrases to replace a deleted N-head. *One* insertion is similar in spirit to *do* support, inserting a dummy element to realize features, in this case, number. As for ellipsis in noun phrases, he provides only an account of the ungrammatical (31):

(31) *The cheese in this package is fresher than **the** in that package.

He proposes that *the* must be altered to the stronger form *that* in order to derive the grammatical sentence in (32):

(32) *The cheese in this package is fresher than **that** in that package.

For related discussion of personal pronouns as determiners, and whether or not they are followed by empty categories, see Corblin (1990), Hewson (1991), and Luján (2000).

2.2 *Deletion vs. interpretation*

Researchers in the 1960s and 1970s generally concur with Ross that ellipsis is a type of null anaphora, but not all agree with his claim that both pronouns and ellipsis are derived by the same (in early frameworks, transformational) rules. There is extensive debate concerning whether ellipsis phenomena (in particular, VP ellipsis and sluicing) are derived by deletion of a copy of an antecedent (with or without the intermediate step of pronominalization as Ross proposes), or whether ellipses are base-generated empty structures, whose content is supplied by rules of interpretation (the 'interpretive' approach, an early illustration of which is Jackendoff's analysis of empty N as PRO). Of central concern in these debates is the definition of 'identity' between null anaphors and their antecedents,

and more specifically, whether null anaphors have internal structure, and if so, which grammatical model best expresses how such structure is derived and interpreted. Work toward resolving these issues leads researchers to sharpen the distinction between ellipsis and other phenomena involving missing material, such as gapping, comparative deletion, stripping, and null complement anaphora, and to move toward a grammatical model which requires a distinct level of Logical Form.

In general, early arguments that ellipsis is derived by deletion under identity hinge on the evidence that an ellipsis site must, at some level of the derivation, have internal syntactic structure in order for the missing phrase to be properly interpreted. Such arguments are raised partially in response to Akmajian's (1968) 'non-expansion hypothesis', in which null anaphors are base-generated as empty, unexpanded non-terminals, associated with their antecedents through rules of interpretation. (Proponents of the strict transformational position on the derivation of anaphora include Postal 1972; Hankamer 1973a; Morgan 1973; Ross 1986; and most of the pre-*Aspects* literature (Chomsky 1965). Defenders of the interpretive approach include Dougherty 1969; Jackendoff 1969, 1971, 1977; Shopen 1972; Wasow 1972; Fiengo 1974; Williams 1977.)

How the notion of 'syntactic identity' is articulated, however, depends on the model of grammar defended. For instance, Wasow (1972) proposes an interpretive theory in which null anaphors are base-generated empty categories with internal structure to which interpretive rules apply. Lexical pronouns, on the other hand, have no internal structure, and are also subject to interpretive rules. Williams (1977) defines syntactic identity in terms of identity of Logical Form, rather than strict surface structure identity, arguing that an ellipsis and its antecedent are related by interpretive rules that apply at LF (in his model, Discourse Grammar). Deletion rules, on the other hand, are restricted to applying to surface structures (Sentence Grammar), to operations that obey Ross's Constraints, such as gapping and comparative deletion. In Williams's model ellipsis (including sluicing, ellipsis in NP, and VP ellipsis) is distinct from gapping and comparative deletion. In Sag's (1980) model, ellipsis, comparative deletion, and gapping are all derived by deletion, an operation that in the case of ellipsis applies to logical forms, in a model of grammar quite different from Williams's. Hankamer and Sag (1976) further elucidate this deletion approach, arguing that ellipsis patterns with stripping and gapping as an instance of "surface" rather than "deep" anaphora, based on, for example, the claim that surface but not deep anaphors require linguistic antecedents. (See Schachter 1977 and Chao 1988 for arguments that ellipsis can have pragmatic antecedents, and Lobeck 1995 for specific arguments that this holds of ellipsis in noun phrases. See also Williams 1977, who suggests (fn. 6) that anaphoric elements dominated by N and NP can be pragmatically controlled, and that all others require linguistic control. There is thus, in his view, no difference between deep and surface anaphora, and no implicit argument for deletion based on the presence or absence of pragmatic control.)

3 The phrase structure of ellipsis in NP

Much of the early research on ellipsis in NP assumes without argument that ellipsis operates on a projection of N, but other work on Germanic and Romance languages explores the phrase structure of ellipsis in more detail, providing important evidence for bar-level distinctions in NP, and sharpening structural distinctions among the different prenominal elements that introduce those projections. This early research on the phrase structure of ellipsis in noun phrases lays important groundwork for arguments that noun phrases are projections of the category Determiner, and for analyzing ellipsis in such phrases as ellipsis in DP.

Jackendoff (1971, 1977) examines certain crucial differences between gapping and ellipsis in NP and VP first noted by Ross (1986), and concludes that gapping and ellipsis in these categories are different operations, (for him, gapping, but not ellipsis, involves deletion), but that both operate on N′, the lowest projection of N. He bases this conclusion on evidence that prenominal adjectives must be included in both operations. An example of ellipsis is given in (33), based on evidence in Jackendoff (1971). (The example is constructed with the ellipsis in a subordinate clause, to distinguish ellipsis from gapping, which cannot occur in subordinate clauses, as pointed out early on by both Ross 1986 and Jackendoff 1971, among others.)

(33) Tureck's performance of Bach on the piano doesn't please me as much as
  a. *[$_{NP}$ Glenn Gould's [$_{N'}$ fabulous [e]].
  b. [$_{NP}$ Glenn Gould's [$_{N'}$ e]]

Ellipsis must also include N and its complements, as illustrated in (34), with an example based on the discussion in Jackendoff (1977):

(34) ***Although** [$_{NP}$ Max's [$_{N'}$ [e] about Sue]] was amazing, Bill's story about her was virtually incredible.

Ronat (1977) comes to the opposite conclusion for French, claiming that in contrast to English, in French N′ *cannot* be empty. Her arguments hinge on evidence that only elements that are dominated by N′ can introduce an ellipted (for her, deleted) noun. Ellipsis of N is impossible with other adjectives or relative clauses dominated by higher projections of N, as ellipsis in this case would leave N′ empty. The relevant contrasts are given below. (See also Milner 1973, 1974 and Kayne 1975 for arguments regarding the distribution of adjectival modifiers and quantifiers in French, and Barbaud 1976 for the distribution of adjectives in French noun phrases.)

(35) a. [$_{NP}$ les [$_{N'}$ deux [$_{N}$ e]]]
  the two [e]
  'the two'

b. [$_{NP}$ la [[$_{N'}$ e] verte]]
the green
'the green (one)'

(36) *[$_{NP}$ le [$_{N'}$ e]]
the [e]
'the one'

(37) *[$_{NP}$ le [$_{N'}$ e] qui est susceptible de te plaire]
the that is susceptible of you please
'the (one) that pleases you'

(38) *[$_{NP}$ le [$_{N'}$ e] susceptible de te plaire]
susceptible of you please
'the (one) that pleases you'

(39) *[$_{NP}$ les [$_{N'}$ e] magnifiques]
the magnificent(s)
'the magnificent (ones)'

In an alternative approach to substantive adjective constructions in French, Herschensohn (1978) argues that, contrary to the analysis proposed by Gouet (1976), certain substantive adjectives are deep anaphors, rather than derived by deletion of a noun, as Gouet proposes. Herschensohn bases her claim on evidence that such constructions can take pragmatic antecedents, a criterion for identification as a deep anaphor, according to Hankamer and Sag (1976). Other, superficially similar constructions require syntactic control, and are thus surface anaphors, involving deleted nouns.

For example, the contrast between (40) and (41) suggests that the substantive adjective *petits* requires a linguistic antecedent and is thus a surface anaphor, derived by deletion of a noun:

(40) Il y avait de grands garçons et de petits aussi.
there were of big boys and of little too
'There were big boys and little (ones) too.'

(41) [Two individuals are looking out a window at (among other things) boys playing]
#Il y avait de petits aussi.
there were of little too
'There were little (ones) too.'

Herschensohn contrasts the substantive adjectival constructions with those discussed by Gouet, which involve regional and brand names. These adjectives appear to be pragmatically controlled:

(42) [Individual standing at a bar]
Un bourgogne blanc, s'il vous plaît.
a burgundy white if you please
'A (glass of) white Burgundy (wine) please.'

In Herschensohn's view, certain substantive adjectives, namely those involving brand names, do not involve deletion of a noun, while others, which require syntactic control, do.

Ronat's work shifts the focus of ellipsis in noun phrases from deletion vs. interpretation to the elements that introduce the ellipted category, and explicitly connects ellipsis with constructions involving partitive *en*. Ronat adopts Kayne's (1975) claim that quantifiers and numerals are dominated by N', and argues that in (43), the empty noun is therefore sister to a numeral in N'. Ronat analyzes such constructions as involving ellipsis, and claims that ellipsis is grammatical because only N, but not N', is empty:

(43) J' en ai mangé [$_{NP}$ [$_{N'}$ un [e]].
I of-them have eaten one
'I have eaten one of them.'

See 4.3 for further discussion of connections between ellipsis in noun phrases and partitive *en* constructions.

4 Ellipsis, proper government, and the Empty Category Principle

Within the Principles and Parameters framework of the early 1980s, empty categories are argued to be base-generated, with their syntactic distribution constrained by various interacting principles of government (in particular 'proper' government) and binding. Within this framework, the focus on ellipsis shifts from deletion vs. interpretation to whether empty categories in ellipsis constructions can be argued to fit into a larger typology of empty [+/−pronominal, +/−anaphor] elements, based on the syntactic conditions under which they are licit.

Zagona (1982, 1988a, 1988b) is first to analyze empty VP in ellipsis constructions as typologically *pro*, an empty pronominal category, constrained by principles of proper government and the Empty Category Principle or ECP of Chomsky (1981). Her analysis captures the earlier generalization that ellipses, like pronouns, seem exempt from Ross's Constraints, and in terms of the Principles and Parameters framework, subject to Principle B of the Binding Theory. (Recall that for Jackendoff 1972, 1977, ellipsis in noun phrases involves an empty PRO, which one might argue is another early precursor of *pro*. Wasow 1972 also suggests that ellipted constituents are base-generated empty proforms.) Zagona argues that

empty *pro* VP in English and Spanish must be properly governed by a head specified for 'rich' agreement, on a par with empty subjects in Romance (Rizzi 1982a). Zagona argues that empty VP satisfies the ECP when properly governed by INFL, and that INFL is only a proper governor when specified for rich agreement features (in this case, Tense features). (See also Chao 1988, who argues that *pro* in VP ellipsis and sluicing constructions is constrained by the ECP.)

The following sections outline the progression of ECP analyses of ellipsis in noun phrases, from 'specifier' government to proper government by the functional categories DET, Q, and NUM. This research sharpens the distinction between ellipsis and substantive adjective constructions, and clarifies connections between empty N in ellipsis constructions and partitives in which ellipted N alternates with the trace of partitive *en/ne*.

4.1 Specifier government in NP

In a first attempt at analyzing ellipsis in NP in the Principles and Parameters framework, Lobeck (1987) extends Zagona's approach to VP ellipsis to both sluicing and ellipsis in noun phrases in English (with a short discussion of French), in an attempt to provide a unified, ECP approach to the distribution of empty categories in ellipsis constructions across categories. She argues that *pro* in ellipsis constructions must be properly governed by a specifier (and thus subject to 'specifier government'), and that SPEC–HEAD agreement features of tense, possession, number, etc. suffice to designate certain specifiers as proper governors. In her framework ellipted projections of N must be properly governed by SPEC(N) specified as [+number] or [+poss], as illustrated in (44). Quantifiers are specified as [+number] in her approach even when singular, accounting for the grammaticality of (44e):

(44) a. The committee endorses every bill the president proposes but the advisors approve only [$_{NP}$ a [few [e]].
b. I really liked those books and I know you'll like [$_{NP}$ these [e]].
c. Sally discussed the committee's decision to vote yes before she mentioned [$_{NP}$ the president's [e]].
d. Even though she already has [$_{NP}$ two [e]], Mary bought three more dogs yesterday.
e. The students went to the bookstore and [$_{NP}$ each [e]] bought a book by Chomsky.

Lobeck adopts Emonds's (1985) arguments that certain grammatical formatives are inserted late in the derivation, and thus unavailable as surface structure proper governors. Possessive NPs, demonstratives, and certain quantifiers are, for example, deep structure SPEC(N), but definite and indefinite articles and the quantifier *every* are inserted into the derivation at PF. In this way, Lobeck explains the ungrammaticality of ellipsis in (45), where SPEC(N) is not filled, and fails to properly govern *pro*:

(45) a. *I really liked this book and I know you'll like [$_{NP}$ the [e]] too.
b. *I'd love to spend a few weeks in Hawaii and I know you'd like to spend at least [$_{NP}$ a [e]] there too.
c. *The committee endorses every bill the president proposes and the advisors approve just about [$_{NP}$ every [e]] too.

Lobeck remarks briefly on the failure of ellipsis in noun phrases in French, illustrated in (46–47):

(46) *Jean a goûté du vin mais il n'a pas goûté [beaucoup[e]].
John tasted some wines, but he didn't taste many [e].

(47) Jean a goûté du vin mais il n'en a pas goûté beaucoup [e].
John tasted some wines but he of-them didn't like many [e].

Lobeck follows Milner (1978b) in analyzing the empty category in (47) as the N' trace of *en*, adopting also Kayne's (1981b) and Hendrick's (1983) arguments that the trace of *en* is licensed by lexical government. This accounts for the subject/object asymmetry illustrated by comparing (47) with (48) (see also Haik 1982):

(48) *Beaucoup [e] en ont goûté.
Many [e] of-them have tasted.

In (48), the trace of *en* is not lexically governed by the verb, and the derivation violates the ECP. Lobeck takes this as evidence that empty categories in NP are not licensed by specifier government in French; rather, the language relies on a different (clitic *en*) strategy to license empty categories. (46) is ungrammatical where the *en* strategy is not employed.

In a comprehensive study of a range of phenomena in English NP, including ellipsis, Olsen (1987) proposes an analysis of ellipsis which crucially involves specifiers and an empty category, but which is not explicitly stated in terms of proper government and the ECP. Olsen's approach also distinguishes between ellipsis in noun phrases and substantive adjectival constructions, arguing for two types of empty N: empty anaphoric N (ellipsis) and empty N specified as [+human, +generic].

Olsen argues that ellipsis in noun phrases involves an empty anaphoric head N (distinct from *pro*), whose content is recoverable from a discourse antecedent. She proposes that only specifiers that can combine with empty N (and that do not interfere with its anaphoricity) can introduce empty N in ellipsis contexts. This situation holds in (49), but not (50), where, in the latter case, anaphoric N has attempted to combine with an attributive adjective, specified for incompatible features. N must be realized here as *one*, or be ruled out:

(49) John's car and Bill's [e]

(50) John's new car and Bill's old one/*[e]

Certain adjectives with appropriate features can combine with empty N that is not anaphoric, but specified as [+human, +generic], in 'substantive' adjectival constructions:

(51) the able [e]

For Olsen, then, there are two types of empty N, neither of which can be analyzed as *pro*, a designation reserved for empty pronominal noun phrases rather than empty heads. Though Olsen does not explicitly state the constraints on ellipsis in terms of 'specifier government', her analysis parallels Lobeck's in relying on feature specification of specifiers to explain the distribution of ellipted nominal projections in English.

The early work on ellipsis and the ECP re-emerges in later work in a Principles and Parameters framework in which proper government is analyzed in more detail as involving licensing and identification. At the same time, researchers are exploring the role of functional categories in X-Bar Theory, including the status of DET as a functional head of DP. Within this framework, ellipsis in noun phrases is reanalyzed as involving licensing and identification by a functional X-0 rather than a specifier.

4.2 Ellipsis in DP

One immediate problem with the notion of 'specifier government' is that it assumes that specifiers, rather than heads, can properly govern their sisters, namely intermediate projections of N (as noted by Contreras 1989). Possessive NPs in SPEC(N) are a good case in point, and fall outside of the typical definition of 'proper governor'. The 'DP Hypothesis' (proposed originally by Brame 1982 and elaborated by Abney 1987 and others) provides an alternative framework within which to analyze licensing and identification in ellipsis constructions, as prenominal elements are analyzed as heads, rather than specifiers. The empty category in ellipsis constructions can therefore be analyzed as properly governed in most cases by the functional head DET, rather than by a (possibly phrasal) SPEC(N).

Torrego (1987) is the first to provide an ECP account of what can now be referred to as ellipsis in DP, arguing that certain determiners in Spanish, Catalan, and Portuguese license empty pronominal N heads in noun phrases. Torrego analyzes this empty category as *pro*, and extends Borer's (1986) argument that *pro* must be licensed by person features (AGR). Torrego's argument hinges on the contrastive distribution of elliptical noun phrases headed by the definite determiner *el* and the demonstrative *este*, and the types of modifiers required in NP when N is empty. In order to claim that *el* governs and thus properly governs (licenses) *pro*, Torrego adopts the DP hypothesis, assuming that determiners head DP, with *pro* in this case as the empty head of the NP complement of DET (as proposed by Hellan 1985 for headless nominals in Norwegian).

Torrego observes that *el* can apparently license empty N when N is modified by *de* + XP, as illustrated in (52a). (Torrego presents a few arguments that *el* is not a clitic, and hence that such constructions involve ellipsis. Suñer 1986 gives an opposing view.) Empty N modified by a 'semantically contentful' PP is ungrammatical, as illustrated in (52b):

(52) a. El [e] de las Meninas no está en este museo.
'The (one) of the Meninas is not in this museum.'
b. Presenciaron los *(asaltos) a las zonas urbanas.
'They witnessed the (assaults) in the urban areas.'

Adjectival modifiers seem to have the same properties as *de* + XP modifiers with respect to ellipsis; empty N in such constructions is apparently licensed, as in (53). (54) illustrates further that such adjectival modifiers can 'save' ellipsis constructions that include semantically contentful PP modifiers:

(53) Los [e] verdes son bonitos.
'The green (ones) are nice.'

(54) a. *Leí los [e] sobre política.
'I read the (ones) about politics.'
b. Leí los [e] cortos sobre política.
'I read the short (ones) about politics.'

From these and other data Torrego concludes that the definite determiner in Spanish is too 'weak' to license empty N alone; the relevant person features for licensing are contributed by *de* + XP. 'Stronger' determiners, such as *este/ese/aquel*, are specified for person. Consequently, they license *pro* without the additional required *de* PP, as illustrated in (55):

(55) a. También acaban de salir estos [e] sobre anatomía.
b. *También acaban de salir los [e] sobre anatomía.
'There also just appear these/the (ones) about anatomy.'

Torrego concludes that *de* + XP modifiers, like adjectives, are [+N], and contribute the relevant AGR features to license empty N that are not contributed by the weak definite determiner. Demonstratives are specified for sufficient features to license *pro*, and thus empty N can occur without the additional presence of *de* + XP. (See also Schroten 1992, Brucart 1987, and Brucart and Gràcia 1986 for related discussion.)

As mentioned above, Contreras (1989) observes that an approach to ellipsis in terms of specifier government is ad hoc, as it extends the ECP to apply to both empty intermediate and maximal projections, and includes specifiers as well as heads in the class of proper governors. Aside from these theoretical considerations he shows that specifier government fails to account for certain empirical distinctions between English and Spanish, and thus must be rejected.

He critiques two parallel analyses of specifier government involving ellipsis in NP, Lobeck (1987) for English and Bosque (1986) for Spanish. Bosque argues that the relevant difference between Spanish and English is that in the former, the article agrees with the head noun in gender and number. Specifiers with this 'rich agreement' properly govern empty N or N'. This rich SPEC–HEAD agreement relation fails to hold between English articles and N, and specifier government fails. (Examples are from Contreras 1989.)

(56) Vi al estudiante de física y al [e] de química.
'I saw the student of physics and the (one) of chemistry.'

(57) Dame este libro de física y ese [e] de química.
'Give me this book on physics and that [book] on chemistry.'

Bosque attributes the ungrammaticality of (58) to the feature specification of Spanish possessives; unlike definite articles and demonstratives, possessives are not specified for gender and number, and hence fail as proper governors:

(58) *Su libro sobre Borges es mejor que su [e] sobre Cortázar
'His/her book on Borges is better than his/her [e] on Cortázar.'

As Contreras points out, Bosque's analysis fails to account for the failure of ellipsis in French, where in possessives, the head N agrees in gender and number with the specifier:

(59) *mon livre de logique et ton [e] de littérature
'my book on logic and yours [e] on literature'

Bosque also fails to explain the fact that in both English and Spanish, numerals (which are not also specified for gender) apparently specifier-govern empty nominal categories, as illustrated in (60):

(60) María compró tres libros de fisica y Juan compró dos [e].
'Mary bought three books on physics and John bought two [e].'

And finally, an approach restricted to gender as a "rich" agreement feature fails to explain why certain, but not all, quantifiers appear to properly govern empty nominals in both English and Spanish:

(61) a. Si bien algunos estudiantes quieren reformas, muchos [e] no la quieren.
b. Although some students want reforms, many [e] don't want them.
c. A propósito de estudiantes, varios [e] quieren verte.
d. Speaking about students, several [e] want to see you.

(62) a. *Aunque no todo politico miente todo [e] es vanidoso.
b. *Although not every politician lies-every [e] is vain.
c. *Si cada [e] tiene una solucion diferente, nunca resolvere todos estos problemas.
'If each has a different solution, I'll never solve all these problems.'

To resolve the various problems with specifier government, Contreras adopts Fukui and Speas's (1986) theory of phrase structure (adapted from Brame's 1981, 1982 original proposal), in which functional categories (DET, COMP, and INFL) head phrases and project to X". Lexical categories N, V, A, and P project to X' as maximal. This distinction in what is analyzed as maximal is predicated on the assumption that only functional categories 'discharge' Kase features to a specifier position, and hence project beyond X'. Kase features include tense and agreement in INFL, [+poss] in DET, and [+WH] in COMP. Contreras proposes that only functional categories can properly govern ellipted nominal projections; hence, only DET specified for certain features that are appropriately "rich" can do so. The article in Spanish is so specified, but the English article is not. He suggests further that the evidence that DET specified as [+poss] can properly govern an ellipted complement suggests that the feature [+poss] qualifies as an appropriately "rich" agreement feature, and DET properly governs N' (a maximal projection, according to Fukui and Speas):

(63) John's book was good, but [$_{DP}$ Mary [$_{D}$'s [$_{N'}$ e]] was even better.

Most of Contreras's arguments concern the status of quantifiers as functional heads. He analyzes certain quantifiers as members of the category Q, heading QP. He supports this hypothesis with evidence that just those quantifiers that properly govern empty nominals select either DP or partitive PP complements. *Todo/all* thus contrasts with *cada/every* in this way, as illustrated in (64–65). (See Giusti 1991a and Löbel 1989 for arguments that Q is a functional head, and Karimi 1989 and Rothstein 1988 for discussion of the phrase structure of quantified NPs in English. See also Van Riemsdijk 1989a for discussion of the distribution of a somewhat different type of empty category in German DP, introduced by a determiner specified for certain features.)

(64) a. todo los problemas/todo del trabajo
b. all the problems/all of the work

(65) a. *cada los problemas/*cada de los estudiantes
b. *every the problems/*every of the students

Contreras suggests that *cada* and *every* are specifiers, and sisters to N'. *Todo* and *all*, on the other hand, are quantifiers that can head QP, and select maximal projections as complements. In such configurations, the functional category Q, an X-0 rather than a specifier, properly governs [e]. In this way he predicts not only

the distribution of ellipted nominal categories in (64–65), but also the contrast between (62a) above, and (66):

(66) Estoy dispuesto a haver una parte del trabajo, pero no todo [e].
'I'm willing to do part of the work, but not all.'

In (66), *todo* selects a DP complement, which can be empty. In contrast, in (62a) *todo* is a sister to N' and thus a specifier rather than a head. Proper government fails, and ellipsis is ruled out.

Contreras claims that quantifiers can occupy SPEC(N), in which case they do not properly govern [e], or they fill Q, and are proper governors of DP. Yet a third option is for quantifiers to head QP and to select an N' complement, a maximal projection in Fukui and Speas's framework. Thus he accounts for the grammaticality of ellipsis in (61a) above, though *muchos/many* does not select DP. These facts are illustrated in (67):

(67) a. muchos de los estudiantes
b. *muchos los estudiantes
c. many of the students
d. *many the students

Contreras argues, contra previous accounts in which ellipted categories are analyzed as *pro*, that [e] in DP is [–anaphor, –pronominal], though it is not bound by an operator (as are other such categories, namely *wh*-trace). The empty category is thus a contextually defined variable, consistent with proposals such as that of Koopman and Sportiche (1982). In the framework he adopts, the ellipted category in noun phrases in Spanish is also analyzed as either N or N', a claim also made by Torrego (1987), and by Ronat (1977) for French. (For discussion of N' ellipsis in Japanese, and how it supports the DP hypothesis, see Saito and Murasugi 1990.)

4.3 Licensing and identification in DP

In a number of articles throughout the 1990s Lobeck refines the licensing and identification conditions on ellipted categories in DP, focusing on how to best formulate the feature specifications of DET and Q that appear to designate these heads with agreement 'strong' enough to license and identify NP *pro* complements of these heads (Lobeck 1990, 1991a, 1991b, 1993). One central issue is that while both the singular numeral *one* and the singular quantifier *each* license empty NP, singular *every* does not.

Lobeck originally argues that numerals and quantifiers, including singular *one* and *each*, are [+number], and specified for strong agreement. She adopts Contreras's proposal that *every*, on the other hand, though [+number] in her framework, fills SPEC(N) rather than Q, and is thus not a possible licensing head for an

empty nominal projection. Lobeck (1995) later revises this approach, ultimately arguing that the relevant feature specification of quantifiers and numerals is not [+number], but [+partitive]. In this way Lobeck includes both singular *one* and *each*, both of which can occur in partitive constructions in English, in the set of potential licensing heads for ellipsis without the stipulation that these singular heads are [+number], and without requiring *every* to occur in a structural position different from *each*. In her framework, DET must be specified as [+poss], [+number] (more specifically, [+plural]), and/or [+partitive] to license and identify *pro* in DP. *Every* is therefore excluded as a licenser of ellipsis because it is both [–number] and [–partitive].

Lobeck also argues, following Ritter (1991), that numerals head NUMP, proposing that NUM specified for strong agreement can also license and identify *pro* in NUMP. In addition, Lobeck attempts a cross-linguistic analysis of ellipsis in DP based on evidence from German and French, proposing a parameter whereby the number of strong agreement features in DET or NUM that is required to identify an empty pronominal NP is proportional to the number of possible strong agreement features in the language. English, a language with relatively poor agreement, requires fewer strong agreement features to license ellipsis (at least one). French, with a somewhat more complex agreement system, requires more features than English (namely at least two), and German, with an even richer system, requires that DET, NUM, or Q be specified for three features. (For a critique of Lobeck's analysis of ellipsis in German DP, see Sleeman 1996, discussed below, and Winkler 1997, who argues that ellipsis is in part predictable based on pitch accent and focus.)

Kester's (1992, 1993, 1994, and other work, notably 1996a, 1996b) central insight is that, in a range of Germanic and Romance languages, a functional head in a SPEC–HEAD agreement relation with an adjective with morphological inflection is specified for "strong" agreement, and licenses empty N. (See also Delsing 1992 for discussion of the role of adjectival inflection in Scandinavian languages, and Olsen 1989 for German.) The empty non-anaphoric N in substantive adjective constructions and empty anaphoric N in ellipsis constructions are licensed in this way. They differ, however, in how empty N is identified. Non-anaphoric N is identified through special adjectival morphology, or by the grammatical gender features of the determiner. Anaphoric N, on the other hand, is identified with a lexical antecedent in the discourse. In Kester's approach, empty N is licensed by an adjective lacking strong agreement only in the default case, namely when N is specified as [+human, +generic, +plural]. (Kester adopts Lobeck's claim that empty N is *pro*, noting that in Dutch, for example, *pro* = N, while in English, *pro* = N'.)

To see how this analysis works, consider (68) (from Lobeck 1993, analyzed in Kester 1996b):

(68) Ich möchte das alte Buch kaufen aber Sie möchten das neue [e].
I wanted the old book to buy but you wanted the New [e].
'I wanted to buy the old book but you wanted to buy the new one.'

Lobeck argues that in (68), the adjective *neue* is a head specified for strong agreement features, based on evidence that adjectives in German express gender, case, number, etc. Adjectives in English lack these features, and thus are not specified for strong agreement and fail to license and identify *pro* in DP. Kester adopts Cinque's (1993) proposal that adjectives are specifiers of functional projections in DP, arguing that it is instead the functional head (F), in a SPEC–HEAD agreement relation with A specified for strong agreement, that licenses *pro* in (68). This situation is illustrated in (69):

(69) $[_{DP}\ [_{D'}$ das $[_{FP}$ neue $[_{F'}\ [_{NP}$ e]]]

Empty N in (69) is identified with its discourse antecedent, and is grammatical.

In (70), empty N is allowed in English, though A lacks features. Kester argues that this is because in English, empty N that is not identified by strong agreement can only survive if it is specified for and identified through its default features [+human, +generic, +plural]. Licensing conditions are also in this default case relaxed, and *pro* is licensed under government by the functional head F:

(70) a. the sick
b. $[_{DP}\ [_{D'}$ the $[_{FP}$ sick $[_{F'}\ [_{NP}$ e]]]]]

In Dutch, on the other hand, non-anaphoric *pro* is [+human, +generic] but can be [+/−plural]. Empty N in this case is therefore not specified for default features, and thus falls under more stringent licensing and identification conditions. Ellipsis in Dutch DP also differs from English, in that empty anaphoric N can be licensed by an adjective. These facts are illustrated in (71–72) and (73), respectively:

(71) [Rijken *pro*] worden alleen maar rijker.
rich *pro* become all more rich
'The rich only become richer.'

(72) [Een zieke *pro*] heeft recht op een goede verzorging.
a sick *pro* has a right to a good care
'A sick person has a right to good care.'

(73) Jan kocht de rode auto en [de groene *pro*].
Jan bought the red car and the green *pro*
'John bought the red car and the green (one).'

Kester accounts for this difference between English and Dutch in terms of the presence or absence of adjectival inflectional morphology. In Dutch, adjectives in both substantive adjective and ellipsis constructions are inflected with *-e* (*schwa*). She argues that in these cases *pro* is licensed by this adjectival inflection, and in ellipsis constructions such as (73), *pro* is interpreted under identity with an antecedent (identification). In the substantive adjective constructions in (71–72), non-anaphoric *pro* is identified by grammatical gender features on the determiner.

Kester extends her analysis to a number of other languages (including German, Swedish, Spanish, and Finnish), concluding that adjectival inflection plays a crucial role in licensing both elliptical and non-elliptical empty N, and that the crucial difference between such constructions lies in the means by which identification conditions are met.

Bernstein's work (1991, 1993a, 1993b) concerns the distribution of the indefinite article in construction with empty N in Spanish and Italian (and also extends to French and Catalan). She argues that terminal vowels on nouns are functional heads, generated independently of their N stems. These functional heads can in turn license null projections of N. Because they are affixes, they must also raise to D, deriving the various orders of determiners, adjectives, and empty N in elliptical constructions in these languages. Her analysis thus provides yet another approach to 'strong' agreement in licensing empty N.

One central distributional difference that Bernstein observes is that in Spanish and Italian, the indefinite article occurs in ellipsis constructions only when affixed with *-o*. Other numerals and quantifiers are not so constrained:

(74) Uno rojo está encima de la mesa
'a red one is on the table'

(75) *Quiero un (grande)
'I want a (big)'

(76) Quiero dos.
'I want two.'

(77) Tengo muchos.
'I have many.'

(78) Ne voglio due.
'CL (I) want two.'

(79) Ne ho molti.
'CL (I) have many.'

She captures this distinction by arguing that in Spanish and Italian, DP dominates another functional category, Word Marker Phrase (WMP), headed by *-o*. The affix *-o* undergoes head-to-head movement, raising from WM to NUM to D. In D, *-o* adjoins to *un-*, the head of a QP in SPEC(NUMP) that has raised to D. In general, then, *uno* derives from head-to-head movement of two separate heads, the Q *un* and the WM *-o*. WM is a functional head that governs and licenses empty N in ellipsis constructions, accounting for the contrast between (74) and (75) above.

To explain the distribution of substantive adjectival constructions in (80), Bernstein proposes two different positions for adjectives (following Cinque 1993).

Pobre occurs below WM, and *mero* above it. In the former case, raising of WM to D is not blocked, but in the latter case movement is blocked by *mero*, and the derivation is ruled out:

(80) a. uno pobre (an impoverished one)
b. *uno mero (a mere one)

Bernstein generalizes her analysis to French, arguing that in this language WM is abstract, but present to govern and license an empty nominal projection. Consider, for example, (81–82), examples of empty nouns in French:

(81) Un très gros chien vit dans cette maison. Un petit vit dans celle d'à côté.
'A very big dog lives in this house. A small [e] lives in that one next door.'

(82) un rouge
'a red [e]'

She bases the grammaticality of (81–82) on the evidence that gender is reflected on some French nouns by an affix, *-e*, as illustrated in (83), suggesting that the final vowels in masculine nouns in French are deleted by a PF rule, but that they are present abstractly. French nouns thus are dominated by a WM projection just as in Spanish, and as a result, the invariable form *un* in French licenses empty N:

(83) a. voisin/voisine
b. cousin/cousine

Bernstein also derives the difference between *un*/*uno* in partitive *ne* constructions from licensing by WM:

(84) Ne ho visto uno/*un rosso
CL I have seen a red (one)
'I have seen a red (one).'

Bernstein assumes, following Cinque (1991) and Cardinaletti and Giusti (1992), that *ne* is basically a clitic NP that raises to cliticize to the finite verb. This raising, she argues, is possible only when WM is present (as reflected by *-o*) to license the trace of *ne*.

In Bernstein's analysis then, ellipsis in Spanish, French, and Italian DP depends on licensing by a lexical or abstract functional category WM, the locus of gender affixes in Romance.

In a comprehensive study of ellipsis in French DP, Sleeman (1996) proposes a unified approach to licensing of empty N, or *pro* (in ellipsis, partitive, and substantive adjective constructions), defining 'strong agreement' for licensing in terms of a single, semantic feature, [+partitive]. Central to her analysis is the

distribution of adjectives that can introduce empty N in French and other languages. Basically, she argues that adjectives are functional projections in DP, following Cinque (1993), but proposes that the relevant feature specification of the licensing head of such projections is [+partitive], rather than overt inflectional morphology. Only adjectives with this feature will be able to introduce ellipsis, as it is only in these contexts that the functional head with which the adjective agrees will be [+partitive], and able to license empty N. (For other approaches to French DP upon which Sleeman draws, see Corblin 1990; Valois 1991a, 1991b; Corver and Delfitto 1993.) Sleeman argues that this approach accounts for a number of contrasts first pointed out by Ronat (1977) and Barbaud (1976) for French, and also for certain cross-linguistic differences between French and Dutch, Spanish, Italian, and English.

Sleeman notes that while overt morphological inflection may be relevant to licensing empty N in Dutch and Spanish (as argued by Kester and Bernstein, respectively), morphological inflection does not seem relevant to licensing empty N in French. For example, the adjectives *intéressante* and *grande*, in (85) and (87) respectively, are both morphologically inflected for gender, but only *grande* licenses ellipsis. The adjectives *vert foncé* in (86) and *facile* in (88), on the other hand, both lack morphological inflection, but only the former licenses ellipsis:

(85) *Malheureusement je n'ai pas entendu l' intéressante.
unfortunately I neg have neg heard the interesting
'Unfortunately, I have not heard the interesting one.'

(86) De ces robes, je préfère la vert foncé.
of these dresses, I prefer the green deep
'Of these dresses, I prefer the deep green one.'

(87) Je prendrai la grande.
I will-take the big
'I will take the big one.'

(88) *Le facile se trouve à la page quarante.
the easy itself finds at the page forty.
'The easy one is on page forty.'

To account for these and other contrasts, Sleeman proposes that only the functional head in a SPEC–HEAD agreement relation with a [+partitive] adjective licenses empty N. She distinguishes two classes of partitive words: D-partitives include cardinals, superlatives, ordinals, and words such as *seul*, *autre*, *prochain*, *suivant*. N-partitives include color adjectives and certain others including *grand*, *petit*, etc., all of which license empty N. Other adjectives do not license ellipsis (adjectives of quality, such as *intéressante* and *facile*).

Sleeman also derives the distribution of quantitative *-en* in French from licensing by a [+partitive] functional head. She argues that *-en* is inherently [+partitive],

but that its empty counterpart, *pro*, is not, and must therefore be licensed by a [+partitive] head to be grammatical. It is not enough, however, that *pro* be licensed; it must also be identified by a [+specific] local element in order to be connected with an antecedent. (See Enç 1991 and Diesing 1992b for relevant discussion of specificity. For discussion of *en/ne* see Milner 1978b; Belletti and Rizzi 1981; Hulk 1982; Kayne 1984a; Cardinaletti and Giusti 1992.)

To illustrate, consider the data below:

(89) Trois *pro* arriveront demain.
three will arrive tomorrow.
'Three will arrive tomorrow.'

(90) *J'ai lu trois. *pro*
I have read three *pro*
'I have read three.'

(91) J'en ai lu trois. *pro*
I of it/them have read three
'I have read three.'

Sleeman explains the contrast between (89) and (90) by proposing that although *pro* is licensed by NUM (*trois*) specified as [+partitive], *pro* in (90) is in an indefinite object, and non-specific. The derivation is ruled out because *pro* is not identified. Sleeman assumes that subject DPs are specific, and thus that *pro* in (89) is licensed by a head specified as [+partitive], and is also specific, and thus identified. (91) is the counterpart of (90) where [+partitive, +specific] *en* is inserted, thus saving the derivation.

In (92), *pro* is identified by the [+partitive] PP, which also makes *pro* [+specific] (as noted by Cardinaletti and Giusti 1992). In (93), *pro* is specific because it is in a definite rather than indefinite DP (cf. (90)):

(92) J'ai lu trois *pro* de ses livres.
I have read three of his books
'I have read three of his books.'

(93) Je préfère le troisième *pro*.
I prefer the third
'I prefer the third.'

Sleeman extends her analysis to predict that only [+partitive] adjectives will introduce empty N in *en* constructions. This prediction seems to be borne out, as illustrated by the contrast between (94) and (95):

(94) J'en ai acheté un rouge.
I of it have bought a red
'I have bought a red one.'

(95) *J'en ai rencontré un fâché.
I of it have met an angry
'I have met an angry one.'

In Sleeman's account, only *rouge*, not *fâché*, is [+partitive] and licenses empty N.

Sleeman's analysis makes a number of interesting cross-linguistic predictions, one of which is that partitive adjectives, in contrast to other types of adjectives, should in fact license ellipsis in DP, contrary to Lobeck's claim that adjectives lack strong agreement and fail to license *pro* in English. Sleeman presents the data in (96) in support of this claim (examples are from Halliday and Hasan 1976):

(96) a. Of the boys, I prefer the eldest *pro.*
b. I like your dress. I will buy the same *pro* as you.
c. Take this piece. I will take the other *pro.*
d. The green *pro* suits you very well.

The grammaticality of ellipsis in (96) suggests for Sleeman that *D*-partitive adjectives license *pro* in English. That (97) is ungrammatical is explained by claiming that in contrast to French, *N*-partitive adjectives do not license ellipsis in English, the color adjective in (96) being an exception:

(97) I will take the small *(one).

Sleeman extends her approach to substantive adjectives, arguing that in French, such constructions do not involve a syntactic empty N, though empty N is present at a lexical level. She again diverges from other analyses that argue that substantive adjective constructions involve *pro* licensed by morphological inflection.

5 Conclusion: current research directions

As we can see from the studies discussed here, research on what can now be analyzed as ellipsis in DP has made important contributions to our understanding of the nature of empty categories, the internal structure of the noun phrase, the properties of morphological inflection and semantic features of functional categories in licensing and identification, and the relationships between ellipsis and other phenomena, including partitive constructions (with clitic *ne*/*en*) and substantive adjective constructions.

Some subsequent work on ellipsis in DP, based on the foundations outlined here, includes Coene (1999) on ellipsis in DP in Romanian and Spanish, Giannakidou and Stavrou (1999) on object ellipsis in Greek, Martí Girbau (1999) on partitives and ellipsis in Catalan, López (2000) on ellipsis in DP and D-linking, Luján (2000) and Kester and Sleeman (2002) on an alternative analysis to ellipsis in Spanish, Pollock (1998) and Kupferman (1999) on noun ellipsis and the clitic *en*, and Panagiotidis (2002, 2003a, 2003b) on the status of the empty noun and *one.*

6 Conclusion: directions

1 Introduction: background

Within modern syntactic theory, focus on the importance of a fundamental distinction between root and non-root clauses is primarily associated with Emonds (1970). In this work, Emonds drew a crucial distinction between two types of transformations: structure-preserving and root transformations. The basic idea was that in the general case transformations could only move a node into a position in which a node of that category could be 'base-generated' (an insight that has remained part of syntactic theory). In this sense, transformations are constrained to be 'structure preserving'. However, Emonds maintained that certain transformations did not obey this constraint; these transformations were, however, limited in their application: they could only apply in a 'root sentence', defined as "either the highest S in a tree, an S immediately dominated by the highest S or the reported S in direct discourse" (Emonds 1970: 6).

Three further developments are crucial to defining the question of 'embedded root phenomena' as a current issue in syntactic theory. The first is the observation, first discussed in detail in Hooper and Thompson (1973), that Emonds was factually incorrect in his characterization of the distribution of the phenomena he attributed to root transformations. As discussed below, these phenomena occur also in a subset of embedded contexts. One strand of the literature on embedded root phenomena – beginning with the Hooper and Thompson article itself – is an attempt to define this subset of embedded contexts, and to explain the principle underlying the definition (in particular, whether these contexts are to be defined in functional/pragmatic, semantic, or syntactic terms).

The second crucial development is the proposal, associated above all with the work of Hans den Besten (Den Besten 1983), but also suggested to a greater or lesser extent in Higgins (1973), Williams (1974), Koster (1975), and Emonds (1976), that there is in fact no need for a stipulative distinction between root and non-root transformations. An important subset of Emonds's root transformations is analyzed as involving movement of some element to the Comp[lementizer] position (or to the specifier of CP; the distinction between these two positions was not made in the early work); such movement is blocked by the presence of a lexical complementizer. In this perspective, the root/non-root distinction is only an artifact of the typical, but not entirely general, correlation of lexical complementizers and embedded clauses. The particular phenomenon most famously reanalyzed as a case of movement to Comp is the Germanic Verb Second (V2) phenomenon, in particular as evidenced in German and Dutch; the empirical strength of the analysis is the immediate explanation for the complementarity of V2 and the presence of a lexical complementizer.

The third advance in the research into embedded root phenomena was the determination that Hooper and Thompson's observations concerning the availability of root transformations in embedded clauses in English in fact extended in some cases at least to the other Germanic languages. In particular, in some of the Germanic languages V2 can co-occur with an overt complementizer, at least in a

subset of contexts. Given the syntactic analysis of V2 just mentioned, the question of defining these contexts is now complicated by the question of the syntactic analysis of these cases of 'embedded V2'.

The structure of this chapter is as follows:

- Section 2 first sets out briefly the question of what constitutes a root clause.
- Section 3 gives a characterization of some important 'root phenomena' that have been discussed in the literature.
- Section 4 reviews proposals to explain the distribution of embedded root phenomena in semantic/pragmatic terms.
- Section 5 presents in more detail the phenomenon most prominent in the literature: that of embedded V2.
- Section 6 draws some general conclusions and suggests directions for future research.

2 What constitutes a root clause?

This section presents clear and less clear cases of 'root' or non-embedded clauses:

- the most straightforward cases of the highest matrix clause;
- coordinations of such clauses;
- other 'paratactic' constructions;
- non-restrictive relatives.

Then, in section 3, some root phenomena are presented.

2.1 The canonical case: highest matrix clause

In the simplest case, a root clause is the highest clausal node in a tree (leaving vague precisely which extended projection is at issue). Importantly, given the proposals mentioned in section 1 that the root/embedded distinction is typically an epiphenomenon, the crucial distinction being the presence or absence of a lexical complementizer, instances of root clauses introduced by a complementizer have been pointed out in the literature. (1a, b) are examples from Frisian (De Haan and Weerman 1986: 98); (2) is an example from Dutch (Den Besten 1983: 62), and (3) examples from Swedish (Andersson 1975: 53):

(1) a. Dat it nou altyd sa moast.
that it now always so must
'Why does it always have to be this way?'
b. Wat oft ik drinke woe.
what whether I drink would
'What would I like to drink?'

(2) Gelachen dat we hebben!
laughed that we have
'How we laughed!'

(3) a. Att du aldrig kan lära dig knipa käft.
that you never can teach REFL keep quiet
'[It's annoying that] you can never learn to keep quiet.'
b. Om du bara kunde lära dig knipa käft.
if you only could teach REFL keep quiet
'If you could only learn to keep quiet!'

2.2 Coordination

Coordinately conjoined sentences that are not embedded are also typically taken to be root clauses, where at least 'and', 'or', and 'but' and their translation equivalents are the canonical conjunctions:

(4) a. This book I read, and/but that one I didn't.
b. Up it goes, or down he comes.

Coordination is too large an issue to discuss here, although many aspects of it are clearly relevant. In particular, there is an extensive literature on various aspects of 'asymmetric coordination' in the Germanic V2 languages, one class of which involves V2 (a 'root phenomenon') occurring in the non-initial conjunct of an embedded coordination, as in (5a) from Höhle (1990: 222) (compare with the expected verb-final order in (5b)):

(5) a. Wenn jemand nach Hause kommt, und da steht der
when someone to home comes and there stands the
Gerichtsvollzieher vor der Tür . . .
bailiff at the door
'When someone comes home, and the bailiff is standing there at the door . . .'
b. Wenn jemand nach Hause kommt, und da der Gerichtsvollzieher
when someone to home comes and there the bailiff
vor der Tür steht . . .
at the door stands
'When someone comes home, and the bailiff is standing there at the door . . .'

Conversely, it has been stated that non-initial conjunct matrix clauses in Old English show some features of embedded clauses: in particular, that they are more likely to be verb/Infl-final (see, e.g., Traugott 1972). However, Pintzuk (1991: 321–344) argues that second conjunct matrix clauses in Old English only show an increased rate of Infl-final order when the first conjunct is clearly Infl-final, and hence that the effect is due to parallelism.

2.3 Other types of 'parataxis'

Coordination is the canonical case of 'parataxis': a combination of clauses neither of which is subordinate to the other. There are, however, other cases that have been analysed in this way, even though they lack the symmetry that coordination (sometimes) displays. Three possible cases are adverbial clauses expressing causation, 'so' clauses in English, and free *dass* clauses in German.

2.3.1 Adverbial clauses expressing causation

It has been observed that a number of languages have (at least) a pair of elements expressing a causal link, one of which is followed by a subordinate clause, the other of which is followed by what appears to be a root clause. Among others, this has been argued to be the case for *parce que* and *car* in French, *because* and *for* in English, *weil* and *denn* in German, *därför att* and *ty* in Swedish. The following discussion focuses particularly on German, because in this language the syntactic contrast between root and subordinate clauses is particularly striking; as will be discussed in more detail in section 5, root clauses are associated with V2 word order (the finite verb follows the first constituent in the clause), while in subordinate clauses the verb is final. While the manifestations of subordinate status are different in the other languages, however, the general pattern described below appears to be the same.

Most obviously a clause introduced by *denn* obligatorily shows V2 word order – the order characteristic of complementizerless root clauses:

(6) a. Er ist böse, denn er ist zu früh aufgestanden.
he is angry for he is too early arisen
'He is angry, for he got up too early.'
b. *Er ist böse, denn er zu früh aufgestanden ist.
he is angry for he too early arisen is
'He is angry, for he got up too early.'

Further, a quantifier in the main clause can only very marginally bind a pronoun in the clause introduced by *denn* (7a); this is in contrast to an adverbial clause introduced by *weil* (because) (7b), but like the pattern found in clausal conjunction (7c):

(7) a. *Niemand$_i$ war böse, denn er$_i$ ist zu früh aufgestanden.
No one was angry for he is too early arisen
'No one$_i$ was angry, for he$_i$ got up too early.'
b. Niemand$_i$ war böse, weil er$_i$ zu früh aufgestanden ist.
No one was angry because he too early arisen is
'No one$_i$ was angry because he$_i$ got up too early.'
c. *Niemand$_i$ war böse, und er$_i$ ist spät aufgestanden.
No one was angry and he is late arisen
'No one$_i$ was angry, and he$_i$ got up late.'

Another fact that distinguishes *denn* and its equivalents in other languages from a subordinator like *weil* and its equivalents is that a clause introduced by *denn* cannot appear in initial position:

(8) a. Julia war glücklich, denn alles war gut gegangen.
Julia was happy for everything was well gone
'Julia was happy, for everything had gone well.'
b. *Denn alles war gut gegangen, war Julia glücklich.
for everything was well gone was Julia happy
'For everything had gone well, Julia was happy.'

(9) a. Julia war glücklich, weil alles gut gegangen war.
Julia was happy because everything well gone was
'Julia was happy because everything had gone well.'
b. Weil alles gut gegangen war, war Julia glücklich.
because everything well gone gone was Julia happy
'Because everything had gone well, Julia was happy.'

Elements like *denn* are sometimes classified as conjunctions on the basis of the above patterns. However, there are strong reasons for drawing a distinction between the two cases (essentially this point is made in De Haan 2001, and see also the comments on some English cases in Huddleston and Pullum 2002: 1319ff). The construction with *denn* shows some features which distinguish it both from coordination and from subordination. In particular, *und* (and) can not only coordinate constituents of different syntactic types, it can also coordinate subordinated clauses. In the following example, note both the V-final word order of both conjuncts and the binding of the pronouns by the quantifier *keiner* (no one):

(10) Keiner$_i$ hat gesagt, dass er$_i$ fertig sei, und dass er$_i$ nach Haus
no one has said that he ready is(SBJ) and that he to home
wolle.
wants(SBJ)
'No one$_i$ said that he$_i$ was ready and that he$_i$ wanted to go home.'

In contrast, it appears that *denn* clauses cannot be associated with subordinate clauses. Not only do clauses introduced by *denn* obligatorily show V2 order, as already discussed, but binding of a pronoun in the *denn* clause is never possible from outside the clause, suggesting that the *denn* clause is obligatorily attached at the highest level of the highest clause:

(11) *Keiner$_i$ hat gesagt, dass er$_i$ fertig sei, denn er$_i$ habe die
no one has said that he ready is(SBJ) for he has(SBJ) the
Arbeit rechtzeitig angefangen.
work on time begun
'No one$_i$ said that he$_i$ was ready, for he$_i$ had begun the work on time.'

Note again the contrast with the behavior of a clause introduced by *weil* (because):

(12) Keiner$_i$ hat gesagt, dass er$_i$ fertig sei, weil er$_i$ die Arbeit
no one$_i$ has said that he$_i$ ready is(SBJ) because he$_i$ the work
rechtzeitig angefangen habe.
on time begun has(SBJ)
'No one$_i$ said that he$_i$ was ready because he$_i$ had begun the work on time.'

Correlated with this is the fact that a *denn* clause, unlike for example an adverbial clause introduced by *weil* (because), cannot form part of the same phonological phrase (or 'focus domain') as the clause to which it attaches, but constitutes an independent phonological phrase, as shown by the contrast between (13a) and (14a):

(13) a. Ich bin FROH, weil er gekommen ist.
I am happy because he come is
'I am HAPpy because he came.'
b. Ich bin FROH, weil er geKOMmen ist.
I am happy because he come is
'I am HAPpy, because he CAME.'

(14) a. *Ich bin FROH, denn er ist gekommen
I am happy for he is come
'I am HAPpy for he came.'
b. Ich bin FROH, denn er ist geKOMmen.
I am happy because he is come
'I am HAPpy, for he CAME.'

Although here we see a contrast between *weil* and *denn*, it has been observed that at least in current speech, *weil* may also be followed by a clause with V2 order. Strikingly, when it does, it patterns just like *denn*: the clause it introduces cannot appear in initial position, pronouns it contains can only very marginally be bound from any other clause, and it constitutes an independent phonological phrase (Wegener 1993).

As can be seen from the glosses, the contrasts between *denn* and *weil* clauses hold also for English clauses introduced by 'for' and 'because', modulo the lack of general V2 in English; similar facts in Swedish are observed in the corpus study of Teleman (1967), cited in Andersson (1975).[1]

Although this section focuses on adverbials expressing causation, similar phenomena have been observed with concessives; thus in spoken German V2 word order is also possible after *obwohl* (although) (Wegener 1993). For discussion and analysis of the different interpretations of these cases, and the interaction with phonological phrasing, see Verstraete (1998, 2002) and references therein.

2.3.2 So *clauses in English*

Parataxis is explicitly invoked in Hoeksema and Napoli (1993) to characterize the relation between the clauses in sentences like (15a) ('Para-So'), which they contrast crucially with the subordinative type in (15b) ('Sub-So'):

(15) a. I fainted, the sun was so hot.
b. The sun was so hot that I fainted

Hoeksema and Napoli point out various ways in which the Para-So construction of (15a) behaves like coordination rather than subordination. Among others, these include the possibility of inversion in either or both clauses (contrast (16a, c) with (16b)) and the failure of an "any" quantified noun phrase in the first clause to bind a pronoun in the second (contrast (17a, c) with (17b)):[2]

(16) a. Down fell Mary, so hot was the sun.
b. *The sun was so hot that down fell Mary.
c. Out went Mary and in came John.

(17) a. *Fred didn't hire anyone$_i$ that day, he was so fed up with him$_i$.
b. Fred didn't need anyone$_i$ so badly that he would hire him$_i$ without an interview.
c. *I don't like anyone$_i$ and I certainly don't need him$_i$.

As discussed below, locative inversion is a typical 'root phenomenon', and so is expected in coordinated root clause, but not in a subordinate clause.[3] The failure of binding can also be explained on the assumption that such binding requires c-command, and that nothing within the first conjunct of a coordination c-commands into the second.

On the other hand, the Para-So construction is argued to differ from ordinary coordination in a number of ways, including the fixed order of the two clauses,[4] and the unacceptability of across-the-board movement. The latter point is illustrated in the contrast between (18a) and (18b):

(18) a. *Who$_i$ did you marry t_i, you loved t_i so much?
b. What$_i$ did John buy t_i and Mary borrow t_i?

This construction therefore looks rather more like the constellation we have seen in the last section. As noted there, clauses with *denn/for* or *weil*+V2 order cannot precede their associated clause, and they also do not allow across-the-board movement:

(19) *Who$_i$ did you marry t_i, for you loved t_i so much?

As will be discussed in section 5.2.3.1, however, even the second clause in the 'subordinative' version of this construction (e.g., 16b) shows some evidence of root phenomena.

2.3.3 Free dass *clauses in German*

One further case that might fall under the general rubric of parataxis is that of 'free *dass*' clauses in German, as described in Reis (1997). This construction is illustrated in (20a, b); note, however, that in contrast to the *denn* clauses discussed above, these clauses are obligatorily verb-final:

(20) a. Ist denn etwas los, dass Max so schreit?
is then something up that Max so shouts
'Is something up, that Max is shouting so much?'
b. Er muss im Garten sein, dass er nicht aufmacht.
he must in-the garden be that he not opens
'He must be in the garden, since he's not opening the door.'

Although these clauses are introduced by the complementizer *dass* (that), Reis demonstrates that they do not behave like adverbial adjunct clauses. The following are only two of the various behaviors that she discusses. First, just as in the paratactic *so* construction and *denn*/'for' clauses, the order is fixed. Here the *dass* clause cannot occupy the clause-initial position:

(21) a. Du bist blöd, dass du kommst.
you are stupid that you come
'You are stupid to come.'
b. *Dass du kommst, bist du blöd.
that you come are you stupid
'You are stupid to come.'

Second, free *dass* clauses cannot appear as sentence fragments in question–answer pairs (20a). This is in contrast to clauses introduced by, e.g., *weil* (22b), but similar to clauses introduced by *denn* (22c):

(22) Wieso/Warum ist Fritz blöd?
why is Fritz stupid?
'Why is Fritz stupid?'
a. *Dass er Ernas Nerzmantel bezahlt.
that he Erna's mink coat pays for
'That he's paying for Erna's mink coat.'
b. Weil er Ernas Nerzmantel bezahlt
because he Erna's mink coat pays for
'Because he's paying for Erna's mink coat.'
c. *Denn er bezahlt Ernas Nerzmantel.
for he pays Erna's mink coat
'For he's paying for Erna's mink coat.'

On the other hand, Reis characterizes these clauses as 'relatively' rather than 'absolutely' unintegrated clauses for three reasons. First, free *dass* clauses do not

necessarily form a separate focus domain/phonological phrase; second, they occur before, rather than after, adverbial clauses introduced by *weil* (because); and third – perhaps most strikingly – they can contain a pronoun that is bound by a quantifier in the matrix clause, even in contexts that do not favor the extension of the binding domain of the quantifier (the 'telescoping' phenomenon (Fodor and Sag 1982; Roberts 1987, 1989; Groenendijk and Stokhof 1990; Poesio and Zucchi 1992)):

(23) a. Jeder$_i$ war blöd, dass er$_i$ darauf eingegangen ist.
Everyone$_i$ was stupid that he$_i$ on it went in is
'Everyone was stupid to go along with it.'
b. Keiner$_i$ ist blöd, dass er$_i$ sich um die Zukunft seiner$_i$
no one$_i$ is stupid that he REFL about the future his$_i$
Kinder Sorgen macht.
children worries makes
'No one$_i$ is stupid to worry about the future of his$_i$ children.'

2.4 Non-restrictive relatives

One final environment whose root/non-root status is hard to determine is that of non-restrictive or appositive relatives. Various ways in which non-restrictive relatives behave like coordinated root clauses are discussed in Ross (1986) and subsequently in Emonds (1979); some of these are taken up in Fabb (1990). Again, one might seek to appeal to the possibility of variable binding as a diagnostic for hierarchical position. Emonds pointed out the contrast between the availability of such binding in a restrictive but not in a non-restrictive relative:

(24) a. *I gave every assistant$_i$, who loved his$_i$ uniform, a new one.
b. I gave every assistant$_i$ who loved his$_i$ uniform a new one.

However, Emonds's examples do not make the necessary point, since they instantiate a more general fact: QPs headed by 'every' cannot be the antecedents of non-restrictive relatives at all, irrespective of binding:

(25) *I gave every assistant, who was working for very little pay, a new uniform.

Fabb avoids this problem by looking instead at the distribution of the negative quantifier 'any', which can be licensed by being c-commanded by 'only' (Linebarger 1987). If 'only' appears in the noun phrase, 'any' can appear in a restrictive but not a non-restrictive relative:

(26) a. *Only the tourists, who have any imagination, go to visit Sicily.
b. Only the tourists who have any imagination go to visit Sicily.

Fabb concludes from (26) that the non-restrictive relative cannot be an adjunct within the noun phrase, in contrast to the restrictive relative. However, the same data also make the further point that the non-restrictive relative cannot be in a position c-commanded by the noun phrase "only the tourists," given that (26a) contrasts also with (27):

(27) Only the tourists visited any sites of interest.

This seems to rule out even a structure in which the restricted relative clause is adjoined to the full noun phrase. This conclusion is strengthened by cases of restrictive relatives that seem necessarily to be in this position, and in which 'any' is licensed:[5]

(28) Only [[a man] and [a woman]] who have had any experience of life together will be able to relate to this film.

Further, a pronoun in a non-restrictive relative cannot be bound by a quantified noun phrase that clearly c-commands the modified noun phrase:[6]

(29) Every student$_i$ sent the professor who had helped her$_i$ a card.
*Every student$_i$ sent Professor Smith, who had helped her$_i$, a card.

Fabb's own conclusion is that the relative clause is not in fact syntactically related to the surrounding clause at all, but is only interpreted with it at a level of discourse structure (a conclusion reached also in Sells 1985 and Haegeman 1988; see also Emonds 1979; McCawley 1982; Safir 1986; Napoli 1989). It should, however, be noted that non-restrictive relatives in V2 languages do not show V2 (thus in German, for example, they are verb-final, as noted in Emonds 1979: 216).

3 Some root phenomena

Section 3.1 provides a selective summary of some of the structural root phenomena that have been discussed in the literature:

- structural phenomena in English:
  - VP preposing;
  - negative constituent preposing;
  - topicalization;
  - left dislocation;
  - directional adverb preposing;
  - prepositional phrase substitution;
  - preposing around 'be' and participle preposing;
  - subject auxiliary inversion;

  - direct quote preposing;
  - complement preposing;
  - right dislocation;
  - 'if–then' conditionals;
- structural phenomena in other languages:
  - Verb Second in Germanic;
  - the distribution of the topic markers *-wa* and *-nun* in Japanese and Korean, respectively.

Section 3.2 gives some examples of non-structural root phenomena: speaker-oriented adverbials and interjections.

Then, in section 4, attempts to provide a semantic explanation for the distribution of these phenomena in embedded clauses are presented and discussed.

3.1 Structural phenomena

The phenomena discussed in Emonds (1970) and subsequently in Hooper and Thompson (1973) are primarily instances of movement to the left periphery of the clause. These include the following constructions:

(30) **VP preposing:**
Mary plans for John to marry her, and marry her he will.

(31) **Negative constituent preposing:**
Never in my life have I seen such a crowd.

(32) **Topicalization:**
This book you should read.

(33) **Left dislocation:**
This book, it has the recipe in it.

(34) **Directional adverb preposing and prepositional phrase substitution (also referred to in the literature as locative inversion):**
a. Up the street trotted the dog.
b. On the wall hangs a portrait of Mao.

(35) **Preposing around 'be' and participle preposing (also referred to as predicate fronting):**
a. More significant would be the development of a semantic theory.
b. Standing next to me was the president of the company.

(36) **Subject auxiliary inversion:**
Will James ever finish reading that book?

(37) **Direct quote preposing:**[7]
"I won first prize," Bill exclaimed.

(38) **Complement preposing:**
Syntax and semantics are related, I think.

(39) **Right dislocation:**
You should go to see it, that movie.

Emonds (1970) and Hooper and Thompson (1973) also discuss some other phenomena, for which the reader is referred to the original works.

More recently, Iatridou (1991) has argued that 'if–then' conditionals (as distinct from conditionals where the consequent is not introduced by 'then') are also a root phenomenon. In her analysis, 'then' occupies the Comp position in the consequent clause, and the 'if' clause the Spec[CP] position. Thus, although no movement is involved, under most analyses this case is predicted to fall together with, e.g., left dislocation or Negative Inversion, since the Spec[CP] position is necessarily filled.

The best-studied 'root phenomenon' is not, however, from English at all, but is the V2 construction found in the other Germanic languages. In languages such as German, Dutch, and Frisian the asymmetry between the position of the verb in main and subordinate clause is particularly striking, as illustrated by the German examples in (40):

(40) a. Er weiß nichts davon.
he knows nothing of it
'He knows nothing about it.'
b. . . . dass er nichts davon weiß.
. . . that he nothing of it knows
'. . . that he knows nothing about it.'

Since Den Besten (1983), the most widely accepted account of this contrast is that German and Dutch are OV and Infl-final but Comp-initial, and that when the complementizer position is not filled by an overt element, the finite verb moves to occupy it; further, some other constituent moves to Spec[CP].

The mainland Scandinavian languages (Danish, Norwegian, and Swedish) show a less dramatic asymmetry, since they are not only Comp-initial, but also VO and Infl-medial (though it is not clear whether the verb moves out of the VP in finite clauses unless it continues to move to Comp). However, given these differences, the same assumptions about movement of the finite verb to Comp and of some other element to Spec[CP] can account elegantly for the difference in the order of the negative element and the verb in matrix and subordinate clauses ((41a, b) and (42a, b)), and also for the restriction of non-subject-initial clauses to root position (see in particular Vikner 1995 for analysis and a detailed description of the data). These examples are from Swedish:

(41) a. Lena köpte inte en ny bok igår.
Lena bought not a new book yesterday
'Lena didn't buy a new book yesterday.'
b. *Lena inte köpte en ny bok igår.
Lena not bought a new book yesterday
'Lena didn't buy a new book yesterday.'

(42) a. *Han beklagade att Lena köpte inte en ny bok igår.
he complained that Lena bought not a new book yesterday
'He complained that Lena didn't buy a new book yesterday.'
b. Han beklagade att Lena inte köpte en ny bok igår.
he complained that Lena not bought a new book yesterday
'He complained that Lena didn't buy a new book yesterday.'

(43) a. Dom betvivlar att vi tycker IFK är bäst.
They doubt that we think IFK is best
'They doubt that we think IFK is best.'
b. ?Dom betvivlar att IFK tycker vi är bäst.
They doubt that IFK think we is best
'They doubt that we think IFK is best.'

English allows only very limited V2; the most uncontroversial cases are negative preposing and matrix questions with subject–aux inversion. In Standard English both are root phenomena; subject–aux inversion in embedded questions is, however, found in a number of Hiberno-English dialects: see Henry (1995) for Belfast English, and McCloskey (1992) for other varieties.

Finally, the analysis of V2 in Germanic has inspired similar analyses in other unrelated languages. It has been observed that in Japanese and Korean, topic phrases marked with *-wa* and *nun* respectively, and interpreted non-contrastively, are disallowed in most embedded contexts, and are thus often taken to be root phenomena. Whitman (1989) argues that the distribution of these topic markers is paralleled exactly by the distribution of clause-final modal particles, although this correlation is not completely uncontroversial. He uses this fact to argue that in these languages topics appear in Spec[MoodP]. Whitman further notes that these non-contrastive topics do in fact occur in a number of embedded contexts, and argues for an analysis along the lines of that proposed for Yiddish in Diesing (1990b) (see sections 5.1.3, 5.2.1). His data and analysis are, however, disputed in Choi (2000).

3.2 Non-structural phenomena

To Emond's (1970) and Hooper and Thompson's (1973) list of root phenomena involving movement, Green 1976 adds some phenomena (again, only from English) which do not involve movement but rather the felicity of certain adverbial adjuncts and interjections, typically having to do with speaker attitude. The

following are some examples; again the reader should refer to the original article for additional cases not listed here:

(44) **Evidentiary 'indeed':**
[Assuming languages can have nasal assimilation rules, this is a natural analysis.]
Indeed, languages must have nasal assimilation rules

(45) **Flat 'indeed':**
[Do you have any children?]
Indeed I do.

(46) **'Lo and behold':**
Lo and behold, there was a unicorn among the roses.

(47) **'Frankly':**
Frankly, Bobby Riggs never had a chance.

As Green herself points out, the degree to which these expressions are really restricted to root clauses varies.

Further cases are given in Banfield (1982), and similar examples can be found for other languages. Reis (1997) gives examples with German *nämlich* (in fact), and Andersson (1975) discusses various adverbials and interjections in Swedish including *för guds skull* (for God's sake), *din idiot* (you idiot), *tyvärr* (unfortunately), and *härmed* (hereby).

4 Semantic/pragmatic explanations for the distribution of embedded root phenomena

As mentioned in the introduction, the issue that arises as soon as 'embedded root phenomena' are recognized is whether there is any systematicity to their distribution, and if so, how it can be characterized. In their work on embedded root phenomena, Hooper and Thompson propose a semantic characterization of the distribution of root phenomena: these occur only in clauses that are asserted (Hooper and Thompson 1973: 472). By their own admission, Hooper and Thompson do not give "an absolute definition" of what constitutes an asserted clause. They state that the assertion of a sentence is "its core meaning or main proposition," and that it "may be identified as that part which can be negated or questioned by the usual application of the processes of negation and interrogation." Sentences may contain more than one assertion (in the case of a coordination, for example); also (crucially), some subordinate clauses are asserted. Based on this notion of assertion, they provide a five-way division of predicates taking sentential complements or sentential subjects:

- Class A predicates (e.g., 'say', 'report', 'be true', 'be obvious'). The verbs in this group are all verbs of saying. Both the verbs and the adjectives in this group can function 'parenthetically', in which case the subordinate clause constitutes the main assertion of the sentence. It is claimed, however, that if the subordinate clause occurs in subject position (as in, e.g., *That German beer is better than American beer is true*) it is not asserted.
- Class B predicates (e.g., 'suppose', 'expect', 'it seems', 'it appears'). In this group also the predicates can function parenthetically, and in this case the subordinate clause is asserted. The distinction between this class and Class A is not made entirely clear, although it is noted that Class B predicates allow 'Neg raising' and tag questions based on the subordinate clause.
- Class C predicates (e.g., 'be (un)likely', 'be (im)possible', 'doubt', 'deny') have complements which are not asserted.
- Class D predicates (e.g., 'resent', 'regret', 'be odd', 'be strange'). These factive predicates have complements which are argued to be presupposed, and hence not asserted.
- Class E predicates (e.g., 'realize', 'know'). These semifactives (factives that lose their factivity in questions and conditionals) have a reading on which the subordinate clause is asserted.

Further, Hooper and Thompson claim that 'reduced' clauses (infinitives, gerunds, and subjunctive clauses) are never asserted, nor are noun complement clauses. Restrictive relative clauses on definite heads are argued to be presupposed (and therefore never asserted); non-restrictive relatives, and restrictive relatives on indefinite heads, are not presupposed (and may be asserted). Adverbial clauses may or may not be asserted (and in some cases may force the main clause itself to be read as presupposed, and hence not asserted (1973: 486–495)).

In addition to claiming that the environments allowing root phenomena must be characterized in terms of a semantic concept of 'assertion', Hooper and Thompson claim that there is a pragmatic explanation for the restriction of 'root transformations' to these environments: these transformations, it is claimed, all have the function of emphasizing a particular constituent (1973: 470), and "emphasis would be unacceptable in clauses that are not asserted" (1973: 472).

Hooper and Thompson's claim that root phenomena can occur in all and only asserted clauses is disputed in Green (1976). Green points out that in at least some cases their claim that a particular clause is asserted is backed up only by the grammaticality of some root transformation occurring in it – clearly a circular argument – and also that some root phenomena occur in the complements to the counterfactive 'pretend' and to the performatives, like 'bet', 'promise', and 'predict' (1973: 390–391). Green herself puts forward a pragmatic hypothesis – that embedded root phenomena are licensed "just in case the proposition they affect, and therefore emphasize, is one which the speaker supports" (1973: 386) – but she argues that this is only one constraint out of many affecting the acceptability of these phenomena.

It is a general problem for work in this area that definitions given are vague and independent evidence for the validity of the concepts used often weak. Subsequent researchers have proposed various modifications of Hooper and Thompson's proposal that "assertion" is a necessary and sufficient condition for the occurrence of root phenomena. Based on data from Swedish, Andersson (1975) argues that the relevant semantic distinction is between clauses that make a statement, ask a question, or give a command (his class of 'semantically main clauses') and those that perform none of these functions ('semantically subordinate clauses'). He also proposes that the non-negative predicates in Class C belong more properly in Class B, while negated Class B predicates belong in Class C. Later work on Germanic has sometimes included further variants of these proposals (see for example Iatridou and Kroch 1992), although typically such work is restricted to finding a basis for the classification of predicates that allow root phenomena in their complements, rather than finding a single semantic concept that will also extend to other syntactic environments ('reduced' clauses, relatives, clauses in subject position, etc.). This is because work on V2 in particular (including that of Andersson 1975) has led to the conclusion that there is an irreducibly syntactic aspect to the distribution of at least the structural root phenomena. A detailed discussion of the verbs in Danish and German that do and do not allow V2 in their complements can be found in Vikner (1995: 71f, and see references therein); Vikner's own conclusion is that there is no single semantic concept that can predict the patterns he reports.

The second aspect of Hooper and Thompson's analysis – that the failure of root transformations to occur in non-asserted clauses is due to the pragmatic incompatibility of emphasis with non-assertion – has not been pursued in subsequent literature. In fact there is counter-evidence to this claim in their own article. They point out that emphasis can be achieved by other means, including clefting (*It's this book that you should read*), and they further point out that clefting is a 'structure preserving transformation', so that Emonds's (1970) proposal would predict, correctly, that it can occur quite generally in embedded contexts. But their proposal appears to be precisely an attempt to to *derive* a (modified version of) Emonds's generalization about the limited distribution of 'non-structure preserving' transformations from an interaction of semantic and pragmatic considerations:

> [W]e can say that these transformations operate only on Ss that are asserted. R[oot] T[ransformation]s are not applicable in presupposed sentences because it is not appropriate to emphasize elements of a sentence whose proposition is already known, whose truth is presupposed, and whose content is relegated to the background.
>
> [. . . A] definition of root transformation in terms of its linguistic function rather than in terms of syntactic structures enables us to explain the otherwise mysterious facts about its applicability. (1973: 496)

If the explanation for the distribution of root transformations is really entirely semantic/functional, then it should apply equally to other constructions that have the same semantic/functional properties, regardless of their status as

'structure preserving'.[8] Hence the felicity of, e.g., clefting in presupposed clauses (e.g., *We regretted that it was precisely this book that had been destroyed*) does constitute evidence against this aspect of their analysis.

5 Embedded Verb Second

This section discusses in some detail the most-studied syntactic root phenomenon: Germanic V2:

- Section 5.1 sets out the main characteristics of embedded V2.
- Section 5.2 presents and discusses analyses that have been proposed.

Then, in section 6, some general conclusions are drawn, and directions for further research suggested.

5.1 The phenomena

This section discusses four main aspects of embedded V2:

- the original observation that the correct generalization about V2 is that it is in complementary distribution with complementizers;
- languages in which this complementarity does not hold in a restricted set of embedded clauses (Frisian, Mainland Scandinavian);
- languages in which this complementarity has been argued not to hold in general (Icelandic, Yiddish);
- the distribution of embedded V2 clauses in German.

5.1.1 The complementary distribution of overt complementizers and V2

The V2 phenomenon itself is sketched above in section 3.1. As mentioned in section 3.1, following the work of Den Besten, it has been generally accepted that the restriction of V2 to root sentences is in fact an epiphenomenon; the real asymmetry is between sentences with and without overt complementizers. V2 is analyzed as the effect of the tensed verb moving to the empty Comp position, and some XP moving to Spec[CP].

This analysis predicts straightforwardly the complementary distribution of an overt complementizer and verb-fronting found in German. However, there is a set of exceptions to this complementarity in a number of other Germanic languages, which have been grouped into two classes. Mainland Scandinavian and Frisian fall into one class, Yiddish and Icelandic into another.

5.1.2 Limited embedded V2: Frisian and Mainland Scandinavian

This section sets out the distribution of embedded V2 in Frisian and Mainland Scandinavian to the extent that it has been established to be similar or identical in these languages. Some possible points of difference will be discussed in section

5.2.3.3. For reasons that will become clear, this pattern is referred to by Vikner (1991, 1995) as 'limited embedded V2'.

In de Haan and Weerman (1986) it is pointed out that in Frisian, a verb-final West Germanic language, V2 can occur in subordinate clauses introduced by a complementizer:

(48) Ik leau dat hy kin him wol rêde.
I believe that he can himself surely save
'I believe that he can take care of himself.'

However, the occurrence of such clauses is restricted:

- First, they occur after verbs of saying and thinking, such as *sizze* (say), *roppe* (call), *tinke* (think), *leauwe* (believe), but not after *hoopje* (hope), *wite* (know), *ferwachtsje* (expect), or *spite* (regret).
- Further, they cannot follow even verbs in the first group if these are negated, modalized (de Haan and Weerman 1986) or questioned (de Haan 2001).
- They are not in general possible as adjuncts (with the exception of rationale clauses introduced by *om't*, *omdat*, or *omreden dat*, and extent clauses licensed by *sa*+degree phrase (de Haan 2001: 6))
- They cannot occur in subject position (Iatridou and Kroch 1992).
- Nor can they be moved into the initial 'topic' position from complement position (de Haan 2001: 10).

The last point is illustrated in (49); this example also illustrates a root phenomenon particular to Frisian: the subject pronoun in the subordinate clause is different in the two sentences, as the clitic *er* cannot appear in the position immediately following the complementizer in an embedded V2 clause, just as it cannot appear in the initial position of a root clause:

(49) a. Dat er it antwurd net witen hie, sei er.
that he the answer not known had said he
'He said that he hadn't known the answer.'
b. *Dat hy hie it antwurd net witten, sei er.
that he had the answer not known said he
'He said that he hadn't known the answer.'

In Mainland Scandinavian (Danish, Norwegian, and Swedish) the distribution of embedded V2 is very similar to that of Frisian. V2 clauses introduced by a complementizer can only appear as the complements of a restricted set of verbs (as in Frisian, these verbs are a subset of the 'bridge' verbs that allow extraction). This restriction is discussed in detail for Danish in Vikner (1991, 1995), where it is noted, however, that the exact list of verbs that allow embedded V2 is not identical from language to language (Vikner 1995: 70–72). In particular, as in Frisian, inherently negative verbs (such as *doubt*, *deny*, *regret*) or verbs taking irrealis complements do not license embedded V2; and again, even the subset of

bridge verbs that allow embedded V2 do not license it when negated or modalized. Whether or not questioning the verb in the matrix clause makes V2 impossible in its complement clause is not clear from the available literature. As in Frisian, V2 clauses are not possible as adjuncts, as sentential subjects (Iatridou and Kroch 1992), or as topicalized complements. Good exemplification of the data for Swedish can be found in Andersson (1975).

5.1.3 General embedded V2: Icelandic and Yiddish

In Icelandic and Yiddish it has been argued that V2 is found generally in subordinate clauses. There is no restriction to the complement position of a particular set of 'bridge verbs'; V2 clauses can also appear in a variety of non-complement clauses, including relative clauses, and clauses in adjunct and subject position (Diesing 1988b, 1990; Rögnvaldsson and Thráinsson 1990; Vikner 1991, 1995; Santorini 1989, 1992; Iatridou and Kroch 1992).

5.1.4 Embedded V2 with obligatorily absent complementizer: German and Frisian

The instances of embedded V2 mentioned in sections 5.1.2 and 5.1.3 are a challenge to the analysis of V2 as involving movement of the finite verb to an unfilled complementizer position, since in all the cases discussed there V2 takes place below an overt complementizer. German also allows embedded V2, but in this case it is only possible when the complementizer is absent, as predicted by the standard analysis outlined in sections 3.1 and 5.5.1 (Vikner 1995). In fact in Frisian also embedded V2 clauses are only optionally introduced by the complementizer *dat* (that); further, there are dialects of Frisian in which, like German, embedded V2 is only possible if the complementizer is absent (Sipma 1913; de Haan 2001). The following data are from German:

(50) a. Sie sagte, daß sie keine Bücher kaufen wolle.
she said that she no books buy wants(SBJ)
'She said that she didn't want to buy any books.'

b. Sie sagte, sie wolle keine Bücher kaufen.
she said she wants(SBJ) no books buy
'She said she didn't want to buy any books.'

c. *Sie sagte, daß sie wolle keine Bücher kaufen.
she said that she wants(SBJ) no books buy
'She said that she didn't want to buy any books.'

d. *Sie sagte, sie keine Bücher kaufen wolle.
she said she no book buy wants
'She said she didn't want to buy any books.'

In other respects, German is typically described as being more like the 'limited V2' languages discussed in section 5.1.2: embedded V2 only occurs in the complements of a subset of 'bridge' verbs (Vikner 1995; Reis 1997), and subordinate clauses with V2 order cannot appear in subject or topic position (Reis 1997).

There are, however, a number of exceptions to these generalizations (Beatrice Santorini, p.c.). Some nouns allow V2 complements:

(51) der Glaube, die Erde sei flach
the belief the earth is(SBJ) flat
'the belief that the earth is flat'

V2 clauses seem also to appear in topic position:

(52) Er habe nichts zu verlieren, sagte er mir.
he has(SBJ) nothing to lose said he me(DAT)
'He had nothing to lose, he told me.'

However, when a V2 clause does appear in the initial position as in (53b), it may not contain a pronoun bound by a quantifier in the other clause (Reis 1997: 139), unlike a V2 clause that has been extraposed to the right (53a) or a verb-final clause whether extraposed or in initial position (53c):

(53) a. Jeder$_i$ möchte gern glauben, er$_i$ sei unheimlich beliebt.
everyone would gladly believe he is(SBJ) very much popular
'Everyone$_i$ would like to believe he$_i$ is extremely popular.'
b. *Er$_i$ sei unheimlich beliebt, möchte jeder$_i$ gern glauben.
he is(SBJ) very much popular would everyone gladly believe
'He$_i$ is extremely popular, everyone$_i$ would like to believe.'
c. Dass er$_i$ unheimlich beliebt sei, möchte jeder$_i$ gern glauben.
that he very much popular is(SBJ) would everyone gladly believe
'That he$_i$ is extremely popular, everyone$_i$ would like to believe.'

Reis's conclusion is that examples like (52) and (53b) are not topicalizations of complement clauses, but that the V2 clauses are main clauses, with the verb of saying part of a V1 parenthetical (note that the subjunctive may appear in root clauses in German).

It should also be noted that in German V2 clauses may appear as the complements to verbs that are negated (54a), modalized (54b), and questioned (54c):

(54) a. Er sagte nicht, er sei fertig.
he said not he is(SBJ) ready
'He didn't say he was ready.'
b. Er würde sagen er sei fertig.
he would say he is(SBJ) ready
'He would say he was ready.'
c. Sagte er, er sei fertig?
said he he is(SBJ) ready
'Did he say he was ready?'

The similarity in distribution of German embedded V2 and the limited embedded V2 found in Frisian and Mainland Scandinavian, described in section 5.1.2, is therefore only partial.

The description of embedded V2 in Frisian that has been given so far is in fact an oversimplification: in addition to the pattern described in section 5.1.2, Frisian also displays the German pattern. That is, if the complementizer is absent, and if there is no intonation break, embedded V2 is possible even if the matrix verb is negated or modalized, and binding of a pronoun within the complement clause is also grammatical (De Haan 2001: 34).

Overall, the German pattern of embedded V2 appears to provide strong evidence for the idea that V2 is not a 'root' phenomenon, but derives instead from the absence of an overt complementizer, an absence which does not correlate perfectly with 'root' status. Rather surprisingly, in den Besten (1983) this conclusion is not drawn; instead den Besten claims that the type of sentence illustrated in (50b) and (54a–c) is not in fact a subordinate clause at all, but rather has essentially the syntax of a direct quotation, despite the occurrence of the subjunctive and the pronominalization pattern. There are, however, strong arguments against this conclusion, including the fact that some of the verbs that can be followed by V2 complements do not allow direct quotations (e.g., *annehmen* 'realize') (Reis 1997). Thus, alongside the examples in section 2.1 of 'non-root' phenomena occurring in 'root' clauses, just when these have an overt complementizer (or a *wh*-word), these German cases appear to be perfect examples of a root phenomenon occurring in embedded clauses just in cases where these lack an overt complementizer (or *wh*-word).

5.2 *Analyses and issues*

This section presents and discusses some of the important issues that have arisen in the analysis of the phenomena discussed in the last section:

- Does V2 under a complementizer always involve recursion of CP, or may it result from a topic position lower than [Spec,CP]?
- What licenses CP recursion?
- Three remaining theoretical questions:
  - How can the behaviour of the 'so . . . that' construction be reconciled with generalizations concerning the distribution of CP recursion?
  - How can an account of embedded V2 in terms of the licensing of CP recursion simultaneously explain the obligatory absence of a lexical complementizer in German and its obligatory presence in Mainland Scandinavian?
  - What is the attachment site of the V2 clause?

5.2.1 *Generalized CP recursion vs. different 'topic' positions*

There is widespread agreement in the literature that the type of embedded V2 found in Mainland Scandinavian and Frisian (limited embedded V2 below an

overt complementizer) is to be explained by the hypothesis that there can be recursion of CP: that is, that the overt complementizer takes as its complement another CP. This clearly allows for the retention of the idea that the finite verb in a V2 clause is in C (in this case, the head of the lower CP projection) and the initial XP in the Specifier of this lower CP. This hypothesis is defended in Holmberg (1986) and Platzack (1986) for Swedish; de Haan and Weerman (1986), Iatridou and Kroch (1992) for Frisian; and Vikner (1991, 1995) and Iatridou and Kroch (1992) for Danish.

More controversial is the correct analysis of the type of embedded V2 found in Icelandic and Yiddish (general embedded V2). Various analyses have been put forward, but they can be divided into two types of approach. In the approach defended most extensively by Vikner (1991, 1995), general and limited V2 should be given a unitary analysis: both types involve CP recursion. In all cases the finite verb is in C and the XP preceding it in the Specifier of this CP; the complementizer is the head of a higher CP. Vikner argues that general embedded V2 arises in a V2 language if and only if the language has both a right-branching IP (e.g., all Scandinavian languages and Yiddish, but not, for example, Dutch, Frisian, or German), and movement of the finite verb to I (e.g., Icelandic, Yiddish, but not Mainland Scandinavian). The reason for this correlation, Vikner proposes, is that a child exposed to such a language has no basis for postulating a difference between root and non-root clauses (Vikner 1995: 159–163).

In the second approach to general embedded V2, it is assumed that in these languages the domain of V2 is not CP, but some smaller clausal constituent. Thus Diesing (1988b, 1990) and Santorini (1989, 1992) have argued for Yiddish, and Rönvaldsson and Thráinsson (1990) for Icelandic, that in these languages the finite verb in a V2 sentence is in I, and the clause-initial XP in Spec[IP], the subject remaining in its VP-internal subject position. Given the explosion of I into a number of distinct functional heads, there are variants of this analysis according to which the subject does not remain within VP but moves into a higher specifier, and the finite verb occupies one of these functional head positions (see for example Thráinsson 1994); the crucial point here, however, is that the verb does not occupy the Comp position, so that no complementary distribution of V2 and overt complementizer is expected.

5.2.2 What limits/licenses CP recursion?

Although there has been considerable debate as to whether CP-recursion is the correct analysis for Yiddish and Icelandic, there has been much less discussion of the basis for the limitations on CP-recursion found in those languages for which it has become a relatively standard analysis for embedded V2 – that is, the languages with limited embedded V2. If CP is a possible complement for Comp, why are there language-internal restrictions on this recursion? Given the demonstrated similarity in these restrictions, what underlying principle could be responsible? Essentially this is a revised version of part of the question addressed in Hooper and Thompson (1973): what is the correct characterization of the contexts licensing CP recursion, and does this characterization lead to an explanation?

Both Authier (1992) and Iatridou (1991) point out that CP recursion in English declarative complements is only possible in environments that also allow 'that' deletion (i.e., environments where a declarative subordinate clause need not be introduced by an overt complementizer). Given prior arguments that 'that' deletion is only possible in CPs governed by a verb, they conclude that this is also a necessary condition for CP recursion. However, more must be said to explain the absence of CP recursion in, e.g., the complements to negative verbs. Basing themselves on the proposal in Laka (1990) that negative and negated verbs select a negative complementizer (and Hegarty's related 1992b proposal for certain factive verbs), Iatridou and Kroch (1992) propose that only semantically empty CPs – or at least, those whose content can be recovered from the lower CP – can be deleted at LF, and only when governed by a verb. If there are two CPs and the higher cannot delete (because there is material in its specifier, or because it has content that cannot be so recovered), then the lower CP is unlicensed.

5.2.3 Some remaining questions

5.2.3.1 The status of the 'so . . . that' construction

One known exception to the generalization that CP recursion is only possible in positions governed by a verb is a particular type of extent clause in Frisian (the following example is from de Haan and Weerman 1986):

(55) Hy is sa meager (dat) hy kin wol efter in reid skûlje.
he is so thin (that) he can well behind a cane hide
'He is so thin that he can hide behind a cane.'

Such examples clearly do not fall under Iatridou and Kroch's (and Authier's) generalization that CP recursion is possible only under government from a verb. Observing that this construction does not license CP recursion in Danish, Iatridou and Kroch conjecture that *dat* (that) in Frisian may have a second lexical entry as a 'coordinating particle'. However, it should be noted that the same construction in English also shows some signs of allowing CP recursion (contra the claims of Hoeksema and Napoli 1993, discussed in section 2.3.2, that this is a clear case of subordination):

(56) a. This kind of equation is so complex that if it has one solution, then it probably has several. ('if–then')
b. She was so happy that off she ran without looking behind her. (locative inversion)
c. Humphrey was so rich that in no circumstances would he use anything other than cash. (negative preposing)

When there is no evidence for CP recursion this construction does not require a complementizer in English, so at least that correlation is maintained (the putative restriction of complementizerless subordinate clauses in English to the

complements of bridge verbs is, however, known to admit relatively common counter-examples, and intuitions about, e.g., complement clauses to nouns are not strong). Thus the example in note 3, repeated here as (57), could potentially be taken to be either an 'inverted' case of the paratactic *so* construction or an instance of subordination plus 'complementizer drop':

(57) The sun was so hot she fainted.

Dutch also allows V2 in the extent clause when the complementizer is absent (Jack Hoeksema, p.c.):[9]

(58) a. Ik werd helemaal nat, zo hard regende het.
I became completely wet so hard rained it
'I got soaked, it rained so hard.'
b. Het regende zo hard, ik werd helemaal nat.
it rained so hard I became completely wet
'It rained so hard I got soaked.'

Van Kemenade (1997: 342) also cites in passing an example of embedded verb movement to C in early Middle English in an extent clause of this type:

(59) þat al is hare blisse se muchel þat ne mei hit munne na muð
that all is their bliss so great that not may it mention no mouth
'that all their bliss is so great that no mouth may mention it'

German, on the other hand, does not allow V2 in an extraposed extent clause (Beatrice Santorini, p.c.). Thus (60b) contrasts with its Frisian and Dutch counterparts in (55) and (58b) above:

(60) a. Er ist so mager, dass er sich hinter einem Schilfrohr verstecken kann.
he is so thin that he REFL behind a cane hide can
'He is so thin that he can hide behind a cane.'
b. *Er ist so mager, er kann sich hinter einem Schilfrohr verstecken.
he is so thin he can REFL behind a cane hide
'He is so thin he can hide behind a cane.'

However, the German counterpart of (58a), where the extent clause is initial, is fully grammatical:

(61) Er kann sich hinter einem Schilfrohr verstecken, so mager ist er.
He can REFL behind a cane hide so thin is he
'He can hide behind a cane, he is so thin.'

This construction then poses unresolved problems for attempts to provide a unified analysis of the distribution of CP recursion.

5.2.3.2 The presence and absence of the overt complementizer

As discussed in section 5.1.4, embedded V2 in German occurs only in the absence of a complementizer. Vikner (1995: 84) points out that there is therefore no reason to hypothesize any kind of CP recursion in this case. However, there is at least some degree of similarity in the distribution of embedded V2 in German and that found in the other 'limited embedded V2 languages' (section 5.1.2), although as noted in section 5.1.4 there are limits to the similarity. If we assume that the similarity needs to be accounted for, we have to ask how this is to be achieved. The proposal in Iatridou and Kroch (1992) suggests a possible analysis. As just discussed, this account adopts Laka's hypothesis of a distinct negative complementizer (and in addition also irrealis and factive complementizers); in contrast to Basque, however, where there is an overt morphological distinction, these complementizers in, e.g., Mainland Scandinavian must be homophonous with the 'unmarked' affirmative declarative one. If we assume that in German the phonetically empty Comp head that hosts the features inducing V2 also carries these affirmative declarative features, but that only the overt complementizer instantiates the negative, irrealis, or factive features, this could explain the lexical restriction on embedded V2.

What would still remain unexplained under this proposal is the unacceptability of embedded V2 in German in positions not governed by a verb. In Iatridou's and Kroch's account, the lack of CP recursion in, e.g., sentential subject position, or the Spec[CP] topic position, follows from the hypothesis that only government by a verb allows for the LF deletion of the topmost CP. But this proposal would not extend to the German case, if V2 in this language does not involve CP recursion at all. An alternative would be to assume instead that the affirmative declarative features in the lower Comp (in the CP recursion context) or on the null Comp (in the German case) have to be licensed under government by a verb.

The issue just raised for German was how to explain the similar distribution of embedded V2 in that language despite any evidence for a recursive CP. Conversely, it also remains to be explained why in the mainland Scandinavian languages and English (but not Frisian: see section 5.1.4) root phenomena in embedded CPs *require* the presence of an overt complementizer. (See Grimshaw 1997b for an explanation for the English case, and Vikner 1995: 84f. for a brief discussion of the Danish facts illustrated in (63), where the complementizer is obligatory only if V2 has applied. The situation is different in Swedish: the complementizer *att* may be omitted whether or not the following clause shows V2.)

(62) a. She believed (that) he would never let her down.
b. She believed *(that) never would he let her down.

(63) a. Hun sagde ??(at) vi skulle ikke købe denne bog.
she said (that) we should not buy this book
'She said that we shouldn't buy this book.'

b. Hun sagde (at) vi ikke skulle købe denne bog.
she said (that) we not should buy this book
'She said that we shouldn't buy this book.'

There are two aspects to this question: the first is why CP recursion is required (that is, why these languages do not behave like German (section 5.1.4)). Even if this is explained, however, a second question arises: why the higher C should delete only at LF and not at PF also, given that some kind of PF Comp deletion has been taken to be the explanation for the optional appearance of 'that' in sentences like (62a) above. A possible explanation for English might be that PF Comp deletion is not the right analysis for (62a), but rather that we need to assume the existence of a zero complementizer. As proposed in Rizzi (1990b), for quite different reasons, this complementizer has a rather richer feature content than its apparent overt counterpart 'that', since it can agree with its specifier (this is the basis for his account of the 'that-trace' phenomenon). If this richer feature content were enough to prevent LF-deletion, that would explain its failure to license CP recursion.

5.2.3.3 The position of the V2 constituent

Leaving aside Yiddish and Icelandic (the languages in which V2 appears in all types of subordinate clause, and which therefore does not appear to be a root phenomeonon), we have found the following examples of embedded V2:

(i) V2 in certain adverbial clauses (most commonly those expressing causation);
(ii) V2 after an optional complementizer (dat) in extent clauses in Frisian and possibly some other languages;
(iii) V2 after an (obligatory) (Danish, Norwegian(?)), or optional (Frisian, Swedish) complementizer in the complement of certain verbs;
(iv) V2 in the complement of certain verbs only when the complementizer is absent (German, Frisian).

We have seen that there is evidence that the type in (i) is attached at a very high point in the structure of the matrix clause (in fact all the evidence indicates that it must be high enough to be outside the scope of any element in the *root* clause). The same is true for the type in (ii).

With respect to the type in (iv) Reis (1997) argues for German (and de Haan 2001 duplicates most of the arguments for the corresponding cases in Frisian) that the attachment site is relatively low: in particular, such clauses obligatorily precede adverbial clauses. This is true even when the latter take scope lower than the subject. In (64), in addition to a reading where the rationale clause modifies the V2 complement clause, there is a grammatical reading where it modifies the matrix – but must still be attached low enough to allow the pronouns in it to be bound:

(64) Keiner$_i$ hat gesagt, er$_i$ komme, bloß weil er$_i$ seine$_i$ Mutter
no one has said he comes just because he his mother
glücklich machen wollte.
happy make wanted
'No one said he was coming just because he wanted to make his mother happy.'

Further, as (64) shows and as Reis also points out, a quantifier in the matrix can bind a pronoun in the V2 clause, again suggesting that the V2 clause attaches low (although it cannot topicalize with the VP, unlike a complement (1997: 140)). Reis's own conclusion is that embedded V2 clauses of this type have exactly the same status (and occupy the same hierarchical position) as the free *dass* clauses discussed above in section 2.3.3.

What about the cases in (iii): that is, embedded V2 in complement clauses in the Mainland Scandinavian languages and the subset of cases in Frisian where the complementizer can appear? De Haan 2001 argues that the Frisian cases should be assimilated to the types in (i) and (ii), and that in all cases the position of the 'embedded' V2 clauses is very high. In fact, he argues that the V2 clause has to attach at the same level as a root CP, to which it stands in a paratactic relation. Among other evidence, in Frisian a quantified subject in the matrix cannot bind a pronoun in the V2 clause, as shown by the contrast in (65):

(65) a. [Ider fan ús]$_i$ sei dat er$_i$ it net wist.
each of us said that he it not knew
'[Each of us]$_i$ said that he$_i$ didn't know it.'
b. *[Ider fan ús]$_i$ sei dat hy$_i$ wist it net.
each of us said that he knew it not
'[Each of us]$_i$ said that he$_i$ didn't know it.'

Further, the clause containing the verb selecting the recursive CP must itself be a V2 clause:

(66) a. Niis sei Teake (dat) hy hie it net witten.
a minute ago said Teake (that) he had it not known
'A minute ago Teake said that he hadn't know that.'
b. *Ik tocht dat Teake niis sei (dat) hy hie it net witten.
I thought that Teake a minute ago said (that) he had it not known
'I thought that Teake said a minute ago that he hadn't known that.'

Preliminary investigation suggests that Dutch embedded V2 is similar to Frisian in these respects. A matrix quantifier cannot bind a pronoun in a V2 extent clause in the 'so . . . that' construction (67b), or in a V2 complement to a verb of assertion (68b) (Jack Hoeksema, p.c.):[10]

(67) a. Iedereen$_i$/niemand$_i$ was zo blij, dat hij$_i$ een gat in de
everyone/no one was so happy that he a hole in the
lucht sprong.
sky jumped
'Everyone$_i$/No one$_i$ was so happy that he$_i$ jumped for joy.'
b. *Iedereen$_i$/niemand$_i$ was zo blij, hij$_i$ sprong een gat in
everyone/no one was so happy he jumped a hole in
de lucht.
the sky
'Everyone$_i$/no one$_i$ was so happy he$_i$ jumped for joy.'

(68) a. Niemand$_i$ zei dat hij$_i$ geen tijd had.
no one said that he no time had
'No one$_i$ said that he$_i$ didn't have time.'
b. *Niemand$_i$ zei hij$_i$ had geen tijd.
no one said he had no time
'No one$_i$ said he$_i$ didn't have time.'

The facts from Mainland Scandinavian remain to be fully explored.

6 Conclusion: directions

Some of the initial work on embedded root phenomena – in particular the article by Hooper and Thompson (1973) – was very ambitious in its scope, aiming to provide a single unified account both for the existence and for the exact distribution of these phenomena. On the other hand, initially the data were exclusively from English, a significant limitation. Some of the major advances in our understanding of these phenomena have come from the introduction of data from other languages, although detailed comparison with data from non-Germanic languages is still required. Despite the widening of the range of languages, the more recent syntactic work has tended to leave aside issues of interpretation.

There is, however, an irreducibly semantic/pragmatic component to the puzzle; although the initial analyses in terms of 'assertion' presented many problems of definition and explanation, no later work that has attempted to go beyond the stipulation of environments in which the various root phenomena obtain has been able to do without appeals to concepts such as factivity, assertion, presupposition, etc. A great deal of progress has been made in understanding the syntax of embedded root phenomena, in particular embedded V2: this progress has come through detailed empirical work on particular languages, and through advances in syntactic theory. However, some of the fundamental questions remain unanswered, and in fact practically unaddressed. In particular, what is the precise nature of the distinction between non-root and root clauses? As we have seen, work on V2 has overwhelmingly followed the proposal that the real distinction is between clauses with complementizers and those without. But while

this proposal has been extremely productive, in one sense it simply pushes the original question one level down: why should there be such a strong (but imperfect) correlation between root clauses and empty complementizer positions?

Progress on this question is likely to come from work on the syntactic encoding of discourse semantic concepts. One version of Hooper and Thompson's (1973) proposal about the association of root-clause phenomena with assertion is that root clauses have their own illocutionary force, while truly subordinated clauses do not. There is a strand of work in modern syntax that has begun to explore the syntactic encoding of such discourse semantic concepts as illocutionary force. Han (2000), citing Sadock and Zwicky (1985) and Palmer (1986), points out that imperatives (morphologically marked as such) are one root phenomenon that never occurs in an embedded context. She attributes this to the existence of an imperative operator located in Comp that includes a feature for the illocutionary feature 'directive', and the assumption that illocutionary force can only be expressed in unembedded clauses (2000: 150ff.). Haegeman (forthcoming), developing proposals about the detailed substructure of the left periphery due to Rizzi (1997), proposes that there is a distinct functional head associated with illocutionary force, and that some clauses are 'truncated' and therefore lack this projection, as well as others associated with, e.g., topicalization.

Much more work needs to be done in this area, on both the syntactic and the semantic side (and also on the correlated intonational distinctions). One obvious question on the semantic side is what it means for a verb complement clause (as opposed to an adverbial clause, where the question is perhaps less difficult) to be 'asserted'. After all, the speaker makes no commitment to the truth of the proposition expressed in the verb complement clause (in fact, as we have seen, factive verbs are typically excluded from this construction). In what sense then is it meaningful to say that these clauses express illocutionary acts of assertion? It seems that it might well be profitable to compare these cases to the 'style indirect libre'. There are some equally obvious questions on the syntactic side: what is the head instantiated by the complementizer that co-occurs with V2 in Mainland Scandinavian and Frisian? Is it really true that heads encoding illocutionary force cannot be embedded? If so, how can this be reconciled with the syntactic evidence for a low position for the kind of embedded V2 clauses found in German and Frisian? Answers to these and related questions have the potential for illuminating an important area in the interface between syntax and (discourse) semantics.

NOTES

I am very grateful for the help that I have received, in the form of comments, data, judgments, and references, from Kersti Börjars, Elisabet Engdahl, Germen de Haan, Jack Hoeksema, Anthony Kroch, Line Mikkelsen, Marga Reis, Beatrice Santorini, Sten Vikner, and John Whitman. None of those named is, however, responsible for the use that has been made of their contribution.

1 The distribution of *because* and *for* in English is not complementary; rather, *for* appears in a subset of the environments in which *because* is possible.

Although Wegener (1993) appears to claim that German *weil* + V2 and *weil* + V-final do not overlap in their interpretations, the native speakers whom I consulted found that *weil* + V-final allowed the interpretations possible for *weil* + V2, as well as the interpretations that are excluded for *weil* + V2, suggesting that the same is true for these variants in German.

In his discussion of Swedish, Andersson (1975) mentions that *därför att* 'because' can be followed by either V2 or non-V2 order. *Därför att* + V2 is necessarily outside the scope of, e.g., negation in the clause to which it attaches; but he is less clear about the status of *därför att* followed by subordinate word order, saying that a reading where it takes low scope is "the natural one and for some people I have asked, the only one" (1975: 24).

2 The paratactic *so* construction in English might be analyzable as a special case of complement preposing, given the following parallels:

- Backwards anaphora:

(i) a. John$_i$ thinks (that) he$_i$ will be promoted.
b. ?He$_i$ will be promoted, John$_i$ thinks.
c. John$_i$ will be promoted, he$_i$ thinks.

(ii) a. John$_i$ is so qualified (that) he$_i$ will be promoted.
b. ??He$_i$ will be promoted, John$_i$ is so qualified.
c. John$_i$ will be promoted, he$_i$ is so qualified.

- Failure of binding in either direction:

(iii) a. No one$_i$ thinks (that) he$_i$ will be promoted.
b. *He$_i$ will be promoted, no one$_i$ thinks.
c. *No one$_i$ will be promoted, he$_i$ thinks.

(iv) a. No one$_i$ is so qualified (that) he$_i$ will be promoted.
b. *He$_i$ will be promoted, no one$_i$ is so qualified.
c. *No one$_i$ will be promoted, he$_i$ is so qualified.

- Impossibility of negation in final clause:

(v) a. John didn't say (that) the boss is an idiot.
b. *The boss is an idiot, John didn't say.

(vi) a. John isn't so stupid (that) he would admit to that.
b. *He would admit to that, John isn't so stupid.

Whether such an analysis could be extended to what Hoeksema and Napoli (1993) take to be an essentially identical construction in Dutch is less clear. Further, in German a V2 extent clause can occur in initial position, as shown in (61), but when the extent clause is not initial, it must be verb-final, and introduced by a complementizer (60a, b). For some discussion of the Dutch and German facts, see section 5.2.3.1.

3 Hoeksema and Napoli also claim that the *so/such*-inversion in (16a) is a root phenomenon, and refer the reader to Hooper and Thompson (1973) and to Green (1976). However, there is no discussion in these earlier papers of this particular type of inversion, unless it is assumed to be an instance of "preposing around 'be'."

4 Hoeksema and Napoli do not discuss in any detail the claim that the order of the two clauses is fixed (1993: 296). In fact it is not at all obvious that this claim is correct, given the grammaticality of the following examples from English:

(i) a. She fainted, the sun was so hot.
b. The sun was so hot she fainted

Similar examples are also grammatical in Dutch (Jack Hoeksema, p.c.): see section 5.2.3.1.

5 The force of Fabb's (1990) examples with 'any' is somewhat weakened by the relative acceptability of some restrictive relatives with 'any' but without an overt licenser:

(i) The tourists who have any imagination go to visit Sicily.

The same point, however, can be made with 'ever' (Beatrice Santorini, p.c.):

(ii) a. Only tourists who have ever had luggage stolen take out enough travel insurance.
b. *Only tourists, who have ever had luggage stolen, take out enough travel insurance.

6 Apparent counter-examples like (ia) are presumably the result of the same 'telescoping' phenomenon as allows the binding in (ib):

(i) a. Every Italian man(i) thinks his mother, who has pampered him(i) since childhood, is a saint.
b. Every Italian man(i) thinks his mother is a saint. After all, she has pampered him(i) since childhood.

7 Although Hooper and Thompson do not give any examples, direct quote preposing may also co-occur with inversion as long as the subject is not a pronoun:

(i) "I won first prize," exclaimed Bill.

8 Of course, one could attempt to defend Hooper and Thompson's position by rejecting their own assumption that clefting and topicalization (or any other root transformation) are sufficiently similar to make a legitimate minimal pair.

9 In Dutch, when the extent clause is initial, it must be followed immediately by the *zo*+AP phrase unless the interpretation is simply one of 'asyndetic conjunction' (Hoeksema and Napoli 1993: 293); in German this order is also preferred, but does not appear to be obligatory (Beatrice Santorini, p.c.).

10 Dutch is also like Frisian and unlike German in that the acceptability of embedded V2 is affected by negation in the matrix:

(i) a. Hij zei (niet) dat hij tijd had.
he said not that he time had
He said/didn't say that he had time.

b. Hij zei (*niet) hij had tijd.
he said not that he time
He said/*didn't say he had time.

(ii) a. Hij was (niet) zo moe dat hij zitten ging.
he was not so tired that he sit went
He was (not) so tired that he sat down.

b. Hij was (*niet) zo moe hij ging zitten.
he was not so tired he went sit
He was (*not) so tired he sat down.

24 Existential Sentences and Expletive *There*

ANDREA MORO

1 Introduction: what is an existential sentence?
2 Basic properties of existential sentences
3 Deriving the basic properties of existential sentences
  3.1 The standard theory: *there* as a place holder for the subject
  3.2 An alternative theory: *there* as a place holder for the predicate
4 On the Definiteness Effect in existential sentences: are there parameters in semantics?
5 Conclusion

1 Introduction: what is an existential sentence?

The label 'existential sentence' can be misleading. On the one hand, it explicitly refers to a semantic property, i.e., to a sentence whose meaning is to predicate the (non-)existence of something; on the other, it really points to a specific syntactic structure: in fact, just to limit the observation to English, although one can express the existence of something by using a predicate of existence like 'to exist' as in *unicorns exist*, the standard terminology would not refer to this sentence as an existential sentence; an existential sentence would rather be a sentence like *there are unicorns* or *there exist unicorns*. Establishing the defining structure of an existential sentence, thus, has become a major goal of syntactic theory (and a logical preliminary step toward a semantic theory of them). In this chapter, I will try to illustrate some basic aspects of the syntax of existential sentences and the problems related to the current treatments for them.[1]

In his *Philosophy of Grammar*, by relying on the comparison of many different languages, Otto Jespersen arrived at a major generalization which one can consider as a good starting point in this field of research:

(1) **Jespersen's generalization:**
"whether or not a word like *there* is used to introduce them [i.e. existential sentences] the verb precedes the subject and the latter is hardly treated as a real subject" (Jespersen 1924: 155).

Of course, such a generalization does not exhaustively answer the questions raised by existential sentences; thus, for example one must still understand in which sense a subject of an existential sentence is "hardly treated as a real subject." Nevertheless, a first non-trivial syntactic property is singled out here: namely, that existential sentences involve (some kind of) subject–verb inversion. For example, we have the following cases in English, French, German, and Italian respectively:

(2) a. There are many girls.
b. Il-y-a beaucoup des filles.
c. Es gibt viele Mädchen.
d. Ci sono molte ragazze.

Moreover, it must be highlighted that the distribution of elements like English *there* or Italian *ci* has become a central issue of modern syntactic theory since at least the nineteenth century (cf. Graffi 2001 for comprehensive reference and extensive critical discussion). In particular, within transformational grammar the distribution of such an element has played a central role in the transition from rule-based grammars to principle-based grammars which characterized the field in the late 1970s, leading to Chomsky's (1981) landmark work. We will come back to these theoretical issues in section 3.1. As a preliminary, let us review some basic properties of existential sentences by referring to English.

2 Basic properties of existential sentences

As we just noted in the introduction, an existential sentence in English is a *there*-sentence with *be* (or *exist*) as a main verb:

(3) There are many girls.

In fact, existential sentences of this type are rare. Generally, existential sentences involve the so called 'coda', i.e., a PP/AP specifying the domain of existence of the individual or set of individuals whose existence is predicated, such as *in the garden* in the following sentence:

(4) There are many girls in the garden.

This more complex structure involving the coda has become the real test case upon which most theories have been shaped. In fact, the idea is that in a sentence

like (4) *many girls in the garden* is an uninflected clausal constituent, i.e., a small clause, of the kind that one can find in sentences like the one in (5):[2]

(5) John saw [$_{SC}$ many girls in the garden].

In other words, the idea is that the PP in the coda is the real predicate of a *there*-sentence while *there* plays the role of a dummy place holder for the structural subject position, technically an 'expletive'. By relying on similar considerations, practically all syntactic frameworks agree on this analysis. Moreover, the existence of copular sentences of the type in (6a) has been considered as an independent piece of evidence in favor of the small-clause analysis, since there are analogous cases involving subject raising from the lower uninflected clausal constituent in (5) yielding (6b):

(6) a. Many girls are [$_{SC}$ t in the garden].
b. Many girls are seen [$_{SC}$ t in the garden].

In other words, a *there*-sentence has been considered as the counterpart of a copular sentence (cf. chapter 18) with the occurrence of expletive *there* in the higher subject position as opposed to the raising of the subject of predication. Formally, the following simplified structures are standardly accepted:

(7) a. There are [$_{SC}$ many girls in the garden].
b. Many girls are [$_{SC}$ t in the garden].

Let us now take the standard structural representation in (7a–b) as correct and focus on some major properties of existential sentences. For the sake of simplicity, consider the following paradigm:

(8) a. *Which girls do you think that there are [t in the garden].
b. What do you think that there is [t in the garden].
c. Which girls do you think that there are [pictures of t] in the garden.
d. There aren't [many girls] in the garden.
e. There aren't [pictures of [many girls]] in the garden.
f. Ci sono [molte foto [delle ragazze]] nel giardino.
there are many pictures of the girls in the garden
g. *Ce le sono nel giardino.
there them are in garden
h. Ce ne sono [molte foto t] in giardino.
there of-them are many pictures in garden
i. To whom do you think that many girls are [indebted t]?
j. *To whom do you think that there are many girls [indebted t]?
k. There are many girls (in the garden).
l. Many girls are *(in the garden).
m. There are many girls angry with John/in the garden/* the cause of the riot.

n. Many girls are angry with John/in the garden/the cause of the riot.
o. There are [many girls impressed t by this theory].
p. *There are [impressed many girls by this theory].
q. John considers [there to be many girls].
r. *John considers [there many girls].
s. John considers [Mary to be the culprit].
t. John considers [Mary the culprit].

The facts illustrated here constitute a core cluster of empirical facts specific to existential sentences. We can briefly review them here referring the reader to Moro (1997: chapters 2, 3, appendix on the history of the notion of copula) and Moro (2000: appendix) for a detailed discussion and references to the original sources for each case.

Let us start by considering movement of and from the subject of an existential sentence: (8a) shows that there can be no *wh*-movement of the subject if the subject is headed by *which*, while (8b) shows that there can be *wh*-movement of the subject if the *wh*-phrase occurring is *what*; (8c) shows that in fact a phrase headed by *which* can be moved out of a *there*-sentence provided that it is extracted from within the subject (as opposed to extraction from within the coda, as in **which girls do you think that there are signatures in many pictures of t*); (8d) and (8e) show the very similar contrast concerning extraction with respect to Quantifier Raising (cf. (8a) vs. (8c)): a quantifier can be extracted across there only if it is moved from within the subject; equivalently the quantified subject cannot take scope over negation in (8d); (8f) and (8d) confirm the very same pattern observed in *wh*-movement and Quantifier Raising in the case of clitic movement in Italian: taking a sentence like (8f) as a baseline, one concludes that cliticization of the whole subject is impossible in (8g) while cliticization of a subpart of the subject is perfectly grammatical in (8h); (8i) and (8j) show that extraction from the XP (here an AP) constituting the coda of a *there*-sentence yields a degraded sentence if compared with extraction from an XP (here an AP) predicate of a copular sentence;[3] (8k) and (8l) let us conclude that while the PP in the copular sentence cannot be suppressed, the one in the coda of a *there*-sentence can; (8m) and (8n) constitute a further contrast between copular and *there*-sentences: (8m) shows that, unlike PPs and APs, DPs cannot play the role of a predicate in the coda of a *there*-sentence, while they can play such a role with copular sentences as in (8n);[4] (8o) and (8p) show that *there* cannot occur with passives, even if they also involve *be*; (8q) and (8r), finally, show that *there* cannot occur in infinitival contexts if *to be* is suppressed, unlike those cases of infinitival predication such as (8u) and (8v).

Before moving to the search for the derivation of these properties of existential sentences, we must also consider the type of subject that can occur in these constructions. In such a case, the situation becomes rather murky, especially since it involves semantic considerations which are presently under debate (for a general illustration and a source of references see Chierchia and McConnell-Ginet 2001). Consider now the following cases:

(9) a. There are [many girls] in the garden.
b. There are [three girls] in the garden.
c. There are [no girls] in the garden.
d. There are [girls] in the garden.
e. *There are [the girls] in the garden.
f. *There are [most girls] in the garden.
g. *There is [every girl] in the garden.

As far as I am aware, there is no undisputed theory which can exhaustively derive the types of determiner which can occur in the subject position of a *there*-sentence from a principled theory.[5] Superficially, however, one can capture the basic intuitive property emerging from (9) by adopting Higginbotham's (1987) terminology and say that only 'adjectival' determiners can head the subject of an existential sentence.[6] Although, as noted, we cannot go through this issue in detail, it could be useful to reproduce here the semantic interpretation of *there*-sentences developed in Moro (1997: chapter 3), which relies on Higginbotham's terminology. Maintaining the discussion at a rather informal level, one can consider a *there*-sentence as the minimal syntactic structure which can 'turn' a DP into a sentence. More explicitly, a noun phrase like *many girls* cannot per se be considered as a sentence; witness the ungrammaticality of **John says that many girls*; nevertheless, a sentence like *there are many girls* is in fact interpreted as if it were a sentence like *girls are many*. In other words, a *there*-sentence takes a DP and forces us to interpret it as equivalent to a copular sentence predicating D^0 of the NP contained in it. From this perspective, the reason why only certain D^0s, namely the adjectival D^0s, can occur in the subject of a *there*-sentence should be less mysterious. The role of *there* is to ensure the proper syntactic condition to force such a 'splitting' process of the DP (and to anticipate the restriction expressed in the coda as a pronoun, if there is any). To give a simple example, the sententence *there are many girls* is interpreted as *girls are many*: this *is* the existential meaning in a syntactic sense.[7] On the other hand, a sentence including a coda like *there are many girls in the room* is a simple extension of the first, i.e., it is interpreted as *girls in the room are many*. The reason why there is this double possibility is most arguably due to the independent reason that when the subject is postverbal it is necessarily focused (see Belletti 1999a and Longobardi 1999 for extensive discussion on postverbal focus in general; see also Quirk et al. 1985 for a discussion of focus as related to *there*-sentences). A simple example should clarify this hypothesis: a sentence like *there aren't many girls but boys* is grammatical whereas **girls aren't many but boys* is not, showing that *girls* is focused only in the *there*-sentence (unless of course preverbal *girls* is emphasized and moved to the proper slot in the left periphery, as in GIRLS *t are many, not boys*). We will leave the semantic issue aside here, referring the reader once again to the cited bibliography for references and tentative proposals, and assuming that the existential meaning is the simplest way to 'make a sentence out of a DP'.[8]

All in all, we can go back to Jespersen's generalization in (1) and give a (partial) explicit characterization of it. Let us factorize the defining properties of existential sentences that we have empirically discovered:

(10) **The defining properties of existential sentences:**
(i) Movement of the subject is impossible.
(ii) Movement from within the subject is possible.[9]
(iii) The determiner of the subject has an adjectival character.

Each property has an independent life, and it is only when the defining properties in (10) are *simultaneously* present in a given minimal structure that the output qualifies as an 'existential sentence'. For example, in English, the preverbal subject of an embedded clause displays the first property in (10) when a *wh*-phrase occupies the intermediate SPEC-CP position (see Rizzi 1990b for a principled explanation):

(11) *Which student do you know [which book C^0[t read t]]?

Turning now to the second property in (10), it is well known that in Italian, clitic extraction is possible from the subject position of a small-clause complement of a verb like *ritenere* (believe), as noted by Burzio (1986), among others:

(12) Gianni ne ritiene [[molti t] intelligenti].
Gianni of-them believes many intelligent

The third property in (10), instead, is manifested in constructions like the following:

(13) John hasn't met [many [girls]].

Simplifying somewhat, let us just focus on the interpretation of the determiner *many*. Here the adjectival character of the D^0 (in the sense of Higginbotham 1987) can be captured by means of the following paraphrase: 'It is not the case that the girls John met are numerous (i.e. many in number)'. Now, note that in a sentence like *There aren't many girls*, the same kind of interpretation of *many* occurs (i.e., "It is not the case that the girls are numerous"). There is therefore a sense in which (13) is not a minimal structure in which *many* functions as an adjectival predicate: in (13), there is at least one other predicate, namely *meet* occurring in the same sentence. Again, the conjecture defended here is that it is only when the defining properties in (10) are simultaneously present in a given minimal structure that the output qualifies as an 'existential sentence'. In such a case, they interact with each other, yielding the only possible interpretation where the D^0 is predicated of the NP. This is the explicit, i.e., formal correlate of Jespersen's generalization.[10]

3 Deriving the basic properties of existential sentences

The cluster of facts reproduced in (8) raises a pointed question: what principles of Universal Grammar generate these apparently unrelated facts and let children acquire them without specific instructions?[11] As noted in the introduction, the theory of the distribution of *there* played a crucial role in shaping the Principles and Parameters framework from its early stage in Chomsky (1981). In this section I will sketch the major lines of reasoning that directed the development of this field and compare two radically alternative proposals that are presently under debate.

3.1 The standard theory: **there** *as a place holder for the subject*

The first point to be observed is that ever since Milsark (1974; see also Milsark 1977), the two following sentences have been considered as generated from the same underlying structure:

(14) a. There are girls in the garden.
b. Girls are in the garden.

In the analysis proposed by Milsark, the two sentences were roughly considered as synonymous: in both cases, it is said that girls have the property of being in the garden. In other words, according to these analyses, the element *there*, always regarded as a noun phrase, had no semantic role in a sentence like *there is a man in the room*. This intuition was strongly supported by the fact that this special noun phrase cannot discharge the function of argument (say, subject or object) in cases like the following:

(15) a. John likes books.
b. *There likes books.
c. *John likes there.

The conclusion was clear enough: although *there* can occur where argumental DPs generally occur, namely in the subject position, it has no semantic content. The ungrammaticality of the above examples was then immediately explained as a violation of the reasonable assumption that semantically null elements are incompatible with theta-roles. From this, an important question naturally arose: what forces *there* to show up in a sentence like *there is a man in the room*? In other words, what principle of grammar rules out a sentence like the following?

(16) *Is a man in the room.

The standard treatment of this puzzle came in the shape of what was called the 'Projection Principle', that is to say, a principle requiring lexical entries to be respected (at all levels of representation). A simple case like the following illustrates this principle:

(17) a. John likes books.
b. *Likes books.
c. *John likes.

Only the first sentence is grammatical because only in the first sentence is the lexical entry of *like* respected. This verb, in fact, requires two arguments: in this case *John* and *books*. In the ungrammatical cases one of the two arguments is missing, and so the Projection Principle is violated. Clearly, the same principle could not immediately be applied to a sentence like **is a man in the room*. In this case, there are no missing arguments; rather they are misplaced. Immediate confirmation of this comes from the fact that a sentence containing exactly the same lexical elements arranged in a different way, like *a man is in the room*, is perfectly grammatical: what this means is that the ungrammaticality of **is a man in the room* cannot be a question of the incomplete realization of the arguments of a lexical head. Although the Projection Principle was clearly not sufficient to account for such cases, there was little readiness to acknowledge the fact that it was simply irrelevant to the phenomenon in question; thus the issue became one of refining the Projection Principle so that it would encompass the offending data. The crucial step was to extend it by exploiting an essential postulate of the theory of clause structure, namely that grammatical functions are defined on the basis of configuration. Thus, the Extended Projection Principle was formulated by Chomsky (1982: 10; see also Chomsky 1981: 28ff.); it required that all sentences have a subject of the predication (at least) at LF. Thus, to the question of why *there* is required in a sentence like *there is a man in the room* an immediate answer was now available: because *there* satisfies the Extended Projection Principle. The function of this semantically null element was then considered to be that of holding the place of the subject of the predication; consequently, it was termed 'expletive of the subject position' or, more simply, 'subject expletive'.[12]

Stowell's (1978) seminal analysis of *be* as a raising verb allowed the formalization of such a relation in the following way:

(18) There_i is $[_{SC}$ a man_i in the room].

The basic relation of predication is contained in the small clause where the subject *a man* is linked to the predicate *in the room*. *There* is inserted (at s-structure) as an alternative to subject DP raising. Coindexing was introduced as a device for indicating that *there* and *a man* have no independent referential properties.

This analysis of the distribution of *there* based on the assumption that the copula selects a small clause has met with general acceptance and has established itself as the standard analysis. It is nevertheless important to notice that an

alternative theory has been discussed in the literature since its original formulation in Williams (1984) (see for example Higginbotham 1987; Reuland and Ter Meulen 1987). This alternative is based on the idea that in a *there*-sentence, the complement of the copula is a noun phrase, not a small clause, while *there* is still regarded as a semantically null place holder of the subject position:

(19) There [is [a man]].

Crucially, in this analysis the idea that *there* plays the role of a subject is pushed to the limit. According to this analysis, *there* is not holding the place of a displaced subject: rather, *there* indeed is the subject, and correspondingly the DP following the copula is analyzed as a predicate. In other words, in a *there*-sentence like *there is a prime number*, the grammatical function of *a prime number* would be exactly the same as the one it has in *seven is a prime number*: in both cases *a prime number* is analyzed as predicate.

As noted before, the analysis of the distribution of *there* has played a central role in the development of generative grammar, although regarding it as an expletive has not been without cost. Let us briefly review the major stages in this development, which all share the fundamental hypothesis that *there* be the expletive of the subject of predication. Perhaps the most dramatic illustration of the shift from constructive rule system to selective principles comes from Chomsky's (1981) analysis of the distribution of *there*. Chomsky proposed that *there*-insertion should be regarded as totally free in noun phrase positions and that ungrammatical cases could be ruled out by the interaction of independent principles. This proposal was highlighted as one of the first and most notable examples of modular interaction:

(20) "insert *there* anywhere" (Chomsky 1981: 88)

Chomsky's idea was that the following examples are just freely generated under (20) and must be ruled out on the base of independent principles:

(21) a. *John likes there.
b. *There is raining.

What are the independent principles ruling out these sentences? The first sentence is essentially a violation of the lexical entry of *like*, which requires it to have two arguments. As for the second case, it could be ruled out by assuming that the lexical entry of *there* requires it to inherit number from an associated DP; since there is no DP at all, the sentence has to be ruled out. Notice that the assumption that *there* has number appears to be independently necessary in view of cases like the following, where the verb agrees with *there* (if, of course, one wants to maintain that agreement takes place under some form of SPEC-HEAD relation):[13]

(22) a. There is a girl in the room.
b. There are girls in the room.

A very different proposal to rule out the ungrammatical occurrences of expletive *there* was suggested by Chomsky (1986b), who pushed to the limit the idea that *there* is a semantically vacuous element. His central argument concerns the interaction of *there* with the Principle of Full Interpretation, which requires that at a certain level only legitimate objects be visible. Since by definition expletives do not have semantic content, they are not legitimate at LF, where grammatical structures undergo interpretation. For this reason, it was proposed that *there* is wiped out at LF and replaced by the DP it is coindexed with. Thus, at LF a *there*-sentence such as (22a) would end up being identical to its raising counterpart:

(23) A girl is [t in the room].

This analysis, generally referred to as the 'expletive replacement hypothesis', had at least three major consequences. We will briefly deal with each of them. The most important consequence is that the distribution of *there* is seen to be determined by the independent principles governing chain formation. The associated DP must move to substitute *there*, thus creating a chain: if locality is not respected in each step of the chain, then the sentence will be ruled out. We can now consider once again the following cases (taken from Chomsky 1991) from the new perspective:

(24) a. There is a man in the room.
b. There are men in the room.
c. There seems t to be a man in the room.

According to Chomsky (1991) they are grammatical because *a man* and *men* can move to the subject position replacing *there*; witness the grammaticality of cases like:

(25) a. [A man] is t in the room.
b. [Men] are t in the room.
c. [A man] seems t to be t in the room.

On the other hand, cases like the following are to be ruled out as instantiating illicit movements:

(26) a. *There seems that a man is in the room.
b. *There seems that John saw a man.
c. *There was thought that pictures of a man were on sale.

In other words, the process of LF replacement of the associated elements yields either ECP (26a–b) or Subjacency violations (26c), as indicated by independent cases such as the following:

(27) a. *[A man] seems that t is in the room.
b. *[A man] seems that John saw t.
c. *[A man] was thought that [[pictures of t] were on sale.

Of course, *there* would still need to inherit number from a DP, but otherwise it was claimed that its distribution can simply be regarded as the result of a more general phenomenon, i.e., chain formation. This was undoubtedly a considerable advance, but, as Chomsky himself explicitly noticed, a major exception survived (see also Borer 1984a) which challenged the system. Consider a pair like the following:

(28) a. *There seems a man to be t in the room.
b. [A man] seems t to be in the room.

Apparently, there is no way to account for the ungrammaticality of (28a) in terms of illicit movement, since movement of *a man* from this position to the matrix clause subject position is fully licensed, as (28b) clearly shows.

A second advantage implied by the expletive replacement analysis concerned Binding Theory. It was soon realized that the hypothesis of *there*-insertion yields a violation of Condition C of Binding Theory, which requires referential expressions not to be bound by an element in an A-position. If we assume that expletives are to be replaced by their associated elements, the question concerning the violation of Binding Theory Condition C by *there*-insertion is solved. The trace counts as an anaphor, and so at LF (where Binding Theory checks the structure) there is no violation of Condition C; rather Condition A, which requires anaphors to be bound (in a local domain), is satisfied.

A third major consequence of this analysis became apparent later, within the so-called 'Minimalist' approach (see Chomsky 1995c and earlier unpublished references cited there). Indeed, expletive replacement has become a fundamental support to this model, as it illustrates the effect of the 'Principle of Greed', which is central to the new system based on 'economy principles'. We will briefly reproduce the essential intuition by considering a sentence like the following (see Chomsky 1993: 32ff., among many other possible sources of citation of the very same case):

(29) There seems to [$_a$ a strange man] that it is raining outside.

In this sentence, the replacement of *there* by *a man* "would yield an intelligible interpretation (something like 'There is a strange man to whom it seems that it is raining outside')." However, "derivations are driven by the narrow mechanical requirement of feature checking only, not by a 'search for intelligibility' or the like . . . benefiting other elements is not allowed" (Chomsky 1993: 33). Thus, this process is not permitted and "the derivation converges with an unintelligible interpretation."

The original hypothesis of 'expletive replacement' has been slightly refined in the Minimalist models (see again references in Chomsky 1995c and many more recent works since then). Following Williams's (1984) original observation, it was realized that *there* could not simply be wiped out at LF. Consider the following contrast:

(30) a. There aren't many men in the room.
b. Many men aren't in the room.

There appears to play the role of a scope marker blocking the wide scope reading of *many men* which is available in the other sentence. The *there*-sentence cannot mean the same as the raising counterpart: in particular, it cannot mean that many men are not in the room. Thus, since scope is assigned at LF, *there* cannot be wiped out and the *there*-sentence cannot be exactly like the raising counterpart. Chomsky then proposed to reduce the replacement of *there* by its associate DP to a process of *there*-affixation which does not eliminate *there* from LF:[14]

(31) [There[a man]] is [t in the room]].

This analysis was considered to solve the problem posed by Williams (1984), and the proposed structure has subsequently met with general acceptance. Even so, certain data remained unexplained, including the ungrammatical **there seems a man to be in the room*, but these have generally been dismissed as 'exceptions'. As a further puzzle, Chomsky (1991) reports an original observation by Kenneth Safir, who discovered the following contrast:[15]

(32) a. [How many men] do you think that there were t in the room?
b. *[How many men] do you think that t were in the room?

The second clause shows a typical *that*-trace effect: the subject of an embedded sentence cannot be extracted across an overt complementizer. The obvious question is why the presence of *there* makes any difference, especially since in this view it is affixed to the subject at LF.

The analysis presented here, based on the idea that *there* is a place holder for the subject of predication, has been adopted as the standard one in modern syntax. Moreover, it has been adopted for many other languages, such as Italian. This extension goes back at least to the pioneering work of Burzio (1986) on the distribution of the equivalent of English *there*, namely *ci*, which seemed to confirm and refine the central intuition that *there*/*ci* is a subject expletive. For example, the following pair in Italian is also generally analyzed as stemming from the same underlying structure, paralleling the case of English *there*:

(33) a. Molte copie del libro sono [t nello studio].
many copies of the book are in the studio
b. Ci sono [molte copie del libro nello studio].
there are many copies of the book in the studio

The major difference between the two languages is that *ci* is a clitic while *there* was standardly analyzed as a full phrase.[16] All in all, we have seen that the standard theory rests on three crucial assumptions: first, the topmost position of the clause structure (SPEC-IP) is where the logical role of subject of predication is defined; second, *there* is a semantically null element; third, any *there*-sentence is associated with a copular sentence where the subject is raised from the lower position.

If one maintains such a standard theory, which in fact is shared by most syntactic theories of the twentieth century, including Jespersen (1924) and Bloomfieldian linguists (cf. Graffi 2001 and references cited there), it would be an easy exercise to conclude that the cluster of facts illustrated in (8) would go uncaptured, or at least would not be captured in a unitary way.[17] In the remainder of this section, an alternative theory will be briefly illustrated which aims at deriving the major syntactic properties of existential sentences from a principled framework, and in a unitary fashion. An important caveat should be made explicit here: the alternative theory I am going to introduce is not widely accepted; in fact it reflects only a minority view: nevertheless, it has been referred to in quite a number of works. Omitting it would make this chapter less exhaustive.[18]

3.2 *An alternative theory:* **there** *as a place holder for the predicate*

The alternative theory presented here relies heavily on the discovery of so-called 'inverse copular sentences' within the unified theory of copular sentences. Since there is a dedicated chapter on this topic in this collection (chapter 18), I will not present this theory in detail, and recommend the interested reader to refer to that chapter or to the original sources.[19] Here I will simply sketch out the essentials of the unified theory of copular sentences, focusing on those aspects which are conceptually strictly related to the alternative treatment of *there*-sentences. The core hypothesis of the unified theory of copular sentences is that, contrary to the standard 'Fregean' assumptions (which go back at least to Chomsky 1981, 1986b, and according to which SPEC-IP can only host the subject of predication), SPEC-IP can also host predicates, provided that they are realized as DPs, a case that can only occur in copular constructions. To illustrate this idea with a simple example, consider the following two sentences:

(34) a. Some pictures of the wall are [t the cause of the riot]. (canonical)
b. The cause of the riot is [some pictures of the wall t]. (inverse)

These sentences are generated by the same underlying structure by raising either the subject or the predicative DP to the preverbal position, yielding a canonical and an inverse copular sentence respectively. Despite the fact that superficially the two sentences are identical, i.e., they are both sequences of the type [DP V DP], it can be shown that they have very different syntactic properties. I will not

go through an illustration of these here (see again chapter 18). The important fact is that inverse copular sentences provide us with the key empirical argument for a reconsideration of *there*-sentences. This is because inverse copular sentences imply that there is no longer need for us to consider *there* as a place holder of the subject of predication: rather, there is a second logical possibility available now, namely that *there*-sentences belong to the more general class of inverse copular sentences. Formally, the following structure holds, where, contrary to the standard analyses previously reviewed here, *there* is analyzed as a raised place holder of the predicate and not as a place holder for the subject inserted in the position where it surfaces:[20]

(35) There are [many girls t].

Before briefly commenting on the advantages of this proposal with respect to the challenge posed by the facts in (8), a residual question remains concerning the coda. If one adopts the proposal that *there*-sentences are inverse copular sentences, there is only one option available, namely that a PP in the coda is an adjunct (since *there* is the place holder of the predicate). In fact, since a PP can be an adjunct of a clausal structure or of a nominal structure, there are two structures available. Taking, for example, a PP like *in the garden*, in a sentence like *there are many girls in the garden*, we have the following two options:[21]

(36) a. [There are [many girls t]] . . . [in the garden].
b. [There are [[many girls [in the garden]] t]].

How can this alternative theory explain the facts in (8)? We will briefly review them and, once more, refer to the more general source in Moro (1997). As a guideline, recall that the central proposal here is that *there* is a place holder of the predicate, not of the subject of predication. Let us start from the more complex facts, namely movement restrictions on the subject of existential sentences. Consider the examples from (8a) through (8h): movement of the subject is impossible, movement from within the subject is possible.

That movement of the subject is impossible (with *wh*-movement, Quantifier Raising, and clitics, as in (8a) (**which girls do you think that there are [t in the garden]*), (8d) (*there aren't [many girls] in the garden*), and (8g) (**ce le sono nel giardino* – there them are in garden)) is not surprising if one adopts the idea that *there*-sentences are inverse copular sentences. Indeed, this is a property characterizing the subject of all inverse sentences (cf. **which pictures of the wall do you think that the cause of the riot is* stemming from the inverse copular sentence *you think that the cause of the riot is some pictures of the wall*, where the predicate *the cause of the riot* is moved out of the small clause to SPEC-IP, leaving the subject *some pictures of the wall* in situ). Essentially, the prohibition on extracting the subject of an inverse copular sentence can be explained by a theory that regards activation of the agreement features on a governing head to be a way of meeting locality conditions on movement, much in the sense that the so-called '*que-qui* rule' is

explained as a way of satisfying the ECP in French in sentences like *l'homme que je pense t que/*qui Jean croit t qui/*que t viendra* (the man that I think that John believes that will come; see Rizzi's 1990b version of the ECP; see also Moro 1993b for some further refinements of the original proposal, and chapter 18 for a defense of a two-principle theory of locality). Since the copula already agrees with the raised predicative noun phrase (*the cause of the riot*), movement of the subject (*which pictures of the wall*) as a whole would violate the ECP. Similarly, the impossibility of moving the whole subject of a *there*-sentence can be explained in the same way. Movement is blocked since the copula already agrees with the raised predicate, namely *there*.

