Praise for *The Blackwell Companion to Syntax*, Volumes I–V

"When I first started studying linguistics in 1960 it was possible for an assiduous student to read almost everything in the field. The success of the discipline has meant that those happy days are, happily, gone forever. Syntax is now so big that no one can read even a fraction of what is on offer. There have been two unfortunate results: first, today's syntacticians keep rediscovering old facts, often reinventing eccentric wheels; second, they keep complaining that other linguists ignore their work. The usual excuses are that the material we ought to have referred to is distributed, seemingly at random, among hundreds of books and articles; life is finite; institutional pressures are unrelenting; and it is hard enough keeping up with work done in one's own framework on one's own area of special interest, without trying to see what rival theorists in adjacent areas might have had to say on the matter at hand, however relevant in the long term their contribution might be.

Such excuses will no longer do. *The Blackwell Companion to Syntax* provides a comprehensive overview of the progress and achievements made in syntax over the last 35 years. A galaxy of international stars under the leadership of two distinguished linguists, Martin Everaert and Henk van Riemsdijk, has constructed an unparalleled and monumental survey of empirical facts and theoretical insights covering the entire field. Whether you are interested in parasitic gaps, Icelandic logophors, or quantifier scope ambiguity, you will find here the essential background to your own contribution. This is a major achievement and the Companion will rapidly become essential reading for all serious linguists."

Neil Smith, University College London

"*The Blackwell Companion to Syntax*, unique in character and designed with great skill and care, is sure to be a rich source of high-quality information on critically important topics, and an invaluable research tool for the study of language."

Noam Chomsky, Massachusetts Institute of Technology

"For any serious researcher interested in theoretical linguistics, this incredible companion will remain an important and extremely useful source of reference for years to come."

Yukio Otsu, Keio University, Tokyo

"The flow of linguistic theory is shaped by the empirical puzzles of the rocks and the banks of the river bed. Any particular rock will have different effects at different points in the river. This Companion assembles the empirical puzzles and that is an enormously valuable service: it enables readers to understand why particular puzzles were of interest at particular stages in the development of theory and it assembles the puzzles into a compendium, in the belief that puzzles need solutions at every point in the development of theory, even if the shape of the solutions changes significantly at different stages of theoretical development.

The compendium of puzzles will be a great resource for young investigators, joining the river at some point and wanting to know what was upstream as they find their way downstream."

David Lightfoot, Directorate for Social, Behavioral and Economic Sciences, National Science Foundation, Arlington, VA

"Looking for a topic to work on? Grab *The Blackwell Companion to Syntax* and read some articles there. Or you may try to think of a topic not covered (if that is possible). Either way, this five-volume set should be within your reach if you want to be an active researcher."

Akira Watanabe, University of Tokyo

"In a rapidly moving field, it is essential to have an accessible repository of the empirical generalizations that fueled the theoretical debates. These generalizations have not only a historical value. It is often the case that the latest theoretical constructs tend to focus on the most recent empirical issues being discussed and ignore the previous ones. In this respect, this book provides a constant reminder of what needs to be incorporated in the current debate. It can be considered the empirical memory of the field."

Joseph Aoun, University of Southern California

"*The Blackwell Companion to Syntax* will be an indispensable source for theoretical, descriptive, and applied linguists alike. Much of the syntactic knowledge accumulated since the *Aspects* is not easily accessible and some of it may even be in the world of oblivion for many linguists. Younger scholars may have difficulties to understand some of the work done in a by now obsolete theoretical framework. Others may want to have easy access to the analytic knowledge of earlier work in their daily research activities. Since the knowledge presented in the Companion is largely independent of the various stages of syntactic theorizing, it can profitably be used by researchers working on syntactic problems whatever their theoretical background may be. The contributions of the present encyclopedia have been written by top scholars in the field covering practically all important issues addressed in syntax during the last forty years or so. It will certainly serve as an essential research tool for a great number of linguists for many years to come."

Ferenc Kiefer, Hungarian Academy of Sciences, Budapest

"*The Blackwell Companion to Syntax* is a very important accomplishment. Everaert and Van Riemsdijk have brought together a large group of internationally reputed researchers, each of whom analyzes a particular empirical domain that has played a central role in the development of syntactic theory. It is a valuable reference and pedagogical tool. I have no doubt that this work will benefit not only undergraduate and postgraduate students of linguistics but anyone interested in syntax and in the remarkable intellectual history of the field."

M. Carme Picallo, Universitat Autònoma de Barcelona

"This is the most impressive collective endeavor in the field of syntax ever attempted. It summarizes the (basic) descriptive results obtained for a great many syntactic phenomena in the last fifty years of research in generative grammar. It is an indispensable work of reference for students and researchers alike."

Guglielmo Cinque, University of Venice

"Since the beginnings of generative grammar, our knowledge of the syntactic aspects of the human language faculty has increased exponentially, with every investigation giving rise to ever deeper investigations and to cross-linguistic research. Every time I write a paper, prepare my lectures, or advise students on their research, I am confronted with the problem of accessing a vast body of syntactic knowledge. With 77 case studies written by leading syntacticians, *The Blackwell Companion to Syntax* is certain to help address this fundamental problem."

Christopher Collins, Cornell University and New York University

"The past 30 years have seen an explosion in the breadth and depth of linguistic research, as focused theoretical perspective has sharpened empirical investigations. The Companion is a time capsule for the results of empirically significant projects, ensuring that the results of the past are not lost in the future. Any scholar who opens the volumes will find there a wealth of wide-ranging, scholarly, and theoretically informed discussion of just about every syntactic phenomenon currently known to the field – from double nominatives to topicalization; from the spray/load alternation to SOV languages. The insightful and rich chapters come from some of the extraordinary researchers of the time period. If the next generation of scholars does not utilize this marvelous resource, it will not be the fault of the editors and authors, and they can be sure that current researchers will profit immediately from this outstanding project."

Jane Grimshaw, Rutgers University

The Blackwell Companion to Syntax

Volume III

Blackwell Handbooks in Linguistics

This outstanding multi-volume series covers all the major subdisciplines within linguistics today and, when complete, will offer a comprehensive survey of linguistics as a whole.

Already published:

The Handbook of Child Language
Edited by Paul Fletcher and Brian MacWhinney

The Handbook of Phonological Theory
Edited by John A. Goldsmith

The Handbook of Contemporary Semantic Theory
Edited by Shalom Lappin

The Handbook of Sociolinguistics
Edited by Florian Coulmas

The Handbook of Phonetic Sciences
Edited by William J. Hardcastle and John Laver

The Handbook of Morphology
Edited by Andrew Spencer and Arnold Zwicky

The Handbook of Japanese Linguistics
Edited by Natsuko Tsujimura

The Handbook of Linguistics
Edited by Mark Aronoff and Janie Rees-Miller

The Handbook of Contemporary Syntactic Theory
Edited by Mark Baltin and Chris Collins

The Handbook of Discourse Analysis
Edited by Deborah Schiffrin, Deborah Tannen, and Heidi E. Hamilton

The Handbook of Language Variation and Change
Edited by J. K. Chambers, Peter Trudgill, and Natalie Schilling-Estes

The Handbook of Historical Linguistics
Edited by Brian D. Joseph and Richard D. Janda

The Handbook of Language and Gender
Edited by Janet Holmes and Miriam Meyerhoff

The Handbook of Second Language Acquisition
Edited by Catherine J. Doughty and Michael H. Long

The Handbook of Bilingualism
Edited by Tej K. Bhatia and William C. Ritchie

The Handbook of Pragmatics
Edited by Laurence R. Horn and Gregory Ward

The Handbook of Applied Linguistics
Edited by Alan Davies and Catherine Elder

The Handbook of Speech Perception
Edited by David B. Pisoni and Robert E. Remez

The Blackwell Companion to Syntax, Volumes I–V
Edited by Martin Everaert and Henk van Riemsdijk

The Handbook of the History of English
Edited by Ans van Kemenade and Bettelou Los

Preface

Generative grammar has always set its aims high. From its inception in the 1950s, the ambition has been to go beyond observational and descriptive adequacy to reach explanatory bliss. Important work would be about 'conditions on transformations' rather than on 'some properties of *wh*-movement in English', about the 'transformational cycle' rather than on verb clusters.[1] This is what science should be like. And while earlier attempts at achieving a semblance of an explanatory theory were often clumsy and inadequate, these past forty or so years have shown that truly fundamental questions can now be asked and addressed.[2] This emphasis on theory has not, of course, altered the fact that linguistics is a thoroughly empirical science, but data and analyses are seen as what they are: tools to help us understand the structure and properties of the human language faculty. It is the fate of tools that when the product is finished they are put away. When some (as it turns out controversial) data from Italian had suggested that the notion of bounding node should be parameterized, we then forgot about the Italian data and happily proceeded with the idea of parameters.[3] Numerous other examples could be added.

More generally, the data and analyses that at some point in the history of generative grammar played an important, sometimes even a crucial, role have a tendency to fade into the background rather quickly.[4] This effect is particularly strong when the piece of theorizing they helped to establish becomes obsolete, but it is even true when the theoretical insight persists over time. As time went on, and as generative grammar (using the term in the broad sense, including all its theoretical diversity), in its explosive success, expanded to dozens of countries, hundreds of universities and colleges, and many hundreds of researchers, the muckheap of once useful but then discarded empirical material continued to grow. Old hands in the field may still be served by a good memory, helping them to dig out some of these rejects if they seem useful at some later stage, but successive new generations of young linguists simply don't have access to the wealth of data, generalizations, and analyses that might be terribly important to their research if only they knew about them.

But it is not only a problem for younger generations. Researchers who like to keep track of developments, particularly (but not only) in those subfields that are not directly related to their own research, or who work in closely related disciplines such as, for instance, psycholinguistics or sociolinguistics, find it increasingly difficult to keep track. Current handbooks are often concerned with current theorizing, but only marginally with the history of the various versions of the theory and even less with the empirical generalizations underlying those theories. As a consequence, an ever smaller percentage of the potentially useful empirical material is treated in standard textbooks, and hence the rest is not part of the knowledge that researchers and students in the field may be expected to possess.

It might be objected that the articles in which all this wisdom is stored are, after all, still around in the journals, in the books, in the libraries. But given their theoretical focus, the titles are often unrevealing as far as the empirical domain is concerned, keywords are notoriously absent or unreliable, relevant data are scattered over several articles, and, most importantly, the presentation of the data in these articles is subservient to the theoretical claims that are made and hence not presented in succinct, didactically useful ways.[5] So searching for the relevant materials, even if you know what to look for, is often hard. For young researchers, such a search task is doubly difficult because very often the descriptive generalizations are presented in a jargon and formalism that were characteristic of the theoretical framework at the time, sometimes decades ago. Who thinks to look up the term 'backward equi' when looking for data relevant to what we now call exceptional case marking (ECM)?[6]

Having a good, theoretically oriented mind is not enough. You cannot gain an understanding of the abstract properties of Universal Grammar without having any ideas about interesting empirical areas that might provide the crucial evidence (or counter-evidence) for your claims. But these flashes of empirical insight can only come if you have enough knowledge in your head to start the neurons firing away. And you can only have that knowledge if you have been taught about a certain range of phenomena in a variety of languages, or if you have had access to a repository of such materials to work through by yourself. The problem is that such courses are rarely taught, the reason being more often than not that the relevant data are not available in a form that is didactically usable.

This is the lacuna that we are hoping to fill with *The Blackwell Companion to Syntax*. In these five volumes, we offer you 77 case studies of syntactic phenomena that should, at least partly, fill the gap and constitute an important research tool for the working linguist and for teachers and students of syntax (and its interfaces). In bringing these chapters together, we were guided by a working definition of what a syntactic case study was supposed to be. The following properties were thought to be central: *a well-delimited empirical area (both as to the construction(s) involved and as to the languages in which the phenomena are found) whose analysis has, at one time or another in the history of generative grammar, played an important role in the theoretical debates at that time*. More often than not, we will find that such results are relatively robust in the sense that they will stand and

be interpretable regardless of various innovations or adaptations of the version of the theory in which they first saw the light.

The so-called 'verb-raising' construction in Continental-West Germanic languages (chapter 75) will serve as an example. Much has been published on this subject, a reasonable degree of consensus exists about the most important properties of the construction, its analyses have been frequently used to support theoretical proposals, etc. Nevertheless, the existence of this complex of facts is hardly known outside the small group of specialists in this field, the main properties cannot be presupposed as common knowledge, and no one in the field can be properly held responsible for ignoring the verb-raising construction. In a situation like that, the chapter's presentation will be oriented toward combining views and formulating them in such a way that they will be accessible to researchers from various approaches to the theory of grammar.

In addition, of course, the delimitation had to be such that the empirical subdomain in question could be treated in manageable chapters. It would have been unthinkable to include a case about relative clauses: even a thick monograph would not do such a topic justice. But the subtopic of free (headless) relative clauses (chapter 27), a topic that in the late 1970s and the 1980s generated a considerable literature, is a typical example of what we had in mind.

What about the theory? We wanted to make the empirical generalizations, the insights into the properties of constructions, the main focus of each chapter. But wherever useful and possible, of course, reference can be and is made to the theoretical issues that the phenomena in question were or even are relevant to. This introduces a certain bandwidth, and indeed some of our authors stress the empirical side more strongly while others swerve more easily into theoretical discussions. With a project this size it has been impractical to impose more uniformity than we have achieved here. It was, frankly, not always easy to convince our authors to take time away from their primary theoretical research to write the chapters we asked them to. And it was also on occasion hard to curb the attention that they tended to give to theoretical issues and their own role in those theoretical developments. More generally, wherever possible we suggested that theoretical issues be addressed in robust, sustainable ways, not in terms that would reflect the fads and the terminological peculiarities typical of a specific brief period in the short history of generative grammar.

It does not take a great deal of knowledge of the field to realize that an enterprise such as the present one is a highly open-ended affair. Even if we had achieved complete coverage at the time of appearance, new cases would soon present themselves. But complete coverage is unattainable in the first place. It is always possible to come up with other potential cases, not represented in the present work. Even now we already have a number of ideas about cases that might be added and which may at some point be added to the present collection. Nevertheless, we believe that the coverage that the present collection achieves is very considerable. So much ground is covered that already it seems doubtful that future graduate students of linguistics could be expected to work through all of this material. If a student manages part of it and has the rest at his or her disposal

as an encyclopedia of linguistic phenomena, we feel certain that his or her research will greatly benefit. As teachers we are frequently confronted by a big question mark in the faces of students or even fellow faculty members when we use terms like 'contraction', 'subdeletion', or 'freezing effect'. And when asked "Where can I read up on this?" we are often faced with our own bad memory and the virtual impossibility of pointing toward one representative text that will concisely and competently explain what kind of phenomena are hiding behind these terms. This, we feel sure, is now a problem of the past.

If, as we are convinced, this *Companion* will become an important research tool in linguistics, a pressing need will also be felt for additional case studies to be added. While it may well be possible to project further volumes in the future, or an updated or extended version of the present publication, it has been clear to us from the start that the best way to make this an incremental enterprise is to publish these cases electronically. This would allow the possibility of reviewing cases now published, adding new cases relatively easily, and allowing discussion fora, etc. When that happens, the way to expanded coverage of the field will be paved. For the moment we refer you to www.syntaxcompanion.org to keep you informed on developments in this area.

One point to make about the references: every individual chapter has a reference section; the consolidated reference list is in volume V, and in the XML CD version the links are to the consolidated list rather than to the end-of-chapter lists. So in the chapter references you may find entries with a, b, etc. after the date even if there is only entry with that author and date in that chapter, because there is more than one entry in the whole five volumes with the same author and date. For example, even if there's only one Chomsky 1995 cited in any one chapter, it will appear as Chomsky 1995a or 1995b or 1995c, because there are three Chomsky 1995 entries in the consolidated references for the whole five volumes, identified as a, b, and c.

As editors of this encyclopedia of case studies, we have had to make many choices. In doing so we were greatly helped by the project group at NIAS, the Netherlands Institute for Advanced Study in the Humanities and Social Sciences, at Wassenaar, in the dunes lining the Dutch coast, in 1996/1997. The definition of what we would consider a typical case study was intensively discussed and ultimately fixed by that group: Reineke Bok-Bennema, Norbert Corver, Denis Delfitto, Joe Emonds, Martin Haiden, Itziar Laka, Eric Reuland, Tim Stowell, Sten Vikner, and, to some extent, Ian Roberts. We were also fortunate to have good input and feedback from Hagit Borer, Jan Koster, and Edwin Williams, our special outside consultants. The original list of cases was also compiled by that group. First sample chapters were produced during that year. And we brainstormed a lot about who would be the ideal author for which chapter. Nevertheless, we accept full responsibility for all the choices that were made.

We do wish to emphasize, however, that it has never been our intention to suggest that the present collection could be interpreted as a kind of canon, in the literary sense of the word (to the extent that literary scholars are still prepared to advocate such a notion). What we say above about the open-ended character of

an enterprise such as this should underline the fact that nobody could pretend that it is at all possible to establish such a canon, even if one tried to.

The first plans for this project were made in 1993. That is when we decided to apply to NIAS to see if we could get together a team of colleagues with whom to discuss the scope, the objectives, and the realization of the present work. The application was approved. We gratefully acknowledge the generous support, financial, logistic, and otherwise, of NIAS and, in particular, Dick van de Kaa and Wouter Hugenholtz, respectively the rector and the director of the institute. The group convened in the splendid isolation of NIAS in the academic year 1996/1997. There, we were happy to be able to work together with the colleagues mentioned above. Ilke van den Ende joined us as a student trainee. We were also happy to be able to organize two workshops at NIAS during that year. A third was held in Los Angeles at USC with the help and support of Hagit Borer and Tim Stowell in 2001. We wish to thank the participants at these workshops for their contributions, and LOT (the Dutch National Graduate School of Linguistics) as well as NWO and KNAW (the Netherlands Organization for Scientific Research and the Dutch Royal Academy of Sciences respectively) for financial support for these workshops. We also wish to thank the BSGM Foundation for an additional grant to the NIAS group. Last but not least we wish to thank those who have assisted us with the administration and correspondence, with the copy-editing and the HTML-conversion and the maintenance of the website: Jenny Doetjes, Bart Hollebrandse, Rob Goedemans, and Hannah de Mulder. Without them we literally and figuratively could not have managed. Thanks are due to NWO and the Utrecht Institute of Linguistics OTS (Language in Use project) for grants that made this assistance possible.

Finally we would like to thank all those at Blackwell who, over the years, have helped us realize this project – Ada Brunstein, Philip Carpenter, Sarah Coleman, Tami Kaplan – and the copy-editing team – Fiona Sewell, Anna Oxbury, Peter Kahrel – for doing such a wonderful job.

Utrecht and Tilburg
Martin Everaert and Henk van Riemsdijk

NOTES

1 Cf. Chomsky (1973); Evers (1975b).
2 See, for example, Chomsky (2004).
3 Cf. Rizzi (1982b).
4 The reverse also holds true. Certain empirical domains have never figured prominently in theoretical debates, and remain, thus, uncharted territory from a descriptive point of view.
5 We should add that publications like *Linguistics Abstracts Online* will, in future, solve part of the problem we note.
6 Cf. Postal (1974).

7 Conclusion

1 Background

According to the canonical Binding Theory (Chomsky 1981), nominal expressions occur in three basic types: (i) anaphors, (ii) pronominals, and (iii) R-expressions. Anaphors are characterized as expressions that have no inherent capacity for reference. Hence, they must depend on some other expression in the sentence for their interpretation (their *antecedent*). Pronominals may, but need not depend on another expression for their interpretation. They are characterized by the fact that their features are drawn solely from a set of grammatical features, phi-features (in many languages just gender, number, and person). R-expressions have some additional features (grammatical and/or lexical).[1] Certain anaphors are like pronominals in that they only consist of phi-features. Other anaphors are morphologically complex and may contain other features as well. Anaphors and pronominals are together often referred to as *pronouns*.

The linguistic encoding of interpretive dependencies between nominal expressions and their antecedents is governed by the Binding Theory. For anaphors, the Binding Theory stipulates that they must be bound in a local domain (Condition A of the Binding Theory). Within the class of anaphors a further distinction is made between reflexive and non-reflexive anaphors. Loosely speaking, reflexive

anaphors have an argument of the same predicate as their antecedent, non-reflexive anaphors do not (for a more precise exposition, see chapter 9).

2 The notion of logophoricity

One of the challenges for the canonical Binding Theory, discussed by Clements (1975) among others, is the fact that the behavior of anaphors is not always clear-cut. Languages may have forms that must be bound in one environment, and need not be bound in another.[2] A typical example is *sig* in Icelandic. It must have a binder in (1a) (and failing this, due to a feature mismatch between *þú* and *sig*, it is ill-formed):

(1) a. *Þú hefur svikið sig.
you have betrayed self
b. María var alltaf svo andstyggileg. Þegar Olafur$_j$ kaemi segði hún sér$_{i/*j}$ áreiðanlega að fara. (Thráinsson 1991)
'Mary was always so nasty. When Olaf would come, she would certainly tell himself [the person whose thoughts are being presented – not Olaf] to leave.'

In (1b) *sér* is without a linguistically expressed antecedent, and yet the sentence is well-formed.[3] Traditionally anaphors such as *sig* in (1b) were called indirect reflexives. Hagège illustrates the indirect reflexive with the Latin example in (2) (Hagège 1974: 289, my gloss and annotation):

(2) (Patres conscripti) legatos . . . miserunt . . . qui a
senators delegates sent who from
rege peterent [ne inimicissimum suum secum haberet sibique
king ask$_{subj}$ that not biggest enemy refl$_2$ refl$_1$-with keep$_{subj}$ refl$_2$-and
dedere].
give$_{subj}$
'The senators$_i$ sent delegates to ask the king$_j$ not to keep their$_i$ biggest enemy$_k$ with him$_j$ and to give [him$_k$] to them$_i$.' (Cornelius Nepos, 23, 12, 2).

Suum, *se*, and *sibi* are all formally anaphors (reflexives in Hagège 1974).[4] As he points out, (2) shows two quite different uses, however. One use (in *secum*) is properly reflexive (rendered as 'refl$_1$' in the gloss), the other use is not, but rather refers to the author of the request (rendered as 'refl$_2$' in the gloss).[5] It is impossible for *sibi* in (2) to refer to individuals different from the senators, as would be the case if it were replaced by the pronominal form *eis*.

This second use is special since the reflexive, although it is technically bound, is not bound in a local domain, contra to what Condition A would lead one to

expect; rather the binding relation crosses two (subjunctive) clausal boundaries. Such a use of reflexive-like forms is not limited to Icelandic or Latin, but widespread over the languages of the world.[6]

Since Clements, the term *logophor* has come to be used for such anaphors. The term *logophor* was earlier introduced by Hagège (1974) for a different purpose, namely, to characterize a class of pronouns in languages from the Niger-Congo family that refer to the 'auteur d'un discours' (the 'source of a discourse', in the terms of Clements 1975). As Hagège puts it: "These pronouns distinguish the individual to which they refer from the speaker himself who uses them, in . . . 'indirect speech'" (Hagège 1974: 287, my translation). They refer to the individual cited, the secondary speaker, as opposed to the primary speaker.

Such a formally distinct series of pronouns for this type of use is found in, for instance, Mundang, Tuburi, and Ewe from the Niger-Congo family. These pronouns bear no formal resemblance to reflexives, hence Hagège considers the term 'indirect reflexive' inappropriate. It is for these, therefore, that Hagège introduces the term 'logophoric'.[7] Yet, as Hagège and Clements noted, the discourse function of such logophoric pronouns is similar to the indirect reflexive (Hagège 1974; Clements 1975).

The parallel between indirect reflexives and logophors is illustrated by the following example from Ewe (Clements 1975):

(3) Tsali gblɁ na-e be ye-e dyi yè gake yè-kpe dyi.
Tsali say to-Pron that Pron beget LOG but LOG be victor
'Tsali$_i$ told him$_j$ (i.e., his father) that he$_j$ begot him$_i$ but he$_i$ was the victor.'

Here LOG is the gloss for the logophoric pronoun *yè*.[8] Only *Tsali*, the source of the reported discourse, can be the antecedent of *yè*. As Clements notes, it is not necessary that the clause containing the logophoric pronoun be subjacent to the clause containing the antecedent. The logophoric pronoun may occur at any depth of embedding. In fact these pronouns do not require a cosentential antecedent – the antecedent can be several sentences back. The subsequent sentences of the discourse will continue to present the events described by the narrator from the point of view of the same individual or individuals (Clements 1975: 170).

The terminology of Hagège, and most of the standard typological literature with him, explicitly distinguishes indirect reflexives from logophoric pronouns. Modern syntactic literature often follows the usage of Clements (1975), which extends Hagège's. In this usage, logophoricity is what characterizes both the special forms of (3) and the non-local and/or free use of anaphors in Icelandic and Latin as in (1b) and (2) and in many other languages (varying from Chinese and Japanese, to Italian and English).

Clements gives the following cross-linguistic characterization of logophoric pronouns (Clements 1975: 171–2):

(i) logophoric pronouns are restricted to *reportive contexts* transmitting the words or thoughts of an individual or individuals other than the speaker/narrator;
(ii) the antecedent does not occur in the same reportive context as the logophoric pronoun;
(iii) the antecedent designates the individual or individuals whose words or thoughts are transmitted in the reported context in which the logophoric pronoun occurs.

Clements observes that in some languages logophoric pronouns may occur in sentences that strictly speaking do not satisfy conditions (i–iii), but that are in some sense modeled on sentences in which these conditions are satisfied. He notes that these conditions are primarily semantic/pragmatic, but does not elaborate on this.

Clements argues that there are no universal syntactic conditions on logophoric pronouns, such as a strict subjecthood condition on the antecedent. Languages do, however, impose varying idiosyncratic conditions on logophors. In Ewe, for instance, logophors are restricted to clauses introduced by the complementizer *be*.[9,10] Icelandic logophoric anaphora requires a subjunctive, in Mandarin Chinese the antecedent must be a living human being, etc.[11]

3 Long-distance anaphora

Much of the syntactic study of indirect reflexives, which will henceforth be referred to by the more neutral term *free anaphors*, has been conducted from the perspective of long-distance anaphora, and the questions they raise for the canonical Binding Theory. As noted in section 1, binding Condition A (Chomsky 1981) expresses that anaphors must be locally bound:

(4) **Condition A:**
An anaphor must be bound in its governing category.
γ is a governing category for α if and only if γ is the minimal category containing α, a governor of α, and a SUBJECT (*accessible to* α).[12]

Anaphors exceptionally allowing an antecedent beyond their SUBJECT are classified as long-distance anaphors. Icelandic logophoric anaphora forms a paradigm case.

Three types of exceptions have been distinguished:

(i) anaphors that are properly bound by an antecedent outside the governing category assigned under (4);
(ii) anaphors that are properly interpreted without a c-commanding antecedent;
(iii) anaphors that are properly interpreted without a linguistically expressed antecedent.

An influential line of research considered (i) as the canonical instance of such exceptions. Within this approach the possibility of non-local binding is captured by parameterizing the factors entering into the computation of the governing category (Manzini and Wexler 1987; see also Dalrymple 1993). Manzini and Wexler revise Condition A as in (5):

(5) **Condition A:**
An anaphor must be bound in its governing category.
γ is a governing category for α if and only if γ is the minimal category containing α, a governor of α, and F (an opacity factor).

F is taken to assume values such as (accessible) SUBJECT, Tense, Agr, or Comp. Particular anaphors may lexically differ in the value they select. Essential in this approach is that all processes interpreting anaphors are uniformly binding processes.

It has been established, however, that the nature of the relation between anaphors and their antecedents is not uniform across domains (Hellan 1988; Thráinsson 1990, 1991; Reuland and Sigurjónsdóttir 1997). Even languages allowing all three options given above do not necessarily allow them under the same conditions. Exceptions of types (ii) and (iii) are not only sensitive to syntactic factors and parameters (Everaert 1986b). They are also subject to specific non-structural conditions to be met by the discourse in which they are embedded. This is what will be focused on next (see also chapter 33).

4 Theoretical issues in logophoricity

Over the last decades logophoricity has received attention from a typological, a syntactic, and a semantic perspective. The first type of perspective is exemplified by work such as Hagège (1974), Hyman and Comrie (1981), Frajzyngier (1985), Wiesemann (1986), von Roncador (1992), Culy (1994, 1997). These works contain an array of important findings about the ways in which logophoricity is encoded cross-linguistically, some quite challenging for theory formation, for instance verbal markings of logophoricity (see, e.g., Curnow 2002). To some extent independent of the details of the typological findings, the semantics of attititudes, reports, perspective, indexicals, and self-representation has drawn the attention of linguists and philosophers. Some illustrative works are Lewis (1979), Chierchia (1989), Kaplan (1989), Reinhart (1991), and, more recently, Higginbotham (2003). In addition, there is a growing body of literature in which typological, syntactic and semantic considerations are brought together under a general perspective. Clements (1975) can be considered the first representative of this approach, followed by Sells (1987). These authors present a general perspective on both logophoric pronouns of the Niger-Congo type and logophoric anaphors. This line of research constitutes an attempt to explicitly incorporate the role of discourse factors in a general Binding Theory (formulated from the perspective of discourse representation theory; Kamp 1981b).[13]

In recent years Tancredi (1997), Safir (2003), Schlenker (2003a), Sigurðsson (2004) presented intriguing endeavors toward an integrated approach based on their contributions toward a general theory of the interpretation of indexicals with respect to the context of utterance, and the accessibility of context in the interpretation of reports. Of crucial importance was the inclusion into the debate of languages like Amharic. In Amharic one finds shifted interpretations of first person pronouns in reportive contexts. If the situation to be reported is one in which John says 'I am hero' English says '*John* says that *he* is a hero.' Amharic, however, say '*John* says that *I* am a hero', where 'I' and 'John' are the same, which is impossible in English. As discussed by Sigurðsson, this type of interpretation is not unique to Amharic, but occurs in a wider variety of languages. Such shifted interpretations of indexicals are not logophoric in the original sense, but contribute to finding the proper constraints on a theory of logophoricity. It would be impossible to bring all these strands together here. We will only be able to focus on a limited number of issues.

From a syntactic and lexical perspective, logophoric pronouns (or in general pronouns with shifted interpretation) and free anaphors pose different theoretical problems. Logophoric pronouns have specific lexical properties, which impose a certain type of interpretation. For them, the questions arise of (i) how this type of interpretation can be characterized; and (ii) why assigning this interpretation is subject to syntactic licensing in some languages, even though it is lexically expressed.

Prima facie, free anaphors have no specific lexical properties imposing a logophoric interpretation (this must be so, since they don't have this interpretation in standard reflexive contexts).

Logophoric pronouns and free anaphors with logophoric interpretation both give rise to the following question: (i) How can logophoric interpretation be characterized?

Different questions are: (ii) How can free anaphors escape the locality conditions on anaphor binding, although they are formally anaphors? (iii) Is long-distance anaphora a unified phenomenon (i.e., do all long-distance dependencies reflect the same type of process)? (iv) How can free anaphors be interpreted as logophors, although, prima facie, they have no specific lexical properties to impose a logophoric interpretation? (v) What are the principles governing the cross-linguistic variation observed?

We will first address the question of how logophoric interpretation can be characterized, keeping discussion at an informal level (for recent discussions with different degrees of formalization, see Safir 2003, Schlenker 2003a, and Sigurðsson 2004).

5 The nature of logophoric interpretation

A question that comes up is how 'special' logophoric interpretation is. The number of languages with a special paradigm of logophoric pronouns is quite

limited. The number of languages with some sort of free anaphor is considerably larger, but, nevertheles, quite a few languages lack that kind of use. So, another way to frame the question is to what extent we find the ingredients for logophoricity also in languages like Dutch, which prima facie appear to lack it. Since logophoric interpretation is held to reflect properties of the 'source of a discourse', as we saw, let's consider these more closely.[14]

Any utterance is an event that happens at some particular time and place, involving a speaker and a hearer (who may be identical).[15] In the notation of Fillmore (1971a) this can be captured by associating an utterance (of a sentence in context) with a *center*, which is a triple consisting of the *time* and the *place* of the utterance, and the *participants* (generally taken to be the speaker and hearer).

It is important to determine how properties of the interpretation of an utterance depend on the center. With the model held constant, the truth-value of a sentence like *Mirella danced the tango* can remain the same regardless of whether it was uttered on January 10, 11, or 12, 1997, and at Trans 10, Building 20, or on Harvard Square. A sentence can be provided with expressions specifying values for time and place. Some expressions, such as *January 12, 1997*, or *Room 0.19, Trans 10*, receive interpretations independent of context of utterance. The interpretation of other elements cannot be given independently of context. These are the elements we will be concerned with here.

Relative interpretation is pervasive in the deictic system, be it local or temporal. The value of *Mirella danced the tango yesterday* is affected when the utterance time is varied. The value of *Mirella danced the tango here* is affected by varying utterance place.

For the interpretation of many texts actual time and location of production play a marginal role or no role. It is sufficient that some coordinate system can be identified with respect to which interpretation of an utterance takes place. This can be the actual time and place of the utterance, it can be a different time and place related to these, or it can be some virtual coordinate system intrinsic to the text itself. This is illustrated in (6):

(6) Mary found out that John failed the test. (Enç 1987)

It is quite possible that this sentence has been uttered in some actual conversation. In that case the moment of utterance must provide the basis for an evaluation of the sentence. This entails that *utterance time* = *evaluation time*. However, if (6) is part of a novel, it must be evaluated against the background of a system that may well be completely virtual. Hence utterance time, as the time of linguistic event in the actual world giving rise to the novel, is irrelevant for the evaluation of the sentence. *Evaluation time*, therefore, must be distinguished from utterance time, although they may coincide, and no linguistic process presumably ever distinguishes the two. What is linguistically relevant is the relation between the temporal coordinate of the utterance as such, i.e., the evaluation time, and the interpretation of the matrix clause and the complement. The past tense expresses

that the moment of Mary's finding out is prior to the evaluation time, and that the moment of John's failing the test is yet earlier. This is a *shifted reading* in Enç's terms. The moments of Mary's finding out and of John's failing the test are the *event times*.[16] This leads to distinctions between *utterance time*, *evaluation time*, and *event time*.

Similar distinctions must be made with respect to the place dimension. So, taking together the place and time coordinates from Fillmore's center, the *position* of an utterance is defined as a pair containing the values for place and time in the associated coordinate system, and a distinction must be drawn among *utterance position*, *evaluation position*, and *event position*.

Thus, for a class of elements the interpretation will vary with the position of the utterance in the coordinate system, even if the interpretation domain is held constant.[17] This is what captures the specific type of context sensitivity of these elements.

As is well known, the role of person in personal pronouns cannot be captured in terms of position as defined here. Suppose that *a* saw *b* on January 12, 1997, and *a* = John, *b* = Bill, but *b* did not see *a* on January 12, 1997. On January 13, 1997, this situation verifies *John saw Bill yesterday* and falsifies *Bill saw John yesterday*. These arguments can also be expressed by personal pronouns such as *I* and *you*. Under the conditions sketched, it is possible for John to truthfully say to Bill *I saw you yesterday*. That is, under these circumstances, *I* = John and *you* = Bill. However, it is equally possible that we have a different situation, in which the speaker has been changed from John to Bill, and consequently *I* = Bill and *you* = John. So, in this situation, Bill can truthfully say to John *I didn't see you yesterday*, but, of course, not *I saw you yesterday*. So, both a sentence and its negation can be truthfully uttered in one and the same position.

This shows that *I* and *you* are indexicals whose context sensitivity cannot be captured in terms of utterance position. They reflect the participants in Fillmore's conception of the center.

An utterance is not just an event that happens at some particular time and place, it is also intrinsically associated with a speaker who utters it and, if it is observed at all, with a person who perceives it. This implies that the role of the speaker–hearer relation as part of the center is quite different from the role of the position. The speaker–hearer relation implies that utterances have directionality. Together, speaker and hearer define the *orientation* of an utterance in a world.[18]

The same caveats apply as with time and place. Just as the actual time and place of an utterance must be generalized to the notion of an evaluation position, the notions of speaker and perceiver must be generalized so as to accommodate the possibility that they are positioned within some derived or virtual reality. I will use the terms *source* and *target* for these parameters (allowing the possibility that source and target coincide), and continue to use the term *orientation* for what they contribute. *Orientation* thus reflects the same type of systematic distinctions as *position*, namely, as *utterance orientation*, *evaluation orientation*, and *event orientation*, but with a restriction, since orientation is, by its very nature,

only a property of *linguistic events*: typically events of saying, but also of dreaming, imagining, etc.

Languages do not necessarily express all these distinctions. Utterance time and evaluation time are generally not formally distinguished, nor are utterance place and evaluation place. However, a distinction between evaluation time and event time is typically linguistically reflected in some way, just like a distinction between evaluation place and event place. Just as in the case of position, utterance orientation and evaluation orientation are expected to coincide. But just as in the case of utterance time vs. event time, we will expect that the contrast between utterance orientation and event orientation does reflect a possible linguistic category.

Although many languages have no special system reflecting event orientation, logophoricity of the Niger-Congo type as described by Hagège and Clements is precisely that: a system linguistically expressing event orientation. But then, logophoricity is nothing mysterious. Relativizing the interpretation of elements with respect to some property reflecting the context of utterance is one of the recurring options among language systems. Logophoricity is nothing but realizing that option with respect to the event orientation of expressions. Logophoric pronouns are just elements lexically marked as expressing this property.

Of course, the question comes up of how rich this lexical property must be. This is one of the recurring themes in any account of pronominal properties that are not prima facie trivial. Our semantic apparatus is so rich that that it would be hard to think of a property that cannot be described.[19] Ideally, however their interpretation should in the end be governed by far more elementary properties of the syntactic structure. In fact, Safir (2003), Schlenker (2003a), and Sigurðsson (2004) all succeed in finding restrictive ways of lexically encoding the relevant properties. Thus, from a broader perspective, the availability of the type of lexical marking that is required needs no more stipulation than any kind of lexical marking does; the ingredients are there, even in languages that have no 'grammaticalized' logophoricity.

It is by no means necessary that the notions we have covered so far, including event orientation, exhaust the context sensitivity of pronoun interpretation. Let's therefore briefly discuss Sells's (1987) taxonomy of discourse factors. Sells (1987: 457) proposes that there are three basic roles in discourse, in terms of which logophoricity phenomena are to be described:

(7) SOURCE: one who is the intentional agent in a communication,
SELF: one whose mental state or attitude the content of the proposition describes,
PIVOT: one with respect to whose (space-time) location the content of the proposition is evaluated.

Below, I summarize Sells's diagnostics for each of these categories. Sells uses Japanese examples, contrasting the anaphor *zibun* with the null object (Ø). For simplicity's sake, I will be using just Sells's translations of his examples, since

the intuitions are actually quite transparent in English as well. SOURCE is illustrated by speaker-evaluative phrases, such as *that fool* in (8):

(8) Taroo heard from Takasi$_i$ that that fool Yosiko was following him$_i$ = *zibun*

Here the SOURCE = Takasi (or the external speaker) is responsible for calling Yosiko a fool. The SELF can be diagnosed by adverbs such as *mysteriously*, as in (9):

(9) Takasi$_i$ said that Yosiko was mysteriously following him$_i$ = Ø

It is the SELF = Takasi for whom the following is mysterious, unlike in (10), which carries what Sells calls a third person point of view (3POV):

(10) Takasi$_i$ doesn't mind, though Yosiko is mysteriously following him$_i$ = Ø

The *though*-clause does not reflect Takasi's point of view, hence *mysteriously* does not represent Takasi's perspective on who is following him.

The notion of PIVOT can be brought out in 3POV environments by verb selection (*come* versus *go*), as in (11):

(11) a. Takasi$_i$ was happy because Yosiko came to visit him$_i$ = *zibun*
b. *Takasi$_i$ was happy because Yosiko went to visit him$_i$ = *zibun*

According to Sells, *Takasi* is not a proper antecedent for *zibun* in (11), since he is not a PIVOT, as required.[20]

Sells argues that SOURCE, SELF, and PIVOT define a range of options for cross-linguistic variation in conditions on antecedency. It is easy to see that the role of SOURCE is covered by what I described as event-orientation. In fact, that of SELF is too. SELF pertains to psychological predicates, which also reflect linguistic events, provided that source and target are identified.

What about PIVOT? PIVOT is understood as the locus to which deictic elements must refer (Sells 1987: 465), and its role is subtle. According to Sells, speakers report that (11b) is acceptable if one imagines that Takasi was out and that Yosiko went to the place where Takasi would normally be expected to be. *Go* and *come* differ as to whether their beginning or their end coincides with the designated space-coordinates of the event representation. If an anaphor is sensitive to whether or not a potential antecedent is a PIVOT, this effectively means that its interpretation is sensitive not only to the intrinsic features of its antecedent (phi-features, etc.), but also to its location in space with respect to the event described. Given that verbs apparently reflect such a sensitivity, to find it in the nominal domain as well need not be very surprising. We may, however, conclude at this point that sensitivity to PIVOT is really something quite different from the notion of logophoricity as such (a conclusion that in fact can already be found in Sells's contribution).

6 Logophoricity and free anaphors

Free anaphors posed the following additional questions: (ii) How, having the form of reflexives, can they escape the locality conditions on anaphor binding? (iii) How, having no specific lexical properties imposing a logophoric interpretation, are they, nevertheless, so interpreted?

6.1 The binding requirement on anaphors

As stated in section 1, the canonical Binding Theory (Chomsky 1981, 1986b) stipulates that anaphors (simplex anaphors such as Icelandic *sig*, Dutch *zich*, and perhaps Latin *se*, clitic anaphors such as Italian *se/si*, French *se*, and complex anaphors such as Icelandic *sjalfan sig*, Dutch *zichzelf*) are referentially defective.[21] A commonly adopted view is that this is so because of (12) (Bouchard 1984):

(12) In order for some argument α to be interpreted it must have a full specification for phi-features.

It appears to be the case that all the simplex anaphors exemplified are underspecified in some respect. Taking that the set of phi-features can be given as [α person, β gender, γ number], we observe that, e.g., *zich* is specified for person (namely third person), but is not specified for gender, or for number. I.e., although *zich* requires a third person antecedent, it is immaterial whether the antecedent is masculine or feminine, or singular or plural. Yet, the general role of lexical and formal features is to constrain the interpretation of the elements carrying them. Therefore, (13) rather than (12) would be expected to hold (Reuland 2001):

(13) If α has fewer phi-features than β, there are fewer constraints on the interpretation of α than on the interpretation of β.

From this perspective, a general binding requirement on anaphors has no intrinsic motivation. The existence of free anaphors as in (1) (see also chapter 33) then provides reason to doubt the correctness of (12), and assume (14) instead:

(14) There is no intrinsic need for anaphors to have a syntactic binder.

Given that free anaphors have a restricted distribution, just as they have a special type of interpretation, this leads to the question in (15):

(15) What principles regulate the free interpretation of anaphors?

Reinhart and Reuland (1991, 1993), Pollard and Sag (1992) and Reuland and Sigurjónsdóttir (1997) show that the syntactic conditions on freedom/exemption

should be sharply distinguished from the semantic and discourse conditions on interpretation. Cole et al. (2001b) show the same from a different perspective (see note 11). Reuland (2001) argues that the obligation for an anaphor to be bound is due to a general economy principle. Encoding an interpretive dependency by a syntactic process takes precedence over alternative ways of interpreting the anaphor. Thus, the availability of syntactic encoding blocks interpretation of the anaphor as free. The encoding process can be agreement based (if both the antecedent and the anaphor are in an obligatory feature-checking relation with a head, such as finite inflection, this establishes a syntactic link for anaphors such as Icelandic *sig*); it can also be movement based (for instance, in the case of English SELF-anaphors, *self* covertly moves onto the verb). Free interpretation of anaphors obtains just in case the syntactic mechanism involved in establishing the link cannot apply (see Reuland 2001 for detailed discussion). The factor can be subjunctive in the case of simplex anaphors such as *sig*/*sibi* in Icelandic or Latin; it can be the structural position of the source with respect to the target in SELF-anaphors in English (coordinate structure constraint, adjunct condition); see chapter 9 for more discussion. In languages where the details of encoding differ, also the details of the blocking factor (or absence thereof) may differ, but the general pattern will be expected to be the same: If a syntactic encoding mechanism is blocked, discourse principles come into play, and the factors that are relevant for discourse based dependencies become visible.

6.2 The logophoric interpretation of free anaphors

The free use of anaphors is essentially pronominal. Just like pronominals these anaphors are potentially referring expressions (see chapter 33). Their referential use falls primarily under discourse theory.

Also in cross-sentential domains, where syntactic binding is unavailable, the choice of an expression to refer to some object in the domain of discourse is not arbitrary. Ariel (1990) extensively discusses the conditions under which one and the same object is referred to by a full NP, an epithet, or a pronoun (see also earlier relevant discussion by Givón 1983). Ariel establishes that there is an inverse relation between the descriptive content of a referring expression and what she calls the accessibility of the discourse referent. The more prominent an element is in the discourse, where prominence can, for instance, be measured in terms of textual distance, the more accessible it is in the theoretical sense Ariel develops. So, whenever the last mention of a discourse referent is sufficiently distant with respect to the mention to come, a full lexical NP or proper name will be used. If it is high on the scale of accessibility, a pronoun is preferred instead. Epithets can be used for referents of intermediate accessibility.

Since anaphors of the type discussed have even lower descriptive content (i.e., fewer phi-features) than pronouns, Ariel's theory predicts that they require discourse referents of higher accessibility than pronouns do. The correctness of this prediction has been obscured by the fact that, in many languages, anaphors may not escape syntactic binding at all, and so the remaining cases were viewed

as anomalies. The interpretation of free anaphors indicates that this prediction is, in fact, correct. In the environments in which they occur, free anaphors take discourse referents that are, indeed, high on the scale of accessibility. That is, they refer to individuals within the domain of interpretation that can be characterized as being the center of consciousness, defining view point, or as perspective holders.[22]

Although such individuals do figure prominently in the discourse, we still have to clarify why it is only these elements that serve as discourse referents for free anaphors, and why not just any forcefully foregrounded discourse entity will do.

That this is so follows from the nature of pronominals as such. We already saw that first and second person pronouns represent source and target of an utterance, respectively. That is, they first and foremost express *orientation*. Generalizing, I will claim that the property of expressing orientation is the basic, unmarked, property of third person pronominals as well. If so, a pronoun can only be used independent of orientation, for instance, deictically, if it has specific features allowing that use. Therefore, a canonical third person pronominal must have at least one feature that is not the direct counterpart of some feature in a first or second person pronoun. A feature that seems identical but is in fact different in third person pronouns from first and second person pronouns is number. As was noted by Benveniste (1966b), the plural *we* does not denote a plurality of individual *I*'s in the same way in which the plural *cats* denotes a plurality of *cat*s or the plural *they* denotes a plurality of individuals.[23] Thus, *I* and *we* are not grammatically, but inherently, singular and plural respectively. I will then advance the hypothesis that it is *grammatical number* (as opposed to the inherent number of *I* or *we*) that enables a use that is independent of orientation. Then, if number (or any other such feature) is absent, as it is in the case of *zich*, *sig*, *se*, etc., the only option for interpretation left will represent precisely that property that is basic, namely orientation. Utterance and evaluation orientation are typically expressed by first and second person pronouns. This leaves open a slot for event orientation. The option for a numberless third person pronoun is, then, to fill this slot and represent event orientation, the reported SOURCE or SELF of a linguistic event (varying from actual utterances to internal monologues, dreams, etc.).[24]

This ties in with the analysis by Koopman and Sportiche (K&S) (1989) of the pronominal system of Abe. Abe has two pronominal classes, O-pronouns and n-pronouns. O-pronouns behave essentially as English pronominals. They respect Condition B, and can be interpreted as bound variables, or referentially. N-pronouns also respect Condition B, but they cannot be bound by either an R-expression or an O-pronoun (other than under conditions indicated below), or bind one themselves. At first sight they allow a referential interpretation, but the number of indexings (taking these to reflect interpretations) available to them in a sentence is limited by the number of Comp nodes dominating them. For instance, two n-pronouns in a root clause are dominated by only one Comp node. Hence, they are obligatorily coindexed. Generalizing, in the case of n Comp

nodes dominating n + i (occurrences of) n-pronouns, i n-pronouns will have to be coindexed with another n-pronoun.

In clauses introduced by the complementizer *kO* (under reportive verbs), they are, however, coindexed with (and bound by) the NP representing the source of the report, regardless of whether this is an O-pronoun or R-expression. In this environment they exhibit the standard features of logophoricity. The basis of the analysis in K&S (1989) is the claim that n-pronouns are logical variables. In this they are deemed similar to first and second person pronouns (n-pronouns are also characterized as +human).

K&S (1989) discuss the status of logical variables in syntactic, rather than semantic terms. A semantic characterization of what it means to be a logical variable, in the sense of K&S, can be based on the idea that these elements reflect event orientation, as discussed above. This entails that they are identified with the source of the report in reportive contexts. This amounts to saying that in these contexts logophoric pronouns are obligatory *de se* pronouns (Chierchia 1989; Schlenker 2003a).[25]

The *de se* analysis alone, however, does not cover the use of n-pronouns in non-reportive contexts. K&S account for the relation between the interpretation of n-pronouns and the number of dominating CPs in non-reportive contexts by assuming that each C, being associated with an operator position, provides a possible A'-binder for the variable. One C, then, directly entails co-interpretation. This insight may be combined with the discourse based approach. Events are syntactically realized as CPs. One may assume that, in general, the orientation of an utterance is not just a pair <*source, target*>, but, in fact, a triple <*source, target, other*>, where *other* refers to *any other participant defining the event*, such as a person talked about. This person is also a participant in the utterance, and thus among the factors determining orientation. If the orientation of each event is unique, the selection of this further participant, once made, enabling it to be referred to by the n-pronoun, must be maintained for the whole CP, thus fixing its interpretation to that one choice. In a complex sentence, with embedded expressions for events (CPs), each event will introduce a possibly different *other*, yielding the dependency pattern found.

7 Conclusion

The logic of our discussion led us to a number of questions. In answer to question (i), we found that logophoric interpretation expresses event orientation. In answer to question (ii), we can say that free anaphors can escape the locality conditions on anaphor binding since there is no absolute binding requirement on anaphors. As discussed in Reuland (2001), the morphosyntactic features of the anaphor will interact with the functional structure of the clause. If movement is involved, the dependency will be subject to standard conditions on movement. The anaphor will be freed if movement is blocked. If agreement is involved, the anaphor will be freed if some factor interferes with agreement. The question (iii)

of whether long-distance anaphora is a unified phenomenon (i.e., do all long-distance dependencies reflect the same type of process?) is discussed in chapters 9, 33, and 40. The answer is negative for reasons set out there. Although free anaphors appear to have no specific lexical properties imposing a logophoric interpretation, they can nevertheless be interpreted logophorically (question (iv)). Due to their poverty of grammatical features they reflect the unmarked properties of personal pronouns, i.e., they express orientation. It is hypothesized that it is the grammatical number feature that enables fully specified pronouns to bypass expressing orientation.

Cross-linguistic variation in free anaphors is essentially due to the interaction of grammatical features with independent properties of grammatical structure. In fact the issue reduces to patterns of variation in general. If 'being logophoric' can be encoded in morphosyntactic features along the lines sketched in the literature cited, also its variation poses no particular problems beyond the issue of variation itself.

We may conclude that the logophoric use of pronouns is not anything special, but just a reflection of basic properties of the pronominal system.

NOTES

While I was finalizing this chapter I came to realize that it is not a paradigmatic instance of a 'Case', as cases were initially conceived for this project. In the area of logophoricity, the fields of typology, formal syntax, and formal semantics, including its philosophical perspective, come together, and a proper synthesis has yet to be established. Moreover, a considerable amount of the literature that is relevant for such a synthesis only appeared after this chapter had essentially been written. The main aim of this chapter is to present the Clements/Sells approach to logophoricity and put the discussion on long-distance anaphora, in particular that of free anaphors, in its perspective. I trust that the selection of further literature cited, although not exhaustive, is broad enough to point the user in the direction of current debates. I am very grateful to three anonymous reviewers whose constructive criticisms led to considerable improvement and broadening of scope. Needless to say, I am alone responsible for any omissions and mistakes.

1 Whether the definition of an R-expression must involve reference to grammatical features, rather than just lexical features, depends on the analysis of bare *wh*-elements. For instance, suppose that *wh* is a grammatical, rather than a lexical feature, as is often assumed. If so, *wh*-words such as *who* or *what* will effectively be bundles of purely grammatical features, non-distinct from the corresponding pronouns in lexical content. Yet, *wh*-elements cannot be A-bound, as in *He$_i$ was wondering whether Mary had asked Cindy whom$_{*i/j}$ Daphne had seen (whom$_{*i/j}$)*. If they are R-expressions this follows from the standard Condition C. Of course, if, as a reviewer suggests, the quantificational character of *who* or *what* is intrinsically lexical, no reference to grammatical features is needed. For current purposes we can leave this issue open.
2 Exceptions in English were noted earlier by Ross (1970b), Cantrall (1974), and Kuno (see, for a summary, Kuno 1987a).
3 See chapters 33 and 9 for further examples from Icelandic and examples from English.

4 In most of the older, but also much of the modern literature the term *reflexive* is used indiscriminately for elements that appear to require an antecedent, regardless of whether they actually reflexivize a predicate. Except for contexts where I actually discuss such literature I will be using the term *anaphor*, following the usage that has become standard since Chomsky (1981).
5 According to Hagège, the former is an 'opérateur de réflexivité' (reflexive operator); the latter refers to a particular participant that is distinguished from the others by being the author of a discourse or a thought, and is, furthermore, also distinguished from the principal speaker.
6 Languages for which this phenomenon has been described in some depth include Icelandic, English, Italian, Japanese, and Mandarin Chinese.
7 That is, 'renvoyant au discours' ('pertaining to the discourse event').
8 *Yè*'s non-high tone, represented by the grave accent, distinguishes it from the non-logophoric strong form *ye*, which bears high tone; the logophoric pronoun is also distinct from a reflexive; in Ewe these are formed by affixing a genetive form of a pronoun to the noun *d,okui* 'self', and, according to Clements, behave much like their English counterparts.
9 This may well be a reflection of the fact that logophoricity occurs in reportive contexts since the complementizer *be* is a 'grammaticalized' form of the verb *bè* 'say'. In fact, as Sells (1987) notes, there is a common tendency for the verb 'say' to develop into a complementizer.
10 Also, the logophoric forms *yè* (singular) and *yèwo* (plural) each allow both third and second person antecedents. In many languages with indirect reflexives this is impossible.
11 There are reasons to believe that the role of subjunctive in Icelandic is less idiosyncratic than Clements implies. In general it is necessary to distinguish between conditions facilitating a logophoric interpretation, and the conditions determining the interpretation that is actually obtained. For instance, Cole et al. (2001b) discuss the variation between two Chinese 'dialects' in Hong Kong, showing that the syntactic conditions under which logophoric interpretation obtains are identical, but that the discourse conditions vary. Too little is known at this point to provide a principled discussion of the licensing conditions on logophoric pronouns in general. Hence, this issue will be left open.
12 See chapter 9 for discussion.
13 See also Dalrymple (1993) and especially Huang (2000) for approaches from different perspectives.
14 Discussion will be limited to personal pronouns. An anonymous reviewer raises the question of whether there are also logophoric place or time pronouns. I have not been able to answer this question, so I will have to leave the issue open.
15 This statement would be completely trivial, were it not for the fact that where there is a significant delay between production and reception of a text occasionally significance should be attached to time and place of reception, rather than to time and place of production.
16 In this I depart from Enç's usage, who uses the term *evaluation time* throughout (distinguishing between shifted and unshifted evaluation times). See for discussion of temporal structure the extensive literature on this subject starting with Reichenbach (1947).
17 This implies that we distinguish between the model and the space-time in which it is embedded. Clearly, formally one might collapse the distinction, as is usually done.

However, some reflection on their behavior with respect to quantification shows that expressions of space-time are different from expressions for individuals. For instance, *Cindy loved every book* clearly has a different status from *Cindy loved every kilometer*. The former is acceptable in an out-of-the-blue context. The latter is not. It becomes acceptable, though, in a context such as *Cindy ran the Amsterdam Marathon. She loved every kilometer* (or . . . *every minute*). Expressions denoting dimensions in space or time must be anchored with respect to the objects they are dimensions of. (See De Jong 1987 for discussion.) Of course, there is a difference between coordinates and dimensions. But this is precisely the heart of the matter. Dimensions can be anchored to objects by virtue of the latter's space-time coordinates, but they cannot be anchored to space-time coordinates directly. To express the same fact in a different manner, objects are available for accommodation, as in *Cindy loved the book*, but dimensions are not, as in **Cindy loved the kilometer* (I think this one indeed merits an asterisk). Thus, however one turns it around, there is an asymmetry between the individuals and the coordinates in a model.

18 Which can be thought of as a vector in space-time. For present purposes an informal notion will do.

19 An interesting example is the issue of the existence of 'monsters'. Kaplan (1989) discusses the possibility that there are indexicals violating the fixity thesis:

Fixity Thesis (a corollary of Direct Reference):
The semantic value of an indexical is fixed solely by the context of the actual speech act, and cannot be affected by any logical operators.

Indexicals violating this thesis he calls 'monsters' and claims they should not and cannot exist in natural language. As shown in Schlenker (2003a) logophoric pronouns and Amharic first person pronouns are in fact such monsters. And he argues that their existence follows from a proper theory of how context is to be accommodated in the interpretation of indexicals.

20 A similar effect obtains by the possibilities of construal for *beloved* in (i) (which Sells attributes to Kuno):

(i) a. Takasi$_i$ told Taroo that his beloved Yosiko hated him$_i$ = *zibun*
b. Taroo heard from Takasi$_i$ that his beloved Yosiko hated him$_i$ = *zibun*
c. Takasi$_i$ got wet because his beloved Yosiko spilled water on him$_i$ = *zibun*

In all cases *beloved Yosiko* is interpreted relative to the PIVOT *Takasi*.

21 To my knowledge virtually all of the literature on anaphora, from Chomsky (1981) to the present (including Reinhart and Reuland 1993), takes this position.

22 See Hellan (1988).

23 See also Kayne (1995) and Reuland (2001) for discussion.

24 One word of caution about terminology. From the perspective developed, the term *third person* has become ambiguous. An element can be third person in the sense that it is marked for person, but as third, rather than first or second person, or in the sense that it is a non-person, an element outside the person system proper (see, for instance, Anagnostopoulou 2003 for discussion of this contrast). From the present perspective, then, only a numberless pronoun, such as *sig*, is properly third person. This ties in with the fact that argumental SE-anaphors (non-local *zich* in Dutch, non-local *sig* in Icelandic, also when it is not logophoric) require a *sentient* antecedent. What is

generally considered to be a canonical pronominal (*he*, *she*, *they*, etc.) is in fact a non-person and only has grammatical third person properties by default, just like R-expressions such as *the Amsterdam Marathon*, *Cindy's running shoes*, etc. This obviously has implications for the grammatical checking of person features. However, discussion of these implications would lead us too far afield.

25 An important reason to strive for a proper semantic characterization of what K&S refer to as a "logical variable" is that bound variable interpretation in its canonical sense needs to be distinguished from a pure *de se* interpretation. As argued in Higginbotham (2003), a *de se* interpreted expression will be able to mimic variable binding behavior, but the opposite does not obtain. (I would like to thank an anonymous reviewer for prompting me to clarify these issues.)

11 Conclusion: economy and long-distance reflexives

1 Introduction: long-distance reflexives and Universal Grammar

A distribution of anaphoric elements roughly like that found in English occurs in languages around the world: there are certain lexical items that occur only with antecedents which c-command them and which are located in the same local domain (roughly, clause) as the anaphoric elements. In contrast, other anaphoric elements are unable to take c-commanding antecedents within the local domain. The fact that so many genetically unrelated, areally separated, and typologically dissimilar languages have anaphoric elements that conform to the same distributional restrictions constitutes convincing support for the view that Binding is determined by principles of Universal Grammar.

While a universalist approach to Binding has a strong foundation in the typology of anaphoric forms, it is also well known that there are many languages in which some forms that can be used as local reflexives can also take antecedents outside their local domain (hereafter, long-distance reflexives). For instance in Chinese, the reflexive *ziji* in (1) can be interpreted as referring to the matrix subject, the intermediate subject, or the lowest subject:

(1) Zhangsan$_i$ renwei Lisi$_j$ zhidao Wangwu$_k$ xihuan ziji$_{i/j/k}$.
Zhangsan think Lisi know Wangwu like self
'Zhangsan thinks Lisi knows Wangwu likes self.'

Are these 'exceptions' to Binding Theory arbitrary (thereby seriously undercutting the universality of Binding Theory and leaving unexplained why so many anaphoric forms in unrelated languages show the same distribution), or do the violations of Binding Theory occur in a restricted domain, due, perhaps, to the interaction of the Binding Theory with other modules of grammar and with extra-grammatical principles governing pragmatics and discourse?

In the sections which follow, we shall examine the extent to which the distribution of long-distance reflexives is arbitrary and varies freely from language to language, and the extent to which the facts follow a similar pattern in a variety of genetically, areally, and typologically unrelated languages. Special attention will be paid to the properties of long-distance reflexives in Asian languages, especially Chinese and Malay/Indonesian. The task of determining the patterns that occur is complicated by the complex relations between syntax and discourse observed with long-distance reflexives. Thus, we devote considerable attention to the issue of which facts are syntactic in nature and which are due to discourse.

In addition to describing the cross-linguistic patterns that require explanation, we consider the adequacy of various theories of long-distance reflexives in accounting for these patterns. Our ultimate conclusion will be that long-distance reflexives are not a unitary phenomenon with a unitary analysis. However, while there is a variety of types of 'reflexives' that can take non-local antecedents, one type, which we shall call 'bound anaphor long-distance reflexives', displays the

typological properties that have been widely identified with long-distance reflexives in the literature. We shall show that, while the discourse properties associated with these forms vary considerably, the syntactic properties (in the strict sense of 'syntactic') appear to be subject to much less variation. We argue that the pattern observed can best be accounted for by one theory of bound anaphor long-distance reflexives, the theory that claims that these forms undergo covert movement to a position close to their ultimate antecedents. There remain, however, problems with the movement analysis that remain as yet unsolved.

2 Typological properties of long-distance reflexives

It has often been observed that long-distance reflexives appear to share a number of characteristics across languages (Giorgi 1984; Pica 1987; and many others):[1]

(2) **Apparent typological characteristics of long-distance reflexives:**
   a. Long-distance reflexives are monomorphemic.
   b. They take subject antecedents.
   c. Their occurrence is, in many languages, restricted to environments in which the antecedent and reflexive are found in specific domains (i.e., specific types of IPs such as infinitival or subjunctive).

Furthermore, it was noted in the Chinese literature (Y.-H. Huang 1984; Tang 1985, 1989) that long-distance reflexives are subject to a 'Blocking Effect': when the subjects of the matrix and the subordinate clauses share features for person, either NP is a possible antecedent for *ziji*. When, however, the subjects of these clauses differ in person, only the subject of the subordinate clause is a possible antecedent for *ziji*: the subordinate subject blocks the matrix subject (and any higher subject regardless of person) from anteceding *ziji*:

(3) Zhangsan_i renwei wo_j zhidao Wangwu_k xihuan $\text{ziji}_{*i/*j/k}$.
Zhangsan think I know Wangwu like self
'Zhangsan thinks I know Wangwu likes self.'

In (3) the presence of third person *Wangwu* as subject of the lowest clause blocks *ziji* from referring to either the intermediate subject *wo* or the main clause subject *Zhangsan*.[2] No similar restriction was noted in the literature on European languages with long-distance reflexives. This raised the question of how the cross-linguistic variation with respect to the existence of the Blocking Effect should be explained and of whether Blocking correlates with any property of the languages in which it occurs or of the forms that are subject to Blocking, a question to which we shall return below.

In addition to the restrictions just mentioned, which were widely interpreted as syntactic in nature, many authors noted that long-distance reflexives are frequently limited to taking antecedents which are 'prominent' in the discourse. The discourse

requirements appeared to vary from language to language, to at least some extent, but they could, in most cases, be reduced to what came to be referred to as 'logophoric' requirements, by analogy with the system of logophoric pronouns occurring in some African languages. This raised the question of how logophoricity should be related to long-distance reflexives. Are long-distance reflexives simply logophoric pronouns masquerading as reflexives, or is the relationship between logophoricity and long-distance reflexives more complex than simple equivalence?

3 The Groningen and Cornell workshops

In order to assess the current state of knowledge and to provide an impetus for further study, a workshop on long-distance anaphors was held by the Department of Linguistics of Groningen University in June of 1987. This workshop resulted in a volume that appeared in 1991 (Koster and Reuland 1991). While there was considerable diversity in the interests of the contributors to that volume, two themes preoccupied many of the authors: (i) what is the nature of the domain restriction on long-distance reflexives?; and (ii) what sorts of logophoric or other discourse conditions are necessary for long-distance anaphora? While there was some brief discussion of Asian languages in several of the chapters in the volume, with the exception of the extended discussion of Mandarin in Huang and Tang (1991), nearly all of the detailed analysis was of European languages. This, of course, reflected the fact that in the 1980s most of the research on long-distance anaphora had been on European languages (especially Italian and Scandinavian languages).

Since the appearance of the Groningen volume, there has been an explosion of interest in long-distance anaphora. A workshop similar to the Groningen one was organized by the authors of this chapter at the Cornell LSA Linguistic Institute in July of 1997, in part to assess progress over the previous ten years. The contributions to the Cornell workshop provided the basis for most of the chapters in Cole et al. (2001a). How did the results of the Cornell workshop differ from those of ten years earlier? The most obvious difference between the research conducted in the 1980s and that conducted in the 1990s is that the focus of the later research is on the anaphoric systems of languages that had received little or no attention in the literature ten years earlier. While research has continued on European languages, a large body of work on Asian languages, especially Chinese, has appeared. Not surprisingly, the properties of long-distance reflexives found in such a wide variety of languages are considerably more diverse than those that were the focus of research in the 1980s, but, despite the diversity, the major themes of the earlier research are prominent in current research as well.

4 Pronoun or bound anaphor?

A fundamental and recurring topic is whether the 'long-distance reflexives' in the language under study have the distribution of pronouns or of bound anaphors.

Early studies like Giorgi (1984) claimed that they have the properties of bound anaphors. As it turns out, the question is in fact a difficult one. The study of the typological characteristics of long-distance reflexives has been frustrating because every proposed characterization of the construction appears to have many counter-examples. If, however, 'long-distance reflexives' are not a single type of morphosyntactic entity, it would not be expected that all long-distance reflexives would have the same properties or the same analysis across languages. In fact, an examination of current research suggests that long-distance reflexives are several distinct sorts of entities, which differ with regard to whether they have the distribution of bound anaphors or of pronouns.[3] If this is correct, it is not surprising that they differ in both syntactic and discourse properties: bound anaphors are generally assumed to require (or strongly favor) a binding relationship with their antecedents, thereby explaining why they require c-commanding antecedents, do not allow extra-sentential antecedents, and require (or strongly favor) sloppy readings in VP ellipsis. In contrast, pronouns are assumed to enter into both binding and coreference relations. Thus, c-command is not required, extra-sentential antecedents are possible, and both strict and sloppy readings are easily available under VP ellipsis.

It may be useful to illustrate the range of variation: inflected reflexives in Turkish (Kornfilt 1997, 2001) provide an example of a form that can be used as a reflexive within the local domain, but which has the distribution of a pronominal when used beyond that domain. Another such example is Malay (Cole and Hermon 1998a, 1998c; Cole et al. 2001b). In these languages apparent long-distance reflexives show none of the characteristics of bound anaphors: outside of the local domain the antecedent does not need to c-command the 'reflexive', extra-sentential antecedents are possible, and strict readings are easy to come by under VP ellipsis. This is illustrated from Malay:

(4) Ahmad$_i$ tahu Salmah$_j$ akan membeli baju untuk dirinya$_{i/j/k}$.
Ahmad know Salmah will buy clothes for self.3sg
'Ahmad knows Salmah will buy clothes for him/herself.'

(5) a. [$_{NP}$ Bapa Siti$_j$]$_i$ tidak suka dirinya$_{i/j/k}$.
father Siti not like self.3sg
'Siti's father does not like her/himself/him.'
b. [$_{NP}$ Ibu Ali$_j$]$_i$ telah mengenalkan dirinya$_{i/j/k}$.
mother Ali already introduce self.3sg
'Ali's mother has introduced him/herself/her to my friends.'

In (4) *dirinya* can be interpreted either as a local reflexive, as referring to the matrix subject, or as referring to some third individual in the discourse. The examples of (5) show that a c-commanding or non-c-commanding antecedent, or an extra-sentential, discourse antecedent are all possible.