The fact that movement from within the subject is possible is indeed less direct to explain. The relevant examples are (8c) (*which girls do you think that there are [pictures of t] in the garden*), (8e) (*there aren't [pictures of [many girls]] in the garden*), and (8h) (*ce ne sono [molte foto t] in giardino* – there of-them are many pictures in garden). Why is movement from within the subject of a *there*-sentence allowed? After all, extraction from the subject position is banned in inverse copular sentences (cf. **which wall do you think that the cause of the riot was a picture of*): if *there*-sentences are indeed inverse copular sentences, why should it be possible? The crucial step to remember is that while extraction of the subject is prohibited by the ECP, movement from within the subject is banned by (some version of) the Subjacency condition (cf. chapter 18 for a detailed discussion). This suggests that raising *there* or *ci*, as opposed to a full phrase like, say, *the cause of the riot*, affects the relations to which Subjacency is sensitive in inverse copular constructions. Although I cannot go through the proposal in a detailed fashion, I would like to illustrate the major lines of reasoning that can be followed to solve this puzzle. Subjacency violations essentially amount to moving across a(n argumental) constituent which is not selected by a head in the proper configuration. The classic examples are extraction from an adjunct (cf. **who do you think that John screamed [while seeing a picture of t]*) or a preverbal subject (**who do you think that [a picture of t] frightened John*): in both cases, the constituent is not selected by a governing head and Subjacency is violated. Why should raising of *there* or *ci*, as opposed to a full phrase like, say, *the cause of the riot*, change the situation? There are two crucial observations to single out: first, predicates have selective capacities; second, the copula is not a predicate, but rather the expression of aspectual and modal aspects of clause structure in the traditional Aristotelian sense. Now, consider *there* or *ci* as opposed to a full phrase like, say, *the cause of the riot*. In the first case, we are assuming them to be predicates, while in the second case the predicate is rather the head *cause*, which is embedded in the larger determiner phrase. Thus, it is not unreasonable to assume that when *there* or *ci* is raised to the preverbal position, the lower subject is c-commanded by the predicate, whereas it is not when *the cause of the riot* is raised. Although the technical details have not been presented here, this should suggest why the theory that regards *there*-sentences as inverse copular sentences is more promising than the standard theory. Let us move on and consider the other empirical facts

observed in (8): it will be clear that these further cases can be derived directly from the alternative theory.

The fact that extraction from the PP in the coda of a *there*-sentence is degraded as in (8i), as opposed to a copular sentence in (8j), follows immediately, since the PP is an adjunct rather than the predicate of the small clause as in the corresponding copular sentence. The fact that the PP can be omitted in a *there*-sentence such as (8k), while it must be present in a copular sentence such as (81), follows immediately if we take *there* to be a place holder of the predicate: the PP can be omitted simply because it is not a predicate as opposed to the case of the copular sentence; rather, it is an adjunct and thus it can be omitted by definition. The fact that a DP (as opposed to APs and PPs) cannot be in the coda of a *there*-sentence such as (8m), while it can occur as a predicate in a copular construction such as (8n), follows, since the DP in the coda is not a predicate but an adjunct and we independently know that DPs cannot occur as adjuncts unless marked by a predicative marker such as *as* (cf. *John phoned *(as) a doctor*). The fact that *there* cannot be inserted in passives unless the subject is raised to the lower preverbal head position, as in (8o) vs. (8p), is a misinterpretation of the facts: the reason why (8o) is grammatical is that the phrase *impressed by this theory* can be interpreted as an adjunct in the coda of the *there*-sentence or as a part of a complex noun phrase containing a reduced relative clause; in fact, the subject of the *there*-sentence itself can be *many girls impressed by this theory* (cf. *many girls impressed by this theory can be easily found in this country*). The fact that the copula cannot be omitted in infinitival *there*-sentences, as in (8r) as opposed to (8q), is a general property of inverse copular sentences: for the predicate to cross over the subject, a landing site must be provided by the copula as in all inverse copular sentences (cf. *John believes the culprit *(to be) Mary* and many more examples discussed in chapter 18); note that the copula must not be present when the predicate is in situ, as in (8s–t). Finally, also note that the major challenging fact for the standard theory noticed in (28a) (**there seems a man to be t in the room*) is also solved. The reason why this sentence is ungrammatical is that the subject and the predicate cannot simultaneously raise out of a small clause (whether or not an adjunct PP occurs):

(37) *There seems [a man to be [t t]] . . . [in the room].

This is not a peculiarity of *there*-sentences, as indicated by the totally symmetric example with full predicative noun phrases:

(38) *The cause of the riot seems [some pictures of the wall to be [t t]].

If the predicative noun phrase *the cause of the riot* is raised, the subject *some pictures of the wall* must stay in situ: they cannot simultaneously be moved for locality reasons (again for the ECP reasons just mentioned). Note that the fact that *there* agrees with the subject can be considered as a reflex of number (and

Case) agreement between subject and (certain types of) predicative nominals, as in *John is the culprit*(**s*)/*the culprit*(**s*) *is John* (see Moro 1997 and references cited there for critical discussion of this issue).[22]

All in all, this alternative theory regarding *there*-sentences as instances of inverse copular sentences appears to solve some questions in a rather natural way.[23] Of course, this approach generates some new questions that the standard theory did not raise, such as why the canonical associate of the inverse *there*-sentence does not have an existential meaning. In other words, if *there are girls* is the inverse counterpart of the canonical *girls are there*, exactly as *the cause of the riot is a picture of the wall* is the counterpart of *a picture of the wall is the cause of the riot*, why doesn't the canonical sentence containing *there* have an existential reading?[24] I will not go through the proposal for such a phenomenon: for our limited purpose here, it will be sufficient to note that clearly the syntactic structure of the canonical counterpart of a *there*-sentence does not instantiate the 'conspiracy' of factors that constitute the defining properties of an existential sentences (cf. (10)). However, since a full treatment will involve the preliminary discussion of many semantic aspects of existential sentences, I will simply recommend the willing reader to the various bibliographical sources and discussions in Milsark (1974, 1977); Safir (1985b); Lumsden (1988); Moro (1997), among others. We can simply conclude our quite limited discussion here by observing that, from a semantic point of view, a *there*-sentence is nothing but the minimal syntactic device that is able to turn a DP into a clausal structure where the NP is predicated of the D^0 (of course, when the latter has an adjectival character in the intended sense).

Summarizing, in this section we have seen some major steps toward the reduction of the complex syntax of existential sentences to a principled framework. We have seen that there are at least three different proposals. A first proposal, stemming from Milsark's (1974) original analysis and further developed by Chomsky in many phases of his work up to the Minimalist approach, has undoubtedly become the standard one: according to this, *there*-sentences are the non-raising counterparts of copular sentences. A second proposal, originally made by Williams (1984) and supported by Higginbotham (1987), among others, considers *there*-sentences to be 'transitive sentences' in that the copula is followed by an argumental noun phrase rather than a clausal constituent. A third proposal, originally elaborated in Moro (1991, 1997), proposes that *there*-sentences are instances of the much broader class of inverse copular sentences. The first two proposals can be considered similar and akin to the Structuralist tradition in that in both cases *there* is regarded as the expletive of the subject of predication, whereas in the third proposal *there* is regarded as a raised predicate. Of course, none of the theories exhaustively explains all problems and issues concerning *there*-sentences: nevertheless, they constitute a step toward a better understanding of these issues, and more generally they illustrate some central topics of syntactic theory. In the next two sections, I will concentrate on a specific comparative problem raised by existential sentences and indicate some further possible extensions related to the exploration of the syntax of *there* and *ci*.

4 On the Definiteness Effect in existential sentences: are there parameters in semantics?

A cursory survey across languages shows that existential sentences raise a sharp comparative issue. Let us focus on the following well-known contrast, which is a word-by-word correspondence between English and Italian:

(39) a. *There is John in this garden.
b. C'è Gianni in questo giardino.

More generally, a DP headed by a definite article or by a universal quantifier or by a proper name cannot be the subject of a *there*-sentence, whereas it may be one in *ci*-sentences. Why are existential sentences different across languages? Traditionally, the restriction which rules out the offending case in English has been formulated by appealing to semantics:

(40) "sentences of the form *there is definite noun phrase* . . . are violations of the surface rules of semantic interpretation rather than of syntactic rules, it appears" (Chomsky 1973; reproduced from Chomsky 1977a: 52).

Since the notion of 'definiteness' plays the crucial role here, this restriction has been called the 'Definiteness Restriction' and the corresponding phenomenon the 'Definiteness Effect'.[25]

Why does the Definiteness Restriction fail to hold in Italian existential sentences? In Moro (1993a) I tentatively asked whether one could sensibly talk of comparative semantics along with comparative syntax and correspondingly of a semantic parameter. Is such a notion plausible? Of course, this is not the place to approach such a fundamental question; nevertheless the specific problem posed by the contrast between English and Italian, and the citation from Chomsky, bring out the importance of this issue. Before attempting any explanation, let us begin by considering the issue from an abstract point of view and asking what kind of answer modern linguistics might in principle allow. Comparative grammar shows that cross-linguistic variations are to be traced back to the interaction of a few independent parameters set by the child on the sole basis of overt evidence. The following citation from Chomsky (1986b) illustrates the current theory:

> There may be general principles that determine how the switches [of a parameter] are set, for example, the subset principle discussed by Berwick 1982, which states that if a parameter has two values + and –, and the value – generates a proper subset of the grammatical sentences generated with the choice of value +, then – is the "unmarked value" selected in absence of evidence; this is a necessary and sufficient condition for learning from positive evidence only, insofar as parameters are independent. (Chomsky 1986b: 146)

So for example, the pro-drop parameter is set by the occurrence of sentences which do not have a phonologically realized subject, by the presence of inverted subjects, etc. It may also be that in the last resort, the proper value of the parameter is decided by the presence of some overt (string of) elements.

If we maintain that the restriction ruling out definite subjects in English is semantic, what kind of evidence should we expect to find that might overtly differentiate the two languages? In other words, how does the child know that definite noun phrases are prohibited in English and allowed in Italian in the context under discussion? Suppose we assume that the application of the Definiteness Restriction is parametric. The subset principle leaves only one option: the unmarked value is that this restriction does apply, for a grammar containing it would generate a proper subset of sentences of a grammar not containing it. Universal Grammar provides the child with the positive value of the parameter. The English child will never have to change it. The Italian child, instead, would eventually shift to the negative value (i.e., the restriction does not apply), since that child hears sentences violating it.

It seems then that we are obliged by this type of reasoning to conclude that natural languages do contain parametric variation concerning semantic restrictions, that is, 'semantic parameters'. Whether or not this conclusion is tenable is hard to decide and definitely an empirical matter. More generally, the possibility of semantic parametrization has not been exhaustively investigated yet, as far as I know, and the issue is still entirely open. Indeed, there may well be a priori reasons for not adopting this view. For example, in the recent Minimalist framework stemming from Chomsky (1995c), it has been proposed that, apart from Saussurean arbitrariness, the field of language variation is "limited to lexical differences, specifically, to differences in the features of the lexical elements that occupy the functional category nodes" (Marantz 1995b: 372; see also Borer 1984a; Manzini and Wexler 1987). On the other hand, other theories have been put forward which purport to show that parametric variations take place in semantics (see, for example, Chierchia 1995c and references cited there).[26]

All in all, to conclude this section, whose major aim is just to highlight the theoretical impact of a simple empirical fact – the contrast in (39) – I would like to observe that the theory of *there*-sentences that considers them as instances of inverse copular sentences suggests a possible treatment of the lack of the Definiteness Effect in Italian: it can be regarded as a consequence of an independent syntactic parameter, avoiding recourse to the notion of a semantic parameter. Let us illustrate the major lines of reasoning. From this new perspective a sentence like *c'è Gianni in giardino* turns out to be similar to *lo legge Gianni un libro*, which is arguably generated as a clitic left dislocation structure in the sense of Cinque (1990c), involving a specifier of a Top^0 position in the left periphery of the clause structure (see Rizzi 1997):

(41) a. Un libro, Gianni lo legge.
a book Gianni it reads

b. In giardino, Gianni c' è.
in garden, Gianni there is

The surface order is obtained by subject–verb inversion (42a–b) involving pro (cf. *pro telefona Gianni* (pro telephones Gianni)) followed by further remnant movement of the lower IP constituent across the topic phrase (42c–d):

(42) a. Un libro, pro lo legge Gianni.
a book it reads Gianni
b. In giardino, pro c' è Gianni.
in garden, there is Gianni
c. pro lo legge Gianni . . . un libro t.
it Gianni reads a book
d. pro c'è Gianni . . . in giardino t.
in garden, Gianni there is

Note that extraction from the postverbal constituent in a clitic left dislocation yields the Subjacency violations we observed in section 2 (cf. (8j)), supporting the analogy proposed here:

(43) a. Di quale autore dici che Gianni legge [un libro t]?
of which author do you say that Gianni reads a book
b. *Di quale autore dici che Gianni lo legge, [un libro t]?
of which author do you say that Gianni it reads a book

In summary, the reason why Italian appears to escape the Definiteness Restriction can be traced back to the convergence of two independent, purely syntactic conditions: first, that *ci*, as opposed to *there*, is a clitic; second, that Italian is a pro-drop language. The first condition allows the subject to raise to the preverbal position; the second one allows subject–verb inversion: the result is an apparent violation of the Definiteness Effect. In the end, we don't need recourse to any semantic parameter, contra the implication of Chomksy's citation in (40).

Of course, since in the postverbal position the defining properties of the existential sentences illustrated in (10) are not all met (in particular there can be no extraction from the subject of an inverted subject, as in **ne hanno telefonati molti t* – of-them have phoned many), the sentence does not have an existential interpretation. Rather, the interpretation of a sentence like *c'è Gianni in giardino* can only be purely locative, as in the canonical counterpart *Gianni c'è*. Once more, as suggested by the formal interpretation of Jespersen's generalization, we must recall that 'existential sentences' are nothing but a conspiracy of independent syntactic factors that force the 'clausal interpretation' of a DP. See the discussion of the examples in (9) here: whenever one factor is missing the interpretation changes. Moreover, it is important to notice that both structural conditions must be realized for a certain language to escape the Definiteness Effect: in French, for example, the propredicative element that occurs in existential sentences is indeed

a clitic, namely *y*, but this is not sufficient for that language to escape the Definiteness Effect: since it is not a pro-drop language, subject–verb inversion is not allowed and the sentence is ruled out if the subject's determiner is not adjectival in the technical sense adopted here.

Interestingly, this explanation for the lack of the Definiteness Effect in Italian has as a consequence an independent issue concerning agreement. Since at least Burzio (1986), it has been noted that in Italian, agreement may fail in existential sentences (this is also true in many other languages, as observed at least since Jespersen 1924):

(44) a. Ci sono molte ragazze in questo giardino.
there are many girls in this garden
b. C' è molte ragazze in questo giardino.
there is many girls in this garden

However, when the subject of the existential sentence is definite, agreement, as in the case of a pronoun, is obligatory:

(45) a. Ci sono loro in questo giardino.
there are they in this garden
b. *C' è loro in questo giardino.
there is they in this garden

If verbal agreement is obligatory when a phrase is raised to SPEC-IP position, as commonly assumed, then the contrast in (35) independently supports the hypothesis that the Definiteness Restriction is circumvented in Italian via movement through preverbal position and subsequent subject–verb inversion, and it explains why the sentence in (45a) can only receive a purely locative interpretation.

5 Conclusion

After a short introduction in section 1 aiming at emphasizing the difficulties of separating semantic and syntactic aspects of existential sentences, in section 2 we explored the defining properties of existential sentences. There it was shown that an existential sentence is the output of a conspiracy of independent factors, in a way originally envisaged by Jespersen (1924) and now formally synthesized in (10). More explicitly, we saw that an existential sentence is the minimal syntactic structure that 'turns a DP into a clause', i.e., that allows the determiner to play the role of the predicate of the NP. In section 3, we took some major steps toward a derivation of a core cluster of specific properties of existential sentences, exemplified in (8), on principled grounds. Moreover, the development of the standard theory stemming from Milsark (1974) and Chomsky's own first works in the field (notably Chomsky 1981) up to the Minimalist program (cf. Chomsky 1995c and many subsequent works) was illustrated. Along with this standard theory, which

regards *there* as a place holder for the subject of predication (an idea that goes back at least to Jespersen 1924 and more generally to Structuralist linguistics), an alternative theory was presented based on Moro's (1987, 1997) unified theory of copular sentences, according to which *there* is rather to be regarded as a raised place holder for the predicate. In section 4 we concentrated on a simple cross-linguistic contrast showing the far-reaching and intricate questions that this raises on general comparative grounds: it was proposed that an apparent semantic contrast (the absence of the Definiteness Effect in the Italian equivalent of English *there*-sentences) should be traced back to purely syntactic conditions.

In this chapter, we have limited our attention to cases where *there* and *ci* occur with the copula (and a few cases involving the so-called 'quasi-copula' *seem*) and illustrated some of the major empirical and theoretical aspects of this field. In fact, it is well known that such elements can also co-occur with other verbs. In English for example, we have already observed that *there* can co-occur with *exist*; in fact, it is well known that *there* can also co-occur with other verbs such as *arrive*, *sink*, etc, namely with a subset of those verbs which give rise to the so-called 'unaccusative or ergative constructions' expressing motion (see Hale and Keyser 2002 for a critical and detailed discussion of *there*-sententeces with verbs other than the copula and the quasi-copula). In Italian, moreover, the equivalent of *there*, i.e., *ci*, can also occur in possessive constructions with *avere* (have), as in *Gianni c'ha un gatto* (Gianni there-has a cat), providing some alternative ideas toward the unified analysis of *have* and *be* across languages that has been pursued at least since Benveniste (1966a). Whether or not the predicative raising analysis offered here as an alternative theory can be extended to those constructions (unaccusative, quasi-copular, and possessive constructions) is a matter that cannot be discussed here. I will simply refer to Moro (1997: chapters 3, 4) for the extension of such a proposal to the empirical cases touched on here, and for a discussion of the consequences it has for the overall design of grammar and language acquisition.

NOTES

1 This chapter touches issues that lie across the rigid boundaries of syntax and semantics as established by didactic needs. Even the label 'existential sentences' itself suggests that crucial semantic facts must be known to approach the field. I have tried to stay away from intricate semantic aspects. The result is that the discussion is necessarily simplistic in many points: I do hope that the references I put in the text will help the reader who wants to master this field in a more detailed fashion. Moreover, since *there*-sentences in the existential reading involve the copula, reading chapter 18 is also highly recommended. I am grateful to the reviewers and to Orin Percus for many helpful suggestions.

2 For the analogy between the complement of the copula in *there*-sentences, perceptual verb constructions, and *averci* (*have-there*) constructions in Italian, see Moro (1997: 236ff.) and references cited there.

3 Of course the AP/PP can also be adjunct to the noun phrases, like the PP in the subject of the following sentence: *many pictures in this book show how big Rome was by the first century* AD.

4 It is important to note that the distinction between 'stage level' and 'individual level' predicates (as stemming from the seminal work by Carlson 1977b) appears to be relevant to describing the type of AP that can be in the coda of an existential sentence. I will not further develop the very interesting semantic aspect of this issue here.

5 See for example Reuland and Ter Meulen (1987).

6 In Higginbotham's words, "by adopting the standard algebraic picture in which restricted quantifiers over a domain D are interpreted as functions from ordered pairs of subsets of D to truth values, we can say that a quantifier q over D is of adjectival character if, for some function f from the subset of D to truth values, q (X, Y) = f (X Ç Y), for every pair X and Y of subsets of D" (Higginbotham 1987: 48).

7 Strictly speaking one should also exclude the possibility that *be* is a predicate of existence: I am assuming here the traditional Aristotelian view that the copula is not a predicate but rather the expression of aspectual and inflectional features of the sentence when they cannot be expressed syncretically on the verb (see chapter 18 and the appendix of Moro 1997 for historical references). Interestingly, the idea that 'existence' cannot be a predicate is explicitly stated by Immanuel Kant in his *Critique of Pure Reason* (for an English citation see Kant 1965: 504–505).

8 For this reason, when the splitting process is not available, the only way to 'rescue' the sentence is to give it a locative meaning (sometimes referred to as 'list reading'). In other words, if *there is John, Mary, and Peter* does not allow any 'splitting' process, the only possible interpretation is to say that the subject (*John, Mary, and Peter*) is predicated the property of being in a certain place (*there*). See also section 4 in this chapter. As for the so-called list interpretation, see Abbott (1992) and references cited there, among others.

9 *Pace* independent restrictions on movement related to the internal structure of the subject itself, of course.

10 Notice that, as with the original insight by Jespersen, there is no reference to a 'word' like *there*, i.e., to a locative element, in (10). Of course, the fact that a locative element frequently occurs in existential sentences is not accidental, since 'location' is indeed a metaphoric way to express existence. Nevertheless, location is per se not obligatory; witness expressions like Chinese *you* (have) to express existence, German *es gibt* (it gives), and the literary Italian *si da/si danno* (one gives/give). Interestingly, note also that the word *existence* itself is etymologically related to location, since it is made of the Ancient Greek prefix *ek-* (from) and the verbal root *sist-* (stay).

11 For the role of *there* in language acquisition see the pioneer work by Hyams (1986).

12 The debt of Chomsky's theory to Fregean thought is indeed explicit: "Rothstein 1983 proposes that the two clauses of the EPP are in fact closely related. We may think of a lexical head as a 'lexical function' that is 'unsaturated' (in roughly the Fregean sense) if it is not provided with appropriate arguments fulfilling the theta-roles it assigns, and we may correspondingly regard a maximal projection (apart from those that are quasi-referential: NP and clause) as a 'syntactic function' that is unsaturated if not provided with a subject of which it is predicated. Then, the EPP is a particular way of expressing the general principle that all functions must be saturated" (Chomsky 1986b: 116).

13 There is an intriguing issue that I am disregarding here, i.e., what exactly is the subject position in which *there* shows up, given the fine-grained taxonomy suggested

by many authors (see for example Cinque 1979; Cardinaletti and Roberts 1990; Poletto 1993; Moro 1997). Arguably, *there* must occupy a lower position than the subject; witness the very well-known fact that no adverbs seem to intervene between the copula and *there*, as opposed to a full DP:

(i) a. the cause of the riot arguably is a picture of the wall
b. there ?*arguably is/arguably's a picture of the wall

Since the debate on this issue is still developing, I will not discuss this issue further here, and simply assume that *there* occurs in the canonical preverbal DP position.

14 The representation given here essentially reproduces the original one given by Chomsky (1991). Later (Chomsky 1993), the DP was placed on the left of *there*, i.e., [$_{DP}$ a man [$_{DP}$ there]], on a par with all other instances of syntactic movement. See also Chomsky (1995c: 273) for a further slight refinement.

15 Safir's own theory of the distribution of *there* relied on the notion of 'unbalanced chain', which I will not introduce here; see Safir (1985b) for a detailed discussion of this issue and many related issues.

16 For a different approach to the categorial status of *there* see Moro (1997, 2000), where it is claimed that it has an intermediate status: it is generated where XPs are, but it behaves like a head, i.e., like a clitic. See also fn. 13 here.

17 For a synthetic review of the general literature on this "standard" view of *there* as a place holder for the subject of predications see Milsark (1974, 1977); Jenkins (1975); Chomsky (1981, 1995c: chapter 1); Safir (1985b); Lumsden (1988); Lasnik (1995a), among others. The literature in the field is indeed vast; for some other bibliographical indications see also the references to Moro (1997: chapters 2, 3, and the appendix on a brief history of the notion of copula).

18 See for example Zwart (1991); Chomsky (1995c: 392); Den Dikken (2002); Koopman (2002).

19 For the original sources see Moro (1987, 1988). For extensive discussion see Moro (1997) or the appendix to Moro (2000).

20 Note that the existence of place holders for predicates is independently assumed across languages: for example, Italian *lo*, French *le*, or English *so* are clear candidates. That a noun phrase can play the role of a propredicate as well as a prosubject should not be surprising: this is because, more generally, the fact that a noun phrase plays the role of the subject or that of a predicate is not an inherent lexical piece of information; rather it is a function of the position in the structure where the noun phrase occurs (cf. *a man killed John* vs. *John is a man*).

21 The second option becomes plausible when one considers examples like *girls in the garden can be very attractive* or *there are girls in the garden in the fresco*. As for the position of the PP in the first sentence, it can be argued that it is in a topic position with successive remnant IP movement. See Moro (2000: 130, fn. 12).

22 I say "certain types" because obviously not all predicative noun phrases must agree in number (and gender) with their subjects, as for example in the following Italian cases:

(i) a. Gianni è un maestro/*una maestra
Gianni is a-mas. teacher.mas./a-fem. teacher.fem
b. I ragazzi sono la causa
the-mas. boys-mas.- are the-fem. cause-fem.

I will not further explore a possible generalization for this phenomenon. See Moro (1997) and references cited there for this rather murky issue.

23 As for the case involving *how many* illustrated in (22), we are led to conclude that *how many* is extracted from the subject and that *men* is pied-piped for locality reasons. For a detailed discussion see Moro (1997).

24 Of course, one could always say that there are two (or even more) different *there*s (cf., for example, Jespersen 1924 or Rothstein 1983 and references cited there): a *there* of existence and a *there* of location, relying on the different phonological status of the two *there*s. However, even disregarding the fact that this seems an ad hoc explanation, the problem is that in languages like Italian, the same problem would be reproduced with exactly the same element, i.e., the clitic *ci*, which does not have two phonological variants. We will approach this issue directly in the next section.

25 For a general survey of the issue see Reuland and Ter Meulen (1987) and references cited there, and the seminal works by Milsark (1974) and Barwise and Cooper (1981).

26 Chierchia's work leads to interesting discussions in the field of noun phrases, stemming from Carlson's (1977b) seminal work; but see Delfitto (2002: 106ff.) for an extensive discussion of this issue and a critical approach to the notion of 'semantic parameter' proposed by Chierchia.

9 Result clauses

1 Introduction

Extraposition may be defined as a process by which an element is moved to the right of, or subsequent to, its canonical position. Examples of extraposition are given in (1–3):

(1) a. That John is a fool is obvious.
    b. It is obvious that John is a fool.

(2) a. A book which was written by Chomsky appeared.
    b. A book appeared which was written by Chomsky.

(3) a. A review of Chomsky's book appeared.
b. A review appeared of Chomsky's book.

The (a) versions are assumed to represent the basic word orders, and the (b) versions are assumed to represent the extraposed versions. The extraposition that is exemplified in (1) is simply termed extraposition, following Rosenbaum (1967); the process in (2) is often called extraposition of relatives, and sometimes extraposition from NP (a term that originates in the period before nominals were analyzed as DPs); and the process in (3) is often called PP-extraposition. In this survey, Rosenbaum's extraposition will be dealt with only briefly, in section 4.1, where we discuss the status of the Right Roof Constraint, but it is necessary to delimit it, in order to emphasize the construction that we will not be talking about.

Rosenbaum's extraposition deals with the alternation in which a clausal argument of a predicate does not appear in its 'normal' position, but rather appears to the right of that position, and that position is occupied by the expletive *it*. We will be discussing another construction in which an element appears to the right of its canonical position but a gap is left. The element is either a PP or a CP. There is another construction in which an element appears to the right of its normal position, but this construction is usually distinguished in the literature from extraposition, and is termed the 'Heavy NP Shift' construction, exemplified in (4):

(4) a. I gave everything I had to John.
b. I gave to John everything I had.

Although the similarities between Heavy NP Shift and extraposition are highly suggestive of a unified analysis, a formal unification of the grammatical analysis of the two constructions has not been made, to our knowledge.

With the focus of discussion hopefully clarified, let us proceed to the question of the etiology of the extraposition construction. Four analyses have appeared in the literature: (i) rightward movement of the extraposed element from its canonical position to a position subsequent to the canonical position (Ross 1986; Akmajian 1975; Baltin 1978b, 1981); (ii) generation of the extraposed element in the extraposed position, perhaps with some interpretive process that treats it as though it were in the canonical position (Culicover and Rochemont 1990); (iii) given that extraposed elements are modifiers of some sort, generating the extraposed elements and the elements that they modify as constituents in the extraposed position, with leftward movement of the elements that are modified (Kayne 1994 and a modification of Kayne 1994 proposed by Wilder 1995); (iv) a 'mixed' analysis proposed by Fox and Nissenbaum (1999), in which some elements are moved rightward, while other 'extraposed' elements are adjuncts that are merged with heads that are moved rightward but are not pronounced in their moved positions.

We will discuss all of these analyses, and compare them, in subsequent sections, but we will first establish some high-level descriptive generalizations about the extraposition construction, as a kind of yard-stick against which to measure the success of each analysis.

2 The position of attachment of the extraposed element

To be neutral among these analyses of extraposition, it would be helpful to introduce some terminology. Let us refer to the phrase which the extraposed element is construed as modifying as the host. For example, the underlined subjects in (2b) and (3b) are hosts.

Hosts can occupy a variety of positions – the subject position is only one. For example, objects can be hosts:

(5) I called somebody yesterday who I couldn't stand.

Objects of prepositions can also serve as hosts:

(6) I talked to somebody about that who was quite knowledgeable.

Wh-phrases, presumably in [Spec, CP], can also be hosts:

(7) Who did you visit who was unhappy about the visit?

Extraposition cases such as (7), in which the host is in a derived position, raise the question of what the host is. If we assume that the *wh*-phrase and its trace form a chain, is the host the head of the chain, or the tail of the chain? Culicover and Rochemont (1990) present evidence that that host is the head of the chain. We will present this evidence below, but for now, it must be taken on faith, because the notion of a host has not been shown to have any theoretical significance; it has only been a terminological matter. It is clear, however, that unless grammatical relations are determined derivationally, i.e., pre-movement, in a way in which they are indelible, some mechanism must be countenanced that can determine the fact that a given extraposed element is the modifier of a given host. Guéron and May (1984) provide such a principle, which they dub the Complement Principle. This is presented in (8):

(8) **Complement Principle (Guéron and May's (11):**
In a sequence of categories α_i, $\beta^{i1} \ldots \beta^n_i$ in a structure Σ, $\beta^1_i \ldots \beta^n_i$ are complements to α_i only if α_i governs $\beta_1 \ldots \beta^n_i$.

They assume the following definition of government:

(9) **(Guéron and May's (12)):**
α governs $\beta =_{df} \alpha,\beta$ are dominated by all the same maximal projections, and there are no maximal projection boundaries between α and β.

Guéron and May assume May's (1985) principle that adjunction creates multimembered projections, and that to be dominated by a node is to be contained

within all of its members. They further assume that Bresnan's S' (i.e., Comp + S) is the maximal projection of S, a non-standard assumption today, the standard assumption being that there is a CP and a TP, both of which are maximal projections. Guéron and May's complement principle will be examined in section 3, but for now, we note that they require that the head of an A-bar-chain be the element that is construed with the extraposed constituent, and there are two independent reasons for allowing extraposed elements to be construed with A-bar-chain heads. The first is based on a fact first noted in Baltin (1978a, 1978b), to the effect that extraposition cannot occur out of a fronted PP:

(10) *In which magazine did you see it which was lying on the table?

The object of a preposition that remains within the VP can be related to an extraposed constituent:

(11) I saw it in a magazine yesterday which was lying on the table.

Crucially, if the preposition is stranded, a fronted *wh*-phrase can more acceptably be related to an extraposed constituent:

(12) ??Which magazine did you see it in which was lying on the table?

The essential contrast here is between (10) and (12). It is true that (11) shows that an extraposed constituent can be related to a prepositional object that is within the VP, but a prepositional object within a PP that is fronted out of the VP cannot launch an extraposed constituent. It seems, however, that a fronted prepositional object that is fronted by itself does more easily launch an extraposed constituent. We will return below to the inability of a fronted PP to host an argument that is related to an extraposed constituent. Unfortunately, the acceptability of (12) seems to be marginal.

A clearer piece of evidence that an extraposed constituent must be related to the head of an A-bar-chain, rather than the tail, is provided by Culicover and Rochemont (1997), who note the contrast between (13) and (14) (their (49) and (50), respectively):

(13) *He$_i$ [$_{VP}$ [$_{VP}$ invited several girls to the party] [$_{CP}$ that John$_i$ dated in high school]].

(14) How many girls did [$_{IP}$ he$_i$ invite to the party] [$_{CP}$ that John$_i$ dated in high school]?

If we assume that the extraposed relative in (13) is adjoined to the VP, co-indexing between a pronominal subject and an R-expression that is within the extraposed relative violates Principle C of the Binding Theory (Chomsky 1981) under standard assumptions. The fact that such co-indexing is acceptable in (14) indicates

that the extraposed relative must be outside of the domain of the subject, which it is if the extraposed relative in (14) is adjoined to CP.

Baltin (1981) shows that there is no unique point of attachment for extraposed constituents. It is shown there that constituents that are extraposed from subject position (relatives and extraposed PPs) are adjoined to IP, while relatives and PPs that are extraposed from within objects are adjoined to VP. The arguments are based on stranding contrasts of extraposed material under VP-ellipsis and VP-fronting processes. Specifically, material that is extraposed from subject position can be stranded when the VP is elided or fronted, and indeed must be stranded under those conditions, while material that is extraposed from object position cannot be stranded when the VP is elided or fronted:

(15) a. Although not many people would ride with Fred who knew just him, some would___who knew his brother.
b. Although no reviews appeared of Chomsky's book, one did___of Jakobson's book.
c. *Although he didn't call people up who are from Boston, he did ___who are from New York.
d. *Although he didn't call people up from Boston, he did___from New York.
e. John said that he would call people up who are from Boston, and call people up who are from Boston he did___.
f. *John said that he would call people up who are from Boston, and call people up he did___who are from Boston.
g. John said that he would call people up from Boston, and call people up from Boston he did___.
h. *John said that he would call people up from Boston, and call people up he did___from Boston.

This would indicate that the generalization about the structural position of extraposed phrases is the following:

(16) An extraposed phrase is adjoined to the first maximal projection that dominates the phrase in which it originates.

Therefore, an extraposed element that modifies a *wh*-phrase in [Spec, CP] would be adjoined to CP, and hence out of the c-command domain of the subject, accounting for Culicover and Rochemont's observations noted in (14). It will be noted that (16) predicts that an element that is extraposed from subject position will follow an element that is extraposed from object position, given that the former would be adjoined to a projection dominating VP, while the latter is adjoined to VP. This prediction appears to be correct:

(17) a. Someone picked some books up which were lying on the table who really didn't want to.

b. *Someone picked some books up who really didn't want to which were lying on the table.

It should be noted that while extraposition is usually thought of as applying to elements that modify nominals, the process is clearly more general. It applies to clausal and PP complements of adjectives and verbs as well (as noted by Baltin 1981):

(18) a. How fond of Sally are you?
b. How fond are you of Sally?

(19) a. How certain that the Mets will win are you?
b. How certain are you that the Mets will win?

(20) a. Believe that Fred is crazy though I may, it doesn't matter.
b. Believe though I may that Fred is crazy, it doesn't matter.

(21) a. Talk to Sally about Martha though I may, it won't matter.
b. Talk to Sally though I may about Martha, it won't matter.

Guéron and May's complement principle does not make reference to the categorial status of the head, and this is one of its virtues, as we see.

3 LF-locality between head and complement

Let us examine more closely Guéron and May's (1984) Complement Principle, repeated here, together with their definition of government:

(8) **Complement Principle (Guéron and May's (11)):**
In a sequence of categories α_i, $\beta^{i1} \ldots \beta^n_i$ in a structure $\sum$, $\beta^1_i \ldots \beta^n_i$ are complements to α_i only if α_i governs $\beta_1 \ldots \beta^n_i$.

(9) **(Guéron and May's (12)):**
α governs $\beta =_{df} \alpha,\beta$ are dominated by all the same maximal projections, and there are no maximal projection boundaries between α and β.

Assuming that the Complement Principle governs locality between an extraposed constituent and its host, S-structure cannot be the level at which the Complement Principle must hold. Guéron and May assume the S-structures advocated in Baltin (1981), in which a constituent that is extraposed from subject position is adjoined to TP, while a constituent that is extraposed from object position is adjoined to VP. They also assume May's (1985) convention regarding adjunction structures, which posits a distinction between projections and members of projections. Adjunction structures are viewed as creating multi-membered projections. Domination by a projection requires containment within all of the members of the projection, so that an adjoined element is not viewed as being

dominated by the node to which it is adjoined; rather, it is viewed as being dominated by the next higher projection. Hence, a relative clause that is adjoined to VP is not dominated by that VP, since it is not contained within the lowest member of that VP (the one to which it is adjoined), while an object would be dominated by the VP. The same argument holds, by parity of reasoning, for relative clauses adjoined to TP.

Hence, the nominal host of an extraposed relative clause would not govern it at S-structure. Guéron and May claim, however, that government by the nominal host of the extraposed relative clause would hold at LF if the nominal QRs (Quantifier Raises) to adjoin still higher than the extraposed relative clause (or PP).

As evidence for the Complement Principle's application at LF, after QR feeds the Complement Principle, it is necessary to bifurcate the class of restrictive relative clause-taking nominals into those that are quantified and those that are not, with the prediction being that only the former will be able to host extraposed relative clauses. The definite determiner *the*, and demonstratives, are not considered to be quantified, and therefore cannot cause the DPs that they head to QR. Therefore, they should not be able to host extraposed relative clauses. It has often been noted, and Guéron and May note as well, that nominals introduced by definite articles indeed do not host extraposed relatives:

(22) *The man showed up that hated Chomsky.

The claim, however, that DPs that are headed by demonstratives do not host extraposed constituents is less obviously true. Guéron and May assign a * to the following example (their (17b)):

(23) *I read that book during the vacation that was written by Chomsky.

However, it is not as bad as (22), and parallel examples are perfect:

(24) Those students will pass this course who complete all of their assignments on time.

It is, however, impossible, it seems, to improve a nominal that is introduced by a pure definite article as an extraposition host. Therefore, the predictions of the LF-locality theory of extraposition do not seem to be clearly borne out. In section 5.2, when we consider the stranding account of extraposition, we will examine an alternative, more overtly syntactic, account of the contrast between definite articles and demonstratives as introducers of extraposed relative clause hosts.

4 The Right Roof Constraint

Assuming that (16) is correct, and that extraposed elements are adjoined to the first maximal projection that dominates their 'hosts', we must ask precisely what mechanism ensures this. If extraposition is a rightward movement process, one

might locate its restriction within the theory of bounding, a specification of the locality constraints on movement. If one takes extraposition as arising from generation of the constituent in its extraposed position, and construal of this element as modifying some element to its left, the locality constraint would be taken to be a specification of the configuration in which this modification construal is licit. A third view of the rightward movement locality conditions was proposed by Kayne (1994), which we will discuss below.

First, however, a bit of history is in order. Ross (1986), taking extraposition to be a rightward movement process, noticed that extraposition had stricter constraints on how far it could move than leftward movement processes, such as *wh*-movement. Specifically, he posited a constraint that has come to be known as the Right Roof Constraint:

(25) **Right Roof Constraint:**
An element cannot move rightward out of the clause in which it originates.

An example of the Right Roof Constraint can be seen below, taken from Baltin (1978b):

(26) *John was believed to be certain by everybody that the Mets would lose.

Assuming the *by* phrase to be in the matrix clause, whose main verb is passive, it follows that the finite complement which follows it, the underlying complement of *certain*, must also be in the matrix clause, and cannot be within the infinitive. Since we have seen that clausal complements of adjectives can extrapose (as seen in (19)), something must be preventing it from extraposing out of the infinitive clause into the matrix clause, and the Right Roof Constraint seems to accurately describe this restriction.

Of course, the fact that the Right Roof Constraint needs to explicitly mention the direction of movement is a defect in a theory of Universal Grammar that incorporates it. It is clear that there is no 'Left Roof Constraint'; *wh*-movement, for example, can clearly extract elements out of the clauses in which they originate:

(27) What was John believed to be certain that we would be assigned___?

Let us put aside for the moment the objection to incorporating the Right Roof Constraint as is into the theory of grammar, while we examine its empirical adequacy.

Following Ross's extensive discussion of the range of syntactic islands, an attempt was made to unify them into a general theory of bounding of movement, a theory of locality of movement in the form of Chomsky's (1973) Subjacency condition:

(28) **Subjacency:**
In the configuration X . . . [$_{\alpha}$ . . . [$_{\beta}$ . . . Y . . .] . . .] . . . X', no element Y can be moved to position X or X', if α and β are both cyclic nodes.

It had been thought in the 1960s and 1970s that a proper subset of the set of maximal projections could be stipulated as cyclic nodes, the set of nodes that were relevant for the transformational cycle. It had been proposed that universally NP (before NPs were reanalyzed as DPs, in Abney 1987) was one of the cyclic nodes, and either CP, IP (in those days, S′ and S respectively), or both were cyclic nodes as a parameter.

Many of the empirical effects of the Right Roof Constraint could be derived from Subjacency, but not all, as shown by Baltin (1981), to whom we will return. Akmajian (1975) showed, however, that the Right Roof Constraint, which mentions only the clause as setting a boundary for rightward movement, is too weak, in that extraposition seems to be much more bounded in its movement, the required boundary being at a subclausal level. Akmajian discussed the ambiguity of (29):

(29) A review of a book by three authors appeared.

The ambiguity hinges on the modification relation between the second PP and the NP that it is taken to modify, with different structures for the subject. Presumably, assuming again that nominal arguments are NPs rather than DPs (for historical fidelity to the work cited, although nothing hinges on this), the structures would be as in (30):

(30) a. $[_{NP}$ A $[_{N'}$ $[_{N'}$ review of a book] $[_{PP}$ by three authors]]]
b. $[_{NP}$ A $[_{N'}$ [review] $[_{PP}$ $[_{P}$ of] $[_{NP}$ a book by three authors]]]]

In (30a), the second PP is within the highest NP, representing the reading in which three authors penned the review, while in (30b) the second PP is within the lowest NP, representing the reading in which three individuals wrote the book. Akmajian noted, however, that PP extraposition of the second PP removes the ambiguity, with the reading corresponding to (30a), rather than (30b):

(31) A review of a book appeared by three authors.

Assuming extraposition to be an instance of movement, movement out of the lowest NP would violate Subjacency, since the PP would have to cross two NPs to move out of the subject, while movement out of the higher NP would only cross one NP, obeying Subjacency.

Baltin (1978a, 1978b) and, independently, Van Riemsdijk (1978a), argued that PPs also had to be counted in the set of cyclic nodes that were relevant to Subjacency. These authors argued on the basis of leftward movement restrictions as well, but one argument, from Baltin (1978a), was the account that inclusion of PP in the inventory of cyclic nodes would furnish of the inability of extraposition of relative clauses to occur out of fronted PPs, noted in (10), repeated here:

(10) *In which magazine did you see it which was lying on the table?

If the PP and the NP that contain the relative clause are both counted for Subjacency, Subjacency rules out extraposition of a relative clause to a position outside of the PP.

A problem for this account, however, is the fact that such extraposition does seem to be possible out of a PP that remains inside of the VP, as noted in (11), repeated here:

(11) I saw it in a magazine yesterday which was lying on the table.

One account of the difference in extraposition possibilities between (10) and (11) relied on a notion of 'reanalysis' of the preposition, causing it to incorporate, in current parlance, into the verb, and presumably pruning the preposition's projections, so that there would be no PP node in (11) that would dominate the NP out of which extraposition took place. The reanalysis account was extremely influential for a number of years, but Baltin and Postal (1996) presented several arguments, to which the reader is referred, that there is no reanalysis of prepositions that occurs within the VP. For example, comparative subdeletion cannot occur in the object of a preposition, while it clearly can to uncontroversial objects, so that the contrast in (32) holds:

(32) a. *John talked to more of these people than he talked to___of those people.
b. John read more of these books than he read___of those books.

The contrast between (10) and (11) seems to be identical to the contrast in (33) and (34), involving anaphoric binding rather than extraposition:

(33) *To whom did he talk about each other?

(34) I talked to them about each other.

On the face of it, the contrast between (33) and (34) would seem to argue for reanalysis of the preposition with the verb, allowing the prepositional object to then c-command the second PP (again assuming subsequent pruning or some sort of analogous device of the preposition's original projection(s)). However, as shown by Baltin and Postal, we get contrary results for Principle B, involving pronouns:

(35) *To whom$_i$ did John talk about him$_i$?

(36) *John talked to Fred$_i$ about him$_i$

Assuming a uniform definition of c-command that would underlie Principle A and Principle B, we would first have to make reanalysis obligatory, to account for the impossibility of binding in (36), but the impossibility of binding in (35) is unexplained, since reanalysis would not be able to apply to the fronted P.

Another possible avenue of pursuit in the account of why PPs that remain within the VP allow extraposition out of them, within the attempt to subsume bounding constraints on extraposition from subjacency, would be the adoption of Chomsky's (1986a) revised formulation of Subjacency in the context of the *Barriers* approach. In this view, subjacency makes reference not simply to the number of maximal projections between the original position of a moved element and the position to which it moves; rather, reference is made to the number of barriers between a moved element and its trace, where a barrier is a maximal projection that is not L-marked (roughly speaking, L-marking means being a complement to a lexical category and being theta-marked by that lexical category). To see the need for relativization of the set of bounding nodes for subjacency to the set of L-marked maximal projections, consider (37), in which *wh*-movement is occurring out of an infinitival complement of a noun that is the semantic head of the object (Chomsky 1986a has similar examples):

(37) Who$_i$ did you announce [$_{DP}$ . . . [$_{NP}$ plans [$_{CP}$ to visit t_i]]]?

This would be ruled out by the earliest formulation of subjacency, but permitted by the *Barriers* approach to subjacency.

With this in mind, if a PP that remains within the VP is a selected complement of the V, and the prepositional object presumably bears the same relation to the P, neither said PP nor its object will be barriers, and subjacency will not be violated. A fronted PP, on the other hand, will be a barrier, since it is not in a configuration to be L-marked. Hence, the difference between (10) and (11) is accounted for.

We must still ask, however, how (26), repeated here, is accounted for if we assume the *Barriers* approach to Subjacency:

(26) *John was believed to be certain by everybody that the Mets would lose.

There is one way in which extraposition out of an infinitival complement that remains within the VP could be ruled out. An ECM infinitive, or an infinitive out of which raising can occur, is standardly analyzed as a TP complement. Although the TP is L-marked, and would therefore not be a barrier by itself, it does dominate the VP, which is a blocking category and a barrier, and therefore the TP would be a 'barrier by inheritance'. Hence, extraction out of the infinitive would cross two barriers – the VP and the CP.

Given that subjacency is taken to induce weak violations, with the number of barriers crossed leading to increased unacceptability, crossing two barriers is taken to induce unacceptability, while crossing one does not. For example, extraposition of the clausal complement of a *wh*-moved adjective does not induce any unacceptability:

(38) How fond are you of Sally?

However, assuming that movement over one barrier is possible, we can see that subjacency is insufficient in and of itself to account for the locality constraints on

the extraposition relation between an extraposed element and its host. For example, a relative clause that is extraposed from object position to a position outside of the VP would only be crossing one barrier, the VP, given that the object is L-marked by V, and yet we saw that such extraposition leads to unacceptability, as seen in (15f), repeated here:

(15) f. *John said that he would call people up who are from Boston, and call people up he did___who are from Boston.

Similarly, if we assume that prepositions L-mark their complements, extraposing a relative clause out of a fronted PP would only cross one barrier – the PP itself. We would therefore have no account of the impossibility of such extraposition, exemplified by (10), repeated here:

(10) *In which magazine did you see it which was lying on the table?

As a matter of historical fact, between the formulation of subjacency in Chomsky (1973), which simply counted cyclic nodes, and the *Barriers* formulation of subjacency in Chomsky (1986a), another formulation of subjacency was proposed by Baltin (1981). In that formulation, there was believed to be an asymmetry between the set of bounding nodes for rightward and leftward movements, such that every maximal projection was considered to be a bounding node for rightward movement, and only a subset of these were bounding nodes for leftward movements. The formulation is given in (39):

(39) **(Baltin 1981: 8) Generalized Subjacency:**
In the configuration A . . . [$_{\alpha}$ . . . [$_{\beta}$ . . . B . . .] . . . l . . . A',
ii. A' cannot be related to B where a and b are maximal projections of any major categories;
iii. A cannot be related to B where α and β are drawn from the following list of phrasal categories; (a) PP; (b) NP; (c) S or S' or both, depending on the specific language.

This asymmetry was motivated by the general impossibility of extraposing out of any VP complement to a position outside of the VP. An example would be the unacceptability of (40b) as opposed to (40a):

(40) a. Become fond of Sally though he may, it won't matter.
b. *Become fond though he may of Sally, it won't matter.

It was assumed in Baltin (1981) that the complement of *become* is an AP, and hence the extraposition in (40b) would involve movement past AP and VP. Clearly, leftward *wh*-movement of the PP is perfectly acceptable:

(41) Sally, of whom I became quite fond___, is an exceptional linguist.

4.1 The status of the Right Roof Constraint

There are some problems with the Right Roof Constraint and its successor, Generalized Subjacency. These problems are of both an empirical and a conceptual nature. Let us begin with an empirical problem.

We noted that PPs that are located within the VP can host extraposition of relative clauses out of them, as in (11), repeated here:

(11) I saw it in a magazine yesterday which was lying on the table.

Without reanalysis, Generalized Subjacency is apparently violated with impunity, since the relative clause, if extraposed, is crossing the NP or DP, as well as the PP dominating the host nominal. It is clear, however, that such violations are not systematically possible. For example, if we adapt Akmajian's example by placing the complex nominal within the VP, the extraposed PP cannot be interpreted as modifying the most deeply embedded nominal:

(42) I read a review of a book yesterday by three authors.

One potential problem may lie in the acceptability of the following:

(43) I would prefer for everyone to leave that you would___.

Sentence (43) seems to be an example of the much-discussed Antecedent-Contained Deletion (ACD) construction, originally discussed by Bouton (1970), and then by May (1985), Baltin (1987), Larson and May (1990), Hornstein (1994), and others. ACD is the phenomenon whereby ellipsis occurs apparently in the antecedent of the elided material. Another example is given in (44):

(44) I read everything you did___.

Assuming that the VP of the relative clause in (40) has undergone VP ellipsis (including elision of the trace of the relative clause operator), the antecedent of the elided VP appears to contain the elided VP, and reconstruction or copying of the antecedent into the null VP would lead to an infinite regress. To solve this problem, it is necessary to perform some operation that would move the relative clause out of the antecedent VP, so that the antecedent does not contain the VP to be elided at the stage at which the identity between antecedent and ellipsis candidate is to be determined.

There have been three main mechanisms in the literature to accomplish this configurational rescue: (i) Quantifier Raising of the DP at LF (May 1985; Larson and May 1990); (ii) extraposition of the relative clause out of the VP (Baltin 1987); (iii) movement of the DP that contains the null VP to [Spec, Agr-O″] for Case-checking reasons (Hornstein 1994).

Consider the difference between (43) and (45):

(45) *I would prefer for everyone that you would to leave.

Presumably the infinitival sequence which follows the infinitive's subject is a non-maximal projection, hence unable to extrapose out of the highest VP. The entire infinitive subject is therefore assumed to be a complex nominal, i.e., a constituent, and hence the relative clause in (45) would have to be contained within its antecedent.

Crucially, the antecedent in (43) is assumed to be the matrix VP, so that (43) means that I would prefer for everyone to leave that you would prefer to leave. However, in order to avoid antecedent containment, the relative clause in (43), if extraposed, would have to cross the TP of which it is subject, the CP, and the DP, violating Generalized Subjacency.

It would seem, therefore, that in at least two situations, when the host of the extraposed element is located within the VP, Generalized Subjacency, an extension of Ross's Right Roof Constraint, is violated. However, it cannot be violated in Akmajian's cases, as in (42).

The conceptual problem with Generalized Subjacency is its stipulative nature. Why should there be an asymmetry between the set of movement barriers for rightward and leftward movement? Moreover, the stipulation of the set of bounding nodes for leftward movement, an embarrassment for pre-*Barriers* formulations of Subjacency, remains in this account.

4.2 *Alternative accounts of the Right Roof Constraint in other approaches to extraposition*

At this point, it may be useful to compare the other two approaches to extraposition – the non-movement account and the stranding account – with respect to how they handle the bounding restrictions on the extraposition relationship. These two accounts will be examined in more detail in subsequent sections, but it will be useful to look at these approaches simply with respect to this issue.

First, with respect to the non-movement account, notice that the Complement Principle, given in (8), will ensure locality between the extraposed element and its host, given that the extraposed element must be adjoined to the minimal maximal projection containing the host (Culicover and Rochemont 1997) in order to be interpreted as a complement. Hence, violations of Generalized Subjacency will be due not to this constraint per se as a primitive, but to the Principle of Full Interpretation (Chomsky 1986b), given that an extraposed element that is adjoined above the first maximal projection that dominates the element that it is supposed to modify will not be in the right configuration to modify that element. Unless there is some other role for the extraposed element to play in the interpretation, it will simply be superfluous, and cause the structure to run afoul of the Principle of Full Interpretation.

It is clear, however, that the problems for Generalized Subjacency remain as problems for the Complement Principle. Without reanalysis, (11) violates the

Complement Principle, just as it violated Generalized Subjacency, and (43), for which reanalysis is even less plausible, violates the Complement Principle in exactly the same way as it violates Generalized Subjacency. In both cases, the extraposed element, assuming that it is adjoined, is adjoined higher than the first maximal projection dominating the candidate for modifiee.

Another alternative to the Right Roof Constraint was proposed by Kayne (1994), within the context of the stranding analysis of extraposition. Recall that the stranding analysis eschews rightward movement of the modifier. Kayne only discusses relative clause extraposition, but presumably the analysis would be extended to extraposition of complements of other types of modifiers, as in (18–21). In Kayne's analysis, the head is moved leftward by normal leftward movement (presumably A-movement), stranding the relative clause. Hence, the "extraposed" position is in fact the base position of the head. This analysis affords us the opportunity to view with a fresh eye Right Roof Constraint violations such as the following (Kayne 1994's (5), chapter 9):

(46) *The fact that somebody walked into the room is irrelevant who I knew.

Kayne notes that if we assume the stranding analysis, the head of the relative clause would have to originate in the matrix clause and move leftward, lowering into the subject noun-complement clause. Given that the nominal is not an argument of the matrix predicate, generating it in this position would violate the theta-criterion, however it is recast in Minimalist terms. Second, the movement would be movement to a non-c-commanding position, violating an assumption that movement is always to a c-commanding position (although see Bošković and Takahashi 1998 for a defense of lowering rules).

Hence, the stranding analysis of extraposition replaces Generalized Subjacency with either of two restrictions: (i) the requirement that arguments be generated in the domain of their heads; (ii) a ban on movement to non-c-commanding positions.

It can be shown, however, that while (ii), the ban on lowering, may be accurate, (i) is not. Turning our attention to extraposition of clausal arguments, discussed by Rosenbaum (1967), consider the following sentence, discussed in Baltin (1978a):

(47) It was believed to be certain by everybody that Fred would win.

Assuming that the *by* phrase is in the matrix clause, the finite complement, certainly an argument of *certain*, must also be in the matrix clause. Extraposition of clausal arguments clearly obeys Generalized Subjacency:

(48) a. That it was obvious to everybody that Bush was a moron surprised me.
b. *That it was obvious to everybody surprised me that Bush was a moron.

It should be noted that (47) contrasts with (26), repeated here:

(26) *John was believed to be certain by everybody that the Mets would lose.

What is the basis of this contrast? One immediate observation that comes to mind is that in (47), the finite complement is related to the expletive in some way, and the expletive has clearly undergone A-movement into the matrix. In (26), the clausal argument cannot be related to any position in the clause in which it resides; there is no expletive, for one thing.

The reanalysis of extraposition, viewed as a rightward movement, as stranding, a leftward movement, is done in the context of Kayne's (1994) Linear Correspondence Axiom (LCA), which maps linear precedence onto asymmetric c-command, such that if A asymmetrically c-commands B (A and B are assumed to be non-terminals), the terminals that A dominates must precede the terminals that B dominates. Therefore, rightward adjunction would be impossible, because the results could not be linearized.

The alternation that is characterized by extraposition must be characterized by any grammar, including one that assumes the LCA as the basis for linear order; one way to capture the relationship between the variant in which the clausal argument appears in subject position and the variant in which it appears in final position (the subject position being occupied by the expletive *it*) would be to generate the clausal argument in final position, and allow it to move leftward into subject position. Hence, the structure in which the clausal argument is in 'extraposed' position, corresponding to (49a), would be more basic than the structure in which the clausal argument is in subject position, corresponding to (49b):

(49) a. It is obvious that Fred is crazy.
b. That Fred is crazy is obvious.

Indeed, this was the tack that Emonds (1970, 1972b) took, in an analysis of the alternation that was an alternative to Rosenbaum's, labeling the leftward movement process 'intraposition'.

If we adopt the leftward-movement characterization of the extraposition analysis, the intraposition view – sentences such as (43), in which clausal arguments are in clauses superior to the ones in which their selecting predicates occur – indicates that Kayne's first suggestion as to how to rule out Right Roof Constraint violations cannot be correct. Arguments would have to be permitted to be generated in clauses that are superior to the ones in which they are arguments, under this view.

The second barrier to leftward movement of all or part of an argument into a lower clause – the fact that such movement would be lowering to a non-c-commanding position – may be more promising. The problem here comes from consideration of the case in which the clausal argument appears in final position, with the subject position apparently occupied by the expletive *it*. No overt movement of the clausal argument occurs here. In earlier times, Emonds (1970, 1972b) suggested that the expletive and the clausal argument were 'co-indexed'. If this were true, the unacceptability of apparent Right Roof Constraint violations that involve clausal argument extraposition, such as (48b), might be due to a requirement that such co-indexing requires c-command.

However, current Minimalism eschews indices in general. A more recent mechanism for the relationship of expletive–associate pairs, which Chomsky (1995c) pursues for *there*-expletives, involves positing the expletive *there* as defective, i.e., missing some of the features of T, in whose specifier position it occurs. The associate of the expletive has these features (Case and phi-features), so that these features would then raise and adjoin to T. However, crucially, Chomsky contrasts English *it*-expletives, which are not defective, so that features of the associate would not raise to T (1995c: 288). If this is correct, then there would seem to be no device to explicitly mark the relationship between the expletive and the clausal argument in the final representation.

However, we would then have to ask what is responsible for the Right Roof Constraint effects in (48b). It can be seen from examples such as (47) that arguments can be higher than their selecting predicates. If there is no device to explicitly relate the expletive and clausal argument pairs in extraposition constructions, then what is responsible for the Right Roof Constraint restrictions in this construction?

In fact, one possible move might be to generate the expletive and the clausal argument together, and move either the expletive or the clausal argument into subject position. In English, the expletive and the clausal argument cannot surface together, for reasons that we cannot explore here, but the two can surface together in Scandinavian languages, according to Chomsky (p.c., citing Dianne Jonas). If this is correct, one can perhaps assimilate Rosenbaum's view of extraposition to Kayne's view of extraposition as, in fact, leftward movement of the non-clausal part of an argument, stranding the clause. In the phenomenon that Rosenbaum analyzed, it would be the expletive itself that is moving leftward, rather than the semantic head of the relative clause. It would be necessary, however, to attribute the Right Roof Constraint effects to a ban on movement to a non-c-commanding position, rather than a requirement that arguments be generated within the same local domain as the heads that license them.

5 The base-generation analysis of extraposition and the stranding analysis in greater detail

5.1 The base-generation analysis

The earliest analysis of the extraposition phenomenon viewed it as arising from rightward movement of clauses and prepositional phrases. There are a number of problems that arise from this analysis of extraposition. One is a theory-internal problem that can be seen from considering extraposition of relatives and PPs from subject position. In Government-Binding theory terms, the Empty Category Principle (ECP), originally proposed in Chomsky (1981) and revised and refined in numerous works in that period, required that traces be properly governed, in the sense of being governed by either a lexical category (later, the trace's theta-role assigner) or its antecedent; traces of categories which were not theta-governed

had to fulfill the latter requirement. The subject position was always a barrier to government, and relative clauses, which have been viewed as adjuncts, are not theta-governed. Hence, as originally noted by Howard Lasnik (cited in Baltin 1987), if a relative clause were extraposed from subject position, and it left a trace, the trace would violate the ECP. Extraposition of a PP complement of a noun would not violate the ECP, since the PP would be governed by the noun, its theta-role assigner.

It is important to note an objection to a movement account of extraposition that was advanced often in the 1970s through the early 1990s that no longer has any force. As noted by Akmajian (1975) in a footnote, and often repeated, one might ask why extraposition could not violate subjacency by successive cyclically moving the extraposed element to adjoin to the first bounding node, and then the next, etc., parallel to the successive-cyclic movement of *wh*-elements, which, of course, superficially violate subjacency, but do not in reality because of the successive-cyclic character of *wh*-movement.

The reason that the question of why successive-cyclicity for extraposition was not possible was even raised in Akmajian (1975), and subsequently, was that successive-cyclicity was supposed to be the norm for movement, an assumption that was crucial in Chomsky (1986a), for example, who used widespread adjunctions to barriers as a means of voiding barrierhood. This assumption is no longer held within, e.g., Minimalism, where it is held that movement is only done for, e.g., feature-checking (Chomsky 1995c) or for some other purpose, pragmatic or semantic (Reinhart 1995, 1997; Fox 1999), a principle known as 'Last Resort' (Chomsky 1991, 1995c; Lasnik 1999). If Last Resort is assumed, something extra must be assumed to allow for successive-cyclic movement. For example, to allow for successive-cyclic raising, Chomsky (1995c) makes a distinction between interpretable features, which are checked but not erased, allowing an element to keep moving to check features of a target, and uninterpretable features, which are deleted as soon as they are first checked. If we assume that extraposition does not check any interpretable features, it could not be successive-cyclic, and the question disappears. Of course, the question within Minimalism, assuming Last Resort, would be what feature(s) extraposition would check. There is no satisfactory answer to this question at this time.

An extremely straightforward argument against a movement account of extraposition is based on a phenomenon originally noted by Perlmutter and Ross (1970). There are extraposed relative clauses with split antecedents, one in each conjunct of a coordination. In this case, there is no single head that could serve as the antecedent for the relative clause. The phenomenon is manifest when the relative clause contains a symmetric predicate, one requiring a plural subject:

(50) A man entered the room and a woman left who were similar.

Interestingly enough, such split antecedence appears to be possible only across conjuncts:

(51) *A man visited a woman (yesterday) who were similar.

It is also only possible when the two antecedents are in parallel positions within the conjuncts; a subject in the first conjunct cannot combine with an object in the second:

(52) *A man entered the room and I saw a woman who were similar.

Needless to say, as Perlmutter and Ross (1970) noted at the time, such cases of extraposition are extremely problematic for a movement account of this construction, since there is no plausible source for the origin of the relative clause within a single nominal. Such cases of extraposition would therefore appear to lend credence to a base-generation approach to extraposition. However, it is necessary to account for the apparent need for parallel positions for the antecedents in the split antecedent construction.

One line that might be pursued in accounting for these restrictions might be to make use of the difference in adjunction sites for relative clauses extraposed from subject position vs. those for relative clauses extraposed from object position. It should be recalled that the former were shown to be adjoined to TP, while the latter were adjoined to VP. Assuming that this difference in adjunction sites is relevant to the reconstruction of the complement relation, such that a complement could be at most adjoined to the maximal projection dominating the element to which it is to be interpreted as complement, the relative clause in (52) would have to be adjoined to the TP conjunction. This would allow the extraposed relative to be interpreted as modifying the subject in the first conjunct, but not the object in the second.

This account would also explain why split antecedence is not possible in simple sentences, as in (51). The extraposed relative could be interpreted as modifying the subject if adjoined to TP, but it would not be able to be interpreted as modifying the object in that case. If it is adjoined to VP, it could modify the object, but could not then modify the subject (if we assume that modifiers cannot be interpreted as being lower than the phrases they modify).

The Complement Principle, in tandem with the Principle of Full Interpretation (Chomsky 1986a), which requires that all elements that are present at LF must be integrated into the sentence in some way, thus accounts for the locality restrictions on 'extraposed' (the term being used in a purely descriptive sense now) elements vis-à-vis the elements that they modify. However, there is a cost. The term *complement* is usually reserved for a phrase that is an X-bar sister of an X^0 head that assigns it a theta-role; it is an argument of that head. Elements that modify higher projections are considered adjuncts. The Complement Principle does not distinguish between complements, which are internal arguments of some theta-role assigning X^0, and adjuncts, so that the underlined elements in both (53a) and (b) are considered complements:

(53) a. A review appeared <u>of Chomsky's book</u>.
b. A man showed up <u>who was quite convincing</u>.

While this may be accurate for the LF grammatical relations of these phrases, it does not reflect their underlying grammatical relations. The same problem shows up clearly in examples of extraposition that modify phrases other than nominals, such as the following, pointed out by an anonymous *Linguistic Inquiry* reviewer to Culicover and Rochemont (1990):

(54) a. How fond of Sally are you?
b. How fond are you of Sally?

The adjective *fond* obligatorily takes a PP headed by *of* as an internal argument, and yet a traceless structure with the Complement Principle would simply note the locality between the 'extraposed' PP and the AP headed by *of* – in other words, placing the PP in the configuration of an adjunct, modifying the AP. Nowhere is, e.g., the obligatory selection between the PP and *fond* reflected in this structure.

In sum, it would seem that the adoption of the Complement Principle obscures what has been thought to be a crucial grammatical distinction between arguments and adjuncts, and complicates the view that there are linking regularities between thematic relations and syntactic positions for realizing those thematic relations (Perlmutter and Postal 1977; Carter 1988; Pesetsky 1995; Gruber 2000).

5.2 The stranding analysis

As noted earlier, the stranding analysis of extraposed constituents (Kayne 1994) generates them, together with their hosts, in the positions in which they ultimately reside, and moves the host into its surface position, minus the relative clause. To see how this works, we must first discuss the analysis of relative clauses within this approach.[1]

First of all, relative clauses are analyzed as CP complements of determiners,[2] and the heads of relative clauses are promoted from within the relative clauses themselves, an analysis first advocated in the 1970s by Schachter (1973) and others. Hence, the structure of, e.g., (55) would be as in (56):

(55) The book that I read.

(56) $[_{DP}\ [_{D}$ the$]\ [_{CP}\ [_{NP}$ book$]\ [_{C'}\ [_{C}$ that$]\ [_{TP}$ I $[_{VP}\ [_{V}$ read$]\ [_{NP}$ t$]]]$

Hence, the nominal 'head' of the relative clause is within the Spec of the CP of the head of the relative clause, and, at least in the case of the determiner *the* introducing the relative clause, does not form a constituent with the determiner. This aspect of the analysis is crucial, as we will see in section 5.2.1, for accounting for stranding possibilities for relative clauses headed by various determiners. Other determiners are not located as the highest head of DP, but are in fact within the NP, such as numerals or the indefinite article *a*:

(57) Two books that I read.

(58) $[_{DP}\ [_{D}\ 0]\ [_{CP}\ [_{NP}$ two books$]\ [_{C'}\ [_{C}$ that$]\ [_{TP}$ I $[_{VP}\ [_{V}$ read$]\ [_{NP}$ t$]]]$

As evidence for this analysis of relative clauses, Kayne notes that the definite article cannot introduce a simple nominal with a postnominal genitive, as in (59):

(59) *The picture of John's.

Postnominal genitives that are introduced by *the* are possible when the nominals are further modified by relative clauses, however:

(60) The picture of John's that we like.

In contradistinction to *the*, numerals can introduce postnominal genitives in simple nominals:

(61) Two pictures of John's.

Briefly, Kayne analyzes nominals such as (61) as being headed by *of*, which he takes to be a determiner (D), and the material to the left of *of* in (61) originates in the NP complement of *of*, which then moves to its specifier. The two stages are shown in (62):

(62) a. $[_{DP}\ [_{D}$ of$]\ [_{NP}$ John's $[_{NP}$ two pictures$]]$
b. $[_{DP}\ [_{NP}$ two pictures$]^{i}\ [_{D}$ of$]\ [_{NP}$ John's $t^{i}]$

However, if *the*, unlike the numerals and the indefinite article, is a D which cannot take a DP complement, the impossibility of postnominal genitives introduced by *the* is accounted for.

With this in mind, we are now in a position to see some advantages of the stranding analysis of relative clause extraposition.

5.2.1 Advantages

It will be recalled that in section 3, we reviewed the claim by Guéron and May (1984) that the hosts of extraposed constituents had to be quantified. One piece of evidence for this claim was the observation that nominals which were introduced by the definite article *the* were impossible hosts for extraposed constituents, as in (22), repeated here:

(22) *The man showed up that hated Chomsky.

Guéron and May tied the impossibility of (22) to the non-quantified status of the head of the relative, but the stranding analysis offers a competing account.

The structure of a complex nominal which is introduced by *the* has the structure in (63):

(63) $[_{DP}\ [_{D}$ the$]\ [_{CP}\ [_{NP}$ man$]\ [_{C'}$ that hated Chomsky$]]$

Crucially, the determiner *the* and the NP *man* do not form a constituent under this analysis, and under the traditional assumption that only constituents can move, the derivation of (22) from a structure which corresponds to (64) would illicitly involve movement of a non-constituent:

(64) e showed up $[_{DP}\ [_{D}$ the$]\ [_{CP}\ [_{NP}$ man$]\ [_{C'}$ that hated Chomsky$]]$

We therefore have two proposed methods of preventing nominals that are introduced by *the* from hosting extraposed relative clauses. The first method, that of Guéron and May (1984), bases the method on the syntactico-semantic properties of the determiner; the second method, relying on Kayne (1994), bases the account on a purely syntactic restriction on the definite article *the* – it is a D^0, higher in the DP than numerals and the indefinite article. Can we find any additional evidence to choose between the Guéron and May account and the Kayne-based account?

We can. It will be recalled that the restriction on demonstratives introducing hosts of extraposed relatives, to the extent that the restriction is real at all, is much weaker than the restriction on *the* introducing hosts of extraposed relatives, as was seen from the perfect acceptability of (24), repeated here:

(24) Those students will pass this course who complete all of their assignments on time.

Demonstratives and *the* are equally definite; consequently, some other factor must be responsible for the distinction between (22) and (24).

It turns out that demonstratives, unlike the definite article *the*, can introduce postnominal genitive constructions:

(65) Those pictures of John's . . .

By the reasoning in Kayne (1994) concerning the postnominal genitive, demonstratives must be lower within the DP than the definite article, perhaps within the NP itself. Hence, the structure of the relative clause in (24) would be, in the relevant respects, (66):

(66) $[_{CP}\ [_{DP}\ [_{DP}\ [_{NP}$ those students$]\ [_{D'}\ [_{D}$ who$]]]_{i}\ [_{C'}\ [_{C}\ [_{TP}\ t_{i}\ [_{T'}\ [_{T}\ [_{VP}$ complete all their work on time$]]]]]$

The prediction would be the following: the ability to introduce a postnominal genitive construction would correlate with the ability to host an extraposed relative clause. More research is needed to see if this correlation holds.

Similarly, the inability of the host of an extraposed relative clause to reside within a fronted PP, noted in the discussion of (10), repeated here, has a natural explanation within the stranding analysis:

(10) *In which magazine did you see it which was lying on the table?

The preposition plus NP do not form a constituent if the head of the relative clause resides within the Spec of CP.

Of course, the fact that apparent prepositional objects that reside within the VP can host extraposed relative clauses, as in (6), repeated here, poses the same problems for the stranding analysis as it did for Generalized Subjacency, discussed in section 4:

(6) I talked to somebody about that who was quite knowledgeable.

5.2.2 Disadvantages

Given that a relative clause that is extraposed from subject position is to the right of the VP, the stranding analysis requires a stage of derivations in which the subject is to the right of VP, with the subject moving to [Spec, AgrP] or whatever the superficial subject position turns out to be. Assuming movement is always to a c-commanding position (a position that is currently predominantly but not universally accepted: Bobaljik and Brown 1997; Culicover and Rochemont 1997), note the following binding contrast involving extraposition from object position:

(67) **(Culicover and Rochemont 1997's ex. (7a) and (b)):**
  a. I sent her$_i$ many gifts last year that Mary$_i$ didn't like.
  b. *I sent her$_i$ many gifts that Mary$_i$ didn't like last year.

The pronominal first object c-commands the second object (Larson 1988b, based on Barss and Lasnik 1986), triggering a Principle C violation (Chomsky 1981) in (a), but if the only difference between the derivation of (67a) and (67b) is the complexity of the moved material into the second object position, Principle C should rule out both (67a) and (67b), as pointed out by Culicover and Rochemont. In short, it would appear that the 'extraposed' constituent is not c-commanded by its host.

A characterization of the positions from which stranding can occur is not a trivial matter. For example, Kayne (1994: 121, (21)) proposes that "A relative clause can be stranded by A-movement only in a non-Case position." However, if we assume, as is standard, that nominals that undergo passive A-movement are in non-Case positions, we would predict from this statement that a relative clause can be stranded in the first object position of a passive double object construction, contrary to fact:

(68) *Someone was given who liked Steinbeck an interesting book.

Kayne in fact discusses such cases, and suggests (1994: 166, fn. 4) that their deviance may be "an extreme case of the constraint against complex specifiers." However this constraint is formulated, it would seem to have to distinguish between specifier positions to which Case is assigned, and specifier positions to which Case is not assigned (or checked), given that the former positions, which don't allow stranding of the relative, do allow the entire DP to occur in them, and the entire DP is presumably more complex than the stranded relative.

If we look again at Culicover and Rochemont's examples, (13) and (14) repeated here, we see that stranding must be possible under A-bar movement:

(13) *He$_i$ [$_{VP}$ [$_{VP}$ invited several girls to the party] [$_{CP}$ that John$_i$ dated in high school]].

(14) How many girls did [$_{IP}$ he$_i$ invite to the party] [$_{CP}$ that John$_i$ dated in high school]?

This would, of course, be possible, if *wh*-movement first involved movement to an intermediate A-bar position that is higher than the surface subject position, as suggested for other cases by Chomsky (1986a). However, we then have no account, other than the necessarily extremely refined constraint against complex specifiers, as to why relatives cannot be stranded in object position, as in (69):

(69) *How many girls did he consider who were from Boston interesting?

(14) would furthermore require first movement of the object to pre-IP position, and then subsequent preposing of the IP as remnant movement to the left of the preposed object. These movements would require independent motivation.

In short, the stranding analysis captures some facts rather neatly, such as the distinction between demonstratives and definite-determiner-headed DPs as extraposition 'hosts', but it also suffers from some shortcomings, such as the binding facts that indicate that extraposition hosts must be lower than the extraposed material (64), the lack of a precise characterization of the positions from which stranding would take place, and the Perlmutter–Ross observation that extraposed relatives can have split antecedents.

6 Extraposition of PP

Barbiers (1995), in discussing extraposition of PPs in Dutch, notes that focus particles cannot precede extraposed PPs, although they can precede PPs that are moved by other processes, such as topicalization. He cites the following pattern:

(70) **(Barbiers 1995: chapter 4, ex. (6)):**

a. Jan heeft [$_{PP}$ pas in EEN stad] gewerkt.
John has just in one city] worked
'John has just worked in one city'.

b. Jan heeft [$_{FoP}$ pas [$_{VP}$ gewerkt] [$_{PP}$ in EEN stad].
John has just worked in one city
'John has worked in just one city'.
c. Jan heeft [$_{PP}$ in EEN stad] [$_{VP}$ gewerkt] pas.
John has in one city worked just
'#John has worked in just one city#. (# means 'unacceptable in this interpretation'.)'
d. *Jan heeft [gewerkt] [$_{PP}$ pas in EEN stad].
John has worked just in one city
e. [$_{PP}$ Pas in EEN stad] heeft Jan gewerkt.
Just in one city has John worked
'John has worked in just one city'.
f. Jan heeft [gewerkt] [$_{PP}$ in pas EEN stad].
John has worked in just one city
'John has worked in just one city'.
g. *Jan heeft [$_{PP}$ in pas EEN stad] gewerkt.
John has in just one city worked

The aforementioned contrast is between (70d) and (70e). Assuming that PP extraposition is rightward movement of the extraposed constituent, we must ask why a PP that is introduced by a focus particle cannot be extraposed. As seen from (70f), focus particles can occur within extraposed PPs; they just cannot introduce them.

Barbiers's account of this fact relies on a general account of the syntax–semantics mapping that he proposes and motivates within that work, and a detailed account of that proposal is beyond the scope of this chapter. Briefly, he proposes a principle of semantic interpretation:

(71) **(Barbiers 1995: 4.10) Principle of Semantic Interpretation:**
I. A node Z establishes a **S(EMANTIC)-RELATION** between a node X and a node Y iff X immediately c-commands Z and Z immediately c-commands Y.
II. Z is a **QUALIFIER** of X iff Z establishes a S(emantic)-relation between X and Y, and X and Y are coindexed.

Barbiers, in his chapter 2, defends a notion of c-command that differs somewhat from standard definitions. It is presented as (72) (his chapter 4, fn. 7):

(72) a. **C-command:**
X c-commands Y iff
(i) X does not dominate Y and Y does not dominate X
(ii) There is a (connected) path of left branches from Z, the minimal node that dominates X and Y, to X
b. Immediate c-command
X immediately c-commands Y iff X c-commands Y and there is no closer c-commander W such that X c-commands W and W commands Y

c. Connected path of left branches
Two paths of left branches A and B are a connected path of left branches AU B iff there is no node that intervenes between the two paths

Armed with this machinery, we are now in a position to describe Barbiers's analysis of extraposition. In essence, the Principle of Semantic Interpretation yields the syntactic configurations for the modification relation (or the Qualifier Relation), and, assuming Chomsky's (1986b) Principle of Full Interpretation, an element that occurs at LF that receives no interpretation causes the structure to be ruled out. A PP argument of a verb must be interpreted as a qualifier of the VP. In order to accomplish this, such PP arguments are generated as left-adjuncts of the VPs of which they are arguments, and the VP then moves leftward to the specifier position of the PP adjunct. Hence, the partial initial structure of (73) (the unfocused variant of (70a), (74):

(73) Jan heeft in een stad gewerkt.

(74) Jan heeft $[_{VP}\ [_{PP}$ in een stad$]\ [_{VP}$ gewerkt$]]$.

The aforementioned movement of the adjoined VP to the specifier of its adjunct PP can take place either before or after Spell Out (Chomsky 1995c), i.e., either overtly or covertly. In any event, the VP movement is motivated by the need to establish the qualification relation, and the LF is, in the essential respects, (75):

(75) Jan heeft $[_{VP}\ [_{PP}\ [_{VP^i}$ gewerkt$]\ [_{PP}\ [_{P}$ in$]\ [_{DP}$ een stad$]]]\ [_{VP}\ t^i]$.

In other words, the extraposition phenomenon is really the leftward movement of the host of the extraposition, in this analysis, motivated to yield the requisite qualification configuration. If the VP and its argument PP do not end up in this configuration, and if there is no other interpretation available, the structure will run foul of the Principle of Full Interpretation.

In fact, this is what happens in (70d), in Barbiers's account. In his analysis of focus particles (Barbiers 1995: chapter 3), the focus particle must immediately c-command either its semantic argument or the trace of its semantic argument. The semantic argument can be either a temporal object or a numeral object; in the former case, it corresponds to a VP, and in the latter case, it corresponds either to a DP or to a PP that contains the DP. It seems that FocPs can be generated as left-adjuncts of any maximal projections. However, FocPs must also be interpreted as qualifiers of their semantic arguments, and must hence be in the requisite configuration with respect to the constituents that denote those semantic arguments. With this in mind, the underlying structure of all of the sentences in (70) is (76):

(76) Jan heeft $[_{VP}\ [_{FocP}$ pas$]\ [_{VP}\ [_{PP}$ in een stad$]\ [_{VP}$ gewerkt$]]]$.

Given that the lowest VP must first move into the Spec of the PP adjunct in order to license the PP as its qualifier, the next structure would be (77):

(77) Jan heeft [$_{VP}$ [$_{FocP}$ pas] [$_{VP}$ [$_{PP}$ [$_{VP^i}$ gewerkt] [$_{PP}$ in een stad]] $_{VP^i}$ t]]].

The movement of VP into the Spec of its PP adjunct may be either overt or covert, as can be the movement into [Spec, FocP]. If the highest PP, with the VP filling the specifier, moves into [Spec, FocP], the focus particle is interpreted as a qualifier of the PP, so that the qualifier would receive a numeral-associated interpretation. Covert movement into [Spec, FocP] of the PP would yield (70b), if movement of the VP into [Spec, VP] is overt. If VP movement into [Spec, PP] is covert, and movement of PP into [Spec, FocP] is covert, we get (70a).

To derive a temporal interpretation for the focus particle, the VP must occupy the focus particle's Spec. This could be accomplished by moving the highest VP overtly into the Spec of FocP, and would correspond to (70c). (70d) is marginally possible, according to Barbiers, with a temporal interpretation, but is ungrammatical with a numeral association for the focus particle, because there is no derivation that would place the focus particle into the requisite configuration with the PP so as to allow it to receive a numeral-associated interpretation.

Barbiers's argument, however, is somewhat weak, in that it seems to overpredict the possibilities with respect to the interaction of focus particles and extraposition (here construed as leftward movement). Overt movement of the VP into Spec PP would cause the VP PP configuration to be a PP. This PP with filled Spec should be permitted to move to [Spec, FocP], where the focus particle will immediately c-command its trace. The result would be (70c), which would simply differ from (70b) in that the latter would involve covert movement into [Spec, FocP], while the former would involve overt movement of the large PP into [Spec, FocP]. Hence, this argument for PP extraposition involving leftward movement is problematic.

7 Variant of the stranding analysis

Wilder (1995) proposes a variant of the stranding analysis in which the 'extraposed' material is not stranded, but rather a larger constituent containing the material is L-moved, leaving a copy of this larger constituent in the original position. The material that appears as extraposed is in fact deleted in the L-moved position, and everything but this material is deleted in the right copy position. To illustrate with a noun-complement that appears in extraposed position, consider (78) (Wilder's (64)), in which bolding indicates deletion:

(78) We talked [about the claim **that Mary will hire Peter**] yesterday [**about the claim** that Mary will hire Peter]

As Wilder notes, his analysis requires the possibility of non-constituent deletion, exemplified in the rightmost deletion in (78).

An advantage of Wilder's analysis is that it accounts for the fact that the extraposed material is not c-commanded by the position in which it is interpreted (in rightward movement accounts, the trace does not c-command its antecedent).

Nevertheless, it seems that there are some aspects of the deletion analysis that are extremely problematic. First, it seems that it over-predicts the reconstruction possibilities. Since the phenomenon of extraposition results from deletion of material at PF, it predicts that the 'extraposed' material will reconstruct to the position in which the material is interpreted, i.e., the L-moved copy of the larger constituent. As Buring and Hartmann (1997a) (cited by Wilder) point out, this prediction is valid for Condition C reconstruction effects when the extraposed material is a noun-complement:

(79) **(based on) Wilder's (53a):**
*We talked [about her$_i$ claim___] yesterday that Mary$_i$ will hire Peter.

However, Fox and Nissenbaum (1999) point out, citing Taraldsen (1981) as the original source of the observation, that extraposed relative clauses do not reconstruct:

(80) **(Fox and Nissenbaum's (11b)):**
I gave him$_i$ an argument yesterday that supports John$_i$'s theory.

Hence, the conflation of both relative clause extraposition and noun complement extraposition is viewed by Fox and Nissenbaum, to whom we will turn in the next section, as inappropriate.

The allowance of non-constituent deletion that is exemplified in (75) also seems problematic. For example, VP ellipsis is standardly viewed as deleting a constituent, and this assumption seems justified by the impossibility of deleting, e.g., a verb plus small-clause subject, leaving the predicate, as in (81):

(81) *Although I don't consider him intelligent, I do **consider him** ambitious.

The allowance of non-constituent deletion that is required in this analysis seems overly powerful as well. For example, it would seem to allow deletion of the verb plus object in a VP-fronting construction, stranding the object relative, which was shown to be impossible, as in (15f), repeated here:

(15) f. *John said that he would call people up who are from Boston, and call people up he did___who are from Boston.

It would also seem to predict extraposition out of a fronted PP, as in (10), repeated here:

(10) *In which magazine did you see it which was lying on the table?

Furthermore, by taking extraposition to be a reflex of deletion of part of the copy of a leftward-moved constituent, it has no account of the Perlmutter–Ross phenomenon of relative clauses with split antecedents, as in (50).

8 All extrapositions are not created equal: a mixed analysis of the phenomenon

Fox and Nissenbaum (1999; also Fox 2002) propose that relative clause extraposition be separated analytically from complement extraposition. For the latter, they propose rightward movement of the complement. For the former, they adopt the view that relative clauses, as adjuncts, should be merged late with the constituents which they modify. Specifically, they propose that extraposed relative clauses are in fact merged with QRed nominals which are interpreted as the heads of those relative clauses, and that QR should be viewed as adjoining the nominal to the right of the projection that immediately dominates the nominal before QR. They propose that the distinction between covert and overt operations be eliminated and replaced by a distinction between pronunciation of the head of a chain (the traditional overt movements) and pronunciation of the tail of a chain (the traditional covert movements). The derivation of, e.g., (82) would be as in (83):

(82) John picked a book up which he really enjoyed.

(83) a. [$_{CP}$ John [$_{VP}$ picked a book up]] [$_{CP}$ which he really enjoyed].
QR yields:
b. [$_{CP}$ John [$_{VP}$ [$_{VP}$ picked a book up] [$_{DP}$ a book]]] [$_{CP}$ which he really enjoyed].
Merger of the relative clause:
c. [$_{CP}$ John [$_{VP}$ [$_{VP}$ picked a book up] [$_{DP}$ [$_{DP}$ a book] [$_{CP}$ which he really enjoyed]]]]].
PF deletion of the head of the QRed nominal chain (represented by bolding):
d. [$_{CP}$ John [$_{VP}$ [$_{VP}$ picked a book up] [$_{DP}$ [$_{\mathbf{DP}}$ **a book**] [$_{CP}$ which he really enjoyed]]]]].

The analysis has some noteworthy aspects. First, because it ties relative clause extraposition to QR, it captures the Guéron and May claim that extraposition of relatives is tied to the QR of the head. Second, because this analysis relies on merger of the extraposed relative in its overt position, it never places it within the constituent that immediately dominates the host's overt position; this accounts for the fact that relatives that are extraposed from object position do not reconstruct to the overt position of the object, exemplified in (80). Because complement extraposition is analyzed as involving rightward movement, by contrast, extraposed complements do reconstruct, as in (79).

It is tempting to apply this analysis of relative clause extraposition to the split antecedence phenomenon, by applying QR in across-the-board fashion for both conjuncts, as in the *wh*-movement example in (84):

(84) What did John give to Sally and Bill give to Martha?

The Perlmutter–Ross example would be derived as in (85):

(85) a. [[a man entered the room] and [a woman left]] [who were similar (QR from both conjuncts yielding (b))
b. [[[$_{DP}$ a man] entered the room] and [[$_{DP}$ a woman] left]] [$_{DP}$ [$_{DP}$ a man] and [$_{DP}$ a woman]]] [who were similar] (merger of the relative clause to the conjoined DP yields (c)
c. [[[$_{DP}$ a man] entered the room] and [$_{DP}$ a woman] left]] [$_{DP}$ [$_{DP}$ [$_{DP}$ **a man**] **and** [$_{DP}$ **a woman**]] $_{CP}$ who were similar]]

It is true that the two nominals in the Perlmutter–Ross example would have to be distinct, but it is possible for two distinct nominals to move across the board, as can be seen from the overt example in (86), with across-the-board topicalization, in a *respectively*-coordination sentence:

(86) This book$_i$ and that magazine$_j$ John bought t_i at Borders and Bill bought t_j at Dalton's respectively.

In fact, we can even derive the parallelism constraints on relative-clause extraposition noted in (50), in which the split antecedents cannot consist of a subject in the first conjunct and an object in the second conjunct, if we assume, following May (1985), that object QR is adjunction to VP, while subject adjunction is QR to TP. There would be no way to create a conjoined DP after QR in such cases to host merger of the relative clause.

There is one noteworthy consequence of the Fox–Nissenbaum analysis of relative clause extraposition, whose salient features are rightward QR followed by late merger of the relative clause. Recall Culicover and Rochemont's (1997) observation, discussed in section 2, that fronted *wh*-phrases can host extraposed relatives, based on the contrast in (13) and (14), repeated here:

(13) *He$_i$ [$_{VP}$ [$_{VP}$ invited several girls to the party] [$_{CP}$ that John$_i$ dated in high school]].

(14) How many girls did [$_{IP}$ he$_i$ invite to the party] [$_{CP}$ that John$_i$ dated in high school]?

In other words, the extraposed relative in (14) must be adjoined to a projection that takes it out of the c-command domain of the subject, presumably CP, in order to ensure that the coindexing indicated in (14) does not cause a Principle

C violation. However, in Fox and Nissenbaum's approach, we are led to first right-adjoin the object to CP, as a parallel to their analysis of QR, before moving the *wh*-phrase to [Spec, CP]. This movement of *wh*-phrases to the right edge of CP before moving to their final resting place is, to the best of our knowledge, unattested, and we are hard pressed to explain the reason for this movement, particularly in a theory which posits movement as a last resort.

We are also hard pressed to explain, in the late merger theory of relative clause extraposition, why reduced relatives do not appear in extraposed position, so that the only phrases that occur in the extraposition construction are PPs and CPs.

9 Result clauses

Finally, another construction that seems to have some affinities with extraposition is the degree-complement construction that is exemplified in (87):

(87) a. John was so hungry that he would eat anything.
b. John was too angry for us to talk to him.
c. John was hungry enough that he would eat anything.
d. John was hungry enough to eat anything.

There is a dependency between the underlined degree words and the clausal phrases to suggest a level of representation at which the clausal phrase is a complement of the degree word. For one thing, the clausal phrase cannot appear without the degree word's presence; for another, the finiteness value of the clausal phrase is determined by the particular degree word, such that *so* requires that the clause be finite, *too* that it be non-finite, and *enough* allows either (88c–d):

(88) a. *John was hungry that he would eat anything.
b. *John was angry for us to talk to him.
c. *John was so hungry to eat anything.
d. *John was too tired that he ate anything.

With these considerations, early analyses of degree phrases posited representations in which the degree word and the clause formed a constituent, in which the clause was a complement of the degree word. An obligatory extraposition process would then move the clause rightward, so that, e.g., (87a) would include (88) in its derivational history:

(89) John was $[_{AP}\ [_{Deg''}\ [_{Deg'}\ [_{Deg}$ so$]\ [_{C''}$ that he would eat anything$]]]]$.

It has been noted, however, by Liberman (1974) that, unlike the extraposition of relative clauses that we have been considering, a degree complement can have multiple antecedents:

(90) So many people read so many books so often that it's hard to keep track of them.

Moreover, there can only be one degree complement in a clause:

(91) *So many people read so many books so often that the lines are immense that we have to restock the shelves that the bookstores are making a mint.

The possibility of split antecedents for the degree complement contrasts with the impossibility of split antecedents for the extraposed relative clause, discussed above in connection with (50).

Furthermore, as Guéron and May (1984) show, the degree complement can occur in a clause that is higher than theclause in which the degree word resides:

(92) **(Guéron and May's (29a)):**
I told *her* that so many people attended last year's concert that I made *Mary* nervous.

The fact that (92) does not have the status of a Principle C violation of the binding theory indicates that the result clause, which contains *Mary*, must be higher in the tree than the matrix object object pronoun. Given that the degree word resides in *tell*'s complement CP in overt syntax, extraposition of the degree complement into the matrix clause would violate the Right Roof Constraint.

As Guéron and May note, however, the degree word can scope out of the clause in which it overtly resides. Hence, (93), originally noted by Liberman (1974), seems to have two understood interpretations, represented by the following logical forms (Guéron and May's (33)):

(93) Mary believed that Harry is so crazy that he acted irrationally.

(94) a. Mary believed $[_{CP}$ so^2 $[_{CP}$ that Harry is e_i^2 crazy $e_j^2]$ $[_{CP}$ that he acted irrationally$]$ $^2]]$.
b. $[_{CP}$ so^2 $[_{TP}$ Mary believed $[_{CP}$ e_i^2 $[_{CP}$ that Harry is $[e_i^2$ crazy $e_j^2]]$ $e_j^2]]$ $[_{CP}$ that he acted irrationally$]$ $^2]$.

The first interpretation of (93), corresponding to (94a), is one in which the extent of Harry's craziness is within the scope of Mary's beliefs, such that Mary believed that Harry's craziness was to such an extent that he acted irrationally. In the second interpretation of (93), corresponding to (94b), Mary believed to such an extent that Harry is crazy that her beliefs caused him to act irrationally.

These two interpretations are claimed to correlate with the syntactic position of the result clause, such that the result clause is analyzed as being adjoined to the CP in which the degree word takes scope. Matrix interpretation of the degree word is said to correlate with the attachment of the result clause to the matrix CP, and this is analyzed by Guéron and May as a reflex of the head–complement

relation being established at LF, a view that has become extremely consonant with the tenets of Minimalism (Chomsky 1995c), in which LF and PF are the only two significant linguistic levels. Therefore, the interpretation of (93), given that the result clause is adjoined to the matrix clause, is one in which the degree word must take matrix scope.

NOTES

1 See Borsley (1997) for a criticism of this approach, and Bianchi (2000) for a response to Borsley's criticisms.
2 While the approach taken in Kayne (1994) is easiest to explain for relative clauses that are introduced by the complementizer *that*, he also shows how this account can extend to *wh*-relatives. The exposition of this extension would take us too far afield. For details, see Kayne (1994: 88–90).

26 Focus Movement (with Special Reference to Hungarian)

KRISZTA SZENDRŐI

1 Introduction
  1.1 Focus movement in generative syntax: an overview
  1.2 Preliminaries
    1.2.1 Definition of focus and the *wh*-test
    1.2.2 Different types of focus: semantic and pragmatic differences
    1.2.3 On the semantics of focus
    1.2.4 Ways of encoding focus in the grammar
    1.2.5 The focus construction
  1.3 Focus movement in Hungarian: basic data
    1.3.1 Preverbal focus in Hungarian
    1.3.2 Scrambling or movement?
    1.3.3 The syntactic position of the focus: adjacency with the verb and complementarity with *wh*
    1.3.4 The semantics of Hungarian preverbal focus
  1.4 Summary
2 Focus assignment under government
  2.1 Focus parameter
  2.2 Preverbal focus languages: Hungarian
  2.3 Postverbal focus languages: Chadic languages
  2.4 Focus and case: discussion

1 Introduction

1.1 Focus movement in generative syntax: an overview

This chapter is concerned with the way focus movement has been analyzed in generative syntax. In languages like Hungarian, discourse functions such as topic or focus are associated with a particular syntactic position. In other words, constituents that serve as the focus or topic of the utterance are displaced from their canonical position in the sentence.

All the analyses in the generative syntax literature agree that the displacement of focus in these languages is an instance of movement. The analyses diverge with respect to the nature of the movement and its trigger. There are two major trends in the literature, as it happens, following the historical development of the field, and a third, newly emerging one. Let us take these in turn.

The first group of analyses argued that focus assignment is similar to case assignment as both are assigned under government in S-structure. The earliest analysis of Hungarian focus movement is due to Horvath (1986). She proposed that a constituent has to appear in the governing domain of the verb in order to be focused. This is what triggers focus movement. Since focus assignment is argued to take place under government at S-structure, there is an obvious parallel

with case assignment in languages like English. One of the main advantages of this proposal is that it predicts a directionality effect: languages that govern to the left have focus movement targeting a left-adjacent position to the verb, while languages with rightward-oriented government have immediately postverbal focus positions. It turns out that this directionality effect shows up in many languages. What one might call a disadvantage of this theory is that it does not readily provide an explanation of the wide-spread similarities between focus constituents and *wh*-elements. Focus movement exhibits quantificational properties and several syntactic and semantic properties of operator-variable dependencies, such as weak crossover and parasitic gap licensing.

This brings us to the second group of analyses of focus movement, whose main tenet is that focus movement is like *wh*-movement. The main advantage of this idea is that it explains both syntactic and semantic considerations that establish a parallel between focus movement and *wh*-movement. The earliest analysis, due to Brody (1990b) and Rizzi (1996), proposed that focus movement, just like *wh*-movement, is triggered by the Focus criterion and the *Wh*-criterion. The focus/*wh*-element has to appear in a specifier–head relationship with its licensor. As checking theory became full-blown, the new analyses proposed specific functional head positions, such as the Focus head, to provide a licensor for the moved focus (e.g., Brody 1995a; Rizzi 1997). There are several advantages to this group of theories. First, the proposed specifier–head licensing accounts for the often-attested adjacency effects between focus/*wh* and verb (or Infl). It provides an explanation for the occurrence of pied-piping in focus movement, as pied-piping is a well-known characteristic of *wh*-movement as well. This is not to say that there are no open questions. In particular, an important issue concerns the status of alleged weak crossover violations involving focus movement. There is an alternative way to account for these data, one that argues that the ungrammaticality of these examples does not stem from a syntactic violation, rather a discourse violation. If so, this undermines the very basis of the analysis of focus movement, in terms of *wh*-movement, as it removes an important syntactic parallel between focus movement and *wh*-movement.

A newly emerging set of analyses capitalizes on the well-known but long-neglected generalization that the focus constituent always bears main prosodic prominence (Chomsky 1971). Until very recently, the fact that, at least in languages like English, the focus constituent bears main stress was regarded as irrelevant for the syntax of focus. All the analyses before had regarded focus as the primary property of syntax; prosody was secondary. In other words, in order to ensure that the focal constituent receives main stress, it was assumed that main stress gets assigned to the constituent that was marked focus in syntax. Thus, all these analyses conformed to what Ladd (1996) called the accent-to-focus view. The new set of analyses takes just the opposite perspective. It is not accent that matches focus, but rather focal interpretation is attached to the constituent that bears accent; this is the focus-to-accent view. One of the main advantages of this approach is that it provides a natural account for certain empirical facts; for instance, for the existence of focus projection. Another, more conceptual, advantage

is that it provides a way to conform to Chomsky's (1995c) Inclusiveness condition, which all accent-to-focus views violate. The focus-to-accent view faces empirical and conceptual issues of its own. For instance, arguably, it assumes a certain kind of look-ahead property, and is therefore incompatible with the T-model as the architecture of the grammar.

This chapter is organized in the following way. This section provides an introduction. First, some preliminary discussion is put forth (section 1.2). The basic concepts such as focus and focus movement are defined and the scope of the chapter is determined. The notion of focus is examined briefly, from both a discourse-pragmatic and a semantic perspective, and a brief review is provided of positions available in the wider linguistic literature on the grammatical encoding of focus. Then the basic syntactic and semantic characteristics of focus movement are described with the help of Hungarian data (section 1.3). The bulk of the chapter is in sections 2–4. Here, one by one, the major lines of analyses concerning focus movement are reviewed. In particular, section 2 concerns analyses that argue that focus assignment is under government and thus liken focus to case; section 3 describes some analyses that draw a parallel between focus and *wh*; and section 4 explains the focus-to-accent view. In all of these sections, the last subsection (i.e., sections 2.4, 3.5, and 4.4) contains a discussion of the main advantages and disadvantages of the line of argumentation under consideration. These subsections are inevitably more speculative than the rest of the section, as their aim is to provide an evaluation of the proposals in both empirical and theoretical terms. Section 5 concludes the chapter.

1.2 Preliminaries

This introduction has three aims. First, the notions of focus and focus construction are defined in a way that is as theory-neutral as possible but nevertheless restrictive enough to determine the set of phenomena under consideration. This will allow for the conclusion that cleft constructions and constructions like English Heavy NP Shift are outside the scope of this chapter (section 1.2). Second, the basic syntactic and semantic characteristics of focus constructions are exemplified with Hungarian data. Two syntactic characteristics that are crucial for further discussion are identified: (i) focus is immediately adjacent to the verb; (ii) focus and *wh*-elements are in complementary distribution (section 1.3). Third, Horvath's (1986) arguments in favor of a movement analysis of the Hungarian focus construction are summarized (section 1.3.2).

1.2.1 Definition of focus and the wh*-test*

A well-formed sentence satisfies all the syntactic, semantic, morphological, and phonological principles of the grammar, and the utterance is an expression of the given language. This does not imply, however, that the utterance of such a sentence can be used appropriately in any discourse context. Discourse is organized by information packaging devices, such as topic, focus, etc. If the information structure of a particular expression does not match the information packaging

required by the context, the expression is infelicitous in that context, albeit grammatically well-formed. For instance, the utterance in (1b) is not felicitous in the context of (1a), even though it is a well-formed expression of English:[1]

(1) a. What did John eat?
b. #John ate the pizza.

It is a well-known characteristic of *wh*-questions that they require an answer whose focus is the constituent corresponding to the *wh*-phrase. In (1b), the focus of the utterance is on the subject, *John*. In contrast, the *wh*-question in (1a) requires an answer whose focus is the direct object. As a result of this incompatibility of information structure, (1b) is not appropriate in the context of (1a). The incompatibility of the question–answer pair in (1) indicates that certain aspects of information structure are grammatically encoded: the utterance in (1b) has some grammatical properties that disallow it in the context of the *wh*-question in (1a), requiring focus on the object.

In this work, focus is taken to be the part of an utterance that is new or asserted. The rest of the utterance is the background (or in some cases the presupposed part). In particular, a diagnostic test to identify the focal part of an utterance is the *wh*-test. As was mentioned above, the part of the utterance that provides the answer to a *wh*-question is the focus. So, the focus of the answer in (2) is the DP_{DO}:

(2) Q: What did John eat?
A: John ate the pizza.

1.2.2 Different types of focus: semantic and pragmatic differences

Different types of focus have been identified in the literature. These include semantico-pragmatic distinctions such as contrastive focus (Rochemont 1986) (3a), identificational focus (Kiss 1998) (3b), or new information focus (3c). Also, focus can be wide (or broad), as in (3c), or narrow, as in (3a) (Chomsky 1971). In this work, all these are taken to be part of the (general) notion of focus:

(3) a. I hate broccoli, not zucchini.
b. A brokkolit utálom. Hungarian
the broccoli-acc hate-I
'It's broccoli that I hate.'
c. A: Do you have any special requirements for food?
B: I hate broccoli.

1.2.3 On the semantics of focus

This is not to say that there are no semantic or pragmatic distinctions between the different types of focus. Szabolcsi (1981b) argued that the preverbal focus position in Hungarian is associated with exhaustive listing in a way that is directly reflected in the truth-conditions of the utterance. Thus a sentence like (4a) means something like (4b):

(4) a. A tanár$_i$ Jánosnak$_j$ adott jelest t_i t_j.
the teacher John-dat gave A+-acc
'The teacher gave an A+ to John.' (Kiss 1994: 27, ex. 55)
b. John is the only person amongst the members of the class (or some other set of people who could have gotten A+) that the teacher gave an A+ to.

In other words, there is a focus operator that checks every member of the contextually given relevant set for the property in question (here the property of receiving A+ from the teacher) and identifies John as the single member of that set of whom the property is true. Similar semantics has been proposed for the English cleft construction and for the focus-sensitive operator *only* (e.g., Rooth 1992). (See Rooth 1996 for an overview of the semantics of focus.)

As strong support for the semantic nature of focus, Szabolcsi (1981b) demonstrated that focusing has an effect on the truth-conditions of the sentence. For instance, compare (5) and (6). (5b) is a logical consequence of (5a), while this is not true of (6b) and (6a). Consequently, conjoining either (6a) or (6b) with the negation of the other one does not yield a contradiction. This is shown in (7):

(5) a. János$_i$ magával vitte Marit és Évát t_i.
John self-com took Mary-acc and Eva-acc
'John took Mary and Eva with him.'
b. János$_i$ magával vitte Marit t_i.
John self-com took Mary-acc
'John took Mary with him.' (Kiss 1994: 28, ex. 59)

(6) a. János$_i$ [Marit és Évát]$_j$ vitte magával t_i t_j.
John Mary-acc and Eva-acc took self-com
'It was Mary and Eva that John took with himself.'
b. János$_i$ Marit$_j$ vitte magával t_i t_j.
John Mary-acc took self-com
'It was Mary that John took with him.' (Kiss 1994: 29, ex. 60)

(7) János$_i$ nem [Marit és Évát]j vitte magával t_i t_j. hanem Marit$_j$ vitte
John not Mary-acc and Eva-acc took self-com but Mary-acc took
magával t_i t_j.
self-com
'It was not Mary and Eva but Mary that John took with him.'
(Kiss 1994: 29, ex. 61)

The same is true for sentences involving *only* and clefts in English:

(8) a. John invited only Mary and Eve. He didn't invite only Mary.
b. It was Mary and Eve that John invited, not Mary.
c. *John invited Mary and Eve. He didn't invite Mary.

However, there is evidence that exclusion may sometimes be absent from the meaning of preverbal focus in Hungarian (Kiss 1987). In these cases, only identification is present. Indefinites often have this property. So, for instance, (9) does not presuppose the existence of a set of groups of people, identifying the set of actors as the only relevant one for which it is true that they are reading in the garden. It simply identifies the set of people that are reading in the garden as actors:

(9) A kertben$_i$ színészek$_j$ olvasnak fel t_i t_j.
the garden-loc actors read prt
'In the garden, actors are reading out loud.'
(based on Kiss 1994: 28, ex. 56)

Similarly, numerals also only express identification and not exclusion. Even though (10b) means that it is exactly 30,000 forints that John spends a month, this is not the result of an operation where 30,000 would be identified as the only member of the set of natural numbers such that John spends that many forints in a month. Rather, as (10b) indicates, focusing the numeral has the effect that an 'exactly' rather than an 'at least' reading is associated with the numeral (Szabolcsi 1981b):

(10) a. János$_i$ elkölt 30 000 forintot egy hónapban t_i t_j.
John prt-spends 30,000 forints-acc a month-loc
'John spends (at least) 30,000 forints a month.'
b. János$_i$ 30 000 forintot költ el egy hónapban t_i t_j
John 30,000 forints-acc spends prt a month-loc
'John spends exactly 30,000 forints a month.' (Kiss 1994: 28, ex. 58)

The fact that exhaustivity disappears in these cases suggests that a sufficiently refined semantic analysis of focus is required to be capable of taking such cases into consideration. Alternatively, it could be argued that such cases make it less clear that the specific focus interpretations can be systematically paired with certain construction types (e.g., exhaustivity with preverbal focus in Hungarian). This chapter does not intend to take a stand on this issue. In general, pragmatico-semantic distinctions such as exhaustivity will only be mentioned below where they are directly relevant for the analyses of certain focus constructions (see, e.g., sections 1.3.4 or 4.3.2). More often than not, such distinctions will be ignored and focus will be treated as a unified phenomenon. This is based on the fact that all types of foci satisfy the *wh*-test, which was argued above to be a characteristic test for focus; all types of foci share a distinctive prosodic marking (main stress or pitch accent); and all types of focus have the discourse status of new or asserted information.

1.2.4 Ways of encoding focus in the grammar

The literature on focus is vast. Without any attempt at an exhaustive mention, works that deal with focus and other discourse roles from a semantic perspective

include Szabolcsi (1981b), Krifka (1991), Diesing (1992b), Rooth (1992), and Schwarzschild (1999). The prosodic aspect of focus is investigated by Gussenhoven (1984), Selkirk (1984, 1986, 1995), Rochemont (1986), Pierrehumbert and Hirschberg (1990), Hayes and Lahiri (1991), and Cinque (1993). Bosch and Van der Sandt (1999) investigate the issue from a performance perspective.

Let us briefly review the literature on focus in light of some questions related to the nature of the interface between the grammar and discourse: does the grammar (in its wide sense; i.e., including phonology but not pragmatics) determine the focus of an utterance? If so, does the grammar encode focus unambiguously? As we shall see, these questions help us divide the positions available in the literature into two classes: those that argue for encoding focus in the grammar directly, and those that argue for underdeterminacy with respect to grammatical encoding of focus.

There is a wide range of views on the issue of the grammatical representation of focus. The spectrum ranges from the functional sentence perspective (i.e., the Prague School) through the discourse-theoretically motivated works (e.g., Gundel 1974; Prince 1979, 1981; Lambrecht 1994) to the strict 'encoding' view of the GB/Minimalist literature.

The Prague School view, at least in its original form (e.g., Dezső 1974; Hajičová and Sgall 1988; Hajičová et al. 1998; and others), did not perceive the representation of focus in the grammar as an issue. For them, discourse notions such as focus and topic were readily available in the grammar itself. Their functionalist and to a large extent descriptivist point of view enabled them to make certain far-reaching generalizations (e.g., the fact that the topic usually precedes the focus, or the tendency for topics to be left-peripheral), and they intended to go no further.

The pragmatic approaches to focus, in particular the different works based on Relevance Theory (Sperber and Wilson 1995; Kempson et al. 2004), advocate a certain underdeterminacy of the grammar with respect to focus. They argue that the focus of an utterance is not fully determined by the syntactic and prosodic make-up of the utterance, although no doubt these contribute to the actual focus.

The GB/Minimalist approaches are the strictest in the sense that they advocate a direct and unambiguous mapping between the grammatical representation of an utterance and its focus. From now on, we will concentrate on these. This is not to say that these approaches would be the only ones that advocate a deterministic encoding of focus in the grammar. There are many proposals, some outside the GB/Minimalist framework, that are not considered here for lack of space. These include King (1993, 1997), Butt and King (1996), Vallduví and Engdahl (1996), Erteschik-Shir (1997), Steedman (2000), and Kempson et al. (2004), among many others.

In the generative literature, the standard view of the late 1980s and early 1990s was and to a large extent still is that focus is directly and unambiguously represented in the syntactic representation (cf. Antinucci and Cinque 1977; Calabrese 1982, 1992b; Abraham and De Meij 1986; Horvath 1986; Rochemont 1986;

Rochemont and Culicover 1989; Brody 1990b, 1995a; Kiss 1995b, 1998; Vallduví 1995; Erteschik-Shir 1997; Rizzi 1997; Vallduví and Vilkuna 1998; Zubizarreta 1998). In other words, the syntactic representation of a sentence would provide the necessary information to identify the focus.

In particular, since Jackendoff's (1972) seminal work, the standard way to encode focus in the syntactic representation is by the syntactic (and semantic) feature [+Focus], or [+F] for short: "I suggest the following way, which does minimal violence to the theory as a whole. One artificial construct is required: a syntactic marker F which can be associated with any node in the surface structure" (Jackendoff 1972: 240). [+F] is freely assigned to a constituent, (11), and the F-marked constituent is taken to be the semantic focus of the utterance, by his focus assignment principle, (12):

(11) **[+F] marking:**
Mark any constituent as [+F].

(12) **Focus assignment:**
The semantic material associated with surface structure nodes dominated by F is the Focus of the sentence. To derive the Presupposition, substitute appropriate semantic variables for the focused material.
(Jackendoff 1972: 240)

Let us illustrate Jackendoff's proposal. In the answer in (2) above, [+F] is assigned to the direct object *pizza*, which is interpreted as the focal part of the utterance. The presupposition of the utterance can be obtained by replacing the focus with a variable. This is shown in (13):

(13) a. John ate [$_{F}$ the pizza].
b. Presupposition: John ate *x*.

As will become clear in the course of this chapter, the idea that focus is encoded in the syntactic representation by means of a syntactic feature, [+Focus], has been fundamental to all GB/Minimalist theories of focus until very recently.[2] It is therefore the most important theoretical assumption in these theories.

1.2.5 The focus construction

Focus as a grammatical notion is universal. There are no known languages that would not have a way to signal that a particular constituent is focused. Predominantly, focus is marked by prosodic prominence, more precisely by main stress or pitch accent or (boundary) tones. Morphological focus marking is also available in many languages. Finally, many languages use specific syntactic constructions to indicate discourse functions such as focus. In what follows, the discussion will center on this group. An informal definition of languages that have syntactic focus constructions is given by Kiss (1995b):

(14) The (discourse-)semantic function 'focus', expressing identification, is realised through a particular structural relation (in other words, it is associated with a particular structural position). (Kiss 1995: 6)

There are two constructions that arguably fall under this definition, but that are not discussed here: clefts and Heavy NP Shift. Apart from space limitations, the main reason for the omission is that they do not always carry a focus interpretation, although it is true that they often or even predominantly do. The fact that they do not necessarily carry focus interpretation is enough for a claim that they are not really 'focus constructions'.

This fact is illustrated for clefts first. It is often claimed that the fronted part in a cleft is the focus of the utterance (e.g., Rochemont 1986; Kiss 1998). This is true in the exchange in (15a), but not in the exchange in (15b):

(15) a. A: I thought you ate the pizza.
B: No, it was the spaghetti I ate.
b. A: I thought it was Peter who ate the pizza.
B: No, it was Peter who ate the spaghetti.

Admittedly, the non-focal clefted phrase is well-formed, because the example in (15b) is echoic. But other cases exist where the clefted phrase does not correspond to the focus of the utterance. In French, as Doetjes et al. (2004) showed, the clefted constituent may only form a part of the focus, rather than be the focus itself. Their examples are given below. In (16), *avec plaisir* 'with pleasure' is not the focus itself. The sentence does not mean that the speaker means to refute a belief that it is not with pleasure that he invites the other one to the seminar. Similarly, (17) does not mean that the person only thanks Nicolas Ruwet and Maurice Gross, but no one else. Rather, as Doetjes et al. argue, these sentences are broad (or wide) focus utterances. So clefting does not serve the need to focus the fronted constituent:

(16) C'est avec plaisir que je vous invite à participer à ce séminaire.
it/that is with pleasure that I invite you to this seminar

(17) C'est à Nicolas Ruwet et à Maurice Gross que je dois l'essentiel de ma formation dans cette discipline.
'It's to Nicolas Ruwet and to Maurice Gross that I owe the essential part of my training in this discipline.'

Heavy NP Shift has similar characteristics. As (18a) illustrates, the rightmost constituent is often the focus of the utterance. However, this is not always the case. First, according to Williams (2003b), Heavy NP Shift is also felicitous as an answer to a question that requires VP focus (see (18b)). Second, the same echoic pattern as above can be also illustrated for Heavy NP Shift, (18c). Finally, as (18d)

shows, discourse-linked phrases may also undergo Heavy NP Shift, (18d) (Fritz Newmeyer, p.c.):

(18) a. A: What did John give to Mary?
B: John gave to Mary all the money in the SATCHEL.
b. A: What did John do?
B: John gave to Mary all the money in the SATCHEL.
c. A: John gave to Joe all the money in the satchel.
B: No, John gave to MARY all the money in the satchel.
d. A: To whom did you give all your books on the phonetic foundations of conventional implicature?
B: I gave to MARY all of those unbelievably ridiculous publications.

In what follows, the discussion will be limited to the cases that fall under a somewhat more restrictive characterization of focus constructions that is given in intuitive terms in (19):

(19) **Focus construction:**
A particular structural relation (in other words, a particular structural position) that is associated with the (discourse-)semantic function 'focus'.

In the next section a description is given of the basic facts concerning the Hungarian focus construction. At the same time, some arguments are put forward based on Horvath's (1986) analysis that the Hungarian focus construction is the result of syntactic movement.

1.3 Focus movement in Hungarian: basic data

This section introduces the basic data concerning focus constructions. The facts enumerated here are exemplified by Hungarian, but most of the properties hold in other languages as well. Further characteristics and facts from other languages are introduced in the following sections as they become relevant for the discussion of the various analyses.

1.3.1 Preverbal focus in Hungarian

Horvath (1986) gives the following generalization for focus in Hungarian:

(20) A constituent (other than V or a projection of V) can be interpreted as the FOCUS of its clause in Hungarian if, and only if, it itself occupies an immediately pre-verbal position, or is contained in a phrase that does so.
(Horvath 1986: 91)

In (21b–c) and (22b–c) it is shown that a focused constituent in Hungarian must appear preverbally. At the same time, as (21a) and (22a) illustrate, the most

natural position of both arguments (see 22a) and adjuncts (see 21a) is postverbal, if the constituent is not focused:

(21) a. Attila félt a földrengéstől.
Attila feared the earthquake-loc
'Attila was afraid of the earthquake.'
b. Attila a földrengéstől félt.
Attila the earthquake-loc feared
'It was the earthquake that Attila was afraid of.'
(Horvath 1986: 91, ex. 1)
c. *Attila félt a földrengéstől.
Attila feared the earthquake-loc
'It was the earthquake that Attila was afraid of.'
(Horvath 1986: 92, ex. 3)

(22) a. Mari az asztalra tette az edényeket.
Mari table-loc put the dishes-acc
'Mari put the dishes on the table.'
b. Mari az edényeket tette az asztalra.
Mari the dishes-acc put table-loc
'It was the dishes that Mari put on the table.'
(Horvath 1986: 91, ex. 2)
c. *Mari az asztalra tette az edényeket.
Mari table-loc put the dishes-acc
'It was the dishes that Mari put on the table.'
(Horvath 1986: 92, ex. 4)

This is also true if a subpart of a DP is focused, as shown in (23):[3]

(23) a. Attila Mari kutyájától félt.
Attila Mari dog-loc feared
b. *Attila félt Mari kutyájától.
Attila feared Mari dog-loc
'It was Mary's dog that Attila was afraid of.'
(Horvath 1986: 143, fn. 2, ex. i, ii)

1.3.2 Scrambling or movement?

Horvath (1986) shows that the focus of an utterance that surfaces in the matrix clause may originate from an embedded clause, even if the embedded clause is finite. This is illustrated for arguments in (24a), and for adjuncts in (24b). (Note that long focus movement is unacceptable for many speakers.)

(24) a. Annát$_i$ mondta hogy t_i jön.
Anna-acc said that comes
'((S)he) said that Anna was coming.' (Lipták 1998: 91)

b. Londonba$_i$ mondtad hogy mész t_i
London-loc said-you that go-you
'You said you were going to London' (Lipták 1998: 92)

As (25) shows, there is no restriction to the number of clauses a focus can cross:

(25) Annát$_i$ mondtad hogy a szomszédok látták hogy t_i jön.
Anna-acc said-you that the neighbors saw that comes
'You said that the neighbors saw that Anna was coming.'
(modified from Lipták 1998: 92)

This indicates that the focus construction is not clause-bound, which led to the general conclusion that the preverbal focus in Hungarian is the result of movement rather than a case of scrambling. Such so-called long focus movement cases are discussed in Horvath (1986), Kiss (1987, 1998), Lipták (1998), and Gervain (2002).

As Horvath shows, an analysis of the preverbal focus as scrambling is independently ruled out, as scrambling into the higher clause is not well-formed even though the matrix predicate may case-mark and/or agree with the moved element. In other words, long focus movement may only target the preverbal position. This is shown in (26):

(26) *A gyerekek mondták a földrengéstől$_i$ hogy Attila félt t_i.
the kids said the earthquake-loc that Attila feared
'The kids said that Attila was afraid of the earthquake.'
(Horvath 1986: 100, ex. 19)

As a further indication that focus constructions involve movement, Horvath (1986) showed that long focus movement observes complex NP islands:[4]

(27) *Az elnököt$_i$ mondtad hogy hallottad [$_{DP}$ a hírt [$_{CP}$ hogy
the president-acc said-you that heard-you the news-acc that
megérkezett e_i]].
prt-arrived
'You said you heard the news that the president had arrived.'
(Gervain 2002: 39, ex. 25)

Focus movement observes adjunct islands as well. So focus movement out of an adjunct clause is blocked:

(28) *Az elnök(öt)$_i$ figyelmeztettek minket [$_{CP}$ hogy meg érkezett e_i]].
the president(-acc) warned-they us-acc that prt arrived
'They warned us that the president arrived.'
(Gervain 2002: 39, ex. 25)

Wh-elements in Hungarian do not occupy the [Spec, CP] position; rather, if they appear in an embedded clause, they follow the complementizer *hogy* 'that'. Thus, an intervening *wh*-element is not expected to block long focus movement. In other words, focus movement is not sensitive to *wh*-islands:[5]

(29) Az elnököt$_i$ mondtad hogy hallottad [$_{CP}$ hogy mikor érkezett meg t$_i$].
the president-acc said-you that heard-you that when arrived prt
'You said you heard when the president had arrived.'

On the basis of the above data, the Hungarian preverbal focus construction is taken to be a case of focus movement, in the sense that it is a movement operation into a position where the moved element is interpreted as focus.

1.3.3 *The syntactic position of the focus: adjacency with the verb and complementarity with* wh

The two syntactic characteristics that proved to be essential in GB and Minimalist analyses of the Hungarian focus construction are the following: (i) the focused constituent is immediately preverbal; (ii) a *wh*-element and a focus are in complementary distribution. As we shall now see, the two properties are in fact closely related.

As Horvath (1986) shows, the distribution of adverbs can be used to demonstrate that focus and verb must be adjacent in Hungarian. Sentence adverbs can precede the focus, or follow the verb, but they cannot intervene between focus and verb:

(30) Mari valószínűleg/hirtelen egy kanál sót *valószínűleg/*hirtelen
Mary probably/suddenly a spoonful salt-acc probably/suddenly
tett valószínűleg/hirtelen a kávéjába
put probably/suddenly the coffee-her-loc
'Mary probably/suddenly put a spoonful of salt in her coffee.'
(Horvath 1986: 102, ex. 23)

The same adjacency requirement is also observed with *wh*-elements. As (31) illustrates, every *wh*-element (except for *miért* 'why') has to be immediately preverbal. So sentence adverbs can precede the *wh*-element, or follow the verb, but they cannot intervene between the two:

(31) Mari ?valószínűleg/?hirtelen mit *valószínűleg/*hirtelen tett
Mary probably/suddenly what-acc probably/suddenly put
?valószínűleg/hirtelen a kávéjába.
probably/suddenly the coffee-her-loc
'What did Mary probably/suddenly put in her coffee?'
(based on Horvath 1986: 102, ex. 23)

The fact that focus and *wh* both need to occupy an immediately preverbal position explains the complementary distribution between the two. This is illustrated in (32). *Ritkán* 'rarely' requires obligatory focusing, so it cannot appear postverbally (32a–b). This restriction is absent if it appears in a *wh*-question. In this case the adverb must occur postverbally and the *wh*-element occupies the immediately preverbal position (32c–f):

(32) a. Ritkán jár ide.
rarely comes *prt*-to
b. *Ide jár ritkán.
c. Ki jár ritkán ide?
who comes rarely here-to
'Who comes here rarely?'
d. *Ki ritkán jár ide?
e. *Ritkán ki jár ide?
f. *Ritkán jár ki ide?

In Hungarian there is a class of elements that are called verbal modifers, which also appear immediately preverbally. This group includes verbal particles (prt), resultatives, depictives, and incorporated prototypical objects that often lack a determiner layer. The immediately preverbal positioning of these is illustrated in (33a–d) respectively:

(33) a. Mari valószínűleg/hirtelen bele *valószínűleg/*hirtelen tett
Mary probably/suddenly prt probably/suddenly put
valószínűleg/hirtelen a kávéjába egy kanál sót.
probably/suddenly the coffee-her-loc a spoonful salt-acc
'Mary probably/suddenly put a spoonful of salt into her coffee.'
b. Mari valószínűleg/hirtelen tönkre *valószínűleg/*hirtelen tette
Mary probably/suddenly res-loc probably/suddenly put-def
?valószínűleg/?hirtelen a kávéját egy kanál sóval.
probably/suddenly the coffee-her-acc a spoonful salt-inst
'Mary probably/suddenly spoilt her coffee with a spoonful of salt.'
c. Mari valószínűleg hidegen *valószínűleg itta
Mary probably cold-loc probably drank-def
valószínűleg a kávéját.
probably/suddenly the coffee-her-acc
'Mary probably drank her coffee cold.'
d. Mari valószínűleg kávét *valószínűleg ivott valószínűleg
Mary probably coffee-acc probably drank probably
reggel.
morning
'Mary probably drank coffee this morning.'

(based on Horvath 1986: 102, ex. 23)

As expected, verbal modifiers are in complementary distribution with foci (and also with *wh*). This illustrated for particles in (34):

(34) Mari *bele egy kanál sót *bele tett bele a kávéjába.
Mary prt a spoonful salt-acc prt put prt the coffee-her-loc
'Mary put a spoonful of salt into her coffee.'
(based on Horvath 1986: 102, ex. 23)

As a final characteristic of preverbal focus, Horvath notes that the immediately preverbal position does not admit free right-branching recursion. This is a characteristic left-branch effect in an otherwise right-branching language (see Emonds 1976: 19), which might be indicating that the focus occupies a left-branch position. As (35) shows, the focus position only admits the head of the relative clause, not the clause itself. Vogel and Kenesei (1990) argued that the reason for this restriction is in fact prosodic. It is due to the requirement that the focus and the verb form one phonological phrase. Thus, material that is itself the size of an intonational phrase, such as a relative clause, cannot intervene between the focus and the verb:

(35) a. *A tanár AZT a gyereket [$_{CP}$ aki túl sokat beszélt] küldte ki
the teacher that-acc the kid-acc who too much-acc talked sent prt
a szobából.
the room-loc
b. A tanár AZT a gyereket küldte ki a szobából
the teacher that-acc the kid-acc sent prt the room-loc
[$_{CP}$ aki túl sokat beszélt].
who too much-acc talked
'The teacher sent out of the room the kid that was talking too much.'
(Horvath 1986: 103–4, ex. 24)

1.3.4 The semantics of Hungarian preverbal focus

Szabolcsi (1981b) argued that the preverbal focus position in Hungarian is associated with exhaustive listing in such a way that it is directly reflected in the truth-conditions. Thus a sentence like (4a) means something like (4b) (repeated here):

(4) a. A tanár$_i$ Jánosnak$_j$ adott jelest t$_i$ t$_j$.
the teacher John-dat gave A+-acc
'The teacher gave an A+ to John.' (Kiss 1994: 27, ex. 55)
b. John is the only person amongst the members of the class (or some other set of people who could have gotten A+) that the teacher gave an A+ to.

In other words, there is a focus operator that checks every member of a contextually given relevant set of entities for the property in question (here the property of receiving A+ from the teacher) and identifies John as the single member of that set of whom the property is true.

Szabolcsi (1981b) also demonstrated that focusing has an effect on the truth-conditions of the sentence. For instance, compare (5) and (6) (repeated here). (5b) is a logical consequence of (5a), while this is not true of (6b) and (6a). Consequently, conjoining either (6a) or (6b) with the negation of the other one does not yield a contradiction. This is shown in (7) (repeated here):

(5) a. János$_i$ magával vitte Marit és Évát t_i.
John self-com took Mary-acc and Eva-acc
'John took Mary and Eva with him.'
b. János$_i$ magával vitte Marit t_i.
John self-com took Mary-acc
'John took Mary with him.' (Kiss 1994: 28, ex. 59)

(6) a. János$_i$ [Marit és Évát]$_j$ vitte magával t_i t_j.
John Mary-acc and Eva-acc took self-com
'It was Mary and Eva that John took with himself.'
b. János$_i$ Marit$_j$ vitte magával t_i t_j
John Mary-acc took self-com
'It was Mary that John took with himself.' (Kiss 1994: 29, ex. 60)

(7) a. János$_i$ nem [Marit és Évát]$_j$ vitte magával t_i t_j hanem Marit$_j$
John not Mary-acc and Eva-acc took self-com but Mary-acc
vitte magával t_i t_j.
took self-com
'It was not Mary and Eva but Mary that John took with himself.'
(Kiss 1994: 29, ex. 61)

Recall also, however, that Kiss (1987) points out that exclusion may sometimes be absent from the meaning of focus. In (9), for instance, no exhaustivity requirement is present on the focused element *színészek* 'actors'. Rather, the group of people outside reading out loud is simply identified as a group of actors:

(9) A kertben$_i$ színészek$_j$ olvasnak fel t_i t_j.
the garden-loc actors read prt
'In the garden, actors are reading out loud.'
(based on Kiss 1994: 28, ex. 56)

1.4 Summary

This introduction had three aims: (i) to give a working definition of focus and focus construction that is precise enough to delimit the range of phenomena that are under discussion; (ii) to introduce basic data and identify some syntactic and semantic characteristics of the Hungarian focus construction; and (iii) to argue that this construction involves syntactic movement rather than scrambling (or PF movement).

2 Focus assignment under government

Armed with the definitions and basic data, we can now turn to the first group of analyses of focus movement: the proposal that focus is assigned under government, like case (this section). First, the original proposal of Horvath (1986) is spelt out (section 2.1). Given that government is known to display directionality effects across languages, both preverbal (section 2.2) and postverbal (section 2.3) focus constructions are analyzed. In the final subsection (section 2.4), several aspects of the proposal are discussed. In particular, it is spelt out that this proposal is committed to the idea that focus, like case, is an S-structure phenomenon (section 2.4.1). Word-order variations and directionality effects found in the world's languages are reviewed in light of the proposal. This seems important, as the proposal assumes that government plays a role in focus assignment, and government is known to display directionality effects with case (section 2.4.2). The morphological aspects of the proposal are discussed in section 2.4.3. Finally, the connection between focus and *wh*-elements as well as verbal modifiers is explored, paving the way to the discussion of the second group of analyses: those that propose that focus movement is like *wh*-movement (section 3).

2.1 Focus parameter

Horvath (1986) observes that the adjacency requirement on focus and the verb, spelt out in section 1.3.3 above, is not restricted to Hungarian. Rather, in other languages such as Basque and Aghem there is also an adjacency requirement on focus and verb, (36a) and (36b):

(36) a. Jon aurten etorri da herri honetara. Basque
John this year come has this town
'It is this year that John came to this town.'
(Ortiz de Urbina 1989: 214–215)

b. à mɔ zí á-fín bç-kɔ Aghem
sub P eat friends fufu
'The friends ate fufu.' (Horvath 1986: 124)

Another grammatical phenomenon that typically requires adjacency with the verb is case. Thus in English, which is a VO language, the object appears immediately postverbally, while in Turkish, an OV language, indefinites, which lack morphological case marking, appear immediately preverbally, (37a) and (37b):

(37) a. John ate (*pensively) the sandwich.
b. Üc cocuk ücü yeni bir araba (*din) almis. Turkish
three child three new a car yesterday bought
'Three children bought three new cars.'

Moreover, it turns out that the order of the verb and the focus follows the directionality of government for case in the language. Thus in Basque, which is an OV language, the focus appears immediately to the left of the V, while in Aghem, which is a VO language, the focus is immediately postverbal. For this reason Horvath proposed that in languages with syntactic focus constructions, the syntactic feature FOCUS is assigned by the verb under government, while in languages where syntactic focus constructions are missing FOCUS is assigned freely at S-structure. Thus she formulated the FOCUS parameter:

(38) **FOCUS parameter:**
   i. FOCUS can be freely assigned to categories in S-structure.
   ii. FOCUS is a syntactic feature inherent to the lexical category V. It can be assigned to other categories by the V under government and adjacency.
   (modified from Horvath 1986: 132)

It is hard to overemphasize the importance of this proposal. By establishing a parallel between case and syntactic focus constructions, Horvath (1986) provided a way to handle the phenomenon of syntactic focus marking. The similarities of case and focus were compelling. Both are subject to the same government-under-adjacency requirement that was fundamental to GB theory. Consequently, languages with focus constructions received a convincing analysis: focus can be treated similarly to case.

The consequences of Horvath's work, both empirical and theoretical, are far-reaching. For instance, they are at least partially responsible for the birth of a whole enterprise of analyses of focus constructions in different languages, culminating in the collection of papers edited by Kiss (1995b) and Rebuschi and Tuller (1999). The details of two of these will be fleshed out here: Horvath's own analysis of Hungarian (section 2.2) and Tuller's (1992) analysis of the Chadic languages (section 2.3). The choice is motivated by the fact that Hungarian has preverbal focus, while the Chadic languages discussed here have postverbal focus constructions.

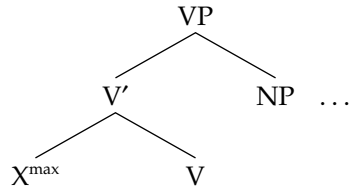
2.2 *Preverbal focus languages: Hungarian*

Recall from section 1.3.3 that Horvath (1986) showed that in Hungarian focused constituents, *wh*-elements, and verbal modifiers are in complementary distribution. The relevant data are repeated here for convenience. If a focused constituent or a *wh*-element is present in the clause, it appears immediately preverbally. The verbal modifier is postverbal in this case. If there is no *wh*-element or focused constituent in the clause, the verbal modifier is immediately preverbal:

(39) Mari hirtelen egy kanál sót/mit/bele *hirtelen tett hirtelen
Mary suddenly a spoonful salt-acc/what-acc/prt suddenly put suddenly
(bele) a kávéjába.
prt the coffee-her-loc
'Mary suddenly put a spoonful of salt/what in(to) her coffee.'

To put it differently, *wh*-elements, focused constituents, and verbal modifiers all appear in the immediately preverbal position. Thus, they are in complementary distribution (see section 1.3.3 for precise data). Horvath argues that this is due to the fact that they literally appear in the same syntactic position. If one occupies this position, neither of the others can appear there. In other words, she proposes that focused constituents (as well as verbal modifiers and *wh*-elements) move to an immediately preverbal position:

(40)



wh/focus/verbal modifier (Horvath 1986: 61)

This allows the verb to govern the preposed constituents, which Horvath claims is necessary for foci according to the proposed FOCUS parameter (see 38 above). She proposes that *wh*-elements target the same position because they are subject to a universal constraint regarding their distribution:

(41) The syntactic position(s) in which non-echo interrogative *wh*-phrases can appear in a language L will be identical to or be a proper subset of the positions in which FOCUS-constituents can appear in a language L.
(Horvath 1986: 122)

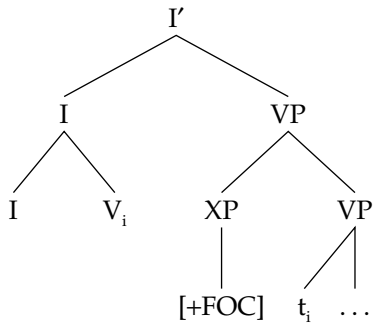
2.3 Postverbal focus languages: Chadic languages

Horvath's (1986) idea that the adjacency requirement between the V and the focus is the result of the requirement that the V governs the focus makes strong predictions for cross-linguistic variation. Languages like Basque, Turkish, Hindi, and Urdu are strict SOV languages, so presumably the direction of government in these languages is to the left. Thus, the prediction is that if these languages have focus constructions, then focus will be immediately preverbal. This is indeed the case, as has been argued among others by Ortiz de Urbina (1995) for Basque, by Kural (1992) for Turkish, and by Butt and King (1996) and Kidwai (1999) for Hindi-Urdu. On the other hand, typical VO languages, where the direction of government is to the right, are expected to have focus constituents in an immediately postverbal position. There are a number of languages that show this pattern. This possibility will be illustrated here by reproducing Tuller's (1992) analysis of Chadic languages.

Tuller (1992) presents an analysis of focus constructions in Chadic languages, which is very close to Horvath's (1986) analysis in spirit. Tuller argues that [+FOCUS] is a feature of Infl and that the focused constituent needs to be in the governing domain of Infl. In the languages she discusses (Western Bade, Podoko,

Tangale, Kanakuru, and Ngizim), the direction of government is to the right, as in English. She argues that in these languages, the V moves to Infl, while the focused constituent adjoins to the VP from the left. As a result, we get a configuration where focus is postverbal and adjacent to the verb and is in the governing domain of the verb in an ECM fashion. This is illustrated schematically in (42):

(42)



The languages under discussion fall into two groups depending on a more precise characterization of their focus constructions. In Type A languages, the focus is directly adjacent to the V from the right. Western Bade and Podoko are languages of this kind. In Type B languages, the head of the direct object or the entire direct object intervenes between the V and the focus on its right. This group includes languages like Tangale, Ngizim, and Kanakuru. Tuller notes that all the Type B languages are SVO and that Type A languages are either SVO or VSO. She argues that this is not an accident; rather, what distinguishes Type A languages from Type B languages is that the trace of the V that undergoes V-movement to I is able to govern (for case purposes) a VP-internal direct object in Type A languages, but not in Type B.

Given the schema in (42), Type B languages face a difficulty. V-to-I movement is necessary to license the focus in the governing domain of Infl. At the same time, since the trace of the verb is unable to govern a VP-internal object, V-to-I movement is not possible, as the direct object would remain caseless. Tuller arges that the head of the direct object incorporates into the V prior to V-to-I, thus bypassing the case problem. Indeed, as the following example shows, in Kanakuru, the head of a complex NP intervenes between the V and the focus, but the relative clause has to follow the focus. This phenomenon is called direct object splitting:

(43) Ad'e [shiruwoi] <u>ŋgadlai</u> [mə shee wura] ane. Kanakuru
ate fish-the cat-the RM she fried up
'<u>The cat</u> ate up the fish that she fried.' (Tuller 1992: 309, ex. 9a)

But in Tangale and Ngizim, there seems to be optionality with respect to the size of the intervening object. The head or the entire object may intervene. See (44)

for a Tangale example. This is unexpected: how could the whole complex NP incorporate into the V? Incorporation usually only affects heads, not complex phrases:

(44) Shag [wamunjaanan] nɔŋ [nam Aisha d'ikɔ]? Tangale
ate food-RM who RM Aisha prepared
'Who ate the food that Aisha prepared?'
b. shag [wamunjaanan Aisha d'ikɔn] nɔŋ
(Tuller 1992: 310, ex. 10)

Tuller offers an elegant solution to the problem. She observes that in all the examples where an entire object intervenes between the V and the focus, the focus is in fact clause-final. So she argues, Tangale and Ngizim have a separate focus construction, one that places the focused constituent in a right-peripheral specifier in the complementizer domain. So the optionality of direct object splitting is merely epiphenomenal. What really happens is that direct object splitting (i.e., incorporation of the head of the direct object into the V) is obligatory in these languages as well, but this can be masked by the presence of an alternative construction that places focus in a right-peripheral, clause-final position.

As a final point, Tuller explains why Kanakuru, the language where the obligatoriness of object splitting is transparent, lacks the clause-final focus position. The answer is simple: it has a clause-initial focus position instead. See (45):

(45) Basha shee tupa ya. Kanakuru
foc 2perf V DO
'Basha sent him.' (Tuller 1992: 324, ex. 28a)

2.4 Focus and case: discussion

So far, analyses of both postverbal and preverbal focus constructions have been sketched. It was shown that Horvath's focus parameter goes a long way toward accounting for the data. In languages with focus movement, the focus moves to a position governed by Infl. Thus the directionality of focus movement follows the directionality of government in the language. Apart from the empirical explanatory value, the theoretical significance of this work is also remarkable in several respects. The discussion of the theoretical implications of this proposal is the topic of this section.

2.4.1 D-structure or S-structure?

First, Horvath's theory provides further support for the position argued for by Chomsky (1971) that focus is established at S-structure, rather than at D-structure or at PF. Case is the prototypical example of an S-structure phenomenon in GB theory. So, by drawing a parallel between case and focus, Horvath emphasizes the S-structure characteristics of focus. Chomsky (1971) and Jackendoff (1972) argued that focus cannot be a D-structure phenomenon as previously assumed,

since focused constituents can be created at S-structure that were not available at D-structure. An example is given in (46). Here the underlying D-structure of (46a) is given in (46b). If focus was determined at D-structure, then we would expect that the focus of the utterance would be as in (46c). So (46d) would be a possible answer to (46a). However, as (46e) indicates, (46d) is not the only possible answer that can be given, and thus (46c) is not the only possible focus of the utterance in (46a); (46f) is also a possible focus:

(46) a. Was it a red-shirted EX-CONVICT that he was warned to look out for?
b. the one he was warned to look out for was X
c. a red-shirted ex-convict
d. No, he was warned to look out for an AUTOMOBILE SALESMAN.
e. No, he was warned to look out for a red-shirted AUTOMOBILE SALESMAN.
f. ex-convict

Chomsky argues that the potential foci of the utterance in (46a), which are *[$_N$ ex-convict]* and *[$_{NP}$ a red-shirted ex-convict]*, are not available at the D-structure representation; rather they are distinguished by the prosody of the utterance: any constituent at S-structure that contains the main stress of the utterance is a potential focus of the utterance.

In another example, Chomsky shows that in certain cases, the S-structure focus of an utterance does not even correspond to a constituent in D-structure. The utterance in (47a) can be felicitously answered by any of the utterances in (47b–d). Presumably the D-structure representation of (47a) is (47e). If so, then the focus indicated in (47c), *[$_{VP}$ likely not even to be nominated]*, corresponds to the string *certain to lose*, which is not a constituent at D-structure in (47e):

(47) a. Is John certain to WIN?
b. No, John is certain to LOSE.
c. No, John is likely not even to be NOMINATED.
d. No, the election will never take PLACE.
e. [John win] is certain

So focus in English is an S-structure phenomenon. Then an analysis, such as Horvath's, that argues that the syntax of focus constructions is similar to the syntax of case is a welcome one, given that case is an S-structure phenomenon as well.

2.4.2 Focus, case, and word order universals

Another advantage of Horvath's proposal is that by providing a parameter of available options for UG, the proposal has a strong predictive power. Languages are not expected to have focus positions such as 'second constituent on the right of the verb' or 'penultimate constituent preceding the verb', which are not attested. It is expected that languages where the direction of government is to the

left will have preverbal, rather than postverbal, focus constructions. And vice versa: languages where the direction of government is to the right are expected to have postverbal focus constructions. There are exceptions to this generalization. For instance, it is certainly controversial to claim that Hungarian, which has a preverbal focus construction, would be an OV language (but see Marácz 1989 and Ackema 2004 for proposals along this line).[6]

Nevertheless, the parallelism with case is quite compelling. This is especially clear in Tuller's analysis of Chadic languages. There it seems that a direct object that requires adjacency to the V for case reasons, and a focus that also requires adjacency to the verb, may even 'compete' for this position in a way that is similar to phenomena involving more than one object requiring case. For instance, in their analysis of double object constructions, Neeleman and Weerman (1999) argued that in double object constructions, where two NPs need to be case-marked by the verb, movement of the verb and VP-shell formation is necessary to provide a second position that is right-adjacent to and therefore governed by the verb.

There is another aspect of the relationship between case and focus that is relevant here, and it is for this reason, too, that Tuller's analysis of the Chadic languages is important. It is a wide-spread belief among linguists, although one that is not often rigorously argued for, that some kind of a functionalist explanation is ultimately right for the well-known and by no means absolute generalization that languages that have rich morphological case systems have free word order. To be more precise, the line of thought would go as follows: if a language marks argument relations by case morphology, then syntactic positions need not mark grammatical functions; rather they mark discourse functions. Hence topic and focus constructions are expected in languages with an elaborate system of morphological argument marking (either in the form of case markers on the arguments or in the form of head-marking on the V). Hungarian, Basque, and Turkish are textbook examples for this claim.

But the generalization is not absolute. For instance, the Chadic languages that Tuller discusses are clear counter-examples to the claim. These languages have strict SVO or VSO/SVO word order. They are by no means free-word-order, non-configurational languages. Nevertheless, they have grammaticalized focus constructions. Furthermore, they are counter-examples to the claim that syntactic discourse function marking necessarily means the presence of morphological argument structure marking. These languages also lack a rich case or head-marking paradigm. An in-depth study of such counter-examples would be enlightening for a formal account of the interactions of morphological and syntactic marking of argument structure and discourse functions.

2.4.3 Focus, case, and morphology

As far as case and focus are concerned, there is also room for establishing morphological parallelism. If syntactic focus constructions are similar to syntactic case assignment, then it is suggestive that one could find the equivalent of morphological case marking as well. There are many proposals in the literature that

identify focus particles that attach to focused constituents in a similar way to that in which morphological case markers attach to NPs. (See the discussion on Somali in section 3.5.3 for a potential example for a morphologically overt focus head.) This, however, only shows that both case and focus can be marked by means of morhological markers. But this is true of many other things, such as tense and aspect. A real parallel would have to be established between morphological case marking and focus particles.

A case that might be interesting to study from this perspective is Japanese and Korean.[7] In Japanese, Vermeulen (2005) argued that the nominative marker *-ga* is actually a focus marker when it appears on adjuncts in the so-called multiple nominative construction. In Korean, if an object is contrastively focused, the object-marker *-lul/-ul* is replaced by the contrastive focus marker *-nun/-un*, which bears main stress. The subject marker *-ka/-i* can be replaced by the topic marker *-nun/-un*. The complementary distribution of the morphological markers suggest that they somehow belong to the same class of morphological markers. This is illustrated in (48):

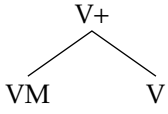
(48) a. Swuni-ka hakkyo-eyse Chelswu-lul manna-ss-ta. Korean
Swuni-sub school-at Chelswu-obj meet-pst-M
'Swuni met Chelswu at school.'
b. Chelswu-nun ku chayk-un sa-ss-ta.
Chelswu-top the book-con buy-pst-m
'Chelswu bought the book.' (Choe 1995: 271, ex. 2a; 285, ex. 35a)

2.4.4 Focus, verbal modifiers, and wh

Horvath (1986) showed that in Hungarian, focused constituents, *wh*-elements, and verbal modifiers are in complementary distribution. They all appear immediately preverbally. She argued that the reason for the complementary distribution is that they literally occupy the same syntactic position.

However, Brody (1990b) challenged this view and argued that this reasoning only applies to focused constituents and *wh*-elements. The complementary distribution between verbal modifiers and foci (or *wh*) is not due to the fact that they occupy the same position. Rather, he proposed that verbal modifiers bear a semantically and lexically close relationship to the verb. Resultatives and verbal particles arguably form complex verbs with the V, and have common theta-grids. This idea has been formulated by Ackerman (1984), who argued that verbal modifiers are base generated in an immediately preverbal position:

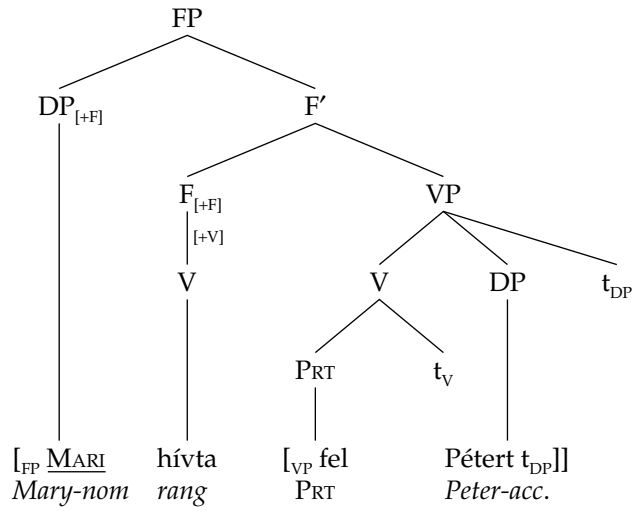
(49)



In contrast, Brody argued, focus and *wh*-elements are different: they occupy a preverbal position as a result of movement of both the focal element and the V.

The analysis is based on similar data from V2 languages like Dutch. Under V2, the verb moves to C. If it has a particle, which is a subclass of verbal modifiers, the particle is stranded in the VP (Koster 1975). The data in (50) illustrate the analysis: the focused element (or the *wh*-element) moves to the specifier of a functional head, while the verb adjoins to this head, leaving the particle behind:[8]

(50)



'Mary rang Peter.'

The main argument in favor of Brody's (1990b) proposal is that focused phrases (or *wh*-elements) and verbal modifiers are not incompatible. They can occur in one clause, but in this case the verbal modifier is obligatorily postverbal. By assuming that verb movement takes place in clauses with focused constituents or *wh*-phrases, Brody can maintain a uniform analysis for the position of verbal modifiers in the sense that these are always adjoined to the base position of the verb. In contrast, Horvath has to assume that the position of the verbal modifier is different in clauses with or without a focus (or a *wh*-element). A further argument in favor of Brody's approach is the syntactic and semantic similarities between focus and *wh* that are not, or at best partially, shared by verbal modifiers. These similarities between *wh* and focus will be the subject of the discussion in section 3.

3 Focus movement is like *wh*-movement

The idea that focus is similar to *wh* rests on both syntactic and semantic considerations that draw a parallel between the two (section 3.2). These considerations gave rise to analyses arguing for the Focus criterion alongside the *Wh*-criterion, which state that a focus or *wh*-element has to be licensed in a specifier–head

relationship with its licensing head. This proposal is illustrated here by the discussion of Ortiz de Urbina's (1995) analysis of focus movement in Basque (section 3.3). Another, highly influential, proposal, in Rizzi (1997), concerns focus movement in Italian. The innovation here is that the licensing head is no longer Infl or C, but rather a designated functional head, the Focus head (section 3.4). This line of analysis is evaluated in section 3.5. Here the notion is discussed that adjacency effects and the presence of pied-piping give support to an analysis of focus movement based on *wh*-movement, as the latter also exhibits both adjacency effects and pied-piping (sections 3.5.1–3.5.2). It would be a strong support for Rizzi's line of thinking if a language with an overt Focus head could be identified. The case of Somali is examined from this perspective, with, however, an inconclusive outcome (section 3.5.3). Finally, an alternative, discourse-based explanation is provided for the alleged weak crossover violations described in section 3.1, which are fundamental to the idea that focus involves movement similar to *wh*-movement (section 3.5.4). By calling into question the parallel between focus movement and *wh*-movement, the discussion in section 3.5.4 shakes the foundations of the proposal that regards focus movement and *wh*-movement as essentially similar.

3.1 The origins of a movement analysis

Before we embark on a trip to discover the characteristics of focus movement that assimilate it to *wh*-movement, let us take a step back and investigate the origins of a movement approach to focus. The idea that focus would be associated with movement stems from two independent factors: (i) the fact that focus is quantificational, and (ii) the assumption that quantificational elements take their respective scopes via quantifier raising (May 1977). Let us take these in turn.

3.1.1 Focus is quantificational

The fact that focus is quantificational can be illustrated by the examples in (51), where (51a) is true while (51b) is false in the context in (51c), even though (51a) and (51b) differ only in focus. In other words, two sentences may differ in truth-value if they only differ in focus:

(51) a. John only gave a book <u>to SUE</u>. True
b. John only gave <u>a BOOK</u> to Sue. False
c. John gave a book and a pen to Sue. He gave nothing else to anybody.

As Szabolcsi (1981b) argued, in Hungarian, where overt focus movement takes place, the effect on the truth-value can be observed even without the presence of a focus-sensitive operator such as *only*. So it is really the focal difference that is responsible for the truth-conditional effect. The Hungarian equivalent of (51) is given in (52) (see also the discussion in section 1.3):

(52) a. János$_i$ [ZSUZSINAK]$_j$ adott t_i t_j egy könyvet. True
John Sue-dat gave a book-acc
'It was to Sue that John gave a book.'
b. János$_i$ [egy KÖNYVET]$_j$ adott t_i t_j Zsuzsinak. False
John a book-acc gave Sue-dat
'It was a book that John gave to Sue.'
c. János$_i$ adott t_i egy könyvet és egy tollat Zsuzsinak. Nem adott
John gave a book-acc and a pen-acc Sue-dat not gave
semmi mást senkinek.
nothing else-acc nobody-dat
'John gave a book and a pen to Sue. He gave nothing else to anybody.'

3.1.2 Weak crossover

The treatment of focus in terms of 'quantifier raising' was first suggested by Chomsky (1976), who noted that backward coreference is ruled out if the full DP is focused, while allowed if not. Thus (53b), as opposed to (53a), is ungrammatical:

(53) a. The man that she$_i$ met LIKED Mary$_i$.
b. *The man that she$_i$ met liked MARY$_i$.
LF: MARY$_i$ [the man that she$_i$ met liked t_i]

Chomsky (1976) argued that the ungrammaticality of (53b) can be explained if one assumes that the focal element undergoes fronting at LF. (53b) is a weak crossover violation resulting from the LF movement of the focused element over the co-indexed pronoun. Thus (53b) is similar to (54a), where the movement of the *wh*-element across a co-indexed pronoun is ruled out as a weak crossover violation. Note that this argument is considerably weakened by the observation, already made by Jackendoff (1972), that focus disregards syntactic islands. This is illustrated in (54b) for a complex NP island:

(54) a. *Who$_i$ does the man that she$_i$ met like t_i?
b. Sam only saw a [$_{NP}$ man [$_{CP}$ who was wearing a RED hat]].

This would mean that focus movement (or maybe LF movement in general) is different from overt movement in that it is not sensitive to islands. This would be an undesirable outcome, especially in light of the facts given in section 1.3.3 that showed that islands are observed by focus movement in languages with focus constructions, like Hungarian. Nevertheless, at least until the early 1990s the alleged weak crossover violation exemplified in (53) was taken to be the strongest argument for the treatment of focus in terms of movement even in languages like English. An evaluation of the strength of this argument will be given in section 3.5.4, where it is shown that (53b) should be analyzed as a discourse violation rather than a violation of the conditions on variable binding.

3.2 *Focus and* wh

3.2.1 Semantic parallelism

An immediate advantage of treating the syntax of focus and *wh* in a similar fashion is the following. While it is unclear what would constitute semantic parallelism between focus and case, focus and *wh* appear to behave in a similar way semantically. Following Jackendoff (1972), we may represent the non-focal part of an utterance by replacing the focus with an appropriate semantic variable, which is existentially bound, as in (55b). Argueably, the *wh*-question in (55c) carries the same presupposition. In a negative answer to a *wh*-question, such as (55d), the presupposition is denied.[9] In other words, what we see is that both focal and *wh*-utterances contain a presupposition. This is partly why a *wh*-test is so appropriate for identifying foci. The *wh*-question provides the necessary presupposition for us, and thus it is easy to identify the focus of the answer: it is the part of the answer that is not contained in the presupposition:

(55) a. It is the man in the red HAT that John saw.
b. ∃x (John saw x)
c. Who did John see?
d. No one. ¬ ∃x (John saw x)

3.2.2 Syntactic parallelism

It has long been noted that focus in languages like Hungarian behaves similarly to *wh*-elements.[10] In particular, recall from section 1.3.3 (and also sections 2.2 and 2.4) that Hungarian focus movement is in complementary distribution with *wh*-movement in simple clauses, suggesting that the focus element and the *wh*-constituent occupy the same surface syntactic position (e.g., Horvath 1986).

Another similarity between focus movement and *wh*-movement is that both may apply successive-cyclically and thus across finite clauses. As was shown in section 1.3.3, Hungarian has long focus movement of the relevant sort. (In section 3.3 we will see examples of long focus movement in Basque.)

A final property of focus movement that is also displayed by *wh*-movement is that it licenses parasitic gaps. This is illustrated for Hungarian in (56): (56a, b) show that *wh*-movement and focus movement license parastic gaps, while (56c, d) show that scrambling or topic movement do not:

(56) a. Mit$_i$ dobott ki Péter t$_i$ anélkül hogy elolvasott volna t$_i$?
what-acc threw prt Peter without that prt-read be-irreal
'What did Peter file without reading?'
b. Fontos iratokat$_i$ dobott ki Péter t$_i$ anélkül hogy
important documents-acc threw prt Peter without that
elolvasott volna t$_i$.
prt-read be-irreal
'It was important documents that Peter filed without reading.'

c. Kidobott fontos iratokat$_i$ Péter t$_i$ anélkül hogy elolvasott
threw-prt important documents-acc Peter without that prt-read
volna t$_i$.
be-irreal
'Peter filed important documents without reading (them).'

d. *Fontos iratokat Péter$_i$ dobott ki anélkül hogy elolvasott
important documents-acc Peter threw prt without that prt-read
volna t$_i$.
be-irreal
'Peter filed important documents without reading (them).'

3.3 Focus criterion: Basque

The analysis of focus as an instance of A-bar movement, similar to *wh*-movement, will be illustrated by Basque. Basque is an OV language (Ortiz de Urbina 1989). It is (split) ergative and has morphological case. It has no morphological focus markers, but just as in Hungarian, focused constituents appear in the immediately preverbal position:

(57) a. Jon herri honetara aurten etorri da.
John this town this year come has
'John came this year to this town.'

b. Jon AURTEN etorri da herri honetara.
'It is this year that John came to this town.'

(Ortiz de Urbina 1989: 214–215)

Ortiz de Urbina (1989, 1995) argues that clauses that have a focused constituent instantiate residual V2 effects. Thus in these cases the focused constituent is clause-initial and the V follows immediately. In this respect focus constituents are parallel to *wh*-words. For this reason, Ortiz de Urbina (1995) proposes an analysis following Rizzi's (1996) *Wh*-criterion, given in (58):

(58) ***Wh*-criterion:**
A. A *wh*-operator must be in a spec–head configuration with an $X^0_{[+wh]}$.
B. An $X^0_{[+wh]}$ must be in a spec–head configuration with an *wh*-operator.

Rizzi's proposal was meant to capture the fact that (i) *wh*-questions in English are residual cases of V2; (ii) in multiple *wh*-questions only one *wh*-element moves overtly. (i) is ensured if it is assumed that (A) applies at S-structure in English. Languages are parameterized with respect to the level of representation where (B) applies. In English multiple *wh*-questions, only one *wh*-element moves to [Spec, CP] overtly; the remaining *wh*-elements move there at LF. So, in English, (A) applies at S-structure, while (B) applies at LF.[11]

In Basque, just as in Hungarian, a focused phrase appears in the specifier of a head bearing a focus feature at S-structure. Any further focused phrases move

there at LF. Brody (1990b) and Ortiz de Urbina (1995) proposed the analysis in (59a). What happens in clauses containing a focused constituent and in *wh*-questions in Basque is that the focus or the *wh*-element moves to the specifier of C to check the [+*wh*] or the [+F] feature of C. (So in Basque, the Focus/*Wh*-criterion applies for both *wh*-words and focus constituents.) Since C itself does not contain a matching feature, Infl has to raise to C to provide the necessary [+*wh*] or [+F] feature. This is illustrated schematically in (59b):

(59) a. **Focus criterion:**
At S-structure and LF the specifier of a $X^0_{[+F]}$ must contain a [+F] phrase.
At LF all [+F] phrases must be in the $X^0_{[+wh]}$ must be in a spec–head configuration with a *wh*-operator.
(modified from Brody 1990: 208)

b. $[_{CP}wh_{[+wh]}/focus_{[+F]}[_{C}\ Infl_{[+wh]/[+F]}\ C]_{\ [+wh]/[+F]}[_{IP}\ [_{I'}t_{Infl}VP]]]$

To be precise, the picture is slightly more complicated. Although in the northern dialects of Basque, the focused constituent may optionally be followed by the inflected auxiliary, with the V remaining in clause-final position, this is not the case in the southern dialects (compare 60b and 60c). In the southern dialects, the V-Aux complex follows the focused constituent, even in the case of periphrastic forms and, unlike in Italian, nothing can intervene between the auxiliary and a verb. The pattern in the northern dialects is similar to the pattern found in V2 constructions, for instance, in Dutch, so it is explained by the Focus criterion. As Ortiz de Urbina (1995) proposed, the pattern in the southern dialects can be accounted for if it is assumed that in addition to I to C movement the V moves to I and the whole V-I complex moves to C:

(60) a. Jonek liburua irakurri du.
John book read has
'John has read the book.'
b. JONEK irakurri du liburura.
c. JONEK du liburua irakurri
'It is John that has read this book.' (Ortiz de Urbina 1995: 200)

The language also displays V1 patterns. As expected, these show up in two cases: as an instance of yes/no questions (61a) and as an instance of what Ortiz de Urbina calls 'verbal focalization' (61b):

(61) a. Irakurri du Jonek liburua?
read has John book
'Has John read the book?'
b. Hil da gure ata.
die has our father
'Our father has died.'
'Our father did die.' (Ortiz de Urbina 1995: 110, ex. 22, 23a)

Ortiz de Urbina claims that this is an instance of movement of the Aux-V complex to C triggered by the [+Q]-feature of C in (61a) and triggered by [+F]-feature on C in (61b).

Note that the northern dialects present a partial problem in the V1 case. In these dialects, the Auxiliary does not have to cliticize onto the V, so it is expected that it is the Auxiliary alone that moves to C in yes/no questions or cases of verb focalization. However, as illustrated in (62a) and (62b) respectively, Aux focalization is grammatical, but yes/no questions are deviant:

(62) a. ba-dut . . . ikusi
ba-aux seen
'I have seen . . .'
b. ??baduzu . . . ikusi
ba-aux seen
'Have you seen . . . ?'

(Ortiz de Urbina 1995: 112, ex. 30a, 31a)

To conclude, Ortiz de Urbina (1995) argued that the focus construction in Basque is similar to the *wh*-construction. They both involve A-bar movement to [Spec, CP], therefore they both instantiate residual V2 (and V1) effects.[12]

Similar proposals have been put forward for many languages. Svolaccia et al. (1995) argue that in Somali, [+F] is a feature of C. (See section 3.5.3 for discussion.) The same was proposed by Vilkuna (1994) for Finnish and by King (1993) for Russian. There are also proposals to the effect that [+F] is on I and that therefore [Spec, IP] is the position targeted by focus movement. Aissen (1992) argued that this is the case in some Mayan languages, for example Tzotzil. A review of the syntactic options available for focus constructions is given by Kenesei (1998).

3.4 Focus as a functional head: Italian

3.4.1 The Focus head

In the spirit of Pollock's (1989) proposal, in the course of the 1990s it became more and more generally assumed that a separate functional head, Focus, is projected in the left periphery of the clause. The focused element moves to the specifier of the Focus head to check features in a spec–head configuration. An abstract schema is given in (63):

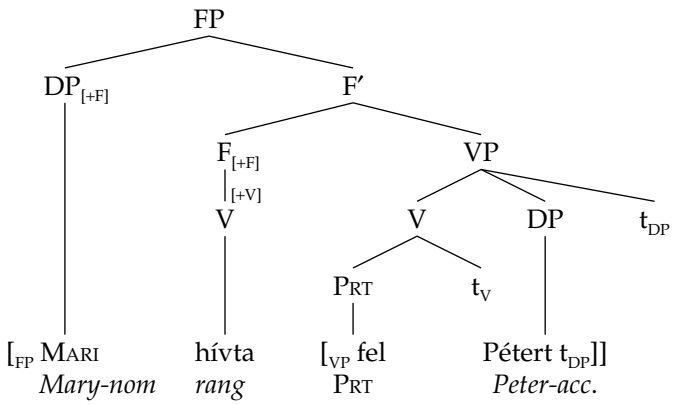
(63) $[_{FP}\ XP_{focus}\ F \ldots [_{VP}V_t_{XP}]$
[+F] [+F]

This was proposed for many languages, with the only differences being the location of Focus with respect to other heads, and whether the movement of the focused constituent (and of the V) is overt or covert. To mention a few: Brody

(1995a) on Hungarian; Laka (1990) on Basque; Ouhalla (1994) on Standard Arabic; and many works in Kiss (1995b) and Rebuschi and Tuller (1999), including accounts for Greek (Tsimpli 1995), Korean (Choe 1995), Western Romance languages (Uriagereka 1995b), and Portuguese (Ambar 1999).

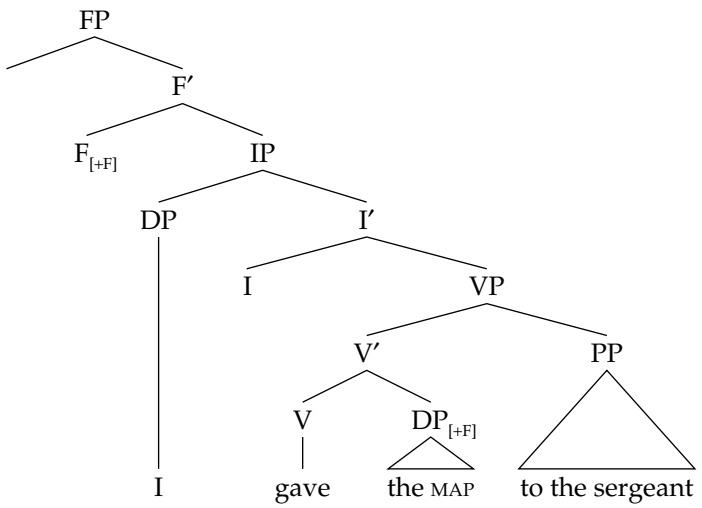
In Hungarian, the Focus head is located in the left periphery of the clause (Brody 1995a, among many others). If the Focus head is strong, as it is in Hungarian, it will trigger overt movement of the constituent bearing [+F]. In a tensed sentence, this is accompanied by V movement to F, thus the focused constituent and the V are adjacent. As already mentioned in section 2.2, the main data supporting V-movement are sentences that contain verbal particles. In Hungarian the default position for particles is preverbal; it is immediately in front of the V. In sentences which have a focused element, the particle follows the verb. Brody (1995a) takes this to be an indication of V-movement. This is illustrated in (64):

(64)



If the Focus head is weak, as it is in the English, the focused constituent will remain in situ (at least in the overt syntax).[13] This is illustrated in (65):

(65)



Rizzi (1997) proposed a similar analysis for the so-called left-peripheral focus in Italian. He argued that the complementizer field in Italian is split in a way that is similar to the proposal about the tense field by Pollock (1989). The topmost complementizer-like head is Force and the lowermost is Finiteness. Topic positions and a unique Focus position are sandwiched between the two. This is shown in the schema in (66):

(66) . . . Force . . . *Topic . . . Focus . . . *Topic . . . Fin . . . IP (* indicates possibility of recursion) (modified from Rizzi 1997, ex. 38)

Movement into the specifier of the Focus head is subject to the Focus criterion, which says that movement is 'last resort' and that it only happens to satisfy LF requirements of the element. In particular, a focal element needs to be in a specifier–head configuration with the Focus head at LF (Rizzi 1997: 6).

3.4.2 Five characteristics of focus in Italian

Rizzi (1997: 8–9) enumerates a number of properties that characterize foci, as opposed to topics. First, topics, but not foci, allow the presence of resumptive clitics:

(67) a. Il tuo libro, lo ho comprato.
'Your book, I bought it.'
b. Il tuo libro ho comprato(, non il suo).
c. *Il tuo libro lo ho comprato(, non il suo).

Focus gives rise to weak crossover violations, while topics do not:

(68) a. Gianni$_i$, sua$_i$ madre lo sempre apprezzato.
b. ??Gianni$_i$ sua$_i$ madre ha sempre apprezzato.
'Gianni his mother always appreciated, not Pietro.'
(Rizzi 1997: ex. 17, 18)

Bare quantificational elements are felicitous foci, but they cannot be topics:

(69) a. *Nessuno, lo ho visto.
'No one, I saw him.'
b. Nessuno ho visto t.
'I saw no one.' (Rizzi 1997: ex. 19a, 20a)

There is no restriction on the number of topics that can appear in a clause, while each clause allows only one focus:

(70) a. Il libro, a Gianni, domani, glielo daro senza'ltro.
'The book, to John, tomorrow, I'll give it to him for sure.'
b. *Il libro a Gianni daro senza'ltro (non a Piero, l'articolo).
'The book to John I'll give, not to Piero, the article.'
(Rizzi 1997: ex. 21, 22)

Finally, topics, but not foci are compatible with a clause-mate *wh*-word:

(71) a. A Gianni, che cosa gli hai detto?
'To John, what did you tell him?'
b. *A Gianni che cosa hai detto (non a Piero)?
'To John what did you say, not to Piero?' (Rizzi 1997: ex. 24a, 25a)

Let us start with the last property of foci, i.e., that they are incompatible with *wh*-elements. Similarly to Horvath (1986) and Brody (1990b), Rizzi (1997) suggests that focus and *wh* are incompatible because they are in complementary distribution. In other words, they target the same position.

Rizzi (1997) argues that the first three properties follow from the assumption that focus is quantificational, while topic is not. In particular, he suggests that the LF representation of focus movement results in a configuration where a quantifier binds a variable, while the LF representation of the topic construction is different. Here there is A-bar binding of a null constant, by a null operator:

(72) a. ?* Who$_i$ does his$_i$ mother really like t$_i$ (= vbl)?
b. John, who$_i$ his$_i$ mother really likes t$_i$ (= nc) . . . (Rizzi 1997: ex. 26)

This characterization of the data would explain why focus gives rise to weak crossover violations, as these are due to semantic variable chains, absent in the case of topics. It would also explain why bare quantificational elements are not possible topics. This is because topic constructions do not provide a variable for the bare quantificational element to bind. Finally, the presence of an overt clitic in the topic constructions disallows the formation of a quantificational chain on the assumptions that quantificational chains bind variables and that overt pronominal clitics are different from traces in this respect: unlike traces, clitics do not license the presence of a variable in the LF representation.

So three seemingly independent generalizations receive a unified explanation. But there is reason to doubt that all three characteristics are a consequence of the proposed quantificational vs. non-quantificational distinction between focus chains and topic chains. The fact that quantificational elements are unlikely topics, the third characteristic difference between focus and topics, also follows from discourse-oriented considerations. Topics, by definition, are referential expressions (Reinhart 1981). So quantificational elements are unlikely topics. To be precise, they are possible topics if and only if they "can be interpreted (pragmatically) as denoting sets" (Reinhart 1981: 65). This possibility is obviously not available for bare quantifiers, but a set denotation can be facilitated by the presence of a lexical restriction. As Rizzi himself notes, quantificational elements with lexical restrictions are much better as topics:

(73) a. Tutto, lo concosco veramente bene.
'Everything, I know it really well.'
b. Tutti i tuoi libri, li ho rimessi a posto.
'All your books, I put them back.' (Rizzi 1997: ex. 34c)

Let us now turn to the explanation Rizzi offers for the fourth characteristic property of focus in Italian: uniqueness. There can be any number of topics in a clause, but each clause allows a unique focus. He offers an analysis based on the idea, going back to Jackendoff (1972), that the focus of an utterance partitions the utterance in the focal part and the presupposition. Thus he assumes that just as the specifier of the Focus head identifies the focus, the complement of the Focus head is the presupposition. Since the non-focal part of the utterance is the presupposition, a second (or third, etc.) focus would be part of the presupposition, and thus by definition would not be focal (Rizzi 1997: 14).[14]

But the claim that the complement of the Focus head would be the presupposition is probably too strong. In fact, under such a view topics that precede a left-peripheral focus would not be part of the presupposition. So one has to weaken the statement that the LF representation of the presupposition is a continuous constituent (e.g., the complement of FP). But this opens up the possibility of a situation where two (or more) foci are identified in a clause and the rest of the utterance would be the presupposition. Such cases are attested. For instance, the Hungarian example in (74) has two foci:

(74) Csak két lány választott csak egy könyvet. Hungarian
only two girls chose only one book-acc
'It was only two girls who chose only one book.' (Kiss 1998: 16)

3.4.3 Left-peripheral vs. right-peripheral focus in Italian

Rizzi claims that the left-peripheral focus can be distinguished from a lower, right-peripheral focus position described in detail by Calabrese (1982), Cinque (1993), Belletti and Shlonsky (1995), and Samek-Lodovici (1996).

One of the characteristics of the left-peripheral focus is that it is not appropriate as an answer to a question indicating non-contrastive new information. Rather, it is allowed as a correction, as in (75) (Rizzi 1997: 5):[15]

(75) a. A: Che cosa hai letto?
What thing have-you read
'What did you read?'
B: #Il tuo libro ho letto.
the his book have-I read
'I read your book.'
b. A: Gianni ma dice che hai letto il suo libro.
John to-me said that have-you read the his book
'John told me that you read his book.'
B: Il tuo libro ho letto (, non il suo)
the his book have-I read not the his
'I read your book, not his.'

Although Rizzi (1997: 6) claims that the right-peripheral focus is in situ, Samek-Lodovici (1996) showed that it can be targeted by movement. For instance, the

example in (76) illustrates this. The canonical order of two internal arguments in Italian is direct object preceding dative PP (see 76a). This order can be altered, as in the answer in (76b), in such a way that main stress falls on the direct object, which is therefore focused:

(76) Piero ha presentato Giorgio a Maria.
Piero has introduced Giorgio to Maria.
a. Chi non hai presentato a nessuno?
who not have-you introduced to no one
b. Non ho presentato a nessuno Gianni.
not have-I introduced to no one Gianni
'I have introduced Gianni to no one.' (Samek-Lodovici 1996)

To the extent that Samek-Lodovici's arguments turn out to be right, they raise a theoretical issue. The point is that according to Rizzi's Focus criterion, the focused element moves to an A-bar position in order to be licensed in this position at LF. Languages are parameterized with respect to the locus of this movement. On the one hand, Hungarian and Italian left-peripheral constructions are overt instances of such a movement operation. On the other, English focus movement is covert; its presence is only indirectly observable, for instance, as it induces weak cross-over violation (Chomsky 1976). In the realm of the Focus criterion, there is no room for a construction that involves overt movement to a designated syntactic position other than the position where focus is licensed at LF. In the case of the Italian right-peripheral focus, this position is targeted overtly, while presumably, a further covert movement step places the focal element in the left-peripheral licensing position (Rizzi 1997: 6). What would be the reason for the (intermediate) overt movement step? The only possible way out seems to be to assume that there is more than one possible licensing position for foci: a right-peripheral one and a left-peripheral one. Thus movement into either of these would satisfy the Focus criterion. But the result of this proliferation of functional landing sites is an increased potential for overgeneration and for loss of predictive power.

A similar point is put forward in Horvath (1995). She argues that languages, such as Aghem, that have a low postverbal focus position pose a problem for the Focus criterion. Her argument is based on the fact that in this language the same low position hosts *wh*-elements as well. Given the assumption that a *wh*-element needs to take scope over the clause at LF for the *wh*-question interpretation to be felicitous, one needs to assume that there is a further covert movement step taking the *wh*-element from the low postverbal position to some high position from which the *wh*-element would take scope over the clause. However, this means that the reason for the focus movement – targeting the low postverbal position – could not have been to satisfy an LF requirement, as proposed by the Focus criterion, since the LF requirement on the *wh*-element is not satisfied without a further movement step. Thus the same question arises as before: what is the trigger for the (overt) movement operation to the postverbal focus position? Horvath's answer is that the trigger for focus movement is an S-structure

requirement that the focus be adjacent to the V. This is clearly orthogonal to the LF requirement that *wh*-elements need to take scope at LF, so the puzzle dissolves. Note that Horvath's solution has an important insight in the sense that she claims that it is an S-structure rather than an LF requirement of the focus that triggers overt movement to some designated position. Nevertheless, the proposed adjacency requirement cannot be the whole explanation, as, for instance, in Italian neither the left-peripheral nor the right-peripheral focus position is obligatorily adjacent to the V.

3.5 Focus movement is like wh*-movement: discussion*

3.5.1 Adjacency requirement

One characteristic property that suggests a similar treatment of focus and *wh* is that in many languages both of these elements require adjacency to the verb. This has been shown for Hungarian in section 1.3.3, for Basque in section 3.3, and for a postverbal focus language Podoko in section 2.3.

The adjacency requirement is often explained by the fact that the focus or *wh*-element is in the specifier of a functional head, while the verb occupies the head position. Therefore, focus (or *wh*) and verb are necessarily adjacent, since there is no intervening syntactic position between a leftward specifier and a head in the head–complement order.

It is important to note that, as Rizzi (1997: 16) shows, in Italian the parallel breaks down, since the adjacency requirement is present for *wh* but not for preverbal focus:

(77) Questo Gianni ti dira' (non quello che pensavi).
this John you-dat say-fut.3 not which that thought.2
'This Gianni will say to you, not what you thought.'
*Che cosa Gianni ti dira'?
what John you-dat say-fut.3
'What will Gianni say to you?' (Rizzi 1997: ex. 48)

Accordingly, Rizzi (1997) hypothesizes that the Focus head attracts the verb in *wh*-constructions, but not in focus constructions.

3.5.2 Pied-piping

Another similarity between focus movement and *wh*-movement is that they both exhibit pied-piping. As the following data illustrate, Hungarian focus movement (cf. 78a) is similar to Hungarian and English *wh*-movement (cf. 78b, c) in that sometimes the moved constituent is bigger than the actual focused or *wh*-element:

(78) a. $[_{FP}\ [_{DP}$ Használt autót] vettem.]
second-hand car bought-I

b. [$_{FP}$ [$_{DP}$ Melyik autót] vetted meg?]
which car-acc bought-you VM
c. [$_{CP}$ [$_{DP}$ Whose car] did you buy?]

On the basis that focus and *wh* both exhibit pied-piping, Kenesei (1998: 40) argues that *wh* and focus should be treated alike, in terms of a syntactic [+*wh*]- and [+F]-feature, and that pied-piping should be accounted for in terms of feature percolation.

Horvath (2000: 197) showed that the parallelism between pied-piping in focus and *wh* does not go all the way in Hungarian. In particular, the *wh*-feature cannot be pied-piped from an object onto the participial clause (79a–b). Nevertheless, focus interpretation of the structurally parallel object in (79c) is allowed. This, she suggests, indicates that a different treatment for focus and *wh* is necessary in the grammar:

(79) a. *az ital amit követelő vendégektől fél a pincér
the drink which-acc demanding guests-loc fears the waiter
'the drink customers demanding which the waiter is afraid of . . .'
b. *Mit követelő vendégektől fél a pincér t?
what-acc demanding guests-loc fears the waiter
'Customers demanding what is the waiter afraid of?'
c. Barackpálinkát követelő vendégektől fél a pincér.
apricot-brandy-acc demanding guests-loc fears the waiter
'It is customers demanding apricot brandy that the waiter is afraid of.'

However, according to Ortiz de Urbina (1999: 317), there is absolute parallelism between the pied-piping properties of focus and *wh* in Basque, suggesting that the Hungarian restriction on *wh*-pied-piping may just be a language-particular property.

Several languages are reported in the literature as exhibiting so-called clausal pied-piping (cf. Hermon 1984 on Quechua; Ortiz de Urbina 1990 on Basque; and Simpson and Bhattacharya 2000 on Bangla). In these cases, a *wh*-word or focus undergoes movement to a designated position inside the embedded clause, while the whole embedded clause gets pied-piped to the matrix *wh* or focus position. This is illustrated for Bangla in (80a, b) and for Basque in (81a, b). (82a, b) illustrate that clausal pied-piping is ungrammatical in Hungarian:

(80) a. jOn [$_{CP}$ ke cole gEche]$_i$ bollo t$_i$?
John who leave gone said
'Who did John say left?'
b. jOn [$_{CP}$ or baba$_i$ aS-be t$_i$]$_k$ Sone ni t$_k$, kintu [$_{CP}$ ma$_j$ aSbe t$_j$]$_l$
John his father come-fut.3 heard not but mother come-fut.3
Suneche t$_l$
heard
'John didn't hear his father but heard his mother.'
(Simpson and Bhattacharya 2000: 9, ex. 25)

(81) a. [Nork$_i$ idatzi du-elat$_i$ liburua]$_k$ esan du Peiokt$_k$?
who write aux-comp book say aux Peio
'Who did Peio say wrote the book?'
b. [Jonek$_i$ idatzi du-elat$_i$ liburua]$_k$ esan du Peiot$_k$.
Jon write aux-comp book say aux Peio
'It is Jon that Peio said wrote the book.'

(82) a. *[Ki jön ide t$_i$ holnap] mondtam Marinak t$_k$
who comes prt tomorrow said-I Mary-dat
b. *[János jön ide t$_i$ holnap] mondtam Marinak t$_k$.
John comes prt tomorrow said-I Mary-dat
'I have told Mary that it is John that will come tomorrow.'

In all of these languages, an alternative derivation exists, where the *wh*-element in the embedded clause undergoes long *wh*-movement targeting the designated position in the matrix clause. In Basque the position of the embedded verb is clause-initial, indicating that the long focus movement is successive-cyclic. In other words, it passes through an embedded designated focus position, thus triggering V1 in the embedded clause. This is not the case in Hungarian, as can be observed from the prt-V order in (83c). It appears that the Bangla data can be analyzed either way:

(83) a. jOn ke$_i$ bollo [$_{CP}$ t$_i$ cole gEche]?
John who said leave gone
'Who said that John left?'
(Simpson and Bhattacharya 2000: 9, ex. 26)
b. Nork/Jonek uste duzu/dut [$_{CP}$ t esan du-ela Mikelek[$_{CP}$ t idatzi du-ela eskutitza]]?
who/Jon think aux say aux-that Mikel write aux-that letter
'Who do you think/It is Jon that I think Mikel has said has written the letter?' (Ortiz de Urbina 1999: 313, ex. 4, 5)
c. Kit/Marit mondta János hogy elment?
who-acc/Mary-acc said-def John that prt-went
'Who did John say left?/It is Mary that John said left.'

3.5.3 Overt manifestations of the Focus head: Somali

The languages discussed so far, namely Italian, Hungarian, and Basque, give no overt morphological evidence for the presence of a Focus head. However, there are languages that have morphological focus markers that have been analyzed as functional heads. Somali is a case at hand.

As reported in Hyman and Watters (1984), in Somali, the marker *-baa/-buu* is attached to a focused XP, while the prefix *waa-* attaches to focused verbs:

(84) a. Cali-baa moos cunay.
Ali-FM banana ate
'Ali ate a banana.'
b. Cali MOOS-buu cunay.
'Ali ate a banana.'
c. Cali moos waa-cunay.
'Ali ate a banana.'

Svolaccia et al. (1995) and Lecarme (1999) question all of Hyman and Watters's (1984) claim. Rather they argue that the focus particles sit in Infl or C, and the [Spec, CP] position is available for focused constituents, while topics adjoin to CP.[16]

The argument that *-baa* is dependent on the V rather than on the preceding NP comes from gapping. Gapping the V in a coordinate structure renders the presence of a focus marker ungrammatical, suggesting that *-baa* is dependent on the V rather than on the NP:

(85) a. Ma Maxamed baa tegay mise Cabdi baa tegay?
Q Maxamed FM went or Cabdi FM went
'Has Maxamed gone or has Cabdi gone?'
b. Ma Maxamed baa tegay mise Cabdi?
Q Maxamed FM went or Cabdi
'Has Maxamed gone or has Cabdi?'
c. *Ma Maxamed baa tegay mise Cabdi baa?
Q Maxamed FM went or Cabdi FM
'Has Maxamed gone or has Cabdi?' (Saeed 1984: 110)

Both Svolaccia et al. (1995) and Lecarme (1999) suggest that a focused constituent appears preverbally as a result of movement to the specifier of a functional head that hosts the focus particle. So the examples above are analyzed as in (86):

(86) a. $[_{CP}$ Cali-$[_{C}$ baa] moos cunay]
Ali-FM banana ate
'Ali ate a banana.'
b. $[_{CP}$ Cali$[_{CP}$ moos-$[_{C}$ buu] cunay]]
'Ali ate a banana.'

If this is on the right track, then Somali is essentially analyzed like Hungarian by Brody (1995a) or Italian by Rizzi (1997). The focus moves to the specifier of a matching functional head. Moreover, the focus feature in Somali is overtly manifest in the form of a morphological marker.

Note, however, that the following data are interesting in this respect. Somali, just like Italian or Hungarian, allows for wide focal sentences. The question–answer pairs appear to look as follows (Svolaccia et al. 1995: 73–75). It seems that both O and VP focus are possible if the O is focus marked and fronted (87a–c). The subject, which is mentioned in the question, has to be a topic or a postverbal

constituent in the answer (87c). It is inappropriate to focus mark the V even in VP-focus (87d):

(87) Q_{VP}: Cali muxuu sameeyay?
Cali what-FM-he did
'What did Cali do?'
Q_O: Cali yuu dilay?
Cali whom-FM-he beat
'Who did Cali beat?'
a. Cali Maryan buu dilay.
Cali Maryan FM-he beat
b. Maryan buu dilay Cali.
Maryan FM-he beat Cali
c. *Cali baa Maryan dilay.
Cali FM Maryan beat
d. *Cali Maryan wuu dilay.
Cali Maryan FM-he beat
'Cali <u>beat Maryan</u>' or 'Cali beat <u>Maryan</u>.'

If the context question suggests IP-focus, the most appropriate answer is to put the marker *-baa* on the subject (88a). To focus mark the object is more marked (88b). It is inappropriate to put either the subject or the object either in prefocal or postverbal position (88c). These positions most probably indicate discourse-linked status, which is incompatible with the context question, which requires an all-focus utterance as the answer:

(88) Q_{IP}: Maxaad hacay?
What-FM happened
'What happened?'
a. Cali baa Maryan dilay.
Cali FM Maryan beat
b. (?)Maryan baa Cali dilay.
Maryan FM Cali beat
c. *Cali Maryan buu dilay.
Cali Maryan FM-he beat
d. *Maryan buu dilay Cali.
Maryan FM-he beat Cali
e. *Maryan Cali baa dilay.
Maryan Cali FM beat
f. *Cali baa dilay Maryan.
Cali FM beat Maryan
'<u>Cali beat Maryan</u>.'

The point of these examples with respect to the functional head status of *-baa* is that the moved element that sits in the specifier of the head bearing focus

morphology is not necessarily the focus of the utterance, albeit it is always part of the focus. This seriously undermines the idea that the trigger for the movement operation would be focus and that the head in question would be Focus head. If it were, then the moved constituent sitting in its specifier would have to receive a focal interpretation obligatorily.

3.5.4 Focus and weak crossover revisited

Recall from section 3.1 that one of the two basic pillars of the analyses that take focus constructions to be a case of syntactic movement, similar to *wh*-movement, is that focus displays weak crossover effects (Chomsky 1976).

The argument goes as follows. Backward coreference is ruled out if the full DP is focused, while allowed if not. Thus (53b), as opposed to (53a) (repeated here as (89a–b)) is ungrammatical:

(89) a. The man that she$_i$ met LIKED Mary$_i$.
b. *The man that she$_i$ met liked MARY$_i$.
LF: Mary$_i$ [the man that she$_i$ met liked t$_i$]

(90) *Who$_i$ does the man that she$_i$ met like t$_i$?

As the LF representation of (89b) indicates, Chomsky (1976) argued the focus is preposed at LF. Thus (89b) is similar to (54a) (repeated here as (90)), where the movement of the *wh*-element across a co-indexed pronoun is ruled out as a weak crossover violation. In a parallel fashion, in (89b), the fronting of the focal element at LF presents a weak crossover violation.

We have already noted that this argument is considerably weakened by the observation of Jackendoff (1972) that focus disregards syntactic islands. This is illustrated in (54b) (repeated here as (91)) for a complex NP island. If focusing involved LF movement, that would mean that focus movement (or maybe LF movement in general) is different from overt movement in that it does not observe islands – an undesirable outcome:

(91) Sam only saw a [$_{NP}$ man [$_{CP}$ who was wearing a RED hat]]

But there are additional arguments against a weak crossover analysis of the lack of backward anaphora with a focused constituent. Williams (1997) points out that a weak crossover account is too restrictive, as it incorrectly predicts that 'backward-and-down' anaphora cases like (92) are ungrammatical. This is because (92) would yield the LF indicated, which contains a weak crossover violation:

(92) Anyone who has written it$_i$ can turn his TERM PAPER$_i$ in to me.
LF: his TERM PAPER$_i$ [anyone who has written it$_i$ can turn t$_i$ in to me].
(Williams 1997: ex. 33a; diacritics added)

Furthermore, an alternative analysis of the relevant data is possible. It is possible to show that (89b) is ungrammatical for a reason that has nothing to do with the

status of the bound pronominal. Rather, what renders the utterance ungrammatical is that *Mary* is an ill-formed focus.

Rochemont (1986) argued for the generalization of c-construability, according to which any constituent is focus if and only if it is not c-construable from the earlier discourse. In other words, a constituent bears prosodic prominence if and only if it is not accessibly discourse-linked (Neeleman and Reinhart 1998). For this reason, utterances such as (93) are ungrammatical, as they contain a focus marked element, *John*, which has just been introduced to the discourse in the previous utterance in a salient way:

(93) John and Mary danced on the floor. *Then JOHN kissed Mary.

This could very well be the reason for the ungrammaticality of (89b) as well. Such examples pose a paradox for discourse. Either the pronoun is not licensed in the absence of an antecedent, or focus on *Mary* is ill-formed. Let us see why this is the case. In (89b) *Mary* bears prosodic prominence, indicating focus. By c-construability this means that it cannot be linked to an entity mentioned in previous discourse. At the same time, the utterance contains a pronoun *he*. Unless they are interpreted deictically, pronouns need an accessible entity in the discourse. If the previous discourse contains an accessible entity as the antecedent of the pronoun, which allows the use of the pronoun in (89b), then this same accessible discourse entity renders focus on *Mary* ill-formed, as it causes a c-construability violation.

If the preceding discourse does not contain an earlier mention of *Mary*, and thus focus on it is allowed by c-construability, then there is no discourse antecedent for the pronoun to rely on. There cannot be one by c-construability. (If there were an antecedent, *Mary* could not be focused, and we just assumed it can be.) Note, however, that it is not completely impossible to use a pronoun when an antecedent is not present in earlier discourse: for instance, in cases when the antecedent is in the same utterance as the pronoun. This is known as backward anaphora. It is even possible for such utterances to be discourse-initial. Some examples are given here from Carden (1982), reported in Reinhart (1981):

(94) a. Because they wanted to know more about the ocean's current, students in the science club at Mark Twain Junior High School of Coney Island gave ten bottles with return address card inside to crewmen of the NY city's sludge barges. (*New York Times*)
b. When she was five years old, a child of my acquaintance announced a theory that she was acquainted with rabbits. (*New York Times*)

In principle, this means that (89) could be a case of backward anaphora, where there is no antecedent available for the pronoun in the previous discourse; rather its antecedent is *Mary* in the same utterance. However, this possibility is ruled out by Reinhart's (1981: fn. 9) generalization, originally proposed by Kuno (1972a), which says that backward anaphora is restricted to cases where the

antecedent is the topic. This is indeed the case in the examples in (94).[17] In contrast, the antecedent is the focus in (89b). Since an element cannot be topic and focus at the same time, (89b) can be ruled out as a discourse violation without any mention of weak crossover.

As a final point, it can be shown that (89b) can be rendered grammatical in certain discourse contexts, indicating that it is not a syntactic (or semantic) but rather a discourse violation. According to c-construability, an entity cannot bear prosodic prominence if it is not a new entity in the discourse. However, there are exceptions to this generalization. Contrastively focused constituents may bear focal prominence even if they are not new:

(95) A: Sally and the woman John loves is leaving the country today.
B: I thought that the woman he loves has BETRAYED Sally.
A: No, the woman he_i loves betrayed $JOHN_i$. (Rochemont 1986)

In (95), *John* is contrastively focused. In fact, the second utterance of A is a correction of B's utterance. So *John*, even though it is not new to the discourse, still does not violate c-construability, as it is contrasted with *Sally* in B's utterance. As we see, coreference between *John* and *he* is allowed. If one pursued an analysis that renders (89b) ungrammatical as a weak crossover violation, one would have to assume that focus fronting does not affect constituents that are contrastively focused, only ones that are new to the discourse. This way, it would be possible to exclude cases like (89) while still permitting cases like (95). However, this assumption would be counter-intuitive in light of the semantics associated with Hungarian focus movement discussed in section 1.3.4. There it was shown that Hungarian focus movement is necessarily contrastive; however, it need not affect foci that are new to the discourse. So under this proposal Hungarian would come out just the opposite of English.

4 Focus and prosodic prominence

4.1 Accent to focus vs. focus to accent

It is a well known characteristic of focus, which has been alluded to previously but not stated explicitly, that at least in English, the focus of the utterance is always marked by some kind of prosodic prominence: main stress or pitch accent. This generalization is the Stress–Focus Correspondence Principle (see 96). This has been known since Chomsky (1971), Jackendoff (1972), and Selkirk (1984, 1986) (in the functionalist literature, Dezső 1974, Harlig and Bardovi-Harlig 1988):

(96) **Stress–Focus Correspondence Principle:**
The focus of an utterance always contains the main stress of the utterance.

Ladd (1996) divides approaches to focus into two groups on the basis of the perspective they take with respect to stress–focus correspondence. All of the

analyses discussed so far exemplify what he calls the 'accent-to-focus' view. In these approaches, focus is determined by the presence of a syntactic (or semantic) focus feature, rather than by the position of stress. The prosodic characteristic of focus is secondary: main stress is assigned to the constituent marked as focus in syntax. This view has its origins in Jackendoff's (1972) proposal, which argued for the presence of syntactic focus marking.

However, we have seen in section 3.5.4 that the reasoning behind the idea that focus movement is like other instances of movement in syntax, such as *wh*-movement, is questionable in languages like English. Rather, certain properties of focus can be explained by discourse principles, not syntactic ones. This opens up the way to question the idea that focus would be a syntactic construct in the first place. In other words, if the arguments that focus movement would be similar to *wh*-movement are weakened, one might wonder why focus movement would be a case of feature-driven movement, even in languages where it happens overtly. In fact, one can go one step further and ask why a syntactic [+Focus]-feature would exist in the first place. The analyses reviewed in section 4.3 take these questions as their starting point. They belong to what Ladd (1996) called the 'focus-to-accent' view. In these proposals, it is assumed that there is an independent prosodic operation, the nuclear stress rule, that assigns main stress to the utterance. The focus is determined on the basis of the prosodic properties of the utterance: a constituent bearing main stress is a possible focus of the utterance. This view goes back to Chomsky's (1971) work and was later revived by Cinque (1993) and others.

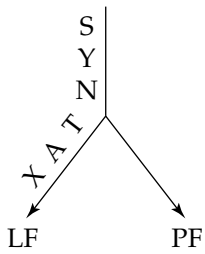
Some of these proposals are described in section 4.3. But before we come to them, we first have to evaluate the reasons for which the previous analyses all assumed the existence of a syntactic [+Focus]-feature. It will become clear from the discussion in section 4.2 that the two perspectives with respect to (96) are fundamentally different in their conception of the architecture of the grammar. The T-model, where phonological information is stripped off before the derivation reaches the conceptual interface, can only be maintained in the accent-to-focus view. This is what prompted all the analyses described above to assume the existence of some form of syntactic focus marking. However, the focus-to-accent view requires the availability of prosodic information at the interface. If focus, a semantic (or pragmatic) notion, is determined by the position of main stress, then it is evident that such prosodic information has to be available at the level of representation where focus is relevant, so the derivation cannot branch into a PF and an LF branch. In contrast, as argued in section 4.4, the accent-to-focus view has a conceptual advantage of its own. It maintains Chomsky's (1995c) Inclusiveness Principle, which is violated by all focus-to-accent views assuming the existence of a syntactic [+Focus]-feature.

4.2 *The accent-to-focus view and the T-model*

In the GB/Minimalist framework, phonological information, which is ultimately relevant for the interface of the grammar in its wide sense with sensori-motor

apparatus (i.e., the articulatory and auditory devices), is separated from syntactic (or syntactico-semantic) information, which ultimately feeds the interface of the grammar with the conceptual-intentional system. This is known as the T-model (see (97)):

(97) **T-model:**
Numeration/Lexicon



One of the motivations behind the T-model is that phonology is a module whose role is merely to interpret the output of the (overt) syntactic component for the sensori-motor apparatus.[18] Consider the Stress–Focus Correspondence Principle in (96). It is clear that it cannot be stated in the T-model at any level of representation (i.e., either at PF or at LF), as it refers to prosodic information and the LF notion focus at the same time.[19]

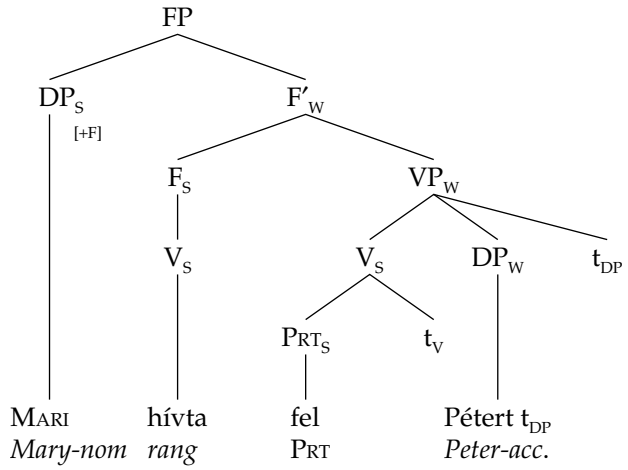
Let us see whether the feature-driven account can be extended to account for (96) without violating the assumptions of the T-model. Although the standard account remained agnostic on the issue of focus–stress correspondence, it can be easily extended to account for the fact that in both English and Hungarian the focused constituent receives main stress. Let us use a tree-based metrical system to indicate stress placement (following Liberman and Prince 1977; Liberman 1979). In this notation, Strong and Weak (S/W) labels are assigned to the binary branching structure, and main stress is on the node that bears S and that is only dominated by nodes bearing S. In this system, main stress falls on the element that bears an S label and that is only dominated by nodes that bear S labels. To derive the fact that main stress falls on the focused element, all we have to assume is the following (Jackendoff 1972: 241; cf. also Selkirk 1996 and Kenesei 1998):

(98) **[+F] interpretation at PF:**
Assign S to the node marked [+F] and to any dominating node.

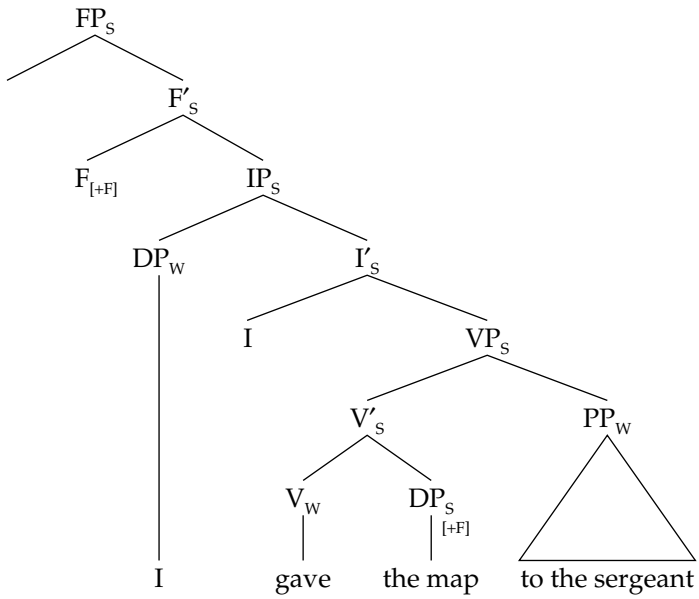
As (99) and (100) illustrate, the feature-based analysis gives the right word order and the right stress pattern in both English and Hungarian. In particular, the [+F]-marked element, *Mari* 'Mary', in (99) is marked S together with the only dominating node, the root node. This ensures that *Mari* 'Mary' receives main stress in (99). Similarly, the focused element bearing [+F] in (100), *the map*, is

assigned an S label by (98), together with all the dominating nodes, such as the W, VP, F, IP, F, and FP nodes. As a result the focused element *the map* will receive main stress:[20]

(99)



(100)



Thus, one may conclude that the feature-driven approach to focus is able to account for the basic syntactic and prosodic facts, while maintaining the hypothesis of no direct PF–LF communication implicit in the T-model. Nevertheless, this approach violates Chomsky's (1995c) Inclusiveness Principle, in the sense that the lexical item where [+F] is introduced into the derivation does not have any

specific lexical property corresponding to the feature [+F]. The terminal node is not itself focused; rather it is part of the focus. So [+F] cannot be taken to be an interpretable feature on the terminal node where it is introduced into the derivation. (See section 4.4.3 for more discussion of this issue.)

4.3 The focus-to-accent view

Ever since Jackendoff (1972), the accent-to-focus view was predominant in the literature until recently. This was due to a variety of factors, one of which is the conceptual issue spelt out above. But there were empirical arguments in favor of this view as well. First, as we have seen in the discussion in section 3, the assumption of a syntactic focus feature is a straightforward way to provide a uniform analysis for languages with focus movement and those without it. But recall that the idea so fundamental to this position, namely the discussion of the alleged weak crossover violations, was challenged in section 3.5.4, where it was shown that an alternative explanation of these facts exists that analyzes these cases as discourse violations. Nevertheless, the presence of syntactic focus movement has to be accommodated in any analysis of focus. The assumption of a syntactic focus feature is useful in this regard, given Chomsky's (1995c) proposal that movement is feature-driven. This issue will be addressed in section 4.3.2. In addition, as Reinhart (1995, forthcoming) notes, the focus-to-accent view crucially relies on the distinction between neutral stress and focal stress, which was challenged both empirically and conceptually during the 1980 (see Reinhart forthcoming for a review). However, Cinque (1993) reopened the issue and argued forcefully that the distinction exists and thus a focus-to-accent view might be tenable. To illustrate how such a proposal would work, let us see Reinhart's (1995, forthcoming) proposal in more detail.

4.3.1 Reinhart's (1995, forthcoming) focus-to-accent view

Reinhart (1995, forthcoming) and Neeleman and Reinhart (1998) assume that it is the prosodic make-up of the utterance, rather than its syntactic characteristics, that encodes focus in the grammar. In particular, in Reinhart's theory, focus is not encoded by a syntactic feature; rather the prosody of the utterance determines the possible foci in accordance with the stress-focus correspondence generalization, following Chomsky (1971). The Stress–Focus Correspondence Principle (96) is repeated here for convenience:[21]

(101) **Stress–Focus Correspondence Principle:**
The focus of an utterance always contains the main stress of the utterance.

In particular, Reinhart (1995, forthcoming) argues that the focus of an utterance is determined by its intonation. A particular utterance may have more than one focus interpretation. They define the set of possible foci for a given utterance as follows:

(102) The focus set of IP consists of the constituents containing the main stress of IP. (Reinhart 1995, forthcoming)

Thus the utterance in (103), where main stress falls on the object, has the focus set given in (104). Accordingly, it is felicitous in the context of the questions in (103), indicating IP, VP, and DP-DO focus, respectively:

(103) a. A: What's this noise?
B: My neighbour is building a DESK.
b. A: What's your neighbour doing?
B: My neighbour is building a DESK.
c. A: What's your neighbour building?
B: My neighbour is building a DESK.
(Neeleman and Reinhart 1998: 333, ex. 53)

(104) Focus set: {IP, VP, DP_{DO}}

In Reinhart's (1995, forthcoming) approach, the output of the grammar is an ambiguous utterance with more than one possible focus interpretation. Depending on the discourse conditions, one interpretation is chosen as the actual focus. However, discourse may only select a member of the focus set, and may not select a constituent outside the focus set. Thus the answer in (103a) is inappropriate in the context of the question in (105), as that context requires DP-SU focus, which is not in the focus set of the utterance. It is equally inappropriate in the context of (106), as that requires focus on the V, which is also not in the focus set of the utterance:

(105) A: Who's building a desk?
B: #My neighbour is building a DESK.

(106) A: Has your neighbour bought a desk already?
B: #No, my neighbour is building a DESK.
(Neeleman and Reinhart 1998: 334, ex. 54)

Reinhart (1995, forthcoming) follows Cinque (1993) in arguing that every language has a neutral, unmarked stress pattern, assigned by the nuclear stress rule (NSR). In English, the result of the NSR is main stress on the rightmost constituent, i.e., on the object in a transitive construction. If the focus set defined by the NSR does not contain the intended focus of the utterance, a special operation may apply to place stress on the constituent in question:

(107) Relocate main stress. (Neeleman and Reinhart 1998: 333, ex. 55)

By (107), in the context of (108a), a marked stress (not the one assigned by NSR) is assigned to the DP-SU, and in (108b) to the V. As a result, the focus set of the

utterance, defined by the main stress, contains the relevant constituents, and the utterances are appropriate in their given contexts. In fact, in their contexts, the utterances do not seem marked; they are perfectly natural:

(108) a. A: Who's building a desk?
B: My NEIGHBOUR is building a desk.
b. A: Has your neighbour bought a desk already?
B: No, my neighbour is BUILDING a desk.
(Neeleman and Reinhart 1998: 334, ex. 56)

Reinhart (1995, forthcoming) argues that there is a very precise sense in which the utterances in (108) can be viewed as marked. They both involve an optional operation: stress shift. Stress shift is an optional operation in the sense that performing it is not necessary to save the derivation from crashing at the interfaces. Stress shift does not apply to turn an otherwise ill-formed expression into a well-formed one, as, for instance, movement of the object to [Spec, TP] in English passives does. Rather, the utterance would be well-formed even if stress shift did not apply. Nevertheless, such optional operations are not totally unrestricted. Reinhart argues that they apply if and only if they have an effect on the interpretation. In other words, such operations can be viewed as marked in the sense that they lead to ungrammaticality unless they derive an interpretation that was otherwise unavailable. This intuition is formalized in the following definition:

(109) **Reference set computation at the interface:**
Take fully derived (syntactically and prosodically) structures D_i and their interpretations I_i as ordered pairs. $<D_1, I_1>$ is ruled out at the interface if and only if there exists $<D_2, I_1>$, and D_2 involves fewer operations (syntactic or prosodic) than D_1.
(cf. Reinhart 1995, forthcoming: 48, following Fox 1995b)

To illustrate how interface economy operates, compare the exchange in (108a) with the infelicitous exchange in (110):

(110) A: What's this noise?
B: #My NEIGHBOR is building a desk.

The same utterance is appropriate as an answer to a question that requires subject focus (cf. 108a), but it is inappropriate as an answer to an all-focus (i.e., IP-focus) question (cf. 110). The stress-shifting operation that places stress on the subject is legitimate under a reading that puts focus on the subject, as subject focus was not available unless stress strengthening applied to the subject. The same operation is, however, illegitimate under a reading such as the all-focus reading, because there exists an expression – the neutrally stressed utterance (103a) – where the optional operation did not apply and where the same all-focus reading is available. In this way, Reinhart (1995, forthcoming) accounts for the

well-known generalization that wide focus readings (i.e., focus on a constituent larger than the stress-bearing element) are blocked from certain positions (see Selkirk 1984, 1986, and many others).

To summarize, Reinhart (1995, forthcoming) argues that the set of possible foci of an utterance is determined by the main stress of the utterance. If focus is required on an element that is not in the focus set of the unmarked utterance, where stress is assigned by the NSR, then an optional stress-strengthening operation may assign stress to the element, to make it available in the focus set of the marked utterance. Reinhart is an advocate of the focus-to-accent view. She argues that it is the set of possible foci, rather than the actual focus of the utterance, that is determined by the grammatical representation of the sentence, where grammatical representation is understood in the wider sense of including the prosodic representation as well as syntactic structure.

4.3.2 Focus movement in the focus-to-accent view

Cinque's (1993) and Reinhart's (1995, forthcoming) revival of the focus-to-accent view has become influential for analyses of focus movement. The idea that the focus of an utterance is determined by the prosodic make-up of the utterance led to the formulation of analyses that take focus movement to be essentially prosodically driven.[22]

4.3.2.1 Zubizarreta (1998): *p*-movement

Zubizarreta's (1998) analysis of certain movement operations in Spanish, which she termed *p*-movement, was one of the first in the literature to be proposed along these lines. She observed that alongside the VSO and SVO orders, VOS order is also grammatical in Spanish. In this order the subject is not right-dislocated. An example is given in (111):

(111) a. Quién te regaló la bottella de vino?
who you-dat gave the bottle of wine
'Who gave you the bottle of wine?'
b. Me regaló la botella de vino <u>MARIA</u>.
me-dat gave the bottle of wine Maria
'<u>Maria</u> gave me the bottle of wine.'

As the question in (111a) indicates, the VOS order in Spanish is felicitous as an answer to a question asking for the identity of the subject. Given that (111b) need not be interpreted contrastively, but rather is felicitous in a question–answer pair, Zubizarreta hypothesizes that the stress on the subject is neutral; in other words, it is the NSR rather than her proposed additional focal stress rule that assigns stress to the subject in VOS structures.

As it is a characteristic property of nuclear stress that it allows for focus projection, it is expected that wide focal interpretations are available in VOS structures, just as in VSO and SVO orders. This is not the case. Zubizarreta (1998: 127) offers the following explanation. The VOS order is not a basic order; rather it is

derived from VSO (or SVO) order by preposing the object. The movement operation is a last-resort operation, triggered only if the subject needs to be focused. It is not feature-driven movement, but rather prosodically motivated movement. Hence the term *p*-movement.

An important argument in favor of this conclusion comes from the fact that the VOS order is only allowed in contexts that indicate that the subject is focused. No other constituent can be contrastively focused in the VOS order by the focal stress rule. (This possibility is not excluded in SVO and VSO orders.) This is illustrated in (112):

(112) *Me regaló la botella de VINO María.
me-dat gave the bottle of wine Maria
'Maria gave me the bottle of wine.'

This can be understood if the fronting of the object was motivated by allowing the subject to be positioned where nuclear stress falls. If the focal stress rule applied and placed focal stress on another constituent, the fronting of the object would have been a superfluous operation, thus ruled out by last resort.

Zubizarreta shows that *p*-movement is a strictly local process, and she concludes that the empirical arguments that are available are insufficient to determine whether it applies prior to Spell Out or after Spell Out. She assumes that it applies in the final stretch of the overt syntactic derivation just before the derivation branches to PF and LF. (Her analysis maintains the T-model, although with significant modifications, including the introduction of a separate level of representation at the point of branching. See Zubizarreta 1998 for discussion.)

4.3.2.2 Stress-driven focus movement

A similar analysis of Hungarian focus movement is put forward in Szendrői (2001, 2003). This analysis takes Reinhart's (1995) proposal as its starting point. It also relies on the fact that main stress in Hungarian is assigned to the leftmost constituent of the clause, rather than the rightmost constituent as it is in English or Italian.

Szendrői argues that Brody's (1990b, 1995a) analysis of Hungarian focus is correct as far as the syntactic configuration is concerned: the focus moves to a specifier of a functional head and the verb adjoins to the head leaving its particle behind (see section 3.4.1). However, the motivation for the movement is not that the functional head in question has a [+Focus]-feature. Rather, the focused element moves in order to be in the position where main stress is assigned. As a result, it can be interpreted as the focus by the Reinhartian assumption that focus is identified as the constituent that contains main stress. Thus Hungarian focus movement is not feature-driven; rather it targets the position where main stress is assigned.

There are at least two important characteristics of Hungarian focus movement that follow from this hypothesis. First, focus movement in Hungarian is unique. In other words, utterances with multiple foci involve only a single instance of focus movement. The other foci remain in situ. This is illustrated in (113):

(113) Q: Mit adtál oda kinek?
what-acc gave-you prt who-dat
'What did you give to whom?'
A: A könyvet adtam oda Marinak, és a tollat adtam oda Péternek.
the book-acc gave-I prt Mary-dat and the pen-acc gave-I prt Peter-dat
A':*A könyvet adtam Marinak oda, és a tollat adtam Péternek oda.
'I gave the book to Mary and the pen to Peter.'

This follows from the fact that the NSR assigns a single main stress, so there is a single position in every clause where main stress falls. If focus movement targets this position, only one focused constituent can be moved. The remaining foci acquire stress by a prosodic operation that assigns extra stresses.

Another characteristic of Hungarian focus that is explained by the proposal that Hungarian focus movement is driven by the need for the focus constituent to get stressed is that verb focusing in Hungarian does not involve the separation of the verbal particle from the verb. Given that verb movement strands the particle, the fact that the prt-V order is undisturbed in cases of verb focus suggests that the verbal complex is in situ. So verb focusing appears not to involve movement:

(114) a. Elvitted a gyereket az állatkertbe?
prt-took-you the child-acc the zoo-loc
'Did you take the child to the zoo?'
b. Elvittem a gyereket az állatkertbe.
*Vittem el a gyereket az állatkertbe.
'I took the child to the zoo.'

This is explained in the stress-driven analysis of focus movement, as main stress falls on the verbal complex by the NSR even if it is in situ. Given that the verbal complex occupies a left-peripheral position within the VP, it receives stress by the NSR and thus may acquire focus interpretation in situ. As there is no reason for it to move, it stays in situ.

So Szendrői (2001, 2003) argues that focus movement in Hungarian is prosodically motivated. It targets a left-peripheral position because the main stress rule in Hungarian is leftward oriented. In contrast, main stress in Italian is rightward oriented, as it is in English. But unlike in English, the prosodic operation of stress shift is not available in Italian. Rather, Italian displays focus movement, just as Hungarian does. However, in contrast to Hungarian focus movement, Italian focus movement targets a right-peripheral position, in accordance with the directionality of the stress rule in the language. This is the right-peripheral focus position that was mentioned in section 3.4.3. (See Lambrecht 1994; Szendrői 2001, 2002; for further discussion on this point.)

4.3.2.3 Hungarian focus movement revisited (Horvath 2000)

Szendrői's (2001, 2003) work is not the only account in the literature concerning Hungarian focus movement and prosody. Horvath (2000) provides a reanalysis

of her earlier work on Hungarian focus movement in light of Reinhart's (1995) proposal that stress determines the focus of an utterance. Horvath notes that in accordance with Reinhart's hypothesis, the fronted focused constituent in Hungarian bears main stress. She accepts Reinhart's view that it is this prosodic property that determines the focal interpretation of the constituent, rather than its position. She proposes that the movement of focused constituents in Hungarian is thus not actually driven by the fact that they are interpreted as foci. Rather, it is another distinctive characteristic of Hungarian focus that motivates the movement to the preverbal position: exhaustive identification.

Recall from section 1.3.4 that a characteristic semantic property of Hungarian focus movement is that it provides an exhaustive listing. Thus preverbal focus in Hungarian "exhaustively identifies the proper subset of a contextually relevant set of entities as the one for which the predicate holds" (Horvath 2000: 201). This is illustrated by the contrast in (115). Horvath shows that (115c), which indicates an answer whose focus is not exhaustive, cannot involve focus movement to the preverbal position:

(115) Q: Kit hívtak meg?
- a. A: Jánost hívták meg.
  John-acc invited prt
  'They invited John (and no one else).'
- b. A':Meghívták *(például/többek között) Jánost.
  invited-they for-example/others among John-acc
  'They invited John, for example/among others'
- c. A":*Jánost például hívták meg.
  John-acc for-example invited prt
  'They invited John, for example/among others'

Horvath (2000) concludes that the preverbal position in Hungarian is a grammaticalized position for exhaustive identification. Thus the movement to the preverbal position is in no sense a case of focus movement; rather it is a case of movement for exhaustive identification.

4.4 Focus and prosodic prominence: discussion

4.4.1 Ways of encoding focus in the grammar

The most basic characteristic difference between the feature-based approach to focus and the prosodically oriented approaches is that the former encode focus in the syntactic representation, while the latter do so in the prosodic representation.

Recall that in section 1.2.2 it was argued that GB and Minimalist approaches to focus are the strictest, in the sense that they advocate encoding focus in the grammar directly and unambiguously. Let us note that in this light, another characteristic difference between the feature-driven approach and the prosodically oriented is that the former determines the unique and unambiguous focus

of the utterance, while the latter define the set of possible foci. The actual focus is selected from this set by the discourse context. Thus, in the focus-to-accent view, there is no one-to-one correspondence between an expression (comprising a syntactic representation and a prosodic representation) and its focus interpretation. Rather there is a one-to-many correspondence; each expression is associated with a set of potential foci.

A final general point with respect to the accent-to-focus view is that stating the Stress–Focus Correspondence Principle at the interface means that some kind of marking of focus that is legible from the prosodic representation should be universal. Being at the interface between the grammar and the conceptual system, it is highly unlikely that there would be a sufficient system of overt cues that would enable the acquisition of this principle. Thus, the stress-based theory makes a strong and easily falsifiable prediction: namely, there is no language where focus is marked *only* by a specific syntactic position without an accompanying prosodic marking (stress or tone) or a morpheme. In contrast, the absence of such languages would be unexpected under the accent-to-focus view.

4.4.2 Adjacency, edge-sensitivity, and directionality

Recall that feature-based approaches to focus movement fall in two classes: those that argue that focus is essentially parallel to case in the sense that there is an adjacency requirement between focus and verb (section 2); and those that argue that focus movement is similar to *wh*-movement (section 3). Let us now examine the stress-based approaches to focus movement in comparison to these approaches.

In a stress-driven approach to focus movement, the quantificational characteristics of focus movement are hard to capture. To the extent that focus movement is really movement for stress, it is unclear why it should be in complementary distribution with *wh*-movement, license parasitic gaps, or instantiate any other characteristics that are normally associated with operator-variable dependencies. Under the view that focus movement is in fact movement for exhaustive interpretation, the quantificational properties of the focus construction are easier to understand, as in this case some kind of operator is involved.[23]

A potential advantage of the stress-based view is that it offers a new perspective on the syntax of focus movement in the following sense. Cross-linguistically, focus movement seems to instantiate characteristics that are typical prosodic properties, such as adjacency, edge-sensitivity, and directionality.

Adjacency requirements are attested elsewhere in the grammar. Many such areas are typically prosodic in nature. The most straightforward case is cliticization. Clitics, which tend to instantiate insufficient prosodic weight, have to appear either immediately to the left or immediately to the right of the verb (or the finite auxiliary or the complementizer) in many languages.[24]

Edge-sensitivity is also often attested in prosody. For instance, extra-metricality is a typical edge phenomenon. For example, in syllables the nucleus is the most sonorous. Sonority increases from the start of the onset toward the nucleus, and decreases after the nucleus toward the end of coda cluster. In English, at the edges of the phonological word, an additional coronal [s] may be added to the

beginning of an onset cluster even if it is followed by a less sonorous consonant, as in *s[tri*, or to the end of a coda cluster even if it is more sonorous than the final consonant of the coda cluster, as in *ark]s*.

Headedness is also edge-sensitive. For instance, in foot structure, iambs are right-headed, while trochees are left-headed. There are feet that have three moras, but these have either left-aligned heads or right-aligned ones; there is no foot structure involving three moras where the middle one is heavy and the ones on the edges are light. As Van der Hulst (1999) argued, stress systems in general are often edge-sensitive.

Finally, left and right directionality is also highly relevant in stress systems, as well as to cliticization (as in enclitics and proclitics). Although left and right asymmetries are often invoked in syntax as well, hierarchical notions such as c-command are the propotypical syntactic cases.

To sum up, the potential advantage of a prosodically oriented perspective on focus movement is that it easily accommmodates edge-sensitivity, adjacency, and left–right directionality, which are all widely attested to be relevant properties of focus constructions. The potential weakness of this approach is that it does not easily accommodate quantificational properties of focus constructions that are characteristic of operator-variable dependencies, unless something extra, such as an operator, is assumed.

4.4.3 The Inclusiveness Principle (Chomsky 1995c)

Another difference between the accent-to-focus view and the focus-to-accent view is that focus is encoded syntactically in the former, but not in the latter. As was shown at the beginning of this section, the latter view gives up the hypothesis of no direct PF–LF communication, or in other words the T-model. This appears to be a shortcoming, although see Jackendoff (1996, 2002b) for arguments to the contrary.

Whatever the nature of the architecture, the accent-to-focus view is not without conceptual difficulties of its own: this approach violates Chomsky's Inclusiveness Principle, which is maintained in the focus-to-accent view. Let us see the argumentation in detail.

As Zubizarreta (1998) observes, the notion of a [+Focus]-feature is conceptually problematic. In fact, Chomsky (1995c: 228) states that:

> a 'perfect language' should meet the condition of inclusiveness: any structure formed by the computation . . . is constituted of elements already present in the lexical items selected for N [the numeration]; no new objects are added in the course of the computation apart from rearrangements of lexical properties . . . Let us assume that this condition holds (virtually) of the computation from N to LF ($N \rightarrow \lambda$).

In the original formulation of the feature-based approach adopted here (Jackendoff 1972), [+F] violates the Inclusiveness condition. In order to see this, recall the original proposal of Jackendoff (11), repeated here for convenience:

(116) **[+F] marking (first version):**
Mark any constituent as [+F].

This proposal violates Inclusiveness in a very precise sense. According to Inclusiveness, in a Minimalist grammar there are two ways a node may acquire some property, i.e., a feature. A terminal node may be assigned a feature from the lexicon. A non-terminal node has to inherit its features from its daughters, which created the non-terminal node via merger. This is formulated as follows (cf. also Chomsky 1995c: 228):

(117) **Inclusiveness:**
a. The properties of a non-terminal node are fully recoverable from its daughters.
b. The properties of terminal nodes are recoverable from the mapping principles [between the lexical-conceptual system and the grammar].
(modified from Neeleman and Van de Koot 2002: 529)

In effect, Inclusiveness ensures that no information may enter the derivation via a non-terminal node, and thus that all the information present in the tree ultimately comes from a terminal node.

Given the first part of the definition of Inclusiveness (117a), it is not possible for a non-terminal node to possess a [+F]-feature if neither of its daughters has that feature. As a first step toward a solution, one may assign the [+F]-feature to terminal nodes, allow for its percolation to non-terminal nodes (cf. Selkirk 1984), and reformulate the LF-Interpretation Principle accordingly. The reformulated principles of [+F]-marking, percolation, and interpretation are given below:

(118) **[+F] marking (second and final version):**
Assign [+F] to a lexical item.

(119) **[+F] percolation:**
Allow the percolation of [+F] from a node to a dominating node.

(120) **[+F] interpretation at LF:**
Interpret the largest [+F]-marked constituent as focus.

Note that this state of affairs violates Inclusiveness in the sense that it still contravenes (117b), the second clause of the definition – thus only in a weaker sense. (An approach based on (116) violates inclusiveness in a stronger sense, as it violates both clauses of (117).) The fact that [+F] satisfies the first clause, (117a), means that it behaves like other syntactic features in the grammar. This is important, as a syntactic encoding of a pragmatic notion would be rather unwelcome if it involved characteristics that are otherwise not normally present in syntax. Nevertheless, [+F] is clearly not a lexical feature. As is clearly stated by Jackendoff (1972), the notion of focus itself is not a property of a constituent, but rather a relation. It encodes the information status of a constituent relative to the rest of

the utterance. If a constituent is focused, then the rest of the utterance is backgrounded (or presupposed). For this reason, focus may never be a property of a single node, let alone a lexical property of that node. So in this sense, an approach that encodes focus in the syntactic computation, such as the feature-driven approaches, will always violate Inclusiveness. (See Szendrői 2004 and Neeleman and Szendrői 2004 for further discussion on this issue.)

5 Conclusion

This chapter was concerned with focus movement. A language has a 'focus construction' if a focused constituent (at least optionally) appears in a non-canonical syntactic position. Jackendoff's (1972) invention, the [+Focus]-feature, and Chomksy's (1976) observation that focus gives rise to weak crossover effects paved the way for an analysis of focus constructions as instances of focus movement. The analyses were presented in three groups, which also by and large correspond to their order of appearance.

The first group of analyses, which includes, for instance, Horvath (1986), regards the often-attested adjacency requirement between the focus and the V (or other functional head, like I or C) as the crucial characteristic of focus constructions. Advocates of this view argue that focus is in important respects similar to case. One of the main advantages of this view is that it is able to accommodate both preverbal and postverbal focus positions.

For the second group, which includes, for instance, Rizzi (1997), the crucial factor is that in focus constructions the focal element is often clause-initial and in complementary distribution with a *wh*-element. Thus they establish a parallel between focus and *wh* in the sense that they argue that focus movement is like *wh*-movement. One immediate advantage of such a view is that it easily accounts for the quantificational properties of focus constructions.

A third, newly emerging set of analyses argues that the characteristic property shared between focus in languages like English and languages like Hungarian is that focus bears main accent, in irrespective of the presence or absence of syntactic focus movement. These analyses therefore emphasize the prosodic characteristics of focus constructions. The focus-to-accent view is incompatible with the standard T-model as the architecture of the grammar, while it maintains Chomsky's (1995c) Inclusiveness condition.

NOTES

1 Infelicity is marked by #. Underlining indicates focus; capitals show the position of main stress.
2 See section 4 for approaches that question the existence of a focus feature.
3 Horvath claims that (23b) is acceptable as an answer to echo questions or as correction, but the author disagrees with this judgment. According to the author's judgments (23b) is marginal even as a correction or as echoic.

Consequently, the echoic patterns illustrated in (15) and (18) for English clefts and Heavy NP Shift respectively cannot be constructed for Hungarian preverbal focus, which shows that preverbal focus in Hungarian is a focus construction according to the definition in (19). This is shown in (i):

(i) A: János a PÉNZESZACSKÓT adta oda Péternek.
John the money-satchel-acc gave prt Peter-dat
'John gave to Peter the money satchel.'
B: *Nem, János a pénzeszacskót adta oda MARINAK.
No, John the money-sacthel-acc gave prt Mary-dat
'No, John gave the money satchel to Mary.'
B': Nem, a pénzeszacskót, János MARINAK adta oda.
No, the money-satchel-acc John Mary-dat gave prt
'No, John gave the money satchel to Mary.'

4 Gervain (2002) showed that speakers who fall into the so-called 'resumption dialect' accept such island violations.

5 Focus movement in Hungarian is not sensitive to subject islands either. Kiss (1987) argues that this is the case because clausal subjects are in a postverbal position, and thus not on a left branch like English clausal subjects:

(i) Marinak$_i$ volt kétséges hogy át adják-e a díjat t_i.
Mary-dat was doubtful that prt give-they-q the award-acc
'It was doubtful whether they would give the award to Mary.'

6 Another problematic issue is raised by languages such as Italian, where more than one structural position can be identified as focus positions. A detailed discussion of this problem is given in section 3.4.3, where Italian focus is discussed.

7 See also Lecarme (1999) for a similar claim in Somali.

8 For a more detailed description of this type of analysis of focus movement, see section 3.3 below.

9 Note that to obtain the existential presupposition at LF, the *wh*-element translates into a variable, while the focal element is replaced by one. Thus, semantic considerations establish a parallel between the non-focal part of an utterance and the *wh*-question. There is no such parallel established between the semantics of a focal element and the *wh*-element itself. So strictly speaking, there is no semantic argument for the parallel treatment of focus and *wh*, only for a parallel treatment of the non-focal part of an utterance with focus and a *wh*-question.

10 Note, however, that as Lipták (2001) convincingly argues, even in languages like Hungarian, a closer inspection of the parallelism reveals many problems with a fully unified treatment of *wh* and focus.

11 Since the appearance of the *Wh*-criterion a whole body of works has been devoted to the analysis of multiple *wh*-questions. It is no longer standardly assumed that multiple *wh*-questions would involve LF movement. See Reinhart (1998), Boškovič (2002), and chapter 44 for alternative proposals and an overview of the relevant literature.

12 Uriagereka (1995b) questions the validity of Ortiz de Urbina's V2-type analysis, mainly on the basis that the affixal Comp attaches to Infl from the right, thus there is no evidence for a leftward C head in the language. Ortiz de Urbina (1999) provides

further evidence for the presence of a functional head in the C-domain that is projected on the left, rather than the right. He suggests that the split-CP hypothesis of Rizzi (1997) might be sufficient to solve the puzzle. There is a Focus head on the left and an additional Force head on the right. It is the latter that contains the affixal complementizer morphology in embedded clauses.

13 But see Kayne (1998) for an analysis that takes focus movement in English to be overt as well.

14 It is precisely this entity, the focus of the presupposition, that Williams (1997) identifies as topic.

15 The inappropriateness of (75a) will be dealt with below.

16 Lecarme (1999) also proposes that the [Spec, CP] position is in fact a case position in this language.

17 As Reinhart (1981) points out, these cases also illustrate that topics can introduce new entities to the discourse.

18 See, for instance, Miller et al. (1997) or Vogel and Kenesei (1990) for support.

19 As we will shortly see, an approach such as Reinhart's has to give up the hypothesis of no direct PF–LF communication (cf. 97). At the same time, it maintains Inclusiveness, as focus in this theory is not encoded in the syntactic computation where Inclusiveness is supposed to hold.

20 Note that this brief sketch glosses over the important issue of the existence of an independent nuclear stress rule. Two approaches are possible. First, the [+F] interpretation principle at PF, (98), only applies if an element with 'marked' focus is present, while in the neutral cases, a nuclear stress rule assigns an S label to the most deeply embedded (or rightmost) element and to all its dominating nodes, ensuring that unmarked stress falls on this element. This was Jackendoff's original proposal, also taken over by Zubizarreta (1998).

Alternatively, one may assume that main stress is always defined by [+F], but [+F] is placed on the most embedded or rightmost element in the unmarked cases. Apart from empirical considerations, the choice between these two approaches raises conceptual issues, which are discussed in more detail in Szendrői (2001) and Neeleman and Szendrői (2004).

21 Other proposals in the literature that take a focus-to-accent perspective include Williams (1997) and Schwarzschild (1999).

22 Other similar proposals include: Costa (1998) on Portuguese; Büring and Gutiérrez-Bravo (2000) on German and Spanish; Arregi (2001) and Elordieta (2001) on Basque.

23 Weak crossover violations are similarly unexpected, but recall the argumentation put forward in section 3.5.4 against the relevance of weak crossover for the syntax of focus.

24 See Neeleman and Weerman (1999) for a prosodic approach to case adjacency.

  5.2 The interpretation of free relatives
  5.3 Transparent free relatives
6 Matching and the syntactic representation of free relatives
7 Conclusion

1 Introduction

A relative clause is a clause that modifies a phrasal constituent, generally a noun phrase.[1] We call the noun phrase that is so modified the head of the relative clause. There are two main positions in which the head can be found with respect to the modifying clause: internal and external. In internally headed relatives, the head NP is inside the relative clause in the position it is expected to have according to the laws governing the syntactic behavior of elements within that clause. This is so despite the fact that the same NP must also satisfy the needs of the matrix clause. English and, more generally, Indo-European languages do not

have any internally headed relatives (but see section 5.3 for a qualification of this statement). Japanese, however, does, as is shown in the following example from Grosu (1994):[2]

(1) [John-ga **ronbun-o** kaita-no]-ga Linguistic Inquiry-ni notta.
John-nom article-acc wrote-NM-nom Linguistic Inquiry-loc appeared
'The article that John wrote appeared in Linguistic Inquiry.'

In (1) the NP *ronbun-o* 'the article' is in every respect the object of the verb *kaita* 'write' in the embedded clause. But in addition, it functions as the subject of *notta* 'appear' in the matrix clause. In this respect, internally headed relative clauses are in sharp contrast with the externally headed relative clauses which are much more familiar from the Indo-European languages. The typical grammatical way of forming relative clauses in English is (2):

(2) I returned *the book* [(that) you finished reading [e] to your children] to the library.

In (2), the head is in its matrix position, while the corresponding position inside the relative clause is empty, indicated by [e] here. There is a sense, then, in which the head has to satisfy a dual set of requirements: those of the relative clause and those of the matrix clause. How does the grammar solve this problem? In an example like (2), the answer is not immediately obvious, since all we have is a complementizer (*that*) at the beginning of the clause and a missing element inside it. But there are alternative ways of expressing the external relative that reveal what is going on:

(3) I returned the book$_i$ [which$_i$ you finished reading [e]$_i$ to your children] to the library.

The relative pronoun *which* is the element that originates in the embedded object position.[3] The relative pronoun is moved from that position by the standard case of A'-movement, generally referred to as *wh*-movement, into the initial position of the relative clause, next to the external head. Relative clauses without an overt relative pronoun such as (2) are derived in very much the same way as (3), the only difference being that the relative pronoun is either deleted or phonologically null. The question which arises immediately is what the relation is between the head and the (overt or covert) relative pronoun. Clearly, the relation is not arbitrary. If we say that the relative element is a pronoun, what we mean is that it is a kind of place holder for, a link to, the head noun phrase. To put it differently, we say that the head is the antecedent of the relative pronoun. One of the ways in which this relation, indicated by the co-indexation of the head with the relative pronoun in (3), manifests itself is the fact that the nature of the head determines, in part, the choice of the relative pronoun. The fact that in (3) *which* must be chosen instead of *who* is a consequence of the fact that its antecedent is non-human, for example.

With this much as background, consider now an example like (4):

(4) You should return *what you have finished reading* to the library.

What we seem to have here is a relative clause without a head. That is, there is neither an internal nor an external head to be found. Such relative clauses are usually called 'headless relatives' or 'free relatives', and they are the central topic of the present chapter. Before turning to a more detailed description of the main properties of free relatives (FRs), however, we must address an alternative analysis which immediately suggests itself. Why can't we say that the italicized clause in (4) is an embedded (or indirect) question? In other words, why can't we equate a sentence like (4) with a superficially similar one such as (5)?

(5) Could you tell me *what you have finished reading*?

The difference has to do with the selectional behavior of the two matrix verbs. They differ in that *return* selects noun phrases while *could you tell me* selects questions. This becomes clear immediately if we replace the *wh*-clause with an unequivocal question (one introduced by *whether*, for example) or by a real noun phrase such as *War and Peace*:

(6) a. *You should return *whether you have finished your book* to the library.
b. You should return *War and Peace* to the library.

(7) a. Could you tell me *whether you have finished your book*?
b. *Could you tell me *War and Peace*?

Similarly, a preposition like *with* cannot take a question as its object, but an NP object is permitted and so is an FR:

(8) a. *I am going to swat this fly with *whether you have finished your book*.
b. I am going to swat this fly with *War and Peace*.
c. I am going to swat this fly with *what you have finished reading*.

As a preliminary conclusion,[4] we may record that questions are pure clauses, CPs, while FRs are noun phrases, that is, NPs or DPs, which contain a CP. This conclusion immediately raises a number of questions, however. If an FR is a DP, which contains a CP, then what exactly is the structure? More specifically, the obvious question to ask is if there is a head at all. In other words, is the structure essentially as in (9a) or as in (9b)?

(9) a. $[_{DP}$ CP]
b. $[_{DP}$ DP CP]

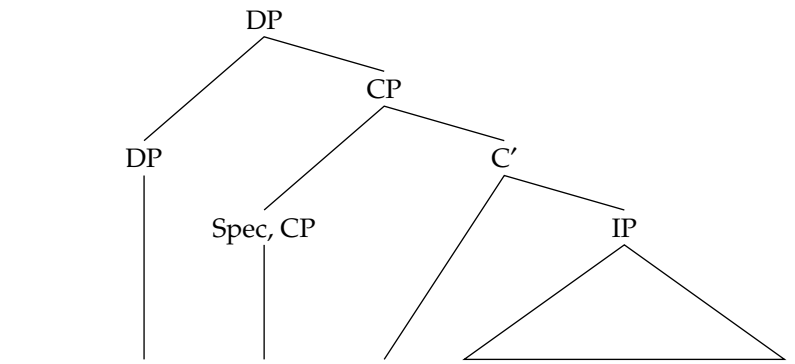
And if there is a head, as in (9b), is it entirely empty or is it phonetically realized in some way? Both options can be interpreted in a number of ways:

(10) a. Head is empty:
- (i) If the DP is truly empty, then this is indistinguishable from (or identical to) (9a).
- (ii) There is an empty element in the head position – most likely PRO or pro.

b. Head is filled:
- (iii) There could be a pronominal element in the head position which ends up being coalesced with the *wh*-element, e.g., *it/that* + *wh* → *what*.
- (iv) The *wh*-word (or -phrase) could be in the head position instead of being in its canonical Spec, CP-position.

We may schematically represent these options in the following manner:

(11)



(i)	e	what$_i$	C^o	you have finished reading e$_i$
(ii)	PRO/pro$_i$	what$_i$	C^o	you have finished reading e$_i$
(iii)	it/that$_i$	*wh*-$_i$	C^o	you have finished reading e$_i$
(iv)	what$_i$	e$_i$	C^o	you have finished reading e$_i$

The main discussion has been about the choice between (ii) and (iii/iv). That will be the topic of section 2. The conclusion will be that, at least in many cases, the *wh*-word/phrase is in the Spec, CP position. This conclusion leads immediately to the question of whether the head position is filled by some phonetically unrealized element, as in (ii), or is entirely absent, as in (i). The general aspects of this issue are dealt with in section 3. In this discussion, one set of phenomena has played a principal role, viz. matching vs. non-matching; that is, the extent to which the *wh*-pronoun/phrase must satisfy in and by itself the requirements (selection, subcategorization, case marking) of both the embedded clause and the matrix clause. These matching effects are discussed in section 4. In determining what the nature of the missing head is, semantic considerations play a considerable role. In fact, many FRs are ambiguous. An example like (4), repeated here as (12a), can be paraphrased as either (12b) or (12c):

(12) a. You should return *what you have finished reading* to the library.
b. You should return that (the thing, sc. the book) which you have finished reading to the library.
c. You should return anything (whatever it is) which you have finished reading to the library.

These readings, and the relevance they might have for the determination of the nature of the missing head, constitute the topic of section 5. Some of these semantic issues reactivate the question of whether FRs and questions are really that different, and consequently what the structural representation of FRs is. This issue is the central topic of section 6.

2 Where is the relative pronoun?

One of the main questions that arise in the context of FRs, as stated in (9) and (10) above, is whether the *wh*-word, or, more generally, the relative pronoun, occupies the position of the head of the relative clause or is in its canonical complementizer (Spec, CP) position. The former analysis, which has come to be called the Head Hypothesis[5] (HH), came to fame by an article by Bresnan and Grimshaw (1978). And the opposition to this hypothesis, gathered under the name of COMP Hypothesis (CH),[6] was initiated in Groos and Van Riemsdijk (1981).

The main reason why this debate was fairly heated and achieved a certain notoriety is to be found in the role that it played in one of the major issues that raged through the field in the late 1970s. This was the question of whether unbounded processes exist in grammar. One of the results in the early 1970s, in particular the theory outlined in Chomsky (1973), was that long-distance processes could be decomposed into chains of successive, local steps in a derivation, the standard example being the analysis of long *wh*-movement in terms of a series of successive-cyclic movements from COMP to COMP. The idea that transformational processes were limited to local domains was embodied in the Subjacency Condition, the cornerstone of Bounding Theory. Suppose now that the HH is correct. This would mean that an FR like the one in (12a) has a structure roughly like that in (13):

(13) $[_{DP}\ [_{DP}\ what_i]\ [_{CP}$ you have finished reading $[e]_i]]$

Clearly, there is a relationship between the *wh*-head and the gap in the FR. This relationship is marked here by co-indexation for expository purposes. The question is, what is the nature of the rule responsible for this dependency? Presumably, it is not movement, since the *wh*-word is in the head position and the null hypothesis would be that, like the heads of regular headed relative clauses, it is base generated there.[7] Bresnan and Grimshaw (1978) proposed to describe the dependency in question in terms of a deletion rule which they call Controlled

Pro Deletion. The idea of the rule is that the position of the gap in (13) is underlyingly occupied by a pronominal element, a (resumptive) element like *it*, *him*, *them*, *then*, or *there*, which is subsequently deleted under referential identity with the head.

Observe now that this rule of Controlled Pro Deletion must be able to apply to head–pronoun pairs over an arbitrary distance, as shown in examples like (14):

(14) $[_{DP}\,[_{DP}\,what_i]\,[_{CP}$ you told Bill that Mary said he should have finished reading $[e]_i]]$

On the basis of this observation, Bresnan and Grimshaw concluded that unbounded transformational processes could not be entirely eliminated from the theory of grammar. But, of course, the conclusion depended heavily on the validity of the arguments supporting the HH. These arguments have to do with one of the most salient properties of FRs: the matching effects which they exhibit.

Consider the following paradigm:

(15) a. We should interview the woman with whom he goes out?
b. *We should interview with whom/whoever he goes out?

(16) a. We should talk to the woman whom he dates.
b. We should talk to whom/whoever he dates.

(17) a. We should talk to the woman with whom he goes out.
b. *We should talk to with whom/whoever he goes out.

(18) a. We should talk to the woman to whom he talks.
b. We should talk to whom/whoever he talks.

In (15) the head of the relative clause is a DP while the *wh*-phrase is a PP. When the head is missing, the result is ungrammatical. This is due to the fact, somehow, that the verb *interview* can only take DP direct objects, not PPs. This is confirmed by the fact that in (16) the situation is reversed. Here we have a matrix preposition, which takes a DP object, and the FR in (16b) indeed starts with a *wh*-phrase, which is a DP. Apparently the categorial requirements in the matrix clause and in the relative clause can be different in the case of headed relatives, but must be identical in the case of FRs. This categorial matching effect is further confirmed by (17), where the matrix preposition cannot take an FR which is introduced by a PP. On the other hand, if the two prepositions (the matrix one and the embedded one) are identical, the result is again (more or less) grammatical, though one of the two prepositions disappears (see section 4.1.2 for more discussion of the missing P phenomenon).

This categorial matching effect is elegantly explained if we assume the HH. The *wh*-phrase is in the head position and must, therefore, satisfy matrix requirements just as regular heads do. The fact that it must also satisfy the embedded

requirements follows from the identity requirement on the rule of Controlled Pro Deletion. A DP-head cannot cause the deletion of a PP-pronominal, etc.

In addition to the categorial matching effect, matching can also be observed in the domain of case marking. German serves as a language which exhibits case matching. Consider the following examples:[8]

(19) a. Wer_{NOM} nicht stark ist muss klug sein.
who not strong is must clever be
'Who is not strong must be clever.'
b. *Wen/*wer Gott schwach geschaffen hat muss klug sein.
whom_{ACC}/who_{NOM} God weak created has must clever be
'Who God has created weak must be clever.'
c. *Wem/*wer Gott keine Kraft geschenkt hat muss klug sein.
who_{DAT}/who_{NOM} God no strength given has must clever be
'Who God has given no strength must be clever.'

(20) a. Ich nehme wen du mir empfiehlst.
I take whom_{ACC} you me recommend
'I take whom you recommend to me.'
b. Ich nehme *wem/*wen du vertraust.
I take who_{DAT}/whom_{ACC} you trust
'I take who you trust.'
c. Ich nehme *wer/*wen einen guten Eindruck macht.
I take who_{NOM}/whom_{ACC} a good impression makes
'I take who makes a good impression.'

(21) a. Ich vertraue wem du vertraust.
I trust who you trust
'I trust who you trust.'
b. Ich vertraue *wen/*wem du mir empfiehlst.
I trust whom_{ACC}/who_{DAT} you me recommend
'I trust who you recommend to me.'
c. Ich vertraue *wer/*wem einen guten Eindruck macht.
I trust who_{NOM}/who_{DAT} a good impression makes
'I trust who makes a good impresion.'

In (19) the FR is in the subject position, in (20) it is in a direct object position, and in (21) it is in a dative object position. In other words, the matrix case requirements are nominative, accusative, and dative respectively. The a-sentences show that the FR is well-formed if the relative clause case requirement is identical to the matrix requirement: nominative in (19), accusative in (20), and dative in (21). Whenever the relative clause case requirement does not match the matrix requirement, as illustrated in the b- and c-examples, the result is ungrammatical. That is, the corresponding meaning cannot be expressed by means of an FR – instead a headed relative clause construction must be used.

The same reasoning as was used in the case of categorial matching applies here. By assuming that the *wh*-phrase of the FR is in the head position, we explain why it must meet the matrix case requirements, while the matching with the embedded case requirements follows from the identity condition imposed on the rule of Controlled Pro Deletion.

Against this analysis of FRs and, concomitantly, against this argument in favor of the view that unbounded deletion rules exist, Groos and Van Riemsdijk (1981) presented strong evidence that at least in some languages the *wh*-phrase occupies the Spec, CP position in FRs. The main argument that these authors present is based on the way in which relative clause extraposition (see chapter 25) applies to FRs. The argument is based on German and Dutch. Illustrations will be exclusively from German. Consider the following placement possibilities for headed relative clauses:

(22) a. Der Hans hat [das Geld, das er gestohlen hat], zurückgegeben.
the Hans has the money, which he stolen has returned
'Hans has returned the money that he has stolen.'
b. Der Hans hat [das Geld] zurückgegeben, [das er gestohlen hat].
the Hans has the money returned which he stolen has
'Hans has returned the money that he has stolen.'
c. *Der Hans hat zurückgegeben, [das Geld, das er gestohlen hat].
the Hans has returned the money which he stolen has
'Hans has returned the money that he has stolen.'

In (22a), the whole DP, including the relative clause, is in the canonical direct object position. In (22b), the relative clause is extraposed. What (22c) shows, however, is that the whole DP cannot be extraposed, a process that would generally be referred to as Heavy NP Shift. Basically, Dutch and German do not have Heavy NP Shift.[9] With this in mind, consider now the question of how we expect FRs to behave, depending on whether we adopt the HH or the CH. On the HH, we expect the *wh*-phrase to remain in situ to the left of the verb under relative clause extraposition, while the rest of the clause would extrapose. On the CH, however, we expect to find all of the phonetically realized elements together undergoing extraposition, while the empty head would remain (invisibly) in situ. The latter is what we actually find:

(23) a. *Der Hans hat [was] zurückgegeben, [er gestohlen hat].
the Hans has what returned he stolen has
'Hans has returned what he has stolen.'
b. *Der Hans hat [e] zurückgegeben, [was er gestohlen hat].
the Hans has returned what he stolen has
'Hans has returned what he has stolen.'

This straightforwardly shows that the HH cannot account for FR-extraposition in German (and Dutch).[10] And in view of the fact that these languages exhibit

categorial matching effects in very much the same way as English does, and that German in addition is subject to full-scale case matching, we must conclude that another way must be found to derive matching effects in FRs.

There are several other considerations which favor the CH over the HH, of which one deserves to be mentioned that has to do with the absence of the complementizer in the FR on the HH. If the *wh*-phrase is in the head position, then what follows it must be the relative clause. The null hypothesis would be that this clause, as in the case of headed relatives, is a CP (an S′ in older versions). Taking things a step further, the null hypothesis would then be that the canonical positions under CP, viz. Spec, CP and C°, have the same properties as in headed relatives. In other words, we would expect the following two paradigms to be fully identical:

(24) I put [the pie] [which/*which that/that/Ø you prepared] in the refrigerator.

(25) I put [what] [*which/*which that/*that/Ø you prepared] in the refrigerator.

In actual fact, they are not. In the case of the FR, (25), both positions must be empty. Similarly, if the position relativized is the subject position,[11] we get a reverse paradigm, as shown in the following two examples:

(26) [The pie] [which/*which that/that/*Ø was in the refrigerator] tasted bad.

(27) [What] [*which/*which that/*that/Ø was in the refrigerator] tasted bad.

The bracketing given in examples (24) through (27) is, of course, that of the HH. Bresnan and Grimshaw (1978) are perfectly aware of this problem. They propose to solve it by assuming that the clause that follows the free relative head is not a full CP (in their terms: S′) but rather a reduced clause, IP (in their system: S). The stipulative nature of such an assumption[12] compels us to look for a more principled solution, however.

If, indeed, we now contrast the above examples with the corresponding bracketings under the CH, a rather different picture results:

(24′) I put [the pie] [which/*which that/that/Ø you prepared] in the refrigerator.

(25′) I put [—] [what/*what that/*that/*Ø you prepared] in the refrigerator.

(26′) [The pie] [which/*which that/that/*Ø was in the refrigerator] tasted bad.

(27′) [—] [What/*what that/*that/*Ø was in the refrigerator] tasted bad.

While this way of presenting the paradigm does not bring out a full parallelism between the headed and the headless relative, one perfectly natural auxiliary hypothesis will do the trick. This is to say that in a free relative, unlike in a headed relative, the *wh*-word may not be absent for reasons having to do with recoverability. Thereby, the ungrammaticality of the third and fourth options in (25′) and (27′) is accounted for, and full parallelism is achieved.

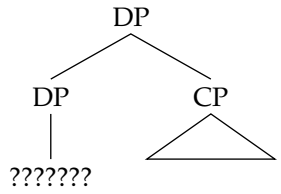
These considerations make it very difficult to maintain the idea that the HH could be correct for either English or languages like Dutch and German. While this does not exclude the possibility that FRs in some other languages might be constructed according to the HH, or, in fact, that both structures might be available in some languages, two main analytical questions arise from the adoption of the CH:

(i) What is the status of the empty head? (see section 3)
(ii) How do we now account for matching effects? (see section 4)

3 The status of the empty head

The early work on FRs, up to Bresnan and Grimshaw (1978) and Groos and Van Riemsdijk (1981), had been carried out in a framework preceding Government and Binding Theory (GB). In this pre-GB framework, traces and PRO did exist, but no systematic account of their contrasting properties had yet been given. This must be at least part of the reason why these authors are not very explicit as to the nature of the empty head on the CH. Bresnan and Grimshaw assume, without further discussion, that the structure of FRs on the CH would have to be as in [$_{DP}$ CP] (9a), while Groos and Van Riemsdijk assume a structure more like (9b), graphically shown here as (28):

(28)



But they too largely ignore the issue of what this empty DP is like, because in their account the *wh*-phrase in Spec, CP fulfills all the functions which the head of a headed relative clause normally fulfills. Grosu (1994) calls this the "head bypass analysis." Somewhat more specific versions of this type of approach have been presented in Hirschbühler and Rivero (1981, 1983) and Harbert (1983b). But if the empty category representing the DP head has no properties at all, then it is as if the head is absent, and we are back with (9a), that is, with a structure like [$_{DP}$ CP]. But if that is the case, then why not go one step further and assume that the FR is simply a CP whose Spec is accessible to government from the outside? This is indeed a logical possibility. But the type of argument presented in

section 2 concerning the distribution of FRs as opposed to regular complement or adjunct CPs suggests otherwise. If the FR as a whole can have the distribution of a DP, then how can this fact be derived in a pure CP analysis? We would have to assume that the accessibility of a DP in the Spec, CP suffices to determine the distribution of the CP, but the question is how. One way in which this could be done is explored in section 6.

It should be noted at this point that any head bypass approach is subject to one major line of criticism: any such analysis violates the theta-criterion. Consider a simple case like *I ate what you cooked*. Here *what* heads a chain whose foot is the direct object of the verb *cook*; hence the chain is theta-marked by the verb. But now, if we say that *what* (and not the whole FR or its empty head) is the target of theta-government by the matrix verb *eat* as well, that chain will be assigned two theta-roles and thus constitutes a theta-criterion violation. Groos and Van Riemsdijk (1981) were not concerned about this because their analysis was pre-GB, but subsequent work tried to explore ways to avoid this problem. The three-dimensional approach, which we will return to in section 6, may well be a way out, but first we will address a number of more orthodox ways to deal with the problem.

The obvious alternative to the head bypass approach is to assume that the empty head DP in (28) is filled with an empty category of an identifiable kind. Clearly, the empty category cannot be a trace, as there is no plausible candidate for anything having been moved out of the head position. Hence the empty category must be either PRO or pro. One might think that PRO can be dismissed immediately, since the FR can occur in governed positions, and then PRO, being the head of the containing DP, would be governed. This is valid reasoning only up to a certain point. Recall that we are still assuming that Spec, CP is subject to government (for category selection and for case) from outside the DP. Now, if we assume that the Spec, CP absorbs government entirely, the empty head of the DP would be ungoverned in all cases, and hence PRO would be tolerated. Observe first, however, that this approach will not avoid the theta-criterion problem. Furthermore, we would have to ask what the control properties of this PRO are. Since actual control by an identifiable controller does not seem to obtain, the only option is to interpret PRO as being arbitrary. As will be discussed in somewhat greater detail in section 5, FRs are either definite/specific, as in (29) or universally quantified, as in (30):

(29) You can't make a pancake with what you bought (=with the thing(s) that you bought).

(30) I will invite who(ever) you tell me to (=everybody that you tell me to invite).

It is an interesting question whether PRO_{arb} can be assumed to cover exactly this range of cases. The answer, at first sight, seems to be no, but so far, modulo some discussion in Grosu (1989), Harbert (1983b), and Suñer (1984b), the issue still remains to be investigated in detail.

Turning now to the second option, could the empty head be pro? This seems a more likely road to success in that pro can occur in governed positions. Exploiting this property, we are led to assume that the pro is identified (or licensed) by some outside element, and that any sensitivity of the *wh*-word in Spec, CP to matrix influences must be mediated by this pro. This is essentially the approach that has been pursued in Suñer (1984b) and Grosu (1994). In view of the fact, however, that matching is a wide-spread phenomenon, and, moreover, that it is a phenomenon that is rather tightly linked to the morpho-phonological shape of the *wh*-words in question (cf. section 4.2.1), mediation by means of some kind of agreement relation between pro and the *wh*-word in Spec, CP seems problematic.[13]

4 Matching effects

As was shown in section 2 in connection with examples (15–18) and (19–21), matching effects are among the most salient and crucial properties of FRs. The present section will discuss the relevant phenomena in greater detail.

4.1 Category matching

4.1.1 The normal case

The discussion about the nature of the head of the FR in section 3, most notably the graphic representation in (28), was simplified in one crucial respect in that it suggested that DPs were the only potential candidates for the status of heads of FRs. In actual fact, FRs can apparently be headed by DP, AP, or PP, as shown in the following examples:

(31) a. The police arrested *who* the witness identified. (DP)
b. They tend to live *in whatever town* their parents used to live. (PP)
c. She will make you *however happy* your ex made you. (AP)
d. I'll play my music *however loudly* you play yours. (AP)

Here the italicized phrases are of the matching type. That is, their category is appropriate for categorial selection both in the matrix clause and in the relative clause. In (31a) *arrest* selects a DP object, and so does the embedded verb *identify*. Similarly, the PP in (31b) is selected both by the matrix instance of *live* and by the embedded instance of this verb. And the same thing is true for the APs (adverbial or not) in (31c, d). This type of matching is absent in regular relative clauses, of course:

(32) a. The police arrested the man to whom the witness pointed.
b. They live in the town that their parents live in.

In (32a) the head is a DP while the *wh*-phrase is a PP. As for PP, (32b) could be a non-matching case, but this is impossible to tell because we do not know whether the head is the DP or the PP. Since APs cannot head relative clauses,

non-matching is impossible to illustrate. Non-matching will indeed result in ungrammaticality, as shown in (33) and (34):

(33) a. *The police arrested *who* the witness pointed.
b. *Zij wonen waarnaast hun ouders gekocht hebben.
they live where next-to their parents bought have
'They live next to what their parents have bought.'
c. *She will make you however happy your ex married.
d. *I'll play my music however loudly you listen to.

(33) represents the case in which the *wh*-phrase properly satisfies the selectional requirements of the matrix, but not those of the relative clause. The ungrammaticality is caused by the following mismatches:

(33') a. matrix DP vs. RelCl PP
b. matrix PP vs. RelCl DP
c. matrix AP vs. RelCl DP
d. matrix AP (adv.) vs. RelCl DP

In the PP case (33b) we encounter again the problem that we do not know whether the preposition is part of the head of the relative clause or outside it. But in a language like Dutch, in which forms equivalent to *whereby* are fully productive, this problem can be overcome. *Waarnaast* 'next to which' is a PP, properly selected by the matrix verb *wonen* 'live' but unsuitable as a direct DP object of the embedded verb *gekocht* 'bought'. In the AP cases, again, the AP is properly selected or interpreted in the matrix, but cannot satisfy the categorial selection requirements of the relative clause.

Similarly, if the *wh*-phrase is appropriate for the relative clause but not for the matrix we again get ungrammatical results, as shown in (34):

(34) a. *The witness pointed *who* the police had arrested.
b. *The police arrested *to who(m)* the witness pointed.
c. *She will marry however happy her ex made her.
d. *I'll play my music whatever rock opera you are listening to.

The mismatches are as follows:

(34') a. matrix PP vs. RelCl DP
b. matrix DP vs. RelCl PP
c. matrix DP vs. RelCl AP
d. matrix AP (adv.) vs. RelCl DP

There is, nevertheless, a certain asymmetry between the DP cases on the one hand and the PP/AP cases on the other hand. This has to do with two additional restrictions that are imposed on the latter but not on the former. Recall that there are two main semantic types of FRs: definite/specific and universally quantified

(cf. (29/30) and section 5.2). Observe now that the DP-FRs come quite readily in both types but that for the PP/AP-FRs there is a very strong bias in favor of the universally quantified type. In fact, when the context strongly imposes the definite/specific reading, the result tends to be quite degraded.[14] Consider (34″):

(34″) a. ?Tomorrow I will speak to who(m) you spoke last night.
b. ?You can't word your letter how rudely they worded theirs.

The second restriction is that the matching requirement, if anything, seems to go beyond the identity of the head of the relative clause. Note, indeed, that in all the above examples of AP/PP-FRs the matrix verb and the embedded verb were identical. Choosing different verbs with identical categorial selection requirements also tends to result in less than fully acceptable examples:

(35) a. ?Why don't you ever dance with whomever I come to parties?
b. ?She always dotes on whomever you can't count.
c. ?I'll keep my bedroom however dark you paint your study.

In view of these restrictions, most of the literature has concentrated on DP-FRs, with the exception of so-called 'missing P FRs', which we return to in section 4.1.2. Before doing so, however, we also need to address the question as to whether categorial matching is an absolute and inviolable requirement. The answer appears to be that it is not.

Consider an English example like the following:

(36) a. *On whatever mattress I sleep gives me a terrible back ache.

Clearly, the FR is headed by a PP and since it occupies a DP-position (the subject position) the sentence is ungrammatical. In English, the effect is quite straightforward, partly because there is a simple way of choosing a matching variant:

(36) b. Whatever mattress I sleep on gives me a terrible back ache.

If we strand the preposition, we end up in Spec, CP with only the *wh*-phrase, which is a DP. But other languages don't allow preposition stranding (see chapter 51), and in such languages, sometimes, the non-matching variant corresponding to (36a) is acceptable. Consider the following example from Romanian, taken from Grosu (1994):

(37) Cu ciene iese Maria e deobicei un om de nimic.
with whom goes-out Mary is usually a man of nothing
'Who Mary goes out with is usually a no-good.'

It should be noted, however, that even in languages that do allow such non-matching FRs, their status tends to be rather marginal and subject to several further conditions. Most importantly, non-matching seems to be largely limited

to ungoverned or at least weakly governed positions. Among the latter, we may include the subject position, as opposed to the object position, for example. With pure adjuncts, of course, there is nothing in the matrix to match with, so this case is untestable. But what we do find is cases of correlatives which can often be analyzed as left- or right-dislocated FRs. (38) is an example of such a construction from Spanish, taken from Suñer (1984b):

(38) Con quien me quiero casar, ése ni me da la hora.
with whom me want to-marry that-one not-even me gives the time
'The one with whom I want to get married does not even give me the time of day.'

Another condition mentioned in Grosu (1994) is that the *wh*-word may not be too deeply embedded within the *wh*-phrase:

(39) Con la foto de quien Maria se fué es muy simpático.
with the picture of who Mary self went is very pleasant
'(The person) with whom Mary went away is very pleasant.'

Finally, it is noted that the best examples of categorially non-matching FRs tend to be proverbs. Grosu (1994) notes, for example, that all examples of non-matching FRs in subject position in Catalan, as provided in Hirschbühler and Rivero (1981), are proverbs, as illustrated in (40):

(40) A qui l' adulació halaga, si la pren la paga.
to whom the flattery pleases if her takes her pays
'He who likes flattery, if he accepts it he pays for it.'

For further comments on non-matching, see also section 4.2.2 below.

4.1.2 Missing prepositions

Returning now to examples like (34a), notice that you might say that a preposition has disappeared. Consider some other examples of this type:

(41) a. He'll remain in whatever town he has been living all his life.
b. Children worry about whatever their parents worry.

In both examples, the preposition appears to fulfill a double role in that it is required both by the matrix clause and by the FR. In (41a) both verbs (*remain* and *live*) select a locative PP, and similarly, in (41b) the *about*-phrase seems to serve as a complement both to the matrix-*worry* and to the embedded *worry*. The impression of a missing preposition is reinforced when we consider variants of (41) in which the preposition in question is actually present:

(42) a. He'll remain in whatever town he has been living in all his life.
b. Children worry about whatever their parents worry about.

From another perspective, however, the absence of the preposition in (41) is hardly surprising, since sharing is what matching is all about. If in simple FRs like *I eat what you cook* the *wh*-word is both the embedded object and the matrix object, then why can't a whole *wh*-PP have a double function in precisely the same way? The question in other words is whether such examples have structure (43a) or (43b):

(43) a. . . . V [$_{PP}$ P [$_{FR}$ [$_{DP}$ *wh*-word]$_i$ . . . V . . . ***P*** [e]$_i$ . . .]] . . .
b. . . . V [$_{FR}$ [$_{PP}$ P *wh*-word]$_i$ . . . V . . . [e]$_i$ . . .] . . .

In (43b) there is no missing P, or rather, there is no P that has to mysteriously disappear. On the other hand, in (43a) the ***P*** is supernumerary and has to disappear somehow. And given that we already need a mechanism to account for matching in the simple case, the most straightforward way of analyzing these cases would be to extend this mechanism to PPs.

There is actually quite a controversy on this point, which is still ongoing. The main protagonists are Larson and Grosu. Larson (1987) defends the analysis with the missing preposition, i.e., (43a), and Grosu (1996) argues against Larson in favor of (43b). For details about this controversy, the reader is referred to these texts.

4.2 Case matching

As in the case of categorial matching effects, the case on the *wh*-word or *wh*-phrase must generally match; that is, the case requirements of the matrix context and those of the FR-context must be identical. The overall approach which we have been pursuing is that the *wh*-phrase is, in fact, a shared constituent: a constituent that originates inside the FR, is moved into the Spec, CP of that FR, and, in that position, serves to satisfy some matrix requirement, be it selection or case government. The phenomenon of case matching, like that of categorial matching, is directly relevant to the choice between the two main approaches to FRs, the HH and the CP, cf. (19–21).

4.2.1 Full matching

The full matching paradigm is exhibited in the following examples from section 2:

(19) a. Wer$_{NOM}$ nicht stark ist muss klug sein.
who not strong is must clever be
'Who is not strong must be clever.'
b. *Wen/*wer Gott schwach geschaffen hat muss klug sein.
whom$_{ACC}$/who$_{NOM}$ God weak created has must clever be
'Who God has created weak must be clever.'
c. *Wem/*wer Gott keine Kraft geschenkt hat muss klug sein.
who$_{DAT}$/who$_{NOM}$ God no strength given has must clever be
'Who God has given no strength must be clever.'

(20) a. Ich nehme wen du mir empfiehlst.
I take whom$_{ACC}$ you me recommend
'I take whom you recommend to me.'
b. Ich nehme *wem/*wen du vertraust.
I take who$_{DAT}$/whom$_{ACC}$ you trust
'I take who you trust.'
c. Ich nehme *wer/*wen einen guten Eindruck macht.
I take who$_{NOM}$/whom$_{ACC}$ a good impression makes
'I take who makes a good impression.'

(21) a. Ich vertraue wem du vertraust.
I trust who you trust
'I trust who you trust.'
b. Ich vertraue *wen/*wem du mir empfiehlst.
I trust whom$_{ACC}$/who$_{DAT}$ you me recommend
'I trust who you recommend to me.'
c. Ich vertraue *wer/*wem einen guten Eindruck macht.
I trust who$_{NOM}$/who$_{DAT}$ a good impression makes
'I trust who makes a good impresion.'

One may wonder, of course, how a language can get away with this tight a restriction. The richer the case system, the fewer the chances that the upstairs and the downstairs requirements can be made to match. The answer to this puzzle is twofold. First, if the *wh*-phrase is truly a shared constituent, then matching is the only option available. Second, all languages in question have the possibility of using what Citko (1999) calls a 'light-headed relative' instead. That is, mismatches can be accommodated by making use of a semantically minimally specified head, generally a pronoun. In German, demonstrative or d-pronouns are normally used for this purpose. For (19–21) the grammatical counterparts of the ungrammatical examples would then be the following:

(19) b'. Der, den Gott schwach geschaffen hat muss klug sein.
c'. Der, dem Gott keine Kraft geschenkt hat muss klug sein.

(20) b'. Ich nehme den, dem du vertraust.
c'. Ich nehme den, der einen guten Eindruck macht.

(21) b'. Ich vertraue dem, den du mir empfiehlst.
c'. Ich vertraue dem, der einen guten Eindruck macht.

In addition to this strategy of using 'light-headed relatives', there are a few other ways in which languages resolve the problem of case mismatches, and this is a topic which is discussed in sections 4.2.3 and 4.2.4.

4.2.2 Mismatches

As in the case of category matching (section 4.1), mismatching does occur with case marking as well. There are three main aspects to be considered here. First,

there are situations in which mismatches appear to be tolerated. Second, mismatches can be resolved under circumstances of syncretism (see section 4.2.3). And third, mismatches may sometimes be resolved by means of case attraction (see section 4.2.4).

A substantial number of cases have been invoked in the literature (see among others Grosu 1994; Pittner 1995). Consider the following examples:[15]

(44) a. Ich liebe^{acc} wer$_{nom}$ Gutes tut und hasse^{acc} wer$_{nom}$ mich verletzt.
I love who good does and hate who me offends
'I love whoever does good and hate whoever offends me.'

b. Ich nehme^{acc} wem$_{dat}$ immer du vertraust^{dat}.
I take whom ever you trust
'I take whomever you trust.'

c. Was$_{nom}$ ein Mädchen ist von gutem Gefühl müssen dergleichen
what a girl is of good feeling must such
Sachen zuwider sein^{dat}.
things repugnant be
'To whoever is a girl of good sense such things must be repugnant.'

NB: subscripts indicate the case of a form, superscripts indicate the case imposed by some predicate.

It is quite clear that such examples constitute prima facie problems for the idea that the *wh*-phrase of the FR is a shared element. A number of remarks are in order, however. First, the data situation is rather complicated here. Some of these examples have a distinctly archaic flavor to them. To the present author, all three are fully ungrammatical. More importantly, the case system of spoken German is subject to considerable decay. Dutch has completely lost morphological case on full noun phrases. In many German dialects, surface case has been lost to varying degrees. Swiss German, for example, has lost the genitive, has a dative that is only marginally distinct from a PP, and the distinction between nominative and accusative, when present at all, is probably more a hypercorrection from Standard German than part of the language itself. Other dialects in the German-speaking countries are less radical, but the dative/accusative distinction is lost in many of them, sometimes with the dative surviving as in the Berlin dialect and sometimes with the accusative winning out as in many Bavarian dialects. This observation may well account for some of the above. If (44a) were from a speaker of Swiss German, for example, we could immediately trace the example's grammaticality to the Swiss dialect situation. In actual fact, the sentence is from Schiller, so the question remains open. Similarly, (44b) is a case of dative–accusative confusion, which may possibly be traced to dialectal factors. (44c) is from Goethe and, to the present-day ear, completely impossible. In his discussion of such examples, Paul (1920: IV, §411) repeatedly points out that such examples are rare, archaic, marked, and not part of present-day German (his grammar came out in 1920).

The second point that needs to be made here concerns the difficulty that arises from such examples for an approach in which the *wh*-phrase is a constituent

'shared' by the matrix and by the FR. If one wants to maintain such an analysis, some way must be found to account for the asymmetry between the upstairs and downstairs environment in terms of their impact on case checking. In all three of the examples cited, the case of the *wh*-word is that imposed within the FR. And indeed, Paul (1920) notes that this is the only type of deviation from matching found in New High German. One way of looking at this would be to say that case is checked inside the relative clause and that (in certain varieties of German) it need not be checked again in the matrix environment. We will not pursue the details of such an approach here. Note, in fact, that an alternative approach in which the head is occupied by some empty element (say pro) does not fare any better, loosely speaking. On such an approach, the null hypothesis would be to say that we find the same patterns that are found with overt pronominal heads (light-headed relatives). The latter exhibit no matching whatsoever. Hence, we would face the task of explaining why much tighter restrictions on the agreement relation between the pronominal head and the *wh*-phrase of the FR come into play when the pronominal head is an empty category. The reader is referred to Grosu (1994) for an account along such lines.

4.2.3 Case syncretism

It is a well-known fact that in case paradigms of a certain complexity, syncretism may be found. That is, a certain morphological case form may be used for two or even more abstract case features. Take the simplex question words in German. These constitute the following paradigm:

	Masc./Fem.	Neuter
Nominative	*wer*	*was*
Genitive	*wessen*	*wessen*
Dative	*wem*	—
Accusative	*wen*	*was*

This table shows that there is syncretism in two respects: the genitive forms syncretize for gender: same form for masc./fem. and for neuter, while the nominative and the accusative forms are identical in the neuter.

If we wish to test, now, whether case matching is affected by syncretism, we must immediately conclude that the genitive syncretism (*wessen*) cannot be tested because the gender switch cannot be tolerated or forced. That is, in an example like (45) it is impossible to force an interpretation in which *wessen* is taken to be, say, feminine in the matrix but neuter in the FR:

(45) Ich bediene mich wessen du dich erinnerst.
I avail myself whose you refl. remember
'I avail myself of who you remember.'

Due to the identity required between the head of the relative clause and the relative pronoun, here conflated into one word, the genitive object of *sich bedienen*

could never be taken to be a feminine noun, while at the same time the genitive object of *sich erinnern* is interpreted as a neuter noun.

Turning to the second instance of syncretism, the test can be successfully constructed. Take the following two fully matching examples:

(46) Was im Kühlschrank liegt ist schimmlig.
what in-the refrigerator lies is moldy
'What is in the refrigerator is moldy.'

(47) Ich esse was du gekocht hast.
I eat what you cooked have
'I eat what you cooked.'

In (46) *was* is a nominative subject both in the matrix and in the FR, while in (47) *was* is an accusative object both in the matrix and in the FR. Consider now, however, what happens when we invert the FRs with respect to the two matrix contexts:

(48) Was du gekocht hast ist schimmlig.

(49) Ich esse was im Kühlschrank liegt.

Both examples are fully grammatical despite the fact that in abstract case feature terms we have a non-matching combination: matrix nominative + FR-accusative in (48), and matrix accusative + FR-nominative in (49). We must conclude that the case-matching effect is concerned with the actual morpho-phonological shape of the case form in question, not with the abstract case features that it represents in a specific syntactic context.