Turning to VP ellipsis, we see that *dirinya* allows both strict and sloppy readings, even in local contexts, as is expected with a pronoun:

(6) John nampak dirinya di dalam cermin; Frank pun.
John see self.3sg at inside mirror Frank also
'John saw himself/him in the mirror and Frank did too.' (= 'Frank saw Frank in the mirror' or 'Frank saw John in the mirror')

(7) Ali cukur dirinya di dalam bilik air; Bill pun.
Ali shave self.3sg at inside bathroom Bill also
'Ali shaved himself/him in the bathroom. Bill did so too.' (= 'Bill shaved Bill' or 'Bill shaved Ali')

To conclude, the relationship between the seeming long-distance reflexive and its antecedent in Malay would appear to be either coreference or Binding, as is the case for personal pronouns.[4]

In contrast, in Kannada long-distance reflexives require c-commanding antecedents, cannot take extra-sentential antecedents, and require sloppy readings under VP ellipsis (Amritavalli 2000; Lidz 2001). Similar facts are found in Hindi-Urdu (Davison 2000, 2001). Example (8) illustrates the VP ellipsis facts in Hindi-Urdu (Davison 2000):

(8) Guatam$_i$ [apnee (aap$_i$)-koo caalaak] samajhtaa hai, aur
Guatam self's self-dat smart consider-Impf is and
Vikram$_j$ bhii$\emptyset$.
Vikram also
'Guatam considers himself smart, and so does Vikram.' (= 'Vikram considers Vikram smart'; ≠ 'Vikram considers Guatam smart')

In these languages long-distance reflexives have the properties associated with bound anaphors, and, like other bound anaphors, appear to require a binding relationship with antecedents.

The situation is more complex in Icelandic (Reuland 2001; and see chapter 33). In Icelandic the reflexive form *sig* can occur with long-distance antecedents in both infinitival and subjunctive clauses. However, *sig* has different properties in each environment: when *sig* and its antecedent are found within an infinitival clause, *sig* behaves like a bound anaphor, but when the domain is a subjunctive clause, it behaves like a pronominal. Thus, in some environments *sig* must be related to its antecedent by Binding while in other environments a relationship of coreference is possible. Finally, in Chinese (both Mandarin and Teochew) the simplex reflexive (*ziji* in Mandarin, *kaki* in Teochew) normally shows the distribution of a bound anaphor: The antecedent must c-command (or subcommand) the reflexive, and VP ellipsis yields only (or predominantly) sloppy readings, as in Hindi-Urdu (Cole et al. 2001b; Huang and Liu 2001; as well as earlier works by many authors). However, in limited discourse contexts *ziji* can take extra-sentential discourse antecedents, as is illustrated in (9), taken from Pollard and Xue (2001):[5]

(9) Zhangsan$_i$ zhidao neijian shi yihou hen qifen; Lisi$_j$ shuo neixie hua
Zhangsan know that-CL thing after very angry Lisi say those word
mingming shi zai he ziji$_{i/j}$ zuodui.
obviously is being with self against
'Zhangsan$_i$ was very angry when he learned that. By saying those words Lisij was obviously acting against himself$_j$/him$_i$.'

The Icelandic and Mandarin facts suggest that the same reflexive form can be a bound anaphor in one grammatical and discourse context and a 'free anaphor' with pronominal properties in another.

To summarize, there appear to be *at least* the following types of 'long-distance reflexives':

- long distance bound anaphors, which show the distribution of bound variables (illustrated by Chechen/Ingush, Chinese, Hindi-Urdu, Kannada);
- forms which are used as reflexives locally and as pronominals non-locally (illustrated by Turkish and Malay);
- forms that are 'primarily' bound anaphor reflexives, but which can be used non-locally in specific syntactic and discourse contexts (Chinese 'free anaphors', Icelandic subjunctives, and long-distance uses of English reflexives: Zribi-Hertz 1989).

If 'long-distance reflexives' do in fact display the diversity just claimed, several conclusions follow:

(i) The distribution and properties of each type of 'long-distance reflexive' (anaphor, pronominal, mixed) need to be investigated separately.
(ii) The factual contradictions both in and across languages may be resolved by distinguishing properly the various types of 'long-distance reflexives'.
(iii) A major problem in understanding the phenomenon of long-distance anaphora is the determination of the grammatical and discourse conditions that license each type of long-distance anaphor. The successful solution to this problem may provide the basis for the development of a theory or theories of long-distance anaphora with sufficient power to predict the properties of a reflexive from its grammatical and discourse context. We shall return in section 11 to a consideration of what might constitute the basis for such a theory.

5 The role of discourse

5.1 Variation among languages and dialects with bound anaphor long-distance reflexives

A second theme in current research is the attempt to characterize the role of discourse/pragmatics vs. syntax in the licensing of long-distance reflexives.

While many aspects of the problem remain unclear, many new facts about the relationship of discourse factors and long-distance reflexives have become known. First of all, the role of discourse varies considerably from language to language, and from form to form within some languages. Nichols (2001) shows that Chechen and Ingush exhibit bound anaphor-type long-distance reflexives. In these languages, however, there is no requirement that the antecedent satisfy logophoric or other discourse conditions.

In many other languages, discourse adds restrictions over and above those of the grammar. For instance, Amritavalli (2000) notes that in Kannada (which also exhibits bound anaphor long-distance reflexives) the antecedent for the reflexive *tannu* must be aware of the state or event described, leading to a preference for the pronoun *avannu* over the long-distance reflexive *tannannu* in sentences like (10) (Amritavalli's 119):

(10) a. ?Sitte$_{i\rightarrow j}$ tannannui$_{i/*j/*k}$ kaaNalu bandaaga raaju sattu hoogidda.
Sita self-acc he-acc to see came then Raju was dead
'?Raju$_i$ was dead when Sita$_j$ came to see self$_{i/*l/*k}$.'

b. Sitte$_{i\rightarrow j}$ avanannu$_i$ kaaNalu bandaaga raaju sattu hoogidda.
Sita self-acc he-acc to see came then Raju was dead
'Raju$_i$ was dead when Sita$_j$ came to see him$_i$.'

Even within the same language, different dialects and varieties may vary with regard to the discourse properties of long-distance reflexives. For example, Cole et al. (2001b) show that there is considerable variation in the discourse conditions on long-distance reflexives in the Chinese dialects of Singapore. In these dialects (in most contexts), the reflexive has the distribution of a bound anaphor, but the logophoric conditions on Singapore Teochew are much stricter than those on Singapore Mandarin: in Teochew, the antecedent of a long-distance reflexive must be aware that he, himself, is carrying out the action described (a *de se* requirement), while in Singapore Mandarin, self-awareness on the part of the antecedent is not required. However, weaker 'PIVOT' conditions (Sells 1987) hold in both Singapore Mandarin and Singapore Teochew. In a paper on Mandarin as it is spoken in Taiwan, Huang and Liu (2000) claim that a *de se* requirement constrains the relationship between matrix subject antecedents and object *ziji* in complement clauses. In contrast, Pollard and Xue (2001: 326) claim that such examples (illustrated by (11)) are not subject to logophoric requirements:[6]

(11) Zhangsan$_i$ zhidao Lisi$_j$ renwei Wangwu$_k$ zui xihuan ziji$_{i/j/k}$.
Zhangsan know Lisi think Wangwu most like self
'Zhangsan$_i$ knows that Lisi$_j$ thinks that Wangwu likes himself/him$_{i/j}$ most.'

Pollard and Xue claim explicitly with respect to (11) that "the key fact about such cases is that any commanding subject qualifies as the antecedent for *ziji on the strength of its syntactic prominence alone*" (emphasis ours). We take such apparent factual contradictions among authors writing about Chinese as indicative of the

fact that the discourse conditions vary in subtle ways from dialect to dialect, and from speaker to speaker within a single dialect. It would appear that the extent of the variation has not been recognized adequately in the literature.

5.2 Absence of logophoric conditions on pronominal long-distance reflexives

A second fact about discourse that emerges from recent work on Chinese is that, while logophoric conditions may (but need not) restrict bound anaphor-type long-distance reflexives, they do not affect pronominal long-distance reflexives. Thus, in Malay 'long-distance' *dirinya* does not require any special perspective or self-awareness (Cole and Hermon 1998a, 1998c; Cole et al. 2001b). Rather, it has the same discourse properties as a personal pronoun. We believe that a similar lack of logophoric restrictions occurs for long distance inflected reflexives in Turkish (as shown by Kornfilt 1997, 2001) as well as for Middle English and Old English pronouns (Keenan 1976a, 2000), which, as discussed in note 4, can also be used for local coreference). Thus, forms that are indeterminate between pronouns and reflexives do not seem to be subject to logophoric conditions.

5.3 Logophoric 'conversion' of reflexives to pronominals

In contrast to the situation in Malay and Turkish, as well as to that in Chechen/Ingush, Hindi-Urdu, Kannada, etc., in languages like English, and in Icelandic subjunctives, a form which in most environments is exclusively a bound anaphor is given special license by a combination of syntax and discourse to function as a pronominal. As was shown by Reinhart and Reuland (1993 and earlier works) and by Zribi-Hertz (1989), this occurs mostly when a reflexive occurs in a non-argument position (though the syntactic conditions vary greatly from language to language) and when the antecedent satisfies logophoric conditions:[7]

(12) a. Philip$_i$ was supposed to be fooling (. . .), because Desiree (. . .) had undoubtedly explained to them the precise nature of her relationship with himself$_i$. (Zribi-Hertz 1989: (43b))
b. But Rupert$_i$ was not unduly worried about Peter's opinion of himself$_i$. (Zribi-Hertz 1989: (46b))

In the examples in (12) the reflexive occurs in a position in which it is not an argument of the verb. From a discourse perspective, the sentences present the situation as pictured in the mind of the antecedent for the reflexive: the use of the reflexive indicates to the reader that the scenes are being viewed from Philip and Rupert's perspective.

Note that in the case of sentences like (12b) VP ellipsis allows either a strict or a sloppy interpretation:[8]

(13) Rupert$_i$ was not unduly worried about Peter's opinion of himself$_i$; nor was Fred$_j$.

The elliptical clause of (13) can be understood to mean either (14) or (15):

(14) Nor was Fred unduly worried about Peter's opinion of Rupert. (strict reading)

(15) Nor was Fred unduly worried about Peter's opinion of Fred. (sloppy reading)

The fact that both strict and sloppy interpretations are easily available shows that in English, as in Icelandic, the reflexive form has taken on the referential properties of a pronoun.

Although the reflexives show the distribution of a pronoun in both Malay and English, the use of reflexives differs in an important way. In English and in Icelandic subjunctives, as discussed by Reuland (2001), a reflexive can only be used as a pronominal in the specific licensing environments just described, while in Malay, Turkish, etc., no special licensing conditions are necessary. This suggests that the Malay/Turkish and the English/Icelandic cases should not be conflated, and that the English/Icelandic type of long-distance reflexive might usefully be viewed as a reflexive that is 'converted' to a pronominal under special syntactic and discourse circumstances,[9] while the Malay/Turkish cases are inherently pronominal (or are indeterminate between an anaphor and a pronominal). (We will discuss and extend Reuland's analysis of the Icelandic facts further in section 11.)

6 Logophoric pronouns and logophoric restrictions on long-distance reflexives

We have seen that the various types of long-distance reflexives (bound anaphor, pronominal and 'de-anaphoric' pronominal reflexives) differ with regard to whether special discourse conditions apply to their use: bound anaphors may be subject to 'logophoric' discourse requirements, but need not be; pronominal (or indeterminate) forms are not subject to these requirements; and 'converted' reflexives are (we hypothesize) always subject to such requirements. We would like to turn to an examination of whether the logophoric requirements on long-distance reflexives are the same as those on logophoric pronouns.

The term 'logophoric pronoun' was coined by Hagège (1974) to describe a special subgroup of personal pronouns used in reported speech in some African languages to refer to the individual whose speech is reported or to the addressee of that speech. For example, in Mupun, as described by Frajzyngier (1993), there are three sets of personal pronouns as well as a set of reflexive anaphors:[10]

(16) **Personal pronouns in Mupun:**

	Set A		Set B		Set C
	Subj.	Obj.	Subj.	Obj.	Subj.
3m.sg	wu	wur	ɗi	ɗin	gwar
3f.sg	wa	war	ɗe	ɗè	paa
3pl	mo		ɗu	ɗun	nuwa

(17) **Reflexives in Mupun:**

	Singular	Plural
1p	sen	sun
2m	sak	suk
2f	sik	
3m	sin	sut
3f	set	

In complements of the verb *sát* 'say', pronouns of set A indicate disjoint reference with the subject of the matrix clause:

(18) wu/wa/mo sát nə wu/wa/mo ta ɗee n-jos.
he/she/they say COMP he/she/they stop stay PREP-Jos
'He$_i$/she$_i$/they$_i$ said that he$_j$/she$_j$/they$_j$ stopped over in Jos.'

In contrast, the set B pronouns are used in indirect speech to indicate coreference with the matrix subject:

(19) wu sát nə ɗi n nas an.
3m say COMP 3m FUT beat 1sg
'He$_i$ said he$_i$ will beat me.'

Set C is used to indicate that the pronoun refers to the addressee of the matrix clause. If the reference is to other persons, the pronoun must be drawn from set A:

(20) a. n-sát n-wur nə wur ji.
1sg-say PREP-3sg COMP 3sg come
'I told him$_i$ that he$_j$ should come.'
b. n-sát n-wur nə gwar ji.
1sg-say PREP-3sg COMP 3sg come
'I told him$_i$ that he$_i$ should come.'

The logophoric pronouns are used to indicate coreferentiality or disjoint reference with the subject or addressee of superordinate verbs of speaking. Whenever coreference is within the same clause a reflexive pronoun is employed:

(21) n-seet nləər n-sen.
1sg-buy shirt PREP-REFL:1sg
'I bought a shirt for myself.'

(22) mu-sarep nləər-mo n-sun.
1pl-buy-pl shirt-pl PREP-REFL:1sg
'We bought shirts for ourselves.'

(23) wu cet mbise n-sin.
3m cook food PREP-REFL:3m
'He cooked for himself.'

To summarize, in a 'classic' logophoric system like that described by Frajzyngier for Mupun, logophoricity is a property of pronouns rather than of bound anaphors, and is licensed by whether the matrix verb is a verb of saying: in Mupun, verbs of thinking like *pan* 'think, remember' do not permit set B and C (logophoric) pronouns, but rather require pronouns from set A (non-logophoric):

(24) wu ben nə wu pan an.
3m think COMP 3m remember 1sg
'He thinks he remembers me.'

According to Frajzyngier (1993: chapter 20), set A pronouns are required in (24), and can be used to indicate either coreference or disjoint reference. This is unlike the case when the matrix verb is a verb of saying. In that case, the use of a set A pronoun indicates disjoint reference:

(25) wu sát nəə wu nas an.
3m say COMP 3m beat 1sg
'He_i said that he_j beat me.'

According to Frajzyngier, the same pattern obtains with set C pronouns, but examples showing the distinction between verbs of saying and verbs of mental activity like 'think' are not provided in the grammar.[11]

Logophoric conditions on long-distance reflexives differ in a number of ways from classic logophoric pronominal systems like that illustrated by Mupun. First, as was shown above, the elements in question belong to different grammatical classes. Pronominal long-distance reflexives (like those in Malay and Turkish) are *not* subject to logophoric requirements. Thus, it cannot be true that when reflexive forms have 'pronominal' usage, they become logophoric pronouns. The logophoric requirements appear to be optionally present for bound anaphor long-distance reflexives and obligatorily present for reflexives which have undergone 'conversion' to pronominals, as in the case of Icelandic subjunctives and English long-distance reflexives. Second, the discourse restrictions on reflexives are different from those on true logophoric pronouns. The choice of logophoric pronouns is determined by whether the higher verb is a verb of saying and whether the antecedent is the subject of that verb or the addressee. In contrast, long-distance reflexives are typically well-formed when the higher predicate is one of saying or of thinking. While a special set of pronouns (set C) exists in

Mupun to indicate coreference with the addressee, no such possibility exists in the case of long-distance reflexives: long-distance reflexives never indicate coreference with the addressee. These facts suggest that the analogy between long-distance reflexives and logophoric pronouns collapses when the two are compared in a fine-grained fashion, and the origin of the discourse conditions on long-distance reflexives is distinct from that of logophoric pronouns. Furthermore, there will be separate sources for the 'logophoricity' of bound variable and 'conversion' long-distance reflexives. These questions are explored in section 11. To conclude this section, while the term 'logophoricity' appears to be too well established to banish it from discussions of long-distance reflexives, it is important to recognize that there is strong evidence against the hypothesis that long-distance reflexives are covert logophoric pronouns. Furthermore, the system of logophoricity found with 'classic' logophoric pronouns is quite different from that found with long-distance reflexives of various types.[12]

7 Logophoricity and attitudes *de se*

We would like to turn now to the question of whether there appears to be any unified use of the concept of logophoricity with respect to one type of long-distance reflexives: those that are interpreted as bound variables. Sells (1987) claims expressly that the term 'logophoricity' has been used for three different though related concepts. Sells's SOURCE is similar to the use of 'logophor' in the literature on logophoric pronouns. The SOURCE is the source of speech, e.g., the subject of a higher verb of saying. Sells's second type of logophoricity, SELF, is the individual whose mental state the sentence describes (subject of verbs of thinking), and PIVOT is the center of deixis or perspective for the sentence (the reference point for indexicals). What these notions share is that they refer to the individual whose point of view or general state of consciousness is expressed by the sentence. According to Sells, languages differ with regard to which type of logophoricity licenses long-distance reflexives, though there are claimed to be implicational relations among different types of logophoricity.

In the spirit of Sells (1987), Huang and Liu (2000) attempt a unified treatment of these types of logophoricity in the domain of long-distance reflexives by proposing that the core meaning of logophoricity is SOURCE. This can be extended in some languages to also include SELF and in other languages to PIVOT as well:

(26) SOURCE $\subseteq$ SELF $\subseteq$ PIVOT

Thus, in some languages only SOURCE will license the use of a long-distance reflexive (e.g., with verbs of saying); in others both SOURCE and SELF will license long-distance reflexives (with verbs of saying or verbs of thinking); in yet others PIVOT, in addition to SOURCE and SELF, may also license long-distance reflexives (e.g., with the aid of deictic expressions like 'come', 'go', 'here', 'there', etc.).

According to Huang and Liu, the logophoricity condition (being a SOURCE, SELF, or PIVOT as required in a given language) is a necessary but not a sufficient condition for the antecedent of a long-distance reflexive. Thus, as noted by Pollard and Xue (2001), there are instances of SOURCE that do not license long distance *ziji* in Chinese:

(27) Zhangsan$_i$ cong Lisi$_j$ chu tingshuo Wangwu$_k$ bu xihuan ziji$_{i/*j/k}$.
Zhangsan from Lisi place hear Wangwu not like self
'Zhangsan$_i$ heard from Lisi$_j$ that Wangwu$_k$ does not like him$_{i/*j}$/himself$_k$.'

In (27) *Lisi* is the SOURCE of communication, but this is not sufficient to permit the use of long-distance *ziji*. According to Huang and Liu, the relation of a long-distance reflexive to its antecedent is mediated through a structure of predication which normally requires the reflexive to be c-commanded by the antecedent. In (27) the SOURCE Lisi does not license the long-distance *ziji* because it does not stand in a predication relation with a suitable predicate that includes the reflexive.

The range of cross-linguistic variations allowed for under (26) is illustrated by the two Chinese dialects presented in Cole et al. (2001b). Cole et al. show that whereas in the Teochew dialect spoken in Singapore, the long-distance *ziji* requires its antecedent to be SOURCE or SELF, in the Mandarin spoken in the same city, PIVOT alone may license long-distance reflexives.

Huang and Liu try to unify the various types of logophoricity by taking them to represent a progressive liberation of the notion of 'core logophoricity' – SELF being an extended (or 'virtual') SOURCE, and PIVOT being an extended (or 'virtual') SELF. This view they share, in part, with Cole et al. (2001b), and with Pan (2001). All these authors explore the possibility that SOURCE and SELF (and for Huang and Liu, also PIVOT) can be reduced to the notion of *de se*. Developing an idea suggested by Chierchia (1989) for Italian, Huang and Liu note that the restriction on *ziji* in the variety of Mandarin they report on is not merely that the antecedent for *ziji* must be the SOURCE of communication, or the individual whose mind the sentence describes (SELF), but, rather, that there is a stronger requirement: the individual in question must be aware that the sentence is a description of an event in which he himself or she herself is a protagonist (a *de se* restriction), or more precisely, that the individual actually ascribes, or is disposed to ascribe, to himself or herself the property denoted by the predicate containing the reflexive. Following Chierchia, the *de se* restriction is taken to be applicable to long-distance reflexives generally. For instance, Chierchia examines the distinction between long-distance reflexives and pronouns in Italian, and notes that sentence (28) is a contradiction, while (29) is not:

(28) Pavarotti crede che i **propri** pantaloni siano in fiamme. Ma non
Pavarotti believes that the self pants are in flame but not
si e' accorto che i pantaloni sono i propri.
realize that the pants are the own
'Pavarotti believes that self's pants are on fire, but he hasn't realized that the pants are his own.'

(29) Pavarotti crede che i **suoi** pantaloni siano in fiamme. Ma non
Pavarotti believes that the his pants are in flame but not
si e' accorto che i pantaloni sono i propri.
realize that the pants are the own
'Pavarotti believes that self's pants are on fire, but he hasn't realized that the pants are his own.'

The contradictoriness of (28) disappears when the personal pronoun *suoi* is substituted for *proprio*. That is, the use of the long-distance reflexive *proprio* requires that Pavarotti realize that it is his own pants that are on fire. No such requirement holds for the personal pronoun *suoi*: in (29) Pavarotti must realize of a certain individual that the individual's pants are on fire. It is not necessary, however, that Pavarotti identify that individual with himself. A *de se* restriction similar to (28) applies in Mandarin, as discussed by Huang and Liu (2000) and by Pan (2001), as well as in Teochew, discussed by Cole et al. (2001b).

The existence of a *de se* restriction in Italian and in certain Chinese dialects suggests that neither SOURCE nor SELF adequately characterizes the discourse requirement in these languages. Rather, an apparent SOURCE/SELF discourse restriction may in fact be an artifact of a stronger *de se* requirement. While languages differ with respect to whether bound anaphor long-distance reflexives are subject to a *de se* restriction, the presence of such a restriction may explain instances of apparent SOURCE/SELF restrictions in languages in which they occur. We shall return to the origin of *de se* below.

8 The dividing line between local and long-distance reflexives

We will turn now to a new topic, one which figures in much current research on reflexives. It is taken as given in discussions of long-distance reflexives that there is a well-defined notion of what constitutes a local reflexive and what anaphoric relations are nonlocal. There are in fact two widely held notions of locality in the generative literature on reflexives. The traditional Binding Theory (Chomsky 1981 and subsequent works) treats the local domain ('governing category') as, roughly, consisting of the clause plus the subject of a non-finite complement clause. In a departure from the Chomskyan approach, Reinhart and Reuland (1993 and earlier work) have argued that the core use of reflexives is to mark co-argumenthood, not intra-clausal coreference.[13] Thus, the expected division would be between anaphors used to mark co-argumenthood and other anaphors, rather than between clause-internal (or governing-category-internal) and clause-external (or governing-category-external) anaphora. Reinhart and Reuland's proposal is provided immediate support by the fact that many Germanic languages distinguish between different anaphoric forms along the lines predicted by Reinhart and Reuland's theory. For example, in Dutch *zichzelf* 'himself' is restricted to co-argument positions:[14]

(30) Max haat zichzelf.
Max hates self-self
'Max hates himself.'

(31) *Max haat zich.
Max hates self
'Max hates himself.'

(32) Max hoorde mij over zich praten.
Max heard me about self talk
'Max heard me talk about him.'

(33) *Max hoorde mij over zichzelf praten.
Max heard me about self talk
'Max heard me talk about him.'

(34) Jan_i zag Piet_j de spullen naast zich_i/*zichzelf_i neerlegen.
Jan saw Piet the gear next.to self self-self
'Jan saw Piet put the gear next to him.'

Examples (30–34) show that the 'true reflexive' *zichzelf* 'himself' is restricted to co-arguments, while the 'pronominal reflexive' *zich* is permitted for both intra-clausal non-co-argument reflexives and long-distance reflexives. Similar facts occur outside Germanic as well. See Lidz (1996, 2001).

While the pattern just illustrated appears to provide prima facie support for Reinhart and Reuland's division of anaphora into co-argument and non-co-argument anaphora, there are purported to be arguments against the definition of locality in terms of co-argumenthood. First, Lidz (2001) argues from Kannada examples much like (30–34) that the distinction between *zich*- and *zichzelf*-type anaphors is not a distinction between co-argument and non-co-argument anaphora. Rather, the two types of anaphors differ in meaning. The apparent anti-locality of the *zich*-type anaphor is due to a distinction between 'pure reflexivity' (*zich*-type) and 'near reflexivity' (*zichzelf*-type). Lidz argues that pure reflexives are compatible only with inherently reflexive predicates or with predicates that have been marked as reflexive by a verbal reflexive marker (as in Kannada). Thus, *zich*-type reflexives are predicted to occur only with reflexive predicates like 'shave' or in cases of non-co-arguments, for which the distinction between pure reflexivity and near reflexivity is not relevant. Lidz argues that this semantic distinction removes an apparently strong empirical support for the division between co-argument and non-co-argument anaphora. In evaluating the force of Lidz's arguments, it is not clear that the facts he adduces are not tangential to the issue of the nature of locality. In any case, Lidz provides additional evidence that the distinction between *zich*-type and *zichzelf*-type anaphors is not devoid of semantic content.

The question of whether the dividing line between local and non-local should be the governing category or the co-argument/non-co-argument distinction is considered by Hestvik and Philip (2001), who present evidence from Norwegian child language that binding of non-co-arguments within the simple clause (locative PPs and possessive reflexives) constitutes an instance of 'core Binding', while Binding into picture NPs is an instance of 'logophoric' Binding. Thus, on the assumption that 'core Binding' is equivalent to the local domain, from the

perspective of child language the local domain appears to include non-co-arguments within the simple clause. A similar point is made by Huang and Liu (2001), who show that 'local' reflexives in Mandarin are not subject to any logophoric restrictions (neither *de se* requirements nor PIVOT-related restrictions like the Blocking Effect). What counts as 'local' for this purpose includes not only non-co-arguments like locatives and benefactives, but also reflexives with subcommanding (Tang 1989) rather than c-commanding antecedents in the same clause: in both Mandarin and other Chinese dialects, when the head of a noun phrase is inanimate (and, hence, in Chinese, not a potential antecedent for a reflexive), the specifier of that noun phrase can serve as antecedent for the reflexive:

(35) Zhangsan$_i$ de jiaoao hai-le ziji$_i$.
Zhangsan's DE arrogance hurt-ASP self
Zhangsan$_i$'s arrogance harmed him$_i$.

In (35) the non-co-argument *Zhangsan* is the antecedent for *ziji*. There is, however, persuasive evidence that *ziji* does not need to meet any logophoric restrictions: in (35) the antecedent is neither SOURCE nor SELF. Furthermore, the Blocking Effect is not exhibited:

(36) Zhangsan$_i$ de biaoqing gaosu wo$_j$ ziji$_{i/*j}$ shi wugude.
Zhangsan DE expression tell me self is innocent
'Zhangsan's expression tells me that he is innocent.'

Thus, the absence of logophoric effects provides strong reason to believe that the relationship between *ziji* and its antecedent is local – despite the fact that *Zhangsan* is not an argument of the same predicate as *ziji*.

We conclude that there are persuasive arguments that there is a division between local and long-distance reflexives along the lines of the locality domain as defined in Chomsky (1981) and related work: the traditional notion of 'governing category'. We would emphasize, however, that evidence for the need for the notion 'governing category' does not in itself provide evidence against the relevance of co-argumenthood for explaining the distribution of *zich-* and *zichzelf*-type reflexives, as proposed by Reinhart and Reuland (1993). Thus, the evidence discussed in this section does not constitute a general argument against the use of co-argumenthood to define one type of locality. It does, however, appear to show that co-argumenthood does not constitute a replacement for the notion of the governing category.

9 A more detailed look at the typological properties of long-distance reflexives

We would like to turn now to a review of the status of the typological properties traditionally associated with long-distance reflexives: monomorphemicity, c-command/subject orientation, and the Blocking Effect.

9.1 Monomorphemicity

It was noted early in the literature that long-distance reflexives are typically monomorphemic while local reflexives tend to consist of more than one morpheme (Giorgi 1984; Pica 1987):

(37) Credo [che Mario$_i$ sostenga che tu abbia parlato di se$_i$ e della
I-believe that Mario claims that you have spoken of self and of-the
sua famiglia in TV]]
his family on TV
'I believe that Mario claims that you spoke about him and his family on TV.' (Giorgi 1984)

(38) Gianni$_i$ pensava [che quella casa appartenesse ancora a se stesso$_i$].
Gianni thought that that house belong still to self self
'Gianni thought that that house still belonged to him.' (Giorgi 1984)

In (37), from Italian, the monomorphemic reflexive *se* takes a long-distance antecedent, while in (38) the bimorphemic *se stesso* is ill-formed with a long-distance antecedent. Similar facts continue to be discovered as new languages are examined. For instance, Davison (2000) summarizes the facts of Hindi-Urdu as follows: "If the simple reflexive [*apnee*] is contained within a nonfinite embedded clause, it may be coindexed with subject antecedents in higher clauses or with the local subject . . . In a nonfinite clause, the complex reflexive *apnee aap* and the reciprocal have only a local c-commanding subject antecedent."

There is, however, a variety of counter-examples to the claim that only simplex reflexives can have long distance interpretations. For instance, the Malay reflexive *dirinya* consists of two morphemes, *diri-* and a third person marker *-nya*. Yet, as was seen above, long-distance interpretations are possible. Similarly, the inflected reflexives *kendisi/kendileri* in Turkish (Kornfilt 1997, 2001) are clearly bimorphemic, consisting of *kendi* 'self' plus *-si* 'third person singular" or *-leri* 'third person plural'. Furthermore, long-distance uses of English reflexives are clearly bimorphemic.

We do not, however, interpret such examples as counter-examples to the generalization regarding the monomorphemicity of long-distance reflexives. Rather, we take examples of this type to show that the generalization that long-distance reflexives are monomorphemic applies only to those long-distance reflexives that are bound anaphors, and not to those that are pronominals. To the best of our knowledge, all bound anaphor long-distance reflexives are monomorphemic.[15]

It does not, however, appear to be true that all monomorphemic reflexives are long distance. For example, the German reflexive *sich* consists of a single morpheme like the Icelandic reflexive *sig* or the Italian reflexive *se*. While these forms are all restricted to third person antecedents, there does not appear to be a division into two morphemes, one meaning 'self' and the other 'him', as is the case for English *himself* or Malay *dirinya*. However, German *sich* is local, while Icelandic

sig and Italian *se* take long-distance antecedents. Thus, monomorphemicity appears to be a necessary but not a sufficient condition for bound anaphor long-distance reflexives.

9.2 C-command and subject orientation

We saw earlier that a c-command requirement and subject orientation are restricted to bound anaphor long-distance reflexives. It has been noted in the literature (e.g., Xu 1994; Yu 1996) that there is a variety of apparent counter-examples to subject orientation. Such counter-examples might be taken to indicate that seeming subject orientation has a functional rather than a grammatical explanation. In this section we would like to examine four questions related to this general issue:

(i) Is subject orientation derivable from logophoric discourse conditions on long-distance reflexives, or does it appear to be a grammatical requirement?
(ii) Can subject orientation be reduced to a requirement that (bound anaphor) reflexives refer to the noun phrase with the highest rank on the following thematic hierarchy?

(39) **Thematic hierarchy:**
Agent < Experiencer < Theme < Other

(iii) In the event that the answer to (ii) is negative, can subject orientation be reduced to the requirement that (bound anaphor) long-distance reflexives refer to the noun phrase with the highest grammatical function on a hierarchy of grammatical functions?

(40) **Hierarchy of grammatical functions:**
Subject < Direct object < Indirect object < Oblique

(iv) In the event that these functional explanations fail, can subject orientation be reduced to c-command?

We shall argue that there is evidence against (i), (ii), and (iii), but that (iv) is consistent with the available evidence, at least if c-command is understood as c-command/subcommand. We shall also examine one type of apparent counter-example to subject orientation: reflexives with experiencer subjects. We shall conclude that the evidence is unclear regarding whether these examples can be reduced to c-command as well, or whether they provide evidence that apparent subject orientation is not grammatical in nature.

The main evidence that subject orientation is not reducible to a discourse requirement is typological. We saw earlier that languages with bound anaphor long-distance reflexives differ regarding whether and which logophoric requirements are respected. Thus, for instance, Chechen and Ingush (Nichols 2001) do not manifest any logophoric requirements. In contrast, in Teochew (Cole et al. 2001b) there are strong logophoric restrictions on the relationship between the reflexive

and its antecedent. Despite this striking difference between Chechen/Ingush and Teochew, both languages manifest subject orientation. A similar point can be made on the basis of the comparison of Singapore Teochew and Mandarin in Cole et al. (2001b, 2004). Although Singapore Mandarin and Teochew differ greatly in the nature of the logophoric requirements found, long-distance reflexives are subject oriented in both cases. Thus, there is no correlation between the existence of subject orientation and logophoric requirements.

We turn next to the question of whether subject orientation could be reduced to the requirement that bound anaphor long-distance reflexives must refer to the noun phrase which is highest on the thematic hierarchy in the domain chosen (as was proposed by Giorgi 1984, inter alia). (We assume that in a multi-clausal structure, the choice of the clause in which the antecedent occurs is independent of the choice of which noun phrase in that clause serves as antecedent.) This hypothesis is given some support by the fact that non-nominative experiencers can serve as antecedents for bound anaphor long-distance reflexives (Giorgi 1984). There is, however, clear evidence that this hypothesis cannot be correct as a general source for subject orientation. With regard to Mandarin, Cole and Wang (1996) show that while objects in postverbal position cannot serve as antecedents for long-distance *ziji*, preverbal objects are possible antecedents:

(41) Wangwu$_i$ shuo Zhangsan$_j$ zengsong gei Lisi$_k$ yipian guanyu ziji$_{i/j/*k}$
Wangwu says Zhangsan give to Lisi one about self
de wenzang.
DE article
'Wangwu says that Zhangsan gave an article about him/himself to Lisi.'

(42) Zhangsan$_i$ yiwei Lisi$_j$ hui ba Xiaoming$_k$ dai hui ziji$_{i/j/k}$ de jia.
Zhangsan thought Lisi will BA Xiaoming take self self's DE home
'Zhangsan thought Lisi would take Xiao Ming back to his home.'

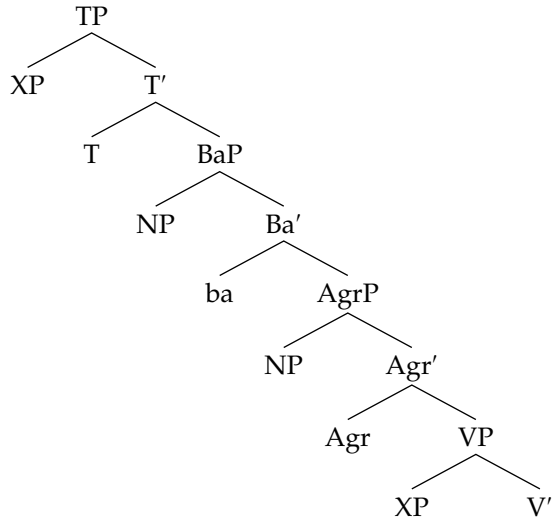
Example (41) shows that *ziji* cannot refer to *Lisi*, the postverbal object of *zengsong gei* 'give', but only to the matrix subject, *Wangwu*, or the complement subject, *Zhangsan*. In contrast, in (42), in which the theme occurs in preverbal position, *ziji* can refer to the matrix subject, *Zhangsan*, the complement subject, *Lisi*, or the theme, *Xiao Ming*. The fact that within the domain of the complement clause either the agent or the theme can be the antecedent for *ziji* shows that 'subject orientation' cannot be reduced to a requirement that the antecedent must be the highest noun phrase on the thematic hierarchy.

The same examples provide evidence against the proposal that subject orientation can be reduced to the requirement that the reflexive must refer to the highest noun phrase on a hierarchy of grammatical functions (at least for Mandarin). In (42) the complement subject, *Lisi*, outranks the complement object, *Xiao Ming*, on a hierarchy of grammatical functions. Despite that fact, the object is a possible antecedent for *ziji*.

Turning now to the hypothesis that subject orientation can be reduced to c-command, there appears to be evidence that this is the case. Under current

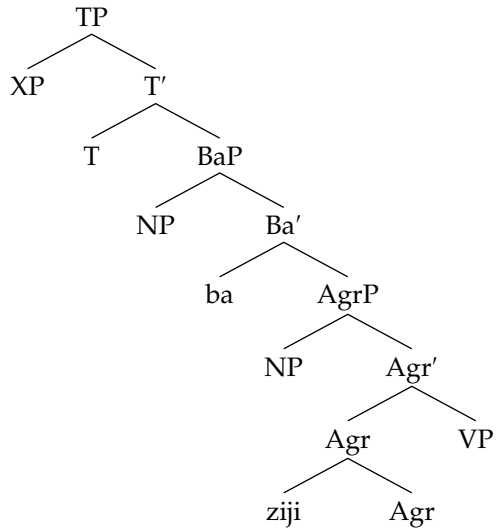
analyses of the *ba* 'preverbal object' construction, *ba* is a functional head and the 'object' of *ba* is the specifier of the maximal projection which is the complement of *ba*, as shown in (43) (adapted from Cole and Wang 1996):

(43)



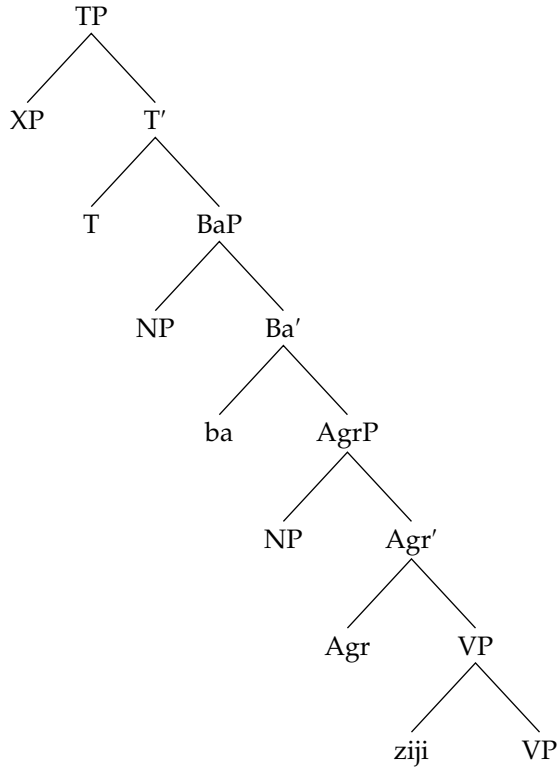
(We show the complement of *ba* as AgrP for the sake of concreteness, but the choice of projections is not relevant to our point here. Another possibility is PREDP.) We shall assume for the moment (i) that TP is the local domain in which Binding is determined; and (ii) that some version of the movement theory of long-distance reflexives applies, under which the reflexive moves to a position in which its antecedent is within the local domain of the reflexive. We shall also, for the moment, assume (iii) that *ziji* adjoins to the head of AgrP (as in Cole and Wang 1996), though this assumption will be dispensed with shortly:

(44)



Given the resulting tree (roughly (44)), c-command alone would predict that the possible antecedents for *ziji* are the subject (the specifier of Tense/AspectP) or the specifier of AgrP (the noun phrase immediately following *ba*). Thus, both subject orientation and the failure of subject orientation in examples like (42) can be shown to be predicted from c-command alone if a movement analysis for *ziji* is assumed. Furthermore, these predictions are not dependent on the assumption that *ziji* adjoins to the head of AgrP (as is generally assumed in the head-movement analysis). If, instead, it is assumed that *ziji* adjoins to VP (as in Huang and Liu 2000), the same predictions are made:

(45)



Thus, we conclude that the reduction of subject orientation to c-command makes more accurate predictions about the distribution of *ziji* than does an analysis in which subject orientation is a primitive, at least if a movement analysis of LD reflexives is assumed. (We shall discuss the status of the movement analysis in section 10 below.)

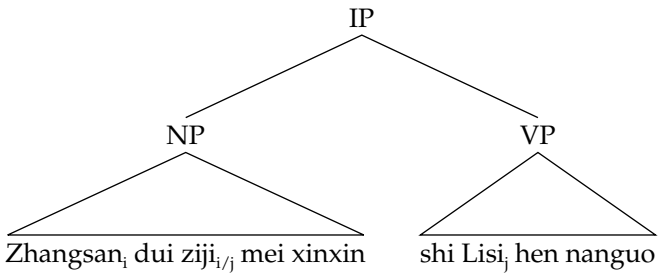
While the reduction of subject orientation to c-command appears to make the right predictions regarding the *ba* construction in Chinese, examples like (46) appear to be counter-examples to subject orientation both as a primitive and as a by-product of a c-command requirement:

(46) Zhangsan$_i$ dui ziji$_{i/j}$ mei xinxin shi Lisi$_j$ hen nanguo.
Zhangsan to self no confidence make Lisi very sad
'That Zhangsan had no confidence in himself made Lisi sad.'

(47) Ziji$_j$ de xiaohai yige ren qu luxing shi Lisi$_j$ hen danzin.
self's DE child alone go travel make Lisi very worried
'That his own child went traveling alone made Lisi worried.'

In (46) and (47) the antecedent for *ziji* can be *Lisi*. The S-structure for such sentences is roughly (48):

(48)



As is apparent from the tree, *Lisi* is not the matrix subject and does not c-command *ziji*. Thus, both in theories in which subject orientation is taken as a primitive and in those in which subject orientation is reduced to c-command, it is predicted that *Lisi* is not a possible antecedent for *ziji*.

While experiencer sentences like (46) and (47) appear to suggest that subject orientation is not one of the core properties of LD reflexives, the fact that apparent counter-examples to subject orientation/c-command are largely restricted to experiencer sentences suggests an alternative approach to the problem: perhaps the LF structure of experiencer constructions differs from the S-structure, and at LF the experiencer c-commands *ziji*. For example, as long ago as Postal (1970c) it was proposed that experiencers are LF subjects. A similar position was taken by Sung (1990). We conclude that the evidence is not conclusive with respect to whether subject orientation is a syntactic phenomenon. If subject orientation is syntactic in nature, it would appear not to be a primitive of grammar or to be derivable from either the thematic hierarchy or a hierarchy of grammatical relations, but rather to derive from c-command.

9.3 The Blocking Effect: typological evidence

The existence of a Blocking Effect based on person has been discussed primarily in the literature on long-distance reflexives in Chinese. The Blocking Effect is illustrated by the contrast between (1) and (3) (repeated here):

(1) Zhangsan$_i$ renwei Lisi$_j$ zhiao Wangwu$_k$ xihuan ziji$_{i/j/k}$.
Zhangsan think Lisi know Wangwu like self
'Zhangsan thinks Lisi knows Wangwu likes self.'

(3) Zhangsan$_i$ renwei wo$_j$ zhidao Wangwu$_k$ xihuan ziji$_{*i/*j/k}$.
Zhangsan think I know Wangwu like self
'Zhangsan thinks I know Wangwu likes self.'

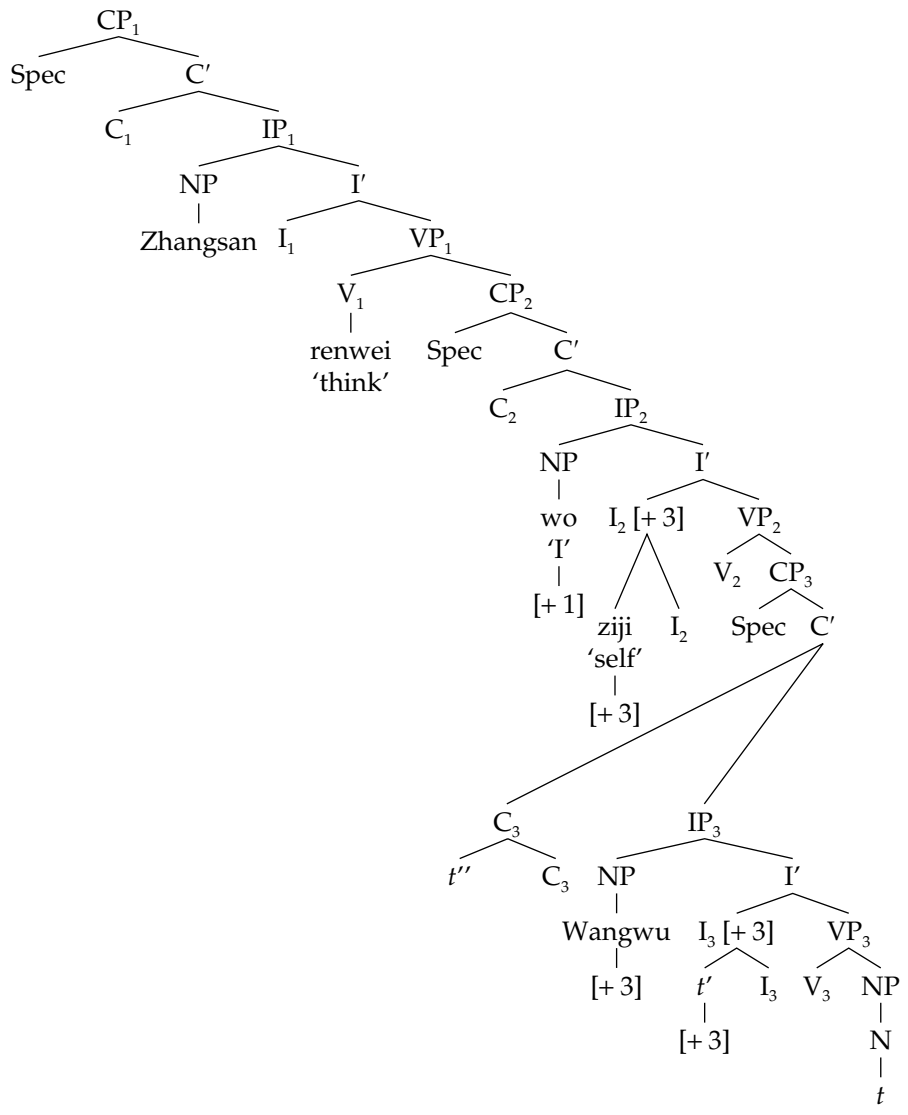
In (1) the person of the subject of the three clauses is identical (third person). In contrast, in (3) a change in person from the lowest clause (third person) to the intermediate clause (first person) prevents the reflexive from referring to the subject of the intermediate or matrix clause. Although the Blocking Effect was analyzed as syntactic in nature in most early studies of Chinese reflexives (e.g., Battistella 1987; Cole et al. 1990; Sung 1990; Huang and Tang 1991), it was originally noted by Y.-H. Huang (1984), who suggested that Blocking has a functional origin. The controversy regarding Blocking remains unresolved. While there is general agreement that certain instances of Blocking Effect are due, at least in part, to discourse/semantic/pragmatic factors, it remains controversial whether grammatical Blocking also occurs. From a typological perspective, the functional/discourse account does not seem to provide an explanation for the distribution of Blocking across languages: why is the Blocking Effect observed only in some languages (e.g., Chinese and Malayalam) and not in others (e.g., Chechen/Ingush, Kannada, Hindi-Urdu, Icelandic, or Norwegian)? Is there a typological difference in the discourse structure among languages that accounts for the cross-linguistic variations, or is the variation due to a difference in syntax?

There is prima facie evidence that syntax plays a significant role in accounting for the distribution of the Blocking Effect in Chinese. Cole et al. (2001b) and earlier work by Cole and Wang (1996), Cole et al. (1990), and others relate the occurrence of Blocking in Chinese to the fact that Chinese lacks verb agreement. The non-occurrence of Blocking in languages like Italian is related to the occurrence of verb agreement in these languages. This topic is debated in detail in Cole and Wang (1996), Cole et al. (2001b), Huang and Liu (2000), Pollard and Xue (2001), and Pan (2001).

According to the agreement theory of Blocking, languages differ with regard to whether INFL (or the appropriate agreement-bearing node) manifests features of person. All languages have a rule of 'subject–verb agreement' which states that spec of IP and I must be non-distinct with respect to phi-features. Chinese (in contrast to Italian) lacks base-generated person feature on INFL. Thus, in most sentences in Chinese spec–head agreement (subject–verb agreement) is vacuous. In contrast, in Italian INFL is base generated with person features, so spec–head agreement will play a major role in determining the grammaticality of sentences.

Structure (49) illustrates how Blocking is achieved by the agreement theory of Blocking:[16]

(49)



It is assumed that the reflexive *ziji* can be generated with any person feature. In the case of (49) it is generated as [+3]. The following Feature Percolation Principles are assumed:

(50) **The Feature Percolation Principles (FPP):**

a. The features of the mother node and the features of the daughter nodes will be identical.

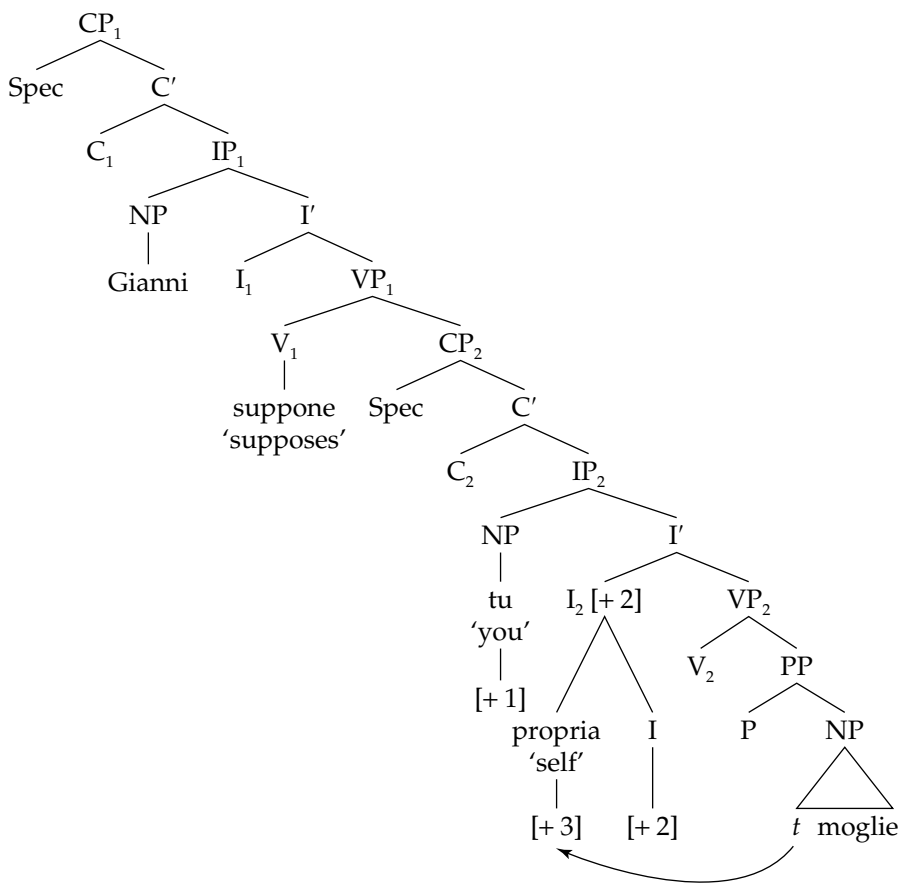
b. If the features of the daughter nodes conflict, the mother node will have the features of the head node.

No problems arise in IP_3. The reflexive adjoins to I. Since I has no base-generated phi-features, the feature [+3] percolates up to I_3. Spec–head agreement checking compares the phi-features of I and of the spec of IP. Since they do not differ, IP_3 is well-formed and the spec of IP_3 is a possible antecedent for *ziji*. Consider now the consequence of adjunction to I_2. The feature [+3] is percolated to I_2. In the case of IP_2 – unlike IP_3 – there is a difference in the phi-features of I_2 and the spec of IP_2. Thus, movement to I_2 results in an ill-formed output. Further movement to I1 would not result in grammaticality. Although there would be no conflicting phi-features at the IP_1 level, movement to I_1 must be via I_2. Thus, the FPP predict correctly the Blocking Effects seen in examples like (3).

The agreement theory of Blocking also predicts that Blocking will not occur in languages manifesting verb agreement, as illustrated by examples like the following from Italian:

(51) Gianni$_i$ suppone che tu$_j$ sia inamorato della propria$_{i/j}$ moglie.
Gianni supposes that you are in love with self's wife
'Gianni supposes that you are in love with his/your wife.'

(52)



In IP_2 in Italian, the reflexive bears the feature [+3] but INFL is [+2]. According to the FPP, when there is conflict among the features of the daughters ([+3] and [+2]), the features of the head ([+2]) percolate up to the mother node (the higher INFL node). Thus, INFL is [+2], and agrees with the subject of the clause, and the sentence is well-formed. As a result, no Blocking Effect is found when INFL is generated with person features, i.e., in a language in which even vestigial agreement is found.

The Chinese facts and the agreement theory of Blocking will be discussed in greater detail in section 10, where we compare the relative adequacy of different theories of long-distance reflexives. We also defer until section 10 the question of which nominals can be blockers; i.e., is it the case that all and only potential antecedents for long-distance reflexives constitute potential blockers? In this section our discussion will be limited to the typology of the Blocking Effect. The distribution of Blocking across languages provides support for the claim that Blocking is (in part) a grammatical (agreement-based) phenomenon, and is not due entirely to discourse.

As was seen, the agreement analysis of Blocking makes the typological prediction that Blocking will occur only in languages that lack even vestigial verb agreement (i.e., person features on INFL). This prediction is corroborated by Chinese languages, which lack agreement and manifest Blocking. It is also corroborated by Hindi-Urdu, Icelandic, and Italian, which have verb agreement and, as predicted, lack Blocking. Furthermore, strong support is provided by the Dravidian languages: in a comparison of Kannada (Amritavalli 2000; Lidz 1996, 2001) and Malayalam (Jayaseelan 2000), it is shown that the facts regarding long-distance reflexives in these two languages are very similar except that Malayalam has lost verb agreement. As predicted by the agreement theory of Blocking, Malayalam manifests a Blocking Effect like that seen in Chinese, while none is found in Kannada or any other Dravidian languages. None of the Dravidian languages, other than Malayalam, has lost verb agreement. Thus, the Dravidian facts provide evidence that the absence of agreement and presence of Blocking in Chinese are not coincidental.

While the Dravidian facts provide corroboration for the agreement theory of Blocking, other languages present problems for the theory. First, the Mainland Scandinavian languages have lost most verb agreement, but long-distance reflexives are not subject to Blocking. This would appear to be a strong counterexample to the agreement theory. This evidence, however, is not as persuasive as might appear. As is pointed out in Sung (1990), the Mainland Scandinavian languages exhibit agreement in predicate adjective constructions:[17]

(53) **Predicate adjective agreement:**

a. Gutten er stor.
the.boy is big
'The boy is big.'

b. Huset er stor.
the.house is big
'The house is big.'

c. Husene/Guttene er store.
the.house/the.boy are big
'The houses/boys are big.'

We assume that agreement in predicate adjective constructions is indicative of the presence of person features on INFL, which are then transmitted to the predicate adjective. Thus, the Mainland Scandinavian languages do not appear to constitute a genuine counter-example to the agreement theory of Blocking. There is, furthermore, some indirect evidence that these languages are not completely without agreement, but are rather similar to English in having a reduced agreement system rather than none at all. In general, two classes of languages manifest subject pro-drop: those with rich agreement systems, like Italian, and those entirely without agreement, like Chinese. Languages which have a reduced form of agreement do not allow pro-drop. The Mainland Scandinavian languages lack pro-drop, which suggests that they retain a reduced agreement system like that found in English.

Finally, Korean may constitute an additional language in which verbs do not agree with their subjects, but for which Blocking is absent.[18] However, Korean exhibits honorific agreement:

(54) atu-nim-i ttokttokha-si-ta.
son-NOMsmart-HON-Decl
'The son is smart.'

Sentence (54) illustrates obligatory honorific agreement in Korean. As in the case of Mainland Scandinavian predicate adjective agreement, honorific agreement may indicate that abstract agreement features are present on INFL. The presence of such features would be expected to result in the absence of syntactic Blocking in the language.[19]

While the apparent counter-examples to the agreement theory of Blocking are less than entirely convincing, it must be recognized that the typological argument in favor of the agreement theory is not as strong as would be desired. So far the only languages that illustrate the correlation between the absence of verb agreement and the Blocking Effect are Chinese and Malayalam. The empirical evaluation of this argument, therefore, must await the examination of additional languages which lack verb agreement and which exhibit bound anaphor long-distance reflexives. Furthermore, even here it is also clear that there are important discourse factors that contribute to the Blocking Effect (see section 10.4.3 below, and Huang and Liu 2000; Cole et al. 2001b), but the typological evidence suggests that it has a syntactic component as well; the evidence is still inconclusive.

10 Theories of long-distance reflexives

We will now turn to an examination of the extent to which various theories of long-distance reflexives predict the typological properties of the construction.

We shall restrict our discussion in this section to bound anaphor long-distance reflexives. Our purpose is to evaluate the adequacy of several current analyses, and to highlight the analytic problems posed by the construction.

10.1 The parameterization of the Binding domain

The earliest generative approach to long-distance reflexives, dating back to the 1980s, was to explain the possibility of non-local antecedents by proposing that languages differ with respect to the definition of the Binding domain ('governing category'). For instance, in English the Binding domain might be the immediate clause in which the reflexive occurs, while in Chinese it might be the root sentence. These differences in Binding domain were taken to be parameters of Universal Grammar along which languages could vary.

It is immediately apparent from the occurrence of both local and long-distance reflexives in the same language that such a parameterization could not be on a language-by-language basis, since the same language typically contains forms with different Binding domains. For instance, in Chinese, while *ziji* appears to take the root clause as its Binding domain, the pronoun *ta* 'he, she' has the same Binding domain as its English equivalent:

(55) Zhangsan$_i$ renwei Lisi$_j$ zhidao Wangwu$_k$ xihuan ta$_{i/j/*k}$.
Zhangsan think Lisi know Wangwu like him
'Zhangsan thinks Lisi knows Wangwu likes him.'

If the binding domain for *ta* were the root sentence, it would be expected that *ta* could not be bound within the root sentence. Not only is this not the case for Chinese, but we are not aware of any language in which personal pronouns are subject to such a requirement.

Furthermore, in Chinese the root clause is not the domain for all reflexive forms. The complex reflexive *ta ziji* cannot take a long-distance antecedent:

(56) Zhangsan$_i$ renwei Lisi$_j$ zhidao Wangwu$_k$ xihuan taziji$_{*i/*j/k}$.
Zhangsan think Lisi know Wangwu like himself
'Zhangsan thinks Lisi knows Wangwu likes himself.'

Thus, the parameterization of the binding domain would have to be different for each anaphoric element, and not for each language (Manzini and Wexler 1987; Wexler and Manzini 1987: the Lexical Parameterization Hypothesis). Additionally, for a variety of reasons, Wexler and Manzini and Manzini and Wexler argue that each parameter must be independent of all other parameters. Otherwise the parameterization will be unlearnable (in the sense of Wexler and Culicover 1980).

The parameterization of the binding domain has been criticized on a variety of bases: as was just noted, the approach fails to predict that across languages the apparent expansion of the Binding domain is restricted to reflexives, and never

occurs with pronouns. Thus, there must be something specific to reflexives that allows them to be long distance. An analysis that predicts similar variation in domain range for other anaphoric elements does not make the correct typological predictions. Furthermore, as was noted by a variety of authors (e.g., Safir 1987; Sung 1990; Hermon 1992) this approach appears to be inadequate as a model for the acquisition of reflexives by children. Most serious from our perspective is that the paramaterization of the Binding domain fails to make the correct typological predictions about the typological properties of long-distance reflexives themselves. Under this approach, in order to account for the fact that long-distance reflexives are monomorphemic, subject oriented, and subject to the Blocking Effect (in some languages), it would be necessary to introduce separate parameters for each of these properties of long-distance reflexives. But, in order for the parameters to be learnable, it is necessary that each parameter be independent of the others. That is, the fact that all these properties occur together is not predicted by the analysis. Thus, this parameterization approach fails to predict the core typological properties of long-distance reflexives. Furthermore, if, in a particular language, a stipulation were added – e.g., that long-distance reflexives must be monomorphemic – this requirement would be entirely stipulative, and would not follow in any way from the principles that license the existence of long-distance reflexives. Thus, this analysis predicts that languages could differ with regard to whether each of the core properties of long-distance reflexives will be found in that language. As a result, the parameterization of the Binding domain does not provide an adequate analysis of long-distance reflexives.

10.2 Cyclical re-indexing

The first analysis to predict some of the typological properties of long-distance reflexives was that of Tang (1985, 1989), who proposed that long-distance reflexives in Chinese should be accounted for in terms of a process of cyclical re-indexing of the reflexive with potential antecedents. Tang proposed the following hypothesis: long-distance reflexives are not simply reflexives with an expanded Binding domain, but rather the process of extending the domain is cyclic in nature. This hypothesis was suggested by the seemingly cyclic nature of the Blocking Effect. It will be remembered that in Chinese a difference in person features between the subject of the clause containing *ziji* and a superordinate clause prevents *ziji* from referring to the subject of the superordinate clause, or any higher clause. That is, all intermediate subjects between *ziji* and its ultimate antecedent must agree in phi-features. Such a requirement is at least suggestive of the possibility that *ziji* must be tested for agreement in phi-features with each potential subject along the path to its final antecedent. That is, the process of checking the feature content of *ziji* against intermediate subjects appears to be cyclic in nature.

Turning to the details of Tang's analysis, this result is achieved in the following way: *ziji* is analyzed as *pro-ziji*. The *pro* element in *pro-ziji* transfers its phi-features to *ziji*. The phi-features of *ziji* are thereby fixed and cannot be changed in the

course of the derivation. *Ziji* with phi-features undergoes an obligatory cyclic indexing process which reassigns to *ziji* the (referential) index of the potential binder in the Binding domain. In order for the indexing to be well-formed, *ziji* must agree with the potential antecedent in phi-features. The indexing process applies iteratively, and, presumably, cyclically. Thus, *ziji* can be assigned the referential index of an antecedent which is separated from its surface position in an unbounded fashion. However, *ziji* can never be assigned the referential index of a nominal that has phi-features that are different from those of the lowest potential antecedent, nor can the phi-features of intervening potential antecedents differ from those assigned to *ziji* on the first cycle. Thus, the Blocking Effect is predicted by the cyclic nature of (re-)indexing.[20]

Tang's proposal has a number of advantages over the parameterization of the Binding domain. First, it provides an analysis of long-distance reflexives that is specific to reflexives, thereby remedying one of the serious deficiencies of the parameterization of the Binding domain. It will be remembered that domain parameterization predicts the possibility of variation in Binding domains for pronouns as well as for reflexives. Cyclic re-indexing also provides an account of why *ziji* is long distance but not *ta ziji*; only *pro-ziji*, which lacks phi-features, is subject to cyclic re-indexing. Because *ta ziji* is generated with phi-features, it is assigned an unchangeable referential feature on the first cycle. That is, the critical difference between *ziji* and *ta ziji* which makes *ziji* long distance is taken to be the presence of lexically specified phi-features on *ta ziji* and their absence on *ziji*. In addition, cyclic reindexing provides an account of the cyclic nature of Blocking, also an important improvement over previous analyses.

The analysis appears, at least, to fail to predict subject orientation, which is stipulated. Furthermore, the analysis of the distinction between local and long-distance reflexives does not make the correct cross-linguistic predictions: any reflexive with lexically specified phi-features is predicted to be purely local. In Italian, however, both long distance and local reflexives are lexically specified as third person (long distance *se* and *proprio* vs. local *se stesso*). The factor which differentiates between local and long-distance reflexives is not feature content, but whether the form is monomorphemic or complex. Monomorphemic forms (*se* and *proprio*) are long distance while the complex form (*se stesso*) is local. Similar patterns are found in other European languages, so it would seem that the presence or absence of person features is not what differentiates local and long distance, but rather whether the form is simple or complex.

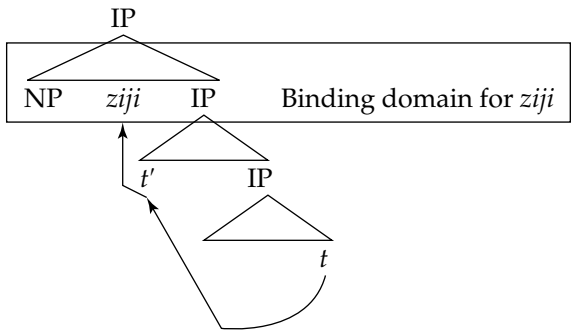
In addition, the analysis provides no explanation of how cyclic re-indexing occurs. From the perspective of contemporary linguistic theory, cyclic re-indexing is implausible as a mechanism: the process of re-indexing is non-local and unbounded, in that it occurs iteratively at ever greater remove from the location of the reflexive, while current expectations would be that both indexation and feature agreement should apply only in a local domain. The absence of a detailed account of the mechanisms by which re-indexing occurs suggests not that the proposal should be abandoned, but that it should be viewed as an incomplete analysis. Cyclic re-indexing might be viewed as a prototype for an analysis of

long-distance reflexives, a schema of properties (re-indexing, cyclic application) that a full analysis of long-distance reflexives should possess.

10.3 Movement analyses

The possibility of a movement analysis for long-distance reflexives was first suggested by Pica (1987, inter alia), an idea that was later developed by Battistella (1987), Huang and Tang (1988, 1991), Cole et al. (1990), and others for Chinese.[21] The basic idea is that long-distance reflexives are only apparently non-local. Rather, the long-distance reflexive moves successive-cyclically in the LF component from the position where it is generated to a position in which it has a local relationship with its ultimate antecedent:

(57)



The movement approach provides a solution to two important problems we noted with respect to the cyclic re-indexing analysis: the absence of a detailed description of the mechanisms involved in re-indexing, and the apparent non-locality of the relationship between the reflexive and its ultimate antecedent. The movement of the reflexive to a position near its ultimate antecedent allows a local account of the co-indexing of the reflexive and its seemingly long-distance antecedent. The seeming long-distance antecedent is in fact an LF-local antecedent. Thus, movement can be viewed as an elaboration of the cyclic re-indexing model earlier proposed by Tang rather than as an entirely new approach.

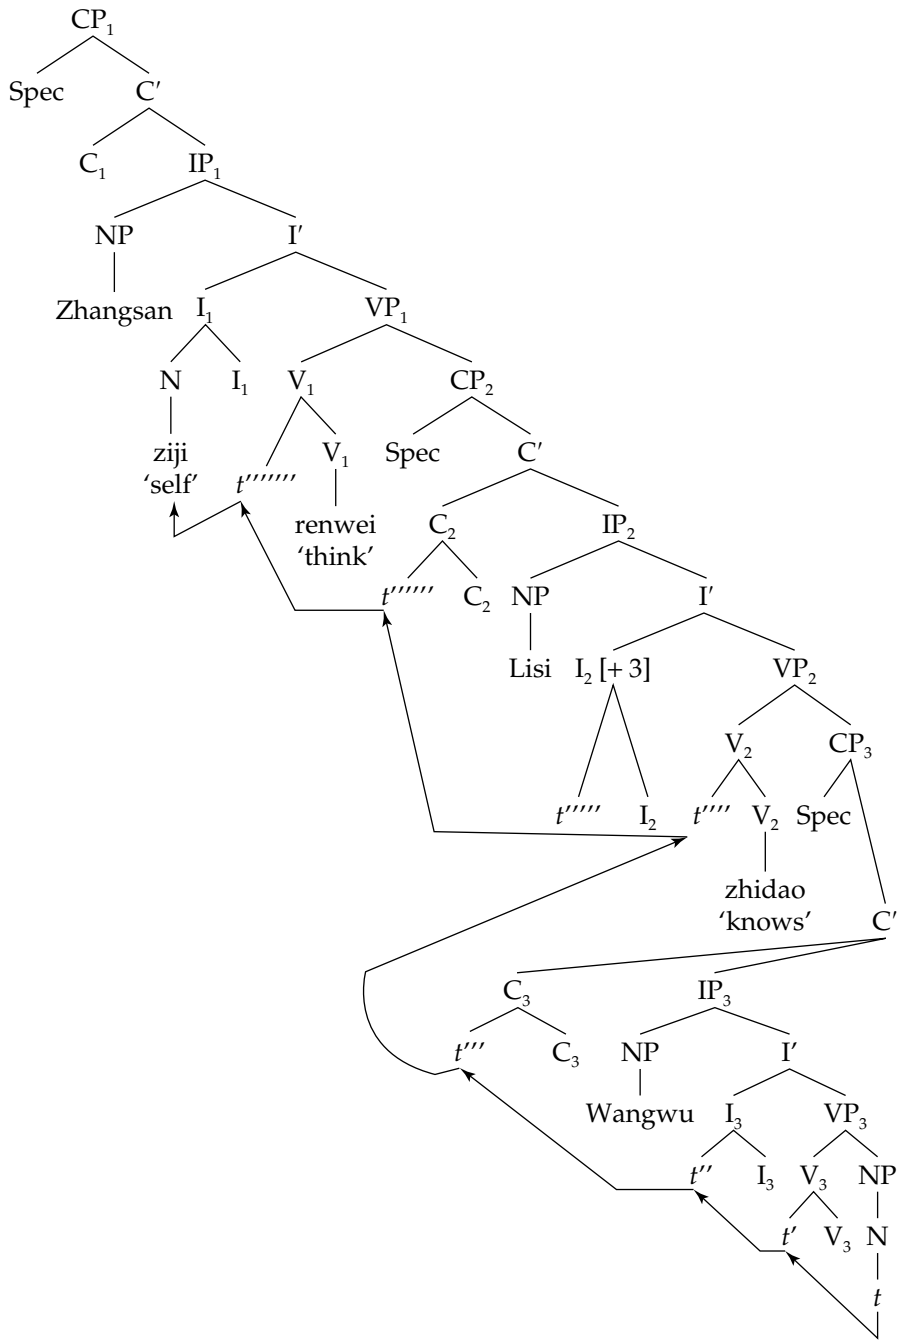
Several questions arise if a movement approach is adopted:

(i) What is the nature of the reflexive movement, XP movement (presumably to an A′-position), of the maximal projection containing the reflexive or head movement of the reflexive noun?
(ii) To what position does the reflexive move?
(iii) What is the motivation of the movement?