With this in mind, let us go back to the main choices listed in (9):

(9) a. $[_{DP}$ CP]
b. $[_{DP}$ DP CP]

One way of characterizing the difference between these two analyses is to say that in (9a) the *wh*-element in Spec, CP is 'shared' between the relative clause structure and the containing matrix structure, while in (9b) the DP-head is part of the matrix and the Spec, CP is part of the relative clause, the relation between the two being mediated by agreement. Accordingly, we may call the former hypothesis the Shared Structure Hypothesis (SSH) and the latter the Distributed Structure Hypothesis (DSH). The case syncretism phenomena just discussed have considerable relevance for the choice between the SSH and the DSH. On the DSH one would not expect the actual morpho-phonological shape of the *wh*-word to play any role, since agreement processes such as those found between the head of a relative clause and the *wh*-word of the relative clause are in terms of features, not in terms of phonetic identity. Agreement as we understand it works in terms of morphosemantic features, not in terms of phonetics.[16]

4.2.4 Case attraction

If case matching is the norm, then the richer a case system, the poorer the options for FRs. In other words, if a language has *n* cases, there are n^2 possible combinations out of which only *n* yield a grammatical output (modulo syncretism). Again, this is not tragic, since a light-headed relative clause construction can always be chosen to avoid the case-matching restriction. But actually there is another way in which languages can, sometimes, escape this case-matching restriction: case attraction. Consider again the examples discussed under the heading 'case mismatches' in (44). In these examples, the case of the *wh*-word is the case imposed within the relative clause. But sometimes the case required by the matrix context is, as it were, superimposed on the *wh*-word. This is a pattern found in Classical Greek, as shown in Hirschbühler (1976a), whose data have been amply used in the later literature. Consider the following:[17]

(50) a. Deitai sou touton ekpiein sun hois$_{dat}$ malista phileis.
he-requests you this to-drink with who best you-love
'He requests you to drink this (sc. wine) with (those) who you love best.'
b. Deitai sou touton ekpiein sun toutois$_{dat}$ hous$_{acc}$ malista phileis.
with those whom

(51) a. Par' hôn$_{gen}$ boêtheis ouch apoleipsei charin.
from who you-help not you-get help
'From who you help you get no help.'
b. Par' ekeinôn$_{gen}$ hois$_{dat}$ boêtheis ouch apoleipsei charin.
from those whom

The b-examples show the corresponding light-headed relative with the distributed case forms. As the a-examples show, the matrix case wins: in (50a) the FR-accusative is superseded by the matrix dative, and in (51a) the FR-dative is superseded by the matrix genitive. The way this is generally expressed is to say that the case of the relative pronoun is attracted to the case of the matrix (the head). From this perspective, we might be tempted to reinterpret the mismatches discussed in section 4.2.2 as constituting the direct counterpart of the attraction cases in (50) and (51). We might then say that in cases like (50) and (51) attraction is downward, while in the cases shown in section 4.2.2. attraction is inverse or upward. By this we mean that the matrix case is imposed (attracted) in a downward direction to the *wh*-element in the FR, or transmitted (attracted) upward from the FR into the matrix context.

If we try to interpret these phenomena from the point of view of the two main hypotheses that we are comparing, the Shared Structure Hypothesis (SSH) and the Distributed Structure Hypothesis (DSH), a certain amount of stipulation seems to be required on both views. On an SSH view, we have to say that two independent structures are glued together in the shared element, but that these two structures are not equivalent: one is dominant and the other is recessive. This is feasible, and comparable phenomena can be found in other areas of grammar,

for example case attraction under long *wh*-movement in Hungarian. On the alternative DSH view, we have to say that the agreement process applying between the (empty) head and the *wh*-element in the FR sometimes does not require full identity of cases but that sometimes the head wins, sometimes the *wh*-element.

It must be recognized, however, that the latter view (the DSH) receives considerable support from the fact that the attraction phenomena just shown are also attested in headed relative clauses. Downward attraction is attested in the following example from Classical Greek, where the b-example shows what the unattracted version would be:[18]

(52) a. Phoboimen an tôi hegemoni$_{dat}$ hôi$_{dat}$ doiê hepesthai.
I-should-fear the leader who he-might-give to-follow
'I should fear to follow the leader whom he might give.'
b. Phoboimen an [tôi hegemoni$_{dat}$ [hon$_{acc}$ doiê]] hepesthai.

Upward attraction, though reported to be rarer in Classical Greek, is also found:

(53) a. Tên ousian$_{acc}$ hên$_{acc}$ katelipe ou pleionos aksia$_{nom}$ estin ê tettarôn
the estate which he-left not more worth is than four
kai deka talantôn.
and ten talents
'The estate which he left is not worth more than fourteen talents.'
b. Hê ousia$_{nom}$ hên$_{acc}$ katelipe ou pleionos aksia$_{nom}$ estin ê tettarôn kai deka talantôn.

Similar examples of upward attraction are also found in Latin:[19]

(54) a. Naucratem$_{acc}$ quem$_{acc}$ convenire volui in navi non erat.
Naucrates whom join I-wanted in ship not was
'Naucrates, whom I wanted to join, was not on the ship.'
b. Naucrates$_{nom}$ quem$_{acc}$ convenire volui in navi non erat.

Upward attraction appears to be rather exceptional (cf. note 18) but downward attraction is frequent enough to permit some generalizations. In particular, it appears that the more marked case must win. In other words, if the matrix case is, say, a dative and the case on the *wh*-word is a nominative, then downward attraction is possible, but not vice versa. Grosu (1994: 108) formulates the case hierarchy as follows:

(55) NOM < ACC < DAT < GEN < . . . < P-CASE

Here, P-Case can be extended to various highly oblique cases in richly case-marking languages. The idea is that a case lower on the hierarchy can replace a case higher on the hierarchy under downward attraction, but not the other way around. As Hirschbühler (1976a) notes, however, there may be asymmetries within one language. In particular, he notes, in Classical Greek[20] attraction is more liberal

in FRs than in headed relative clauses. In his formulation, an accusative may be attracted to a genitive or dative in headed relatives, but in FRs, neuter nominatives, accusatives, and datives may be attracted to datives or genitives.

5 Types of free relatives

5.1 Questions vs. free relatives

Since FRs are clauses with an initial *wh*-word, they look like questions. As was pointed out in the introduction (examples (5) ff.), FRs can generally be distinguished from questions without any problems since they differ in their subcategorizational properties. Nevertheless, when an FR occurs in a non-subcategorized position, say as an adjunct, then the distinction tends to be blurred. Consider:

(56) *Whatever Bill says*, it always comes out wrong.

Is the italicized part of this example a question or an FR? Subcategorization is not a factor here. The presence of *-ever* would seem to suggest that this is an FR, since embedded *wh*-questions do not take *-ever*. On the other hand, a close paraphrase of (56) has *no matter* prefixed to the *wh*-word, which is generally impossible in argument FRs:

(57) a. No matter what Bill says, it always comes out wrong.
b. ?*This dog attacks no matter who crosses its path.

Furthermore, *whether* can occur in this type of clause, and *whether* is normally limited to questions and excluded in FRs:

(58) (No matter) whether Carl talks or not, he will be convicted.

Semantically, such subordinate clauses appear to be a special subtype of concessive clauses, which does not help much if we try to determine whether they are questions or FRs.

There are, indeed, a number of other indications that FRs are closer to questions than headed relative clauses are. Consider first the fact that adjunct clauses like the ones above can sometimes contain multiple *wh*-phrases:

(59) a. Whichever CD you buy in whatever store, you always pay too much.
b. *This dog attacks whoever crosses whatever street.
c. *a person who crosses what street.
d. Who crossed what street?

As these examples show, there are multiple questions (59d) but no multiple relative clauses (59c), but multiple *wh*-phrases in the concessive clauses under consideration are possible.[21]

More generally, a second indication that FRs are closer to questions than headed relatives comes from the choice of pronoun that we find in them. In some languages such as German, questions are constructed by means of *w*-words, while headed relatives clauses make use of *d*-words (demonstrative pronouns):

(60) a. Peter fragte wen ich vorziehe.
Peter asked whom I prefer
'Peter asked whom I prefer.'
b. Peter hasst den Mann den ich vorziehe.
Peter hates the man whom I prefer
'Peter hates the man whom I prefer.'
c. Peter hasst wen ich vorziehe.
Peter hates whom(ever) I prefer
'Peter hates whomever I prefer.'

As (60c) shows, FRs pattern like questions and not like headed relative clauses in that they uniformly take *w*-words.

In German, what is at stake is essentially a morphological choice,[22] but there are languages in which the syntax of relative clauses and questions is more radically different. This is the case, for example, in Swiss German. Swiss German forms relative clauses by means of an invariable complementizer element *wo* and a resumptive personal pronoun in situ, which is sometimes deleted (cf. Van Riemsdijk 1989b). Questions, on the other hand, are formed by means of *w*-phrases that are moved to the front of the clause in the same way as in English or Standard German. Again, we find that FRs pattern with questions in this respect:

(61) a. De Peter wet wüsse mit wem s Susi redet.
the Peter wants know with whom the Susi talks
'Peter wants to know with whom Susi talks'
b. De Peter redet mit em maa wo s Susi mit em redet.
the Peter talks with the man that the Susi with him talks
'Peter talks with the man that Susi talks with.'
c. De Peter redet mit wem s Susi redet.
the Peter talks with whom the Susi talks
'Peter talks with whoever Susi talks.'

In conclusion, there is a variety of phenomena that suggest that FRs as a construction occupy a position somewhat intermediary between questions and (headed) relative clauses.[23]

5.2 The interpretation of free relatives

The main distinction among different types of headed relatives that comes to mind is the one between restrictive relatives on the one hand and non-restrictive or appositive relatives on the other. But this distinction is not helpful in coming

to grips with the essential semantics of FRs.[24] It is more helpful to contemplate what types of (pronominal) heads we use when we paraphrase FRs. Consider the following examples with their paraphrases:

(62) a. I ate what the waiter put on my plate.
b. I ate the thing that the waiter put on my plate.

(63) a. I will eat whatever the waiter will put on my plate.
b. I will eat anything/everything that the waiter will put on my plate.

It appears, then, that there are two main subtypes of FRs, definite FRs and universally quantified FRs. Note that the addition of *-ever* to the *wh*-word tends to disambiguate potentially ambiguous examples, since *-ever* pretty much forces the universally quantified reading. The opposite is not true, however. *Wh*-words without the suffix *-ever* can nevertheless have universal force, as in:

(64) I will eat what happens to be on the menu.

On closer inspection, in fact, even an example like (62a) can be interpreted with universal force: at that time my condition was such that I would eat whatever the waiter put on my plate. Furthermore, as the two alternatives in (63b) show (everything vs. anything), there is some question as to the precise nature of the type of universal quantification that is involved. By (63a) we mean either that I will eat all the food items that the waiter puts on my plate, or that I will eat any item from a larger set of items that the waiter chooses to put on my plate. The latter interpretation is often referred to as 'free choice *any*'. This observation also leads us to re-evaluate the above statement that *-ever* forces the universally quantified meaning, since a *wh-ever* FR sometimes also has a meaning that comes close to that of a definite noun phrase, but one that the speaker of the sentence is not able to identify at the point of speaking. This is illustrated in (65):[25]

(65) Everyone who went to whatever movie the Avon is now showing said it was very boring.

As noted in Jacobson (1995), this differentiates such an FR from truly universally quantified noun phrases, since the latter cannot be referred to by *it*:

(66) *Everyone who went to every movie the Avon is now showing said it was very boring.

The observation that the two subtypes of FRs are, at least sometimes, quite close to each other invites the question as to whether it is possible to unify the two. Jacobson (1995), which the following account paraphrases closely, suggests that this can be done by means of the notion of a maximal plural entity. It is important that the term *plural* is used in a broad way here: if in a given domain there is only one atomic individual with a given property, then the maximal

plural entity with that property is the one consisting of just this atomic individual. We may then assume that an FR like *what Mary recommended* denotes the set of maximal plural entities that Mary recommended (rather than any set of individuals that Mary recommended). Given the fact that this set may be limited to a single atomic entity, we now have an account for the fact that FRs at times seem to be singular definites and at times universals: we always have a singleton set. If there is only a single entity that Mary recommended, then the FR will be equivalent to a singular definite. And if there is more than one entity, then the FR will denote the single entity composed of all entities that Mary recommended, which amounts to a universal interpretation.[26]

5.3 Transparent free relatives

Intuitively speaking, we may say that the *wh*-element in a FR constitutes the link between the relative clause CP and the containing matrix structure. This is true regardless of whether this link is mediated by some empty pro-head or by anything else. There is, however, a very special type of free relative in which the initial *wh*-element (always *what*) is almost like a dummy element, while the relative clause contains a small-clause predicate that has most of the properties of the pivotal element, the element that provides the link between the relative clause CP and the matrix structure. Without prejudice to the formal analysis of such free relatives, which will be discussed in section 6, I will call this pivotal or link element the 'shared element' or 'shared structure'. This type of relative clause, which has been dubbed 'transparent free relative' (TFR) by Wilder (1999), can be exemplified by (67):[27]

(67) *What appeared to be **a jet airliner*** had landed on the freeway.

The TFR is in italics, and the boldfaced noun phrase is the shared constituent. TFRs are different from regular FRs in a variety of ways, and most of the differences have to do with the presence of a shared element that is distinct from the *wh*-element. The following is a succinct list of such properties:[28]

(i) **Indefinites allowed.** FRs are either definite or universal (cf. section 5.2), but an indefinite predicate nominal expression can turn a TFR into an indefinite. (67) does not mean 'the thing that looked like a jet . . .' but rather 'something that looked like a jet . . .' or even, more directly, 'a jet airliner had landed on the freeway'. That this is so is demonstrated further by the fact that TFRs are permitted in contexts that are diagnostic for indefinites, such as *there*-insertion constructions:

(68) a. There was a jet on the freeway.
b. *There was the jet on the freeway.
c. *There was what had incurred extensive engine failure on the freeway.
d. There was what appeared to be a jet on the freeway.

(ii) **Intensional modifier.** The meaning of the TFR minus the shared constituent is that of a hedge or an intensional modifier. In that sense, the TFR is similar to that of adjectives like *alleged*:

(69) a. They served me what they euphemistically referred to as a steak.
b. They served me an alleged steak.

Both (69a) and (69b) leave open the possibility that the entity in question is not what the noun says it is. That is, in both cases this entity may well not be a steak.

(iii) ****-ever.*** As is to be expected on the basis of property (i), *-ever* cannot be suffixed to the *wh*-element in a TFR:

(70) *There was whatever appeared to be a jet on the freeway.

(iv) **Plural agreement.** When used as a subject, the *what* of a TFR can trigger plural agreement on the verb, which it can never do in regular FRs:

(71) a. What *seems/seem to be several jets *was/were landing on the freeway.
b. What pleases/*please me most adorns/*adorn the living room wall.

(v) **Reference to [+human].** In TFRs, *what* can refer to humans, which is impossible in regular FRs:

(72) a. She invited what I took to be a policeman to stay overnight.
b. *She invited what was carrying a baton and a gun to stay overnight.

(vi) **No island sensitivity under extraction.** Extraction, for example by *wh*-movement, out of some constituent contained in a headed relative or a FR is prohibited by island constraints (specifically, the Complex Noun Phrase Constraint subsumed under Bounding Theory). However, extraction out of a TFR is acceptable or only weakly deviant:[29]

(73) a. *Who did you order a picture that represented the sole possession of?
b. *Who did you order what represented the sole possession of?
c. Who did you order what was advertised as a first-rate picture of?

(vii) **Conjunction of (un-)likes.** As is well known, only constituents of identical categorial status can be conjoined under coordinate conjunction. Consider now a TFR with a predicate adjective. If we interpret such a relative clause from the point of view of a regular FR, the categorial status will be determined by the *wh*-word (*what*); that is, it will count as a noun phrase. But if the predicative adjective determines the categorial status, the clause will have the distributional properties of an AP. With this in mind, consider (74):

(74) a. *He dislikes trains and what I consider inconvenient.
b. He dislikes trains and what I consider an equally inconvenient alternative.
c. He dislikes trains and what the government proposes to replace them with.

(74a, b) are TFRs, while (74c) is a regular FR. On the assumption that it is the predicate that counts, (74b) is OK since two noun phrases are conjoined, while (74a) is ungrammatical because an NP is conjoined with an AP. Note, in fact, that (74a) can, with some difficulty, be interpreted as a regular FR: he dislikes trains and anything that I consider inconvenient. While such a reading may not be the most plausible one, (74a) is grammatical on that reading. There is a complication here, however. The verb *dislike* subcategorizes NPs and not APs. Hence, on the TFR-reading, (74a) is ungrammatical regardless of conjunction of unlikes because it includes the substatement **he dislikes inconvenient*. This is important in its own right, of course, but the full force of the 'conjunction of unlikes' argument can be seen in an example like the following:

(75) a. *The creature changed from a frog and slimy into a prince and radiant.
b. *The creature changed from a frog and what can only be termed slimy into a prince and what truly deserves to be called radiant.
c. The creature changed from a frog and a slimy abomination into a prince and a prospective lover.
d. The creature changed from a frog and what can only be termed a slimy abomination into a prince and what truly deserves to be called a prospective lover.

(viii) **Idiom chunks.** The small-clause predicate in the TFR can be an idiom chunk that is part of a matrix idiom expression:

(76) a. Nick$_i$ lost what according to the dictionary are called his$_i$ marbles.
b. (*)Nick$_i$ lost what his$_i$ marbles cost in the store.

Note that (76b) is in principle grammatical as a regular FR, but the idiomatic reading disappears completely.

(ix) **Bound anaphors.** Similarly, bound anaphors that are part of the small-clause predicate can be bound by an antecedent in the matrix structure, which is impossible in regular FRs:

(77) a. They$_i$ live in what is often referred to as each other's$_i$ backyard.
b. *They$_i$ live in what Fred uses each other's$_i$ backyard for.

(x) **Case matching.** While in regular FRs it is the *wh*-word/phrase that is subject to case-matching requirements (cf. section 4.2), in TFRs it is the predicate nominal in the small clause that is subject to such a restriction. Predicate nominals only occur in the nominative and in the accusative, hence dative and genitive play no role here:

(78) a. Gestern ist was als ein$_{nom}$ Meteorit identifiziert wurde^{nom} bei uns eingeschlagen^{nom}.
yesterday has what as a meteorite identified was near us struck
'Yesterday, what was identified as a meteorite struck at our place.'

b. Gestern ist was Experten als $\begin{Bmatrix} *\text{ein}_{nom} & \text{Meteorit}_{nom} \\ ??\text{einen}_{acc} & \text{Meteoriten}_{acc} \end{Bmatrix}$ identifiziert haben^{acc} bei uns eingeschlagen^{nom}.
yesterday has what experts as a meteorite identified have near us struck
'Yesterday, what experts identified as a meteorite struck at our place.'

c. Wir haben was als $\begin{Bmatrix} ??\text{ein}_{nom} & \text{Meteorit}_{nom} \\ *\text{einen}_{acc} & \text{Meteoriten}_{acc} \end{Bmatrix}$ identifiziert wurde^{nom} gesehen^{acc}.
we have what as a meteorite identified was seen
'We have seen what was identified as a meteorite.'

d. Wir haben was Experten als einen$_{acc}$ Meteoriten$_{acc}$ identifiziert haben^{acc} gesehen^{acc}.
we have what experts as a meteorite identified have seen
'We have seen what experts identified as a meteorite.'

(79) a. Gestern ist was als eine$_{nom}$ Sternschnuppe identifiziert wurde^{nom} bei uns eingeschlagen^{nom}.

b. Gestern ist was Experten als eine$_{nom/acc}$ Sternschnuppe identifiziert haben^{acc} bei uns eingeschlagen^{nom}.

c. Wir haben was als eine$_{nom/acc}$ Sternschnuppe identifiziert wurde^{nom} gesehen^{acc}.

d. Wir haben was Experten als eine$_{acc}$ Sternschnuppe identifiziert haben^{acc} gesehen^{acc}.

In (78a, d) the matrix and the TFR case requirements (both indicated by superscripts on the verbal complex) are identical. Hence, matching is satisfied. In (78b, c) we have conflicting requirements. No matter what case we have on the predicate nominal, the result is degraded. There does seem to be a contrast, however in that the TFR requirement is absolute, while non-matching in the matrix yields only mild deviance.[30] (79) contrasts minimally with (78) in that the masculine noun *Meteorit* has been replaced by the feminine noun *Sternschnuppe*. In the feminine paradigm, there is no distinction between the nominative and the accusative forms. In other words, we have case syncretism. As observed before for regular FRs, syncretism resolves the case conflict, and hence we have a grammatical result for all examples.

(xi) **Inflection.** The predicate constituent in the TFR sometimes inflects as if it were part of the matrix rather than part of the relative clause. A straightforward case of this phenomenon is found with adjectives in Dutch. Predicate adjectives in Dutch are uninflected, but attributive adjectives must be inflected. Roughly speaking the rule is that an attributive adjective must be inflected by the suffix *-e* ([ə]) unless the noun it modifies is indefinite neuter singular:

(80) a. Deze auto is duur/*dure.
this car is expensive
'This car is expensive.'
b. een *duur/dure auto
an expensive car
'an expensive car'

This pattern shows up in identical fashion in TFRs:[31]

(81) a. Deze auto is wat je duur/*dure zou kunnen noemen.
this car is what you expensive could call
'This car is what you could call expensive.'
b. een wat je zou kunnen noemen *duur/dure auto
a what you could call expensive car
'a what you could call expensive car'

From the point of view of adjectival inflection, then, we may say that the adjective, which is ostensibly inside the relative clause, acts as if it were fully a constituent of the matrix structure. Observe, however, that the adjective must also be a constituent of the relative clause, because otherwise the relative clause is incomplete: [*what you could call *(expensive)*]. This then is another simple, straightforward piece of evidence that the small-clause predicate in a TFR is 'shared' between the matrix and the relative clause.

6 Matching and the syntactic representation of free relatives

Matching phenomena are among the most salient properties of FRs (cf. section 4), and accordingly one of the main analytical questions is how these matching phenomena are to be accounted for. Perhaps the most salient issue here is whether the link between the relative clause and the matrix is a direct one or an indirect one. Consider a simple example (cf. (4)):

(82) You should return *what you have finished reading* to the library.

On the direct approach, the *wh*-word/phrase of the relative clause is at the same time part of, or at least accessible to, whatever syntactic and semantic requirements the matrix clause imposes, in this case subcategorization of a direct object and accusative case. The alternative is to assume that there is an empty head, which acts as an intermediary between the relative clause and the matrix. As before (cf. section 4.2.3), we may call the former type of analysis the Shared Structure Hypothesis (SSH) and the latter type the Distributed Structure Hypothesis (DSH). On the DSH, the relevant properties of the *wh*-element (category, case, person, number, etc.) are present as features on the empty head, and it is the empty head which is responsible for any checking or

licensing processes that are relevant for the matrix structure. On the SSH, the empty head plays no such role and may well be entirely absent in that the *wh*-element is directly accessible to any checking or licensing imposed by the matrix. Both hypotheses can be defended and have been defended, as was shown in section 3.

The existence and the properties of TFRs, which were discussed in section 5.3, shed new light on this issue, however. As was shown, it is the small-clause predicate which constitutes the link with the matrix environment, whereas the clause-initial *wh*-element is, in a sense, a dummy element, which plays no role in the matching process. The question then is whether it is plausible to assume that there could be a relation, a kind of agreement process, between the small-clause predicate and the empty head of the TFR. If we examine again the various properties of TFRs listed in section 5.3, we immediately see that such an indirect approach is quite implausible. Perhaps the single most impressive argument comes from the fact that the small-clause predicate can be inflected like a matrix element, as shown in (81). Without further discussion, we will therefore assume that the SSH is to be preferred for TFRs. Furthermore, given that we have to find a way to implement the SSH, we will also assume that regular FRs are to be accounted for in terms of the SSH.[32] A further extension of the SSH, and of the insights derived from TFRs in particular, is that internally headed relatives may now be directly interpreted as relative clauses in which the internal head is shared with the matrix structure (cf. (1)).[33]

The implementation of the SSH is far from trivial. In order to see this, consider the case of a TFR with a shared attributive adjective such as the one in (81), repeated here for convenience:

(81) a. Deze auto is wat je duur/*dure zou kunnen noemen.
b. een wat je zou kunnen noemen *duur/dure auto

The DP in (81b) consists, linearly, of the following constituents:

(83) $[_{DP}$ D^{o} CP N]

But what is missing here is the fact that the noun in (81b) is modified by an attributive adjective. Hence, perhaps the correct way of describing the structure is (84):

(84) $[_{DP}$ D^{o} CP AP N]

But both of these structures are very problematic. First, both assume that full, finite CPs are permissible in the prenominal position, even though in the languages in question (English, Dutch, etc.), regular relative clauses always have to follow the noun. Second, as we have seen, there is an AP missing in (83), whereas in (84) the AP, that is, the small-clause predicate in the TFR, is missing inside the CP, which is therefore incomplete and should be as ungrammatical as, say, **a man whom Mary described as*.[34] One way to put this problem is that from the point of

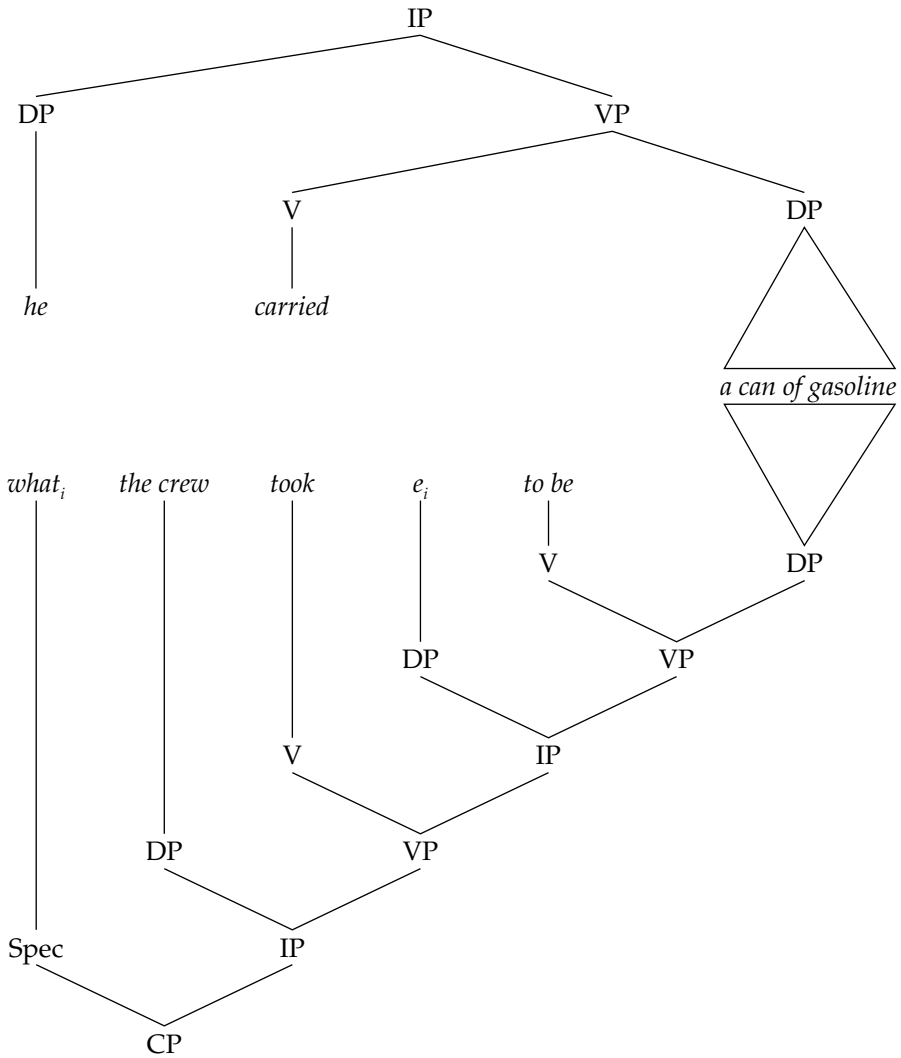
view of the DP, the CP should be invisible (except for its AP), whereas from the point of view of TFR (the CP), the AP should not be missing. That is, we have a classical case of conflicting tree structures here, and one way to resolve such conflicts is to assume that, just as in the case of reanalysis, a single string of terminal elements (words) can be associated with more than one tree structure.[35]

Pursuing this idea, consider the following TFR, adapted from an example by Kajita (1977):

(85) He carried what the crew took to be a can of gasoline.

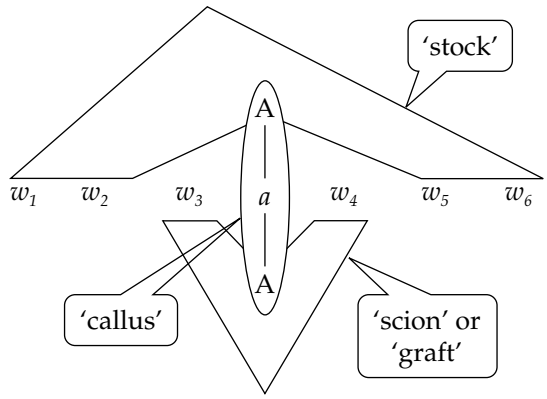
Such a TFR could then be represented by the following 'multidimensional' tree structure:

(86)



The arguments for such an approach have been explored in Van Riemsdijk (1998d, 2000, 2001). In these works, a terminology is also suggested to describe complex tree structures such as (86). For this purpose, the botanical metaphor of 'grafting' has been used. Accordingly, we can call the shared constituent the 'callus', the host tree is called the 'stock', while the subtree which is grafted onto the stock is called the 'graft' or the 'scion'. Graphically:

(87)



Needless to say, a proposal along such lines is far from unproblematic. First of all, a more formal theory of such representations must be developed. It is believed that a framework such as that presented in Moltmann (1992) would be a likely candidate for this task. The formalism which is chosen will then have to form the basis for substantive restrictions on the types of representations that are allowed under such a theory of grafting. Among many other considerations, it is important to recognize that there is an asymmetry between the stock and the scion, in that the former constitutes the matrix structure and the latter the embedded insert. One important aspect of this asymmetry shows up when we consider linearization. Indeed, if we look at a structure like (86), the question immediately arises as to how the conflicting lines of terminals should be linearized: the upper before the lower or vice versa? The answer has to be that the terminal elements constituting the scion are pronounced adjacent to, that is, directly before and after, the callus.

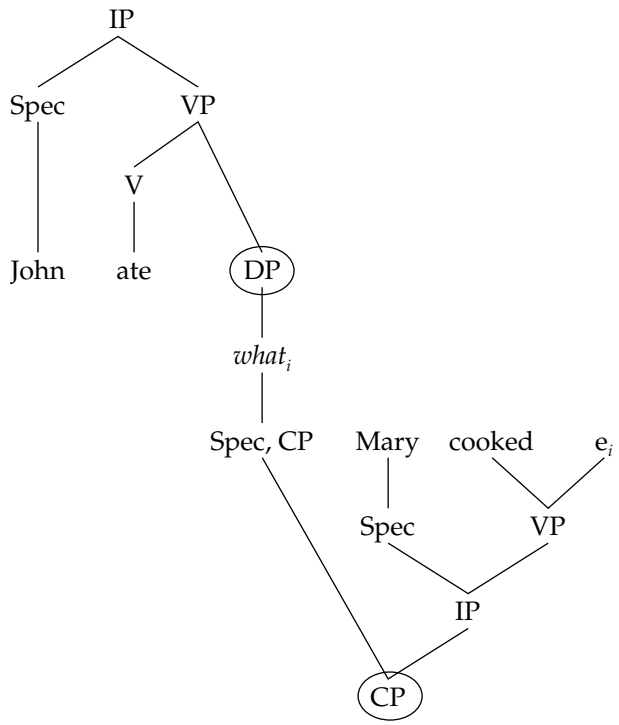
A second aspect that must be taken into account is the fact that matching is sometimes not fully realized. The simple assumption would be that for two syntactic trees to be grafted together by the 'fusion' of two substrings of terminal elements, the terminals in question have to be fully identical. But that is too simple. Consider again, for example, the Dutch example (81). In (81b) we have an apparent mismatch in that the stock (the matrix) requires the inflected form of the attributive adjective (*dure*), while the scion (the TFR) requires the uninflected form of the predicative adjective (*duur*). But in this case, we might be able to solve the problem by taking into account the morphological structure. Suppose the relevant part of the stock has a structure something like [$_{\text{DegP}}$ [$_{\text{AP}}$ *duur*] [$_{\text{INFL}}$ *-e*]]. We might then say that the predicative adjective in the scion has

the structure [$_{DegP}$ [$_{AP}$ *duur*] [$_{INFL}$ -ϕ]] and that the grafting process affects just the AP, not the DegP, leaving the INFL markers in the respective substructures. Needless to say, this would only be possible if one of the two morphological markers is -ϕ. It is unlikely, however, that the cases of imperfect matching in which either the stock or the scion is dominant in imposing its morphology, as discussed in section 4.2.2 as well as in connection with example (78) and note 29, can all be accounted for in this manner. It is important to recognize, though, that such cases of imperfect matching require stipulative solutions on the alternative analysis according to the DSH.

But once we have taken the radical step of adopting the grafting approach, it is natural to extend the theory of grafting to regular FRs as well, thereby implementing the Shared Structure Hypothesis for FRs. A simple FR such as (88) will then be represented as in (89):[36]

(88) John ate what Mary cooked.

(89)



7 Conclusion

Free relatives exhibit a considerable number of properties that deserve the attention of syntacticians. The most salient of these is a variety of types of matching

phenomena which raise a number of fundamental questions as to whether they have a head at all, and, if they do, what the nature of that head is. Depending on the answer to this question, we may be led to revise the theory of phrase structure in such a way that grafted structures with multiple connected trees such as those discussed in section 6 must be permitted to exist.

NOTES

Thanks are due to Alex Grosu and Paul Hirschbühler for helpful discussion and suggestions for improvement respectively. My knowledge of and thinking about free relatives has been influenced by literally dozens of colleagues and friends over almost a quarter century now. To all of them I can now only extend a collective thank you.

1 Within certain limitations, PPs, CPs, and APs can also be modified by a relative clause, as in:

   (i) They left the books downstairs, which is not the safest place for them to be.

   (ii) John wondered whether to trust the FBI, which is a rather stupid thing to ask yourself.

   (iii) Bill turned out to be quite intelligent, which is a quality not often found in his family.

   Note, however, that these are constructed most easily if the relative clause contains a noun (here: *place* and *quality* respectively) which, in a sense, translates the PP or AP into an NP. Furthermore, relative clauses of this kind are always non-restrictive. Free relatives (FRs), on the other hand, can be formed on NP/DP, AP, and PP, though various restrictions apply there as well (see, for example, section 4).

2 It should be noted, however, that this is not the only way to construct relative clauses in Japanese. In fact, internally headed relative clauses are rather restricted in their use. See, among many others, Kurosawa (2003) for discussion and references.

3 In other languages, the embedded position is occupied by a so-called resumptive pronoun, and there is no special pronoun which is moved to a position adjacent to the head of the relative clause (see chapter 55).

4 In actual fact, the distinction between questions and FRs is not quite as unproblematic as the text argument suggests. See section 5.1 for more discussion.

5 The Head Hypothesis has precursors in Bresnan (1973a) and Hirschbühler (1976b). Rooryck (1994b) points out that the term 'Head Hypothesis' is potentially misleading, since it might suggest that the head is a category of type X^o rather than XP; in the present text we will continue to use the term Head Hypothesis, however.

6 The COMP Hypothesis was first introduced in Kuroda (1968a). It was also defended in Hirschbühler (1978) and received further support in Rooryck (1994b), and in Jacobson (1995) and earlier unpublished materials by the same author cited there. This hypothesis has been adopted most frequently in the current literature.

7 If a raising analysis of relative clauses is assumed, this assumption is challenged.

8 The examples are taken from Groos and Van Riemsdijk (1981: 177). In these examples, genitives have not been included because of the severe limitations on their occurrence in modern German.

9 Things are slightly more complex in that it might be better to say that Heavy NP Shift does exist but is limited to stylistically highly marked contexts. The text argument is not affected by this complication, however, since the extraposition of FRs is not stylistically limited in any way.

10 It might be objected that (23a) is ungrammatical for independent reasons, namely the fact that the extraposed relative clause lacks a complementizer. That is, (23a) could be ungrammatical for the same reason as (ib) without *that* is:

(i) a. I'll take the book (that) you gave me into consideration.
b. I'll take the book into consideration *(that) you gave me.

Note, however, that the argument rests primarily on the grammaticality of (23b), and note furthermore that the obligatory absence of the complementizer in FRs on the HH is a puzzling aspect of that analysis in the first place, as will be discussed in the text directly.

11 This was pointed out in Groos and Van Riemsdijk (1981). See also Grosu (1994) for discussion.

12 The relevance of this particular consideration in the present context is attributed in Grosu (1994) to an unpublished talk by Polly Jacobson.

13 For a much more differentiated and detailed discussion, see Grosu (1994).

14 I am using a single question mark here to accommodate the more liberal speakers, but in actual fact many speakers would find '?*' or even '"*" more appropriate. Furthermore, languages tend to differ considerably with respect to the extent to which such restrictions are imposed. See Grosu (1994) for an overview of a range of languages including German, Hebrew, French, and Romanian.

15 The examples given here are cited in Grosu (1994). (44a, c) are taken from Paul (1920).

16 One might object that the lexical representation of a form like *was* could be an underspecified feature matrix. Suppose, for example, that nominative and accusative are [−oblique] in German, as opposed to genitive and dative. Suppose furthermore that there is a second feature, say [accusative], that distinguishes the nominative and the accusative. A form like *wer* would then be [−obl, −acc], but *was* could be underspecified and have the representation [−obl]. By non-distinctness, [−obl] would satisfy both nominative and accusative contexts. An approach along such lines is questionable, however, for a number of reasons. To mention just one, *was* must be fully specified for the purposes of subject–predicate agreement, as shown by the following contrast:

(i) a. Was_{nom} ist ein_{nom} guter Wagen?
what is a good car
b. *Was_{acc} nennst Du ein_{nom} guter Wagen?
what call you a good car

a′. *Was_{nom} ist $\text{einen}_{\text{acc}}$ guten Wagen?
b′. Was_{acc} nennst du $\text{einen}_{\text{acc}}$ guten Wagen?

Beyond such considerations, theoretical questions may be asked about the degree of language specificity of the feature systems involved in case morphology, about the compatibility of underspecification with checking and/or assignment approaches to case features, etc. But such considerations are beyond the scope of the present survey.

17 The examples from Classical Greek in this section are cited from Hirschbühler (1976a). The sources he gives are as follows. (50) is X.A.1.9.25, cited from J. Hadley and F. Allen, *A Greek Grammar*, New York 1912, section 996, a, 2. (51) is Aesch. 2,117, cited from W. Goodwin, *A Greek Grammar*, Ginn 1892, § 1033. (52) is X.A.1.3.17, cited from H. Smyth, *Greek Grammar*, Cambridge: Harvard University Press 1956, § 2522, b. And (53) is L.19.14. cited from Goodwin, *Greek Grammar*, § 1035. The Latin example (54) I have taken from Grosu (1994), who cites it from F. Schwyzer, *Griechische Grammatik*, Munich 1950, section II, 641.

18 See note 17.

19 See note 17. Grosu (1994) also cites some examples from what he calls archaic German, the examples again being taken from Schwyzer, *Griechische Grammatik*, 16, as well as from H. Paul, *Mittelhochdeutsche Grammatik*, Tübingen 1904, § 345. Without going into details, these examples are indicative of the limitations that such cases of upward attraction are subject to. Four of the five cases are correlative in nature, which means that it is the correlative pronoun which occupies the matrix position and has the appropriate, i.e., unattracted, case. The head of the relative clause is correspondingly a kind of left-dislocated noun phrase and much freer to have its case determined by outside forces. Also, in four of the five cases the competing case is the nominative.

20 Interestingly, the sensitivity of subject–predicate agreement noted in note 16 is also found in cases of downward attraction. An instructive example is discussed in Quicoli (1972), who took it from Andrews (1971). The importance of such examples for the theory of FRs was discovered in Hirschbühler (1976a). Consider the following example (P.C. 50, a, cited in Smyth, *Greek Grammar*, 16:

(i) a. emmenomen hois$_{dat}$ hômologêsamen dikaiois$_{dat}$ ousi$_{dat}$ ê ou
we abide by- those we-have-agreed just being or not
'Do we abide by those things which we consider just, or not?'
b. emmenomen toutois$_{dat}$ ha$_{acc}$ hômologêsamen dikaia$_{acc}$ onta$_{acc}$ ê ou

It would appear that any analysis in which the case on the relative pronoun starts out as an accusative and is then attracted to a dative under influence of the matrix structure must be problematic, because subsequent (re)application of case agreement between that *wh*-element (or its trace) and the predicative modifier will flagrantly violate the strict cycle condition, or what replaces it in more recent syntactic frameworks.

21 More generally, as argued in Izvorski (2001), such concessive free relative clauses have the status of free adjuncts. Izvorski argues that these should be analyzed as bare CPs, thereby accounting for the possibility of multiple *wh*-elements, which are absent in other types of FRs. It should be noted here that under an analysis in terms of grafts, as suggested in section 6, and in particular in connection with (89), all FRs are considered to be bare CPs. The difference would then be that free adjunct FRs, unlike the other types of FRs, do not have their *wh*-word grafted onto some XP-position in the matrix clause.

22 See Wiltschko (1998) for some related discussion.

23 There are several other distinctions between headed relative clauses and FRs that deserve to be mentioned. First, the structure of the *wh*-phrase tends to be more limited in FRs than in headed relatives. For English, such differences are minimal, but in Dutch and German, for example, only simplex *w*-words can introduce an FR. The following examples are from German:

(i) Ich esse was/*welche Speisen Maria mir serviert.
I eat what/whichever dishes Maria me serves
'I eat whatever (dishes) Maria serves me.'

A second remarkable difference concerns the finite vs. infinitival distinction. In many languages, including English, relative clauses can sometimes be infinitival. FRs however, at least in English, cannot be infinitival, as shown by the following contrasts:

(ii) a. The books that/which you should read are lying on the table.
The books (*that/*which) (for you) to read are lying on the table.
What/whichever books you should read is/are lying on the table.
*What (for you) to read is lying on the table.

24 There is a second distinction that is more or less tangential to our main concern, viz. the distinction between realis FRs and irrealis FRs (cf. Grosu and Landman 1998). This distinction is not found in English or any of the other Germanic languages, which only have the normal, realis, type of FR, but it does exist in Romance, Slavic, and Semitic. Irrealis FRs look like normal FRs except that they exhibit an irrealis verb form. (i) is an example from Romanian, example (78b) in Grosu and Landman (1998):

(i) Nu mai avem ce locuri moi să vizită m.
not more have-we what places new SUBJUNCTIVE visit
'There are no longer any places for us to visit.'

Grosu (1994) argues that irrealis FRs differ in a number of significant ways from ordinary FRs:

- There are no matching effects such as those found in regular (realis) FRs; cf. section 4.
- Unlike realis FRs, irrealis FRs allow multiple *wh*-phrases (and in this sense the adjunct FRs discussed in section 5.1 are perhaps more like irrealis FRs):

(ii) Nu mai avem pe cine cu cine împerechia.
not more have-we ACC who with who to-match
'We no longer have any pairs to match.' (said by an unsuccessful matchmaker)

Note, finally, that the absence of infinitival FRs remarked upon above does not extend to irrealis FRs. This is shown in (ii), and a French example such as (iii) may also be an instance of an irrealis FR:

(iii) Je n'ai pas où aller.
I have not where go
'I do not have any place to go to.'

25 The main references for the semantics of FRs are Jacobson (1995) and Grosu and Landman (1998).

26 Grosu and Landman (1998) build on this proposal and extend it to an overall typology of relative clauses. More specifically, they define a type of relative clause which they call *maximalizing relatives* and which they show includes degree or amount

relatives, free relatives, (certain) internally headed relatives, and correlatives. Dayal (1995, 1997) further argues that definite FRs (identity FRs) and universal FRs (free-choice FRs) are both definite, and that *-ever* contributes a modal dimension to the interpretation of the definite description by ensuring that it denotes a generalized quantifier that includes only those properties that are true of the bearer, regardless of identity.

27 The special status of TFRs has apparently first been noticed by Nakau (1971). Further discussion can be found in Kajita (1977), McCawley (1988), Wilder (1998, 1999), Van Riemsdijk (1998d, 2000, 2001), and Grosu (2002).

28 Properties (ii) and (vii) are from McCawley (1988) and Kajita (1977) respectively. Properties (i) and (iii–vi) are from Wilder (1998, 1999), while properties (viii–xi) are from Van Riemsdijk (2000, 2001).

29 A similar and in certain ways even more instructive case concerns rightward detachment of PPs out of noun phrases in Dutch, a necessary condition in order for extraction of *wh*-elements out of such a PP to be possible. In other words, in order for extraction to be possible in (ia), the PP must be detached as in (ib), while extraction in (ic) is prohibited. See Van Riemsdijk (1997b) for discussion:

(i) a. Waar heb je de conceptversie (gisteren) ___ van afgewezen?
what have you the draft version (yesterday) ___ of rejected
'What did you reject the draft version of?'
b. wh_i . . . [$_{NP}$ X] . . . [$_{PP}$ e_i *van*]
c. *wh_i . . . [$_{NP}$ X [$_{PP}$ e_i *van*]]$_{NP}$

If we apply this rightward detachment of the PP to a PP that is part of the predicate nominal in a TFR, it turns out that the landing site of the detached PP must be in the matrix structure in order for extraction to be possible, whereas extraction out of a rightward-detached PP inside the relative clause yields strongly ungrammatical results:

(ii) a. Waar heb je [wat hij een conceptversie noemde] gisteren van
what have you what he a draft called yesterday of
afgewezen?
rejected
'What did you reject what he called a draft version of?'
b. *Waar heb je [wat hij een [conceptversie ___] [___van] noemde] afgewezen?

30 It is not entirely clear whether this contrast is comparable to the phenomena of imperfect matching observed in section 4.2.2, or whether the contrast is rather an illusion that stems from the fact that the apparent TFR can also be interpreted as a regular FR, in which case the *was* is the element that trivially (due to nom/acc-syncretism) satisfies the conflicting case requirements.

31 Note, incidentally, that the word order within the relative clause is different in the two cases because in (81a) the predicative adjective precedes the verb while in (81b) it follows it. As a matter of fact, in the predicative case (81a) both orders are possible, while in the attributive case only the order V-PRED is possible. There is a simple reason for this contrast. As is the case in many languages, including English, prenominal attributive adjectives must be adjacent to the noun (**the proud of his father boy*). German, which, like Dutch, is verb final, lacks this possibility of extraposing the

small-clause predicate of the TFR. Consequently, attributive adjectives in German can never be modified by a TFR.

32 See Grosu (2002) for a defense of the DSH.

33 It is interesting to note that the notion of 'shared elements' also plays a central role in the analysis of Japanese (internally and externally) headed relative clauses within the framework of Dynamic Semantics presented in Kurosawa (2003).

34 Wilder (1999) proposes to adopt (84), but with a second, identical, occurrence of the small-clause predicate inside the CP. Backward deletion then applies to that small-clause predicate. Such an analysis is problematic, however (cf. Van Riemsdijk 2001). One of the problems concerns the position of the deletion site. Backward deletion (like Right Node Raising, for example) is subject to the constraint that backward deletion can only apply to right-peripheral elements. But the shared element in TFRs need not be clause-final at all, as is shown among other things by German examples such as (78) and (79).

35 In addition to reanalysis (as frequently assumed for pseudo-passives like *this must be looked into* or *John was taken advantage of*), there are various other syntactic phenomena of this kind (see Lakoff 1974b for an early discussion of such phenomena). A simple example from Kajita (1977) illustrates a case which is quite similar to that of TFRs: the *far from* construction. In examples like (i):

(i) a far from simple matter

simple is the semantic head, and it is also the syntactic head in that it is adjacent to the noun, as required by the general adjacency requirement on attributive adjectives. Nevertheless, if *simple* is the head, then what could *far from* be? It is a non-constituent, and it certainly looks as if *far* takes a PP-complement, as it regularly does, and that the preposition *from* takes an adjectival complement, as it is known to do. As is argued in Van Riemsdijk (2001), this case can also be resolved by means of multiple tree structures being associated with a single string of terminals.

36 A proposal for a multidimensional analysis of FRs which is quite similar to the proposal sketched here is Citko (1998).

  4.4 Absence of Freezing
5 Conclusion

1 Introduction

This chapter discusses the phenomenon of Freezing. Freezing is an island effect that is associated with certain movement-derived structures. The general idea is that a phrase from which, in principle, an element can be extracted turns into an island for extraction when that phrase has been involved in some movement process, either as the moved item or as the site to which the moved phrase gets attached. Thus, phrases that have been moved become islands for extraction;

they get frozen, so to speak. And phrases to which an element has been attached via some movement operation also turn into islands (i.e., frozen domains).

The organization of this chapter is as follows. In section 2, two early generative studies will be presented that discuss the phenomenon of Freezing, namely Ross (1974b) and Wexler and Culicover (1980). Section 3 discusses the frozenness of moved constituents and section 4 deals with the frozenness of certain movement-derived configurations (involving adjunction).

2 Ross's ISP and Wexler and Culicover's Freezing Principle

2.1 The Immediate Self-Domination Principle

As Ross pointed out in his seminal dissertation (1986, dissertation 1967), certain phrase structure configurations are inaccessible to transformational rules. These island effects led to the formulation of a number of constraints in linguistic theory, such as the Complex NP Constraint, the Sentential Subject Constraint, and the Coordinate Structure Constraint. In Ross (1974b), the question was raised whether (some of) the island constraints could be subsumed under a more general island constraint. He argued that the Complex NP-configuration (CNPC) and the Coordinate Structure configuration (CSC) shared one phrase structural property: the containing node out of which an element is removed is a self-dominating node, i.e., a node which immediately dominates another node of the same type. This is illustrated in (1):

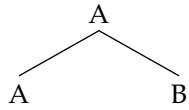
(1) a. $[_{NP}\ [_{NP}$ the fact] $[_{S}$ which they uncovered]]
b. $[_{ConjP}\ [_{ConjP}$ his socks] or $[_{ConjP}$ his gloves]]

The CNPC and the CSC were unified under what Ross called the Immediate Self-Domination Principle:[1]

(2) **The Immediate Self-Domination Principle (ISP):**
No element may be Chopped out of a node which immediately dominates another node of the same type.

Given the fact that self-dominating nodes represent Chomsky-adjunction configurations, the ISP states that extraction of a constituent out of an adjoined structure is prohibited. Schematically:

(3)



As implied by the ISP, islandhood holds not only for base-generated adjunction configurations, but also for movement-derived adjunction configurations. Ross illustrates this with the island-creating effect of the transformational rule Complex NP-Shift, which moves a constituent to the right of the clause:[2]

(4) a. She will send [a picture of the Waco Post Office] [to Inspector Smithers].
b. She will send t_i [to Inspector Smithers] [a picture of the Waco Post Office]$_i$.

(5) a. [The Waco Post Office]$_j$ she will send [a picture of t_j] [to Inspector Smithers].
b. ??[The Waco Post Office]$_j$ she will send t_i [to Inspector Smithers] [a picture of t_j]$_i$.

As Ross (1974b: 103) observes, "it is more difficult to chop constituents from the shifted constituent than it is to chop them from an unshifted one."[3] Compare (5a) and (5b). The ISP accounts for this contrast: After NP-shift, we get a phrasal S-node which immediately dominates another S-node; removal of a constituent out of this (S-)adjunction configuration is blocked.

2.2 *The Freezing Principle and the Raising Principle*

The island-creating effect of certain movement operations was independently observed by Wexler and Culicover (1977, 1980), who proposed a theory of locality on the basis of learnability considerations. They discern two types of 'frozen' nodes:

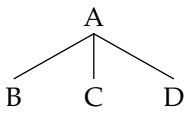
- nodes that are frozen because they are non-structure preserving (i.e., having a non-base-immediate structure) (frozenness because of the so-called Freezing Principle (see (7));
- nodes that are frozen because they are moved/raised (frozenness because of the Raising Principle (see (9)).

The first type of frozen node is the result of the application of a non-structure-preserving adjunction operation: a syntactic node gets frozen if a transformation changes the structure of that node so that it is no longer a base structure. Thus, those nodes that represent derived structures that are not base generable form islands for transformational rules. Such rules which derive a non-base-generable node A are dubbed rules which are 'non-structure-preserving at a node A'. This notion is the opposite of 'structure-preserving at a node A', which is defined as follows (definition taken from Culicover 1982):[4]

> A transformation is structure-preserving at a node A just in case the structure immediately dominated by A after the transformation has applied to A is a structure that could have been generated immediately below A as a base expansion by the phrase structure rules.

Given this definition, we could say that the derived structure represented by node A in (6) forms an island for extraction, if there is no Phrase Structure rule A → B C D which can base generate this order in the base component of the grammar. That is, the output B C D is non-base generable, but is the result of some transformational rule which is non-structure preserving at node A.[5] Such nodes to which a non-structure-preserving transformation has applied are frozen nodes. The principle of grammar which blocks extraction out of frozen nodes can now be stated as in (7):

(6)



(7) **Freezing Principle (FP) (Wexler and Culicover 1980: 119):**
If a node A of a Phrase-marker is frozen, no node dominated by A may be analyzed by a transformation.

Consider now the following examples:

(8) a. Who_j did John [$_{VP}$ send an expensive book about horned frogs [to t_j]]?
b. *Who_j did John [$_{VP}$ send t_i [to t_j] [an expensive book about horned frogs]$_i$]?

If the base structure of the VP consists of the sequence V NP PP (i.e., VP → V NP PP in terms of phrase structure rules) and if the structural change of Heavy NP-Shift corresponds to the structure [$_{VP}$ V PP NP] – a non-base-generable order – it follows by the definition of 'non-structure preserving' that the VP in which Heavy NP-Shift has applied is frozen. The Freezing Principle in (7) states that it is impossible to analyze this frozen VP. This is illustrated in (8): even though *wh*-fronting may apply to the object of the preposition *to* in (8a), it is impossible to strand the preposition in (8b), a structure in which Heavy NP-Shift has applied. The node to which the adjunction is made, i.e., VP, is frozen.

Let us next turn to the second type of frozen node: that is, a node that is frozen because it has undergone Raising, i.e., (structure-preserving) movement of a constituent from one cyclic domain to another (S and NP being the traditional cyclic domains; cf. Chomsky 1973). More specifically, Wexler and Culicover formulate the locality principle as follows:

(9) **Raising Principle (RP) (Wexler and Culicover 1980: 143):**
If a node A is raised, then no node that A dominates may be used to fit a transformation.

Wexler and Culicover illustrate the application of the Raising Principle with the following example (among others):

(10) a. [$_S$ [$_{NP}$ Some people *from Philadelphia*] greeted me].
b. [$_S$ [$_{NP}$ Some people t_i] greeted me [*from Philadelphia*]$_i$].
c. *[What city]$_j$ did you expect [$_S$ [$_{NP}$ some people t_i] to greet you [$_{PP}$ from t_j]$_i$]?

In (10b), a PP has been extraposed from the cyclic node NP to a sentence-final position within the dominating cyclic node S. As shown by (10c), this PP cannot be analyzed by a transformation like *wh*-fronting. In this respect, it differs from an example like (11), in which the NP has been extracted from a (non-extraposed) PP which is part of an NP occupying a VP-final object position:

(11) This is the only city [*WH*$_j$ that [you have to provide [an analysis [$_{PP}$ of t_j]]]].

Importantly, the derived structure in (10b) (displaying the linear sequence V NP PP) is a possible base structure. Compare, for example, (10b) with example (12):

(12) [$_S$ Some people [$_{VP}$ [$_V$ greeted] [$_{NP}$ me] [$_{PP}$ with enthusiasm]]].

Given the fact that the derived order V NP PP is also a base-generable one, the frozenness of the extraposed PP cannot be explained, then, in terms of the Freezing Principle, which holds for non-structure-preserving contexts. It is the Raising Principle, as stated in (9), which blocks extraction of the complement of P. More particularly, the moved PP is the frozen node.

Since in both cases, frozenness of A implies non-analyzability by transformational rules, the two subcases of freezing may be subsumed as subcases of a generalized Freezing Principle stating (cf. Wexler and Culicover (1980: 542; note 6)):[6]

(13) **The generalized Freezing Principle:**
A node is frozen if (i) its immediate structure is non-base, or (ii) it has been raised.

The essential characteristic of the Freezing Principle is clear from the following quotation from Wexler and Culicover (1980: 120): "In line with the Freezing Principle, we may think of the base grammar as providing *characteristic structures* of the language. Transformations sometimes distort these structures, but only these characteristic structures may be affected by transformations."

2.3 Freezing and the Cycle

Some further illustrations of the frozenness of moved constituents will be given in section 3. First, it is important to note the role of ordering of transformations in a derivation. The frozenness of moved constituents presupposes an ordering on the application of transformational rules. If no ordering were imposed, one

might simply propose an alternative potential derivation of a sentence like (8b) according to which extraction of the complement to P applies before the heavy object NP is shifted rightward. In that case, P-stranding takes place prior to Heavy NP-Shift.

Although originally, ordering was defined at the level of specific transformational rules (rule A applying before rule B, etc.), it was captured by the more general principle of the Cycle as introduced in Chomsky (1964a).[7] In line with this principle, the rule shifting the heavy NP to a position adjoined to VP must apply first, because it involves the smallest domain, viz. VP. The rule which fronts the NP-complement to P must follow PP-extraposition, since it involves a larger cyclic domain, viz. CP. Thus, the Principle of the Cycle will require that rightward movement takes place first in those structural contexts. In the rest of this chapter, the principle of the Cycle is supposed to regulate the transformations in the derivation of the various constructions that will be discussed; the application of this principle of grammar in the derivation of a given construction will not always be explicitly mentioned.

3 The frozenness of raised constituents

3.1 The frozenness of rightward-moved constituents

Consider the following structures that have been argued to involve rightward movement of the phrase in italics. In (14), the phrase *a book about linguistics* has undergone Heavy/Complex NP-Shift. The examples in (15) illustrate PP-extraposition (see chapter 25). (16), finally, exemplifies the phenomenon of CP-extraposition; in these examples, extraposition from within a noun phrase has taken place:

(14) I gave – to John *a book about linguistics*.

(15) a. I saw [a book –] yesterday *about lazy pronouns*.
b. John put his finger – yesterday *into his sister's throat*.

(16) a. John announced [a plan –] yesterday *PRO to fix Mary's car*.
b. John met [a child] yesterday *who read Syntactic Structures*.

The examples in (17) show that after Heavy/Complex NP-Shift, the noun phrase has become an island for extraction. Thus, a rightward-moved noun phrase is frozen:[8]

(17) a. *What$_j$ did you give t_i to John [a book about t_j]$_i$?
b. *Who$_j$ did you see t_i yesterday [some beautiful pictures of t_j]$_i$?
c. *Horned frogs$_j$, John sent t_i to Horace [an expensive book about t_j]$_i$.

The frozenness of extraposed PPs is shown by the ill-formedness of the following examples:[9,10]

(18) a. *[What kind of pronouns]$_j$ did you read [a book t_i] yesterday [about t_j]$_i$?
b. *[Whose throat]$_j$ did John put his finger t_i yesterday [into t_j]$_i$?

Thus, after extraposition of PP, preposition stranding is blocked. As shown in (19), preposition stranding is generally permitted if the PP occupies its base position:

(19) a. [What kind of pronouns]$_i$ did you read [a book about t_i] yesterday?
b. [Whose throat]$_i$ did John put his finger [into t_i] yesterday?

As shown in (16), a clause can be extraposed out of a noun phrase. It is well known that a non-extraposed clause constitutes an island for extraction (cf. Ross's 1986 CNPC). As Wexler and Culicover (1980) observe, there is no complex NP after extraposition of the clause; however, removal of an element from within the clause is still impossible. This is exemplified in (20). This opacity of the extraposed clause follows if moved phrases are frozen, i.e., non-analyzable for subextraction operations (i.e., Wexler and Culicover's RP):[11]

(20) a. *[Whose car]$_j$ did John announce [a plan t_i] yesterday [PRO to fix t_j]$_i$?
b. *[Which book]$_j$ did you meet [a child t_i] yesterday [who read t_j]$_i$?

In short, the above phenomena show that rightward-moved constituents are frozen, i.e., constituents contained within the moved phrase cannot be moved to a position external to it.

3.2 The frozenness of leftward-moved constituents

Let us next turn to those Freezing effects in which the frozen constituent is one which has undergone leftward movement and ends up left-adjoined to some higher phrase. In English, the following examples of embedded topicalization have been analyzed as instances of leftward adjunction to IP (S) (cf. Baltin 1978b, 1982; Johnson 1986; Lasnik and Saito 1992):

(21) a. I think that [reviews of his books]$_i$ John never reads t_i.
b. I think that [articles about vowel harmony]$_i$ you should read t_i carefully.

Under the assumption that the topicalized phrase is adjoined to IP, we get the following structure:

(22) . . . [$_{CP}$ . . . [$_{IP}$ NP_i [$_{IP}$ . . . t_i . . .]]]

This structure would be unanalyzable for further transformations both under Ross's ISP and under Wexler and Culicover's Freezing Principle (or generalized Freezing Principle). Under the ISP, the node IP would be a frozen node, since it is a self-dominating node. Under the Freezing Principle, as defined by Wexler and Culicover, IP would be a frozen node if the adjunction is non-structure preserving.

As shown by the following examples from Lasnik and Saito (1992: 101), extraction out of the clause-internally topicalized noun phrase yields a very marginal sentence (see chapter 23):[12]

(23) a. ??Vowel harmony$_j$, I think that [articles about t_j]$_i$ [$_{IP}$ you should read t_i carefully].
b. ??Who$_j$ do you think that [pictures of t_j]$_i$ [$_{IP}$ John wanted t_i]?

Embedded topicalization also applies to PPs:

(24) I think that [to Mary]$_i$ John gave a book t_i.

As Postal (1972) observed, extraction of the complement to P is impossible (cf. (25a)) in a derived structure like (24). In other words, P-stranding is blocked after the PP has been topicalized within the embedded clause. The islandhood of the moved PP in (24) could also be characterized as a Freezing effect. Of course, extraction is permitted from the base position (cf. (25b)):

(25) a. ?*Who$_j$ do you think that [$_{PP}$ to t_j]$_i$, John gave a book t_i?
b. Who$_i$ do you think that John gave a book [$_{PP}$ to t_i]?

Other ill-formed extraction patterns given in the literature as illustrations of the freezing effect involve (leftward) scrambling. In languages like Dutch and German, it is impossible to remove an element out of a phrase that has been scrambled leftward in the so-called Middle Field of the clause (cf. Webelhuth 1989; Müller 1998). Consider, for example, the contrast between (26) and (27) from Dutch. In (26), the PP-complement to V is in its base position (i.e., the position following the adverbial phrase); extraction of the R-pronoun *daar* from within the PP is permitted (cf. (26b)). In (27), on the contrary, the PP has been scrambled and does not occupy its base position any more. As a consequence, extraction of the R-pronoun out of the PP is impossible:[13]

(26) a. Jan had nog nooit daarvan gehoord.
Jan had yet never there-of heard
'Jan had never heard of it.'
b. Daar$_i$ had Jan nog nooit [t_i van] gehoord.
There had Jan yet never – of heard
'Jan had never heard of it.'

(27) a. Jan had [daarvan]$_i$ nog nooit t_i gehoord.
Jan had there-of not yet – heard
'Jan had never heard of it.'
b. Daar$_i$ had Jan [t_i van] nog nooit gehoord.
There had Jan – of yet never heard
'Jan had never heard of it.'

Adopting an analysis in which the scrambled PP is left-adjoined to the VP, we get a structure like (28):

(28) . . . [$_{IP}$ . . . [$_{VP}$ PP$_i$ [$_{VP}$ ADVP . . . t_i V . . .]]]

Ross's ISP would analyze the VP node as a frozen node, since it is a self-dominating node. Given the frozen status of VP, this structure would be unanalyzable for further transformations. According to Wexler and Culicover's theory, the frozenness of the VP would be attributable to the Freezing Principle. If the VP containing the leftward scrambled PP is non-structure preserving (i.e., having a non-base-immediate structure), it is frozen and therefore unanalyzable for further transformations.

3.3 Freezing and substitution

The Freezing phenomena discussed thus far involve an adjunction configuration (i.e., if one follows the standard approach to these phenomena): a moved phrase XP that has been (left- or right-)adjoined to another phrase YP forms an island for extraction. Of course, one could propose to generalize the frozenness of moved phrases to all moved constituents, i.e., not only phrases that are input to an adjunction operation but also those that are input to a substitution operation. In that case, A-movement of a noun phrase to [Spec, IP] and A'-movement of a phrase to [Spec, CP] would result in frozenness of the moved constituent.[14]

Freezing as a result of A-movement can be illustrated by means of the following examples from German (taken from Müller 1995):

(29) a. Worüber$_j$ ist von keinem [ein Buch t_j] gelesen worden?
About-what is by no-one a book-NOM read been
'No one has read a book about what?'
b. *Worüber$_j$ ist [ein Buch t_j]$_i$ von keinem t_i gelesen worden?

These examples represent passive constructions. In German, the nominative NP can remain in its base (i.e., direct object) position. As shown by (29a), *wh*-extraction of *worüber* from within the nominative NP that occupies its base position is possible. The ill-formedness of (29b) shows that A-movement of the noun phrase to [Spec, IP] turns the raised NP into a frozen constituent; subextraction of *worüber* is not allowed.

As shown by (30), A-movement also induces a Freezing effect in English (cf. Huybregts 1976; Lasnik and Saito 1992; Collins 1994a). Unlike German, English does not permit VP-internal nominative subjects in passive constructions; A-movement to [Spec, IP] is obligatory:[15]

(30) a. *Who$_j$ do you think that [$_{IP}$ [pictures of t_j]$_i$ were painted t_i]?
b. *Which cars$_j$ were [$_{IP}$ [the hoods of t_j]$_i$ damaged t_i]?

Freezing as a result of A′-movement to [Spec, CP] is exemplified in (31) (cf. Johnson 1986):[16]

(31) a. ??[Which guy]$_j$ did you ask [which picture of t_j]$_i$ she bought t_i?
b. ??[Which guy]$_j$ did you wonder [which story about t_j]$_i$ I had told t_i?

Observe that *wh*-movement out of an in situ *wh*-phrase yields a better result:

(32) a. ?[Which guy]$_j$ did you buy [which picture of t_j]?
b. ?[Which guy]$_j$ did you tell me [which story about t_j]?

Given the ungrammaticality of the examples in (29b), (30), and (31), one might want to generalize the Freezing effect to all types of phrasal movement (i.e., A-movement, A′-movement involving adjunction, and A′-movement involving substitution); see Müller (1998) for such a proposal.

3.4 Analyses of the frozenness of moved constituents

3.4.1 Locality

The islandhood of moved constituents has never had a very prominent place in general theories of locality. Other island effects, such as the complex NP-island and the *wh*-island, have received much more attention in attempts to come to a more general, unified theory of locality. Neither Chomsky (1977b) nor Chomsky (1986a) contains a discussion of the phenomenon of freezing. Johnson (1986: 3.2.2) shows, however, that the islandhood of moved constituents follows quite straightforwardly from Chomsky's Barriers theory.[17] After having been moved, a phrase occupies a non-L-marked position (say, non-theta-governed). As a result of this, the phrase forms a Blocking Category (BC) and a Barrier for constituents that are dominated by it. Because the moved phrase is a BC, the maximal projection immediately dominating it (e.g., VP or IP) is also a Barrier. Movement out of constituent that has itself been moved thus crosses two Barriers, and hence violates the Subjacency Condition.

Let us take as an illustration the examples in (17b) and (23b). The derived structures of these sentences is the following:

(33) *[$_{CP}$ Who$_j$ did [$_{IP}$ you [$_{VP}$ [$_{VP}$ see t_i yesterday] [some beautiful pictures of t_j]$_i$]]]?

(34) *[$_{CP}$ Who$_j$ do [$_{IP}$ you think [$_{CP}$ t_j' that [$_{IP}$ [pictures of t_j]$_i$ [$_{IP}$ John wanted t_i]]]]]?

In the derivation of (33), the NP *some beautiful pictures of who* undergoes Heavy NP-Shift and gets adjoined to the VP. Since the shifted NP does not occupy its base position (i.e., sister to V), the NP is not L-marked and hence forms a BC and a Barrier for extraction. When the *wh*-phrase *who* is moved out of the shifted NP to the specifier of the embedded CP, it crosses three Barriers: the shifted NP, the higher VP, and IP.

In (34), the noun phrase *pictures of who* has been topicalized within the embedded clause. It ends up in a position left-adjoined to the IP-node. Extraction out of the topicalized NP to the [Spec, CP] of the embedded clause violates the Subjacency Condition. Two Barriers are crossed: the moved NP is a blocking category and a barrier, since it is not L-marked; the IP to which the moved phrase is adjoined is a barrier by inheritance.

3.4.2 Incomplete antecedents

In Huybregts (1976), the Freezing phenomenon is explained in terms of a restriction on antecedents. He points out that by adopting Trace theory (cf. Chomsky 1973, 1976) it is possible to give a unified explanation of certain ill-formed relationships between an antecedent-phrase and an element that is linked to it. His starting point is the observation made by George Williams (1971) that incomplete antecedents (i.e., antecedents from which an element has been removed) are bad as antecedents for pronominal elements. Consider for this the following pair (taken from Huybregts 1976):

(35) a. The man who spoke to [the mother of the boy]$_i$ said she$_i$ was ill.
b. *The boy who$_j$ I saw [the mother of t$_j$]$_i$ said she$_i$ was ill.

In (35a), the (complete) noun phrase *the mother of the boy* can function as the antecedent of the pronoun *she*. As shown by the ill-formedness of (35b), an antecedent–anaphor relationship is impossible when the antecedent (*[the mother of t$_j$]*) is incomplete. Thus, schematically, the following configuration is impossible:

(36) . . . Z . . . [$_X$ . . . t$_z$ . . .]$_i$ . . . pron$_i$
where t$_z$ is a trace of the moved element Z

Huybregts points out that the Freezing-effect configuration correponds to the configuration in (36), the only difference being that instead of a lexical pronoun we have an empty element, more specifically "a trace":

(37) . . . Z . . . [$_X$ . . . t$_z$ . . .]$_i$ . . . t$_i$
where t$_z$ is a trace of the moved element Z and t$_i$ the trace of the moved element X

In short, the Freezing effect is explained in terms of a restriction on antecedents: phrases from which an element has been removed are not proper antecedents for a dependency relation (e.g., antecedent–pronoun, antecedent–trace). This is stated more formally as follows (Huybregts 1976: 346):

(38) **Antecedent condition:**
No rule can refer to X, Y in the structure:
. . . X . . . [$_{\alpha}$ . . . Y . . .] . . . Z . . .
where Z is linked to α

Consider now how (39) is ruled out by this constraint:

(39) ??[$_{CP}$ Who$_j$ do [$_{IP}$ you think [$_{CP}$ t$_j$′ that [$_{IP}$ [pictures of t$_j$]$_i$ [$_{IP}$ John wanted t$_i$]]]]]?

The syntactic structure in (39) violates the Antecedent Condition: t$_i$ is the trace of the incomplete antecedent noun phrase *[pictures of t$_j$]*.

3.5 Thawing effects

The generalization formulated thus far is that a moved phrase forms an island for extraction. It was shown that a phrase XP that allows subextraction of an element when it occupies its base position turns into an island when it is in a derived position. Movement, in other words, has a Freezing effect.

Although in general it seems true that a node gets inaccessible for subextraction after movement, it has been observed that sometimes movement has a thawing effect. That is, sometimes extraction out of a phrase XP gets better after XP has been moved to some position. In other words, movement of XP makes it (more) transparent for extraction.

Lasnik and Saito (1992: 100ff.), for example, observe such a thawing effect in the case of A′-moved subject NPs. They agree with the observation that extraction is better from a direct object NP in its base position than from one in a derived position (e.g., [Spec, CP] (cf. (31)) or adjoined to IP (cf. (23)). They point out, however, that for subject-NPs we have the opposite effect: extraction from a subject-NP in [Spec, IP] (cf. (40)) is worse than removal from a subject-NP that has been moved to [Spec, CP] (cf. (41a)) or to a position adjoined to IP (cf. (41b)). In other words, movement of a subject NP to [Spec, CP] or a position adjoined to IP has a thawing effect; extraction from the subject NP is better when it is in a derived position (examples drawn from Lasnik and Saito 1992: 101, 102):[18]

(40) ?*Who$_j$ do you think that [pictures of t$_j$] are on sale?

(41) a. ??Who$_j$ do you wonder [$_{CP}$ [which picture of t$_j$]$_i$ [$_{IP}$ t$_i$ is on sale]]?
b. ??Who$_j$ do you think that [$_{IP}$ [pictures of t$_j$]$_i$ [$_{IP}$ Mary believes t$_i$ are on sale]]?

The question, of course, arises how to account for the Freezing effect with moved object NPs and the thawing effect with moved subject NPs. Or if one puts it in terms of Subjacency, why does extraction out of a moved object NP yield a Subjacency violation and movement out of a moved subject weaken the Subjacency effect?

Lasnik and Saito account for the observed asymmetry in the following way. On the basis of the thawing effect in sentences like (41), they conclude that A'-moved constituents (i.e., A'-binders) are non-barriers. Formally, this is achieved by adopting the following definition of barrier:

(42) G is a barrier for b if:
  a. G is a maximal projection;
  b. G is not an A'-binder;
  c. G is not L-marked; and
  d. G dominates b.

Thus, the moved object NPs in (23) and (31), the topicalized subject NP in (41b), and the *wh*-moved subject in (41a) do not constitute Barriers for extraction; they are A'-binders and therefore transparent for extraction.

The subject NP in (40), on the other hand, does not occupy an A'-position. Not being an A'-binder, the subject NP forms a Barrier for extraction; extraction out of the non-moved subject NP yields a Subjacency violation.

If A'-binders do not constitute Barriers for Subjacency, the question arises what accounts for the marginality (i.e., "??") of the examples in (23), (31), and (41). Lasnik and Saito argue that their marginality is due to Kuno's (1973a) Internal Constituent Constraint (ICC). This constraint roughly states that extraction cannot take place from clause-internal constituents. Extraction is only possible from phrases that are in a clause-external (i.e., right-peripheral) position. This is exemplified by the following contrastive pair:

(43) $^{??}\text{Who}_j$ did you give [pictures of t_j] to Bill?

(44) Who_j did you see [several pictures of t_j]?

Clearly, the moved phrases in (23), (31), and (41) are not in right-peripheral position within the embedded clause. Extraction out of these phrases violates Kuno's ICC constraint. Notice that extraction out of the subject NP in (40) violates both Subjacency and the ICC.

Summarizing, Lasnik and Saito interpret the 'frozenness' of A'-moved constituents in terms of Kuno's ICC, rather than in terms of Subjacency. Clearly, the frozenness of rightward moved constituents (see section 3.1) cannot be subsumed under the ICC, since after rightward shift has applied to some phrase, this phrase is in a clause-external (i.e., peripheral) position. Furthermore, the ill-formedness of these rightward movement constructions cannot be explained in terms of Subjacency, if movement is really involved; this for the reason that under such a movement analysis, the rightward-moved phrase is an A'-binder, which, following the definition in (42), does not count as a barrier. Lasnik and Saito (1992: 104) are aware of the impossibility of explaining the islandhood of "rightward moved phrases" in terms of Subjacency. They point out this problem for their analysis on the basis of relative clauses that have been extraposed from a noun phrase (cf.

(20)). They conclude that the problem can be solved if it is assumed that "extraposed" relative clauses are simply base generated in a right-peripheral position (see chapter 25). Being not in a derived A'-position, the relative clause counts as a Barrier for extraction.

3.6 (Apparent) counter-examples to Freezing

Thus far we have seen that when a phrase has been dislocated, it functions as an island for elements that are contained within the moved phrase. Extraction from within the displaced phrase is impossible. When a PP has been extraposed, or when an NP undergoes Heavy NP-Shift, movement from these phrases is barred. There are structures, however, where extraction from a moved phrase appears to be possible. One such case, which was already noted in Wexler and Culicover (1980: 342), is given in (45) (see also Johnson 1986):

(45) a. Who$_j$ is it obvious [that Mary met t_j]?
b. What$_j$ was it clear [that Mary had bought t_j]?

Under a traditional analysis of these constructions, the postverbal clause has been moved from subject position.[19] The expletive element *it* is inserted in the vacated subject position, and forms a chain with the extraposed clause.

If movement is involved, the question, of course, arises why extraction out of the clause is not blocked. That is, why doesn't the extraposed clause constitute a frozen domain? Wexler and Culicover (1980) point out that one way out of this difficulty is to adopt the view that such 'extraposition' structures as in (45) are not transformationally derived. Rather, the right-peripheral subject clause is base generated in a right peripheral position (cf. Koster 1978d). Since the argument clause is base generated, no Freezing effect is invoked.

Absence of Freezing has also been noted for SOV-languages like Dutch and German, which have their clausal complement to V in extraposed position at 'surface structure'. While the direct object NP occurs in a preverbal position (cf. (46)), its clausal counterpart must occur in a postverbal position (cf. (47)). Consider, for example, the following examples from Dutch:

(46) a. Jan heeft nooit zulke dingen gezegd.
Jan has never such things said
'Jan has never said such things.'
b. *Jan heeft nooit gezegd *zulke dingen*

(47) a. ?*Jan heeft nooit [dat hij Marie aardig vond] gezegd.
Jan has never that he Marie nice considered said
'Jan has never said that he liked Marie.'
b. Jan heeft nooit – gezegd [dat hij Marie aardig vond]

According to the traditional analysis (cf. Koster 1975), the base position of the direct object is the preverbal position, i.e., the position where the direct object noun phrase can occur in 'surface structure'. This means that the postverbal direct object clause occupies a derived position. Hence, a Freezing effect is expected. As shown by the following example, however, extraction out of the extraposed clause is possible:

(48) Wie$_i$ heeft Jan t$_j$ gezegd [dat hij t$_i$ aardig vond]$_j$?
Who has Jan – said that he – nice considered
'Who did John say that he liked?'

Given the transparency of the clause in (48), it has been argued that the right-peripheral clause in fact occupies its base position (cf. de Haan 1979; Hoekstra 1983). There are various ways of implementing this, depending on one's theoretical assumptions. If one adopts directionality of case assignment (cf. Koopman 1984; Travis 1984), one could say that the direct object NP in (46a) is base generated to the left of the verb in Dutch, since V assigns case to the left in Dutch. Since the clause does not permit case, it is base generated to the right of the verb (as in (47b)). Under this analysis, both the preverbal direct object and the postverbal direct object clause are sisters to V, if it is assumed that theta-role assignment is not subject to a directionality requirement.

Another way to go would be to adopt Kayne's (1994) Antisymmetry theory and assume that all languages are underlyingly SVO. This means that the direct object clause in (47b) (and (48)) simply occupies its base position in Dutch (see Zwart 1993 for discussion). Consequently, no Freezing effect is expected to be invoked. Notice, however, that under this analysis, the surface position of the direct object noun phrase in (46a) is a derived position; the DO-NP is generally taken to be moved to the specifier of some functional head, e.g., AgrO. If one adopts the view that movement induces Freezing, one would expect extraction out of the preverbal direct object to be impossible. It turns out, however, that extraction out of the direct object NP is allowed. Consider, for example, the following Dutch sentence, where the *wh*-element *wat* has been moved out of the direct object noun phrase (see chapter 66):

(49) Wat$_i$ heb jij nog nooit [t$_i$ voor dingen] gezegd?
What has you yet never – for things said
'What kind of things haven't you ever said?'

Of course, one could stipulate that movement never induces any Freezing effect. Scambled constituents, however, typically display a Freezing effect in a language like Dutch (see, e.g., (27), where a PP-complement has been scrambled). Possibly, the absence of Freezing should be related to certain types of movement (e.g., movement to [Spec, AgroP]) but not to others. This, obviously, is something which needs further investigation.

4 The frozenness of adjunction sites

As already mentioned in section 2.2, Wexler and Culicover (1980) observed that it is not only the raised node which gets frozen, but also the syntactic domain within which the transformation has applied. That is, a phrase is frozen for further movement rules once it has been the site of adjunction. Or to put it differently again, transformations cannot apply to derived structures that are not also base-generable structures.

Two Freezing configurations can be distinguished, then: (i) a configuration in which a moved phrase ZP has been right-adjoined (cf. (50a)), and (ii) a configuration in which a moved phrase has been left-adjoined (cf. (50b)):

(50) a. *[YP_j [$_{XP}$ . . . t_j . . . t_i . . .] ZP_i]
b. *[YP_j [$_{XP}$ ZP_i [$_{XP}$ . . . t_j . . . t_i . . .]]

In section 4.1, I will consider constructions instantiating (50a). In section 4.2, the frozenness of left-adjunction configurations (50b) will be discussed.

4.1 The frozenness of right-adjunction configurations

Wexler and Culicover (1980) observed the following contrast:

(51) a. Who_j did John [$_{VP}$ send [$_{NP}$ an expensive book about horned frogs] [$_{PP}$ to t_j]]]?
b. *Who_j did John [$_{VP}$ send t_i [$_{PP}$ to t_j] [an expensive book about horned frogs]$_i$]?

In (51a), the direct object noun phrase is in its base position and extraction of the NP out of the prepositional indirect object is possible. In (51b), on the contrary, extraction out of the PP is no longer possible. This islandhood, they argue, does not reside in the PP, since the PP has not been moved; it is simply in its base position. The islandhood, however, relates to the Heavy NP-Shift operation that moves the direct object to the right periphery of the clause and attaches it to VP. This Heavy NP-Shift operation derives a string that is non-base generable; that is, it is a non-structure-preserving rule. As a consequence, the VP to which the shifted NP has been adjoined gets frozen. Extraction out of this frozen domain is not allowed. Schematically:[20]

(52) . . . [$_{VP}$ [$_{VP}$ send t_j to who] *an expensive book about horned frogs*$_j$]]

Some additional examples that illustrate this Freezing effect are given in (53–54) (examples taken from Wexler and Culicover 1980: 279 and Culicover 1982):

(53) a. Who_j did John give [a book about amphibians] [to t_j]?
b. *Who_j did you [$_{VP}$ [$_{VP}$ give t_i [to t_j]] [a book about amphibians]$_i$]?

(54) a. [Which country]$_j$ did they elect [the colonel who had engineered the recent coup] [President of t_j]?
b. *[Which country]$_j$ did they [$_{VP}$ [$_{VP}$ elect t_i [President of t_j]] [the colonel who had engineered the recent coup]$_i$]?

4.2 The frozenness of left-adjunction configurations

Freezing effects with left-adjunction configurations have also been noted in the literature. Wexler and Culicover (1980: 271ff.), for example, interpret the ungrammaticality of the following examples in which an indirect object NP undergoes *wh*-movement as a Freezing effect:

(55) a. *Who did John give a book about astronomy?
b. *Mary, I gave a book about astronomy.

Their reasoning goes as follows: the double object construction in (56b) derives from (56a) (see chapter 21). In their analysis, the direct object NP and the indirect object PP are sisters to V:

(56) a. John [gave [a book about astronomy] [to Mary]].
b. John [gave [Mary] [a book about astronomy]].

They argue that the string in (56b) is derived by (right-)adjunction of the indirect object NP to the verb:[21]

(57) [$_{VP}$ [$_{V*}$ V *NP2*] NP1 –]

Since the phrase structure rule V → V NP is not a rule of the base, Dative Shift is a non-structure-preserving rule. NP2 is dominated by a frozen node (V*) after Dative Shift and therefore cannot be moved by later transformations.

Another left-adjunction configuration that invokes a Freezing effect is the embedded topicalization environment. As shown by the following examples from Johnson (1986), a *wh*-phrase cannot be moved out of an embedded clause in which embedded topicalization has applied:[22]

(58) a. *What$_j$ did you say [that [$_{IP}$ [$_{NP}$ on the porch]$_i$ [$_{IP}$ you put t_j t_i]]]?
b. *[To whom]$_j$ did you believe [that [$_{IP}$ [$_{NP}$ my book]$_i$ [$_{IP}$ you gave t_i t_j]]]?

Of course, extraction of *what* and *to whom* is permitted when no embedded topicalization has taken place:

(59) a. What$_j$ did you say that you put t_j on the porch?
b. [To whom]$_j$ did you believe that you gave my book t_j?

4.3 Analyses of the frozenness of adjunction sites

The intuitive content of the Freezing Principle is that a phrase is frozen for further movement rules once it has been the site of adjunction. The question arises whether this principle can be subsumed under another, more general condition. Johnson (1986) proposes that the Freezing effect can be explained in terms of the Subjacency Condition. Adopting a *Barriers*-style approach toward island phenomena, he reinterprets the frozenness of adjunction sites in terms of the notions Blocking Category (BC) and Barrier (cf. Chomsky 1986a). More specifically, he argues that adjunction of a phrase ZP (e.g., a rightward-moved NP) to a node XP (e.g., VP) turns XP into a BC and a Barrier. It is further assumed that the node created by adjunction is a Barrier by inheritance. So the ill-formed configurations in (50) can now be ruled out as follows: after (left- or right-)adjunction, XP is a BC and a Barrier. Because XP is a BC, the dominating XP* is a Barrier by inheritance. Hence movement of YP out of this adjunction configuration will violate Subjacency, since it must cross two Barriers: XP and XP*:

(50) a. *$[YP_j\ [_{XP^*}\ [_{XP} \ldots t_j \ldots t_i \ldots]\ ZP_i]]$ (extraction out of a right-adunction configuration)

b. *$[YP_j\ [_{XP^*}\ ZP_i\ [_{XP} \ldots t_j \ldots t_i \ldots]]]$ (extraction out of a left-adjunction configuration)

A crucial assumption in Johnson's Subjacency account of the Freezing effect is that the two nodes of the adjunction structure (i.e., XP and XP*) count as separate maximal projections. So adjunction creates an additional category. The adjoined item (ZP) is dominated by this 'new' node (XP*), but is not dominated by the original node to which it is adjoined (XP). Being separate maximal categories, both XP and XP* form Barriers for extraction.[23] Another assumption made by Johnson is that double adjunction to one phrase is barred. If this assumption were not made, movement of YP could circumvent a Subjacency violation by first adjoining to XP or XP*.

The ill-formedness of examples like (53b), where Heavy NP-Shift has applied within VP, can now be explained as follows: after adjunction of the shifted NP to VP, the lower VP is a BC and a Barrier. Because VP is a BC, the dominating VP* is a Barrier by inheritance. Movement of the *wh*-phrase to [Spec, CP] will violate Subjacency, since it must cross two Barriers, viz. VP and VP*.

The ungrammaticality of the examples in (58) featuring embedded topicalization is derived as follows: in accordance with the principle of the Cycle, topicalization within the embedded clause applies before *wh*-movement of the *wh*-phrase to [Spec, CP] (where *wh*-movement applies successive-cyclically). After the topicalized phrase has been adjoined to IP, IP is a BC. The dominating IP is a barrier by inheritance. Hence movement of the *wh*-phrase to [Spec, CP] will violate Subjacency, since it must cross two Barriers: IP and IP*.

4.4 Absence of Freezing

In sections 4.1 and 4.2, several adjunction configurations were discussed that induce islandhood. Rightward Heavy NP-Shift turns the VP-node into a frozen structure, and embedded topicalization invokes freezing at the IP-level. As Wexler and Culicover (1980) have already pointed out, there are structural environments where apparently an adjunction operation has applied but no freezing is invoked. They observe, for example, that extraposition of a PP out of a direct object NP (cf. (60)) or a subject NP (cf. (61)) does not invoke freezing of the VP and the IP, respectively, to which the PP arguably has been adjoined:

(60) a. Mary is the person [$_{CP}$ *OP*$_j$ that [IP I gave *a book* [$_{PP}$ to t$_j$] *about Fred*]].
b. What$_j$ did you [$_{VP}$ put *a folio* [$_{PP}$ on t$_j$] *about decorative arts in the sixteenth century*]?
c. ?Who$_j$ did you buy *a picture* [$_{PP}$ for t$_j$] *of my great aunt Florrie*?

(61) a. [Which newspaper]$_j$ did *a review* appear [$_{PP}$ in t$_j$] *of that new book by Fred*?
b. Who$_j$ did *the editor* talk [$_{PP}$ to t$_j$] *from the New York Times*?
c. [How necessary]$_j$ will *an analysis* be t$_j$ *of these samples*?

Wexler and Culicover interpret the absence of Freezing by stating that extraposition of PP is in fact a structure-preserving operation, i.e., an operation that does not give rise to an adjoined structure. That is, extraposition of PP yields an output which is independently generable by PS-rules. Thus, they interpret it in terms of the structure-preserving nature of the movement rule.

Johnson (1986) argues that the absence of the Freezing effect in such examples directly follows if Extraposition of PP is not syntactic movement but rather a Stylistic (i.e., PF-movement) operation, along the lines of Rochemont (1978, 1982). Under such an analysis, *wh*-movement (a syntactic operation) would take place before PP-extraposition (a PF-operation). Thus, when *wh*-movement takes place, an adjunction configuration has not yet been created.

The absence of Freezing in such examples as (62), where CP-extraposition has applied, may be explained along the same lines:

(62) a. Who$_j$ was it obvious [$_{PP}$ to t$_j$] [that Mary had left]?
b. Who$_j$ was it clear [$_{PP}$ to t$_j$] [that Mary had left]?

One may explain the absence of Freezing by saying that the extraposed clause is simply base generated in a right-peripheral position. Alternatively, one could reason along the lines of Johnson and say that CP-extraposition applies at PF. Consequently, at the point in the derivation where P-stranding applies, no adjunction configuration has yet been created.[24]

5 Conclusion

The Freezing phenomenon is an intriguing island phenomenon that has received relatively little attention in studies on locality effects on movement, certainly compared to such island phenomena as the Complex NP-Constraint, the *Wh*-Island Constraint, and the Subject condition. The major purpose of this chapter was to give an overview of (i) the various ill-formed movement patterns that fall under the Freezing effect and (ii) the types of explanations that have been given in the generative literature for this island phenomenon. Two major types of frozen phrases were discussed: (i) moved/displaced phrases, on the one hand, and (ii) phrases representing adjunction configurations, on the other hand. Of course, the explanation of the Freezing phenomenon depends on one's assumptions about movement (e.g., is movement really involved in construction Y?) and about derived structures (e.g., is the derived structure really an adjunction configuration?).

NOTES

I would like to thank Peter Culicover and an anonymous reviewer for helpful comments and suggestions. All errors are mine, of course.

1 The ISP is counter-exemplified by sentences like (i), in which an element is removed from one conjunct. See Ross (1986) and Lakoff (1986) for discussion of such extractions from coordinate structures:

(i) a movie WH_i that we [[$_{VP}$ sat around all day] and [$_{VP}$ watched t_i]]

2 The judgment in (5b), i.e., "??," is the one given in Ross (1974b). Wexler and Culicover (1980) assign a "*" to sentences in which a constituent is extracted from a phrase that has undergone Heavy/Complex NP-Shift.

3 The island-creating effect of movement was already hinted at in Ross (1986: 172ff.). He observes that no element of an extraposed relative clause may be relativized or questioned:

(i) *[The coat [which$_j$ [a girl t_i] came in [who had worn t_j]$_i$]] was torn.

As a first suggestion for the explanation of this ill-formed sentence, he proposes the following constraint:

(ii) **The Frozen Structure Constraint:**
If a clause has been extraposed from a noun phrase whose head noun is lexical, this noun phrase may not be moved, nor may any element of the clause be moved out of that clause.

Ross points out that the ungrammaticality of (i) can be reduced to his CNPC if the rule of Extraposition from NP (see chapter 25) follows such movement rules as

Question formation and Relative Clause formation. In other words, rule ordering makes it possible to account for the ill-formedness of example (i) in terms of the CNPC. So extraction of *which* takes place before the relative clause modifying *a girl* has been extraposed.

4 The notion of structure preservation was first incorporated into the theory of transformations by Emonds (1970). See also Emonds (1976).

5 The non-base-generable structure does not necessarily have to be a Chomsky-adjunction configuration. That is, structures containing a moved constituent that is attached via daughter-adjunction also form islands for extraction. See Wexler and Culicover (1980: 571, note 15).

6 Although in the literature, the Freezing effect is typically asscoiated with the phenomenon of movement (i.e., a constituent cannot be moved out of a dominating node that is frozen), we should point out that in Wexler and Culicover (1980) Freezing has a broader coverage. They argue, for example, that the rule of Gapping (a deletion rule) is sensitive to the Freezing effect (see chapter 29). While Gapping is allowed in a (prepositional) double object construction like (i), it is blocked after the Dative shift transformation has applied (cf. (ii)):

(i) John *gave* a book to Mary, and Bill – a magazine to Fred.
(ii) *John *gave* Mary a book, and Bill – Fred a magazine.

The VP in (ii) is a derived environment in which the non-structure-preserving operation Dative Shift has applied. As a consequence of this, the VP-node is frozen; Gapping is not permitted in such an environment. See Wexler and Culicover (1980: 276) for further discussion.

7 Chomsky and others initially assumed that only a subset of nodes, primarily S, S', and NP, were cyclic. It was Edwin Williams who, in his (1974) doctoral dissertation, proposed that all nodes were cyclic.

8 The examples (17a, b, c) are taken, respectively, from Lasnik and Saito (1992), Johnson (1986), and Wexler and Culicover (1980).

9 See, among others, Huybregts (1976), Koster (1978a), Wexler and Culicover (1980), and Johnson (1986).

10 PPs that have been extraposed from a subject noun phrase are also frozen domains for extraction:

(i) *What$_j$ did [a review t_i] came out yesterday [of t_j]$_i$?

11 Ross (1986) also observes the islandhood of clauses that have been extraposed out of a noun phrase. See note 3 for discussion.

12 The given judgments "??" are from Lasnik and Saito (1992).

13 See also Corver (1997a) for freezing effects within the AP-domain that are due to scrambling.

14 Wexler and Culicover (1980) did not treat the islandhood of A-moved NPs in terms of a (generalized) Freezing Constraint, since A-movement operations (like Passive formation) are structure preserving.

15 Huybregts (1976) observes that Freezing is also found in structures like (i), where Directional Adverb Preposing (i.e., Locative Inversion) has applied. If these locative inversion patterns are derived by movement to [Spec, IP] (see Hoekstra and Mulder 1990), we have another instance of Freezing induced by A-movement:

(i) a. Peter claimed [$_{IP}$ [$_{PP}$ near that town]$_i$ is situated [an old ruin] t_i].
b. *[That town]$_j$ he said [$_{IP}$ [$_{PP}$ near t_j]$_i$ is situated [an old ruin] t_i].

16 Torrego (1985) observes that in Spanish an NP can be extracted from a fronted *wh*-phrase in Comp (i.e., [Spec, CP]):

(i) este es el autor [del que]$_i$ no sabemos [$_{CP}$ qué libros t_i] leer (Spanish)
this is the author [by whom] we don't know [what books –] to read

Torrego further shows that the impossibility of extraction from a subject-NP is overcome by *wh*-movement of the subject to [Spec, CP]:

(ii) *esta es la autora [de la que]$_i$ [$_{IP}$ [varias traducciones t_i] han ganado premios internacionales]
this is the author by whom several translations have won international awards

(iii) [de la que autora]$_i$ no sabes [$_{CP}$ [qué traducciones t_i] han ganado premios internacionales]
by what author don't you know what translations have won international awards

17 Baltin (1984) discusses the impossibility of extracting out of an extraposed PP in terms of Huang's (1982a) Condition on Extraction Domains. See Collins (1994a) and Müller (1998) for a Barriers-type account of various Freezing effects. It should further be noted that in some marginal cases it appears that a verb L-marks a constituent moved to Spec, CP of its complement; see, for example, the Spanish examples from Torrego (1985), which are also referred to in note 16.

18 Lasnik and Saito (1992) do not adopt the VP-internal subject hypothesis. So the subject noun phrase is base generated in [Spec, IP]. As pointed out by an anonymous reviewer, it should be noted that the judgments in (40–41) are very subtle and not at all certain. For certain speakers, (41b) turns out to be as bad as (40).

19 See, e.g., Rosenbaum (1967); Emonds (1976); Stowell (1981); Safir (1982).

20 In (52), the moved element is Chomsky-adjoined. In the representation given by Wexler and Culicover (1980), daughter-adjunction is used.

21 The Dative Shift operation depicted in (57), obviously, involves lowering; i.e., the moved indirect object is placed in a landing position that is lower in the tree than its original extraction site. Lowering operations are ruled out in current theories on movement. For discussion of more recent analyses of the double object construction, see chapter 21.

22 As shown in Baltin (1978b), embedded topicalization does not always create islands:

(i) He's a man [[to whom]$_j$ [[liberty]$_i$ we could never grant t_i t_j]].

23 See also Lasnik and Saito (1992: 84ff.) for this. In Chomsky's Barriers theory (1986a), a different interpretation is given to adjunction structures: following May (1985), he assumes that the adjunction site (XP) and the node created by adjunction (XP*) form one maximal projection together. That is, XP and XP* are segments of one maximal projection.

24 If the position is taken that CP-extraposition applies at PF, the question obviously arises why it is impossible to extract from non-extraposed sentential subjects, while it is possible from extraposed ones.

5 Parallelism and scope
6 Conclusion

1 Introduction

Gapping is an ellipsis in which a verb is removed in one, or more, of a series of coordinations. (1) is emblematic:

(1) Some ate beans and others, rice.

The name comes from Ross (1970a), who appears to be the first to have systematically studied the process. The set of cases for which Gapping is responsible remains controversial, though there is consensus on a certain range of them. A more-or-less standard criterion is that Gapping occurs only in coordinate structures. The two main candidates that don't meet this requirement, but which nonetheless superficially appear to be instances of Gapping, are list-like answers to questions, like those in (2), and comparative constructions, like those in (3):[1]

(2) Q: Who met who?
A: Jerry, Sarah; Sally, Mark; Trish, Betsy

(3) Sally met more parents than Tom, kids.

Many treatments of Gapping – most modern ones – leave these cases out, and so shall I in what follows.

If Gapping is restricted to coordinations, then one task is to determine whether Gapping is a special instance of one of the many forms of ellipsis found in coordinations, or, if it isn't, how to distinguish it from the others. This problem looms large because Gapping is commonly credited with being able to elide more than just the finite verb. Ross, for example, gave it the ability to elide the quite remarkable set of strings in (4):

(4) a. I want to try to begin to write a novel and Mary ~~wants to try to begin to write~~ a play.
b. ?I want to try to begin to write a novel, and Mary ~~wants to try to begin~~ to write a play.
c. ?I want to try to begin to write a novel, and Mary ~~wants to try~~ to begin to write a play.
d. ?I want to try to begin to write a novel, and Mary ~~wants~~ to try to begin to write a play. (Ross 1970a: 250, (2c))

(Strike-outs will indicate elided material, from here out.) In fact, however, there is a sharp degradation in these particular examples that favors (4a) over the others. I suspect this is because in (4b–c) material left behind by Gapping matches that in the antecedent clause; in general, these 'remnants' must contrast with parallel terms in the antecedent clause, as we shall see below. If this property of (4b–c) is remedied, the result is improved:

(5) a. I want to try to begin to write a novel, and Mary ~~wants to try to begin~~ to review a play.
b. I want to try to begin to write a novel, and Mary ~~wants to try~~ to set out to review a play.
c. I want to try to begin to write a novel, and Mary ~~wants~~ to get ready to set out to review a play.

There remains some awkwardness, especially in (5b) and (5c), perhaps because of the strain involved in contrasting so many terms.

2 Ellipsis in coordinations

Nonetheless, in principle the strings in (5) are Gappable, and this raises the possibility that Gapping could figure in a wide range of coordinations. It might be responsible for creating (6a) or (6b):

(6) a. Jerry met ~~the kids from OshKosh~~ and Sally scrutinized the kids from OshKosh.
b. Sam ate and ~~Sam~~ was put to bed.

(6a) is an example of what Postal (1974) called 'Right Node Raising', which here removes the object of the first conjunct. There are two potential, non-gapping, sources for (6b). It could be that there is an elision process, as indicated, distinct from Gapping which removes material at the edges of a coordinate. That such a process – what Ross (1986) calls 'Forward Conjunction Reduction' – exists has been widely speculated. The other potential source would deny that there is any ellipsis at all, and instead let the VPs *ate* and *was put to bed* conjoin to jointly take *Sam* as subject. Both treatments have their problems, and evidence distinguishing them is difficult to find.[2]

One feature that distinguishes (1), (4), and (5) from (6) is that the clause holding the Gapped material in (1), (4), and (5) contains remnant material at the left and right edges, but this isn't so in (6). Jackendoff (1971) suggests that this should be taken as a defining trait of Gapping.

Restricting Gapping in this way, however, is not how Ross (1970a) would have done it. The goal of his paper, in fact, is to defend the thesis that the conjunct in which a verb is Gapped is determined by the linear position that that verb would have had to other terms in its sentence if it hadn't elided. Ross suggests that if the verb would have preceded its complements, then it will Gap from the second, or subsequent, conjuncts, and the first conjunct will hold the antecedent. If the verb would have followed its complements, on the other hand, then it will Gap from the initial conjuncts, and the antecedent will be found in the final one. So, for instance, he suggests that in languages like Japanese and Russian, where a complement may precede its verb, Gapping is responsible for producing sentences such as (7):

(7) a. Watakusi-wa. sakana-o ~~tabe~~ Biru-wa gohan-o tabeta. Japanese
I-Top fish-ACC eat beer-TOP rice-ACC ate
'I ate fish and Bill rice.'

b. Ja vodu ~~pila~~ i Anna vodku pila. Russian
I water drank and Anna vodka drank
'I drank water and Anna vodka.' (Ross 1970a: 251, (5b), (10b))

In such cases, of course, the Gapped verb makes up the right edge of the clause it has been elided from, and this violates Jackendoff's criterion.

Further, if Jackendoff's criterion is relaxed, then examples like (8) could also be seen as instances of Gapping:

(8) Mary left early, and Sally ~~left early~~ too.

In this case, the finite verb of the second conjunct would have Gapped along with the adverb *early*, and removed all of the second conjunct except its subject. Gapping might also be credited with (9), which could be seen as a special instance of the forward conjunct reduction case in (6b):

(9) Jill ate rice yesterday and ~~Jill ate~~ porridge today.

Note that unlike (6b), however, the analysis which denies any ellipsis in (9) is less plausible. Such an account would have to treat *rice yesterday* and *porridge today* as constituents.

In fact, Jackendoff's criterion is not generally adopted, and some of these cases are reasonably classed as Gapping. But for examples like (6a), the consensus appears to be that they are not, in fact, Gapping. Some superficial differences between cases of Right Node Raising, and canonical instances of Gapping, like those in (1), are the following.

Gapping allows a mismatch in inflectional class between the Gapped verb and its antecedent; but Right Node Raising resists this:

(10) a. He likes beans and you ~~like~~ rice.
b. *He always ~~complains~~ and you sometimes complain.

Right Node Raising is able to remove part of a word, as in (11b), but Gapping isn't:

(11) a. *Carly is overpaid and Will under~~paid~~.
b. Carly is over~~paid~~, and Will underpaid.

Right Node Raising needs the material it elides to make up a contiguous string, but Gapping can (apparently) elide discontinuous strings, as the contrast in (12) illustrates:

(12) a. Carrie gave a set of directions to me, and Will ~~gave~~ a map ~~to me~~.
b. *Carrie ~~gave~~ a set of directions ~~to me~~, and Will gave a map to me.

And Right Node Raising can strand prepositions, but Gapping can't (a point made in Neijt 1979):

(13) a. *John is confident of a successful outing and Peter ~~is~~ dependent on ~~a successful outing~~.
b. John is confident of ~~a successful outing~~ and Peter is dependent on a successful outing.

(Neijt 1979: 40, (85a), (86a))

Hankamer (1979: chapter 1) and Maling (1972) argue that finite verb ellipsis in verb-final languages, like Turkish, is actually Right Node Raising. The jury is still out on languages like Japanese; but in general, there appears to be no uniformly agreed-upon instance of Gapping applying to delete material in the first conjunct, in the way that Ross suggested.

The cases in (8) and (9), on the other hand, are better candidates for Gapping. The case in (9) can be put together with examples like (14), in which various kinds of phrases follow the left conjunct:[3]

(14) a. Did you tell John about our plans or Peter? (Ross 1986)
b. Sally talked about the meeting passionately and about its consequences too.
c. James left unhappy today and unappreciated too.

Ross (1986) analyzed these as involving extraposition of a phrase consisting of *and* or *or* and the string that follows it. (14b), for instance, would have a source like *Sally talked about the meeting and about its consequences too passionately*, and would be formed by moving the underlined phrase to the end of the sentence.[4] But Neijt (1979) argues that they derive instead from Gapping; so (14b) would come from something like (15):

(15) Sally talked about the meeting passionately, and ~~Sally talked~~ about its consequences too.

One of her arguments on behalf of the Gapping interpretation is that it could make sense of the fact that examples like (16) are blocked:

(16) *That dress has been designed by my grandma and made.
(Neijt 1979: 64, (141a))

There is no obvious reason why this shouldn't be derived from *That dress has been designed and made by my grandma*, under Ross's analysis. But if Gapping must always include the verb, and we shall see evidence for this shortly, then the ungrammaticality of (16) would be explained if its source is Gapping.

Another reason for believing that some form of ellipsis produces examples such as (9) and (14) is that it could also create examples such as (17):

(17) Betsy wanted to read a book or a magazine.

In fact, (17) has a meaning which is suggestive of such a source.[5] On one reading, (17) describes a particular desire that Betsy has: she desires to read something that is either a book or a magazine. But on another of its readings, (17) is synonymous with (18), which claims that Betsy has one or the other of two desires:

(18) Betsy wanted to read a book or Betsy wanted to read a magazine.

This second reading for (17) would be a straightforward consequence of deleting from the second disjunct of (18) *Betsy wanted to read*. Schwarz (1999) argues for this conclusion, and notes that it makes sense of the fact that (19) gets only this latter reading:

(19) Either Betsy wanted to read a book or a magazine.

This follows from the plausible thesis that *either* marks the left edge of a disjunction, which would force (19) to be a disjunction of clauses from which all but the object has Gapped in the second clause.

These are reasons, then, for believing that ellipsis can produce examples like (9), (14), and (17); and given Neijt's argument from (16), Gapping is probably the form of ellipsis responsible.[6] But note that for cases like (17), it is not necessary that Gapping be the only source. It is consistent with standard views of coordination that (17) could arise by disjoining *a book* and *a magazine* in the embedded clause. And this, or something like it, could be the appropriate representation for this sentence when it gets the first of the interpretations described (i.e., Betsy has a desire to read a book or a magazine).

3 The No Embedding Constraint

To see the reason for classifying (8) as a Gapping construction, it is necessary first to appreciate one of the constraints that controls which strings can Gap. Hankamer (1979) discovered that Gapping cannot affect a verb that is in an embedded clause, as in (20):[7]

(20) *Alfonse stole the emeralds, and I think that Mugsy ~~stole~~ the pearls.
(Hankamer 1979: 19, (23))

He noted also that the antecedent to a Gap cannot be in an embedded clause. (21) illustrates:

(21) *I think that Alfonse stole the emeralds, and Mugsy ~~stole~~ the pearls.

If (21) is understood as a (somewhat awkward) conjunction of two clauses, rather than as a single clause with an embedded coordination, it is ungrammatical. Now, when Ross's examples in (4) are considered, we can see that there is nothing wrong with a verb in an embedded clause being part of the Gapped material or its antecedent. Rather, what the contrast between (20) and (21) shows is that the Gapped material, and its antecedent, must include the verb of the conjoined clauses. In fact, it is likely that this constraint is even stronger, preventing a Gap or its antecedent from excluding the highest verb of the conjuncts, so I will formulate it as in (22):

(22) **The No Embedding Constraint:**
Let A and B be conjoined or disjoined phrases, and β be the string elided in B whose antecedent is α in A. Then α and β must contain the highest verb in A and B.

It's this constraint that forms the foundation for Neijt's argument from the ungrammaticality of (16) that (9) and (14) are created by Gapping. Because the

No Embedding Constraint requires Gapping to elide at least the verb, it'll block (16). And note too that the No Embedding Constraint would also prevent Gapping from being able to create (6b), since the verbs of the second conjunct remain in this example.

The validity of the No Embedding Constraint turns then on whether (6b) should be classed as a Gapping construction, and also on whether examples such as (23) are instances of Gapping:

(23) Some have eaten chocolate, and others might ~~eat~~ fruit.

Levin (1986) argued that cases like (23) are produced by an ellipsis process distinct from Gapping, dubbing it 'Pseudogapping', to enforce her conclusion. Pseudogapping differs from Gapping in being able to apply in contexts other than coordinations, as in (24):

(24) Sally should eat legumes because she won't ~~eat~~ broccoli.

Furthermore, there are languages which have Gapping, but which don't allow Pseudogapping. German is such a language, as the contrast between (25a) and (25b) indicates:

(25) a. Sally hat Kumquats gegessen und Dieter Bier getrunken.
Sally has kumquats eaten and Dieter beer drank
'Sally ate kumquats and Dieter drank beer.'
b. *Sally hat Kumquats gegessen weil Dieter Natto hat.
Sally has kumquats eaten since Dieter natto has
'Sally ate kumquats because Dieter natto.'

And German examples parallel to (23) are ungrammatical, again suggesting that these cases cannot be produced by Gapping:

(26) *Sally hat Kumquats gegessen und Dieter hat Natto.
Sally has kumquats eaten and Dieter has natto
'Sally ate kumquats and Dieter natto.'

For this reason, then, I'll adopt a formulation of Hankamer's constraint like that in (22), and assume that neither (6b) nor (23) arises through Gapping.

So far as is known, Gapping is the only ellipsis process constrained by the No Embedding Constraint. To the extent that the No Embedding Constraint is unique to Gapping, then, it can be used as a diagnostic for it. And, according to this diagnostic, examples such as (8) are produced from Gapping. When the second conjunct in (8) is embedded under a verb, as in (27), the result is ungrammatical:

(27) *Mary left early, and I think Sally too.

Putting together these various observations, we can formulate a preliminary definition of Gapping as follows:

(28) **Gapping:**
In a structure A *c* B, where *c* is *and* or *or*, Gapping deletes a string in B that is identical to a string in A and satisfies the No Embedding Constraint (i.e., (22)).

This captures the fact that Gapping is restricted to coordinations (with the caveat about (2) and (3)), removes material from the second of two conjuncts, and is subject to Hankamer's No Embedding Constraint. It also entails, because of the requirements in the No Embedding Constraint, that Gapping can only elide verbs. Neijt (1979) argues that this outcome is correct as well, citing examples such as those in (29) to illustrate that Gapping is prevented from applying to Prepositions, Adjectives, and Quantifiers:[8]

(29) a. *Several inches above the ground and several feet ~~above~~ sea level.
b. *A five year younger or 10 year ~~younger~~ sister.
c. *He ran a few seconds faster or a few minutes ~~faster~~ to his house.
d. *Bill drank much too much or a little bit ~~too much~~ wine.
e. *John bought a little bit more or a lot ~~more~~.
(Neijt 1979: 27, (54c, e–h))

And though there are cases, like (30), which look as though they could be achieved if Gapping applies to Nouns, she suggests that these are the products of another ellipsis process, 'Deletion', exemplified by examples such as (31):[9]

(30) One dog with five legs, another ~~dog~~ with a cow's liver, and a third ~~dog~~ with no head. (Neijt 1979: 27, (54a))

(31) One dog with five legs walked in after another ~~dog~~ with no head left.

Setting aside the issue of Nouns, it should be noted, however, that there are contexts in which Adjectives would appear to be able to Gap:

(32) a. Malfoy made Snape happy about his potions and Hagrid ~~happy~~ about his Griffons.
b. Hermoine considered Voldemort frightened of Dumbledore and Malfoy ~~frightened~~ of Harry.

So far as I have been able to determine, other categories are not susceptible to Gapping in these contexts, however:

(33) a. *Ron let Harry in the dungeon and Filtch ~~in~~ the common room.
b. *Dudley considers some witches friends of mine and others ~~friends~~ of yours.

Let us continue to restrict Gapping to strings with verbs in them, then, pending an explanation for the exceptional cases in (32).[10]

There is another, somewhat subtler, consequence of defining Gapping as (28) does. Because (28) requires that the antecedent to a Gapped string be found in the conjunct or disjunct immediately preceding, it will prevent a Gap from finding a more distant antecedent in situations in which there are more than two coordinates. It will correctly prevent examples such as (34), for instance:

(34) *John invited Sue, Peter kissed Mary, and Max ~~invited~~ Betsy.
(Neijt 1979: 71, note 7 (iv))

Because the antecedent to *invited* is not found in the immediately preceding conjunct, it cannot Gap in the final conjunct. On the other hand, an example such as (35) is permitted, as Gapping can apply from right to left, taking the conjuncts pair-wise:

(35) John invited Sue, Peter ~~invited~~ Mary, and Max ~~invited~~ Betsy.

So the Gapped *invited* in the final conjunct finds its antecedent in the immediately preceding conjunct, and this middle *invited* in turn Gaps under identity with the antecedent in the first conjunct.

4 Gapping and constituency

Let's turn next to the question of how to characterize the set of strings that Gapping can elide. As we have seen in (5a) and (12a) – repeated below as (36) – Gapping can delete strings of terms that are not typically thought to make up constituents in English:

(36) a. I want to try to begin to write a novel and Mary ~~wants to try to begin~~ to review a play.
b. Carrie gave a set of directions to me, and Will ~~gave~~ a map ~~to me~~.

Standard parses of English sentences do not form a constituent of *want to try to begin* that excludes *to review a play*; nor do they allow discontinuous strings, like the *gave to me* sequence in (36b), to form a constituent that excludes intervening material. Because syntactic processes are very typically restricted to affecting just constituents, these cases are surprising. If we think of Gapping as a rule that targets strings in a clause and deletes them, then this would be a counter-example to this otherwise valid generalization about such rules.

But it's not that Gapping can delete just any string. Hankamer (1979), for example, observes that there are contrasts like (37):

(37) a. Charley writes with a pencil and John ~~writes~~ with a pen.
b. *Charley writes with a pencil and John ~~writes with~~ a pen.
c. *Charley writes with a pencil and John ~~writes with a~~ pen.
(Hankamer 1979: 18)

It appears that Gapping is prevented from taking part of a preposition phrase and leaving the rest. And, similarly, Gapping cannot elide a portion of an object noun phrase either, as in (38):

(38) a. Charley wrote several books on syntax and Jill ~~wrote~~ several books on semantics.
b. *Charley wrote several books on syntax and Jill ~~wrote several~~ books on semantics.
c. *Charley wrote several books on syntax and Jill ~~wrote several books on~~ semantics.

There have been two broad approaches to capturing constraints such as these. In one, generalizations about the shape that the remnants may have are sought; and in the other, generalizations about the elided strings themselves are formulated.

4.1 Conditions on remnants

Hankamer's own approach was of the first kind. He described the constraint responsible for (37) and (38) in terms of a restriction that requires the remnants of Gapping to be 'Major Constituents', which he defined as phrases which are immediate daughters of S (or IP, in modern parlance). Because he held a skeptical view about the existence of VP, this meant that subjects, adverbs, PPs, and objects qualified as Major Constituents, but nothing else. If we admit the existence of VP, we might formulate this along the lines he resorts to in Hankamer (1973a: 18): "A 'major constituent' of a given sentence S_0 is a constituent either immediately dominated by S_0, or immediately dominated by VP which is immediately dominated by S_0." That we should allow Gapping to see VPs, and therefore adopt this formulation, is indicated by cases such as (39), in which an auxiliary verb has elided:

(39) Some have prepared kumquats and others ~~have~~ baked pies.

While the status of examples such as (39) is somewhat controversial – Ross (1970a) classed them as ungrammatical, and Siegel (1987), where they are marked grammatical, assumes that they are not produced by Gapping – the present consensus appears to be that they are both grammatical and Gapping. That they are Gapping is suggested by the fact that they appear to meet the criteria (28) uses to define Gapping. For example, auxiliary verbs may delete like this only in coordinations (compare (40a)), the antecedent must be in the first coordinate (witness (40b)), and it is subject to the No Embedding Constraint (as (40c) suggests):

(40) a. *Some have prepared kumquats while others ~~have~~ baked pies.
b. *Some ~~have~~ prepared kumquats and others have baked pies.
c. *Some wanted to have prepared kumquats, and others wanted to ~~have~~ baked pies.

To the extent that (39) is grammatical, then, it shows that Gapping can leave the verb+NP string as a remnant. We have already seen, however, that the auxiliary verb+NP string in (41) does not constitute a legitimate Gapping remnant (this sentence, to the extent that it is grammatical, comes about by way of pseudogapping):

(41) Some have prepared kumquats and others have ~~prepared~~ pies.

Thus, we seek a way of distinguishing these two cases. That is, in a string *have*+participle+NP, we want to allow participle+NP to be able to survive as a remnant from Gapping, but prevent *have*+NP from being a remnant. While it may not be utterly necessary, it seems reasonable to adopt the commonplace view that the participle+NP string is embedded within the *have*+participle+NP string, and distinguish them that way. (This is just what the No Embedding Constraint, in fact, does.) But this will require the existence of VPs. Thus we should adopt the definition of major constituent that recognizes the existence of VPs.

Hankamer's constraint hasn't been widely adopted. One straightforward difficulty is that the notion 'major constituent' has not been grounded in anything more general. That is, so far as other syntactic processes are concerned, major constituents don't appear to behave as a class, making their use in constraining Gapping somewhat dubious. Moreover, there seem to be counter-examples to Hankamer's constraint. Sag points out,[11] for instance, that it would not permit instances of Gapping like those in (36a), repeated in (42a), and it's hard to see how to modify the constraint so that it could distinguish (42a) from (42b):

(42) a. I want to try to begin to write a novel and Mary ~~wants to try to begin~~ to review a play.
b. *I want to try to begin to write a novel and Mary ~~wants to try to begin~~ ~~to~~ review a play.

There is, however, evidence that the remnants to Gapping must be able to be factored into constituents. And, indeed, it is likely that they must be partitionable into maximal projections. This would explain the contrast between (38a) and (38b), as well as that between (37b) and (37c). And it would extend to account for the badness of examples such as (43):

(43) a. *Some read angry letters and others ~~read angry~~ reports.
b. *Some bought books about themselves and others ~~bought~~ reports ~~about themselves~~.
c. *Some remember your mother and others ~~remember your~~ father.

d. *Some brought every package and others ~~brought every~~ wrapper.
e. *Some appeared almost happy and others ~~appear almost~~ rich.
f. *Some talked only to Smith and others ~~talked only~~ to Jones.

In each of the examples in (43), a subconstituent of the noun phrase, adjective phrase, or prepositional phrase has survived Gapping. If the material that would make these subconstituents full NPs, APs, or PPs is restored, the examples become grammatical. Let's adopt, then, this rather watered-down version of Hankamer's condition on remnants:

(44) **The Constituency Condition of Remnants:**
Let P(x) be a parse for a string x. If A is a string of words in a coordinate, from which the substring B has Gapped leaving the string C, then there must be a way of factoring C into a series of maximal projections found in P(A).

This leaves the ungrammaticality of (37b) and (38b, c) to be explained; and also fails to shed light on the contrast between (42a) and (42b). We will review below a way of deriving the Constituency Condition that extends to these cases.

Another proposed constraint on remnants is that there may be no more than two of them.[12] Jackendoff (1971) points to contrasts like the following, as evidence:

(45) a. *Arizona elected Goldwater Senator, and Massachusetts McCormack Congressman.
b. *Millie will send the President an obscene telegram, Paul the Queen a pregnant duck.

(Jackendoff 1971: 25, (23))

But this effect is probably related to the fact that the remnants in Gapping constructions are used to introduce 'new' information into the discourse, a point that Kuno (1976) draws attention to. One way this can express itself is for the remnants, and the parallel terms in the first conjunct – I will call them 'correlates' from now on – to be focused. Gapping constructions can therefore be thought of as appropriate in contexts in which there is an implicit question that the remnants and correlates serve as answers to. (46), for example, might be thought of as addressing a topic that is expressed by the question: 'Who likes what?':

(46) Jerry likes beans and Sally kumquats.

When sentences with Gaps in them are explicitly offered as answers to questions, it is much easier to have more than two remnants:

(47) Who will send who what?
Sally will send Ron pickles, and Martha Hermione kumquats.

Or when the remnants have more descriptive content to them than names do, and are therefore more suitable for introducing new information, the results also improve:

(48) Arizona elected a right-wing bastard to the Senate and Massachusetts a moderate wank to the Congress.

This property of the construction probably also plays a role in examples that Hankamer (1973a) judged unacceptable and credited to what he called the No Ambiguity Constraint. Some of his examples are in (49):

(49) a. Jack calls Joe Mike and Sam ~~calls Joe~~ Harry.
b. Jack told Harry that Nixon was a fairy, and Alex ~~told Harry~~ that Agnew had warts.
c. Max wanted to put the eggplant on the table, and Harvey ~~wanted to put the eggplant~~ in the sink. (Hankamer 1973a: 3, (57–9))

Hankamer argued that these do not get the interpretation that would result from the pattern of Gapping shown because there is another interpretation available that blocks these. This other interpretation, which might be produced by Conjunction Reduction or Gapping or both, is indicated by the ellipses shown in (50):

(50) a. Jack calls Joe Mike and ~~Jack calls~~ Sam Harry.
b. Jack told Harry that Nixon was a fairy, and ~~Jack told~~ Alex that Agnew had warts.
c. Max wanted to put the eggplant on the table, and ~~Max wanted to put~~ Alex in the sink.

Hankamer suggested that when Gapping produces ambiguous results, as in these cases, those interpretations which would place the Gap at the leftmost edge are favored, hence the interpretation in (50) but not (49). But Kuno (1976) argues that these contrasts too are an artifact of the requirement that Gapping remnants introduce new material.[13] He points out that when names are used, the tendency already present to treat the material within VP as new information will be strengthened. This will, by itself, favor the interpretation in (49) over that in (50), since in neutral contexts the subjects of the first conjunct will not be taken to introduce new material and will, as a consequence, not be suitable correlates for remnants in the second conjunct. This tendency can be overcome, however, if the correlate status of the subject is signaled lexically, as in (51):

(51) a. Some call Joe Mike and others ~~call Joe~~ Harry.
b. Some told Harry that Nixon was a fairy, and others ~~told Harry~~ that Agnew had warts.
c. Some wanted to put the eggplant on the table, and others ~~wanted to put the eggplant~~ in the sink.

Or if the sentences are uttered with appropriate stress, placed on the subjects but not the objects; or if they are uttered in a context that makes it clear which arguments are furnishing new information.[14]

Here, then, is our second condition on the remnants:

(52) **Kuno's Novelty Condition on Remnants:**
The phrases in the coordinate that are left over from Gapping introduce new information.

This and the Constituency Condition on Remnants in (44) are the best candidates for constraints on what Gapping leaves behind. The remainder of the conditions on Gapping tend to be found in constraints on the strings that can Gap.

4.2 Constraints on the Gapped string

Ross and Hankamer took ellipsis rules in general, and Gapping in particular, to be a phenomenon which deletes a 'variable' in the structural description of a transformational rule. On this conception, the remnants could be thought of as 'targets' in the transformational rule, and the variable that corresponds to the string surrounding these targets would be subject to the ellipsis process. Thus, the structural description could select maximal projections, accounting for the Constituency Condition on Remnants, and Gapping would delete the rest of the clause.[15] Now this predicts that the constraints which Ross (1986), for example, identifies as holding of these variables should play a role in defining which strings Gapping can affect. Neijt (1979) is the fullest systematic study of this prediction, and she concludes that it is largely confirmed. Ross's constraints, later incorporated into more general constraints such as Subjacency, are now typically held to govern the distance that things can move. So one way of judging this thesis is to see if there is a match between the strings past which things can move and the strings that can Gap. This is essentially what Neijt sought. Some of her examples are in (53–55):

(53) a. *John came home to find his wife sick, and Bill ~~came home to find~~ his child ~~sick~~.
*My wife, who I came home to find sick, was in a lousy mood.
b. *John must be a fool to have married Jane, and Bill ~~must be a fool to have married~~ Martha.
*The woman who John was a fool to have married was Jane.
c. *Tom went to Florida to learn to play tennis and Bill ~~went to Florida to learn to play~~ squash.
*What did Tom go to India to become?
d. ??John was upset having received A– for the course, and Bill ~~was upset having received~~ B– ~~for the course~~.
??What grade was John upset having received for the course?

(Neijt 1979: 131–2, (53))

(54) a. *John wondered what to cook today and Peter ~~wondered what to cook~~ tomorrow.
*When did John wonder what to cook?[16]
b. *John asked which candidates to interview this morning and Peter ~~asked which candidates to interview~~ this afternoon.
*When did John ask which candidates to interview?
(Neijt 1979: 138, (73))

(55) *John discussed my question of which flowers they saw and Bill ~~discussed my question~~ (of) which animals ~~they saw~~.
*Which flowers did John believe the claim that Peter saw?
(Neijt 1979: 134, (56), and 136, (64))

In (53) we see instances of the Adjunct condition which prohibits movement out of an adjunct clause and will have the consequence of preventing Gapping from including part of an adjunct. In (54) are instances of the *Wh*-Island Constraint, which prohibits movement out of indirect questions and here blocks Gaps from including part of an indirect question. And in (55) is an instance of the Complex Noun Phrase Constraint, which prevents movement out of clauses embedded within NPs, and would therefore prevent Gaps from similarly reaching into an NP.

Neijt also notes some differences between constraints on movement and those on Gapping. She notes, for instance, that Gapping cannot affect a string that reaches into a finite clause. There is a difference, then, between examples like (56) and those that Ross described (such as Ross's (57), in which Gapping reaches into a non-finite clause):

(56) a. *Charles decided that 20 boys are coming along and Harrie ~~decided that~~ 30 girls ~~are coming along~~.
b. *The first letter says that you should pay tax and the second letter ~~says that you should pay~~ V.A.T.
(Neijt 1979: 142–3, (86))

(57) I want to try to begin to write a novel, and Mary ~~want to try to begin to write~~ a play.

There is no visible corresponding constraint on movement in English; certainly *wh*-movement is not prevented from coming out of finite clauses:

(58) a. How many girls did Charles decide are coming along?
b. What did the first letter say that you should pay?

Neijt suggests that Gapping is subject to Chomsky's (1977a) Tensed S Condition, which prohibits extraction from finite clauses. When this constraint applies to movement operations, as in (58), Chomsky argued that it can be satisfied if the

moved phrase moves first into the Comp (or Specifier of CP) position of the finite clause it is going to escape. He formulated the Tensed S Condition so that it could move things out of finite clauses only if they are in Comp: descriptively, at the left edge of the clause. That this particular formulation of the Tensed S Condition is at play in the Gapping construction, Neijt argues, is indicated by the fact that when the remnant is in the Comp position of the finite clause, the result is improved. Thus, she contrasts (56) with the relatively grammatical (59):

(59) a. Charles may decided which boys are coming along and Max ~~may decide~~ which girls ~~are coming along~~.
b. The first letter says how much tax you should pay and the second letter ~~says~~ how much V.A.T. ~~you should pay~~.

(Neijt 1979: 142, (85))

But there are problems with this way of characterizing such examples. The contrast between (56) and (59) is conceivably traced back to the availability of another ellipsis process restricted to questions. This process – also first systematically studied by John Ross[17] – is known as Sluicing and exemplified by (60):

(60) I can remember which women Mary knows, but I can't recall which men ~~Mary knows~~.

In general, Sluicing elides the sentence that follows a *wh*-phrase, when that elided sentence has an antecedent previous to it, and when certain conditions on contrastiveness are met.[18] If Sluicing is capable of eliding just a portion of the sentence it affects, then examples like those in (59) could conceivably be produced through a combination of Gapping (eliding the main highest verbs of the conjunct) and Sluicing (eliding the material in the embedded interrogative).

Nonetheless, even if the examples in (59) are not produced by Gapping alone, Neijt's conjecture that Gapping obeys the Tensed S Condition remains consistent with the data. In general, then, her catalogue of facts supports the hypothesis that Gapping targets the class of strings that are allowed to lie between the target and landing site of a movement operation. In current syntactic theory, these strings are no longer characterized in terms of variables in the structural description of a transformational rule. Movement transformations are instead processes whose parts are partitioned out to independent modules of the grammar, and the constraints on the distances that movement operations may traverse are thought to emerge as a consequence of how these modules play out. A natural way of interpreting the match between what can Gap and what can be traversed by movement is that Gapping can act on the constituents that are formed by movement. This presently seems to be the consensus view: Gapping is capable of acting on the output of a movement operation that relocates remnants. Sag (1980) may have been the first to propose something along these lines. He suggests[19] that the variable which Gapping

deletes on the surface must correspond to a constituent formed at Logical Form by moving the remnants. He relates the movement of the remnants at Logical Form to their bearing focus, which he followed Chomsky (1980b) in supposing induced a kind of Focus Movement.

Pesetsky (1982), who similarly concludes that the strings which Gap are formed by movement,[20] brings forward additional data that fit this interpretation of the island effects in (53–55). He notes that not only are islands obeyed by the Gapped string, but the strength of island violations is reproduced as well. For instance, there is a strong difference in violations of the *wh*-island condition that depends on the position from which the term escaping the island originates. Extraction of objects from *wh*-islands is considerably better than extraction of subjects, as the pair in (61) illustrates:

(61) a. ??Which food does this man know why you ate?
b. *Which food does this man know why makes you sick?

This contrast is preserved in Gapping contexts:

(62) a. ??This man knows why you eat spaghetti, and that man, macaroni.
b. *This man knows why spaghetti makes you sick, and that man, macaroni.
(Pesetsky 1982: 644, (120b), and 645, (121))

Further, Pesetsky argues that other constraints on multiple questions are found in Gapping. One of those constraints, Superiority, prevents *wh*-movement from moving a term past a c-commanding interrogative phrase. This is what is responsible for the contrast in grammaticality in (63):

(63) a. Who gave what to Mary?
b. *What did who give to Mary?

Pesetsky reports a similar contrast for the remnants in Gapping. If one of those remnants is a *wh*-phrase, then it cannot have been moved past a c-commanding remnant; the contrast in (64) mirrors that in (63):[21]

(64) a. Bill asked which books I gave to Mary, and which records, to John.
b. *Bill asked which books Mary likes, and which records, John.
(Pesetsky 1982: 646, (126), (127))

It's unclear how to formulate Superiority so that it will cover both cases; but in general, the match between (63) and (64) suggests that a similar process is involved in creating both constructions. If the in situ *wh*-phrases in (63) move – a popular approach to these sorts of multiple questions – then the hypothesis that Gapping remnants move as well makes sense of the match.

Moreover, this thesis has the interesting side-effect that it explains the Constituency Condition on Remnants. To the extent that movement operations can only target constituents, they will pick out just those strings as remnants which parse as constituents. Moreover, it goes beyond the Constituency Condition and offers a method for blocking the bad examples in (37) and (38) as well. If remnants are just phrases that move, then the cases in (37b) and (38b) would have to arise by moving an NP away from its determiner, and this is not possible. To produce the ungrammatical (37c) and (38c), it would be necessary to move a DP out of a prepositional phrase, and though this is normally quite possible in English, there are movement operations which are constrained in this way. 'Scrambling' in the Germanic languages, for instance, is incapable of stranding prepositions; indeed, Scrambling in the Germanic languages is blocked from moving constituents out of embedded finite clauses as well, matching in this respect the constraint on Gapping that (56) illustrates. Finally, Scrambling in the Germanic languages is plausibly able to move infinitival clauses (the evidence is unclear), but probably cannot move VPs out of embedded clauses. This would explain why embedded infinitival clauses can be remnants (as in (42a)) but embedded VPs cannot (as (42b) shows).

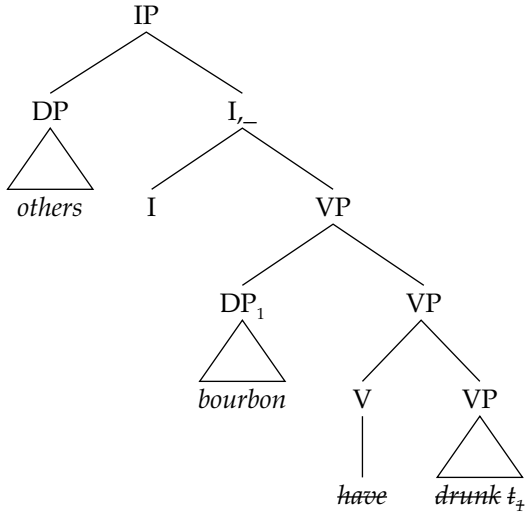
Thus, many of the constraints on remnants and on the strings that can Gap are accounted for if the thesis that Gapping can be fed by movement is given the more specific form in (65):

(65) Gapping elides an XP from which the remnants have scrambled.

Under this interpretation of the facts, examples such as (66) or (68) would have representations like (67) and (69):

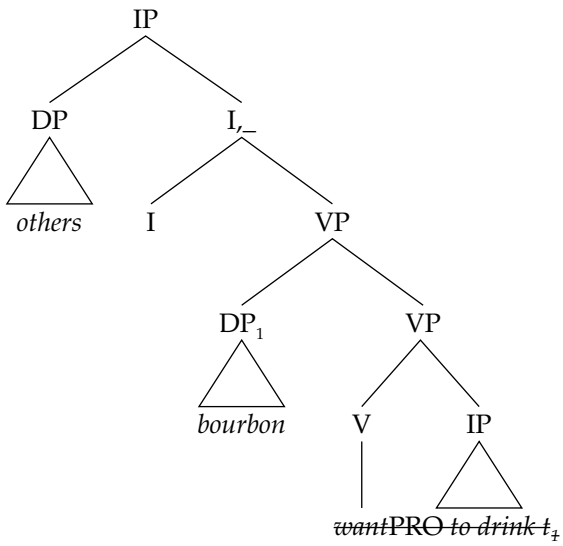
(66) Some have drunk whiskey and others ~~have drunk~~ bourbon.

(67)



(68) Some want to drink whiskey and others ~~want to drink~~ bourbon.

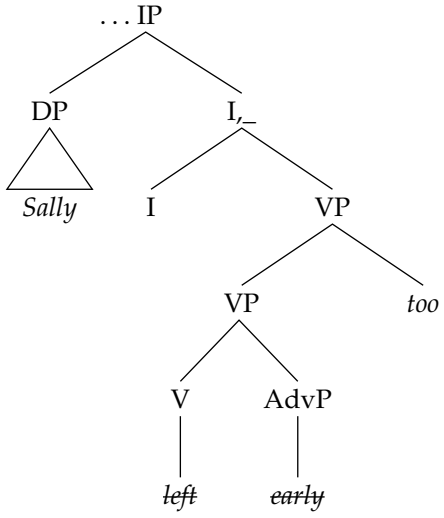
(69)



To produce examples like (8), repeated here as (70), we let Gapping elide the VP without accompanying scrambling, as in (71):

(70) Mary left early, and Sally ~~left early~~ too.

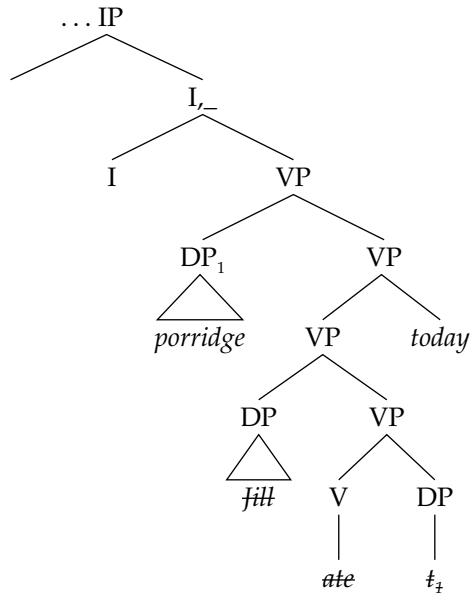
(71)



And to manufacture examples like (9), repeated below as (72), we should adopt the thesis that subjects can be generated within the VP, and let (9) arise when the subject remains in this position, as in shown in (73):

(72) Jill ate rice yesterday and ~~Jill ate~~ porridge today.

(72)



By and large, then, if Gapping can elide VPs, and can do so after terms within that VP have scrambled out, a certain range of central cases can be accounted for.

5 Parallelism and scope

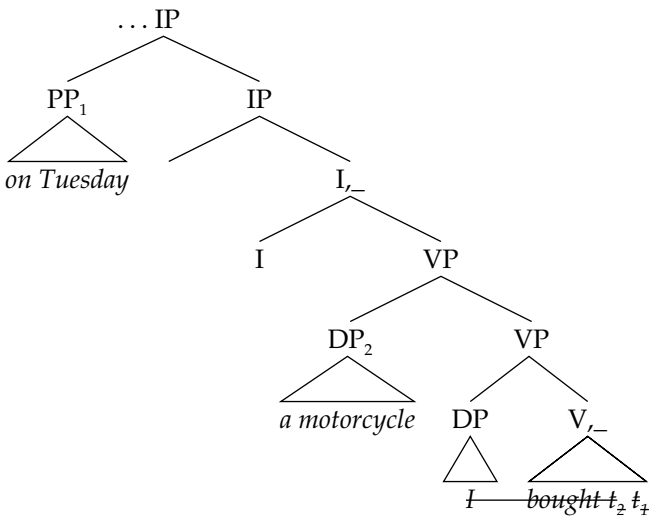
The odd property of this thesis is that it requires English surface forms to be able to be produced by the Scrambling process that is so transparently a part of, say, German or Dutch word order. English surface forms, however, do not otherwise appear to have been created by Scrambling. One of the unsolved problems of Gapping, then, is to fit the thesis in (65) to the more general syntax of English sentences, or to find a replacement for (65).

If such a fit can be found, however, the technique (65) allows can also be extended to cases such as (74), in which Gapping has elided the subject along with the verb:

(74) On Monday, I bought a car and on Tuesday ~~I bought~~ a motorcycle.
(Oirsouw 1987: 146, (158))

(Cases such as these are also found in Kuno 1976: 307, (31a) and Sag 1980: 266, (3.4.16).) If we assume that the topicalized PPs in this example are adjoined to IP, then we can combine the techniques used to manufacture (71) and (72) to give the Gap in (74) the representation in (75):

(75)



Through this case, another fact about Gapping can be observed: there is a matching requirement on the word order found in the antecedent clause and the clause with the Gap.[22] (76) is relatively ungrammatical when compared to (74):

(76) *I bought a car on Monday, and on Tuesday, a motorcycle.

This fact might be related to another requirement on Gapping: the scope of quantifiers in the antecedent clause must be parallel to those in the clause with the Gap. In (77), for example, if *some girl* has narrower scope than *every book* then *some boy* must also have scope narrower than *every pamphlet*:

(77) Some girl read every book and some boy every pamphlet.

If *some boy* has scope wider than *every pamphlet*, then *some girl* is going to have wider scope than *every book*. In other words, (77) does not support interpretations paraphrased in (78):

(78) a. There is some girl who read every book, and for each pamphlet, there is some boy or other who read it.
b. For each book, there is some girl or other who read it, and there is some boy who read every pamphlet.

The same parallelism can be demonstrated for quantificational arguments which are included in the ellipsis, as in (79):

(79) Some read a story by Grimm to every child and others a story by Seuss.

Just as in (77), the relative scopes of *every child* and *a story by Grimm* must match the relative scopes of *every child* and *a story by Seuss*. A similar parallelism is found in other forms of ellipsis – VP ellipsis, pseudogapping, and sluicing – and it is presently thought that the close relationship between ellipsis and deaccenting is responsible (see Fox 1999; Merchant 2001). To the extent that word order expresses information structure, including the focus semantics of a clause, it may be possible to relate the matching requirement that (76) illustrates with the parallelism effect found in cases such as (77) and (79).

If the parallelism constraint on the scope of arguments that (77) and (79) illustrate is something that Gapping shares with other ellipsis processes, it also displays some unique scopal properties. Oehrle (1987), Siegel (1987), and McCawley (1993) note that modals and negation in the antecedent clause sometimes behave as if they scope over the entire conjunction. For example, in (80a), *must* is understood to scope over the coordination, producing the interpretation paraphrased by (80b):

(80) a. I tried it in both positions, one of which must have been the locked position and the other one the unlocked position, but it wouldn't work either way.
b. I tried it in both positions, for which it must have been that one was locked and the other unlocked, but it wouldn't work either way.
(McCawley 1993: 249, (20g))

The same is found for *didn't* in (81a), which favors an interpretation in which it has the entire conjunction in its scope, yielding the meaning (81b) indicates:

(81) a. Kim didn't play bingo and Sandy ~~didn't~~ sit at home all evening.
b. not ((Kim played bingo) and (Sandy sat at home all evening))
(Oehrle 1987: based on 205, (28))

Siegel suggests that this fact emerges only when Gapping has affected just the modal or negation and nothing else. Thus, she points to a contrast between (80a) and (82), in which Gapping has removed *can't* along with the verb that follows:[23]

(82) Ward can't eat caviar and his guest ~~can't eat~~ beans. (Siegel 1987: 53, (3))

Indeed, unlike (80a), this sentence can be understood as synonymous with *Ward can't eat caviar and his guests can't eat beans*, in which *can't* is within each conjunct. It is also possible, however, to understand (82) so that *can't* has scope over the conjunction, that is, to be synonymous with 'It's not possible for Ward to eat caviar and his guest eat beans'.

Perhaps related to these instances of surprising wide scope are cases in which the subject of the antecedent clause takes an unexpectedly wide scope, as McCawley discovered by way of the example in (83); other examples, from Johnson (2000b), are in (84):

(83) No one's$_1$ duck was moist enough or his$_1$ mussels tender enough.
(McCawley 1993: 248, (15a))

(84) a. Not every girl$_1$ ate a GREEN banana and her$_1$ mother, a RIPE one.
b. No boy$_1$ joined the navy and his$_1$ mother, the army.

In each of these cases, the quantificational subject of the first conjunct can, as indicated by the indices, bind the pronoun found in the second conjunct. This is normally not possible, as (85) shows, presumably because the contents of the second conjunct do not normally fall within the scope of the material in the first:

(85) a. *Not every girl$_1$ ate a GREEN banana and her$_1$ mother ate a RIPE one.
b. *No boy$_1$ joined the navy and his$_1$ mother joined the army.

There is something about Gapping, then, that allows the material in the antecedent clause to have scope over the clause with the gap, and therefore over the conjunction housing both clauses.

McCawley relates these latter examples of exceptional scope to another exotic property of Gapping. It is sometimes possible, he shows, for Gapping to elide a part of the subject along with the verb. Some of his examples are (86):

(86) a. Too many Irish setters are named Kelly and German shepherds, Fritz.
b. The duck is dry and mussels, tough.
c. Your daughter is 16 and son, 17½.
d. How many states have a veterinary school or cities a zoo?
(McCawley 1993: 245, (1a, c, d), and 246, (6a))

McCawley argues that it's only terms in 'determiner position' which are able to Gap in this way, pointing to the ungrammaticality of examples such as (87):

(87) a. Italian red wines are outstanding and white wines excellent.
b. Red wines from Italy are outstanding and white wines excellent.
(McCawley 1993: 246, (10a', a''))

The reason that McCawley connects these startling instances of Gapping with the puzzling wide scope of the determiners in (83) and (84) is that, in some of these cases, the scope of the Gapped determiner also appears to be required to have wide scope. For example, he points to (88a) and notes that it has a paraphrase something like (88b) rather than (88c):

(88) a. Not enough linguists study Russian, literary scholars French, or engineers Japanese.
b. Not enough linguists, literary scholars and engineers study Russian, French and Japanese respectively.

c. Not enough linguists study Russian or not enough literary scholars study French or not enough engineers study Japanese.
(McCawley 1993: 247, (12a))

The fact that the paraphrase involves conjunctions rather than the disjunctions the sentence actually uses indicates that the negation built into *not enough* has wide scope. The same thing can be seen in (89a), whose paraphrase in (89b) perhaps makes clearer the wide scope aspect of these cases:

(89) a. No cat should eat Puppy Chow or dog, Whiskers.
b. It's not the case that any cat should eat Puppy Chow or that any dog should eat Whiskers.

It would seem, then, that the fact that quantificational determiners are capable of escaping the scope of the disjunction, or conjunction, in a Gapping context is a precondition for these instances of Gapping. This, perhaps, is why the determiner *a* seems unable to Gap in these contexts – another discovery in McCawley – since when *a* takes wide scope it does so by means quite different from other quantifiers:

(90) *A soup was too salty and pie too sweet, but otherwise the food was outstanding.
(McCawley 1993: 245, (5a))

To fit these instances of determiner Gapping into the framework in (65) for understanding the constituency of gaps is quite a challenge. It would seem to require moving all of the subject, except its determiner, along with whatever other remnants there are, out of the VP, and then Gapping that VP. For some recent attempts at just that, see Lin (2001) and Johnson (2000a, 2000b).

McCawley's paraphrase of (88a) in (88b) brings out another aspect of the Gapping construction: it has a superficial similarity to the use of *respectively* in coordinations. Not only does a Gapping sentence like (91a) mean something very like what (91b) means, they both involve focus on the related, compared, terms in a similar fashion:

(91) a. Jill ate beans and Jerry ~~ate~~ rice.
b. Jill and Jerry ate beans and rice respectively.

Moreover, the constraints on the strings that may Gap roughly match the constraints that the *respectively* construction places on the distance between the coordinated phrases that are being related. So, for instance, just as a string that includes a part of an adjunct clause cannot be Gapped (witness (92a)), so also is it impossible to relate two coordinates with *respectively* across an adjunct (as in (92b)):

(92) a. *Tom went to Florida to learn to play tennis and Bill ~~went to Florida to learn to play~~ squash.
b. *Tom and Bill went to Florida to learn to play tennis and squash respectively.

Similarly, *respectively* seems unable to relate coordinates that are separated by a finite clause in the same way as (56a) (repeated here as (93a)) indicates that Gapping cannot reach into a finite clause:

(93) a. *Charles decided that 20 boys are coming along and Harrie ~~decided that~~ 30 girls ~~are coming along~~.
b. *Charles and Harrie decided that 20 boys and 30 girls are coming along respectively.

The match isn't perfect: *respectively* can apply to a coordinated argument within a prepositional phrase, as in (94a) and, as we've seen, Gapping cannot target a remnant in this position (compare (94b)):

(94) a. John and Jill stood beside Jim and Mary respectively.
b. ?*John stood beside Jim and Jill ~~stood beside~~ Mary.

Still, to a large degree, the constraints on these two constructions are the same. This has led some to attempt to derive one construction directly from the other (see Hudson 1976 and Moltmann 1992 for extended analyses along these lines, and Dougherty 1970, 1971, Goodall 1987b, and Muadz 1991 for some relevant discussion). Another coherent approach, however, would be to give to both Gapping and *respectively* a syntax that triggers the same family of constraints.[24]

6 Conclusion

An important open question is how Gapping fits into the larger typology of ellipsis. As sketched above, it is possible to distinguish Gapping from Right Node Raising and other coordination-specific ellipses processes.[25] To the extent, however, that Gapping is restricted to coordinations, there is some reason for finding a common underlying licensing environment for all these phenomena. This is the direction that Goodall (1987b), Steedman (1990, 1996), Muadz (1991), Moltmann (1992), Munn (1993), Zoerner (1995), and many others take. Johnson (2000a, 2000b) expresses a variant of this school that attempts a reduction of Gapping to across-the-board movement. But Gapping also has similarities with the sorts of ellipses that are found in Sluicing and VP Deletion, and this has animated an attempt to overcome the difficulties sketched above for equating these phenomena; see Hartmann (1998), Coppock (2001), and especially Lin (2002).

In summary, Gapping is a process that elides VPs from which remnants have moved, sometimes by Scrambling. Unlike other ellipses processes, Gapping is found only in coordinations and is uniquely subject to the No Embedding Constraint.

NOTES

1 To see Gapping playing a role in (3), one must imagine the VP *met kids* following *than* out of which *met* has Gapped.
2 See Dougherty (1970, 1971) and Burton and Grimshaw (1992) among others.
3 See Rooth and Partee (1982) for a description of this ambiguity and an analysis that stands as an alternative to the one based on Gapping described here.
4 Chinese has the interesting property of favoring instances of Gapping like these over the more familiar ones in (1), suggesting that these two cases are not completely identical. See Paul (1999) for discussion.
5 And see Munn (1993) for a more recent treatment along these lines.
6 Though, see Sag 1980 for reasons for thinking that an independent ellipsis process is responsible (and Neijt 1979: 57ff. for counter-arguments).
7 A point also made by Chomsky (1980b: 190).
8 An anonymous reviewer points out that the *either/or* diagnostic of Gapping described above, examples like 'either in the house or the barn' would suggest that prepositions can Gap. For some indication that the placement of *either* cannot be reliably taken to mark the left edge of a disjunct, and therefore that Schwarz's analysis will have to be modified, see Johannessen (1993, 1998).
9 This issue concerning the distinction between Deletion and N Gapping is discussed in Jackendoff (1971).
10 To find contexts in which Adverbs or Complementizers (such as *whether* or *that*) Gap is not possible (because no material within an Adverbial Phrase or Complementizer Phrase can stand to the left of an Adverb or Complementizer), so whether these categories can Gap is undeterminable.
11 His examples are slightly different than mine, but not meaningfully. See Sag (1980: 273).
12 This is how the constraint is commonly framed, but Jackendoff (1971: 26) expresses it as follows: "In by far the most acceptable examples of Gapping, then, there is only one unlike constituent in the second verb phrase, and all the rest must delete."
13 In combination with various processing pressures.
14 For other problems with the No Ambiguity Constraint, see Quirk et al. (1972: 580ff.); Stillings (1975); Langendoen (1976); Sag (1980: 211ff.).
15 This is essentially how Sag (1980) formulates the process, which he then couples with a version of Bresnan's (1976c) Relativized A-over-A Condition to capture some of the cases that Hankamer's Major Constituent requirement was aimed at.
16 This, and the question corresponding to (54b), are ungrammatical on the construal in which *when* comes from the embedded clause.
17 See Ross (1969b).
18 For a recent analysis of Sluicing, see Chung et al. (1995) and Merchant (2001).
19 See Sag (1980: 288).

20 He conjectured that the movement operation occurred on the surface, not at Logical Form as in Sag's work, and that the remnants were moved into Comp position (what would in present terminology be the Specifier of CP).
21 I don't find the contrast in (64) as strong as that in (63).
22 A constraint pointed out in Hankamer (1979) and Pesetsky (1982: 658).
23 It should be noted that Gapping is not always successfully able to affect strings with negation in them. Ross (1970a), for instance, points to cases like (i) and suggests that Gapping is generally incapable of eliding *not*:

(i) *I didn't eat fish, Bill ~~didn't eat~~ rice, and Harry ~~didn't eat~~ roast beef.

See also Jackendoff (1971); Stillings (1975); Sag (1980: 195).
24 See Beck (2000) for an approach along these lines.
25 See McCawley (1998: chapter 9) for a useful canvass.

  3.6 Approaches to the conflict between internal and external constituency in English gerundives
  3.7 Broader issues of constituency in mixed categories
4 Conclusion

1 Introduction

All languages are confronted with the problem of expressing propositions as arguments of larger propositions. Typically, this is done in one of two ways. The first, and by far the better researched and understood, is through finite or non-finite complement clauses, as in English examples such as (1–4):

(1) Everyone assumed *that the tree was dying*.

(2) Everyone assumed *the tree to be dying*.

(3) *That the tree was dying* saddened us all.

(4) *For the tree to be dying* would be devastating.

The second strategy is nominalization. In this device, the proposition is expressed by means of a phrase projected from a noun (or perhaps its determiner) that is related lexically or syntactically to the predicate of the corresponding clause. English examples related in this way to (1–4) are:

(5) Everyone expected *the death of the tree*.

(6) Everyone expected *the tree's death*.

(7) *The death of the tree* saddened us all.

(8) *The tree's death* saddened us all.

Many languages have a particular nominalization strategy characterized by essentially full productivity. The poster child for this sort of construction is the English *ing* construction exemplified in (9–13):

(9) The orchestra went on strike after *playing the overture*.

(10) We didn't approve of *them doing that*.

(11) We didn't approve of *their doing that*.

(12) We didn't approve of *doing that*.

(13) *Their playing the overture so badly* disgusted the audience.

In the generative literature, as well as in traditional work on many languages, constructions of this sort are referred to as the gerund or the gerundive nominalization. Generative inquiry into the properties of English gerundives dates to the origins of the discipline and has continued sporadically since then.

More recently, it has been realized that the puzzling properties of constituency, case, movement, and control that characterize the English gerundive have counterparts in many other languages as well, and the inquiry has expanded considerably. Since much of the work discussed below is concerned with the English construction, it may be appropriate in this introduction to address two potential confusions that can arise in considering the English data and their implications.

One concerns the relationship between true gerundives of the type illustrated above and a superficially similar nominalization exemplified by (14–17) below and referred to variously in the literature as the 'nominal gerundive', 'action nominalization', or 'derived nominalization in *ing*':

(14) The opera began after *the playing of the overture*.

(15) We thought that *his repeated retuning of the instrument* was unnecessary.

(16) *The constant retuning of instruments* seems to be a feature of early music concerts.

(17) *Their playing of the overture* was excruciating.

The contrast between these types of nominalization has been noted repeatedly, as in Chomsky (1970), Fraser (1970), Wasow and Roeper (1972), and Horn (1975). The derived nominalization (DN) type in (14–17) poses no particularly interesting problems. The *ing*-affixed verb form appears to be of nominal category and its projection has exactly the properties one should expect: it occurs in argument positions canonically occupied by nominal projections; it can include determiners, genitive subjects, and adjectival modification; and its internal complements require the preposition *of*. Also, the construction is limited in productivity, as shown by pairs such as (18, 19):

(18) Several factors led to *her achievement of legendary status*.

(19) *Several factors led to *her achieving of legendary status*.

Thus, one may conclude that this sort of example represents merely one of many partially productive lexical nominalization mechanisms provided by English, parallel to affixations and stem changes such as those in (20–22):

(20) We objected to *their retention of the documents*.

(21) *Her disavowal of vegetarianism* is quite recent.

(22) *The loss of his investment income* made Fred a wage slave.

True gerundives of the type shown in (9–13) (sometimes called 'verbal gerundives', 'VP gerundives', or 'sentential gerundives') are quite a different matter, and their analysis has presented difficult questions which will be taken up below.

The second potential confusion concerns the complements of certain 'perception verbs' in English:

(23) a. I saw *them climb the hill*.
b. I heard *them laugh like idiots*.

(24) a. I saw *them climbing the hill*.
b. I heard *them laughing like idiots*.

This construction has spawned a fairly long and contradictory literature in generative grammar, but its relevance in the present context resolves to the question of whether it is sensible to regard the italicized constructions in (24) as instances of the gerundive construction. Reasonable people (e.g., Reuland 1983 and Johnson 1988) have disagreed about this, but it would seem to be prudent to exclude such examples from consideration here, since they show a clear divergence from the syntactic patterns seen in true gerundives. These differences include the following.

First, the case of the apparent subject in such examples is always accusative. While accusative case subjects are sometimes possible in true gerundives, as noted in section 2.1 below, genitive is far more common. When genitive case is substituted in examples such as (24), the result is ill-formed:

(25) a. *I saw their climbing the hill.
b. *I heard their laughing like idiots.

Second, both A- and A'-extraction from the apparent subject position of examples such as (24) are easily possible:

(26) a. They were seen climbing the hill.
b. They were heard laughing like idiots.

(27) a. Who did you see climbing the hill?
b. Who did you hear laughing like idiots?

As noted in 2.2 below, A'-extraction from the subject position of true gerundives is decidedly vexed, and A-extraction (as in (28), is entirely impossible:

(28) *They were enjoyed playing the concerto.

Finally, the position occupied by *them* in (24) must be lexically filled, while true gerundives, such as that in (29c), have no such requirement:

(29) a. *I saw climbing the hill.
b. *I heard laughing like idiots.
c. I enjoyed climbing the hill.

The fact pattern shown here is compatible with an analysis in which perception verbs are ditransitive object control predicates similar in relevant respects to verbs such as *force* and *persuade*, which take nominal objects followed by infinitival complements. If this is correct, the structure of an example such as (24a) would be something like (30):

(30) I saw them$_i$ [PRO$_i$ climbing the hill].

Whether the bracketed constituent in (30) is a gerundive or something else, perhaps a 'small clause', as suggested by Reuland (1983), will not be pursued here. The only important point for present purposes is that examples such as these should be left out of consideration in the discussion that follows, since crucial factual judgments can be obscured if one confuses these rather problematic cases with the core examples of the gerundive construction.

2 Theoretical and descriptive issues in the analysis of gerundives

2.1 Constituency

The basic problem presented by the English gerundive construction, and by similar nominalizations in many languages, is that there is a contradiction between its internal structure and what would appear, on the evidence of its distribution in larger structures, to be its category type. Like the DN structures discussed above, gerundives occupy argument positions canonically assigned to nominal projections (NP) or their functional shells (DP). The most convincing examples of this are provided by structures containing psychological predicates, raising predicates, extraposition, prepositional arguments, or subject embedding, since these are the positions where there is the most unequivocal contrast between the distribution of nominal and sentential categories. In all these instances, gerundives have a distribution that parallels that of lexical nominals and contrasts with that of finite clauses:

(31) a. We were amazed that they left the city.
b. *We were amazed their leaving the city.
c. *We were amazed their decision.

(32) a. It seems that they left the city.
b. *It seems their leaving the city.
c. *It seems the departure.

(33) a. It is false that they left the city.
b. *It is false their leaving the city.
c. *It is false that story.

(34) a. *We talked about that they left the city.
b. We talked about their leaving the city.
c. We talked about the decision.

(35) a. *Fred said that that they left the city surprised him.
b. Fred said that their leaving the city surprised him.
c. Fred said that nothing surprises him anymore.

Despite this distributional evidence for nominal constituency, the internal structure of gerundives resembles in nearly all respects that of a sentence. Nominal objects are possible (36a), articles and quantificational determiners are barred (36b, c), and modification is adverbial (36d, e). Finally, as Pullum (1991) may have been the first to notice, the gerundive *ing*-form itself does not seem to be morphologically nominal, as shown by the resistance to pluralization exemplified in (36f.). The only respect in which these gerundives have an internal structure resembling that of a nominal projection is that they accept genitive case subjects, and even here the data are mixed: accusative case sometimes occurs in place of genitive under conditions that are not at all well understood (36g, h):

(36) a. Leaving the city is difficult.
b. *The leaving the city is difficult.
c. *Some leaving the city is difficult.
d. Leaving the city quickly is difficult.
e. *Rapid leaving the city is difficult.
f. *Leavings the city is difficult.
g. Their leaving the city surprised everyone.
h. ?Them leaving the city surprised everyone.

One further peculiarity of the internal structure of gerundives that has sometimes been taken as evidence of a non-sentential internal structure is that they do not permit modal auxiliaries:

(37) a. *John's must leaving was surprising.
b. *John's musting leave was surprising.

It is not clear that this fact has any structural implications, however. Modals are also barred from infinitivals, and it may be that both these facts are to be attributed to the morphological deficiency of English modals, which are restricted to finite inflectional forms.

It was once supposed that the categorial contradictions present in the English gerundive represented an unusual and highly marked phenomenon. Abney, in the course of his detailed study of gerundives (1987), remarks for instance that he was able after some effort to find a construction with the mixed properties of the English gerundive only in Turkish. This speculation was reinforced by evidence of historical instability in the properties of the construction within English.

There are literary examples ranging from the seventeenth to at least the mid-nineteenth centuries which seem to show the construction exhibiting different properties from those it has today. Typical is the following sentence from Act I, Scene 4, of Shakespeare's *Macbeth*:

(38) Nothing in his life became him like the leaving it.

The co-occurrence here between the definite determiner and the nominal object is entirely impossible in contemporary English, as shown by examples such as (36b). Wescoat (1994) notes several such instances, and a wealth of similar examples is found in Poutsma (1923) and Jespersen (1909). Emonds (1990) discusses further issues in the history of the English gerundive construction, as does Abney (1987).

More recently, however, investigations into a number of languages as historically remote from each other as Finnish, Kikuyu, and Quechua have revealed the existence of constructions with properties that closely resemble the categorial peculiarities of the English gerundive. Many of these constructions are nominalizations, as one might expect, but some are not. Taken as a whole, this work seems to show that something more general is at stake here than the analysis of a peculiar construction in a particular language, and has given rise to the term 'mixed category' to describe the problematic constructions in a more general fashion.

An example of the sort of facts that have emerged is found in Finnish. The language has four morphologically distinct non-finite verb forms, referred to in traditional grammars as the first through fourth infinitives. The first infinitive (formed with the suffix *-da*) corresponds exactly to the infinitives of Indo-European languages: it is indeclinable, and its object arguments bear the same cases as they would in a finite clause. It is, in other words, unambiguously verbal in nature. The fourth infinitive (in *-minen*) is often described (for instance in Lehtinen 1967) as a 'verbal noun', and for good reason: its characteristic suffix is morphologically related to a noun-forming suffix found in complex nominals not related to verbs, such as *Englantilainen* 'English' and *päskiäinen* 'related to excrement, foul person'; it is inflected for case, and its object arguments appear in genitive case. The form thus appears to be the exact analogue of the English DN gerundive and similar lexical nominalizations found in many other languages. In contrast to these examples of well-behaved categorial integrity, the second and third infinitives (in *-de* and *-ma* respectively) have mixed properties that are exactly analogous to those of English gerundives, within the limits of the syntactic and morphological parameters that distinguish the languages. Both forms are clearly nominal, accepting case and possessor affixes (the apparent analogue of English gerundives being restricted to cased positions), yet requiring clause-like case marking on their object arguments (the analogue of the presence of non-prepositional objects in English gerundives).

2.2 *Subject properties*

A second issue concerns the properties of the internal subject position. As noted above, lexical subjects may occur here, and genitive and accusative case alternate in the position under unclear conditions. However, gerundives also occur without audible subjects. These empty subjects are subject to control or to arbitrary interpretation, depending on their structural environment, a fact which has led most authors to assume the presence of PRO:

(39) PRO revealing one's emotions is often dangerous.

(40) Fred's revealing his emotions was tasteless.

(41) We regretted PRO performing the piece so badly.

(42) We regretted their performing the piece so badly.

This raises two issues. First, it is another respect in which the internal structure of gerundives appears to be sentence-like. While a number of people have suggested that PRO can occur in nominal categories, the evidence for this is somewhat slender. No one who acknowledges the existence of PRO at all, however, would doubt its presence in the subject position of non-finite clauses. Thus (39, 41) are exactly to be expected if gerundives are sentential. Further, Wasow and Roeper (1972) point out that control (and thus PRO) does not occur in DN gerundives, which are unquestionably nominal. Thus, (43) is not necessarily a claim about George's feelings about his own well-drilling:

(43) George regrets the drilling of all those oil wells.

This difference in control properties was exploited in a language acquisition study reported in Roeper (1982), in which it is argued that children show evidence of prior knowledge of the contrast in control between DN and true gerundives.

Second, the alternation between controlled PRO and lexical subjects in examples such as (39–42) is reminiscent of the situation in the subject position of infinitival complements of mixed control verbs such as *want* or *expect*:

(44) We expected them to understand the argument.

(45) We expected PRO to understand the argument.

Examples like these are an old source of puzzlement in generative analysis and have yet to receive a really satisfactory treatment, although they are no longer so obvious an embarrassment as they were in GB analyses incorporating the 'PRO Theorem' (Chomsky 1981).

2.3 *Extraction and interrogatives*

There is at least one minor issue concerning A'-extraction from gerundives. The construction shows a subject–object asymmetry that is unusual when compared with analogous phenomena in finite clauses and infinitivals:

(46) a. Who did she claim read the book?
b. What did she claim he read?

(47) a. Who did you want to read the book?
b. What did you want them to read?

(48) a. *Whose did you regret playing the piece?
b. *Who(m) did you regret playing the piece?
c. Which piece did you regret their playing?

The resistance to extraction of genitive subjects shown in (48a) is not in itself particularly mysterious, since genitive subjects behave the same in ordinary nominals, as noted originally by Ross (1986 (original dissertation 1967)) in his discussion of the Left Branch Condition.

(49) *Whose did you see book?

From this point of view, (48a) is at most another indication that gerundives are nominals of some sort. Interestingly, however, accusative subjects of gerundives also resist extraction, as shown in (48b), although many speakers do not find this sort of example as repulsive as those with genitive subjects, and published claims about their status differ. Reuland (1983) and Abney (1987) cite sentences such as (50) as grammatical, while Johnson (1988) assigns double question marks to analogous examples:

(50) Who(m) do you approve of studying linguistics?

A related issue raised perhaps first in Stowell (1981) and taken up later by Reuland (1983), Abney (1987), and Johnson (1988) is the absence of interrogative gerundives:

(51) I asked what she had done.

(52) I asked what to do.

(53) *I asked what (her) doing.

Stowell and Reuland took this as evidence that gerundives do not have a complementizer position that can accept interrogative elements. Abney's analysis, in which gerundives are not sentential, actually predicts this result.

2.4 Exceptional distributions

Occasionally, for instance in Battistella (1983) and Milsark (1988), it has been noticed that gerundives can in some circumstances show exceptions to the nominal distribution pattern shown in (31–35). The gerundive in (54) seems quite acceptable in a position normally allotted to sentential, rather than nominal, constituents. It is important, by the way, that these examples be read without

'comma' intonation breaks after *pleasant*. In the presence of such intonation breaks, the contrast in judgments disappears:

(54) It is pleasant walking in these woods.

(55) It is pleasant that we can walk in these woods.

(56) It is pleasant to walk in these woods.

(57) *It is pleasant this walk through the woods.

Interestingly, examples such as (56) become quite unacceptable when the gerundive has a subject:

(58) *It is pleasant our walking in these woods.

This phenomenon has been little researched, but the properties seen here would seem to indicate that if gerundives are generally nominal projections of some kind, there are nonetheless some like (54) that are not. There are additional complications, however. Michaelis and Lambrecht (1996) discuss examples such as *It's amazing the people you see here*, in which non-propositional nominals occupy a position that seems to be the same as that occupied by the gerundive in (54). The existence of such examples raises the possibility that gerundives in examples such as (54) might be nominal categories after all. As Michaelis and Lambrecht point out, however, the structures they studied always seem to carry an exclamatory force and a marked intonation contour. This is not true of gerundive examples such as (54), so it is not clear what if any relationship there is between the cases, especially since an intonation break after *pleasant* repairs examples such as (57) and (58), as noted above.

2.5 *The 'doubl-*ing*' phenomenon*

Beginning with Ross (1972b), a surprisingly copious literature has assembled around judgments of the sort shown in (59–62), showing that some, but not all, sequences of contiguous *ing*-affixed forms result in degraded acceptability. It is generally conceded that the examples in which iterated *ing*-forms are well-formed are those in which the second *ing*-form is a gerundive, while those exhibiting degraded acceptability contain some different construction in this position:

(59) They kept talking.

(60) *They were keeping talking.

(61) They enjoyed singing.

(62) They were enjoying singing.

Several approaches have been taken to the description of this phenomenon, ranging from purely descriptive statements to attempts to explain the phenomenon as a consequence of larger generalizations, such as an avoidance of morph repetition.

2.6 *How many* ings *are there and how do they arise?*

One of the enduring puzzles of English syntax is that there seem to be several affixes with the phonological shape *ing*, raising questions about how many distinct morphological elements they actually represent and how they are introduced into derivation. In addition to gerundives and the derived nominals and perception verb complements mentioned in the introduction, this affix appears in progressive aspect (63), in adverbial adjuncts (64), in a number of non-propositional nouns such as those in expressions like *fine clothing*, *wire fencing*, *wool carpeting*, *mine tailings*, and in adjectives such as *astonishing*, *terrifying*, *interesting*, *amusing*:

(63) They were walking down the street.

(64) Walking down the street, we saw a rainbow in the distance.

While most work on the gerundive and related phenomena has left this apparent syncretism unexplored, there have been some attempts (e.g., Milsark 1988; Emonds 1990; Siegel 1998) to reduce it in some way.

3 Generative literature related to the gerundive construction

Below are descriptions of a number of works which include discussion of the issues surrounding the analysis of gerundives. Many have been mentioned in passing in previous sections. Where convenient, they are grouped in thematic categories.

3.1 *Beginnings*

Early discussion of the gerundive appears in Chomsky (1975a (written in 1955–1956)), Lees (1960), and Rosenbaum (1967). The Chomsky and Lees works contain attempts to derive gerundive structures from structures underlying the 'kernel sentences' most closely approximating them by insertion of appropriate morphology and the use of generalized transformations. Rosenbaum, writing after the replacement of generalized transformations by expanded phrase structure operations (Chomsky 1965), takes gerundive complements to be present at deep structure but differentiated from other complement types by the application

of a transformation inserting the 'POSS-ing' complementizer. Emonds, in his 1970 discussion of root and structure-preserving transformations, notes the distributional differences between gerundives and complement clauses, particularly with respect to extraposition. He suggests that gerundives are generated in argument positions, while other (non-nominal) complements are generated in rightward adjunct positions and sometimes 'intraposed' to the argument positions in which they may appear in matrix structures. While these works are largely concerned with questions peculiar to their time, they still reward consultation in some ways. They introduce a number of the issues that animate later inquiry, such as the alternation between accusative and genitive case subjects, the resistance of gerundives to extraposition, the ambiguity of *of*-phrases in gerundives with respect to subject or object interpretation, the existence of gerundives with both nominal and prepositional objects, and the multiplicity of distinct constructions employing the formative *ing*. Rosenbaum's book, in particular, is laden with facts of great importance to later work.

3.2 *Chomsky (1970); Fraser (1970); Wasow and Roeper (1972); Marantz (1997); Harley and Noyer (1998)*

Jacobs and Rosenbaum (1970) contains two articles taking opposing positions on the derivational properties of DN gerundives: Chomsky's "Remarks on Nominalization" and Bruce Fraser's "Some Remarks on the Action Nominalization in English." Chomsky's paper argued on the basis of productivity and internal morphology that gerundives of the type seen in (9–13) above were sentential complements (transformationally derived, in the view current at the time), while derived nominals in general (and gerundive derived nominals such as (14–17) above) were lexically derived. Fraser's paper was an effort to refute these arguments and defend transformational derivation for both true and DN gerundives. Wasow and Roeper (1972) is primarily noteworthy for its careful discussion of the distinction between true and DN gerundives ('verbal' and 'nominal' gerundives in their terminology).

The distinction between true and DN gerundives has been revisited more recently by Harley and Noyer (1998 (a paper first presented in 1997)). Chomsky (1970) had noted that English verbal particles may occur in either their internal or their external positions in gerundive nominals, but only in the internal one in DN nominals:

(65) John's marking up the book was discourteous.

(66) John's marking the book up was discourteous.

(67) John's marking up of the book was discourteous.

(68) *John's marking of the book up was discourteous.

For Chomsky, this constituted an argument that DN gerundives were lexical nominalizations, while true gerundives were syntactically derived. Harley and Noyer attempt to provide an alternative treatment of examples like (70) that does not make use of Chomsky's distinction between lexical and syntactic derivation, since the distinction is unavailable in the theory of Distributed Morphology which they assume. On their account, DN gerundives differ from true gerundives (and from sentences as well) in that they lack certain functional projections that provide a target for movement of the object DP to the left of the particle in examples such as (66). Marantz (1997) provides a similar reanalysis of Chomsky's observations that also relies on a difference in functional content between gerundives and other nominalizations, in this case an agent-licensing category 'v-1' which is claimed to inhabit sentences and gerundives, but not other nominalizations. The goal here is to account for the distinction between examples such as (69) and (70) without maintaining a distinction between the lexicon and the syntax:

(69) *John's growth of the tomatoes . . .

(70) John's growing the tomatoes . . .

*3.3 Ross: 'doubl-*ing*' and succeeding work*

Ross's (1972b) article introduced the doubl-*ing* phenomenon to discussion. He took the facts as evidence for a 'transderivational constraint' on grammaticality related to the possibility of an overt subject occurring in the structures. Compare (71–74) with (75, 76):

(71) They kept talking.

(72) *They were keeping talking.

(73) They enjoyed singing.

(74) They were enjoying singing.

(75) *They kept our talking.

(76) They enjoyed our singing.

The facts discussed in Ross's paper form the material for a discussion that has been surprisingly long-lived. Milsark (1972) and Emonds (1973) argued independently that the doubl-*ing* phenomenon can be derived more simply from the observation that *singing* in (73, 74, 76) shows evidence of nominal constituency, while *talking* in (71, 72, 75) does not. Put otherwise, complements of *enjoy* are gerundives, while those of *keep* and other verbs that trigger doubl-*ing* are not. An account in Williams (1983a) is built on the same observation, but generalizes the descriptive mechanism in an attempt to account for certain properties of

non-gerundive complements of 'perception verbs' such as *see* and *watch* (see examples (23) through (27) above). An analysis of gerundives developed by Milsark (1988) entails that PRO subjects of gerundives carry genitive case in instances like (73, 74), allowing the doubl-*ing* phenomenon to be assimilated to the case-based analysis of restrictions on *to*-contraction suggested in Jaeggli (1980). In a number of papers, Pullum and others (Pullum 1974, 1991; Pullum and Zwicky 1999) have argued the necessity for a more intricate and purely descriptive account of doubl-*ing* incorporating structural information of greater detail than that envisioned by Milsark and Emonds. Menn and MacWhinney (1984) have attempted to embed the facts in a broader analysis of morph repetition constraints. A similar approach within an optimality theoretic framework is to be found in Yip (1998).

3.4 *Responses to the question of the sources and apparent multiplicity of* ings

In the earliest work on English complementation, the gerundive *ing* and the progressive *ing* were taken to be independent entities introduced into derivations though different syntactic processes, and other instances of the formative were left out of consideration as lexical phenomena outside the realm of the syntax. Typical are Chomsky (1957, 1964b, 1975a), Lees (1960), and Rosenbaum (1967), where the progressive *ing* is introduced as an auxiliary element by phrase structure expansion and reordered by affix movement, while the gerundive *ing* is introduced by generalized complementation or nominalization transformations (Chomsky and Lees) or as a special POSS-ing complementizer (Rosenbaum and much following work). Chomsky (1970) retains aspects of this position, in that derived nominals are regarded as lexical, while gerundives are transformationally derived. More recently, Reuland (1983), Baker (1985b), Abney (1987), Johnson (1988), Milsark (1988), Emonds (1990), and Zucchi (1993) have agreed that the gerundive *ing* takes part in a process of syntactic affixation that is in some respects reminiscent of the early work cited above. Most have been silent about the question of how many distinct *ing* affixes must be assumed for English, but Milsark and Emonds have argued that there is only one. The adjective-forming *ing* affix has come under particular scrutiny in Fabb (1984), Brekke (1988), and Borer (1990). In an interesting variation on this question, Siegel (1998) has noticed that gerundives with genitive subjects have different aspectual properties from those with PRO subjects. She proposes that this is because the progressive *ing* is morphologically related to the gerundive *ing* when the subject of the gerundive is PRO, but not when it is an overt genitive DP.

3.5 *Issues of case and lexicality in gerundive subjects*

Most work on gerundives has taken the genitive to be the usual subject case in these structures and treated accusative as an idiosyncrasy or ignored it entirely. Notable exceptions are Reuland (1983), Abney (1987), and Johnson (1988).

Early treatments of the genitive, such as Rosenbaum's (1967) POSS-ing complementizer, were stipulative in the spirit of the time, but more recent analyses have sometimes aimed at greater explanatory depth. One example is Abney (1987), in which genitive case results from agreement with the D head of the gerundive in exact analogy with the treatment of genitive specifiers in ordinary DPs. Another is Milsark (1988), where a different structural analogy between gerundives and non-gerundive nominals is exploited to the same purpose.

Reuland (1983) and Johnson (1988) have taken opposing positions on the problem of accusative case subjects. Reuland suggests that accusative case arises through transference from the inflectional head (*ing*) of a gerundive when the gerundive is governed by a matrix verb that assigns accusative case. Johnson (1988), on the other hand, holds that accusative case is assigned directly to the subject by an external case assigner in the manner of exceptional case marking in the infinitive complements of verbs such as *believe*. Abney (1987) claims that accusative case in gerundive subjects arises through internal assignment by whatever inflectional element is peculiar to these structures.

All the above attempts to grapple with the subject case problem must also deal with the alternation exemplified in (39–42) between lexical subjects of whatever case and PRO. Under the GB assumptions that underlie much of this work, this means that a way must be found to allow the subject positions of gerundives to be both governed (when lexical subjects are present) and ungoverned (when PRO is). Johnson's response is to allow gerundives to occur as both IP and CP complements (S and S' in earlier work), the former allowing external government of the subject and the latter preventing it. Reuland tries to resolve the problem by means of a particular claim about verb raising and affix movement in English. Milsark deals with it by locating the derivational recategorization of gerundive verb forms in the PF component, where, on his assumptions, the recategorization will be relevant to Case Theory but not to Binding Theory.

3.6 Approaches to the conflict between internal and external constituency in English gerundives

In early work on this issue, the recourse was to assume that verbal gerundives had a complex phrasal identity consisting of a sentence exhaustively dominated by NP, as in (77):

(77) $[_{NP}[_{S}$ Fred's asking the question]]

Thus, the conflict between the internal and external properties of these structures was resolved by main force. However, with the advent of X'-Theory, and later in the extremely impoverished and restrictive phrase structure system assumed in the Minimalist program, such an approach is rendered impossible, and the problem is red-flagged in a fairly dramatic way. A number of responses are distinguishable in the literature. Horn (1975) claims that gerundives are non-sentential; rather, he

regards them as direct NP projections of the gerundive marker *ing*, which he takes to have nominal constituency and to accept VP complements. Jackendoff (1977) suggests that the affixation of gerundive *ing* forms a deverbal noun that forms the head of a nominal projection. Schachter (1976a) suggests a somewhat similar analysis in which gerundives are NPs projected from the *ing*-affixed verb through an intermediate VP. Schachter's approach, although it dispenses with a sentential constituent in gerundives, does not resolve the X'-Theoretic difficulties that cast the earliest phrase structure analysis of gerundives into doubt. An analysis similar to Schachter's is developed within the framework of Generalized Phrase Structure Grammar by Pullum (1991). The analyses of Marantz and of Harley and Noyer mentioned in section 3.2 above also share this general approach.

At least as often, it has been assumed that verbal gerundives are sentential in nature, and means other than nominal constituency have been enlisted to derive the fact that they are distributed into positions characteristically occupied by nominal projections. Stowell (1981) contains perhaps the most ingenious and principled account of this type. He proposes a category-neutral base in which all differences in the internal structure of different phrasal categories are derived from general principles of grammar, primarily Theta-Theory and Case Theory. In this approach, so-called 'NP positions' are those to which abstract case is assigned, while a principle of case resistance bars from such positions any category headed by a category that itself assigns case. Thus, there should be a complementarity between positions occupied by nominal projections (case receivers) and those occupied by verbal or inflectional projections (case assigners). The exception presented by gerundives then can be construed as their being case-receptive (thus occupying 'NP positions'), despite being projections of the case-assigning element INFL. Stowell resolves the contradiction by claiming that case resistance further demands the presence of a tense feature which is not present in the gerundive INFL. Kornfilt (1984), discussing a propositional nominalization in Turkish that strongly parallels the English gerundive, also opts for a sentential analysis, but extends it to the point of claiming that in Turkish at least, not only the gerundive but also ordinary nominals containing possessive elements are instances of IP. Other authors adopting the sentential analysis include Reuland (1983) and Johnson (1988).

Milsark (1988) attempts to have the constituency issue both ways. Adapting ideas from Fabb (1984b) and Baker (1985b), he claims that *ing* is an affix without set categorial features, and that gerundives arise through the attachment of this affix by a process of syntactic affixation. This allows gerundives to be thought of as fundamentally sentential constructions that may exhibit either nominal or sentential (or adjectival or prepositional, for that matter) properties in larger phrase structure depending upon what sort of categorial features the affixation introduces. Emonds (1990) gets similar results by taking *ing* to be a nominalizing affix whose attachment can take place at more than a single level of derivation.

One of the most detailed and influential accounts of the constituency problem and many of its consequences is given in Abney (1987). Abney's analysis is, like

several mentioned above, one in which gerundives (at least those with genitive subjects) are not sentential constituents. It differs from those cited, however, in that it incorporates the 'DP Hypothesis', in which determiners are complement-taking heads that project a functional phrase category DP. Noting with certain previous researchers that the sentential properties of gerundives (e.g., the presence of nominal objects) are essentially confined to the VP Abney claims that gerundives are headed by a determiner whose major peculiarity is that it takes VP rather than NP complements. A secondary property of this determiner is that it undergoes an agreement relationship with its genitive specifier exactly as does whatever D head is present in non-gerundive examples with genitive specifiers, such as *Fred's book*, accounting for the one 'nominal' internal property of gerundives, the presence of genitive case subjects. Since what have traditionally been thought of as NP positions are DP positions in this theory, the structural conflict that lies at the heart of inquiry into the gerundive is neatly resolved: gerundives are simply DPs whose sentence-like properties result from the fact that their D heads agree with their specifiers and take VP complements. Essentially this analysis is adopted by Zucchi (1993), as well.

3.7 Broader issues of constituency in mixed categories

Since the mid-1980s, a number of books and papers have investigated the broader topic of 'mixed categories' that first came to the attention of the field through the study of the English gerundive. Since nearly all the instances that have been discussed concern nominalizations, a particularly useful and thorough descriptive compilation is Koptjevskaja-Tamm (1993), where nominalizations from a variety of languages are classified according to syntactic and morphological properties.

Perhaps the earliest study of mixed category phenomena in a language other than English is Hale and Platero (1985). They are concerned with a class of nominalized clauses in Navajo that exhibits sentential internal structure but is found in positions normally occupied by nominal projections, exactly as is the case with English gerundives. In order to describe this, they propose that the structures under discussion are projections of a feature complex they identify as [+N, +S], where the latter feature identifies the internal structure of the construction and the former identifies its external distribution. A very similar analysis of English gerundives is proposed within a lexicalist framework by Lapointe (1993).

Another interesting work which shares this general point of view is Lefebvre and Muysken (1988). The data they report are from Quechua, a language which exhibits a variety of morphologically and semantically distinct verbal nominalizations that do the work of a variety of clause types in languages such as English. All of them bear unmistakable signs of nominal constituency in that their heads bear case affixation, like the Finnish second, third, and fourth infinitives mentioned in section 2.1 above. The arguments of these nominalizations, however, show a striking mixture of case-selection properties. Some assume cases parallel

to those found in finite clauses; others show case selection parallel to that in projections headed by simple nouns; still others show various mixtures of properties. Lefebvre and Muysken suggest that these phenomena arise because nominalizations comprise a lexical category which is distinct from both nouns and verbs and is defined by the features [+N, +V]. In the process of phrasal projection, items of this category are subject to a neutralization whose effect is to convert them either to [+N, −V] or [−N, +V]. Depending on which option is taken, the resulting structure will exhibit either nominal or sentential internal properties.

Borsley and Kornfilt (2000) approach the mixed-categories problem by making use of the more abstract and articulated theory of phrase structure that has become familiar within the Principles and Parameters framework since the time of Lefbvre and Muysken's work. Adapting from Grimshaw (1991) the idea that particular functional heads are definitionally associated with particular lexical categories, they suggest that the properties of mixed categories arise when the functional structure dominating a verb projection is composed of one or more noun-type functional categories in a position superordinate to the verb-type functional categories normally associated with such projections. They apply this analysis to data from a variety of languages, most prominently Turkish and English, and claim that many of the particular facts about the precise ways that categories may be 'mixed' follow from their approach. As Borsley and Kornfilt note, their analysis has roots that can be traced to Abney (1987), whose analysis proceeds from the notion that gerundives contain a determiner that takes VP rather than NP complements. It also resembles in some ways those of Marantz (1997) and Harley and Noyer (1998). The common thread in this work is an attempt to explain various properties of gerundives or other mixed-category constructions by appeal to the selection and distribution of functional heads.

Still another analysis of nominalizations that depends crucially on the properties of functional heads is that of Alexiadou (2001). While her major concern is not with gerundives or mixed categories per se, responses to many of the issues that are highlighted in these structures are scattered throughout the book. Her conception of the role of functional heads contrasts with that of Grimshaw (1991) and Borsley and Kornfilt (2000), in that she adopts a position (familiar in the theory of Distributed Morphology) in which functional categories determine the categorial identity of major lexical items. In this approach, it is not that lexical heads determine the type and distribution of functional heads, but rather the opposite.

Yoon (1996) addresses a different aspect of the comparative study of mixed nominalizations. Citing an observation of Pullum (1991), Yoon notes that the *-ing* affix in English gerundives does not appear to be morphologically nominal. Thus, pluralization is impossible in examples such as (78), no matter how many excursions the dog experiences. This contrasts with the situation in DN gerundives and other lexical nominalizations, as shown in (79):

(78) a. John enjoys walking his dog frequently.
b. *John enjoys walkings his dog frequently.

(79) a. There were many outdoor readings of *Midsummer Night's Dream* last summer.
b. There seem to be more performances of Dvořak these days.

The Navajo nominalizations discussed in Hale and Platero (1985) seem to be similar to the English gerundives in (78) in this respect. In languages such as Korean, however, and in other languages mentioned above such as Quechua and Finnish, the heads of nominalizations are morphologically nominal, as shown by their ability to take nominal inflections. Indeed, in languages of the Korean–Quechua–Finnish type, this is often the strongest evidence that 'mixed' nominalizations are mixed at all. Yoon's response to this fact is to attribute the nominal properties of the English gerundive not to the affix *-ing*, as is usually done, but to a phonetically null nominalizing affix that is applied to the participial *-ing* form of a verb. This affixation is assumed to be free to apply either in the lexicon or in the syntax, as is the affixation of *-ing* in many prior analyses. Because the null affix is applied syntactically in gerundives, the nominal character of a gerundive is not visible in the lexical morphology of its head. Lexical application of the null nominalizer, as in (79a), results in a form with overt nominal properties, as does lexical attachment of nominalizing affixes in languages of the Korean–Quechua–Finnish type.

Much of the work discussed above is couched in theoretical frameworks in which syntactic derivation, movement, and empty categories assume substantial explanatory weight. Such frameworks range from the early transformationalism of the 1950s and early 1960s to recent approaches such as Government-Binding Theory and various versions of the Minimalist program. There have also been a number of investigations of mixed categories within theories that attempt to replace these notions with an expanded theory of lexical structure and/or a complex system of construction-specific phrase structure rules. Generally, this literature focuses on the English gerundive, but it is clearly intended to have implications extending into the broader world of mixed categories found in other languages.

Pullum (1991) and Lapointe (1993), both cited briefly above, are examples of this sort of work. Another is Malouf (2000). This account is typical of work within the theory of Head-Driven Phrase Structure Grammar, relying on a system of head features and construction-specific lexical rules to specify the syntactic properties of the gerundive. Malouf's article is well worth consulting for its critical summary of other analyses of the gerundive, whatever one's degree of familiarity with HPSG. Bresnan (1997) cites a number of types of mixed categories in a variety of languages and offers an analysis within the framework of Lexical Functional Grammar. Her essential insight is one that is shared to one or another degree by Abney (1987), Zucchi (1993), and Borsley and Kornfilt (2000), among others: mixed categories are not mixed randomly; rather, they exhibit a property of 'phrasal coherence' by which the characteristics of their different category types are localized in different parts of the construction. Bresnan conceptualizes

this as the result of nested categories of different types anomalously sharing a single head, and she develops a formal account for expressing this within the construct system of LFG. A somewhat similar idea is found in Wescoat (1994), where it is proposed that a single word in a terminal string may represent more than one lexical head standing in an unordered relation to one another. The effect of this is to allow the head of a gerundive construction to function simultaneously as a noun and a verb.

4 Conclusion

Like pretty much everything else in generative syntax, inquiry into the properties of gerundives and other mixed categories is very much a work in progress. The studies cited above have revealed a number of interesting facts, and some of those facts have been to some extent explained. The explanations are partial and shallow, however, and it seems clear that no theoretical approach has been able to provide a fully convincing account of the properties of these constructions. One should not be surprised at this. Explanations are always contingent and never complete, and those in linguistics are if anything more contingent and less complete than those in many fields.

It is interesting to note how this study has developed historically. It arose from an initial concern among generative grammarians with the properties of a particular, putatively rather marked construction: the English gerundive. As inquiry advanced, it became clear that the properties involved were actually more widespread than at first was believed. Thus the particular and peculiar became the general, if still rather peculiar. Many larger inquiries within generative syntax have similar pedigrees; one need only think of the way that case theory, thematic theory, and the study of argument structure grew out of an initial concern with the properties of the passive construction, or the manner in which the study of operator-variable dependencies proceeded from the study of informational questions and the crossover phenomenon.

NOTE

This chapter has benefited greatly from the contributions of two conscientious, well-informed, and extremely polite reviewers. My sincere thanks to you, whoever you are.

10 Conclusion

1 Introduction: scope of the chapter

Syntacticians of most persuasions would acknowledge a pre-theoretic distinction between 'lexical' (or 'content') words and 'grammatical' (or 'function') words in all languages. The conventionally accepted distinction between the

two classes seems to be that the former allows novel coinages (open class), while the latter does not (closed class). Thus, while one can coin a new noun or verb, the number of pronouns, prepositions, and auxiliary verbs in a language remains relatively fixed, not open to coinages. Following this terminology, we can use the term 'grammatical verb' to refer to special closed classes of verbs that do not permit the addition of new members, except perhaps through the process of grammaticalization.

Grammatical verbs typically include auxiliaries, indicating meanings of relative time, perfectivity, or progression, and modal auxiliaries, indicating meanings such as those of obligation or permission (see chapter 70). They also include special verbs of possession (*have*) and existence (*be*), as well as the class of words often referred to as co-verbs, especially in the literature on East Asian languages.

In a large number of languages, grammatical verbs also include a special class of verbs called light verbs. The present chapter focuses on light verbs, specifically seeking to distinguish them from the other classes when empirical evidence is presented. For detailed discussions of the other subclasses of grammatical verbs, see modals (see chapter 70), the have/be distinction, causatives (see chapter 6), verb particle constructions (see chapter 76), the Chinese *ba* construction, the East Asian passive (see chapter 12), and serial verbs (see chapter 59).

Light verbs, which form a closed class, are limited in number, but are part of a construction that is extremely productive. The examples in (1b) and (1c) below illustrate a light verb construction in Malayalam, a South Indian language:

(1) a. anu skuuLilninnə wannu.
Anu school-from came
'Anu came from school.'
b. anuwinə santooSam wannu.
Anu-DAT happiness came
'Anu became happy.' (To Anu, happiness came.)
c. anuwinə aanayooTə deeSyam wannu.
Anu-DAT elephant-to anger came
'Anu became angry with (toward) the elephant.' (To Anu, anger came . . .)

The verb in all the sentences in (1) is *wannu* 'came'. In (1a), this verb acts as a full verb. In (1b) and (1c), however, it is a light verb. It does not have the meaning of change of physical location associated with the verb *come*. Intuitively, the predicate in (1b) is *santooSam wannu* 'became happy', with a single argument, Anu. The predicate in (1c) is *deeSyam wannu* 'became angry', with two arguments, Anu and the elephant. The source of the difference in valency – that is, the number of arguments – is located in the nouns *santooSam* 'happiness' and *deeSyam* 'anger' respectively. In other words, the nouns 'host' the light verb, and bear part of the predicative burden. Together, they form a 'complex predicate' (Jespersen 1954–1958; Cattell 1984; Grimshaw and Mester 1988, among others), each incomplete as a predicate in isolation.

One may characterize a light verb as an independent grammatical verb that forms a complex predicate together with a host. This characterization obviously prompts the question of what a complex predicate is. A possible answer is that a complex predicate is a construction in which two morphs, both of which are semantically predicative, jointly head a single syntactic clause.

Stated at this level of generality, complex predicates manifest themselves in a wide range of constructions, not all of which necessarily involve a light verb. Thus, resultative constructions are analyzed as complex predicates, because they involve the combination of two predicates in a single clause (Simpson 1983; Levin and Rappaport Hovav 1995; Hale and Keyser 1997; Wunderlich 1997b). However, this construction does not have a light verb. Likewise, verbal affixes that in some way affect the valency, argument meaning, or case marking in a clause form complex predicates with their verbal host. (See Baker 1988a; Alsina 1996; Alsina et al. 1997; Ackerman and Webelhuth 1998.) However, these morphemes, though grammatical elements, are not light verbs, because they are not independent words. Other complex predicate constructions without light verbs include the verb + particle (see chapter 76) or verb + preposition structures.

A light verb, then, is a grammatical verb that functions as a member of a complex predicate construction. In this chapter, our concern is with complex predicate constructions that contain a light verb. This would exclude complex predicate constructions in which elements smaller than words, such as affixes, or constructions larger than words may serve the same semantic function as light verbs in some languages. To give an example, the applicative function – namely, that of adding an argument meaning, most commonly that of a beneficiary – is borne by a verbal affix in many languages (for instance, the Bantu languages, Indonesian, Malay, and Yimas: Foley 1997), or by special constructions, such as the dative construction in English. In yet other languages such as Malayalam and Mandarin, this function is fulfilled by a complex predicate with a light verb. Our concern is restricted to the last type.

It must be noted that Radford (1997: 264) defines a light verb as "an affixal verb (often with a causative sense, like that of *make*) to which a noun, adjective, or verb adjoins." Under Radford's definition, a causative affix, an applicative affix, and in fact any verb-forming affix that involves an operation on argument structure or event structure would be a light verb. Such a definition stands in contrast to the one we assume in this chapter, namely, that a light verb is a word-level (X^0) unit, and that while affixes in combination with nouns, adjectives, or verbs may form complex predicates, they are not light verbs.

2 'Light verb' and its host

Original use of the term 'light' verb is due to Otto Jespersen, although the phenomenon was observed long before; Gilchrist (1796) called it a 'subservient' verb. Jespersen describes it as an insignificant verb which is placed next to an

"important idea" to carry the markings of person, number, and tense (Jespersen 1954–1958: VI, 117–118).

Cattell (1984) lays out a range of relevant data on complex predicates from English, as well as issues surrounding their analysis. While complex predicates were variously explored under the guises of compound verbs, composite predicates, and serial verbs in a considerable amount of sporadic work over the years (discussions are found, for instance, in Ross 1986 (original dissertation 1967); Chomsky 1975b; Jackendoff 1972, 1974a; Higgins 1979 (original dissertation 1974); Oehrle 1976; Wierzbicka 1982), Cattell seems to have set the stage for the phenomenon of complex predicates to become a central preoccupation in most major syntactic theories, beginning with Grimshaw and Mester's (1988) analysis of the Japanese verb *suru* 'do'. (See also Ackerman 1987; Baker 1988a; Sells 1988, 1991; Krishnamurti 1989; Miyagawa 1989a; Rosen 1989; Mahajan 1990; Huang 1992a; Mohanan 1994; Butt 1995, 1997; Alsina 1996; Matsumoto 1996a; Alsina et al. 1997; Cinque 1997a, 1997b; Ackerman and Webelhuth 1998; Wilson 1999.)

Let us use examples of the light verb construction in English to develop an intuitive sense of the phenomenon. The verbs in (2a), (3a), and (4a) are full verbs; their counterparts in (b) are light verbs:

(2) a. Pat made a snowman.
    b. Pat made a dash across the puddle.

(3) a. Pat took May to the park.
    b. Pat took a bath.

(4) a. Pat gave Pip a toy.
    b. Pat gave a gasp.

The light verbs in these examples have three characteristic properties. The first is that a light verb is identical in form to a heavy or full lexical verb in the language. Thus, each of the verbs in (b) in (2–4) has a counterpart that is not a light verb, as shown in (a).

Intimately related to this is the second property: that it is typical for the light verb not to have the entire meaning content associated with its full counterpart; it is often seen as an 'incomplete predicate' (Butt 1995; Alsina 1996). Part of the predicative burden is borne by its host, as in (1b) and (1c). Meshchaninov (1982: 158) describes the loss of meaning in the grammatical verb as follows: "Having become a linking verb, the verb loses one of its obligatory meanings – lexical meaning – and preserves another meaning – syntactic meaning." A complete predicate "exists only in the union" of both meanings. The extent to which the core meaning of the verb is weakened or "bleached" (Masica 1976) in the light verb depends on the particular verb in each language. Perhaps an extreme instance of 'lightness' or semantic bleaching of a grammatical verb whose sole purpose is to bear the grammatical features of agreement and tense may be the

so-called 'dummy' verb *do* in certain '*do* support' constructions illustrated in (5) (see Grimshaw 1997b for a discussion):

(5) a. Did Pat give Pip a toy?
b. Pat gave Pip a toy, and so did May.

The dummy verb *do* in these examples is often taken to be devoid of any semantic content, even though such a position is not unchallenged (Penhallurick 1985; Hewson 1990; Hirtle 1997; also see Kroch 1989b and Stein 1990 for a historical perspective).

The third property of light verbs such as those in (2–4) is that at some level of abstraction, the verb and the following noun seem to create a single predicate-like unit that is equivalent to a single verb. Thus, *to take a bath* and *to give a gasp* are equivalent to *to bathe* and *to gasp* respectively.

In (1–4), the host of the light verb is a noun. A light verb can also take an adjectival or verbal host. In languages like Hindi (a language of northern India) and Urdu (a language spoken in Pakistan and in northern India, almost identical in structure to Hindi) we find all three types of light verb constructions, illustrated by the examples from Hindi/Urdu in (6):

(6) a. raam-ne niinaa-kii **madad kii**. (Noun + Verb)
Ram Nina's help did
'Ram helped Nina.'
b. raam-ne kamraa **saaf kiyaa**. (Adj. + Verb)
Ram room clean did
'Ram cleaned the room.'
c. raam **has paDaa**. (Verb + Verb)
Ram laugh fell down
'Ram burst out laughing.'

The light verbs that take a verbal host, as in (6c), raise difficult analytical as well as theoretical problems, brought out by a comparison of different constructions involving V–V sequences:

(7) a. raam-ne rootii **khaaii**.
Ram bread ate
'Ram ate bread.'
b. raam-ne rootii **khaaii hai**.
Ram bread ate is
'Ram has eaten bread.'
c. raam rootii **khaataa hai**.
Ram bread eats is
'Ram eats bread.'
d. raam-ne rootii **khaa lii**.
Ram bread eat took
'Ram ate the bread (all of it).'

e. raam-ne rootii **khaa Daalii**.
Ram bread eat put/flung
'Ram ate up the bread (finished all of it, forcefully).'

A Hindi/Urdu grammarian would agree, perhaps reluctantly, that in (7b), the second verb in the verb–verb sequence might be treated as an 'auxiliary' that in combination with the first verb indicates perfective aspect; in (7c), it may be a 'modal auxiliary', expressing habitual action together with the first verb; and in (7e), it is a 'light verb', expressing completion and forcefulness. But we would be hard pressed to find a justification for these labels, at least on a cross-linguistic basis if not within Hindi/Urdu. Now, how about the second verb in (7d)? It may traditionally be considered a modal, indicating completion. However, Butt (1995) argues that it must be treated as a light verb, as it contributes to the argument structure of the complex predicate.

The analytical challenge posed by examples like (7a–e) are illustrative of problems raised by complex predicate constructions in general. How do we distinguish between light verbs and modal verbs? Is such a distinction between two types of grammatical verbs necessary? How do we distinguish between complex predicates on the one hand, and serial verbs (see chapter 59) and control constructions on the other? Are there clusters of cross-linguistic generalizations that converge on these distinctions? These are not easy questions to answer. In the rest of this chapter, we will point to partial answers when there is empirical evidence to make a principled distinction. (See Butt 1995 for an extended discussion.)

Perhaps one of the sources of the problem of a cross-linguistic characterization of light verbs is the multiplicity of intuitions associated with the term 'light verb', namely, that it is a verb that (i) has a full verb counterpart; (ii) can contribute to the argument structure of the clause; (iii) does not uniquely determine the argument structure of the complex predicate; (iv) permits a non-verb to function as a predicate; and (v) forms a single syntactic predicate with its host. Thus, *be* in *John is asleep* or *The flower is red* is a light verb by (iii), (iv), and (v) but not by (i) and (ii). The second verb in (7e) is a light verb by (i), (ii), (iii), and (v), but not by (iv). By (v), a verb that involves syntactic control cannot be a light verb. Switching between these intuitions often results in inconsistent conclusions.

In the following sections, we will first look at some of the central questions (section 3) of analysis and theory that the light verb phenomena give rise to. We then go on to a survey of light verbs that take a nominal host (section 4), a verbal host (section 5), and an adjectival host (section 6), and the lightest of light verbs, *do* (section 7), examining clusters of morphological, syntactic, and semantic properties of light verbs across languages that have intrigued syntactic theories, and some of the analyses that have emerged as a response to the phenomena. Our main concern will lie with the substance of the theoretical hypotheses that have emerged, some of which are consensual, and others still controversial. Their implementation within various syntactic frameworks is only of secondary interest.

3 Central questions that light verbs raise

There are three broad questions that studies of the light verb construction, whether language-particular or cross-linguistic, must pay attention to, so as to make possible the emergence of a theory of the light verb construction. They are:

(i) What is a cross-linguistic characterization of complex predicate constructions such that they can be distinguished from other constructions involving auxiliaries, serial verbs, control/raising verbs, and (noun) incorporation?
(ii) Within the class of complex predicates, what are the similarities and differences between those that involve a light verb and those that don't? These include, on the one hand, complex predicates without an incomplete predicate, such as resultatives, and, on the other, those that involve affixation, such as morphological causatives.

Having addressed these questions, the next obvious question would be:

(iii) What are the parameters of variation among complex predicates, and what are the limits of variability?

On the basis of currently available studies, we can identify the following typological parameters of variation in terms of the various kinds of information that belong within grammar; in other words, different levels of representation within the organization of grammar. The terminology used in the formulation of the questions tries to be as framework-neutral as possible, and should be translatable into the different theories with the appropriate framework-internal vocabulary:

- In terms of **grammatical categories**, do the light verb and its host form a single constituent? Is the host a lexical (X^0) or a phrasal (X^{bar}) category? Is the light verb a lexical or phrasal category? Do the light verb and the host, when combined, form a lexical or phrasal category?
- In terms of **grammatical functions**, do the light verb and its host form a single complex predicate? Or do they remain as two separate predicates, as in control or raising constructions? Does the host have an independent function?
- As for the **argument structure** of the construction, does the light verb contribute to the valency and nature of the arguments of the complex predicate? Does the host contribute to this structure? Does the complex predicate have a single argument structure, or an embedded argument structure composed of main and subordinate argument structures?
- How do the light verb and the host contribute to the other aspects of the syntactic behavior of the complex predicate, such as **case marking** and **agreement**?

- What is the contribution of the light verb and the host to the meaning of the complex predicate? What is the relation between the meaning of the light verb and its full counterpart?
- What are the meanings that typically lend themselves to light verb formation across languages?

A comprehensive theoretical account of the light verb construction must await the availability of detailed grammars that address these questions in individual languages, to ensure the coverage of all the attested patterns.

4 Nominal hosts

4.1 Complex predicates in English

The expression in boldface in (8a) is recognized in the literature, at least beginning with Chomsky (1975b), to be somehow different from that in (8b):

(8) a. Pat **made the claim** that the snowman was innocent.
b. Pat **disproved the claim** that the snowman was innocent.

The complex expression *made the claim* in (8a) is perceived as a complex predicate; the expression *disproved the claim* is not. A number of syntactic and semantic properties distinguish the two constructions, justifying the claim that the expression in bold in (8a) is indeed a complex predicate, where a predicative noun combines with a light verb to form a single syntactic predicate.

To begin with, intuitively, *make the claim* is a single 'semantic unit' that is equivalent to the single verb *claim*. Thus, *John made the claim that . . .* is equivalent to *John claimed that . . .* In contrast, *disprove the claim* does not form a single semantic unit. This difference in semantics has correlates in syntax, for instance, in the contrast between (9a) and (9b):

(9) a. ?Who did you make the claim that Bill saw ___?
b. *Who did you disprove the claim that Bill saw ___?

In order to account for what looks like a violation of the Complex NP Constraint in (9a), Chomsky (1975b) postulates a rule of restructuring which takes the structure in (10a) as the input, yielding (10b) as the reanalyzed structure, where *make the claim* is a single V:

(10) a. $[[\text{make}]_{V}$ [the claim that $S]_{NP}]$
b. $[[\text{make the claim}]_{V}$ [that $S]_{\text{S-bar}}]$

In contrast, *disprove the claim* has only one structure:

(11) [[disprove]v [the claim that S]np]

If the representations relevant for Subjacency are (10b) and (11), the contrast between (9a) and (9b) would follow automatically. However, the reanalyzed structure in (10b) does not account for the contrast between (12a) and (12b):

(12) a. That Bill defeated Pat John did not claim ___.
b. *That Bill defeated Pat John did not make the claim ___.

The ungrammaticality of (12b) must follow from the structure in (10a), which treats *the claim that Bill defeated Pat* as a noun phrase. Thus, to account for the contrast between (9a) and (9b), one must assume the availability of the structure in (10b). However, in order to account for the contrast between (12a) and (12b), one must assume that the structure is as in (10a), and that the structure in (10b) is not available.

The need for the two conflicting groupings in (10) illustrates the 'dual' nature of complex predicates. Now, these two structures cannot both belong to the same level of representation because that would constitute a logical contradiction.

One way to capture the intuition underlying the distinction between (10a) and (10b) is as in (13), where, in (13b), *make the claim* is a single unit in its function as a predicate (equivalent to (10b)), but its categorial structure is (13a) (identical to (10a)):

(13) a. $[[\text{make}]_{V}$ [the claim that S$]_{NP}]$
b. $[[\text{make the claim}]_{PRED}$ [that S$]_{COMPL}]$

The structure relevant for relating a gap with its antecedent (governed by Subjacency or its equivalent) is the one in (13b), while the structure relevant for determining the position of the gap is the one in (13a).

The above discussion illustrates a recurrent characteristic of complex predicates with nominal hosts, namely, the mismatch between the structure in terms of grammatical categories and in terms of grammatical functions. The rest of section 4 outlines the central analytical and theoretical problems surrounding light verb constructions with nominal hosts.

4.2 *Light verbs with nominal hosts in Hindi: a case study*

In order to understand the phenomenon of light verbs with nominal hosts, and the theoretical questions they raise, it would be best to look closely at the construction in one language. As the language for illustration, we will use Hindi, where we find a duality of structure similar to that shown in English (section 4.1). Hindi offers a particularly fruitful starting point for exploring a cross-linguistic characterization of the complex predicate construction: it exhibits not only extremely productive complex predicate formation with nominal, verbal, as well as adjectival hosts (6a–e), but also a split among N+V complex predicates into two distinct types (Mohanan 1994, 1997).

Hindi has noun + verb sequences that are clear instances of constructions that are not complex predicates, as in (14). There are also instances of sequences that are uncontroversially complex predicates, as in (15). The verbs in (15) are the light counterparts of those in (14):

(14) a. kal æksiDent **huaa**.
yesterday accident happened (M)
'There was an accident yesterday.' (An accident happened yesterday.)
b. raam-ne apnaa homwark **kiyaa**.
Ram-ERG self's homework did (M)
'Ram did his homework.'
c. raam-ne niinaa-ko kitaab **dii**.
Ram-ERG Nina-DAT book gave (F)
'Ram gave a book to Nina.'

(15) a. kamre-kii **safaaii huii**.
room-GEN cleaning happened (F)
'The room got cleaned.' (Cleaning of the room happened.)
b. raam-ne kamre-kii **safaaii kii**.
Ram-ERG room-GEN cleaning did (F)
'Ram cleaned the room.' (Ram did cleaning of the room.)
c. raam-ne niinaa-kii kahaanii-par **dhyaan diyaa**.
Ram-ERG Nina-GEN story-on attention gave (M)
'Ram paid attention to Nina's story.'

In complex predicates like *madad kar* 'help do' in (6a), *safaaii ho* 'cleaning happen' in (15a), *safaaii kar* 'cleaning do' in (15b), and *dhyaan de* 'attention give' in (15c), the host noun (N) and the light verb (V), both predicative elements, combine to give a functionally single clausal nucleus. The N+V complex predicate construction in these examples exhibits certain clusters of properties that are recurrently found in the construction across languages, and can form an initial basis for a unified theory of complex predicates, including the parameters of variation available to the construction.

A striking trait of sentences with the N+V complex predicate in Hindi is that both the verb and the noun participate in determining the structure of the clause. Thus, in (15a) and (15b), the nominal host in the complex predicates is the same, but the verb is different. (15a) has one argument, (15b) has two. This difference in valency must therefore be contributed by the light verb. As for the contribution of the noun, the data involving the light verb *aa* 'come' provide a telling example. This verb in its capacity as a full verb has two arguments, as shown by (16): the entity that comes, and its locative destination:

(16) raam mere ghar **aayaa**.
Ram my house came
'Ram came to my house.'

In (17), the same verb 'come' functions as a light verb:

(17) a. mohan-ko **hasii** **aayii**.
Mohan-DAT laughter came
'Mohan had the urge to laugh.' (Laughter came to Mohan.)
b. mohan-ko kahaanii **yaad** **aayii**.
Mohan-DAT story memory came
'Mohan remembered the story.' (Memory of the story came to Mohan.)
c. mohan-ko anu-kaa **dhyaan** **aayaa**.
Mohan-DAT Anu's attention came
'Mohan thought of Anu.' (Thought of Anu came to Mohan.)
d. mohan-ko anu-par **krodh aayaa**.
Mohan-DAT Anu-on anger came
'Mohan was angry with Anu.' (Anger on Anu came to Mohan.)

In (17a), there are two arguments: the entity that comes, laughter, and its destination, Mohan. But the destination is an abstract one; it is an experiencer. In addition to the destination being an experiencer, the sentences in (17b–d) have an extra argument, not sanctioned by the verb *aa* 'come'. This argument must therefore be sanctioned by the noun. Furthermore, the case marking of the additional argument can differ depending on the noun: in (17b) it is nominative, in (17c) genitive, and in (17d) locative. (The case differences exhibited in (17b–d) on non-subjects can also appear on subjects: Mohanan 1997: 436). If we assume that differences in non-structural case marking indicate differences in argument meaning, then the meanings of the additional arguments in these sentences must also be different.

In short, the nominal host in a complex predicate can contribute to the number of arguments, their meaning, and the case assigned to them, and so can the light verb. This property of the complex predicate in Hindi is demonstrable in other languages of South Asia as well. We can state our observations so far as (18):

(18) In the N+V complex predicate, the N and V together act as a single predicate. However, both the N and the V are predicates in their own right: they can contribute to the number of arguments, argument meanings, and case marking in the clause.

Evidence from the behavior of reflexives, which at least in some varieties of Hindi take either the grammatical subject or the logical subject as their antecedent, shows that functionally, the complex predicate is a single clausal nucleus (Mohanan 1997: 443–444). Categorially, however, the N and V are concatenated phrasally, as shown by the topicalizability of the light verb (Mohanan 1997: 447–448). We can state this mismatch as follows:

(19) Functionally, the N and V form a single predicate; however, they are phrasally combined: they do not have a lexical status.

Even though the nominal host is part of the predicate, and a predicate in its own right, it is also an argument of the light verb in Hindi. This is shown by the fact that the nominal host can be the subject of a passive. Furthermore, the light verb exhibits agreement with its host in number, gender, and person; verb agreement in Hindi can only be induced by a subject or an object in nominative case. This leads to our next conclusion:

(20) Although the N is a predicate, and part of the complex predicate, it is, in some cases, also simultaneously an argument of the V.

In terms of the property in (20), the N+V complex predicates in Hindi appear to split into two classes. There is a small group of nominal hosts that are different from the rest in certain syntactic patterns. A nominal host belonging to this class cannot trigger verb agreement; it cannot be the subject of a passive; a negative word indicating syntactic negation can precede it; and it can gap and be gapped in a coordinate construction. All these differences follow naturally if we assume that the host in these instances is not an argument of the light verb.

The structural properties in (18–20) present a challenge. How must the compositionality of complex predicates be formally expressed such that the semantic and syntactic representation of the light verb and its host, together with the structural relation between the two, derives the semantic and syntactic properties of the complex predicate? What kind of syntactic and semantic theory can describe this compositionality? While framework-internal analyses of different aspects of different types of complex predicates are available, covering rich data with recurrent clustering of properties, answering the above questions requires bringing together all of the fragments into a comprehensive picture. We do not as yet have such an integrated theory of complex predicates.

4.3 Complex predicates, noun incorporation, and raising/control

As mentioned earlier, the light verb construction rose into prominence in theoretical syntax with the study of the Japanese light verb *suru* 'do' in Grimshaw and Mester (1988) (G&M). The central problem that G&M address is illustrated by the Japanese construction in (21a), and its behavioral contrast to (21b):

(21) a. John-wa Bill-to AISEKI-o shita.
John-Top Bill-with table-sharing-Acc *suru*-past
'John shared a table with Bill.'
b. John-wa Bill-to AISEKI shita.
John-Top Bill-with table-sharing *suru*-past
'John shared a table with Bill.' (G&M: 206)

In both (21a) and (21b), the verb *suru* 'do' appears to form a single unit with the preceding noun at some level of grammatical structure. The overt difference

between them is that while the preceding noun in (21a) carries accusative case marking, that in (21b) is a bare noun. G&M claim that while (21a) is an example of a complex predicate construction with *suru* as a light verb, (21b) is an example of the noun incorporation construction.

Subsequent literature (Ahn 1990; Huang 1992a; Matsumoto 1996a, 1996b; among others), however, disputes the claim that *suru* in (21a) is a light verb, and argues that (21a) is not an example of a complex predicate construction, but rather a raising/control construction involving a main verb and a complement clause. Yet other works accept that *suru* in (21a) is a light verb, but reject the G&M claim that it is an empty verb without its own argument structure. (For a detailed discussion of the issues and analyses related to *suru*, see Butt 1995: 201–221.)

In order to get a clear understanding of the issues involved in the different constructions, therefore, it would be productive to explore what properties constitute the necessary conditions for a construction to be called complex predicate (CP) or noun incorporation (NI), and how they are both different from raising/control constructions. One way to identify the parameters along which the differences can be characterized is in terms of the categorial and functional properties of the N+V sequences. The first distinction to recognize is that CP and NI constructions involve a single syntactic clause, while raising/control involve a matrix clause and an embedded clause.

Within the single-clause constructions, the relevant parameters include the categorial status of the nominal host (N), the light verb (V), and the complex predicate ([N, V]), and the functional status of the nominal host. A possible way to distinguish the two constructions is as follows:

				NI	**CP**
(22)	Categorial status	a.	of N	Lexical	Lexical or phrasal
		b.	of V	Lexical	Lexical or phrasal
		c.	of [N, V]	Lexical	Lexical or phrasal

				NI	**CP**
(23)	Functional status of N	a.	as argument	Yes	Maybe
		b.	as predicate	No	Yes

Whether the specifications in (22) and (23) should be accepted as criterial of CP and NI constructions is for future research to determine.

The parameters in (22) and (23) point to possible cross-linguistic variability in N+V complex predicates. One parameter of variation is the argumenthood of the nominal host (23a). As indicated earlier, Hindi itself distinguishes two classes, one in which the host is a syntactic argument, and another in which it is part of the predicate without any argument status. Another parameter of variation is the categorial level of the host (22a). In Hindi, it is a lexical category. In a language like Malayalam, in contrast, the host is a phrasal category (Mohanan 1983). Such typological variations deserve careful study.

Other variations in N+V complex predicates appear in languages like Korean (Ahn 1990; Sells and Cho 1991). The host noun, a lexical category, participates in three types of complex predicates, each displaying a different cluster of syntactic properties. One is lexically concatenated, and is syntactically unanalyzable; it obeys the lexical integrity principle (Ackerman 1987; Di Sciullo and Williams 1987; Simpson 1991; Sells 1994; Bresnan and Mchombo 1995; Mohanan 1995), which prohibits subconstituents of a lexical unit from undergoing syntactic reordering; examples are *kwen-hata* 'encourage' and *ceng-hata* 'decide'. The second and third types are phrasally concatenated: adverbs and negatives can intervene between the N and V. The phrasally combined complex predicates fall into two classes in terms of their behavior with respect to replies to yes/no questions, gapping, and the ability to take accusative marking. The two classes are distinguished by the fact that in contrast to the nominal hosts in examples like *phantan hata* 'judge' and *sayngkak hata* 'think', those in examples like *yenkwu hata* 'research' and *kongpwu hata* 'study' can be omitted in the reply to a yes/no question, can be gapped independently of the light verb, and can take the accusative marking *(l)ul*.

5 Verbal hosts

5.1 Causative light verbs

We now turn to the light verbs that combine with verbal hosts. Consider the English examples in (24), where (24b) is a causative (see chapter 4) version of (24a):

(24) a. Pat combed Ellen's hair.
b. Pat made Jan comb Ellen's hair.

(24b) is an example of a syntactically biclausal causative. If the object *Ellen* in (24b) is replaced with the pronoun *him*, the pronoun can take *Pat* as its antecedent. On the other hand, if we replace it with the reflexive *himself*, the reflexive cannot take *Pat* as its antecedent. These facts follow from the conditions of disjoint reference and reflexive binding (Binding Conditions B and A respectively in GB/Minimalist syntax), given that *make* and *comb* belong to different clauses in (24b).

Now consider the German sentence in (25a), and its causative versions in (25b, c):

(25) a. Ellen hat den Jungen gekämmen
Ellen has the boy combed
'Ellen combed the boy.' (Ackerman and Webelhuth 1998: 275)
b. Ellen ließ den Vater den Jungen kämmen.
Ellen cause the father the boy comb
'Ellen made the father comb the boy.'
(Ackerman and Webelhuth 1998: 279)

c. Ellen ließ den Jungen von seiner Schwester kämmen
Ellen cause the boy by his sister comb
'Ellen had the boy combed by his sister.'
(Ackerman and Webelhuth 1998: 275)

Ackerman and Webelhuth (1998) argue that (25b) behaves like a bi-clausal structure, exactly like the English example in (24b). However, the behavior of (25c) leads them to conclude that the sentence is monoclausal. Given that the verb *ließ* in (25c), which is an independent verb (not an affix), forms a single syntactic predicate with the following verb and contributes to the argument structure of the clause, it follows from our earlier characterization that *ließ* is a light verb in (25c), and that *ließ . . . kämmen* is an example of a complex predicate. In contrast, the sentence in (25b) is an example of a bi-clausal raising/control construction, and *ließ* is not a light verb.

Additional evidence from disjoint reference also points to the conclusion that (25c) is monoclausal, while (25b) is bi-clausal. Thus, if 'the boy' in (25b) is replaced with the pronoun *ihn*, the pronoun can take as its antecedent the subject *Ellen* (Miriam Butt, p.c.). But if 'his sister' in (25c) is replaced by the pronoun, it cannot take Ellen as its antecedent. Together with the rest of the evidence, then, disjoint reference shows that (25c) has a single syntactic clause. This situation illustrates the possibility, even within a single language, of an analytical causative being either a complex predicate construction with a light verb as in (25c), or a raising/control causative such as that in (24b) and (25b).

In the following sections, we will take a closer look at some more light verbs that take verbal hosts. We will see that the issues related to the analysis of N+V complex predicates discussed earlier resurface in a slightly different guise in the analysis of V+V complex predicates.

5.2 *Applicative light verbs in Malayalam*

5.2.1 *'Give' compounding*

The phenomenon of applicatives has generally been viewed as one in which an indirect object, oblique object, or non-argument appears as an object of the clause (henceforth 'applied object'). The dative construction in English, illustrated in (26b) below, can be understood as a restricted version of the phenomenon of applicatives:

(26) a. Miko sang a song for Jomo.
b. Miko sang Jomo a song.

Languages vary with respect to the theta-role of the applied object; a particular language may allow one or more of the following: beneficiaries, goals, instruments, locatives (Baker 1988a; Bresnan and Moshi 1990; Alsina and Mchombo 1993; Foley 1997). In languages with restricted instances of the applicative, including English, the applied object is typically a beneficiary.

As mentioned earlier, the applicative complex predicate may involve a light verb in some languages, for instance Malayalam. (Note that in the applicative in English, the verb bears no overt verbal marking.) The applicative in Malayalam has been described as give-compounding (Mohanan 1983, 1989), because it involves a V+V predicate in which the second V is the word for 'give'. (See Wong 1995 for a construction with similar effects in Mandarin involving the verb *gei* 'give'.)

Consider the triadic verb *koTukk-* 'give' in (27):

(27) uma ammuwinə oru pustakam koTuttu.
Uma Ammu-DAT one book gave
'Uma gave a book to Ammu.'

Applicatives in Malayalam are formed through a productive V+V compounding, where the second V is *koTukk-* 'give', as illustrated in (28b):

(28) a. uma oru paaTTə paaTi.
Uma one song sang
'Uma sang a song.'
b. uma baalanə oru paaTTə paaTi koTuttu.
Uma Balan-DAT one song sang gave
'Uma sang Balan a song.'
c. *uma baalanə oru paaTTə paaTi.
Uma Balan-DAT one song sang
d. uma baalanə-weeNTi oru paaTTə paaTi.
Uma Balan-DAT-for one song sang
'Uma sang a song for Balan.'
e. *uma oru paaTTə paaTi baalanə koTuttu.
Uma one song sang Balan-DAT gave
Intended: #'Uma sang a song and gave it to Balan.'

The verb 'sing' in (28) is dyadic. In (28b), where it occurs with 'give' in a V+V compound, 'give' contributes to the clause an additional beneficiary argument. An even more telling example of such argument addition is given in (29):

(29) a. ani aLaweTukkaan ninnu.
Ani measurement-take-INF stood
'Ani stood for the purpose of having her measurements taken.'
b. ani ammuwinə aLaweTukkaan ninnu koTuttu.
Ani Ammu-DAT measurement-take-INF stood gave
'Anu stood for Ammu to take her measurements (for Ammu's benefit).'
c. *ani ammuwinə aLaweTukkaan ninnu
Ani Ammu-DAT measurement-take-INF stood

On the basis of (28) and (29), one might be tempted to treat the syntactic effect of this compounding as one of increasing valency. However, as (30) shows, even

though it involves the additional meaning of a beneficiary, it is not necessary that give-compounding always adds an argument to the clause:

(30) a. uma aniye kuukkaan paThippiccu.
Uma Ani-ACC shout-INF taught
'Uma taught Ani to shout.'
b. uma anik'k'ə kuukkaan paThippiccu koTuttu.
Uma Ani-DAT shout-INF taught gave
'Uma taught Ani to shout.'
c. *uma anik'k'ə kuukkaan paThippiccu
Uma Ani-DAT shout-INF taught
d. *uma aniye kuukkaan paThippiccu koTuttu.
Uma Ani-ACC shout-INF taught gave

The object of 'teach' in (30a) is in the accusative case. Its counterpart in (30b), where the predicate is a give-compound, is in the dative case. Also, (30b) has the added meaning that the teaching was either desired by or beneficial to the learner. (30a) carries no such implication. In other words, the second argument in (30a) is a 'theme', while that in (30b) is both a theme and a beneficiary. There is no additional argument in (30b).

What we have here is a complex predicate construction in which the verb 'give' functions as a light verb. It adds the meaning of beneficiary to the clause, which may or may not result in the addition of an independent beneficiary argument. It also requires the beneficiary to be in the dative case. The benefit in this construction is the entire event described by the host of the light verb. Thus, in (28b), Uma is the agent, Balan is the beneficiary, and the event of Uma's singing a song is the theme that benefits Balan.

If the argument meanings of the full verb *koTukk-* 'give' in (27) are compared with those of the light verb in (28b), (29b), and (30b), an interesting difference appears. The dative argument in (27) is a recipient who is not necessarily a beneficiary. Thus, we can add *ravik'k'ə weeNDi* 'for Ravi' to (27), to mean 'Uma gave a book to Ammu for Ravi.' In other words, a beneficiary can be added to the sentence as an adjunct. In contrast, such a beneficiary adjunct cannot be added to a complex predicate construction with the light verb *koTukk-*. This suggests that the dative argument of the complex predicate V-*koTukk-* is a beneficiary, not merely a recipient.

Furthermore, the dative argument of the full verb can be the recipient of an undesirable theme. For instance, a sentence in which *pustakam* 'book' in (27) is replaced by *wiSam* 'poison', which is harmful to the recipient, is entirely acceptable. In contrast, the event that is of benefit to the dative argument in the light verb construction cannot be undesirable to the beneficiary. Thus, in a context in which Balan dislikes Uma's singing, the sentence in (28b) is unacceptable.

In sum, the special characteristics of the light verb 'give' in Malayalam can best be understood as a grammaticalization of the full verb 'give'. (31) below gives the parallel properties that bring out the effects of grammaticalization:

(31)	**Property**	**Full verb**	**Light verb**
a.	number of arguments: three	√	√
b.	Argument meanings:		
	(i) Agent	√	√
	(ii) Recipient	√	Desirable benefit
	(iii) Theme	√	√
c.	Theme:		
	(i) Concrete entity	√	No
	(ii) Event	No	√
d.	Transfer from agent to recipient	√	No
e.	Case of recipient/beneficiary: dative	√	√

The difference between the full verb and the light verb lies in their semantics: (i) the dative argument of the light verb is a beneficiary, (ii) the theme is an event, not an entity, and (iii) no transfer is involved.

It must be pointed out that the verb 'give' appears recurrently across languages as the indicator of the applicative meaning. Some examples are given below. Each of the examples appears to be an applicative with a light verb 'give':

(32) mama féng-**gèí** Xiàóqí yì tiáo qúnzi. Mandarin
mother sew-give Xiaoqi one CL skirt
'Mother sewed Xiaoqi a a skirt.' (Wong 1995: 12)

(33) i e prani a karu **gi** **yu**. Sranan
I plant the corn give you
'I'm planting the corn for you.' (Sebba 1987: 50)

(34) a séi dì wòsu **dà** dì wòmi. Saramaccan
he sell the house give the man
'He sold the house for the man.' or 'He sold the house to the man.'
(Byrne 1987: 177)

(35) nws xa ib qho khoom **pub** kuv. White Hmong
3sg send one class. goods give 2sg
'She sent me some things (as a present).' (Jarkey 1991: 244)

Heine and Reh (1983) observe that the applicative morpheme in a number of African languages developed historically from the verb for 'give'. Ahn (1990) and Matsumoto (1996b) argue that the apparently parallel construction in Japanese and Korean involving the verbs for giving and receiving are not complex predicate constructions; rather, they are constructions involving a main verb and a complement clause. Given our characterization of light verb as part of a complex predicate, we must conclude that the verbs 'give' and 'receive' in this construction in Japanese and Korean are not light verbs. However, given that these constructions resemble those of the applicative light verb constructions, an alternative

view of light verbs would be to delink their characterization from complex predicatehood, and define them as grammaticalized, bleached verbs that have a 'full' counterpart, whether or not they are part of a complex predicate. The wisdom of such a recharacterization of light verbs cannot be assessed without further investigation.

5.2.2 'Get' compounding

Another light verb construction which involves the addition of a beneficiary meaning is what may be called get-compounding. The Malayalam example in (36) is a simple sentence with the verb *kiTT-* 'get' as a full verb:

(36) anuwinə looTTari kiTTi.
Anu-DAT lottery got
'Anu won a lottery. (Anu got a lottery.)'

The verb *kiTT-* 'get' participates as a light verb in a complex predicate construction. Compare the give-compounding version of (37a) in (37b) with its get-compounding version in (37c):

(37) a. anu oru keikkə uNTaakki.
Anu one cake made
'Anu baked a cake. (Anu made a cake.)'
b. uma anuwinə oru keikkə uNTaakki koTuttu.
Uma Anu-DAT one cake made gave
'Uma made Anu a cake.'
c. anuwinə oru keikkə uNTaakki kiTTi.
Anu-DAT one cake made got
'Anu got the benefit of someone baking a cake.'

In the example of get-compounding in (37c), Anu is the beneficiary of the theme, namely, the event of baking a cake.

Consider another example of get-compounding in (38b):

(38) a. kuTTi skuuLil etti.
child school-in arrived
'The child arrived in school.'
b. ammak'k'ə kuTTi skuuLil etti kiTTi.
mother-DAT child school-in arrived got
'The mother received the benefit of the child arriving in school.'

Give-compounding requires an agent and a beneficiary; if the host does not have a beneficiary, the light verb supplies one, either as an argument or as an argument meaning. However, if the host does not have an agent, the light verb cannot combine with it. Thus, a give-compounding version of (38a) is not possible to create, because (38a) does not have an agent to begin with.

Like give-compounding, get-compounding requires a beneficiary, and the light verb adds it if one is not already available. The beneficiary in (37c) and (38b) is not an argument of the verbal host; it is contributed solely by the light verb. In contrast to 'give', however, the light verb 'get' does not permit the expression of the agent. Thus, the agent of the host in (37c) is unexpressed; expressing the agent of 'make' in any form would render the sentence unacceptable.

A comparison of the main verb *kiTT-* 'get' and its light counterpart shows the following differences:

(39)

	Property	**Full verb**	**Light verb**
a.	Number of arguments: two	√	√
b.	Argument meanings:		
	(i) Recipient	√	Beneficiary
	(ii) Theme	√	√
c.	Theme:		
	(i) Concrete entity	√	No
	(ii) Event	No	√
d.	Transfer to recipient	√	No
e.	Case of recipient/beneficiary: dative	√	√
f.	Agent cannot be an argument	√	√

The properties of get-compounding, then, are that (i) the complex predicate has two arguments; (ii) the logical subject is a beneficiary, not just a recipient; and (iii) the theme is an event, not an entity. The two complex predicate constructions, 'give'-applicative and 'get'-applicative, are parallel in that they both add a beneficiary meaning to the clause, where the benefit is an event; they differ in that the former requires an agent, while the latter prohibits one. This difference follows naturally from the argument structures of the full verbs.

The discussion of give-compounding and get-compounding in Malayalam shows that the idea of deriving the light verb through semantic bleaching of the full verb is not viable if bleaching is interpreted as implying the strong claim stated in (40):

(40) The semantic structure of the light verb is a proper substructure of the semantic structure of the full verb.

The light verbs *koTukk-* 'give' and *kiTT-* 'get', unlike their full counterparts, require that their dative argument be the beneficiary of a desirable outcome. In other words, they impose a semantic condition not found in the full verb. Hence, (40) could not be correct.

The general characteristics illustrated by the behavior of the applicative light verbs in Malayalam can now be summarized as follows. A light verb may impose a requirement on an argument of the complex predicate; if the host does not satisfy this requirement, the light verb may either contribute an additional argument (addition) or add the required argument meaning to an existing argument

(merging). A light verb may also impose a requirement that results in suppressing a semantic role of the host, thus preventing it from being expressed as an argument (suppression). Finally, it may require its host to contain a specific argument, as in the case of an agent in give-compounding. These properties support the conclusion that it is necessary to factor apart the semantic information and the valency information conflated in theta-role labels like agent, recipient, beneficiary, and theme.

5.3 *Aspectual and modal light verbs in Hindi/Urdu*

Complex predicates of the form V+V are so prevalent in the South Asian languages that a detailed description of their meanings has long been a central preoccupation of grammarians of these languages. Masica (1976) lists the varied and manifold meanings that light verbs bring to the complex predicate: they connote "completion, suddenness, directionality, benefaction, intensity, violence, stubbornness, reluctance, regret, forethought, thoroughness, etc." However, he suggests that these various modal and aspectual meanings "can all be brought under one banner: greater specification of features of the action already latent in the main verb itself or those that are compatible with it but have not yet been specified." The light verb unfolds the "latent semantics" of the host, "characterizing the manner and implications of its performance more precisely" (Masica 1976: 143).

In a detailed description of data from the various Indo-Aryan languages of South Asia, particularly Hindi and Marathi, Hook (1974) postulates a category called 'vector verb', roughly equivalent to what we have called 'light verb'. (Bahl 1967 proposes the term 'explicator' to refer to this class of verbs.) Of the two verbs V+V in a 'compound verb', the first is the host, and the second the vector or light verb. Including the less common and less productive ones, Hook catalogues 68 light verbs in Hindi (of which 24 are commonly used), as well as the various verbs that each of them accepts as its hosts.

In extensive work on complex predicate constructions with verbal hosts in Urdu, Butt (1995) lays out two constructions that she argues must be treated as complex predicate constructions, namely the permissive and the aspectual complex predicate, illustrated in (42) and (43) respectively. The sentence in (41) is the corresponding simple sentence with a single verb:

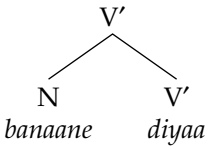
(41) anu-ne haar banaayaa.
Anu-ERG garland made
'Anu made a garland.'

(42) raam-ne anu-ko haar banaane diyaa.
Ram-ERG Anu-DAT garland to make gave
'Ram let Anu make a garland.'

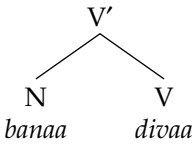
(43) anu-ne haar banaa diyaa.
Anu-ERG garland make gave
'Anu made a garland (completely).'

The permissive construction illustrated in (42) is entirely productive. The aspectual complex predicates, however, exhibit certain interesting combinatorial restrictions. The light verb can determine the case of the subject of the clause, and must be compatible with the host in terms of whether or not the subject of the clause can be volitional. The notions of the inception and completion of an event also play a role in limiting the combinatorial possibilities (Ramchand 1997); thus, a light verb may serve to pick out or focus on the point of inception. In short, the light verb brings its own semantics and argument structure to the construction, as in the N+V complex predicates.

On the basis of evidence from patterns of agreement, control, reflexive binding, and disjoint reference, Butt demonstrates that the light verb and its host form a single syntactic predicate in (42) and (43), behaving exactly like the simple predicate in (41). On the other hand, the patterns of scrambling, negation, modification, and coordination displayed by the constructions lead to the conclusion that they need not form a single constituent in phrase structure. Butt argues that in the phrase structure of (42), the infinitival verbal host is in fact nominal, and the light verb is not a lexical category; rather, it is a V^{bar}, as is the combination:



In (43), on the other hand, the light verb and the host are both V^0 sisters, their mother node being a V^{bar}:



The V+V complex predicates in Urdu, Hindi, and the other Indo-Aryan languages of South Asia raise questions about distinctions among grammatical verbs, particularly aspectual auxiliary, modal auxiliary, and light verb. In (42), the meaning is that of permission, typically found in modal auxiliary. However, as Butt argues, the construction in Urdu involves a complex predicate with a light verb which adds an argument to the clause, a property not associated with modals. Hence, we may conclude that the Hindi verb 'give' in (42) is a modal light verb, unlike the applicative light verb 'give' in Malayalam.

In (43), the verb 'give' adds the aspectual meaning of completion. One might ask if this grammatical verb should be treated as an aspectual light verb, or as an aspectual auxiliary in (43). It does not add an argument. However, it requires a particular argument meaning, namely that of conscious choice, of its subject.

This could be used as justification for classifying it as a light verb, if it were the case that all grammatical verbs that contribute/require specific argument meanings are light verbs. However, given that modal auxiliaries – for instance, *can*, *will*, *shall*, and *must* in English – generally express meanings such as volitionality, intentionality, ability, and obligation, which belong to the same class of meanings as conscious choice, it is difficult to use this property as criterial. The only reason for treating 'give' in (43) as a light verb, then, is that unlike the modal auxiliaries in English, light verbs have full counterparts. One may therefore suggest that a grammatical verb is a light verb if it has a full counterpart. However, this criterion also runs into problems when faced with examples like (44) and (45):

(44) anu us ghar-me rahtii hae.
Anu that house-in stays is
'Anu lives/stays in that house.'

(45) a. anu haar banaatii hae.
Anu garland makes is
'Anu makes garlands.'
b. anu haar banaatii rahtii hae.
Anu garland make stay is
'Anu keeps making garlands.'
c. anu haar banaa rahii hae.
Anu garland make stay is
'Anu is making garlands.'

A comparison of (44) and (45) shows that the grammatical verb *rah-* 'stay/remain/continue' in (45b, c) has a full verb counterpart in (44). By the criterion of pairing with full verbs, therefore, *rah-* in (45b) and (45c) should be a light verb. However, this verb in (45c) is viewed without question as an auxiliary. We must conclude that either the treatment of *rah-* in (45c) as an auxiliary is not viable, or that the property of pairing with a full verb is not a sufficient condition for light verbs.

It is widely agreed that auxiliaries (including modals) and light verbs, while they need not form a single phrase structure constituent, nevertheless form a single predicate with their hosts in terms of syntactic function. Now, distinguishing between auxiliaries, light verbs, and modals, Butt and Lahiri (1998) cite as an example of a modal the following sentence with an embedded structure:

(46) naadyaa xat likhnaa caahtii hae.
Nadya letter write-INF wish/want-IMPF is
'Nadya wants to write a letter.'

However, it is unclear how (46) can be distinguished from a raising construction. If we take light verbs and auxiliaries (including modals) to be grammatical verbs that involve a single functional clause, the legitimacy of (46) as a modal construction

is called into question. What (46) shares with modals is simply a modality meaning, which in this instance is expressed by a full verb.

A possible way to distinguish between auxiliaries and light verbs may be in terms of their contribution to the event structure of the clause: while auxiliaries participate in the modification of the event structure of their host, light verbs come with their own event structure, no matter how bleached. This is what makes a light verb a semantic predicate in its own right, allowing it to contribute arguments and argument meanings, and determine the case of arguments (Mohanan 1994; Butt 1995, 1997; Butt and Lahiri 1998). Though this is a possible move to make, it is unclear how one can in a non-ad-hoc way establish on an empirical basis the distinction between having an independent event and modifying an existing event.

6 Adjectival hosts

As mentioned earlier, the resultative construction in English has been treated as a complex predicate construction where the complex predicate is composed of a verb and an adjective (Simpson 1983; Jackendoff 1990b; Levin and Rappaport Hovav 1995; Hale and Keyser 1997). The construction is illustrated in (47):

(47) a. The potter baked the clay hard.
b. The elf licked the plate clean.
c. They painted the Volkswagen purple.

While (47) illustrates complex predicates made up of a verb–adjective combination, these examples are not of interest in a discussion of light verbs, because the range of verbs that participate in the construction do not form a closed class, and therefore are not grammatical verbs.

We do, however, find true light verb constructions with adjectival hosts, such as those in (48) from Hindi:

(48) a. kamraa **saaf huaa.**
room clean became
'The room became clean.'
b. raam-ne kamraa **saaf kiyaa**.
Ram room clean did
'Ram cleaned the room. (Ram did the room clean.)'

Compare (48a, b) with (15a, b), where the host is a noun; the meaning is only minimally different. Like N+V and V+V complex predicates, A+V complex predicates like those in (48) are entirely productive in Hindi.

The A+V complex predicates in Malayalam display an interesting twist. The language does not allow native adjectives to appear in the preverbal position in a complex predicate: adjectives, whether derived or underived (of which there are no more than a handful), must undergo nominalization to appear preverbally.

Alternatively, they undergo verbalization, in which case they do not require a light verb. Yet, surprisingly, there is widespread borrowing of adjectives from English to create A+V complex predicates such as those in (49), parallel to those from Hindi in (48):

(49) a. muri **kLiin aayi**.
room clean became
'The room became clean.'
b. raaman muri **kLiin aakki**.
Raman room clean caused to become
'Ram cleaned the room. (Ram made the room clean.)'

The borrowing of adjectives is productive; thus, the word 'clean' in (49a) and (49b) can be replaced by 'tidy', 'neat', 'dirty', 'dark', 'bright', or 'yellow', all with acceptable results. The A+V construction in Hindi and Malayalam reconfirms what we have observed before, namely that the light verb can determine the transitivity of the complex predicate independently of the host.

7 The ubiquitous light verb *do*

As mentioned earlier (section 4.3), Japanese and Korean have complex predicate constructions in which the light verb is 'do': *suru* in Japanese and *hata* in Korean. The equivalent of the verb 'do' appears to be one of the most pervasive light verbs across languages: *kardan* in Persian; *kar-* in the Indo-Aryan languages of South Asia, including Hindi, Gujarati, and Bengali, and *gar-* in Nepali; *ces-* in Telugu; *maad-* in Kannada; *paNN* in Tamil; and *cey* in Malayalam.

In all these languages, the light verb 'do' is completely productive, taking as its host not only native words but also words borrowed from English. An interesting quirk found in this productive complex predicate formation pattern in the South Asian languages is that typically, if the host is a native word, it is a noun; if the host is borrowed from English, it is a verb. Examples that illustrate this asymmetry are given in (50) and (51). While the illustrations are given only from two languages, the phenomenon is prevalent across the languages of the region:

(50)

	Hindi		**Malayalam**		**Gloss**
a.	puujaa	kar	puuja	cey	to worship
b.	upkaar	kar	upakaaram	cey	to do a favor
c.	madad	kar	sahaayam	cey	to help
d.	tyaag	kar	tyaagam	cey	to sacrifice

(51)

	Hindi		**Malayalam**		**Gloss**
a.	allow	kar	allow	cey	to allow
a.	edit	kar	edit	cey	to edit
c.	insist	kar	insist	cey	to insist
d.	wash	kar	wash	cey	to wash

In V+V complex predicates like those in (51), the borrowed English verb is incorporated into the language, with appropriate phonological adaptation.

In both Hindi and Malayalam, if the X in the X-*do* complex predicate is a native word, in which case X is a noun, as in (50), then the complex predicate is transitive, with an agent. If, on the other hand, the X is a borrowing from English, and hence a verb, the complex predicate may be either transitive or intransitive.

Among V+V complex predicates where the host is intransitive, Hindi and Malayalam diverge: Hindi requires that the host be unergative, while Malayalam allows both unergative and unaccusative hosts:

(52)	**Hindi**	**Malayalam**	**As in the sentences:**
a.	jump kar	jump cey	The cat jumped.
b.	jog	jog	Meg jogged.
c.	*arrive	arrive	The train arrived.
d.	*break	break	The teapot broke.

There is clearly a language-internal regularity visible in the phenomenon. However, the cross-linguistic details of the pattern of X+do, as well as the pattern of complex predicates of the form A+V (section 6), both of which involve words borrowed from English, appear at least for now to defy a principled account.

8 The relation between the full verb and the light verb

When talking about light verbs, a question that must be asked, whether or not it can be adequately answered, is: what is the relation between a lexical verb and its grammatical counterpart? Although the semantic and syntactic properties of a light verb are not identical to those of its full independent counterpart, there is clearly a systematic synchronic relation between the two. Thus, all analyses of complex predicates acknowledge that there is something light or incomplete about the light verb in relation to the full verb. Yet some central aspect of the syntax and semantics of the full verb is typically preserved in the light verb, whether it be valency, argument meanings, or case assignment. How, then, are the two verbs related? How must the relatedness be expressed by linguistic theory?

One of the explanations for the relation between full and light verbs has been in terms of the historical perspective. Historically, when a lexical form undergoes grammaticalization to become a grammatical form, the change is often manifested as a cline. (See Hopper and Traugott 1993: 103–113 for a detailed discussion of clines, and caveats.) A very general grammaticalization cline suggested for verbs is the following: full verb > auxiliary > clitic > affix. (See Bybee 1985; Bybee and Dahl 1989, for studies of cross-linguistic verbal clines, and Lord 1976 for similar grammaticalization patterns.) On this cline of grammaticalization, one

of the intermediate stages between the full verb and the auxiliary is represented by Hook's (1974) vector verb (Hopper and Traugott 1993). The large and variable repertoire of light verbs listed in the various Indo-Aryan languages of South Asia, as well as the restrictions on the semantic classes of verbs each of them accepts as its host, suggest a need to treat them as a class distinct from auxiliaries, closer to the full verbs.

Butt and Lahiri (1998), however, argue that light verbs do not belong on the grammaticalization cline mentioned above. The reasons they provide on the basis of light verbs in Urdu and Bengali are the following. First, V+V as well as N+V complex predicates have been around for at least two thousand years, and though absent in Vedic, are found in Classical Sanskrit texts, as well as in Prakrit and Pali. Interestingly, the structural ambiguity between a participial reading and a complex predicate reading found in Sanskrit is found in the complex predicate constructions in the Urdu, Bengali, and Hindi of today.

Second, while old participle forms have grammaticalized to affixes in the tense–aspect system, light verbs have remained intact. Furthermore, they interact with all the tenses and aspects, rather than forming a subclass within the system.

Finally, it is interesting to note that the basic set of verbs that appear as light verbs display a striking resemblance across languages. The languages, many of them genetically and areally unrelated to one another, range from Korean, Japanese, Chinese, Persian, and the various language families of South Asia, including Indic (Hindi, Bengali, Marathi, Sinhala), Dravidian (Malayalam, Tamil, Telugu), Tibeto-Burman, and Munda, to Amerind languages like Tepehua, African languages like Yoruba, and creoles like Sranan. The verbs that have light counterparts are typically selected from a set that includes 'do', 'become', 'have', 'make', 'come', 'go', 'move', 'give', 'take', 'put', 'throw', 'release', 'fall', 'rise', 'hit', and 'strike'. What these verbs appear to have in common is that they are the semantically simplest verbs in any language (Grimshaw 1997b). They are relatively unspecified for information, other than, for instance, movement and directionality. This absence of semantic specification renders them amenable to service in a variety of constructions (Butt and Lahiri 1998).

This brings us back to our question: how do we express the relation between the full verb and the light verb in syntactic theory? Butt and Lahiri suggest two possibilities. One is to assume that, for every verb that has a full as well as a light manifestation, there are two lexical entries: one with specification of the full verb, and the other for the light verb. The other is to postulate a single underspecified representation for each verb, which lends itself to use either as a full verb or as a light verb, depending on what is required by the larger context of the clause. Butt and Lahiri favor the latter as the more plausible assumption.

Whatever the formal solution (e.g., full specification, underspecification, or deletion of specification), the substantive challenge at the level of grammar is that of stating the general laws (rules or constraints) that relate light verbs and their full counterparts. The challenge at the level of Universal Grammar is that of capturing the cross-linguistically recurring patterns in such laws, not available at the current stage in linguistic theory.

9 Theoretical Issues and problems of analysis

9.1 Variety of structure in complex predicates

As we have seen, complex predicate constructions involving light verbs display a confusing array of structures and properties. First, the host of a light verb can be a verb, noun, or adjective. Some languages allow all three types of hosts.

In terms of the parameters of variation with respect to phrase structure, we have seen that a light verb, its host, and the entire complex predicate may be either a lexical category or a phrasal category. In N+V complex predicates in Hindi, the host is a lexical category (section 4.2), while in the parallel N+V complex predicates in Malayalam, the host is a phrasal category (Mohanan 1983). The light verb in N+V complex predicates in Hindi is a phrasal category (section 4.2), while that in the causative predicate in Catalan is a lexical category (Alsina 1997). Like the N+V (section 4.2) and V+V (section 5.3) complex predicates in Hindi, the entire causative predicate in Catalan must be treated as a phrasal category, but in Chichewa, it is a lexical category (Alsina 1997).

We have also found that in addition to being a predicate, and part of a complex predicate, a nominal host can also be an argument of the light verb. Hindi has two types of N+V complex predicates, the difference between them being precisely that the host is an argument of the light verb in one type but not in the other.

9.2 Diversity in analysis

In addition to the clear cases of the language-internal and cross-linguistic variability in the structure of complex predicates, we also find considerable divergence in the claims that have been made on complex predicates and light verbs in various languages. It is unclear at this point if the diversity of claims is a reflection of further cross-linguistic variability of the construction, or if it is a function of differences in analyses whose empirical claims need to be tested. Wherever the latter is the case, it is important to look for empirical evidence to choose from among the analyses.

Most treatments of complex predicates involve the combination of two semantic predicates into a single syntactic predicate. A brief look at the diversity of analyses of complex predicates available in the literature reveals four classes of issues.

9.2.1 'Movement' and 'restructuring' vs. multidimensionality

The first issue has to do with the problem of expressing how a light verb and its host behave like a single syntactic predicate with respect to functional structure, even though they may be two independent units with respect to categorial structure. This problem has two solutions (section 4.1). One solution involves a syntactic transformation of one representation into another. For instance, in an analysis of N+V complex predicates in English, Chomsky (1975b) employs

restructuring to transform the categorially motivated structure [[make] [the claim that . . .]] (10a) to the functionally motivated structure [[make the claim] [that . . .]] (10b). The same need for reanalysis, or 'restructuring', appears in V+V complex predicates as well. Variants of the transformational approach are employed in the treatments of complex predicates in GB, including movement in Logical Form (Baker 1988a; Jayaseelan 1988; Speas 1990; Huang 1992a; Chomsky 1995b; Cinque 1997a, 1997b). These approaches share with Relational Grammar the essential idea of 'clause union', or the hypothesis that such phenomena involve the reduction of a bi-clausal structure into a monoclausal one (Aissen and Perlmutter 1976, 1983).

The alternative solution involves two parallel linked representations. Within this approach, one structure is categorial (13a), as in the first solution, but the other is functional (13b); the two structures are related through principles of correspondence rather than the procedure of transformations. This is the strategy adopted, for instance, in the LFG-inspired treatments of complex predicates (Alsina 1992, 1996; Mohanan 1994, 1997; Butt 1995, 1997; Matsumoto 1996a; among others).

The choice between these approaches to the mismatch between functional and categorial information derives from the commitments of the particular model or framework that the individual linguist employs, and is particularly difficult (though not impossible) to test on empirical grounds. We will not pursue this issue here.

9.2.2 *How empty are light verbs?*

The second issue is that of expressing the contributions to the complex predicate by the light verb and by the host. Some approaches, such as that of Grimshaw and Mester (1988), assume that the light verb has no syntactic or semantic information to contribute, and that the relevant requirements of the host are projected up to the complex predicate. This assumption is clearly untenable in the light of the range of phenomena that we have reviewed so far, whether the host is nominal, verbal, or adjectival. Other approaches (Alsina 1992, 1996; Mohanan 1994, 1997; Butt 1995, 1997; Matsumoto 1996a; among others) assume, on the basts of large bodies of evidence, that both the light verb and its host can make a contribution to the complex predicate. The light verb can even contribute meanings to the complex predicate not found in the full verb (section 5.2).

9.2.3 *Complex predicate formation: event structure or argument structure?*

The third issue concerns the representation of the information contributed independently by the light verb and the host. In frameworks that make use of theta-role labels of the traditional sort, valency information is conflated with the semantics of the arguments. As demonstrated by the phenomena we have reviewed in applicatives in Malayalam (section 5.2), valency must necessarily be factored apart from argument meanings: a light verb can require the addition of

an argument meaning, which can be satisfied either by merging the meaning with an existing argument, or by adding a new argument.

The V+V complex predicates (section 5.3) also raise questions about argument structure. Given that a complex predicate has two semantic predicates and one syntactic (functional) predicate, how do we articulate the relation between the semantics and the syntax? In other words, how do two semantic predicates merge as a single syntactic predicate?

Differences among analyses in terms of this question crucially hinge on differences in the conception of the level of argument structure, the issue having to do with the representation of thematic role information. On the one hand, works like Rosen (1989), Grimshaw (1990), and Mohanan (1994) argue for a skeletal argument structure that represents valency and argument hierarchy information, without any semantic content. Butt (1995), on the other hand, incorporates semantic information at the level of argument structure, adopting Jackendoff's (1990b) Lexical Conceptual Structure representations directly into argument structure. Alsina's (1996) argument structure is less elaborated than that in Butt, but richer than the skeletal argument structure in that it includes proto-role information (Dowty 1991).

Given these differences, variants of at least two possible views of complex predicate formation emerge, yielding two types of analyses. In one type, Alsina (1996), for complex predicates in the Bantu languages and in Romance, and Butt (1995), for V+V complex predicates in Urdu, formulate complex predicate formation in terms of the correspondence of two argument structures and a single functional structure. In other words, each of the two semantic predicates has its own argument structure, with an embedded a-structure representation.

Mohanan (1994), in contrast, formulates N+V complex predicate formation in Hindi as a correspondence of two semantic structures and a single argument structure. The crucial difference between the two approaches is that the complex a-structure hypothesis implies the possibility of two logical subjects (highest argument in a minimal a-structure) in a single functional clause, while the simple a-structure hypothesis entails a single logical subject. In Hindi, evidence on the basis of which to choose between the two comes from facts of reflexive binding, which is sensitive to logical subjecthood: a reflexive in this language takes as its antecedent either a grammatical subject or a logical subject. It is extremely difficult to find examples of complex predicates in which, given a compositional argument structure, the logical subjects of the embedded predicate and the matrix predicate would be distinct. However, in the rare examples that can be found among N+V complex predicates, only one of them can bind the reflexive. This points to a representation with a single argument structure without embedding (Mohanan 1994). The hypothesis of dual logical subjects is therefore untenable at least for the N+V complex predicates in Hindi. Whether this is true of the V+V complex predicates in the literature remains to be seen.

In the absence of relevant evidence, we may entertain a parametric choice between simple and complex argument structures available to languages in complex predicate formation. How do we decide which choice is appropriate in

a particular instance? What is the kind of empirical evidence, such as that described above from reflexive binding in Hindi, that would allow for the choice between the alternative analyses? Or are they empirically equivalent variants, resulting from minor individual differences in the conception of the organization of grammar? These are questions for future research.

10 Conclusion

We hope that it is clear that research since the early 1980s, whether descriptive or theoretical, and regardless of specific frameworks, has contributed considerably to our understanding of the phenomenon of complex predicates and their formation. While unanswered questions abound, the wealth of data keeps growing.

In the preceding sections, we have addressed the questions outlined at the beginning of the chapter, here briefly summarized:

(i) How can we characterize the complex predicate construction in such a way that it can be distinguished from other constructions involving grammatical elements?
(ii) How can we characterize the light verb construction as a special case of complex predicates, to be distinguished from other types of complex predicates?
(iii) How do complex predicates vary, and what are the limits of their variability?

1 Introduction

Every language is equipped with some means to make speech polite, less offensive, less assertive, or less direct.[1] One typical way to do so is to employ an interrogative or a subjunctive in place of a command or an imperative sentence. For example, the interrogative (1b) and the subjunctive (1c) are considered to be more polite expressions than the imperative (1a):

(1) a. Pass me the salt.
b. Will you pass me the salt?
c. Would you pass me the salt?

Similarly, a statement can be made less direct if it is converted to a negative question or a tag question. (2b) and (2c) sound softer and less pushy than (2a):

(2) a. It is expensive.
b. Isn't it expensive?
c. It is expensive, isn't it?

Another typical way to make speech polite is to designate particular expressions or words as polite versions for certain referents. For example, many European languages have two forms that refer to the second person, and one is considered to be more polite or less intimate than the other. In French, *vous* is used rather than *tu* when the speaker feels a need to show some distance from the addressee. Similarly, in polite speech, less direct expressions or euphemisms are preferred to direct ones: *pass away* for *die*, *bathroom* for *toilet*, etc.

Having observed these cases, polite speech may be characterized in terms of how a certain idea or referent is expressed, and what is at issue is how certain words are used in addition to their original or primary functions. Then polite speech may be considered to be better investigated in the realm of the use of language or pragmatics rather than in that of formal grammar. However, there are languages that exhibit particular grammatical constructions that are productive and primarily just for polite speech. Japanese is such a language and in what follows, I will describe the constructions in Japanese that have to do with honorifics.[2]

2 Honorific forms in Japanese: overview

For making speech polite, Japanese makes use of the strategies described above as well. That is, questions can be used in place of requests, interrogative forms are considered less direct than straight declaratives, pronouns have several forms which are used differently depending on who they refer to, who the addressee is, and under what sociological situation the utterance is made; particular euphemisms are available for certain expressions, etc. However, what makes the polite speech of Japanese different from these strategies is that it possesses a productive system that is primarily for honorifics. In Japanese grammar, it is widely accepted that Japanese exhibits (at least) three types of honorifics: Performative Honorific (PH) or Hearer Honorific (HH), Subject Honorific (SH), and Object Honorific (OH) or Non-Subject Honorific (NSH).[3] Each honorific type exhibits its own peculiarities, and honorifics are to be considered in terms of the following three conditions; (i) morphological conditions, (ii) grammatical conditions, and (iii) contextual or pragmatic conditions. To illustrate, let us take (3) as an example:[4]

(3) Sato-san-ga Honda-san-ni hon-o kasi-ta.
Sato-Nom Honda-Dat book-Acc lend-Past
'Sato lent a book to Honda (Sato let Honda borrow a book).'

This sentence has the plain or basic form of the predicate *kas(u)* 'lend'. However, the predicate may take any of the three 'honorific' forms; *V-mas-u*, *o-V-ni nar-u*, and *o-V-su-ru*, without altering the 'logical' meaning, that is, 'Sato lent a book to Honda (Sato let Honda borrow a book).' These forms represent the three types of Japanese honorifics:

(4) a. HH: Sato-san-ga Honda-san-ni hon-o kasi-*masi*-ta.
Sato-Nom Honda-Dat book-Acc lend-polite-Past
'Sato lent a book to Honda.'
b. SH: Sato-san-ga Honda-san-ni hon-o *o*-kasi-*ni nat*-ta.
Sato-Nom Honda-Dat book-Acc HP-lend-SH-Past
'Sato lent a book to Honda.'
c. NSH: Sato-san-ga Honda-san-ni hon-o *o*-kasi-*si*-ta.
Sato-Nom Honda-Dat book-Acc HP-lend-NSH-Past
'Sato lent a book to Honda.'

The HH form indicates that the speaker presents her speech in a polite way, being respectful to the hearer or addressee. With the SH form, the speaker elevates the referent of the subject without degrading anyone else including the speaker. NSH, on the other hand, downgrades or demotes the subject, which in effects elevates the referent of a non-subject. Thus, if the speaker utters (4a), she intends to show that she feels it appropriate to express her respect for the addressee, when expressing the logical content of the sentence that is the same as (3). (4b) indicates that the speaker is respectful to the subject of the predicate, *Ms./Mr. Sato*, while her attitude toward the addressee and the indirect object, *Ms./Mr. Honda*, is neutral or unspecified. With (4c), on the other hand, the speaker expresses her respect for a non-subject, the indirect object *Ms./Mr. Honda* in this case, but does not show any particular respect for the addressee or the subject of the sentence. HH and the other honorifics, SH or NSH, are not mutually exclusive and if the speaker considers it appropriate to show her respect for both the addressee and the subject of the sentence, the logical content of (3) is expressed in the form (5a), where the *o-V-ni nar(i)* part involves the SH marking and the *mas(i)* part the HH marking. In (5b), the speaker is respectful toward both the addressee, being marked by *mas(i)*, and the (indirect) object of the sentence, which has to do with the *o-V-si* morphology:

(5) a. HH & SH: Sato-san-ga Honda-san-ni hon-o *o*-kasi-*ni nari-masi*-ta.
b. HH & NSH: Sato-san-ga Honda-san-ni hon-o *o*-kasi-*si-masi*-ta.

One may wonder how the speaker expresses her respect for both the subject and the object, which is certainly a possible situation sociologically. However, it is impossible to do so grammatically: one predicate cannot take the SH and NSH forms at the same

time.[5] The speaker must put one higher than the other and choose an honorific form accordingly. It seems that when the speaker's respect is to be directed toward both the subject and the object, SH is used, since NSH has the function of making the subject humbler (lower than the object), while SH simply elevates the subject, leaving the status of the object intact (neutral or possibly respectful).

The honorific markings appear not only on verbs, as in (4) and (5), but also on adjectives and on the copulative predicate, as shown in (6–7):

(6)	**Adjectives**	***yasasi-i***	**'kind-pres.'**
	a. Plain:	Yamada-san-wa 'Yamada is kind.'	yasasi-i.
	b. HH:	Yamada-san-wa	yasasi-i-*des*-u.
	c. SH:	Yamada-san wa	*o*-yasasi-i / *o*-yasasi-ku-te-*irassyar*-u.
	d. NSH:	Does not apply	

(7)	**Copula**	***da***	**'be-pres.'**	
	a. Plain:	Hanako-san-wa 'Hanako is a teacher.'	sensei	da.
	b. HH:	Hanako-san-wa	sensei	*des*-u /de *gozaimas*-u.
	c. SH:	Hanako-san-wa	sensei	de *irassyar*-u.
	d. NSH:	Does not apply		

The basic functions and morphological forms of the three types of honorifics are summarized in (8–10):

(8) **Hearer Honorifics (HH) – respect is due to the addressee:**

a. Verbs: The polite predicate *mas-u* is attached to the connective form of a verb.[6]

b. Adjectives: *Des-u* is attached to the indicative form of an adjective.

c. Copula: The polite form of the copula, *des-u* or *de gozaimas-u*, is used instead of the plain *da*.

(9) **Subject Honorifics (SH) – respect is due to a subject:**

a. Verbs:[7] Either (i) or (ii), where (i) is considered to be more polite than (ii):

(i) *HP-V-ni nar-u*; the sequence of the honorific prefix (HP) (*o-* or *go-*), the connective form of a verb, the particle *ni*, and the predicate *nar-u* 'become'.[8]

(ii) The form equivalent to the passive morpheme *(r)are-ru* is attached to a verb stem.

b. Adjectives:[9] An HP is prefixed, as in *o-utukusi-i* 'beautiful'. Optionally, the SH suppletive form of the verb *ir-u* 'be, exist' (*irassyar-u*) attaches to the connective form of an adjective, as in *o-utukusiku-te-irassyar-u*, which makes the form politer than the one without.

c. Copula: The connective form of the copula (*de*) is followed by the SH suppletive form of the verb *ir-u* 'be, exist', *irassyar-u*.

(10) **Non-Subject Honorifics (NSH) – respect is due to a non-subject:**
a. Verbs:[10] HP-V *su-ru*: the sequence of HP, the connective form of a verb, and the predicate *su-ru* 'do' or its suppletive NSH form *itas-u*.
b. Adjectives: No NSH forms
c. Copula: No NSH forms

The formation of honorifics given above applies only to native words. There is a large number of Sino-Japanese (SJ) predicates that necessarily involve a native predicate to hold a tense morpheme: SJ verbs consist of a verbal noun (VN) and the light verb *su-ru* 'do', as in *ryokoo su-ru* 'travel' and *dokusyo su-ru* 'read', and SJ adjectives are made up of an adjectival noun (AN) and the copula *da*, as in *byooki da* 'be sick', *kirei da* 'beautiful'.[11] Examples follow:

(11) **SJ verbs, e.g., *syookai su-ru* 'introduce-Light Verb-Pres.':**
a. HH: Hayasi-san-ga Ito-san-ni Jun-o syookai si-masi-ta.
Hayasi-Nom Ito-Dat Jun-Acc introduce-LV-Polite-Past
'Hayashi introduced Jun to Ito.'
b. SH: Hayasi-san-ga Ito-san-ni Jun-o go-syookai ni nat-ta.
go-syookai nasat-ta
go-syookai s-are-ta.
introduce-Hon-Past
c. NSH: Hayasi-san-ga Ito-san-ni Jun-o go-syookai si-ta.
go-syookai itasi-ta.

(12) **SJ adjectives (Nominal Adjectives) – *genki-da* 'fine-copula':**
a. HH: Ono-san-wa genki {desu./ de gozaimas-u.}
'Ono is sick.'
b. SH: Ono-san wa o-genki {da./ de irassyar-u.}
c. NSH: No NSH form

The formation of the SJ honorific forms is summarized in (13) and (14):

(13) **HH:**
a. SJ verbs: The same as (8a); i.e., the polite predicate *mas-u* is attached to the infinitive form of the light verb *su-ru*, as in *si-mas-u*.
b. SJ adjectives: The same as (8c); i.e., the copula is converted to the polite form.

(14) **SH:**

a. SJ verbs: Either (i), (ii), or (iii), and the hierarchy of the politeness goes (ii) > (i) > (iii):
   (i) HP-VN-*ni nar-u*; basically the same as (9ai), but a VN is used in place of the connective form of the verb.
   (ii) HP-VN *nasaru*: *nasaru* is the suppletive SH form of the verb *su-ru* 'do'.
   (iii) HP-VN *s-are-ru*: basically the same as (9aii) and the passive morphome is attached to the verb *su-ru*.

b. SJ adjectives: The same as (9c); i.e., the connective form of the copula, *de*, is followed by the suppletive SH form of the verb *ir-u* 'be, exist', *irassyar-u*.

Besides predicates, nouns can be prefixed by an HP, as in *go-kazoku* 'family', *o-tegami* 'letter', *o-udon* 'Japanese noodles'. These form may mark HH as in (15a), in which *o-* is attached to the plain form *hana* 'flower', which indicates that the speaker is most probably female, and SH as in (15b), where the respect is paid to the genitive-marked noun *Sato-sensei*, which serves as the subject of the SJ noun, *kooen* 'lecture':[12]

(15) a. Hanako-ga o-hana-o kat-ta.
Hanako-Nom PH-flower-Acc buy-Past
'Hanako bought flowers.'

b. Sato-sensei-no go-kooen-ga mamonaku hazimar-u.
Sato-teacher-Gen PH-lecture-Nom soon begin-Pres
'Professor Sato's lecture will soon begin.'

In the above, I have presented a rather detailed description of the honorific forms, intending to show that honorific processes in Japanese are not just peripheral phenomena but involve various grammatical aspects of Japanese. To properly understand them, lexical, morphological, syntactic, and pragmatic considerations are called for. In what follows, I will mainly discuss SH and NSH, since they involve not only the honorific form of a predicate but the grammatical presence of an item to the referent of which the speaker's respect is due. The occurrence of HH, on the other hand, is triggered by the addressee and does not grammatically affect other items in a sentence, and vice versa. For this reason, I will not discuss HH any further in the following. See Harada (1976) and Ide and McGloin (1990) for relevant discussion on the use of HH.

3 Subject Honorification (SH)

As briefly mentioned in the previous section, SH forms are licensed by the subject of the sentence, which clearly indicates that SH is to be described within

sentence grammar. Within generative grammatical studies, Harada (1976) proposes an analysis of honorific processes in terms of transformational rules. His rules for SH not only specify under what syntactic condition SH is triggered but also derive the morphological forms described in (9a). In a more recent framework, Toribio (1990) and Ura (1999) present an analysis in terms of feature checking between the subject and the SH form of a predicate. In both approaches, the key to SH is the syntactic presence of a particular type of subject.

3.1 The conditions on the subject

As the above description of SH indicates, the SH form is allowed only when the subject refers to a person to whom the speaker's respect is due. Observe the following examples:

(16) a. Sensei-ga warat-ta.
teacher-Nom laugh-Past
'The teacher laughed.'
b. Sensei-ga o-warai-ni nat-ta.
teacher-Nom HP-laugh-Hon-Past
'The teacher laughed (honorific).'
c. {*Watasi-ga/ *Imooto-ga} o-warai-ni natta.
I-Nom sister-Nom HP-laugh-Non-Past
'{I/My sister} laughed (honorific).'

(17) a. Sensei-ga gakusei-ni hon-o watasi-ta.
teacher-Nom student-Dat book-Acc pass-Past
'The teacher passed a book to students.'
b. Sensei-ga gakusei-ni hon-o o-watasi-ni nat-ta.
teacher-Nom student-Dat book-Acc HP-pass-Hon-Past
'The teacher passed (honorific) a book to students.'
c. *Gakusei-ga sensei-ni hon-o o-watasi-ni nat-ta.
student-Nom teacher-Dat book-Acc HP-pass-Hon-Past
'The student passed (honorific) a book to the teacher.'

The subject of the (b) sentences is *sensei* 'teacher', who is considered to be looked up to in ordinary social circumstances, and the use of the SH forms is appropriate. The subject of (16c), on the other hand, is the speaker herself or the speaker's family member. Since pragmatic conditions on honorifics involve (18) as a basic rule, (16c) is inappropriate:

(18) The speaker may not pay respect to or show contempt for herself or the members of her in-group.[13]

Similarly, (17c) is inappropriate, since *gakusei* 'student' is ordinarily not subject to respect. Note that *sensei* 'teacher' as the object of the sentence does not trigger SH.[14]

On the basis of these facts, Harada proposes an analysis where the feature of the subject triggers SH, which involves a set of lexical, morphological, and syntactic transformations that give rise to the forms described in (9) and (14). Details aside, under his analysis, the predicate takes (i.e., is converted into) its SH form, if the subject is an NP that refers to a person "socially superior to the speaker (SSS)" to whom respect is due. He proposes (19) as the first rule of the set of SH transformations:[15]

(19) **Subject Honorific Marking:**
Mark the predicate as [Subject Honorific] if its subject is an SSS.

Though (19) is a transformational rule, it is clear that Harada considers it a kind of agreement process, triggered by the SSS subject. In a more recent framework, where agreement is considered to be a feature-checking relation between the two items in question, (19) can be restated as in (20):

(20) The SSS feature of the subject NP must be checked by the SSS feature of the predicate.

This is the direction that has recently been pursued by Toribio (1990) and Ura (1999) within the Minimalist framework.

3.2 SH as agreement

Toribio (1990) accounts for SH in terms of agreement between specifiers and heads. As will be reviewed in more detail in section 3.3, Toribio analyzes the regular SH form of a predicate – i.e., *HP-V-ni nar-u* – in the following way: (i) the connective form of a verb, which she considers gerundive, is a nominal whose category is D; (ii) an HP attaches to D, just as ordinary nouns (Ds) undergo HP prefixation (cf. section 2); (iii) *-ni* is the oblique case assigned by the verb *nar-u*; (iv) *nar-u* is a raising verb (see also Suzuki 1989).

Given this morphological analysis of the SH form, the checking of the features relevant to SH proceeds as follows: the subject generated at the Spec of a predicate phrase (equivalent to *v*P in the sense of Chomsky 1995c) stops at the Spec of gerund DP (and at the Spec of the VP of *nar-u*) on the way to the Spec of TP and has its SH feature checked against the honorific feature of D, which is specifically marked by the presence of HP. That is, the SH feature is considered as an agreement feature that resides in the subject DP, and it is checked independently of its Case feature. In Toribio's system, the Case feature is checked against T, while the SH feature is checked against D of the gerund.[16]

Toribio's analysis is not only plausible but seems essentially on the right track. However, it is necessary to closely examine the mechanisms she seems to assume in more detail before adopting it as the right analysis. For example, she does not provide any direct evidence that shows that the SH feature and the nominative

Case feature of the subject are checked independently by different heads or at different sites. That is, as far as the data she presents are concerned, it seems possible to analyze the predicate *nar-u* with the tense feature as possessing all the relevant features that can check the features of the subject. In Toribio's system, the SH feature is checked at the Spec of gerundive (i.e., connective) D, which is marked by an HP. Thus, if no HP is involved in the SH form, which is possible in some suppletive SH forms, she wrongly predicts that the SH feature of the subject is not checked, or she has to assume that the SH form itself checks the SH feature of the subject. To see this point, observe (21) with suppletive SH predicates, which involve only predicates without an HP:

(21) a. {Sensei-ga/ *Gakusei-ga} soo ossyat-ta.
teacher-Nom student-Nom so say(Hon)-past
'{The teacher/The student} said so.'
b. {Sensei-ga/ *Gakusei-ga} Kobe-ni irassyar-u.
teacher-Nom student-Nom Kobe-to go(Hon)-past
'{The teacher/The student} went to Kobe.'