In general, analyses have been divided between two approaches: head movement of the reflexive to a functional head, generally INFL or AGR (works by Pica 1987, Battistella 1987, Cole et al. 1990, and others) or adjunction of the reflexive

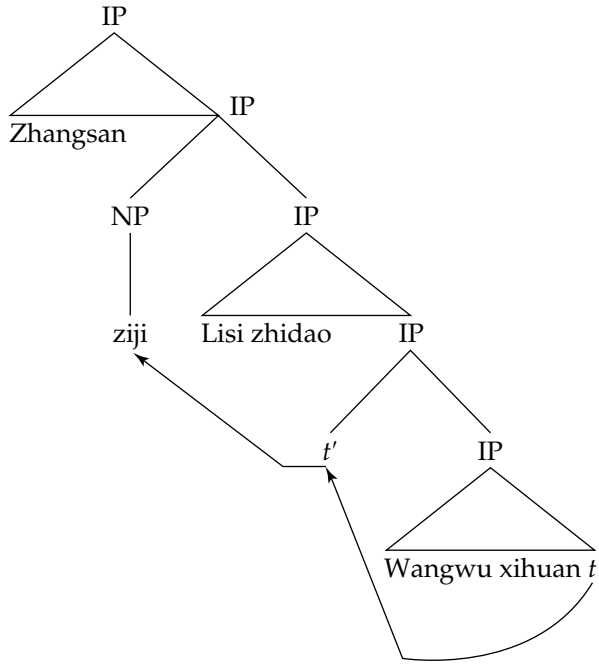
XP to the IP immediately below the antecedent (Huang and Tang 1991; Huang and Liu 2001):[22]

(58)



In (58) the reflexive noun *ziji* moves by head movement from the position in which it is originally inserted to the INFL of the clause in which the antecedent occurs. The alternative analysis, in which the XP reflexive adjoins to the IP below its antecedent, is illustrated in (59):

(59) **XP adjunction to IP:**[23]



In (59) the XP *ziji* moves by successive-cyclic adjunction to IP from the subordinate clause to a position in which it is adjoined to the IP below the clause containing the antecedent. Note that (58) and (59) differ in two ways: the type of movement (head movement vs. XP movement) and the position to which the reflexive moves (a functional projection in the clause containing the antecedent vs. adjunction to the clause below that in which the antecedent occurs). These two points are in fact separable. Thus, while no one has made such a proposal in the literature, a derivation like (60) is possible:

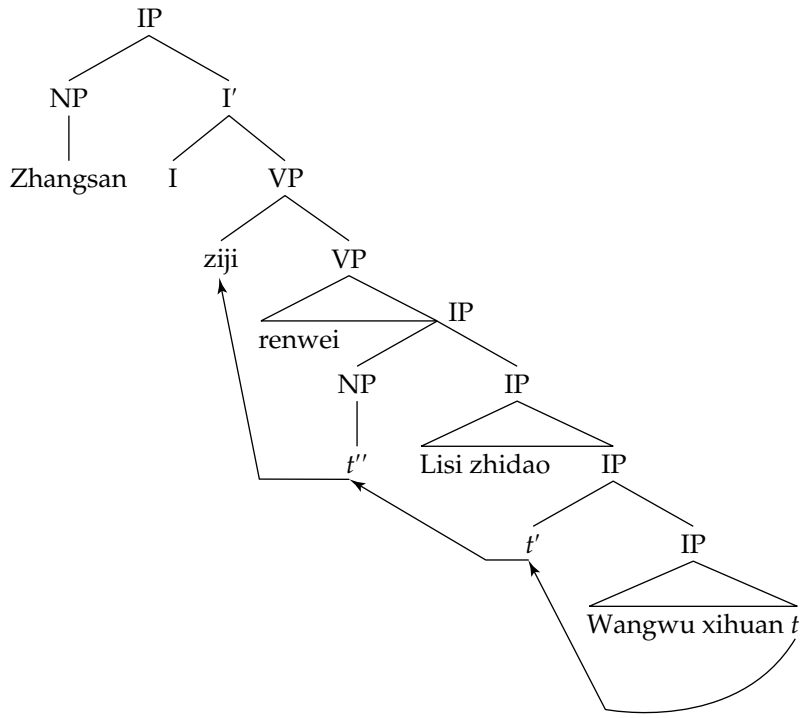
In (60) *ziji* has moved by head movement to a position roughly equivalent to the position occupied by *ziji* in (59). Similarly, in (61) the XP containing *ziji* adjoins to the VP of the clause in which the antecedent for *ziji* is found:

(61)



10.4 Relative adequacy of differing approaches to movement

10.4.1 Morphological complexity vs. phi-features

We shall now turn to an examination of the degree to which the various versions of the movement analysis predict the primary typological properties of the construction. First, given certain auxiliary assumptions, head movement (derivation (58) and (60)) predicts that long-distance reflexives will be simplex and local reflexives complex.[24] At least in the case of complement clauses like those illustrated here, we may assume that nothing blocks the movement of the noun *ziji* from the clause in which it is generated to matrix INFL (in 58) or COMP (in 60).[25] On the assumption that inter-clausal XP movement is only via the specifier of CP, and making the further assumption that movement via specifier of CP is not possible for reflexives (perhaps because this route is restricted to operators and *ziji* is not an operator), XP reflexives would not be able to move from clause to clause. Thus, it is predicted that only X^0 reflexives can be long distance.

A related but not identical prediction is made by the XP adjunction analysis, again making use of auxiliary assumptions.[26] On the assumption that the property that distinguishes long-distance reflexives from local reflexives is that the former lack phi-features while the latter have them, and making the further assumption that only reflexives without phi-features can be long distance, it would be predicted that only reflexives that are not distinguished for person can be long distance. However, as we saw earlier, while this is a correct characterization of Chinese, it is not in fact generally the case that reflexives with phi-features cannot be long distance. It will be remembered that Chinese *ziji*, Italian *se* and *proprio*, and Icelandic *sig* are all restricted to third person antecedents. But, despite the fact that they are generated with phi-features, *se*, *proprio*, and *sig* can take long-distance antecedents. Thus, an explanation of the simplex nature of long-distance reflexives as due to the correlation between morphological simplicity and the absence of phi-features may seem to be accidental.

The seeming advantage we see here of X^0 movement over XP movement is not absolute, however, as it depends on a battery of auxiliary assumptions, as noted. Alternative assumptions could be made and the argument could be turned around completely. For example, it has been assumed that the bare reflexive *zibun* in Japanese, *ziji* in Chinese, and *proprio* in Italian are operators or operator-bound (see Chierchia 1989; Katada 1991; Huang and Liu 2000), but compound reflexives like *karezisin*, *taziji*, and *se stesso* are not. A similar assumption could be made for *se* and *sig* but not their compound XP counterparts. This distinction between X^0 and XP reflexives can be attributed to the fact that the XP reflexives contain a pronominal component which makes them 'definite' on a par with other pronouns. Such 'reflexive pronouns' (as the traditional term implies), like the normal personal pronouns, are not operators. The bare reflexives, being devoid of a pronominal component, are indefinite operators on a par with indefinite quantifiers like *somebody*, *everybody*. Now, since operators are subject to A′-XP-movement, and A′-XP-movement is well known for creating (apparent) long-distance dependencies (albeit through successive local movements), the fact that bare, monomorphemic reflexives may have long-distance antecedents simply follows from the typical property of operator movement, under the assumption that they are XP operators undergoing LF A′-movement. On the other hand, it is well known that head movement is much more restricted than XP-A′-movement (due to the Head Movement Constraint (HMC), etc.: see note 25), a head-movement approach to bare reflexives may lead us to expect that it allows only local Binding, contrary to fact.

10.4.2 Subject orientation

Turning next to subject orientation, it will be remembered that we argued earlier that subject orientation appears to be reducible to c-command. As shown in section 9.2, subject orientation can be predicted correctly regardless of whether the movement in question is head movement or movement of a maximal projection. What is, however, relevant for the prediction of subject orientation is whether the reflexive moves to a functional projection within the clause containing

the ultimate antecedent or whether the movement is adjunction to the IP below the clause containing the ultimate antecedent.

Consider an example like (62), in which both the matrix and the complement subjects are potential antecedents for *ziji*, but in which the matrix object is not:

(62) Zhangsan$_i$ gausu Lisi$_j$ Wangwu$_k$ bu xihuan ziji$_{i/*j/k}$.
Zhangsan told Lisi Wangwu not like self
'Zhangsan told Lisi that Wangwu does not like him/himself.'

We shall consider two possible derivations for (62). If *ziji* moves to a functional projection within the matrix clause:

(63) [$_{IP}$ Zhangsan$_i$ ziji$_{i,*j,k}$ gausu Lisi$_j$ [$_{IP}$ Wangwu$_k$ bu xihuan *t*]]

the only potential long-distance antecedent is predicted to be *Zhangsan*, since *Lisi* fails to c-command *ziji* at LF. If the movement of *ziji* is to a functional projection in the complement clause:

(64) [$_{IP}$ Zhangsan$_i$, gausu Lisi$_j$ [$_{IP}$ Wangwu$_k$ ziji$_{*i,*j}$ bu xihuan *t*]]

it is predicted that only *Wangwu* is within the local domain of *ziji* at LF, thereby yielding the local interpretation. The interpretation in which *ziji* is co-indexed with *Lisi* is predicted not to occur because there is no derivation in which *Lisi* both c-commands *ziji* and is within the local Binding domain of the reflexive.

In contrast, if *ziji* adjoins to the complement IP, it is predicted that *Zhangsan*, *Lisi*, or *Wangwu* are potential antecedents:[27]

(65) [Zhangsan$_i$, gausu Lisi$_j$ [$_{IP}$ ziji$_{i,j,k}$ [$_{IP}$ Wangwu$_k$ bu xihuan t]]

In (65), unlike (63), *Lisi* c-commands *ziji* and is within the Binding domain of the reflexive.[28] In fact, this interpretation does not occur, a fact which would appear to provide evidence that *ziji* must move to a functional position within the clause in which the antecedent occurs rather than adjoin to the complement clause.

This conclusion, however, is again not necessary. For one thing, as just pointed out in connection with (61), the XP-movement theory could require *ziji* to be adjoined to the matrix VP in (65), where it would not be c-commanded by *Lisi*, thus deriving subject orientation. Second, as just pointed out in connection with (60), head movement of *ziji* could land it at C of the complement CP below the matrix verb in (63), where it is c-commanded by *Lisi*, thus incorrectly allowing

an object antecedent. This latter situation also seems unavoidable even if *ziji* lands finally in the matrix I, since the HMC would require the head to have moved through C^0 on its way to matrix I. Assuming the possibility of reconstruction (cf. note 27), the head-movement hypothesis actually does not ensure subject orientation.

The issue of subject orientation is also complicated by the existence of various counter-examples to subject orientation, such as the experiencer constructions discussed in section 9. Thus, it is a matter of controversy whether it is desirable to predict the occurrence of subject orientation. Ultimately, this question will be decided by the consensus that develops regarding the analysis of constructions like the experiencer construction, a topic which is beyond the scope of this chapter.

10.4.3 The Blocking Effect

Before it is possible to evaluate how well different approaches to reflexive movement account for the Blocking Effect, it is necessary to give further consideration to what Blocking facts need to be explained and whether the appropriate explanation is grammatical or in terms of discourse/pragmatic principles. We shall first consider some facts from Chinese that show that Blocking is not entirely grammatical in nature. It will be remembered that the agreement theory of Blocking predicted that only subjects should induce Blocking. However, as was first shown by Xu (1993) and Yu (1991), first and second person non-subjects can also induce a Blocking Effect:

(66) a. Zhangsan$_i$ shuo [[ni$_j$ zuo de chunshi] haile ziji$_{*i/j}$].
Zhangsan say you do silly deeds harm self.3sg
'Zhangsan says that the silly things you have done have harmed you.'
b. Zhangsan$_i$ shuo [[Lisi$_j$ zuo de chunshi] haile ziji$_{i/j}$].
Zhangsan say Lisi do silly deeds harm self.3sg
'Zhansan says that the silly things Lisi has done have harmed him/you.'

In (66a) the subcommanding specifier of the subordinate subject (*ni* 'you') differs in person features from the matrix subject, but the subordinate subject itself (*ni zuo de chunshi* 'silly deeds you have done') does not: both are third person. However, the subcommander prevents the matrix subject from anteceding *ziji*. In (66b), however, the subcommander and the matrix subject are both third person, and the matrix subject is a possible antecedent for *ziji*.

Furthermore, going beyond Xu and Yu's examples, at least for many speakers, the Blocking Effect can be induced by a non-c-commanding nominal that is not a possible antecedent for *ziji*:

(67) a. Zhangsan$_i$ cong ni$_j$ nar ting shuo Mali$_k$ hen taoyan ziji$_{??i/*j/k}$.
Zhangsan from you there hear say Mary very hate self
'Zhangsan heard from you that Mary hates herself.'

b. Zhangsan$_i$ cong Lisi$_j$ nar ting shuo Mali$_k$ hen taoyan ziji$_{i/*j/k}$.
Zhangsan from Lisi there hear say Mary very hate self
'Zhangsan heard from Lisi that Mary hates herself.'

While neither *ni* 'you' in (67a) nor *Lisi* in (67b) is a possible antecedent for *ziji* (since they fail to c-command/subcommand *ziji*), the fact that *ni* is second person prevents the matrix subject from anteceding *ziji* (or, for some speakers, makes it more difficult for the matrix subject to antecede *ziji*). In contrast, when *ni* is replaced by a third person nominal (*Lisi*), it is not problematic for the matrix subject to be the antecedent for *ziji*.

Reduced felicity is also found when a first or second person pronoun occurs in a position in the sentence which the agreement theory of Blocking would predict to be irrelevant to Blocking:

(68) a. Zhangsan$_i$ zhidao Mali$_j$ gen ziji$_{??i/??j}$ shuoguo ni xiang qu Taiwan.
Zhangsan knows Mary with self said you want go Taiwan
'Zhangsan knows Mary told him/herself that you want to go to Taiwan.'
b. Zhangsan$_i$ zhidao Mali$_j$ gen ziji$_{i/??j}$ shuoguo Lisi xiang qu Taiwan.
Zhangsan knows Mary with self said Lisi want go Taiwan
'Zhangsan knows Mary told him/herself that Lisi want to go to Taiwan.'

The second person nominal in (68a) does not intervene between *ziji* and its antecedent. Despite this fact, (68a) is less felicitous than (68b), in which *ni* 'you' is replaced by a third person nominal, *Lisi*. While explanations for (66) are possible in variants of the agreement theory of Blocking,[29] examples like those of (67) and (68) cannot be explained by such an account. These facts suggest that Blocking must have a major discourse component, which can be summarized as below, using the terminology of Sells (1987):

(69) **Discourse requirement in Chinese:**
a. The antecedent for an LD reflexive must be the internal PIVOT.
b. The presence of a first or second person pronoun anywhere in the sentence constitutes an external PIVOT, which blocks the possibility of an internal PIVOT.

In fact, something more general than (69b) seems to hold: the presence of *any* distinct PIVOT in a given sentence blocks the possibility of another PIVOT serving as the antecedent of an LD reflexive. The Blocking element can be a PIVOT associated with a first or second person pronoun as illustrated above, or it may be associated with a third person nominal element. For example, in Huang and Liu (2000), it is shown that a third person DP may induce Blocking if it is introduced deictically. In the example below, the pointing finger indicates that the speaker points to the referent of *neige ren* 'that person' in uttering the sentence:

(70) Zhangsan shuo [☞ ta qipian-le ziji].
Zhangsan said he/she cheate-Perf self
'Zhangsan said that he/she cheated himself/herself.'

The reflexive must be bound by *ta* but not by *Zhangsan*. This happens because the deictic use of *ta* establishes it as an (external) PIVOT, thus blocking the possibility of a distinct PIVOT as an LD antecedent of *ziji*.

Another case of PIVOT-Blocking occurs in sentences with multiple occurrences of *ziji*. In the example below (from Pan 1997), note that the most deeply embedded clause contains two occurrences of *ziji*:

(71) Zhangsan renwei Lisi zhidao [Wangwu ba $ziji_1$ de shu song-gei-le $ziji_2$
Zhangsan think Lisi know Wangwu BA self's books gave to self's
de pengyou].
friends
'Zhangsan thinks that Lisi knows that Wangwu gave self's books to self's friends.'

While both $ziji_1$ and $ziji_2$ may take *Zhangsan* or *Lisi* as their long-distance antecedents, the two reflexives may not take separate LD antecedents so that $ziji_1$ refers to *Zhangsan* while $ziji_2$ refers to *Lisi*, or vice versa. The sentence cannot mean that Zhangsan thinks that Lisi knows that Wangwu gave Zhangsan's books to Lisi's friends, or that Zhangsan thinks that Lisi knows that Wangwu gave Lisi's books to Zhangsan's friends.

Note that in (71) (as in (70)), all noun phrases involved are in the third person, so agreement cannot play a role in accounting for the Blocking Effect observed. From a discourse perspective, however, a natural explanation is that Blocking again occurs as a result of potential pivotal conflicts. In particular, having *Zhangsan* as a long-distance antecedent for one occurrence of *ziji* presupposes its status as an (internal) PIVOT of the sentence, and this prevents *Lisi* from being also a PIVOT and a potential long-distance antecedent for another occurrence of *ziji*; and vice versa.

In short, it is clear that Blocking has a discourse component along the lines of (72):

(72) **Discourse requirement in Chinese (revised):**
a. The antecedent for an LD reflexive must be a PIVOT.
b. The presence of a PIVOT (external or internal) in a sentence prevents a reflexive from taking any other distinct DP as a long-distance antecedent.

Having made a strong case for the relevance of discourse, a natural question arises: does this mean that Blocking is a purely discourse phenomenon? We think not. First, the typological facts that led to the agreement theory of Blocking are

not explained by the discourse theory of Blocking (if the typological facts hold up when more languages are examined). Second, there are facts internal to Chinese that give support to an agreement-based approach, independent of the discourse principle in (72). Cole and Wang (1996) note that while both subjects and the nominals following *ba/bei* are possible antecedents for LD reflexives (as discussed in section 9.2), subjects create strong Blocking Effects while the nominals following *ba/bei* do not:

(73) a. Zhangsan$_i$ yiwei wo$_j$ hui ba ni$_k$ dai hui ziji$_{*i/j/k}$ de jia.
Zhangsan thought I will BA you take back self 's home
'Zhangsan thought I would take you back to *his/my/your home.'

b. Zhangsan$_i$ yiwei wo$_j$ hui bei ni$_k$ dai hui ziji$_{*i/j/k}$ de jia.
Zhangsan thought I will by you take back self 's home
'Zhangsan thought I would be taken by you back to *his/my/your home.'

c. Zhangsan$_i$ yiwei Lisi$_j$ hui ba ni$_k$ dai hui ziji$_{i/j/k}$ de jia.
Zhangsan thought Lisi will BA you take back self 's home
'Zhangsan thought Lisi would take you back to his/my/your home.'

d. Zhangsan$_i$ yiwei Lisi$_j$ hui bei ni$_k$ dai hui ziji$_{i/j/k}$ de jia.
Zhangsan thought Lisi will by you take back self 's home
'Zhangsan thought Lisi would be taken by you back to his/my/your home.'

The sentences of (73a–b) show that a second person nominal following *ba/bei* is a possible antecedent for *ziji*. The nominal following *ba/bei*, however, does not block reference to the subject of that clause. A first person subordinate subject, however, blocks reference by *ziji* to the matrix subject. In contrast, in (73c–d), in which the subordinate subject is third person, reference to the matrix subject is possible. This pattern is explained if only subjects result in Blocking (since only subjects occur as the specifier of AGR), but any c-commanding nominal (including the nominals following *ba/bei*) is a potential antecedent for *ziji*.[30]

The facts of (73) appear to contradict the claim made earlier in this section that the occurrence of a first or second person pronoun anywhere in the sentence will cause a Blocking Effect. In fact, however, a comparison of (73c–d) with (74) shows that a mild Blocking Effect has occurred in (73):

(74) a. Zhangsan$_i$ yiwei Lisi$_j$ hui ba Xiao Ming$_k$ dai hui ziji$_{i/j/k}$ de jia.
Zhangsan thought Lisi will BA you take back self 's home
'Zhangsan thought I would take Xiao Ming back to his/my/your home.'

b. Zhangsan$_i$ yiwei Lisi$_j$ hui bei Xiao Ming$_k$ dai hui ziji$_{i/j/k}$ de jia.
Zhangsan thought Lisi will by you take back self 's home
'Zhangsan thought I would be taken by Xiao Ming back to his/my/your home.'

While in (73c–d) it is possible to understand *ziji* as referring to *Zhangsan*, this reading is much more salient in (74). That is, a mild Blocking Effect occurs in (73c–d) due to the occurrence of a second person pronoun following *ba/bei*. The strength of the Blocking, however, is much less than in (73a–b), in which a first person pronoun occurs in subject position. This is precisely the pattern that would be expected if agreement-based Blocking is *independent of* discourse Blocking. Discourse-based Blocking would result in some degree of Blocking simply because a first or second person pronoun occurs, thereby introducing an external PIVOT to the sentence. Agreement-based Blocking, however, would occur only when there is a change in the person of the subject. Thus, Blocking by subjects should be stronger than Blocking by non-subjects, since in the case of subjects both agreement-based Blocking and discourse-based Blocking occur. In the case of non-subjects, however, only discourse-based Blocking would apply. The pattern just described would have no explanation if all Blocking is due entirely to discourse constraints. Thus, the pattern of Blocking found in *ba/bei* sentences constitutes an argument that both agreement-based and discourse-based Blocking exist in Chinese.

An additional argument that the Blocking Effect has a grammatical as well as a discourse basis is provided by a close examination of sentences in which a third person subject blocks a first or second person antecedent, as in (75):

(75) Zhangsan$_i$ renwei [wo$_j$ zhidao [Wangwu$_k$ xihuan ziji$_{*i/??j/k}$]].
Zhangsan think I know Wangwu like self
'Zhangsan thinks that I know that Wangwu likes himself.'

Let us consider (75) from the perspective of discourse. The presence of *wo* 'I' in (75) is predicted to force the speaker to be the external PIVOT in (75), thereby preventing *Zhangsan* from being the internal PIVOT. Since only the PIVOT can be the antecedent for LD *ziji*, it is predicted that the possible antecedents for *ziji* in (75) are the local subject, *Wangwu* (since local subjects are not affected by logophoric conditions), or the intermediate subject, *wo* (since *wo* is the PIVOT), but not the matrix subject, *Zhangsan* (which is neither local nor the PIVOT). That is, first and second person are predicted to block third person (since first and second person induce an external PIVOT), but third person is predicted not to block first and second person.[31]

It is true that Blocking of first person by third person is somewhat weaker than Blocking of third person by first person, as in (76):

(76) Zhangsan$_i$ renwei [Wangwu$_j$ zhidao [wo$_k$ xihuan ziji$_{*i/*j/k}$]].
Zhangsan think Wangwu know I like self
'Zhangsan thinks that Wangwu knows that I like myself.'

However, the hypothesis that blocking is due entirely to discourse predicts that reference by *ziji* to the intermediate subject in (75) would be as well-formed as is reference to the intermediate subject in (1) (repeated here):

(1) Zhangsan$_i$ renwei Lisi$_j$ zhidao Wangwu$_k$ xihuan ziji$_{i/j/k}$.
Zhangsan think Lisi know Wangwu like self
'Zhangsan thinks Lisi knows Wangwu likes self.'

This, however, is not the case; reference to the intermediate subject is worst in (76), bad in (75), and good in (1).

These gradations in well-formedness are not predicted by either the grammatical or the discourse hypothesis alone. If, however, both discourse and grammar play a role in the Blocking Effect, the gradations of well-formedness are predicted correctly: (1) is best because it does not violate either grammatical or discourse restrictions; (75) is somewhat ill-formed because it violates grammatical but not discourse conditions; finally, (76) is worst because it is ill-formed in terms of both grammar and discourse.

We conclude that there is considerable evidence that the Blocking Effect in Chinese is due in part to discourse and in part to grammar. As far as we can tell, the grammatical component in Blocking seems best explained by the agreement theory of Blocking. Thus, we shall now examine whether the agreement theory of Blocking is compatible with the theories of reflexive movement that are under consideration.

The analysis in section 9.3, in which the agreement theory of Blocking was introduced, assumed that reflexives move by head movement and that the final position of the reflexive is the INFL or AGR of the clause containing the antecedent. Thus, the traditional head-movement analysis is fully compatible with the agreement theory of Blocking: the reflexive adjoins to INFL/AGR, and, in those languages in which INFL/AGR is generated without phi-features, the reflexive passes its phi-features to INFL/AGR. If the specifier of INFL/AGR does not agree with INFL/AGR (and, hence, the reflexive) in phi-features the sentence will be ill-formed. Let us turn next to the variant of the movement analysis, the XP-movement analysis, in which the reflexive adjoins to IP rather than to INFL/AGR. In this analysis the reflexive is not adjoined to INFL/AGR, so it is not immediately apparent why the phi-features of the reflexive should be passed to INFL/AGR. Thus, it might appear that XP-movement fails to predict the grammatical component in Blocking. Let us assume, however, that the Feature Percolation Principles ((50), repeated here) assumed for head movement also apply in the case of XP-movement:

(50) **The Feature Percolation Principles (FPP):**
a. The features of the mother node and the features of the daughter nodes will be identical.
b. If the features of the daughter nodes conflict, the mother node will have the features of the head node.

According to (50), if a reflexive with the feature [+3] is adjoined to IP, the feature [+3] will be passed on to all projections of I unless I has features that conflict with

[+3]. Thus, on the assumption that the reflexive is adjoined to the projection-bearing agreement (IP or AGRP), the XP-movement analysis makes the same predictions as the head-movement analysis. Both variants of movement appear to make correct predictions regarding the grammatical component of the Blocking Effect.

To summarize, in all the three areas considered, the two variants of the movement approach appear to be equally adequate. Under different assumptions, both head movement and XP movement are able to predict that long-distance reflexives are monomorphemic and (strictly) local reflexives complex. With regard to subject orientation, head movement and XP movement make the same predictions. The determining factor with regard to subject orientation is whether movement is movement to an initial position in the clause subordinate to that containing the antecedent, or movement to a position in the cause containing the antecedent. Finally, the grammatical component of the Blocking Effect is correctly predicted by both variants of movement. We conclude that movement theories of long-distance reflexives appear to capture well the core typological properties of long-distance reflexives. The facts that distinguish between the two variants on movement appear to be quite subtle in nature, and in the few cases in which there are differential predictions, the predictions are due primarily to subsidiary assumptions. Thus, we conclude that the evidence does not allow a clear decision regarding which variant of movement is to be preferred.

10.5 Long-distance reflexives in islands

We have shown in section 10.4 that movement analyses appear to make a number of desirable predictions regarding bound anaphor long-distance reflexives. There is, however, a serious problem with the movement analyses. An LF-movement analysis predicts that LD reflexives should not be grammatical in environments out of which movement is blocked. Thus, LD reflexives are predicted not to occur in syntactic islands (Ross 1986, inter alia), but such sentences are well-formed:

(77) ***Ziji* within the relative clause:**
Zhangsan renwei [Wangwu kanjian [$_{CP}$ neige taoyan ziji de ren$_k$]].
Zhangsan think Wangwu see that dislike self REL person
'Zhangsan thinks Wangwu saw the person who dislikes him/himself (Zhangsan, Wangwu or the person).'

(78) ***Ziji* within the adjunct clause:**
Zhangsan renwei [Wangwu shuo [$_{CP}$ rugoo Lisi piping ziji], ta jiu bu qu.
Zhangsan think Wangwu say if Lisi criticize self he then not go
'Zhangsan thinks that Wangwu said that if Lisi criticized him/himself (Wangwu, Lisi or Zhangsan), then he won't go.'

The structure of (77–78) is roughly that of (79–80) or (81–82), depending on which variant of the movement analysis is chosen (the island structure is shown in boldface):

(79) **LF structure of *ziji* within the relative clause (head movement):**
Zhangsan [$_{I}$ ziji] renwei [Wangwu kanjian [neige [$_{CP}$ **taoyan** *t*] de ren$_{k}$]].
Zhangsan self think Wangwu see that dislike REL person
'Zhangsan thinks Wangwu saw the person who dislikes him/himself (Zhangsan, Wangwu or the person).'

(80) **LF structure of *ziji* within the adjunct clause (head movement):**
Zhangsan [$_{I}$ ziji] renwei [Wangwu shuo [$_{CP}$ **rugoo Lisi piping** *t*], ta
Zhangsan self think Wangwu say if Lisi criticize he
jiu bu qu].
then not go
'Zhangsan thinks that Wangwu said that if Lisi criticized him/himself (Wangwu, Lisi or Zhangsan), then he won't go.'

(81) **LF structure of *ziji* within the relative clause (XP movement):**
Zhangsan renwei [$_{IP}$ ziji] [$_{IP}$ Wangwu kanjian [neige [$_{CP}$ **taoyan** ***t***] de ren$_{k}$]].
Zhangsan think self Wangwu see that dislike REL person
'Zhangsan thinks Wangwu saw the person who dislikes him/himself (Zhangsan, Wangwu or the person).'

(82) **LF structure of *ziji* within the adjunct clause (XP movement):**
Zhangsan renwei [$_{IP}$ ziji] [$_{IP}$ Wangwu shuo [$_{CP}$ **rugoo Lisi piping** *t*]], ta
Zhangsan think self Wangwu say if Lisi criticize he
jiu bu qu.
then not go
'Zhangsan thinks that Wangwu said that if Lisi criticized him/himself (Wangwu, Lisi or Zhangsan), then he won't go.'

In (79–82) the reflexive moves out of a modifying or adjunct clause, a movement that violates Subjacency or the Constraint on Extraction Domains (or contemporary analogues), and which thus would be predicted to result in ungrammaticality.

Explanations for such violations of island constraints have been proposed for both head movement and XP movement. For example, Huang and Tang (1991) argue that this pattern of island violation by XP movement in LF is in fact not surprising, given what we know about the syntax of *wh*-in-situ. Since Huang (1982b), it has been well known that argument *wh*-phrases in situ do not exhibit Subjacency or CED effects (although adjunct *wh*-phrases do). This is true both of normal *wh*-questions in Chinese-type languages and of multiple questions in English-type languages. Thus, in Chinese it is possible to ask a question about an argument within a relative clause or an adjunct, as shown in (83–84); and in English a direct multiple question may have one (more) of its *wh*-phrases located within such an island, as shown in (85–86):

(83) Ni zui xihuan [shei xie de shu]?
you most like who write DE Book
'You like the books that who wrote most?'

(84) Ni shi zai [shei lai-le yihou] cai zou de?
you be at who came after then leave Prt
'You left after who had come?'

(85) Who bought the books who wrote?

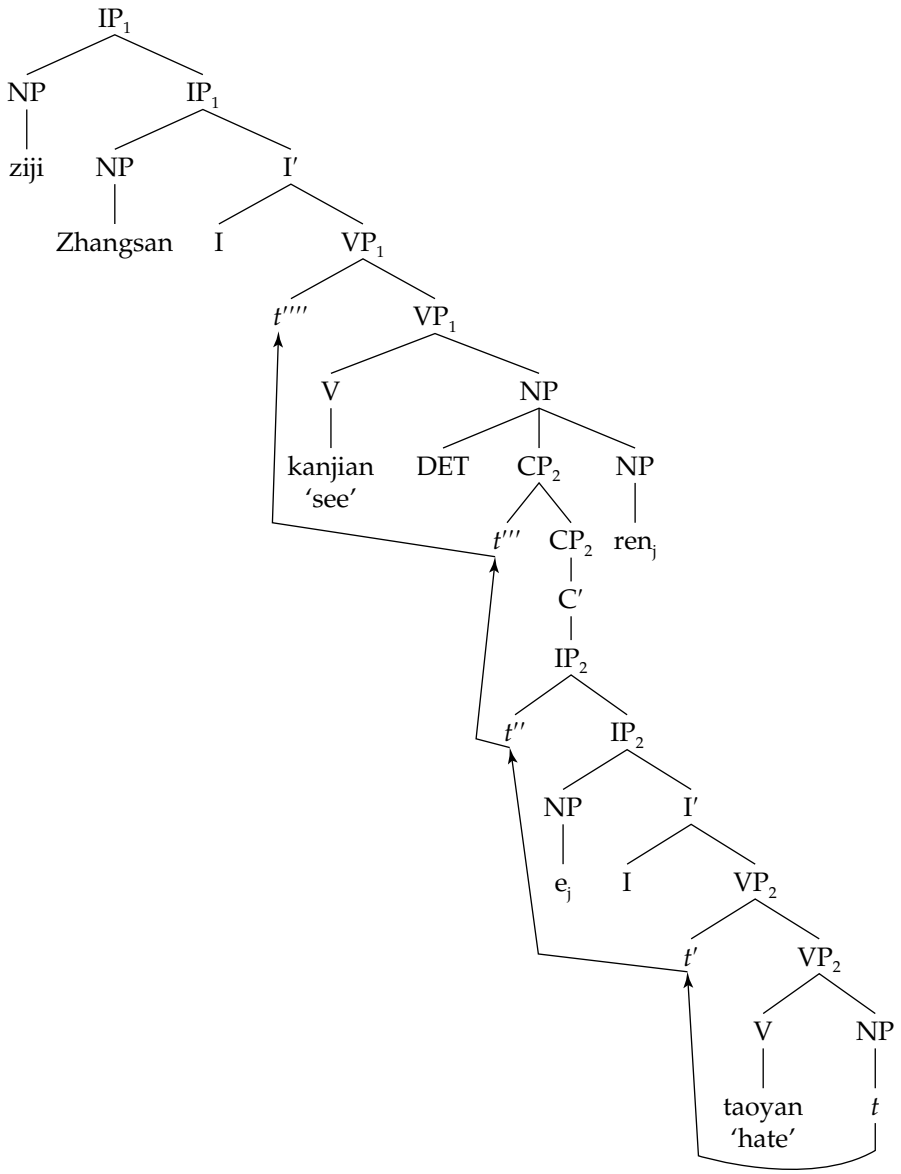
(86) Who left after who arrived?

Given the pattern exhibited by (83–86), the island violations described in (81–82) in fact come as no surprise. In all these cases, LF movement affects an argument. A *wh*-in-situ in argument position seems to exhibit no LF island effects, so an LD reflexive, also an operator occurring in argument position, also exhibits no LF island effects. In other words, given the facts of (83–86) as they are, the facts of the LD reflexive represented by (81–82) present no new empirical problem, and no surprise. Whatever explains the well-formedness of (83–86) can also explain the well-formedness of (81–82).

Of course, the facts of (83–86) themselves pose a theoretical problem, as to why covert extraction of arguments in LF should differ from overt extraction in Syntax. This question is addressed in Fiengo et al. (1988), where it is argued, on the basis of the *Barriers* system, that the observed island violations shown in (83–86) are only apparent violations. In line with the *Barriers* framework, Fiengo et al. assumed (i) that IP adjunction is not available in overt Syntax but available in LF, where QR, an IP adjunction operation, applies; (ii) that adjunction of α to a category β has the effect of 'debarrierizing' the boundary of β;[32] and (iii) that *wh*-in-situ phrases are both quantifiers and interrogative phrases: they move first qua quantifiers by successive-cyclic adjunction and then qua interrogatives by substitution into Spec, CP. Given the availability of IP adjunction, it is in fact a consequence of the *Barriers* system that *wh*-in-situ may escape the effects of island constraints, since all island barriers may be voided by the adjunction operation. That is, the island violations are only apparent; given the possibility of successive adjunction, no island effects are visible at all.

Huang and Tang (1991) proposed that the fact that LD reflexives do not exhibit island effects simply follows from the *Barriers* system as explicated by Fiengo et al. (1988), under the assumption that the bare reflexives are operators that undergo IP adjunction in LF, on a par with argument *wh*-phrases in situ (which involve an additional step of movement into Spec, CP). The availability of LD binding in (81–82) comes about because *ziji* could move out of a relative clause or adjunct island by successive cyclic adjunction. The following illustrates successive cyclic adjunction out of a relative clause:

(87)



Although covert argument extraction in general does not display island effects, it has also been well known that covert adjunct extraction does so:

(88) ***Wh*-extraction of adjuncts out of islands:**
a. *Suiran Lisi weishenme mei lai, ni haishi bu shengqi?
though Lisi why not come you still not angry
'Though Lisi didn't come why, you weren't angry?'

b. *Ni zui xihuan [ta weishenme mai de shu]?
you most like he shy buy REL book
'You like the book that he bought why?'

To account for the argument–adjunct asymmetries of this sort and other related facts, it was proposed by Huang (1982b) that while Subjacency/CED obtains only in overt syntax, the Empty Category Principle obtains in both overt Syntax and LF. Recall that the successive-cyclic adjunction hypothesis was used to explain the lack of covert Subjacency/CED effects by showing that, given the availability of successive-cyclic adjunction through IP in LF, such island effects are in principle invisible. The question now arises why, given the availability of successive-cyclic adjunction, covert adjunct extraction still displays clear ECP effects.

In order to solve this problem, Fiengo et al. (1988) suggested that adjunction to a maximal projection debarrierizes that projection only for Subjacency, but not for Government. Therefore, the extraction of arguments out of islands will be predicted to be well-formed since arguments are always lexically governed (or theta-governed). In contrast, the extraction of adjuncts will result in a violation of proper Government, since the adjunction node blocks proper Government from the outside.

As indicated in note 32, the idea is that adjunction debarrierizes a barrier by breaking a barrier into two segments, thus allowing an item to cross one segment at a time out of the barrier. Fiengo et al.'s proposal amounts to saying that, while a segment of a barrier is not enough to block movement, it is strong enough to block proper Government. This is not an unreasonable assumption since there is independent evidence that Government is blocked by 'weak barriers'. For example, a negative phrase does not create a Subjacency barrier, but does count as a barrier for ECP (Ross's 1986 'inner islands'; also Rizzi 1990b). Furthermore, complements to factive or non-bridge verbs must count as barriers for ECP:

(89) a. This book, which you like, has won the Pulitzer Prize.
b. This book, which you don't like, has won the Pulitzer Prize.

(90) a. This book, as you know, has won the Pulitzer Prize.
b. *This book, as you don't know, has won the Pulitzer Prize.

(91) a. What did you regret that John had stolen?
b. *Why did you regret that [John had stolen the key t]?

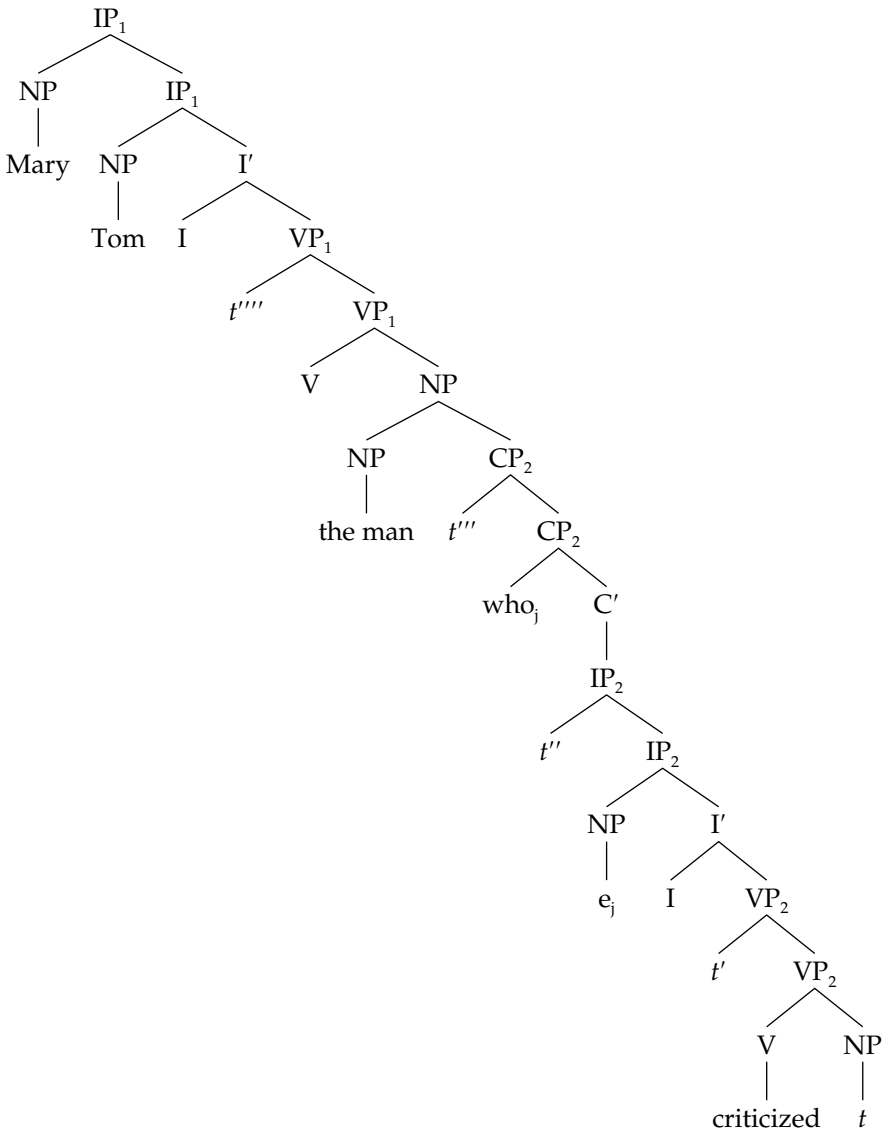
(92) a. What prize did John whine that he never got?
b. *Why did John whine that [he never got that prize t]?

Although this approach to (apparent) island violations of the LD reflexives seemed satisfactory given the set of assumptions made in the *Barriers* framework, it is ultimately called into question because the *Barriers* framework depends on stipulations some of which seem entirely unexplained. For example, while the

Barriers system allows covert IP adjunction (to allow for QR and similar processes), it specifically prohibits IP adjunction in overt syntax. This is necessary for the system to work, as Chomsky (1986b) notes, or most island effects would not be derived at all. For example, if IP adjunction were allowed in overt syntax, (overt) movement out of a complex NP would be licit – as shown in (93) and (94) – an incorrect result:

(93) *Mary, Tom saw the man who criticized *t*.

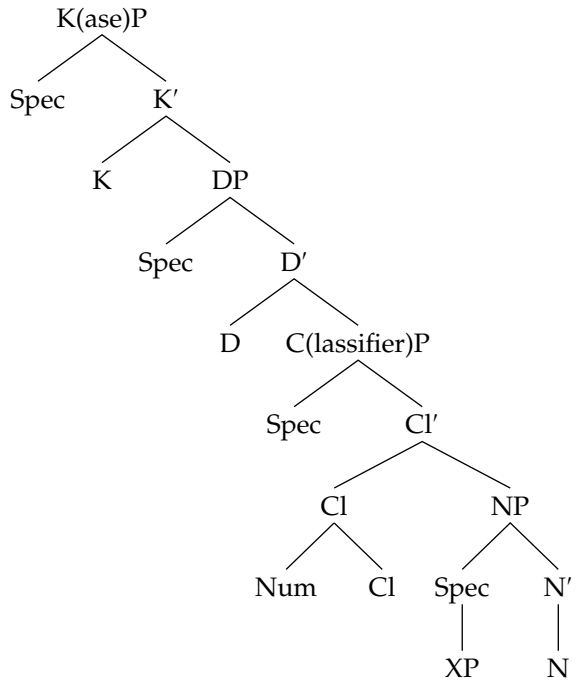
(94)



In other words, the *Barriers* system must include arbitrary stipulations in order for it to work in overt syntax, and at the same time not include such stipulations for it to work in covert syntax. Such undesirable stipulations undercut the fundamental assumptions of current Minimalist thinking. Thus, this account of why LD reflexives are possible in islands seems untenable.

An approach to this problem within the context of the head-movement analysis was proposed by Sung and Cole (1991). Sung and Cole argue that head movement can provide an account of the island facts if more complex structures are adopted for Chinese, based on Tang (1990). Tang proposed that Chinese relative clauses have the following structure:

(95) **Tang's structure for the Chinese noun phrase:**

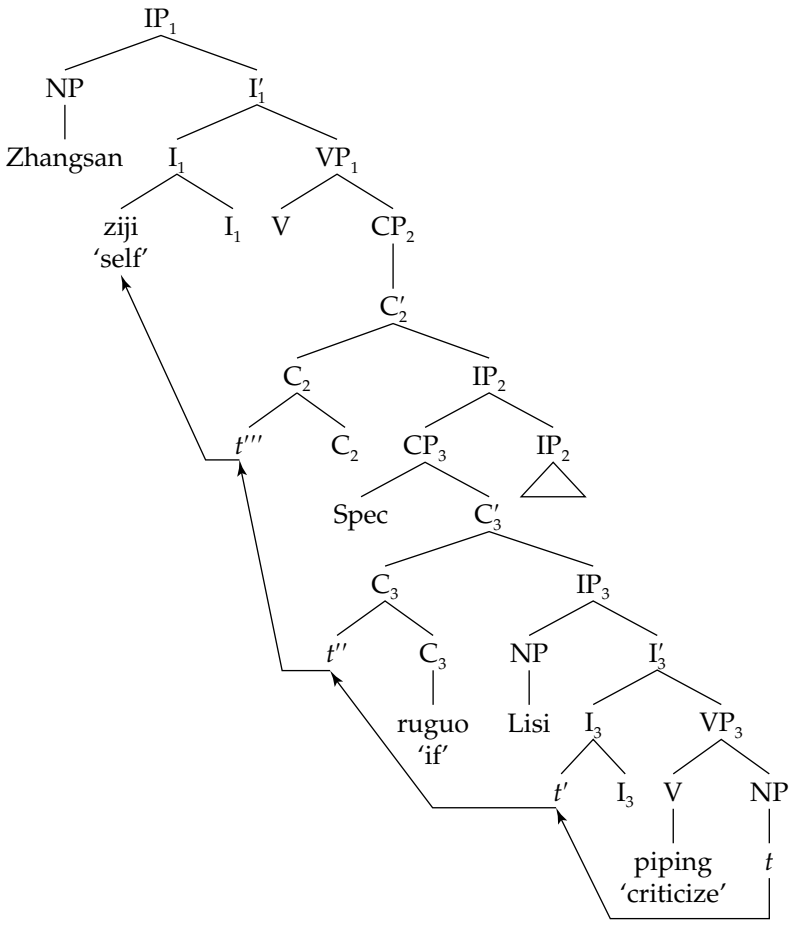


According to Sung and Cole, given Tang's proposed structure for the Chinese relative clause, with slight modification in the assumptions made in *Barriers* (Chomsky 1986b), relative clauses and adjunct clauses will be predicted not to be islands for head movement but to be islands for XP movement:

(96) **Modified assumptions:**
In order for a head to L-mark a maximal projection, it must: (i) be a lexical rather than a functional head; and (ii) govern the maximal projection.

Let us consider the application of head movement to a reflexive inside an adjunct clause:

(97)



Per (97), the movement of *ziji* to C_2 will make C lexical. This will also cause C_2 to L-mark CP_3. Thus, the extraction of *ziji* will be well-formed. The assumptions in (88) will not allow the extraction of an adjunct XP from an adjunct. This is because an XP cannot move to C_2 and void the islandhood of CP_3. Thus, given (97), head movement makes the correct predictions regarding extraction from adjuncts.

We shall turn next to reflexives in relative clauses:

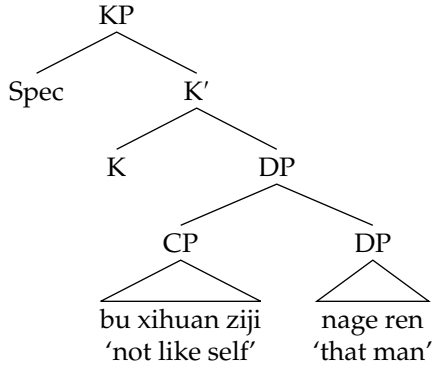
(98) a. **Predeterminer relative clause in Chinese:**
ec lai zheli de nage ren
come here REL that man
‘the man that came here’

b. **Postdeterminer relative clause in Chinese:**
nage ec lai zheli de ren
that come here REL man
‘the man that came here’

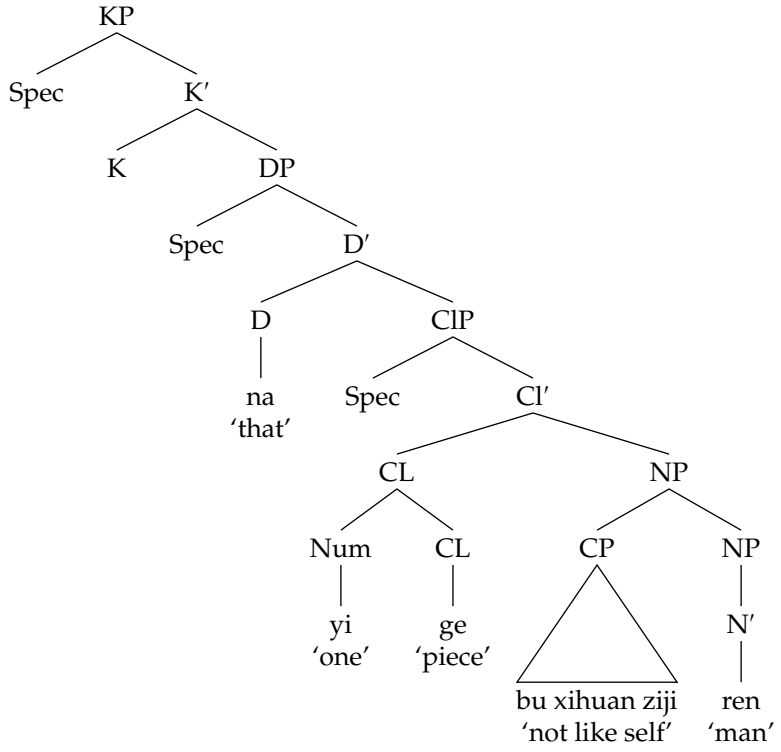
In (99a–b) the CP is governed by a functional head: K in the case of (99a) and Cl in the case of (99b):

(99) a. Zhangsan bu xihuan bu xihuan ziji de nage ren.
Zhangsa not like not like self REL that man
'Zhangsan does not like the man who does not like him/himself.'
b. Zhangsan bu xihuan nage bu xihuan ziji de ren.
Zhangsa not like that not like self REL man
'Zhangsan does not like the man who does not like him/himself.'

(100) a.



b.



In (100a–b) the modifying clause is governed by a functional category: K in the case of (100a) and Cl in the case of (100b). Thus, if *ziji* moves by head movement to K or Cl, the governing functional category will thereby become lexical and CP will cease to be a barrier: in both (100a) and (100b) the movement of *ziji* to the functional category governing the modifying CP makes that functional category lexical, and thereby debarrierizes the CP. But the movement of an XP from a modifying clause would not have that effect, since an XP could never move to an X^0 position. Thus, while adjunct and relative clause CPs are predicted not to be barriers for head movement, they are predicted to be barriers for XP movement.

The account just described, like that proposed for XP movement, suffers from both empirical and theoretical defects. From an empirical perspective, it makes the prediction that the existence of an LD reflexive inside an island enables other elements to move out of the island. This is so, because once *ziji* head-moves to I and L-marks the island, the island ceases to be an island for the movement of other categories as well. But this prediction is clearly incorrect for either overt movements (as in (101)) or covert movements (as in (102)):

(101) *Lisi, Zhangsan bu xihuan [t song-gei ziji de shu].
Lisi Zhangsan not like [t gave self DE book]
'*Lisi_i Zhangsan_j does not like the books that [t_i gave to self_j].'

(102) *Zhangsan, bu xihuan [weishenme piping ziji de ren].
Zhangsan not like [why criticize self DE person]
'*For what reason x, Zhangsan_j does not like the person who criticized self_j for x.'

Specifically, the account predicts that these sentences would be grammatical just in case the reflexive is bound LD by *Zhangsan*, but not if it is locally bound. But this prediction is not fulfilled. It should be noted, however, that this objection may not hold if the L-marking of the island is viewed as applying only at the stage of the derivation when the moved head governs the island, and not at subsequent stages in the derivation when the reflexive has moved on to its ultimate target. On this view *ziji* debarrierizes the island for itself but not for subsequent movement.

More generally, this account suggests that head movement should, in general, be possible from inside islands, but in fact, with the exception of LD reflexives, head movement is very local in nature. For instance, verbal inflection from one clause does not move by head movement onto the verb of a higher clause. Thus, an account that allows heads the freedom to move irrespective of barriers that affect XP movement would seem to make precisely the wrong claim for all putative head-movement constructions other than reflexive movement. With respect to theory, the account just proposed is based on the assumption, taken from *Barriers*, that islandhood is due to movement across an un-L-marked node. However, the notion of L-marking, based on Government, seems quite antithetical to

the fundamental assumptions of Minimalism. Thus, this explanation for the occurrence of LD reflexives in islands seems implausible.

We have argued at some length that two seemingly plausible explanations for the occurrence of LD reflexives in islands are both inadequate. We therefore conclude, that the fact that reflexives can occur in islands continues to pose non-trivial theoretical questions as to their explanation. To conclude this section, we have shown that while movement has important advantages over other analyses of long-distance reflexives, the analysis suffers from the absence of a satisfactory explanation of the occurrence of reflexives in islands. This suggests that a new analysis is needed, one which has the advantage of predicting correctly the core typological characteristics of LD reflexives and which is compatible with, or predicted by, an optimal theory of movement and constraints.

11 Conclusion: economy and long-distance reflexives

We would like to end this chapter by examining the ways in which the facts described in previous sections might contribute to our understanding of how long-distance reflexives fit into the anaphoric possibilities for natural language. We have seen that there appear to exist three kinds of entities which might be considered 'long-distance reflexives' in a pre-theoretical sense: long-distance bound anaphors, forms which are indeterminate between local reflexives and pronouns, and reflexives which undergo 'conversion' from bound anaphor to pronominal in specific syntactic and pragmatic contexts. Reuland (2001; and see chapter 33) discusses two types of reflexives (local reflexives and those that have undergone 'logophoric conversion' to pronominals), and notes that they are in complementary distribution: local reflexives undergo 'conversion' to pronominals when (i) anaphoric binding is blocked in the syntax and (ii) they satisfy certain logophoric conditions. This distribution suggests that local reflexives are given pronominal interpretation only if, given the specific syntactic properties of the language in question, they lack an eligible local antecedent as bound anaphors (e.g., per Reuland, Binding is blocked by subjunctive mood in Icelandic). That is, the complementarity derives from a principle of Avoid Pronoun, which requires that a form which is inherently capable of interpretation as either a pronominal (i.e., by coreference) or an anaphor (by Binding) must receive interpretation as a bound anaphor in contexts where an anaphoric interpretation is possible.

Why might such a preference for anaphoric interpretation exist? Reuland argues that the complementarity can be explained if we assume that local reflexives constitute a chain, a single syntactic object, perhaps as a result of movement of the reflexive. Reuland proposes that interpretation in which syntax and semantics work in tandem (i.e., by chain formation, in which a Binding relationship is forced by the existence of the chain) is inherently 'cheaper' than interpretation

by coreference (in which real-world information plays a role in the interpretive process).[33] Thus, whenever a single form can either form a chain (and, hence, receive a bound anaphor interpretation) or be interpreted pronominally, the possibility of the more economical chain interpretation should eliminate the possibility of pronominal interpretation. Pronominal interpretation should occur only when, for some reason, chain formation is blocked.[34]

We would like to extend this proposal from local reflexives to bound anaphor long-distance reflexives. Let us assume that this type of long-distance reflexive is derived by movement, putting aside the problems discussed in section 10.5. (We also abstract away from the issue of whether the movement is head movement or phrasal movement, whether it is adjunction to IP or to AGR, and what drives the movement.) If bound anaphor long-distance reflexives are derived by movement, chain formation must also occur in the case of bound anaphor long-distance reflexives. This predicts that in languages in which long-distance chain formation is possible, a c-command relationship would hold between the reflexive and its antecedent, and the reflexive would receive a sloppy rather than a strict interpretation under ellipsis. This extension of Reuland's analysis would predict that only when chain formation is somehow blocked would a pronominal interpretation become possible. This prediction appears to be correct, at least with respect to Chinese. As was pointed out by Yu (1992, 1996) and others, when *ziji* is unbound syntactically it receives a pronominal interpretation which is subject to logophoric requirements:

(103) Bu qinchu ziji shenme shihou neng qu Meiguo niansu;
not clear self when can go US read.book
Xiao Li ye zheme juede.
Little Li also thus feel
'It is not clear when I can go to the US to study. Little Li feels the same way.'

In (103) there is no syntactic binder for *ziji*. As predicted, the absence of a syntactic binder allows *ziji* to receive a pronominal interpretation, as is shown by the fact that the elliptical clause can receive either a strict or a sloppy interpretation ('Xiao Li says it is unclear when I can go' or 'Xiao Li says it is unclear when he can go'). Thus, Reuland's theory of economy, together with the movement theory of bound anaphor long-distance reflexives, predicts that both local and bound anaphor long-distance reflexives will be able to receive a pronominal interpretation only when there is no syntactic binder available.

We will next examine the predictions of Reuland's analysis with regard to long-distance reflexives like those in Malay and Turkish, forms that are interpreted as pronominals when they are long distance. Are such forms counter-examples to Reuland's theory of economy? In the context of Reuland's theory, the fact that such forms have the properties of pronominals rather than bound anaphors tells us that, unlike the case with bound anaphor long-distance reflexives, chain formation must be impossible. There is, in fact, evidence with respect to

local uses of Malay *dirinya* that chain formation has failed to apply. Example (5a) (repeated here) shows that even in a local context c-command is not required for *dirinya*:

(5) a. $[_{NP}$ Bapa Siti$_j]_i$ tidak$_k$ suka dirinya$_{i/j/k}$.
father Siti not like self.3sg
'Siti's father does not like her/himself/him.'

Examples with *dirinya* are to be contrasted with the complex reflexive *dirinya sendiri*, which requires a local antecedent and which is ill-formed when the potential antecedent does not stand in a c-command relation to the reflexive:

(104) $[_{NP}$ Ibu Ali$_j]_i$ telah menyiram air di dirinya sendiri$_{i/*j}$.
mother Ali already splash water on self.3sg alone
'Ali's mother already splashed water onto herself.'

We therefore conclude that *dirinya*, unlike *dirinya sendiri*, cannot participate in chain formation.[35] Since chain formation is blocked with this form, there will not be competition between pronominal and anaphoric *dirinya.* Thus it is expected that apparent long-distance reflexives employing forms like *dirinya* will have the distribution of a pronominal rather than that of a bound anaphor.

We have shown that an extension of Reuland's analysis successfully predicts the syntactic properties of each type of apparent long-distance reflexive. We will turn now to the discourse properties. We will start with bound anaphor long-distance reflexives. These have been argued to consist of chains between the surface site of the anaphor and a position in which a c-commanding antecedent is located within the local domain (roughly, the governing category) of the reflexive. Such a chain may be long distance (inter-clausal) when otherwise permitted by the structure of the language and by principles of Universal Grammar (such as principles of chain formation).[36] The problem raised by discourse for this analysis is why logophoric conditions might apply to the relationship between the head of the chain and the antecedent, with variation from language to language. We would like to suggest that the answer may be provided by viewing the chain as uninterpretable unless it is related to an antecedent by a predication relation along the lines suggested in Huang and Liu (2000). While a variety of technical problems remains unsolved with respect to this proposal, we propose that discourse principles, which may vary from language to language, determine whether the predication relationship would be subject to logophoric requirements. Thus, in the case of bound anaphor long-distance reflexives, logophoricity may restrict the relationship between the chain and the ultimate antecedent. However, the relationship between the head and tail of the chain would be a syntactic relation which would not be subject to logophoric requirements. In Huang and Liu's terms, predication of a chain structure on the ultimate antecedent establishes a relation at the interface level between syntax and discourse. It is then natural that such a mediation process is subject to both discourse and

syntactic restrictions. But the relation between elements internal to a chain structure would be strictly syntactic, not subject to extra-sentential considerations.

We turn next to those reflexives which can be used long distance only when they lack a c-commanding antecedent in their local domain (e.g., English and Icelandic subjunctives). Why are such reflexives obligatorily subject to logophoric requirements when logophoric requirements are optional in the case of movement chains (predication, according to Huang and Liu) and absent entirely in the case of the Malay/Turkish type of reflexive, in which chain formation is blocked? Reuland proposes that the answer can be found by examining the fundamental semantic content of pronouns. The semantic contribution of pronouns is to express orientation vis-à-vis the speech act (speaker, perceiver). This orientation is the lexical content of personal pronouns like *I* and *you*. In the case of anaphors that undergo 'conversion' to pronominals, orientation is not lexically specified, since these forms are radically deficient in lexical content. While 'classical' personal pronouns express only speech-act orientation, 'de-anaphoric' pronouns lack even that lexical content. In order to be well-formed, they must take their orientation from the context. That is, they must satisfy conditions of logophoricity.

Turning, finally, to 'pronominal' long-distance reflexives like those found in Malay and Turkish, Reuland's theory would predict that, unlike *sig*, they must include a specification of orientation in their lexical content, as must third person personal pronouns. It is not immediately apparent how the specification of orientation could be demonstrated without circularity, so we will leave this question open for future discussion.

NOTES

We would like to thank Anna Cardinaletti, Guglielmo Cinque, Bernard Comrie, Martin Everaert, Zygmunt Frajzyngier, David Gil, Alessandra Giorgi, Giuliana Giusti, Rita Manzini, Nicola Munaro, Eric Reuland, Walter Schweikert, and Li-May Sung for their very helpful comments and suggestions regarding various parts of this chapter. Special thanks are due to Yassir Tjung for his help in preparing this chapter for publication and to Peter Fröhlich of the Max Planck Institute for Evolutionary Anthropology for technical help in preparing the trees. This work was supported in part by funding from the National Science Foundation (grants SBR-9729519, INT-9423291, and BCS-9121167), the Max Planck Institute for Evolutionary Anthropology Leipzig, the Netherlands Organization for Scientific Research (NWO), the Utrecht Institute of Linguistics OTS of the University of Utrecht, the Dipartimento di Scienze del Linguaggio of the Università Ca' Foscari di Venezia, and by the Commissione Per gli Scambi Culturali Fra Italia e Stati Uniti (the Italian Fulbright Commission).

1 See Cole and Hermon (1998a) for a summary of the typological characteristics of long-distance reflexives.
2 It is a matter of controversy in the Chinese literature whether a third person subject blocks reference to a first or second person subject, or whether Blocking occurs only when the intervening subject is first or second person. (It is uncontroversial that the

Blocking Effect is stronger when the blocker is first or second person.) For differing positions on the facts, see Cole et al. (2001b) on the one hand, and Huang and Liu (2000) and Pan (2001) on the other.

3 But note that this position is denied by Pollard and Xue (2001), who argue against a division between anaphors and pronouns, at least with respect to Chinese *ziji*.

4 It is argued in Cole and Hermon (1998c) that *dirinya* is not lexically specified as either a pronoun or an anaphor. Rather, *dirinya* lacks specification for the feature [anaphor].

The existence of forms which are not specified as either pronominal or anaphoric is not unique to Malay. Keenan (1976a, 2000) argues that in both Old English and Middle English there is only a single form that is used for local and interclausal anaphora:

(i) syðþan he hine to guðe gegyred hæfde
once he_i(nom) him_i(acc) for battle girded had
'Once he had girded himself for battle' (*Beowulf* line 1473, c.750)

(ii) At Thebes, in his contree, as I sayde,
Upon a nyght in sleep as heihymi leyde
(Chaucer, *The Knight's Tale*, verse 1384)

5 This is example (6) in Pollard and Xue (2001).

6 Example (1) in Pollard and Xue (2001).

7 The nature and origin of the logophoric conditions are discussed in greater detail in section 11. We would like to emphasize that the syntactic environments making possible a free interpretation of anaphoric forms may be quite different cross-linguistically. As was pointed out to us by Eric Reuland, whereas in English the relevant condition is whether the anaphor is a syntactic argument of a predicate, in Icelandic the crucial factor is whether *sig* is in the domain of a subjunctive verb. As discussed in Reuland (2001; see also chapter 33) and Cole et al. (2001a), the crucial factor is whether something prevents the anaphor from being hooked up to its antecedent by a syntactic process. In Icelandic, this is the blocking of chain linking by the subjunctive. In English, this could be, according to Reinhart and Reuland (1991), the impossibility for SELF to covertly move to the predicate from a non-argument position. (Of course, to obtain well-formedness, appropriate discourse requirements must be met as well.)

8 There seems not to be any way to construct an analogous test sentence in the case of (12a).

9 It is not important for us that the pronominal reflexive is literally 'converted' from the anaphoric reflexive by a process of derivational morphology. We shall use this term simply to mean that the pronominal use of the reflexive is somehow specified as 'marked' or 'secondary'.

10 These tables are adapted from Frajzyngier (1993). All Mupun examples are taken from Frajzyngier as well. Some of the discussion of the examples is based on a presentation made by Frajzyngier at the Max Planck Institute for Evolutionary Anthropology in Leipzig and on personal communications.

11 Examples are, however, provided for verbs of perception:

(i) n-naa wur wur pə dəm n-kaano.
1sg-see 3sg 3sg PREP go PREP-Kano
'I saw him going to Kano.'

Note that a series A pronoun *wur* is used despite the fact that the two instances of *wur* are coreferential.

12 A very similar point is made by Culy (1997), who argues that true logophoric pronouns are primarily devices for indirect discourse and that the representation of point of view is not a central use of these forms.

13 Our presentation is a considerable simplification of Reinhart and Reuland's position. See Reinhart and Reuland (1993) for a full exposition of their proposal.

14 Examples (30–33) are from Lidz (2001). Example (34) is from Everaert (1991).

15 In some cases it is not clear whether a form is a bound anaphor reflexive or a pronominal. The string *ta ziji* in Mandarin appears to be ambiguous between a local bound anaphor and a pronoun *ta* modified by an emphatic reflexive *ziji*. Thus, Tang (1985, 1989), Sung (1990), and others have argued that all instances of apparent long-distance *ta ziji* are in fact instances of the pronoun *ta* modified by an emphatic reflexive rather than a complex anaphor. It must be recognized, however, that there are no completely convincing syntactic tests that demonstrate that all cases of apparent long-distance *ta ziji* are really the pronoun *ta* modified by *ziji*.

One argument in favor of the proposal that long-distance *ta ziji* involves pronominal *ta* is found in Cole et al. (2004), published in Chinese, which shows that long-distance *ta ziji* (and its Teochew counterpart *i kaki*) manifest the discourse conditions of the personal pronouns *ta* and *i*, and not those of the long-distance reflexives *ziji* and *kaki*: while *ziji* and *kaki* are subject to various logophoric conditions (see Cole et al. 2001b), no such conditions apply to long-distance *ta ziji* and *i kaki*. This state of affairs would be expected if *ta ziji* and *i kaki* are really the third person pronoun modified by an intensive reflexive, but not if they are bound anaphor long-distance reflexives. (Similar considerations apparently hold for Cantonese as well.)

16 The discussion anticipates some of the discussion of the Movement Theory of LD reflexives which is presented in section 10.

17 Example (46), from Norwegian, was provided to Li-May Sung by Arild Hestvik (p.c.).

18 The facts about Blocking in Korean are less clear than those regarding Blocking in Chinese. While some speakers have told us that Blocking occurs with the reflexive *casin*, others have disagreed. Contrary to earlier work on this topic by Cole et al. (1990) and subsequent papers, we assume here that Blocking does not hold in Korean.

19 Honorific agreement does not result in the absence of pro-drop, however.

20 We have ignored some details of Tang's analysis that are not relevant to the current discussion.

21 Dates of publication do not give a clear idea of the chronological development of the approach. It appears that the idea first originated with Pica, and was then applied to Chinese by Battistella. It was later further developed independently by Huang and Tang and by Cole, Hermon, Sung, and colleagues.

22 See Katada (1991) for discussion of an LF-movement approach to the long-distance reflexives in Japanese.

23 Adjunction to additional maximal projections such as VP and CP might also be posited.

24 The auxiliary assumptions made here are those made by Cole et al. (1990) and similar works.

25 This goes against a familiar version of the Head Movement Constraint, though, which prohibits a head from moving out of CP. It could also be excluded by a constraint against ?improper movement? from a lexical head to a functional head and then back to a functional head (V-I-C-V, etc.), analogous to the constraint against improper movement from A- to A′- to A-positions (see Travis 1984; Li 1990).