The SH forms of the verbs *iw(u)* 'say' and *ir(u)* 'be, exist' are not of the expected *o-V-ni nar-u* form (i.e., *?*o-ii-ni nar-u*, **o-i-ni nar-u*), but the suppletive forms *ossyar(u)* and *irassyar(u)*, respectively, which cannot be analyzed into a sequence of separate items. That is, in (21), the SH verbs themselves involve the features responsible for checking the features of the subject. It thus seems reasonable to assume that the checking of the relevant features take place all at once at TP, the subject being at the Spec of TP and the verb at the head of T. In order to argue that the SH feature is an agreement feature independent of the Case feature, which Toribio assumes, we need to examine the cases where Case and SH are clearly triggered by different elements. Ura (1999) examines such cases.

The sentences examined so far all involve a subject marked by Nominative *ga*. However, Japanese also allows Dative subjects. Observe (22):

(22) a. Sensei-ga eigo-ga {wakar-u/ o-wakari ni nar-u.}
teacher-Nom English-Nom understand-Pres HP-understand-Hon-Pres
'The teacher understands English.'
b. Sensei-ni eigo-ga {wakar-u/ o-wakari ni nar-u.}
teacher-Dat English-Nom understand-Pres HP-understand-Hon-Pres
'(the same as (22a))'

Certain stative predicates take a Dative subject, provided that the object is marked Nominative (cf. Kuno 1973c). Dative-marked subjects, just like Nominative-marked subjects, trigger SH, as the examples in (22) show (cf. Harada 1976; Shibatani 1977). It is clear from the examples in (23) that what triggers SH is not a Nominative-marked NP (DP) but the item that serves as a subject, irrespective of whether it is marked Nominative or Dative:

(23) a. Taro-ga sensei-ga {wakar-u/ *o-wakari ni nar-u.}
Taro-Nom teacher-Nom understand-Pres HP-understand-Hon-Pres
'Taro understands the teacher.'
b. Taro-ni sensei-ga {wakar-u/ *o-wakari ni nar-u.}
Taro-Dat teacher-Nom understand-Pres HP-understand-Hon-Pres
'(the same as (23a))'

In (23), the subject is *Taro* and the object is *sensei* 'teacher'. Though *sensei*, which is SSS in Harada's sense, is marked Nominative, it cannot trigger SH.

To account for this phenomenon, Ura proposes the system described in (24) within the Minimalist framework:

(24) (i) The EPP-feature (or D-feature) of T is strong.
(ii) The dative subject of the Dative Subject Construction (DSC) is generated at the Spec of VP (more precisely, at the Spec of *v*P) and assigned the inherent Dative Case *-ni*, which the stative predicates that exhibit DSC can assign to a DP.
(iii) Agreement (i.e., SH) is independent of Nominative Case.
(iv) T's agreement feature is strong, but its Nominative Case feature is weak.
(v) T's Nominative Case feature can check more than one Nominative Case.

Ura's system assumes the basic mechanisms of the Minimalist program: (24i) guarantees the syntactic presence of a nominal at the Spec of TP. With respect to (22), the phrases *sensei-ga* in (22a) and *sensei-ni* in (22b) satisfy this requirement. (24ii) applies only to a Dative subject. The subject *sensei* occurs at the Spec of VP (rather *v*P) but can be marked Dative if the predicate is of the type that allows DSC. With other types of predicates, a subject is marked Nominative. Regardless of its Case types, the subject is raised to the Spec of TP to check the EPP feature of T. The subject at the Spec of TP can also check T's agreement feature, which is strong (to be checked before Spell Out). The well-formedness of SH is relevant to this agreement checking. The subject *sensei* in (22) properly meets the SH feature of the predicate, while *Taro* in (23) does not. (24iv) and (24v) are necessary assumptions to account for a Nominative object. The Dative subject, being at the Spec of TP, checks T's EPP feature and agreement feature but not T's Case feature. Thus, some DP that is not a subject must be present to check T's Nominative Case feature. The Nominative object DP does it in (22b) and (23b). Furthermore, given (24v), T's Case feature can check the Nominative Case of more than one DP, which accounts for the multiple occurrences of Nominative DPs in (22a) and (23a); the Case features of not only the subject DP but also the object DP are checked by T's Case feature. Thus, to account for the cases of Dative subjects, (24iii) plays a crucial role. Without this assumption, the fact that a Dative subject triggers SH cannot be easily explained.

Another piece of evidence for considering the agreement (or SH) feature independent of the Case feature obtains in tenseless complements with an SH predicate. Observe the following examples:

(25) a. Sensei-ga sake-o nomi-sugi-ru.
teacher-Nom sake-Acc drink-exceed-Pres
'The teacher drank sake too much.'
b. Sensei-ga sake-o o-nomi-ni nari-sugi-ru.
teacher-Nom sake-Acc HP-drink-Hon-exceed-Pres
'(the same as (25a))'

(26) a. Sensei-ga kankokugo-o hanas-e-ru.
teacher-Nom Korean-Acc speak-can-Pres
'The teacher can speak Korean.'
b. Sensei-ga kankokugo-o o-hanasi-ni nar-e-ru.
teacher-Nom Korean-Acc HP-speak-Hon-can-Pres
'(the same as (26a))'

The predicate *sugi-ru* 'exceed' in (25) is a raising predicate and its complement takes the connective form, which presumably does not involve the tense feature. (25b) is derived in the following way: the complement subject *sensei-ga* checks the SH of the embedded predicate and then moves to the Spec of the matrix T to check its Nominative Case feature. Thus, the Case feature and the SH feature are checked by separate heads. The matrix predicate of (26) is the potential *-(rar)e* and exhibits the control construction. The predicate of the complement clause is of the root form and its subject is PRO. Whatever Case PRO may assume, it is not Nominative (or PRO may not have any Case), but the SH feature of the embedded predicate should be checked against PRO. Thus, (26) also indicates that the SH feature may be independent of the Nominative Case feature.

Thus, Dative subjects of DSC and tenseless complements of the Raising and Control constructions support the claim that the checking between the subject and the SH-marking on the predicate is done independently of the Case feature, and the feature involved between the two may be some kind of agreement. In Ura's system, it is simply assumed that the SH (or agreement) feature of T, which is inherited from the SH form of the predicate via head-to-head movement, is checked against the subject. Let us now go back to Toribio (and also Suzuki 1989) to examine the structure and morphology of the SH predicate and see exactly what is responsible for checking the SH (or agreement) feature of the predicate.

3.3 The structure of the SH construction

Now that it is established that the SH feature checking is independent of the Nominative Case checking, let us see which head is really responsible for SH checking. In section 3.2, we have briefly reviewed Toribio's analysis, in which the

SH feature of SH predicates resides in the connective (i.e., 'gerundive' in her terms) V with an HP, rather than *nar-u*, the predicate that actually carries the tense feature. Let us examine this claim more closely.

Both Suzuki (1989) and Toribio (1990) claim that the honorific predicate that has the sequence *HP-V-ni nar-u* is to be analyzed as having a complex structure where *nar-u* is a higher predicate, taking a connective verb as its complement. Suzuki presents several arguments for analyzing the *HP-V-ni* part of the SH form as a 'gerundive' nominal.

First of all, as discussed in section 2, an HP attaches not only to the connective form of a verb but also to a noun and an adjective. Assuming that nouns and adjectives in Japanese are categorically [+N], if the connective form of a verb is in fact nominal, i.e., [+N], the HP attachment is generalized: an HP attaches to the head of [+N].[17] Beside the simplicity in the description of the HP attachment process, the nominal nature of the connective form of the SH predicate is syntactically attested. As described in section 2 ((9a) in particular), the connective form is followed by *-ni*, which can be analyzed as Dative Case or the connective form of a copula. Whichever it may be, *-ni* attaches to a nominal category. This is seen in (27):

(27) a. Sensei-ga sinbun-o o-yomi-*ni* nat-ta.
teacher-Nom newspaper-Acc HP-read-Hon-past
'The teacher read (honorific) the newspaper.'
b. *Sensei-ga sinbun-o o-yomi nat-ta.
c. Hanako-ga isya-*ni* nat-ta.
Hanako-Nom doctor-NI became
'Hanako became a doctor.'
d. *Hanako-ga isya nat-ta.
e. Seito-ga sizuka-*ni* nat-ta.
Pupil-Nom quiet-NI became
'The pupils became quiet.'
f. *Seito-ga sizuka nat-ta

The distribution of *-ni* of the SH form, exemplified in (27a, b), is the same as that of the noun (27c, d) or of the nominal adjective (27e, f). If it is assumed that the category that precedes *-ni* is a nominal category, the status of *-ni* being Dative Case seems justifiable. The nominal nature of the connective form is also supported, even if *-ni* is taken to be a copula. As shown in (28), the copula takes a noun or an adjective, but crucially not a verb:

(28) a. Hanako-ga isya {da./desu.}
Hanako-Nom doctor copula (plain/polite)
'Hanako is a doctor.'
b. Seito-ga sizuka {da./desu.}
Pupil-Nom quiet copula (plain/polite)
'The pupils are quiet.'

c. * Sensei-ga sinbun-o yom-u {da./desu.}
teacher-Nom newspaper-Acc read copula (plain/polite)
'The teacher read a newspaper.'

As compared to the ungrammaticality of (28c), the copula can directly take the SH predicate without *-ni* or *-ni nar-u*, as shown in (29):[18]

(29) a. Sensei-ga sinbun-o o-yomi da. (=o-yomi-ni nat-te i-ru)
teacher-Nom newspaper-Acc HP-read copula HP-read-Hon-exist-Pres
'The teacher is reading the newspaper.'
b. Sensei-ga biiru-o o-nomi da. (=o-nomi-ni nat-te i-ru)
teacher-Nom beer-Acc HP-drink copula HP-drink-Hon-exist-Pres
'The teacher is drinking beer.'

Sentences in (29) are SH but the meaning of the sequence of the *HP-V-copula* differs from the *HP-V-ni nar-u* one. The former is equivalent to that of the *HP-V-ni nat-te iru*. The presence of *-te-ir-u* after a V indicates either the progressive aspect, like *be V-ing* in English, or the perfective aspect, similar to the function of *have V-en*. If the connective form in (29) is [+N], we can generalize the above fact as follows: the copula takes a [+N] category.

What is of particular interest is that not all the occurrences of the connective form are considered nominal, but only those of the SH predicate (i.e., the connective form with an HP prefixed to it). Thus, replacing *(te)-iru* with a copula in non-SH expressions gives rise to ungrammatical sentences:

(30) a. Sensei-ga sinbun-o yon-de-i-ru.
teacher-Nom newspaper-Acc HP-read-Hon-exist-Pres
'The teacher is reading the newspaper.'
b. *Sensei-ga sinbun-o yomi- da.
teacher-Nom newspaper-Acc read copula

The ungrammaticality of (30b) seems due to the verb status of the connective form here. In short, the connective form can be followed by a copula only when it is nominal. The presence of an HP and *-ni* and the replaceability of *-ni nar-u* with a copula are both owing to the nominal nature of the connective form of SH.

Another instance where the connective form of SH behaves differently from other occurrences of the connective form is observed in conjoined sentences, as in (31):

(31) a. Tanaka-sensei-wa otya-o o-nomi-ni nari, Kato-sensei-wa coffee-o
Tanaka-teacher-Top tea-Acc HP-drink-Hon Kato-teacher-Top coffee-Acc
o-nomi-ni nat-ta.
HP-drink-Hon-Past
'Prof. Tanaka drank tea and Prof. Kato drank coffee.'

b. Tanaka-sensei-wa otya-o o-nomi-ni, Kato-sensei-wa coffee-o o-nomi-ni nat-ta.
c. *Tanaka-sensei-wa otya-o o-nomi, Kato-sensei-wa coffee-o o-nomi-ni nat-ta.
d. Tanaka-sensei-wa otya-o nomi, Kato-sensei-wa coffee-o non-da.
drink-past

These are conjoined sentences, and the predicate of the first conjunct is not marked with a tense morpheme. As seen in (31a) and (31d), a typical way to conjoin sentences is to make the verb of the first conjunct into the connective form. SH sentences such as (31b) exhibit another way to conjoin sentences; i.e., delete the *nar-u* part and end the first conjunct with *-ni*. Note crucially that the connective form with an HP cannot serve the function of conjoining sentences, as the ungrammaticality of (31c) shows. The behavior of 'HP-V (connective)' here (i.e., (31b)) is exactly parallel to nouns and adjectives, as shown in (32) and (33):

(32) a. Taro-ga sensei-ni nari, Hanako-ga isya-ni nat-ta.
Taro-Nom teacher-Cop become Hanako-Nom doctor-Cop become-past
'Taro became a teacher and Hanako became a doctor.'
b. Taro-ga sensei-ni, Hanako-ga isya-ni nat-ta.
c. *Taro-ga sensei, Hanako-ga isya-ni nat-ta.

(33) a. Mati-ga kirei-ni nari, mura-ga benri-ni nat-ta.
town-Nom clean-Cop become village-Nom convenient-Cop become-past
'The town became clean and the village became convenient.'
b. Mati-ga kirei-ni, mura-ga benri-ni nat-ta.
c. *Mati-ga kirei, mura-ga benri-ni nat-ta.

The generalization seems to be that the [+N] category cannot function as a sentential conjunction. This generalization can be maintained if the HP-V (connective) is considered as [+N], which accounts for the ungrammaticality of (31c) along with that of (32c) and (33c).

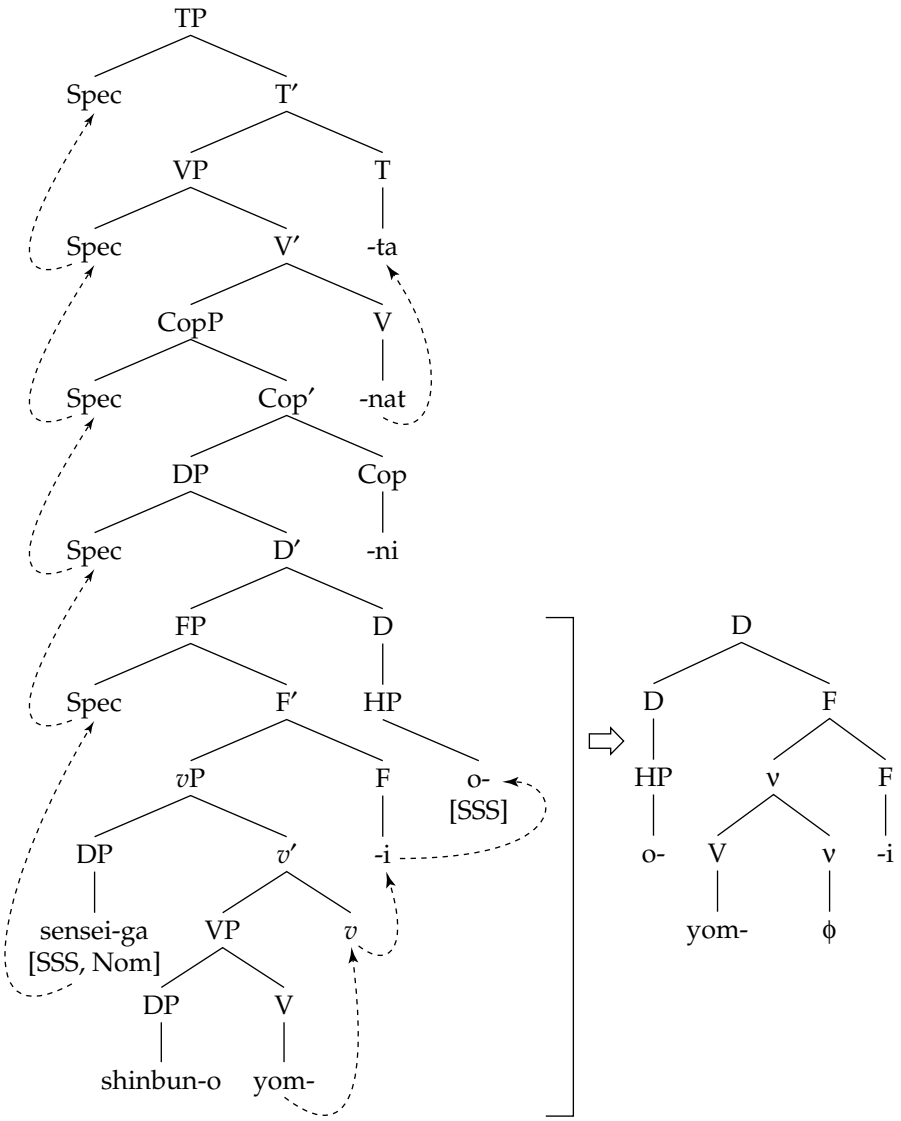
Given these facts, Suzuki (1989) analyzes the HP-V part of the SH predicate as a gerundive DP, *-ni* as Dative Case that is assigned to a gerundive DP, and the predicate *nar-u* as a higher predicate that takes a gerund as its argument. Toribio's (1990) analysis is essentially the same.[19] Taking it that these two analyses are essentially on the right track, in the following discussion I would like to propose a structure that is a modified version of the two analyses. I consider *nar-u* a raising predicate rather than a control predicate, adopting Toribio's claim, since the behavior of *nar-u* in other instances clearly indicates *nar-u* is a raising verb.[20] As for where the [+N] property of SH verbs lies, I would like to assume that it is at the head of D and what resides at D is an HP. That is, an HP, being a bound morpheme with an agreement feature (i.e., an SSS in the sense of Harada), attracts a verb and forces a DP with SSS to be raised to the Spec of DP. As for the connective form, if the generalization that an HP attaches only to a [+N] category

must be maintained, we need to assume that the connective *-i* morpheme has the category feature [+N]. I leave it open exactly what category it may be: some kind of functional category that selects a VP. Note, however, that the connective form itself is not always a nominal, as the data in (31) suggest, and it can be [+N] or [–N]. We will come back to this issue when we discuss NSH in section 4.

To summarize, sentence (34), for example, is analyzed in the way described in (35):

(34) a. Sensei-ga sinbun-o o-yomi-ni nat-ta.
teacher-Nom newspaper-Acc HP-read-Hon-past
'The teacher read the newspaper.' (honorific)

(35)



The main predicate *yom-* 'read' is a transitive and I assume that it has a VP-shell (*v*P-VP) structure. The *v*P is a complement of *-i*, which gives rise to the connective form. As just mentioned, I consider the category of *-i* to be some kind of functional category (FP), and it has the [+N] feature when used for SH. The FP is a complement of DP whose head is an HP. The HP requires an item with the SSS feature at its Spec. Due to this requirement, the subject of *yom-*, *sensei-ga* 'teacher-Nom', is attracted and moves to the Spec of DP. As discussed above, *-ni* may be analyzed as Dative Case, assigned by *nar-u* 'become'. However, in (35) I take it as a copula. *Nar-u* takes a copula phrase (CopP). The subject, whose Agreement feature (SSS) has checked off at the Spec of DP, finally moves to the Spec of TP to have its Case feature checked. As for the Accusative Case of the object, following the general practice, it is covertly checked off by the Accusative Case feature of *v*.

3.4 On honorific prefixes

In the previous section, an HP of the SH form is analyzed as a kind of agreement feature, which attracts the connective form of a verb to its head and a DP. This analysis of an HP is not merely motivated by SH-verbs but supported by honorific or polite forms of nouns and nominal adjectives. As briefly stated in section 2, an HP attaches to a noun as in *o-heya* 'room', *go-hon* 'book', *go-syumi* 'hobby', *o-kao* 'face', *o-karada* 'body, health condition', *o-kuruma* 'car'. The presence of an HP makes speech polite in the sense of HH and is used more often in female speech. It has another function when its occurrence is related to honorifics, SH and NSH; that is, the referent of the noun with an HP is made specific and identifiable in the sense that the possessor of the referent is taken to be a target of the speaker's respect. Note that nouns without an HP can be definite or indefinite, specific or non-specific, depending on given contexts.[21] Thus, in the context of (36), the noun *hon* 'book' most probably refers to an indefinite, non-specific book:

(36) Hanako-ga hon-o kat-ta.
Hanako-Nom book-Acc buy-Past
'Hanako bought a book.'

Nouns with an HP, however, often refer to specific items which can be identified in a given discourse. In (37a) and (37b), the meanings change depending on whether the HP *go-* is attached to *hon* 'book'. Without the HP *go-*, *hon* would refer to any book, but with *go-*, it would most probably refer to the one that the teacher wrote or owns (i.e., the teacher's book).[22] Because of this function of an HP, the use of *go-hon* in (37c) and (37d) sounds somewhat funny, since people do not usually return their own books to the library or borrow them from it:[23]

(37) a. Sensei-ga hisyo-ni (go)-hon-o o-watasi-ni nat-ta.
teacher-Nom secretary-Dat HP-book-Acc HP-pass-Hon-Past
'The teacher passed (his) book to the secretary.'

b. Sensei-ga (go)-hon-o o-sagasi-ni nat-te i-ru.
teacher-Nom HP-book-Acc HP-search-Hon-Prog-Pre
'The teacher is looking for (his) book.'
c. *?Sensei-ga tosyokan-ni go-hon-o o-kaesi-ni nat-ta.
teacher-Nom library-to HP-book-Acc HP-return-Hon-Past
'The teacher returned his book to the library.'
d. *?Sensei-ga tosyokan-de go-hon-o o-kari-ni nat-ta.
teacher-Nom library-at HP-book-Acc HP-borrow-Hon-Past
'The teacher borrowed his book from the library.'

If an HP is in fact a head D and has a definite (and/or specific) feature, this fact naturally follows.

This function of an HP seen in nouns is carried over to the use of an HP in the SH form. That is, the presence of an HP in the SH construction indicates that the event that is described by an SH predicate refers not to any indefinite event but to a definite/specific one. The event must be identifiable, and only a particular individual is to be predicated of the SH predicate. That is, an SH predicate is an open predicate that must be closed by the subject with SSS. The presence of an HP in the SH predicate guarantees this. It is pragmatically natural (and perhaps mandatory) that those that carry the SSS feature are to be identifiable individuals or classes in a given context. Perhaps due to this, the sentences in (38), where the subject is non-specific and indefinite, are not quite felicitous:[24]

(38) a. ?*Misiranu hito-ga hon-o o-kai-ni nat-ta.
stranger-Nom book-Acc HP-buy-Hon-Past
'The stranger bought (his) book.'
b. ?*Dareka-ga o-warai-ni-natta.
teacher-Nom HP-laugh-Hon-Past
'Someone laughed.'

The definite/specific nature of HPs is distinctively observed in the following examples:

(39) a. Watasi-ga o-heya-o soozi si-ta.
I-Nom HP-room-Acc clean-Past
'I cleaned {SSS's/*my} room.'
b. O-kuruma-ga koware-ta.
HP-car-Nom HP-break-Hon-Past
'{SSS's/*my} car got broken.'
c. Go-syumi-wa sakanaturi des-u.
HP-hobby-Top fishing-Cop-Pres
'{SSS's/*my} favorite pastime is fishing.'

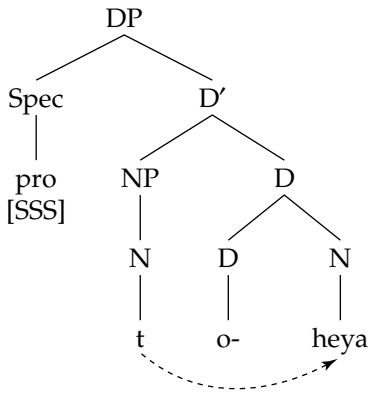
(40) a. Zisin-ni-tuite-no go-kenkyuu-ga syoo-o uke-ta.
earthquake-about-Gen HP-research-Nom prize-Acc receive-Past
'{SSS's/*my} research on earthquakes received a prize.'

b. Asia-e-no go-ryokoo-ga kizi-ni nat-ta.
Asia-to-Gen HP-trip-Nom article-Cop become-past
'{SSS's/*my} travel to Asia was put in an article.'
c. Go-seityoo-ga tanosimi da.
HP-growth-Nom pleasure Cop
'We are looking forward to {SSS's/*my} (process of) growing up.'

In (39), the possessors of the common nouns are not expressed; however, with the presence of an HP, they are to be SSSs and not those owned by the speaker (or her in-group members) or someone who is not worthy of respect. Similarly, the actor/undergoer of the actions/processes expressed in (40) is to be an SSS. Note that if these nouns are used without an HP, the possessor/actor/undergoer can be anyone including the speaker or someone in the speaker's in-group. Thus, it is clear that an HP has the function of making the head noun specific and identifiable, demanding some kind of agreement.

The analysis provided for the SH construction in terms of an HP is applicable to nominals. That is, an HP is a head of D, which takes an NP as its complement, and requires an item with SSS to be at the Spec of D, so that the SSS feature of D is checked off through Spec–Head agreement with the item in Spec. The HP agreement in DPs is illustrated in (41), where pro (null pronominal cagetory) is tentatively posited at the Spec of D, which carries the feature [SSS]:

(41)



3.5 SH-like processes

3.5.1 Honorific passives

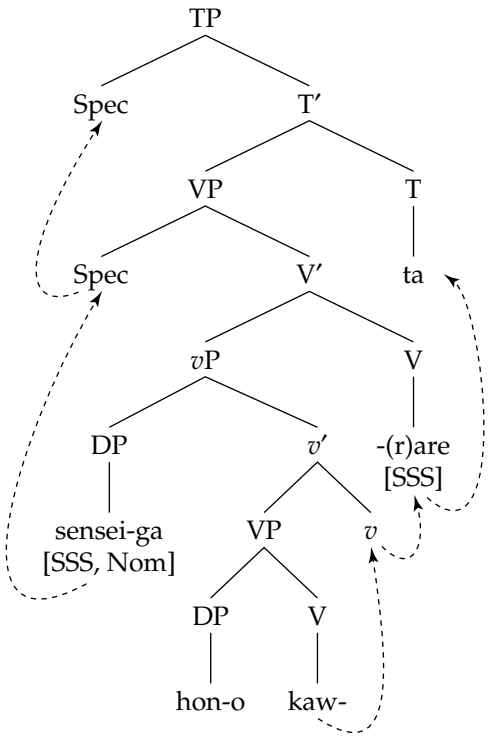
The SH process discussed above is with the morphological form of *HP-V-ni nar-u* (i.e., (9ai)) and it is described as a process of agreement between a subject and a DP-head which is an HP. However, as briefly touched upon in (9aii), there is another type of SH that makes use of the passive morpheme *-(r)are*. Some examples are given in (42):

(42) a. {Sensei-ga/ *watasi-ga} hon-o kaw-are-ta.
teacher-Nom I-Nom book-Acc buy-Pass-Past
'{The teacher/I} bought a book.'
b. {Sensei-ga/ *watasi-ga} kodomo-o sikar-are-ta.
teacher-Nom I-Nom child-Acc scold-Pass-Past
'{The teacher/I} scolded the child.'
c. {Sensei-ga/ *watasi-ga} taore-rare-ta.
teacher-Nom I-Nom fall-Pass-Past
'{The teacher/I} fell down/ill.'

As the grammaticality contrast between *sensei* 'teacher' and *watasi* 'I' on the subject shows, the presence of *-(r)are* is allowed only with an SSS subject, the same condition as for SH with the form of *HP-V-ni nar-u*. To distinguish these two types of SH, let us call them *Rare*-SH and *Naru*-SH, respectively.

Given the facts in (42), it may be natural to account for *Rare*-SH along similar lines to those for *Naru*-SH. That is, *-(r)are* is taken as some kind of predicate that requires an SSS subject. To ensure it, let *-(r)are* have the SSS feature which is to be checked off by an item with the same feature via Spec-Head agreement. This is done if a subject with the SSS feature moves into the Spec of *-(r)are* on the way to TP-Spec, where its Nominative Case feature is checked off. In this analysis, the derivation of (42a) proceeds as described in (43):

(43)

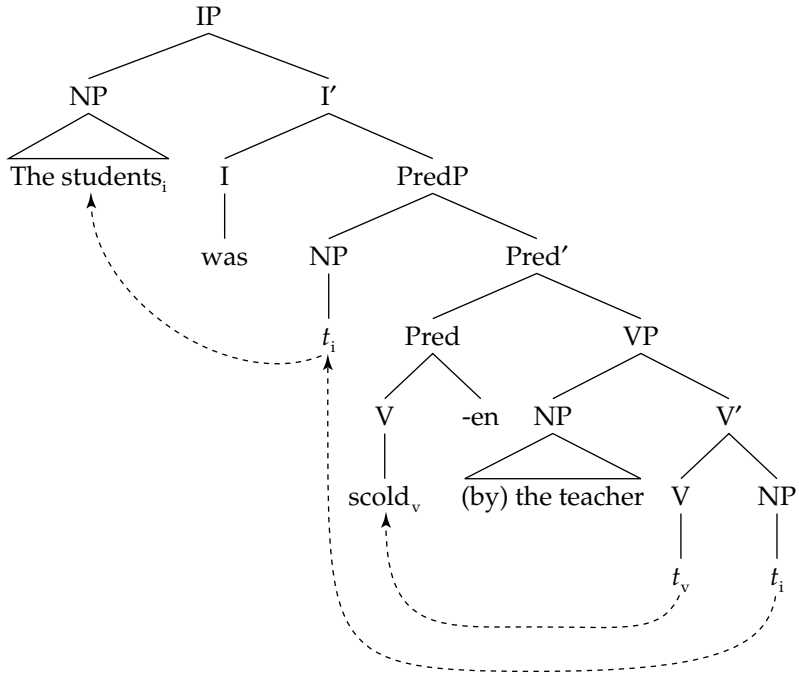


This accounts for the fact that *Rare*-SH requires an SSS subject; however, this analysis cannot explain why the predicate *-(r)are* is used for both passives and SH. The analysis (43) suggests that it is a mere coincidence that *-(r)are* is used for both SH and passives.

Hasegawa (1988), on the other hand, claims that *-(r)are* in passives and *-(r)are* in SH are essentially the same predicate. Before presenting her analysis of *Rare*-SH, let us briefly review how she accounts for passives. In her system, the passive morpheme (including *-en* in English) is a predicate that takes a VP complement. The category of this predicate may be [+N], as in the case of English *-en*, or [–N], which is the case of *-(r)are* in Japanese. The [+N] passive predicate requires Case and absorbs (or is Case-assigned by) the (object) Case feature of the complement predicate. This is done when the complement predicate head-moves to the passive predicate. This gives rise to the typical passive construction, where Object Case is not assigned to the logical object, and the logical object is raised to subject position to receive Nominative Case. The derivation is shown in (44), where an English passive is exemplified:[25]

(44) a. The student was scolded by the teacher.

b.



It is well known that Japanese exhibits (at least) two types of passives; one is called the direct passive, basically equivalent to typical passives like passives in English, and the other is called the indirect passive, where the logical object, if there is one, is marked with Object Case as in actives, but the extra argument

shows up as the affectee or experiencer of the event expressed by the complement VP. Observe the examples given in (45):

(45) a. Sensei-ga kodomo-o sikat-ta.
teacher-Nom child-Acc scold-Past
'The teacher scolded the child.'
b. Kodomo-ga sensei-ni sikar-are-ta.
child-Nom teacher-Dat scold-Pass-Past
'The child was scolded by the teacher.'
c. Taro-ga sensei-ni kodomo-o sikar-are-ta.
Taro-Nom teacher-Dat child-Acc scold-Pass-Past
'Taro got his child scolded by the teacher.'

(45a) is an active sentence, (45b) is a direct passive, and (45c) an indirect passive. Hasegawa's system, which accounts for these passives, is summarized in (46):[26]

(46) a. *-(R)are* is [–N] and may or may not absorb Case.
b. *-(R)are* can be either a two-place predicate, requiring an experiencer subject and a complement VP, or a one-place predicate, without a subject.
c. Direct passives obtain when *-(r)are* is a one-place predicate and absorbs Case.
d. Indirect passives result when *-(r)are* is a two-place predicate and does not absorb Case.

The direct passive, the case of (46c), is basically the same as the passive of English illustrated in (44). The indirect passive, the case of (46d), is described in (47), which illustrates the derivation of (45c):

(47) $[_{TP}$ Taro$_i$-ga $[_{VP1}$ t_i $[_{VP2}$ sensei-ni kodomo-o sikar]-(r)are] ta.]

The experiencer *Taro* is the subject of *-(r)are* and raised to TP-Spec to receive Nominative Case. The object of the complement verb receives Object Case just like the object of the active counterpart. The complement subject, *sensei*, receives *-ni*, which is a sort of default case given to an argument DP that receives neither Nominative nor Objective Case.[27] This accounts for both direct and indirect passives.[28]

Given (46a) and (46b), there must be two other possible cases to be examined besides (46c) and (46d), however: (i) *-(r)are* is a one-place predicate and does not absorb Case, and (ii) *-(r)are* is a two-place predicate and absorbs Case. Case (ii) can be ruled out easily; the object of the complement ends up not receiving any Case; Nominative Case is given to the matrix subject and Object Case absorbed by *-(r)are*. What is relevant to the present discussion is case (i). If *-(r)are* does not absorb the Object Case of the complement verb, a complement object should be able to receive Object Case, as in (47), while the subject of the complement moves

to the Spec of the matrix TP to receive Nominative Case. What this gives rise to is (42b), repeated here as (48). This is in fact the case of SH with *-(r)are*:

(48) a. Sensei-ga kodomo-o sikar-are-ta.
teacher-Nom child-Acc scold-Pass-Past
'The teacher scolded the child.'
b. [$_{TP}$ Sensei$_i$-ga [$_{VP1}$ t_i [$_{VP2}$ t_i kodomo-o sikar]-(r)are] ta.]

Thus, in Hasegawa's system, *Rare*-SH is a kind of passive, which she calls honorific passive, and is derived as a natural consequence of her analysis of passives.

What is not accounted for in Hasegawa's analysis is the agreement between the subject and *-(r)are*. If *-(r)are* in SH is the same as the one in passives, why does only the former require a particular type of subject, namely an SSS subject? Note that the subjects of direct and indirect passives do not have to be SSS. There seem to be two ways to go about this. One is rather ad hoc but assumes that the intransitive *-(r)are* that does not absorb Case is marked SSS, which is essentially the same as saying that *-(r)are* in *Rare*-SH is an honorific verb different from the passive *-(r)are*: there is no explanation of why the same morpho-phonological form of *-(r)are* is used in SH and in passives. The other, which Hasegawa suggests, is to consider the SSS condition on the subject of *Rare*-SH to be a matter of language use and not a matter of formal grammar. That is, the basic function of *-(r)are* as a one-place predicate is to quantify an event so as to conceal or make vague the agentivity of the event; a function similar to modals or predicates like *seem*, *likely*, etc. In the case of the direct passive, the object becomes the subject, and the agenthood of the logical subject is set in the background of the event in question. In the case of the honorific passive (*Rare*-SH), the logical subject remains as a subject, receiving Nominative Case. Pragmatically, however, the subject becomes a target of respect with the presence of *-(r)are*, which has a function of presenting the event as if the referent of the subject was put in the situation where she (involuntarily) ends up acting in a certain way or undergoing certain changes. It is considered in Japanese that presenting an activity or event as a natural occurrence is more polite and respectful to the referent of the subject than doing so as a willful act of the subject, as many traditional Japanese grammarians maintain (cf. Tokieda 1941; Ohno 1966; Hashimoto 1969; Kikuchi 1994). Note that the one-place *-(r)are* that gives rise to *Rare*-SH is a raising predicate just like *nar-u* 'become', which appears in *Naru*-SH. If this view is in fact on the right track, what is common in *Rare*-SH and *Naru*-SH is the presence of a raising predicate but not the process of agreement, which is possible only when an HP is present.

A piece of indirect evidence that supports the view that *-(r)are* does not necessarily require a subject with SSS is seen in another use of *-(r)are*: the one-place *-(r)are* takes place in the so-called *zihatu* 'voluntary, spontaneous, circumstantial' mood, which is considered to be the original use of *-(r)are* among traditional grammarians:[29]

(49) a. (Watasi-ni-wa) sore-ga kuyam-are-ru.
I-to-Top it-Nom regret-Pass-Past
'I regret it./The given circumstances make me regret it.'
b. (Sensei-(ni)-wa) doo omow-are-masu-ka.
teacher-to-Top how think-Pass-Polite-Past
'How do you think, Professor?'

In this construction, the subject of the complement verb is usually marked by *-ni* (rather than *-ga*) and the presence of *-(r)are* indicates, as the gloss suggests, that the subject cannot help but end up feeling or thinking in a certain way or that given circumstances put the referent of the subject in a particular feeling/thinking mood. The predicates that can appear in this construction are confined to feeling/thinking verbs. If such verbs are used with *-(r)are* and take an SSS subject, it is not clear if it is to be taken as an instance of the SH construction or of the voluntary construction. This seems to suggest that the interpretation or function of *-(r)are* is not lexically or grammatically fixed but that its syntactic structure is uniform regardless of how it function is interpreted. Whether a certain occurrence of *-(r)are* functions as passive, SH, or voluntary mood depends on the context. Therefore, it seems reasonable to conclude that no formal process of agreement is involved in *Rare*-SH.[30]

3.5.2 *The* yagar-u *construction*

As opposed to honorifics, there is a construction where an agreement process similar to SH is observed between the subject and the predicate, but the relevant feature is not SSS or honorific but the opposite of it; something like contempt, disgust, or repugnance. Observe (50):[31]

(50) a. {Aitu-ga/ *ano kata-ga/ *ore-ga} kane-o
he(Vul)-Nom that person(Hon)-Nom I(Vul)-Nom money-Acc
nusumi-yagat-ta.
steal-Vul-Past
'{He/That person/I} stole money.'
b. {Aitu-ga/ *ano kata-ga/ *ore-ga} kaeri-yagat-ta.
he(Vul)-Nom that person(Hon)-Nom I(Vul)-Nom leave-Vul-Past
'{He/That person/I} went back home.'
c. {Aitu-ga/ *ano kata-ga/ *ore-ga} kaze-de
he(Vul)-Nom that person(Hon)-Nom I(Vul)-Nom cold-with
taore-yagat-ta.
fall-Vul-Past
'{He/That person/I} came down with a cold.'

In (50), both *aitu* and *ano kata* refer to a third person individual but they differ in vulgar/honorific features: *aitu* with the feature of vulgarity and repugnance vs. *ano kata* with SSS. When the predicate is followed by *yagar-u*, the item with SSS or the first person, even in its vulgar form like *ore*, cannot be a subject.

Pragmatically and sociologically speaking, the use of the predicate *yagar-u* is limited and disfavored, since this expression is considered vulgar, offensive, and ill-mannered. For example, it is extremely rare for a woman to use it and it is never used in formal situations. However much suppressed the use of *yagar-u* may be, its morphological and syntactic conditions are clear and rigid: *yagar-u* attaches to the connective form of a verb and requires the syntactic presence of someone/something toward which the speaker feels disgust or repugnance. Thus, it may appear to be appropriate to capture this process in a way similar to SH, but the relevant feature is not SSS but repugnance (RPG for short).

As for SH, we have observed two types: *Naru*-SH and *Rare*-SH. The former is analyzed in terms of agreement between the subject and the head of a gerundive DP, an HP. As for the latter, as I suggested just above, the requirement on the SSS subject, though it is possible to analyze it in terms of agreement as shown in (43), is not syntactic but pragmatic in nature. Let us see which type *yagar-u* is to be analyzed as. If it is like *Naru*-SH, it involves a syntactic agreement. That is, (50a) can be analyzed in a way like (51), where the relevant feature is RPG, not SSS:

(51) $[_{TP}$ Aitu$_i$-ga $[_{VP1}$ t_i $[_{VP2}$ t_i hon-o nusumi] -yagat] ta]
[RPG] [RPG]

Here, *yagar-u* is analyzed as a raising predicate that takes a VP complement. The complement subject passes through the Spec of *yagar-u* on its way to Spec of TP. If *yagar-u* in fact requires agreement with the subject with RPG process, it can check the feature of the subject when the subject stops at the Spec of *yagar-u*. This analysis is plausible; however, the existence of the following types of sentences suggests that what is at issue is not agreement between the subject and *yagar-u*, but what semantic or pragmatic function *yagar-u* has in relation to its complement VP:

(52) a. Ame-ga furi-dasi-yagat-ta.
rain-Nom fall-start-Vul-Past
'Rain started to fall down (vulgar). (It started to rain.)'
b. Kuruma-ga koware-yagat-ta.
car-Nom break-Vul-Past
'The car broke down (vulgar).'

In (52), the subject is inanimate and the complement predicate is unaccusative. What the speaker expresses with *yagar-u* in these examples is contempt or repugnance not toward the subject but rather toward the entire event expressed by the complement. That is, what (52a) expresses is the speaker's repugnance toward the fact that it started to rain, but not toward the rain itself. The same explanation applies to the examples in (50): what the speaker is disgusted about is not just the subject but the entire event. If so, the syntax of *yagar-u* is more like *Rare*-SH (cf. (47)): there is no syntactic agreement between *yagar-u* and the subject, and what *yagar-u* does is to quantify or modify the event expressed by a complement

VP toward which the speaker feels repugnance. Note in passing that if the event is agentive, the *yagar-u* construction may appear to express the speaker's repugnance toward the subject rather than the entire event, as observed in examples like (50). This is due to the pragmatic fact that the responsibility of the occurrence of an agentive event would most probably fall on an agentive subject, which gives rise to the interpretation that the subject is a target of the speaker's repugnance. That is, though the *yagar-u* construction itself does not require a particular subject, unlike SH, as long as agentive events are concerned, it appears that *yagar-u* agrees with the subject. To conclude, however much *yagar-u*, *Rare*-SH, and SH look similar to each other with respect to the fact they all (often) involve particular types of subjects, only SH involves syntactic agreement between the predicate and the subject; the other two processes, *yagar-u* and *Rare*-SH, merely involve predicates, *yagar-u* and *rare*, that qualify over events expressed by their complement VPs.

3.6 On the optionality of agreement

The above discussion has been developed under the assumption that SH is a syntactic agreement process. Namai (2000), however, argues against considering SH as syntactic agreement, claiming that some characteristics of SH do not go along with what syntactic agreement should exhibit. That is, typical syntactic agreement, such as subject–verb agreement in European languages, takes place in a one-to-one fashion without exception as long as structural conditions are met. SH in Japanese, on the other hand, seems to take place optionally, sometimes involving more than one item and sometimes not being triggered. He provides the following examples:

(53) a. Sensei-ga go-seisiki-ni o-yame-ni nat-ta.
teacher-Nom HP-officially HP-resign-Hon-Past
'The teacher officially resigned.'

b. [A sensei to B sensei]-ga [otagai-ga kyoogisita koto]-o
and -Nom each other-Nom discuss fact-Acc
o-mitome-ni nat-ta.
HP-admit-Hon-Past
'Teacher A and Teacher B admitted that they (each other) discussed.'

c. C sensei-ga wakaku-te o-utukusi-i.
teacher-Nom young-and HP-beautiful-Pres
'Teacher C is young and beautiful.'

d. C sensei-ga o-wakaku-te utukusi-i.

e. C sensei-ga o-wakaku-te o-utukusi-i.

f. Sensei-ga o-zyoobu/*o-yuumei/yuumei da.
teacher-Nom HP-tough/HP-famous/famous Copula
'The teacher is tough/famous.'

g. Sensei-ga o-katai/*o-tadasii/tadasii.
teacher-Nom HP-strict/HP-right/right
'The teacher is strict/right.'

Let us first consider (53b) and (53c–e), which seem to indicate that SH is optional. In (53b), the subject of the complement predicate and that of the matrix predicate refer to the same individual, but only the matrix predicate appears in the form of SH. Similarly in (53c–e), the conjoined predicates, which refer to the same subject, can be in the form of SH, but need not be so. These facts seem peculiar, as Namai argues, if the honorific process is an agreement process triggered by the presence of an SSS subject: how come the same item sometimes triggers honorifics and other times does not? This criticism does not apply to the analysis presented above, however. What triggers is not an SSS item but the presence of D, whose head is HP. Under this view, the process is not optional but mandatory whenever an HP is present. That is, the SH predicate requires the presence of an SSS item that checks off its SSS feature, but not the other way around: an SSS subject does not require the presence of an SH predicate. Hence, (53b) and (53c–e) do not pose any problem.

Similarly, (53f, g) are not problematic to the proposed analysis, either. All there is to be said is that not all adjectives or nominal adjectives take an HP and consequently SH cannot be formed with adjectives that do not allow an HP. If a predicate has no honorific form, no honorification is observed.

The problem that (53a) raises is concerned with the fact that the SSS subject agrees both with the predicate and with the adverb: how can a single subject agree with more than one item? The fact in (53a) is basically the same as the fact in (54), where both the predicate and the object are in the honorific form, referring to the SSS subject:

(54) Sensei-ga gakusei-ni go-hon-o o-kasi-ni nat-ta.
teacher-Nom student-Dat HP-book-Acc HP-lend-Hon-Past
'The teacher lent her/his book to the student.'

As discussed in section 3.4, the honorific form of a noun is a DP whose head is an HP, which is checked by the possessor of the noun. The possessor may be a phonologically null pronominal (pro) which may be controlled by the subject of the sentence. If so, the subject *sensei* in (54), which agrees with the predicate, does not syntactically agree with the object but merely controls the null pronominal that resides at the possessor position of the object. This analysis of (54) can apply to the adverb in (53a). Suppose that the adverb, which is an adverbial form of a nominal adjective, is headed by D, which is an HP. The HP requires a phonologically null item at its Spec, which is controlled by the subject of the sentence.

Thus, all the arguments that Namai presents against considering honorification as syntactic agreement do not apply to the proposed analysis, where honorification is considered not as a process that is triggered by an SSS nominal, but as a process through which the honorific form of a predicate (or rather an HP head of the DP which is a part of the honorific predicate) demands agreement. The proposed analysis can maintain that agreement is one-to-one and mandatory, as long as the predicate in question is of the honorific form. What may need to be

considered is what triggers the presence of the honorific form to begin with. We will speculate on it in section 5.2 below.

4 Non-Subject Honorification (NSH)

As briefly touched upon in section 2, when the speaker wants to express her respect for the referent of a non-subject, the verb appears in the NSH form, which is *HP-V(connective)+su-ru* (or *HP-V(connective)+ita-su*, with the NSH form of *su-ru* in place of *su-ru*). Some examples follow:

(55) a. Hanako-ga sensei-o o-yobi si-ta.
Hanako-Nom teacher-Acc HP-call do-Past
'Hanako called the teacher.'
b. Taro-ga sensei-o o-tasuke si-ta.
Taro-Nom teacher-Acc HP-help do-Past
'Taro helped the teacher.'
c. Hanako-ga sensei-ni go-yotei-o o-kiki si-ta.
Hanako-Nom teacher-Dat HP-schedule-Acc HP-ask do-Past
'Hanako asked the teacher about his/her schedule.'
d. Taro-ga sensei-ni hon-o o-kaesi si-ta.
Taro-Nom teacher-Dat book-Acc HP-return do-Past
'Taro returned the book to the teacher.'

The relevant feature that triggers NSH is the same as SH, namely SSS, and *sensei* 'teacher', which is the object in (55a) and (55b) and the indirect object in (55c) and (55d), is considered to be marked with this feature. The verb form for NSH and the one for SH are quite similar; i.e., both have an HP and the connective form of the verb. Thus, it may appear that the only difference between SH and NSH is what triggers this particular verb form: the subject for SH and the object for NSH. However, there are some crucial differences between the two honorifics.

4.1 Characteristics of NSH

Let us examine the characteristics of NSH in relation to SH. The first and obvious difference between NSH and SH has to do with predicate forms: the honorific form of the predicate, the sequence of an HP and the connective form of the verb, is followed by *su-ru* 'do' in the case of NSH, whereas it is followed by *-ni nar-u* 'become' in SH. We will discuss the function of *su-ru*, in contrast to *nar-u*, in section 4.2.1.

Second, as noted by Harada (1976), the occurrence of NSH is conditioned not only by the presence of SSS but also by predicate types. That is, NSH is allowed only when the predicate is agentive (i.e., when the subject serves as an agent role). Compare SH and NSH below:

(56) a. Sato-sensei-ga/ni gakusei-ga o-wakari-ni nar-u.
Stato-teacher-Nom/Dat student-Nom HP-understand-Hon-Pres
'Prof. Sato understands the students.'
b. *Gakusei-ga/ni Sato-seisei-ga o-wakari su-ru.
student-Nom/Dat Sato-teacher-Nom HP-understand do-Pres
'The students understand Prof. Sato.'

(56) has the predicate *wakar-u* 'understand', whose subject is not an agent (probably an experiencer). The grammaticality of (54a) shows that the non-agentive subject *Sato-sensei* triggers SH, while the same referent when used as an object cannot make a well-formed NSH. Recall that adjectives do not have NSH forms but SH forms (cf. the contrast between SH in (57a)/(58a) and NSH in (57b)/(58b)), and this is due to this condition. Adjectives are not agentive predicates:

(57) a. Sato-sensei-{ga/ni} obake-ga o-kowa-i
o-kowakute irassyar-u.
Sato-teacher-Nom/Dat ghost-Nom HP-afraid-Hon-Pres
'Prof. Sato is afraid of ghosts.'
b. *Gakusei-{ga/ni} Sato-sensei-ga o-kowa-i
student-Nom/Dat Sato-teacher-Nom HP-afraid-Pres
'Students are afraid of Prof. Sato.'

(58) a. Sato-sensei-ga gakuseitati-ga o-suki da.
o-suki de-irassyar-u.
Sato-teacher-Nom students-Nom HP-like-Copula-Hon-Pres
'Prof. Sato is fond of the students.'
b. *Gakuseitati-ga Sato-sensei-ga o-suki da.
student-Nom Sato-teacher-Nom HP-like-Pres
'Students are fond of Prof. Sato.'

Third, the trigger of NSH is not limited to an (indirect) object. As seen in (59), the possessor of the (indirect) object gives rise to NSH. Note that the possessor of the subject cannot trigger SH. Compare (59) and (60):[32]

(59) a. Kyoko-ga sensei-no-(o)-kaban-o o-moti-si-ta.
Kyoko-Nom teacher-Gen-HP-bag-Acc HP-hold-do-Past
'Kyoko held the teacher's bag (for her/him).'
b. Taro-ga sensei-no-(o)-kata-o o-momi-si-ta.
Taro-Nom teacher-Gen-HP-shoulder-Acc HP-massage-do-Past
'Taro massaged the teacher's shoulders (for her/him).'
c. Hanako-ga sensei-no-o-taku-ni hana-o o-todoke-si-ta.
Hanako-Nom teacher-Gen-HP-house-to flower-Acc HP-deliver-do-Past
'Hanako delivered flowers to the teacher's house.'

(60) a. *Sensei-no-(o)-kaban-ga o-koware-ni nat-ta.
teacher-Gen-HP-bag-Nom HP-break-Hon-Past
'The teacher's bag got broken.'
b. *Sensei-no-(o)-kata-ga o-kori-ni nat-ta.
teacher-Gen-HP-shoulder-Nom HP-stiff-Hon-Past
'The teacher's shoulders got stiff.'
c. *Sensei-no-o-taku-ga o-yake-ni nat-ta.
teacher-Gen-HP-house-Nom HP-burn-Hon-Past
'The teacher's house got burnt down.'

The mere presence of the SSS possessor of the (indirect) object is not enough for NSH to take place, however. As will be seen in section 4.3, there must be some beneficial effects observable on the side of the SSS referent. Compare (59), which is grammatical, with ungrammatical (61):

(61) a. ?*Kyoko-ga sensei-no-(o)-kuruma-o o-tukai-si-ta.
Kyoko-Nom teacher-Gen-HP-car-Acc HP-use-do-Past
'Kyoko used the teacher's car (for her/him).'
b. ?*Gakusei-ga sensei-no-(go)-hon-o o-yomi-si-ta.
student-Nom teacher-Gen-HP-book-Acc HP-read-do-Past
'The students read the teacher's book (for her/him).'

To carry a bag is an act favorable to the possessor of the bag, but to use her car or read her book may not necessarily be a beneficial act for its owner (or designer/author). Thus, the key to the well-formedness of NSH is, as Matsumoto (1997) extensively discusses, benefactivity on (or 'benefit transfer' to, in her terms) the referent to whom the speaker's respect is due, which results from the described event. The same point can be made by the following examples, where NSH is observed but no obvious SSS item seems present:

(62) a. Kyoko-ga syasin-o o-tori-si-ta.
Kyoko-Nom photo-Acc HP-take-do-Past
'Kyoko took a picture (for SSS).'
b. Hanako-ga biiru-o o-nomi-si-ta.
student-Nom beer-Acc HP-drink-do-Past
'Hanako drank beer (for SSS).'

The acceptability of (62) depends on whether the activity expressed by the NSH form is beneficial to an SSS, which is implicit in the given context. That is, (62a) is acceptable, if Taro took the SSS's portrait or if Taro's act of taking a picture is of benefit to the SSS. Similarly, (62b) is appropriate, if the beer Hanako drank is the SSS's beer and her drinking it is considered to be of benefit to the SSS.[33] If we assume that the NSH form indicates that there should be an agreement process, we expect there to be an item with SSS syntactically present somewhere in a

structure, as a null possessor of the (indirect) object or a null beneficiary argument. In what follows, we will defend such an analysis.

A piece of evidence that suggests that NSH is sensitive to syntactic structure is seen in a fact that Harada (1976) points out. Observe (63), modified from Harada's example (67). *Syookai-su-ru* 'introduce' is a three-place predicate and requires both an object and an indirect object, both of which are possible candidates for a trigger of NSH. If NSH simply requires the pragmatic presence of an SSS, we may expect there to be ambiguity in (63). This prediction is not borne out, however:

(63) a. Hanako-ga Yamada-san-ni Sato-san-o go-syookai-si-ta.
Hanako-Nom Yamada-Dat Sato-Acc HP-introduce-do-past
'Hanako introduced Sato to Yamada.'
b. *Taro-ga otooto-ni Yamada-sensei-o go-syookai-si-ta.
Taro-Nom brother-Dat Yamada-teacher-Acc HP-introduce-do-past
'Taro introduced Prof. Yamada to his younger brother.'
c. Taro-ga Yamada-sensei-ni otooto-o go-syookai-si-ta.
Taro-Nom Yamada-teacher-Dat brother-Acc HP-introduce-do-past
'Taro introduced his younger brother to Prof. Yamada.'

In (63a), the speaker has respect for *Yamada*, the indirect object, not for *Sato*, the direct object. This difference is more clearly seen in the contrast between (63b) and (63c): the speaker's close relative is not subject to the speaker's respect and cannot be an indirect object when the predicate is of the NSH form. The fact in (63) suggests that there should be a structural condition on the choice of a relevant SSS, to which we will turn in section 4.2.

The following summarizes the characteristics of NSH observed in the above:

(64) a. NSH is triggered by an item with SSS.
b. The NSH involves *su-ru* 'do', not *ni-nar-u* 'become', which is used for SH.
c. The NSH is possible only with a predicate that has an agentive subject.
d. A trigger of NSH is either a direct object, an indirect object, a possessor of an (indirect) object, or an implied beneficiary.
e. NSH is possible only when the event expressed by the NSH predicate favorably affects its trigger; i.e., the trigger must be the beneficiary of the event.
f. When both a direct object and an indirect object are SSS, no ambiguity is observed, but an indirect object wins out and is considered to be the beneficiary.

4.2 An analysis of NSH

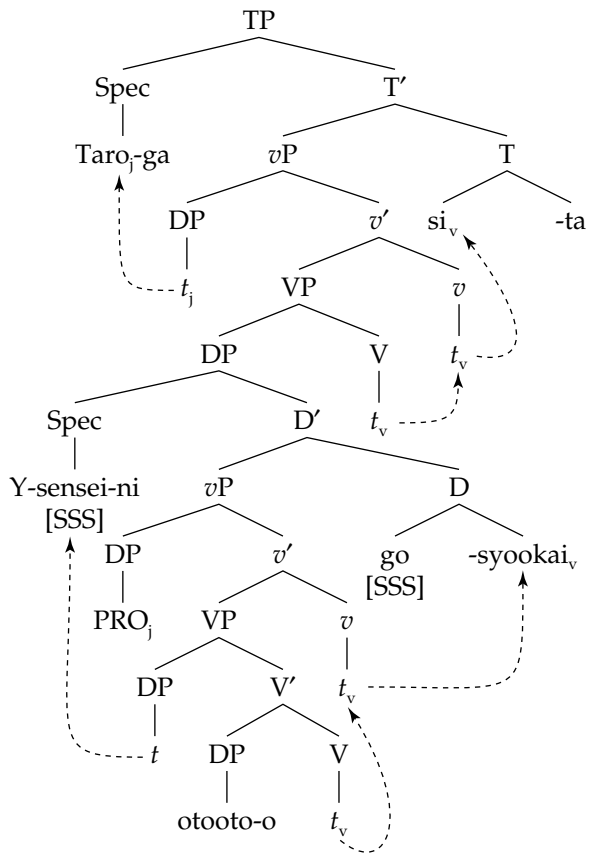
Given (64), in particular the fact that NSH is sensitive to SSS and involves an HP, which SH also exhibits, it seems plausible to consider NSH as some kind of agreement process just like SH, *HP-V-ni nar-u*. Harada's (1976) analysis is along this line and is presented in (65):[34]

(65) **Harada's Object Honorific marking:**
Mark the predicate as [Object Honorific] when an SSS is included in (a) the indirect object, if the predicate is ditransitive, or (b) the direct object, if the predicate is transitive. (Harada 1976: 530)

In Harada's system, since there was no principled way to express (64f) in the given framework (i.e., Standard Theory), the rule (or agreement process) is disjunctively stated. In a more recent framework, Toribio (1990) attempts to account for (64f) in terms of a condition on the distance of movements, assuming that an indirect object resides structurally higher than a direct object.

Toribio's analysis for NSH is essentially the same as her analysis for SH, except that the higher predicate that takes an NSH predicate is a control verb, namely *su-ru* 'do', not a raising verb *nar-u* 'become', which SH makes use of. That is, the honorific part (i.e., *HP-V(connective)*) is a DP and D attracts an item with SSS. When both an object and an indirect object exist, as in ditransitives, the higher one, the indirect object, moves to the Spec of D. According to this analysis, sentence (63c) is derived in a way shown in (66). Compare this with the derivation of SH, namely (35):[35]

(66)



Toribio's analysis, presented here, seems to work; however, some discussion is called for concerning the predicate *su-ru*, the categorical status of the honorific part of the predicate (i.e., *HP-V(connective)*), and a possessor of an (in)direct object.

4.2.1 Su-ru *in NSH*

As stated in (64b), NSH involves *su-ru* 'do', not *nar-u* 'become', which SH employs, but the honorific part (i.e., *HP-V(connective)*) is the same for both SH and NSH. It is thus natural to consider that the difference between *su-ru* and *nar-u* is responsible for the functional difference between SH and NSH. *Su-ru* and *nar-u* are not used exclusively for honorifics but have their independent uses; they function as main verbs. Typical uses of *su-ru* and *nar-u* as main verbs are exemplified in (67) and (68), respectively:

(67) a. Taro-ga tenisu-o. su-ru.
Taro-Nom tennis-Acc do-Pres
'Taro plays tennis.'
b. Gakusei-ga syukudai-o su-ru.
student-Nom homework-Acc do-Past
'The students did their homework.'

(68) a. Ha-ga akaku nat-ta.
leaf-Nom red become-Past
'The leaves turned red.'
b. Hanako-ga isya-ni nar-u.
Hanako-Nom doctor-Cop become-Pres
'Hanako will become a doctor.'

Su-ru and *nar-u* as independent predicates can be analyzed in a way similar to 'do' and 'become' in English, respectively. That is, *su-ru* is transitive and requires an agentive subject, while *nar-u* is a raising predicate. This difference between *su-ru* and *nar-u* as an independent predicate is reflected in the honorific structures, as seen in (35) for SH and (66) for NSH: for SH, which uses *nar-u*, the raising structure is posited and for NSH, which uses *su-ru*, the control structure is assumed and the subject is agentive.

The functional difference between SH and NSH is due to this structural difference between *su-ru* and *nar-u*. That is, SH expresses the speaker's respect toward the subject of the predicate, and it does not matter whether the subject initiates an action or simply undergoes changes. No condition is placed on the subject, which is characteristic of the raising predicate *nar-u*.

NSH, on the other hand, involves *su-ru* 'do'. Though we have been calling NSH 'honorific', the function of NSH is not really to indicate respect for the referent of the SSS item, but rather to present the subject (the one who affects the SSS) and her action in a humble way. As mentioned in note 3, section 2, NSH is called the 'humble form' in traditional Japanese grammar. That is, by presenting the subject in a humble way, it relatively elevates someone who is affected by the

subject's action. Thus, the subject in NSH is considered to be responsible for the occurrence of the event, which explains why NSH is possible only with activity predicates. In terms of structure, the subject of *su-ru* in NSH is an agent, initiator, or controller of the event expressed by the NSH predicate.

The characterization of *su-ru* in contrast to *nar-u* mentioned above suggests that *su-ru* in NSH is essentially the same as the transitive *su-ru* exemplified in (67). However, there is one crucial difference between *su-ru* in NSH and the main verb *su-ru* in (67). As is clear from the above examples, *su-ru* in (67) takes a DP marked by Accusative *o*, whereas what precedes *su-ru* in NSH does not take any Case marker. If a DP must be Case marked, the fact that the honorific predicate is not followed by a Case marker requires some explanation.

In section 3.3, referring to Suzuki (1989), we have seen that the honorific part of the predicate, HP-V(connective), is a DP. The evidence for its DP (or nominal) status includes (69):

(69) a. It is prefixed by an HP, which is a D head.
b. It is followed by *-ni*, which may be a Case marker (or postposition) or the connective form of the copula, *da* (cf. (27)).
c. It can be followed by the copula, *da/des-u* (cf. (28–30)).
d. It cannot end the first conjunct in the conjoined structure (cf. (31–33)).

In short, it is only nominals ([+N] categories) that can be preceded by an HP and followed by a Case marker (postposition) or a copula. And nominals cannot end the first conjunct.

If the honorific part of NSH is also nominal, it is expected to behave in a similar way. However, as is clear from the above examples, the honorific part of NSH never appears before *-ni* (or any case marker or a copula); hence, (69b) and (69c) do not apply to NSH. Let us see if criterion (69d) is relevant. Observe (70):

(70) a. Hanako-ga Sato-san-o miokuri, Taro-ga Kida-san-o demukae-ta.
Hanako-Nom Sato-Acc see-off Taro-Nom Kida-Acc meet-Past
'Hanako saw Sato off and Taro went to meet Kida.'
b. Hanako-ga Sato-sensei-o o-miokuri-si, Taro-ga
Hanako-Nom Sato-teacher-Acc HP-see-off-do Taro-Nom
Kida-sensei-o o-demukae-si-ta.
Kida-teacher-Acc HP-meet-do-Past
'Hanako saw Prof. Sato off and Taro went to meet Prof. Kida.'
c. *Hanako-ga Sato-sensei-o o-miokuri, Taro-ga Kida-sensei-o
Hanako-Nom Sato-teacher-Acc HP-see-off Taro-Nom Kida-teacher-Acc
o-demukae-si-ta.
HP-meet-do-Past
'Hanako saw Prof. Sato off and Taro went to meet Prof. Kida.'

(70a), which is a simple conjoined sentence with the plain verb form, does not involve NSH, and the first conjunct ends with the connective form of the predicate.

When the NSH form is used, as shown in (70b) and (70c), the honorific form alone cannot end the first conjunct, even though it is in the connective form. The presence of *si-* (the connective form of *su-ru*) is needed to end the first conjunct. Thus, if (69d) is a characteristic of [+N] categories, the honorific part of NSH is most probably [+N].

In view of the behavior of *su-ru*, however, the nominal status of the honorific part of NSH is not quite obvious. As mentioned above and also in section 2, *su-ru* can be used not only as a main verb, as exemplified in (67), but also as a light verb, which often appears with an SJ nominal (cf. (11)). Observe the following examples, (71) with the main verb *su-ru* and (72) with the light verb *su-ru*:

(71) a. Hanako-ga {syukudai-o su-ru./ ?*syukudai su-ru.}
Hanako-Nom homework-Acc do-Pres homework-do-Pres
'Hanako will do her homework.'
b. Kyoko-ga {eigo-no benkyoo-o su-ru./ *eigo-no benkyoo su-ru.}
Kyoko-Nom English-Gen-study-Acc do-Pres English-Gen-study do-Pres
'Kyoko studies English.'

(72) a. Syorui-ga {hunsitu si-ta/ *hunsitu-o si-ta.}
document-Nom disappear-do-Past disappearance-Acc do-Past
'The document got lost.'
b. Kyoko-ga {eigo-o benkyoo su-ru./ *eigo-o benkyoo-o
Kyoko-Nom English-Nom study-do-Pres English-Acc study
su-ru.}
do-Pres
'Kyoko studies English.'

The main verb *su-ru* is a transitive predicate, taking an agentive subject and a theme object that is marked by Object Case *o*. The light verb *su-ru*, on the other hand, takes place with an expression that represents an action or change of state (e.g., an SJ nominal), which is crucially not marked by the Object Case *o*; i.e., the light verb *su-ru* itself does not have a Case-assigning property, unlike the main verb *su-ru*.

Taking into consideration these facts about the two types of *su-ru*, *su-ru* in honorifics seems to behave ambiguously between the main verb *su-ru* and the light verb *su-ru*. It is like the main verb *su-ru* in that it requires an agentive subject, but it is like the light verb *su-ru* in that the NSH form of the predicate that precedes *su-ru* is not (Accusative) Case-marked. As for the behavior in the conjoined structure, NSH is similar to the case of the light verb *su-ru* construction, to the extent that the connective form of *su-ru* is required in the first conjunct, as observed in the grammatical contrast between (73) and (74):

(73) a. Kyoko-ga eigo-no benkyoo-o si,
Kyoko-Nom English-Gen-study-Acc do
Taro-ga kankokugo-no kenkyuu-o su-ru.
Taro-Nom Korean-Gen-research-Acc do-Pres
'Kyoko studies English and Taro researches Korean.'

b. Kyoko-ga eigo-no benkyoo-o, Taro-ga
Kyoko-Nom English-Gen-study-Acc Taro-Nom
kankokugo-no kenkyuu-o su-ru.
Korean-Gen-research-Acc do-Pres
'(the same as (73a))'

(74) a. Kyoko-ga eigo-o benkyoo-si, Taro-ga kankokugo-o
Kyoko-Nom English-Acc study-do Taro-Nom Korean-Acc
kenkyuu su-ru.
research-do-Pres
'(the same as (73a))'
b. *Kyoko-ga eigo-o benkyoo, Taro-ga kankokugo-o
Kyoko-Nom English-Acc study Taro-Nom Korean-Acc
kenkyuu su-ru.
research-do-Pres
'(the same as (73a))'

It is clear that the Accusative Case-marked item with the main verb *su-ru* is a DP, but the categorical status of what precedes the light verb *su-ru* remains controversial. It is analyzed as verbal in Hasegawa (1991), as nominal in Terada (1990), and as category-neutral (verbal noun) in Kageyama (1993) (cf. also Grimshaw and Mester 1988). The exact analysis of the honorific part (*HP-V(connective)*) of NSH seems to depend on how *su-ru* is analyzed or whether *su-ru* in NSH is a main verb or a light verb, or of yet a different kind. It is beyond the scope of this chapter to discuss *su-ru* further, however. See also Miyamoto (1997) and Takahashi (2000).

In short, the honorific part of NSH behaves differently from that of SH, which is clearly nominal. It does not positively exhibit the nominal characteristics listed in (69), but there is not enough evidence that indicates otherwise, either.

4.2.2 Possessor ascension

Toribio does not discuss the case of NSH triggered by a possessor of an (in)direct object and it is not clear from her analysis, which is illustrated in (66), how such a case is accounted for. If NSH is in fact an agreement process, the possessor must somehow be detached from the (in)direct object DP and raised to the Spec of DP whose head is an HP. That is, there must be a process of possessor ascension involved in the NSH of this type.

Possessor ascension, as a matter of fact, is widely observed in Japanese. See the following examples:

(75) a. Sengetu *Hanako-no* musuko-ga kekkon-si-ta.
last month Hanako-Gen son-Nom marry-do-past
'Hanako's son got married last month.'
b. **Hanako-no* Sengetu musuko-ga kekkon-si-ta.
Hanako-Gen last month son-Nom marry-do-past
c. *Hanako-ga* (Sengetu) musuko-ga kekkon-si-ta.
Hanako-Nom last month son-Nom marry-do-past
'(the same as (75a))'

(76) a. Taro-ga nakanaka *tyuugokugo-no* tango-ga oboer-are-na-i.
Taro-Nom easily Chinese-Gen word-Nom memorize-can-not-Pres
'Taro cannot memorize Chinese words easily.'
b. *Taro-ga *tyuugokugo-no* nakanaka tango-ga oboer-are-na-i.
Taro-Nom Chinese-Gen easily word-Nom memorize-can-not-Pres
c. Taro-ga *tyuugokugo-ga* (nakanaka) tango-ga oboer-are-na-i.
Taro-Nom Chinese-Nom easily word-Nom memorize-can-not-Pres
'(the same as (76a))'

The possessor of the subject in (75a) and that of the object in (76a) can be detached from the head noun and receive *-ga*, as in the (c) examples above. Note that the head noun and its possessor cannot be separated by a sentential adverb, such as *sengetu* 'last month' or *nakanaka* 'easily', if the possessor is marked Genitive *no*, which indicates that the possessor and the head noun form a constituent, while they can be separated if the possessor is marked Nominative *ga*. This fact can be described in terms of possessor ascension; namely, when a possessor overtly moves out of a DP, it receives a sentential structural Case, Nominative *ga*.[36]

If we assume that possessor ascension takes place not only overtly but also covertly, the NSH triggered by the possessor of an (in)direct object can be accounted for: the possessor (or its SSS feature) is raised to the Spec of the DP whose head is an HP. A possible problem with this analysis is that SH would never be triggered by the possessor of a subject, as the following sentences show (see also (60)):

(77) a. *Sensei-no* o-kuruma-ga koware-ta.
teacher-Gen HP-car-Nom break-down-past
'The teacher's car broke down.'
b. *Sensei-ga* o-kuruma-ga koware-ta.
teacher-Nom HP-car-Nom break-down-past
'It is the teacher whose car broke down.'
c. **Sensei-no* o-kuruma-ga o-koware-ni nat-ta.
teacher-Gen HP-car-Nom HP-break-down-Hon-past
d. **Sensei-ga* o-kuruma-ga o-koware-ni nat-ta.
teacher-Nom HP-car-Nom HP-break-down-Hon-past

Regardless of whether possessor ascension occurs overtly or covertly, *sensei*, the possessor of the car, cannot trigger SH. This remains a problem as long as SH and NSH are considered essentially the same agreement process. We have to leave this problem open.

4.3 An NSH-like process: the benefactive predicate age-ru

In the above, we have observed that NSH is possible only when the referent of the SSS, (the possessor of) the (in)direct object, is affected in a favorable way, or is to be taken as the beneficiary of the event. If non-favorable effects are expected

on the possessor of the (in)direct object, NSH is not allowed. Relevant examples are given below:

(78) a. Gakusei-ga Yamada-sensei-o uttae-ta.
student-Nom Yamada-teacher-Acc sue-Past
'The student sued Prof. Yamada.'
b. *Gakusei-ga Yamada-sensei-o o-uttae-si-ta.
student-Nom Yamada-teacher-Acc HP-sue-do-Past

(79) a. Gakusei-ga Tanaka-sensei-o party-ni sasot-ta.
student-Nom Tanaka-teacher-Acc party-to invite-Past
'The students invited Prof. Tanaka to the party.'
b. Gakusei-ga Tanaka-sensei-o party-ni o-sasoi-si-ta.
student-Nom Tanaka-teacher-Acc party-to HP-invite-do-Past

(80) a. Kyoko-ga sensei-no kuruma-o nusun-da.
Kyoko-Nom teacher-Gen-car-Acc steal-Past
'Kyoko stole the teacher's car.'
b. *Kyoko-ga sensei-no (o)-kuruma-o o-nusumi-si-ta.
Kyoko-Nom teacher-Gen-HP-car-Acc HP-sue-do-Past

(81) a. Kyoko-ga sensei-no kaban-o mot-ta.
Kyoko-Nom teacher-Gen-bag-Acc hold-Past
'Kyoko held the teacher's bag.'
b. Kyoko-ga sensei-no (o)-kaban-o o-moti-si-ta.
Kyoko-Nom teacher-Gen-HP-bag-Acc HP-hold-do-Past

In (78–79), the SSS is the object, but NSH in (78) is inappropriate. Similarly in (80–81), the possessor of the object is SSS, but of the two (b) examples here, only (81b) is allowed. The difference in grammaticality (or acceptability) seems to relate to how favorable the action is to the SSS object. 'Suing' or 'stealing' is not beneficial to the one who is sued or whose property is stolen, and NSH is not appropriate in such situations. This fact suggests that the structural presence of an SSS is not enough to trigger NSH. One way to deal with this problem is leave it to the realm of how NSH is used, maintaining that syntax allows NSH to be triggered freely in non-beneficial situations such as (78) and (80) but the pragmatic condition regarding beneficial transfer rules them out. This may well be a correct way to consider the above contrast, and in fact Matsumoto (1997) advocates such a direction.

In the following, however, I would like to explore a more syntactically oriented possibility. Let me first point out that there is a construction in Japanese which behaves similarly to NSH; i.e., both express beneficial effects on the (in)direct object (or someone in the context). Observe (82):

(82) a. Hanako-ga Taro-o tasukete age-ta.
Hanako-Nom Taro-Acc help-give-past
'Hanako helped Taro.'

b. Hanako-ga Taro-ni syasin-o misete age-ta.
Hanako-Nom Taro-Dat photo-Acc show-give-past
'Hanako showed Taro the photo.'
c. Hanako-ga Taro-no-kaban-o motte age-ta.
Hanako-Nom Taro-Gen-bag-Acc hold-give-past
'Hanako held Taro's bag (for him).'

The sentences in (82) do not involve NSH, but the presence of the predicate *age-ru* in addition to the main predicate indicates that the action is done in favor of the object in (82a), the indirect object in (82b), and the possessor of the object in (82c), characteristics shared by NSH.[37,38] When beneficial effects are not expected on these constituents, the use of *age-ru* is inappropriate, just like the case of NSH observed in (78b) and (80b):[39]

(83) a. *Hanako-ga Taro-o uttaete age-ta.
Hanako-Nom Taro-Acc sue give-Past
'Hanako sued Taro (for him).'
b. *Hanako-ga Taro-no kuruma-o nusunde age-ta.
Hanako-Nom Taro-Gen-car-Acc steal-give-past
'Hanako stole Taro's car (for him).'

The similarity of NSH and the *age-ru* construction is striking, and it seems desirable that this similarity should be captured. So let us assume that the two constructions involve the same structure. That is, NSH always involves *age-ru* or its null counterpart. Let us suppose that *age-ru* (or its null counterpart) is a predicate that takes a VP complement and obligatorily assigns a beneficiary role to the item that moves into its Spec. The predicate of the VP may be of the NSH *o-V-su* form, which gives rise to the NSH construction, or of the basic form, which renders sentences like (82). This approach predicts that the NSH and *age-ru* should be able to co-occur, and this prediction is borne out, as seen in (84), where *age-ru* in its suppletive NSH form, *sasiage-ru*, takes its place with the NSH complement:[40]

(84) a. Gakusei-ga sensei-o o-tasuke si(te sasiage)-ta.
student-Nom teacher-Acc HP-help-do-give-Past
'The student helped the teacher.'
b. Hanako-ga sensei-ni syasin-o o-mise si(te sasiage)-ta.
Hanako-Nom teacher-Dat photo-Acc HP-show-do-give-past
'Hanako showed the photo to the teacher.'
c. Hanako-ga sensei-no-(o)-kaban-o o-moti-si(te sasiage)-ta.
Hanako-Nom teacher-Gen-HP-bag-Acc HP-hold-do-give-past
'Hanako held the teacher's bag.'

Irrespective of whether *sasiage-ru* is present, the meaning and function of the sentences remain basically the same. This state of affairs can be explained along the lines suggested above. Suppose that the benefactive predicate *age-ru* has two

NSH forms, *sasiage-ru* and its phonologically null counterpart, and the NSH *o-V-su* form always requires the presence of the NSH benefactive predicate (or to put it the other way around, the complement VP of the NSH benefactive predicate, *sasiage-ru* or its null counterpart, must be of the NSH *o-V-su* form). Then, regardless of whether *sasiage-ru* is present, the two versions of (84) are considered to be equally NSH examples, and (84) without *sasiage-ru* (an instance of ordinary NSH) in fact involves the null counterpart of *sasiage-ru* in the structure. What is crucial here is that the two forms of NSH in (84), either with *sasiage-ru* or without it, both involve the same syntactic structure.[41] Then the requirement of beneficial effects on the SSS, which may be an (in)direct object, its possessor, or someone identifiable in the context, can be subsumed under the requirement on the item checked by the benefactive predicate, *age-ru*, *sasiage-ru*, or the phonologically null counterpart of *sasiage-ru*. The benefactive predicate, irrespective of its form, requires a beneficiary item in its Spec. The beneficiary item may be raised from inside the complement VP or may be directly generated at its Spec independently of the VP. When it is raised from inside the complement VP, we obtain sentences where a syntactic argument (or its possessor) appears as a beneficiary. If it is directly generated (or merged) at the Spec of the benefactive predicate, the beneficiary is interpreted as being someone in the context. Since the beneficiary itself can be phonetically null in Japanese, just as any argument identifiable in discourse may (cf. note 38), we obtain NSH (and the *age-ru* construction) where no obvious beneficiary item is present. In this way, we can maintain that NSH always involves an SSS item that is syntactically present.[42]

5 Related issues

5.1 Honorifics and pro-drop

The descriptions and analyses of honorific phenomena presented above are basically along the lines of Harada's (1976) proposal. In particular, it is his insight that SH and NSH are viewed as agreement processes, and we have so far been concerned mainly with how agreement processes are accounted for, mainly referring to Toribio (1990) and Suzuki (1989). There is another interesting phenomenon that seems to have to do with the agreement of SH and NSH, namely, pro-drop.

In the linguistic literature, the phenomena of pro-drop or null arguments have been captured in two ways: licensed (i) by agreement (Chomsky 1981; Rizzi 1982a) or (ii) by (null) topic (Huang 1984; Hasegawa 1984).[43] Japanese has been considered as the latter type, and Huang and Hasegawa analyze null arguments (*e*) in (85) as variables bound by null topics:

(85) a. Taro-ga *e* tasuke-ta.
Taro-Nom help-Past
'Taro helped (her/him).'

b. *e* Hanako-o tasuke-ta
Hanako-Acc help-Past
'(She/He) helped Hanako.'

These sentences are acceptable only when the null arguments (the object in (85a) and the subject in (85b)) refer to the items registered (as topics) in a given discourse, as pointed out by Kuno (1973c). Due to the variable status of null arguments, an object of a complement sentence cannot be null if it refers to the matrix subject:[44]

(86) Hanako$_i$-ga [watasitati-ga $e_{*i/j}$ tasuke-ru] to omot-ta.
Hanako-Nom we-Nom help-Pres Comp think-Past
'Hanako$_i$ thought that we will help *her$_i$/him$_{j'}$.'

In (86), if the *ec* is in fact a variable, it cannot be locally A-bound by *Hanako*, the matrix subject, due to Condition C of Binding Theory. Once honorifics are involved, however, a null object that refers to the matrix subject is allowed:

(87) Sensei$_i$-ga [watasitati-ga $e_{i/j}$ o-tasuke-su-ru] to o-omoi ni nat-ta.
teacher-Nom we-Nom help-Pres Comp HP-think-Hon-Past
'The teacher$_i$ thought that we will help her$_i$/him$_{j'}$.'

The contrast here seems to suggest that the *e* that is not agreement-related is a variable and needs to be topic-bound, but the one that is agreement-related can be a pronominal and can refer to a matrix constituent, as any pronominal can.

Note in passing that the benefactive predicate can also license a null object in a complement sentence, as is shown in (88):[45]

(88) Hanako$_i$-ga [Taro-ga $e_{i/j}$ tasukete-kure-ru] to omot-ta.
Hanako-Nom Taro-Nom help-give-Pres Comp think-Past
'Hanako$_i$ thought that Taro will help her$_i$/him$_j$.'

If the benefactive predicates *age-ru* and *kure-ru* involve syntactic agreement, as was suggested above, the grammaticality of (88) can naturally be accounted for along with the grammaticality of (87).[46]

5.2 Honorific concordance

With reference to sentences (53b) and (53c–e), we saw that what is responsible for honorific processes is not the presence of an item with SSS but rather the presence of the honorific form of a predicate. Because of this, it appears that honorific marking on predicates is optional and an SSS subject or object does not always give rise to honorific forms. Thus, as discussed in section 3.6, what matters is whether an SSS item is present when the predicate is of the honorific form, and not whether predicates are in the honorific form when an SSS item is present.

This does not mean that the use of honorific forms is completely arbitrary, however. Observe the following data:

(89) a. Sensei-ga *?aitu-o/ano kata-o o-home-ni nat-ta.
teacher-Nom the guy(Vul)-Acc/that person-Acc HP-drink-Hon-Past
'The teacher praised that guy/that person.'
b. Taro-ga *go-hon-o/hon-o nakusi-yagat-ta.
-Nom HP-book-Acc/book-Acc loose-Vul-Past
'Taro lost the book.'

What (89a) shows is that if the predicate is of the honorific form, other items in the sentence cannot be of the vulgar form. The opposite is also true, as (89b) shows: when the predicate is of the vulgar form, the honorific or polite form for the object noun is inappropriate. Thus, there seems to be some kind of honorific or politeness concordance among items in a sentence. This does not mean that concordance should always be strictly observed, however:

(90) a. Sensei-wa go-zibun-o seme-ta.
teacher-Top HP-self-Acc blame-Past
'The teacher blamed herself.'
b. Sensei-wa zibun-o o-seme-ni nat-ta.
c. Sensei-wa go-zibun-o o-seme-ni nat-ta.

(91) a. Sensei-wa go-zibun-de o-kuruma-o araw-u.
teacher-Top HP-self-Acc HP-car-Acc wash-Pres
'The teacher washes her car by herself.'
b. Sensei-wa zibun-de kuruma-o o-arai-ni-nar-u.
c. Sensei-wa go-zibun-de o-kuruma-o o-arai-ni-nar-u.

These sentences are honorifics, and they all express the speaker's respect for the subject *sensei*. Only in the (c) examples is the concordance observed, however. In the (a) examples, the predicates are of the plain form but the object and the adverb are of the honorific form. In the (b) examples, only the predicate is of the honorific form and other items are of the plain form. The situation here is basically the same as in (53b) and (53c–e) in section 3.6, where only one predicate is in the honorific form while the other is of the plain form, even though both predicates refer to the same SSS subject.

This fact may be considered in the following way. Suppose that the speaker's intention to indicate her respect for an SSS subject or object is a kind of operator over a sentence, and this operator requires at least one item in the sentence to be in the honorific form. If the sentence contains more than one item that is of the honorific form, the operator unselectively binds it, which in effects explains the partial concordance observed in the above. The ungrammatical cases in (89) are due to the conflict between the two such operators: the honorific operator and the vulgar operator cannot take place at the same time.[47]

6 Conclusion

It was Harada (1976) who first extensively discussed the phenomena of honorifics in Japanese in generative grammar, considering SH and NSH to be agreement processes that involve the feature [SSS], socially superior to the speaker. Following this basic insight of his and referring to my more recent predecessors along the same lines (Suzuki 1989; Toribio 1990; Ura 1999), I have worked out in more detail how 'agreement' happens within the framework of checking theory. It is shown that the morphosyntactic characteristics of SH and NSH play an important role in accounting for exactly how agreement takes place. In particular, I have shown that the presence of an HP and the connective form of a predicate, which is characteristic of SH and NSH, is not just a mere indication of honorifics but is the key to the agreement between the honorific predicate and the SSS item, a subject for SH and a beneficiary non-subject for NSH.

This chapter started out with a rather detailed description of the morphology of Japanese honorifics. Such details have often been glossed over in syntactic studies on this phenomenon that pay attention mainly to the syntactic relation between the items relevant to this process, disregarding exactly what shape the honorific predicate exhibits. However, I have shown in later sections that the morphological details of the honorific predicate – such as the presence of an HP, the connective form of the predicate, the presence or absence of *ni*, and the existence of the predicate *nar-u* for SH and *su-ru* for NSH – are all crucial for a better understanding of how honorifics work in this language. For example, the existence of an HP is responsible for the 'definite' interpretation of the event expressed in SH and NSH, which incidentally explains why a noun with an HP is taken to be 'definite' if it is used in honorific context.

In addition to SH and NSH, I have examined the cases which behave similarly to these honorifics: *rare*-honorifics and the *yagar-u* construction, in relation to SH, and the *age-ru* 'give' benefactive construction, with regard to NSH. I have argued that the differences in morphological shape between SH and the above two cases are not accidental and that these are in fact different syntactic processes. The similarity results from the pragmatic uses of the constructions in question, not from their syntactic structures. As for NSH, I have shown that it and the *age-ru* construction exhibit strikingly similar behaviors, which are the very characteristics that are to be captured in NSH: the obligatory presence of a beneficiary and its structural position. I have suggested that NSH actually involves the predicate *age-ru*, which may show up as its humble (or NSH) form, *sasiage-ru*, or as its null counterpart.

Because it appears that honorific processes take place 'optionally', allowing a subject (or beneficiary non-subject) with [SSS] to occur without a honorific predicate, it has sometimes been claimed that they are not 'agreement' processes, which are characterized as being 'mandatory' and 'one-to-one' (cf. Namai 2000). If one considers that the occurrence of an [SSS] noun phrase 'triggers' honorification, which has been the view often assumed since Harada (1976), its application

certainly looks 'optional', and the 'one-to-many' or 'one-to-zero' relations appear to be allowed. If the presence of an honorific form is taken to be responsible for requiring an item to 'agree' with it in terms of [SSS], however, the process can be regarded as 'mandatory' and 'one-to-one', meeting the characteristics of 'agreement'. This is the view that this chapter specifically advocates.

NOTES

1 In what follows, we will not be concerned with pragmatic or semantic notions of 'politeness', nor will we get into the discussion on what constitutes 'politeness in speech'. See Brown and Levinson (1987) for relevant discussion.

2 Though there are other languages, such as Korean, Tibetan, Javanese, etc. that have a grammatical system of honorifics, only Japanese is examined in this chapter.

3 The terms 'Perfomative Honorifics' (PH), 'Subject Honorifics' (SH), and 'Object Honorifics' (OH) are due to Harada (1976). Kuno (1987b) uses 'Hearer Honorific' (HH) instead of PH and 'Non-Subject Honorific' (NSH) for OH. In the traditional grammar of Japanese, PH or HH, SH, and OH or NSH are called *teinei-go* 'polite forms', *sonkei-go* 'respect forms', and *kenzyoo-go* 'humble forms', respectively. In the following discussion, I will follow Kuno's tgerminology; namely, HH, SH, and NSH, since it seems to express the phenomena more accurately than Harada's.

4 The affix *-san* that follows a person's name is a kind of courtesy title, similar to Mr., Ms., Miss or Mrs., but can be used for the second person as well, being equivalent to 'you, Mr./Ms. Sato'. The use of *-san* is obligatory in plain and polite speech, but strange in vulgar speech, when referring to a second or third person adult. Those that are due special respect, such as teachers, doctors, lawyers, are customarily addressed and referred to with *sensei* 'teacher, professor' rather than *-san*. Neither *-san* nor *sensei* is used in reference to the speaker herself or members of her in-group when talking to her out-group members. See section 3.1 for relevant discussion, and note 13 for more on in-groups and out-groups.

   The following abbreviations are used in glosses: Nom for the nominative case marker, *-ga*; Acc for the accusative case marker *-o*, Dat for the dative case marker *-ni*, Gen for the genitive case marker -no, Past for the past tense marker *-ta*/*-da*, Pres for the present tense marker *-ru*/*-u* (*-ru* after a consonant stem verb and *-u* for a vowel stem verb), Pass for the passive predicate, *-rare* (for a consonant stem verb)/*-are* (for a vowel stem verb), and Cop for the copulative predicate. For morphological items related to honorifics, HP is used for the polite prefix *go-*/*o-*, Hon for the SH form, Vul for the vulgar form.

5 A reviewer of this chapter pointed out to me that Sells and Iida (1991) provide the following example where the referents of both the subject, *sensei* 'the teacher', and a non-subject, the indirect object *Yamada-san* 'Mr./Ms. Yamada', are supposed to be elevated with the use of the predicate that involves both SH and NSH forms. (With the use of *masi-ta*, the address is also respected.)

   (i) Sensei-ga Yamada-san-ni hon-o o-sasiage-ni nari-masi-ta.
   teacher-Nom Yamada-Dat book-Acc HP-give(NSH)-SH-polite-past
   'The teacher gave a book to Mr. Yamada.'

The grammaticality of this example, however, is quite dubious. Sells and Iida incidentally note that this type of construction is not possible for some speakers, a group to which I certainly belong. It seems to me that this type of sentence 'derivatively' results given the pragmatic need to express the respect for the referents of the subject and the object. However, as mentioned in the above, as far as the grammar is concerned, SH and NSH function in the opposite directions for expressing the speaker's respect – SH elevates the subject directly by making use of the SH form, while NSH elevates a non-subject by downgrading the subject – and the presence of the SH and NSH forms on a single predicate thus gives rise to a contradiction. Thus, I consider that sentences such as (i) are not allowed grammatically but may take place under certain pragmatic situations.

6 The verb form used in honorifics is sometimes referred to as 'infinitive' or 'gerundive' in the literature. For example, Harada (1976) calls it 'infinitive' and Toribio (1990) takes it to be 'gerundive'. However, the terms 'gerundive' and 'infinitive', are misleading, since it is hard to tell in Japanese what morphologically, semantically, or syntactically constitutes 'infinitive' or 'gerundive', and it does not seem too meaningful to argue whether some form is infinitive or gerundive without addressing this question. Verbs in Japanese conjugate in terms of various functions (present tense, perfect tense, conditional, volitional, etc.), and the form that appears in honorifics is traditionally called *renyoo-kei* 'connective form', the form that connects to another predicate. To avoid unnecessary confusions, I will use the term 'connective form' in the following to refer to the form of the verb that is used in honorifics. The term 'gerundive' is saved for phrases (not for a particular form of predicates) that are nominal in structure (i.e., DPs) and involve a VP inside.

The connective form is identical to the root form if the verb belongs to the class of vowel verbs (verbs whose stem ends with either /i/ or /e/). But if the verb belongs to the class of consonant verbs (verbs whose stem ends with a consonant), the connective form has the form of the stem with the vowel /i/. See McCawley (1968b) for the morpho-phonology of the conjugation system of Japanese predicates.

7 There are quite a few suppletive SH forms for commonly used verbs (such as *irassyar-u* for *ik-u* 'go', *omesiagari-ni nar-u* for *tabe-ru* 'eat', *goran-ni nar-u* for *mi-ru* 'see', *ossyar-u* for *i-u* 'say', *nasa-ru* for *su-ru* 'do', etc.), which are to be learned item by item. Though some suppletive forms exhibit sub-regularities that may be of some interest to the morphosyntax of Japanese, I will not get into details here. See Harada (1976).

8 Though there are exceptions, the distribution of the honorific prefix (HP) *o-* and *go-* is mainly determined by the etymological characteristics of the item that they attach to; *o-* for native words and *go-* for Sino-Japanese words. Most loan words from European languages do not take any honorific prefix. The honorific prefixes *o-* and *go-* are not solely for predicates and they attach to adjectives and nouns. Some examples are given in (i). We will consider the honorific forms of Sino-Japanese (SJ) predicates in (11) and (12):

(i)				
	Native verbs:	yom-u	o-yomi-ni nar-u	'read'
	SJ verbs:	kenkyuu su-ru	go-kenkyuu ni nar-u	'research'
	Native adjectives:	utukusi-i	o-utukusi-i	'beautiful'
	SJ adjectives	rippa da	go-rippa da	'fine'
	Native nouns:	kao	o-kao	'face'
	SJ nouns:	kazoku	go-kazoku	'family'

9 As will be discussed in section 3.6, there are some adjectives (and Sino-Japanese adjectives) that do not take an honorific prefix (HP), *o-* or *go-*:

(i)	Adjectives:	tadasi-i	*o-tadasi-i	'right'
		hiku-i	*o-hiku-i	'low'
		yawaraka-i	*o-yawaraka-i	'soft'
	SJ adjectives:	mutyuu-da	*go/o-mutyuu-da	'crazy about'
		nigate-da	*go/o-nigate-da	'bad at'
		yuumei-da	*go/o-yuumei-da	'famous'

For these adjectives, the form Adj-*te/de-irassyaru*, the connective form of an adjective followed by the suppletive honorific form of *i(ru)* 'exist, be', can optionally be employed, as in *tadasiku-te irassyaru* 'right', *mutyuu-de irassyaru* 'crazy about', etc.

10 Just like SH forms, there are suppletive NSH forms such as *itas-u* for *su-ru* 'do', *moos-u* for *i-u* 'say', *ukagaw-u* for *kik-u* 'ask' or *ik-u* 'go', etc.

11 For characteristics of Sino-Japanese predicates, see Kageyama (1976, 1991, 1993), Grimshaw and Mester (1988), Hasegawa (1991), Terada (1990), Miyamoto (1997), Takahashi (2000), etc.

12 The presence of an HP does not always indicate honorifics. For some common nouns, such as *o-hasi* 'chopsticks', *o-soba* 'noodles', *o-syooyu* 'soy sauce', etc., the use of the HP *o-* is not particularly taken as a polite or honorific marker, but rather as a part of the words themselves. Without the HP *o-*, they may sound rough, especially in female speech. See section 3.4 for more discussion on the use of HP.

13 The concept of the speaker's 'in-group' and 'out-group' has to do with the social and psychological distance or closeness that the speaker feels toward other individuals around her. The speaker's close relatives, like parents and siblings, belong to her in-group, while strangers are considered to be out-group members. Whether one belongs to the speaker's in-group or out-group is relative and constantly shifts depending on conversational contexts. For example, the speaker's colleague can be an in-group member with respect to those who do not belong to their workplace (i.e., customers, employees of other companies, etc.) but she can be an out-group member with respect to the speaker's family members. In today's Japanese, close relatives are almost invariably considered to be 'in-group' members, as (19) suggests; however, the higher status of family members like parents or grandparents can be subject to honorification under formal situations and/or in the families of the upper class, where classical standards in the use of the language are preserved (or recommended).

14 NSH is possible in the context of (17c) and (i) is grammatical. NSH will be discussed in section 4 below:

(i) Gakusei-ga sensei-ni hon-o o-watasi-si-ta.
student-Nom teacher-Dat book-Acc HP-pass-NSH-Past
'The student handed the book to the teacher.'

15 In Harada's system, if the predicate is marked [Subject Honorific] via (19), the following transformations apply that give rise to appropriate SH forms: the honorific prefixation of an HP; the honorific infinitivization, which brings about the connective form; the particle *-ni* attachment to the connective form of the verb; the predicate *nar-u*-attachment; the Spell Out of an HP to either *o-* or *go-*, etc. The structure of the SH form will be discussed in sections 3.2, 3.3, and 3.4 below.

16 It is not quite clear in Toribio's analysis what triggers this Spec–Head agreement. She states: "it appears that predicates in Japanese can agree with the honorific feature of noun phrases, just as in some languages predicates agree with the person, number and gender features of their arguments" (1990: 537). "The subject also raises to SpecD where it triggers honorification through Spec–Head agreement, under the assumption that all specifiers and heads are involved in an agreement relationship which may be realized morphologically" (1990: 539). I do not provide a tree structure that shows Toribio's analysis here. We will discuss her system more closely in section 3.3, and the tree structure (35) below represents our analysis, which is a modified version of her analysis.

As will be discussed in section 3.6, to account for the optional realization of honorifics, it is necessary to consider that the honorific predicate requires the SSS subject but not the other way around.

17 Not all the occurrences of connective forms take an HP. For example, *sugi-ru* 'exceed', as in (25a), cannot take an HP, unless it is part of an SH as in (25b). Thus, if the existence of an HP is an indication of [+N], the connective form must assume either [+N] or [–N], just as the *-ing* form of English may. See Harada (1976) and Kuno (1987b) for relevant discussion. See also the discussion concerning (30–33) below.

18 Though *-ni* in the SH predicate is often considered to be a case particle (as in Toribio 1990 and Suzuki 1989), the facts in (27–29) strongly suggest that it is a copula. To the extent that nominal adjectives (NAs) never occur independently without a copula, or with a case marker other than *-ni*, *-ni* that follows an NA seems most probably a copula. This in turn suggests that the *-ni* of the SH predicate may also be a copula.

19 However, there are minor differences between Suzuki's analysis and Toribio's: Suzuki considers *nar-u* to be a control verb, while Toribio analyzes it as a raising verb; in Suzuki's analysis, the [+N] status of gerunds lies in I, which consists of an HP and the gerundive morpheme *-i*, and agreement checking takes place between the head I and the subject in the Spec of IP, while in Toribio's analysis, it is D that gives rise to the [+N] status of the gerund and the head D has the nominalizing morpheme *-i*. When the subject is raised to the Spec of DP, Spec–Head agreement takes place, which triggers the attachment of an HP to *V-i* in the D head.

20 *Nar-u* occurs in the copulative construction and the predicate adjective/nominal adjective construction, which are exemplified below as well as in (32) and (33). Just like *become* in English, *nar-u* in these constructions is best analyzed as a raising predicate rather than a control predicate:

(i) Hanako-ga isya-ni nat-ta.
Hanako-Nom doctor-copula become-Past
'Hanako became a doctor.'

(ii) Ryoori-ga tumetaku nat-ta.
dish-Nom cold become-Past
'The dishes became cold.'

(iii) Gakuseitati-ga sizuka-ni nat-ta
students-Nom cold become-Past
'The students became quiet.'

21 As briefly mentioned in section 2 (note 12 in particular), some nouns ordinarily involve an HP without specifically marking honorifics (especially in female speech),

as in *o-soba* 'noodles', *o-sara* 'dish', *o-sake* 'sake', etc. In such examples, the presence of an HP does not necessarily make the noun identifiable in the sense that is discussed in this section. The types of nouns that are particularly relevant to the discussion of this section include those that refer to body parts, such as *kao* 'face' and *karada* 'body, health'; SJ activity nouns, such as *kooen* 'lecture', *ryokoo* 'travel', *kenkyuu* 'research'; and picture nouns, like *syasin* 'photo', tegami 'letter'.

22 That is, as briefly stated above, the HP on a noun not only helps identify its referent but specifies it in terms of its possessor, to whom the speaker's respect is due. As will be discussed in section 5.2, there is some kind of concordance among the occurrences of honorific expressions. Thus, when the noun is with an HP as in (37b), the predicate is expected to be in the form of honorifics, either SH or NSH, and the possessor of the noun is the target of the speaker's respect, which the predicate form indicates by making use of SH or NSH.

23 The indefinite use of *go-hon* in (37c) and (37d) may be acceptable in hyper-polite speech, where the presence of an HP on nouns simply marks the speech polite, as briefly mentioned in section 2. See note 21 above. Cf. Ide and McGloin (1990).

24 This does not mean that indefinite DPs cannot be a subject of SH predicates. As (i) shows, indefinite DPs are acceptable as long as they represent a class or a kind of people to whom respect is due:

(i) a. Misiranu sensei-ga hon-o o-kai-ni nat-ta.
unknown teacher-Nom book-Acc HP-buy-Hon-Past
'Some teacher bought a book.'
b. Donataka-ga o-warai-ni nat-ta.
someone(Hon)-Nom HP-laugh-Hon-Past
'Someone laughed.'

In (ia), the subject is a stranger but the speaker knows that whoever she may be, her social status is that of a teacher; therefore, respectable. Similarly, in (ib), the subject is someone not identifiable. But *donataka* 'someone (honorific)' is the honorific form of *dareka* 'someone', and the speaker knows that whoever she may be, she belongs to a class of people to be looked up to.

25 In Hasegawa's system, the preposition *by* is inserted to give Case to an agent as the last resort when it cannot receive structural Case.

26 In Hasegawa's original analysis, whether the complement object receives Object Case is determined by whether the complement verb moves to *-(r)are* at (or before) S-structure or at LF. I assume (46a) here, since the same result obtains if *-(r)are* optionally absorbs Case.

27 See Hasegawa (1988) for details. See also Takezawa (1987) for *ni* Case.

28 (46) also accounts for indirect passives with an intransitive verb, exemplified in (i):

(i) Hanako-ga ame-ni hur-are-ta.
Hanako-Nom rain-Dat fall-Pass-Past
'Hanako got rained on.'

The subject of *-(r)are*, the affectee of the complement event, moves to the Spec of TP to receive Nominative Case.

29 Thus, Hasegawa's claim that *Rare*-SH, voluntary-*(r)are*, and Passive-*(r)are* are different manifestations of the same *-(r)are* accords with the historical developments of *-(r)are*;

the most basic use of *-(r)are* is taken to be its voluntary use, from which the SH use and the passive use are derived. See Hashimoto (1969).

30 If the subject is phonologically present and appears with *-ni* as in (49b), the construction is most probably an instance of the *zihatu* 'voluntary' use of *-(r)are*. Marking the subject with *-ni* is characteristic of this construction.

31 As will be mentioned immediately below, *yagar-u* is used only in vulgar speech, and other expressions involved in sentences with *yagar-u* must equally be vulgar. Because of this requirement, (50) has vulgar pronoun forms, *aitu* instead of ordinary *anata* 'you', *ore* instead of *watasi* or *boku* 'I', which are neutral in terms of level of speech. See section 5.2 for discussion of politeness concordance among the items in a sentence.

32 As noted in section 3.4, a noun and its possessor agree, and when the possessor is an SSS, the noun may take an HP. See (41).

33 Given this state of affairs, there seem to be two ways to deal with NSH: (i) NSH is taken to be a syntactic process and the syntactic presence of the beneficiary (i.e., the item with SSS) is posited even if its presence is not too obvious; or (ii) NSH is a pragmatic process and the existence of a beneficiary is implied in the context but not necessarily in a syntactic structure. The second approach is suggested in Matsumoto (1997) and Mori (1993), among others; however, I would like to pursue the syntactic approach, (i), in the following discussion.

34 Harada (1976) notices that the trigger of NSH does not have to be an (indirect) object but can be 'included' in it. He speculates that there may be a hierarchy like the following that is responsible for determining the applicability of honorification:

(i) a. Subject
    b. Indirect object
    c. Direct object
    d. 'Non-terms' of grammatical relation

35 Thus, Toribio's account of the facts in (64f) is along the line of the Minimal Link Condition. In order to make her analysis go through, she needs to assume a version of the specified subject condition; that is, PRO, the subject argument, does not prevent the checking of the SSS feature of the (in)direct object.

36 In Japanese, Nominative *ga* can be multiply assigned. There are several ways to account for this fact. I assume that *ga* is given to a DP that is governed by Tense (i.e., at (inner or outer) Spec of TP, at outer Spec of VP whose head is stative) (cf. Hasegawa 1984; Tada 1992; Takezawa 1987). Nominative *ga* given to a subject, which is at inner Spec of TP, is one instance of this process.

37 *Age-ru* can be an independent predicate that means 'give':

(i) Hanako-ga Taro-ni hana-o age-ta.
    Hanako-Nom Taro-Dat flower-Acc give-past
    'Hanako gave flowers to Taro.'

38 The unmarked interpretation of (82) is, as has just been stated, to take Taro as a beneficiary; however, this is not the only interpretation; the beneficiary may not be Taro but an individual phonologically unexpressed but understood in the given discourse. That is, (82a) for example, may be interpreted as 'Hanako helped Taro for someone implicit in the context.' As will be discussed immediately below, I will

present an analysis where *age-ru* involves a beneficial role which can be identical with an argument of the predicate to which *age-ru* attaches, or implicit (i.e., a null pronominal category) but identifiable from the discourse. See note 42 for relevant discussion.

39 If the action of 'suing' or 'stealing' is considered to be for the benefit of someone (who may be the object), (83) is allowed, a reading with which we are not concerned here.

40 If *age-ru*, not in its honorific form *sasiage-ru*, is used with NSH, the sentence is inappropriate:

(i) *Gakusei-ga sensei-o o-tasuke si-te age-ta.
student-Nom teacher-Acc HP-help-do-give-past
'The students helped the teacher.'

As will be discussed in section 5, there must be some concordance ensured among the items in honorific sentences.

41 Though the two versions of (84), either with *sasiage-ru* or without, have basically the same meaning and function, the version with *sasiage-ru* sounds more polite. This fact does not follow from the analysis here, however.

42 This is what Hasegawa (2000) presents as an analysis of the *age-ru* construction and NSH. In order to make this analysis go through, we have to allow an item to be doubly theta-marked; once inside the complement VP and the second time at the Spec of the benefactive predicate. Within the Government and Binding framework, the theta-criterion prohibits an item from receiving a theta-role multiple times. However, in view of the recent developments of the theory where a theta-role is identified by a particular syntactic position, it seems probable that we may pursue the direction where multiple theta-role assignment is allowed under certain circumstances (e.g., when a theta-assigning head requires feature checking), and the proposal here falls under such a case. (Cf. Hornstein 1999.)

43 Another possibility that is often assumed in Japanese syntax is to allow a null pronoun rather freely. Under this assumption, the interpretation and distribution of null pronouns are taken care of in pragmatics, not in formal grammar. Cf. Kameyama (1988) and Nakamura (1991).

44 When the complement subject is an empty category (*ec*), it can refer to the matrix constituent, as shown in (i), suggesting that it can be pronominal. In Huang's analysis, as long as Binding Condition B is observed, a null argument can be a pronominal and is co-indexed with the closest nominal element, the matrix subject in (i). In Hasegawa's analysis, PRO, a kind of pronominal, is allowed at the subject position. Thus, in either analysis, the null complement subject can be a variable or a pronominal but the null object can only be a variable, which is responsible for the contrast between (86) and (i):

(i) Taro$_i$-ga [*ec*$_i$ Hanako-o tasuke-ru] to tikat-ta.
Taro-Nom Hanako-Acc help-Pres Comp swear-Past
'Taro swore that he will help Hanako.'

45 *Kure-ru*, rather than *age-ru*, is used here. The meanings and functions of *kure-ru* and *age-ru* are the same, but the use of *kure-ru* indicates that the speaker's empathy is with the object of the sentence, while *age-ru* indicates it is with the subject. Since the speaker tends to have empathy with the subject in active sentences, the speaker's empathy is with *Hanako*, the subject of the matrix clause, in (88). The intended reading

on the *e* is *Hanako*, which is the object of the complement sentence; hence, *kure-ru* must be used rather than *age-ru* (cf. Kuroda 1965; Kuno 1978a; Kuno and Kaburaki 1977 for relevant discussion).

46 It was Kuroda (1965) who first pointed out that the process of zero pronominalization (i.e., the interpretation of empty pronominals) is affected by the presence of benefactive predicates like *age-ru* and *kure-ru*; the same contrast seen in (86) and (88). As stated above, how empty pronominals are analyzed is a rather controversial issue in Japanese syntax, and it is beyond the scope of this chapter to settle this problem. Thus, the analysis presented here must be taken as a case study that attempts to capture the phenomena that involve both pronominals and honorifics (benefactive predicates) within the framework of Hasegawa (1984).

47 I owe to Jacquline Guéron (p.c.) the idea that the occurrence of honorifics may be due to some kind of politeness operator over a sentence.

33 Icelandic Logophoric Anaphora

ERIC REULAND

1 Introduction
2 Subjunctives
3 Infinitives
4 Summary of the facts
5 The interpretation of *sig*: binding vs. coreference
6 Conclusion: issues for further research

1 Introduction

As outlined in Thráinsson (1976a),[1] *sig* in Icelandic may take a long-distance antecedent, when the clause that contains *sig* is infinitive or subjunctive (i.e., the antecedent may be beyond the nearest c-commanding subject), in violation of Condition A of the Binding Theory. However, if *sig* is contained in an indicative clause, it can only refer to the local antecedent. This is exemplified in (1):[2]

(1) a. Jón_j skipaði Pétri_i [að PRO_i $\text{raka}_{\text{infinitive}}$ $\text{sig}_{i,\,j,*k}$ á hverjum degi].
John ordered Peter to shave SIG every day
b. Jón_j segir [að Pétur_i $\text{raki}_{\text{subjunctive}}$ $\text{sig}_{i,\,j,*k}$ á hverjum degi].
John says that Peter shaves SIG every day
c. Jón_j veit [að Pétur_i $\text{rakar}_{\text{indicative}}$ $\text{sig}_{i,*j,*k}$ á hverjum degi].
John knows that Peter shaves SIG every day

The proposals in the literature to account for the long-distance use of *sig* in sentences like (1a) and (1b) can be divided into two groups. One group assumes a unified Binding analysis of long-distance *sig* in subjunctives and infinitives. One of these analyses is Anderson's (1986) 'Tense-Agreement' account of Icelandic anaphora. Anderson postulates an 'anaphoric domain' in which *sig* has to be bound by a 'superordinate subject'.[3] Infinitive complements always constitute an anaphoric domain whereas in subjunctives an anaphoric domain is established

when a rule of 'Tense-Agreement', which copies the tense of the matrix clause onto the subjunctive complement, has applied. It follows that *sig* can take a long-distance antecedent out of infinitives and subjunctives, given that an anaphoric domain has been established in subjunctives. Thus, the same account, stated in terms of an anaphoric domain, is given for long-distance *sig* in infinitives and subjunctives.[4] Also, both the Parameterized Binding Theory, developed in Wexler and Manzini (1987),[5] and the head movement analysis of anaphors, proposed in Pica (1985, 1987),[6] treat long-distance *sig* in subjunctives and infinitives in a parallel fashion. Within the Wexler and Manzini (1987) Parameterized Binding Theory, the governing category for *sig* is determined by [+indicative mood], and thus the antecedent possibilities for *sig* should be the same out of infinitives and subjunctives. Similarly, Pica (1987) proposes that *sig* undergoes head movement out of infinitives and subjunctives at the level of Logical Form, again predicting parallel antecedent possibilities on the two conditions.

The other approach to long-distance anaphora in Icelandic maintains that the long-distance use of *sig* out of subjunctives is ruled by discourse factors rather than syntactic principles. Thráinsson (1976a, 1990, 1991), Maling (1984), Sells (1987), Sigurðsson (1990), and Sigurjónsdóttir (1993) observe that the antecedent possibilities of long-distance *sig* in subjunctives are not constrained by structural conditions such as c-command but rather by discourse factors such as perspective or point of view. Also, as pointed out by Thráinsson (1976a, 1990), the presence of a subjunctive complement is not enough to license long-distance use of *sig*. Thus, only a certain type of subjunctives allow *sig* to take a long-distance antecedent, in particular, subjunctives which imply "a report from the higher subject's 'point of view.'" (Thráinsson 1976a: 229). Subjunctives which state a fact about the matrix subject and do not convey the higher subject's perspective or point of view, on the other hand, do not allow *sig* to be co-indexed with the matrix subject. Thus, the long-distance use of *sig* is not uniquely determined by the presence of a subjunctive complement. Rather, it seems as if discourse information can only be accessed if there is a subjunctive. If it can, it still has to be of the 'right kind'.

Hagège (1974) and Clements (1975) subsume the use of long-distance *sig* in subjunctives under logophoricity (see chapter 38). This idea was further pursued in Maling (1984). A semantic characteristic of logophoric pronouns is that they are used in 'reportive contexts' to refer back to an individual (other than the speaker-narrator) whose speech, thought, feeling, or point of view is reported on in the sentence (from Maling 1984: 211, 231). As discussed most extensively by Sigurðsson (1990), this more or less sums up the semantic properties of *sig* when it takes a long-distance antecedent out of subjunctives.

These two approaches to long-distance anaphora in Icelandic make different predictions regarding the antecedent possibilities of *sig*. According to the first approach, long-distance *sig* should be subject to the same constraints in subjunctive and infinitive clauses; i.e., structural conditions such as c-command and discourse factors should play the same role in both domains. The second approach predicts that long-distance *sig* in subjunctives and infinitives is governed

by different factors. Whereas discourse factors should be relevant for the logophor *sig* in subjunctives, such factors should not play a role in the infinitive case, where the interpretation of *sig* should only be constrained by structural principles.

Such a difference between infinitival and subjunctive domains does not by itself exclude the possibility that strictly grammatical factors play a role. For instance, it could be that some grammatical factor associated with subjunctives, but not with infinitives, entails that logophoric interpretation is in principle admissible, whereas discourse factors determine whether the ensuing interpretation is well-formed. This possibility will be discussed later. Until then the two approaches will be discussed at a more general level.

In the literature, the focus of research has been the subjunctive domain and how it differs from the indicative. Much less attention has been paid to the infinitive case, and until now the different tests for discourse vs. syntactic principles have not been applied systematically to the two domains. This calls for a more detailed analysis of the mechanisms governing *sig* in subjunctives and infinitives, and an attempt will be made to give the relevant data for each case.

2 Subjunctives

It is a well-known fact that long-distance *sig* in subjunctives in Icelandic can take as its antecedent a non-c-commanding DP. Thus, as first observed by Maling (1984), the DP *Jón* can serve as the antecedent for *sig* in sentences like (2), although it does not c-command the anaphor.

(2) a. $[_{DP}$ Skoðun Jóns$_i$] er [að sig$_{i,acc}$ vanti$_{subj}$ hæfileika].[7]
opinion John's is that SIG lacks talents
'John's opinion is that SIG lacks talents.' (cf. Maling 1984: 222)

b. $[_{DP}$ Álit Jóns$_i]_j$ virðist [t_j vera [að ég hati$_{subj}$ sig$_i$]].
belief John's seems be that I hate SIG
'John's belief seems to be that I hate SIG.'

c. Björn sagði Pétri frá $[_{DP}$ ósk Jóns$_i$] um [að Ari sýndi$_{subj}$ sér$_i$
Björn told Peter about wish John's about that Ari showed SIG
virdingu].[8]
respect
'Björn told Peter about John's wish that Ari showed SIG respect.'

Furthermore, *sig* in subjunctives can refer to a non-c-commanding matrix object, as illustrated in (3):

(3) ?Jón$_i$ er masókisti. Þad gledur Jón$_i$ [að ég muni$_{(subj.)}$ lemja sig$_i$ í hausinn med spýtu á morgun].
'John is a masochist. It pleases John that I will hit SIG in the head with a stick tomorrow.' (cf. Sigurjónsdóttir 1993)

These sentences show that the antecedent possibilities of *sig* in the long-distance subjunctive case are not constrained by a c-command requirement. (There may some ill-understood variation among speakers. Sigurðsson 1990 presents another case showing the same point.) By comparing these sentences to the ones in (4), we see that the antecedent–anaphor relations are discourse-dependent. The antecedent of *sig* must be the person (distinct from the speaker-narrator) whose perspective or point of view is reported in the sentence:

(4) a. *[$_{DP}$ Skoðun Jóns$_i$] fær mig til að halda [að sig$_{i,\ acc}$ vanti$_{subj}$ hæfileika].
opinion John's leads me to to believe that SIG lacks talents
'John's opinion leads me to believe that SIG lacks talents.'
(cf. Maling 1984: 222)

b. *[$_{DP}$ Vinur Jóns$_i$] telur [að ég hati$_{subj}$ sig$_i$].
friend John's believes that I hate SIG
'John's friend believes that I hate SIG.'

c. *Þetta vandamál$_i$ krafðist þess [að við hugsuðum$_{subj}$ stödugt
this problem demanded it that we thought constantly
um sig$_i$].
about SIG
'This problem demanded that we constantly thought about SIG.'
(cf. Sigurðsson 1990: 335)

In the ill-formed sentences in (4), the co-indexed DP bears the same structural relation to *sig* as in the well-formed sentences in (2). The difference between these two sets of sentences is that in (2), *Jón* is the person (distinct from the speaker) whose opinion, belief, or wish is reported in the sentences. In (4a, b), on the other hand, the sentences are not reported from *Jón*'s point of view; rather it is the first person pronoun 'me' in (4a) and the DP 'John's friend' in (4b) which carry the perspective of these sentences. This analysis is further supported by the example in (4c), which shows that an inanimate DP, which cannot possibly be a perspective holder, cannot serve as the antecedent for *sig* in subjunctives.[9]

Also, it has been noted in the literature (Maling 1984: 232; Sigurðsson 1990: 336) that passives in Icelandic do not in general allow their subject to serve as a long-distance antecedent for *sig* in the cases considered. If *sig* in embedded subjunctives is ruled by discourse factors, the derived subject of a passive should not be able to serve as an antecedent for *sig*, since a derived subject does not carry the perspective or point of view of the sentence. This is illustrated in (5):

(5) a. Jón$_i$ sagði Pétri$_j$ [að ég elskaði$_{subj}$ sig$_{i,*j}$].
'John told Peter that I loved SIG.'

b. Pétri$_j$ var sagt (af Jóni$_i$) [að ég elskaði$_{subj}$ sig$_{*i,*j}$].
'Peter was told (by John) that I loved SIG.'

In (5a) *sig* takes the perspective-holding subject *Jón* as its antecedent, but in the passive sentence in (5b), where neither *Jón* nor *Pétur* bears the perspective of

the sentence, *sig* cannot refer to the c-commanding subject or to the object of the *by* phrase.[10]

The minimal pair in (6), reported in Sells (1987: 451), is further evidence that the antecedent possibilities of *sig* in subjunctives are determined by discourse factors:

(6) a. Barnið$_i$ lét ekki í ljós [að það hefði$_{subj}$ verið hugsað vel
the child put not in light that there had been thought well
um sig$_i$].
about SIG
'The child didn't reveal that SIG had been taken good care of.'

b. *Barnið$_i$ bar þess ekki merki [að það hefði$_{subj}$ verið hugsað
the child bore it not signs that there had been thought
vel um sig$_i$].
well about SIG
'The child didn't look as if SIG had been taken good care of.'

The difference in grammaticality between (6a) and (6b) can be attributed to the fact that in the (a) sentence, the report is made from the child's point of view; i.e., it is the child, and not the speaker, who didn't reveal that he/she had been taken good care of, whereas in the (b) sentence, it is the speaker who reports that the child didn't look as if he/she had been taken good care of. Hence, *sig* in subjunctives demands an antecedent that bears the perspective or point of view of the sentence, and whether or not this DP c-commands the anaphor is irrelevant.

3 Infinitives

In contrast, *sig* in infinitives can only take a matrix subject and not a matrix object as an antecedent (cf. Thráinsson 1979, 1991; Sigurjónsdóttir 1993). This is illustrated in (7):

(7) a. Jón$_i$ skipaði mér$_j$ [að PRO$_j$ lemja$_{inf}$ sig$_i$].
John ordered me to hit SIG

b. *Eg$_j$ hótaði Jóni$_i$ [að PRO$_j$ lemja$_{inf}$ sig$_i$].
I threatened John to hit SIG

Note that the contrast between (7a) and (7b) could follow from the difference in perspective these sentences show, but it could also follow from the difference in c-command. If *sig* in infinitives must be c-commanded by its antecedent, it follows that *sig* can take the c-commanding subject in (7a) as an antecedent but not the non-c-commanding object in (7b).[11] (8), however, shows that in infinitives c-command is crucial. These sentences contain a constituent that is a possible perspective holder, but does not c-command *sig*. These sentences are ruled out:[12]

(8) a. *[$_{DP}$ Skoðun Jóns$_i$]$_j$ virðist [t$_j$ vera$_{inf}$ hættuleg fyrir sig$_i$].
opinion John's seems be dangerous for SIG
'John's opinion seems to be dangerous for SIG.'
b. *[$_{DP}$ Ósk Jóns$_i$]$_j$ er líkleg til [t$_j$ að hafa$_{inf}$ slæmar afleidingar fyrir sig$_i$].
wish John's is likely to to have bad consequences for SIG
'John's wish is likely to have bad consequences for SIG.'
c. *[$_{DP}$ Álit Jóns$_i$]$_j$ er sagt [t$_j$ hæfa$_{inf}$ sér$_i$ vel].
belief John's is said suit SIG well
'John's belief is said to suit SIG well.'

Thus, the sentences in (8) show that for *sig* in infinitival clauses, discourse factors are unable to compensate for the lack of c-command. This contrasts with the situation in subjunctives discussed earlier, where we saw the antecedent possibilities of *sig* are determined by discourse properties (cf. (2) and (3)). Moreover, if the antecedent of *sig* in infinitives is only constrained by structural conditions, one expects that the derived subject of a passive should be a possible antecedent for *sig*, since the subject c-commands *sig*, even if it is not a perspective holder. This is indeed the case, as witnessed by the examples in (9) and (10):

(9) Jón$_i$ sagði [Maríu$_j$ hafa$_{inf}$ látið [mig þvo$_{inf}$ sér$_{i,j}$]].
John said Mary have made me wash SIG
'John said Mary to have made me wash SIG.'

(10) María$_j$ var sögð (af Jóni$_i$) [t$_j$ hafa$_{inf}$ látið [mig þvo$_{(inf.)}$ sér$_{j,*i}$]].
Mary was said (by John) have made me wash SIG
'Mary was said (by John) to have made me wash SIG.'

As exemplified in (10), *sig* in an infinitive complement can take the subject of a passive sentence as an antecedent, although this subject does not carry the perspective or point of view of the sentence. This shows that only c-command determines the antecedent possibilities of *sig* in infinitives.[13]

4 Summary of the facts

There are consistent differences between the conditions on long-distance antecedents for *sig* in subjunctive and infinitive complement clauses. *Sig* in subjunctives is constrained by discourse factors; in particular, the antecedent of *sig* has to be the person (other than the speaker-narrator) whose perspective or point of view is presented in the sentence, and whether or not this antecedent c-commands *sig* is irrelevant (cf. examples (2), (3), and (4)). The antecedent possibilities of *sig* in infinitives, on the other hand, are uniquely governed by the structural condition of c-command, and discourse factors are not reflected in this domain (cf. example (8)). Thus, *sig* in subjunctives cannot refer to an inanimate DP (cf. example (4c)) or normally to the derived subject of a passive (cf. example (5b)), since these DPs

cannot serve as perspective holders. Although non-local inanimate antecedents of *sig* are considered dubious (presumably since *sig* is marked for person), subjects of passive sentences (cf. example (10)) can serve as antecedents for *sig* in infinitives, just on the basis of c-command. Moreover, *sig* in infinitives cannot take a non-c-commanding matrix object as an antecedent (cf. example (7b)), whereas *sig* in subjunctives can, given that the object bears the perspective or point of view of the sentence (cf. example (3)).

If the mechanisms governing *sig* in subjunctives and infinitives were of the same type, as proposed by Anderson (1986), Wexler and Manzini (1987), and Pica (1985, 1987), among others, these differences would be unexpected. Non-c-commanding antecedents should then be equally available in infinitives and in subjunctives, and non-perspective-holding DPs (such as inanimate and passive subjects) should be able to serve as antecedents for *sig* in subjunctives just as in the infinitive case. It appears that the Icelandic data are only consistent with analyses that differentiate between the mechanisms governing long-distance *sig* in subjunctives and infinitives.

5 The interpretation of *sig*: binding vs. coreference

Since Reinhart's work on anaphoric relations, it has been established that syntactic binding requires c-command (see Reinhart 1983a for detailed discussion of the properties of the c-command relation). One might, of course entertain the possibility that, nevertheless, syntactic binding of some sort is involved in cases such as (2), since certain types of binding, such as variable binding, appear to allow violations of c-command (as in *every boy's mother loves him*).[14]

However, as discussed in Thráinsson (1991: 60), the strict/sloppy identity ambiguity typically associated with pronouns also shows up with *sig* in the long-distance subjunctive case and is sensitive to differences in c-command. (11) shows the strict/sloppy ambiguity:

(11) Jón$_i$ telur [að prófessorinn muni fella$_{subj}$ sig$_i$ á prófinu] og Ari$_j$ telur það líka.
'John believes that the professor will fail SIG on the test and Ari believes so too.'
a. = Ari believes that the professor will fail Ari on the test.
b. = Ari believes that the professor will fail John on the test.

Where *sig* in subjunctive contexts is not c-commanded by its long-distance antecedent, the sloppy reading is much harder to obtain. This is illustrated in (12):

(12) Skoðun Jóns$_i$ er [að sig$_i$ vanti hæfileika] og það er skoðun
opinion John's is that SIG lacks talents and that is opinion
Péturs$_j$ líka.
Peter's too
'John's opinion is that SIG lacks talents and that is Peter's opinion too.'

a. ??Peter's opinion is that Peter lacks talents.
b. = Peter's opinion is that John lacks talents.

This is evidence that the relation between *Jón* and *sig* in a subjunctive context such as (12) must be one of co-reference, rather than syntactic binding.[15]

The conclusion is strengthened by the fact that *sig* may occur, and be interpreted, without any linguistic antecedent whatsoever:

(13) María var alltaf svo andstyggileg. Þegar Ólafur$_j$ kæmi segði hún sér$_{i/*j}$ áreiðanlega að fara. (Thráinsson 1991)
'Mary was always so nasty. When Olaf would come, she would certainly tell himself [the person whose thoughts are being presented – not Olaf] to leave.'

In such cases *sig* must be able to get its interpretation just as pronominals do. If in subjunctive contexts *sig* and its antecedent may be related not by binding, but by coreference, this is at variance with the canonical view of anaphors (Bouchard 1984; Reinhart and Reuland 1991), requiring the underspecified element to obtain its missing phi-features, directly or indirectly, from its antecedent in the syntax by chain formation of some sort.[16] It would still be possible to develop a theory in which *sig* acquires its phi-features from a covert source, for instance a null-operator. If one allows *sig* is to pick up its phi-features from a discourse antecedent in (13) one must be careful not to make the theory of syntactic relations vacuous. Construing a contentful analysis along these lines is a non-trivial matter.

Another, perhaps more straightforward, interpretation is that there is no intrinsic necessity for anaphors to be syntactically linked to their antecedent in order to be interpreted.

6 Conclusion: issues for further research

Consistent differences are found between the conditions on long-distance antecedents for *sig* in subjunctive and infinitive complement clauses. The interpretation of *sig* in subjunctives is constrained by discourse factors; the interpretation of *sig* in infinitives involves a structural relation with its antecedent.

Ideally, these differences should follow from a general theory about the interplay between structural conditions and discourse factors, and about the nature of logophoric interpretation. Developing such a theory is still one of the concerns of current Binding research.

One of the starting points for such a theory is what is known about the nature of logophoric interpretation. Another starting point is what is known about other languages. Napoli (1979) observes that Italian *se/si* can only have a long-distance antecedent in positions where it cannot cliticize. In Reuland (1990) it is argued that cliticization leads to the syntactic encoding of an interpretive dependency. In English, *himself* can have a logophoric interpretation in positions where establishing

a syntactic dependency by head movement of SELF to the verb would be blocked (Reinhart and Reuland 1991). What is observed in these languages appears to be governed by a regularity: free reflexives are syntactically licensed not by what is the case, but by what is blocked. Insofar as Icelandic logophoric *sig* requires a subjunctive, ideally, Icelandic also should fall under this pattern. If so, the role of the subjunctive should be that of blocking a syntactic connection between *sig* and its antecedent. This possibility is pursued in Reuland (2001). Yet this issue cannot be considered to be settled. As pointed out by Halldor Sigurðsson, there are speakers who accept logophoric reflexives in indicative environments provided the indicative can be interpreted as having perspective semantics. This is reminiscent of the conditions on long-distance anaphors in Faroese (Barnes 1986), discussed in chapter 40. A more extensive discussion would lead us beyond the scope of this chapter, though.[17]

NOTES

This chapter is based on work with Sigrídur Sigurjónsdóttir. I am very grateful to Halldur Sigurðsson, Sigrídur Sigurjónsdóttir, and an anonymous reviewer for their helpful comments.

1 See also Thráinsson (1979, 1990, 1991); Maling (1984, 1986); Anderson (1986); Rögnvaldsson (1986); Sells (1987); Sigurðsson (1990); Sigurjónsdóttir (1993); among others.

2 One may abstract away from the two different verb classes which have different effects on the interpretation of *sig*. With one class of verbs, like the verb *raka* 'shave' exemplified in (1), *sig* can take either a local or a long-distance antecedent in the infinitive and subjunctive domain, whereas with the other class of verbs, *sig* can only refer to the long-distance antecedent. These facts will not be discussed, since the class of verbs only affects the interpretation of *sig* in the local domain, which is not the domain that concerns us here. These lexical effects in Icelandic (first noted by Thráinsson) are described by Hyams and Sigurjónsdóttir (1990); Sigurjónsdóttir and Hyams (1992); and Sigurjónsdóttir (1993). Similar lexical effects have been discussed by Everaert (1986b) and Reinhart and Reuland (1989, 1991, 1993) for Dutch and by Hellan (1988) for Norwegian.

3 Anderson (1986: 76) gives the following definition of an anaphoric domain: "The ANAPHORIC DOMAIN of A is the minimal S or NP containing A, a governor of A, and a subject of either tensed S or NP which c-commands A."

4 Anderson's proposal accounts for the fact that in embedded infinitives in Icelandic, *sig*, but (normally) not the pronouns, can take the matrix subject as its antecedent, whereas both *sig* and the pronouns can refer to the matrix subject in subjunctives. The obligatoriness of *sig* in this domain in infinitives follows from Anderson's analysis, since an infinitive and its matrix clause always constitute an anaphoric domain. The rule of Tense-Agreement, on the other hand, optionally applies to the subjunctive clause, and hence either an anaphoric domain is established and *sig* refers to the matrix subject, or there is no anaphoric domain, in which case a pronoun is used

to refer to the long-distance antecedent. An alternative analysis for these facts is proposed in Sigurjónsdóttir (1993).

5 See also Manzini and Wexler (1987); Koster (1984); and Yang (1984).

6 See also Lebeaux (1983, 1985) and Chomsky (1986b).

7 Note that *sig* in Icelandic does not have a nominative form (see Everaert 1990a). Hence, *sig* can occur in subject position only with those verbs that select a non-nominative subject, i.e., with the so-called 'quirky' case verbs in Icelandic. The verb *vanta* 'to lack, need', which appears in example (2a), is one of these verbs and takes an accusative subject. Quirky subjects in Icelandic have been discussed by a number of authors: see, for example, Andrews (1976); Thráinsson (1979); Bernódusson (1982); Zaenen et al. (1985); and Sigurðsson (1989, 1992).

8 Note that there are two DPs in this sentence whose perspective or point of view are being reported, i.e., *Jón* and *Björn*. Hence, *sig* could also take *Björn* as its antecedent.

9 Objects are generally not the perspective-holding DP of a sentence, and hence rarely qualify as antecedents for the logophor *sig* (see Sigurðsson 1990: 334).

10 As observed by Sigurðsson (1990: n. 22), the exceptions to this generalization show that the passive as such does not block long-distance coreference of *sig*. Thus, as illustrated in (i), the derived subject of a passive (*honum* 'him' in this case) can serve as an antecedent for *sig* in subjunctives, given that it carries the perspective or point of view of the sentence. As pointed out by Sigurðsson: "made x to believe" implies "x believes":

(i) Honum$_{i\ (dat.)}$ var talin trú um [ad sig$_{i\ (acc.)}$ vantadi$_{(subj.)}$ hæfileika].
Him was made belief about that SIG lacked talents
'He was made to believe that SIG lacked talents.'
(cf. Maling 1984: n. 28)

11 I am making the standard assumption here that in (7b) *hótaði* is first merged with its theme object *Jóni*. Subsequently, the subordinate clause is merged.

12 These and other non-attributed examples are from Reuland and Sigurjónsdóttir (1997).

13 As Halldor Sigurðsson points out, under the copy theory of movement some of the infinitival cases discussed here fall under a clause-internal scenario. He also points out that to his ear (i) is only slightly less natural than (2a):

(i) Krafa Jóns$_i$ til okkar$_j$ um [að PRO$_j$ styða sig$_i$ við þessar
demand John's to us about to support SIG under these
aðstæður] er skiljanleg.
circumstances is understandable
'John's demand that we support him under these circumstances is understandable.'

If so, this indicates that perspective may play some role in non-subjunctive domains as well, under conditions that are so far ill-understood. Furthermore, in the case of long-distance binding *sig* appears also to favor an animate antecedent in infinitives. This is reflected in the fact that the sentences in (ii) are not as good as their counterparts in (9) and (10) (in contrast to what is reported in Reuland and Sigurjónsdóttir 1997):

(ii) a. ??Jón$_i$ sagði [þetta vandamál$_j$ hafa$_{inf}$ neytt okkur$_k$ til [að PRO$_k$ leysa$_{inf}$ sig$_j$]].
John said this problem have forced us to to solve SIG
'John said this problem to have forced us to solve SIG.'
b. ??Þetta vandamál$_j$ var sagt [t$_j$ hafa$_{(inf.)}$ neytt okkur$_k$ til [að PRO$_k$ leysa$_{inf}$ sig$_j$]].
this problem was said have forced us to solve SIG
'This problem was said to have forced us to solve SIG.'

The sentences in (iii) are perfect, however:

(iii) a. Jón sagði [þetta vandamál$_i$ hafa minnt á sig$_i$].
John said this problem have reminded of SIG
b. Þetta vandamál$_i$ var sagt [t$_i$ hafa minnt á sig$_i$].
this problem was said have reminded of SIG

Further discussion will be left to another occasion.

14 Note, that even in these cases appearances may be deceptive, since binding is only allowed under the reading where *every boy* also scopes over *mother*, which is compatible with an adjunction structure, such that under a definition of c-command that reflects the segment–category distinction *every boy* does c-command *him* (see Reuland 1998 for discussion).

15 Locally bound *sig* does not allow a strict reading. This is illustrated in (i):

(i) Jón$_i$ rakaði sig$_i$ og Pétur$_j$ gerði það líka.
'John shaved SIG and Peter did so too.'
=/= Peter shaved John.

Yet in the long-distance infinitive case both readings are possible:

(ii) Jón$_i$ skipaði prófessornum$_j$ [að PRO$_j$ fella$_{inf}$ sig$_i$ á prófinu] og Ari gerði það líka.
'John ordered the professor to fail SIG on the test and Ari did so too.'
a. = Ari ordered the professor to fail Ari on the test.
b. = Ari ordered the professor to fail John on the test.

This may indicate that what forces the sloppy reading in (i) is not a property of the antecedent–anaphor relation, but a property of the predicate. In (i) the copied predicate is intrinsically reflexive, whereas (ii) has no reflexive predicate (see Sigurjónsdóttir 1993) for discussion of intrinsic reflexives in Icelandic).