26 The auxiliary assumptions employed here are adapted from Huang and Tang (1991).
27 We assume that *ziji* can be reconstructed to its original position or interpreted in the adjoined position.
28 The Binding domain for a reflexive adjoined to IP would be the matrix clause.
29 See Cole et al. (1993) for such an analysis.
30 It will be remembered that the nominals following *ba/bei* are analyzed as specifiers of their projections rather than as objects of prepositions. Thus, they c-command *ziji*.
31 This is similar to the predictions made earlier by Pan (1995, 1997, 2001), who bases his predictions on a variant of the *de se* hypothesis.
32 See Chomsky (1986b) for more details. Adjunction of α to β has the effect of splitting the node β into two 'segments' with β now located between the two segments: $[_\beta\ \alpha\ [_\beta \ldots t_\alpha \ldots]]$. Thus, by adjoining itself to β, α crosses one half of the boundary of β (the lower segment $[_\beta$). Now, if α is moved out further, it will cross the other half (the higher segment $[_\beta$). In this way, by adjunction to β, α may get out of the boundary of β, not by crossing the entire boundary of β at once, but by crossing one segment at a time.
33 Reuland phrases his account in terms of cross-modular operations. A syntactic chain requires only two cross-modular operations while coreference requires four. See Reuland (2001) for the details of how the evaluation is conducted.
34 There is a point of similarity here with Pollard and Xue (2001), who propose that reflexives are interpreted on discourse/pragmatic considerations once they are not 'bound' syntactically.
35 Reuland speculates that number plays a critical role in determining whether a form is able to undergo chain formation, and, hence, show the distribution of a bound anaphor. *Dirinya* appears to be a counter-example to the proposal that number is the only feature that could block chain formation: while the reflexive root *diri-* is inflected for person, inflection for number is not possible.

    It should be noted that number appears to distinguish *diri-* from personal pronouns. In the pronominal system it is possible to distinguish *dia* '3p pronoun' (singular or plural) from *mereka* or *diaorang* '3ppl pronoun' (obligatorily plural). No such distinction exists for *diri-*: the only possible form is *diri-nya* '3p', and number cannot be indicated.

    We have seen, however, that *dirinya* does not permit chain formation. Thus, it cannot be the presence or absence of number which is critical for distinguishing between forms that allow chain formation and those that do not.
36 That is, long-distance chains would be permitted when the reflexive is monomorphemic and when no domain restrictions block the chain. For instance, in Icelandic a finite clause boundary would block chain formation.

  2.5 Dutch
  2.6 German
  2.7 Frisian and Yiddish
3 Capturing the variation
  3.1 LF-movement of SE and Relativized Minimality
  3.2 The VO–OV contrast
4 Conclusion: long-distance Binding and Minimalism

1 Introduction

The canonical Binding Theory of Chomsky (1981) is based on a two-way distinction between pronominals and anaphors. An anaphor must be A-bound and a pronominal must be A-free in its governing category. This two-way distinction is not exhaustive. As already observed in the 1970s (for instance, Ross 1970b; Kuno 1972b; Cantrall 1974; Hagège 1974; Clements 1975; Thráinsson 1976a, 1976b), certain elements that are formally identical to anaphors can be A-bound outside their governing category, or need not be linguistically bound at all. An important further observation was that, cross-linguistically, the two-way distinction between anaphors and pronominals found in English is the exception rather than the rule. In particular, many Germanic languages have a contrast between simplex anaphors, such as Icelandic *sig*, Norwegian *seg*, Dutch *zich*, etc., and complex anaphors of the general form <*pron*> *SELF*, where *pron* stands for a pronominal or simplex anaphor, which gives rise to three-way and four-way contrasts, not even counting

anaphoric possessives. It took some time before systematic endeavors were undertaken to assess the theoretical implications of these observations.

The first attempt to systematically address the questions posed by the Germanic languages as a group is Everaert (1986b), who developed an approach to Binding based on chain theory, and explains cross-linguistic differences in Binding domains on the basis of independent structural differences between languages. Subsequently, Manzini and Wexler (1987) developed a theory of parameterization of Binding domains based on lexical differences between anaphors. Hellan (1988) proposed that Binding involves the interaction between two types of conditions: containment conditions that are purely structural (such as c-command) and connectedness conditions that require a particular substantive relation between the anaphor and its antecedent, such as predication command (the anaphor is contained in a constituent predicated of the antecedent) or perspective command, which requires that the antecedent qualify as a perspective holder. (As we will see, the latter type of condition is a typical indicator of logophoricity.)

One result of these works is that a distinction was discovered between local anaphors, which must be bound in their governing category, and long-distance anaphors, which are exempt from Condition A of the Binding Theory.[1] A second result is that the contrast between simplex and complex anaphors reflects properties of argument structure (as shown by Everaert 1986b; Hellan 1988).

The differences found by Thráinsson (1976a, 1976b), Maling (1984, 1986), Anderson (1986), Hellan (1991a), and Thráinsson (1991) between long-distance Binding into finite clauses (indicative or subjunctive) and long-distance Binding into infinitival clauses show that a further distinction exists. Only long-distance Binding into infinitival clauses reflects structural Binding. The other occurrences of long-distance anaphors are logophoric (as discussed by Clements 1975; Sells 1987). As such, their distribution is much freer, and they are governed by discourse, rather than by purely structural factors. (See chapters 9, 33, and 38 for discussion.) It will be important to further elucidate this distinction between structural Binding of anaphors and their interpretation by discourse processes in terms of a general theory of interpretive dependencies.

Below we will summarize some of the basic facts about the major Germanic languages, before once more addressing the nature of the pattern they present.[2]

2 Anaphors across Germanic languages

2.1 English

English has a two-way distinction between anaphors and pronominals. English anaphors (*myself*, *yourself*, *himself*, *ourselves*, *yourselves*, *themselves*) are SELF-anaphors. English anaphors are either locally bound or logophoric. Bouchard (1984) was the first to make a systematic contrast between anaphors obeying the canonical, structural, Binding principles and anaphors exempt from those, giving rise to dependencies that prima facie involve long-distance Binding. Pollard and

Sag (1992, 1994) and Reinhart and Reuland (1991, 1993) state precise structural conditions under which SELF-anaphors are exempt from Condition A of the Binding theory. Their results indicate that many apparent cases of long-distance Binding can be analyzed as instances of logophoricity. It has been argued by Siemund (2003) and others (particularly Baker 1995) that other instances of exempt *himself* can be appropriately analyzed as representing a pronoun plus an intensifier (that is, *himself* = *him* + *himself*). Basically, this seems correct, although further research into the principles governing the distinction between logophoric and intensified instances of *himself* is still needed. A limited number of inherently reflexive predicates (mostly verbs of grooming, such as *wash*) allow the absence of an overt object where other languages require an overt anaphor (see chapter 9 for more discussion of English). This is a manifestation of the interplay between Binding and properties of argument structure, a phenomenon that is fairly residual in English but prominent in other Germanic languages.

2.2 Icelandic

Icelandic has a four-way distinction resulting from the fact that the SELF element *sjalfan* combines both with the third person SE-anaphor *sig* and with the elements in the pronominal paradigm (*hann*, etc.). In addition, Icelandic has a possessive third person anaphor *sin*. The anaphors *sig* and *sjalfan sig* must be bound by a subject, just like the possessive anaphor. When the antecedent is not a subject, *hann sjalfan*, etc., is used instead of *sjalfan sig*, and the corresponding pronominal form instead of *sig* or *sin*. In the first and second person the standard pronominal form is used throughout, with *sjalfan* where a complex anaphor is required. *Sjalfan sig* must be locally bound (i.e., bound within its governing category). *Sig* can be long-distance bound or interpreted logophorically. Icelandic freely allows violations of the Specified Subject Condition (SSC) (Chomsky 1973) with Binding into infinitives and DPs. Long-distance Binding of *sig* may cross a number of clausal boundaries, as illustrated in (1), where *Jón* is a possible binder for *sér*:

(1) Jón$_i$ sagði [Maríu$_j$ hafa$_{(inf.)}$ látið [mig þvo$_{(inf.)}$ sér$_{i,j}$]].
John said Mary have made me wash SE
'John said that Mary had made me wash him.'

Logophoric interpretation is possible only for an anaphor which is in the domain of a subjunctive, and which appears in a reportive context. For logophoric interpretation the antecedent need not c-command the anaphor. In fact, the antecedent need not be linguistically expressed at all. A systematic comparison between long-distance Binding and logophoric interpretation in Icelandic is given in chapter 33.

2.3 Faeroese

Faeroese, as it is described by Barnes (1986), has a three-way distinction. The SELF element *sjálvan* combines with the third person SE-anaphor *seg*, forming a

complex anaphor *seg sjálvan*. In addition, Faeroese has a pronominal paradigm and a possessive anaphor *sín*. Combining a third person pronominal with *sjálvan* appears to give an emphatic pronominal rather than an anaphor. The distribution of simplex and complex anaphors in local Binding contexts is largely determined by properties of the predicate and appears to essentially follow the pattern found for Dutch. The complex anaphor is exclusively local. As Barnes (1986) notes, some speakers may allow a stressed variant of the simplex anaphor, and others colloquially even an unstressed one, where the majority requires a complex anaphor. Faeroese freely allows SSC violations with Binding into infinitival clauses and DPs as in (2):[3]

(2) a. Pætur$_i$ sá Mikkjalsa$_j$ bílæt av sær$_{i/j}$/sær sjálvum$_j$/hunum$_o$.
Peter saw Miichael's picture of SE/SE-SELF/him
b. Jógvan$_i$ bað meg$_j$ PRO$_j$ raka sær$_i$/honum$_{i/o}$.
Jógvan asked me to shave SE/him

The antecedent of an SE-anaphor must be the subject of a predicate containing the SE-anaphor. Thus, for instance, the indirect object of a subject-control verb is not a possible antecedent for an anaphor in its complement:

(3) Eg$_i$ lovaði Jógvani$_j$ PRO$_i$ at raka honum$_j$/*sær$_j$.
I promised Jógvan to shave him/SE

Faeroese also allows binding into finite complements subject to restrictions that are similar to the conditions on logophoricity in Icelandic (see chapter 33):

(4) Jógvan segði, at Mortan hevði verið glaður, um Guðrun hevði kyst seg.
Jógvan said that Mortan would be happy if Guðrun had kissed SE

The majority of speakers allows both *Mortan* and *Jógvan* as antecedents for *seg* in (4). Objects, such as *Jógvan* in *Eg fortaldi Jógvan* . . . 'I told Jógvan' appear not to be possible antecedents. Barnes reports a relatively sharp Blocking Effect if intervening subjects do not have the same specification for person. So (5) is a variant of (4) in which the nearest subject is first person and the result is ill-formed:

(5) *Jógvan$_i$ segði, at tú hevði verið glaður, um eg hevði kyst seg$_i$.
Jógvan said that you would be happy if I had kissed SE

Such a contrast has not been reported for Icelandic. Given the impoverished verbal morphology of Faeroese (number contrasts but no person contrasts) as compared to Icelandic, this contrast is consistent with extant accounts of the Blocking Effect if number and person are checked separately. Note that the double intervention is not crucial; two-clause sentences with only the higher subject matching in features are also bad. However, if in (5) the nearest subject *eg* is replaced by *Guðrun*, and the mismatching subject is in a higher clause, the

reading with *seg* dependent on *Jógvan* becomes considerably better. This fact merits further investigation.

Barnes mentions that this long-distance antecedency relation in Faeroese is almost exclusively found in the complements of verbs corresponding to English *say, believe, want, learn (information), feel, intend*. These are typically verbs of the sort licensing logophoricity in other languages, inducing a reportive context. As in Icelandic, the antecedent need not c-command the anaphor as in (6), or be linguistically expressed:

(6) Vón hennara$_i$ var at sær$_i$ fór at dáma tann nýggja prestin.
Hope her was that SE was going to like the new minister

What makes Faeroese particularly interesting is that, in contrast to Icelandic, it does not have an overt distinction between indicative and subjunctive. That subjunctive is not a necessary condition for licensing logophoricity is not new by itself. Many other languages (such as Chinese and Japanese, and also English) have logophoricity without a (relevant) subjunctive. The interesting question is what sets the Faeroese inflectional system apart from that of the mainland Scandinavian languages (and other Germanic languages) where logophoricity (at least involving *seg*-type anaphors) does not occur. Is it the particular feature composition of INFL or a particular distribution of the features over functional projections? Is it the fact that in subordinate clauses both V_{fin} *Adv* order and *Adv* V_{fin} order are allowed? (Or do these reduce to the same factor?) Is the subjunctive perhaps still covertly represented? To answer such questions, further investigation of the Faeroese facts is necessary.

2.4 Mainland Scandinavian

Mainland Scandinavian (Danish, Norwegian, Swedish), like Icelandic, has a four-way distinction (for discussion see, among others Hellan 1980, 1988; Vikner 1984, 1985a; Hestvik 1991, 1992). The SELF element *selv* combines both with the third person SE-anaphor *seg* and with the elements in the pronominal paradigm (*ham*, etc.). In addition, these languages have a possessive anaphor *sin*. The Norwegian anaphoric system may serve as a model for the system of mainland Scandinavian languages in general, since the systems are very similar. The main difference among the mainland Scandinavian languages is reported to be that Swedish *själv* differs from *selv* in not being obligatory in a case like *Johan fraktade sig* 'John despised himself' as it is in Norwegian (Hellan 1988: 97, fn. 10). The anaphors *seg* and *sig selv* must be bound by the subject of a predicate containing the anaphor. The same holds true of the possessive anaphor. When the antecedent is not a subject, *ham selv*, etc., is used instead of *seg selv*, and the corresponding pronominal form instead of *seg* or *sin*. As in Icelandic, in the first and second person the pronominal forms are used, with *selv* where a complex anaphor is required. Unlike Icelandic, Norwegian does not have a systematic use of *seg* as a logophor. This may well correlate with the absence of subjunctive in Norwegian (but see

the discussion of Faeroese above). As in Icelandic, X-*selv* is local, and bare *seg* allows long-distance Binding. The following example illustrates long-distance Binding in Norwegian (from Hellan 1991a: 30):

(7) Jon_i bad oss forsøke å få deg til å snakke pent om seg_i.
John asked us (to) try to get you to talk nicely about SE
'John asked us to try to get you to talk nicely about him.'

For both possessive and non-possessive forms the upward bound on the Binding domain is the minimal tensed S (Hellan 1991a: 31), in accordance with Chomsky's (1973) Tensed -S Condition. This is illustrated by the ill-formedness of (8):

(8) *Jon_i var ikke klar over at vi hadde snakket om seg_i.
John was not aware over that we had talked about SE
'John was not aware that we had talked about him.'

One of the outstanding questions in the theory of Binding is what factors are involved in the limitations on long-distance Binding in languages such as Dutch and German as compared to Norwegian and other Scandinavian languages.

2.5 *Dutch*

Dutch distinguishes between pronominals (first and second person singular and plural, third person singular masculine, feminine and neuter, third person plural common gender), SE-anaphors and SELF-anaphors. The SE-anaphor *zich* only occurs in the third person (no singular/plural contrast). In environments where *zich* would be used for the third person, the first and second person are realized by a canonical pronominal form. Although, in general, complementarity between pronouns and anaphors holds, as in other languages, it should be noted that third person feminine singular *haar*, and to some extent also third person plural common gender *hun*, are not as bad as one might expect on the basis of Condition B. There is a SELF-anaphor *zichzelf*. In the first and second person the SELF-anaphor is realized as the corresponding pronominal plus *zelf*. Binding of these SELF-anaphors is strictly local.

Full pronominals combine with *zelf* as well in Dutch. Koster (1985) argues that the resulting element is an anaphor that is not subject to a local Binding requirement. The conditions on its interpretation show logophoric characteristics. *Zich* in positions corresponding to those of exempt anaphors in English is impossible in Dutch; *zichzelf* in such positions must have its antecedent in the local domain, as in (9):

(9) Max_i telde vijf toeristen in de kamer behalve *zich_i/zichzelf_i/*hem_i/hemzelf_i.
'Max counted five tourists in the room apart from himself.'

Logophoric interpretation of first and second person SELF-anaphors is available under similar conditions to those that apply in English.

Long-distance Binding of *zich* is possible, but it is more limited than long-distance Binding of Icelandic *sig* and Norwegian *seg*. *Zich* in *te*-infinitives (corresponding to *to*-infinitives) cannot be bound from the outside, as in (10), whereas *zich* in causative or perception verb complements can, as in (11) (see Everaert 1986b for extensive discussion):

(10) Ik hoor dat Jan_i Piet gevraagd heeft een boek voor $\text{zich}_{*i}/\text{hem}_i$ mee te brengen.
I hear that John Peter asked has a book for SE/him to bring
'I hear that John_i has asked Peter to bring a book for SE/him_{*i}.'

(11) Jan_i hoorde Marie een lied voor $\text{zich}_i/\text{hem}_i$ fluiten.
John heard Mary a song for SE/him whistle
'John heard Mary whistle a song for SE/him.'

This latitude is restricted to *zich* in PPs. In the following cases with *zich* in direct object position, only local Binding is possible (in (12a) both readings are pragmatically OK; in (12b), where the local reading is pragmatically disfavored, the non-local reading is still impossible):

(12) a. Jan_i voelde Marie_j $\text{zich}_{*i/j}/\text{zichzelf}_{*i/j}$ verdedigen.
John felt Mary SE/SE-SELF defend
'John felt Mary defend SE/SE-SELF.'
b. Jan_i hoorde Marie_j $\text{zich}_{*i/??j}/\text{zichzelf}_{*i/j}$ verwensen.
John heard Mary SE/SE-SELF curse
'John heard Mary curse SE/SE-SELF.'

With causative Exceptional Case Marking (ECM) constructions, judgments about object (relative to the lower verb) *zich* are essentially the same:

(13) Jan_i liet Marie_j $\text{zich}_{*i/j}/\text{zichzelf}_{*i/j}$ wassen.
John let Mary SE/SE-SELF wash
'John let Mary wash SE/SE-SELF.'

Indirect object *zich*, does, however, allow a non-local reading:

(14) Jan_i liet Marie_j $\text{zich}_{i/??j}/\text{zichzelf}_{*i/j}$ een boek brengen.
John let Mary SE/SE-SELF a book bring
'John let Mary bring SE/SE-SELF a book.'

Note that in some of these cases, replacing *zich* with a pronominal is less than entirely well-formed under the intended interpretation:

(15) a. Jan$_i$ voelde Marie$_j$ hem$_{??i}$ verdedigen.
John felt Mary him defend
'John felt Mary defend him.'
b. Jan$_i$ hoorde Marie$_j$ hem$_{?i}$ verwensen.
John heard Mary him curse
'John heard Mary curse him.'

With causative ECM constructions, judgments about embedded object *hem* get sharper when the predicate is an intrinsic reflexive, as illustrated by the contrast between (16a) and (16b):

(16) a. Jan$_i$ liet Marie$_j$ hem$_{*i}$ wassen.
John let Mary him wash
'John let Mary wash him.'
b. Jan$_i$ liet Marie$_j$ hem$_{?i}$ verdedigen.
John let Mary him defend
'John let Mary defend him.'

Embedded indirect object *hem* is fine, though:

(17) Jan$_i$ liet Marie$_j$ hem$_i$ een boek brengen.
John let Mary him a book bring
'John let Mary bring him a book.'

2.6 German

German distinguishes between pronominals (first and second person singular and plural, third person singular masculine, feminine and neuter, third person plural common gender), and an anaphor, *sich*, which only occurs in the third person (no singular/plural contrast) and which superficially resembles an SE-anaphor. In the type of environments that require the anaphor for the third person, the first and second person are realized by a canonical pronominal form. There is an anaphoric form *sich selbst* which superficially resembles a SELF-anaphor. In the first and second person it is realized as the corresponding pronominal with *selbst*. Antecedents for these forms need not be strictly local. The theoretical implications of this are difficult to assess, given the fact that *selbst* occurs as a focalizing particle and focalization generally contributes to exemption (see Reinhart and Reuland 1993).[4] Also an interplay between Binding and argument structure is less easily observable in German. The form *sich* can be used in most positions where Dutch has *zichzelf*. Yet some contrast shows up in restrictions for *sich* to bear stress. For further discussion of *sich* versus *sich selbst*, see chapter 9.

Interestingly, in positions corresponding to those of exempt anaphors in English, *sich selbst* or *ihn selbst* are preferred, as in (18):[5]

(18) Max_i zählte fünf Turisten im Zimmer ausser *$sich_i$/sich $selbst_i$/*ihm_i/ihm $selbst_i$.
'Max counted five tourists in the room apart from himself.'

Logophoric interpretation of *sich* and *sich selbst* with non-local antecedents is impossible in German. It is possible to have *sich* in a true expletive construction, though, as in (19):

(19) Es hat sich ausgekuschelt.
It has SE out-schmoezed
'Schmoezing is over now.'

Logophoric interpretation of first and second person *selbst*-forms is available under similar conditions to those for the corresponding SELF-anaphors in Dutch and English.

Long-distance Binding of *sich* is possible, but, as in Dutch, it is more limited than long-distance Binding of Icelandic *sig* and Norwegian *seg*. *Sich* in *zu*-infinitives (corresponding to *to*-infinitives) cannot be bound from the outside, as in (20) and (21), whereas, to a certain extent, *sich* in causative or perception verb complements can, as in (22):

(20) $Hans_i$ befahl Peter [PRO ihn_i/*$sich_i$/*$sich_i$ selbst jeden Tag zu rasieren].
John ordered Peter him/*SE/*SE SELF every day to shave
'John ordered Peter to shave him every day.'

(21) Ich hörte, dass $Johann_i$ Peter gebeten hat ein Buch für *$sich_i$/ihn_i mitzunehmen.
I heard that John Peter asked has a book for SE to bring
'I heard that $John_i$ has asked Peter to bring a book for SE_{*i}.'

(22) $Johann_i$ hörte Maria ein Lied für $sich_{\%i}$/ihn_i pfeifen.
John heard Mary a song for SE/him whistle
'John heard Mary whistle a song for SE/him.'

Apparently there is variation in the acceptance of the *sich*-variant in (22), indicated by the % sign before the subscript. Insofar as there is such latitude in ECM, it is limited to *sich* in PPs. In the following cases, with *sich* in direct object position, Binding is only local (in (23a) both readings are pragmatically OK; in (23b), where the local reading is pragmatically less plausible, the non-local reading is still impossible):

(23) a. $Johann_i$ fühlte $Maria_j$ $sich_{*i/j}$/sich $selbst_{*i/j}$ verteidigen.
John felt Mary SE/SE-SELF defend
'John felt Mary defend SE/SE-SELF.'

b. Johann$_i$ hörte Maria$_j$ sich$_{*i/j}$/sich selbst$_{*i/j}$ verwünschen.
John heard Mary SE/SE-SELF curse
'John heard Mary curse SE/SE-SELF.'

With causative ECM constructions, judgments about object *sich* are essentially the same (note that a main clause reading of the pronoun is unobjectionable, unlike the case in Dutch):

(24) Karl$_i$ liess Paul$_j$ sich$_{*i/j}$/ihn$_{i/*j}$/ihn selbst$_{i/j}$ rasieren.
Charles let Paul SE/him shave
'Charles let Paul shave SE/him.'

Indirect object *sich* does not allow a non-local reading either:[6]

(25) Karl$_i$ liess Paul$_j$ sich$_{*i/j}$/ihm$_{i/*j}$ ein Buch besorgen.
Charles let Paul SE/him a book bring
'Charles let Paul bring SE/him a book.'

Gunkel (2003) reports the following variation. Whereas adjunct PPs equally allow both the anaphor and the pronominal in ACI, as in (26), there is a difference between two types of complement PPs in (27) and (28):[7]

(26) Karl$_i$ liess mich neben sich$_i$/ihm$_i$ schlafen.
Charles let me next to SE/him sleep
'Charles let me sleep next to SE/him.'

(27) a. Karl$_i$ liess uns nur ungern über ??sich$_i$/ihn$_i$ schimpfen.
Charles let us only unwillingly at SE/him scold
'Charles let us scold him only unwillingly.'
b. Karl$_i$ liess mich an ?sich$_i$/ihn$_i$ einen Brief schreiben.
Charles let me to SE/him a letter write
'Charles let me write a letter to SE/him.'

(28) Er$_i$ liess mich mit sich$_i$/ihm$_i$ spielen.
He let me with SE/him play
'He let me play with SE/him.'

From the perspective of our discussion of long-distance anaphora, it is important that German exhibits the same type of restrictions in this domain as Dutch and is quite unlike the Scandinavian languages.

2.7 *Frisian and Yiddish*

Frisian and Yiddish are to be mentioned only for sake of completeness in this connection. Since Frisian lacks an SE-anaphor and the forms used instead are

truly pronominal, the question of long-distance Binding of SE-anaphors does not arise. Long-distance Binding of pronominals is, of course, possible throughout. One might still wish to understand, though, what is precisely the nature of the difference between *himself*, etc., in English, and *himsels*, etc., in Frisian. This issue still requires further investigation.

In exempt positions, the form *pronominal-SELF* has the same full range of logophoric possibilities as its counterpart in English and Dutch. For the purpose of the discussion of long-distance anaphors in Germanic it can, henceforth, be ignored.

Yiddish has a simplex anaphor *zikh*, which as in many Slavic languages is used for all persons, and a complex form *zick aleyn*, which in its use appears to be closer to German *sich selbst* than to Scandinavian *seg selv*.[8] A thorough analysis of Yiddish anaphora appears to be lacking. The literature (for instance, Weinreich 1971: 100–101) provides no indication that Yiddish has any long-distance or logophoric use of *zick* or *zick aleyn*.

3 Capturing the variation

As described in the previous section, there is considerable variation within Germanic in the domains in which SE-anaphors must be bound. As we saw, SE-anaphors may allow their antecedent in a position considerably beyond the governing category as computed in the canonical Binding Theory. The pattern has been taken to suggest that there are at least three possible (non-local) Binding domains across languages.

Systematic attempts to account for the variation observed include parameterized versions of the Binding Theory, with Binding-Theory-specific parameters, as proposed in Koster (1985) and Manzini and Wexler (1987), and a chain-based analysis in which the variation follows from chain formation interacting with independent structural differences, as proposed in Everaert (1986b). Manzini and Wexler, for instance, hypothesize that the governing category may vary across languages and anaphor types in terms of an opacity factor. The notion of an opacity factor generalizes the role of the subject in the canonical formulation of the Binding Theory:

(29) a. *b* is a governing category for *a* iff *b* is the minimal category containing *a*, a governor of *a* and F (F an opacity factor).
b. Possible values of F include: (i) (accessible) SUBJECT, (ii) Agr, (iii) Tense, (iv) indicative Tense, (v) Root Tense.

Descriptively, this approach is quite successful. However, it leaves open by what principles the set of possible values of F can be restricted (otherwise predicting too many possible domains). Moreover, it treats Binding in all domains on a par, not distinguishing between logophoric dependencies and structural Binding.

Everaert (1986b) summarized the variation in the Binding of SE-anaphors we observed in terms of the following three domains:

(30) i. small clauses (causatives and complements of perception verbs);
ii. non-finite clauses (including both *to*-infinitives and small clauses);
iii. non-indicative clauses (including subjunctive tensed clauses and non-finite clauses).

Since the extension of the third domain involves logophoricity, variation in structural Binding domains appears to be limited to just domains (i) and (ii). Moreover, we saw that in Dutch and German the possibility of long-distance Binding does not extend to anaphors in the object position of the embedded verb. So the two relevant domains can be characterized as follows:

(31) i. small clauses (causatives and complements of perception verbs, except for the object argument of the lower verb);
ii. non-finite clauses (including both *to*-infinitives and small clauses).

Everaert, followed by Reinhart and Reuland (1991), observes that the choice between (i) and (ii) is linked to an independent syntactic factor: (i) is found in the Germanic OV languages Dutch and German, (ii) in the Scandinavian VO languages.

There is a variety of proposals in the literature to capture the subject orientation and non-locality of SE-anaphors. Most of them explore the idea in Lebeaux (1983) and Chomsky (1986b) that restrictions on Binding correlate with restrictions on movement (cf. Pica 1985, 1987; Battistella 1987; Cole et al. 1990; Huang and Tang 1991; Hestvik 1991, 1992).

That SE-anaphors move can be argued to follow from the fact that they are underspecified for phi-features. Bouchard (1984) argued that in order to be interpreted, an argument requires a full specification of phi-features. From that perspective, being underspecified, SE-anaphors must acquire phi-features in the course of the derivation. This requirement can be met by association with an element carrying them.

One line, then, is to analyze the association of SE with a source for phi-features as an instance of X^0- (head-) movement (assuming that SE is a head in, for instance, the D-position). The set of available sources is restricted: since heads can only move to head positions, the SE-anaphor can only receive the necessary features from another head. Verbs will not do (nor will prepositions, etc.), since they do not contain phi-features. A c-commanding NP will not do either, since it is a maximal projection. The only element that meets the requirements that it c-commands the anaphor, is in head position, and carries phi-features is AGR.[9] The result is summarized in (32):

(32) SE-heads associate with AGR at LF.

One may assume here that AGR is inside T (so the movement is to T), though nothing hinges on this detail. Since AGR is always co-indexed with the subject and SE-anaphors always associate with AGR, it follows that SE-anaphors, in their grammatical (non-logophoric) use, are subject-oriented.

This general approach raises a number of issues, both internal to the general theory in its form near the end of the 1980s, and with respect to subsequent developments.

3.1 LF-movement of SE and Relativized Minimality

Everaert (1986b) formulated a representational theory of anaphoric dependencies where proper Binding requires that the co-indexing between anaphor and antecedent creates a licit chain-type object. The anaphor must be properly governed by the index of its antecedent. This, in turn, requires a *Barriers*-style licensing of indices by a sequence of governing heads (see the discussion of NP-raising in Chomsky 1986b):

(33) $DP_i\ [_Z \ldots Z_i\ [_Y \ldots Y_i\ [_X \ldots X_i \ldots SE_i]]]$

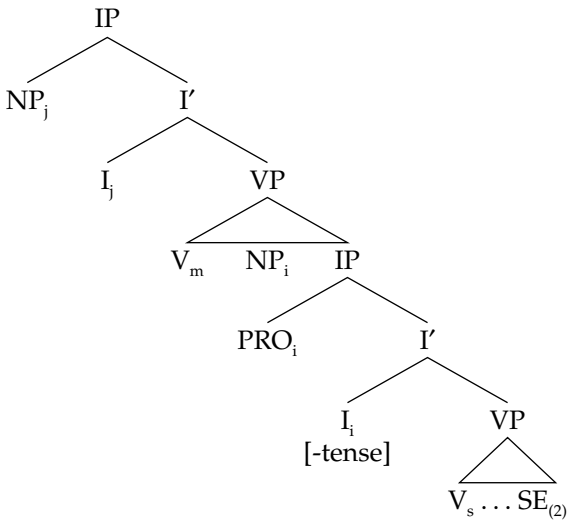
Lebeaux (1983) and, subsequently, Chomsky (1986a), in an endeavor to subsume Binding Theory under Movement Theory, developed an approach to Binding involving covert movement (LF-movement). Near the end of the 1980s it was found that movement obeys some form of Relativized Minimality condition (Rizzi 1990b). If SE-movement instantiates head-movement, it follows from any implementation of Relativized Minimality that subjects are not intervenors. In principle this could yield an extension of the Binding domain beyond the minimal governing category. However, the framework of Chomsky (1986a) puts severe limitations on head-to-head movement. The movement 'passing through H' sketched in (34a) is always illicit, since the intermediate trace violates the Empty Category Principle (ECP) (as discussed in, for instance, Baker 1988a). 'Long' head-movement skipping H as in (34b) is also ruled out:[10]

(34) a. $[_b\ a_i\ b] \ldots [_H\ t_i\ H] \ldots t_i$
b. $[_b\ a_i\ b] \ldots H \ldots t_i$

Roberts (1991b) argued that long movement is allowed if H is not a head of the same type, i.e., not an intervenor in the sense of Relativized Minimality. However, if (34b) is taken as the general model, it is predicted that SE always associates with the nearest source of phi-features, namely the local AGR. Since the actual binder may be higher up, one must either assume a dissociation between being a binder and being a source for phi-features, or assume that Binding is a by-product of attracting a larger constituent than just the anaphor. The former option underlies approaches modeled after Chinese (see Battistella 1987; Cole et al. 1990; Huang and Tang 1991; Huang and Liu 2001; see also chapter 9).

Another approach models the LF domain extension of anaphors on the overt formation of complex predicates in verb-raising languages like Dutch (Reinhart and Reuland 1991). This comes down to claiming that such anaphor movement uses massive covert pied-piping. SE first adjoins to its governing verb.[11] From there, V moves to I, taking SE along. The V/I complex thus formed may then move up further to a higher V, yielding a new complex, then to yet a higher I, etc., until SE with the V/I complex arrives at a position where SE associates with AGR. For an object control complement the structure is illustrated in (35). AGR is represented by the index on I; the SE-anaphor is, then, eventually bound by the subject of the matrix clause, as, e.g., in Norwegian (36) and (37):

(35)



First $V_sSE_{(2)}$ is formed. Subsequently, $V_sSE_{(2)}$ moves to I_1, amalgamating in that position, then $SE_{(2)}/V_s/I_i$ moves up to V_m, and finally, $SE_{(2)}/V_s/I_i/V_m/$ moves up to I_j. Here the SE-marked Verb is amalgamated with I_j, and SE may pick up the latter's phi-features. Interpretability only requires that SE gets its features at some point, not whether this happens when the verb merges with the lower I_i, with the higher I_j, or even with some higher-up I. Thus, in both (36) and (7) (repeated here as (37)) the anaphor will be able to be bound by the highest subject as required:

(36) Jon$_j$ bad oss snakke om seg$_j$.
John$_j$ asked us to talk about SE$_j$

(37) Jon$_i$ bad oss forsøke å få deg til å snakke pent om seg$_i$.
John asked us to try to get you to talk nicely about SE

Since finite clauses are opaque for 'Verb raising' and similar head-to-head movements, it follows that the upper bound for the Binding of an SE-anaphor is the first finite clause containing it (thus, this type of Binding observes the 'Tensed-S Condition'). One may still wonder, though, what triggers such generalized verb raising. So far, this theoretical problem has no generally accepted solution.

3.2 The VO–OV contrast

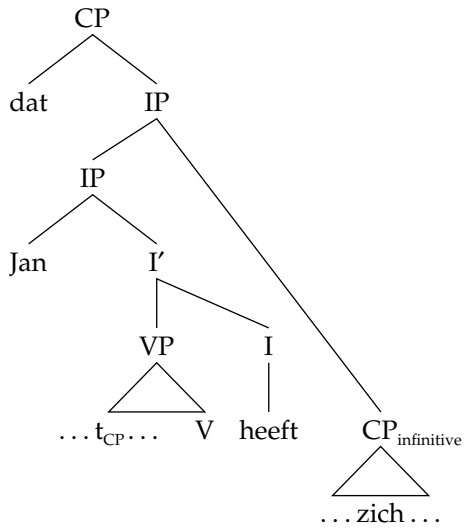
An important question arising from this body of facts is how the contrast in Binding possibilities between Scandinavian VO and Dutch/German OV languages follows. As we saw, reporting an observation by Everaert (1986b), in Dutch and German *zich/sich* in *to*-infinitives cannot be bound from the outside, as illustrated in the Dutch example (38), whereas in causative or perception verb complements they can, as in (39). In Scandinavian languages, Binding is possible into both types of clauses:

(38) Ik hoor dat Jan_i Piet gevraagd heeft een boek voor $zich_{*i}$ mee te brengen.
I hear that John Peter asked has a book for zich to bring
'I hear that John has asked Peter to bring a book for him.'

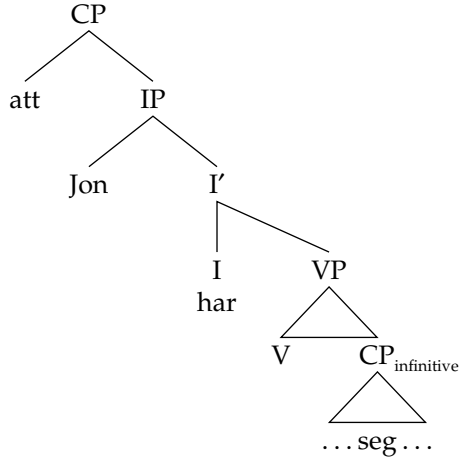
(39) Jan_i hoorde Marie een lied voor $zich_i$/hem_i fluiten.
John heard Mary a song for SE/him whistle
'John heard Mary whistle a song for SE/him.'

Everaert (1986b) was the first to propose that this contrast follows from a difference in the configuration involving binder, matrix verb, and bindee, due to a difference in the position of attachment of the infinitival clause in OV/VO languages (using a framework in which the base position of the infinitival clase is to the left of the verb in OV languages, and to its right in VO languages). Reinhart and Reuland (1991) implemented this idea as follows. The embedded clause originates to the left of the verb, and is subsequently extraposed, leaving the trace indicated by t_{CP} in (40) (using the then standard idea of rightward extraposition). If the extraposed *te*-clause moves to the right of the finite verb in Dutch (there is no possibility of attachment between V and I), the lowest available attachment site is that of adjunction to IP; thus the clause must end up higher than the finite verb, as indicated in (40a), omitting details. *Zich* and any verb within $CP_{infinitive}$ it attaches to are not c-commanded by the higher V-I complex (e.g., *heeft* in (40)). Hence, they cannot form a chain headed by a higher I/AGR using the procedure illustrated in (35). This makes it impossible for *zich* to be interpreted. In Scandinavian, being VO, the complement clause stays in the VP (possibly after VP-adjunction) and is c-commanded by I, so the necessary chain can be formed. This is illustrated in (40b):

(40) a.



b.



The general structure of this account is thus based on the idea that the OV structure creates a discontinuity in any chain-type dependency between anaphor and antecedent that is mediated by the governing verb of the constituent containing the anaphor. As such it is independent of the specific mechanism for chain formation assumed.

This particular implementation depends on the assumption that there is rightward movement/extraposition of *te*-infinitives. As is well known, this assumption is incompatible with most versions of current syntactic theory.[12]

However, Everaert's insight that the OV structure creates a discontinuity prohibiting the establishment of the relevant dependency is not dependent on this particular implementation. In the next section it will be shown that it can also be implemented in theories without extraposition.

The other contrast between the OV and the VO languages concerns the impossibility of LD Binding of direct object *zich/sich* in Dutch and German (and indirect object *sich* in German) even in small clauses. This fact is also discussed in Everaert (1986b) (see also Reis 1976). Everaert notes that overt verb raising applies in Dutch and German, but not in the Scandinavian languages. On the basis of this fact Everaert proposes that the contrast can be reduced to a difference between full verbs and verb traces as licensers of anaphors. It will be interesting to investigate to what extent this view of the contrast can be maintained in current conceptions of clausal structure.

4 Conclusion: long-distance Binding and Minimalism

There is a tension between the requirement that arguments require a full specification of phi-features in order to be interpreted, and the fact that logophoric *sig* in Icelandic can be interpreted without an overt source for phi-features. This tension can be resolved by abandoning the requirement of full specification. This is discussed in chapters 33 and 38.

The general line that SE-anaphors move in order to acquire phi-features is also problematic from the perspective of the Minimalist program (Chomsky 1995c, 2000, 2001b), insofar as it is based on a self-serving movement of the anaphor that is not triggered by an independent requirement of feature checking. In this respect, a composite movement in which the anaphor associates with a verbal projection for Case checking, and the verbal projection moves further for independent reasons, holds more promise.

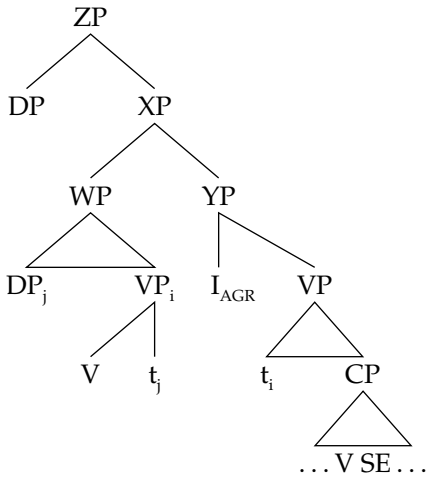
Any approach should do justice to the fact that these anaphoric dependencies are sensitive to variable properties of syntactic structure. That is, at least part of the computations involved is carried out within the computational system of human language in the Chomsky (1995c) sense (C_{HL}). This requires implementing subsystems of Binding in terms of merge, move, and check. Also, any analysis should enable one to capture the role of the SOV/SVO contrast. For sake of concreteness, let's therefore assume that establishing a syntactic dependency with the antecedent is at least the preferred mode of interpretation of SE-anaphors (see Reuland 2001), and that this is accomplished by movement and chain composition (Chomsky and Lasnik 1993), leaving aside the precise specification of the triggers.

What most current approaches to the phrase structure of Germanic SOV languages have in common is that an 'extraposed' clause is in fact assumed to have been left behind in a low position by movements depleting the original verb phrase from verb and nominal arguments, where the latter material actually moves higher in the structure. There are two types of approach: one in which the VP gets depleted by a combination of head-movement and XP-movement, the other in which there is only XP-movement; cases where prima facie only V is

moved are analyzed as involving moving a remnant VP (as for instance in Koopman and Szabolcsi 2000). For reasons of space it will not do to go into the details of the various extant analyses. It is important to note that there is a considerable class of analyses that all share the following structural pattern (for ease of exposition I am using traces and X'-notation with some unspecified labels in the representations; no theoretical status should be attributed to these notations).

In an SOV structure there is at least one step in which a phrase, properly containing the verb that originated as a sister to the complement clause, moves up to a position to the left of its inflection:

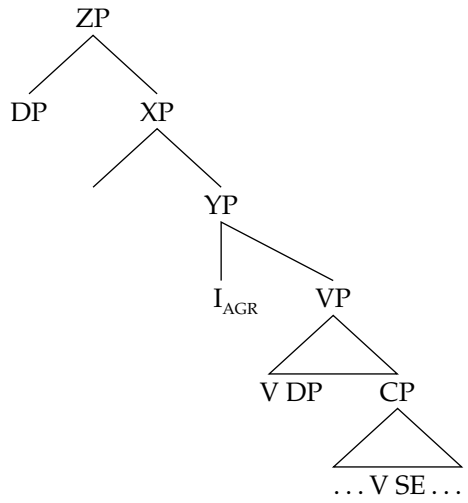
(41)



Suppose this position is combined with our earlier assumption that the verb must mediate in forming a chain-based relation between SE-anaphor and I_{AGR} and subsequently the antecedent. For the sake of concreteness, one may assume that this is accomplished by post-cyclic chain composition along the lines discussed by Chomsky and Lasnik (1993) and subsequently Reuland (2001). It is easily seen that moving the verb (or a constituent containing it) from the sister position of the infinitival clause (indicated by t_i), crossing I_{AGR}, disrupts the possibility of forming a DP, I_{AGR}, V, . . . SE chain. Assume that a dependency (checking relation, or agreement) holds between DP and I_{AGR}. The next link in the dependency cannot be V, since it moved across. It cannot be t_j either, since, being the tail of the V-constituent that crossed I_{AGR}, it is inert. Hence, t_j cannot participate in the formation of the dependency. Other options are equally unavailable, hence forming the dependency is blocked, and SE in the lower clause cannot be syntactically linked to the matrix DP.

In the Scandinavian SVO languages the verb stays to the right of inflection, hence lower than the latter. Since there is no crossing, nothing prohibits the matrix V from mediating in establishing a chain relation between SE and the matrix I_{AGR} and subsequently the subject:

(42)



Precisely because in small clauses and bare infinitivals in Dutch and German, no 'extraposition' structures obtain, binding into these constructions is possible, except when some other process interferes. Further research is necessary to determine how Yiddish could fit in with this pattern.

Obviously, this sketch can be no more than a suggestion, since the details of timing and computation need more justification than can be provided here.

A precise analysis clearly depends on a very important issue, namely the identity of the precise mechanism involved in establishing a dependency between anaphor and antecedent. In principle, the process that previous analyses analyze as LF-movement of SE-anaphors can be implemented as feature movement in the sense of Chomsky (1995c), triggered by standard checking requirements involving EPP and Case (as, for instance, in Reuland 2001) followed by chain composition. Alternatively, the basis of the dependencies could be found in the AGREE relation (Chomsky 2001b). Hornstein (2001) and Kayne (2002) develop analyses in which at least some Binding relations are directly encoded by movement. Discussing these implementations would carry us beyond the scope of this chapter, and will have to wait for another occasion.

NOTES

I would like to thank Patrick Brandt, Martin Everaert, and two anonymous reviewers for their very helpful comments. The usual disclaimers apply.

1 Note that the first GB account of the contrast between local and long-distance binding is Giorgi (1984), which is mainly based on Italian.
2 I will put aside reciprocals, since they would not add much to the main issues that should be discussed.
3 The subscript *0* indicates that the pronominal is free.

4 Non-local antecedents of *selbst*-forms are illustrated in (i) and (ii), provided by an anonymous reviewer:

(i) Ich möchte nicht dass Hans für jemand anderen arbeitet. *Ich* möchte dass er für *mich selbst* arbeitet.
'I do not want John to work for somebody else. I want him to work for myself.'

(ii) Hans will nicht, dass ich für jemand anders arbeite. Deshalb lässt er mich nur für sich selbst arbeiten.
'John does not want me to work for somebody else. Therefore he lets me work only for himself.'

Note that in these cases the *selbst*-form is heavily focused. The precise role of structure vs. focus still merits further investigation. As the reviewer points out, *selbst* combines with third person pronouns as well, but there is no reason to treat such forms as anaphors (or logophors).

5 See, among others, Reis (1976), Everaert (1986b), and Gunkel (2003) for discussion of the German facts. I would like to thank Patrick Brandt (p.c.) for help with the data.

6 Some speakers marginally allow this reading, however. An anonymous reviewer points out that there is one type of exception to this locality pattern. It involves ECM constructions in which the embedded verb is non-agentive, as illustrated in (i):

(i) a. ?Hans$_i$ sah sich$_i$/*ihm$_i$ den Gegner unterliegen.
John saw SE/him$_{DAT}$ the opponent$_{ACC}$ underlie
'John saw that the opponent was being defeated by him.'
b. Sie$_i$ liess sich$_i$/*ihr$_i$ die Sonne ins gesicht scheinen.
She let SE/her the sun in the face shine
'She let the sun shine in her face.'

As the reviewer notes, there is extensive discussion of these data in the literature, with disagreement on their grammaticality (see among others Reis 1976; Grewendorf 1983, 1989; Gunkel 2003).

7 Gunkel (2003) attributes the difference to the semantic status of the prepositions involved. Notice, however, that some further factors may have to be controlled for in order to obtain the full picture. Patrick Brandt (p.c.) reports that if *nur ungern* is omitted from (27a) the contrast gets much sharper, as in (i), and similarly if one has the DP–PP order as in (ii):

(i) Karl$_i$ liess uns über *sich$_i$/ihn$_i$ schimpfen.
Charles let us at SE/him scold
'Charles let us scold him.'

(ii) Karl$_i$ liess mich ein Päckchen zu ??sich$_i$/zu ihm$_i$ schicken.
Charles let me a package to SE/him send
'Charles let me send a package to him.'

Further research will no doubt shed more light on these contrasts.

8 I am very much indebted to Sten Vikner (p.c.) and Beatrice Santorini (p.c.) for their help in clarifying the status of Yiddish.

9 With Borer (1989), one may assume that both infinitival and finite INFL are associated with AGR, which is anaphoric in the former case. Anaphoric AGR bears phi-features just like finite AGR; hence it is equally suitable as a 'host' supplying these features to the SE-anaphor. In order to allow subjects of small clauses as antecedents of SE-anaphors, we have to assume that small clauses carry AGR too. Much of the current literature makes this assumption, although direct empirical arguments like those for anaphoric AGR in infinitival clauses are lacking.

10 Note that we are assuming that SE-movement is an instantiation of canonical head-movement. Although it may be tempting to equate SE-movement with clitic movement of some sort, clitic movement seems to be freer (see Kayne 1990 for discussion), and may well be a different phenomenon. (It certainly involves different conditions; also witness the fact that languages may have SE-anaphors without having true clitics.)

11 This has no effect on the verb's interpretation, since SE is neither a reflexivizer nor a clitic which satisfies a grid position lexically; it just leaves the relevant thematic position unsaturated, until it receives phi-features.

12 As noted by an anonymous reviewer, another problem appears to be posed by the fact that at least German CP-infinitives (*zu*-infinitives) need not be extraposed. Yet in these structures also long-distance Binding from outside the *zu*-infinitive is prohibited, as illustrated in (i):

(i) dass Hans_i uns_j $[_{CP}$ PRO_j ihm_i/*sich_i ein Buch mitzubringen] bat

Pursuing this issue would lead us beyond the scope of this chapter, however.

1 Introduction

Our current understanding of 'locality' conditions on movement goes back in one form or another to Ross's (1986) Constraints on Variables in Syntax (originally a 1967 PhD dissertation), and Chomsky's (1973) Conditions on Transformations. We will here follow the tradition of Ross and Chomsky in analyzing these relations in terms of 'movement', although the issues we explore arise in similar fashion under alternative approaches to these long-distance relations. Ross claimed that movement is essentially unbounded (limitations arising from islands). By contrast, Chomsky argued that movement is required to take place in short successive steps. As we will see, the issue re-emerges in the most modern version of generative grammar, the Minimalist program. For the phenomenon we investigate here, long NP-movement, we take Chomsky's view as a starting point, since it has been so influential.

'Long NP-movement' is an umbrella term for cases of non-local A/NP-movement,[1] where the locality factors are traditionally considered to be (i) tense

(1), and (ii) the presence of a subject (2), reflexes of Chomsky's (1973) Tensed-Sentence Condition (3), and Specified-Subject Condition (4) respectively:

(1) *Mary is believed ___ like**s** John.

(2) *John is believed **Mary** to like ___ .

(3) **Tensed-Sentence Condition (TSC):**
No rule can involve X, Y in
. . . X . . . [$_{\alpha}$ . . . Y . . .] . . .
where α is a finite clause.

(4) **Specified-Subject Condition (SSC):**
No rule can involve X, Y in
. . . X . . . [$_{\alpha}$Z . . . Y . . .] . . .
where Z is the subject of α.

One of the major discoveries of the early 1970s was that in certain central respects, NP-movement obeys the same constraints as the process associating an anaphor with its antecedent. Chomsky's (1973) explanation was that this fact is simply a special case of the generalization that all rules obey (3) and (4). The significance of such an approach was that it allowed for a great reduction in the descriptive power of transformations, leading ultimately to the modern notion of Move α. Thus, (1–2) are similar to (5–6):

(5) *Mary believes [*herself* **is** likely to win the race].

(6) *Mary believes [that **John** likes *himself*].

Chomsky's approach by no means claimed that NP-movement and anaphor binding are a 'natural class' of processes. They pattern alike only because all rules of grammar behave this way. Of course, in Chomsky (1973), it was noted that pronominal coreference did not in fact obey the constraints, and *wh*-movement obeyed them only by stipulation. Moreover, the constraints were specifically stated in such a way that (COMP-to-COMP) movement was granted an exemption. Apparently, certain rules had to be designated as obeying the constraints, others as not obeying them.

Chomsky (1976) proposed an alternative. There is exactly one type of rule conforming to the constraints, namely, rules of construal (which concern themselves with antecedent relations). Other rules are not constrained (if we set aside Lasnik's 1976 Rule of Disjoint Reference). Thus, NP-movement itself is not constrained. Rather, the 'trace' left behind by movement is an anaphor, subject to the same rule of construal as any other anaphor. This approach ultimately led to Binding Condition A (Chomsky 1981):

(7) **Binding Condition A:**
An anaphor must be bound in its governing category (GC) (where GC is defined in terms of tense and subject).

For Chomsky (1973), some instances of long-distance movement fell under the purview of Subjacency:

(8) **Subjacency:**
No rule can involve X, Y, if Y is not subjacent to X. (Y is subjacent to X if they are contained in all the same cyclic categories [clause or NP] or if they are in adjacent cyclic domains.)

But, at the time, there was no particular application of Subjacency to NP-preposing, presumably because SSC and TSC imposed tighter constraints. With the Chomsky (1981) reformulation and incorporation of SSC and TSC into Condition A of the Binding Theory, Subjacency did become potentially relevant to NP-preposing, particularly the instances which came to be known as 'superraising', a name due to Guiseppe Longobardi. We turn to these instances now.

2 Superraising

The first published discussion of the phenomenon appears in Chomsky (1981: 58). Chomsky presents the following example, of a type reportedly considered by Longobardi:

(9) *John seems [that it is certain [*t* to like ice cream]].

According to Chomsky, Longobardi noted the potentially problematic nature of such examples. The name 'superraising' was by analogy with the super-Equi of Grinder (1970), illustrated in (10):

(10) John_i said that it would disturb Sue [PRO_i to make a fool of himself in public].

But while Equi (i.e., control of PRO) is possible at a distance (in particular, across an expletive subject), raising is evidently not, and that is Chomsky's concern. Chomsky reasons that the trace *t* in (9) is governed, satisfying one of its requirements, and its antecedent is in a non-theta-position, satisfying another. He concludes that Subjacency is responsible for the ungrammaticality of (9). Chomsky mentions, but immediately rejects, the possibility that (9) is an SSC (later in the book incorporated into Condition A) effect: "While there are, as we shall see, binding theory violations of a structural form similar to [(9)], they seem very different in level of acceptability from the completely ungrammatical [(9)], indicating that [(9)] is not a binding theory violation" (1981: 58). Chomsky does not

explicitly spell out this point either here or later in the book, but he presumably has in mind the kind of example he discusses on (1981: 214):

(11) They think it is a pity that pictures of each other are hanging on the wall.

The point is that the distance between *each other* and its antecedent *they* here is comparable to or greater than the distance between *t* and its antecedent *John* in (9). Thus, even under the Chomsky (1981) assumption that the trace of NP-movement is an anaphor, Condition A of the Binding Theory, repeated in (12), cannot handle (9) without incorrectly ruling out (11):

(12) An anaphor must be bound in its governing category.

There is one other construction on which the Chomsky (1973) and Chomsky (1981) accounts diverge. As Lasnik (1985) pointed out, (13) is indistinguishable from (14), as far as TSC and SSC are concerned:

(13) *John$_i$ is believed [that he$_i$ likes t_i].

(14) *John$_i$ is believed [that Mary$_j$ likes t_i].

The movement of *John* in both examples unequivocally violates both TSC and SSC, since the movement is out of the bracketed finite clause, and is across a subject. Yet in (13), unlike in (14), the trace left by movement conforms to (12): the governing category of *t* is the embedded S, and in that embedded S *t* is bound by *he*. Lasnik (1985), extending the ideas of Rizzi (1986b), proposes to account for (13) by the condition in (15), from Chomsky (1981: 333):

(15) Where α_i,α_{i+1} are successive members of a chain, α_i must locally bind α_{i+1}.

In (13), this condition is violated since *he*, rather than *John*, locally binds *t*. Hence, *John* and *t* cannot constitute a chain, and the theta-criterion is violated. Chomsky (1986b) also proposed an analysis of examples like (13) in terms of a chain requirement, but a different one: that a chain can't contain two Case positions.

3 An ECP account

As noted above, Chomsky (1981) proposes that Subjacency is responsible for the unacceptability of superraising examples as in (9), repeated here as (16):

(16) *John seems [that it is certain [*t* to like ice cream]].

Chomsky's initial argument for a Subjacency account was that (16) is worse than a typical Condition A violation. However, as observed by Lasnik and Saito (1984),

it is also worse than a typical Subjacency violation. They go on to point out, following an observation of Chomsky's, that (16) falls under their formulation of the Empty Category Principle (ECP), a constraint that typically results in severe degradation. The ECP was first formulated in Chomsky (1981), and has undergone many changes. For present purposes, let us adopt the following formulation, approximately that of Lasnik and Saito:

(17) **Empty Category Principle:**
A trace must be properly governed.

In Lasnik and Saito's formulation, there are two ways to satisfy the proper government requirement, roughly as follows:

(18) **Lexical government:**
α, a lexical head, lexically governs β iff α governs β and α assigns Case or a theta-role to β.

(19) **Antecedent government:**
α antecedent-governs β iff α binds β and α and β are not separated by an S' boundary (unless β is in Comp).[2]

A sentence like (1) (repeated here as (20)) is redundantly ruled out by the ECP, since it also violates Condition A of the Binding Theory, but we saw that other cases of illicit NP-movement are not ruled out by Condition A:

(20) *Mary is believed [*t* likes John].

The trace in (20) is not properly governed. It is certainly not a complement of any head, lexical or otherwise, and it is not in a position Case-marked by a lexical head. Furthermore, its binder is too far away: *John* is outside the minimal S' containing *t*, and *t* is not in Comp. So (20) violates the ECP. (20) contrasts with the standard raising construction in (21):

(21) Mary is believed [*t* to like John].

From the definition given above, the trace in (21) is not properly governed by *believed*, since this trace is not a complement to *believed*. However, under the Lasnik and Saito formulation, antecedent government is satisfied, since the only S' that contains the trace is the entire S', given that (21) is an 'S'-deletion' configuration. On the other hand, the superraising example, repeated here as (22), is correctly excluded:

(22) *John seems [that it is certain [*t* to like ice cream]].

Note that if lexical government were simply government by a lexical head, (22) would be ruled in. Since *certain* governs the trace in (22) (S' not being a barrier

to government), it would lexically govern this trace. Under the more restrictive definition in (18), *certain* cannot properly govern the subject position of the lower clause because it assigns neither a theta-role nor Case to it. However, as Lasnik and Saito (1992: 129) note, there are examples of superraising that do not readily fall under their ECP account. One such case (attributed to Mark Baker) is shown in (23):

(23) *John seems [that it was told *t* [that Mary was a genius]].

This example involves raising of *John* from the object position of *told* to the matrix subject position, and is clearly ungrammatical. But unlike the trace in (22), *t* in (23) satisfies the ECP as stated above, since it is theta-marked, and hence lexically governed, by the verb *told*. Note that this trace is not antecedent-governed, since its antecedent is too far removed from it. Given this fact, Chomsky (1986a) suggests that all traces must be antecedent-governed regardless of whether they are lexically governed or not (see also Jaeggli 1982; Koopman and Sportiche 1985; Stowell 1986; Aoun et al. 1987).

4 Relativized Minimality

At this point, we turn to the major post-*Barriers* analysis of long NP-movement, viz. Rizzi (1990b), which also plays a crucial role in recent 'Minimalist' versions of locality. The essence of Rizzi (1990b) is a locality notion of 'Relativized Minimality'.

Rizzi's condition differs from previous ones in that it pays crucial attention to the type of position targeted for movement. Roughly speaking, Relativized Minimality prevents a syntactic dependency from being established across an intervening element of the same kind, since the intervening element would be a closer antecedent for the lower position in the dependency. Thus, the dependency in (24) is blocked if Y is a potential antecedent for Z (where potential antecedenthood is independent of indexing):

(24) . . . X . . . [. . . Y . . . Z . . .]

(24) can be seen as a generalization and extension of the condition in (15).

Rizzi investigates three kinds of syntactic dependencies, based on the types of positions involved: A-chains (the concern of this chapter), A-bar chains (operator-variable chains), and head-chains. Rizzi argues that dependencies like those in (25) are ill-formed because they are blocked by an intervening potential antecedent, the boldfaced item in each example:

(25) a. *John seems [that **it** is likely [*t* to win]].
b. *How do you wonder [**whether** [to solve the problem *t*]]?
c. *Have they **could** [*t* left]?

Under this view, superraising as in (25a) arises when an element moving to a subject position (i.e., an A specifier position) crosses another A specifier position.

As mentioned above, Relativized Minimality is an extension of the locality constraint in (15), first formulated by Chomsky (1981) and further developed by Rizzi (1986b). Rizzi (1986b) argued that a well-formed A-chain cannot be established across an intervening argument with the same 'referential index'. This configuration is schematized in (26), where Y blocks the dependency between the co-indexed X and its trace *t*. Let us follow McGinnis (1998), and refer to this type of condition as Indexical Locality:

(26) $\ldots X_i \ldots [\ldots Y_i \ldots t_i]$

Although similar in spirit to Relativized Minimality, Indexical Locality constrains dependencies only between elements with the same referential index, and not between elements of the same position type. In fact, even though Rizzi (1986b) does not discuss examples of the superraising type, Indexical Locality presupposes that an A-chain across an intervening A-position is well-formed. For example, Rizzi (1986b) contrasts ill-formed dependencies like (27) with well-formed ones like (28). By Relativized Minimality, however, depending on the details of the structure, one might expect that the A-chain between *Gianni* and its trace in (28) would be blocked by the intervening argument *gli*:

(27) *Gianni$_i$ non si$_i$ sembra t_i [t_i fare il suo dovere].
Gianni not SI seems do the his duty
'Gianni does not seem to himself to do his duty.'

(28) Gianni$_i$ non gli$_j$ sembra t_j [t_i fare il suo dovere].
Gianni not to-him seems do the his duty
'Gianni does not seem to him to do his duty.'

Rizzi's (1986b) explanation of the contrast between (27) and (28) has been applied to (abstractly) similar contrasts in Albanian (Massey 1990, 1992), and in German and Japanese A-scrambling (Miyagawa 1997; Yatsushiro 1997, 1999). We refer to Snyder (1992) and McGinnis (1998) for extensive discussion, and ramifications.

5 Raising across experiencer

A second potentially problematic case for Relativized Minimality is the possibility of raising into a higher clause past a non-clitic experiencer, as in (29):

(29) John seems to Mary [*t* to be the best].

The experiencer appears to be in an A-position c-commanding into the embedded clause, since the quantified DP experiencer *every poet* in (30a) can bind the pronoun *his* in the embedded clause, yielding the following interpretation: for each poet P, John seemed to P to be P's most devoted admirer. Further evidence appears in (30b), where the experiencer pronoun gives rise to an apparent Condition C effect:

(30) a. John seemed to every$_i$ poet [*t* to be his$_i$ most devoted admirer].
b. *Mary$_j$ seemed to him$_i$ [t_j to like John$_i$].

Further, the construction is reasonably acceptable even if the raised subject binds an anaphoric experiencer, as in (31). Cases like this potentially violate both Indexical Locality and Relativized Minimality:

(31) John$_i$ seems to himself$_i$ [t_i to be beautiful].

As we will see, the problem posed by such examples persists in the Minimalist framework.

6 Economy

The guiding intuition to capture locality in an economy-based Minimalist framework has been that in "the 'bad' cases, some element has failed to make 'the shortest move.'" (Chomsky 1993: 14). This intuition follows directly from Relativized Minimality. In a classic superraising configuration such as the following, *John* has not made the shortest move, as it has bypassed the intermediate subject position occupied by *it*:

(32) *John seems that it is likely to win.

Standard TSC examples, such as (1) (repeated here as (33)), also have a derivation that can be excluded in this manner:

(33) *Mary is believed likes John.

Assuming the VP-internal subject hypothesis (VPISH), *Mary* has moved from the lower VP-internal position. If the movement is in one fell swoop, subject position

of the lower clause is skipped, in violation of shortest move. However, it is also obvious that (33) is also excluded on standard Minimalist assumptions concerning movement and feature checking: all movement must be assumed to be triggered by feature-checking requirements. When the subject moves in one fell swoop from its base position (internal to the lowest VP) to matrix SpecIP, this creates the right configuration for checking the features (Case and agreement) of matrix I, and satisfies the Extended Projection Principle (EPP)[3] in that matrix clause, but leaves the features of embedded I unchecked, and the EPP requirement of its clause unsatisfied. This derivation, therefore, is independently excluded without appeal to locality/shortest move.

An alternative derivation might involve successive-cyclic movement, with *Mary* first moving to the Spec of the embedded IP. However, in this instance, the Case feature of the matrix finite Infl will not be checked even when *Mary* moves to the higher Spec, as the nominative Case feature of *Mary* has been checked off.[4]

Ura (1994, 1996) refers to cases like (33) as 'hyperraising'. Impressionistically, hyperraising stands for cases where an element appears to have done too much checking; superraising stands for operations which move an element across a closer potential checker. The conception of checking and movement underwent a substantial change in Chomsky (1995b). Chomsky (1995b) distinguishes between uninterpretable and interpretable features. According to Chomsky, only uninterpretable features (e.g., Case) are inaccessible after checking. Interpretable features (e.g., agreement and categorial features of a nominal expression) can participate in more than one checking operation (see Lee 1994 for further development). As for Move, Chomsky proposed a change in perspective, arguing that movement is better conceived of in terms of 'attraction'. That is, movement is driven by the needs of the position to which movement takes place. Shortest move is thus reconstrued as 'closest attract' (see also Oka 1993).

The change from Move to Attract is more than a mere terminological one. It allows a reduction in computational complexity (shifting from a global to a more desirable local type of Economy). This is so since the ultimate position where a moving item will have its features checked may be many derivational steps away from the initial position of that item. Thus, from the point of view of the moving item, all of the steps of movement prior to the final one are locally gratuitous, contributing only toward a future need. If, on the other hand, each position to which movement takes place has a requirement (e.g., the EPP) that must be satisfied, that need is determined immediately at that point of cyclic derivation.

The interpretable/uninterpretable-feature distinction meshes with this view of movement if, as suggested by Chomsky (1995b), the EPP is satisfied by the categorial D feature of a nominal expression. In successive-cyclic movement, the intermediate checking operations do not cause the moving element to lose its feature, and thereby that feature remains accessible for further attraction.

There is one type of hyperraising that is not yet accounted for. Recall that in the standard instances, such as (33) above, in the path of movement there are two (or more) Case positions. Assuming the Case feature of *Mary* is checked off in the

lower Spec of IP, the matrix Infl will wind up with its Case feature unchecked. Alternatively, if the lower Spec of IP is skipped, its Case (and agreement and EPP) features will remain unchecked. One might then expect that A-movement from a Case position to a non-Case position would be possible. But it is not:

(34) *Mary's belief [John to be likely [*t* will win]].
cf. Mary's belief that John is likely to win.

Note that the clausal analogue of (34) is easily accommodated:

(35) *Mary believes [John to be likely [*t* will win]].

Here, the accusative Case feature of the matrix verb *believe* will not be checked, since *John* must have checked the nominative Case feature of the embedded finite Infl. But in (34), there is no such Case feature in the matrix, since nouns have no structural Case feature. This is evidenced by the contrast in (36):

(36) a. Mary believes John to be likely to win.
b. *Mary's belief John to be likely to win.

Another type of example abstractly displays the same problem. Eduardo Raposo notes (p.c. to Noam Chomsky; see also Raposo and Uriagereka 1996: 775, fn. 35) that Chomsky's (1995c) system incorrectly rules in a particular variant of superraising:

(37) *It seems [that *t* was told John [that IP]].

Raising of *it* to matrix Spec of IP is evidently legitimate, because its interpretable EPP/categorial feature still makes it accessible for further computation. Having lost its Case feature in the embedded clause, *it* cannot check the uninterpretable Case-feature of matrix Infl. But as Raposo observes, it is still possible to raise *John* (or its relevant formal features) in the LF component to check the Case features of both matrix finite Infl and *John*.[5] No uninterpretable features remain unchecked (being interpretable, the categorial/EPP features of *John* need not be checked), so the derivation converges, incorrectly in this instance. To rule out this possibility, Chomsky (2000) postulates that an element having checked its Case features cannot be 'attracted' for mere EPP-checking. In particular, Chomsky argues that the role of Case in the grammar is to make an element visible for Attraction (of the A-movement sort). This correctly rules out (37): having checked its Case features, *it* cannot Move to matrix I. The uninterpretable Case feature of matrix I remains unchecked, causing the derivation to crash.

Note that care is required if we are to continue to rule out the classic superraising configuration, as in (23), repeated here as (38):

(38) *John seems [that it was told *t* [that Mary was a genius]].

Even though *it* is no longer a potential attractee (having already checked its Case), it must still count for the purposes of closest Attract, thus preventing the attraction of *John*, an instance of what Chomsky (2000) calls 'defective intervention'.

7 Equidistance

Chomsky (1993: 182ff.) considers an apparent instance of superraising (a violation of the 'Shortest Movement' requirement) that arises in the context of his claim that an object NP must raise to SpecAGRoP to check off its Case feature. The combination of an Object-related functional projection (AGRoP) outside of VP and the VPISH gives rise to a situation where the object must cross either the subject or its trace (depending on the timing of Object raising):

(39) $[_{\text{AGRoP}}$ ___ $[_{\text{AGRo'}}$ AGRo $[_{\text{VP}}$ Subject-NP/$t_{\text{subject-NP}}$ $[_{\text{V'}}$ V Object-NP]]]]

To avoid a violation of Shortest Move, Chomsky proposes a mechanism of Equidistance according to which two targets of movement (i.e., two potential landing sites) are equidistant if they are in the same minimal domain. The minimal domain of a head H is (roughly) the specifier of HP and the complement of H. Crucially, Chomsky allows for the possibility of 'domain extension'; in particular, the minimal domain of H may be extended if H moves to a head X. When that happens, the minimal domain of the chain headed by H comprises SpecXP, SpecHP, and Complement of H (in addition to any adjoined elements, which we ignore here). Returning to (39), Chomsky's characterization of Minimal Domain and Equidistance allows for the object NP to move to SpecAGRoP across the subject NP or its trace without causing a Shortest Move/Minimality violation only if V moves to AGRo. Chomsky's Equidistance account has played a major role in the analysis of overt Object raising for Case (especially in instances of Object Shift in Scandinavian languages), since the operation appears to be tied to verb raising ('Holmberg's Generalization'; see Holmberg 1986 and much subsequent work). Contrast (40) and (41)[6] (we follow the literature in assuming that negation *ekki* marks the left-edge of VP):

(40) a. Jólasveinarnir borðuðu ekki búðinginn.
The Xmas troll ate not the pudding
'The Xmas troll didn't eat the pudding.'
b. Jólasveinarnir borðuðu búðinginn ekki.

(41) a. Jólasveinarnir hafa ekki borðað búðinginn.
The Xmas troll has not eaten the pudding
'The Xmas troll has not eaten the pudding.'
b. *Jólasveinarnir hafa búðinginn ekki borðað.
c. *Jólasveinarnir hafa búðinginn borðað ekki.

As an alternative to the admittedly complex definition of Minimal Domain and the relaxation of locality under Equidistance, several researchers (notably, Koizumi 1995 and Lasnik 1999a) have adopted a VP-structure in which AGRoP is located below the base position of the subject, the so-called 'Split-VP' hypothesis in (42):

(42) $[_{VP}$ Subject-NP $[_{V'}$ V $[_{AGRoP}$ AGRo $[_{VP}$ [V Object-NP]]]]]

If (42) is adopted, the issue of superraising in situations of overt Object raising is eliminated entirely.

8 Typological variation?

Given how 'deep' the principles are preventing long NP-movement, one would a priori expect such movement to be prohibited universally. However, Ura (1994, 1996) has presented evidence that many languages differ from English in accepting hyperraising and/or superraising constructions. The following are examples from Romanian (hyperraising; Grosu and Horvath 1984: 351) and Mandarin Chinese (Ura 1994: 10):

(43) a. S-a nimerit ca toţi băieţii să fie bolnavi.
refl-have.3sg hit-part that-subj all boys subj be-3pl.subj sick
'It happens that all boys were sick.'
b. Toţi băieţii s-au nimerit să fie bolnavi.
all boys refl-have.3pl hit-part subj be-3pl.subj sick
'All the boys happened to be sick.'

(44) a. Keneng Zhangsan reng le nei kuai rou gei la.
possible Zhangsan throw ASP that piece meat to he
'It is possible that Zhangsan tossed that piece of meat to him.'
b. Ta_i keneng Zhangsan reng le nei kuai rou t_i.
He possible Zhangsan throw ASP that piece meat
'He is possible that Zhangsan tossed that piece of meat.'

Ura argues that all languages that allow superraising or hyperraising also have 'multiple subject constructions', which, if analyzed as involving multiple specifiers, make all 'subjects' equally accessible to a higher target position, hence equally eligible for attraction. In this type of language, a nominal expression can escape from a clause by first moving to a specifier position in that clause. Note, though, that while that might permit derivations of superraising constructions, it does not suffice to allow hyperraising. For the latter construction, as Ura observes, it is necessary to weaken the normal requirement that a Case 'assigner' check a Case. He thus proposes that languages that allow hyperraising have optional Case-feature checking in certain circumstances. How to fit this naturally

into the Minimalist program is not entirely clear. However, see Zwart (1997b), where it is claimed that Ura's generalization about multiple Specs is spurious. Zwart explains away many of the problematic illicit NP-movements as cases of non-raising (hyperraising) or topicalization (superraising). Clearly, further research is needed in that area before theoretical conclusions can be drawn.

An area where the logic of Ura's account is widely assumed is double object constructions. It is now generally accepted that languages split into two groups when it comes to the behavior of the two objects in ditransitive structures (see Anagnostopoulou 2003 for a comprehensive survey and justification of the dichotomy). Some languages are said to be symmetric, allowing both objects to take part in the same set of operations (passivization, incorporation, reflexivization, etc.), while other languages are asymmetric: they invariably favor the indirect object (Goal NP) for syntactic purposes. On the basis of pairs like (45) and (46), English is characterized as an asymmetric language, whereas the Bantu language Kinyarwanda falls into the symmetric language type (data from Baker 1988a: 175):

(45) a. John was given the book (by Frank).
b. *The book was given John (by Frank).

(46) a. Umugore y-a-haa-w-e igitabo.
Woman SP-Past-give-Pass-Asp book
'The woman was given the book.'
b. Igitabo cy-a-haa-w-e umugore.
Book SP-Past-give-Pass-Asp woman
'The book was given (to) the woman.'

Anagnostopoulou (2003) shows in detail that the contrast between symmetric and asymmetric languages does not reduce to a Case difference (say, availability of inherent Case), and argues that the contrast must be accounted for in terms of locality. She follows Ura (1996) and McGinnis (1998, 2002) in taking the structure in (47) to be the base structure for ditransitives cross-linguistically:

(47) $[_{\text{VP-1}}$ Goal-NP [V-1 $[_{\text{VP-2}}$ V-2 Theme-NP]]]

The asymmetry observed in (45) falls out immediately from (47): the Goal NP is closer than the Theme-NP for movement. Symmetry of the type found in (46) arises from the possibility of 'leapfrogging': movement of the Theme-NP to an extra specifier position made available by V-1 (48):

(48) $[_{\text{VP-1}}$ Theme-NP $[_{\text{VP-1}}$ Goal-NP [V-1 $[_{\text{VP-2}}$ V-2 $t_{\text{Theme-NP}}$]]]]

Once the Theme-NP has moved to SpecVP-1, it can be targeted by syntactic processes taking it outside VP without superraising. The parametric difference between English and Kinyarwanda thus boils down to the availability of multiple VP-specifiers.

9 Experiencer paradox

Another item on the 'problematic' list for the Minimalist program was already a major stumbling block in the GB-era. It concerns cases of raising past an experiencer, as in (29), repeated here as (49):

(49) John seems to Mary [*t* to be the best].

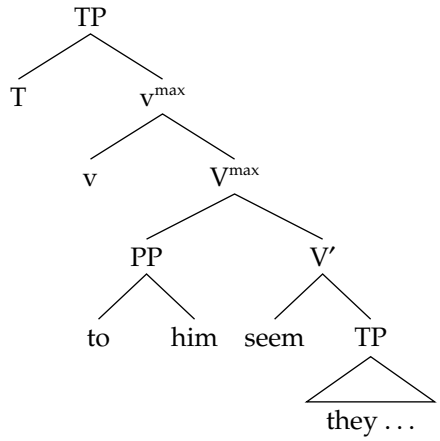
Chomsky (1995b) notes the problematic nature of these cases. He also notes, following work by Esther Torrego (1996, 1998), that some languages, like Spanish, behave as expected. That is, subject-raising past the experiencer is disallowed. Languages like French and Italian, where raising is allowed in some cases (when the experiencer is a clitic, for instance), contribute to make the area murkier still. Here, we will confine ourselves to the solutions to be found in the Minimalist literature for English, referring to Boeckx (1999) and McGinnis (1998) for discussion of the parametric issue.

Kitahara (1997) addresses the experiencer paradox, instantiated in (50), repeated from (30b) above, and suggests a derivational account, which is similar to one independently proposed by Ferguson (1994, 1996):

(50) Mary_j seemed to him_i [t_j to like John_i].

To ensure c-command by *him* into the embedded clause and thus account for the Condition C effect, and at the same time to allow raising of *they* out of the embedded clause and past *him*, Kitahara suggests that *him* does not c-command into the embedded clause at the point in the derivation when raising applies. Kitahara gives roughly the structure in (51), but his line of reasoning would be applicable on virtually any standardly assumed structure:

(51)



Assuming any of the usual definitions of c-command, in (51) *him* does not c-command *they*, since the PP-node dominates the former but not the latter. Raising is thus licit.

With respect to the disjoint reference effect, Kitahara assumes, following Chomsky (1993 and later works) that binding is an interpretive procedure established by inspecting LF. To achieve the relevant configuration, Kitahara suggests that *him* covertly raises and adjoins to P to check its Case. Following this movement, *him* c-commands into the embedded clause, which forces the disjoint reference effect. There is one immediate problem for Kitahara's account. Raising is evidently possible even across simple nominal experiencers. Parallel to (50), we find the following (which, following standard assumptions, we take to be a case of raising, although the evidence is less clear than in (49)):

(52) John strikes Mary [as *t* being the best].

And here too, there is evidence that the experiencer c-commands into the clausal complement:

(53) *They strike him$_i$ [as *t* being angry at John$_i$].

Perhaps one could argue that contrary to superficial appearances, *him* in (53) is contained in a PP, but one headed by a null P. Kitahara's account could then be maintained.

There is also a somewhat more abstract problem with Kitahara's account. Kitahara's account crucially relies on the a priori reasonable assumption that covert movement of a nominal expression can affect anaphoric possibility. However, Lasnik (1995b) argues that such movement does not affect anaphoric (or any other) interpretive relations. First, some background is in order. In a series of writings, beginning with Chomsky (1986b), Chomsky argued that the 'associate' of *there* undergoes some sort of covert raising in such a sentence as (54):

(54) There is a man here.

This provides the basis for an account of the familiar superficially bizarre agreement paradigms displayed by these constructions, with the verb agreeing with something that is not its formal subject:

(55) a. There is/*are a man here.
b. There are/*is men here.

But, as is well known, for all anaphoric purposes, the associate behaves as if it is in situ. The following data (based on Den Dikken 1995a; see Lasnik and Saito 1991 for similar examples in Exceptional-Case-Marking (ECM)/subject-to-object-raising-contexts like *John believes there to be a man in the room*) are representative:

(56) a. *Some applicants* seem to *each other* to be eligible for the job.
b. *No applicant* seems to *his* interviewer to be eligible for the job.

(57) a. *There seem to *each other* to be *some applicants* eligible for the job.
b. *There seems to *his* interviewer to be *no applicant* eligible for the job.

10 Feature movement

The movement theory of Chomsky (1995c) provides a rather natural resolution of this near contradiction, as discussed by Lasnik (1995b). Chomsky argues that when movement is for feature-checking purposes (perhaps always the case), a priori only formal features ought to move. For overt movement, Chomsky suggests that this will cause morpho-phonological problems. Hence, overt movement will typically demand the 'pied-piping' of an entire word or phrase. Covert movement, on the other hand, does not feed into the phonological component, so the more economical movement of mere formal features is possible, hence necessary. Under the reasonable assumption[7] that mere displacement of formal features (leaving behind the semantic properties of the item) is not enough to affect semantic relations, the contrast between (56) and (57) is explained. In the former examples, an entire expression, referential properties and all, has moved; in the latter, only formal features have moved, so the anaphor in (57a) and the bound variable pronoun in (57b) are unlicensed.

Returning now to Kitahara's account, we see that his covert/feature movement must affect binding relations: that is crucial to capture the Condition C effect. But there is no immediately obvious way to distinguish Kitahara's raising from that in the existential sentences. Perhaps the essence of Kitahara's account could be captured with not the nominal expression undergoing covert movement, but rather the preposition. If a preposition P were to be analyzed as just a bundle of formal features (rather plausible for *to*), covert 'incorporation' of P into the verb arguably could affect the c-command relations between the complement of that P and items outside the PP.

Feature communication triggered another proposal in the realm of A-movement. Manzini and Roussou (2000) suggest that A-movement does not exist. Rather, A-elements are base generated in their surface positions, and attract theta-roles (conceived of as features, as suggested by Lasnik 1995c). For superraising, Manzini and Roussou's proposal faces the same problem as the more conventional view of A-movement. To exclude superraising, Manzini and Roussou adopt the following principle, dubbed Scopal MLC (Minimal Link Condition):

(58) **Scopal MLC:**
A target attracts everything down to the next attractor.

As Boeckx (2000) shows, this is still inadequate in dealing with the raising-past-experiencer cases just discussed.

Note that conceiving of theta-roles as movement features brings control into the realm of raising, and suggests the possibility that Rosenbaum's (1967) Minimal Distance Principle, stated in more modern terms in (59), should be looked upon as a special case of Relativized Minimality, or one of its minimalist instantiations, as Hornstein (1999) argues:

(59) **Minimal Distance Principle:**
The subject of an infinitival complement of a predicate P selects as its controller the minimal c-commanding noun phrase in the functional complex of P.

If something like this is correct, the longstanding puzzle of shifting control (Farkas 1988, etc.) might fall under the purview of variation with respect to superraising. (For further discussion, see Boeckx and Hornstein 2003; Hornstein 2003.)

11 Agree

In 2000, Chomsky sharpened the Move-F account. Despite its adequacy in dealing with data like (57), feature movement raises a series of non-trivial technical questions. In particular, feature movement takes the form of (head-)adjunction, which violates the Minimalist conception of the Cycle known as the Extension Condition, the requirement that all operations expand the Phrase Marker. Chomsky (2000) dispensed with feature movement as such[8] and proposed the operation Agree to capture the essential effects of feature movement.[9] Agree amounts to a process of long-distance feature checking (or valuation) with no displacement. The configuration in which it obtains is very reminiscent of the notion of long-distance government under c-command (see especially Raposo and Uriagereka 1990). In an Agree analysis, a Probe (attractor) searches inside its c-command domain for a Goal (attractee) with a matching feature. Once the Goal is found, it checks the features of the Probe, triggering agreement. Viewed in this light, covert 'movement' (long-distance agreement) is decomposable into a Matching and a Checking/Valuation procedure.

Since Agree is taken to underlie Move (see Chomsky 2000, 2001b), we expect it to be subject to the same locality constraints. In particular, we expect no 'Super-agree'. The restriction on Japanese object (honorific) agreement discussed in Boeckx and Niinuma (2004) offers a relevant case.

The basic facts are as follows: if the verb is transitive and the object is of the relevant sort (appropriate social rank vis-à-vis the speaker, say), object agreement (here glossed as OH, short for Object Honorification) obtains (60). If the verb is ditransitive, the verb agrees in honorification with the indirect object (61). Crucially, the direct object is inaccessible for agreement in such cases even if it is of the relevant sort, and the indirect object isn't (62):

(60) Taro-ga Tanaka sensei-o o-tasuke-si-ta.
Taro-Nom Prof. Tanaka-Acc help-OH-past
'Taro helped Prof. Tanaka.'

(61) Hanako-ga Tanaka Sensei-ni Mary-o go-syookai-si-ta.
Hanako-Nom Prof. Tanaka-Dat Mary-Acc introduce-OH-past
'Hanako introduced Mary to Prof. Tanaka.'

(62) *Hanako-ga Mary-ni Tanaka Sensei-o go-syookai-si-ta.
Hanako-Nom Mary-Dat Prof. Tanaka-Acc introduce-OH-past
'Hanako introduced Prof. Tanaka to Mary.'

Here, the predicate is ditransitive, as in (61), but this time the NP bearing the relevant feature to trigger honorification functions as the direct object. In such a case, object honorification (i.e., agreement between the verb and the direct object) is impossible.

Boeckx and Niinuma (2004) argue that the restriction observed in (62) falls under Relativized Minimality. Since switching the surface order of the direct object and of the indirect object via overt A-movement (short-distance scrambling) does not affect agreement marking (63), these authors claim that it must be the case that object agreement takes place prior to word-order permutation:

(63) *Hanako-ga Tanaka Sensei-o Mary-ni go-syookai-si-ta.
Hanako-Nom Prof. Tanaka-Acc Mary-Dat introduce-OH-past
'Hanako introduced Prof. Tanaka to Mary.'

They take this to mean that agreement takes place under Chomsky's derivational version of Agree, which applies as soon as the Probe (say, *v*) is introduced into the derivation. The intervention effect in (62) follows if the dative element c-commands the accusative element, as in (47).

Examples like (64) (Chomsky 2000: 149, n. 93(ii), attributing the example to Erich Groat) suggest that Agree may take place more than once. Specifically, it may target more than one INFL, just like in 'hyperraising' cases (in (64) *two men* agrees with both embedded and matrix INFLs):

(64) ?There look as though there are two men in the room.

Interestingly, as Fujii (2003) observes, there exists a 'hyperraising' analogue to the 'hyperagree' case in (64). Consider (65):

(65) Two men look as though they are in the garden.

We do not know at this point why English forces the presence of a resumptive pronoun (*they*) in the embedded clause in hyperraising cases, but we find the

parallel between Agree and Move intriguing. (66) shows that Move followed by Agree is disallowed:

(66) *There look as though two men are in the room.

The unacceptability of (66) suggests that overt movement of X to Y (Move) followed by Agree between X and a higher head Z (Agree) is disallowed. More precisely, since Agree underlies Move, the sequence of operations in (67) is disallowed:

(67) Agree (X, Y) + Move (X, Y) + Agree (X, Z)

(67) is reminiscent of instances of 'Improper Movement' (an option considered in the context of superraising by Chomsky 1995b: 326):[10]

(68) A-movement + A-bar movement + A-movement

If the existence of 'Improper Agree' (67) can be confirmed, the parallelism between Move and Agree would be strengthened.

12 Conclusion

Needless to say, many mysteries remain. Perhaps the most significant of them, as noted above, is how to permit raising across an experiencer at all, but then how to block it where it is not allowed. Another, as noted by Manzini in a reprise of an observation by Lasnik and Saito discussed above, is why a violation of closest Attract in the case of A-movement leads to more severe degradation than a mere Subjacency violation, in particular, a *wh*-island violation, which has been analyzed in precisely the same terms. It seems that we have not yet found the true generalizations in this realm.

NOTES

1 Keeping definitions maximally simple, A-movement refers to movement to subject/object positions, i.e., basically anything targeting non-operator(-like) positions.
2 S' becomes CP in the extended X'-theory of Chomsky (1986a), and movement to Comp becomes movement to Spec of CP. Likewise, clause (S) becomes InflP (IP), and its subject position Spec of IP.
3 This is the requirement that every clause have a subject, suggested by Chomsky (1981) and further developed by Chomsky (1982).
4 This is, in effect, the Minimalist version of the chain condition of Chomsky (1986b).
5 Chomsky quite generally assumes that Case can be 'checked' in the covert component.
6 Overt Object Shift in Scandinavian languages correlates with overt verb raising to T (not just V-raising to AGRo). This can be captured under Chomsky's account by

forcing V-movement to T to allow for movement of the VP-internal subject NP to SpecTP across SpecAGRoP (see Bobaljik and Jonas 1996 for detailed discussion).

7 Developed in detail in Lasnik (1995b).

8 Accordingly, Chomsky also dispenses with head-movement in narrow syntax. For an argument in favor of Chomsky's position, see Boeckx and Stjepanović (2001).

9 See Lasnik (2002) for arguments in favor of feature movement over Agree.

10 Chomsky was worried about excluding a derivation in which an element X A-bar-raises across an A-element Y before landing into an A-position Z, as depicted in (i):

(i) John seems [*t'* [it was told *t* [that it was raining]]].

7.4 How is the logical object promoted to subject?
8 Conclusion

1 Introduction

In this chapter, we will provide an overview of the properties of so-called middle constructions. A thorny issue that immediately arises in a discussion of middles is the proper delimitation of the subject of inquiry. It is not always easy (as we will see) to distinguish middles from a wide range of related sentence types, such as passives, inchoatives or anti-causatives, instrumental subject clauses, true reflexives, and others.[1] In all cases that will be considered true middles in this chapter the following statements hold:

(1) a. The external argument of the non-middle counterpart of the middle verb cannot be expressed as a regular DP-argument in the middle.
b. If the non-middle counterpart of the middle verb has a direct internal argument role, the subject of the middle sentence carries this role.
c. The middle verb is stative, non-episodic. The middle sentence is a generic statement. It expresses that the argument mentioned in (b) has a particular individual-level property, or that events denoted by the verb or the verb–argument combination have a particular property in general.

Some examples of middle sentences as they will be understood here are given in (2):

(2) a. Bureaucrats bribe easily.
b. La Tour Eiffel se voit de loin. French
the Eiffel Tower REFL sees from afar
'The Eiffel Tower can be seen from afar.'
c. Dit boek leest als een trein. Dutch
this book reads like a train
'This book is very easy to read.'

Languages turn out to allow a range of syntactically and/or morphologically different middle constructions. Cross-linguistically, there are middles with and without a reflexive marker, agentive and non-agentive middles, personal and impersonal middles, argument and adjunct middles. Such contrasts will be discussed below.

In some languages, constructions that conform to the criteria in (1) do not have episodic counterparts, and obligatorily get a modal semantics: the middle verb is accompanied by an element expressing to what extent the activity expressed by the verb can be carried out, using an adverb like 'easily', a modal auxiliary, or negation. Such middles will be referred to as 'type I middles'. In another group of languages, middles have formally identical episodic counterparts, with a passive interpretation. (Sometimes they can even use the equivalent of a *by*-phrase, typical for passives, to express the verb's underlying subject.) Such middles will be referred to as 'type II middles' from now on.

In the next section, we will discuss in what respects middle constructions in languages with either type of middle differ from various kinds of lookalikes. Section 3 will discuss the properties of type I middles in more detail, sections 4–5 those of type II middles. In section 6 restrictions on middle formation are discussed. Section 7, finally, reviews the different analyses that have been proposed in the literature for middles.

2 What is a middle and what is not?

A description of what middles are as in (1) is in part syntactic and in part semantic. It is syntactic because it concerns the syntactic projection (or non-projection) of the base verb's external argument and the change in grammatical function of its internal argument. It is semantic because it concerns the stative character of middle verbs and the generic character of middle sentences. In this section, a number of both semantic and syntactic properties will be added to this definition, in the following way. A number of constructions from different languages will be reviewed that are similar to middles, either because they are to some extent synonymous, or they are translation equivalents of middles, or they are morphologically similar. In each case, the difference between this construction

and the middle as defined earlier will be added to the definition of the middle, unless it voids the definition, in which case the particular class is added to the class of middles.

2.1 Middles vs. the middle voice

In Ancient Greek, reflexive/passive morphology is used in a construction that is neither truly reflexive nor truly passive. An example is (3):

(3) eklegomai
choose-REFL
'choose for oneself' (not: 'choose oneself' or 'be chosen')

In such cases, the underlying verb's external argument is syntactically present, but there is a difference from the simple active use of the verb: the morphological marker provides the additional semantics that the action expressed by the verb is directed toward this external argument itself or that it is to this argument's benefit. Because this semantics gives the construction a somewhat intermediate status between the active and the passive, the verb is said to occur in the 'middle' or 'medial' voice in (3). The construction is very different from middles in the sense of (1), however. A crucial difference is the very fact that the external theta-role of the verb in (3) can still be assigned to a syntactic DP-argument. Moreover, in contrast to middles as in (1) with an overt reflexive marker, the reflexive marker in (3) expresses that there truly is a coreference relation between the subject and another argument of the verb. In many languages, the same semantics is expressed by reflexive pronouns:

(4) a. She bought herself a pen.
b. Ona kupila sebe ručku. Russian
she bought SELF-DAT a pen
'She bought herself a pen.'
c. Ze rukte zich de haren uit het hoofd. Dutch
she tore SELF the hairs out the head
'She tore the hairs out of her head.'

We can safely conclude that verbs in the middle voice in languages like Ancient Greek are not middle verbs in the sense of (1), and we will leave them out of consideration henceforth.

2.2 Middles vs. reflexives

In almost all type II and German middles, a morphological marker is present that is identical to the one occurring in reflexive sentences. There are a couple

of obvious differences between true reflexives and middles, however. In a true reflexive, the reflexive marker can be replaced by a direct object without affecting the semantic role of the grammatical subject. The grammatical subject expresses the 'logical' subject; it carries the verb's external theta-role. In a middle, replacing the reflexive marker with the direct object has the effect of changing the grammatical subject's semantic role: with the reflexive marker – i.e., as a middle – the grammatical subject carries the verb's internal argument role; with the reflexive marker replaced by direct objects, the only possible interpretation of the grammatical subject is as the logical subject. This distinction is illustrated below for German:

(5) a. Sie erschoss sich. (*sie* is logical subject)
she shot REFL
'She shot herself.'
b. Sie erschoss den Sheriff. (*sie* is logical subject)
she shot the sheriff
'She shot the sheriff.'

(6) a. Dieses Modell malt sich leicht. (*dieses Modell* is logical object)
this model paints REFL easily
'It is easy to paint this model.'
b. Dieses Modell malt ein Stilleben. (*dieses Modell* is logical subject)
this model paints a still life
'This model paints a still life.'

In some cases, reflexive verbs have no non-reflexive counterpart, in which case replacing the reflexive marker by a direct object is impossible. Such verbs are called 'inherent reflexives'. Middles are never inherent reflexives; in other words, a middle always has a corresponding non-reflexive verb. This in itself serves to distinguish between middles and reflexive verbs.

2.3 *Middles vs. inchoatives*

Inchoative verbs (also referred to as anti-causative verbs) express a change of state of their grammatical subject. They are similar to middles in lacking the expression of the logical subject argument. Also, in many languages they are morphologically identical to middles.

However, there are also substantial differences between middles and inchoative verbs. A crucial difference is that with inchoative verbs the semantics of an implied agent-like role is entirely absent, whereas in a middle this agent-like role is implicitly present (even though it is not assigned to an argument). Also, in contrast to type I middles, inchoatives can be eventive. These distinctions find their expression in a number of different properties.

2.3.1 *Full reflexive adjuncts*

In a middle sentence, a reflexive adjunct can refer to the implicit agent (see also section 7), as in the following examples from French (Fagan 1992: 58, from Ruwet 1976):

(7) a. Cela se dit facilement de soi-même.
that REFL says easily of oneself
'It is easy to say that about oneself.'
b. Ce genre d'objet s'achète facilement pour soi-même.
this type of thing REFL buys easily for oneself
'One easily buys this type of thing for oneself.'

In an inchoative sentence, this type of reflexive adjunct is impossible:

(8) Quand tout s'effond autour de soi (*même), on perd la tête.
When everything REFL collapses around one (*SELF), one loses one's head
'When everything collapses around one, one loses one's head.'

2.3.2 For-*phrases*

Middle sentences can contain a *for*-phrase, which appears to refer to the implicit agent (though see section 7.3). In a sentence with an inchoative verb this is impossible:

(9) Deze deur sluit makkelijk, zelfs voor kleine kinderen. Dutch
this door closes easily even for small children
'Even for small children it is easy to close this door.'

(10) Wilde bloemen verwelken makkelijk in een vaas (*zelfs voor ouden van dagen).
wild flowers wilt easily in a vase even for OAPs
'Wild flowers easily wilt in a vase (even for OAPs).'

2.3.3 *Interpretation of* easily

The semantic presence or absence of the agent role correlates with the interpretation of a modifier like 'easily' (Fellbaum 1986). In a middle, the interpretation of this modifier is 'not difficult to do'; in an inchoative the interpretation is 'at the slightest provocation'. This is illustrated by the contrast between (11) (middle) and (12) (inchoative):

(11) Nieuwe deuren sluiten makkelijk/zonder moeite/*zomaar. Dutch
new doors close easily/without effort/all by themselves
'It is easy to close new doors.'

(12) Wilde bloemen verwelken makkelijk/zomaar/*zonder moeite in een vaas.
wild flowers wilt easily/all by themselves/without effort in a vase
'Wild flowers wilt quickly in a vase.'

Fellbaum shows that, at least in English, the two adverbs differ syntactically as well as semantically. In the 'not difficult' reading, the adverb occurs sentence-finally, whereas it may precede the verb in the other reading:

(13) a. This book reads easily.
a'. *This book easily reads.
b. Such cups wash easily.
b'. *Such cups easily wash.

(14) a. Small chicks die easily when left alone.
a'. Small chicks easily die when left alone.
b. Glass breaks easily.
b'. Glass easily breaks.

Note also that the inchoative, with the 'at the slightest provocation' reading for the adverbial modifier, can do without the adverb without a significant change in meaning of the predicate. The middle, with the 'not difficult' reading for the adverb, is bad or degraded without it:

(15) a. *The book reads.
b. ??Such cups wash.
c. Small chicks die when left alone.
d. Glass breaks.

2.3.4 Stativity

Like any eventive predicate, an inchoative verb may occur in a stative context. When this happens, inchoatives become even more similar to middles than when they are eventive. The position and interpretation of adverbs like 'easily', however, indicate that a difference is still present. An example like (16a) thus is a stative inchoative verb, as is further illustrated by the impossibility of adding a *for*-phrase. It is also possible to derive a middle from transitive *melt*, in which case the adverb must occur sentence-finally and a *for*-phrase is possible (16b):

(16) a. Butter easily melts in the sun (*for bad cooks).
b. Butter (*most easily) melts most easily in a good frying pan (even for inexperienced cooks).

Rapoport (1999a) proposes to distinguish between two types of middles, namely agentive and non-agentive middles, which correspond to 'ordinary' middles and stative inchoatives as just discussed. The data in (16) are a first indication that non-agentive middles should not in fact be treated as middles, but as inchoative verbs in a stative context. This is further corroborated by the properties of the Norwegian 's-passive', which appears to be a Type II middle construction. Such s-passives are fine when derived from transitive verbs, but impossible when derived from unaccusative verbs (Øystein Nilsen, p.c.):

(17) a. Disse filene ødelegges lett (av analfabeter).
these files destroy-S easily (by illiterates)
b. Det bankes (mye) på døra.
it knocks-S a-lot on the-door
'(Frequently) there is knocking on the door.'
c. *Det vokses (mye) på grøten.
it grows-S a lot on the-porridge
'Somebody is growing (a lot) on the porridge.'

If stative inchoatives were a type of middle sentences, or in other words, if middle formation did not affect or use the presence of an external theta-role of the base verb, we would expect Norwegian s-passives to allow both types of verb as base. In fact, (possibly stative) inchoative verbs in Norwegian are derived using a full reflexive, and can easily be distinguished from the s-passive.[2]

To summarize, we have added the following defining property to middles (see also Iwata 1999):

(18) In a middle, the logical subject argument of the underlying verb is semantically present.

Whether or not (18) implies that this subject is also present syntactically in a middle (even though not assigned to a regular argument position: see (1a)) will be discussed in section 7.

2.4 *Middles vs.* Easy-to-please *constructions*

Easy-to-please constructions (constructions with '*tough* movement') are semantically very similar to middles. Here are some examples of this construction:

(19) a. This book is easy to read.
b. These trees are hard to cut down.

In *easy-to-please* constructions, the grammatical subject seems to be the verb's underlying object. Also like middles, *easy-to-please* constructions are generic statements and do not allow passive *by*-phrases. These two properties are illustrated below:

(20) a. *I witnessed these trees being hard to cut down.
b. *This book is easy to read by an experienced editor.

Furthermore, like many middles, the construction has a modal semantics, and as in these middles this semantics is independent of the adjective involved:

(21) Deze bomen zijn (niet/goed/moeilijk) te vellen.
these trees are (not/smooth/difficult) to cut down

If the main predicate were the adjective, it should be impossible to leave it out, contrary to the above Dutch data. We conclude that, at least in the Dutch *easy-to-please* constructions, the adjective modifies the modal semantics of the construction just as the adverb does in a middle.

However, *easy-to-please* constructions and middles also show some substantial differences, which make it impossible to treat them both on a par. A major difference involves the restrictions on either. In contrast to what seems to be the case for the *easy-to-please* construction, middles cannot be formed from just any transitive verb (see section 6). Some pairs showing this contrast are given in (22):

(22) a. *This article understands only with difficulty.
a′. This article is hard to understand.
b. *This problem explains easily.
b′. This problem is easy to explain.
c. *Geld verliest gemakkelijk. Dutch
money loses easily
c′. Geld is makkelijk te verliezen.
money is easy to lose
d. *Pijn ondergaat niet gemakkelijk. Dutch
pain undergoes not easily
d′. Pijn is niet gemakkelijk te ondergaan.
pain is not easy to undergo

Along the same lines, it is clear that the range of modifiers that can be used in *easy-to-please* constructions does not match the range of modifiers that can be used in middles. Some modifiers can only be used in *easy-to-please* constructions (23), whereas others only occur in middles (24):

(23) a. This book is impossible to read.
b. *This book reads impossibly.

(24) a. This meat cuts just like that.
b. *It is just like that to cut this meat.

There is a further distinction between *easy-to-please* constructions and middles in English. Consider an adjectival passive embedded under the verb get:

(25) I can't get this book finished.

This construction can be incorporated into an *easy-to-please* construction, but not into a middle:

(26) a. This book is easy to get finished.
b. *This book gets finished easily.

In general, it seems that middle formation targets (possibly complex) V^0s, and the grammatical subject must be an argument of this verb (see section 6). In contrast, *tough*-movement targets entire phrases and "the dependency path in a *tough* construction can be arbitrarily long" (Dalrymple and Holloway King 2000). That is, not only can logical objects of the verb in the adjective's direct complement appear as grammatical subject, but logical objects of more deeply embedded complements as well. This contrast is illustrated in (27) ((27b) and (27c) from Dalrymple and Holloway King 2000):

(27) a. Such a film is easy to make a complete mess of.
a'. *Such a film easily makes a complete mess of.
b. This book is hard to get her to avoid reading.
b'. *This book easily gets her to avoid reading.
c. This house is too old to get anyone to try to renovate.
c'. *This house easily gets anyone to try to renovate.

Concluding, middles, comprising both the English-type (type I) and the French-type (type II), have some properties which set them apart from apparently similar constructions. We will now discuss the properties of one type of middles that do not apply to the other, starting with type I middles.

3 Type I middles

Type I middles have a number of properties that allow them to be clearly identified as a class distinct not only from (stative) inchoatives, but also from many other constructions in the relevant languages.

3.1 Middles and modality: the property reading, potentiality, and stativity

A type I middle expresses a generic modal reading that can be roughly paraphrased as 'anyone could (Adv) V'. For example, *this meat cuts easily* can be paraphrased as 'anyone could cut this meat with ease'. This property of type I middles has two further properties as a necessary corollary, namely that such middles are stative predicates and that they (usually) contain some form of modification of the modality. These properties will be expanded on in this subsection.

3.1.1 Middles as stative predicates

A type I middle sentence is always stative. It cannot be used in any context that forces eventivity, like perceptual report, or as the answer to a question like 'what are you doing?' or 'what is happening?':[3]

(28) a. *Ik zie het boek moeilijk lezen. Dutch
I see the book with-difficulty read
b. Wat gebeurt er? #De baby verschoont moeilijk.
what happens EXPL? the baby cleans with-difficulty
'What is happening? It is difficult to change the baby's nappies.'

This is an obvious difference between middles and use of the same underlying verb in other diatheses, like active, passive, inchoative, etc.:

(29) a. Ik zie Marie de suiker oplossen.
I see Mary the sugar dissolve.
'I see Mary dissolve the sugar.'
b. Ik zie de suiker opgelost worden (door Marie).
I see the sugar dissolved be (by Mary)
'I see the sugar being dissolved (by Mary).'
c. Ik zie de suiker oplossen.
I see the sugar dissolve
'I see the sugar dissolve.'

(30) What is happening?
a. Marie lost de suiker op.
Mary dissolves the sugar
b. De suiker wordt opgelost (door Marie).
the sugar is dissolved (by Mary)
'The sugar is being dissolved (by Mary).'
c. De suiker lost op.
the sugar dissolves

The stativity of middles, or more precisely their genericity, has been analyzed in different ways semantically. For example, Condoravdi (1989) argues there is quantification over events in middles, as in habituals (i.e., *bureaucrats bribe easily* is supposed to mean 'all events of bribing a bureaucrat will be easy events'). Fagan (1992), on the other hand, argues there is quantification over potential subjects (i.e., *bureaucrats bribe easily* is supposed to mean 'all instances of a bureaucrat will have the property of being easy to bribe'). Either way, the stative (perhaps habitual) reading of middles is always accompanied by potentiality (maybe modified by the adverb or other modifier: see below): a middle expresses any subject's ability to perform the action expressed by the predicate. The modality results in the stativity, not the other way around. This can be seen from examples like (31–32), which contrast ordinary stative predicates to middles:

(31) a. John plays Mozart beautifully, but I can't (play Mozart/play Mozart beautifully).
b. John loves to ski, but I can't (ski).

c. *This book reads easily, but I can't (read it).
d. *This egg peels easily, but I can't (peel it).

(32) a. #John plays Mozart beautifully, so I can do so too.
b. #John loves to ski, so I do too.
c. This book reads easily, so I can read it too.
d. This egg peels easily, so I can peel it too.

These examples show that potentiality does not occur without stativity, but stativity is fine without potentiality.

3.1.2 Modification of potentiality

A very well-known property of middles in languages like English, German, and Dutch is that they almost invariably come with a modifier like 'easily':

(33) a. Bureaucrats bribe ??(easily/only after a good lunch/ . . .).
b. Dieses Buch liest sich *(leicht/schwer/ . . .). German
this book reads REFL easily/with-difficulty
c. Zo'n stuk zingt *(niet gemakkelijk/lekker/ . . .). Dutch
such-a piece sings not easily/comfortably

We have to say 'almost invariably', because such modification is in fact not necessary under specific circumstances (Roberts 1987; Fagan 1992). First of all, the presence of a modal voids the need for an adverb:

(34) This meat may cut, but you never know.

When it is not obvious from the meaning of the verb and its arguments that a particular action is in fact possible, modification can also be left out altogether. In that case, merely expressing the fact that anybody can do it fulfills the Gricean maxim of relevance:

(35) a. This dress buttons.
b. Dieses Kleid knöpft sich zu. German
this dress buttons (Fagan 1992: 147)

Alternatively, all modification present might be negation, expressing the absence of potentiality, or focus, emphasizing the nature of the potential event:

(36) a. Dit vlees snijdt niet. Dutch
this meat cuts not
'This meat won't cut.'
b. Die aardappels ROOIEN, niet te geloven! Dutch
those potatoes dig-up, not to believe
'I can't believe how easy to dig up those potatoes are!'

In similar cases, there is no potentiality modification either, but the way the action is carried out is specified to some extent. See (37) (cf. Fagan 1992):

(37) a. Stows on floor or shelf. (Fagan 1992)
b. Das Wort *Thron* schreibt sich mit *th*.
the word *Thron* writes REFL with *th*
'The word *Thron* is spelled with *th*.' (Drosdowski 1970: 601)
c. Deze bloes sluit met een enkele knoop. Dutch
this blouse fastens with a single button
'This blouse is fastened with a single button.'

3.2 Middles and passives: the external theta-role

In a middle sentence, in most cases the underlying verb's internal argument surfaces as the grammatical subject of the sentence. In this respect, middles are very similar to passives. It is nevertheless quite clear that type I middles are not passive. First of all, they don't show passive morphology; in fact, in Dutch and English they do not show any morphology at all. Second, type I middles do not allow the expression of the base verb's external theta-role in a *by*-phrase:

(38) a. Such texts are usually translated by a professional translator.
b. Such texts do not translate easily (*by professional translators).

We can add two more defining properties to type I middles:

(39) a. Type I middles lack passive morphology.
b. Type I middles do not allow (the cognate of) passive *by*-phrases.

Despite the absence of passive *by*-phrases, type I middles do allow a *for*-phrase, as briefly discussed above. It has been argued, notably by Stroik (1992a), that this phrase is the expression of the logical subject role of the middle verb, like the *by*-phrase is in a passive. On the other hand, it has also been argued that the *for*-phrase is licensed by the adverbial modifier typically present in a middle (Hoekstra and Roberts 1993a) or by the modal semantics of the complete middle sentence (Zribi-Hertz 1993; Ackema and Schoorlemmer 1995). We will come back to this issue in section 7. For now, we note that, on an observational level, not all middles allow a *for*-phrase:[4]

(40) a. This book reads like mud (*for John).
b. These pizzas deliver very smoothly (*for anyone with a moped).
c. This dress buttons (*for everyone).

3.3 Middles and **lassen***-middles*

Many languages have a construction that is semantically very similar to middles, but which involves an auxiliary verb. Following Fagan's (1992) terminology, we will

refer to such sentences as '*lassen*-middles' (a term referring to the auxiliary *lassen* 'let' that occurs in them in German). Examples are given below:

(41) a. Dieses Buch lässt sich leicht lesen. German
this book lets REFL easily read
'This book is easy to read.'
b. Het antwoord laat zich raden. Dutch
the answer lets REFL guessed
'The answer is easy to guess.'

These constructions are sometimes synonymous with middles, but they do not share the restrictions found on middle formation in the relevant languages. For example, *lassen*-middles allow the expression of the main verb's external theta-role in a *by*-phrase, which is impossible in true type I middles:

(42) a. Dit probleem laat zich door schoolkinderen niet makkelijk oplossen.
this problem lets REFL by schoolchildren not easily solve
'This problem cannot easily be solved by schoolchildren.'
b. *Dit boek leest niet makkelijk door schoolkinderen.
this book reads not easily by schoolchildren

Second, *lassen*-middles can be episodic, which, as noted, is impossible in type I middles:

(43) a. Het probleem liet zich in tien minuten oplossen.
the problem let REFL in ten minutes solve
'The problem could be solved in ten minutes.'
b. ?*Het bleek dat dit boek makkelijk in tien minuten leest.
it turned out that this book easily in ten minutes reads
'It turned out that it is easy to read this book within ten minutes.'

Third, the formation of *lassen*-middles does not show the same restrictions that hold for middle formation with respect to what kind of verbs undergo it. This will be discussed in section 6, when we have seen what those restrictions are.

Finally, a difference between real middles and *lassen*-middles that shows up in Dutch is that, whereas the real middle does not contain a reflexive marker in this language, such a marker is obligatory in the *lassen*-middle:

(44) Het antwoord laat *(zich) raden.
the answer lets REFL guess

We conclude that *lassen*-middles are not type I middles (see also Fagan 1992). This leaves two possibilities. Either they are not middles at all, or they are the counterpart in the relevant languages of type II middles (on which, see sections 4 and 5).

3.4 Impersonal middles

Some languages with type I middles have a construction very similar to middles, but which differs from 'ordinary' middles in being derived from intransitive verbs. Some examples of such 'impersonal middles' from Dutch are given in (45):

(45) a. Het loopt lekker op deze schoenen.
it walks comfortably on these shoes
'These shoes are comfortable to walk in.'
b. Het zit lekker in deze stoel.
it sits comfortably in this chair
'This chair is comfortable to sit in.'
c. Het rijdt moeilijk met slecht zicht.
it drives difficult with poor view
'It is difficult to drive when the view is poor.'

The question is whether these constructions should be treated as middles. They presumably should, since they fulfill all criteria identified for middles in general. Impersonal middles are stative predicates:

(46) a. *Ik voelde het lekker zitten op deze stoel.
I felt it comfortably sit on this chair
'I could feel it was comfortable to sit in this chair.'
b. Wat gebeurt er? #Het zit lekker op deze stoel.
what happens? it sits comfortably on this chair

Moreover, impersonal middles do not allow the expression of the verb's logical subject as an argument. They also fulfill all criteria identified specifically for type I middles. For instance, they express potential modality or a value judgment. Thus, *het rijdt lekker op deze fiets* 'it rides comfortably on this bike' can be paraphrased as *op deze fiets kun je lekker rijden* 'you can ride comfortably on this bike'. This modality is identical to what is found in personal middles. Also like ordinary middles, impersonal middles do not allow *by*-phrases:

(47) a. *Door ouden van dagen zit het lekker op deze stoel.
by old-of-days sits it comfortably on this chair
'This chair is comfortable for the elderly.'
b. *Het rijdt prettig op deze fiets door grote mensen.
it rides nicely on this bike by tall people
'Tall people can ride very well on this bike.'

As can be seen from the examples above, impersonal middles have the same morphological form as other middles, meaning they do not show any particular morphology at all in Dutch.

Our conclusion is that impersonal middles are true middles without any reservations. This, of course, has interesting consequences for the restrictions on middle formation, to be formulated below.

3.5 Adjunct middles

Dutch has a further type of middle-like sentence, which seems related to impersonal middles. Some examples are provided in (48):

(48) a. Deze stoel zit lekker.
this chair sits comfortably
'This chair is comfortable to sit on.'
b. Deze tafel eet prettig.
this table eats pleasantly
'This table is pleasant to eat at.'
c. Deze naalden breien lekker.
these knitting-needles knit nicely
'These knitting-needles are nice to knit with.'

In such sentences, the grammatical subject is an element that would seem to be expressed as an adjunct in the active counterpart of the sentence. This is why they are generally called 'adjunct middles'. Like impersonal middles, they derive from intransitive verbs (as in (48a, c)), or from transitive verbs whose objects are not expressed (as in (48b)). Thus, from some verbs it is possible to form both an ordinary middle, with the logical object functioning as the grammatical subject, and an adjunct middle. An example is given in (49):

(49) a. Ik stop de deken in in het bed.
I put the blanket in in the bed
'I tuck in the blanket in the bed.'
b. Deze deken stopt makkelijk in.
this blanket puts easily in
c. Dit bed stopt makkelijk in.
this bed puts easily in

Like impersonal middles, adjunct middles behave like true middles of the type I persuasion. Thus, they are stative, and the sentence they head is a generic statement expressing potential modality (*deze stoel zit lekker* 'this chair sits comfortably' roughly means the same thing as *op deze stoel kun je lekker zitten* 'you can sit comfortably in this chair'). Also, like any middle, adjunct middles do not allow the expression of the logical subject of the verb as a syntactic argument, nor do they allow this element to be expressed in a *by*-phrase:

(50) a. Deze fiets rijdt lekker (*door studenten).
this bike rides comfortably (by students)

b. Dit bureau schrijft lekker (*door romanschrijvers).
this desk writes nicely (by novelists)

They also show the same morphology as other middles, i.e., none in Dutch. We will come back to this interesting construction in section 6.2. For now, we conclude that it is to be included in the general class of middles.

3.6 Middles and instrumental subject clauses

There is a close similarity between Dutch adjunct middles, as discussed in the previous subsection, and another sentence type in which instruments can surface as grammatical subjects of transitive verbs. This latter type is quite common across languages (in contrast, it seems, to adjunct middles, which do not occur in any of the languages mentioned so far except Dutch). Some examples of these so-called 'instrumental subject clauses' are given in (51):

(51) a. This pen/ink writes very well.
b. The key opened the door.
c. Deze pen schrijft heel goed. Dutch
this pen writes very well
d. De zon droogt de tomaten. Dutch
the sun dries the tomatoes

At first sight, this construction might seem to be a type of adjunct middle after all, which would mean that adjunct middles are much more wide-spread than it seemed. However, there are good reasons to distinguish instrumental subject clauses from adjunct middles (cf. Hoekstra and Roberts 1993a; Cornips 1996).

First and foremost, instrumental subject clauses may be transitive (see (51b, d)), whereas adjunct middles can never be transitive:

(52) Deze theedoek droogt (*de borden) lekker.
this towel dries (the dishes) nicely
'This towel is good to dry (the dishes) with.'

Second, instrumental subject clauses, although often used to express properties and therefore stative, can be used in eventive sentences:

(53) a. I thought you wanted to get rid of that pen? I did, but look: now it's writing well!
b. Wat gebeurt er? De zon droogt de tomaten!
what happens? the sun dries the tomatoes!

Finally, Cornips (1996) provides evidence for the distinction from the diachrony of dialects on the southern Dutch–German border, in the area of the Limburg province, and in the adjoining Rhineland. In the late nineteenth century, three

dialect groups allowed instrumental subject clauses without a reflexive marker. Adjunct middles either do not exist in these dialects or, which is more relevant to the argument, require a reflexive marker. (The modern variants of these dialects all allow instrumental subject clauses with a reflexive.) Relevant examples from Rhineland dialects are provided below (from Cornips 1996: 51–52):

(54) a. Der Saal sengt sich legt. (adjunct middle with reflexive marker)
this hall sings REFL easily
b. Der Enk schrief got. (instrumental subject clause without reflexive marker)
this ink writes well

Following Cornips, we conclude that instrumental subject clauses should be distinguished from middles even in languages that allow adjunct middles.

4 Type II middles

Many languages have middle constructions that differ from type I middles according to a number of important criteria, probably the most salient of which is the ability of these middles to occur in episodic sentences. It seems all languages of this type use the (historical) equivalent of a reflexive morpheme in middle sentences. Such middles occur, for example, in Italian, Spanish, French, Greek, Norwegian, Russian, and Serbo-Croat. We illustrate this with French:

(55) a. Cette étoffe se repasse rapidement.
this fabric REFL irons rapidly
'This fabric can be ironed rapidly.' (Zribi-Hertz 1993: 348)
b. La Tour Eiffel se voit de loin.
the Eiffel Tower REFL sees from afar
'The Eiffel Tower can be seen from afar.' (Hulk and Cornips 1998)
c. Cette histoire se raconte facilement.
this story REFL tells easily
'This story can be told easily.' (Gross 1975: 102)
d. Les enfants, ça s'invite facilement.
the children, that REFL invites easily
'It is easy to invite children.' (Fagan 1992: 99)

Above we have shown that any middle, whether type I or type II, differs from passives and inchoatives in the same language. Type II middles may be harder to distinguish from inchoatives because they can be episodic, but still there is a distinct sense in which the original verb's external theta-role is involved in the event in a middle, whereas it is not in the inchoative counterpart.

Type II middles need to be distinguished from different types of reflexive constructions that occur in the relevant languages. First and foremost, it needs to

be established whether or not type II middles can be distinguished from reflexive-marked passives, whose argument configuration is identical to that in middles. Section 5 will be devoted to that issue. In this section, we will review the differences between middles and other types of reflexive constructions in languages with type II middles.

4.1 Impersonals and transitivity

The first distinction we need to make is between type II middles and impersonals. Languages like French and Italian have impersonal constructions that superficially look like impersonal middles in languages like Dutch and German. Some examples are given in (56):

(56) a. Si lavora sempre troppo. Italian
REFL work always too-much
'One always works too much.' (Cinque 1988: 522)

b. Oggi, a Beirut, si è sparato tutta la mattina. Italian
today, in Beirut, REFL is shot whole the morning
'Today, in Beirut, one shot the whole morning.' (Cinque 1988: 542)

c. Il se chante/dort/travaille souvent ici. French
it REFL sings/sleep/works often here
'People often sing/sleep/work here.' (Zubizarreta 1987: 153)

Such impersonal sentences are not middles. They freely occur with specific time reference, in which case they have a (generic) third person plural subject interpretation. Also, as opposed to Dutch and German impersonal middles, they can never occur with the adverbial modification typical for middles. On this basis alone, we conclude that impersonals in Italian and French should not be treated as type II middles. We therefore also conclude that French and Italian middles cannot be derived from intransitive verbs. This property they share with English middles, but not German and Dutch ones.

4.2 Middles and intrinsic reflexives

Some intrinsically reflexive verbs look very much like middles, but they have a special semantics of their own that cannot be derived from the combination of the verb's semantics and the semantics of a middle. Consider, for instance, the meaning of the French examples in (57) (from Zribi-Hertz 1982: 348):

(57) a. Cette couleur se voit.
this colour REFL sees
'This colour is gaudy.'

b. Cela s'entend bien.
this REFL hears well
'Of course.'

It is more than likely that these inherent reflexives are in fact lexicalized true middles.[5]

5 Type II middles and reflexive-marked passives

5.1 The same or different?

Type II middles in many languages are formally indistinguishable from a sentence type most easily described as 'reflexive-marked passive'. Reflexive-marked passives use the formal markers of reflexives in a sentence with an argument configuration similar to a passive. An example from Italian (from Cinque 1988: 554) is given in (58):

(58) Qui, gli spaghetti si mangiano spesso.
here the spaghetti REFL eat often
'Here spaghetti is often eaten.'

Such reflexive-marked passives allow episodic use, unlike the strictly stative type I middles. Specific time reference in such examples results in a passive reading, including a syntactically active agent (compare section 7). In some languages, reflexive-marked passives can even take the equivalent of a passive *by*-phrase, sometimes depending on style or register of the utterance (as an Italian: see Cinque 1988: 529).

These reflexive-marked passives raise some interesting questions with respect to the properties and analysis of middles. The first one is, of course, whether we can distinguish between type II middles and reflexive-marked passives. Should the middle be separated from the reflexive-marked passive, or be treated as a special instance of the latter? If we do want to distinguish the two, then what is the nature of the distinction between middles and reflexive-marked passives in languages that have them?

In distinguishing between type II middles and reflexive-marked passives we will first take the narrow view of middles as 'the equivalent of a type I middle'. The question we want to answer then is the following: in a language with type II middles, are there systematic differences between the equivalent of a type I middle and reflexive-marked passives?

The literature seems to be divided on this issue. On the one hand, emphasis is put on the similarities between middles and reflexive-marked passives, leading to a view that there is no true distinction between the two (see, for instance, Authier and Reed 1996). On this view, there is no special category of middle sentences, because any middle sentence will have an episodic, and therefore by the narrow criterion just mentioned non-middle, counterpart. These counterparts may even take *by*-phrases in some languages (French, Greek), apparently voiding the dichotomy between passives and middles in these languages.

In contrast, there are those authors who concentrate on the differences between 'true' middles and reflexive-marked passives, and conclude that, even though episodic counterparts exist, middles have special behavior of their own that needs an explanation (Cinque 1988, among others).

In this section, we will provide an overview of reflexive-marked passives in languages with type II middles to see how and whether the properties of reflexive-marked passives (in their passive reading) have been found in the literature to be distinguishable from those of sentences with the middle interpretation found in type I middles. Relevant issues to be addressed are modality and aspect, the presence of the external theta-role, and restrictions on the formation of either construction.

5.2 *Genericity and modality*

The first difference between reflexive-marked passives and type I middles is that these passives lack the obligatory modal character of type I middles and the obligatory generic character that seems to come with it. Also, they allow a wider range of modal shades than the potential reading that is always a property of type I middles.

5.2.1 *Modality*

Reflexive-marked passives either have no intrinsic modality to their semantics, or they express prescriptive modality (Fagan 1992). In the latter case, they focus on how something is always done and therefore should be done, and not, like a type I middle, on the fact that anybody could do it in some way. This semantic property is illustrated by the French examples in (59):

(59) a. Les maximanteaux, ça se porte sur une minijupe.
the maxi-coats, that REFL wears on a mini skirt
'Maxi-coats, they're worn over a mini skirt.' (Ruwet 1976: 89)

b. Le bébé se change toutes les trois heures.
the baby REFL changes every three hours
'The baby is changed every three hours.' (instruction to babysitter)
(Zribi-Hertz 1982: 349)

c. Les cuisses de grenouilles se mangent avec les doigts.
the legs of frogs REFL eat with the fingers
'Frog's legs are eaten with one's fingers.' (Boons et al. 1976: 131)

5.2.2 *Events and event quantification*

Earlier (see section 3.1) we have seen that the stative aspectual properties of type I middles are a direct consequence of the type of modality expressed in them. It is therefore only to be expected that the different modal properties of reflexive-marked passives lead to different aspectual properties as well. In particular, the potential absence of modal semantics in such passives corresponds to the absence of the obligatorily stative properties of type I middles:

(60) a. La question se traite actuellement à l'Assemblée.
the issue REFL discusses now in Parliament
'The issue is being discussed now in the National Assembly.'
(Zribi-Hertz 1982: 349)

b. La question est en train de se discuter dans la salle du conseiller.
the issue is in process of REFL discuss in the hall of Council
'The issue is being discussed at the council hall.'
(Zubizarreta 1987: 150)

c. Les vivres se distribueront tout à l'heure au premier étage.
the victuals REFL distributes all-at-the-hour on-the first floor
'The food will be distributed in a while on the first floor.'
(Zribi-Hertz 1982: 349)

Because of the eventivity of reflexive-marked passives, generic quantification over the event will lead to something like a middle reading, but with the modal distinction observed at the beginning of section 5.2.1. A true middle expresses potentiality; the generically used reflexive-marked passive expresses how things are always done, which leads to prescriptive modality.

There are two different views on the nature of the stativity found in middles across languages, which seem to correspond to whether the authors are dealing with type I or type II middles. As described earlier, type I middles are generally treated as true statives, which Fagan (1992) argues should be treated as quantifying over potential subjects (not events). The opposite is argued for by Condoravdi (1989), whose view on stativity in (type II) middles involves quantification over events. Unfortunately, these authors do not generally narrow down their sample of middles sentences to those that, if such a distinction were warranted, would be likely to be true middles instead of reflexive-marked passives. A notable exception is Cinque's (1988) article on Italian reflexives, in which it is argued that Italian middles are true statives in exactly those cases where they are true middles, and not otherwise. Cinque (1988: 563) provides the following example from Italian:

(61) *?Il sindaco ha il vantaggio di essersi già corrotto ieri.
the mayor has the advantage of already REFL being bribed yesterday

The ungrammaticality of specific time reference in this middle indicates its stative character.

A similar view is found in (Fagan 1992). Fagan argues that Condoravdi's (1989) argument concerning type II middles is based on what Fagan refers to as non-core cases of middles – in other words, reflexive-marked passives.

5.2.3 Adverbial modification

It is quite clear that there is a correlation between the notion that type II middles may just be passives and the absence in such passives/middles of the obligatory adverbial modification found in type I middles. The ambiguity of the following

French example shows that such modification may not even have a middle reading when present:

(62) Le grec se traduit facilement.
the Greek REFL translates easily (Fellbaum and Zribi-Hertz 1989: 23)

This example can either mean 'Greek has the property of being easy to translate' (property reading typical for 'true' middles) or 'Greek is translated with ease' (passive-like reading). A minimal pair like this suggests that there may be a true structural and/or semantic distinction between reflexive-marked passives and true (type II) middles. The presence of a truly passive reading distinct from a middle reading is further corroborated by the fact that the passive can have an episodic counterpart:

(63) Les examinateurs constatent que le grec se traduit ce jour-là plus facilement que l'araméen.
the examiners note that the Greek REFL translates that day more easily than the Aramaic
'The examiners note that on that day Greek is translated more easily than Aramaic.' (Fellbaum and Zribi-Hertz 1989: 23)

There is no evidence for an episodic counterpart of the true middle reading.

The hypothesis that the true middle should be distinguished from a reflexive-marked passive in languages with type II middles is further supported by cases like those in (64):

(64) a. Ce genre de livres s'achète surtout dans les gares.
this type of books REFL buys especially in the stations
'This type of book is bought especially in train stations.'
(Hirschbühler 1988: 105)

a'. *Ce roman s'achète bien.
this novel REFL buys well (Hirschbühler 1988: 105)

b. Ce client se reçoit au petit salon.
this client REFL receives in-the small parlour
'This client is received in the small parlour.' (Zribi-Hertz 1982: 349)

b'. ?Les petits colis se reçoivent facilement.
the small packages REFL receive easily (Fagan 1992: 98)

It turns out that reflexive-marked passives do not always have correlates that can be modified by the typical middle modifiers 'easily' or 'well'.

5.2.4 Type II middles and capability

Both type I and type II middles express potentiality, i.e., any subject's ability to perform the action. However, even within this middle reading there is an important distinction. Whereas type I middles usually require a modifier of this

potentiality, type II middles may express a middle reading without modification. The middle reading without modification is illustrated in (65) (cited in Fagan 1992: 184, from Zribi-Hertz 1982: 348). Note that the English equivalents in (66) are ungrammatical:

(65) a. Ce papier se lave.
this paper REFL washes
'This paper is washable.'
b. Cette racine se mange.
this root REFL eats
'This root is edible.'
c. Cette solution se discute.
that solution REFL debates
'That solution is debatable.'

(66) a. *This paper washes.
b. *This root eats/consumes.
c. *That solution debates.

Other cases of what Fagan refers to as non-core middles are also of this type, lacking the type of modification that is obligatorily found in type I middles (see the examples in (59) above).

If such sentences are treated as true middles, their existence should be interpreted as an argument in favor of the idea that there is no real distinction between type II middles in their middle and passive readings. If the truly middle reading were a different animal, as suggested by the evidence from the type of genericity involved (sections 5.2.1 and 5.2.2) and the interpretation of adverbs (section 5.2.3), we would expect the same degree of obligatoriness of the adverbial modification in the true middle reading as in type I middles.

This suggests that examples like (65) should in fact not be treated as middles in the narrow (type I) sense. The difference between their reading and the one found in type I middles is clear from the following two general paraphrases:

(67) a. **Type II middle without adverbial modification (X se-V):**
'X has a property such that it is possible for X to be V'ed.'
(e.g., *ce papier se lave* (65a) 'this paper has a property such that is possible for it to be washed')
b. **Type I middle (X V Adv):**
'X has a property such that it is possible for anyone somehow to V X.'
(e.g., this paper washes easily 'this paper has a property such that it is possible for anyone to wash it with ease')

The paraphrase of the type II middles without modification actually involves a passive, and although it is of course dangerous to base arguments on paraphrases, this suggests that they might be variants of the reflexive-marked

passive, not the true middle. It follows that in order to maintain a real semantic and/or syntactic distinction between a reflexive-marked passive and the true middle in a language with type II middles, we need to classify the rather middle-like reading of examples like (65) as being really passive. This means it must be shown that it patterns with the passive and not with true middles with respect to the type of genericity involved, as well as with respect to the other criteria that will be discussed in the remainder of this section: the status of the external argument and restrictions on the formation of these constructions.

5.3 Properties of the understood subject

As has been shown above, there is a difference between the status of the external theta-role of the underlying verb in passives and type I middles (see also section 7 for discussion of this difference). In order to establish the status of the middle reading of type II middles, the status of the original verb's external theta-role needs to be demonstrated.

5.3.1 By-*phrases*

Some languages with type II middles allow reflexive-marked passives that contain the equivalent of English *by*-phrases. (68a) is an example from older/non-standard French (from Fagan 1992: 184, Zribi-Hertz 1982: 348); (68b) is a Greek example (from Lekakou 2002: 28):

(68) a. Les permissions de copier s'accordent par le directeur.
the permits to copy REFL grant by the director
'Permission to copy is grant by the director.'
b. Afto to vivlio diavazete efxarista akomi ki apo megalus.
this the book read-PASS-3sg with pleasure even and by grown-ups
'This book is a pleasure to read even for grown-ups.'

Such reflexive-marked passives either are episodic or have an episodic counterpart, as opposed to true middles, which can never be used episodically. This can be shown by forcing a true middle interpretation on a reflexive-marked passive, in which case adding a *by*-phrase makes the example ungrammatical:[6]

(69) a. *Ce genre de surface se nettoie bien par les femmes de ménage.
this type of surface REFL cleans well by the housewives
'This type of surface is easy to clean for housewives.'
b. *Les livres de poche se vendent bien par les petits marchands.
the books of pocket REFL sell well by the small merchants
'Small paperback books are easy to sell for small merchants.'

The occurrence of a *by*-phrase in some variants of type II middles is an indication of the distinction that can be made in all languages with such middles, regardless of the properties of the reflexive-marked passives in them: in the reflexive-marked

passive, the underlying verb's external theta-role is syntactically active in a way that it is not in a type I middle. There are some further observable consequences of this difference.

5.3.2 Controlling a purpose clause

The understood agent of a reflexive-marked passive may control the PRO subject of a purpose clause, whereas the understood agent of a type I middle may not. An Italian example (from Cinque 1988: 562) is provided in (70):

(70) Quell'uomo politico si può corrompere (facilmente) per dimostrare la propria influenza.
that politician REFL can bribe (easily) to show one's influence
'It is easy to bribe that politician to show one's influence.'

5.3.3 Secondary predicates

Similarly, a reflexive-marked passive may control the subject of a small clause, but not in its true middle reading. This is shown for Italian in (71) (from Cinque 1988: 562):[7]

(71) a. Il museo del campo si può visitare facilmente anche nudi.
the camping museum REFL can visit easily even naked
'The camping museum can easily be visited even when nude.'
b. Il museo del campo ha il vantaggio di potersi visitare facilmente (*anche nudi).
the camping museum has the advantage of REFL visiting easily (even naked)
'The camping museum is easy to visit (even when nude).'

5.4 Restrictions

Above, we have seen that the formation of type I middles shows lexical and other restrictions that are not found in the formation of passives in the same language. (This issue is discussed in more detail in section 6.) In order to establish whether type II middles should be treated as variants of reflexive-marked passives or not, it is worth taking a look at the existence of restrictions on the formation of these constructions.

5.4.1 Non-finite contexts

Reflexive-marked passives are claimed not to occur in infinitival contexts. Nevertheless, some exceptions to this generalization have been identified in the literature. This might also be an indication of distinctions in the behavior of true middles and (other) reflexive-marked passives.

The exception concerns control in Italian. Only middle-like reflexive-marked passives are to some extent acceptable in this context, as opposed to obvious passive reflexives (Cinque 1988: 560):

(72) a. (?)Questo vestito ha il vantaggio di lavarsi più facilmente di altri.
this suit has the advantage of washing-REFL more easily than others
'This suit has the advantage of being more easy to wash than others.'
b. (?)Questo tavolino ha il vantaggio di trasportarsi con estrema facilità.
this table has the advantage of transporting-REFL extremely easily
'This table has the advantage of being extremely easy to transport.'
c. *Neanche il nemico ha la proprietà di uccidersi senza rimorsi.
not even the enemy has the property of killing-REFL without remorse
d. *Carlo ha il vantaggio di odiarsi facilmente.
Carlo has the advantage of hating-REFL easily

This seems to distinguish exactly between what we have been referring to as true middles and reflexive-marked passives.[8]

However, there is a second class of cases where type II middles occur in infinitival contexts, but which are unlikely to have the status of true middles. This class of examples concerns reflexive-marked passives in Spanish and Italian ECM constructions involving verbs of perception, as in (73) ((73a) from Cinque 1988: 561; (73b) from Suñer 1975). The Spanish example especially does not seem to have generic time reference, which means a true middle reading is excluded. It seems, then, that occurrence in an infinitival context does not discriminate between a true middle reading and a passive reading of the reflexive-marked passives:

(73) a. Non ho mai visto spendersi cosí tanti soldi come quest'anno. Italian
I've never seen spend-REFL so much money as this year
'I've never seen so much money being spent as this year.'
b. Al anunciársele a Juan el resultado le echaron chispas los ojos. Spanish
at-the announce-INF-REFL-him to John the result from-it threw sparks the eyes
'When one announced the result to John, his eyes sparkled.'

5.4.2 *Non-third person*

It is sometimes claimed that type II middles may occur with third person grammatical subjects only. The question is whether this holds for such middles in their passive reading, the middle reading, or both. Also, if it should hold, the question is whether it is a grammatical restriction or something else, for example an anti-animacy condition on the subject.

In Italian, the restriction holds at least in the middle reading. The following example is provided by Cinque (1988: 565):

(74) *Io mi trasporto facilmente.
I REFL transport easily
'I'm easy to transport.'

It should be noted that this restriction does not hold for other uses of the reflexive element, such as with unaccusatives/inchoatives or inherent reflexives.

In French, the restriction does not hold at a grammatical level, given examples like the following (from Grimshaw 1982: 146):

(75) Si tu étais une chemise, tu ne te vendrais pas pour trop cher.
if you were a shirt you NEG REFL sell-SUBJ NEG for too expensive
'If you were a shirt, you would not be sold for much.'

However, it looks as though the restriction might hold at the level of animacy: a middle like this may be awkward to derive for a first or second person subject because, everything else being equal, this imposes animacy on the subject. If this animacy effect of a first or second person pronoun is explicitly excluded, as in the metaphorical example in (75), the middle is grammatical.[9]

The Italian example is provided in an explicitly middle reading; the French one looks more like a reflexive-marked passive. As a result, the examples illustrating compatibility with first and second person subjects provide no additional insight into the properties of the middle reading of type II middles.

5.5 Conclusion

So should we conclude that there is only one reflexive middle/passive construction in languages with the 'type II middle', or that there is a real distinction between a reflexive-marked passive and a true middle with reflexive marking in the relevant languages? Probably we want to say both, but at different levels: the construction does seem to have two truly distinct readings, which impose their own restrictions on the environments they occur in. However, almost all the distinctions discussed were of this semantic nature, so there is very little evidence on which to base a syntactic distinction between the two constructions. On the basis of the evidence presented in the literature, therefore, we conclude that type II middles are true middles that are syntactically parasitic on an independently occurring reflexive-marked passive construction. Note that type I middles are parasitic on an independently occurring syntactic construction as well, namely on simple active sentences. In fact, we do not know of any language that has a special morphological or syntactic form for middles only. It would seem to make sense, then, to define the middle as a semantic category which can be expressed by a variety of syntactic constructions cross-linguistically, as argued by Condoravdi (1989) and Lekakou (2002).[10]

6 Restrictions on middle formation

Not every verb can undergo middle formation. The proper characterization of the verbs that can undergo the process – i.e., the question of what exactly makes these different from those that are not eligible for middle formation – is notoriously difficult. A number of proposals have been made, which we will discuss in this section. Many of them manage to adequately capture a large number of

verbs that can undergo middle formation with a single generalization. Not surprisingly, these characterizations often overlap to a significant extent. We will see that none of these generalizations is without its problems, however, and it seems fair to say that the jury is still out on the issue.

In the discussion that follows, it is important to keep the distinction between type I and type II middles in mind. Type I middles seem to impose more restrictions on the type of verb that can occur in them than type II middles, and the discussion has mainly focused on the former in this respect. Where appropriate, we will make a comparison with type II middles.