16 According to Reinhart and Reuland (1991) *sig* is, therefore, covertly moved to I/AgrS. In this position, it is proposed, it not only copies the phi-features from Agr, but also the index that Agr receives by agreement with the subject. Hence the subject orientation of this type of anaphor.

17 For relevant discussion see Sigurðsson (2004).

6 Arguments of modals
7 Conclusion

1 Introduction

Reference to non-overt arguments has been made in the description of a wide range of syntactic phenomena. Some of them (PRO, *pro*, A/A'-traces) are relatively well understood and there exists a certain consensus regarding their analysis. There is another class of non-overt arguments, often referred to as implicit arguments, for which no such consensus prevails. Implicit arguments do not seem to form a unified class. To appreciate this, let us examine some cases which have been argued to involve implicit arguments:

(1) **Implicit arguments of passives (vs. middles and unaccusatives):**
  a. This ship was sunk [PRO to collect the insurance]. (passive)
  b. # This ship sank [PRO to collect the insurance]. (unaccusative)
  c. *This ship sinks easily [PRO to collect the insurance]. (middle)

(2) **Implicit arguments of nouns:**
   a. the negotiations [PRO to achieve a peaceful settlement]
   b. the use of drugs [PRO to fall asleep]
   c. the playing of the game [PRO to prove a point]

(3) **Null objects (cf. Rizzi 1986a):**
   a. Questo conduce (la gente) alla seguente conclusione.
      this leads the people to-the following conclusion
      'This leads (people) to the following conclusion.'
   b. Questo conduce (la gente) a [PRO concludere quanto segue].
      this leads the people to conclude what follows
      'This leads people to conclude what follows.'

(4) **Implicit arguments of adjectives (from Roeper 1987a):**
   a. It is necessary/*inevitable [PRO to go].
   b. It is wise/*probable [PRO to go].

(5) **The bearer of the obligation of a deontic modal:**
   a. The books can be sold [without PRO reading them].
      (from Chomsky 1982 via Williams 1985)
   b. *The books might have been sold [without PRO reading them].
      (from Kratzer 1991)

(6) **Implicit arguments of agentive suffixes (e.g., *-able*):**
   Goods are exportable [PRO to improve the economy].

The above list includes the implicit argument of a passive (section 2), the implicit argument of a noun (section 3), null objects (section 4), the implicit argument of an adjective (section 5), the bearer of the obligation argument of a deontic modal (section 6), and the implicit argument associated with agentive suffixes like *-able*.[1] What unifies this class? It is felt that all of these examples involve a missing nominal element. The evidence for this missing nominal element comes from the fact that (1–3) all involve an infinitival with a PRO subject. Something, it is argued, must be controlling these PROs. There is no NP argument in the relevant structures that could be doing so. The element held responsible for Control is the implicit argument.

In principle, null subjects (PRO, *pro*) could have been called implicit arguments, given that they are non-overt and indisputably arguments. Furthermore there have been analyses in the literature according to which PRO/*pro* are not syntactically expressed (for PRO see Partee and Bach 1980; Chierchia 1984b; Klein and Sag 1985, among others; for *pro* see Alexiadou and Anagnostopoulou 1998, etc.). However, by convention, PRO/*pro* are not grouped together with the cases of implicit arguments in (1–3). This is why in this chapter we do not discuss PRO/*pro*.

From its inception, the literature on implicit arguments has defined them as syntactically active elements that nevertheless do not occupy a syntactically projected position.[2] Consider, for example, the following definitions for implicit arguments that have been proposed in the literature:

(7) Implicit arguments are not the mysterious shadowy presences they are sometimes made out to be. They are really nothing more than the argument slots in the argument structure . . . A 'weak' theta-criterion is all that is needed to give implicit arguments, since these are nothing more than unlinked argument roles. (Williams 1985: 314)

(8) An implicit argument is a conceptual argument that is neither expressed syntactically nor bound to an argument that is expressed syntactically. (Jackendoff 1987: 409)

(9) An argument is implicit only if it is in a structural position to license a thematic PP but no thematic PP occurs. (Roeper 1987a: 274)

However, not all researchers have followed this understanding of implicit arguments. Some have proposed that what they call implicit arguments are realized as *pro* (cf. Epstein 1984; Rizzi 1986a; Borer 1998) and PRO (cf. Roeper 1987a). But even if it is assumed that all of the non-overt arguments in (1–3) are syntactically realized as *pro*/PRO, given that (1–3) are not the canonical environments for *pro*/PRO, it is justifiable to include them in a discussion of implicit arguments. By general assumption, then, the term 'implicit arguments' is reserved for those covert elements about whose syntactic representation we still have doubts.

In (1–6), we have a list of environments which have been claimed to involve implicit arguments. That these different environments have been argued to involve implicit arguments should not, by itself, be taken to indicate that they should receive a uniform analysis. It has been questioned whether some of the members of the list in (1–6) are truly implicit. For example, Baker et al. (1989) argue the passive suffix *-ed is* the agent of the passive, i.e., it is not implicit. Even if an argument is implicit, the question of how it is to be represented stays open. The implicit argument may be represented at a level of thematic structure, or as a null PRO/*pro* subject or object. In what follows, the cases in (1–6) and the analyses proposed for them will be discussed one by one. Throughout we will focus on the diagnostics that have been proposed for detecting the presence of an implicit argument. We will examine what exactly these diagnostics test.

2 Implicit arguments in passives and middles

2.1 Implicit arguments in passives

A classic case where an implicit argument has been argued to be present is that of a passive. Passives have been contrasted with unaccusatives, which in contrast to passives have been argued to not involve an implicit agent:

(10) a. The ship was sunk.
b. The ship sank. (Roeper 1987a)

Intuitively, it seems clear that the passive in (10a) has implied agency as part of its meaning while the unaccusative in (10b) does not. In case the ship sprang a leak on its own and sank, (10b) would be true but not (10a). For (10a) to be true, there must have been someone who was responsible for sinking the ship.[3]

If by implicit argument we mean a non-overt element that is nevertheless part of the interpretation of a predicate, then the facts about the interpretation of (10a) are enough to show that passives involve an implicit agent and unaccusatives do not. However, the literature on implicit arguments aims to go beyond just showing that a particular non-overt argument is part of the semantic representation. It attempts to show that implicit arguments take part in syntactic processes and that therefore implicit arguments are syntactically real. Once it is granted that implicit arguments are syntactically real, additional questions arise that pertain to the representation of these arguments.

The primary tests used to demonstrate the syntactic reality of the implicit agent of a passive are licensing of *by* phrases, the ability to control, and compatibility with adverbs like *deliberately*. The argument from *by*-phrase licensing goes as follows. Passives allow for an overt *by* phrase while unaccusative verbs do not (cf. 11). The implicit agent in the passive is taken to be responsible for this licensing:

(11) a. The ship was sunk by Bill.
b. *The ship sank by Bill. (Roeper 1987a)

Next we turn to the argument from Control. The implicit agent of a passive can control the PRO subject of a rationale clause. Unaccusatives do not have an implicit agent argument and so Control is not possible:

(12) a. *The boat sank to collect the insurance.
b. The boat was sunk to collect the insurance. (Manzini 1983a)

If we take it as given that only syntactically active elements can control PRO then it follows that the implicit agent of the passive must be syntactically real.[4]

A related point is made by the fact that adverbs like *deliberately* can appear in a passive sentence and be associated not with the syntactic subject but with the implicit agent. In contrast, in (13b) there is no implicit argument and *deliberately* can only be associated with the lone argument of *sink*, namely *the boat*. Consequently (13b) is perceived as pragmatically deviant:

(13) a. The boat was sunk deliberately.
b. # The boat sank deliberately.

If we assume that adverbs like *deliberately* can only be associated with syntactically real elements, it follows that the implicit agent of the passive is syntactically real.

The argument for the syntactic reality of implicit argument therefore rests upon our acceptance of the assumptions behind the argument from *by*-phrase licensing, the ability to control, and compatibility with adverbs like *deliberately*. We already know that passives have implicit agents as part of their semantics. It is not clear that postulating that this implicit agent is represented syntactically is necessary for explaining the possibility of *by* phrases. It may be the case that syntactically unexpressed agentivity is all that is needed for licensing a *by* phrase.

Next we turn to the argument from the acceptability of *deliberately*. Again it is not clear that anything more than the presence of an implicit agent in the semantic representation is needed. We are left with the argument from Control. The implicit argument is able to control the PRO subject of a rationale clause. So the question is whether the ability to control requires the controller to be syntactically realized.

Williams (1985) provides several arguments in support of the claim that controllers need not be syntactically realized. The first argument is based on the observation that the implicit agent of a noun like *attempt* controls the PRO subject of the complement clause in both (14a) and (14b):

(14) a. Attempts [PRO to leave]
b. Yesterday's attempts [PRO to leave]

If it is assumed that the implicit agent of *attempt* in (14a) is a PRO that occupies the position occupied by *yesterday* in (14b), we expect the PRO to be absent in (14b). However, the implicit agent of *attempt* controls the PRO subject of the infinitival clause in both (14a) and (14b). Williams (1985) takes this to suggest that the implicit agent in (14b) is able to control the subject of the infinitival clause without being syntactically realized. Williams's argument depends upon the assumption that the PRO that realizes the implicit agent would appear in the position occupied by *yesterday*. However, this is by no means a necessary assumption, given the acceptability of (15):

(15) yesterday's teachers' strike (Tom Roeper, p.c.)

If the implicit agent can be generated in a position lower than *yesterday*, both (14a) and (14b) can have implicit agents and the parallelism between (14a) and (14b) with respect to Control follows. In other words, the argument against realizing the implicit agent as a PRO subject vanishes.

Williams (1985) argues that Control of rationale clauses does not require the controller to be syntactically realized. In fact, the examples that he provides demonstrate that even the presence of an implicit argument is not necessary:

(16) Grass is green [to promote photosynthesis].
(from Williams 1974 via Williams 1985)

In (16), *grass* is not a sensible controller. *Green* does not have any implicit argument either. Instead what promotes photosynthesis is the circumstance of grass being green. Williams (1985) also points out that in the right context the ungrammatical *the boat sank in order to impress the king* becomes acceptable. Consider a situation where a playwright is rationalizing the design of his play and utters:

(17) The boat sank in order to impress the queen and move her to murder her husband by the end of Act iii. (from Williams 1985)

Since Williams's examples show that the PRO subjects of rationale clauses can be controlled even in the absence of any implicit argument, the proposal that all controllers must be syntactically realized is weakened.

2.2 Implicit arguments in middles

The contrast between passives and unaccusatives carries over to middles. Middles are incompatible with overt *by* phrases:

(18) a. Bureaucrats were bribed by managers.
b. *Bureaucrats bribe easily by managers.
(Keyser and Roeper 1984: 406, ex. 75)

Either they lack an implicit agent argument, or the implicit argument of a middle is unable to control the understood subject of a rationale clause or a subject-oriented adverb:

(19) a. This bureaucrat was bribed [PRO to avoid the draft].
b. *This bureaucrat bribes easily [PRO to avoid the draft].
(Baker et al. 1989)

(20) a. This bureaucrat was bribed deliberately.
b. *This bureaucrat bribes deliberately. (Baker et al. 1989)

Despite these tests, the English middle construction has been assumed to involve an implicit agent. For example, Fiengo (1980), Condoravdi (1989), Fagan (1992), Zribi-Hertz (1993), and Ackema and Schoorlemmer (1995) argue that the implicit agent of the middle is present at a (lexical)-semantic level, while Stroik (1992a) and Hoekstra and Roberts (1993b) propose that the agent of the middle is syntactically realized. Of course any theory which proposes that an agent is present in middles needs to provide an account of why middles fail the tests for agentivity shown in (18–20), all of which the implicit agent of the passive passes.

There are several reasons that have been advanced for assuming that middles involve an implicit agent. The first is the contrast in meaning that is perceived between (21a, b):

(21) a. The clothes hang easily. (from Keyser and Roeper 1984)
b. The clothes are hanging on the line. (from Marantz 1981)

Keyser and Roeper (1984) observe that (21a) implies that it is easy for someone to hang clothes, whereas there is absolutely no implied agent in the unaccusative (21b).[5]

The second reason for postulating an implicit agent in the middle is that even though middles do not license *by* phrases, they can contain a *for*-PP whose argument seems to be identical to the agent of the middle verb:

(22) a. French books read easily for educated people.
b. Latin texts do not translate easily for Bill.

The licensing of agentive *for*-PPs has been used to argue for the syntactic presence of an agent in the middle. For Stroik (1992a), the *for*-phrase is an overt realization of the agent argument that for him is always syntactically present in the middle as PRO.

The third argument for agentivity comes from the incompatibility of middles with a phrase like *all by itself*:

(23) a. *This kind of bread cuts easily all by itself.
b. *This wood carves easily all by itself.
c. *This ice crushes easily all by itself.

The ungrammaticality of (23a–c) has been used by Keyser and Roeper (1984) and Fagan (1992) as an argument in favor of the middle's agentivity.

However, Rapoport (1999a) challenges the conclusion that the middle necessarily involves agentivity, noting that the above tests for agentivity do not hold for all middles. As Ackema and Schoorlemmer (1995) noted, not all middles allow for *for*-phrases:

(24) a. These books don't sell (*for the average shopkeeper).[6]
b. (On shoe chest:) Stows on floor or shelf (*for tidy people).

Rapoport (1999a) further points out that many middles are in fact compatible with *all by itself*:

(25) a. This kind of glass breaks easily all by itself.
b. Milk chocolate melts smoothly all by itself.
c. These heavy windows open easily all by themselves.
d. These comic books sell (easily) all by themselves.

Rapoport (1999a) therefore concludes that middles do not have an implicit agent. The fact that the implicit agent of the middle is syntactically inactive (cf. 18–20) receives a very natural explanation under Rapoport's (1999a) proposal – there

simply isn't an implicit agent in the English middle. The English middle is not inherently agentive.

The licensing of *for*-phrases in (22) and the unacceptability of *all by itself* with certain middles in (23) are related by Rapoport (1999a) to the Instrumental/Manner (I/M) component in the meanings of certain verbs. Inherent in the meaning of *cut*, *carve*, and *crush*, the verbs in (23), is the means or manner involved in the action described by the verb (the I/M component). Rapoport argues that the I/M component brings along with it an implication of a proto-agent and this implication is responsible for the agentivity effects discussed above. Not all verbs have an I/M component as part of their meaning, and with such verbs there is no agentivity effect (cf. 24, 25).

To sum up, we do not need to postulate an implicit agent in middles across the board. Some middles don't have any agentivity effects, and the agentivity effects in the one that do can be accounted for without postulating an implicit argument.

Rapoport's conclusions, however, can be challenged on the following grounds. The predicates which demonstrate the absence of agentivity (cf. 18–20) also have unaccusative counterparts. This makes it possible to analyze (18–20) not as middles but as generic unaccusatives.[7]

3 Implicit arguments of nouns

One argument for the syntactic visibility of implicit arguments of nouns comes from the fact that they participate in Binding Theory.

(26) a. **Condition A:**
Respect for oneself is important. (from Williams 1985)
b. **Condition B:**
Admiration of him (*admirer* ≠ *admiree*) (from Williams 1985)
c. **Condition C:**
The realization that John was unpopular (*realizer* ≠ *John*)
(from Ross 1969c via Williams 1987b)

A natural way to account for the syntactic visibility of implicit arguments involves projecting them syntactically as PRO subjects. If we do that, the Binding effects in (26) follow directly. In addition to participating in Binding, implicit arguments are also able to control and be controlled/bound themselves (cf. 27a, b respectively):

(27) a. The attempt [PRO to leave] (*attempter* controls the PRO)
b. John made an attempt [PRO to leave]. (*John* is the attempter.)

Williams (1985, 1987b) notes that the Binding and Control judgments stay unchanged even if the noun in question has an overt NP in its specifier position:

(28) a. Yesterday's attempt [PRO to leave] (*attempter = leaver*)
b. Yesterday's decision [that John was the best candidate] (*decider ≠ John*)

Williams assumes that a PRO agent would occupy the position occupied by *yesterday's*. Thus a PRO should be blocked in (28a, b). Since the Binding and Control judgments stay unchanged, Williams argues that Binding and Control do not require a syntactically projected NP. He proposes that non-syntactically projected implicit arguments are also visible to Binding and Control. Non-syntactically projected implicit arguments are made visible to syntax by statements like the following:

(29) For *attempt*, and similar nouns, the Agent controls (or is associated with) the subject of the embedded clause. (Williams 1985: 302, ex. 14)

(30) An implicit argument c-commands X if the verb (or noun) of which it is an implicit argument c-commands X.
If an implicit argument is coindexed with X and c-commands X, then it binds X. (Williams 1985: 303, ex. 17)

The result of these statements is that the Binding and Control effects discussed above follow naturally.

With his system, Williams (1985) is able to derive the fact that Condition C effects surface with respect to all the implicit arguments of triadic predicates:

(31) a. *The promise that John would win was made to him yesterday.
b. *The promise that John would win was made by him yesterday.

Since Williams (1985) is arguing against a PRO subject of NP, he takes the facts in (31) to correctly show that just syntactically representing the agent is inadequate. This is so because in (31a) the Condition C effect is triggered by the goal-implicit argument and not by the agent-implicit argument. Then Williams goes on to conclude that the implicit agent should not be syntactically represented at all. This latter move is not forced by the facts. The facts are equally compatible with the syntactic projection of the implicit arguments of *promise* as null pronouns. Both the subject and direct object of *promise* would c-command into the complement of *promise* and yield the observed Condition C effects.

Moreover, Williams's conclusion that implicit arguments are not syntactically projected is based on the assumption that an agent projected as PRO would necessarily be occupying the location occupied by *yesterday's*, which is presumably [Spec, DP]. If we assume, as is plausible, that the agent projected as PRO could occupy the [Spec, NP] position (assuming that PRO needs no case), then the facts in (28) do not come as a surprise and Williams's argument against the syntactic projection of implicit arguments is defused. To be sure, the facts are compatible with Williams's proposal. They are also, however, compatible with the syntactic projection of implicit arguments as null pronouns.

3.1 Optionality of implicit arguments of nouns

The treatment of anaphors within NPs in Chomsky (1986b) assumes that NPs have implicit agents that are projected as subjects which are visible for the Binding Theory:

(32) a. They$_i$ told [$_{NP}$ stories about each other$_i$].
b. *They$_i$ told [$_{NP}$ my stories about each other$_i$].
c. *They$_i$ told [$_{NP}$ stories about them$_i$].
d. They$_i$ told [$_{NP}$ my stories about them$_i$]. (Chomsky 1986b: 166)

(33) a. They$_i$ heard [$_{NP}$ stories about each other$_i$].
b. *They$_i$ heard [$_{NP}$ my stories about each other$_i$].
c. They$_i$ heard [$_{NP}$ stories about them$_i$].
d. They$_i$ heard [$_{NP}$ my stories about them$_i$]. (Chomsky 1986b: 166)

Chomsky (1986b) argues that the object of *tell* and *hear* in (32, 33a, c) has an implicit subject on a parallel with the overt subject in (32, 33b, d). Since there is an overt subject in the object of *tell* and *hear* in (32, 33b, d), the object constitutes the Binding domain of the anaphor/pronoun. (32, 33b) are ruled out because the anaphors are not bound in their Binding domain and (32, 33b) are acceptable because the pronouns are free in their Binding domain.

(32, 33a) by themselves are compatible with there being an implicit subject in the *story* NP bound by the matrix subject and the anaphor bound by this implicit subject, or with there being no implicit subject and the Binding domain of the anaphor being large enough to include the matrix subject, which is its binder. The relevant evidence in favor of postulating an implicit subject comes from the contrast between (32c) and (33c).

The verbs *tell* and *hear* differ in how they combine semantically with their object *story*. Consider the contrast in interpretation between (34a) and (34b):

(34) a. John told [stories about Mary].
b. John heard [stories about Mary].

In (34a), the subject of *tell* has to be interpreted as the 'agent'/narrator of the story. It is claimed that there is no such requirement in (34b). The process by which the implicit arguments of a noun receive their interpretation will be discussed in section 3.2. For now, we can represent the difference between *tell* and *hear* by stipulating that the 'agent'/narrator argument of the complement of *tell* must be the same as the agent of *tell*. *Hear* does not bring in such a requirement. This is shown in (35):

(35) a. John$_i$ told [IMP$_{i/*j}$ stories about Mary].
b. John$_i$ heard [IMP$_{i/j}$ stories about Mary].

The contrast between (32c) and (33c), repeated below in (36), now follows.

(36) a. They$_i$ told [IMP$_{*i/*j}$ stories about them$_i$]. (IMP$_i$ is ruled out by Condition B; IMP$_j$ is ruled out by *tell*.)
b. They$_i$ heard [IMP$_{j/*i}$ stories about them$_i$]. (IMP$_i$ is ruled out by Condition B; IMP$_j$ is allowed by *hear*.)

The presence of the implicit argument as the subject in (36a, b) makes the object NP become the Binding domain for *them*. Since in (36a), the implicit argument is obligatorily coreferent with the matrix subject, we have a violation of Condition B in (36a). Since *hear* in (36b) does not require obligatory coreference, (36b) has a representation where the 'agent'/narrator of the story is different from the subject of *hear*. This representation does not trigger a violation of Condition B. Condition B is still relevant for (36b) – it blocks the interpretation of (36b) where the hearers are the narrators.[8]

Let us now re-examine the analysis of anaphors inside the NP complements of anaphors in (32, 33a), repeated here as (37a, b):

(37) a. They$_i$ told [IMP$_{i/*j}$ stories about each other$_i$].
b. They$_i$ heard [IMP$_{i/*j}$ stories about each other$_i$].

The analysis makes the right predictions concerning the grammaticality of (37a, b). However, it seems to make the wrong prediction concerning the interpretation of (37b). As Williams (1985) notes, the representation in (37b) suggests that *each other* can be bound by *they* only if *they* also bound the 'agent'/narrator argument of *story*. This seems wrong, since it seems possible for *they* to bind *each other* even when someone other than *they* are narrating the stories.

For this reason, Chomsky (1986b) concludes that the presence of implicit arguments as subjects is optional. The optionality of implicit arguments needs to be further constrained. The presence of implicit arguments as subjects cannot be optional everywhere. If we assume full optionality, we lose our explanations for cases like the following:

(38) a. *They$_i$ told [IMP$_i$ stories about them$_i$]. (Condition B)
b. *The IMP$_i$ realization [that John$_i$ was sick] upset him$_i$. (Condition C)

A possible line of attack is to assume that implicit arguments are obligatorily present in nominal complements when the semantics of the embedding verb requires them (as in (38a), discussed in section 3.2) and in nominalizations (as in 38b). In other circumstances, as is the case with *hear*, we could assume either optionality or even complete absence of the implicit agent of the noun.

3.2 Control of implicit arguments of nouns

We have seen evidence that implicit arguments participate in Binding and Control. This evidence shows that the implicit agent of a passive and of certain noun

phrases can control PRO subjects. We also saw that the implicit arguments of nouns were subject to the Binding Theory. Next we see that not only can implicit arguments of nouns bind/control, they can also be bound/controlled. We also see that the implicit agent of a passive differs from the implicit arguments of nouns in that it cannot be bound/controlled.

Williams (1985) discusses a set of facts which show that the Binding/Control of implicit arguments differs considerably from the Control of PRO subjects of infinitival clauses. We know that depending upon the verb, we can have either subject or object control:

(39) a. Gillian persuaded Stuart$_i$ [PRO$_i$ to leave]. (*Persuade* is an object control verb.)
b. Gillian$_i$ promised Stuart [PRO$_i$ to leave]. (*Promise* is a subject control verb.)

The choice depending upon the verb is which argument of the verb will control the PRO subject of the infinitival clause. There is no choice regarding what is controlled, which is always the PRO subject. Control of implicit arguments of nouns displays a markedly different pattern:

(40) a. John made an attempt to leave. (*John* is agent of *attempt*.)
b. John took a picture of Mary. (*John* is maker of *picture*.)
c. John performed an operation on Harry. (*John* is agent of *operation*.)
d. Mary underwent an operation. (*Mary* is theme and not agent of *operation*.)

While in (40a–c), the matrix subject controls/binds the implicit agent of *attempt/picture/operation* respectively, in (40d), the matrix subject controls/binds the implicit theme of *operation*. The difference clearly lies in the meaning of *undergo* vs. *make/take/perform*.[9]

As discussed above, this kind of choice concerning what is controlled is not found in cases where it is the subject of an infinitival clause that is being controlled.

Control of implicit arguments of nouns also allows for so-called double Control, as in (41):

(41) Mary gave John a kick. (*Mary* is the agent and *John* the patient of *kick*.)

The existence of a choice concerning what is controlled (cf. 40) and the possibility of double Control (cf. 41) has been argued by Williams (1985) to show that implicit arguments should not be realized as PRO subjects. We think that these facts are actually agnostic about the issue of syntactic projection.

To see this, let us examine how Williams derives the contrast between (40c) and (40d):

(42) a. John performed an operation on Harry. (Agent of *perform* must be the same as the agent of its theme.)
b. Mary underwent an operation. (Agent of *undergo* must be the same as the patient of its theme.)

Williams proposes that verbs can specify associations between arguments and their argument structures. Thus *perform* takes two arguments, an agent and an event, and requires that its agent be the agent of the event which is its complement. *Undergo* also takes an agent and an event, but it identifies its agent with the patient of its complement event. Clearly every theory needs to specify such associations.

Now let us also assume that all the implicit arguments of *operation* are syntactically projected as null pronouns. For *operation* to successfully appear with *perform* and *undergo*, its agent and theme arguments will have to be identified with the agent of *perform* and *undergo* respectively. We do not take Williams's arguments as having demonstrated that the implicit arguments are not syntactically projected. The question of whether these implicit arguments are syntactically projected stays unresolved. Note also that the possibility of double Control, as in *Mary gave John a kick*, is not problematic once we recognize that the process by which the implicit arguments of *kick* are associated with the arguments of *give* is not a syntactic process along the lines of PRO-Control.

3.3 Differences between implicit arguments of nouns and passives

3.3.1 Controlling implicit arguments of passives

Unlike the implicit arguments of nouns, which can be bound/controlled by c-commanding NPs, the implicit agent of a passive seems to be resistant to being bound by a c-commanding NP. Baker et al. (1989) note that the implicit argument of a passive cannot be interpreted as coreferential with the syntactic subject of the passive. Thus (43) is not equivalent to (44) under any interpretation:

(43) a. They were killed.
b. They were admired.

(44) a. They committed suicide.
b. They admired themselves.

This point is further demonstrated by (45), where the *by* phrase is bound by the syntactic subject of the passive. Since the *by* phrase is co-indexed with the implicit argument of the passive, this forces the implicit argument of the passive to be co-indexed with the syntactic subject of the passive. This in turn is responsible for the ungrammaticality of (45):

(45) * They$_i$ were killed by themselves$_i$.

For Baker et al. (1989), the implicit agent of the passive is overtly realized by *-ed*. Therefore if the syntactic subject of the passive were to be co-indexed with the agent, we would have the following configuration:

(46) They$_i$ . . . -ed$_i$ . . . t$_i$ (where *they* c-commands *-ed* and *-ed* c-commands the t$_i$)

Baker et al. (1989) argue that the configuration in (46) is to be ruled out. It seems, though, that the facts are more general. The implicit agent of the passive cannot be taken as referring to any c-commanding NP. This point is made by (47), where we find a disjoint reference effect even though there is no crossover:

(47) John wants Mary to be seen. (Williams 1987b)

As Williams (1987b) notes, the implicit agent of the passive is disjoint from *John*, or at the very least is vague in the same way as *John wants Mary to be seen by somebody* is. Neither sentence can mean *John wants to see Mary*. Williams's (1987b) suggestion is that the implicit agent of the passive is existentially quantified over. Consequently it cannot be bound by a c-commanding NP and acts like an R-expression for the purposes of Binding Theory.

Williams (1987b) argues that passive implicit arguments differ from other implicit arguments in that passive implicit arguments cannot be controlled/bound. This intuition is developed and made explicit in independent work by Lasersohn (1997). Lasersohn (1997) notes that implicit arguments come in at least two distinct types, existentially quantified (as in 48a) and deictic (as in 48b, c):

(48) a. John was killed. ($\approx \exists x$ kill(x,J))
b. John is stronger. ($\neq \exists x$ stronger-than(J,x))
c. John arrived. ($\neq \exists l$ arrive(J,l))

Lasersohn (1997) notes that existential quantification seems to represent the semantics of the passive quite well. However, existential quantification seems to give very weak truth-conditions for (48b). For (48b) to be true, John must be stronger than some contextually salient person. It is not enough that he be stronger than someone. Similarly, Lasersohn notes that (48c) doesn't just mean that John arrived *somewhere*. It means that he arrived at the pragmatically relevant location.[10]

3.3.2 *Differences in Control by implicit arguments of nouns and passives*

That an implicit agent of a noun is able to control the PRO subject of the infinitival complement of the noun is uncontroversial:

(49) the attempt [PRO to leave] (*attempter* = *leaver*)

We have also seen instances where implicit arguments seem to control the PRO subjects of infinitival adjuncts:

(50) a. The destruction of the city [PRO to impress the general] (*destroyer* = *impresser*)
b. The game was played nude.

There is disagreement in the literature concerning whether (50) involves Control of the PRO subject by the implicit argument or whether it involves some other mechanism. Roeper (1987a) argues for the former position. In support of his position, Roeper (1987a) notes the contrast in (51):

(51) a. *The boat sank to impress the king.
b. The boat was sunk to impress the king.

The unacceptability of (51a) and the acceptability of (51b) are correlated by Roeper (1987a) with the availability of a potential controller in (51b) in the form of the implicit agent of the passive. No such implicit agent is available in (51a) and hence the former is unacceptable.

Roeper (1987a) offers another set of examples that argue more specifically for a particular syntactic representation of the implicit argument:

(52) a. The destruction of the boat to collect the insurance.
b. *The boat's destruction to collect the insurance.

Roeper argues that in (52a) the implicit agent of *destruction* occupies a position from which it can control the PRO subject of the infinitival adjunct. He takes the presence of *the boat's* in (52b) as blocking the implicit agent from appearing in the position where it appears in (52a). Therefore the implicit agent is not able to control the PRO subject of the infinitival adjunct.

Roeper's account for the ungrammaticality of (52b) leaves unexplained why (53) is grammatical:

(53) Yesterday's attempt [PRO to leave]

Williams (1985) suggests that whatever blocks the implicit argument from being syntactically projected in (52b) should also block it from being syntactically projected in (53). Yet Control by the implicit argument is possible in (53).

For this reason among others, Williams (1985) argues against a uniform analysis of the examples in (54):

(54) a. The attempt [PRO to leave] (Control into a complement)
b. The destruction of the city [PRO to impress the general] (Control into an adjunct)

Williams (1985) argues that only the PRO in (54a) is controlled by the implicit argument of *attempt*. The PRO in the adjunct clause in (54b) is controlled by other mechanisms. The theoretical motivation for doing so is that for Williams, implicit

arguments are invisible beyond the first projection of their predicate. Thus while the implicit agent of *attempt* is visible to the infinitival complement, the implicit agent of *destruction* is not visible to the infinitival adjunct.

The empirical motivation comes from examples like (55), which show that the implicit agent of a passive is not always able to control the PRO subjects of infinitival adjuncts:

(55) a. *The boat was sunk [PRO to become a hero]. (Lasnik, p.c., via Williams 1985)
b. *Mary was arrested [PRO to indict Bill]. (Williams 1974)
c. *The game was played [PRO mad at Bill]. (Williams 1985)

If the two kinds of Control seen in (54) are handled by the same mechanism, then Williams argues that it is not clear why the implicit argument is unable to control PRO in (55). Therefore Williams provides an alternative account according to which the controller of the PRO in (56) is not the implicit agent of the passive:

(56) a. The game was played [PRO nude].
b. The ship was sunk [PRO to impress the general].
c. The boat was destroyed [PRO to collect the insurance].

He proposes that the controller of the PRO in (56a) is the subject *the game* and not the implicit agent of the passive. The predicate *nude* is predicated of *the game*. Williams suggests that this is plausible since "one may call a game nude if it is played by nude people" (p. 309). If we modify the adjunct predicate suitably to make such a predication unreasonable, the sentence becomes unacceptable. This is why (55c) is ungrammatical. While nudity can be derivatively predicated of a game, the property of being mad at Bill cannot be.[11]

This leaves us with (56b, c). In (56b), the inanimate subject *the ship* cannot be the agent of the infinitival adjunct. Here Williams suggests that the entire clause controls the subject of the infinitival adjunct. He refers to this kind of Control as S-Control. The entire clause *the ship was sunk* controls the PRO in the infinitival adjunct – it is the fact that the ship is sunk which is to impress the general. Similarly, Williams relates the acceptability of (56c) to the (marginal) acceptability of *That will collect you some insurance*. The ungrammaticality of (55a, b) is related by Williams to the incoherence of the boat's sinking becoming a hero and Mary's arrest indicting Bill.

On a parallel with S-Control, Williams suggests that cases of apparent Control of the subject of an infinitival adjunct by the implicit agent of a noun be analyzed as involving N'-Control:

(57) [the $[_{N'}$ destruction of the boat]$_i$ [PRO$_i$ to impress the general]]

The ungrammaticality of **the boat's destruction to impress the general* is analyzed by Williams in terms of the attachment site of the infinitival adjunct. The infinitival

adjunct, Williams assumes, must be attached in an NP-internal position. As a result, *the boat's destruction* cannot serve as a controller because under the relevant structure, it does not even form a constituent:

(58) *[[the boat's] [$_{N'}$ [$_{N'}$ destruction] [PRO to impress the general]]]

Williams does not indicate why *destruction* by itself cannot control the PRO.

The initial examples in (51) that were taken to demonstrate the role of implicit arguments in controlling the PRO subjects of infinitival adjuncts are argued by Williams to demonstrate not the role of implicit arguments but the presence of a purposeful agent. He offers (16), repeated here as (59a), where there is no obvious implicit argument, and (17), repeated here as (59b), which shows that the unacceptable (51b) becomes acceptable given the right context:

(59) a. Grass is green [PRO to promote photosynthesis].
b. The boat sank in order to impress the queen and move her to murder her husband by the end of Act III.

As for why the ergative *sink* requires an elaborate context to participate in (apparent) Control, Williams suggests that this is so because the use of the ergative *sink* strongly implies that there is no theta-theoretic agent for *sink*. Hence to make (51b) acceptable we need a context where the absence of a theta-theoretic agent does not contradict the existence of a purposeful agent. These requirements are satisfied in (59b), but not in (51a).

Williams (1985) is able to provide an explanation for a puzzling contrast noted in Chomsky (1982: 46):

(60) a. *The books were sold without PRO reading them.
b. The books can be sold without PRO reading them.

(60a) is ungrammatical because the event of book-selling cannot serve as the controller of the PRO subject of the infinitival adjunct. Why then is (60b) grammatical? Williams suggests that *can* has an implicit argument and that the *without* clause is an argument of the modal *can*. Therefore the implicit argument of *can* is able to control the PRO subject of the *without* clause. It is able to do so because the *without* clause in (60b) is the complement of *can* and not an adjunct clause as in (60a).

The above generalizations notwithstanding, it is worth noting that the constraints on Control into adjuncts by implicit (and even overt) arguments are poorly understood. A number of additional factors enter into the picture that influence whether an implicit argument is able to control into the adjunct. A nonexhaustive list of relevant factors includes:

- the role of modality (see section 6);
- the location of the theme (e.g., **the boat's destruction to collect the insurance* vs. *the destruction of the boat to collect the insurance*; see Roeper 1987a);

- the nature of the rationale clause (e.g., *the ship was sunk to collect the insurance* vs. *??the ship was sunk to become a hero* vs. **the vote was taken to be elected president*; see Roeper 1987a);
- the +/–human nature of the implicit argument and the overt subject (*The stairs were washed before entering the apartment*, where the 'washer' must be +human, and not –human like rain, and controls the adjunct clause, vs. *Mary was washed before entering the apartment*, where both the +human washer and Mary are potential controllers; see Manzini 1986a; Kawasaki 1993; Landau 2001);
- the need for a discourse topic, which can remove the requirement for a grammatically represented controller altogether:

(61) a. After collecting some money, a bank account was opened by the/ *a businessman.
b. After pitching the tents, darkness fell quickly.
(from Kawasaki 1993 via Landau 2001)

Williams's photosynthesis cases can be seen as a limiting case of the factors discussed above. Because of these confounds, the import of the data concerning Control by implicit arguments into infinitival adjuncts remains unclear.

4 Null objects

In the introduction, we discussed the question of what non-overt arguments would be covered in our discussion of implicit arguments. In particular, we decided not to cover the silent subjects of non-finite clauses. This was because we assume that the subjects of non-finite clauses are actually syntactically projected (possibly due to the Extended Projection Principle) and realized as PRO. The question then arises of how null objects like in (62) are to be analyzed:

(62) a. This leads (people) to the following conclusion.
b. Italian:
Questo conduce (la gente) alla seguente conclusione.
this leads the people to-the following conclusion
'This leads (people) to the following conclusion.'
(from Rizzi 1986a)

Given the projection principle one might conclude that in both (62a) and (62b), the null object is syntactically projected and occupied by some null pronominal element. However, Rizzi (1986a) provides several arguments against giving the English (62a) and the Italian (62b) a uniform analysis. The primary theoretical motivation for providing a non-uniform analysis for null objects in English and Italian comes from the fact that English does not seem to have *pro*, the kind of null pronominal that could serve as a null object. In contrast, Italian is known to

be a null-subject language; i.e., it has *pro*, at least in the subject position of finite clauses, and it is plausible that *pro* can also appear in other case-marked positions.

The empirical motivation comes from the fact that null objects in Italian, in contrast to null objects in English, seem to be syntactically active. They can control, bind, and be modified by adjuncts, while null objects in English seem to be able to do none of the above.

We have already seen in (62a) that certain verbs in English do not require overt realization of the object. (63a) shows that if there is an infinitival clause with a PRO subject, then the object needs to be overt. In other words, the null/implicit object cannot serve as a controller. This is, of course, an instantiation of Bach's Generalization that object controllers in English cannot be omitted (see Bach 1979; Bresnan 1982a):[12]

(63) a. English:
  i. This leads people [PRO to conclude what follows].
  ii. *This leads [PRO to conclude what follows].
  b. Italian:
  i. Questo conduce (la gente) alla seguente conclusione.
  this leads the people to-the following conclusion
  'This leads (people) to the following conclusion.'
  ii. Questo conduce (la gente) a [PRO concludere quanto segue].
  this leads the people to conclude what follows
  'This leads people to conclude what follows.' (from Rizzi 1986a)

In Italian, as (63bii) shows, an object controller can be omitted. Null objects in Italian can bind reflexive pronouns, as shown by (64):

(64) a. La buona musica riconcilia ___ con se stessi.
  the good music reconciles with oneself
  'Good music reconciles one with oneself.'
  b. Un bravo psicanalista puó restituire ___ a se stessi.
  a good psychoanalyst can give back oneself
  'A good psychoanalyst can give one back to oneself.'
  (from Rizzi 1986a)

The third diagnostic for the syntactic activeness of null objects in Italian is that they can be modified by adjunct small clauses (cf. 65):

(65) a. Di solito, Gianni fotografa ___ seduti.
  in general Gianni photographs seated.Pl
  'In general, Gianni photographs one (when one is) seated.'
  b. Di solito, quel famoso pittore ritrae ___ vestiti di bianco
  in general that famous painter portrays dressed.Pl in white
  'In general, that famous painter portrays one (when one is) dressed in white.' (from Rizzi 1986a)

There is also a difference in the productivity of the null-object option in English and Italian. In English, the possibility of omitting the object seems highly restricted and subject to seemingly idiosyncratic restrictions. For example, the verb *incite* allows for its object to be omitted while the nearly synonymous *push* (cf. 66) does not:

(66) a. ?An unpopular law can incite ___ against the government.
b. *An unpopular law can push ___ against the government.

In Italian, in contrast, null objects with *arb* interpretation seem to be generally available in generic contexts across a wide range of verbs.

The above differences between English and Italian with respect to the omission of the object lead Rizzi (1986a) to conclude that in Italian, an omitted object is syntactically projected and realized as a *pro*, while in English, an omitted object is not syntactically projected. Instead it is realized as an implicit argument. Rizzi (1986a) assumes that arguments can be lexically saturated, and suggests a modification of the Projection Principle according to which only lexically unsaturated arguments need to be syntactically projected (see also Manzini 1992b). For Rizzi, Italian therefore does not constitute a violation of Bach's Generalization that object controllers cannot be omitted, because in Italian, they are not omitted. They are just realized as *pro*. A background assumption here is that the implicit argument corresponding to the omitted object cannot serve as a controller. In not being able to serve as a controller, the implicit argument corresponding to the omitted object differs from the implicit arguments of passives (section 2) and nouns (section 3).

The absence of syntactically realized null objects in English seems to be a relatively recent phenomenon. Visser (1969) notes that (as in Italian) in Old English, Middle English, and Early Modern English, arbitrary null objects could function as controllers (examples from Visser 1969 via Rizzi 1986a):

(67) a. thet uerste . . . *somoneth to worthsipie* god (1340, *Ayenbite of Inwit*)
b. When he *commaunded to receiue* the man . . . into the church again, in what church *commaunded* he *to receiue* him? (1532–1533, Thomas More, *Works*)
c. I then *advised to fly.* (1725, Alexander Pope, *Odyssey*)

5 Implicit arguments of evaluative predicates

Evaluative predicates have been argued to have implicit arguments. The evidence for the presence of implicit arguments comes from the interpretation of the infinitival complements of evaluative predicates like *fun*:

(68) It is fun [PRO_{arb} to play basketball].

Epstein (1984) notes that the interpretation of (68) is (69a) and not (69b):

(69) a. $\forall x$ It is fun for x [x to play basketball]. (For everyone it is the case that if they play basketball, it is fun for them.)
b. It is fun $\forall x$ [x to play basketball]. (If everyone plays basketball, it is fun.)

The fact that (68) can only mean (69a) and not (69b) reveals that the PRO_{arb} in (68) is not an instance of uncontrolled PRO. Instead it is controlled by a non-overt benefactive/experiencer argument of *fun* (see also Safir 1991). (70) shows that this implicit argument of *fun* can also be overtly realized:

(70) It is fun **for Lucy** [for Joe to play basketball]. (Epstein 1984: ex. 9)

Epstein (1984) assumes that the implicit argument of the evaluative adjective is syntactically projected as a null pronoun *pro*. He proposes that this *pro* is very similar in interpretation to the pro_{arb} discussed for Spanish in Suñer (1983). Spanish, in contrast to English, is a *pro*-drop language. Bhatt and Izvorski (1998) develop Epstein's basic insight and reduce several instances of 'uncontrolled' PRO to instances of Control by an implicit argument. They provide further evidence for the role played by the implicit argument in the Control of the PRO subject of the infinitival clause. PRO without an overt controller is only found in the complement of an adjective if the adjective allows for an implicit argument:

(71) a. [PRO to dance] is fun.
b. *[PRO to dance] is uncertain/unlikely.
(from Bhatt and Izvorski 1998)

Fun allows for an implicit argument which specifies who something is fun for. *Uncertain/unlikely* lack such an argument. They do not allow us to express who something is unlikely/uncertain for. (71b) is ruled out because, unlike *fun* in (71a), *uncertain/unlikely* do not have an implicit argument that could serve as a controller.

Bhatt and Izvorski (1998) further point out that the quantificational force/arbitrary nature of PRO_{arb} does not need to be stipulated. Instead, they propose the quantificational force comes from the presence of genericity. Evidence comes from the fact that 'uncontrolled' PRO does not always have a universal/arbitrary (= *arb*) interpretation. The *arb* interpretation is only available in generic environments. In episodic environments, the 'uncontrolled' PRO picks its interpretation from the local context:

(72) a. It is difficult [PRO_{arb} to dance the dance].
b. This morning, it was difficult [PRO to dance the tango] since the floor was slippery and we were all hungover.

In (72a, b), the PRO is controlled by the implicit argument of *difficult*. However, in (72a), the implicit argument is bound by a generic operator, and this is why the PRO in (72a) has an *arb* interpretation. (72b) receives an episodic interpretation and there is no a generic operator to bind the implicit argument. Consequently the implicit argument picks up its reference from the local discourse context. This is part of the general context-sensitivity of implicit arguments. See Condoravdi and Gawron (1996) for details.

There are locality constraints on the relation between the implicit argument and the PRO it controls. The implicit argument that controls the PRO needs to be in the immediately higher predicate. This is shown by the contrast in (73):

(73) a. *It is easy to be likely to dance the tango.
b. It is likely to be easy to dance the tango.
(from Bhatt and Izvorski 1998)

In (73b), the implicit argument of *easy* can act as a local controller. In (73a), however, the implicit argument of *easy* is unable to act as a controller for the PRO because of the intervening predicate *likely*, which does not provide a controller. On the basis of the above data, Bhatt and Izvorski (1998) conclude that PRO can receive an *arb* interpretation iff there is a generically bound implicit argument in the immediately higher predicate.

6 Arguments of modals

Since Ross (1969a), Perlmutter (1971), Jackendoff (1972), and Kratzer (1991), among many others, we have known that modals fall into two two classes with respect to whether or not they have a non-propositional argument, which has sometimes been called their external argument. Epistemic modals are semantically monadic; they only take a proposition as an argument. In contrast, deontic modals may be semantically monadic, taking a proposition, or semantically dyadic, taking a proposition and an individual. In Brennan's (1993) terms, this is the contrast between *ought to be* deontic modality and *ought to do* deontic modality.

Bhatt and Izvorski (1998) argue that cases of PRO_{arb} in infinitival questions can also be assimilated to control of PRO by an implicit argument:

(74) a. Bill knows [how PRO_{arb} to behave onself].
b. $Matt_i$ knows [what $PRO_{i/arb}$ to do with his_i/one's life].

Infinitival questions are always modal and the covert modality that surfaces in them is never epistemic. This is shown by the fact that (75) cannot be paraphrased as 'Hafdis know how fast it is possible to drive on I-95':

(75) Hafdis knows [how fast PRO to drive on I-95]. (from Bhatt 1999)

Since the covert modality in infinitival questions is always deontic, the modal can have implicit arguments, and these implicit arguments can control the PRO. When the implicit arguments are bound by a generic operator, we get what is usally called PRO_{arb}, and when it is associated with the matrix subject, we have Control.

The role of modality in contributing an implicit argument that can participate in Control is also shown by the paradigm in (76):

(76) a. *The books were sold [without PRO reading them].
(from Chomsky 1982 via Williams 1985)
b. The books can be sold [without PRO reading them].
(from Chomsky 1982 via Williams 1985)
c. *The books might have been sold [without PRO reading them].
(from Kratzer 1991)

The contrast between (76a) and (76b) has already been discussed in section 3.3.2. Let us focus on the contrast between (76b) and (76c). The modal in (76b) is a deontic modal and so it can have an implicit argument that can serve as a controller. This possibility is unavailable in (76c), where the modal is epistemic and does not have implicit argument. Consequently (76c) is ungrammatical.

As with other instances of implicit arguments, there seems to be no consensus regarding whether the implicit arguments need to be syntactically projected. Ross (1969a), Perlmutter (1971), and Jackendoff (1972), among many others, proposed that what we have been calling the implicit argument of a deontic modal is really not implicit at all. They assume a Control structure like in (77):

(77) $John_i$ must [PRO_i leave].

The subject of the modal is taken to be the bearer of the obligation. In recent work, this assumption has been questioned in Bhatt (1997) and Wurmbrand (1999a). Both authors argue that there are environments where the bearer of the obligation is not syntactically represented (cf. 78):

(78) There must be fifty chairs in this room by 5 p.m. (said to a caterer)

In (78), it is clear that the caterer is the bearer of the obligation, and yet the bearer is not part of the syntactic representation. This is enough to show that at least in some cases, the so-called external argument of a deontic modal does not have an obvious syntactic realization. Both Bhatt (1997) and Wurmbrand (1999a) provide additional arguments that modals, deontic or epistemic, never have external arguments; i.e., the bearer of the obligation is never represented syntactically. The bearer of the obligation (= the implicit argument) does have a role to play in the semantics and is identified pragmatically.

7 Conclusion

In sections 2–6, we saw a range of syntactic environments which have been argued to involve implicit arguments. In each of these environments, we investigated whether the putative implicit arguments were syntactically active and whether they were syntactically realized. That implicit arguments are syntactically active was shown to be the case – implicit arguments can control, they are subject to Binding Theory, and some of them can be bound/controlled. The evidence concerning the question of whether implicit arguments are syntactically realized or not is, however, more equivocal. Unlike Williams (1985, 1987b), we are unable to conclude that implicit arguments are not projected syntactically. However, we are also unable to conclude that the environments discussed in sections 2–6 must involve syntactic projection of the implicit arguments.

We find the existence of elements that are syntactically active but not syntactically projected conceptually problematic. In order to allow for elements that are syntactically active without having a syntactic realization, Binding Theory and Control Theory need to be modified. Otherwise, implicit arguments would be invisible to these modules of the grammar. Assuming syntactic realization in the form of a null pronoun (PRO/*pro*) allows us to keep Binding Theory and Control Theory unchanged. This can be taken as an argument in favor of syntactic realization of implicit arguments. Indeed this proposal has been made by several of the scholars working on implicit arguments – for passives see Borer (1998), for null objects in Italian see Rizzi (1986a), for evaluative adjectives see Epstein (1984), and for implicit agents of nouns see Roeper (1987a).

Toward the beginning of this chapter, we noted that implicit arguments did not form a unified class. This point continues to hold even if we assume that implicit arguments are uniformly syntactically projected. Implicit arguments differ in their interpretation. Implicit arguments of passives receive an existential interpretation, while the interpretation of implicit locative arguments of unaccusatives and implicit comparison classes is context-dependent. In section 5, it was noted that implicit arguments of evaluative predicates can receive both context-dependent and *arb*/generic interpretation. Finally, while null dative objects in English (*John said to leave*) are context-dependent, the null objects in Italian discussed in section 4 can only receive *arb* interpretation.

This difference in interpretation has consequences for whether an implicit argument can be bound or not. Partee (1989) notes that certain implicit arguments of nouns can be bound:

(79) **Implicit contextual variables (cf. Mitchell 1986; Partee 1989):**
   a. John visited a local bar.
   b. Every sports fan in the country was at a local bar watching the playoffs.
   c. Every participant had to confront and defeat an enemy.

She also notes that these implicit variables pattern with overt bound pronouns in displaying weak crossover effects:

(80) a. #?The leader of the local union wrote a letter to every untenured professor in the state.
b. Every untenured professor in the state received a letter from the leader of the local union.

(from Partee 1989)

(81) **Implicit arguments (from Partee 1989):**
a. Only the nearest photographer got a good picture of Reagan.
b. #?Only the nearest photographer got a good picture of every senator.
c. Every senator directed a smile at the nearest photographer.

(82) **Overt pronouns (from Partee 1989):**
a. Only his top aide got a good picture of Reagan.
b. #?Only his top aide got a good picture of every senator.
c. Every senator directed a smile at his top aide.

If lexical representations do not contain free variables, the existence of bound readings is an argument for the structural representation of the above implicit arguments.[13]

What is of particular interest here is that the implicit agent of a passive cannot be bound at all:

(83) a. Every journalist wants [Kylie to be interviewed].
b. Every journalist wants [Kylie to be interviewed by him].
c. Every journalist wants [Kylie to be interviewed by someone].
(83a) ≠ (83b), (83a) ≈ (83c)

The absence of the bound reading is further brought out in (84):

(84) a. Every journalist wants [Kylie to be interviewed], # not anyone else.
b. Every journalist wants [Kylie to be interviewed by him], not anyone else.
c. Every journalist wants [himself to interview Kylie], not anyone else.
(# indicates that the contrast cannot be with the journalist.)

The absence of a bound reading follows once we note that these implicit arguments are existentially bound. It is worth noting here that a proper treatment of the implicit argument of a passive as existentially bound will need to account for the fact that these implicit arguments do not support discourse anaphora. The proposal developed by Koenig and Mauner (1999) handles this property of passive implicit arguments. An analysis will also need to handle cases where there is an overt *by* phrase as well as cases like *Attention needs to be paid to oneself*, where the implicit argument has arbitrary interpretation and is probably bound by a generic operator.

The case of implicit arguments of nouns is tricky. At first it seems that variable Binding of the implicit argument is possible:

(85) John/Every student made an attempt [PRO to leave]. (*John* is the attempter, *every student* binds the implicit argument.)

But note that unlike variable Binding, there is no optionality here. No one else could have been the *attempter*. This is more akin to *Control*. There also seem to be locality considerations: Binding/Control of the implicit argument only seem to be possible when the noun in question is a co-argument of the binder/controller, as in (85):

(86) a. Annie believes that the attempt [PRO to leave] was unsuccessful.
b. Annie believes that her attempt [PRO to leave] was unsuccessful.
c. Annie believes that the unique contextually salient attempt by someone to leave was unsuccessful.
(86a) ≠ (86b), (86a) ≈ (86c)

The general pattern found here can be described as follows. The implicit arguments of nouns can be combined with the embedding predicate. If this does not happen, the arguments are existentially quantified and cannot be bound from above.

Even though we will not report on the bindability of the other cases of implicit arguments discussed in this chapter, on the basis of our examination of these cases we can nevertheless say that implicit arguments do not form a unified class with respect to variable Binding. Whether a particular implicit argument can be bound and, if it can, what the exact conditions under which it can be bound are depends upon the particular properties of the implicit argument under study.

NOTES

1 The above list is not intended to be exhaustive. Larson (1988a) uses the term 'implicit argument' more generally to cover, in addition to the cases discussed in the main text, optional but non-iterable phrases such as phrases of source, path, goal, and instrumentality:

(i) a. John ran ($_{Source}$ from the house) ($_{Goal}$ to the store) ($_{Path}$ along the river).
b. John cut the salami ($_{Instrument}$ with a knife).

Also relevant are cases of possessor raising, which have been analyzed as involving nominals with an implicit possessor argument (cf. Hole 2005), degree arguments of adjectives, implicit contextual variables (cf. Mitchell 1986; Partee 1989), and implicit contextual restrictions/situation variables (cf. Kratzer 2004).

2 Approaching this question from a more semantic angle, Engelberg (2002: 375) offers the following characterization:

(i) a verb's predicate constant has an implicit argument iff either (i) the verb has a variant with an explicit argument (i.e., an argument that gets syntactically realized) in the same semantic realization or (ii) there is a morphologically related verb with an explicit argument in the same semantic relation.

This is perhaps a good place to point out that the focus of this chapter will be limited to syntactic and, to a more limited extent, semantic properties of implicit arguments. We will not delve into the rich psycholinguistic literature on this topic, such as Härtl (2003), and in particular a vital body of work developed by Jean-Pierre Koenig and Gail Mauner (see Mauner and Koenig 2000 as a point of entry), which has important implications for the question of whether there are implicit arguments in passives, middles, and unaccusatives respectively.

3 Our attention here is restricted to passives whose implicit argument is an agent. Implicit arguments of passives are not restricted to being agents, e.g., experiencers (cf. i):

(i) The noise was heard at a great distance.

4 The following example reveals that the notion of agency relevant here needs to be broad enough to include non-animate causers:

(i) The part was automatically rotated to insert four screws. (Tom Roeper, p.c.)

5 It might seem that it is the adverb *easily* in (21a) that contributes the agentive interpretation. That this is not the case is shown by (i):

(i) The ship sank easily.

The presence of *easily* in (i) does not force an agentive interpretation.

6 The example improves considerably with the addition of *well*: 'These books don't sell well for the average shopkeeper.' Further, there are also speakers for whom (24a) is grammatical.

7 There is a rich literature on middle and passive constructions involving *si* in the Romance languages. The discussion in Cinque (1988) seems to suggest that *si* constructions in Italian, which can be both middles and passives, allow Control when the *si* construction can be passive but not when it can only be a middle. See Cinque (1988), Vinet (1988), and Dobrovie-Sorin (1994a, 1998) for details.

8 It is likely that the hearers-as-narrators reading is ruled out by the pragmatics of the verb *hear*. It is hard to construe *John heard a story about Mary* as John hearing a story about Mary where John is the narrator of the story. Presumably whatever makes it hard to construe the hearer as the narrator here can be used to block this reading in (36b). Then we can dispense with the implicit argument in (36b) or equivalently assume it to be fully optional. This point is relevant for the discussion of optionality at the end of this section.

9 Note that all these examples are plausibly analyzed as involving 'light' verbs, e.g., *take*, *perform*, *undergo*, *give*. Arguably the noun-phrase complement of a light verb contributes to the argument structure in a way that is different from what its contribution would be if it were an ordinary argument DP.

10 Lasersohn (1997) shows that the semantic contribution of existentially quantified implicit arguments differs from the semantic contribution of deictic implicit arguments with regard to distributivity.

11 We find *The movie was watched nude*, which is parallel to (56a), acceptable. However, it seems a much greater stretch to refer to a movie that is watched nude as a nude movie.

12 Closely related to Bach's Generalization is Visser's Generalization that verbs do not passivize when they involve subject Control. (cf. i):

(i) a. *It was preferred [PRO to leave]. (vs. He_i preferred [PRO_i to leave].)
b. *It was tried [PRO to leave]. (vs. He_i tried [PRO_i to leave]).

That the reason behind the ungrammaticality of (ia, b) is subject Control can be demonstrated by considering a verb like *promise* that takes both finite and infinitival complements:

(ii) a. $John_i$ promised Mary [PRO_i to be on time].
John promised Mary that he would be on time.
b. *Mary was promised by $John_i$ [PRO_i to be on time].
Mary was promised by John that he would be on time.

When there is no problem associated with Control, it is possible to passivize *promise*, as the contrast in (iib) shows.

As Bresnan (1982a) points out, Visser's Generalization is to subjects what Bach's Generalization is to objects. Certain counter-examples to both Visser's Generalization (cf. iii) and Bach's Generalization (cf. iv) have been noted in the literature:

(iii) a. Mary was never promised to be allowed to leave.
b. It was decided to leave. (from Bresnan 1982a)

(iv) Louise signaled (Tom) to follow her.

Bresnan (1982a) suggests that the exceptions in (iii, iv) involve *anaphoric* Control, a form of Control that is distinct from *functional* Control. Bach's Generalization and Visser's Generalization, she argues, follow from the properties of functional Control, but not of anaphoric Control.

The ungrammaticality of (iib) could be due to the failure of a passive implicit argument to control the subject of its infinitival complement, but alternatively it could be due to the failure of certain subject Control predicates to passivize, for currently unknown reasons. The latter seems more likely because some subject Control predicates can in fact passivize and with them the implicit argument can control (cf. iiia/b).

13 This is not, however, the conclusion that Partee (1989) comes to herself.

1 Introduction: what is inalienable possession (IA)?

1.1 Definition of IA

Inalienable possession (IA) is a construal associated with certain structures which contain two nominals, one which denotes a body part and another which denotes the possessor of the body part.

These two nominals form a single constituent when a DP denoting the possessor (POSS DP) is embedded in a DP denoting the body part (BP DP). The respective order of POSS DP and BP N head varies over languages and over morphosyntactic classes. In Romance, a pronominal POSS DP is prenominal while the full form is postnominal (1). In English the POSS DP is usually prenominal whether it is a pronoun or a full DP (2):

(1) a. le bras de Jean
b. son bras

(2) a. *the arm of John
b. John's arm
c. his arm

In this configuration, the IA construal is a subcase of the possessive construal. An N denoting a concrete object can replace the BP N:

(3) a. le livre de Jean
b. son livre

(4) a. *the book of John
b. John's book
c. his book

Structures like (5) and (6) are thus ambiguous: the head N denotes either an object physically disjoint from its possessor, such as the cast of a hand by Rodin which the owner bought (alienable possession), or a part of the possessor's body (inalienable possession, IA):

(5) la main de Jean/sa main

(6) John's hand/his hand

In some languages, however, the IA construal is associated with a structure containing disjoint BP and POSS nominals. French has a number of such structures, the best known of which are listed below.

In structure I (7), the direct object denotes a body part and the subject denotes the possessor:

(7) Structure I
  a. Jean lève la main.
     Jean raises the hand
  b. Jean donne la main à Marie.
     Jean gives the hand to Marie

In Structure II (8), the direct object denotes the body part but a Dative nominal, clitic or full DP, denotes the possessor.

(8) Structure II
  a. Je lui prends la main.
     I him take the hand
     'I take his hand.'
  b. Je prends la main à la petite fille.
     I take the hand to the little girl
     'I take the little girl's hand.'

In Structure III (9), the direct object denotes the POSS DP while the BP DP is embedded in a PP adjunct to VP:

(9) Structure III
  a. Marie a frappé Jean sur la main.
     'Mary hit John on the hand.'
  b. Marie a tiré Jean par les cheveux.
     'Mary dragged John by the hair.'

Such structures, which contain disjoint POSS and BP DPs, are referred to as 'inalienable possession structures'. This is a misnomer, as there seem in fact to be no structures, in French or in any other language examined from this point of view, which are exclusively associated with the IA construal. Either IA is a subcase of the possessive construal of a DP with genitive (or dative) modifier, or it is construed on certain sentential structures which happen to contain a DP denoting a human being and another DP denoting a body part.

For example, French has a 'double object' structure which contains an ACC and a DAT DP. The construal of the Dative DP depends on the lexical choice of verb and direct object. The Dat is construed as GOAL in (10a), SOURCE in (10b), BENEFACTIVE (BEN) in (10c), inalienable possessor in (10d), alienable possessor in (10e), and LOCATION in (10f):

(10) a. J'ai donné un livre à Pierre.
     I gave a book to Pierre

b. J'ai pris un livre à Pierre.
I took a book 'to' (from) Pierre
c. J'ai cassé sa tirelire à Pierre.
I broke his piggy-bank to Pierre
d. J'ai tordu le poignet à Pierre.
I twisted the wrist to Pierre
e. Je ne connais pas de maîtresse à cet homme.
I do not know (of) any mistress to that man
f. J'ai connu Pierre à Paris.
I met Pierre in Paris

The multiplicity of construals does not motivate referring to the double object structure as an 'inalienable possession structure' any more than as a 'goal structure', etc.

However, just as we will misleadingly refer to the relation between the BP DP and the POSS DP in Structures I–III as 'inalienable possession' (IA), we will, also misleadingly, refer to structures with disjoint DPs which permit this construal as 'Inalienable possession structures' (IA-structures) in quotes, to designate the single one of their possible construals which interests us. When discussing theories which do posit special IA structures, we will use the term without quotes.

1.2 Constraints on IA in English

Structures I and II do not allow the IA construal in English:

(11) Structure I
a. *John raised the hand. (cf. (7a))
b. *John gave the hand to Mary. (cf. (7b))

(12) Structure II
a. *I took him the hand. (cf. (8a))
b. *I took the hand to/for the girl. (cf. (8b))

Structure I becomes grammatical in English – and ambigous between the alienable and inalienable construals – if we replace 'the hand' by 'his hand':

(11') a. John raised his hand.
b. John gave his hand to Mary.

As the only difference between (11) and (11') is the form of the determiner, the contrast between them suggests that the grammatical status of the definite determiner is crucial for the IA construal on disjoint DPs. The French definite determiner permits a construal in (7) which its English counterpart excludes in (11).

Extrapolating from the contrast between French (7) and English (11) in Structure I, we may attribute the ungrammaticality of the English counterpart of Structure II in (12) in part to the construal of the definite determiner. Only in part, however, for Structure II does not allow the IA construal in English even if we replace 'the hand' in (12) by 'his/her hand' in (12'):

(12') a. *I took him his hand.
b. *I took her hand to/for the girl.

The contrast between French (8) and English (12) seems to be attributable to a different syntactic distribution of theta-roles in the double object structure. In the French structure, the DAT DP may be construed as either GOAL or SOURCE, as in (10a, b) above. Under the IA construal, however, the DATIVE may be construed as the POSS DP only if it is SOURCE rather than GOAL, as in (13a). If the DAT is GOAL, only the subject may be construed as POSS DP, as in (13b):

(13) a. Ils lui ont pris/arraché la main.
they to-him took/pulled out the hand
b. Ils lui ont donné/tendu la main.
they to him gave/extended the hand

In the English double object stucture, for some reason, the indirect object is always Goal, never Source:

(14) a. J'ai donné/prêté/vendu un livre à Jean.
'I gave/lent/sold a book to John.'
'I gave/lent/sold John a book.'
b. J'ai pris/volé/arraché un livre à Jean.
*'I took/stole/snatched a book to John.'
*'I took/stole/snatched John a book.'

Other French structures which allow the IA construal may be assimilated either to Structure I, with subject as POSS DP, or to Structure II, with DAT POSS DP. They all exclude the IA construal in English:

(15) a. Jean a les yeux bleus. (I)
b. *'John has the blue eyes.'[1]

(16) a. Marie est entrée, la tête haute. (I)
b. *'Mary entered, the head held high.'

(17) a. Jean a fait un geste de la main. (I)
b. *'John made a gesture with the hand'.

(18) a. Je lui ai mis de l'eau sur la tête. (II)
b. *'I put (to) him water on the head.'

Like genitive DPs or double object sentences, these structures allow the IA construal by accident, not by design: none of them is devoted exclusively to IA:

(19) John a un livre.
'John has a book.'

(20) Marie est entrée, furieuse.
'Marie entered, furious.'

(21) Jean a fait un succès de son affaire.
'John made a success of his business.'

(22) Je lui ai mis de l'eau sur ses chassures.
*'I put to him water on his shoes.'

1.3 Questions to answer

The IA construal raises the same syntactic questions as any other construal involving disjoint nominals, such as anaphora, predication, or quantification:

(i) What are the structural constraints on the IA construal?
(ii) How is the IA construal associated with the structures which allow it? In particular, how can the POSS DP be construed simultaneously as a syntactic and semantic argument of V and as a semantic argument of N?
(iii) What determines the difference between languages with respect to the IA construal? Can one predict which natural languages are like French, and allow IA in Structures I–III, and which are like English, allowing it only in Structure III? In terms of acquisition, what information does a child need in order to conclude that her/his grammar contains sentences like (7) and (8)?

We will review the major literature in the generative framework which attempts to answer these questions. We will first examine syntax-oriented theories. While these theories more or less adequately express the syntactic constraints on the IA construal, they turn out to be inadequate with respect to apparent semantic constraints. We then review theories of IA which integrate an explicit semantic filter in their syntactic analyses. We will comment both on the empirical adequacy of these theories and on their status with respect to the principle of economy of the grammar.

2 Syntax-based theories of IA

2.1 The binding hypothesis (Guéron 1983, 1985)

2.1.1

The IA construal is subject to syntactic constraints:

(i) The possessor is obligatory.

(23) a. Jean a les yeux bleus.
Jean has the eyes blue
'Jean has blue eyes.'
b. (Marie, en admirant Jean) *Les yeux bleus sont charmants.
'(Marie, admiring Jean) The blue eyes are charming.'

(ii) Locality. The POSS DP must be in the same minimal sentential domain as the BP DP. (In (24) below, indices indicate an IA relation between Poss and BP DPs. In (25), indices indicate both the IA relation within the embedded sentence and control of the subject of the embedded infinitival by an argument of the matrix sentence.)

(24) a. Jean_j semble [t_j lui_i prendre la main_i].
Jean_j seems [t_j to her/him_i to take the hand_i
'Jeans seems to take her/his hand.'
b. *Jean_j lui_i semble [t_j prendre la main_i].
Jean_j seems to him/her_i [t_j to take the hand_i)
'Jean seems to him/her to take the hand.'

(25) a. Jean_j a persuadé Marie_i de [PRO_i lever la main_i].
'Jean persuaded Mary to raise her hand.'
b. *Jean_j a persuadé Marie_i de [PRO_i lever la main_j].
'Jean persuaded Marie to raise his hand.'

(iii) Asymmetric c-command. The Possessor must c-command the body part nominal or its trace:

(26) a. Jean_i lève la main_i.
'Jean raised the hand.'
b. L'ennemi lui_i a arraché la main_i.
the enemy to-him pulled out the hand
'The enemy pulled out his hand.'
c. La main_i lui_i a été arrachée t_i par l'ennemi.
the hand to him was pulled out by the enemy

(27) a. Jean_i tourne la tête_i.
John turns the/his head

b. La tête$_i$ lui$_i$ tourne t$_i$.
the head to him turns
'His head is spinning.'

(28) a. *Les cheveux$_i$ entourent Marie$_i$.
the hair surrounds Marie
b. *Le frère de Jean$_i$ a levé la main$_i$.
the brother of John raised the hand

(29) a. Marie$_i$ a les yeux bleus$_i$.
Mary has (the) blue eyes
b. *Les yeux bleus$_i$ sont à Marie$_i$.
the blue eyes are to Mary/Mary's

These same properties characterize the independently established relation of anaphoric binding.

(i) Obligatory antecedent:

(30) a. John hates himself.
b. *I hate himself.

(ii) Locality:

(31) a. John persuaded Mary$_i$ [PRO$_i$ to wash herself]
b. *John$_j$ persuaded Mary$_i$ [PRO$_i$ to wash himself$_j$]

(iii) C-command:

(32) a. John perjured himself.
b. *John's mother perjured himself.

On the basis of the identity of the structural constraints on anaphora and on the IA construal of disjoint nominals, Guéron (1985) reduces the latter to a case of the former. The IA construal corresponds to one form of anaphoric binding, that of obligatory control. In sentences like (5) or (6), the determiner of the BP DP is construed as PRO, a pronominal anaphor controlled by a c-commanding argument of the immediately dominating sentential domain.

The (a) and (b) sentences of (33) and (34) are thus parallel:

(33) a. Jean$_i$ veut [PRO$_i$ venir]
b. Jean$_i$ lève [LA$_i$ main]

(34) a. Je lui$_i$ dis de [PRO$_i$ venir]
b. Je lui$_i$ prends [LA$_i$ main]

And just as PRO may have a generic or arbitrary (ARB) construal in the absence of a controller, a PRO determiner may have a generic or ARB interpretation under the same circumstances (cf. Authier 1990; Authier and Reed 1992):

(35) a. [PRO vivre] seul est désagréable.
'[PRO to live alone] is disagreable.'
b. Il est important [PRO de savoir ce que l'on veut].
'It is important [PRO to know what one wants].'

(36) a. Avec ces gants, [les doigts] ne gèlent jamais.
'With these gloves, the fingers never freeze.'
b. Un peu de natation muscle souvent [le dos].
'A little swimming often develops the back muscles.'

2.1.2

Guéron accounts for the difference between French and English with respect to Structures I and II on a morphological basis. The French determiner *le*, *la*, or *les*, marked for number and gender, is homophonous with third person pronominal clitics marked for number, gender and person. Anaphoric binding may be assimilated to agreement in that it relates the theta-features of disjoint constituents. Guéron formulates the hypothesis that only a determiner marked with theta-features may be identified in syntax as an anaphoric pronominal bound by an antecedent, deriving the IA construal.

Her hypothesis makes the strong and testable prediction that the IA construal exists in Structures I and II only in languages in which the definite determiner has variable theta-features which identify it as a pronominal, and that it is lacking in languages in which the definite determiner is invariable. IA is thus predicted to exist in Romance, where the definite determiner is morphologically identical to a pronominal, as well as in languages like Russian, which has both null pronouns with abstract phi-features and null determiners. But it is predicted not to exist in languages like English, Arabic, or Hebrew, in which the definite determiner is invariable.

Support for the hypothesis that the grammaticality of the IA construal in I and II depends on the existence of phi-features in the determiner of the BP DP comes from English itself. Whereas IA is excluded in English when the BP DP has a definite determiner, it is possible with an indefinite determiner:

(37) a. John wouldn't lift a finger to help.
b. Can you give me a hand?
c. Raise one hand for 'aye', two hands for 'nay'.

(38) a. We held hands/linked arms/rubbed noses.
b. She entered the room, arms akimbo.

Unlike the definite determiner *the*, the indefinite determiner has a feature for number in English: 'a' is singular and zero is plural. Its number F suffices to identify the indefinite determiner as a pronominal subject to the binding relation which underlies the IA construal in I and II.

2.1.3

Syntactic and morphological constraints on the IA construal do not suffice to identify the set of grammatical 'IA structures', however. Lexical choice plays a crucial role.

Although Guéron identifies the IA construal with anaphoric binding, many verbs which allow reflexive anaphora reject IA in Structure I:

(39) Jean se lève.
Jean self raises

(40) Jean lève la main.
Jean raises the hand

(41) Jean se lave/se gratte/se chatouille.
Jean self washes/scratches/tickles

(42) *Jean lave/gratte/chatouille la main.
Jean washes/scratches/tickles the hand

To account for these constraints on choice of verb, Guéron (1983, 1985) proposes that under the IA construal, in addition to their anaphoric relation, the POSS DP and the BP DP constitute two links of a LEXICAL CHAIN. The notion of lexical chain is weaker than that which characterizes a chain formed by A or A' movement. Whereas the latter imply referential identity of antecedent and trace, a lexical chain requires only non-distinctness of the referents of its links. Under the IA construal, the BP being included in the body, the antecedent DP and bound DP have overlapping reference. They may thus constitute two links of a lexical chain. The assumption that two links of a chain obey the same constraints as anaphora accounts for the locality restriction on the IA construal. Independent constraints on chains automatically exclude certain IA structures which anaphora alone could not filter out.

Every chain is asociated with a single theta-role. It follows that IA is ungrammatical whenever the body part DP and the possessor DP are assigned two different theta-roles by the verb. The chain hypothesis thus accounts for the ungrammaticality of sentences like (42b) above ('Jean lave la main') in which the POSS DP is AGENT while the BP DP is THEME.

A subset of such sentences is acceptable, however. This subset has been described in semantic terms by Hatcher (1944) and Kayne (1975): the subset of sentences of type I which are acceptable under the IA construal denote a natural physical gesture.

Guéron proposes that in the acceptable structures, verb and direct object are reanalyzed in syntax as a single verb. Under reanalysis the case and theta-features of the DO are absorbed by the verb. At the level of construal, the subject binds the determiner of the body part N but, its theta-role having been absorbed at an earlier stage, the direct object is not associated with a theta-role, and the IA construal does not violate the theta condition on chains.

Reanalysis of verb and DO occurs in the grammar independently of IA. 'Light verbs' reanalyze with their object to create an idiomatic complex verb:

(43) a. John took his time/a shower/ten/a leak.
b. John had a fit/a ball/a hard time.
c. Mary made an error/an omission/her way through the crowd.

(44) a. Jean a pris la fuite/une douche/son pied.
John took flight/a shower/his foot, i.e. had fun
b. Jean a fait une scène/une erreur/l'idiot.
John made a scene/an error/the idiot = played the fool

Reanalysis between verb and object deriving an idiomatic meaning may also occur in reflexive structures. While the reflexive construal of V + DO is more or less transparent in (45), it is less so in (46b), as Kayne has pointed out (class lectures in the seventies):

(45) a. John washed himself.
b. John hates himself.

(46) a. John threw Bill out the window (with his bare hands)
b. John threw himself out the window (*with his bare hands)

Reanalyzed V + direct object characteristically has a special meaning. 'Natural gesture' is the special meaning which corresponds to syntactic reanalysis of an action verb + a direct object denoting a body part.

Structure II (8), in which the indirect object rather than the subject is the POSS DP, accepts a greater variety of lexical choices than Structure I:

(47) a. *Jean lave/gratte/chatouille la main. (= (42))
Jean washes/scratches/tickles the hand
b. Je lui lave/gratte/chatouille la main.

Guéron proposed the notion of lexical chain in order to exclude non-reanalyzed cases of Structure I. The proposal that theta-roles do not form a unified class makes it possible to use the same notion to account for the greater lexical span of Structure II. Guéron distinguishes PRIMARY theta-roles, assigned lexically by the verb, from SECONDARY theta-roles, which are not lexically assigned. Only

PRIMARY theta-roles count for the theta-role condition on lexical chains as stated in (48):

(48) A lexical chain is associated with a single primary theta-role.

AGENT, PATIENT, THEME are primary theta-roles selected by V. The sentences of (47a) above are excluded by (48) because two primary theta-roles are associated with a single lexical chain.

The sentences of Structure III (example (9)) III all contain a dative DP construed as a BENEFACTIVE (BEN) argument. The BEN theta-role is not selected by the verb: it is acceptable in any structure containing a direct object (DO) and a verb which denotes an action (cf. Leclère (1978) for a detailed account).

The transitive verb of (49a) and the unaccusative verb of (49b) license a BENEFACTIVE argument because they select a direct object and denote an action. But unergative (50), which lacks a DO, excludes the BENEFACTIVE dative, as does any structure like (51) in which VP denotes a state rather than an action:

(49) a. Jean lui a cassé sa poupée (à la petite fille).
Jean to-her broke her doll (to the little girl)
b. Il lui est arrivé quelque chose.
it to-him happened something = something happened to him

(50) *Je lui cours.
I run on him

(51) *Je lui aime sa bicyclette.
I like her bicycle to her

A DAT DP may be construed as inalienable possessor of a definite direct object denoting a body part in the very same syntactic environments in which it is construed as a BENEFACTIVE when the DO does not denote a BP or has a genitive determiner. Transitive (52a) and unaccusative (52b) are acceptable but unergative (53) and stative (54) are not:

(52) a. Je lui ai pris la main.
I to-him took the hand
b. Les bras m'en tombent t.
the arms to-me fall over that

(53) *La tête lui bouge.
the head to-him moves

(54) *Je lui aime les mains.
I to-her like the hands

Guéron identifies the POSS DP with the BENEFACTIVE DP. Only the lexical content of the direct object distinguishes the two construals. Being non-selected, the benefactive has only a secondary theta-role. A lexical chain containing dative BEN plus nom. or acc. THEME is therefore compatible with the chain criterion (48).

An argument in favor of the hypothesis that the POSS DAT is a subcase of BEN DAT in French is the fact that any difference of acceptability between full NP and clitic dative under the BEN construal of the dative also pertains under the possessor construal. In French, the BEN and the POSS DP preferably or obligatorily take the form of a clitic (cf. Dorel 1980; Nicol 1997).

(55) a. Je lui ai pris la main.
b. ?? J'ai pris la main à Pierre.

(56) a. Le bandeau lui enveloppe la tête.
b. *Le bandeau enveloppe la tête à ce garçon.

(57) a. Je lui ai mis de l'eau sur la tête.
b. *J'ai mis de l'eau sur la tête à Jean.

In languages such as Hebrew, in which either the full dative DP or the clitic is an acceptable BENEFACTIVE, the same is true of the DAT POSS DP under the IA construal (Landau 1999).

2.1.4

Any analysis of IA must account not only for the contrast between French and English in Structures I and II, but also for the lack of contrast between them with respect to Structure III. Guéron (1985) proposes that III illustrates not A- but A'-binding. In (58) below, the BP DP contains an empty category (ec) argument of the relational head N. The e.c. is construed as a variable A'-bound by the possessor DP outside the nominal domain:

(58) I hit John$_i$ [PP on [DP the head e$_i$]]
J'ai frappé Jean$_i$ [PP sur [DP la tete e$_i$]]

As suggested above, A-binding may be reduced to feature-agreement. In particular, it depends on the existence of phi-features in the bound nominal. A'-binding links not phi-features but rather operator Fs such as +*wh*, NEG, or Focus. It therefore does not manifest phi-feature dependencies.

A-binding, a form of phi-feature agreement, occurs, like other forms of agreement, within a single argument domain. A'-binding, on the contrary, links an argument within an argument domain to an operator on the periphery of this domain. There is thus a complementary distribution between the IA construal in I and II, in which both DPs are in a single argument domain, and that in III, in which the body part DP is within an adjunct to the VP or sentence which contains the POSS DP.

IA is thus predicted to occur freely in Structure III in all languages which manifest A'-binding, including those in which, as in English or Hebrew, an invariable determiner blocks the A-binding IA construal in I and II.

2.1.5

Guéron's hypothesis simplifies the grammar by reducing the unknown, the principles governing the IA construal, to the known, the grammatical principles governing A- and A'-binding.

The analysis has a number of problems, however:

(i) Guéron claims that the relation between the disjoint DPs in I and II is anaphoric binding, like reflexivization or control. Yet in sentences like (59), the number and gender Fs of the BP DP do not match those of the POSS DP. This situation creates ungrammaticality in reflexive or control structures, as shown in (60). So it is not clear what motivates the proposed binding relation between the subject and the direct object in (59):

(59) Le jeune homme$_i$ a levé les mains$_i$.
sg. m. pl. fem.
'The young man raised his hands.'

(60) a. *Le garçon$_i$ s$_i$'est levé elles-memes$_i$.
m. sg. pl. fem.
the boy self raised themselves
b. *Jean$_i$ veut [PRO$_i$ partir seules$_i$]
John wants PRO to leave alone
m. sg. m. sg. f. pl.

(ii) Guéron's analysis has recourse to ad hoc auxiliary hypotheses. As Koenig (1999) points out, Guéron pays for the simplicity of reducing IA to anaphora in I and II with a new and otherwise unnecessary type of chain, which does not imply identity but only non-distinctness of its links.

(iii) The distinction between PRIMARY and SECONDARY theta-roles, which Guéron uses to exclude most cases of lexical chain in Structure I, while including a larger number of cases in Structure II, is another unwelcome innovation. Furthermore, it wrongly predicts that structures like (61), which contain two predicates each of which presumably assigns a Primary theta-role to its subject, are ungrammatical.

(61) a. Elle$_i$ est entrée [la tête$_i$ haute].
b. Marie$_i$ a [les cheveux$_i$ blonds].

(iii) The hypothesis that Verb and DO are reanalyzed as a single verb in Structure I is plausible, but no explanation is given for the semantic constraint

on the output. Why is reanalysis limited to VPs which denote gestures, rather than, say, thoughts, feelings or intentions? Reanalysis of verb and object in idioms often denotes, on the contrary, feelings:

(62) a. Mon coeur n'a fait qu'un bond.
'My heart made but one leap = I reacted strongly.'
b. J'ai les boules.
'I have the balls = I'm nervous.'
c. Ce spectacle m'a arraché des larmes.
'This show ripped out tears from me.'

(63) a. She wears her heart on her sleeve.
'She reveals all her feelings.'
b. My heart fell t.

Subsequent syntax-based analyses of IA assimilate the IA construal to other independently established syntax-sensitive construals such as binding or predication.

2.2 The A'-binding hypothesis (Tellier 1990)

2.2.1

Tellier proposed that IA structures, like Topicalization, Relative Clause or Tough-movement, reduce to A'-binding plus Predication:

(64) a. $John_i$ [OP_i I like t_i].
b. $Mary_i$ is tough [Op_i PRO to talk to t_i].
c. The man [$Whom_i$ you met t_i].

Tellier proposes that DP, like CP, is an argument domain. An ec argument of the head N may be construed as a variable bound by an operator at the periphery of the domain. The operator is identified by a referential DP outside the domain, deriving a predication construal.

Whereas virtually all verbs take arguments, only some Ns do. Tellier distinguishes (non-deverbalized) Ns which take arguments, such as body-part or kinship terms, from Ns such as *dog*, which do not.

In (65), the ec complement of the relational N *main* is construed as a variable A'-bound by an operator in Spec DP. This operator is identified by the closest DP, *lui*, construed as subject of the predication:

(65) Je lui_i prends [Op_i la main e_i].

Tellier cites the occurrence of parasitic gaps in IA to support the A'-binding hypothesis not only for Structure III, as Guéron did, but also for Structures I and II:

(66) This is a book that I read t before buying e.

(67) a. Jean$_i$ a mis [la main t$_i$] sur [la tête t$_i$].
John has put the hand t on the head t
b. Les cheveux$_i$ lui descendent t$_i$ de [la tête t] aux [pieds t].
the hair to-her descends from the head e to the feet t

2.2.2

Tellier was one of the first linguists to argue for the hypothesis that non-deverbalized Ns may have an argument structure and that DP functions, like CP, as a domain for A'- binding and predication.

The A'-binding hypothesis overgenerates with respect to IA, however. While all relational Ns can project argument ecs subject to A'-binding, not all of these admit the IA construal. Kinship terms, for example, which are intrinsically relational and allow A'-binding and parasitic gaps, cannot replace a BP DP in an 'IA structure':

(68) a. un garçon dont je connais le père.
a boy of-whom I know the father
un garçon [CP dont$_i$ [IP je connais [DP Op$_i$ le père t$_i$]]]
b. un garçon dont le père se dispute avec la mère.
a boy of whom the father quarrels with the mother
un garçon [CP dont$_i$ [Op$_i$ le père t$_i$] se dispute avec [Op$_i$ la mère e$_i$]].

(69) a. *Je lui ai frappé [le père t].
I to-him hit the father
b. *Je lui ai poussé [la mère t] contre [le père e].
I to-him pushed the mother against the father

Nor does *wh*-type A'-binding into a DP obey the same lexical constraints as the IA construal:

(70) a. une fille dont Jean admire [le corps t] plus que [l'âme e].
a girl of whom Jean admires the body more than the soul
b. *Jean lui admire le corps/l'ame.
Jean to-her admires the body/soul

Moreover, Nouns which do allow an 'extended IA' construal, such as items of clothing and objects held in the hand, typically lack lexical arguments:

(71) a. Jean a tombé la veste.
'Jean dropped the jacket.'
b. Ho perduto l'ombrello. (Italian)
'I have lost the umbrella.'

Finally, the A′-binding + Predication hypothesis does not account for the contrast between English and French in 'IA structures'. English has the same relational Ns and sentential A′-binding and Predication structures as French. Therefore the theory incorrectly predicts that it will have the IA construal in Structures I and II, just as it has it in Structure III.

2.3 The Predication hypothesis (Vergnaud and Zubizarreta 1992)

2.3.1

Vergnaud and Zubizarreta (V&Z) also assimilate IA to predication but without an A′-binding component. For V&Z, the body-part N functions as a predicate which contains an implicit empty category construed as a variable. This variable can be bound by a determiner functioning as an operator or else by a DP external to the predicate domain, construed as subject of a predication. In (72), the predicate variable in N is bound by the dative DP:

(72) a. Je lui prends la main.
je lui_i prends [DP la [NP main]]
vbl_i

According to V&Z, Predication is subject to the structural constraint of M-Command (Williams 1980): the subject DP and the predicate NP must mutually c-command each other.

It appears at first glance that M-command does not hold in (72), where dative *lui* c-commands the predicate NP *main* but DP, a maximal projection, blocks c-command of *lui* by *main*. V&Z propose, however, that D projects a maximal projection DP only if it has a construal. If the determiner is identified as an expletive, a dummy element, then it does not project a DP, and the nominal is analyzed as NP. The assumption that *la* in (72) is an expletive allows M-command between *lui* and the N *main*, deriving the predicational IA construal.

M-command also seems to be lacking in (73), where *la main* c commands *Marie* but the latter is embedded in a maximal projection, PP, which blocks c-command of the BP NP by the POSS DP:

(73) J'ai pris la main à Marie.
J'ai pris la main [PP à Marie]

V&Z propose that *à* not being a lexical P but merely a case assigner, it does not project a PP capable of blocking c-command of the BP NP by the Poss DP; once again predication obtains.

For V&Z, as for Guéron, the construal of the determiner of the BP DP underlies the difference between French and English in Structures I and II. For them, the crucial factor is not the morphology of the determiner but its semantic

construal. The contrast in (74) shows that, in French, the definite determiner can function as an expletive element, while in English it cannot:

(74) a. Jean admire la beauté, la charité et la bonté.
b. *'John admires the beauty, the charity and the kindness.'

V&Z further argue that the syntactic distinction between NP with expletive determiner and DP with meaningful determiner has semantic consequences. NPs denote types while DPs denote tokens. Under the IA construal, the BP NP denotes a type. This is why it does not allow non-restrictive adjectives, which only modify tokens:

(75) a. Je lui ai pris la main.
I to-her took the hand
b. *Je lui ai pris la belle main.
I to-her took the beautiful hand

According to V&Z, the claim that the BP NP has a type reference under the IA construal is supported by the fact that it is subject to backward pronominalization. Backward pronominalization is a property of coreference, not of anaphora or binding:

(76) Parce qu'elle est fragile, le médecin leur a couvert la tête d'une cagoule.
because it is fragile, the doctor to-them covered the head with a hood

V&Z identify an NP with a type construal as a target of distributivity. They further seem to identify distributivity with inalienable possession.

In (77), the plural subject triggers a distributive construal of the type BP NP. Although the N *estomac* is singular, it is construed as having plural reference:

(77) a. Le médecin a examiné l'estomac aux enfants.
b. Le médecin leur a examiné l'estomac.

In English, where D functions as an operator, not as an expletive, and the body-part Noun is construed as a token, not a type, the distributive interpretation would not be available:

(78) a. The doctor examined the children's stomachs.
b. *The doctor examined the children's stomach.

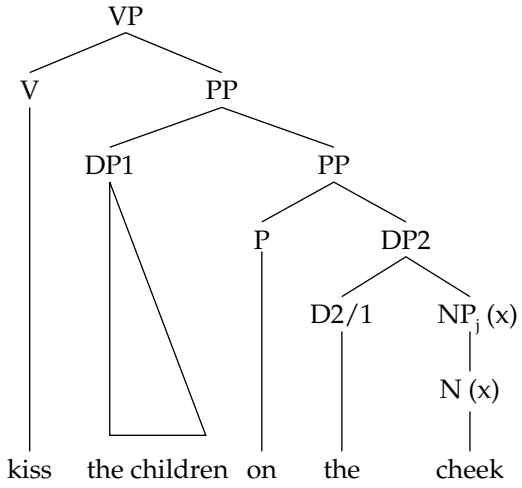
V&Z suggest that NPs which denote types and are subject to a distributive construal, as in (79), define a class of 'extended IA structures':

(79) On a donné le même ordinateur, à Marie, Jeanne, et Suzanne.
'We gave the same computer to Mary, Jean, and Sue.'

For Structure I, V&Z adopt the reanalysis proposal of Guéron (1983, 1985).

For Structure III, acceptable in both French and English, V&Z propose that the BP DP and the POSS DP form a 'metonymic binding chain'. In (80) below, the plural direct object binds the determiner of the BP NP containing the semantic variable. This binding relation is licensed by semantic metonymy:

(80) I kissed the children on the cheek.
J'ai embrassé les enfants sur la joue.



2.3.2
This hypothesis, like all the others reviewed here, has empirical and theoretical problems.

(i) The M-command requirement on predication incorrectly rules out structures in which the BP NP is embedded in a PP with a lexical P head. In (81), the dative DP c-commands the BP NP but the PP projection of the lexical P *sur* blocks c-command of the dative by the BP DP:

(81) Je lui$_i$ ai mis de l'eau [PP sur [NP la tête$_i$]].

In (82), a small clause (sc) projection prevents M-command:

(82) Il a [sc la main heureuse]/[les epaules larges]/[la taille fine].
he has [the hand happy] [the shoulders large] [the waist thin]

In (83), the sc containing the BP NP is adjoined to VP. But c-command between an argument of a sentence and an element in an adjunct is never symmetrical, as (84) shows:

(83) Elle est entrée, [sc la tête haute]/[les cheveux en desordre].
she is entered [the head high] [the hair disheveled]

(84) a. $Mary_i$ entered the room [PP without PRO_i smiling].
b. *[[PRO_i to enter the room [PP without $Mary_i$ smiling]] is unusual.

(ii) V&Z propose that Predication depends on the structural relation of M-command. However, as Koenig (1999) points out, they subject M-command to an interpretive constraint: the BP NP c-commands the POSS DP only if its determiner is construed as an expletive. To define a semantic condition on a syntactic relation is to abandon the autonomy of syntax hypothesis and thus to weaken the grammar.

(iii) Koenig (1999) also points out an empirical problem with the analysis: distributivity is not in fact excluded from nominals with genitive DP in English. He cites (85a, b), which for me are slightly marginal. However I find (86a, b) perfect:

(85) a. ?The doctor examined the children's stomach.
b. ?The children all raised their hand.

(86) a. Children, before speaking in class, you must raise your hand.
b. The guests are having trouble finding their place at the dinner table.

Distibutivity into a possessive DP with prenominal genitive is perfect in French:

(87) a. Le médecin a examiné leur estomac.
'The doctor examined their stomach.'
b. Les messieurs ont enlevé leur chapeau.
'The gentlemen took off their hat.'
c. Les invités cherchent leur place à table.
'The guests are looking for their place at the table.'

As a DP with a genitive determiner denotes a token, not a type, distributivity cannot in general require a type interpretation of the target nominal.

V&Z are no doubt correct to identify distributivity as a property of predication, but apparently wrong to identify distributivity with the IA construal.

Distributivity may target a VP whose direct object, if present, need not refer at all, not even to a type. Distributivity is a property of all sentences with idiomatic VPs, in which the direct object has no reference (it does not lend itself to leftward pronominalization), neither token nor type:

(89) a. The children threw a fit/*?fits.
'The children had a tantrum.'
b. The explorers gave up the ghost/*ghosts.
'The explorers died.'
c. We'll hit the road/*roads now.
'We'll leave now.'
d. OK you guys, take a powder/*powders.
'Ok you guys, leave!'

When not lexically triggered by an operator such as *each*, distributivity is semantically triggered whenever a plural DP is subject of a predicate which can only apply to one individual at a time. The predicate may or may not contain an object:

(90) a. John, Sam, and Bill died/were born in 1940/got married last year.
b. My children love me.
c. Three dogs bit Bill.

Finally, the distributive interpretation of a DP does not imply that it is subject to the IA construal. Structure (91), in which *le même ordinateur* is construed distributively is not an 'IA structure' at all. Under the IA construal of a double object structure, the dative DP must be SOURCE not GOAL (cf. (13) above). (91) and (92) show that a non-BP DP object has a distributive reading only if the IO is GOAL not SOURCE. The conditions underlying the distributive reading of a non BP-DP are thus distinct from those underlying the same reading of a BP DP:

(91) a. On a donné le même ordinateur à Marie, Jeanne, et Suzanne.
b. *On a donné la main à Marie, Jeanne, et Suzanne.

(92) a. On leur a ecrasé la main (à Marie, Jeanne et Suzanne).
b. *On leur a acheté le même ordinateur (à Marie, Jeanne, et Suzanne).

2.3.3

Neither Guéron nor V&Z accounts for the fact that the IA construal is not always excluded in English when the BP DP has a definite determiner. In English, IA is excluded in Structure I if the BP N has no modifier, as in (92), but is acceptable, as in French, if N has a restrictive modifier, as in (93) and (94):

(92) a. Jean lève la main.
b. *John raises the hand.

(93) a. Jean a levé la main droite (pas la main gauche).
b. Jean a levé la main qui etait blessée.

(94) a. I asked John to raise the right hand (not the left one).
b. John raised the hand which was wounded.

If the definite determiner functions as an operator in (92), as both theories claim, it must not so function in (93) and (94).

The lack of contrast between English and French in (93) and (94) recalls structure III, which has the same status. Can the two groups of examples have something in common which has so far been overlooked?

2.4 The Possessor-Raising hypothesis (Szabolsci 1983; Landau 1999)

If IA is the name of a construal associated with a variety of structures, there is nothing to say about the derivation of 'IA structures': there is no such grammatical object.

There is a respectable literature devoted to an alternative theory, however. Under the Possessor-Raising hypothesis, a POSS DP is generated within a DP denoting a possessed item, and raises out of its host to a position in VP in syntax. This hypothesis has been advanced for possessive structures in general in both relational grammar and in generative grammar.

2.4.1

Szabolsci (1983) claims that in Hungarian a dative POSS DP generated within the DP denoting a possessed object can and sometimes must move out of its host.

Hungarian has two possessive structures. In both of them, the possessed object agrees in phi-features with the possessor. The structures differ in that the lexical POSS DP is marked NOM in one case (95) and DAT in the other (96). The possessed DP may denote a BP or any other nominal such as 'a guest', 'a hat', etc.:

(95) a. az en-0 kar-ja -i - m
the I-NOM arm-poss-pl-1sg.
'my arms'

b. az en-0 vendeg-e-m
the I-NOM guest-poss-1sg.
'my guest'

(96) a. en -nek- e - m a kar-ja -i - m
I-dat-poss-1sg. the arm-poss-pl-1sg.
to me DAT the arms
'my arms'

b. en -nek-em a vendeg- e- m
I dat -1sg. the guest-poss-3sg.
to me DAT the guest
'my guest'

A NOM POSS DP is located to the right of the definite determiner *az* while a DAT possessor is to its left. Szabolsci proposes that the NOM DP is in Spec Infl within DP while the DAT DP is in a type of Spec COMP position, Spec Komp. Thus DP and CP have analogous structures, with both subject and peripheral Spec positions.

Support for this hypothesis comes from *wh*-movement, where Comp functions as an escape hatch for movement in both the nominal and the sentential domain. A DAT DP located in Komp may raise out of its nominal host to a higher position in the sentence, while a NOM DP in Spec IP may not.

In Hungarian, all FOCUS elements, including *wh*-elements, obligatorily move to a Comp-like Focus position in the sentence. So whenever the possessor is a *wh*-word it must be marked dative, as in (97), and raise to the Focus position. The *wh*-marked DP may raise as a whole (98), or else the Dative POSS DP in KOMP may raise independently (99):

(97) ki-nek a kar-ja-0
who-dat the arm-poss-3sg.

(98) [FOCP kinek a karja]$_i$ hosszu t_i
to-who the arm (is) long?

(99) [FOCP kinek]$_i$ hosszu [DP t_i a karja]
to-who (is) long the arm?

2.4.2

Landau (1999) makes a similar claim for structures containing a POSS DATIVE in both Hebrew and French.

Landau proposes that in both languages, the POSS DP is generated in the Spec position of the DP which denotes the possessed object. In Modern Hebrew, Dative case cannot be checked in this position, so the DAT Poss DP obligatorily raises to Spec VP, the only position in which DAT case can be checked:

(100) a. Gil sataf le-Rina et ha-panim.
Gil washed to-Rina ACC the face
Gil sataf [VP le-Rina$_i$ [DP t_i et ha panim]]
b. Gilles lui a lavé la figure.
Gilles lui$_i$ a lavé [DP t_i la figure]

As in Hungarian, the possessed object may denote not only a body part but any concrete object:

(101) a. ha-yalda kilkela le-Dan et ha-radio.
the girl spoiled to Dan acc. the radio
b. Gil savar le-Rina et ha-miskafayim.
Gil broke to Rina acc. the glasses

Again as in Hungarian, topicalization and *wh*-movement show that the POSS DP and the BP DP can be disjoint, as expected uner the Possessor-Raising hypothesis (cf. Borer and Grodzinsky 1986):

(102) [li] hem kilkelu [et ha-radio], ve-[laxem] hem kilkelu [et ha-televizia].
to me they spoiled acc. the radio and-to-you they spoiled acc. the-tv

(103) [le-mi] ha-yalda kilkela [et ha-radio]?
to who the girl spoiled acc. the radio
'Whose radio did the girl spoil?'

The Possessor-Raising hypothesis neatly accounts for locality, obligatory antecedent, and C-command constraints on IA as properties of movement.

Furthermore, the Possessor-Raising hypothesis accounts for locality constraints on IA better than Guéron's control hypothesis. Control occurs not only into an argument but also into an adjunct:

(104) a. Jean a voulu [PRO danser].
b. Jean est venu [pour PRO danser].
c. Jean a dansé [sans PRO tomber].

In Hebrew, however, although the POSS DP can bind a trace within either a direct object DP or one embedded in a locative, directional or instrument PP, it cannot bind into a purpose or privative adjunct:

(105) a. Gil yasav le-Rina ba-mitbax. LOC PP
Gil sat to Rina in the kitchen
b. Gil ganav le-Rikna me-ha-tik. DIR PP (SOURCE)
Gil stole to Rina from the bag
c. Gil hitkaleax le-Rina im ha-sabon. INSTR PP
Gil bathed to Rina with the soap

(106) a. *Gil pitpet le-Rikna lem'an ha-hofa'a. PURPOSE
Gil chatted to Rina for the performance
'Gil chatted for the benefit of Rina's performance.'
b. *Gil hitaleax le-Rikna bli ha-sabon. PRIVATIVE
Gil bathed to Rina without the soap
'Gil bathed without Rina's soap.'

As A-movement is blocked from an adjunct, the Possessor-Raising hypothesis automatically accounts for the ungrammaticality of the sentences of (106), while the control hypothesis incorrectly predicts their well-formedness.

Construal is also simpler under a movement hypothesis than under the binding hypothesis. Under the movement hypothesis, the POSS DP is construed in the position of its trace, movement having been triggered for formal reasons alone. The semantic relation of possession is explained by whatever accounts for the same relation within a DP: Landau proposes that the POSS DP receives a possessor theta-role from the D head. The possessor construal need not be derived from binding or from the notion of 'lexical chain'.

Landau makes an interesting attempt to account for lexical constraints on IA in purely structural terms. Recent theories propose the existence of both a VP and a vP node in the sentence (cf. Chomsky 2000). While the VP node is always

projected, vP, situated directly above VP, is projected only if the verb selects an Agent argument.

Landau assumes that dative case can only be checked in Spec VP, and that Hebrew lacks VP shells (cf. Larson 1988b). So Possessor Raising must fail if Spec VP is already occupied by an argument in d-structure. Agentive transitive verbs like *wash* or *spoil* accept Possessor Raising because they select an Agent argument merged in Spec vP. Spec VP is free to lodge the raised dative possessor:

(107) Gil sataf le-Rina et ha-punim.
Gil washed to Rina the face
[IP Gil_j sataf [vP t_j [VP le-$Rina_i$ tv [DP t_i et ha panim]]]]

Spec VP can also host a POSS DAT when V is unaccusative:

(108) ha-kelev ne'elam le-Rina.
the dog disappeared to Rina
[DP t_i he-kelev]$_j$ ne'elam le-$Rina_i$ [t_j]

But a transitive verb such as like or see, with two internal arguments, THEME and EXPERIENCER or PERCEIVER, excludes possessor raising. In (109), for example, the second internal argument occupies Spec VP, and there is no position in which dative case can be checked. In terms of the Minimalist framework of Chomsky (1995c), (109) crashes because it contains an unchecked uninterpretable case feature:

(109) *Gil ra'a le-Rina et ha-punim.
Gil saw to Rina the face
[IP Gil_j [VP t_j ra'a [DP le-Rina et ha panim]]]
NOM *DAT ACC

If Landau's analysis of the POSS DAT in Hebrew extends, as he claims, to IA structures in French, then Guéron's analysis of IA as anaphoric binding must be incorrect. Under her analysis, the acceptability of IA in French II, which is parallel to POSS DAT structures in Hebrew, requires a determiner with phi-features. Languages like Hebrew or Arabic, with invariable definite determiner, should not have the 'IA Structures' I and II, but, like English, only Structure III.

The Possessor-Raising analysis encounters both theoretical and empirical problems, however.

Chomsky (2000) tightens the grammar by eliminating case checking as a motivation for movement. If one adopts this approach, then POSS DP raising is not forced by case checking, and there must be another F which triggers it, at least when the moved element is not *wh*-marked. But it is not clear what this F could be, since the DP is construed in its original position.

In Hungarian and Russian, as well as, apparently, in earlier Hebrew, a POSS DP with oblique case generated within DP can stay in situ rather than raise to

VP or CP. The fact that a (non-*wh*-) possessor DP can remain in the position in which it is generated and construed sheds doubt on the Possessor-Raising hypothesis altogether. If a POSS DP can check its FFs in the Spec DP which includes it, then it must do so, for reasons of economy, by the Principle of Last Resort (Chomsky 1995c).

Possessor Raising violates a well-established constraint on extraction: extraction from a DP with a definite determiner is grammatical only if DP is construed as non-specific (cf. Enç 1991). This construal usually requires that the main verb have existential force, thus, that it does not presuppose the referentiality of its direct argument. Verbs which imply physical change of the denotatum of the direct object exclude extraction to the degree that they presuppose the existence of the physically affected object:

(110) a. Who did you meet/see/recognize/look for [the brother of t]?
b. *Who did you wash/beat/kill/spit at [the brother of t]?

Yet the same type of sentence which excludes *wh*-extraction because the object is bodily affected by the action of the verb, is the only type which allows the IA construal. Verbs with an existential construal, which do not affect the object and therefore allow *wh*-extraction, reject the IA construal.

(111) a. Je lui ai lavé/pincé/écrasé le bras.
b. *Je lui ai cherché/vu/reconnu le bras.

The fact that Possessor Raising violates the well-established specificity constraint on extraction from DP sheds further doubt on its existence.

Nor is there any necessity for a DAT DP to raise to Spec VP in Hebrew in order to check its case there. A DAT DP is already merged in Spec VP under its other, non-possessive, construals. Borer and Grodzinsky (1986) distinguish three construals of the dative in Hebrew: reflexive, benefactive, and possessive. Each construal is subject to syntactic and thematic constraints. Only the possessive DAT functions as an argument undergoing movement. The possessive and the benefactive may take either full or clitic form but the reflexive only has clitic form. Under the possessive construal, the dative is obligatorily associated with an object in VP; under the reflexive construal, it is obligatorily associated with the external argument; while under the benefactive construal it takes scope over the VP as a whole. These properties suffice to distinguish three construals of the same syntactic object. As none of them can be shown to depend on movement, the simplest theory generates the DAT DP in VP as a single syntactic constituent subject, in Hebrew as in French, to a variety of construals at the syntax–semantics interface.

The hypothesis that perception verbs block raising of the POSS DAT DP on the basis of their theta-grid leads Landau to exclude grammatical (112) from the data to be explained by his theory:

(112) Gil ra'a le-Rina et ha-pupik.
Gil saw to-Rina acc. the belly-button

Landau notes that sentences like (112) are acceptable under a possessive construal only if the acc. DP denotes a body part or an item of clothing. He considers such structures 'quasi-idiomatic': they are acceptable only if they involve embarrassment to the possessor of the body part. The more intimate the body part, the easier it is to have Possessor-Raising with a perception verb.

Instead of eliminating such structures from consideration, one may, on the contrary, consider them as crucial evidence that the IA construal is not determined by the theta-grid of the verb.

Cheng and Ritter (1987), among others, proposed, on the basis of contrasts like that between between (109) and (112), that the acceptability of IA structures depends on the semantic notion of affectedness: the referent of the BP DP must be affected by the action the verb denotes. Landau challenges this claim with a list of examples in which the possessed object is clearly not affected. A ring which one seeks is not affected by the action; it may not even exist. A kitchen is not affected by people laughing in it:

(113) a. Gil xipes/maca le-rina et ha-taba'at.
Gil sought/found to Rina acc. the ring
b. Gil madad/cilem le-Rina et ha gina.
Gil measured/photographed to Rina acc. the garden

(114) a. Gil caxak le-Rina ba-mitbax.
Gil laughed to-Rina in the kitchen
'Gil laughed in Rina's kitchen.'
b. Gil histakel le-Rina al ha-kova.
Gil looked-at to Rina on the hat
'Gil looked at Rina's hat.'

The evidence provided in (113) and (114) to show that the POSS DAT structure in Hebrew lacks an affectedness constraint suggests that the analysis of this structure cannot be extended to the French 'IA structure' II, which is subject to such a constraint.

The data suggest that the Hebrew structure is not in fact an 'IA structure' at all, but, rather, a 'possessive structure', which, like all possessive structures, can denote IA if it happens to contain both a [+human] DP and a BP nominal. The examples of (113) and (114), which show the absence of affectedness, crucially do not contain body-part DPs. The discussion of (112) shows that affectedness does apply whenever the DP happens to be a body part (or an article of clothing). Only those Hebrew structures which contain body-part objects are comparable to Structure II in French. Hebrew possessive structures with non-body-part DPs don't even exist in French with a possessive rather than a benefactive reading:

(115) a. Je lui ai cherché/trouvé la bague.
I to her looked for/found the ring
b. Je lui ai photographié la cuisine.
I to-her photographed the kitchen
c. *Je lui ai ri dans la cuisine.
I to-her laughed in the kitchen

In French, the IA construal of Structure II is a subcase of the benefactive construal of the same sentence. In Hebrew, the IA construal of Structure II is a subcase of the possessive construal of the same structure, just as for French *son bras/son livre* or English *his arm/his book*, except that the POSS DP and the BP nominal are disjoint in Hebrew.

That the IA construal is not a subset of BEN construals in Hebrew is shown by the ordering of constituents. In French both BEN and POSS DP may follow the possessed object DP:

(116) a. J'ai cassé sa poupée à Marie. BEN
I broke her doll to Marie
b. J'ai pris la main à Marie. POSS
I took the hand to Marie

In Hebrew, however, the DAT DP precedes the possessed object under the possessive construal but follows it under the BEN construal. Thus the possessor interpretation is obligatory only in (117a). In (117b), *le-Rina* has a Benefactive interpretation, and the face can be either Rina's or Gil's, according to Landau:

(117) a. Gil sataf le-Rina et ha-punim. (= (107))
Gil washed to-Rina the face
b. Gil sataf et ha-panim le-Rina.
Gil washed the face to-Rina

Similarly, when a non-body part, the dative DP is construed as benefactive in (118a), where it follows the object, and possessive only where it precedes the object, as in (118b):

(118) a. Gil lakax et ha-tik le-Rina.
Gil took acc. the bag for Rina
b. Gil lakax le-Rina et ha-tik.
Gil took Rina's bag

Whether the IA construal is a subset of the set of BEN construals, as in French, or of the set of possessive construals, as in Hebrew, the data show that affectedness is pertinent for the IA subset whether or not it is a property of the non-IA superset.

3 Semantic or conceptual based theories of IA

The structure-based theories of IA presented above do not filter out all the ungrammatical IA construals. Affectedness is one type of semantic constraint on some cases of IA. Other, apparently lexical, constraints also turn out to involve a semantic calculation.

(i) *Constraints on verbs* In structure I, it is not so much the choice of verb which is restricted as the interpretation of the structure. As mentioned above, Hatcher (1944) and Kayne (1975) note that the VP must describe a simple physical gesture. (119a) contrasts in grammaticality with (119b) because 'lever la main' denotes a physical gesture while 'laver la main' does not.

(119) a. Je leve la main.
I raise the hand
b. *Je lave la main.
I wash the hand

In most cases of IA, the VP must denote an action, not a state.

(120) a. Je leve la main.
I raise the hand
b. *Je regarde la main.
I look-at the hand

(121) a. Je lui prends/gratte/chatouille la main.
I to-her take/scratch/tickle the hand
b. *Je lui aime/admire/adore la main.
I to-her like/admire/adore the hand

(122) a. I hit Bill on the hand.
b. *I admired Bill on the hand.

The contrasts between (109) and (112) in Hebrew and between (123a) and (123b) in French show that the notion of action goes beyond lexical definition:

(123) a. *Je lui vois la figure/la tête/le nez.
I see to-him/her the facé/the head/the nose
b. ?Je lui vois les jambes/le ventre/le cul!
I see to-him/her the legs/the stomach/the ass

Under the IA construal, the action of the verb must affect the body part DP. (123b) is better than (123a) because in traditional society, a look at a person's private body parts is experienced as a quasi-physical attack. (123) should be less

acceptable in a nudist colony, or when discovering a body buried under an avalanche, where there is presumably no embarrassment and no 'affect'.

(ii) *Constraints on adjectival modifiers* Under the IA construal, the BP DP may not contain a non-restrictive adjective, which does not restrict the set of objects which N denotes, as in (127) below, but represents, rather, the point of view of the speaker, as in (124b):

(124) a. Jean a levé la main.
b. *Jean a levé la belle main.

This constraint is a general property of DPs containing a bound variable:

(125) a. un homme dont j'ai rencontré [la belle-fille t]
a man I met [the daughter-in-law of t]
b. *un homme dont j'ai rencontré [la belle fille t].
*a man I met [the beautiful daughter of t].

(126) a. Everyone loves his son.
b. *Everyone loves his intelligent son. (OK if restrictive)

The reference of a DP with a semantic free variable, whether it is syntactically PRO, a *wh*-item, or a covert predicate variable, depends on the successful construal of a binding relation at the syntax–semantic interface. The insertion of an evaluative adjective like 'belle' in (125) or 'intelligent' in (126) presupposes the referentiality of the evaluated object independent of the truth value of the sentence. This creates a semantic contradiction.

The insertion of a restrictive modifier, on the other hand, as in (127), does not create a presupposition of referentiality but merely adds a restriction to the definition of the set of objects N denotes:

(127) a. Jean a levé la main gauche.
b. Jean a levé la main qui a été blessée.

That it is its (non-) restrictive construal, not the adjective itself, which is crucial for IA is shown in (128) below, from Nicol (1997):

(128) a. Je lui ai lavé la main sale.
b. *Je lui ai lavé le nez sale.

(iii) *Only body part DPs participate in IA* This constraint on the IA construal is largely correct. Although it is possible to extend the IA construal to a limited class of objects in contact with the body, such as clothing or objects held in the hand, in no case may a physically separate object such as a member of the family participate in a structure construed as IA rather than Benefactive:

(129) a. Jean tombe la veste.
b. Ho perduto l'ombrello.
c. *Elle lui lave le fils.
d. *Elle soulève le cousin.

Italian, unlike French, appears to allow kinship terms under the IA construal:

(131) a. Gianni e Maria non hanno aiutato neppure la (propria) figlia.
b. *Jean et Marie n'ont meme pas aidé la (propre) fille.

However, as Delfitto and D'hulst (1995) point out, Italian, unlike French, allows a genitive pronoun between the det and the head N:

(132) a. la sua figlia
b. *la sa/sienne fille

Moreover Italian, unlike French, has null pronominals. (132) is not an 'IA construction' at all, but a standard possessive structure, equivalent to *sa (propre) fille* in French.

In order to account for these apparent semantic factors, some linguists have incorporated explicit semantic conditions into their analyses of IA. These analyses happen to target mainly structure II.

3.1 Cheng and Ritter (1987)

Cheng and Ritter posit the same IA structure for Mandarin Chinese and for French. The structure contains P and V heads which assign an 'affected theme' theta-role. This theta-role functions indirectly as a lexical-semantic filter on the construal.

(133a) and (b) in Mandarin correspond to (134a) and (b) in French.

(133) a. Ta ba Lisi da-shang-le shou.
he BA Lisi hit-wounded-ASP hand
'He (prt) wounded Lisi's hand.'
b. Ta ba juzsi bo-le pi.
he BA orange peel-ASP skin.
'He (prt) peeled the skin from the orange.'

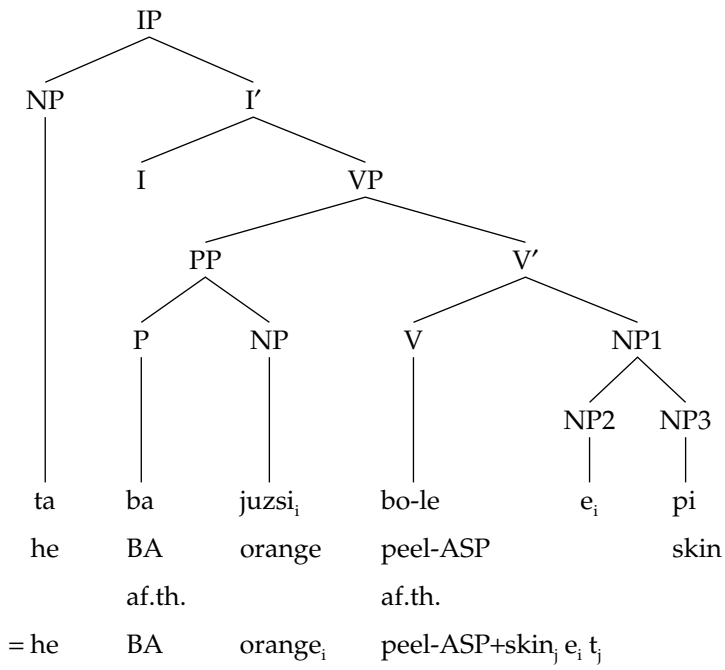
(134) a. Il a lui blessé la main (à Marie).
b. *Il lui a epluché la peau (à l'orange).

Although French admits only body part DPs under the IA construal whereas Chinese allows part–whole relations in general, the relevant structure is subject to the same constraints in both languages. Locality must be respected. The DP cannot contain a non-restrictive adjective. The relation excludes kinship terms

and alienable possession: *son* may not replace the BP NP *hand* in (133a) nor may a pronoun replace *orange* in (133b). The DP must be affected by the verb.

(133c) shows the structure of (133b) in Mandarin:

(133) c.



In (133c), both the particle *ba* and V *peel* assign the theta-role "affected theme" (af.th). The complement of the verb is a small clause (NP1) whose subject (NP2) is an ec bound by the preverbal NP and whose predicate (NP3) denotes the possessed nominal. Lack of non-restrictive adjectival modification in IA automatically follows from the predicative status of NP3.

In Logical Form, NP3 raises onto the verb, forming a complex predicate. In (133), the verb *peel* and the sc predicate *skin* jointly assign the theta-role of 'affected theme' to the preverbal NP *orange* which binds the small clause subject.

This syntactic analysis of Structure II does not extend to other 'IA structures', however. In (135a), two Ns would raise to V, one of which is embedded in a PP, which is a barrier to syntactic raising in French. In (135b) the two raised Ns are predicates of different NPs; but no verbal predicate, not even a complex one, can have two subjects:

(135) a. Je lui$_i$ ai mis la main$_i$ sur la tête$_i$.
b. Je lui$_i$ ai mis la main$_j$ sur la tête$_i$.

Unlike French II, the Mandarin structure is not limited to body parts but includes part–whole relations, while eschewing kinship terms. Interestingly, Structure III in English and French has the same property:

(136) a. I took the baby by the arm.
b. I took the pot/the knife by the handle.
c. We sang the song from the beginning (to the end).
d. We climbed the mountain to the top.

(137) a. *I wounded him on/through/via the son.
b. *I dragged him with the daughter.

(138) a. J'ai pris le bébé par le bras.
b. Je lui ai lu l'histoire du début à la fin.
c. J'ai pris le couteau par le manche.

(139) a. *Je l'ai blessé par le fils.
b. *Je l'ai pris avec la fille.

Instead of taking IA as the construal of disjoint DPs shared by Structure III in English and French and Structure II in Mandarin, we may instead take the less lexically restricted part–whole construal of the disjoint DPs as basic. Then, just as IA is a subconstrual of possession in genitive DPs in general and in structures with disjoint DPs in Hebrew, and a subconstrual of BEN structures in French II, it is a subconstrual of the part–whole interpretation of disjoint DPs in Mandarin II and in English and French III. No structure is limited to the IA construal.

3.2 Koenig (1999)

Koenig adopts anaphoric control as the syntactic theory of IA, and adds to it a semantic constraint based on a kind of affectedness.

An IA structure would be one which contains a body-part NP with a lexically inserted covert reflexive possessor subject. The covert subject is construed as PRO and is subject to anaphoric binding, as in Guéron (1983, 1985). All structures containing the configuration (140), in which a DP with anaphoric possessor is bound by an antecedent, are subject to a semantic constraint involving the denotatum of NP1 and that of NP2 with respect to the situation the sentence describes:

(140) $NP1_i \ldots NP2\ Poss_i$

(141) Semantic Constraint on the Antecedent of a Body Part NP in the Inalienable Possession Construction: An NP1 can only be the antecedent of the (unexpressed) possessive anaphor of a BP NP2 if the BP is the active zone of the referent of NP1 (Koenig 1999: 238).

Let *x* and *y* be two entities filling the argument postions O1 and O2 in the same sentence. *x* is the active zone of *y* iff the semantic role entailments which characterize O2 are true of *x* (Koenig 1999: 239)

(141) accounts for the grammaticality of (142–144) below:

(142) Jean a poussé la balle de la main.
Jean pushed the ball with the hand

(143) a. Marie lui a lavé les pieds.
Mary to-him washed the feet
b. Marie a lavé les pieds au saint homme.
Mary washed the feet to the holy man

(144) Les pieds nous demangent.
the feet us itch

In (142), the NP *Jean* (= *y* in (141)) has the theta-role of ACTOR. The theta-role entailment of an ACTOR is that it causally initiates the action in which it participates. The active zone of *Jean* is that part of his body which bears that same entailment. Since *Jean* may not initiate the action of pushing the ball without the hand also causally initiating the action, the actor entailment holds of both the hand (= *x* in (141)) and *Jean*. So (142) passes the semantic filter (140).

In (143) *lui/le saint homme* has the BENEFICIARY/MALEFICIARY theta-role whose theta-role entailment is that the bearer profit/suffer from the occurrence of the event. In (143) both *lui/le saint homme* and *les pieds* profit from the event.

In (144), both *nous* and *les pieds* have the theta-role entailment of the PATIENT of the action (*les pieds* having an additional role of cause).

In ungrammatical (145), however, *Marie* is ACTOR but *les pieds* does not share its theta-role entailment: *les pieds* do not causally initiate the action. (145) is ungrammatical because it violates the Semantic Constraint (140).

(145) *Marie a lavé les pieds.
Mary washed the feet

Koenig concludes that the necessity for Constraint (140) to filter IA structures which binding theory alone accepts shows that the grammar can impose non-configurational semantic conditions on syntactic processes. In particular, model-theoretic notions such as theta-role entailments must be available to grammatical description.

The semantic filter proposed by Koenig has the advantage of recognizing, and attempting to make explicit in terms of the notion 'active zone' the fact that affectedness involves not only the verb and the BP DP in a sentence but also the relation between the POSS DP and the BP DP with respect to the situation they participate in.

The empirical coverage of the analysis is insufficient, however. It predicts that (140) should function in the same way for all IA structures since all of them contain the configuration (139). It thus cannot account for the contrasts in (146) and (147). Although *le nez* or *la main* is the active zone of the antecedent DP in both sentences, only one of the sentences is grammatical:

(146) a. Je l'ai frappé sur le nez.
b. *Je lui ai frappé le nez.

(147) a. Le lutteur a écrasé la main à son adversaire.
b. *Le lutteur a écrasé son adversaire à la main.

Moreover, the notion active zone suggests that IA sentences invariably denote actions. But IA can be construed on a stative sentence also. It is hard to interpret 'les yeux' or 'les epaules' as having any active zone relation to Jean in (148):

(148) Jean a les yeux bleus, les epaules larges, etc.

The crucial claim that the antecedent DP and the BP DP must share the same theta-role entailments in an IA-structure cannot be tested, for no independent criterion of a theta-role entailment is given. One way to test theta-role entailments is by syntactic distribution: two NPs must have the same theta-role entailment if they appear in the same syntactic environments. But BP DPs, which are [–animate], do not appear in the same syntactic environments as AGENTS and BENEFACTIVES which are typically [+animate]:

(149) a. Jean a battu Pierre avec ses mains nues. AGENT
'Jean beat Pierre with his bare hands.'
b. *Les mains de Jean ont battu Pierre.
'The hands of Jean beat Pierre.'

(150) a. J'ai cassé le pied à Jean. BEN
'I broke the foot to Jean.'
b. *J'ai cassé le pied à la table.
'I broke the foot to the table.'

(151) a. Beulah, peel me a grape. BEN
b. *Beulah, peel the fruit salad a grape.

Similarly, the subject in (152a, b) is a BEN or PATIENT, which bears the brunt of the state which the verb denotes. But as *les pieds* cannot replace *il* in (152c), what motivates the claim that the two DPs have the same theta-role entailment?

(152) a. Il souffre des pieds.
'He is suffering in the feet.'
b. Il souffre.
'He is suffering.'
c. *Ses pieds souffrent.
'His feet are suffering.'

Finally, the analysis makes no attempt to situate IA within the theory of grammar. Each language would have its own list of IA constructions. If so, one should

expect each language to have its own list of control, anaphora, *wh*-, focus, passive-middle constructions, etc. While this is true, descriptively, to some extent, much progress has been made towards deriving individual constructions from a general theory of principles and parameters. The assumption that each language has a list of specific syntactic structures is a step backwards.

3.3 Jackendoff (1996), Nicol (1997)

For Cheng and Ritter (1987), affectedness is a lexical-semantic Feature of the THEME theta-role assigned by the particle *ba* in Mandarin and by certain verbs in Mandarin and French. For Koenig (1999), affectedness is a semantic constraint on IA, which somehow intervenes in the syntactic derivation, although it is not clear where and how.

Jackendoff (1996) is more explicit on this last point. He proposes a grammar with parallel structures in which phonological, syntactic and conceptual rules all feed a derivation. Semantic or phonological principles can block or favor a syntactic structure at any point in the derivation via correspondence rules which link the separate components:

(153) PHONOLOGY↔Corr. rules↔SYNTAX↔Corr. rules↔
CONCEPTUAL STRUCTURE

Nicol (1997) applies Jackendoff's model to the grammar of IA. Nicol addresses the question why the IA Structure II is more productive in French with a clitic than with a full dative POSS DP. He proposes that the answer to this question lies in the correspondence rules linking Syntax to Conceptual Structure.

Although V&Z treat the full and clitic dative forms as equivalent, Dorel (1980) had already shown that while both forms are acceptable under the GOAL construal of the DAT DP, this is not always the case under the BENEFACTIVE or IA construals:

(154) a. Marie a donné un cadeau à son pere. GOAL
Marie gave a present to her father
b. Elle lui a donné un cadeau.

(155) a. Marie a cassé son jouet à Pierrot. BEN
Marie broke his toy to Pierrot
b. Marie lui a cassé son jouet.

(156) a. Jean a caressé la joue à Marie IA
Jean carressed the cheek to Marie
b. Jean lui ai caressé la joue.

(157) a. Marie va lui casser la vaisselle. BEN
b. *Marie va casser la vaisselle à sa mere.
Marie will break the dishes to her mother

(158) a. Jean lui a donné un coup dans les dents. IA
b. *Jean a donné un coup dans les dents à Max.
Jean gave a blow in the teeth to Max

Nicol notes that all speakers accept both the clitic and the full form with dynamic verbs, in particular under an idiomatic construal:

(159) a. Paul tirait les cheveux à sa petite soeur.
Paul was pulling the hair to his little sister
b. Paul lui tirait les cheveux.

(160) a. Le fisc casse les pieds aux contribuables.
the taxman breaks the feet of (harrasses) the taxpayers
b. Le fisc leur casse les pieds.

(161) a. Cet incident a ouvert les yeux à Marie-Jeanne.
this incident opened the eyes to Marie-Jeanne
b. Cet incident lui a ouvert les yeux.

In the standard dialect of French, however, sentences like (162a), cited by V&Z as grammatical (cf. (77a) above), are acceptable only with a clitic, not with a full DP:

(162) a. *Le docteur a examiné la gorge à la petite fille.
the doctor examined the throat to the little girl
b. Le docteur lui a examiné la gorge.

Nicol reviews in detail the distribution of clitic and full DATIVE DPs in Structure II in terms of the lexical-semantic type of the verb, the target of its action, and the affect of the action on the BP DP and/or the Poss DP. He distinguishes three classes of verbs: type A accepts only the clitic, type B accepts neither clitic nor full DP, and type C accepts both clitic and full DP.

Type A: verbs of static contact, lacking 'affect': coller, toucher, envelopper, effleurer, etc.:

(163) a. *Les bandelettes enveloppaient la tête à la momie.
the bands envelopped the head to the mummy
b. Les bandelettes lui enveloppaient la tête.

(164) a. *La robe colle à la peau à Christine.
the dress sticks to the skin to Christine
b. La robe lui colle à la peau.

Type B: verbs of inchoative contact and of impact: atteindre. attraper, blesser, frapper, poignarder, taper, etc.:

(165) a. *Le jeune homme a attrapé/blessé le visage à son agresseur.
b. ?? Le jeune homme lui a attrapé/blessé le visage.

Type C: verbs which imply dynamic contact or change of state with affect: serrer, enlacer, briser, casser, éclaircir, nettoyer, amputer, inciser, lever, pousser, traîner, etc.:

(166) a. Il a serré la main à son pire ennemi.
he shook the hand to his worst enemy
b. Il lui a serré la main.

(167) a. Il a cassé le bras à son adversaire.
he broke the arm to his opponent
b. Il lui a cassé le bras.

(168) a. La charbon noircissait le visage aux mineurs de fond.
the coal blackened the visage to the miners
b. La charbon leur noircissait le visage.

(169) a. Le chirurgien a amputé le bras au soldat.
the surgeon amputated the arm to the soldier
b. Le chirurgien lui a amputé le bras.

Nicol proposes that every IA structure is linked by a correspondence rule to a lexical conceptual structure (LCS). The same verb may appear in several structures, linked to as many LCS. The sentences of (170) correspond to two LCS, which both include the dynamic LC primitive GO:

(170) a. Le blessé$_i$ a levé la jambe$_j$.
the wounded man raised the leg
b. L'infirmier$_i$ leva la jambe$_j$ au blessé$_k$.
the nurse raised the leg to the wounded man

The LCS (171) corresponds to the syntactic structure (170a). It contains three lines, one which indicates dynamic movement; a second, which indicates a part–whole relation between *jambe* and *blessé*; and a third, which indicates that the *blessé* is affected by the action (Nicol 1997: 510):

(171) $\begin{bmatrix} \text{GO } ([\text{JAMBE}]_j, [_{\text{Path}} \text{ UP } [\ ]]) \\ [\text{BE}_{\text{Iden}} ([\gamma], \text{PART OF } [\alpha])] \\ \text{AFF } (\text{BLESSE}_i^{\alpha}) \end{bmatrix}$

LCS (172) corresponds to structure (170b). It differs from (171) in that it contains a causative notation in the first line and includes two affected participants instead of one in the third line:

(172) $\begin{bmatrix} CS_{entrain} + ([\alpha], GO ([JAMBE]_j, [_{Path} UP [\ ]]) \\ BE_{Ident} ([\gamma], PART OF [\beta])] \\ AFF (INFIRMIER^{\alpha}_{i}, BLESSE^{\beta}_{k}) \end{bmatrix}$

Nicol proposes that an IA structure with full lexical Dative is acceptable only if (i) the LCS contains the conceptual primitive GO, (ii) the direct object is TARGET of the action, and (iii) the dative DP is AFFECTED.

The ill-formedness of stative (173) is due to the absence of the GO primitive in its LCS. And that of (174a), which contrasts with (174b), is due to the absence of AFFECT in its LCS:

(173) *Je lui ai admiré les jambes.

(174) a. *La belle prit la main au Prince. (Type B)
b. Le judoka prit le bras à son adversaire. (Type C)

Structure III is related by a correspondence rule to an LCS in which there is an AFFECT primitive, but no TARGET. In such cases, the Affect is global.

Nicol also locates the difference between English and French with respect to Structure II in the determiner of the BP DP, not in its morphology, like Guéron, nor in its construal, like V&Z, but via a language-specific correspondence rule of English which targets the determiner.

Structures I and II are associated with an LCS in which the BP DP corresponds to a TARGET of AFFECT, while Structure III is associated with an LCS with global affect: not only the BP but the POSS DP is affected by the action of the verb. English has a special correspondence rule, (171), which requires Global rather than local AFFECT whenever the determines a DP denoting a possessed item:

(175) [DO the N] = Possessor = [+Affected: [–Target]]

Nicol concludes from his detailed study of the distribution of the DAT DP in Structure II that syntactic analysis alone cannot distinguish grammatical from ungrammatical IA structures. Each structure must be linked to an LCS which functions as a semantic filter on its construal.

Nicol's analysis shows that the semantics of the IA construal is more complex than was previously supposed. AFFECT is not a defining property of all IA structures: there is no affect in class A of Structure II (cf. (59–60)). When affect is a property of IA, it may be targeted, as in French I and II, or global, as in Structure III.

The analysis has weak spots, however. One concerns the justification for parallel grammatical components, the other the notion of affect.

In Jackendoff's LCS component, a vocabulary of primitive conceptal notions combine to form LCS formulas which correspondence rules link to syntatic structures. Any theory of grammar which relates syntax and meaning must, like Jackendoff's, assume the existence of a limited repertory of semantic primitives,

and must furthermore relate each syntactic structure to a meaning. It is not evident, however, that LCS formulas and correspondence rules are necessary to accomplish these tasks. It must be shown that a grammar with less machinery, which maps primitive conceptual notions directly onto the morphemes of a syntactic output, and interprets these as a function of the compositional interpretation of the syntactic structure, cannot give the same results as one which appeals in addition to LCS and correspondence rules.

Under Nicol's account of IA, the correspondence rules which link syntactic structures to LCS are subject to language-particular constraints, such as that which stipulates that all IA structures in English must have global affect. Such an account is descriptive at best, rather than explanatory.

The non-equivalence of the theta-role entailments of POSS and BP DPs raises the question of the pertinence of the notion 'affect'. This notion is never defined, for good reason: it changes from structure to structure. In structures with BEN dative, affectedness refers to the psychological consequence of a situation on an individual. In 'IA structures', affectedness, when pertinent, involves physical contact. Psychological affect may be construed as a quasi-physical attack, as shown by Hebrew (112) and French (123), and by the idioms based on IA in (176):

(176) a. (i) Il a perdu la tête. (Structure I)
(ii) He lost his head.
b. (i) Tu me casses les pieds. (Structure II)
(you to me break the feet = you bore me)
(ii) I gave him a piece of my mind.
c. (i) Je l'ai regardé droit dans les yeux. (Structure III)
(ii) I looked him straight in the eye.

Inanimate objects are not subject to psychological affect, so *handles* cannot replace *legs* in structure II. Yet *handles* can easily replace *legs* in Structure III. Affect must therefore refer to something different in III than in II:

(177) Je lui ai vu les jambes (à Marie).
I to-her saw the legs (to Marie)

(178) *Je lui ai vu la poignée, à la casserole.
I to-it saw the handle, to the pot

(179) a. John pulled her by the arm.
b. I picked the pot up by the handle.

Finally, not all 'IA structures' involve affect (cf. (180)). Whatever it is, affect is not a general property of the IA construal:

(180) a. Les bandelettes lui couvrent le front.
the bands to her cover the forehead

b. Les cheveux lui descendent de la tête aux pieds.
the hair to her descends from the head to the feet

4 A return to binding

4.1 IA as anaphora

'Alienable' as well as 'inalienable possession' often involves phi-feature agreement between the possessor DP and the possessed NP. In Romance possessives, the head agrees in number and gender with a pronominal genitive. In the English genitive, either the prenominal POSS DP is a pronoun ('my book') or D bears an 's morpheme ('John's book') which functions as an AGR head (cf. Zribi-Hertz 1998). In Hungarian, the N which denotes a possessed item agrees in number and gender with the possessor.

Other possessive structures do not manifest phi-feature agreement between the POSS DP and the possessed N. Such is the case in French when the POSS DP is post-nominal ('les livres de ma cousine' – 'the books (m. pl) of my cousin (f.sg.)'), or when the DAT possessor and the possessed object are disjoint, as in Hungarian, Hebrew, or English III.

This last point may be incorrect, however. Perhaps Guéron (1983, 1985) was too hasty in concluding that the definite determiner does not function as a pronominal in English. The theory of the IA construal would be unified in an elegant manner if the definite determiner could be construed not only as an operator or an expletive, but also as a pronominal.

In English, the definite determiner has pronominal properties. The TH morpheme of *the* corresponds to a deictic F in the demonstrative paradigm THIS, THAT, THOSE.