Roughly, one can focus on three things when trying to establish the proper restrictions on middle formation: it may be that the verb itself must have a particular property for middle formation to be possible; it may be that the logical object/grammatical subject must have a particular property; or it may be that the logical subject must have a particular property. Of course, properties of these three elements are often linked, so, as noted, the proposed restrictions overlap to a significant extent. Also, combinations of demands on properties of these three elements are possible. Nevertheless, to get a clear classification of the various approaches it is useful to distinguish these factors.

6.1 *Properties of the verb*

Fagan (1992) proposes that aspectual properties of the verb are crucial in determining whether or not it can undergo MF (see also Roberts 1987). Fagan uses Vendler's (1967b) classification of verbs into four aspectual types:[11]

(76) a. activities: express an ongoing action with no inherent end-point (examples are *run*, *smoke a pipe*, *play the piano*, *push something*);
b. accomplishments: express an event with an internal time structure and an end-point (examples are *paint a picture*, *make a chair*, *build a house*);
c. achievements: express instantaneous events (examples are *recognize something*, *reach the summit*, *cross the border*);
d. states: do not express an event or activity (examples are *have something*, *love somebody*, *know something*).

According to Fagan, the crucial restriction on middle formation in English and German is the following:

(77) **Aspectual condition:**
Only (transitive) activities and accomplishments undergo middle formation.

Consider how examples of each aspectual class fare with respect to middle formation. The contrast in grammaticality between the examples in (78) and (79) on the one hand and those in (80) and (81) on the other lends support to Fagan's generalization in (77):

(78) a. This pipe smokes nicely.
b. Die Butter schmiert sich wie von selbst. German
this butter butters REFL as-though by itself
c. A Steinway piano plays easily.
d. Diese Gitarre spielt sich leicht. German
This giutar plays REFL easily

(79) a. Bob Ross-style pictures paint easily.
b. Dieses Buch liest sich leichter als das andere. German
this book reads REFL more easily than the other
c. Sturdy clear plastic boxes . . . assemble in seconds.
(Fagan 1992: 68)

(80) a. *A red-winged blackbird recognizes easily.
b. *Ein Spatz erkennt sich leicht. German
a sparrow recognizes REFL easily
c. *Such high summits do not reach easily.
d. *Hohe Gipfel erreichen sich nicht leicht. German
high summits reach REFL not easily

(81) a. *That answer knows easily.
b. *Diese Antwort weiß sich leicht. German
this answer knows REFL easily
c. *Such a nice person loves only too easily.
d. *Ein solcher netter Mensch liebt sich leicht. German
a such nice person loves REFL easily

However, there are also some more recalcitrant data for (77), as also discussed by Fagan. A famous contrast in middle formation is that between *sell* and *buy*. The former but not the latter can undergo the process (see (82)). Nevertheless, *buy something* is an accomplishment no less than *sell something*, and hence it should be eligible for middle formation according to (77):

(82) a. The new Saramago sells like water in a desert.
b. *The new Saramago buys with great difficulty, the distribution is bad.

To account for this contrast, Fagan proposes an additional constraint, which must hold of the grammatical subject of the construction (see also the next subsection). The condition is that the entity expressed by this subject (i.e., the logical object) must have properties such that it can be held responsible for the action that the predicate expresses (see also Van Oosten 1977, 1986):[12]

(83) **Responsibility condition:**
The grammatical subject of a middle (if present) must have properties such that it can be understood to be responsible for the action expressed by the predicate.

Consider how this accounts for the *sell–buy* contrast. A book can have properties which make it responsible for being sold easily: it can be well written, or have an attractive cover, or contain a lot of sex and violence, and so on. In contrast, although it can be difficult to buy a book because it is hard to find, or because you do not have enough money, those are not properties of the book itself. It is very hard, if not impossible, to imagine a book having intrinsic properties which makes buying it easy or difficult. Hence the unacceptability of (82b). Other verbs that pass the aspectual condition in (79), but nevertheless fail to undergo middle formation because of (83), include *discuss* and *invite*.

Some other potential counterexamples to (79), which nevertheless do comply with (83), include achievement verbs, as illustrated in (84) and (85):

(84) a. The glass broke.
b. The children broke the glass.
c. Glass breaks easily.

(85) a. The explosives detonated.
b. The engineer detonated the explosives.
c. High explosives detonate easily.

The problem here is that most of these verbs take part in the causative–inchoative alternation (see the (a) and (b) examples in (84–85)). This makes it unclear whether the (c) examples in (84–85) just involve generic instantiations of the inchoative alternant in the (a) examples (which we have assumed to not involve middle formation: see section 2.3), or whether they can also be genuine middles based on the transitive causative alternant in the (b) examples. (The former analysis is possible for the relevant examples in any case, so the question is whether they are ambiguous between a middle and a generic inchoative reading or only have the latter reading.) Note that, if the (c) examples are middles, they can be explained by an appeal to (83): glass certainly has properties which make it easy to break it, and explosives can be made in such a way that it is easy to detonate them.

Semantically, the (c) examples do appear to be ambiguous between a reading in which an external causer is implied and a reading in which this is not the case (compare *glass breaks easily, it is so brittle* with *glass breaks easily, you can do it with your bare hands*). This might indicate that middle formation is applicable to the (b) examples, which, given that they are achievements, would run counter to (77). Nevertheless, this should be established on the basis of more solid syntactic evidence for the supposed ambiguity of the (c) examples. For English, such evidence is hard to come by, although in section 2.3.3 we discussed the interpretation of *easily*, data that Fellbaum (1986) advances as evidence for the distinction.

For Dutch, it is a bit easier to distinguish the inchoative reading of examples like (84c) and (85c) from their potential middle reading. Dutch shows solid evidence for a syntactic distinction between unergative and unaccusative verbs (see, for instance, Hoekstra 1984b; Hoekstra and Mulder 1990; Ackema 1999). As is

apparently the case in every language showing the distinction, inchoatives are unaccusatives syntactically (cf. Hale and Keyser 1993a; Levin and Rappaport Hovav 1995; Reinhart 2000b). Middle verbs behave like unergatives in Dutch, however (Ackema and Schoorlemmer 1995; see also section 7).

One test distinguishing unergatives from unaccusatives in Dutch is auxiliary selection in the perfect tense: unergatives take *hebben* 'have', unaccusatives *zijn* 'be'. The perfect tense of an example like (86a) can be formed with either. Use of *hebben* goes together with a middle reading, in which an implied logical subject argument is present (see (86b)). Use of *zijn* goes together with an inchoative reading, with no implied second argument present (see (86c)):

(86) a. Vazen breken gemakkelijk.
vases break easily
b. Dit soort stenen heeft/*is altijd gemakkelijk gebroken. (said by one stonecutter to another)
this sort stones has/is always easily broken
'Stones of this type always have had properties such that it is easy for people to break them.'
c. Dit soort glazen ??heeft/is altijd nogal gauw gebroken.
this sort glasses has/is always rather quickly broken
'Glasses of this type have always had properties such that they break rather quickly.'

It turns out that examples like (84c) and (85c) in this language can have either an unergative or an unaccusative structure, and that this corresponds to the two different readings, with an external cause implied in the former but not in the latter case.

Of course, as already noted, there is language variation with respect to which verbs can undergo middle formation, so it might be that Dutch and English differ with respect to the aspectual constraint in (77). In this respect, Fagan notes that at least in French (with type II middles in our terms) middle formation is much less restricted, compared to English. Even some apparent state verbs are possible targets for the process, as the example in (87) shows:

(87) La Tour Eiffel se voit facilement de ma fenêtre.
the Tower Eiffel REFL sees easily from my window
'The Eiffel Tower can easily be seen from my window.'

The question is whether we can link such language variation to other differences between the languages. Is there any reason why English should comply with the aspectual restriction in (77) while French apparently should not?

Hulk and Cornips (1998, 2000) argue that the presence of a reflexive marker in French but not English middles is responsible for the different aspectual restrictions on middle formation in both languages. They argue that the relevant aspectual restriction really is the same for all languages, but that the reflexive can help

in complying with this restriction. Their aspectual treatment is slightly different from Fagan's. In particular, they argue that only so-called incremental verbs – i.e., verbs whose object delimits or 'measures out' the event referred to by the predicate (cf. Tenny 1987) – are eligible for middle formation:

(88) **Delimited event condition:**
Only verbs with a logical object argument that delimits the event expressed by the predicate can undergo middle formation.

An object delimits and measures out an event when the progress of the event can be measured by looking at how far the object is 'affected' by it (see also the next subsection on the general notion of affectedness). For example, the event described by *mow the lawn* is measured out by properties of the object: we know that the mowing of the lawn is halfway when half the lawn is affected by it, and that the end-point of mowing the lawn is when the entire lawn is affected. Compare this with *listen to music*: this is an event that is not measured out by properties of the object. The music is not affected by listening to it, so we cannot say that we have ever done half or whole of listening to music, in contrast to having done half or whole of mowing the lawn.[13] This contrast comes close to the distinction between activities and accomplishments in Vendler's classification in (76). This means Hulk and Cornips's restriction to incremental verbs would seem to be somewhat overly restrictive, in that it is difficult to account for the cases of true activity verbs that Fagan cites as undergoing middle formation in English. Consider *this piano plays easily: play a piano* is an activity, not a delimited event measured out by how it affects the piano. (Also, as we will see in the next subsection, in Dutch and German it is possible to form middles of some verbs that do not have a direct object at all, which consequently cannot fall under this classification.)

Be that as it may, the point Hulk and Cornips want to make is that the reflexive element can turn a non-delimited event into a delimited one. They argue that the reflexive "has the effect of presenting the situation expressed by the predicate as involving a transition" (p. 212). This has the effect that the predicate now complies with the above-mentioned criterion of being delimited, so that it is eligible for middle formation. Hulk and Cornips present minimal pairs from Standard Dutch and a dialect spoken in the southern province of Limburg, Heerlen Dutch. In contrast to Standard Dutch (and English), Heerlen Dutch uses the reflexive element *zich* in middles. It turns out that Heerlen Dutch, like French, allows middles of some verbs which in standard Dutch do not undergo the process. Hence, this might be attributed, as it is by Hulk and Cornips, to the aspectual effect the reflexive is supposed to have on the predicate. The relevant examples are given in (89–90):

(89) a. *Frans verwerft gemakkelijk. Standard Dutch
French acquires easily
b. *French acquires easily.

c. Frans verwerft zich gemakkelijk. Heerlen Dutch
French acquires REFL easily
d. Le français s'acquiert facilement. French
the French REFL-acquires easily

(90) a. *Dat herkent gemakkelijk. Standard Dutch
that recognizes easily
b. *That recognizes easily.
c. Dat herkent zich gemakkelijk. Heerlen Dutch
that recognizes REFL easily
d. A quoi ça se reconnait un flic belge? French
at what that REFL recognizes a cop belgian
'How do you recognize a Belgian cop?'

The reflexive cannot turn just any predicate into a delimited one, however. Apparently, for some events it is impossible altogether to construe them as a transition, and thereby as delimited. Such predicates do not undergo middle formation even in languages in which the construction contains a reflexive. Hence, as Hulk and Cornips note, it cannot be said that the 'affectedness' condition simply does not apply to languages like French and Heerlen Dutch (cf. Zubizarreta 1987; Cinque 1988). There still are aspectual restrictions on middle formation in French (see (91)) and Heerlen Dutch (see (92)) too (examples from Hulk and Cornips 1998):

(91) a. *Les pommes, ça s'aime beaucoup.
the apples, that REFL likes a lot
'Apples are very nice.'
b. *Ça se hait partout.
that REFL hates everywhere
'People hate that everywhere.'

(92) a. *Die antwoorden weten zich gemakkelijk.
those answers know REFL easily
b. *Zo'n dingen haten zich vreselijk.
such things hate REFL terribly

Although the contrast between standard Dutch and Heerlen Dutch is very suggestive, the proposal that the presence of a reflexive element affects the aspectual characteristics of a predicate in such a way that it becomes possible to make a middle from it is not without its problems either. One problem that presents itself is constituted by German. Like Heerlen Dutch, German uses reflexive *sich* in middles. Nevertheless, according to Fagan (1992), in German more or less the same aspectual restrictions on middle formation hold as those operative in English, rather than the more liberal ones of French. Compare (93) (from Wagner 1977 and Fagan 1992) with (91) and (92):

(93) a. *Diese Krankheit erkennt sich nicht leicht.
this illness recognizes REFL not easily
b. *Deine Unsicherheit bemerkt sich unschwer.
your uncertainty notices REFL easily
c. *Der Kirchturm sieht sich leicht trotz des Nebels.[14]
the church tower sees REFL easily despite the mist

Conversely, though less clearly for reasons we will see directly, it might be that there are languages that do not use a reflexive in middles but which are nevertheless more liberal in their choice of eligible verbs than English, Dutch, and German. In particular, languages that lack a special marker or morphology not only in middles (like English, etc.), but also in passives seem to be more like French/Heerlen Dutch in this respect. For instance, in a number of (heavily deflected) creole languages like Negerhollands (with Dutch-based lexicon), examples like the following are possible (see Bruyn and Veenstra 1993):

(94) Am sal graf mi am. Negerhollands
he will bury with him
'He will be buried with him.' (Bruyn and Veenstra 1993: 65)

Of course, as in languages with reflexive-marked passives (section 5), the question here is whether such sentences are truly ambiguous between a passive and a middle.[15] At least in the case of Sranan (another such creole), it appears that sentences of this types are ambiguous and do have both a middle and a passive reading (Lilian Adamson, p.c.).[16]

Another problem for restricting middle formation to predicates with a 'delimiter' object, at least if this were to be regarded as a universal constraint, is the existence of languages with impersonal middles, that is, middles formed from verbs that do not take an object argument (section 3.4). This will be discussed in more detail in the next subsection.

6.2 Properties of the grammatical subject/logical object

The 'classical' restriction concerning the properties the grammatical subject/logical object must have in order for a middle to be well-formed is the following:

(95) **Affectedness condition:**
The logical object/grammatical subject in a middle must be affected by the action expressed by the middle verb.

We have already seen a particular implementation of this condition in the previous subsection, where we discussed proposed aspectual restrictions on middle formation. Recall that Hulk and Cornips (1998) argue that (95) is really a condition on the aspect a VP must have in order for middle formation to be possible.

(In particular, the VP must express an event that is delimited and 'measured out' by the object.) However, the condition has also been put forward in more general terms: only when the properties of the thing denoted by the logical object argument are affected by the action denoted by the verb is middle formation supposed to be possible.

Jackendoff (1990b) supplies the following test to distinguish affected objects ('Patients' in his terms) from non-affected ones. Take a transitive sentence of the type XP V YP. If this fits into the frame 'what happened to YP was XP V YP' or into the frame 'what XP did to YP was (XP) V YP', then YP is a Patient. So the difference in acceptability between (96) and (97) indicates that the object arguments of verbs like *invade* and *destroy* are Patients, whereas the object arguments of verbs like *know* and *recognize* are not:

(96) a. What happened to Afghanistan was both the USSR and the US invaded it.
b. What the Russians and the Americans did to Afghanistan was destroy it.

(97) a. #What happened to the answer was everybody knew it.
b. #What the tourists did to the Eiffel Tower was recognize it.

The condition in (95) can hence be restated more concisely as follows:

(98) **Affectedness condition:**
A middle verb must have a Patient argument.

A condition like (98) was originally proposed to account for a difference between verbal passives and passive nominals. Whereas virtually any object can be promoted to subject in the former, the latter is restricted by an affectedness condition on this argument (Anderson 1977b):

(99) a. Afghanistan was invaded by the USSR and by the US.
b. Afghanistan was destroyed by the USSR and by the US.
c. The answers to most of the exam questions were known in advance.
d. The spy was not recognized even by his mother.

(100) a. Afghanistan's invasion by the US
b. Afghanistan's destruction by the US
c. *the answer's knowledge by the students
d. *the spy's recognition by the secret service

Now, as noted by Jaeggli (1986a) and others, a similar restriction appears to apply to middle formation. For instance, the contrast in (100) can be replicated with (type I) middles:

(101) a. Defenseless countries invade easily (said by one aggressor to another).
b. Defenseless cities destroy easily (said by one bomber to another).
c. *Simple answers know easily (said by one student to another).
d. *Security staff recognizes easily (said by one thief to another).

Given that this condition is a more general version of the one in (88), we have also already encountered some potentially problematic data, even if we leave out of consideration that languages with type II middles are more flexible in how to comply with it (recall the French–English contrast). In fact, it would seem that, in its general form in (98), it is relatively easy to think of counter-examples even in languages like English. Consider, for example, the following examples (see also Hale and Keyser 1986; Fagan 1988):

(102) a. Greek does not translate easily.
b. Zulke stukken zingen lekker. Dutch
such pieces sing nicely
c. Das Buch liest sich leicht. German
the book reads REFL easily

Neither of these cases complies with the affectedness condition: you cannot say 'what he did to Greek was translate it' or 'what happened to the piece was the choir sang it.'

As already hinted at, another problem for the affectedness condition on middles, at least as a universal condition, is formed by impersonal middles in Dutch and German. Consider the following examples:

(103) a. Het werkt lekker met een muziekje op. Dutch
it works nicely with a music-DIM on
'It is nice to work with some music on.'
b. Het loopt prettig op deze schoenen. Dutch
it walks comfortable on these shoes
'These are comfortable shoes to walk in.'

(104) a. Es lebt sich gut als Sekretärin in Bonn. German
it lives REFL well as secretary in Bonn
(Brinker 1969: 9)
b. Über dumme Fehler schimpft sich es leicht German
about dumb mistakes grumbles REFL it easily
(Fagan 1992: 44)

The pronoun in subject position in such cases is, of course, in no way affected by the action expressed by the verb. This expletive-like element, though it may function as grammatical argument (see Bennis 1986), is not referential at all, let alone referring to some affected entity.

As already discussed in section 3.5, Dutch has yet another variant of middle in which an unexpected entity appears in subject position, namely what seems to be an adjunct rather than an argument of the verb (cf. Hoekstra and Roberts 1993a; Ackema and Schoorlemmer 1994). For example, next to (103b), (105) is also possible:

(105) Deze schoenen lopen prettig.
these shoes walk comfortably

Middles of this type, too, are productive. Some more examples are given in (106):

(106) a. Deze naalden breien lekker.
these needles knit nicely
b. Deze stoel zit prima.
this chair sits fine
c. De snelweg rijdt makkelijker dan de binnenstad.
the highway drives easier than the inner city

The grammatical subjects here correspond to adjuncts in the active non-middle counterparts of these sentences (see (107)). Note that these are PP-adjuncts and that the preposition is not realized when the adjunct is promoted to subject under middle formation in (106):

(107) a. Ze breit altijd met deze naalden.
she knits always with these needles
b. Ze zit altijd in dezelfde stoel.
she sits always in the same chair
c. Ze rijdt liever op de snelweg dan in de binnenstad.
she drives preferably on the highway than in the inner city

So it seems clear that the grammatical subjects in (106) are not Patient arguments of the verb (compare *#what happened to the needles was she knit with them*, *#what she did to the chair was sit in it*, etc.). Indeed, they do not appear to be arguments of the verb at all, given their apparent adjunct status in (107). Though they are genuine counter-examples to the affectedness condition, there is a snag here, however. It turns out that you cannot just promote any adjunct to subject in a Dutch middle. Compare (106) with (110), for example. It is possible to make impersonal middles from the active examples in (108), as illustrated in (109), but adjunct middle formation is not felicitous now:

(108) a. Ze breit altijd met een muziekje op.
she knits always with a music-DIM on
b. Ze zit altijd voor de tv.
she sits always in-front-of the tv
c. Ze rijdt altijd met grote haast.
she drives always with great hurry

(109) a. Het breit lekker met een muziekje.
it knits nicely with a music-DIM
b. Het zit het beste voor de tv.
it sits the best in-front-of the tv
c. Het rijdt niet prettig met grote haast.
it drives not comfortably with great hurry

(110) a. *Een muziekje breit lekker.
a music-DIM knits nicely
b. *De tv zit het beste.
the tv sits the best
c. *Grote haast rijdt niet prettig.
great hurry drives not comfortably

The question, then, is what the difference is between the subjects/logical adjuncts in (106) and those in (110). It might be that the difference is spurious, and that it is just less straightforward to think of a sensible interpretation for the missing preposition in (110) than it is in (106). This is more or less the line Kerstens (2000) takes. According to Kerstens, any adjunct can become subject in a middle. Hence, he would presumably argue that the examples in (110) really are fine, although they may be pragmatically odd. On the other hand, Ackema and Schoorlemmer (1994) argue that there is a syntactic difference between the sources of (106) and (110), residing in a different status of the PPs in (107) and (108). According to Ackema and Schoorlemmer, in the former case the PPs are not adjuncts at all, but rather arguments of the verb.

There are several tests to distinguish argumental PPs from adjunct PPs (see Hornstein and Weinberg 1981; Baker 1988a; Neeleman 1997; among others). For example, according to Hornstein and Weinberg, preposition stranding in English is allowed only with argumental PPs, not with adjunct PPs. At least colloquial Dutch allows for P-stranding (though it is considered substandard by some speakers), and the same distinction seems to apply here. Compare, for example, (111) with (112):[17]

(111) a. Welke naalden breide je mee?
which needles knitted you with
b. Welke stoel zat je in?
which chair sat you in
c. Welke weg reed je op?
which road drove you on

(112) a. ?*Welk muziekje breide je mee?
which music knitted you with
b. ?*Welke tv zat je voor?
which tv sat you in-front-of
c. ?*Hoeveel haast reed je mee?
how-much-hurry drove you with

Another test is whether or not the PP can be extracted from a weak island: arguments are extractable from such islands; true adjuncts are not (see Chomsky 1986a; Cinque 1990c; Rizzi 1990b). Let us see how the PPs in question behave when extracted from an indirect question (a *wh*-island). Although the contrast is not always very clear, in general there does seem to be a contrast, with the PPs splitting along the same lines again:

(113) a. ??Met welke naalden vroeg je wie er breide?
with which needles asked you who THERE knitted
b. ??In welke stoel vroeg je wie er zat?
in which chair asked you who THERE sat
c. ??Op welke weg vroeg je wie er reed?
on which road asked you who THERE drove

(114) a. ?*Met welke muziek vroeg je wie er breide?
with which music asked you who THERE knitted
b. ?*Voor welke tv vroeg je wie er zat?
in-front-of which tv asked you who THERE sat
c. *Met hoeveel haast vroeg je wie er reed?
with how-much hurry asked you who THERE drove

If these tests, and the rather shaky judgments on examples like this, can be considered reliable enough, then this would indicate that the examples in (106) are derived from sources which have an argumental PP rather than a true adjunct. If so, Dutch does not have real adjunct middles. Rather, what seems to happen in 'adjunct' middle formation is that an argument that is normally expressed as a PP loses its P when promoted to subject in a middle. Barring a few exceptions, PPs do not make good subjects (see Neeleman 1997 for discussion), so it seems what happens here is that the argument is stripped of its P specifically to make it an eligible subject.

The process by which a PP loses its P and is turned into a direct argument of the verb is reminiscent of so-called applicatives in some languages (e.g., Bantu languages like Kinyarwanda and Chimwi:ni). In applicatives, too, a dependent of the verb that is usually expressed as a PP is turned into a direct NP argument. In this case, the process is marked by special morphology on the verb, an applicative morpheme. An example from Kinyarwanda is given in (115) (from Baker 1985a: 400 – as can be seen from the glosses, the applicative is very similar to the English dative alternation, though it applies to more types of arguments):

(115) a. Umugabo y-oohere-je ibaruwa kw'iiposita.
man send letter to-post-office
b. Umugabo y-oohere-je-ho iposita ibaruwa.
man send-APPLIC post-office letter

According to Baker (1988a), an applicative morpheme is in fact the preposition of the PP in the (a) example, now incorporated into the verb. Baker shows that this process of P-incorporation is possible only from argumental PPs, not from adjunct PPs (as expected, given that adjuncts are strong islands; cf. Huang 1982a). Given that adjunct middle formation in Dutch seems to be sensitive to this same distinction, a process similar to applicative appears to take place here. There is of course a clear difference: no overt reflex of the preposition is present on the verb in Dutch adjunct middles. It is absolutely impossible to express the P:

(116) a. *Deze naalden mee-breien/breien-met prima.
these needles with-knit/knit-with fine
b. *Deze stoel in-zit/zit-in lekker.
this chair in-sits/sits-in nicely

Ackema and Schoorlemmer (1994) therefore propose that in Dutch P-incorporation does not take place in syntax, as in Kinyarwanda, but at the level of Conceptual Structure (cf. Jackendoff 1990b); i.e., before projection to syntax (to two separate syntactic heads) takes place.

In short, it seems that when 'promotion to subject' in middles takes place (impersonal middles aside), only arguments can be so promoted. Then there is language variation as to whether an applicative-like process is available that can turn argumental PPs into argumental DPs and thus into potential grammatical subjects.

In fact, not every DP argument can always be promoted to subject under middle formation, not even when it would be of the right type semantically (so when it is a bona fide Patient, or a delimiter, or something similar). In particular, middle formation turns out to give bad results when a verb takes more than one internal argument. In other words, it is sensitive to the following condition:

(117) **Anti-double object condition:**
Verbs in a double object construction do not undergo middle formation.

Consider a verb like *sell*, which can optionally take a second internal argument, namely a Goal, next to its Patient argument. This verb forms perfectly acceptable middles (as in (118b)), but when the Goal argument is present in a double object construction, middle formation is not possibly any more (as shown in (118c)). Note that middle formation is equally impossible when the Goal argument rather than the Patient is promoted: see (118d) (cf. Kayne 1982):

(118) a. I sold (the linguists) the books.
b. Such books sell well.
c. *Such books sell linguists well.
d. *Linguists sell such books well.

It seems fair to say that this restriction is still ill understood (but see Everaert 1990b, Ackema and Schoorlemmer 1994, Hulk and Cornips 1998, Zwart 1998, Kerstens 2000, and Steinbach 2003 for some suggestions).

Another proposed restriction on the grammatical subject is one that we have taken for granted so far, but which is certainly not trivial: it must be an argument of the middle verb:

(119) **Argument sensitivity:**
The grammatical subject of a middle (if present) must be an argument of the middle verb.

That this is not trivial can be seen when we consider the grammatical subject in passives, for which this condition does not hold. Thus, exceptionally, case-marked subjects of some infinitival complements can become the grammatical subject of the matrix verb under passivization, but not under middle formation:

(120) a. He was believed to be a rich man.
a'. *He believes to be a rich man easily. (*on middle reading)
b. She was expected to win the race.
b'. *She expects to win the race only with difficulty. (*on middle reading)

This concludes the syntactic restrictions on the subject (the logical object) of the middle verb.

A final generalization that has been proposed is a semantic one again. This a restriction on what this argument should not be, rather than what it should be, for it to be promotable under middle formation:

(121) **Anti-effectedness condition:**
The subject in a middle should not be an effected object of the verb.

This restriction has been proposed by Zwart (1998), who derives it from an incompatibility between the syntactic structure he proposes for middles and the one in which verbs with effected objects occur. The notion 'effected' should not be confused with the notion 'affected' in (95). An effected object is one that comes into existence by the action denoted by the verb. So verbs like *build*, *paint*, *write*, and *knit* can take an effected object, as the Dutch examples in (122) illustrate:

(122) a. Bob bouwde een nieuw huis.
Bob built a new house
b. Bob schilderde een landschapje.
Bob painted a landscape-DIM
c. Bob schreef een detectiveroman.
Bob wrote a detective novel
d. Bob breide een nieuwe trui.
Bob knitted a new sweater

The house in (122a) comes into existence as a result of the building. Similarly, the picture is created by the painting, the novel by the writing, and the sweater by the knitting. Note that, looking at it from an aspectual point of view, this is a subcase of Vendler's class of accomplishments, or, in Tenny's (1987) terms, these are subcases of the aspectual type in which the object 'measures out' the event described by the verb. That means the condition in (121) seems to be in opposition to both Fagan's aspectual condition in (77) and the one proposed by Hulk and Cornips (1998) (see (88)). Nevertheless, the following examples appear to indicate that middle formation is indeed impossible with verbs with an effected object:

(123) a. ??Dit huis bouwt niet makkelijk.
this house builds not easily
b. ?*Dit schilderij schildert gemakkelijk.
this painting paints easily
c. ?M'n nieuwe boek schrijft niet gemakkelijk.
my new book writes not easily
d. ?*Deze trui breit moeilijk.
this sweater knits difficult

Note, however, that examples like this are independently ruled out by another restriction on middle formation we have already encountered, one that seems to be necessary next to other conditions one might want to propose anyway (see also the next subsection). This is the 'responsibility' condition in (83), which states that the subject of a middle "must have properties such that it can be understood to be responsible for the action expressed by the predicate". The subjects in (123) cannot possibly comply with this restriction, precisely because they only come into existence as a result of that action.

This interfering factor can be neutralized by using generic arguments as subjects (logical objects). A specific house that comes into being as a result of some building action cannot have any properties before it is finished (i.e., before it actually is that specific house) which could make it responsible for building being difficult.[18] However, a generic class of (a particular type of) houses certainly can have properties such that building a house of that type is difficult. As it turns out, examples like (123) are fine with generic subjects:

(124) a. Dat soort huizen bouwt niet makkelijk. (said by one builder to another)
that kind houses builds not easily
b. Zo'n landschapje schildert gemakkelijk.
such-a landscape-DIM paints easily
c. Dat soort flutromannetjes schrijft gemakkelijk.
that kind dross-novel-DIM-PLUR writes easily
d. Zulk soort truien breit niet moeilijk.
that kind sweaters knits not difficult

On the whole, we have seen that, at least cross-linguistically, various types of constituent can become the subject of a middle. An attempt to capture the restrictions on middle formation by invoking a particular condition concerning properties of this element is therefore likely not to work for all instances of middles. Nonetheless, it remains to be explained why, although there are other possibilities, the 'affected object' seems to be the prototypical thing to get promoted to subject in a middle. In the next subsection we will see that this might be a side effect of a condition about what properties the logical subject argument must have for middle formation to be possible.

6.3 Properties of the logical subject

Just as there is a 'classic' condition on the grammatical subject of a middle, namely the affectedness condition discussed in the previous subsection, there also is a 'classic' condition on the logical subject (i.e., the suppressed argument), namely that it be an Agent (Abraham 1986; Pitz 1987; Roberts 1987):

(125) **Agentivity condition:**
The logical subject in a middle must be an Agent.

Consider again the contrast between the possible middles in (126) and the impossible ones in (127):

(126) a. Bureaucrats bribe easily.
b. That book reads well.
c. Greek does not translate easily.

(127) a. *The Eiffel Tower sees easily.
b. *The answer knows easily.
c. *Spies don't recognize easily.

It seems clear that, whether or not other conditions are capable of capturing this distinction, it (also) follows from (125). Useful tests that indicate whether or not an argument is an Agent in the relevant sense are the possibility of using agent-oriented adverbials like *intentionally* or *on purpose*, and use of the 'what XP did to YP' frame (see section 6.2), in which XP is an Agent.[19] These tests indicate that the subject argument of *bribe*, *read*, and *translate* are Agents, whereas the subject arguments of *see*, *know*, and *recognize* are not:

(128) a. The Mafia boss intentionally bribed the bureaucrats.
b. What Mary did was read a good book.
c. What Harry did was translate a Greek text.

(129) a. #The tourist intentionally saw the Eiffel Tower.
b. #What most of the students did was know the answer.
c. #James Bond intentionally recognized the other spy.

Nevertheless, Fagan (1992) argues that (125) fails to be general enough, for both English and German. She gives an example from German of a verb which appears to have a very non-Agent-like subject argument, but which is nevertheless attested to form a middle, namely *sterben* 'die':

(130) So schnell stirbt es sich nicht.
thus quickly dies it REFL not
'One doesn't die that quickly.' (Brinker 1969: 9)

This example is remarkable for another reason, namely that *sterben* is an unaccusative verb in German, which means an internal rather than an external argument has been suppressed. Such verbs do not usually undergo middle formation. In Dutch, too, the same verb, *sterven*, can marginally occur as a middle, as in (131) (from Ackema and Schoorlemmer 1994):

(131) ??Het bejaardenhuis sterft rustiger dan het slagveld.
the old-people-home dies more-quietly than the battlefield

The example has a similar status to examples of passives formed from unaccusatives (on which, see Everaert 1986b; Zaenen 1993); that is to say, it has an 'intentionally playing with language' effect with somewhat jocular overtones. This same effect in fact holds of the German example in (130), as well as of other constructed examples of middles from unaccusatives (thanks to Susi Wurmbrand for discussion of the German data):

(132) a. ?Een judomat valt beter dan een betonnen vloer. Dutch
a judomat falls better than a concrete floor
b. ?In Schiphol kommt es sich leicht an. German
in Schiphol arrives it REFL easily PARTICLE

What is crucial is that such examples have precisely the same status as an active example in which the verb in question is deliberately used agentively in contrast to its normal usage, giving rise to the 'funny' effect:

(133) a. ☺ Grootvader stierf opzettelijk te vroeg om het testament nog te kunnen laten veranderen.
Grandfather died on-purpose too early to the testament still to can let change
'Grandfather intentionally died too early (for us) to have the testament changed.'
b. ☺ Wat de minister van buitenlandse zaken steeds doet is te laat arriveren
what the minister of foreign affairs constantly does is too late arrive
'What the minister for foreign affairs constantly does is arrive too late.'

Hence such examples are not counter-examples, but rather seem to give extra support to the agentivity condition: it is possible to construct them to the same extent that it is possible to use the verbs in question agentively.

However, counter-examples to (125) in the other direction are rather more easy to come by. That is to say, there are cases in which a verb that does have an Agent for its subject argument nevertheless cannot undergo middle formation. Fagan cites the following examples from English and German (the latter from Wagner 1977):

(134) a. *The finish line reaches easily.
b. *This wall hits easily.
c. *That dog kicks easily.

(135) a. *Mit der Bundesbahn kommt es sich leicht zur vorgesehenen Zeit an.
with the national-railway arrives it REFL easily at-the planned time PARTICLE
b. *Dieses Ziel erreicht sich nicht leicht.
this goal reaches REFL not easily

Concerning these, we must first remark that (134b) and (135a) do not seem to have implicit Agent arguments in the relevant sense (i.e., Actor arguments in Jackendoff's sense; see note 19): #*What the car did was hit the wall*, #*Sue and Mary intentionally arrived on time*. The former does have an agentive use, however (*John hit Bill on purpose*), and at first sight middle formation is not much better in this use (??*Bill hits easily*; although there is a movie in which Humphrey Bogart states *"I don't slap that easily"*).

However, it seems these examples are again independently ruled out by the responsibility condition in (83), which, as noted, appears to be needed next to whichever other conditions on middle formation might hold. (As noted in section 6.1, Fagan, too, explicitly argues that it is needed alongside the aspectual condition in (77).) Consider the example in (134a): a finish line cannot have any properties that make reaching it easy. (The distance between start and finish line can be such that reaching the finish line is easy – but that distance is not a property of the finish line. A crooked finish line is not easier or more difficult to reach than a straight one, nor a white one easier to reach than a red one, etc.) Examples with (the agentive use of) verbs like *hit* and *kick* appear to improve considerably when a generic subject is used (see (136)), as it is more easy to imagine a class of things having properties which make it easy or difficult to hit/kick them than an individual object (compare also the previous subsection on effected objects), indicating that (83) is responsible for the deviance of at least (134b, c).

(136) a. Big dogs kick more easily than little ones. (said by one utter bastard to another)
b. Quick opponents do not hit easily. (said by one boxer to another)

There is a close relation between the agentivity condition on the logical subject in (125) and the affectedness condition on the grammatical subject in (95) (and as we have seen, in turn there is a close relation between this affectedness condition and the aspectual conditions on middle formation in terms of the *Aktionsart* that the active VP counterpart to the middle must have; see (77) and (88)). Many verbs that have an Actor/Agent for their subject argument will have a Patient for their object argument.

This brings up the question of whether the agentivity condition and the affectedness condition are just two sides of the same (perhaps aspectual) coin, or whether one takes precedence over the other. Ackema and Schoorlemmer (1994) argue that the agentivity condition must take precedence, since it can explain some exceptions to the affectedness condition, as we have encountered them in section 6.2. These are repeated below:

(137) a. Greek does not translate easily.
b. Zulke stukken zingen lekker. Dutch
such pieces sing nicely
c. Das Buch liest sich leicht. German
the book reads SICH easily

These cases are formed from verbs that take an Actor as their first argument, but a non-Patient as their second one ('What Harry did was translate Greek', #'What happened to Greek was Harry translated it'; 'What the choir did was sing Handel's *Messiah*', #'What happened to Handel's *Messiah* was the choir sang it'; etc.). Their well-formedness therefore indicates that (95) is a consequence of (125) in combination with the fact that many Actor-verbs also take a Patient, rather than the other way around.

More importantly, perhaps, is that cases for which (95) cannot be relevant, namely impersonal middles in German and Dutch (see section 3.4) – that is, middles of verbs with an apparent non-argument as grammatical subject – still must comply with (125). As Ackema and Schoorlemmer show for Dutch, the same distinction between Actor-taking verbs and non-Actor-taking verbs is relevant for impersonal middle formation on the basis of intransitives:

(138) a. Jan werkte opzettelijk zonder overall.
Jan worked on-purpose without overall
a'. Het werkt prettig in zo'n overall.
it works comfortably in such overalls
b. Marie liep opzettelijk de verkeerde kant op.
Marie walked on-purpose the wrong way to
b'. Het loopt prettig op deze schoenen.
it walks comfortably on these shoes
c. Carolien zat opzettelijk op de verkeerde plaats.
Carolien sat on-purpose on the wrong seat
c'. Deze stoel zit niet lekker.
this chair sits not comfortably

(139) a. #De zwerver stonk opzettelijk naar alcohol.
the tramp stank on-purpose to alcohol
a'. *Het stinkt gemakkelijk zonder je tanden te poetsen.
it stinks easily without your teeth to brush
b. #De oorlogsveteraan trekkebeende opzettelijk.
the war-veteran limped on-purpose
b'. *Het trekkebeent niet gemakkelijk over grote afstanden.
it limps not easily over great distances
c. #Marie vergiste zich opzettelijk.
Marie erred REFL on-purpose
c'. *Het vergist zich vlug in ingewikkelde situaties.
it errs REFL quickly in complicated situations

Let us make a short summary of where we stand at this point concerning the restrictions on middle formation. The first thing to note is that these restrictions differ significantly from language to language, to the point that, as argued by Authier and Reed (1996), some constructions that have been termed middles because of their form might be more properly labeled as a type of passive (see also section 5). At least for type I middles it can be said that, when looking at which verbs can occur in the construction, there seems to be some sort of core type. The core type is a verb that takes an Actor for its logical subject and a Patient for its logical object, which in its active use forms a VP with these arguments that, aspectually speaking, expresses a delimited event or accomplishment.

Nevertheless, there can be exceptions with respect to all three separate factors that play a role here (the presence of an Actor argument, a Patient argument, the expression of a delimited event). Middle formation is sometimes possible when one of these factors is not complied with, and it is sometimes impossible even when all of them are. At least some of these exceptions are captured by a separate condition on the middle verb's grammatical subject/logical object argument, namely that it must be possible to hold it responsible for the action denoted by the middle verb.

6.4 Comparison with passive and **lassen***-middles*

We have discussed similarities and differences between middles, passives, and so-called *lassen*-middles already in sections 3.2–3.3. Now that we have seen which restrictions appear to apply to (type I) middle formation (with all due caution because of the exceptions we have also seen), it is useful to come back to this issue, to put it in sharper relief as it were.

Here are the various restrictions that have been claimed to hold of middle formation, as we discussed them in the previous subsections, in a row:

(140) a. **Aspectual condition:**
Only (transitive) activities and accomplishments undergo middle formation.

b. **Responsibility condition:**
The grammatical subject of a middle (if present) must have properties such that it can be understood to be responsible for the action expressed by the predicate.
c. **Delimited event condition:**
Only verbs with a logical object argument that delimits the event expressed by the predicate can undergo middle formation.
d. **Affectedness condition:**
A middle verb must have a Patient argument.
e. **Anti-double object condition:**
Verbs in a double object construction do not undergo middle formation.
f. **Argument sensitivity:**
The grammatical subject of a middle must be an argument of the middle verb.
g. **Anti-effectedness condition:**
The subject in a middle should not be an effected object of the verb.
h. **Agentivity condition:**
The logical subject in a middle must be an Agent (Actor).

Let us see how the constructions that appear to be similar to middles fare on these. First consider passives. These in fact comply with not one of these restrictions. Thus, achievements are often expressed by unaccusative verbs, which cannot be passivized for independent reasons (Perlmutter 1978; Burzio 1986; Zaenen 1993), but in other cases they can undergo passivization as readily as accomplishments and activities (see (141a–b)). A number of statives, too, can be passivized (as in (141c–d)):

(141) a. The spy was not recognized by anybody.
b. Op 23 januari werd eindelijk de top bereikt. Dutch
on 23 January was finally the top reached.
c. Cecilia Bartoli's voice is universally loved.
d. Dat wordt door veel mensen niet getolereerd. Dutch
that is by many people not tolerated

The grammatical subject in a passive need not have properties which can make it responsible for the action expressed by the verb:

(142) a. The new Saramago can be bought in any good bookshop.
b. Het voorstel werd uitvoerig besproken in het parlement. Dutch
the proposal was elaborately discussed in the parliament

These same examples show that verbs with non-delimiting, and non-Patient, objects can be passivized. Double object constructions usually allow for passivization, although there is language variation as to which object can be promoted to subject. Thus, in standard English only the IO can be promoted, in Dutch only the DO, whereas in Norwegian either one can be promoted (Åfarli 1992):

(143) a. Mary was given some books.
b. Die boeken werden Marie tegen een spotprijs aangeboden. Dutch
those books were Marie against a cheap-price offered

We have already discussed the fact that passives do not comply with Argument Sensitivity: see (120). The grammatical subject in a passive can also be an effected argument:

(144) a. This picture was painted by Picasso.
b. Toen werden er minder huizen gebouwd dan nu. Dutch
then were there fewer houses built than now

Finally, the logical subject argument, which can be expressed in a *by*-phrase in passives, can be virtually any type of argument. It need not be an Agent (or Actor):

(145) a. The Eiffel Tower could be seen in the distance.
b. De herrie werd gelaten door het publiek ondergaan. Dutch
the noise was resignedly by the audience undergone

Consider next so-called *lassen*-middles (cf. section 3.3). In some respects this construction behaves just like the middle (it is presumably for this reason that the construction has been termed a middle in the first place). Typically, for example, the grammatical subject must obey the responsibility condition; see (147) below. Let us see how *lassen*-middles fare on the list of proposed restrictions in (140).

First, the only aspectual class of verbs that seems to resist *lassen*-middle formation are states – achievements are fine:

(146) a. De roodgestreepte buikschuiver laat zich gemakkelijk herkennen aan zijn rode strepen. (accomplishment verb) Dutch
the red-striped bellyslider lets REFL easily recognize on his red stripes
'The red-striped bellyslider is easily recognizable by its red stripes.'
b. *Anne-Sofie laat zich makkelijk bewonderen. (state verb) Dutch
Anne-Sofie lets REFL easily admire
'It is easy to admire Anne-Sofie.'

As noted, *lassen*-middle formation is restricted by the responsibility condition:

(147) a. *De nieuwe Saramago laat zich moeilijk kopen. Dutch
the new Saramago lets REFL difficult buy
'It is difficult to buy the new Saramago.'
b. ?*Zo'n voorstel laat zich niet gemakkelijk bespreken. Dutch
such-a proposal lets REFL not easily discuss
'It is not easy to discuss such a proposal.'

The logical object/grammatical subject need not be a delimiter or Patient argument:

(148) a. Deze piano laat zich moeilijk bespelen. Dutch
this piano lets REFL difficult play
'This piano is difficult to play on.'
b. Zo'n daad laat zich moeilijk verklaren. Dutch
such-a deed lets REFL difficult explain
'Such a deed is difficult to explain.'

Lassen-middle formation is also possible from double object constructions in Dutch. Interestingly, it seems that in contrast to what happens in passives, it is the IO rather than the DO that gets promoted to subject:

(149) a. *Boeken laten zich bezwaarlijk dat soort mensen verkopen. Dutch
books let REFL problematically that sort people sell
'It is problematic to sell books to such people.'
b. ?Dat soort mensen laat zich bezwaarlijk boeken verkopen. Dutch
that sort people let REFL problematically books sell
'It is problematic to sell books to such people.'

Lassen-middle formation is not possible from ECM verbs, apparently showing its argument sensitivity (see (150a)). However, for rather ill-understood reasons, not even passive is possible from ECM verbs in Dutch and German (see (150b); cf. Bennis and Hoekstra 1989). So in this respect there is no difference between these constructions:

(150) a. *Zo'n man laat zich makkelijk liedjes horen zingen. Dutch
such-a man lets REFL easily songs hear sing
'It is easy to hear such a man sing songs.'
b. *Kaatje werd een liedje horen zingen. Dutch
Kaatje was a song heard sing
'Kaatje was heard singing a song.'

It seems effected objects do not make very good grammatical subjects in *lassen*-middles (perhaps in contrast to true middles – see (124)):

(151) a. ?*Dat soort truien laat zich moeilijk breien. Dutch
that sort sweaters lets REFL difficult knit
b. ?*Zo'n soort boek laat zich gemakkelijk schrijven. Dutch
such sort book lets REFL easily write

Finally, where it concerns the logical subject, *lassen*-middles behave like passives rather than middles. This argument can be expressed in a *by*-phrase, and need not be an Agent/Actor:

(152) a. Deze componist laat zich inspireren door de schilderkunst.
this composer lets REFL inspire by the fine-arts
'This composer draws his inspiration from the art of painting.'
b. Het begrip 'subject' laat zich door postmodernisten begrijpen als 'individu.'
the notion 'subject' lets REFL by postmodernists understand as 'individual'
'The notion of "subject" is understood by postmodernists as "individual."'

We may conclude that *lassen*-middles are similar to middles in the kind of semantics they express: they are generic statements, ascribing a property to the grammatical subject. Presumably as a result of this, a number of similar restrictions apply to *lassen*-middles and true middles. However, in other respects the *lassen*-middles are more like passives, which might indicate that syntactically they are unlike real middles. This brings us to the question of what the proper analysis of middle formation is, and whether or not this motivates a syntactic difference with passives.

7 Possible analyses

7.1 Preliminary: what is a middle in the first place (again)?

To repeat an important point, the proper analysis of middles crucially depends on what is included in the category 'middle' and what is not. If we define the category semantically, every construction that expresses the same type of semantics that an English sentence like *this books reads easily* expresses qualifies as a middle. In that case, constructions with different syntax will fall under this rubric, both cross-linguistically and within a single language.

Above, we have seen that middles in French potentially have different syntactic properties from those in English. Similarly, given a semantic definition *lassen*-middles would fall under the same class as 'true' middles in Dutch and German, but we have also seen that, syntactically speaking, this construction deviates in a number of respects from the plain middles. It is a very interesting question in its own right what causes this variation in the way the 'middle semantics' can be expressed. In this section, however, we will consider what the proper syntactic analysis of individual middle constructions is. We will focus on type I middles. Given that type II middles behave very much on a par with passives syntactically, we might assume, following Authier and Reed (1996) and Lekakou (2002), that, syntactically, they *are* passives. Without further discussion, we will assume that in passives the object is promoted to subject by an instance of A-movement, and that the logical subject is still present syntactically (it may be assigned to the participial morphology, for instance; see Jaeggli 1986a; Baker et al. 1989).[20] Alternatively, type II middles must be assumed to have the syntax of type I middles. See section 5 for details of this discussion.

7.2 Two types of analysis

Let us consider, then, how to analyze type I middles; that is, middles in which the verb appears in its active form and without any special morphology. Very roughly, two types of analysis can be distinguished.

According to one analysis, there is no significant difference in the way the verb projects its arguments in an active construction, a passive, or a middle. Only the type of element that receives the external argument is different: in an active sentence this is a subject DP, in a passive and a middle it is an empty pronominal argument which does not end up in the surface subject position. This position is subsequently filled by moving the object, which has received the verb's internal theta-role, to this position. In other words, in this approach middles are analyzed just like passives; the differences between the two constructions then follow from their different semantics. Such an analysis was proposed by Keyser and Roeper (1984), and has been developed in various detailed ways, notably by Hoekstra and Roberts (1993a) and Stroik (1992a). In (153) the analysis Hoekstra and Roberts would assign to a middle like *bureaucrats bribe easily* is given; in (154) the analysis Stroik would assign to it:

(153) $[_{IP}$ bureaucrats$_i$ $[_{VP}$ pro $[_{V'}$ bribe t_i easily]]]

(154) $[_{IP}$ bureaucrats$_i$ $[_{VP}$ $[_{VP}$ $[_{V'}$ bribe t_i easily]] PRO]]

In both analyses it is assumed that the object is promoted to subject by an instance of A-movement. Both analyses also assume the verb assigns its external theta-role to an empty pronoun in the syntactic structure. The only difference (which we will not go into here) is that Hoekstra and Roberts assume this pronoun is an instance of *pro* (an empty subject of the type that occurs in finite clauses in pro-drop languages like Italian) in VP-internal subject position, whereas Stroik assumes it is an instance of PRO (an empty subject of the type that occurs in infinitival clauses) in VP-adjoined position.

In the second type of analysis it is assumed that the way the verb's arguments are projected syntactically is different in middles, compared to the way they are projected in active and passive clauses. Such approaches presuppose that at the semantic level of representation at which the verb's argument structure is defined, operations are defined that can affect the way these arguments are projected syntactically.[21] (For various approaches along these lines, see Williams 1981a; Di Sciullo and Williams 1987; Grimshaw 1990; Jackendoff 1990b; Reinhart 2000b). What happens in a middle, then, is that the verb's highest theta-role (the role for the logical subject) is not assigned in syntax at all, and that the role for the logical object is assigned directly to the syntactic subject. According to this type of analysis, of which instances can be found (Fagan 1988, 1992; Roberts 1987; Ackema and Schoorlemmer 1994), the middle *bureaucrats bribe easily* would be analyzed as in (155). (To keep the comparison with (153–154) clear, it is assumed in (155) that subjects in English are merged in a VP-internal position and undergo

A-movement to spec-IP to check their case features – but the point is that the logical object argument is projected as a subject directly, not as an object.)

(155) $[_{IP}$ bureaucrats$_i$ $[_{VP}$ t_i $[_{V'}$ bribe easily]]]

Thus, we see that the two types of analysis differ on two main points, concerning the status of the logical subject argument and of the logical object argument. The points of contention are:

(156) What happens to the verb's logical subject theta-role?
Answer of the 'syntactic' account of middles: it is assigned to an empty pronoun in syntax.
Answer of the 'argument structure' account: it is not assigned syntactically.

(157) How can the element that receives the logical object theta-role become the grammatical subject?
Answer of the 'syntactic' account: the verb's logical object theta-role is assigned regularly to a DP in object position, and this DP undergoes A-movement to subject position.
Answer of the 'argument structure' account: the verb's logical object theta-role is promoted from an internal theta-role to the external theta-role.

It is important to note that these two properties of these analyses are really independent of one another.[22] It is imaginable, for instance, that the object is promoted to subject by A-movement in syntax while the logical subject is not represented syntactically. We will therefore discuss these issues separately.

7.3 Is the logical subject syntactically present?

Like black holes in astronomy, invisible syntactic elements can be detected indirectly, by the effect they have on their environment. If an empty subject argument is present in syntax, we expect it to have syntactic effects; if it is not, no such effects should be observable. For example, the empty subject *pro* assumed to be present in finite clauses in pro-drop languages like Italian lets itself be detected by the effect it has on the agreement on the verb: *parl-o* 'talk' is only possible in the presence of a first person singular subject, *parl-a* 'talk' only in the presence of a second person singular subject, and so on. The question is then whether we can detect a potentially present empty logical subject argument.

We will discuss four different types of argumentation that have been put forward to argue for the syntactic presence of the logical subject in a middle.

7.3.1 'Classic' agent identifiers

At least for passives, it seems we can identify a syntactically present logical subject. There are some 'classic' arguments for this.

It turns out that an Agent argument uniquely licenses some other syntactic elements. Examples of such elements are agent-oriented adverbs, purpose clauses (where the PRO subject of the purpose clause is controlled by the logical subject argument of the passive verb; see Chomsky 1981; Manzini 1983b; Jaeggli 1986a), and of course *by*-phrases, which overtly express the relevant argument.[23] Relevant examples of these agent-diagnostics are given in (158):

(158) a. The boat was sunk on purpose.
b. The boat was sunk ec_i [PRO_i to collect the insurance].
c. The boat was sunk by the enemy.

In this respect, middles differ from passives:

(159) a. *Such texts translate easily deliberately.
b. *Such texts translate easily to win the Translator's Prize.
c. *Such texts translate easily by an experienced translator.

However, there are also some phenomena that indicate syntactic activity by the logical subject argument in middles. For example, secondary predicates predicating over the logical subject are sometimes acceptable in a middle:

(160) a. Physics books read poorly when drunk.
b. Dat soort artikelen leest gemakkelijker met een slok op. Dutch
that sort articles reads easier with a drink up
'That sort of article is easier to read when drunk.'

Possibly related to this is the fact that, as observed by Stroik (1992a), certain gerundive adjuncts are acceptable in middles with an understood subject that appears to be controlled by the middle verb's logical subject argument (examples from Stroik):

(161) a. Most physics books read poorly [even after [PRO reading them several times]].
b. Bureaucrats bribe best [after [PRO doing them a favor or two]].

Hence, as opposed to control into purpose clauses, control of the logical subject into such gerund clauses is possible. The question is then whether the type of control that occurs in these examples necessitates the syntactic presence of the controller or not. This matter will be the topic of the next subsection.

7.3.2 Control

There are two types of control, usually termed 'obligatory control' and 'non-obligatory control' (cf. Chomsky 1981; Bresnan 1982c; Manzini 1983b; Bouchard 1984; Koster 1987; Landau 2000; Wurmbrand 2002). In certain syntactic environments, the empty subject of an infinitive needs to be controlled by a syntactic

constituent in a c-commanding position, so-called 'obligatory control'. In other syntactic environments, there can also be a syntactic controller, but in this case it need not c-command the PRO subject of the infinitive. This kind of control is referred to as 'non-obligatory control'. In cases of non-obligatory control there need not be a syntactic controller at all, and PRO can have arbitrary reference. In this second type of environment, PRO can also be controlled by a non-syntactically realized, so-called 'implicit', argument of the matrix verb. A good example of this is dative control, as discussed by Rizzi (1986a) and Roeper (1987a). They note that, in contrast to a direct object controller (Bach 1979), a dative controller can be freely omitted in English:

(162) John shouted/said/gave the order (to Bill) [PRO to leave].

If the dative argument of verbs like *shout* is left implicit, it can nevertheless function as a controller. Crucially, as shown by Rizzi (1986a: 550–551), there are reasons to believe that implicit dative controllers of this type are not syntactically represented as an empty *pro*. Rizzi shows that implicit dative objects in English differ from empty direct objects in Italian (which he argues should be represented as *pro*) in not being able to function as antecedent in a binding relation. He concludes from this that "the understood dative . . . does not correspond to a structurally represented position" (1986a: 551). This means that control by an implicit, not syntactically realized, argument is possible in principle. According to Koster (1987), the only infinitivals whose PRO subject must be obligatorily controlled in English are argumental infinitivals that resist a *for*-complementizer. If this is correct, it would mean that the subject PRO of the adjunct gerunds in (161) need not be controlled by a syntactically present c-commanding antecedent, but can be controlled by an implicit argument as well. This is corroborated by the observation that a typical implicit argument like the Experiencer argument of adjectives like *difficult* or *cooperative* can also control this subject, as is shown in (163) (from Ackema and Schoorlemmer 1995):[24]

(163) a. Most physics book are very difficult [even after [PRO reading them several times]].
b. Bureaucrats usually are more cooperative [after [PRO doing them a favor or two]].

In short, whether or not examples like (161) indicate the syntactic presence of the logical subject argument depends on whether the type of control they involve requires the syntactic presence of the controller. It is doubtful that they involve obligatory control.

7.3.3 Binding

In contrast to some control relations, anaphoric binding relations always require the antecedent to be syntactically present. A stronger argument could, therefore,

be made if the logical subject argument could also function as the antecedent in a binding relation.

Stroik (1992a) argues that, indeed, the middle verb's logical subject can act as antecedent in a binding relation. In particular, it seems that it can bind anaphors that occur in the grammatical subject/logical object:

(164) a. Books about oneself never read poorly.
b. Letters to oneself compose quickly.

Although on the surface there is no c-command relation between the *pro* or PRO that is supposed to receive the verb's logical subject theta-role and the grammatical subject, such a c-command relation obtains before the object moves to subject position in an analysis like that in (154):

(165) $[_{IP}\ [_{VP}\ [_{VP}\ [_{V'}$ compose letters to oneself$_i$ quickly]] PRO$_i$]] $\rightarrow$
$[_{IP}$ letters to oneself$_i$ $[_{VP}\ [_{VP}\ [_{V'}$ compose t$_i$ quickly]] PRO]]

Belletti and Rizzi (1988) have shown on the basis of Binding facts with experiencer verbs in Italian that A-moved elements can optionally reconstruct for Binding purposes. Put differently, Condition A of the Binding Theory can be satisfied both before and after A-movement. Thus, the *oneself*s contained in the surface subjects in (165) can be bound by the empty pronoun representing the logical subject in the underlying representation of these sentences.

In turn, Ackema and Schoorlemmer (1995) argue that, in examples like (164), the anaphoric elements need not be bound at all. In general, anaphoric elements that are contained inside larger NPs behave like logophoric elements, which do not need a syntactic antecedent. Pollard and Sag (1992) and Reinhart and Reuland (1993) argue that only co-arguments of a predicate are subject to the conditions imposed by the Binding Theory. Hence, if an anaphoric element is contained within such an argument, rather than constituting an argument itself, it escapes Binding Principle A. In that case, it can occur in a position in which its apparent antecedent does not c-command it (as in (166a), from Jackendoff 1972) or in which no such antecedent is even present (in (166b), from Ross 1969b):

(166) a. The picture of himself that John saw in the post office was ugly.
b. Physicists like yourself are a godsend.

According to Ackema and Schoorlemmer, the same holds for the examples in (164) as well. They point out that the same NPs, containing the same anaphoric elements, can occur in the subject position of a VP headed by a (non-middle) unergative verb, in other words by a verb that does not have a suppressed/empty/implicit argument in any case:

(167) a. Books about oneself cause headaches.
b. Letters to oneself usually stink.

This means that the data in (164) are inconclusive with respect to the question about the syntactic presence of the implicit argument of the middle verb. If the argument of the middle verb is itself a licensed anaphoric element, we may conclude that an indivisible syntactic binder is present. However, such cases are impossible, as shown by (168):

(168) *Yourself photographs easily.

This example does not show the *non*-presence of the logical subject argument either, because anaphors cannot occupy nominative positions anyway (see the Icelandic examples discussed in Maling 1984; Everaert 1986b). This independent explanation for the ungrammaticality of (168) makes it impossible to judge whether the subject is a bound anaphor, and therefore whether an invisible binder should be assumed in this sentence.

All in all, we conclude that this piece of evidence for a syntactically active logical subject is flawed.

7.3.4 For-*phrases*

Another empirical argument for the syntactic presence of the logical subject argument that Stroik (1992a) puts forward is quite straightforward: it seems this argument can be expressed overtly after all, namely as a *for*-phrase (similar, then, to the *by*-phrase in passives). Some examples are given in (169):

(169) a. No Latin text translates easily for Bill.
b. ?Die stoel zit niet lekker voor opa. Dutch
that chair sits not comfortably for grandpa
'That is not a comfortable chair for granddad.'

Judgments about such sentences tend to diverge. Some speakers find *for*-phrases in middles odd, in both English and Dutch (the question mark in (b) reflects our own judgments). However, let us focus on the issue of whether, for those speakers that accept them, *for*-phrases are the overt realization of the logical subject argument of the middle verb. There are alternative possibilities. For example, Hoekstra and Roberts (1993a) assume that the *for*-phrase is an Experiencer argument of the adverb (*easily* in (169a), *lekker* in (169b)). This is somewhat hard to maintain in general, however, since *for*-phrases can also be present when there is no adverb (when the modal semantics is only expressed by negation or a modal verb, for example):

(170) (?)That Ancient Greek text won't translate for Bill.

However, the *for*-phrase could also be an adjunct that expresses the experiencer that is induced by the modal semantics associated with the construction as a whole (see Zribi-Hertz 1993; Ackema and Schoorlemmer 1995). In general, it appears that in active sentences with similar modal semantics, similar *for*-phrases

can occur, as illustrated in (171).[25] Since every argument of the verbs in (171) is already syntactically expressed, at least in these cases the Experiencer *for*-phrase cannot be an argument of the verb:

(171) a. As both of those spells do not cost anything in material components, she may cast these things easily for herself.
b. In counseling, he was not able to express feelings easily for himself.
c. He was surprised the arrangements went so smoothly for himself, his wife, and four children.

Stroik (1999) addresses this issue and presents an interesting argument for the assumption that in middles like (169) the *for*-phrase is really an argument of the verb. It is based on Reinhart and Reuland's (1993) assumption, mentioned above, that only co-arguments of a predicate enter into binding relationships. In particular, it is based on Reinhart and Reuland's version of Condition B of the Binding Theory, which reads as follows:

(172) **Condition B:**
A reflexive semantic predicate is reflexive-marked.

Stroik's argument is as follows. In an example like (173) below, the logical subject argument and the logical object argument seem to refer to the same entity, so that the predicate is reflexive:

(173) Mary photographs easily only for *her/herself.

In this case the *for*-phrase needs to contain a reflexive-marking element, namely a *self*-anaphor. This appears to be unexpected in case the *for*-phrase is not an argument but an adjunct, since in that case it cannot reflexive-mark the predicate – only arguments of the predicate can. If it were an adjunct, the reflexivity of the predicate would be unlicensed, in violation of Condition B in (172).

There is a difficulty with this argument, however. It tries to establish that the *for*-phrase is an argument of the middle predicate, but it appears that in order for it to go through it must presuppose precisely that: only when the *for*-phrase is an argument do we know for sure that the middle predicate is in fact reflexive in (173). It is not a priori clear that we are dealing with a reflexive predicate here. To us, the semantics of the example seems to indicate that this is not so, as the proper meaning of (173) would appear to be 'an arbitrary person photographing Mary is only easy for Mary herself', rather than 'Mary photographing Mary is only easy for Mary herself'. If the predicate is indeed non-reflexive it may not be reflexive-marked (as stated by Condition A of Reinhart and Reuland's Binding Theory: a reflexive-marked predicate is reflexive). In that case, the *for*-phrase in fact must be an adjunct rather than an argument (since it should not reflexive-mark the non-reflexive predicate), and the *self*-anaphor it contains must be logophoric (see above).

At least for Dutch, it can be shown that the *self*-form in examples like (173) is indeed logophoric, not anaphoric. In contrast to English, where *himself* can be either anaphoric or logophoric, the third person reflexive in Dutch has a different form in the two uses. When it is anaphoric it has the form *zichzelf* 'ZICH-self'; when it is logophoric it has the form *hemzelf/haarzelf* 'himself/herself' (cf. Anagnostopoulou and Everaert 1999: 115–116). It turns out that, insofar as *voor*-phrases are acceptable in Dutch middles in the first place, it is the logophor that can occur here, while the anaphor leads to unacceptable results:

(174) a. ?Marie fotografeert alleen gemakkelijk voor haarzelf.
Marie photographs only easily for herself
b. ?*Marie fotografeert alleen gemakkelijk voor zichzelf.

(175) a. ?Dit model schildert alleen voor hemzelf gemakkelijk.
this model paints only for himself easily
b. *Dit model schildert alleen voor zichzelf gemakkelijk.

There is a distinction with passives again. In passive *by*-phrases the anaphor rather than the logophor is used when the predicate is reflexive, which indicates this phrase is indeed the overt expression of the suppressed argument here:

(176) a. Marie werd door ?*haarzelf/zichzelf gefotografeerd.
Marie was by herself/REFL-self photographed
b. Rembrandt werd regelmatig door ?*hemzelf/zichzelf geschilderd.
Rembrandt was frequently by himself/REFL-self painted

If the *for*-phrase is not an argument in (173), this leaves open the question of why the bare pronoun *him* cannot be used in it just as well as logophoric *himself*. We will not offer an account of this here, but it is presumably related to the focus that *only* induces on the relevant phrase. Compare the following cases in which an adjunct containing a pronominal element receives a similar focus reading:

(177) a. John_i allows Bill to drink from the flask only after himself_i/$*\text{him}_i$
b. Mary_i reads books with herself_i/$*\text{her}_i$ on the cover only.

This concludes the discussion of the empirical arguments that have been given for the presence of the logical subject argument in type I middles.

7.3.5 A conceptual argument and conclusions

A conceptual argument for the syntactic presence of the logical subject in middles has also been put forward, the most explicit form of which can be found in Hoekstra and Roberts (1993a). The argument is one of the 'Occam's Razor' type. In general, it is better, because more explanatory, in theory construction to assume less than to assume more. Therefore, it is better to do without rules or

principles that can manipulate a verb's argument structure. It is simpler to assume a verb always projects its arguments in the same way in syntax (compare Baker's 1988a Uniformity of Theta Assignment Hypothesis). If so, there is no way that the logical subject argument is not projected in a middle too.

Of course, Occam's-Razor-type arguments only go through if all else in the two theories compared is equal. This is not the case here, however. Almost inevitably, there is a cost to not assuming there are operations on argument structure, namely having to assume there are empty subjects in finite clauses in non-pro-drop languages like English and Dutch. Hoekstra and Roberts (1993a) give an account of why this element can be licensed in these languages in restricted circumstances only. In this account they extend case theory so as to include a special *pro*-licensing inherent accusative case (alongside structural accusative case) in English and Dutch. This means that the two approaches do not make more vs. fewer assumptions; rather, they make different assumptions. One elaborates on the theory dealing with how arguments are projected in syntax; the other elaborates on the theory dealing with how syntactically projected arguments are licensed. It is not a priori clear which one should be enriched and which one should be cut down on.

We conclude that the evidence brought forward to show that the verb's logical subject argument is syntactically present in type I middles is not convincing. It may well be that type II middles differ from type I middles in precisely this respect (see above).

7.4 How is the logical object promoted to subject?

In theories assuming there is no place for operations affecting the way a verb's basic argument structure is realized syntactically, the middle verb's logical object argument must be merged as an object. That it ends up as the surface subject must therefore be a consequence of syntactic movement, namely the well-known 'raising to subject' type of A-movement that has also been argued to occur in passives (Chomsky 1981; Jaeggli 1986a), with unaccusative verbs (Burzio 1986), and from the complement of so-called 'raising' verbs (Chomsky 1981). Under this view, then, middles are seen as another instance of such unaccusative constructions.

In theories in which operations can be defined over argument structures such that a verb does not project the same arguments in the same way in every instance, promotion of an internal argument to an external argument can be seen as the result of such an operation. Williams (1981a) indeed proposes that there are general Externalize(X) operations, where X is some designated argument. Roberts (1987) proposes that the logical object argument of the middle verb ends up as its grammatical subject as a result of an Externalize(Theme) operation applying to the argument structure of the middle verb. In this scenario, the logical object argument is merged directly as an external argument, in the subject position. As a result, the middle is not an unaccusative, but rather an unergative construction.

As Hoekstra and Roberts (1993a) point out, however, any rule of the type Externalize(X), with X a particular type of argument, is unlikely to capture the full range of data. Various types of argument can become the subject in a middle, not only Themes (as in (178a)) but also Locations (as in (178b) or Experiencers (as in (178c)):

(178) a. Hay loads easily.
b. This truck loads easily.
c. Children scare easily.

An analysis in terms of Externalize(X) also does not extend to impersonal middles as they occur in Dutch and German, and presumably also not directly to adjunct middles as they occur in Dutch (see sections 3.5 and 6.2).

Ackema and Schoorlemmer (1994) argue that, nevertheless, the relevant data are not incompatible with approaches in which the logical object is merged as an external argument. For this to be possible, the property of being an external argument must not be regarded as a designated property of a particular argument in the verb's argument structure, as in Williams's (1981a) original conception. Instead, argument structures as a whole can have the property that one of the arguments they contain must be projected as an external argument.[26] The one that is normally projected as such is the one that is highest on some thematic hierarchy (cf. Baker 1988a; Grimshaw, 1990; Jackendoff 1990b). According to Ackema and Schoorlemmer, the defining property of a (type I) middle is that precisely this argument receives arbitrary interpretation and is not projected syntactically. They suggest that in case the a-structure is marked as having to project one of its arguments externally, the argument that is the next one down on the thematic hierarchy automatically becomes the external argument (see also Bouchard 1984).

This approach can be extended to impersonal middles and adjunct middles, as follows. If the Actor/Agent is suppressed, intransitive verbs have no other argument left that can be merged as a DP subject. If the a-structure nevertheless contains the instruction that there should be an external argument, a language may have either or both of two last resort strategies. One is to insert a dummy external argument, resulting in an impersonal middle. The other is to turn a PP argument into a DP argument, eligible for being a subject, before projection to syntax takes place. (This is effected by an applicative-type operation; see section 6.2.) This results in an adjunct middle. This, of course, does not account for why these constructions are limited to certain languages only.

As far as the theory goes, then, both approaches can account for promotion of the logical object. Recall that under the 'move the object to subject position' approach, middles are expected to pattern with unaccusative constructions, whereas under the 'pick the next argument after the suppressed one as external argument' approach, middles are expected to pattern with unergative constructions. Ackema and Schoorlemmer (1995) argue that, at least for Dutch, the data seem to indicate that middle verbs behave like unergatives. We will mention two of the clearer pieces of data here.

A first difference between unergatives and unaccusatives in Dutch concerns their choice of auxiliary in the perfect tense. As in Italian, unergatives take the cognate of *have*, namely *hebben*, as perfect auxiliary, whereas unaccusatives take the cognate of *be*, namely *zijn* (cf. Perlmutter 1978; Burzio 1986):[27]

(179) a. Ze hebben/*zijn gelopen/gefietst/gezwommen/gedineerd.
they have/are walked/cycled/swum/dined
b. Ze *hebben/zijn gearriveerd/gevallen/gestorven/ontsnapt.
they have/are arrived/fallen/died/escaped

Middles uniformly take *hebben*:

(180) a. Dit soort vlees heeft/*is altijd gemakkelijk gesneden.
this type meat has/is always easily cut
'This type of meat has always been easy to cut.'
b. Deze trui heeft/*is altijd gemakkelijk gewassen.
this sweater has/is always easily washed
'This sweater has always been easy to wash.'

Second, unaccusatives but not unergatives allow their past participle to function as an attributive modifier of a noun:

(181) a. *de gelopen/gefietste/gezwommen/gedineerde mensen
the walked/cycled/swum/dined people
b. de gearriveerde/gevallen/gestorven/ontsnapte mensen
the arrived/fallen/died/escaped people

Middles again pattern with unergatives in not being able to occur as a prenominal past participle:

(182) a. *het altijd gemakkelijk gesneden vlees
the always easily cut meat
'the meat that has always been easy to cut'
b. *de altijd lekker gelopen schoenen
the always comfortably walked shoes
'the shoes that have always been nice to walk in'

If such data tell us anything about whether the argument of the verb is an external one or an internal one (cf. note 27), then middles in Dutch are part of the class of verbs whose argument is external. (Note, again, that there may be language variation in this respect, and that possibly type II middles as they occur in Romance and Slavic are different.)

Another type of evidence that might decide between the two views was already briefly mentioned in section 6.2. A-movement of NPs to subject position is not restricted to arguments of the verb whose subject position they fill. For example, the subject of the complement to a verb like *believe* (an 'Exceptionally Case Marked' subject) can be raised to the matrix subject position in a passive:

(183) a. I believe [John to be a fool].
b. $John_i$ is believed [t_i to be a fool] by everyone.

If promotion to subject is the result of an operation over the argument structure of the middle verb, then of course an element that is not part of that argument structure cannot be thus promoted.

In contrast to passives, middle verbs appear to disallow promotion of an element that is an argument in their complement rather than being an argument of the middle verb itself. Compare (183b) and (184):[28]

(184) *John believes to be a fool easily.

Hoekstra and Roberts (1993a) argue that there is a class of examples in which a non-argument of the verb is promoted to subject, namely resultative constructions. They argue that in such constructions the internal argument of the verb is a Small Clause (SC). The second DP in the clause then is not an object of the verb, but the subject of the secondary predicate in this SC (see (185)). Nevertheless, such DPs can become the subject of a middle (see (186)):

(185) a. Mary hammered [$_{SC}$ the metal flat].
b. Jan maakte [$_{SC}$ de kwast schoon]. Dutch
John made the brush clean
'John cleaned the brush.'

(186) a. Such metal hammers flat easily.
b. Deze kwast maakt gemakkelijk schoon. Dutch
this brush makes easily clean

The strength of such arguments, of course, depends on the strength of the syntactic analysis according to which the promoted DP is or is not an argument of the middle verb. Thus, not everyone would agree that ECM subjects are not arguments of the matrix verb (see, e.g., Bierwisch 1990), thus making the impossibility of promoting them in a middle no argument for the a-structure approach. Similarly, but to opposite effect, it has been argued that the second DP in (185) is an argument of the verb as well as of the secondary predicate (see Carrier and Randall 1992; Neeleman and Weerman 1993; Neeleman 1994a; Williams 1980, 1994), so in that case the possibility of promoting it to subject is not an argument for the A-movement approach.

8 Conclusion

As we have seen, when we define 'middle' as a particular type of semantics, then languages vary considerably in the syntactic means they use to express this semantics. At least, it seems safe to conclude that the constructions that have

been put into the rubric 'middle' in various languages differ significantly in their syntactic properties. The question is whether this language variation can be connected to other properties of the languages. In other words, we should wonder why in Dutch and English a middle verb, in contrast to a passive, does not show any special morphology or other marker indicating that we are dealing with a middle; why in German, French, and Serbian a reflexive is used; and why in French and Serbian but not in German this makes the construction identical to one type of passive. This interesting issue has not been addressed very often yet, though see Hulk and Cornips (1998) and Lekakou (2004) for some suggestions. There is certainly a lot more to be said about middles.

NOTES

1 A note on the terminology used here: when it is important to distinguish between the verb when it is used in the particular non-active mood under discussion here, and the complete construction in which such a verb is used, we will use the term 'middle verb' for the former and 'middle sentence' (or 'middle construction') for the latter. Where this distinction is not relevant, we will simply use 'middle' to refer to both.

2 It might be argued that the *s*-passive really is a true passive, in which case the impossibility of derivatives from unaccusative verbs is predicted and the construction would not bear on the issue at hand. It does not, however, take ordinary passive morphology. This is exactly equivalent to the status of other type II middles, which are almost indistinguishable from passives except morphologically.

3 Note that adding a time adverbial to a generic sentence is possible without necessarily affecting its generic character. Consider a clause with an individual-level predicate like *resemble*. It is perfectly feasible to add *yesterday* to such a clause without this turning the clause into an episodic one. Consider example (i):

(i) Yesterday Frida resembled her grandfather.

If Frida has had cosmetic surgery since yesterday, (i) makes perfect sense. The same holds for middles. One can add a time adverbial to *bureaucrats bribe easily* without this meaning that middles (of type I) lose their genericity; for example, *bureaucrats bribed easily last year, but since the anti-corruption campaign they don't any more*.

4 There is also considerable speaker variation in how good *for*-phrases in middles are considered to begin with, but we will ignore this here.

5 The existence of such cases is used by Fagan (1992) to argue for a lexical derivation of all middles in French. However, by this argument the same should be true for reflexive-marked passives, because some reflexive-marked passives also have special, non-compositional semantics, as the following example from Fagan (1992: 145) shows:

(i) Cela ne peut pas se payer.
that not can not REFL pay
'That cannot be had for money.'

We think that basically any syntactic construction can give rise to lexicalized instances (cf. Jackendoff 1996).

6 Authier and Reed (1996) claim that in Canadian French, episodic middle sentences obligatorily take *by*-phrases. Even if we follow their argument that this pleads for a unitary approach to the passive and the middle readings, it seems a very unlikely generalization, given that neither French nor related languages show this pattern in ordinary passives. We expect to find at least an equally passive variant of such a clause in which the *by*-phrase can be left out, and probably also a stative variant of such a middle which also allows a *by*-phrase. In any event, such a correlation is not valid cross-linguistically, since, for example, Russian reflexive-marked passives with *by*-phrases can only be statives (Gerritsen 1990).

7 Perhaps unexpectedly, some examples of this with type I middles are in fact acceptable: see section 7.

8 A similar phenomenon can be found in Norwegian, where the middle-like *s*-passive can be found in control structures, but the morphological passive cannot, as illustrated in the following examples (Øystein Nilsen, p.c.):

(i) Denne suppa må spises kald.
this soup must eat-S cold

(ii) *Denne suppa må bli spist kald.
this soup must be eaten cold

9 Treating the restriction as one on animacy is not possible for Italian, since it is unproblematic to have an animate subject in Italian type II middles also when they have the middle reading:

(i) Quell'uomo politico ha il vantaggio di potersi corrompere facilmente.
this politician has the advantage of be-able-REFL bribe easily
(Cinque 1988: 562)

10 An interesting question, then, is whether we can predict which languages will use reflexive-marked passives to express the middle and which will use the active. According to Lekakou (2002), it can be made to follow that if a language has imperfective aspectual morphology available to make generic sentences, it will have type II middles; otherwise it will have type I middles.

11 These classes really express VP-aspect, in that properties of the object are relevant in determining in which class a certain expression belongs (see Tenny 1987; Verkuyl 1972, 1993). It might hence seem to be more appropriate to refer to this approach as one based on *Aktionsarten* rather than verb aspect, but since the latter is how Fagan refers to the approach herself, we will keep it under this rubric.

12 The 'if present' clause must be added because of the existence of impersonal middles (see section 3.4), which do not have a subject. Obviously, this shows that (83) cannot be taken to be an absolute condition on all middle formation.

13 That in practice you stop listening to music after a while is not described by *listen to music* itself. This predicate is not delimited; it does not have an inherent end-point (readers who do not see this are advised to listen to Wagner's *Parsifal*).

14 Interestingly, Hulk and Cornips (1998) note that *see* is a verb which in Heerlen Dutch, too, is not eligible for middle formation (**De Eiffeltoren ziet zich gemakkelijk*; compare with (87)), making it not entirely comparable to French after all. We might speculate that this 'in-between' status of Heerlen Dutch is due to pressure from Standard

Dutch, with its restricted aspectual possibilities for verbs to undergo middle formation; see Cornips (2000) for interesting sociolinguistic research and relevant data with respect to this issue.

15 Compare also Verrips (1996), where it is shown that Dutch L1 learners go through a stage in which a construction that is clearly a passive rather than a middle is not marked morphologically.

16 For Negerhollands this cannot be ascertained directly any more, since the language is extinct.

17 The preposition *met* 'with' changes its form to *mee* when stranded.

18 In normal usage, though, *this house* can also refer already to the unfinished thing, and that thing can have properties which make the continuation of the building difficult. Presumably because of this, the example really does not seem so bad to us at all.

19 This test is from Jackendoff (1990b), where the relevant argument is termed Actor. The distinction Jackendoff makes between two tiers at Conceptual Structure, a thematic tier and an action tier, allows him to distinguish the highest argument at the action tier, termed Actor, from the highest argument at the thematic tier, termed Agent. The latter is a general Cause argument which can but need not be an Actor (cf. also Grimshaw 1990, Levin and Rappaport Hovav 1994, and Reinhart 2000b for somewhat comparable proposals, worked out differently). Ackema and Schoorlemmer (1994) argue that the relevant argument for the condition on the logical subject in middle formation is the Actor in Jackendoff's sense, not the Agent/Cause.

20 But see Di Sciullo (1990) for an analysis of middles in Italian that goes against this assumption.

21 It is sometimes argued that two different types of such levels and/or two different types of such operations should be distinguished (see, for instance, Spencer and Sadler 1998; Aranovich and Runner 2001), but our discussion does not hinge on this.

22 To illustrate that partitioning into these two types of analysis is necessarily simplifying things somewhat, Massam (1992) proposes an interesting analysis of middles in which the verb's internal theta-role is assigned regularly to object position, but in which there nevertheless is no A-movement to subject position. This is possible because Massam assumes that the DP we see in subject position is really a non-thematic element, which functions as antecedent for an empty pronoun in object position. Hence, Massam would assign the *bureaucrats bribe easily* example the following structure (where 'ec' stands for the appropriate empty category, according to Massam an empty reflexive pronoun):

(i) $[_{IP}$ bureaucrats$_i$ $[_{VP}$ $[_{\bar{V}}$ bribe ec$_i$ easily]]]

The same analysis is proposed by Steinbach (2003) for German middles (for discussion see also Lekakou 2004).

23 However, it should be noted that, certainly where purpose clauses are concerned, the claim that these must be licensed by an Agent argument has not gone unchallenged; see, for instance, Grimshaw (1990).

24 At least, there does not seem to be an independent reason to assume that in English the Experiencer argument of such psych-adjectives is syntactically present. Tóth (2000) argues that in Hungarian this type of argument must be syntactically represented.

25 A reviewer remarks that the *for*-phrases in middles differ from experiencer *for*-phrases. Thus, she or he finds there is a contrast between (i) and (ii):

(i) No Latin text translates easily for Bill.

(ii) It happened much too quickly for me.

According to the reviewer, the *for*-phrase in (ii) is an experiencer adjunct that can be paraphrased as 'from X's perspective'. In contrast, the *for*-phrase in (i) can only be interpreted as the logical subject of *translate*, according to the reviewer: she or he totally rejects a paraphrase 'from Bill's perspective, no Latin text translates easily' for this example. In our view, this paraphrase expresses exactly what (i) means. A syntactic difference between the two *for*-phrases does exist, but not the one intended by the reviewer. Rather, the *for*-phrase in (ii) is an argument of the degree word *too*, whereas the one in (i) is an adjunct to the verb.

26 There is a lively debate on whether this property can be reduced to some semantic property of the predicate and, if so, what the proper semantic property is in this respect. For various views see Borer (1994); Levin and Rappaport Hovav (1994); Van Hout (1996); Reinhart (2000b); and the papers in Alexiadou et al. (2004).

27 It should be noted here that there is disagreement in the literature on whether the different choice of auxiliary is connected to a syntactic difference between unergatives and unaccusatives (taking an external or an internal argument). Several authors have argued that auxiliary selection is related to semantic differences between the two classes of verbs alone (see, for instance, Van Valin 1990; Zaenen 1993; and Lieber and Baayen 1997). Fagan (1992) argues that this holds for German as well and that syntactic unaccusativity in fact does not exist in this language. However, others argue that the differences between unergatives and unaccusatives do reflect a syntactic distinction in the languages under discussion (see, for example, Burzio 1986, 2000; and other papers in Reuland 2000). Specifically with respect to auxiliary selection see (Hoekstra 1986b, 1999; Vikner and Sprouse 1988; Ackema 1999). Finally, it is also possible that in constructions like (180) it is the auxiliary *hebben* itself that undergoes middle formation (!), which would presumably also void the argument. An analysis along these lines is developed by Kerstens (2000).

28 Ackema and Schoorlemmer (1995) also mention the impossibility of promoting an idiom chunk to subject in a middle, vs. the possibility of doing this in a passive:

(i) a. Advantage$_i$ was taken t_i of John.
b. *Advantage takes easily of naive customers.

However, it seems clear that (ib) is impossible for independent semantic reasons: it does not make sense to make a generic statement ascribing some property to an idiom chunk.

Excursion 2: OV vs. VO
4 Conclusion: questions and answers

1 Introduction: the mittelfeld in OV and VO

1.1 What is the 'mittelfeld'?

The term 'mittelfeld' refers to one of five segments ('fields' in the topological model) of a clause. The topological field scheme (for an accurate exposition based on German see Höhle 1986) partitions a clause into five segments: pre-field (Vorfeld) – left bracket – midfield (Mittelfeld) – right bracket – post-field (Nachfeld). The example sentence in (1) illustrates the maximal expansion. It provides material in all five standard segment frames plus the left dislocation frame (LD), preceding the clause proper:

(1) (Wer das liest)$_{,\text{LD}}$ dem$_{\textbf{pre-F}}$ *fällt*$_{\textbf{LB}}$ nicht sofort$_{\textbf{MF}}$ *auf*$_{\textbf{RB}}$
(who this reads) him$_{\text{dat}}$ *falls* not immediately *up*
wo es sich befindet$_{\textbf{post-F}}$
where it itself locates
'He who reads this surely does not immediately realize where it is located.'
(auf-fallen 'fall up' = realize, come to mind; particle + verb combination)

The mittelfeld (MF) is that segment of a clause that is sandwiched by the left bracket *segment* (LB; Germ. *linke Klammer*) and the *right bracket segment* (RB; Germ. *rechte Klammer*). It is worth emphasizing that the MF does not correspond to a constituent in terms of a phrase structure representation, simply because the verb position is assigned to a separate segment frame, namely the right bracket. In phrase structure terms, the left bracket position is C^0. The right bracket is the position of the clause-final verb. So the mittelfeld includes everything between C^0 on the left and the verbs on the right. The exact mapping is theory-dependent and therefore differs, depending on the chosen model (see section 3.1).

For the left bracket frame, the alternative realizations are as follows: the finite verb in a verb-first (2a) or verb-second clause (1), the imperative verb form in a clausal imperative construction, or a complementizer (2b). The left bracket may be empty as in infinitival clauses (2c) or embedded *wh*-clauses (2d). The pre-field (Germ. *Vorfeld*) immediately precedes the left bracket; the post-field (Germ. *Nachfeld*) follows the right bracket. In GB-terminology, the post-field is the extraposition area. The left dislocation segment is external to the clause frame, and therefore it requires pronominal coreferencing as a mechanism of linking its content to the clause. In (1), the demonstrative pronoun in the pre-field is coreferent with the left-dislocated free relative. In clauses without accessible pre-field (e.g., in verb-first interrogative clauses), the resumptive demonstrative is located in the middle field:

(2) a. $_{LB}$ *Fällt* $_{MF}$ der Leserin sofort etwas *auf*?
strikes the reader immediately something up?
'Does something immediately come to the mind of the reader?'

b. $_{LB}$ *daß* $_{MF}$ der Leserin sofort etwas *auffällt*
that the reader immediately something up-strikes

c. (*ohne*$_{Prep.}$) $_{MF}$ der Leserin sofort *aufzufallen*
(without) the reader immediately up-to-strike
'without coming immediately to the mind of the reader'

d. $_{PF}$ wem $_{LB}$ – $_{MF}$ sofort etwas auffällt
whom immediately something up-strikes

In OV-languages, the mittelfeld is easy to identify. It is the segment of a clause whose left boundary is immediately after the position of the sentence-initial complementizer or the finite verb and whose right boundary is right before the position of the clause-final verb(s) or stranded verbal particles (see 2a, b).

1.2 The mittelfeld in German as an OV language

In German, an OV language, the mittelfeld is in principle open for all constituents of a clause, that is, arguments (3b, d, e), adjuncts (3c, d) and predicates (3b), of all categories, namely noun phrases, PPs, clausal constituents (3c, d, e), or particles (3d). Unlike Dutch, German allows a genuinely empty mittelfeld (3a), and in fact it must be empty in constructions as in (3a), since an expletive pronoun is ruled out. As for clausal constituents, the preferred though not grammatically enforced position is the post-field (see section 2.5 for more details). In the post-field, predicates, particles, and noun phrases are generally ungrammatical, except for heavy-NP-shift constructions. The post-field hosts extraposed clauses and PPs.

(3) a. **Intransitive passive:**
$_{LB}$ als $_{MF}$ [*empty*] geschossen wurde *empty post field*
when shot was

b. **Secondary predicates:**
daß $_{MF}$ er sein Steak *betrunken roh* aß
that he^{i} his steak^{j} drunk^{i} raw^{j} ate

c. **Adverbial case:**
daß $_{MF}$ [als wir vorbei fuhren] geschossen wurde
that [when we passed by] shot was
'that (someone) shot when we passed by'

d. **Finite argument clause:**
Ich habe $_{MF}$ ja [*daß die Erde rund sei*] nie bezweifelt.
'I have *PART*. [that the earth is flat] never doubted.'

e. **Infinitival clause:**
Bis jetzt hat $_{MF}$ [diese Frage zu stellen] noch keiner gewagt.
until now has *PART*. [this question to ask] not-yet anyone dared

Note that in Dutch there is a stricter ban against clausal arguments in the MF (see section 2.5). Infinitival argument clauses in the MF must undergo V-raising (= clause union operation that integrates parts of the infinitival clause into the matrix clause). Clausal infinitivals are therefore found only in extraposed or topicalized positions, that is, in the post-field or the pre-field, respectively. This is not the only reason why the Dutch equivalent of (3e) is ungrammatical: the first reason is that a clausal infinitive must not occur in the MF, and second, a (clausal) object cannot occur in front of the transitive subject in Dutch.

1.3 The mittelfeld in a VO language

What corresponds to the OV-Mittelfeld in a VO language? The Scandinavian Germanic languages are both VO and V2-languages; English is a 'residual' V2-language (notably in interrogative constructions). So, the topological segmentation tailored to capture the main subparts of a clause in a V2-language can be applied in an analogous manner to a VO-clause. The pre-field and the left bracket are easy to identify. But where exactly is the MF located?

(4) a. $_{pre\text{-}F}$ Never before [$_{LB}$ had] he *read* such a good article.
b. $_{pre\text{-}F}$ Aldrig før [$_{LB}$ had] han *læst* sådan en god artikel. Danish[1]
c. $_{pre\text{-}F}$ Nie zuvor [$_{LB}$ hatte] er so einen guten Artikel *gelesen*. German
d. $_{pre\text{-}F}$ Nooit tevoren [$_{LB}$ had hij zo'n goed artikel *gelezen*. Dutch

The MF is less easy to identify. In OV languages, the right bracket is the position of the verbal head of the main VP. Thus, the entire VP is part of the MF, if we stretch the notion *mittelfeld* and include the right bracket into the MF, as its right boundary. With this proviso, it does not seem to be too difficult anymore to identify the MF in an VO language, despite the absence of a manifest right boundary: the MF in a 'verb-second' VO language is that segment of a clause that is in between the V2 position (= the position of a clause initial complementizer or the fronted finite verb) as the left boundary and the right edge of the VP as

the right boundary. The extraposition area corresponds to the post-field of an OV clause:

(5) Did $_{MF}$ more people misidentify the mittelfeld $_{post\text{-}F}$ than the prefield?

In OV languages, it is easy to see that a comparative clause that is split off is necessarily extraposed. Hence, it is safe to conclude that the comparative clause in (5) is in the post-field of the VO clause.

For descriptive purposes, the primary utility of the notion MF rests on one's non-commitment in terms of the fine-grained details of phrase structure. It can serve as a theory neutral label for a well-defined portion of a clause in an OV language whose exact phrase structure analysis may remain open or even controversial. The prima-facie utility of the notion MF for VO languages is less obvious than for OV languages. Nevertheless, it can serve as a frame of reference for issues of cross-linguistic comparison. It is of considerable heuristic value for questions regarding the proper analysis of the crucial grammatical parameters that are constitutive of the OV vs. VO clause type, however.

2 Mittelfeld phenomena: a survey

2.1 Serialization variation: scrambling

The model language for this survey is German because of its wealth of word-order alternations in the mittelfeld. Compared to other Germanic OV languages, as for instance Dutch, the potential of word-order variation in German is very great. For example, all six possible serialization permutations of the three DPs in the mittelfeld of (6a) yield a fully grammatical order. One of the five alternative serializations for (6a) is given in (6b). In Dutch, however, DP arguments must not be permuted.

(6) a. daß das Objekt dem Subjekt den ersten Platz streitig macht
that the object$_{NOM}$ the subject$_{DAT}$ the initial place$_{ACC}$ contested makes
'that the object competes with the subject for the initial place'

b. daß dem Subjekt den ersten Platz das Objekt streitig macht
that the subject$_{DAT}$ the initial place$_{ACC}$ the object$_{NOM}$ contested makes

Ross (1986), who furnished not only the name for this phenomenon, placed it outside grammar proper and treated it as a stylistic rule. In *The Minimalist Program* (1995c: 324), Chomsky considers a similar move. However, the fact that scrambling interacts with structurally determined phenomena (e.g., anaphor and variable binding) plus the fact that the very existence of scrambling in a given language is grammatically conditioned[2] militates against attempts to disqualify scrambling as a genuine phenomenon of grammar. The following grammatical properties characteristic of scrambling in German (Stechow and Sternefeld 1988;

Grewendorf and Sternefeld 1990; Müller 1995: 95–102; Haider and Rosengren 1998), some of which are inappropriately characterized in the literature, will be discussed in the given order:

(i) Scrambling proper (in German) is clause-bound and confined to the mittelfeld.
(ii) There is no instance of obligatory scrambling.
(iii) Scrambling applies to arguments of all categories (i.e., DP, PP, CP).
(iv) Scrambling of potential binders extends their respective binding domains.
(v) Scrambling produces scope ambiguities (as a chain effect).
(vi) Scrambling can be iterated.
(vii) Scrambling reorders arguments (object shift does not; see section 2.3.1).

Scrambling is usually discussed as a clausal phenomenon, but in fact it should be seen as a more general phenomenon in the context of head-final projections (Haider 1991a; Corver and Van Riemsdijk 1997; Haider 1997c). In German, scrambling is found within VPs (see (2)) and within APs (see (3)), but not within NPs and PPs, as they are head-initial.

(7) a. [$_{VP}$ Dem Subjekt den ersten Platz streitig gemacht] hat das Objekt.
b. [$_{VP}$ Den ersten Platz$_i$ dem Subjekt e$_i$ streitig gemacht] hat das Objekt.

(8) a. der [$_{AP}$ *dem Briefträger* in vielen Merkmalen nicht unähnliche] Sohn
the [the postman in many features not dissimilar] son
der Nachbarin
(of)-the neighbour
'the son of the neighbour resembling the postman in many features'
b. der [$_{AP}$ in vielen Merkmalen *dem Briefträger* nicht unähnliche] Sohn
the [the in many features the postman not dissimilar] son
der Nachbarin
(of)-the neighbour

Property (i): Scrambling is clause bound, in contrast to *focus fronting*.

The claim that scrambling is clause bound is uncontroversial for cases of extraction out of finite clauses, as illustrated in (9), but it holds also for extraction out of infinitival clauses. Apparent counterevidence is controversial. It is open to an alternative analysis as a clause-union construction, due to V-raising.

Sentences (9a) and (9c) are unacceptable. The examples (9b) and (9d) are cases of focus fronting (FF; see Neeleman 1994b: 395f. for Dutch), a construction that occurs less frequently in written than in oral style, presumably because of the necessity of a manifest intonation contour, namely, a rise–fall contour, here indicated by / and \, respectively. Keep in mind that scrambling and FF are two clearly distinct phenomena. For instance, FF may be applied to elements that do not scramble, such as selected manner adverbials or VPs (see the contrasts in (9f) and (9g)).

(9) a. *daß die Lösung$_i$ niemand geglaubt hat, [daß er e$_i$ gefunden hätte]
that the solution no one believed has that he found had

b. daß /SO eine Lösung$_i$ NIE\mand geglaubt hat,
that such a solution no one believed has
[daß einer e$_i$ gefunden hätte][3]
that someone found had
'that no one believed that anyone had found such a solution'

c. *daß niemand [sie zu besuchen]$_i$ geglaubt, [dass er sich e$_i$ leisten kann]
that no one [her to visit] believes that he REFL afford can

d. daß [sie zu be/SUchen]$_i$ NIE\mand glaubt, dass er sich e$_i$ leisten kann
that [her to visit] no one believes that he REFL afford can
'that no one believes that he can afford to visit her'

e. Da habe ich mich$_i$ angefangen, e$_i$ damit zu beschäftigen.[4]
there have I myself$_i$ begun [therewith to engage]
'So I began to engage myself for it.'

f. daß sie ja [/SO viel]$_i$ NICHT\ geglaubt hat
that she Prt [so much] not believed has
[daß man dafür e$_i$ bezahlen müsse]
[that one for-that pay must]

In (9a) and (9c), the scrambled constituent is in the mittelfeld of the matrix clause, that is the clause that embeds the clause with the trace of the scrambled constituent. This type of long-distance displacement is ungrammatical in German, with one exception however: (9b) and (9d) are acceptable, but only with a specific intonation contour. This construction is the result of long-distance movement. Sentence (9e) is an example of a construction whose analysis is controversial ('third infinitival construction', see Den Besten and Rutten 1989; Grewendorf and Sabel 1999; Haider 1993: ch. 9, 2002).

Excursion 1: topicalized V-projections are VPs

Scrambling is found within topicalized V-projections. For the theoretical modeling of scrambling it is relevant whether these constituents are just VPs or VPs within higher functional projections. In the first case, scrambling must be analyzed in terms of the structure of the VP. In the latter case, however, the analysis of scrambling may be framed in terms of movement to specs of functional heads.

Claim
Topicalized projections must not contain the trace of the finite verb. Therefore, topicalized V-projections are VPs, rather than VPs *within* functional projections.

Background
If the fronted constituent contains a functional projection on top of VP, part of the head chain of V-movement that relates the finite verb in V2-position and its base position in the VP would be within the topicalized constituents. This would incur a crossing violation in that the trace is not within the non-breaking hyphen domain of its antecedent. This is easy to demonstrate with the contrast between (1a) and (1c) because in German, stranded particles of verb–particle combinations identify the base position of the verb:

(1) a. [Einen Fehler nachgewiesen] hat er ihm noch nie.
[*Einen Fehler nachgewiesen*] *hat er ihr noch nie.*
[a mistake PRT-proven] has he her never ever
'given her proof of a mistake, he never ever has'
b. *Er wies*$_j$ *ihr noch nie einen Fehler nach-e*$_j$.
he proved$_i$ her yet ever a mistake PRT-e$_i$
c. *[*Einen Fehler nach-e*$_j$] *wies*$_j$ *er ihr noch nie.*
[a mistake PRT-e$_i$] proved$_i$ he her never ever
'Given her proof of a mistake, he never ever has.'

The examples in (1) feature a particle verb. When the finite verb moves to [Spec, C], the particle is stranded (1b). Example (1c) shows that the stranded particle cannot be part of the fronted constituent. In other words, the trace of the finite verb must not be part of the topicalized constituent. Sentence (1c) demonstrates that the topicalized constituent cannot contain the trace of the finite verb: its unacceptability is due to a crossing violation. The trace of the verb in (1c) fails to be in the c-command domain of the moved verb.

The argument
If the topicalized constituent in (1a) contained the trace of the finite verb it would be predicted to be ungrammatical, contrary to the facts. The conclusion must therefore be that the topicalized phrase does not contain the trace of the finite verb. For (1a) this means that the topicalized constituent must be a complement of the auxiliary. It is only in this case that the finite auxiliary would not have to pass through the functional head of a functional projection that hosts arguments of the main verb (see 2a). So if the topicalized constituent in (1a) is not a VP but a VP within a functional projection, this functional projection must be a complement of the auxiliary (2a).

Unavoidable though this conclusion is, it is unwanted because it is bound to overgenerate. The structure in (2a) induces ungrammaticality, as (2b), illustrated in (3b), indicates.

(2) a. $[_{\text{AUX-VP}}\ [_{\mathbf{FP}}\ \text{XP}\ \text{F}^0\ [_{\text{VP}}\ \ldots\ \text{YP}\ \ldots\ \text{V}^0]]\ \text{V}_{\text{AUX}}]$
b. $[_{\text{AUX-VP}}\ [_{\mathbf{FP}}\ \text{XP}\ \text{F}^0\ [_{\text{VP}}\ \ldots\ \text{YP}\ \ldots\ \text{V}^0]\ (\mathbf{*ZP})]\ (\mathbf{*ZP})\ \text{V}_{\text{AUX}}]$

(3) a. Gesprochen *mit ihr* / *Mit ihr* gesprochen hat er nicht mehr.
spoken to her / *to her* spoken has he not any-more
b. *daß er nicht mehr gesprochen *mit ihr hat*
c. daß er nicht mehr *mit ihr* gesprochen *hat*
d. daß er nicht mehr gesprochen *hat* mit ihr

PP objects may be 'extraposed'. The first chunk in (3a) (*Gesprochen mit ihr*) is VP topicalization with an extraposed PP. A VP with extraposition is ungrammatical in the base position (see 3b). If the topicalized constituent in (3a) is a functional projection that allows extraposition, it should allow extraposition in the base position, but this is not the case. Example (3c) is the version with the unextraposed PP. Extraposition of the PP targets a position after the finite verb (3d). One might object that the distributional properties in the base position are obscured by an intervening factor, namely, V-raising. Each verb is raised to the next higher V-position, forming a head cluster. But this objection is without force. If it were so, (4c) would be predicted to be grammatical: If V-raising out of the VP amalgamates the sequence of verbs at the end of the clause, the VP nevertheless remains a target of extraposition. The prediction is then that in a double-object clause extraposition may place a relative clause that goes with the first object in between the second object and the verb cluster:

(4) a. daß er *jenen*^{i} etwas gegeben hat, *die*^{i} *ihn darum*
that he those something given has who him therefore
gebeten haben
asked have
'that he gave something to those who had asked him for it'
b. [*jenen*^{i} etwas gegeben *die*^{i} *ihn darum gebeten haben*] hat er noch nie
c. *daß er *jenen*^{i} etwas, e_i *die*^{i} *ihn darum gebeten haben* [gegeben hat]$_i$

Relative clauses can be extraposed in a fronted VP (4b). Example (4c) is ungrammatical, although it could be analyzed as a functional projection with extraposed relative clause and the verb raised to the higher verb, which subsequently moves to the right hand functional head.

In sum, there is robust enough evidence for VP topicalization and against topicalization of VP within functional projection(s). Hence, topicalized V-projections are a valid testing ground for VP-internal structure.

Property (ii): Syntactically, scrambling is optional. There is no obvious *syntactic* trigger.

Scrambling is optional in the sense that there is no syntactic context that makes an unscrambled order ungrammatical. This is generally acknowledged (see for instance Müller 1995: 95–100). However, there are semantic and pragmatic

aspects of word-order variation. But, the semantic and/or pragmatic effects induced by scrambling cannot be taken to be grammatical triggering factors of Scrambling since the specific interpretation effects that are claimed to trigger Scrambling are found in unscrambled structures as well. Scrambling seems to reduce, but not to induce or replace, the interpretation potential. Sentence (10a) has the definite DP after an indefinite pronoun (morphologically identical with the interrogative form and specifically chosen here because it does not scramble). So the definite DP is likely to be in situ. Analogous considerations apply to (10b, c). Generic interpretation (10a), indefinite specific (10b), and definite specific (10c) interpretations of DP are available for DPs in situ as well as for scrambled DPs. What can get lost by the scrambling of indefinites is the existentially bound interpretation. Note, however, that the strong interpretation (generic (10a) or specific (10b)) is available in the base position as well. The grammar-theoretic reason will be analyzed below.

(10) a. **Existential or generic:**
dass ja wer *(die) Pockenviren* ausrotten sollte
that PRT who the pockvirus exterminate should
'that surely someone should exterminate the pockviruses'

b. **Indefinite specific:**
wenn wer *eine rothaarige Frau* sucht, dann ist das Maria
if who a red-haired woman seeks, then is this Mary
'if someone is looking for a red-haired person, then this is Mary'

c. **Definite specific:**
daß er wem *ihr Kleid* gezeigt hat, hat Anna nicht gefallen
that he who_{DAT} her Dress shown has, has $Anna_{NOM}$ not liked'
'that he has shown her dress to someone Anna did not like'

The only case for allegedly obligatory Scrambling (cf. 11a) – indefinites cannot occur in the domain of negation in German – rests on a controversial premise, namely, the premise that the negation universally c-commands the whole VP. This premise is unfounded, at least for German and Dutch.[5] There are elements, for instance indefinite W-pronouns, that do not scramble (cf. 11b) but occur in front of the negation (11c).

(11) a. *daß jemand nicht *wen* verjagte
that someone not someone chased

b. */??Daß mitunter wen_i jemand e_i beleidigt, kommt vor.
that sometimes someone someone offends, happens

c. daß mitunter wer wen nicht beleidigt, kommt vor
that sometimes someone someone not offends happens
'that it sometimes happens that someone does not offend somebody'

The fact that scrambled indefinites may lose their indefinite or unspecific interpretation is but an epiphenomenon, and not the trigger, of Scrambling. Example

(11b) is ungrammatical because an indefinite scrambled out of the minimal domain of argument-projection (MAC = minimal argument complex)[6] cannot receive an existential reading: it has left the domain of existential closure. The generic or indefinite–specific interpretation that indefinites receive outside the MAC is incompatible with the lexical semantics of indefinite pronouns.

The examples in (12) illustrate that the very interpretation (cf. 12) that is applicable to scrambled indefinites is available already in the base position. In other words, scrambling eliminates interpretation options, but it does not add or generate them. In a triggering account, the 'generated' interpretation would be an element of the triggering mechanism.

(12) a. daß ja Fisch/einen Fisch keiner bestellte
that PRT fish/a fish nobody ordered
'that nobody ordered fish/a fish'
b. daß ja keiner Fisch/einen Fisch bestellte
that PRT nobody fish/a fish ordered

The bare indefinite in (12) is interpreted generically in (12a), and so it can be interpreted in (12b). With an indefinite article, the NP in (12a) can be interpreted as specific, and so it can in (12b). The loss of the existential reading in (12a) is a by-product of scrambling, however. The scrambled DP has left the minimal argument complex, which means that it has left the domain of existential closure.

Property (iii): Scrambling applies to arguments of all categories (i.e., DP, PP, CP).

Irrespective of the category of an argument, namely as a DP, as a PP (13a), as a finite CP (13b), or as an infinite CP-construction (13c), an argument may scramble.[7]

(13) a. daß dort jetzt [auf Peter]$_i$ jemand e_i wartet
that there now for Peter someone waits
'that someone is waiting for Peter there now'
b. $^{(?)}$weil ja heutzutage [daß die Erde rund ist]$_i$ niemand e_i ernsthaft bezweifelt
since PRT today [that the earth round is] nobody seriously doubts
c. daß doch [diese Tür aufzubrechen]$_i$ keiner je e_i versucht hat
that PRT [this door to open] nobody ever tried has
'that nobody ever tried to open this door'

Note that the examples have the scrambled constituent to the left of the subject but to the right of modal particles and temporal adverbials. This, plus the fact that they are well-formed in the absence of focus intonation, indicates that focus movement is not at stake. However, as the question mark in (13b) indicates, non-extraposed finite (scrambled) clauses are slightly marginal; but they are equally marked in the position of the trace as well. They are best when extraposed or in the position immediately after C^0, the focus movement position.

A remark on the scrambling properties of adjuncts seems to be appropriate here: if there are alternative positions, this is not enough for claiming scrambling. Scrambling can be assumed only if there is a privileged start position. This is not entirely clear for adjuncts. If, however, adjuncts can be generated in alternative positions, scrambling is not at stake. This is claimed for Dutch by Neeleman and Weerman (1999). Arguments for base positions of adverbials in German are developed in Frey and Pittner (1998).

Property (iv): Scrambling of possible binders extends their respective binding domains.

Scrambling a potential binder creates new binding possibilities if scrambling enlarges the c-command domain on the binder. This holds for principle-A effects (14a), for principle-C effects (14b), and for Q-binding of pronouns (14c). Note that the discussion of variable binding in scrambling constructions in the literature may involve controversial data judgments (see Frey 1993; Müller and Sternefeld 1994). In all cases, binding in the base-positions[8] is impossible: the non-scrambled version of (14a) would be ungrammatical, (14b) would be grammatical, and in (14c) the pronoun could not get a Q-bound reading.

(14) a. daß man die Zeugenaussagen$_i$ einander^i e$_i$ anglich
that one the testimonies$_{ACC}$ each other$_{DAT}$ adjusted
'that the testimonies were adjusted to one another'

b. *daß man Peter$_i$ [Peters$_i$ Vater] e$_i$ nicht übergeben hat
that one Peter Peter's father$_{DAT}$ not surrendered has

c. daß man fast jeden$_i$ seinem^i Vorgesetzten e$_i$ ankündigte
that one almost everyone his boss$_{DAT}$ announced
'that almost everyone was announced to his boss'

The counterpart of an extended binding domain as an effect of scrambling a potential binder is the destruction of a binding configuration by scrambling the bindee across a binder. Note that this is a property of A-movement, but not A'-movement. A'-moved bindees are reconstructed for binding.

Scrambling of a bindee across a binder destroys binding relations that hold in the base position for principle-A effects (15a), for principle-C effects (15b), and for Q-binding (15c). Binding of a fronted reflexive by a nominative (15d) is exceptional, since in this case F-binding applies, that is, binding by the functional head, whose F-features agree with the nominative (see Haider 1989, 1993: 167; for a detailed implementation see Frey 1993).[9] This is a nominative, not a subject effect: ECM-subjects (for instance, in ECM-constructions) behave like objects: scrambling of the bindee across the binder in (15e) is ungrammatical.

(15) a. *daß man aneinander$_i$ die Bilder^i e$_i$ anglich
that one to-each-other the pictures assimilated

b. daß man [den Vater des Polizisten^{i}]$_{j}$ dem Polizisten/ihm^{i} e$_{j}$
that one the father$_{ACC}$ of-the policeman the policeman/him$_{DAT}$
nicht übergeben hat
not handed over has
'that the father of the policeman was not handed over to the policeman/him'

c. ?daß man [seinen^{i} Vorgesetzten]$_{j}$ jedem^{i} e$_{j}$ ankündigte
that one his boss$_{ACC}$ everyone$_{DAT}$ announced

d. daß sich$_{i}$ bei diesem Fall viele^{i} e$_{i}$ geirrt haben
that REFL with this case many erred have
'that in this case many erred'

e. *daß man sich$_{i}$ keinen^{i} e$_{i}$ vorstellen ließ
that one himself nobody introduce let

These examples demonstrate that binding applies at the target position of Scrambling and not at the respective base positions (see Frey 1993). Hence, reconstruction is not at issue. Note that this distinguishes structures resulting from scrambling from those resulting from topicalization (16a, b):

(16) a. Aneinander$_{i}$ hat man die Bilder^{i} e$_{i}$ angeglichen.
to-each-other has one the pictures assimilated
'The pictures were assimilated to one another.'

b. *[Aus Peters^{i} Wagen]$_{j}$ hat man ihn^{i} e$_{j}$ gezerrt.
out of Peter's car has one him dragged
'Peter was dragged out of his car.'

In A'-chains, binding is checked in the lower position. So (16a) meets condition (A) and (16b) violates condition (C). The relevant contrasts are (15a) versus (16a) and (15b) versus (16b).

Property (v): Scrambling produces scope ambiguities.

Scrambling of quantifiers across quantifier-sensitive elements produces scope ambiguities. Unlike binding, which depends on the surface position of the head of a movement chain, scoping refers to chain-links (cf. Frey 1993): a quantifier Q can get a wide-scope reading with respect to a phrase E, if at least one member of the chain of E is c-commanded by Q (see also Aoun and Li's (1993b) scope principle[10]). Since scrambling – under some of the current analyses – produces chain links, it is predicted to produce scope-ambiguities.

(17) a. **Ambiguous scope:**
daß man [*mindestens ein* Bild]$_{i}$ *fast* *jedem* Experten e$_{i}$ zeigte
that one at least one picture$_{ACC}$ (to) almost every expert$_{DAT}$ showed
'that at least one picture was shown to almost every expert'

b. **Unambiguous scope:**
daß man *mindestens einem* Experten *fast jedes* Bild zeigte
that they (to) at least one $\text{expert}_{\text{DAT}}$ almost every $\text{picture}_{\text{ACC}}$ showed

The ambiguity of (17a) is a scrambling effect. The wide-scope reading of the existentially quantified expression follows from its surface position. It c-commands the universal quantifier. The universally quantified expression, on the other hand, c-commands a trace of the scrambled existential-quantifier expression. Hence this phrase can be assigned to the scope of the lower quantifier. The order of the objects in (17b) – DAT before ACC object – is a base order, given the head verb *zeigen* ('show').

Property (vi): Scrambling can be iterated.

Example (6), repeated for convenience, is representative: In the mittelfeld of a clause with three arguments, the arguments can be serialized in any order. So, there are orders in which more than one argument changes place. Hence, scrambling, unlike wh-movement, is not restricted to a single application.

(6) a. daß das Objekt dem Subjekt den ersten Platz streitig macht
that the $\text{object}_{\text{NOM}}$ the $\text{subject}_{\text{DAT}}$ the initial $\text{place}_{\text{ACC}}$ contentious makes
'that the object disputes the right of the subject for the initial place'
b. daß dem Subjekt den ersten Platz das Objekt streitig macht
that the $\text{subject}_{\text{DAT}}$ the initial $\text{place}_{\text{ACC}}$ the $\text{object}_{\text{NOM}}$ contentious makes

If (6a) reflects the base order, (6b) is the result of scrambling the objects across the subject. Note that the resulting order of the scrambled objects is free: changing the order of the dative and the accusative object in (6b) does not affect grammaticality.

Property (vii): Scrambling reorders arguments (*object shift* does not; see 2.3.1).

In a genuine scrambling language like German (or e.g. Japanese), scrambling produces the complete permutation set of argument order variants for a given clause (see the discussion of ex. 6). The term 'scrambling' is sometimes used in a wider sense: in the discussion of Dutch word order, 'scrambling' is used to refer to the order variation between an argument and an adverbial (see section 2.2.1). 'Object shift' denotes a phenomenon found in Scandinavian languages: pronominal objects (in Icelandic any kind of object) may precede pre-VP adverbials if the VP is beheaded, that is, if the verb is finite and moved to the V2 position. The Dutch phenomenon and the Scandinavian object shift share the property of order conservation: the relative order of arguments must not change. So, it is justified and necessary – at least on the descriptive level – to distinguish scrambling proper from variants of object shift, as in Scandinavian languages and Dutch. It is still an unsettled issue as to whether object shift should be analysed as an argument-movement phenomenon or as an adverb-related pheonomenon (see Neeleman and Weerman 1999: 38ff.).

2.2 Base positions of arguments

2.2.1 Base order as a function of A-structure projection

In German, scrambling cannot be identified without reference to the A-structure of the particular verbal head. The reason is this: the German base order is not a function of grammatical relations (e.g. Case), but directly reflects the ranking of the arguments in the A-structure of the given head. The ranking is a function of the hierarchical organization of lexical–conceptual structure in the lexical entry of a head.

Several verb classes can be distinguished in German with respect to the serialization type determined by their respective A-structure. It is worth emphasizing that this is not a peculiarity of German. German compares with Icelandic in this respect. V-class dependent base orders are also familiar from Icelandic (Kress 1982; Yip et al. 1987). In this language, variant base orders are easy to identify just because of the lack of scrambling. They can be read off from the surface order of DPs inside a VP. Thus, this is a safe indicator that the ordering type is neither an idiosyncratic property nor dependent on scrambling.

A given order of arguments that is the result of scrambling for one verb class (cf. 18a, c, e) may be a base order for another verb class (cf. 18b, d, f). Therefore, a naive inspection of the order of DPs in terms of their case functions does not reveal whether a given order is a base order or a scrambling order. What is needed is an empirically reliable test criterion for the identification of antecedent–gap configurations that are indicative of scrambling. The patterns in (18) are possible base orders for nominal arguments in German (cf. Haider 1997d).

(18)	a.	NOM > ACC:	anfassen	bedauern	interpretieren. . . .
			'touch'	'regret'	'interpret'
	b.	ACC > NOM:	ängstigen	beeindrucken	interessieren. . . .
			'frighten'	'impress'	'interest'
	c.	NOM > DAT:	helfen	gratulieren	widersprechen. . . .
			'help'	'congratulate'	'oppose'
	d.	DAT > NOM:	gefallen	fehlen.	imponieren. . . .
			'appeal/please'	'lack'/'be missing'	'impress'
	e.	NOM > DAT > ACC:	anvertrauen	verbieten	zeigen. . . .
			'entrust'	'forbid'	'show'
	f.	NOM > ACC > DAT:	aussetzen	unterordnen	zuschreiben. . . .
			'expose' to	'subordinate'	'attribute'

The verbs listed in (18a) through (18f) are all verbs that require *have* as an auxiliary, so the patterns (18b, d) cannot be explained away as an ergative–unergative effect. The subject of the verb in these two classes receives a Theme interpretation. If an Agent interpretation is chosen, the verbs must be allocated into classes (18a) and (18c), respectively.

It is worth emphasizing that in Dutch, a language without nominal case-marking,[11] base orders with a nominative following an object are found only with unaccusative verbs.[12] What is called Scrambling in the literature on Dutch is the

variation in the relative order of arguments and certain adverbials. Genuine Scrambling is the permutation of arguments. This is absent in Dutch. The reason has to be sought in the implementation of case checking.

What determines the base order? The base order reflects the order in which the arguments are discharged into the syntactic structure: the asymmetric ranking order of the arguments in the argument grid is mapped onto an asymmetric syntactic structure. A higher ranked argument ends up in a higher position in the syntactic constituent structure (c-structure).

(19) A-structure c-structure (head-final)
H^0: <A <B <C>>> $_{\text{(ranked) lexical A-structure}} \Rightarrow$ [A [B [C h^0]]] $_{\text{syntactic c-structure (head-final)}}$

For present purposes it is sufficient to accept that ranking is a function of the A-structure of a lexical head. The ranking of the A-structure in the lexical entry is not idiosyncratic (but see also Emonds 1991b). It seems to be determined by the conceptual structure.

In order to avoid begging the question, syntactic criteria for the identification of base vs. derived order are needed in order to ascertain whether a given serialization is the result of scrambling or whether it is a base order. Moreover, the test should be sensitive for antecedent–gap constellations that go together with scrambling in order to verify or falsify the assumption that scrambling involves chain formation.

A set of diagnostics with the desired property is found at the phonology–syntax interface. The first diagnostic property is the availability of a maximal focus potential under a nuclear stress intonation. The second property is scope inversion under rise–fall intonation. This property can be explained without additional assumptions if there is an antecedent–gap configuration with the rise intonation on the antecedent and the fall intonation on the constituent adjacent to the gap.

2.2.2 Focus potential

It is by now widely accepted that maximal or wide focus (the whole utterance focused) is possible only in clauses where the focus exponent (i.e., the constituent carrying the nuclear accent) is both in its base position and in the sister position of the head. In order to be a felicitous answer to a question like 'What is the case?' or 'What has happened?', wide focus potential is required. Scrambling of the most deeply embedded argument destroys this constellation since then the most deeply embedded A-position is a trace – and traces cannot be stressed. Stress on any other position yields only a restricted focus domain. So, scrambling of the lowest argument in the base order results in the loss of maximal focus potential. With this in mind, let us test utterances for the potential extension of their focus domain by looking at them in the question context mentioned above. Whenever the focus of a clause with a V-adjacent argument is restricted (and the utterance is consequently an unacceptable answer in the given context) we know that the expected focus exponent in structural terms is not the closest argument to the verb. A closer argument must have left a trace in its own base position closer to the verb and thereby lower in the VP. This test will therefore not only tell us

which one of two alternative constellations is the base constellation, but also that the scrambled phrase has left a trace. Let us look at some representative examples. The examples in (20) contrast a verb with NOM > ACC base order (*interpretieren*, 'interpret') and one with ACC > NOM base order (*interessieren*, 'interest'):

(20) a. **Maximal focus:**
daß Linguisten Bal***LAD***en interpretieren
that linguists$_{NOM}$ ballads$_{ACC}$ interpret$_{3pl}$
b. **Maximal focus:**
daß Linguisten Bal***LAD***en interessieren
that linguists$_{ACC}$ ballads$_{NOM}$ interest$_{3pl}$
c. **Minimal focus:**
daß Balladen$_i$ Lingu***IST***en e$_i$ interpretieren
that ballads$_{ACC}$ linguists$_{NOM}$ interpret$_{3pl}$
d. **Minimal focus:**
daß Balladen$_i$ Lingu***IST***en e$_i$ interessieren
that ballads$_{NOM}$ linguists$_{ACC}$ interest$_{3pl}$

In (20c, d) only the DP with the focus exponents are possible focus domains. They do not allow maximal focus. Note that the order of arguments in terms of case is different in (20c, d). The utterances would be felicitous answers only to questions such as 'Who interprets ballads?' for (20c) and 'Who do ballads interest?' for (20d), but not to a question such as 'What happened?'. Equally felicitous answers to the questions would be the sentences in (20a, b), respectively, but with stress on the first DP:[13]

(21) a. **Minimal focus:**
daß Lingu***IST***en$_{NOM}$ Balladen$_{ACC}$ interpretieren
that linguists ballads interpret
b. **Minimal focus:**
daß Lingu***IST***en$_{ACC}$ Balladen$_{NOM}$ interessieren
that linguists ballads interest

The stress pattern in (20c, d) is identical with the stress pattern in (21a, b) – a DP preceding another DP is stressed – and so is the focus potential, namely, minimal focus only. This parallelism is evidence for the existence of a trace in (20c, d): Only with the trace in the base positions are the structures of (20c, d) and (21a, b) equivalent with respect to the positioning of the focus stress.

The same contrast as illustrated in (20) for subject and object can be observed with pairs of verbs that differ in the base order of double objects: For a minority class of verbs, ACC–DAT, and not DAT–ACC, is the base order:

(22) a. **Maximal focus:**
Es hinterließ jemand einer Frau eine ***NACH***richt.
there left someone a woman$_{DAT}$ a message$_{ACC}$

b. **Non-maximal focus:**
Es hinterließ jemand eine Nachricht einer ***FRAU***.
there left someone a message$_{ACC}$ a woman$_{DAT}$
c. **Maximal focus:**
Ein Lehrer setzte einen Schüler einer großen Ge***FAHR*** aus.
a teacher exposed a pupil$_{ACC}$ (to) a great danger$_{DAT}$
d. **Non-maximal focus:**
Ein Lehrer setzte einer großen Gefahr einen ***SCHÜ***ler aus.
a teacher exposed (to) a great danger$_{DAT}$ a pupil$_{ACC}$

The basic difference between the two verb classes is obvious: in the DAT–ACC class, the dative argument is typically an experiencer; hence it denotes an animate discourse referent. In the ACC–DAT class, the dative-marked argument frequently has a non-animate denotation since it typically codes for a goal or source relation. This difference – experiencer vs. goal – is reflected as a difference in the argument ranking in the argument structure of the respective verbs. Note, however that it is not simply an animacy-triggered difference:

(23) a. **Maximal focus:**
daß man ja seine Kinder$_{ACC}$ den *LEH*rern aussetzen muss
that one PRT one's children (to) the teachers expose must
b. **Non-maximal focus:**
daß man ja den Lehrern seine ***KIN***der$_{ACC}$ aussetzen muss
that one PRT (to) the teachers one's children expose must
c. **Maximal focus:**
Er hat das erste Gedicht$_{ACC}$ seiner ***MUT***ter gewidmet.
he has the first poem (to) his mother devoted
d. **Non-maximal focus:**
Er hat seiner Mutter das erste Ge***DICHT***$_{ACC}$ gewidmet.
he has (to) his mother the first poem devoted

In (23a, b) all DPs involved denote animate individuals, but nevertheless the base order is identical with the base order in (22c), namely ACC–DAT. On the other hand, an animate dative as in (23c) has no influence on the base order. This becomes understandable if one bears in mind that in the lexical–conceptual structure of a verb like *devote*, animacy is irrelevant for ranking because the animate argument nevertheless is a goal argument.[14] Analogously, in the DAT–ACC class, animacy has no effect on the base order either:

(24) a. **Maximal focus:**
daß er dem Buch das *VOR*wort hinzufügte
that he (to) the book the preface added
b. **Non-maximal focus:**
daß er das Vorwort dem BUCH hinzufügte
that he the preface (to) the book added

c. **Maximal focus:**
daß er der Firma den Fi*NANZ*chef abwarb
that he the company the financial manager levied
'that he enticed the financial manager away from this company'

d. **Non-maximal focus:**
daß er den Finanzchef der *FIR*ma abwarb
that he the financial manager the company levied

In sum, the only word order that allows maximal focus is the order in which the stress exponent is not higher than the lowest argument position in the VP. Stress on a higher position yields minimal focus potential only. This is the key for identifying a scrambling trace in between a focus exponent that is adjacent to the verb in PF and the verb. Of course this test is intrinsically limited, since it is applicable only for the A-position closest to the verb.

2.2.3 Scope

Scrambling changes scope relations. If the scrambled element is a scope-sensitive one, its scope domain gets wider by virtue of being moved to a position higher in the tree. If it moves across another scope bearing element, scope ambiguities arise (see Frey 1993). Let us examine the following example:

(25) Question: Wie steht es mit der Beantwortung all der Fragen?
how stands it with the answering all the questions?
'What about the answers to all the questions?'
Answer: Du weißt doch, . . .
you know PRT, . . .
You know, . . .

a. daß mindestens einige Schüler fast ALLe Fragen beantworten
that at least some pupils almost all questions answer
konnte
could
'that some pupils could answer almost all questions'

b. daß [mindestens einige Fragen]$_i$ fast ALLe Schüler e_i beantworten
that at least some questions almost all pupils answer
konnten ∃∀,∀∃
could

In (25a), the only unforced reading is scope according to the overt order. In (25b) two readings are available; one corresponds to the surface linear order, the other reading, to the base order: Since the trace of the scrambled object is in the scope of the subject, the subject can get scope over the scrambled DP. This is in accordance with our assumption that (25a) is the base order and (25b) the scrambled order, resulting in a chain. Let us now apply this diagnostics to a verb with the base order pattern ACC–NOM, namely *interessieren* ('interest').

(26) a. daß einige Linguisten fast ALLe Balladen interessierten ∃∀
that some linguists almost all ballads interested
'that some linguists were interested in almost all ballads'
b. daß [einige Balladen]$_i$ fast ALLe Linguisten e_i interessierten ∃∀,∀∃
that some ballads almost all linguists interested

The verb *interessieren* projects the argument structure EXP < THEME/CAUSE into the base order with the result that ACC precedes NOM. We, therefore expect (26b) but not (26a) to give rise to two readings. This expectation is fulfilled. Analogous considerations apply to the other verb classes mentioned in section 2.2.1. Compare the following examples:

(27) a. daß er einen Kandidaten fast ALLen Tests unterzogen hat ∃∀
that he one candidate almost all tests subjected has
'that he subjected one candidate to almost all tests'
b. daß er [einem Test]$_i$ fast ALLe Kandidaten e_i unterzogen hat ∃∀,∀∃
that he one test almost all candidates subjected has

As expected, (27a) with the base order ACC > DAT yields only one reading, whereas (27b) gives rise to two readings. The converse pattern is characteristic for verbs with the base order DAT > ACC:

(28) a. daß er zwei Kandidaten fast ALLe Fragen stellte ∃∀
that he two candidates almost all questions put
'that he asked two candidates almost all questions'
b. daß er [zwei Fragen]$_i$ fast ALLen Kandidaten e_i stellte ∃∀,∀∃
that he two questions almost all candidates put

In both cases, thus, the scrambled order and only the scrambled order – DAT > ACC in one case, and ACC > DAT with the other V-class – results in two readings.

2.2.4 The base order of arguments in German is not a function of their grammatical relations

German does not provide compelling evidence for, but displays considerable amount of evidence against, the contention that the base order is a function of the syntactic licensing relation (case checking), and in particular against the contention that case-checking obligatorily requires a functional head in the Spec position of which case-features are checked, overtly or covertly. The data presented in the scrambling section in connection with the issue of semantically determined base order types is one body of evidence.

In this section, four issues will be addressed. First, the exclusion of non-argumental expletives. If there is a functional Spec position for subjects, this Spec position would license clause internal, non-argumental expletives. But, this kind of clause internal expletives is ungrammatical in German, and this cannot be attributed to pro-drop. Second, the opacity of spec-positions. A phrase in a

Spec position and in particular a subject is predicted to be opaque for extraction. This prediction is incorrect. Third, even covert movement to a spec-position must be ruled out, since the LF resulting from LF-raising out of fronted VPs is ill-formed. The conclusion must be that the unscrambled positions of arguments in the German clause structure are the base generated, preverbal argument positions within the V-projection.

In addition to these three areas of theory-internal considerations there is a set of data that bears directly on phrase-structure decisions, namely, evidence from VP topicalization in German. It provides as immediate as possible evidence for the claim that in German clause structure, unlike in English, all argument positions may remain in their VP-internal position in surface structure (see also Excursion 1).

2.2.4.1 Subject inside topicalized VPs

Subjects may appear in the topicalized V-projection if two conditions – a semantic and a syntactic one – are met. First, the subject must be non-specific. At best, the VP denotes a property of an event in the scope of a quantifier, which accounts for the contrast between (29a) and (29b). This instance of a specificity effect was first noted by Kratzer (1984).[15]

(29) a. **Indefinite unspecific subject:**
[Ein Außenseiter gewonnen] hat da nie.
an outsider won has here never

b. **Definite specific subject:**
*[Der krasse Außenseiter gewonnen] hat da nie.
the rank outsider won has here never

c. [Linguisten gespeist] haben hier schon oft.
linguist dined have here already often

d. *[Die Linguisten aus Wien gespeist] haben hier schon oft.
the linguist from Vienna dined have here already often

e. [Kinder gespielt] haben hier nie.
children played have here never

f. *[Ihre Kinder gespielt] haben hier nie.
her children played have here never

It is worth emphasizing that subjects within topicalized VPs do not prevent the licensing of anaphors as in the following examples. A solution is proposed in Frey (1993): The anaphor is bound by the functional head that licenses the nominative, which in turn functional head c-commands the anaphor.

(30) a. [Ein Wunder^{j} ereignet]$_{i}$ *hat* sich^{j} hier noch nie e_{i}.
a miracle occured has REFL here never ever
'A miracle has never ever occured here'

b. [Wunder^{j} ereignet]$_{i}$ *haben* sich^{j} hier noch nie e_{i}.
miracles occured have REFL here never ever

Note that these facts are highly problematic for remnant topicalization analyses (see Den Besten and Webelhuth 1990). According to this analysis, what appears to be the topicalization of a part of the VP is analyzed as the result of the interaction of VP-topicalization and scrambling: scrambling removes constituents from the VP. Then, the partially emptied VP is fronted across the elements that have been moved out. However, this analysis overgenerates in the crucial case, namely, with unergative subjects whose base position precedes the base positions of the objects.

(31) a. daß er das Beste$_i$ [den Armen e$_i$ geschenkt] hat
that he the best the poor given has
b. [Den Armen geschenkt] hat er das Beste.
the poor given has he the best
c. daß heute den ersten Preis$_i$ [ein Außenseiter e$_i$ gewonnen] hat
that today the first prize an outsider won has
d. ??/* [Ein Außenseiter gewonnen] hat heute den ersten Preis.
an outsider won has today the first prize
e. [e$_{(i)}$ e$_{(j)}$ gewonnen] hat heute den ersten Preis$_j$ ein Aussenseiter$_i$.
won has today the first prize an outsider

The very same analysis that has been proposed for the handling of (31a) fails with (31d), although the crucial part of the derivational procedure would be identical: Scramble the object out of the VP (31c), and then topicalize the VP. The same procedure must be iterated in (31e). The ungrammaticality of (31d), however, remains a surprise under remnant VP movement.

Ergative subjects whose base position is lower than the position of an object behave as expected. This is no surprise, since the nominative DP is generated in the position of the direct object. Note, however, that the remnant-topicalization approach must allow vacuous scrambling for non-scrambling items: if in (32a, b) the dative is an indefinite pronoun, which does not scramble, it must nevertheless be considered to have been scrambled out of the VP before the VP has been moved to the clause initial position.

(32) a. [Ein Fehler unterlaufen] ist hier noch nie einem
a mistake 'under-occured' is here never ever a
Professor/wem.
professor/someone$_{DAT}$
'Never ever has here a professor committed a mistake'
b. Unangenehme Fragen gestellt werden auch hier manchmal den
unpleasant questions asked were also here sometimes the
Professoren/wem.
professors/someone$_{DAT}$

The crucial difference between the subjects in the examples above and the unergative subjects is this: the base position of the ergative subjects (32) in the

VP is lower than the base position of the dative object. This is not an exclusive property of ergative subjects. Transitive subjects in idiom chunks behave as expected, for the following reason: the specificity constraint (Kratzer 1984) applies to subjects in fronted VPs. This constraint becomes void for non-referential subjects, hence subjects as parts of idioms are possible. Syntactically, they are nevertheless true subjects of transitive verbs.

(33) a. daß den Mann dabei schon oft die Wut gepackt hat
that the man it-with already the the anger seized has
'that at this occasion the man often got angry'
b. [Die Wut gepackt] hat ja den Mann dabei schon oft.
the anger seized has the man it-with already often

In sum, transitive subjects in topicalized VPs are grammatical and the VP-internal position is therefore a licit surface position for nominative DPs in German. The counterpart in the VO language family is Icelandic. Postverbal nominatives in combination with a non-nominative preverbal subject evidence the possibility of VP-internal nominative assignment.

2.2.4.2 Expletive non-argumental subjects

Descriptively speaking, a subject is a non-argument expletive subject if there is a lexical item for the canonical subject position for which the verb does not provide any argument relation. The test case is the passive of an intransitive verb. In German, expletive subjects in the mittelfeld are ungrammatical. It is instructive to compare Dutch and German in this respect. The examples and the judgments in (34a–c) are taken from the descriptive grammar of Paardekooper (1963: 55). He states explicitly that the apparent optionality of an expletive in constructions like (34b) – that is, with a non-extraposed local adverbial – is an effect of the presence of a (local) adverbial. This can be observed in English as well, in a different construction, though (see 34d).

(34) a. In deze Hoek wordt volgens mij gefluisterd. Dutch
in this corner is according to me whispered
b. ?Volgens mij wordt in deze Hoek gefluisterd.
c. *Volgens mij wordt gefluisterd in deze Hoek.
d. On this spot (there) will stand a huge tower.
e. dat *(er) gelachen werd
that (there) laughed was
f. daß (*es) gelacht wurde German
that (there) laughed was
g. Er werd gelachen. Dutch
there was laughed
h. Es wurde gelacht. German
there was laughed

In Dutch, the expletive subject in clause-internal position in (34e) is obligatory, in German it is obligatorily missing (34f), although the respective elements can be found as expletives, but only in the spec-C position (34g, h). If German had an obligatory Spec position for the subject in the *mittelfeld*, the expletive would have to appear in this position, just like in Dutch.

The fact that in Dutch, but not in German, there is a structural subject position (arguably either as a [Spec, VP] or as a functional Spec position) finds support in the distribution patterns of fronted pronouns: in German and in Dutch, pronouns are fronted to the left edge of the VP. In Dutch, this is a position following the Spec position that hosts the subject. Hence fronted pronouns in Dutch but not in German must not precede the subject if the subject occurs in the Spec position (cf. Kieft 1967: 301; see also section 4.3).

(35) a. Toen vond mijn broer *het* opeens tussen oude kranten. (= 35c)
then found my brother it suddenly between old newspapers
b. *Toen vond *het* mijn broer opeens tussen oude kranten.
c. Damals fand *es* mein Bruder plötzlich zwischen alten Zeitungen.
d. Nog nooit had de jongen *zich* meer ingespannen dan dit jaar. (= 35f)
never ever had the boys REFL more struggled than this year
e. *Nog nooit had *zich* de jongen meer ingespannen dan dit jaar.
f. Noch nie hatte *sich* der Junge mehr angestrengt als in diesem Jahr.

This set of data indicates that the subject position in Dutch is structurally different from the subject position in German. Given that pronoun fronting targets the left edge of the VP, the subject is VP-internal in German, but VP-external in Dutch. The contrast in (35) is easy to account for if the absence of an expletive subject in German is a function of the absence of a functional subject position. If there is a Spec position for the subject, on the other hand, this position legitimates and triggers the presence of an expletive. The obligatory absence of a subject-expletive in intransitive passives and in presentative constructions (see 36) in German calls for a structural explanation (cf. Haider 1993, 1990a). Invoking a language-specific pro-drop option is an ad-hoc patch-up strategy that does not adequately capture the empirical situation.

(36) a. dat (er) gisteren iemand vertrokken is
b. daß (*es) gestern jemand abgereist ist
that (there) yesterday someone left has
'that someone left yesterday'

Accounts in terms of pro-drop as an independent parametric difference disregard an important fact, namely, that there are semantically empty subjects in German

which must not be dropped (see 37). If German were pro-drop, pronominal subjects in these constructions would have to be expected to be dropped. Alleged semi-pro-drop languages such as German should drop exactly these pronominal subjects. These data are counter-evidence for the semi-pro-drop hypothesis.

(37) a. **Quasi argument:**
daß *(**es**) sich dabei um einen Irrtum handelt
that (it) REFL. it-by at an error deals
'that it is a mistake'

b. **Intransitive middle construction:**
daß *(**es**) sich in dieser Stadt gut lebt
that (it) REFL. in this city well lives

c. **Extraposition:**
daß *(**es**) zu gefährlich ist, diese Route zu benützen
that (it) too dangerous is this route to take
'that it is too dangerous to take this route'

The verb *handeln* in (37a) takes two semantically empty arguments, namely, *es* ('it') as a subject and a reflexive as an object, plus PPs that host the DPs that are equated. Semantically, the verb establishes an equation relation between the DPs contained in the PPs. Example (37b) is the intransitive middle construction with the verb *leben*. In German, the middle of an intransitive verb introduces an expletive subject and a reflexive object. The example in (37c) is an extraposition construction. Dropping the pronominal subject that goes together with the extraposed subject clause is optional for some predicates but not for all, as the predicate in (37c) illustrates. A pro-drop account that treats German as a semi-pro-drop language, which drops non-referential pronouns, would incorrectly predict that the pronominal subject should drop in all these constructions.

If, on the other hand, no functional projections in the mittelfeld call for lexical material for at least their Spec positions, the absence of obligatory Spec positions in the mittelfeld is the direct grammatical reason for the absence of subject expletives. There is no room for an expletive subject and consequently no need for invoking an exceptional type of pro-drop (cf. Haider 1990a).