Like pronouns and unlike anaphors, demonstratives, with or without a head N, trigger coreference over a sentence boundary:

(181) a. The apples look good.
b. They are good.
c. Allow me to offer you this one.
d. This is the best one.

Like pronominals and unlike anaphors, the demonstrative can have ostensive reference.

(182) a. Thank God he left (said of an obstreporous guest).
b. This is beautiful.

Like pronominals, demonstratives denote only objects when they vary in phi-features but they denote predicates and propositions when they are invariable:

(183) a. Mary est belle.
f. f.
b. Je le/*la sais.

(184) a. John is sick, and he won't come to the party.
b. (i) I know it/*them.
b. (ii) I know that/*those.

(185) a. Mary is both beautiful and smart.
b. That/*those she is.

Let us add *the* to the paradigm of demonstrative pronominals bearing a deictic F. We may now characterize the IA construal as anaphora in the widest sense, including both anaphoric and pronominal binding.

Unlike pronouns or deictic *this/that*, the definite determiner may not appear without an accompanying N in English or French:

(186) a. It is too big.
b. This is too big.
c. *The is too big.
d. The box is too big.

However, in other languages, such as Spanish, an isolated determiner may be construed as a head modified by a clause:

(187) El bañarse immediatamente despues de comer es peligroso.
(The to-swim right after to-eat is dangerous)

The contrast between *the* and *the box* in (18c, d) recalls a similar contrast between bare *wh*-words like French *que* or Portuguese *que*, and full *wh*-DPs such as *quel livre* or *que livro*. The bare forms have a more restricted distribution than the full forms (cf. Ambar 1987, for a full discussion):

(188) a. Je sais quand/où/à qui tu as parlé.
b. *Je sais que tu a dit.

(189) a. Que livro a Joana comprou?
(What book Joana bought?)
b. *Que a Joana comprou?
(What Joana bought?)

Like the bare WH morpheme, the bare TH morpheme needs a lexical item to determine its range, in place of its missing phi Fs.

The hypothesis that *the* may be construed as a pronominal morpheme in *the boy* just as *le* may be construed as an anaphoric morpheme in *le bras* illuminates certain properties of IA.

Like a pronominal or a deictic element, 'the N' participates in discourse anaphora. There need not even be an antecedent if the intended referent is unique in context:

(190) a. A boy entered. He sat down.
b. A boy entered. The boy sat down.

(191) a. Get him out of here.
b. The sun is shining.
c. John and Mary sold the car.
d. I forgot to turn off the gas.

'The N' can be related to a discourse antecedent by metonymy as well as by identity:

(192) a. Le roi est mort. Les drapeaux sont en berne.
b. The king is dead. The flags are flying at half-mast.

This is harder for a pronoun, which normally has to match its antecedent in phi-features, yet it can be forced:

(193) a. I saw the Joneses last night.
b. *I like him.
c. I like HIM better than HER.

The pronominal determiner *one* is construed referentially when it has a F for number, and generically when it does not:

(194) a. These pears are for sale.
Give me the firmest ones.
b. One does what one can to survive.
*Ones do what ones can to survive.

The, having no phi-features, also allows generic reference:

(195) a. Dr Jones has studied the kidney for years.
b. Mrs Smith often goes to the opera.

Most often, however, *the* is not generic, but functions as a pronominal linked to a discourse topic. The N predicate of the DP is linked to the topic by a part–whole or metonymy relation. The discourse topic may be created explicitly, like *the body* or *the Jones family* in (196), or it may be derived implicitly from the lexical

items in the sentence, like the implicit 'the body' in (195a) or the information that John and Mary own a car in (198c):

(196) a. The hand is an important part of the body.
b. When swimming, one should keep the hands close to the body.
c. In the Jones family, the father does all the housework.

(197) a. These gloves keep the fingers warm as toast.
b. Swimming is good for the back.

(198) a. Gianni e Maria hanno venduto la machina.
b. Jean et Marie ont vendu la voiture.
c. John and Mary sold the car.

V&Z argue for the hypothesis that the BP DP has a type denotation by showing that backward pronominalization, which is a criterion for coreference rather than binding, applies to French IA:

(199) Parce qu'elle est sensible, le médecin a décidé de leur protéger la tête d'une cagoule.
(Because it is sensitive, the doctor decided to protect to them the head with a hood)

Backward pronominalization also occurs in English, however, where, according to V&Z, nominals refer to tokens rather than types. The evidence of (200) suggests that backward coreference is not type reference associated with NP, but normal pronominal coreference of two DPs.[2]

(200) a. Because they are so sensitive, the doctor said to keep the eyes out of the sun at all times.
b. Because it is still fragile, the doctor advised keeping the arm in a sling for two weeks more.
c. Because it is a gas-guzzler, John and Mary sold the car.

More precisely, it seems that in all cases of backward pronominalization, the sentence implies a discourse topic to which the pronoun and the full DP refer independently.

Just as pronouns are in complementary distribution with anaphors, pronominal *the hand* is in complementary distribution with anaphoric *la main*. An anaphor is used when a bound pronominal and its antecedent are co-arguments of the same domain, while a pronominal is used if they are in different argument domains. Thus, PP contains an anaphor when V and P define a single predicate, as in (201a), but a pronoun in (201b), where PP functions as an adjunct (i, ii) or as predicate of a small clause (iii, iv).

(201) a. (i) She threw water on herself/*her.
(ii) Mary told stories about herself/*her.
(iii) Mary has a fixation on herself/*her.
b. (i) Come sit beside me/*myself.
(ii) Mary heard stories about her/?? herself.
(iii) She saw a serpent next to her/*herself.
(iv) She put the key behind her/*herself.

In the 'IA Structure' III, the definite determiner is embedded in an adjunct, which excludes anaphors. *The* in (201c) replaces the pronoun in (202b) not the anaphor in (202a):

(202) a. *I hit him on himself.
b. I hit him on his arm.
c. I hit him on the arm.

The construal of the French determiner *le* with respect to IA may target either its phi-features or its [+D] F. In the first case, *le* N is a bound anaphor in Structures I and II. In the second case, *le* N is a bound pronominal in Structure III. In English, the IA construal is not possible in structures like I and II because its definite determiner lacks phi-features.

Because the domains of anaphoric and pronominal binding are complementary, we may conclude that whenever English has the same 'IA structure' as French, the determiner is functioning as a pronoun in both languages. As noted above, the antecedent and bound DP are in different domains when the latter is in a PP adjunct in Structure III. They are also in different domains even in Structure I whenever the determiner of the BP DP defines an argument domain distinct from that of its antecedent.

Consider the sentences in (203) and (204), which are grammatical in both English and French:

(203) a. Le médecin a demandé à Jean de lever la main droite.[3]
b. ? The doctor asked John to raise the right hand.

(204) a. Le medecin a demandé à Jean de lever la main qui lui faisait mal.
b. The doctor asked John to raise the hand which hurt him.

Following Kayne (1994), we propose that the addition of restrictive material in sentences like (204) allows the determiner to function as the head of a restrictive relative clause internal to DP:

(205) [CP1 He raised [DP the [CP2 $hand_i$ [C' $which_i$ [IP t_i hurt]]]]]

Extending this analysis to (203), we may take *le* to function in general as an anaphoric element within the syntactic domain of its governor, but as a pronominal when it heads its own syntactic domain.

4.2 [+D] as a phi-feature

Phi Fs may be either formal features (FF), destined to be erased in syntax after checking, or referential features (RF), destined to be construed at the interface. For example, number and person are formal features on predicates but referential features on arguments. Korean has a FF for 'honorificity' which is a morphologically visible agreement F on V, but an intrinsic RF of certain lexical items such as 'mother' or 'professor' (cf. Kang 1999). Gender is a FF in French which appears on N, A, and participial heads, but a RF in English, where no lexical head is marked for gender. The same morpheme may carry a FF in one context and a RF in another. In English, *s* is a referential number F on N (*book* vs. *books*) but a formal [nb. + pers.] F on V (*John runs*) and a formal person F on D (*John's book*). In Hungarian number and person (but not gender) are formal FFs which appear on N or V under agreement with a DP in Spec Agr.

Formal Fs on a head are valued under agreement between the head and a DP in its Spec position. They are also valued on an N head under local binding, as in reflexive sentences, which also falls under F-agreement. RFs appear on the DP which determines agreement in Spec, or binds an anaphor within an argument domain or a pronominal over domains.

In English, [+D] is a referential, pronominal F which is bound over argument domains, as in Structure III or in sentences like (203b) and (204b) above. But nothing prevents a language from treating [+D] as a FF under local agreement.

The Construct State (CS) DP in Hebrew exhibits agreement in 'definiteness' between DP in Spec AGR and the N head which raises from AGR to D:

(206) beit ha sefer
[DP beit$_i$ [AGRP ha sefer AGR t$_i$]]
+D +D
house the book

'Definiteness' would correspond to the construal of [+D] as a formal O-F defining an agreement relation between the DP in Spec AGR and the N head. When N raises to D, the locus of reference in DP, the formal +D F of N is construed as a referential F, establishing the referentiality of the DP as a whole. Raising from N to D has the function of changing the construal of +D from FF in AGR to RF in D.

When the Possessor and the possessed object are distinct DPs in Hebrew, [+D] is a referential F. This is shown by the fact that the POSS DP may be related to the possessed object over a PP boundary, as in (207). This boundary blocks anaphoric relations such as agreement, binding or A-movement:

(207) Gil niskav le-Rina al ha-mita.
Gil lay to-Rina on the bed
'Gil lay on Rina's bed.'

Anaphora is local agreement involving FFs while pronominalization is non-local agreement between referential Fs. [+D] functions in Hebrew as a formal F below D and as a referential F in D. +D is solely a referential F on D in English and French. If it were a FF, we might expect those languages to have CS. But neither English nor French have a referential DP without a pronominal specifier or a (in)definite determiner to carry the +D F. In French, in the absence of a +D phi-F, a Noun can obtain a +D RF under Spec-Head agreement on the CP level within DP, as illustrated in (208b), perhaps via transfer of the referential +D F of the determiner to the formal +D F in the particle *de* in Comp:

(208) a. *fille le roi t
b. la fille du roi
[DP la [CP fille [C' de [AGRP le roi AGR fille]
+D +D +D

5 Semantic constraints on IA and the Minimalist Program

The minimalist framework of Chomsky (2000) integrates the hypothesis of Distributive Morphology (Halle and Marantz 1993) according to which syntactic nodes contain only the formal features necessary to trigger 'merge' and 'move'. Words are inserted late, in the phonology. Construal at the interface must then be limited to the interpretation of referential Fs and the syntactic configurations in which they appear.

Certain primitives of Jackendoff's theory could function at the syntax–semantics interface as the conceptual counterparts of referential Fs. The syntactic articulation of these RFs would be determined compositionally on autonomously derived syntactic structures.

Notions such as GO or IDENTITY plausibly correspond to FFs of verbal heads construed as RFs and concepts at the interface. Such notions are easy to grasp and necessary throughout the grammar. GO distinguishes states from events. This distinction is crucial for filtering verbal forms like the progressive, and for matching time adverbials with VPs. IDENTITY translates a F on the copula which distinguishes predicative from identificational sentences ('John is my best friend' vs. 'My best friend is John') and is necessary to derive cleft and pseudo-cleft construals.

Other notions which are essential for construal correspond to entire substructures, not to syntactic heads. 'Part of' in (172) and (173) above is a concept which is both easy to grasp and crucial for the construal of partitive DPs and for

filtering extraction from DP of French *en* or Italian *ne*, but it requires defining relations between nominals within a structure.

A conceptual primitive may be easily construable and independently necessary in the grammar yet not be crucial for the IA construal. GO, which is a plausible semantic primitive, is not pertinent for the construal of the IA examples of (209):

(209) a. Marie a les yeux bleux.
Marie has blue eyes.
b. Elle est entrée la tête haute.
She entered, head held high.
c. Les cheveux lui descendent de la tête aux pieds.
Her hair goes down from her head to her feet.

As for AFFECT, this notion, if it is one, cannot be defined on a head, as it must at the least relate a nominal to a situation. Nor is it easy to grasp, as its meaning changes with each structure, nor is it a necessary property of IA.

The fact that no syntax-based analysis of IA has yet been able to account for the interpretive constraints which filter these structures does not imply that such analyses cannot do so in principle and that the syntactic component must incorporate semantic constraints. The theories we have sampled above, which propose semantic constraints, are unable to account for the full range of the data.

What needs to be discovered is a still unknown FF or Fs whose referential counterparts interact at the syntax–semantics interface with other formal features and with the construals of syntactic configurations to derive the equivalent of affect where it is needed, in dynamic IA sentences, for example, but not where it is unwanted, in stative sentences.

Some of the formal and lexical Fs which are crucially involved in the semantic calculus of IA have already been discovered: Formal phi-Fs and the [+D] F, lexical Fs such as [+animate] and the semantic 'body-part' F which together changes a 'possessive' construal into an 'IA' construal. Crucial syntactic constraints include c-command, locality, and whatever defines an argument domain. The missing FF will interact at the interface with these other Fs and with the construal of the sentence as denoting an action or a state. As the list of FFs available to natural language is small, the missing feature or features should not be impossible to identify.

NOTES

1 A reviewer notes, interestingly, that one can say (i) but not (ii) in English. She or he asks whether (15a) might not represent a 'type' reading of the object DP in the sense of Vergnaud and Zubizarreta (1992).

(i) He raised his hand.

(ii) *He has his blue eyes.

(ii) is possible, in fact, under a special reading, as the answer to a question like "What does John have going for him anyway that Mary is so smitten?" Exactly the same is true for (iii) in French, first pointed out by A. Culioli (p.c.):

(iii) (*) Il a ses yeux bleus.

For us, this data suggests, not necessarily a type construal of the DP, but a difference in interpretive domains. Pronominal reference is acceptable only if the DP containing the pronominal is situated in an interpretive domain distinct from the domain which contains the antecedent. In the acceptable readings of (ii) and (iii), such a domain is defined by presupposition.

2 A reviewer notes, very pertinently, that in fact definite DPs in English can denote types (e.g., 'The dog is a mammal' – my example), contrary to V and R's claim, and suggests that the DPs in both (198) and (199) denote types. We believe there is no contradiction between this hypothesis and the text suggestion that *the* is a pronominal in English. According to Carlson (1977a), types, or KINDS, are individuals, like names and pronouns. The characterization of *the eyes* in (199a) as a type/kind, does not prevent it from being construed as an individual with the discourse function of referring back to an implicit topic, the body. *The eyes* would function with respect to *the body* like *him* with respect to *John* in ordinary pronominalization: each entity includes a subset of the features of an antecedent to which it must be linked in order to refer.

3 Schmitt (2000) provides a Kaynean analysis of adjectives like *wrong* which are precisely the ones allowed with IA BPs.

1 Introduction

In this chapter, we will consider a phenomenon known as *inverse linking*, a term coined by May (1977) to describe the most salient readings of sentences such as 'Someone from every city despises it'.[1] What is interesting about this sort of sentence is a particular 'quirk' in its interpretation, in that the embedded quantifier phrase preferentially receives a wide-scope interpretation. In the example at hand, 'every city' has scope over 'someone', so that it is naturally read as meaning that for each city, there is at least one person that despises that city. Inverse linking has prompted much discussion since the early 1970s in the linguistic literature. Our aim here is to explore the influence the inverse linking phenomenon has had on syntactic theory, especially with respect to the syntactic representation of quantifier scope. By examining such issues, we hope to demonstrate how the understanding of this phenomenon has highlighted the difficulties in investigating the link between language and meaning.

In the discussion to follow, we will initially address research conducted during the 1970s and 1980s on the significance of inverse linking for the issue of the logical representation of natural language in general, and on notions of covert, syntactic movement in particular. As we will see, inverse linking was one of the strongest examples for motivating post Surface Structure (SS) movement of quantifier phrases, a form of covert movement called Quantifier Raising (QR). Ironically, although the effect of these examples is acknowledged in the post-eighties literature, post-eighties theories of QR are generally incompatible with inverse linking. In an effort to rid ourselves of this irony, we will focus on two of the principal works on inverse linking, viz., Larson (1985c) and May (1985). We hope to re-establish the judgments concerning this type of quantifier interaction while also discussing some of the specifics of Larson's and May's theoretical machinery.

2 Linked and non-linked quantification

In this section we will argue for a parallelism between Quantifier Phrases (QPs) that interact with each other within a complex NP and QPs that interact as arguments to the same verb or predicate relation. First we will discuss the kind of syntactic constructions relevant for inverse linking. We will then demonstrate how such constructions reveal scope ambiguities (or lack thereof) that mirror the ambiguities found with subject and object quantifiers. Finally we will also demonstrate how quantifiers within complex NPs undergo the same type of scope freezing effects as regular subject and object quantifiers.

To begin, inverse linking involves complex NPs with the syntactic structure shown in (1a) below. The preposition can be locative in nature (in English this includes *at*, *from*, *in*, and *on* to name a few) or it can simply serve as a connector to a relational noun (in English, this preposition is normally *of*). The relevant NPs each have quantificational determiners such as *every*, *some*, *a*, *two*, *three*, *at least four*, *few*, *most*, etc. Some example phrases appear in (1b):

(1) a. $[_{NP}$ Det $[_{NP}$ $[_{N}$ Noun] $[_{PP}$ $[_{P}$ Preposition $[_{NP}$ . . .]]]]]
b. Someone in every building, every man from a small town, at least three women on each committee, a parent of every child . . . etc.

These complex NP constructions demonstrate at least two types of scope interactions: an inversely linked interpretation where the embedded quantifier takes scope over the main NP and a surface-scope reading with the opposite interaction. Some prepositions like *with* and *without* resist any inversely linked interpretations, only allowing the surface-scope reading. For example, (2a) is a statement about the resignation of most of the boys that are with every committee, rather than a statement about each committee having most of its boys resign. Similarly, (2b) states that there is at least one woman that is without every lipstick color. It cannot be read as making any claims that for every lipstick color, there is at least one woman without that color.

(2) a. Most boys with every committee resigned from their duties.
b. At least one woman without every lipstick color appeared on the news.

However, other than *with* and *without*, normally most prepositions demonstrate the same kind of scope interactions that are found with verbs and other predicates. For example, the sentences in (3) can have either an inverse-scope interpretation or a surface-scope interpretation. Whether the quantifiers interact as arguments to the verb or as members of the same complex NP seems to make little difference. (See also Gillon (1996) who makes similar observations about distributivity and collectivity effects in such constructions.)

(3) a. Someone joined every committee.
b. Someone on every committee voted for the amendment.
c. At least one woman is on five of the committees.
d. At least one woman on five of the committees voted for the amendment.
e. Every boy in the school skipped two classes.
f. Every boy in two classes went to the washroom.
h. Two sisters met each committee member.
g. Two sisters of each committee member came to the meeting.

Also, just as inverse scope is blocked by sentential complements to verbs, so too is the inversely linked interpretation blocked in complex NPs with sentential complements. For example the sentences in (4a) and (4b) can only have a surface-scope interpretation where there is one boy that annoyed all of the parents:

(4) a. A boy knew that he annoyed every parent.
b. A boy that annoyed every parent skipped school.

Similarly, just as negative quantifiers in the object position cannot scope over universal subjects, so too are negative quantifiers prohibited from scoping over universals that contain them:

(5) a. Everyone joined no committees.
b. Everyone on no committees felt uninvolved.

The sentence in (5a) cannot be interpreted as saying that there are no committees that everyone joined. Similarly (5b) cannot be interpreted as saying that there are no committees such that everyone on such a committee felt uninvolved. Parallelism between the two types of constructions remains even to the point of having the same type of idiosyncratic scope restrictions.

Such parallelism suggests that perhaps both types of scope interactions should receive similar explanations within linguistic theory. However, there are some instances where this parallelism breaks down. For example, negative quantifiers do not seem to allow for an inversely linked interpretation when they have a universal quantifier embedded within. This is a bit puzzling considering that

such interactions are permitted when the negative quantifier is the subject and the universal quantifier is the object. (Thanks to an anonymous reviewer and Kyle Johnson for drawing our attention to such breakdowns in parallelism.)

(6) a. Nobody on every committee voted for the amendment.
b. Nobody joined every committee.

The sentence in (6a) cannot have an interpretation where for every committee, nobody on that committee voted for the amendment. In contrast, (6b) can have an interpretation where for every committee, nobody joined that committee. Yet, even though the parallelism breaks down slightly here, similar constructions without the universal quantifier seem to allow for the inversely linked reading. For example, the sentence in (7) can have an interpretation where there are three cities such that nobody in those respective cities voted for the incumbent:

(7) Nobody in three cities voted for the incumbent.

In summary, the examples of parallelism seem too systematic to ignore. In fact, not only do complex NPs demonstrate the same type of scope ambiguities, they also conform to constraints similar to those governing verb-argument quantification. For example, consider some of the scope-freezing effects mentioned in Fox (1999), and accounted for by his principle of Scope Economy:[2]

(8) a. Two volunteers greeted every producer.
b. Two volunteers greeted every producer. Bill did too.

The sentence in (8a) is true, whether it was the same two volunteers that greeted each producer, or two different volunteers for each producer. However, (8b) can only be true in the situation where it was the same two volunteers. The same kind of scope-freezing effect also exists for NP-embedded prepositional objects. Consider the sentence in (9):

(9) a. Two volunteers greeted the producer of every movie.
b. Two volunteers greeted the producer of every movie. Bill did too.

The sentence in (9a) is true whether it was the same two volunteers that greeted each producer, or two different volunteers for each producer. The sentence in (9b) is only true if it was the same two volunteers, just as in (8b).

The similarities in scope restrictions do not end here. NP-embedded prepositional objects also demonstrate a scope-freezing effect involving pronominal binding, and a similar kind of effect can be exhibited with quantifiers in verbal argument positions. This is particularly relevant for inverse linking, since binding is usually hypothesized to require a specific syntactic configuration: that of c-command. To demonstrate the similarities, consider the sentences in (10):

(10) a. Some politician disappointed every female voter.
b. Some politician disappointed every female voter before finishing his acceptance speech.
c. Some politician disappointed every female voter that voted for him.

The sentence in (10a) is true whether there is one politician that disappointed all the female voters, or whether for each female voter, a different politician disappointed her. However, as noted by Hornstein (1995), in (10b) and (10c) where 'he' and 'him' are understood as being bound by 'some politician', only the former reading is possible; the one where there is one politician that disappointed all the female voters. The same kind of scope-freezing effects exist for inversely linked constructions, as we observe in (11):

(11) a. At most two senators on every committee voted for the bill.
b. At most two senators on every committee voted to abolish it.
c. At least one senator on every committee that he thought was worthy of his attention, voted for the bill.

(11a) is true in a situation where on each committee, many senators voted for the bill, but where only two senators that were on all the committees voted for the bill. Such a situation characterizes the surface-scope interpretation of the sentence in (11a). In contrast, (11b) is not true in a similar situation: a situation where on each committee, many senators voted to abolish that same committee, but where only two senators that were on all the committees voted to abolish each of those committees. In (11b), the binding of the pronoun 'it' by 'every committee' forces the sentence to only permit the inversely linked interpretation. Binding of the pronoun 'he' by 'at least one senator' in (11c) has the opposite consequence. Much like (10c), only the surface-scope interpretation is available. This is demonstrated by the fact that the sentence is false in a situation where the following two facts hold: (i) for every committee there is one senator on that committee who both voted for the bill and thinks that his committee is worthy of his attention, and (ii) every senator thinks that there are some committees that he is not on, that are worthy of his attention.

In summary, the quantifier positions in inversely linked constructions demonstrate similar kinds of ambiguities and interpretive restrictions as quantifiers in regular argument positions. Such similarities suggest that any theory that provides a separate explanation of the quantificational ambiguities in complex NPs is missing a strong generalization about the parallelism between complex NPs and their sentential counterparts.

3 Initial accounts

In this section, we explore the earlier syntactic theories and their accounts of inverse linking before discussing more modern syntactic theories with a focus on how they could possibly deal with deriving inversely linked interpretations.

The beginning of the linguistic history of the inverse-linking phenomenon started with Hintikka (1974), who used such interpretations as evidence for a theory of branching quantification. Gabbay and Moravcsik (1974), in response to an unpublished draft of Hintikka's paper, also take note of such interpretations in their efforts to incorporate branching quantification into a Montague style semantics, as does Reinhart (1976) in her discussion of binding. However, although these authors used these constructions within their linguistic analysis, no author discussed the full syntactic complexity of inverse linking until May (1977). It was within this work, that May's main premises were introduced arguing for a syntactic level of Logical Form (LF) and a syntactic operation called QR, and it was amongst these issues that inverse linking had its greatest influence. So, here is where we will begin our discussion, exploring some of the details discussed in May (1977) before examining some of the more recent literature.

May (1977) hypothesized that scope ambiguity could be derived by syntactic movement. He conjectured that there was another syntactic level beyond Surface Structure called Logical Form (LF) derived by syntactic movements obeying familiar constraints on such movements. It was at this level that QPs moved to adjoin to a phrase above all inflectional elements; in the parlance of the day, adjoining to S. C-command relations determined scope interpretations. In sentences with multiple quantifiers, all else being equal, the final arrangement of the QPs was indeterminate relative to surface order, either QP free to move above the other, scope ambiguity being dependent on this choice.

One of the important insights recognized at the time by May was that syntactic constraints affected the possibilities of semantic interpretation vis-à-vis the possible scope order of multiple QPs. Although it is important to show the ability of syntactic theory to derive permissible interpretations, it is equally important (if not more so) to demonstrate that some inadmissible interpretations can be explained by syntactic conditions. For May (1977), inversely linked constructions were a prime example for demonstrating such a syntax–semantics interaction.

To see why, consider the sentences in (12):

(12) a. *Which did the girl kiss boy?
b. Which boy did the girl kiss?

These sentences demonstrate the well-known condition that overt movement affects a whole *wh*-phrase, not just part of that phrase. As May (1977) saw the examples in (12), it is only the *wh*-element 'which' that is targeted for movement, but a certain syntactic constraint, the 'Condition on Analyzability', (hereon COA), requires the whole NP 'which boy' to move. May used this movement restriction to derive interesting results in inversely linked constructions. Consider the sentence in (13):

(13) Each of the members of a key congressional committee voted for the amendment. (May 1977: 62, (2.1d))

According to May's theory of QR, the quantificational elements 'each' and 'a' are targeted for movement. Thus, in compliance with the COA, the entire phrase 'a key congressional committee' and 'Each of the members of . . .' must move to adjoin to the S-phrase. This means that the following two LF forms can be derived for the sentence in (13), where '*y*' marks the original position of 'a key congressional committee' and '*x*' marks the original position of 'Each of the members of a key congressional committee':

(14) a. *[$_S$ [Each of the members of y]$_x$ [$_S$ [a key congressional committee]$_y$ [$_S$ x voted for the amendment]]]
b. [$_S$ [a key congressional committee]$_y$ [$_S$ [Each of the members of y]$_x$ [$_S$ x voted for the amendment]]]

(14a) represents the interpretation where 'each' scopes over 'a key congressional committee' (i.e., where every member of any of the congressional committees voted for the amendment), whereas (14b) represents the inversely linked interpretation (i.e., where there is one congressional committee such that each of its members voted for the amendment). The interesting result for May was that (14a) is ill-formed since 'a key congressional committee' does not properly bind the variable '*y*'. As a result (14a) is ruled out by a general syntactic condition barring the occurrence at LF of unbound traces of movement (see Proper Binding Condition in Fiengo 1977).[3] What is of importance to note here is the general form of the argument May employs: syntactic constraints can explain the restricted interpretation of inversely linked constructions, and thus provide evidence that covert QR exists as a mechanism for explaining quantifier ambiguity.

By the mid 1980s, inverse linking was generally taken to be centrally important for establishing an operation of quantifier movement. As May (1985: 72) put it, "inverse linking serves as an existence argument for the level of LF itself," and the structures and operations employed to account for inversely linked sentences were also used to account for simpler structures without embedded quantification. The relevance of inverse linking in establishing the existence of a level of LF did not go unnoticed in the subsequent literature. Chomsky and Lasnik (1995: 65), in their review of Government and Binding theory, state, "The examples of 'inversely linked' quantification discussed by May . . . clearly indicate that S-Structure configuration does not suffice." Hornstein (1995: 25), in his review of LF through the period under discussion, also states that inverse linking provides strong evidence for LF. Although neither of these reviews gets into the full complexity of the issues surrounding inverse linking, they do acknowledge the importance of the phenomenon, especially in sentences that have inverse linking combined with pronominal binding, as in (15):

(15) Someone from every city despises it. (May 1985: (26))

The sentence in (15) can be interpreted with the quantifier 'every city' binding the pronoun 'it' (i.e., for every city, someone from that city despises it, it being

the city). On the standard assumption that this form of binding requires c-command, and on the assumption that the object position of the preposition does not c-command the Verb Phrase (VP), 'every city' must move from its apparent surface position to a higher position c-commanding the pronoun.[4]

With such observations peppered throughout the recent literature on LF, one would think that the theories of QR and LF since 1985 would at least be able to account for the phenomenon. In many cases, however, this does not seem to be borne out.

This lacuna is acknowledged by some authors. For example, Kayne (1998: 183) in trying to reduce covert movement to overt movement, mentions inverse linking as a problem that will have to be reanalyzed within his framework. However, an account within Kayne's theory would require that the QP in the prepositional complement, such as 'every city' in (15), somehow c-command a trace of the subject QP from its surface position. Although a solution via Kayne's analysis might be possible, it seems difficult to naturally create an overt structure for sentence (15) with the inversely linked interpretation, where 'every city' c-commands the VP or at least the trace of the VP, while also c-commanding the QP 'someone from . . .' or at least the trace of the QP. The structure would have to be something like (16):

(16) $[[_{IP}$ [someone from t_1] $t_2]_3$ [[every city]$_1$ [$[_{VP}$ despises it]$_2$ t_3]]]

Crucial to this structure is that the object of the preposition is overtly in a separate phrase from the actual preposition. Certainly a very suspicious consequence, especially considering that sentences such as 'Someone from incidentally every city despises it' are unacceptable in English. Further research may be able to establish or avoid this problem, but either way, the road ahead for Kayne's hypothesis seems very rocky indeed.

While Kayne makes it known that he is aware of the problem, others do not. For example, Aoun and Li (1993b) never mention inverse linking. Yet, the phenomenon is very problematic for their theory. Consider their two principles that they employ to syntactically derive quantifier scope; the Minimal Binding Requirement and their Scope Principle:

Scope Principle:
A quantifier A may have scope over a quantifier B iff A c-commands a member of the chain containing B. (Aoun and Li 1993b: 21)

Minimal Binding Requirement: (MBR)
Variables must be bound by the most local potential A-bar-binder.[5]

Now consider a much simpler version of the sentence in (15) without the pronoun.

(17) Someone from every city loves Esme.

In a sentence like (17) with the inversely linked interpretation, Aoun and Li (1993b) must hypothesize, in accordance with their Scope Principle, that 'every city' c-commands at least one member of the chain containing 'someone from x'. However, if 'every city' has scope broader than the operator 'someone from x', then its variable would be within the scope of the quantifier 'some'. It is unclear what consequences this would have for the MBR. According to the MBR the trace of 'every city' must be bound by its closest A-bar binder. Whether appearing in the restrictor phrase of a quantifier would violate the MBR is an issue that warrants some attention. Such a discussion might have led Aoun and Li to a more detailed definition of quantifier scope and variable interactions. (See the generalized structure in (18), where the potentially offending variable is the complement of the preposition.)

(18) [. . . [every city]$_x$ . . . [[some [one [from x]]] . . . t_y loves Esme]]

However, potential problems do not stop here. In the case of a non-inversely linked interpretation (where quantifiers maintain surface scope), it is doubtful whether there is a means of deriving the required interpretation. This is especially problematic considering sentences such as (19) where an inversely linked reading is impossible:

(19) Someone with every known skeleton key opened this door.

The sentence in (19) can only be a statement about one person who happens to have every known skeleton key. Clearly, the QP 'someone with x' has scope over 'every known skeleton key'. According to Aoun and Li's Scope Principle, a QP may have scope over another QP only if it c-commands a member of the chain containing that QP. For a sentence like (19), this would require having 'someone with x' scope over a variable for 'every known skeleton key'. Yet, 'every known skeleton key' must scope over 'someone with x' in order to bind the variable 'x'. Not only would this need multiple movements of 'every known . . . key' in order to create a variable that 'someone with x' could bind, but it would also require that 'someone with x' be closer to the variable of 'every known . . . key', thus violating the MBR. (See the generalized structure in (20), where the offending variable is t_x.)

(20) [. . . [every known . . . key]$_x$ . . . [[some [one [with x] . . .]] . . . t_x . . . t_y loves Esme]

Another mechanism could be used to derive the surface scope interpretation (see Larson 1985c; and Heim and Kratzer 1998, who derive the surface scope through type shifting), but such a mechanism would miss the generalization that inversely linked and surface-scope interpretations within complex noun phrases seem to parallel the scope interactions between subjects and objects within sentences.

Other syntactic theories suffer from comparable difficulties. For example, as first noted by Fox (1999: 46, n. 35), theories that rely on explaining scope variation through case checking are particularly challenged by inverse linking. Such theories include Hornstein (1995), and Kitahara (1996). In each of these theories, case-checking movements are employed to account for the ambiguous quantifier interpretations, scope being determined by c-command relations (see Kennedy 1997a for arguments against replacing QR with case checking). However, movement motivated by case checking is a procedure usually applied to verbal arguments. It is unclear how case checking would work for prepositional objects. To account for inverse linking and pronomial binding (required for the most salient interpretation of sentences like (15) above), these theories would need the prepositional object to move to a case-checking position c-commanding the NP complement and the VP object. Hypothesizing such a case-checking movement seems a little too problem-specific to be plausible.

However, there is a second group of problems for case-checking accounts of inverse linking. Hornstein's own arguments concerning inverse linking claim that non-quantificational NPs are not able to c-command out of PPs that are embedded within NPs, while in contrast QPs seem to have this ability (see Hornstein 1995: 25, and note 4 in this chapter). Yet, in a theory of movement for case-checking purposes, there should not be any difference between the movement of QPs and other non-quantificational NPs. Hence, it cannot be just the case-checking position that allows a QP to move and c-command out of an [NP PP] constituent. The obvious way out of this dilemma is to hypothesize a type of movement targeting quantifiers specifically. But this would just be reintroducing QR, when the whole purpose of case-checking theories of quantifier scope was to eliminate this rule.

Before concluding this section, it is important to note that the problems for theories of quantifier scope and inverse linking are even more general than those mentioned above. Many theories of quantifiers in natural language have an underlying assumption that QPs need to adjoin at some kind of propositional level in order to be interpretable. This assumption seems to be supported by the fact that the embedded QP can bind a variable in the object position in sentences like (15) above, repeated below as (21).

(21) Someone from every city despises it.

Since binding is thought to involve c-command, the fact that 'every city' can bind the object seems to suggest that 'every city' is in fact adjoined at a propositional level. (Note that all the propositional levels in such a sentence necessarily dominate the object position of the verb.) However these facts become problematic when considering non-inversely linked interpretations. If QPs need to take scope at a propositional level, then the embedded QPs such as 'every city' should be able to c-command the object even in non-inversely linked interpretations. Yet this is not the case. Consider the sentence in (22) below:

(22) At most two senators on every committee voted to abolish it.

The sentence in (22) can have a non-inversely linked interpretation where the voters are (at most) two senators that are on every committee. Yet (22) does not permit 'every committee' to bind the pronoun in the object position of 'abolish'. If the QP were able to bind the pronoun then the sentence should be true when the following two facts held: (i) on each committee, more than two senators voted to abolish that same committee, and (ii) there are at most two senators that are on every committee and that voted to abolish each of those committees. (22) however is not true in such a situation. Such judgments seem to suggest that the embedded QP does not adjoin to the propositional level when it is interpreted within the scope of the QP containing the preposition. To capture such facts, a means separate from QR might seem necessary (for example see Larson 1985c; Heim and Kratzer 1998). Yet in deriving the surface scope with a separate kind of procedure, one wonders whether the theory fails to capture the similarities between subject and object scope interactions and the interactions between quantifiers in complex NPs. Having two separate mechanisms predicts that the similarities are merely coincidental.

In summary, it appears that inverse linking has not been as central to theories of LF and QR as it was in the seventies and eighties, despite the emphasis on this phenomenon in originally motivating a need for such theories. Even authors that were aware of the data and its importance have conspicuously left it out of their analyses.

4 Re-acquainting ourselves with the eighties

Thus far, we have reviewed the early importance of inverse linking and noted its fading influence within the more recent literature. Yet, as just discussed, this fading influence is by no means justified. In an effort to understand somewhat more deeply what is at stake with inverse linking, we shall examine in some detail the discussions of Larson (1985c) and May (1985). However, before launching into a detailed review, a little background.

As mentioned in section 2, prior to the theories being considered in this section sentences with inversely-linked, complex NPs were thought to be unambiguous (see May 1977: 65 who states this opinion directly; yet also see Gabbay and Moravcsik 1974: 143, who implicitly assume the same judgment). However, things changed in 1985.[6] In *Logical Form*, May (1985: 72) suggests that surface scope interpretations are indeed available,[7] and this altered the status of the original arguments developed by May (1977), which used the lack of a surface scope interpretation as support for claiming that quantifier interpretation involved syntactic restrictions. Furthermore, in the early eighties, notions of subjacency became more prevalent as a means of restricting syntactic movement. In the traditional account of inverse linking (May's 1977 account), the QP in the complement

position of the preposition moved out of the subject NP to the adjoin at the sentential level. This movement was in direct violation of subjacency.

It was in this environment that Larson (1985c) and May (1985) built their syntactic theories in an effort to capture the subtleties of inverse linking.

4.1 Larson (1985c)

Before reviewing the details of Larson's analysis of inverse linking, it is appropriate to recognize his motivations. As we will see below, a great deal of his arguments tacitly assume that syntactic positions are mirrored by functional, logical combination (following Montague 1974 in this regard). With this underlying concern, Larson begins by exploring whether the object of a preposition moves at some syntactic level or not. For Larson (1985c), this concern was not as straightforward as it was for May (1977), who assumed that the quantifiers embedded within the prepositional phrase took sentential scope. However, Larson demonstrates that this is not necessarily always the case. Consider the sentence in (23):

(23) Max needs a lock of mane from every unicorn in an enchanted forest.
(Larson 1985c: (4a))

According to Larson, the sentence in (23) has a reading where 'every unicorn' scopes over 'a lock of mane' but where 'every unicorn' scopes under the intensional operator of the verb. In other words, (23) can have a *de dicto* reading, even when the object and the embedded quantifier are inversely linked. To establish this, Larson claims that (23) is true in the following context: "Max requires locks of unicorn mane for the performance of some magic spell. The spell stipulates no particular forest nor any particular pieces of mane. It is only necessary that he have some bit of mane from every unicorn in whatever forest is selected" (Larson 1985c: 2).

Larson argues from this example that "if we are to retain Montague's analysis of intensional object NPs, then the fact that each of these NPs may be read de dicto clearly entails that such quantification must take place *before* the object NP is combined with the intensional verb" (Larson 1985c: 2). In other words, as long as intensional verbs are thought to have scope only over their objects, then sentences such as (23) must demonstrate an inversely linked reading localized within the object NP itself. Furthermore, Larson claims that this internal NP derivation can be accomplished via a small modification of Montague's Grammar (Montague 1974). No syntactic operations need apply.[8]

This is an interesting conjecture that at first seems to undermine the syntactic enterprise of describing inverse linking. However, Larson quickly moves on to the problematic data for his *in-situ* theory of inverse linking. Consider the examples of pronomial binding as in (15) repeated here as (24):

(24) Someone from every city despises it.

Assuming that 'every city' is a generalized quantifier of type <<e,t>, t> (Barwise and Cooper 1981), then 'every city' must combine with a predicate such as "$\lambda x \exists y$ (PERSON(y) and FROM(y,x) and DESPISE(y,x))." Otherwise, 'every city' would not be able to bind the object pronoun (represented as the variable 'x' in the relation 'DESPISE'). However, this predicate contains the logical representation of the transitive verb and its arguments. This suggests that 'every city' must combine at the sentential level and not within the NP subject. A minor alteration to Montague's Grammar will not be able to derive the pronomial binding while maintaining that the QP remains within the NP. For Larson, the obvious solution is to move the quantifier out of the NP and let it combine sententially above the subject. Perhaps syntactic movement is required after all.

But now there is something of a paradox taking shape. There are two reasons that Larson thinks that movement out of the subject NP in (24) should not be permitted. First, complex NPs are typically an 'island' for movement, as demonstrated by the unacceptable (25):

(25) *Which city does [someone from e] despises it. (May 1985: (30a))

However, whether 'islands' apply to covert movement has always been a controversial subject in the syntactic literature,[9] so this might be taken as only weak motivation for not allowing movement out of the NP. His second reason for restricting movement is somewhat stronger. According to Larson, allowing movement to the sentential level predicts some unattested interpretations. Consider the sentence in (26):

(26) Two politicians spy on someone from every city. (Larson 1985c: 5 (12))

If the quantifier embedded in the PP is permitted to take sentential scope, then like a normal verb object it should be able to scope over the subject. Furthermore, since the embedded quantifier would be able to scope out of the NP, it should not need to carry that NP with it when it moves. In other words, movement out of the NP (without any further restrictions) seems to predict that (26) should have an interpretation where the embedded quantifier 'every city' has scope over the subject 'two politicians', but where 'someone' has scope under 'two politicians'. This means that (26) should be true in the situation where the following two facts hold: (i) For every city, there are two politicians who each spy on someone from that city; (ii) no politician spies on more than one person nor on the same person as another politician. But as Larson observes, (26) is not true in this circumstance.

This result is particularly damaging since (26) does seem to allow an interpretation where the embedded quantifier 'every city' has scope over the subject, but where the object also has scope over the subject. For example, (26) is true in the situation where the following two facts hold: (i) for every city, there is someone from that city that two politicians are spying on, and (ii) it is not the same politicians doing the spying in each city.[10]

In observing the interpretations available for (26), Larson makes the following generalization. If the quantifier embedded in the object's PP has scope over the subject, then the object must also scope over the subject. This result would make perfect sense if the embedded quantifier were unable to move out of the NP, since to move this quantifier above the subject would require moving the whole NP.[11]

Larson's observations seem to lead to contrary conclusions. Evidence from pronomial binding suggests that the embedded quantifiers move outside of the NP in which they are embedded, while the absence of certain interpretations suggests that the embedded quantifiers are unable move out of the NP.

4.2 Is Larson's Generalization really general?

Stepping back a little from Larson's approach, it seems appropriate at this point to examine the judgments concerning (26) a little more closely, for there are some apparent difficulties surrounding Larson's claims about this example. First of all, (26) involves a bare indefinite numeral quantifier and the indefinite quantifier 'someone'. As has been demonstrated repeatedly in the linguistic literature (see Reinhart 1997 for both a demonstration, and a list of other works), such quantifiers do not have the same scopal behavior as other quantifiers. Second, May (1985: 82–3) reports a counter-example to Larson's Generalization. Consider the sentence in (27):

(27) Some student will investigate two dialects of every language.

According to May (1985), there is an interpretation of (27), where 'every language' is understood as taking scope over 'some student', which in turn takes scope over 'two dialects'. Ignoring for the moment the indefinites in (27), how is it possible to tell that (27) has the interpretation that May claims? Normally, one would construct a situation that isolates the meaning. However, any situation where May's interpretation is true, is also a situation where, for every language, there are two dialects that were each investigated by a student.[12] This makes it impossible to isolate the interpretation where the subject has scope over the object from the interpretation where the object scopes over the subject (this is assuming that 'every language' has widest scope). So, to use Reinhart's (1997: 341) turn of phrase when explaining just this point, "there is no obvious way to know" whether the sentence has the scope reading it is claimed to have or not.

To avoid both the problem with the choice of quantifiers, and the problem with May's (1985) counter-example, consider the sentence in (28):

(28) More than half of the students will investigate at least one dialect of every language.

The sentence in (28) contains the quantifiers 'every', 'more than half', and 'at least one'. Each of these quantifiers does not demonstrate the wide-scope behavior

as exhibited by the bare numeral quantifiers and the indefinite 'someone'. (For example, none of the quantifiers seems to be able to scope outside of the modal operators in a conditional sentence as do 'two' and 'some'.) In addition, it is easy to isolate the reading where the embedded QP has widest scope, and the subject scopes over the object. For example, consider the situation where two-thirds of the students were assigned to investigate a dialect from every language except one: the excluded language differing for each student. Also, for each language, more than half of the students investigated a dialect from it, but no student investigated the same dialect as another. It seems difficult to understand (28) as being true in such a situation, even though this interpretation should be available if Larson's Generalization did not hold. This is despite the fact that (28) is true in the situation where, for every language, there is at least one dialect that more than half of the students will investigate.

So, perhaps Larson's Generalization does indeed hold.[13]

4.3 *Quantifier retrieval and storage*

So, how does Larson account for the observations under consideration? Building on a system first hypothesized by Cooper (1983), Larson proposes a dual operation for moving quantifiers: Quantifier Storage followed by Quantifier Retrieval. This process, often called Cooper storage, was one of the leading theories of quantifier movement and *wh*-movement during the early eighties. Leaving the (important) algorithmic details for the reader to explore independently, we will review the general design of the system. The idea proposed by Cooper was that during the course of combining the logical representations of the sub-sentential phrases into the logical representation of the entire sentence (from the bottom of the tree up), two possible operations could apply to QPs. Either, a QP could be combined and processed like other phrases, thus allowing the quantifier to take surface scope, or the QP could be stored, replaced by a variable, and later combined at the sentential level. When it is combined at the sentential level, the variable is abstracted, thus forming a predicate which can then be logically combined with the QP, represented as a Generalized Quantifier.[14]

In this manner, a QP is able to move into a position where it can take wide scope (the object moving above the subject, for instance). Cooper also worked in the notion of islands into his storage and retrieval system. For him, islands can be incorporated by adding a constraint which renders a phrase that is an island (an NP for instance) uninterpretable if there is a QP of some kind already in storage. To quote Larson (1985c: 8), the desired result of this kind of constraint is "to require that all stored quantifiers in the interpretation of an island node be quantified out or 'discharged' before that node is combined semantically with another constituent."[15]

Larson (1985c) modifies this system, by changing Cooper's storage operation (Quantifier Storage) into a push-down mechanism. Thus, for Larson multiple QPs could be stored at the same time, the only constraint being that the quantifiers have to be retrieved in the reverse order that they were stored. The

consequence of this is that if two quantifiers are stored, then the resulting interpretation will almost always have the inverse scope of the surface word order.

With this minor change, Larson can now explain the apparent paradox noted above. In inversely linked constructions, the embedded QP cannot be stored and then later retrieved at the sentential level. This would violate Cooper's island constraint. However, Larson redefines Cooper's constraint, such that if the NP is a QP, then this QP can be stored on top of the embedded QP. The island constraint thus would not apply, since the island would be in storage.[16]

In this way, the embedded QP is allowed to have sentential scope through movement, but only if the NP in which the QP is embedded is itself stored and combined at the sentential level. Since the storage system employs a push-down mechanism, the resulting structure after retrieval necessitates that the embedded QP scope over the NP in which it was embedded. A welcome result, considering the scope-freezing effects already mentioned to exist in this section and in section 1 above. For example, recall that in sentences like (22) above, repeated here as (29), pronominal binding forces the inversely linked interpretation:

(29) At most two senators on every committee voted to abolish it.

In Larson's system, 'every committee' has to combine at the sentential level in order to bind the pronoun 'it'. In effect, the push-down mechanism guarantees that 'every committee' scopes over 'at most two senators' when there is a pronoun acting as a bound variable in the VP.

Also, this kind of quantifier movement easily accounts for Larson's generalization, mentioned above. In sentences such as (28), repeated as (30), there are three quantifiers:

(30) More than half of the students will investigate at least one dialect of every language.

To move 'every language' above 'more than half of the students', 'at least one dialect' would have to be stored as well, otherwise the movement would violate the island constraint. Thus, before 'every language' could be retrieved, 'at least one dialect' would first have to be discharged at the sentential level, where it would scope over the subject. Even if the subject itself were stored, the push-down mechanism guarantees that in the resulting interpretation, quantifier scope will be the exact inverse of the surface word order ('every language' having scope over 'at least one dialect' which scopes over 'more than half of the students'). In this way, Larson's system forces the object to scope over the subject whenever the QP embedded in the object scopes over the subject.

This is a very strong result. Not only does Larson's system account for the available, inversely linked interpretations, it also rules out potentially invalid interpretations. Furthermore, Larson can maintain a unified account of island effects between covert and overt movement.

However, although Larson's system works well for inversely linked constructions and even common declaratives, its Achilles heel seems to be double object constructions. As noted by Breuning (2001), double object constructions seem to only allow surface scope. Consider the sentence in (31):

(31) My daughter Esme showed at least one newborn baby every wooden toy in the room.

The sentence in (31) is true in the situation where there is one newborn to whom Esme showed each of the wooden toys, but it is false in the situation where Esme showed every wooden toy to a different newborn. The second situation is what characterizes the inverse-scope reading. In Larson's system, if the objects of ditransitive verbs are subject to Quantifier Storage and Retrieval, then it would be difficult to explain why the inverse-scope reading is unavailable. Especially problematic, is the fact that the sentence in (32) is acceptable:

(32) What did Esme show her mother?

Since Larson employs his quantifier movement operations to account for *wh*-movement, the grammaticality of (32) suggests that these operations should apply to double object constructions.

4.4 Switching tactics: the basic argument of May (1985)

Like Larson, May (1985) is chiefly concerned with where the embedded quantifier moves. However, unlike Larson, he has no intent to maintain an isomorphism between syntactic structures and some kind of logical representation. May's underlying theme is that syntax simply constrains or enhances the range of flexibility involved in semantic interpretation, not that it determines this interpretation. With this in mind, let's consider May's (1985) theory of inverse linking.

In contrast with his earlier work, May (1985) is a little bothered by the idea of moving a quantifier out of an NP island. He asks rhetorically, "Why can QR extract a phrase from NP in mapping onto LF, but *wh*-movement cannot in mapping onto S-Structure?" (May 1985: 69). In the end, May thinks that island constraints are in a certain sense inapplicable to Quantifier Raising (see the discussion below). Nonetheless, with this question serving as background motivation, May (1985) proposes an alternative to his earlier theory of inverse linking. Instead of raising the embedded QP out of the NP to a sentential position in order to derive the inversely linked reading, May suggests that the QP adjoins to the NP in which it is embedded. Under this hypothesis the representation of 'Someone from every city despised it' would be as in (33) (see May 1985: 70–1):

(33) $[_S\ [_{NP1}\ [\text{every city}]_x\ [_{NP2}\ \text{someone from } x]]_y\ [_S\ y\ \text{despised it}_x]]$

In (33), the subject NP 'someone from every city' still adjoins at the sentential level, however 'every city' adjoins to the NP 'someone from *x*'. Of course, now

that May has this structure, the obvious question is how to derive the scope relations and quantifier binding effects. Crucial to both of these issues are May's (1985) definitions of c-command, Government, and his Scope Principle. The definitions of c-command and Government are quite straight forward, and are presented below.

C-command:
A c-commands B iff every maximal projection that dominates A dominates B, and A does not dominate B.

Government:
A governs B iff A c-commands B and B c-commands A, and there are no maximal projection boundaries between A and B.

The Scope Principle is a little more complex, but it can be summed up informally as follows. If two QPs are not in a Government relation with each other, then scope is dependent on constituency hierarchy. However, for any set of quantifiers that are all governed by one member of that set, any quantifier ordering is possible. For example, take a set of quantifiers A, B, and C, where A governs B and C, then the possible quantifier orderings would be ABC, ACB, CAB, CBA, BAC, and BCA. The scope relation would be dependent on the quantifier order that is chosen.[17]

In considering the application of the Scope Principle to inverse linking, May relies on his articulation of adjunction structures on which the segments of a maximal projection, such as the segments of the NP in the adjunction structure in (33), are not themselves maximal projections, but only parts thereof. Thus, any element adjoined to some phrase is not dominated by that phrase. What this means for adjunction structures of the form $[_{XP1}$ A $[_{XP2} \ldots]]$, is that A will always c-command XP, and XP will also c-command A. In addition, since the only nodes intervening between A and XP are the segments of XP, A governs XP.

The consequence for the QP and the NP in (33), is that 'every city' governs 'someone from x'. In principle, this means that either scope relation should be available: the inversely linked interpretation or the surface scope interpretation. However, since the NP contains a variable that must be bound by the QP, only the inversely linked interpretation is permitted by May (see May 1985: 75, where this aspect of the Scope Principle is fully spelled out).

So, what about surface scope interpretations? As mentioned earlier, unlike May (1977), May (1985) recognizes that he has to account for surface scope interpretations. To get this interpretation, May raises the embedded QP to adjoin to the NP-internal PP rather than to the NP itself. For example, the sentence 'At most two senators on every committee voted for the bill', under the surface scope interpretation where 'at most two senators' scopes over 'every committee', would have the representation in (34) (see May 1985: 72):

(34) $[_S [_{NP}$ At most two senators $[_{PP1} [$every committee$]_x [_{PP2}$ on $x]]]]_y [_S\, y$ voted for the bill]]

In (34), constituency hierarchy determines that 'At most two senators . . .' has scope over 'every committee'. In this way, May (1985) is able to separately derive both kinds of scope relations for inversely linked constructions. But, as has been discussed throughout this paper, being able to derive scope ambiguity is not enough. What is important is to explain the lack of certain interpretations through syntactic means. In this area, May's theory offers some explanation, although maybe not quite as much as Larson's theory reviewed in the previous section.

In terms of the benefits of May's theory, consider the lack of surface scope availability in sentences such as (11b) above, repeated as (35):

(35) At most two senators on every committee voted to abolish it.

The sentence in (35) would have the following two possible derivations according to May.

(36) a. $[_S\ [_{NP1}$ [every committee]$_x$ $[_{NP2}$ At least two senators from x]]$_y$ $[_S\ y$ voted to abolish it$_x$]]
b. $[_S\ [_{NP}$ At most two senators $[_{PP1}$ [every committee]$_x$ $[_{PP2}$ on x]]]$_y$ $[_S\ y$ voted to abolish it$_x$]]

As mentioned in section 2, 3, and 4.3, when 'every committee' is interpreted as binding the pronoun 'it', the sentence in (35) can only have the inversely linked interpretation. This is exactly what May's structures would predict. Assuming that a QP must c-command a pronoun in order to bind it, only the structure in (36a), the inversely linked representation, would allow 'every committee' to c-command 'it'. In (36b) the maximal projection NP dominates 'every committee' but not the pronoun.[18]

However, even though May can account for the pronoun binding effects, Larson's Generalization is still a problem. This is not surprising considering that May (1985) claims to have a counter-example to this generalization. But as we saw in section 4.2, the counter-example is rather weak. Recall that Larson's Generalization maintains that a QP, embedded in the object, cannot scope over the subject unless the object also scopes over the subject. Since May (1985) does not have island restrictions that apply to QR (more on this later), the embedded QP is free to move to a position where it scopes over the subject, while the object can move to adjoin to a phrase below the subject. Yet, even if island constraints were maintained, Larson's Generalization would still be out of reach for May's theory. Consider the sentence 'Two politicians spy on someone from every city'. May's account would allow a representation such as in (37):

(37) $[_S\ [_{NP1}\ [_{NP1'}$ [every city]$_x$ $[_{NP2'}$ someone from x]]$_y$ $[_{NP2}$ Two politicians]$_z$] $[_S\ z$ spied on y]]

In (37), 'every city' is adjoined to 'someone from x', and this whole object phrase is adjoined to the subject phrase 'two politicians'. There are two interesting

things about this structure, first 'every city' does not move past the NP island, second 'every city' governs both 'someone from *x*' and 'two politicians'. According to May's (1985) Scope Principle, (37) should allow the interpretation where 'every city' has scope over the subject 'two politicians', while the object 'someone from *x*' has scope under the subject. Larson's Generalization is still violated.[19]

4.5 Simplifying May's theory and accounting for Larson's Generalization

Since Larson's Generalization is a problem for May's theory, it seems appropriate to discuss some minor changes to May's (1985) proposal that would allow for an account. While the validity of this generalization is not beyond doubt, (cf. section 4.2 and note 13), it will still be useful to see how small alterations to a theory can dramatically affect its descriptive adequacy.

Early in his chapter on inverse linking, May (1985) uses concern about island restrictions to motivate his adjunction structure. Later in the text (1985: 80), he explicitly denies the notion of islands having any effect on LF movement, proposing a new constraint as a replacement.[20] This constraint involves forbidding double adjunction as represented by the template in (38):

(38) $[_{XP1} \ldots [_{XP2} \ldots [_{XP3} \ldots]]]$.

As a result of this restriction, if an argument has already adjoined sententially, then the embedded QP cannot adjoin sententially. Thus, the constraint forces it to adjoin to the NP or PP in which it is embedded. May (1985) suggests that this may be a general constraint on phrase structure, but in the context of the theory, he only needs it to apply to quantifiers (i.e., no two quantifiers can adjoin to the same phrase).[21]

As pointed out by Kayne (1994: 19), the prohibition against double adjunction structures can be reduced to a constraint involving asymmetric c-command. For example, May (1985) would not have needed to hypothesize a new constraint if his definition of the Scope Principle were something more akin to a definition similar to Hornstein's (1995):

Scope Principle:
A Quantifier Phrase QP1 scopes over a Quantifier Phrase QP2 iff QP1 asymmetrically c-commands QP2.

With this definition, May's double-adjunction constraint follows naturally (i.e., it can be derived from the definition). Any two QPs adjoined to the same phrase would mutually c-command each other. This means that neither QP would scope over the other. An interpretation would be impossible. The problem is that this definition of the Scope Principle would also predict that May's NP adjunction structure could not account for inverse linking, at least not as long as May kept

the same definition of c-command. However, notice that if the definition of c-command were altered slightly, then the NP adjunction structure would get the same scope interpretation as May's original theory would have predicted. Consider the definition below:

C-command:
A c-commands B if and only if every maximal projection that dominates A dominates B, and A excludes B. (For a similar definition see Kayne 1994.)
A *excludes* B if and only if no segment of A dominates B (Chomsky 1986a: 9).

With this new definition of c-command and the new Scope Principle, let's revisit the NP adjunction structure in (36a), repeated as (39) below:

(39) $[_S\ [_{NP1}$ [every committee]$_x$ $[_{NP2}$ At least two senators from $x]]_y$ $[_S\ y$ voted to abolish it$_x]]$

In (39), 'every committee' still c-commands 'at least two senators' and the pronoun in the VP as before. However, with the new c-command relation, 'at least two senators from x' does not c-command 'every committee', since a segment of 'at least two senators from x' dominates 'every committee'. This means that 'every committee' has scope over 'at least two senators from x', exactly the same result as in May's original theory.

On the surface, these changes to May's theory seem to simplify the definition of the Scope Principle without changing the descriptive adequacy of the system (at least within the limited domain of the inverse linking data). However, there is more. If movement out of an NP island is forbidden at the level of LF, then this new variation of May's theory can account for Larson's Generalization. With island constraints limiting movement, the only way for a QP embedded in the object to move to a position where it c-commands the subject is for the QP to adjoin to the object NP, and for the object NP to either adjoin to the subject NP, or somewhere above the subject NP. The two possibilities are represented in (40):

(40) a. $[_S\ [_{NP2}\ [_{NP1'}$ [every city]$_x$ $[_{NP1}$ someone from $x]]_y$ $[_{NP2}$ Two politicians$]_z]$ $[_S\ z$ spied on $y]]$

b. $[_?\ [_{NP1'}$ [every city]$_x$ $[_{NP1}$ someone from $x]]_y \ldots [_? \ldots [_S\ [_{NP2}$ Two politicians$]_z$ $[_S\ z$ spied on $y]]]]$

No matter which option is taken, the object NP will always asymmetrically c-command the subject: in (40a) the subject NP has a segment that dominates the object, and in (40b) there is a maximal projection (whatever the node above S would be) that dominates the subject but not the object. Either way, if the embedded QP raises to a position that asymmetrically c-commands the subject, then the object must also raise and asymmetrically c-command the object.

In summary, with adjustments to May's (1985) analysis, we are able to account for Larson's Generalization as long as island restrictions apply to Quantifier

Raising. The key modification involved in obtaining this result, was to alter the Scope Principle from a definition that involves Government to one that employs asymmetrical c-command.

4.6 Is there any need for Government?

May (1985) does provide some evidence in support of his use of Government, at least in terms of his Scope Principle. In light of the possibility of eliminating this notion from May's account, it seems appropriate to review some of the motivations for using this relation.

As noted, in May's original proposal a relative scope interpretation is possible when two QPs c-command each other. In support of this May brings forward cross-binding Bach-Peters type sentences, as in (41), in which both pronouns can be simultaneously construed as bound variables, with a fixed scope interpretation of the quantifiers:

(41) Some pilot who shot at it hit the navigator of every MIG that chased him.
(May 1985: 70 (34))

Higginbotham and May (1981) present a semantic account of these cases in terms of absorbed quantifiers; the account is generalized to all *n*-tuples of mutually c-commanding quantifiers in May (1989).[22]

Another argument for Government deals with donkey anaphora. May assumes that a Heim-style, unselective binding mechanism can account for sentences where an indefinite quantifier seems to be interpreted as a universal. For example, the sentence 'Everybody that owns a donkey beats it' has an interpretation where it is implied that every donkey is beaten by its owner. Crucial to May's analysis is that unselective binding can apply only if a variable could not be otherwise interpreted (see May 1985: 75). This is relevant to inverse linking since inverse linking constructions demonstrate donkey anaphora. For example, in 'Every owner of a donkey beats it', the indefinite phrase 'a donkey' is permitted to have a universal interpretation: the interpretation where every donkey is once again beaten by its owner.

May is able to derive this interpretation through his Scope Principle. Recall that May's Scope Principle allows for any ordering of QPs that are in a Government relation. Thus, in a structure such as (42), either 'every owner of *x*' can be positioned to scope over 'a donkey', or 'a donkey' can be positioned to scope over 'every owner of *x*':

(42) $[_S\ [_{NP1}\ [\text{a donkey}]_x\ [_{NP2}\ \text{Every owner of } x]]_y\ [_S\ y \text{ beats it}_x]]$

Normally, only the latter position would be permitted, otherwise the variable '*x*' would not be bound by 'a donkey'. However, in the option where 'every owner of *x*' precedes 'a donkey', unselective binding is permitted to apply. There is a

variable that could not be otherwise interpreted (i.e. '*x*'), and 'every' would be in a position where it would scope over the pronoun 'it', the indefinite phrase 'a donkey' and the variable '*x*'. It is the freedom of positioning created by May's Scope Principle that derives the proper environment for unselective binding.

This having been said, there is another construction that would allow May to derive the proper environment for unselective binding: namely (43) below:

(43) $[_S$ Every owner $[_{PP1}$ [a donkey]$_x$ $[_{PP2}$ of $x]]_y$ $[_S$ y beats it$_x]]$

In this construction, 'every' once again has scope over 'a donkey', the pronoun 'it', and the variable '*x*'. Furthermore, the pronoun 'it', if it is represented as a variable, is uninterpretable unless unselective binding is employed. In the end, donkey anaphora can be derived without the intricacies of May's Scope Principle. Thus, perhaps in this case there is an alternative.

In contrast, there are some phenomena that are easily explained by May's Government relation, but not by other theories. For example, consider the sentences in (44):

(44) a. What does somebody from every city despise.
b. What does everybody despise. (May 1985: 70 (32))

(44b) allows for a pair-list answer (i.e., Brad, the local school board, and Jerry, the teachers association). (44a) does not. On May's view, the pair-list reading of a question arises when 'what' is interpreted as scoping under 'every'. Assuming that the subject QP adjoins to the S-phase, and that the *wh*-element is adjoined above the S-phrase, then May has a natural explanation for the differences between (44a) and (44b). In (44b), 'what' governs 'everybody'. However in (44a), the NP to which 'every city' is adjoined, blocks 'what' from governing 'every city' and vice versa. Constituency determines that 'what' must scope over 'every city'. It is difficult for any other theory to account for the contrast between (44a) and (44b), which makes this lack of the pair-list reading one of the strongest arguments in support of May's Government definition of the Scope Principle.

4.7 Leaving the eighties

To summarize, this section reviewed two theories of inverse linking that were developed in the eighties. Although the details are a little dated, the basic properties of the theories are still well motivated by the data. Both theories were not only able to derive the inversely linked interpretation, but also showed how scope interpretation was restricted by (their) syntactic principles. As a result, both May (1985) and Larson (1985c) are empirically more adequate than the

theories reviewed in section 3, and while they are couched within principles and mechanisms that are not wholly compatible with some contemporary approaches to syntax (e.g., the Minimalist approach of Chomsky 1995c), their essentials remain viable accounts of inverse linking phenomena. The challenge for more current syntactic theories is to account for the inverse linking data at least as well as May and Larson did in the mid-eighties. There are some interesting attempts. For instance, Breuning (2001) has suggested that object quantifiers move to adjoin to VP: the only position where they are interpretable. Inverse scope of the subject and object is a side effect of choosing to interpret the subject in its internal VP position, rather than its nominative case checking position higher than the VP. Assuming, as Sauerland (2005) does, that QPs embedded in NPs must scope over those NPs for interpretability reasons, Larson's Generalization can be accounted for. If the object NP and the object-embedded QP are adjoined to the VP, then for the subject to be interpreted below the embedded QP, it would have to be interpreted in its VP internal position. This position is also below the NP-object. Thus Larson's Generalization holds. However, within the Minimalist framework there still remains the question of how to derive surface scope interpretation of inversely linked constructions without arbitrary stipulation (i.e., without Type-Shifting).

Also, there are more general problems with inverse linking that eventually have to be addressed in any syntactic theory of quantifier interpretation. One particularly puzzling difficulty is why with certain prepositions an inversely linked interpretation is blocked. For example, 'A man with every woman likes her' disallows an interpretation where the man can vary for each woman. In addition, 'every woman' seems to have trouble binding the pronoun 'her'. (See Gabbay and Moravcsik 1974: 143, who were the first to note the semantic restriction involved with this preposition.) Why this should be so is unclear, but perhaps it is related to aspects of the internal structure of NPs, and the argument/adjunct distinction.

5 Conclusion

In this review of inverse linking phenomenon, we have considered various approaches, from the classic accounts of the 1970s and 1980s to more recent proposals. One of our main themes in outlining this history has been to observe how inverse linking has been employed in motivating syntactic explanations for primarily semantic effects. These arguments have taken the form of first accounting for known semantic interpretations through syntactic mechanisms, and then explaining the lack of certain interpretations through restrictions derived from the syntactic mechanisms. It is through the execution of arguments of this form that the syntactification of semantic phenomena becomes plausible. Another theme developed in this essay is that inverse linking remains central to any syntactic theory which purports to account for logical representation of natural language quantification.

NOTES

1 The 'inverse' label stems from the fact that the quantifiers are interpreted in the inverse of their surface word order, 'every city' has scope over 'someone' in the example sentence, whereas the 'linking' label is used to describe how the broader scope quantifier binds a variable contained within the restriction of the narrower scope quantifier.

2 Fox's Scope Economy restricts the ability of the object to scope over the subject, if the following VP-elided sentence does not have a quantifier for a subject. This codifies an observation initially due to Fiengo and May (1994: 231ff.).

3 Note that the issue here is not whether the scope order of the quantifiers shown in (14a) is possible. As noted by May (1977, 1985) and Gabbay and Moravcsik (1974), this ordering of quantifiers is possible, just not with the logical structure given in (14a). Rather, the representation will be one in which the scope of the narrow-scope quantifier is wholly *contained* within the restriction of the broader-scope quantifier. We might paraphrase this reading as something like 'Each of the members who are on a key congressional committee voted for the amendment'. Hence the moniker 'relative reading' given this construal in May (1977). In May (1985), these cases are analyzed by allowing for NP-internal adjunction structures. Larson (1985c) also discusses these cases in his efforts to establish the quasi-syntactic operation of quantifier retrieval (based on Cooper 1983).

4 Hornstein (1995: 25) provides an argument that non-quantificational elements in the prepositional object position do not c-command into the VP. He uses the lack of so-called 'sloppy' readings of the pronoun to demonstrate his case. According to Reinhart (1983a), sloppy readings of pronouns require c-command even with non-quantification noun phrases. So consider the sentences in (i) and (ii):

(i) John loves his mother and Bill does too.

(ii) The woman who likes John loves his mother, and the woman who likes Bill does too.

The sentence in (i) can be interpreted with the sloppy reading as John loves John's mother and Bill loves Bill's mother. On the other hand, (ii) cannot be interpreted as referring to one woman liking John's mother and the other liking Bill's. The reason for this, according to Reinhart, is that 'Bill' c-commands the elided VP in (i), but not in (ii). Hornstein claims that the sentence in (iii) also lacks the sloppy reading:

(iii) People from LA love its beaches, and someone from NYC does too.

In other words, (iii) cannot mean that people from LA love LA beaches, and someone from NYC loves NYC beaches. Hence NYC cannot c-command the elided VP. However, note that May (1985: 68) claims that sentences such as (iii) can have sloppy readings. For example, May claims that (iv) can be interpreted as saying that nobody from NYC rides NYC subways, but everybody from Tokyo rides Tokyo subways:

(iv) Nobody from New York rides its subways, but everybody from Tokyo does.
(May 1985: 65, (29))

Also, Fiengo and May (1994) have argued at considerable length that Reinhart's claim itself is incorrect, and that sloppy readings are possible in the absence of c-command.

5 Note that the trace in the VP subject position is not a variable, but a trace that is A-bound by the subject in Spec-IP.

6 As an aside, it is interesting that there are some difficulties in linking scope to c-command notions, while leaving the quantifiers in their surface positions. The two competing structures for the QP + PP constituent are $[_{QP1}$ Q [N $[_{PP}$ [P QP_2]]]] and $[_{QP1'}$ $[_{QP1}$ Q [NP]] $[_{PP}$ P $[QP_2]]]$. In the first structure, QP_1 does not c-command QP_2 since it dominates QP_2. Q does c-command QP_2, but if scope was based on the c-command properties of Q, then it is unclear how Q could ever c-command outside of QP_1 (which it must to get sentential scope). In the second structure QP_1 can c-command QP_2, as long as the definition of c-command does not exclude inclusion of categories. Unfortunately, many definitions do maintain such an exclusion.

7 The evidence that May considers come from sentences such as 'Every house near a river faces danger from flooding' or 'The head of every public authority in New York was Robert Moses' (May, 1985: 72). Other examples that do not rely on the vicissitudes of definite and indefinite articles (on the latter, see Reinhart 1997; Diesing 1992b; Fodor and Sag 1982, among others) can be adduced:

(i) Less than three senators on every committee voted for the bill.

(ii) Every senator on more than two committees voted for the bill.

(i) is true in the situation where several senators on each committee voted for the bill, but only one or two senators that were a member of every committee did. (ii) is true in the situation where every senator that was on more than two committees voted for the bill but no committee was unanimous in their vote.

8 Larson's modification consists of reducing two expressions, A and B of the type <<e,t>, t> to one expression, C of the type, <<e,t>, t>, where C = λQ [A [λ*x* B-with-*x*-in-formula (Q)]]. For example, suppose A = λS ∃(*x*) [E(*x*) and S(*x*)], and suppose B = λR∀ (*z*)[(W(*z*) and From(*z*,*q*)) ⊃ R(*z*)]. C would then equal λQ (λS∃(*x*) [E(*x*) and S(*x*)]) λ*q* (λR∀(*z*)[(W(*z*) and From(*z*,*q*)) ⊃ R(*z*)]) Q, which reduces to λQ (∃(*x*) [E(*x*) and ∀(*z*)[(W(*z*) and From(*z*,*x*)) ⊃ Q(*z*)]). The representation of a QP as λP ∃(*x*)[Man(*x*) and R(*x*) and P(*x*)] where R is a free variable which can be λ-abstracted, is from Bach and Cooper (1978) who use it to account for relative clauses. Thus PPs can be bound into QP.

9 This is a main theme of May (1985, especially ch. 3). See also remarks in Reinhart (1997), who argues that as a matter of principle, all movement whether covert or overt should obey the same movement restrictions. One of the first extensive discussions of the relevance of LF islands can be found in Huang (1982a).

10 Although this situation is true of both the interpretation where 'someone' has scope over 'two politicians' and the interpretation where 'two politicians' has scope over 'someone', the lack of the second interpretation in the previous situation suggests that it can only be the first interpretation that makes the sentence true.

11 As an aside, we note that Heim and Kratzer (1998) use Larson's Generalization to argue for the NP internal structure.

12 To be more explicit, whenever it is true that for every language there is some student that is investigating two dialects from that language, it is also true that for every

language there are two dialects of that language that are being investigated by some student. It just happens to be the same student for the second proposition.

13 There is some other evidence in support of Larson's Generalization, although matters here are quite subtle, as well as theory dependent. If an object and subject are scopally commutative (according to Fox's (1999) definition), then Fox's Scope Economy should prevent the quantifier embedded in the object from scoping over the subject. Consider, the sentence in (i), where the object and subject are scopally commutative:

(i) A volunteer greeted an exchange student from every country.

Can this sentence have a reading in which the quantifier "every" has scope over "a volunteer"? To isolate this reading, consider the situation where the following two facts hold: (1) no volunteer greeted more than one of the exchange students, (2) For every country, an exchange student from that country was greeted by a volunteer. The sentence in (i) seems false in such a situation. This is interesting because this sentence can have the interpretation where there is one volunteer that greeted each of the exchange students. If Fox's Scope Economy blocks the object from moving over the subject, then the sentence in (i) demonstrates that the object must be able to scope over the subject in order for the internal NP quantifier to do so.

14 The following is an informal description of the operation. To store a quantifier, replace its position by a variable (actually by ^λP P(x), but basically this is the same thing), and then store the ordered pair <QP, x> where x marks the 'variable address' for the quantifier. Then, to retrieve the quantifier, first λ-abstract the variable given in the 'variable address', and finally apply the quantifier. For example, consider 'Esme loves everybody'. First replace the QP with a variable, leaving 'Esme loves x' with <everybody, x> stored. Then λ-abstract and combine, leaving 'Everybody λx (Esme loves x)' after retrieval. For a critical notice of Cooper (1983), see May (1987).

15 For a more thorough description of Cooper's approach, see Cooper (1983: 134ff.). Note that Cooper like many other linguists treats *wh*-elements as quantifiers.

16 Larson (1985c: 8) re-defines Cooper's constraint on quantifying out of islands as follows: If α is a structural description and $\alpha \in I$, then INT assigns no interpretation β′ to [β . . . α . . .], where $\beta' = <\Phi, <Q', x_n>>$, and where $\alpha' = <\Psi, <Q', x_n>>$. I = {NP, Q, R} where Q and R are [+WH] S's.

17 This is an informal presentation. May's more formal definition is as follows. "Let us call a class of occurrences of operators Ψ a Σ-sequence if and only if for any Oi, Oj ∈ Ψ, Oi governs Oj, where . . . members of Σ-sequences are free to take on any type of relative scope relation" (May 1985: 34).

18 Because May is unconcerned with maintaining a Montagovian semantics, binding need not be equated with λ-abstraction, as it was with Larson (1985c).

19 An alternative to (37), would be a double adjunction structure as in (i) below, where the complex object NP is adjoined sententially along with the subject:

(i) $[_{S1}\ [_{NP1}$ [every city]$_x$ $[_{NP2}$ someone from x]]$_y$ $[_{S2}\ [_{NP2}$ Two politicians]$_z$ $[_{S3}\ z$ spied on y]]]

May (1985) actually has a constraint on double adjunction, so (i) is an invalid derivation according to May, and hence not mentioned as a possible derivation in the main text. However, even if (i) were permitted, 'every city' still governs both 'someone' and 'two politicians'. Thus this structure would also violate Larson's Generalization.

20 May (1985: 80) notes the following to show that extraction from islands is possible via QR: "One case is brought up by van Riemsdijk and Williams (1981), who point out that a question such as *Who knows which pictures of whom Bill bought* allows an interpretation in which whom is paired with who in asking a multiple direct question. Representing this, on the view here, involves extracting from an island, so as to move whom to a higher clause."

21 The actual phrasing of the constraint is "only one operator can be adjoined per projection level." (May 1985: 81).

22 Conceivably the LF representation of (41) could be one in which the relative clauses are extraposed. If so, the resulting structures would be compatible with the revised proposal. However, as Guéron and May (1984) argue, extraposition is typically undone at LF (although see Lechner 1999; and Fox 2002, who challenge this assumption).

  5.3 Deriving the similarities and the differences between CLD and CLLD
6 CLLD in the noun phrase

1 Introduction

The phenomenon referred to as 'left dislocation' (LD) is exemplified in (1). LD is characterized by the presence of a phrase in the first position of the clause which is connected with that clause through the intermediary of some anaphoric element referred to as the *resumptive* element (see chapter 55).

(1) John, I like him.

In (1) the DP *John*, appears in sentence initial position, to the left of the material contained within the clause, and is connected with the clause through the intermediary of the pronoun *him*.

In LD constructions, the clause is considered to be 'about' the left dislocated element. This is often referred to as the *aboutness* requirement.

2 Types of left dislocation

It has been observed that there are various instances of LD across languages or even within a language. In addition to (1), we find constructions of the type illustrated in (2) (see Van Haaften et al. 1983). As can be seen in (1–2), the resumptive element can be a regular personal pronoun as in English, or a demonstrative pronoun as in Dutch (2a) or a clitic pronoun as in languages such as Italian, Romanian, Spanish, Hebrew, Arabic, and Greek (2b):

(2) a. Die man die ken ik niet.
the man that know I not
'That man, I don't know him.'
b. Ton Jani den ton ksero.
the-acc John-acc neg cl-acc know-1sg
'John, I do not know him.'

(2a) is known as Contrastive Left Dislocation (CLD), while (2b) is referred to as Clitic Left Dislocation (CLLD). CLD is a typical Germanic construction. A further type of Left Dislocation is Hanging Topic Left Dislocation (HTLD), illustrated in (1) and again in (3) with a Spanish example, where the role of the resumptive element is performed by an epithet:[1]

(3) Bernardo estoy segura que nadie confia en ese idiota.
Bernardo (I) am sure that nobody has confidence in that idiot
'(As for) Bernardo, I am sure that nobody has confidence in that idiot.'

Hanging topics can be introduced by an 'as for' phrase (4). However, as (3) shows, the presence of these phrases is not obligatory:

(4) As for the circus the elephants are fine.

All types of LD respect the *aboutness* requirement. The aboutness requirement is usually met by the resumptive element, but in some languages a weaker, purely semantic form is sufficient. This seems to be true in French, as pointed out in Hirschbühler (1975):

(5) Oh tu sais moi la bicyclette je n' aime pas me fatiguer.
oh you know me the bicycle I neg like not me tire
'Oh you know, me, the bicycle I don't like to tire myself.'

This type of LD is referred to as Loose Aboutness Left Dislocation (LALD) in Van Riemsdijk (1997a).

As Van Riemsdijk (1997a) points out, much of the variation among these types can be related in some form or other to the resumptive element. In particular, different types of LD arise depending on the obligatoriness of the resumptive element, its form, and whether it is subject to movement operations. For instance, in (6) we see that in Spanish the dislocated phrase in CLLD cannot be construed with an epithet, while this is possible in HTLD, cf. (3):

(6) a. A sus amigos Pedro los invitó a cenar.
acc his friends Pedro cl-acc invited-3sg to dine
'As for his friends, Pedro invited them to dinner.'
b. *A sus amigos Pedro invitó a cenar esos idiotas.
acc his friends Pedro invited to dine these idiots
'As for his friends, Pedro invited these idiots to dinner.'

On the other hand, resumption via an epithet phrase is possible in other languages, e.g., Lebanese Arabic (Aoun and Choueiri 2000). As shown in (8), the dislocated phrase can appear embedded under a verb like 'to doubt', hence it is CLLD-ed and not HTLD-ed (see section 3.2):

(7) Ha-l-muttahame rəfto ənno ha-l-ma duube n abasit.
this-the-suspect.f know-2p that 3p-the idiot imprisoned-3sf
'This suspect, you know that this idiot was imprisoned.'

(8) Bʃəkk ʔənn ʔəχt-e byaʕrif Saami ʔəza naʒafiit
doubt.1S that sister my know.3Sm S. whether passed.3SF
ha-l-maSZuube b-l-fafiS.
this-the-idiot in the exam
'I doubt that my sister Sami knows whether this idiot passed the exam.'

Epithets can be used as resumptive elements and can be interpreted as bound variables in certain contexts, as they are pronominal in nature. Jackendoff (1972), Lasnik (1976), Hornstein and Weinberg (1990) claim that the epithet phrases are inherently pronominal. On the other hand, Aoun and Choueiri (2000) claim that epithet phrases are similar to pronominals only when those occur with the pronominal morpheme in, e.g., Lebanese Arabic.

A second issue concerns the position of the pronominal. It appears to move in CLLD and CLD, but not in HTLD. The movement arguably is to Spec,CP for CLD, while in CLLD the clitic adjoins to a verb.

A further difference between the various types of LD concerns the base generation vs. movement of the LD-ed element in sentence initial position. The most significant asymmetry between HTLD and CLD/CLLD is that the latter two constructions show certain forms of 'connectivity' between the LD-ed phrase and the sentence internal position (whether this is bound or not by a clitic) which are entirely absent in HTLD (see Van Riemsdijk and Zwarts 1974; Cinque 1990c; Van Haaften et al. 1983, among others). Thus CLLD and CLD contrast with

HTLD in that these two can be treated as movement constructions with respect to connectivity criteria, while HTLD cannot.[2]

The connectivity phenomena that are absent from HTLD but do occur with CLD/CLLD can be summarized as follows (and see the contributions in Anagnostopoulou et al. 1997):

(i) Idiom chunks are found in LD-ed position in CLLD and CLD but not in HTLD.
(ii) Bound pronouns can occur embedded in a larger LD-ed constituent in CLLD and CLD but not in HTLD.
(iii) Bound pronominal variables can occur within a LD-ed constituent in CLLD and CLD but not in HTLD.
(iv) Case connectivity is obligatory in CLLD and CLD but not in HTLD.

In section 3, I discuss the differences between HTLD and CLLD. In section 4, I pay particular attention to the issues of debate concerning the proper characterization of CLLD. In section 5, I turn to the differences between CLLD and CLD.

3 HTLD and CLLD

3.1 Differences between the two constructions

That HTLD and CLLD are two distinct constructions becomes apparent if we consider their basic properties (see Cinque 1990c; Dobrovie-Sorin 1990; Anagnostopoulou 1997; and others).

(i) First of all, there is a sharp intonational break between the LDed XP in HTLD and the rest of the sentence; such pause is not present in CLLD. Although the LD-ed phrase in CLLD is separated from the clause that follows it via a comma, the intonational break between the two is much weaker than that present with HTLD.

(ii) The LD-ed phrase in CLLD can be any maximal phrase, as is illustrated in (9a) and (9b) with Italian examples. This contrasts with HTLD which allows only for LD-ed NPs.

(9) a. Al mare ci siamo già stati.
to the seaside there have-1pl already been
'To the seaside, there we have already been.'
b. Bella non lo é mai stata.
beautiful not it is ever been-3sg.fem
'Beautiful, she has never been.'

(10) *To John I have already spoken to him.

(iii) The LD-ed element in CLLD can occur in front of any subordinate type, as the Italian sentence in (11) suggests:

(11) L' unica person che a Gianni non gli ha mia fatto un favore.
the only person which to John not him has ever done a favor
'The only person which to John not to him has ever done a favor.'

HTLD typically occurs in root contexts, as the ungrammaticality of the Spanish example in (12) indicates:

(12) *Sin embargo estoy segure que Bernardo nadei confia en ese idiota.
without embargo am sure that Bernardo nobody confides to this idiot
'On the other hand, I am sure that, Bernardo, nobody has confidence in this idiot.'

(iv) In CLLD there is no theoretical limit to the number of the LD-ed phrases. HTLD allows no more than one LD-ed phrase. This is evident in the contrast between the Italian and English sentences shown in (13):

(13) a. Di vestiti a me Gianni in quel negozio non mi ce ne ha
clothes to me Gianni in that shop not to me there of them has
mai comprati.
ever bought
'As for clothes, for me, Gianni has never bought them in that shop.'
b. *Mary John she likes him.

(v) In languages like Spanish and Greek, the IP internal resumptive element in CLLD, if present, can be a clitic pronoun only. No such requirement holds of HTLD. In fact in HTLD the resumptive element can be a clitic-doubled pronoun or an epithet, as the Greek examples in (14–15) show:

(14) Ton Petro ton nostalgo poli.
the Peter-acc him mis-1sg much
'Peter, I miss him much.'

(15) O Petros ton nostalgo ton gliko mu/afto poli.
The Peter-nom him miss him sweet my/this much
'As for Peter, I miss my sweety/this guy much.'

On the other hand, in Lebanese Arabic CLLD the resumptive element can be an epithet, cf. (8).

(vi) In CLLD there is obligatory connectivity between the LD-ed phrase and IP internal position. There is no such connectivity in HTLD. One such case is Connectivity with respect to Binding Theory, as is clear in the following Italian

examples, where the distribution of the reflexive and personal pronoun correlates with their distribution in non LD-ed positions, i.e., base positions:

(16) A lei/*a se stessa Maria dice che non ci pensiamo mai.
of her/of herself Mary says that not there we think ever
'Mary says that we never think about her.'

(17) A *lei/a se stessa Maria non ci pensia.
of her/of herself Mary not there she think
'Mary does not think about herself.'

Another case of connectivity is with respect to Case in languages exhibiting case morphology such as Greek. In HTLD there is no obligatory case agreement between the LD-ed phrase and the nominal expression clause internally. CLLD, on the other hand, forces case agreement. In (18a), the HTLD-ed element bears nominative Case, while the Case borne by the clitic clause internally is accusative, i.e., the Case of the LD-ed element in HTLD and the Case of the clitic clause internally do not need to match. On the other hand in (18b), an embedded clause where only CLLD is possible, case matching is obligatory, i.e., both the LD-ed phrase and the clitic must bear accusative:[3]

(18) a. I Maria tin ematha kala tosa hronia.
the Mary her learnt well so many years
'As for Mary, I know her after so many years.'
b. Ipe oti ti Maria/*i Maria tin emathe kala tosa hronia.
said that the Mary-acc/*nom her learnt well so many years
'He said that as for Mary, he knows her well after so many years.'

Furthermore, LD-ed idiom chunks are ill formed in HTLD but can be well formed in CLLD:

(19) a. *I tihi tu kathe ftohos tin ekane pigenodas stin Ameriki.
the luck-nom his every poor her did going to America
b. Tin tihi tu kathe ftohos tin ekane pigenodas stin Ameriki.
the luck-acc his every poor her did going to America
'Every poor person made his luck by going to America.'

(vii) A further and crucial difference between CLLD and HTLD is that only CLLD is subject to locality constraints. The fact that the relation between the LD-ed element and the resumptive pronoun in CLLD is sensitive to islands (cf. (20b), and see the discussion in section 4.3), while this is not the case in HTLD seems to suggest that CLLD is derived by a type of *wh*-movement. As the contrast in (20) shows, HTLD is not sensitive to a relative clause island, while CLLD is:

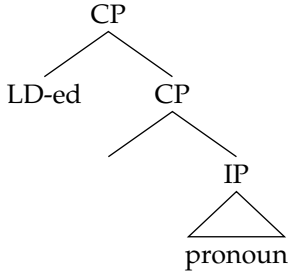
(20) a. I Maria htes gnorisa ton andra pu tin pandreftike.
the Mary-nom yesterday met the man that her married
'As for Mary, I met yesterday the man that married her.'
b. *Tin Maria htes gnorisa ton andra pu tin pandreftike.
the Mary-acc yesterday met the man that her married

While it is uncontroversial that HTLD involves base generation of the LD-ed phrase in sentence initial position, whether or not CLLD displays actual movement of the LD-ed phrase remains a matter of controversy, since CLLD does not behave like *wh*-movement in all respects. On the one hand, Cinque (1977), Dobrovie-Sorin (1990), Mahajan (1990), Sportiche (1996b) and Kayne (1994) claim that there is actual movement in CLLD. On the other hand, Cinque (1990c), Iatridou (1994), and Anagnostopoulou (1994) among others claim that that there is no such movement involved. In the next section I present the structural analysis of HTLD and CLLD and in section 4 I come to the arguments in favor of and against the movement vs. base generation analysis for CLLD.

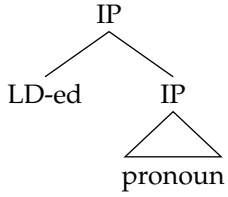
3.2 Syntactic analysis of HTLD and CLLD

Generally, HTLD elements are represented as being CP adjuncts (21a), while CLLD elements are considered by some researchers to be IP adjuncts (21b) while others analyze them as CP adjuncts, the resumptive element being contained within IP in both cases:[4]

(21) a.



b.



The main argument for analyzing HTLD-ed elements as CP adjuncts comes from the observation that these phrases occur only in root contexts. The main argument for analyzing CLLD-ed elements as IP adjuncts relies on the fact that these phrases occur in all types of embedded contexts and not only in so-called

CP-recursion (Iatridou and Kroch 1992) environments. This is illustrated below with an example containing an adverbial adjunct from Greek:

(22) I Maria ine harumeni tora pu ton Jani ton paratise.
the Mary is happy now that the John him left
'Mary is happy now that she has left John.'

In order to understand the line of argumentation it is necessary to briefly discuss CP-recursion here. The phenomenon of CP-recursion is discussed most prominently on the basis of Germanic data. In certain embedded contexts as shown in (23a) with a Frisian example (from Iatridou and Kroch 1992: 4) verb second order can occur, while in others (23b, c), only the verb final order is allowed (see chapter 23):

(23) a. Pyt sei dat hy hie my sjoen.
Pyt said that he had me seen
'Pyt said that he had seen me.'
b. Pyt betreueret dat er my sjoen hie.
Pyt regrets that he me seen had
'Pyt regrets that he had seen me.'
c. *Pyt betreueret dat er my hie sjoen.

According to de Haan and Weerman (1986), CP-recursion occurs in just those environments and with just those verbs that allow deletion of the overt complementizer. Iatridou and Kroch claim that this restriction suggests that CP-recursion occurs only when the embedded clause is governed by a local L-marking head. As expected, clauses not governed by a lexical head (adjunct clauses (24) and sentential subjects) do not allow embedded V2:

(24) *Ik sil fuortgean at jo wolle dizze film net sjen.
I will leave if you want this film not see

Crucially, CP-recursion is possible under specific conditions, namely it occurs only when the embedded clause is selected by a certain kind of verb. These verbs are referred to as 'bridge' verbs in the literature, e.g., verbs like *say, whisper*, etc. The Greek example in (22) does not contain a CP-recursion environment, since it exemplifies an adverbial clause. Thus it is difficult to maintain the CP adjunction hypothesis, as the LD-ed phrase in (22) follows the complementizer *pu* and no second C position is contained in the clause.

It should be pointed out here that Rizzi (1997) associates CLLD phrases with special projections in the CP domain, which is now split into a number of specified projections such as FocusPhrase and TopicPhrase (25). LD-ed elements occupy Topic Phrases. Current research investigates whether these Topic projections have different properties.

(25) [ForceP [TopicP [FocusP [TopicP [FinP]]]]]

4 CLLD: movement vs. base generation

At first sight the properties of CLLD seem to suggest that this construction differs from HTLD precisely in involving movement.[5,6] However, matters are not that simple. There are two related considerations. First, CLLD does not behave like *wh*-movement in all respects, as will be discussed below in section 4.2. Second, one important issue a movement analysis for CLLD has to address is the co-occurrence of movement with a clitic pronoun that matches in features the putatively moved phrases. Essentially two possibilities suggest themselves. The first consists in regarding the construction as an instantiation of the clitic-doubling phenomenon. The second consists in regarding the clitic pronoun as an overt spelling out of the pronominal features left on the (*wh*-) trace. As Cinque and others point out, neither proposal is without problems.

In what follows I first discuss certain problems with the view that CLLD is derived via movement through a clitic-doubling input construction and I then turn to arguments for the non-*wh*-movement nature of CLLD.

4.1 CLLD and clitic doubling

Clitic doubling is a common construction in many languages, such as Romanian, dialects of Spanish, Lebanese Arabic and Greek, in which a clitic agreeing in features with the object appears along with the object (see chapter 14). This is illustrated in (26) with an example from Greek:

(26) To agorasa to vivlio tu Jani.
it bought the book-acc the John-gen
'I bought John's book.'

In the languages that have clitic doubling the issue therefore arises whether this construction is the source for CLLD which is derived by movement of the doubled element to the sentence initial position, as shown in (27):

(27) [DP to vivlio]$_i$ to agorasa t_i

However, there are certain problems with the view that clitic doubling is the source for CLLD.

First, as Cinque (1990c) points out there are languages that have CLLD (28a), but do not have clitic doubling (28b). One such a language is Italian. Hence for these languages a clitic-doubling input structure could not be assumed:

(28) a. *Lo conosciamo Gianni.
him know-1pl Gianni
b. Gianni lo conosciamo.
Gianni him know-1pl

Second, there are languages in which doubling is subject to Kayne's Generalization while CLLD is not. Rio Platese Spanish presents such a case:

(29) Lo vimos a Juan. Rio Platese Spanish
Him saw-we a Juan
'We saw Juan.'

(30) Lo vimos Juan.
him saw-we Juan
'We saw Juan yesterday.'

Third, while the cases of doubling reported in the literature are limited to (doubling of) DPs, the dislocated constituent in CLLD can be any maximal phrase. The Italian data in (31) (Cinque 1990c: 58) exemplify CLLD of PPs and APs:

(31) a. A casa, non ci sono stato ancora. Italian
To home, not there am been yet
'I haven't been home yet.'
b. Di questa faccenda, non ne voglio più parlare.
Of this matter, not of-it want anymore talk
'I don't want to talk about this matter anymore.'
c. Bella, pare che non lo sia mai stata.
Beautiful, seems that not it is ever been
'It doesn't seem that she has ever been beautiful.'

Forth, there are semantic classes of NPs that appear in CLLD structures but cannot be clitic doubled. As the Greek examples in (32) show, while CLLD of numeral noun phrases is allowed, clitic doubling is not (see Iatridou 1994):

(32) a. Tria provlimata mono o Kostas ta elise.
three problems only the Kostas them solved
'Only Kostas solved three problems.'
b. *Mono o Kostas ta elise tria provlimata.
only the Kostas them solved three problems

Finally, there are languages that have an animacy requirement on clitic doubling, such as Spanish (see Torrego 1998 for a recent discussion and references therein), but not on CLLD. As the contrast in (33) shows, while clitic doubling is sensitive to the [+/–animate] nature of the doubled NP (i.e., doubling of [–animate] DPs is ungrammatical), this is not the case with CLLD, where [–animate] DPs can occupy sentence initial positions:

(33) a. Lo vimos a Juan.
him saw to Juan
'We saw Juan.'

b. *Lo vimos el/al libro.
it saw the/to the book
c. El libro lo compramos ayer.
the book it bought yesterday
'As for the book, we bought it yesterday.'

These differences are unexpected if CLLD is the movement counterpart of doubling, arguing against the reduction of CLLD to an underlying clitic-doubling source. For this reason, Cinque (1990c), Iatridou (1994) and Anagnostopoulou (1994) propose that in CLLD the LD-ed phrase is base generated in a left peripheral adjunct position. The main problem for base-generation analyses of CLLD is that they have to appeal to special mechanisms in order to derive the connectivity property of CLLD (for selective island sensitivity, see Demirdache 1991 and Iatridou 1994). In section 4.3, I come back to this issue.

In particular, Iatridou proposes that CLLD is a predication structure: the LD-ed DP is the subject of predication and it is base generated in a position adjoined to the clause which forms the complex predicate; the open position necessary for the clause to function as a variable is provided by the cl-pro chain:

(34) $[_{CP/IP}\ XP_{LD\text{-}ed}\ [_{CP/IP}\ cl\ pro]]$

*4.2 CLLD and its (non-)*wh*-movement nature*

I highlight some differences between CLLD and constructions involving object fronting as the result of focus/*wh*-movement (see chapter 26).[7] Here I compare OVS/OSV orders with OclS/OScl-V orders, that is constructions where the object appears in a peripheral position and is not resumed by a clitic clause internally to constructions where a resumptive clitic is present.

First of all, there are interpretational and intonational differences. In CLLD the fronted object constitutes old information and cannot be stressed. In OSV, where the object is fronted as a result of movement, the object is new information and receives focal stress. This is illustrated below with an Italian example:

(35) a. Il tuo libro lo ha comprato.
the your book it have bought
'As for your book, I have bought it.'
b. IL TUO LIBRO – ho comprato.
the your book have bought

There are further differences between CLLD and focus movement. As (35) shows, in CLLD there is a clitic present within the clause. On the other hand, a focalized element is incompatible with a resumptive clitic (see Cinque 1990c; Tsimpli 1995; Rizzi 1997). Moreover, a CLLD-ed element never gives rise to Weak Crossover effects (WCO). Such effects are, however, detectable with focus:

(36) a. Gianni sua madre lo ha sempre apprezzato.
Gianni his mother him has always appreciated
'As for Gianni, his mother has always appreciated him.'
b. ??GIANNI sua madre – ha sempre apprezzato.
Gianni his mother – has always appreciated

The fact that no WCO violation occurs in (36a) indicates that the postverbal empty category is not a variable.[8]

It has been suggested that such behavior with respect to WCO leads to a distinction between two types of A'-binding. Specifically, Lasnik and Stowell (1991) assume that WCO is a distinctive characteristic of A'-relations involving genuine quantification. Thus, A'-dependencies must be split into those involving a quantifier that binds a variable, and those that involve non-quantificational A'-binding, but rather binding of a null constant (nc) (see Rizzi 1997):

(37) a. *Who does his mother like t (vbl)
b. John who his mother like (nc)

Assuming WCO to be a diagnostic of what constitutes a quantifier–variable binding relation leads us to conclude that Focus involves quantificational A' binding, while CLLD does not (see Rizzi 1997). According to Rizzi, if Focus is quantificational and CLLD is not, then the difference exemplified in (36) follows as well. In (36b) the focalized element must bind a syntactic variable, hence a clitic cannot be present, since the clitic is an overt pronominal head, its trace is an X^0 trace. So the example with a clitic would be ruled out by the Principle of Full Interpretation which requires that quantifiers bind variables.

Another difference between the two constructions concerns the type of elements that can/cannot appear in CLLD. In Italian, bare quantificational elements cannot appear in CLLD constructions, while they easily allow focalization:

(38) a. *Nessuno lo ho visto.
nobody him have seen
b. NESSUNO – ho visto.

Moreover, a clause can contain several CLLD elements but only one focus, hence the ungrammaticality of (39):

(39) *A GIANNI IL LIBRO darò.
to Gianni the book I will give

Similar effects are observed when we compare CLLD to *wh*-movement. According to Cinque (1990c), if CLLD involved *wh*-movement, then the object clitic that appears in this constructions must be either the spell-out of a *wh*-trace or an instance of clitic doubling. Assuming for the moment that the first option cannot be maintained for the reasons discussed above, let us consider the second one.

First, note that the clitic in CLLD does not seem to behave like a *wh*-trace, given that licensing of parasitic gaps is not permitted. Hence it does not have the properties of a variable.

(40) *Gianni l'ho cercate per mesi senza trovare e.
Gianni I have him looked for for months without finding

With respect to the licensing of parasitic gap constructions, Demirdache (1991) points out that the reason for the ungrammaticality of the example in (40) is that the trace is indirectly bound by the pronoun. She assumes Haik's *convention on variable binding* ((i) a trace must be locally A'-bound, (ii) a pronoun must be A'-bound). This condition allows the index of any variable to percolate to the maximal projection immediately dominating it. The idea is the following: a pronoun need not be locally A'-bound, a trace, however, must be locally A'-bound. This predicts that when the pronoun is to the right of the parasitic gap the parasitic gap is licensed. Such is the case in Greek (see also next section):

(41) a. To Jani i Maria ipe horis na agapa oti tha ton pandrefti.
the John the Mary said without subj love that fut him marry
'As for John, Mary said, without loving him, that she will marry him.'
b. *To Jani i Maria ipe oti tha ton pandrefti horis na agapa.
the John the Mary said that fut him marry without subj love

Second, the clitic that occurs in CLLD does not occur in ordinary *wh*-constructions, as is shown in (42):

(42) Chi (*lo) hai visto.
whom him you have seen

According to Cinque, a *wh*-operator is incompatible with a clitic, due to the quantificational nature of the *wh*-phrase. This is supported by an asymmetry between quantified NPs and bare quantifiers with respect to CLLD in Italian. As discussed in Cinque (1990c: 15), CLLD of bare quantifiers in Italian does not require a resumptive clitic:

(43) Qualcuno (lo) troveremo.
someone him we will find
'Someone, we will find him.'

When the clitic is present the quantifier is interpreted as specific, when the clitic is absent the quantifier is interpreted as non-specific (see also Dobrovie-Sorin 1990 for Romanian).

However, according to Demirdache (1991), this difference could be made to follow from the difference of the level of representation at which movement takes

place. While *wh-* and focus movement take place in the syntax, CLLD involves LF movement of an operator.

Third, under the assumption that *wh*-movement is constrained by Subjacency as re-formulated in Chomsky (1986a), then CLLD does not involve *wh*-movement. There appear to be perfectly grammatical CLLD structures that Subjacency would exclude, if they were derived by *wh*-movement:

(44) a. Loro il libro credo che a Carlo sia siguro che non glielo
they the book believe that to Carlo is certain that not him-it
daranno mai.
will give ever
'It is certain that they will never give the book to Carlo.'
b. *A cui non so quando si saprà cosa daranno.
to whom not know when one will know what they will give

In (44) three different constituents are LD-ed from the most deeply embedded clause. Whatever derivation is chosen a violation of Subjacency will ensue, as is the case with *wh*-movement in (44). See Cinque (1990c: 63ff. for details).

Another property suggesting that CLLD does not involve *wh*-movement is that, unlike ordinary *wh*-constructions, it apparently cannot avail itself of successive cyclic derivations. If we consider adjuncts, which have to move through any intermediate Spec,CP (see chapter 64), we detect a clear contrast between ordinary *wh*-movement constructions and CLLD. Consider the Italian examples below:

(45) PER QUESTA RAGIONE ha detto che se ne andrà.
for this reason has said that will leave
'For this reason, he said that he will leave.'

(46) Per quale ragione ha detto che se ne andrà?
for which reason has said that will leave
'For which reason did he say that he will leave?'

(47) *Per questa ragione ha detto che se ne andrà.
for this reason has said that will leave

(45), a sentence involving focus, and (46), a *wh*-question, are grammatical, but the corresponding example involving CLLD in (47) is not. If CLLD does not involve any form of movement, the contrast directly follows.

The above facts then seem to suggest that CLLD is not immediately compatible with a movement analysis. However, in the literature arguments have been presented, see e.g. Demirdache (1991), Iatridou (1994) and Aoun and Benmamoun (1998), which seem to suggest that CLLD or at least certain types of CLLD do involve *wh*-movement. We will discuss their arguments in the next section.

4.3 CLLD and island effects

As mentioned above, according to Cinque, the relation between the LD-ed element in CLLD and the clitic is not one of movement. As the following Lebanese Arabic data show, the relation between the CLLD-ed NP and the clitic can violate islands, such as the Adjunct Condition, and the Complex NP constraint (see Aoun and Benmamoun 1998: 571):

(48) a. Səʔt ʔənno Naadya rəht mən duun ma təhke maʔ-a.
heard that Nadia left-2sm without comp talking with her
'I heard that Nadia, you left without talking to her.'
b. Səʔt ʔənno ha-l-kteeb hkiit mʔ l-walad yalli katab ʔal-ee.
heard that this the book talked-2sm with the boy who wrote on it
'I heard that this book, you talked with the boy who wrote on it.'

This is expected under a base-generated approach to CLLD, since movement obeys strong (and weak) islands.

However, as has been mentioned earlier on, CLLD in some languages, such as Italian, Hebrew and Greek, is constrained by islands. This is illustrated below with Greek examples containing a relative and an adjunct clause respectively (taken from Iatridou 1994):

(49) a. *Ton Kosta sinandisa tin kopela pu ton ide.
the Kostas met-1sg the girl that him saw-3
b. *Tin efimerida apokimithike diavazondas tin.
the paper fell-3sg asleep reading it

Note, however, that in the languages in which CLLD is constrained by islands it displays selective island sensitivity in the sense that long distance CLLD freely violates weak islands, illustrated below with a *wh*-island:

(50) To forema den ksero pu na to valo.
the dress neg know where subjt it put
'As for the dress I do not know where to put it.'

In other words, CLLD is sensitive to strong islands, but not to weak islands.

This is paradoxical under the base-generated approach: if islands constrain movement and not base-generated relations, why is the relationship between the clitic and the CLLD-ed element constrained by certain types of islands? Cinque (1990c) proposes as a solution that islands in fact do not distinguish movement from base-generated representations. Specifically, Cinque argues that connectivity and selective island sensitivity are properties of chains, regardless of the origin of these chains, i.e., whether they are created via movement or not. In fact Cinque uses CLLD in order to argue in favor of his notion of 'Binding Chain', i.e., a chain which is defined in terms of referential indices (Rizzi 1990b) and can

hold at an arbitrary distance, in the sense that it shows insensitivity to Relativized Minimality Effects. For a phrase to enter a binding relation with its trace, it must not only occupy an A'-position and receive a referential theta-role, but also it must have intrinsic referential properties, properties that allow it, for example, to be D-linked in Pesetsky's (1987b) terms. What is crucial for Cinque is that sensitivity to strong islands is a property that characterizes chains regardless of whether they involve movement or base generation. In other words Binding is sensitive to strong barriers only. Hence strong islands, which are properties of chains, constrain the chain between binding relations between the LD-ed element and the operator variable chain created by the clitic. On the other hand, weak islands (*wh*-islands, inner islands, factive islands) constrain movement. Hence CLLD is not sensitive to conditions that directly affect movement.

On the other hand, Iatridou (1994) and Demirdache (1991) have tried to show that the island sensitivity problem is only apparent, because CLLD does involve some movement after all.[9] Specifically, Iatridou (1994) argues that the LD-ed element in CLLD is generated as an adjunct to the lower CP, the one containing the clitic, from which it moves to the higher clause, hence CLLD involves some type of movement. If this is correct, it should be possible to test such a movement. One such test involves parasitic gaps, as mentioned in the previous section. If the alleged movement crosses an adjunct containing a parasitic gap, then the acceptability of that sentence would confirm the existence of such a movement. This movement forms an A'/A' chain which licenses the parasitic gap, and is in fact acceptable in Greek. (51) is compared with (52) which has the parasitic gap in a position not crossed by the movement out of the LD-position. This sentence is ungrammatical:

(51) To Jani$_i$ i Maria ipe horis na agapa t_i oti tha ton pandrefti.
the John the Mary said without subj love that fut him marry
'As for John, Mary said, without loving him, that she will marry him.'

(52) *To Jani$_i$ i Maria ipe t_i oti tha ton pandrefti horis na agapa.
the John the Mary said that fut him marry without subj love

It has also been pointed out in the literature that a language can have both a type of CLLD formed by base generation and a type of CLLD formed via movement. For instance, Aoun and Benmamoun distinguish between two types of CLLD in Lebanese Arabic. Type 1 is base generated and hence freely violates islands. Type 2, on the other hand, is generated via movement and hence shows a different behavior. In particular Aoun and Benmamoun show that CLLD does not exhibit a uniform behavior with respect to this interaction: *wh*-movement and topicalization across a CLLD-ed NP related to a clitic within an island is consistently ruled out. However, *wh*-movement and topicalization across a CLLD-ed NP which is not separated from its clitic by an island is possible. This is schematically represented in (53):

(53) a. [WH/Top) Np/PP]j CLLD-edNP$_i$ V+clitic$_i$ tj
b. *[WH/Top) Np/PP]j CLLD-edNP$_i$ [island clitic$_i$] tj

They argue that the former construction (53a) is a result of movement. If this is so, it is expected that in this language only the former construction would show reconstruction effects (see chapter 54). This seems to be borne out. Consider the following sentences:

(54) a. Təlmiiz-a əəitaan bt?rfo ?ənno kəll m?allme ? aasasət-o.
student-her the naughty know-2 that every teacher punished him
'Her naughty student, you know that every teacher punished him.'
b. *Təlmiiz-a əəitaan fallaytp ?alblma kəll m?allme ?aasasət-o.
student-her the naughty left-2 before every teacher punished him
'Her student, you left before every teacher punished him.'

In (54a) the pronoun within the CLLD-ed NP can be interpreted as bound by the quantifier phrase 'every teacher'. Bound pronouns must be c-commanded at LF by the elements that bind. The relevant bound reading follows the assumption that the CLLD-ed NP reconstructs under the subject QP. In (54b), on the other hand, no reconstruction takes place since the CLLD-ed NP is base generated in its position. Aoun and Benmamoun account for the interception effects observed in (54) as follows: a moved CLLD-ed NP reconstructs and therefore does not intercept *wh*-movement. A base-generated CLLD-ed NP cannot reconstruct and therefore does not intercept *wh*-movement.[10]

Anagnostopoulou (1994) shows that there are in fact two types of reconstruction effects: full reconstruction effects which presuppose movement, and partial reconstruction effects which do not presuppose movement. As she points out, CLLD in Greek does not exhibit full reconstruction effects. Consider the examples in (55):

(55) a. *O Janis tis$_i$ epestrepse to vivlio tis Marias$_i$.
the John her returned the book-acc the Mary-gen
b. *TO VIVLIO TIS MARIAS$_i$ tis$_i$ epestrepse o Janis.
the book the Mary her returned the John
c. To vivlio tis Marias$_i$ o Janis tis$_i$ to epestrepse.
the book the Mary the John her it returned

In (55a) the indirect object is co-indexed with the possessive genitive inside the direct object phrase. Under this interpretation the sentence is ruled out as a Condition C violation. (55b) is also bad. Under the assumption that focus fronting involves actual movement of the XP, the status then of (55a) and (55b) is identical. On the other hand, (55c) is acceptable. The genitive contained within the CLLD-ed direct object can be coreferential with the indirect object clitic IP-internally. There is no Condition C effect in CLLD which does not involve actual movement.[11] Anagnostopoulou further argues that connectivity characterizes

CLLD because of the existence of a chain which permits transmission of features relevant for Binding Theory.

4.4 Movement approaches to CLLD

In this section I come to discuss analyses that favor a movement approach to the CLLD derived from a clitic-doubling input structure. Agouraki (1993), Kayne (1994), Sportiche (1996b), and Grohmann (2000a), among others, argue in favor of analyses along these lines, which straightforwardly explain the connectedness properties of CLLD.

Before I present such analyses, it is necessary to address one of the arguments against this view, namely the fact that languages such as French lack clitic doubling, but do have CLLD. French has right dislocation, a construction that is superficially similar to clitic doubling. If the movement analysis for CLLD were on the right track, the result would be that the distinction between clitic doubling and right dislocation can no longer be stated.

Right dislocation is a construction in which a clitic co-occurs with a phrase to its right as illustrated in (11) with an example from French (see chapter 14):

(56) Je l' ai vu, l' assassin. French
I him have seen, the murderer
'I saw him, the murderer.' (Jaeggli 1986b: 33)

Clitic doubling and right dislocation are subject to different constraints. For instance, in right dislocation, the dislocated phrase is set off from the rest of the sentence with a sharp intonational break, as illustrated in (57), while no such break is required before the object in clitic doubling, as illustrated in (58):

(57) Parece que tuvieron que llevarla de urgencia a los Estados Unidos la hija de Coronel Martínez. Rio Platese Spanish
'It seems that they had to take her urgently to the United States the daughter of Coronel Martinez.'

(58) Parece que tuvieron que llevarla a la hija de Coronel Martinez de urgencia a los Estados Unidos.
'It seems that they had to take her the daughter of Coronel Martinez urgently to the United States.'

In languages such as Greek in which clitic doubling is restricted to certain types of DPs, it is possible for a DO clitic to co-occur with an indefinite in CLLD and right dislocation, but not in clitic doubling:

(59) To pino pu ke pu ena uzaki.
it drink now and then a glass of ouzo
'I drink a glass of ouzo every now and then.'

Kayne (1994) and Zubizarreta (1998) relate right dislocation to CLLD. Kayne (1994: 82–3) proposes that in both clitic doubling and right dislocation, the DP doubled by the clitic is base generated in an argument position, thus unifying structurally clitic doubling with right dislocation. These authors have argued that clitic doubling, right dislocation, and CLLD have the same underlying structure with a clitic doubling a DP in all three constructions. The doubled DP starts out as a complement of the verb as in (60), and is never generated in a left or right peripheral position. The clitic could be analyzed as the head of a determiner phrase, in whose specifier the LD-ed phrase is originally generated (Torrego 1998).

(60) $[_{CP}\ DP_{LD\text{-}edi}\ [_{IP}\ clV\ t_i]]$

To express the intonational and interpretational differences between right dislocation and doubling, Kayne suggests that the former construction is an instance of CLLD at LF, i.e., the right dislocated phrase undergoes LF-movement of the CLLD type. Covert CLLD is triggered by a feature having the effect of a particular intonation contour at PF. No such feature is present in clitic doubling. On the other side, Zubizarreta (1998: 198, n. 57) suggests that right dislocation involves clitic left dislocation followed by leftward movement of the TP across the left dislocated constituent. Given the distributional differences between right dislocation and clitic doubling mentioned above, the latter approach is descriptively more adequate as it captures the fact that right dislocated elements occupy a peripheral position in the sentence, unlike doubled elements. In Kayne's proposal, this difference is not explained. See also Cecchetto (1996), and Agouraki (1993).[12]

In the next section I turn to a brief discussion of the specificity associated with CLLD.

4.5 CLLD and specificity

Generally, since CLLD involves a topic phrase in the left periphery of the clause, the elements that may appear in this position are specific. However, there exists a cross-linguistic asymmetry with respect to LD of bare quantifiers. For instance, in Greek (Anagnostopoulou 1999b) bare quantifiers either undergo CLLD, in which case a clitic is required and the quantifiers are generally interpreted as specific, or they undergo focus-movement, in which case the clitic is necessarily absent (this is always the case with focus-movement in Greek, cf. Tsimpli 1995 for discussion and references):

(61) a. Kapjon i Maria ton epiase na andigrafi.
someone the Mary him caught-3 subj cheat-3
'Mary caught somebody cheating.'

b. *Kapjon tha vrume alla den kserume pjon.
someone fut find-1pl but neg know-1pl who-acc

c. KAPJON tha vrume alla den kserume pjon.
someone fut find-1pl but neg know-1pl who-acc
'We will find someone but we do not know whom.'

Second, as Demirdache (1991) points out, measure phrases and idiom chunks which are non-referential can be connected to a clitic:

(62) a. 70 chili non li pesa.
seventy kilos not them weigh
'He does not weigh 70 kilos.'
b. Giustizia non la fara mai.
justice not her do ever
'As for justice, he will never do it.'

Demirdache also observes that since any type of XP can be LD-ed why should a predicate, as in (63) below, be able to enter into a referential binding relation with a clitic?

(63) Messo da parte non lo e mai stato.
got out of the way not it he ever was

Moreover, in languages such as Greek, the presence of a clitic is licit in *wh*-constructions, as exemplified in (64):

(64) Pjon apo tus filus tu o Janis ton agapai perisotero.
who from the friends his the John him love-3 more
'Who of his friends does John love more?'

The above data are discussed in Iatridou (1994) and Anagnostopoulou (1994). Both authors note that the presence of clitics is legitimate in *wh*-constructions in which the *wh*-phrase is D-linked (Pesetsky 1987b). Iatridou then argues that CLLD is in general only possible with D-linked DPs, a fact which explains why clitics are possible with D-linked interrogatives: these do not have the syntax of questions but rather they involve CLLD of a D-linked *wh*-phrase.

I now turn to a discussion of the similarities between CLLD and CLD.

5 CLLD and CLD

As mentioned in the introduction CLD is a typical Germanic construction which is characterized by the fact that the resumptive element inside the matrix clause is a demonstrative pronoun, which must be adjacent to the LD-ed element.

5.1 The common properties of CLLD and CLD

CLD and CLLD have a number of properties in common.[13] Investigation of these similarities led researchers to propose a uniform account of CLLD and CLD (see in particular Van Haaften et al. 1983; Demirdache 1991; Anagnostopoulou 1994,

1997; Wiltschko 1997b). The discussion below concentrates on data from Greek and Dutch:

(i) In both constructions the left peripheral XP is understood as a topic.
(ii) Both have a gap in the argument position, while HTLD has a lexical pronoun in that position.
(iii) The left peripheral XP is an adjunct (see section 5.3 for details).
(iv) CLLD like CLD are unbounded, as (65) shows:

(65) a. To Jani skeftika oti o Petros ipe oti ton ide.
the John thought that the Peter said that him saw
'As for John, I thought that Peter said that he saw him.'
b. Jan die dacht ik dat Piet zei dat hij gezien had.
Jan that thought I that Piet said that he had seen
'As for Jan, I thought that Piet said that he had seen him.'

(v) Both constructions are sensitive to islands:

(66) a. *Ti Maria htes gnorisa ton andra pu tin pandreftike.
the Mary yesterday met-1sg the man that her married
b. *Jan die vertelde Piet het verhaal dat hij verslagen had.
Jan that told Piet the story that he beated had

(vi) There is connectivity in both:

(67) a. Ton eafto tu o Janis ton aporipti.
the self his the John him rejects
'John rejects himself.'
b. Zichzelf daar praat Jan niet over.
himself there talks Jan not about

There are similar restrictions on the type of elements that may occur in the fronted position. It is standardly assumed that D-linking or referentiality are the most crucial factors involved. For example, bare quantifiers as in (68a) and (69a) are ungrammatical, while restricted QPs as in (68b) and (69b) are not:

(68) a. *Kathena ton ksero.
everybody him know-1sg
b. Kathena ston kipo ton iksera.
everybody in the garden him knew-3sg

(69) a. *Iedereen die ken ik.[14]
everyone that know I
b. Iedereen in de tuin die kende ik.
everyone in the garden that knew I

5.2 The differences between CLLD and CLD

However, CLLD and CLD are by no means identical. In fact they display a number of differences, listed below:

(i) In CLLD the resumptive pronoun is a clitic. In CLD the d-word can be stressed and can be replaced by a phrasal category. As Zwart (1993: 248), points out, the presence of the d-pronoun is not obligatory, while the presence of the clitic is obligatory:

(70) Marie (die) kust Jan niet.
Mary that kisses John not
'Mary, John doesn't kiss.'

Grohmann (2000a) suggests that when the d-pronoun is not present the construction is similar to focalization:

(71) Jan die z'n ouders ken ik niet.
John that his parents know I not
'John, I do not know his parents.'

(ii) In CLLD the clitic can be clause internal, whereas the d-word must be the first element after the LD-ed phrase. In root clauses, since Dutch requires V-to-C movement, the verb immediately follows the d-pronoun:

(72) Ton Jani i Maria ton kseri.
the John the Mary him knows

(73) *Jan die ik ken niet.
Jan that I know not

(iii) CLLD can involve stacking of LD-ed phrases. This is not possible in CLD:

(74) *Jan op school die daar zag ik niet.
John at school that there saw I not

(iv) CLLD displays selective island sensitivity in the sense that long-distance CLLD freely violates *wh*-type islands (see section 4). CLD is sensitive to all islands:

(75) *Jan die weet ik niet waarom Piet geloofde.
Jan that know I not why Piet believed

(v) Finally, the LD-ed phrase in CLLD can occur at the front of any subordinate type clause. CLD basically occurs in root contexts:

(76) *Ik denk dat Jan die ik niet ken.
I think that Jan that I not know

5.3 Deriving the similarities and the differences between CLD and CLLD

In the literature, it has been argued that the LD-ed phrase in CLD is a CP adjunct, and the d-pronoun is moved to Spec,CP from its base position, as illustrated in (77):

(77) $[_{CP}\ XP_{LD\text{-}ed}\ [_{CP}$ d-pronoun t]]

CLD has been analyzed by some researchers as involving raising of the LD-ed element to the sentence initial position, i.e. Spec,CP (see, e.g., Grohmann 2000a).[15] Wiltschko's (1997b) analysis also accepts that the LD-ed phrase in CLD is in CP, but proposes that it is parasitic on the syntactic operator chain between the topicalized pronoun and its trace.

Demirdache (1991) and Anagnostopoulou (1997) propose that CLD and CLLD can be unified, both involving the general schema in (78):

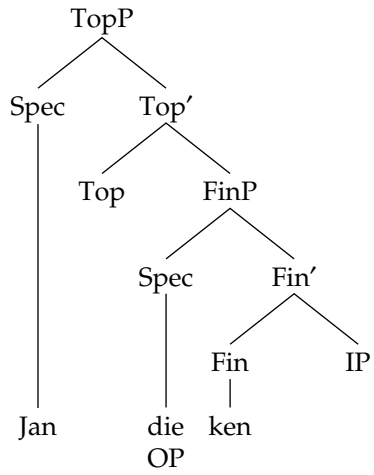
(78) $[_{FP}\ XP_{LD\text{-}ed}\ [_{FP}$ Operator t]]

According to Anagnostopoulou (1994, 1997), predication licenses both cases of (78). The d-pronoun and the clitic head a predicate variable chain, the LD-ed XP being the subject of predication. This approach captures the parallelism between two constructions in a straightforward manner. A clitic-doubling alternative to CLLD, on the other hand, seems to miss a generalization. The differences between these two construction types can be accounted for in terms of a difference in adjunction sites. Specifically, CP-adjunction is forced in CLD, but not in CLLD.

As discussed in section 3.2, embedded CLLD is free to apply everywhere, a fact which suggests that the LD-ed phrase in CLLD is adjoined to IP, contrary to what Demirdache (1991) and Iatridou (1994) have proposed. Recall that Iatridou and Kroch (1992) have argued that the phenomenon of CP-recursion is possible under CPs that are selected by a bridge verb. If the correct analysis of embedded CLLD is in terms of CP-recursion, then Iatridou and Kroch's analysis is not compatible with it, as the conditions on CP-recursion are systematically violated in the case of embedded CLLD. Hence a more correct analysis seems to be one in which the LD-ed phrase is adjoined to IP. On this view, the differences between CLD and CLLD can be captured if one assumes that CLD requires a matrix CP.[16]

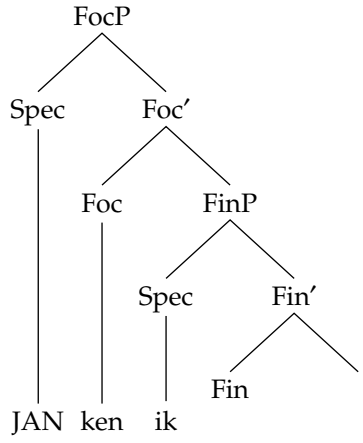
Haegeman (2001), on the other hand, adopts Rizzi's analysis of the split CP and assumes that in Dutch root clauses the finite verb occupies Fin. She assumes that a fronted topicalized constituent occupies the specifier of TopP and that the doubling *die* pronoun occupies the specifier of FinP. When the pronoun is absent, it is assumed that a non-overt analogue occupies the specifier of TopP. This non-overt analogue is taken to be a null operator, OP:

(79)



A further refinement needs to be added here. In V2 languages such as Dutch, fronted objects receive either topic interpretation ('old information') or focal interpretation ('new information'), in which case they will have focal stress. One may assume that when fronted constituents receive topic interpretation the structure is as in (79) above, with an overt or non-overt topic operator. When focal, Haegeman assumes that the structure is as in (80) with the fronted constituent moved to Foc and the verb moves to Foc:

(80)



6 CLLD in the noun phrase

Within noun phrases, there exists a construction in which both a possessive pronoun and a possessor DP are present. This pattern is found in many languages. (81) provides a non-exhaustive list of examples (Haegeman 2001; Alexiadou et al., forthcoming):

(81) a. Per sin bil — Norwegian
Peter his car
b. ae mand hans hus — W. Jutlandic
a man his house
c. dem Vater seine Katze — German
the father his cat
d. em bueb zini Mutter — Swiss German
a child his mother
e. Peter z'n Kat — Dutch
Peter his cat
f. Marie eur katte — W. Flemish
Mary her cat
g. Epkema syn plan — Frisian
Epkema his plan
h. the Man of Lawe his Tale — Middle English
i. li serf sum pedre — Old French
the serf his fater
j. Jón hin-ós — Krio
John his house
k. Peter sua filho — Malayo-Portuguese
Peter his son

The particular instantiation of the construction is not homogeneous cross-linguistically. For instance, in languages with overt morphological case the possessor DP may be associated with different case-forms. In German (81c), the possessor DP *dem Vater* appears in the dative case. The Swiss German possessor *em bueb* in (81d) is a 'nominative pendens'; both in German and in Middle English the doubled construction occurs with a dative possessor, but it may also occur with a genitive possessor. The genitive possessor is illustrated in (82a) for German and in (82b) for English. Middle Dutch doubled possessors occur in the genitive case, illustrated in (82c):

(82) a. bringt ja des teufels sein Gepäck.
bring ja the devil-gen his pack
b. God Mars'es his vigour Sir Robert's his shape
c. alle des conincks sijn landen
all the king-gen his lands

Corver (1990) argues at length that in (81e) above *z'n* occupies the same position as genitive '*s*, i.e., D^0. That this is so is suggested by the fact that they are mutually exclusive:

(83) a. Jans auto
Jan's car

b. Jan z'n auto
   Jan his car
c. *Jans z'n auto

Corver further suggests that this possessor is actually generated in Spec,DP. Note that the possessor in Spec,DP is not assigned case from outside its clause:

(84) a. Ich habe dem Mann seinen Wagen gesehen.
   I have the man-dat his car seen
b. Dem Mann sein Wagen wurde gestohlen.
   the man-dat his car was stolen

In (84) the possessor bears dative case, i.e., an oblique case form. It is not assigned structural case from outside. However, the DP containing the possessor is assigned case by a governing case-assigner, the verb and Infl.

It is a characteristic property of this construction that it only occurs with third person pronouns. First and second person pronouns, on the other hand, are unacceptable, as can be seen in the following Dutch (85a) and German (85b) examples:

(85) a. *mij m'n moeder
   my my mother
b. *euch Brüdern euer Haus
   your Brothers-dat your house

This restriction to the third person is not exclusive to left dislocation of DPs but it is prototypical of left-hand satellites in general. As de Wit (1997) observes, CLD is also sensitive to this:

(86) *Ik/mij die kent Jan niet.
   I/me that knows Jan not

In fact, others have noticed the similarities between these constructions and CLD and CLLD. Giusti's (1996) analysis for the doubling construction assimilates the pattern to the Romance left dislocation structure. She proposes that the DP-possessor parallels the topicalized constituent in the CLLD pattern and occupies the specifier of a TopP in the DP domain. The doubling possessive pronoun in her analysis corresponds to the doubling clitic. Though this analysis is on the right track, Haegeman (2001) discusses some points that need refinement. For one thing, we cannot always identify the preposed possessor with the topic in the CLLD constructions. In CLLD constructions, typically, the dislocated DP cannot be a bare quantifier:

(87) *Personne je ne l'ai vu.
   nobody I not him have seen

According to Haegeman (2001), in West Flemish the doubling pronoun may be a bare N-quantifier, in which case the DP has the features of an indefinite DP, witness the obligatory expletive construction in (88b):

(88) a. dat zyn niemand zen zoaken
that are no one his business
b. Niemand zen voader zou ter da keunen verdroagen.
no one his parents would there that be able to support

The topicalized element in a CLLD construction can also be a strong pronoun, an option which is at best extremely marginal for the possessor construction:

(89) a. Lui je ne l'ai pas vu.
him I not him have not seen
'As for him, I have not seen him.'
b. *T'is zie eur boek.
it is she her book

Another argument against assimilating the doubled DP to the topic is that the doubled DP may also be an interrogative element, which is compatible with focus interpretation (i.e., new information), but not with topic interpretation (i.e., 'given information'):

(90) Wien zenen boek is da?
who his book is that

The variety of elements that can double the possessor pronoun suggest that they cannot just be seen as DP-topics. Below we shall propose that the doubling construction may indeed involve some form of topicalization inside the DP, but that, contrary to what seems to be suggested by Giusti, it need not always do so.

In fact, Haegeman (2001) takes (91) to support the parallelism between dislocation and doubling possessives:[17]

(91) Over minister-president v.A. die zijn fouten hebben we gepraat.
about prime minister v.A. that his mistakes have we talked

In (91) the possessive DP *minister-president v.A.* is actually doubled by two elements. (i) Immediately adjacent to it there is the doubling *die*-pronoun which also typically occurs in the left periphery of the Dutch clause and precedes the finite verb. (ii) In addition there is the possessive pronoun *zijn* in POSS. Given this close parallelism between Dutch dislocation and doubling possessives in (91), Haegeman takes the Dutch pattern as the closest clausal parallel for the doubling construction.

The example offers an exact match for the dislocation structure as shown by the schematic patterns in (92):

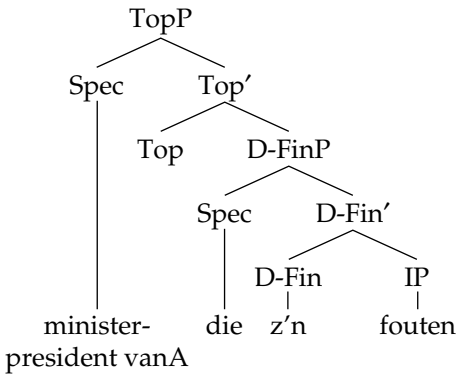
(92) a. Jan die vertrekt
Jan die leaves

b. Jan die z'n vertrek
Jan die his departure

While the data do confirm Giusti's intuition that the doubling construction finds a parallel in the dislocation pattern, we also see that the *die* pronoun in the dislocation pattern does not correspond to the possessive itself. In fact, (91) suggests that the matching elements in 'third' position are the finite verb in the clause and the pronoun in the DP.

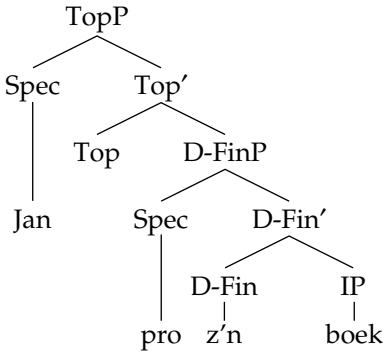
By analogy with the split CP, Haegeman (2001) assumes a split DP, i.e., the category D is in fact a shorthand for a hierarchically organized set of functional projections. Haegeman proposes that the DP-internal category which encodes (in)definiteness corresponds to FinP in the CP layer. In the same way that FinP can be dominated by TopP and by FocP, the relevant projection DP can be dominated by TopP. Adapting Corver's DP structure along the lines of Rizzi's split CP she proposes the following representation for the DP in (93):

(93)



The question arises how to represent possessive structures without the doubling *die* pronoun. Based on the analogy with the clausal domain and assuming that possessors are subject analogues, Haegeman proposes that in the absence of an overt *die* pronoun the doubling possessor may still be inserted in the specifier of the TopP and that that there is a null pronominal under [Spec,D-FinP]:

(94)



NOTES

1 For a discussion on the status of epithets as resumptive elements see Aoun and Engdahl (1985), McCloskey (1990), Demirdache (1991), Shlonsky (1992), Choueiri (1999).
2 Van Riemsdijk (1997a) points out that there is a partial correlation between movement properties and connectedness.
3 Note that case connectivity is possible between the LD-ed noun phrase in Greek HTLD and the clitic. The point here is that it is not obligatory as is the case with CLLD.
4 In a system like Rizzi's (1997), HTLD elements would occur in the highest topic construction, while CLLD elements would occupy lower topic positions. According to Rizzi, topic projections hosting CLLD elements can be multiple.
5 The literature on CLLD is very rich (see Cinque 1990c; Iatridou 1994; Zubizarreta 1998, among many others and references therein).
6 The discussion on CLLD does not include the status of preverbal subjects in pro-drop languages, which have been argued by some researchers to be in a CLLD-ed position (see Alexiadou and Anagnostopoulou 1998 and references therein). Their A vs. A' status is still a matter of controversy (see Cardinaletti 1997).
7 It is generally assumed that focus movement applies much like *wh*-movement (see Cinque 1990c; Rizzi 1997).
8 Demirdache (1991) points out that the immunity to WCO simply shows that the pronoun does not have the interpretation of a logical variable. It does not show that the construction does not involve *wh*-movement.
9 Though the two approaches share certain common properties, they differ in the details. For instance, Iatridou assumes that it is the dislocated XP that undergoes A'-movement, whereas Demirdache assumes that the dislocated XP is generated in the position where it appears at S-structures and it is the IP-internal pronoun that undergoes movement. Second, Iatridou assumes that movement takes place at S-structure, whereas Demirdache proposes that movement takes place at LF. However, both share the property of suggesting that CLLD is selective sensitive to islands because movement originates from an A'-position.
10 Aoun and Benmamoun further propose that the type of movement involved in CLLD in Lebanese Arabic takes place actually at the PF component. Specifically, pre-spell-out the CLLD-ed NP remains in the specifier of a clitic phrase, an A-position, therefore no interception with *wh*-movement and topicalization is observed. A PF movement operation does not feed LF. At LF the CLLD-ed element is still located in the specifier of the clitic phrase. Hence the "reconstruction effects."
11 Anagnostopoulou shows that the Condition C effects do not disappear under clitic doubling, hence providing an argument that CLLD cannot be reduced to clitic doubling.
12 The specifics of the overall analysis of Agouraki are crucially different. In the spirit of Sportiche (1996b), Agouraki (1993) proposes that clitics are functional heads heading their own projection and they may co-occur with full DPs in argument positions (clitic doubling). The doubled DPs may raise overtly to the specifier of the clitic head and from there they can move further on (CLLD). Agouraki points out that CLLD has mixed A/A' properties, similar to scrambling. She proposes to account for this similarity by postulating that the movement step of the DP to the clitic position has

A properties (akin to an agreement process) while movement beyond this domain has A′ properties (cf. Mahajan 1990 for short-, medium-, and long-distance scrambling; Sportiche 1996b, who proposes to unify the syntax of clitic constructions and scrambling; and Alexiadou and Anagnostopoulou 1997a, who argue that the counterpart of short scrambling is clitic doubling, substantiating Sportiche's claim with evidence from binding).

13 There is an obvious parallelism between the structure of relative clauses and that of left-dislocated constructions. This is particularly true in languages such as Dutch and German: both relative clauses and CLD are characterized by a nominal head and a fronted d-pronoun (see the contributions in Anagnostopoulou et al. 1997).

14 Zwart (1993: 250) points out that this example is not very bad under a restricted reading.

15 Vat (1997) contains a discussion of the derivation of CLD by comparing the T-model to the NP-Structure model of Van Riemsdijk and Williams (1981).

16 Note, however, that given recent proposals about the set of functional categories that form the left periphery of a clause embedded CLLD-ed phrases could be argued to be situated on specifiers of functional projections within the C system.

17 Note that at least some speakers of Standard Dutch judge the example as ungrammatical.