2.2.4.3 Extraction out of subjects

Further corroborative evidence for the claim that subjects in German are VP-internal is the lack of opacity effects with subjects in German: there are no clear-cut structural subject–object asymmetries for extraction or *wh*-in-situ constructions. If a subject were moved to a Spec position, this would render it an opaque domain for extraction out of this phrase. A decade of research on extraction restrictions proved the 'subject condition' to be a robust phenomenon. A subject in a functional Spec position is opaque for extraction because phrases in functional Spec positions are opaque. Consequently, non-opaque subjects must be subjects that are not in functional Spec positions. They are VP-internal:

(38) a. *What$_i$ would [to discuss e$_i$ with him] be worthwhile?
b. $^{(?)}$What$_i$ would it be worthwhile [to discuss e$_i$ with him]?
c. Was$_i$ würde sich [mit ihm e$_i$ zu besprechen] denn noch lohnen?
what would itself with him to discuss PRT PRT pay
d. Nur das$_i$ würde sich [mit ihm e$_i$ zu besprechen] ja noch lohnen.
only this would itself with him to discuss PRT PRT pay
e. Was/das$_i$ würde [mit ihm e$_i$ zu besprechen] wohl noch Spaß machen?
what/this would with him to discuss PRT PRT fun make

Since the subject clause in (38c–e) is systematically not opaque for extraction, it cannot be assigned to a functional Spec position. So, if there were a medial Spec position in (38c–e), its status would be that of a pronominal empty category. Fronting the clause across this empty pronominal element in (39b) should produce the same effect as fronting a clause across an overt pronominal antecedent in (39a). In addition, the empty pronominal in the [Spec, I] position would force extraposition. Examples (39c–e) illustrate the contrast between extraposed and non-extraposed complements in the presence of a pronominal antecedent.

(39) a. *[Alles mit ihm zu besprechen]$_i$ würde *es*^{i} sich nicht lohnen e$_i$.
everything with him to discuss would it itself not pay
b. [Alles mit ihm zu besprechen]$_i$ würde e$_i$ sich nicht lohnen.
everything with him to discuss would itself not pay
c. daß *es* sich nicht lohnen würde [alles mit ihm zu besprechen]
that it itself not pay would everything with him to discuss
d. daß (**es*) [alles mit ihm zu besprechen] sich nicht lohnen würde
that (it) everything with him to discuss itself not pay would
'that it would not pay to discuss everything with him'

The contrasts in (39) follow immediately if the embedded-subject clause is not in relation with an empty pronominal in an [IP, Spec] of the matrix clause. The empty category in (39b) is the single trace of the fronted clause and there is no other empty category the clause is coindexed with.

Please bear in mind that the structural conditions are necessary but not sufficient for extraction. The 'bridge verb quality' (remember that verbs of saying are bridge verbs for clausal objects, but not factive verbs like *regret*) is an additional independent factor that should be controlled if you try to countercheck the generalizations. Sometimes the impression of a subject–object contrast may arise because therere are only few subject-related bridge verbs, that is, verbs with a semantic relation to the subject argument that is of a similar semantic quality as the thematic relation to the objects of verbs like verbs of saying, etc. (Try *träumen* 'dream' with a subject clause and a dative object and you have a candidate for extraction out of a finite subject clause; see Haider 1993: 158ff.)

2.3 Pronouns

Unstressed pronouns have properties of their own that differ from non-pronominal DPs:

- Serialization preference: fronting to the left edge (see the parametric factors below).
- Order pattern by case: nominative before accusative before dative (same for Dutch).
- Serialization restrictions with respect to information-structure-sensitive particles and adverbials.

2.3.1 Fronting

Unstressed pronouns tend to be fronted. Pronoun fronting applies both to argumental pronouns as well as to pronominal adjuncts as *there*. Cross-linguistically, the domain of fronting may appear to be different at first glance on comparing the patterns. In German, object pronouns are fronted to a position following the topmost functional head, that is, the complementizer or the finite verb. In Dutch, an object pronoun must not be fronted across an unergative subject (40b). In English, pronouns are fronted within the VP to a position after the verbal head. In the continental Scandinavian languages (41), pronouns must be fronted across clause-internal adverbials and negation in the so-called obligatory object-shift configuration (cf. Vikner 1995 and chapter 46 in this *Companion*).

(40) a. daß [es$_i$ jeder e$_i$ zurücksteckte]
that it everyone back-put
b. *dat het$_i$ iedereen [e$_i$ terugzette]
that it everyone back-put
that everyone [put it back e$_i$]

(41) a. Studenterne læste den$_i$ alligevel ikke e$_i$. Danish
students read it/there after-all not
b. Studenterne læste alligevel ikke artiklen/*den.
students read after-all not article-the/it/there

Despite the apparently diverse patterns, the serialization of unstressed pronouns in the Germanic languages is uniform. It is the parametric diversification of a single condition: if a pronoun can be fronted, it is fronted as close as possible to the left edge of the VP. Once it is realized that in general in German but not in Dutch, the surface-subject position is VP-internal it is easy to provide a simple descriptive generalization for the range of fronting in a Germanic OV language: Pronoun fronting targets the highest accessible VP-internal position. In German this is the left edge of the mittelfeld. In Dutch it is a mittelfeld-internal position, namely, the left edge of the VP with the transitive subject in a (functional) position outside the VP. In VO languages, pronouns targeting the left edge of the VP

end up in positions immediately following the V. In English and in Scandinavian languages, pronoun fronting can be observed only in contexts in which fronting does not affect argument order. The position targeted by fronting is closest to the left edge of the VP. In the Scandinavian languages there is an additional possibility, namely object shift. The pronouns may be fronted to the left edge of the VP provided that the overt head of the VP is not crossed. This is possible only if the verb has moved as the finite verb to the V2-position (see 41).

In German there are distributional restrictions that seem to differentiate between pronoun fronting and scrambling. Fronted negation ('light negation') in non-asserted clauses (i.e., conditionals, indirect questions) and information-structuring particles may precede scrambled NPs, but not fronted pronominals (see Haider 1997c):

(42) a. wenn damals *nicht/doch* den {Mann$_i$, *ihn$_i$} jemand e$_i$ gewarnt hätte
if then not/PRT the man, *him someone warned had
'if/since someone would have warned {the man, him} then'
b. wenn damals {den Mann$_i$, ihn$_i$} *nicht/doch* jemand e$_i$ gewarnt hätte

In (42a) the object is fronted across the subject. The result is ungrammatical for a pronominal but it is perfect for a non-pronominal DP if a particle of the kind discussed above precedes. The following example, however, shows that the restriction against pronouns in the c-command domain of the particles including negation is independent of fronting. It holds in the base position, too:

(43) a. daß der Mann ja doch die Frau/*sie gesehen hat
that the man PRT PRT the woman/her seen has
'that the man has seen her/the woman after all'
b. daß der Mann sie/die Frau ja doch gesehen hat
that the man her/the woman PRT PRT seen has

The contrast between (43a) and (43b) parallels the contrast in (42) and it is therefore independent of scrambling. The only difference between scrambling and pronoun fronting is an order restriction. The preferred order for fronted pronouns is NOM–ACC–DAT; there is no such restriction for scrambled non-pronominal DPs (cf. Lenerz 1993).

2.3.2 Order restriction for pronouns: NOM–ACC–DAT

The order restriction holds uniformly, that is, irrespective of the base order induced by the verbal head. Whatever base-order pattern the verbal head requires for is arguments; pronominal arguments are ordered according to the template in the headline. If the order deviates from the standard serialization nominative < accusative < dative (cf. 44b with a stressed pronominal subject), then the pronoun that follows, and thereby deviates, is stressed and as a stressed (= strong) pronoun exempted from the restriction.

(44) a. daß niemand/er$_{NOM}$ ihn$_{ACC}$ ihr$_{DAT}$ vorstellte
b. daß *ihn ihr* niemand/**ER** vorstellte

The same ordering patterns are found in Dutch. This is remarkable because of the Dutch prohibition against scrambling a direct object in front of the indirect object. So, this is additional evidence that the order of pronominal arguments cannot be a result of scrambling, nor can it be taken as an indicator of the base order for arguments. For both issues Dutch provides the relevant counterevidence. Since DP objects cannot be reordered by scrambling, the pronoun order cannot be achieved by scrambling. On the other hand, if the pronoun order would be the base order for arguments, the canonical Dutch order for non-pronominal arguments – IO before DO – would have to be analyzed as an instance of scrambling the IO across the DO. The result would be over-generating an ungrammatical DO before IO order as a base order.

The examples under (45) show that the demonstrative *dat* ('that') (see 45b) and the strong form *haar* appear in the order of non-pronominal forms, whereas the other pronouns come in the order direct object before indirect object.

(45) a. Had Jan/*hij het zich* niet ingebeeld?
had Jan/he it himself not imagined
b. Had Jan/*hij zich dat* niet ingebeeld?
had Jan/he himself it not imagined
c. Eigenlijk had Jan/*hij zich haar* heel anders voorgesteld.
actually had Jan/he himself she completely different imagined
d. Eigenlijk had Jan/*hij ze zich* heel anders voorgesteld.
actually had Jan/he she himself completely different imagined

The Dutch data provide immediate evidence for a general, cross-linguistically relevant, issue that is hard to tackle with German data, namely, that the difference between the Dutch patterns of pronominal and non-pronominal DPs is evidence against the assumption of a case driven underlying order for DPs in general.

The invariant pronoun order in German might be (and has in fact been, see Müller 1995) identified with an invariant case-driven underlying order for DPs in general, and the V-dependent serializations discussed above could be taken to be scrambling variants. The Dutch data clearly forbid this hypothesis, however. As in German, the pronominal direct object precedes a pronominal indirect object. For non-pronominal objects, the inverse order is required. But Dutch scrambling does not cross DP arguments. So the order of non-pronominal DPs cannot be a scrambling effect, and consequently, the pronominal order cannot be the base order of DPs in general.

If the pronoun order were the underlying order for DPs in general, non-pronominal DPs would have to be scrambled obligatorily into the opposite order. But there is neither a trigger nor positive evidence for this kind of scrambling so these data support the hypothesis of an A-structure determined base order for

non-pronominal arguments in German. But what is the source of the order restriction for personal pronouns?

It is worth emphasizing that the order pattern NOM–ACC–DAT is not triggered by fronting. It applies also to pronouns that are not fronted to the left edge of the MF, as (46) illustrates, and it holds also for non-adjacent sequences of pronouns (see 47). Of course, non-pronominal DPs (see 47c) do not follow this restriction.

(46) a. daß endlich einer sie uns vorstellen/zeigen sollte
that after-all someone them$_{ACC}$ us$_{DAT}$ introduce/show should
b. *daß endlich einer uns sie vorstellen/zeigen sollte
that after-all someone us$_{DAT}$ them$_{ACC}$ introduce/show should

(47) a. daß bei dieser Gelegenheit *sie* einer *uns* kurz
that at this occasion them$_{ACC}$ someone us$_{DAT}$ briefly
vorstellen/zeigen sollte
introduce/show should
b. ?daß bei dieser Gelegenheit *uns* einer *sie* kurz
that at this occasion us$_{DAT}$ someone them$_{ACC}$ briefly
vorstellen/zeigen sollte
introduce/show should
c. daß bei dieser Gelegenheit *den Besuchern* einer *die Bilder*
that at this occasion den Besuchern someone the pictures
kurz zeigen sollte
briefly show should

2.3.3 Particle distribution

Particularly instructive for the analysis of pronoun positions is the serialization pattern with respect to certain sentence particles (e.g. *ja*, *denn*) are used for information structuring. They partition the clause into the backgrounded and the asserted part:

(48) a. weil *sich*$_j$ **ja** niemand dem Mob e$_j$ in den Weg gestellt hat
since PRT nobody the mob in the way put has
'since nobody tried to stop the the mob'
b. *weil ja *sich*$_j$ niemand dem Mob e$_j$ in den Weg gestellt hat
c. wenn *sich*$_j$ nicht noch jemand der Meute e$_j$ in den Weg wirft, . . .
d. *wenn nicht *sich*$_j$ noch jemand der Meute e$_j$ in den Weg wirft, . . .
e. weil ja unter diesen Umständen *sich* niemand dem Mob in den Weg stellen könnte

The descriptive generalization behind the pattern (48) is this: if a pronoun is fronted, it cannot exclusively constitute the extendable VP-domain in the scope of a sentence particle. Thus in (48b, d), the extendable VP-domain contains only a pronoun that follows a sentence particle. This is unacceptable. The well-formed

serialization is (48a, c), with the pronoun preceding the particle. It is worth emphasizing that this is not a strict positional effect of an edge effect. Note that the fronted pronouns may be separated from the preceding functional head position (see 48e) by frame adverbials such as *unter diesen Umständen* ('under these circumstances'), *angesichts der drohenden Gefahr* ('in view of the threatening danger'). The resulting expression becomes acceptable.

It would be premature to conclude that if pronouns are fronted they must be fronted to a specific position preceding sentence particles. What we suggest is that the crucial factor behind the ungrammaticality of (48b, d) is a stress property, in that personal pronouns avoid accented positions. The position following the particle receives secondary stress. If this is the correct characterization, this implies that a fronted pronoun *can* occur in the c-command domain of a sentence particle, provided the pronoun is not the highest element within the c-command domain of the particle.

The examples in (49) contrast, as expected, with the corresponding examples in (48). If a scrambled DP (preceding the fronted pronoun in this case) ends up higher than the domain of the particle, this DP receives the secondary stress. The slight degradation in (49) is to be blamed on the pronoun in this domain for a semantic reason. As non-referential material it could and hence should precede the particle.

(49) a. $^{(?)}$weil ja [*dem Mob*$_i$ sich$_j$ niemand e$_i$ e$_j$ in den Weg gestellt hat]
b. $^{(?)}$wenn nicht [*der Meute*$_i$ sich$_j$ noch jemand e$_i$ e$_j$ in den Weg wirft], . . .

The distribution with respect to adjuncts is analogous to the pattern found with sentence particles. Pronouns may be preceded, as mentioned above, by frame adverbials and adverbials of reasoning but not by lower adverbials.

(50) a. daß *unter diesen Umständen* sich$_i$/sie$_i$ Max (ja) e$_i$ verstecken hätte müssen
b. daß *in vielen Fällen* sich$_i$/sie$_i$ Max e$_i$ (ja) nicht rechtzeitig informiert hat
c. $^{??}$daß (ja) *hier* sich$_i$/sie$_i$ niemand e$_i$ verstecken mußte
d. $^{??}$daß (ja) *gestern* sich$_i$/sie$_i$ niemand e$_i$ rechtzeitig informiert hat

The deviant sentences in (50) contain two candidates whose serialization disobeys the interface condition of mapping syntactic domains properly onto semantic domains: the pronoun is in too low a domain and the adjunct is too high. The pronoun as a background item is in the domain of an event adjunct that modifies the assertion part and the adjunct c-commands an unnecessary big domain.

2.4 Constraints on a well-formed mittelfeld

2.4.1 Empty mittelfeld

In this section, syntactic restrictions on elements in the mittelfeld are briefly reviewed (see also section 2.2.4.2). The trivial case to start with is an empty

mittelfeld. As mentioned in the introduction section, the mittelfeld in German, but not in Dutch, may be radically empty, as in (51a) versus (51b). An expletive subject is ungrammatical in German, but mandatory in Dutch.

(51) a. Wurde (*es) gelacht?
was (there) laughed
b. Werd *(er) gelachen?

As in English locative constructions (52a), a locative PP may substitute for the expletive in Dutch in an intransitive passive (52b). That the PP replaces the expletive in English becomes obvious in wh-constructions. The locative PP as wh-element does not trigger *do*-support (52c, d).

(52) a. On this spot (there) will stand a huge tower.
b. In deze hoek werd gefluisterd.
c. *Out of which* box jumped a rabbit?
d. Out of which box did *there* jump a rabbit?

It would be misleading in my opinion (I will motivate this later) both for German and for Dutch or English to characterize the absence of an expletive as a case of (semi-) *pro-drop*. Quite a few attempts in that direction have been made in the 1980s (McKay 1985; Safir 1985a, 1985b; Koster 1987; Platzack 1987; Grewendorf 1989).

It is misleading for German because German does not allow pro-drop for expletives in the clear cases. It is misleading for English and Dutch because (52a) and (52b) are not cases of pro-drop, but cases of locative preposing. If pro-drop of expletives would be available for Dutch, dropping the expletive in (51b) should not be ungrammatical. Independent evidence can be found in presentative constructions. An expletive in the otherwise empty mittelfeld is required in Dutch but forbidden in German.

(53) a. Es ist jemand gekommen – Ist (*es) jemand gekommen?
b. Er is iemand gekomen – Is (er) iemand gekomen?

The absence of an expletive in the German mittelfeld is the reflex of a structural condition and not a case of expletive pro-drop, because there are obligatory expletive subjects in German:

(54) a. **Quasi argument:**
Gestern hat *(es) geregnet.
Yesterday has it rained
b. **Expletive subject of intransitive middles:**
Hier plaudert *(es) sich angenehm.
here chats it itself pleasantly
'Here it is pleasant to chat.'

c. **Pronominal correlate of extraposition:**
War *(es) sehr peinlich, daß . . . ?
Was it embarrassing that . . . ?

Next, let us briefly look at a derivationally emptied mittelfeld. Although the mittelfeld may be empty from the beginning, it must not be emptied derivationally. In other words, topicalization of the whole mittelfeld as in (55a) is ungrammatical if the mittelfeld portion of the resulting clause thereby becomes empty. This must not be confused with the case of (55c), in which the mittelfeld contains only a single constituent that is fronted to the pre-field. For details see Haider (1988, 1997b).

(55) a. *[Eine Hymne gesungen]$_i$ wurde$_j$ e_i e_j.
a hymn sung was
b. [Eine Hymne gesungen]$_i$ wurde$_j$ dabei noch nie e_i e_j.
a hymn sung was it-with never ever
c. [Eine Hymne] erklang.
a hymn sounded

The crucial difference between (55a) and (55b) is that the movement in (55a), but not in (55b), is string-vacuous. But why should string-vacuous movement matter in (55a) but not in (55c)? An answer is suggested in Haider (1988): in string-vacuous derivations, the well-formedness conditions for the target and the source structure must be met simultaneously. This is the case for (55c). In the base structure, the order conforms with the Complement+head configuration, as a derived structure is conforms to a (Spec–Head) configuration. In (55a), the Spec constituent in the derived structure is not a possible constellation in the non-derived order because of obligatory V-raising (i.e., cluster formation): the participle and the auxiliary ought to be adjoined to each other. Of course this is not the case in (55a) because the functional-head position targeted by the finite verb would not accept a verb cluster, only the single finite verb.

2.4.2 Banned from the mittelfeld

Let us turn now to the next question: are there grammatical restrictions for phrases in the mittelfeld? First, there are no category restrictions. Arguments and adjuncts in the mittelfeld are allowed in all possible categories, that is, DP, PP, and CP, infinitival, and to some extent, finite CPs as well.

(56) a. Ich habe ja [daß 2 plus 2 vier ergibt] nicht bezweifelt.
I have prt [that 2 plus 2 four yields] not doubted
b. Du mußt aber [sobald das Licht erscheint] sofort den
you must however [as-soon-as the light appears] immediately the
Knopf drücken.
button press
c. Ich werde [was ich gefunden habe] niemandem zeigen.
I shall what I found have nobody show

d. ??Mich hat ja [ob er es getan hat] nicht wirklich interessiert.
me$_{ACC}$ has PRT [whether he it done has] not really interested
e. ??Mir hat sie [wer es getan hat] ja nicht gesagt.
me$_{DAT}$ has she [who it done has] PRT not said
f. *Zu mir hat sie [er sei krank] gesagt.
to me has she [he is$_{SUBJ}$ ill] said

Finite CPs in the mittelfeld are found as declarative argument clauses of a subset of verbal predicates (56a) or as adverbial clauses of all kinds (56b) or as free relatives (56c). Argumental CPs in the function of indirect *wh*-clauses are unacceptable or at least highly marginal (56d, e). Embedded V2-clauses are ungrammatical in the MF (56f); they must be extraposed.

Second, there are strict dependency restrictions. Constituents that are not 'VP-compatible' are excluded from the German mittelfeld. A constituent XP is VP-compatible if it is an argument of V^0, or an adjunct of V^0, or its extended projection, or a secondary predicate of an argument of V^0 (57). VP-incompatible constituents are phrases without a dependency relation to the V^0 head of the VP, for instance 'wrongly extraposed' elements.

(57) a. Er^i hat [das Steak^j betrunken roh^j gegessen^i].
he has the steak drunk raw eaten
b. He^i [ate the steak^j raw^j drunk^i].

Note that secondary predicates and extraposable attributes like relative clauses behave differently. The former can be part of a topicalized VP (58a), while the latter cannot (58b), unless the antecedent is contained in the VP (58c).

(58) a. [Betrunken roh gegessen] hat nur einer sein Steak.
drunk raw eaten had only one his steak
'Only one has eaten his steak raw drunk.'
b. *[Entdeckt, [den^i er gemacht hat]] hat er ja einen Fehler^i.
discovered [which he made has] has he indeed a mistake
c. [Einen Fehler^i entdeckt, [den^i er gemacht hat]] hat er in der Tat.
a mistake discovered [which he made has] has he well indeed has
'He has indeed discovered a mistake that he made.'

The examples in (59) illustrate that wrongly detached (= extraposed) clauses (e.g., relative clauses, comparative clauses) cannot occur in the MF but only in the post-field. The relation between an extraposed argument clause and the correlate pronoun in the MF follows the same pattern (60). Fronting to the pre-field is unacceptable in all these cases. Note that this asymmetry (OK in post-field, but not OK in pre-field) raises a non-trivial problem for movement approaches to extraposition (see Culicover and Rochemont 1990; Haider 1997c) since in both cases the trace would guarantee the proper identification of the extraction site.

(59) a. *Er hat alles^{i} auf Anhieb [was sie gesagt hat]^{i} auch verstanden.
b. Er hat auf Anhieb [was sie gesagt hat] auch verstanden. (note that this is a free relative)
c. *Sie hat mehr^{i} Leuten die Geschichte [als^{i} notwendig war] erzählt.
d. Sie hat mehr^{i} Leuten die Geschichte erzählt [als^{i} notwendig war].

(60) a. Bisher hat (*es^{i}) den meisten [per e-mail benachrichtigt zu werden]$^{(i)}$ genügt.
b. Bisher hat (es^{i}) den meisten genügt [per e-mail benachrichtigt zu werden]$^{(i)}$.
c. [Per e-mail benachrichtigt zu werden]$^{(i)}$ hat (*es^{i}) bisher den meisten genügt.

Let me repeat: structural expletives, that is, expletives for Spec–Head positions, are banned from the German MF, but obligatory in the Dutch one, as the contrast between (61a) and (61b) illustrates. Note that the very same element is the required expletive for the pre-field in the respective language. It would be misleading to attribute the absence of an expletive in German to pro-drop of non-referential subjects because quasi arguments (62a), subjects of middle constructions (62b) and the correlates of extraposed clauses (62c) cannot be dropped freely.

(61) a. Mitunter steht (***es***) jemand an der Tür.
sometimes stands it someone at the door
'Sometimes there is someone at the door.'
b. Soms staat *(**er**) iemand aan de deur.
c. **Es** steht mitunter jemand an der Tür.
d. **Er** staat soms iemand aan de deur.

(62) a. Heute hat *(es) gehagelt.
today has it hailed
b. Mit ihm plaudert *(es) sich.
with him chats it itself pleasantly
'He is pleasant to chat with.'
c. Eigentlich ist *(es) peinlich, daß man das häufig übersieht.
actually is it embarassing that one this frequently overlooks

2.4.3 Remarks on the IPP

The IPP construction (*infinitivus pro participio* 'infinitive instead of a past participle') raises a problem – at least in German – for the delimitation of the MF because in this construction, at least the finite verb (in a non-V2 clause type) may apparently appear in the MF, as the following examples illustrate.[16] In Dutch IPP-constructions the finite verb cannot precede a non-verbal intervener (63d).

(63) a. daß er für ihn nicht *hatte* die Firma am Leben halten wollen
that he for him not had the company at life keep want$_{\text{Infinitive}}$
(Mann)

b. Gerda, die sie nicht *hatte* in der Familie grau werden sehen
Gerda, who she not had in the family grey become see$_{\text{Infinitive}}$
(Mann)

c. daß der Tod ihr *werde* in unabsolviertem Zustand auflauern dürfen
that the death her would in unabsolved state waylay may$_{\text{Infinitive}}$
(Werfel)

d. *dat hij graag wilde kraanvogels fotograferen
that he with-delight wanted cranes photograph
(Haeseryn et al. 1997: 949)

Presently, the theoretical modeling of the IPP construction is still controversial. Basically there are two competing approaches: either the finite verb is moved to a position in the MF, or (portions of) the VP (are)/is moved out of the MF to the right.

2.5 Differences between German and Dutch word order in the MF

2.5.1 Do not change the relative order of DP arguments in Dutch

It is handbook-knowledge for Dutch (see Haeseryn et al. 1997)[17] that – contrary to German – the relative order of DP arguments must not be permuted in the mittelfeld. This holds for subject–object order (64), as well as for the order of the indirect object before the direct object (65).

(64) a. dat (er) iemand krakers oppakt
that (there) someone squatters arrests
'that someone arrests squatters'

b. *dat (er) krakers$_i$ iemand e$_i$ oppakt
that (there) squatters someone arrests

(65) a. dat ik de jongen het/een boek gegeven heb
that I the boys the/a book given have
'that I gave the/a book to the boys'

b. *dat ik het/een boek$_i$ de jongen e$_i$ gegeven heb
that I the/a book the boys given have

What is called a Scrambling order in the literature on Dutch refers to the serialization options of adverbials relative to arguments. If there are two possible serializations, one with a DP following an adjunct (66a) and one with a DP preceding an adjunct (66b), scrambling refers to the latter order.

(66) a. dat de politie/iemand *altijd/vandaag* krakers oppakt
that the police/someone always/today squatters arrests that
'that the police/someone always arrests squatters'
b. dat de politie/iemand krakers$_{(i)}$ *altijd/vandaag* (e$_i$) oppakt
that the police/someone squatters always/today arrests

If (66b) is indeed a result of scrambling (either by adjunction or by substitution into a suitable [F, Spec], (65b) should in principle be a potential result of the same process that derives (66b). The Scrambling analysis of (66b) presupposes that the time or frequency adverb precedes the VP boundary. So the object is moved across the VP boundary into a position preceding the VP, suitable for hosting a scrambled direct object. But this is exactly what would be necessary to derive (65b): the indirect object would stay in situ and the direct object would be scrambled. Since (65b) is ungrammatical, Scrambling does not provide a satisfactory solution for (66b) as long as the ungrammaticality of (65b) remains unaccounted for.

A satisfactory account must pay attention to the Dutch–German contrasts in addition to the argument–adjunct contrasts above. In section 2.2.1, a crucial difference was located in the case system, namely, the lack of morphological case in Dutch, which has consequences for case checking. The lack of morphological case distinctions for DPs requires a hierarchical implementation of case checking. First come, first checked. This implies that objects cannot be permuted unless they are morphologically identifiable. PP-arguments can scramble but DPs cannot.

In sum, scrambling of DP objects is ungrammatical in Dutch if arguments are permuted. The grammar-theoretical reason seems to be the identification of object arguments in terms of their abstract case ranking. This statement does not include subjects and PP-objects, and for a good reason: they are morphologically identifiable and may therefore enter chain relations in the middle field, that is, they may scramble. The subject is identifiable by overt agreement, PPs are categorially identified. This fact is not properly stressed in current syntactic literature, although descriptive grammars like Haeseryn et al. (1997)[18] are quite explicit in this respect. As for scrambling of PP-objects, see (67):

(67) a. Het is verkeerd om [een huis *aan Jan* te schenken].
it is wrong C^0 [a house to Jan to give-away]
b. Het is verkeerd [om [*aan Jan* een huis te schenken]].
it is wrong [C^0 [to Jan a house to give-away]]
'It is wrong to give a house to Jan.'
c. Toen heeft hij [de oplossing aan de studenten verteld].
then has he [the solution to the students told]
d. Toen heeft hij [aan de studenten de oplossing verteld].
then has he [to the students the solution told]
'Then he told the solution to the students.'

One of the alternative orders in the bracketed constituents in (67) is a scrambling order. Since PP objects follow DP objects in the base order, it is safe to assume that (67b) and (67d) are the result of Scrambling with a trace in the base position of the PP object to the right of the direct object.

Fronting of subjects (see (68)) is found with passive and unaccusative subjects, that is nominative DPs whose base position follows an object position. In this case there are two options. The nominative DP may stay in situ in itsVP-internal position or it may move across the object. The following examples are quoted from Haeseryn et al. (1997: § 22.5.6.2.). The existential-closure reading is lost if an indefinite nominative is fronted, unless *er* is inserted, as in (68c). This is the reason why (68b), with an indefinite article and an existential reading, is unacceptable:

(68) a. Daarom werd de burgermeester het/een schilderij aangeboden.
therefore is the mayor the/a painting offered
'Therefore the/a painting is offered to the mayor'
b. Daarom werd [het/*een schilderij]$_i$ de burgermeester e_i aangeboden.
therefore is the/a painting the mayor offered
c. Daarom werd er [een schilderij]$_i$ de burgermeester e_i aangeboden.
Therefore is there a painting the mayor offered

If *er* in (68c) is analyzed as an expletive for a subject position as a functional Spec position, the fronted nominative is VP-internal, that is, adjoined to the VP, as a consequence of scrambling. So, there exists genuine scrambling in Dutch, that is, permutation of the order of arguments. This is support for the theory of scrambling described in section 3.6 that Dutch is an OV language with hierarchical identification of case for DP objects. A nominative DP is not confined to a structurally unique configuration. This can be inferred from the fact that a nominative can appear in the position of the direct object (cf. 68a) or in a VP-initial position (cf. 68c). The preconditions for Scrambling are therefore met for a nominative DP that follows an object in the base order: there is more than one position available in the domain of the projection of the verbal head.

Similar considerations apply to PP objects. PPs are not identified by case. Rather the head of the PP, which is selected by V, identifies them^0. There is no structurally unique identification position for a PP. The PP may in principle appear in any position in the VP: it can precede or follow a DP object (see 67) or a subject, as in (69).

(69) a. dat (er) voor je vader niemand wat meegebracht heeft
that (there) for your father no one something presented has
'that no one brought father anything'
b. dat (er) aan dit jongetje niemand snoepjes gegeven heeft
that (there) to this boy no one cookies given has
'that no one gave this boy cookies'

2.5.2 No infinitival clauses in the midfield in Dutch

In Dutch, sentential infinitival complements cannot be projected in the position in which nominal complements would be projected (70a): They are either replaced by a clause union construction ('V-raising', 70d) or they are extraposed (70e).

(70) a. *dat Jan [het boek terug te geven] (niet) vergat
that Jan [the book back to give] (not) forgot
b. daß Jan [das Buch zurückzugeben] (nicht) vergaß
that Jan [the book back-to-give] (not) forgot
c. eine Kür, die$_i$ sicher [*pro* e$_i$ spektakulär zu nennen] nicht
a free-exercise, that surely [spectacular to call] not
übertrieben wäre[19]
exaggerated would-be
d. dat Jan het boek niet vergat terug te geven
e. dat Jan niet vergat [het boek terug te geven]
f. daß [sein Buch zurückzugeben] keiner vergaß
that [his book return] nobody forgot

German allows infinitival clauses as objects (70b) and subjects (70c), and the sentential argument may scramble (70f). The clause-union construction is available in German, too, but it is optional. For verbs that optionally allow a clustering construction in German, these sentences are systematically ambiguous between a construction with clausal embedding and a simple clause structure with V-clustering:

(71) a. daß uns [zwischen zwei Strukturen zu wählen] erlaubt wird
that us [between two structures to choose] permitted is
b. daß uns zwischen zwei Strukturen [zu wählen erlaubt wird]
that us between two structures [to choose permitted is]

This ambiguity is the source for the case alternation in the construction with a passive matrix verb or a matrix unaccusative verb that selects an infinitival complement:

(72) a. daß der$_{NOM}$/den$_{NOM}$ Brief einzuwerfen vergessen wurde
that the letter to post forgotten was
b. daß uns $^{(?)}$der$_{NOM}$/den$_{NOM}$ Text zu entziffern gelungen ist
that us$_{DAT}$ the Text to decipher succeeded is

If the clausal construction is forced by splitting the potential verbal cluster (73), the nominative option is cancelled, as expected, since the nominative is licensed only in the clustering (= clause union) construction.

(73) a. daß [*der$_{NOM}$/den$_{NOM}$ Brief einzuwerfen] *leider* vergessen wurde
that [the letter to post] unfortunately forgotten was
b. daß uns *l*[*der$_{NOM}$/den$_{NOM}$ Text zu entziffern] *endlich* gelungen ist
that us$_{DAT}$ [the Text to decipher] finally succeeded is

It is presently not evident what the (micro-)parametric source of this grammatical contrast between the German and the Dutch system of sentential complementation is.

3 Theoretical accounts of word-order variation in the MF: Scrambling

Theoretical accounts of scrambling are directly connected with particular assumptions on clause structure. The given clause structure determines whether scrambling is applicable and what the range of word-order variation is. As for clause structure, there is much more consensus on the empirically adequate structure for VO languages, notably English, Romance, and Scandinavian languages, than there is consensus on what the proper clause structure for an OV language like German or Dutch is. Section 3.1 highlights two controversial issues, namely, the positioning of the argument under agreement (i.e., the nominative subject) and the positioning of functional heads targeted by the finite verb – and their implications for the implementation of adequate scrambling mechanisms. Section 3.2 briefly surveys the theoretical approaches on scrambling that are discussed one after the other in section 3.3.

3.1 Clause structure controversies

- Where are – if there are any – the (covert) functional head positions in the mittelfeld?
- Where are – if there are any – the specs of the functional head positions in the mittelfeld?

In current Generative versions of German grammar, the mittelfeld is equated with the VP plus the cascade of functional projections above the VP. The functional head positions are assumed either to be clause final or clause medial and empty, except the top V2 position. Most if not all phrases in the mittelfeld, notably the arguments, are taken to be moved to distinct functional Spec positions.

The resulting structures are in conflict with a wide range of empirical issues of German syntax, however. Presently, its plausibility is borrowed more from the relative success of the structural analysis for VO languages than from the satisfactory coverage of German data. In the following section two problem areas will be highlighted. One is the position of the clause-final finite verb; the other, the evidence for or against Spec positions in the MF.

3.1.1 Is the overt position of the clause-final finite verb a functional head position?

There is good evidence for the claim that the surface position of the finite verb in the clause-final position in a German or Dutch clause is not a derived position, that is, not a functional-head position (e.g., associated with features like finiteness, agreement, or tense). Its positional properties are those of the position of the lexical head of the VP. Like an English finite main verb (cf. 74a), the finite verb in German stays in its head position as the head of the V projection. For verb-final clauses, there is no evidence of overt movement of the finite verb to the right or of movement to the left, and there is robust counter-evidence for the assumption that a clause-final finite verb in German or Dutch is moved to a functional-head position. An overt V-to-F-movement analysis for the positioning of the finite Verb – either to an F-head that follows (cf. 74b) or to a preceding F-head (74c) – is in conflict with evidence that bears directly on V-movement:

(74) a. [C^0 [. . . [F1-e [F2-e [V^0. . .]]]]] [VO, e.g., English]
b. *[C^0 [[[. . . V^0] F2-e] F1-e . . .]] [OV + final functional heads]
c. *[C^0 [. . . F1-e [F2-e [. . . V^0]]]] [OV + preceding functional heads]

As originally noted by Höhle (1991) and discussed in Haider (1993: 62f.), finite denominal verbs derived from complex nouns occur in verb-final clauses in German, but not in V2 or V1 clauses (see (75)). The corresponding case of Dutch (cf. Koopman 1995) is the case of complex verbs (see (76)) with a separable prefix preceded by an inseparable one (*her-* as in 76b, c).

(75) a. daß sie es uraufführten
that they it ur-performed (*ur* = as a premiere)
b. *Uraufführen$_i$ sie es e$_i$?
ur-perform they it?
Do they ur-perform it?
c. *Führen$_i$ sie es urauf-e$_i$?

(76) a. dat hij het *her*opbouwde
that he it re-up-built
b. *Hij bouwde het *her*op.
c. *Hij *her*opbouwde het.
d. Hij bouwde het op.

In descriptive terms, the problem seems to arise because two requirements get into conflict, namely, the requirement to strand a prefix (separable prefix, *an-* in German, *op-* in Dutch) with the requirement to pied-pipe a prefix (inseparable prefix, like *her-* in Dutch and *ur-* in German).

The most straightforward case is that of verbs with two prefixes, each one of the class of separable prefixes (see also Vikner 2002). Each of these prefixes

requires stranding, so there is no way to meet these requirements if there is more than one prefix. Since prefixing is a productive word-formation rule in German, it is safe to presusuppose that these verbs illustrate a phenomenon of German core grammar.

(77) a. wenn sie den Kurs *mit-an*-kündigen
if they the course with-an-nounce (= announce together)
b. *Man *kündigt*$_i$ den Kurs *mit-an*-e$_i$.
c. *Man *an-kündigt*$_i$ den Kurs *mit*-e$_i$.
d. *Man *mit-an*-kündigt$_i$ den Kurs e$_i$.

Both prefixes, *an-* in (78a) and *mit-* in (78b), require stranding. In the combination (77a), there is no possibility to simultaneously meet this requirement. If *an-* is stranded (77b), *mit-* remains attached to the following prefix and hence is not stranded. Stranding the prefix *mit-* (77c), however, is possible only if the following prefix is pied-piped with the verb. But this violates the stranding requirement of the second particle. Needless to say, pied-piping both particles is ungrammatical as well (77d).

(78) a. Sie kündigen$_i$ den Kurs an-e$_i$.
b. Sie diskutieren$_i$ heute mit-e$_i$.

What these data show is that the conflict arises once the verb is overtly moved. As long as it stays, the issue of stranding does not arise. So the fact that finite forms are possible even for these verbs shows that they do not require overt movement.

If they had to be moved in order to become finite, further movement to the V2 position could not be blocked, except by ad-hoc mechanisms. 'I-to-C' is an automatic process that cannot be blocked by idiosyncrasies of the morphological make-up of verbs. English proves this point: if a verb does not move to I' it does not move to C, and if it moves to I, it moves to C in the contexts of I-to-C movement. It is safe to conclude, therefore, that clause-final finite verbs are not overtly moved to intermediate functional head positions. If overt V-to-I were required, doubly prefixed verbs would be predicted to occur only in nonfinite forms (because of the impossibility of licit V-to-I). The fact that they are grammatical as finite forms, but only in clause-final position, is a clear case against overt V-to-I in German and Dutch. Thus, if there is no overt movement, there is no need to assume a post-VP functional-head position. If there are covert positions they can just as well be assumed to be in pre-VP positions.

3.1.2 Are there positions in the German MF that are functional Spec positions?

In this section, three issues will be addressed that are problematic for a [Spec, F] analysis of the subject position or other argument positions. First, if there were a functional Spec position for subjects, this Spec position would license

clause-internal expletives. But clause-internal expletives are ungrammatical in German, and this cannot be attributed to pro-drop. This point was already addressed in section 2.2.4.2. Second, subjects in Spec positions are predicted to be opaque for extraction. This prediction is incorrect (cf. 3.1.2.1). Third, covert movement can be ruled out, since the LF resulting from LF-raising out of fronted VPs is ill-formed (cf. 3.1.2.2).

3.1.2.1 Expletive subjects as evidence for a functional Spec position

The ungrammaticality of non-argumental expletive subjects in the mittelfeld in German is direct evidence against the need of a functional Spec position for the subject if pro-drop can be excluded. The relevant data are discussed and analyzed in section 2.2.4.2. German does not allow non-argumental expletive subjects and their absence cannot be attributed to pro-drop. We therefore conclude that if there were obligatory functional Spec positions in the MF, at least one of them would require lexical support. In all languages with a functional subject position, this position must be lexicalized unless the language is pro-drop. This is a consequence of the EPP (Extended Projection Principle). The fact that German requires overt argumental expletive subjects but forbids purely structural expletives points directly to the conclusion that structural expletives do not occur because there is no structural position to host them. If this is correct, the overt positions of the subject and the objects are VP-internal in German.

3.1.2.2 Covert movement to a Spec position?

Finally, the fact that VP topicalization with a VP-internal unergative subject is grammatical in German (cf. 79) is clear and sufficient evidence at least for the following conclusion: no (obligatory) overt movement of a nominative to a functional Spec position – that is, movement to AgrS – in German.

(79) a. [Ein Wunder^j ereignet]$_i$ *hat*^{j} sich^j hier noch nie e_i.
a miracle occured has REFL here yet never
'A miracle has never ever occured here.'
b. [Wunder^j ereignet]$_i$ *haben*^{j} sich^j hier noch nie e_i.
miracles occurred have REFL here yet never
c. [Aussenseiter^j gewonnen]$_i$ *haben*^{j} es noch nie e_i.
outsiders won have it never ever

VP-topicalization in (79) cannot be reanalyzed as the topicalization of a functional projection in order to save the claim that nominatives are overtly moved to a functional Spec position: if the topicalized projection in (79) contains the functional head in whose Spec position the nominative occurs, this functional head is a head position. The topicalized constituent would then have to contain the trace of the finite verb as well. Clear instances of this structure are ungrammatical, however. In German, the topicalized constituent cannot contain the trace of the finite verb. It must be analyzed as VP and not as a more complex functional projection containing the VP (cf. the discussion of example (77)):

(80) a. [Ein Schiff$_{NOM}$ untergegangen]$_j$ ist$_i$ hier noch nie e$_j$ e$_i$.
[a boat down-went] has here yet never
'A boat did not yet sink here'
b. *[Ein Schiff$_{NOM}$ unter-$_i$]$_j$ ging$_i$ hier noch nie e$_j$.
[a boat down-e$_i$] went$_i$ here yet never
c. Ein Schiff ging$_i$ hier noch nie unter-e$_i$.
a boat went$_i$ here yet never down-e$_i$

Example (80a) is compatible with the standard analysis, that is, VP topicalization, as well as with the alternative analysis as a topicalized functional projection. If it were a functional projection, however, (80b) would be structurally parallel to (80a) – both would contain the trace of the finite verb – and therefore both should be grammatical or ungrammatical. That the topicalized constituent in (80b) contains the trace of the finite verb is signaled by the stranded verbal prefix *unter*, because *untergehen* is a verb with a separable prefix (cf. 80c). The prefix is stranded in the base position of the verb. The standard analysis correctly predicts (80b) to be ungrammatical because the trace of the topicalized VP is not lexically head-governed. In (80a), the topicalized VP is a complement of the copular verb.[21]

Having established that there is no overt movement of the subject to Agr-S, we have to check the possibility of covert movement. Again, VP topicalization with a subject is a suitable testing ground: The topicalized VP as a *wh*-moved phrase in a Spec position is opaque for extraction, and, consequently, covert movement, that is, extracting the subject out of the topicalized VP, is ruled out. Reconstruction of the VP plus subsequent extraction would violate the cycle. So, there is no covert movement either. A re-check with quantifiers confirms the opacity of a fronted VP for covert extraction with or without reconstruction:

(81) a. **Wide scope of the universal Q:**
Jeden Passagier hat er zweimal befragt.
every passenger has he twice questioned
b. **Narrow scope of the universal Q:**
[Jeden Passagier befragt] hat er zweimal.
every passenger questioned has he twice
c. **Wide scope of the universal Q:**
[Zweimal befragt] hat er jeden Passagier.
twice questioned has he every passenger

In (81b) the domain of the universal Q is the fronted VP; it does not c-command into the MF. The quantifier in the mittelfeld c-commands the trace of the fronted VP, so the VP belongs to the scope domain of the mittelfeld quantifier. If a quantifier could be Q-raised out of the fronted VP, it ought to get scope over the Q in the mittelfeld. Moreover, (81b, c) show that the fronted VP cannot be treated as a remnant VP, that is, it cannot contain the trace of either the frequency adverbial (81b) or the quantified object. Since one would c-command the trace of

the other within the fronted VP, either (81b) or (81c) would get a second scope reading, but this is not the case.

3.2 A grammar-theoretic perspective on free word order in the MF

The key issues to be addressed in this section are:

- Is scrambling base-generated free word order?
- Is scrambling the result of movement?
- Is scrambling triggered movement?
- Movement by adjunction or movement to functional Spec positions (or both)?
- A- or A'-chains? Are parasitic gaps evidence for scrambling as A'-chaining?

The theoretical positions available in syntactic theory have all found their (at least part-time) advocates. Nevertheless, the ultimate and uncontroversial insight is still missing. It is therefore worthwhile to focus on the problematic areas of each of the competing candidates for an empirically and theoretically satisfactory theory of scrambling. Here is the set of theoretically available options to chose from. The position of a phrase in a clause-bound scrambling position is:

- a base-generated argument position;
- a base-generated adjunct position;
- the head of an A'-chain targeting a Spec position;
- the head of an A'-chain targeting an adjoined position;
- the head of an A-chain targeting a Spec position;
- the head of an A-chain targeting an adjoined position.

The baseline hypothesis to start with is that scrambling does not involve any derivational machinery at all. The word-order variation called scrambling is but a set of individually available serialization patterns, each of which is a possible base-generated order of A-positions. This possibility for German – suggested first in Haider (1984) as an option provided by the German case system – has been revived vigorously in more detail and greater theoretical depth and on theoretically up-to-date foundations by Fanselow (1998) for German. Scrambling as base-generated A'-positions with subsequent lowering to theta positions on LF has been suggested by Bošković and Takahashi (1998). These approaches will be referred to as the base-generation approaches. In this perspective, a scrambling language is characterized as a language with a clause structure that allows a choice of positions for arguments. Potential sources of counter-evidence are phenomena indicative of antecedent–gap relations and typological overgeneration.

The next and more widely assumed general option is the derivational approach, in which scrambling is the result of re-arranging a given base order.

This general option is narrowly channeled by syntactic theory. The two main channels are A-chaining or A'-chaining with the additional bifurcation as to whether movement targets a Spec position or a position adjoined to a (lexical) projection. The evaluation of these proposals calls for a clarification of the basics of German clause structure as the underlying source of some controversies. A crucial theoretic issue is the issue of optionality vs. triggered movement. Traditionally, scrambling is considered to be optional modulo various side effects. Of course, these side effects could be reflexes of a hidden triggering mechanism. Explorative attempts to uncover these mechanisms produced various triggering scenarios, syntactic ones (e.g., movement to case-checking positions) as well as semantic (e.g., movement triggered by definiteness features) or pragmatic ones (e.g., movement triggered by information structuring features like topicality). Undoubtedly, scrambling influences the information structure conveyed by a clause, but it is far from obvious that this is the result of a grammatical causality of movement.

Once movement is granted, several questions arise. What type of movement is scrambling an instance of? The two basic options – A'-movement or A-movement – have been exploited and even been combined because of an apparent simultaneous aggregate of A- and A'-properties (Webelhuth 1992). The grammatical phenomenology of the parasitic-gap construction has played an important role in this respect. Another question relates to the nature of movement. Is it movement to a Spec position or is it adjunction? Adjunction is a less well-studied area and tends to be shunned in current grammar research in favor of movement-by-substitution into Spec positions. Here is a selection of suggestions from the scrambling literature:

Structure:

- Base generated A-positions: Haider (1984); Kiss (1994); Fanselow (1998).
- Base generated A'-positions: Bošković and Takahashi (1998).
- Scrambling as A-movement: De Hoop and Kosmeijer (1995).
- Scrambling as A'-movement: Müller and Sternefeld (1994).
- Scrambling as the result of both A and A' movement: Webelhuth (1989); Mahajan (1994b).

Triggers:

- Untriggered scrambling (syntactically optional): Haider and Rosengren (1998); Saito and Fukui (1998).
- Scrambling triggered by (strong/weak) case features: De Hoop (1992).
- Scrambling triggered by a topic-feature: Müller (1995: 107, 1998).
- Scrambling triggered by a scrambling-feature: Grewendorf and Sabel (1999).
- Scrambling triggered by theta-features on LF: Bošković and Takahashi (1998).

3.3 The grammar-theoretic modeling of scrambling: a critical survey

3.3.1 Scrambling: base-generated word order?

Pro:

- Occam's razor: if base-generated, no additional derivational devices required.
- Shifts the optionality issue to structure generation rather than to the application of movement.

Con:

- Positive evidence for antecedent-gap properties.
- Missing generalization on the OV vs. VO asymmetry (esp. Icelandic).

The idea that the 'scrambled' order is a base-generated order can be implemented in various ways. The common property is that there are no antecedent – gap relations, that is, movement chains, involved. The first possibility is the single level implementation. The alternative orders are taken to be alternative realization of V projections. In this perspective, scrambling languages are languages with free base orders. The second possibility is a dual level implementation: the alternative surface orders are related to a single structure on a hidden level, namely, LF. Again, this allows various alternative implementations. One possibility is the combination of a free base order with LF movement to checking positions. This characterizes a scrambling language as a language that differs from non-scrambling language in the checking system. The relevant feature is checked covertly rather than overtly. For a particular implementation of this strategy, see Fanselow (1998). Another possibility for base-generating scrambled order is suggested by Bošković and Takahashi (1998). The scrambled positions are base-generated adjunction positions generated in a generalized merger operation that need to be related to base position. This is managed at LF. The difference between this hypothesis and a movement hypothesis is that at surface structure there are no movement chains, and on LF, operations are foreseen that are forbidden for overt movement processes (e.g., lowering).

The direct criterion of success for these hypotheses is obvious. If they are right, scrambling does not involve antecedent gap relations on surface structure. On the other hand, evidence of movement traces is counterevidence for these proposals. A more indirect criterion is the typological question: Why is (clause-bound) scrambling strongly correlated with head-final projections? How is this captured in a theory of base-generable alternative orders.

Note that in a VO language like Icelandic, VP-internal reordering is in general ungrammatical, despite of the fact that there are alternative, verb specific ordering patterns. Only for the *give*-type double object constructions, both, DAT–ACC and ACC–DAT order is available (see Holmberg and Platzack 1995, ch. 7; Haider

2000d). If this order variation is interpreted as scrambling (rather than alternative base orders), it strengthens the point that scrambling is confined to the domain of the verb. Scrambling to the left, accross the verb, is not possible.

The base-generation approach opens various possibilities for a specific interplay between PF and LF. For instance, a subset of the scoping data could be captured in the following way: scope could either be read off the PF order or from the LF configuration, given that there is a fixed order of feature-checking positions at LF (cf. Fanselow 1998, sect. 3.5) or a fixed order of base positions in Bošković and Takahashi's (1998) approach. Lets assume the LF-order is DAT–ACC:

(82) a. **PF:**
daß er [mindestens eine $\text{Frage}_{\text{ACC}}$] [fast jedem $\text{Kandidaten}_{\text{DAT}}$] stellte
that he at least one question almost every candidate put
'that he asked almost every candidate at least one question'

b. **LF:**
[jedem $\text{Kandidaten}_{\text{DAT}}$ [mindestens eine $\text{Frage}_{\text{ACC}}$ [stellte . . .]]]
every candidate at least one question put

The fact that the sentence in (82) is ambiguous with respect to the scope of the quantified DPs can be captured in the following way. Scope is read off either at Spell Out, that is, from the surface order, or after Spell Out, that is, from LF. If scope is read off the surface order (82a), the accusative DP has wide scope. But at LF (82b), the dative feature has wide scope by virtue of LF-movement into the checking position for dative, which is higher than the position for accusative.

This approach has shortcomings, however. If it is assumed that in general dative is checked at LF in a higher position than the accusative, then the inverse scoping effects for the base order class ACC–DAT (18f) would not follow (cf. 83). Analogous considerations apply to the class ACC–NOM (18b), DAT–NOM (18d). Whatever order is taken to be the LF order will run into problems with the converse base-order class of verbs:

(83) a. **Unambiguous scope:**
daß man ja fast alle Kandidaten mehr als einem Test
that one PRT almost every candidate more than one test
unterzog
undergo
'that almost all candidates had to undergo more than one test'

b. **Ambiguous scope:**
daß man ja [mehr als einem Test]$_i$ fast alle Kandidaten e_i
that one PRT more than one test almost every candidate
unterzog
undergo
'that almost all candidates had to undergo more than one test'

Scoping either at surface structure or at LF, with the dative higher than the accusative at LF, predicts (83a) to be scope-ambiguous: at the surface, the accusative c-commands the dative and at LF the converse applies. Example (83b), on the other hand, is predicted to have the unique scope property that corresponds to the surface order because surface order and LF order coincide. In fact, the scope data do not match these predictions. They follow from an ACC–DAT base order (83a) plus Scrambling (83b): Scrambling introduces the ambiguity because of chain formation (see the discussion of property (vi), section 2.2.1).

From a more general theoretic perspective, first, the free choice between surface structure and LF as the relevant level of representation for the semantic interface would be unique for scoping and therefore ad hoc, since the fact that all binding relations are determined by the surface order in German forbids the going to and fro between surface structure and LF. Note that in our approach the surface structure is the relevant representation at the syntax–semantic interface. Second, and most importantly, the interplay between PF and syntax (cf. the data discussed in section 2) that becomes manifest in a structurally determined position of sentence accent, focus potential, and chain-connectivity for topic–focus accent (rise–fall intonation), would have to be discarded in order to await redesigning in yet unexplored ways. Third, and most important on the theoretical level, the base-generation approach does not provide insights as to why Icelandic – a language with as rich a case system as German – does not allow free argument order, although it allows various verb-specific order patterns that parallel the German verb-specific base-order patterns. In Icelandic the same verb-class-dependent word orders as in German are attested (cf. Haider 2000d). But still there is neither free word order within VP nor, in the case of Object shift, outside of VP (cf. Collins and Thráinsson 1996: 418; but see Holmberg and Platzack 1995, ch. 7). The fact that, for instance, a dative may precede or follow an accusative, depending on verb class, is incompatible with the assumption that checking is taking place in specific Spec positions of functional heads before Spell Out. So checking features have to be diagnosed as weak for Icelandic. But if checking is postponed to LF, the free word order in the VP, if there were any free word order, should be visible just as in German. But this is not the case and therefore these data are in conflict with the assumption of a correlation of strict word order and feature strength.

If scrambling were just free base-ordering in a language with morphologically identifiable grammatical functions, the clear-cut OV–VO contrast is unaccounted for. If, however, Scrambling word order is the result of chain-formation, the OV–VO contrast is expected: in VO languages, Scrambling chains would sandwich the verbal head, that is, the target position of Scrambling would precede the head, but the base position would be in the domain of the head. In VO languages, however, left-adjunction to VP projects structures in which the target as well as the gap are in the domain of the verbal head. This is an essential fact for the understanding of the grammatical nature of scrambling; in languages with mixed head directionality, scrambling is confined to constituents with final heads. An example is German, with Scrambling in VP and AP, but not in NP and PP.

Finally, 'free' word order is not 'arbitrary' word order (in the absence of factors that are instrumental for grammatical reordering preferences) in German. What is the only word order in English is exactly what is the only neutral word order – which we equate with base order – of the corresponding V-class in German, which of course can be checked only with verbs with the same meaning and, *ceteris paribus*, the same construction type:

(84) a. **Maximal focus:**
Peter zeigte seiner Schwester das neue RAThaus.
Peter showed his sister the new town hall
'Peter showed his sister the new town hall.'
b. **Minimal focus:**
Peter zeigte [das neue Rathaus]$_i$ seiner SCHWEster e_i.
Peter showed the new town hall his sister
'*Peter showed the new town hall his sister.'

Of course, English may use a PP instead of a bare DP with the inverted order between the objects. This is the only option for the verbs in (85), however.

Dative functions like Goal (85a) or Beneficiary (85b) are not coded with bare DPs in languages without morphological relation marking. So English does not allow double-object constructions corresponding to ACC–DAT base orders in German. Instead, the argument coded with dative in German appears as a PP in English (*aussetzen*, 'expose to'; *unterordnen*, 'subject to'; *unterwerfen*, 'submit to', etc.):

(85) a. Er hat uns einer ernsten Gefahr ausgesetzt.
he has us a severe danger exposed
'He exposed us to a severe danger.'
b. Er hat der Frau die Tür geöffnet.
he has opened the woman the door
'He opened the door to the woman.'

This fact, however, is additional support for our assumption that the argument order in the lexical entry (as the result of mapping the lexical–conceptual structure on the lexical argument structure) is not arbitrarily but semantically determined and that it determines the syntactic configuration by ranking-geared discharge of the A-structure into syntactic structure.

3.3.2 Does scrambling target functional Spec positions?

Pro:

- It gives simple characterization of the movement targets: Spec positions of empty functional heads.
- It is a widespread assumption in the literature because of its immediate compatibility with widely accepted assumptions on the organization of clause structure.

Con:

- Scrambled XPs lack the syntactic properties of phrases in functional Spec positions.
- Scrambling, unlike object shift in Scandinavian languages, does not reflect a unique order of functional projections.

There are at least three independent issues that are hard to reconcile with the assumption that the scrambled constituent is in a Spec position. First, scrambled XPs are transparent for extraction (contra Diesing 1992b; see also Müller 1998). Second, Scrambling may occur within a constituent fronted to [Spec, C]. If this constituent is a higher functional projection, crossing violations are predicted for head-movement chains that involve the finite verb. Third, neither a multiple F-spec analysis nor a multiple F-projection analysis can capture the freedom of scrambling orders in German. An analysis in terms of functional projections would be justified if there were a strictly fixed sequence of scrambled XPs as in the case of Icelandic Object shift.

Let us start with the argument from extraction patterns, that is, transparency for extraction. In a language with easily identifiable Spec positions, for example English, XPs in Spec are opaque for extractions:

(86) [Spec, IP]: *Who$_i$ has [a picture of e$_i$] been sold?

XPs, topicalized to positions between [Spec, IP] and C^0, are opaque as well (cf. 87b). This indicates that this position is either a Spec position or it is a position adjoined to IP. In both cases, extraction is illicit, as the evidence suggests:

(87) a. (that) [a picture of this painter] virtually everyone has admired
b. *Who$_i$ has [a picture of e$_i$] virtually everyone admired?
c. (that) [with him] I should talk at once
d. *Who$_i$ should [with e$_i$] I talk at once?

The ungrammaticality of (87d) cannot be attributed to an adjacency requirement for V and the preposition.[22] Cross-linguistic evidence can be found, for instance, in Danish (see Vikner 1995: 248) where prepositions can be stranded at some distance from the verb.

In German, Scrambling does not create opaque domains for extraction. This is easy to demonstrate for scrambled infinitival clauses. Neither Scrambling nor 'extraposition' has any effect on extractability:

(88) a. daß schon mal jemand [ihn damit zu überzeugen] versucht hat
that already PRT someone him with-that to convince tried has
'that someone already tried to convince him with this'

b. Wen$_i$ hat (denn) [e$_i$ damit zu überzeugen]$_j$ schon mal jemand e$_j$
who has PRT [with-that to convince] already PRT someone
versucht?
tried
'Who did someone try to convince with this?'

c. Wen$_i$ hat (denn) schon mal jemand versucht [e$_i$
who has PRT already PRT someone tried
damit zu überzeugen]?
with-that to convince

Diesing's (1992b: 32f.) claim that scrambling creates opaque domains is based on inadequately chosen data. She adduces '*was-für* split' constructions as the main body of evidence. The contrast in (89) is interpreted as the result of an opacity effect incurred by Scrambling.

(89) a. Was$_i$ hat denn jeder von euch [e$_i$ für Witze] erzählt?
what has PRT everyone of you for jokes told
'What kind of jokes did everyone tell?'

b. ??Was$_i$ hat [e$_i$ für Witze] denn jeder von euch erzählt?
what has for jokes PRT everyone of you told

The degraded acceptability of (89b) cannot be the result of scrambling, however. Sentence (90a), with a scrambled object DP, is perfectly acceptable. The degradation is of a different nature: it is not extraction out of, but scrambling of, a *wh*-marked DP across a particle like *denn* that induces ungrammaticality (cf. 90b). Example (89b), just like (90b), is ungrammatical, not because of extraction, but because of illicit scrambling of a *wh*-DP to the left of the particle, as the contrast between (90b) and (90c) illustrates. Sentence (89b) is the counterpart of (90b), just like (90a) is the counterpart of (90c).

(90) a. Was$_i$ hat denn damals [e$_i$ für Witze]$_j$ jeder von euch e$_j$ erzählt?
what has PRT at that time for jokes everyone of you told
'What kind of jokes did each of you tell at that time?'

b. *Wem hat [was für Witze]$_i$ denn damals jeder von euch e$_i$
whom has what for jokes PRT at that time everyone of you
erzählt?
told

c. Wem hat denn damals [was für einen Witz]$_i$ jeder von
whom has PRT at that time what for a joke everyone of
euch e$_i$ erzählt?
you told
'To whom did each of you tell what kind of jokes at that time.'

What is essential, though, is not so much the particle as such but the adjacency to the C^0 position: dropping the intervening adverbial in (91a) reduces

the acceptability considerably. The marginality of (91b) is of the same nature, but this is completely unexpected in Diesing's account because the subject of (91b) is the subject of an unaccusative verb and it may stay in its base position.

Whatever theoretical reason might be behind this restriction, it is independent of structural considerations with respect to the position of the particle *denn*. In (91a), the split is possible despite the presence of *denn* if the phrase with the extraction site is preceded by another element.

(91) a. Was$_i$ hat ??(*damals*) [e$_i$ für Ergebnisse] (*denn*) jeder von euch
what has at that time for results PRT everyone of you
erzielt?
achieved
'What kind of results did at that time everyone of you achieve?'

b. ??Was$_i$ fielen$_j$ [e$_i$ für Gläser] um-e$_j$?
what fell [for glasses] down
'What kind of glasses fell down?'

The fact that extraction out of a scrambled constituent in front of the particle is perfectly grammatical (see 91a) proves that what rules out (89b) and (90b) cannot be a positional effect on extraction proper.

Next, let us inspect the second area of counter-evidence and examine the hypothesis that scrambled XPs are hosted by F-specs above VP. If this is the case, a topicalized constituent with scrambled arguments must be analyzed as a topicalized functional projection, whose Spec is hosting the scrambled XP. It is important, however, to note that these F-projections must be lower than the starting point of the head chain that leads to the V2 position of the finite verb. That this is so, is easy to demonstrate with the contrast between (92a) and (92b).

(92) a. [Ein Fehler$_i$ einem Linguisten e$_i$ *auf*gefallen] ist dabei noch nie.
an error a linguist *up-struck* is at-that yet never[23]
'In this connection, no linguist ever noticed an error.'

b. *[Ein Fehler$_j$ einem Linguisten e$_j$ *auf*-e$_i$] fiel$_i$ dabei noch nie.
[an error a linguist up-e$_i$] struck$_i$ at-that yet never

c. [Einem Linguisten *ein Fehler* aufgefallen] ist dabei noch nie.
a linguist an error conspicuous-made is at-that yet never

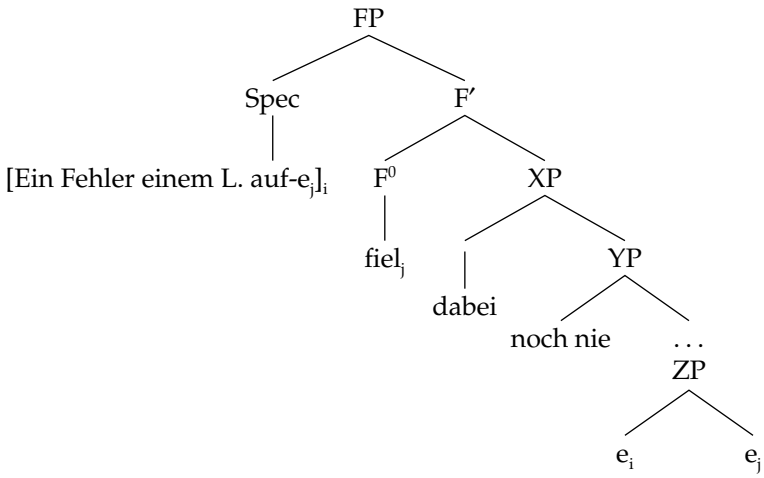
d. Es fiel$_j$ dabei einem Linguisten ein Fehler auf-e$_j$.
it fell at-that a linguist an error on-e$_i$
'In this connection, a linguist noticed an error.'

The examples in (92) feature an unaccusative subject. Its base position is the position following the indirect object (92c). In (92a, b), the subject is scrambled across the indirect object. If the target position of Scrambling in (92a, b) is the Spec of a functional projection that dominates the base position of the finite verb, the corresponding functional head is a head on the movement path of the finite verb from its base position to the V2 position. For the example chosen in (92b)

this conclusion is unavoidable since the clause contains only the main verb. When it leaves its basic V-projection in order to start its travel up to the topmost F-projection, it will unavoidably travel through all the intermediate functional heads up to the top projection.

With this in mind, let us proceed to the argument that (92b) demonstrates that the topicalized constituent cannot contain the trace of the finite verb. The particle in (92b, d) is an indicator for the position of the trace of the finite verb, since the verb is one with a so-called separable particle (cf. 92d) that is stranded by V2. Topicalizing the constituent that contains the trace of the verb incurs a crossing violation: the trace of the verb in (92b) fails to be in the c-command domain of the moved verb.

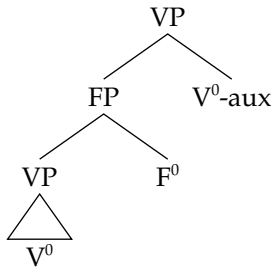
(93)



Thus, if the topicalized constituent in (92a) contained the trace of the finite verb, it would be predicted to be ungrammatical, contrary to the facts. The conclusion must be, therefore, that the functional projection that hosts the scrambled item cannot contain the auxiliary. It must be a complement of the auxiliary. Only in this case does the finite auxiliary not pass through the functional heads of the Scrambling domain:

(94) a. $[_{\text{Aux-VP}} \ldots [_{\text{FP}} \text{XP}_i \text{ F}^0 [_{\text{VP}} \ldots \text{e}_i \ldots \text{V}^0] \text{ V}_{\text{Aux}}]$

b.



Unavoidable though this conclusion is, it is unwanted, and so is the premise, therefore, which it is derived from. It is unwanted for at least the following two reasons (i) there are no plausible candidates for FP; (ii) this structure leads to overgeneration. As for the first reason, the Scrambling domain indicated in (93) is confined to the complement domain of the auxiliary, that is the FP in (94a, b). This domain cannot contain the subject-agreement projection because of (92b). So the Scrambling of the nominative in (92a) cannot have targeted the default A-position for the subject (AgrS) because this projection is higher and includes the base position of the auxiliary. This implies that Scrambling must stop short exactly in case the projection is topicalized. In all the other cases Scrambling may target higher positions. This is unavoidable again because adverbials that relate to the finite verb must be higher in the structure, but scrambled items may precede these adverbials.

On the one hand, scrambled constituents may precede these adverbials in the middle field (95d, f) but, on the other, Scrambling may take place within the topicalized constituent that must not contain these adverbials (95b, e).

(95) a. *[Sein Argument *leider/vermutlich* allen mehrmals
his argument unfortunately/probably everyone many-times
erklären] mußte er.
explain had-to he

b. [Sein Argument$_j$ allen e$_j$ erklären]$_i$ mußte er *leider/vermutlich*
his argument everyone explain had-to he unfortunately/probably
mehrmals e$_i$.
many-times
'Unfortunately/probably, he had to explain his argument more than once to everyone.'

c. daß er sein Argument allen *leider/vermutlich* mehrmals
that he his argument everyone unfortunately/probably many-times
erklären mußte
explain had-to
'that unfortunately/probably he to explain his argument to everyone had more than once'

d. *[Sein Argument$_j$ *gestern* allen e$_j$ erläutert] hat er doch.
his argument yesterday everyone explained has he PRT

e. [Sein Argument$_j$ allen e$_j$ erläutert]$_i$ hat er doch *gestern* e$_i$.
his argument everyone explained has he PRT yesterday
'He explained his argument to everyone yesterday.'

f. daß er sein Argument doch *gestern* allen erläutert hat
that he his argument PRT yesterday everyone explained has
'that he explained his argument to everyone yesterday'

What this entails is at least that a Spec position targeted by Scrambling cannot be a single uniquely identified position. Scrambling in this scenario must be able to optionally target either a Spec position that is lower than certain adverbials or

one that is higher. It is unclear, moreover, what kind of functional heads could provide these lower Spec positions. It cannot be an agreement position because of (92b): AgrS would have to be higher in the structure. It cannot be an aspectual position either, because these F-heads must be accessible for the respective auxiliaries and therefore higher. In fact, there is no obvious candidate. Postulating an F-head in this case is motivated only by the premise that Scrambling targets an F-spec. What this amounts to is equivalent to what is defended in section 4, namely, that the extended VP is the Scrambling domain.

As to the second reason, overgeneration is a serious problem for (93). If an auxiliary selects an FP rather than a VP, this opens room for elements intervening between the VP that contains the main verb and the following auxiliary. But in German this room is not available though extraposed prepositional objects are VP-final (96a), they may not intervene between the VP and the following verb (96b).

(96) a. [Gewartet *auf uns*]$_i$ hat sie nicht e$_i$.
waited for us has she not
b. *daß sie nicht [gewartet *auf uns*] hat
that she not waited for us has
c. daß sie nicht gewartet hat *auf uns*
that she not waited has for us

The third issue mentioned at the beginning of this section is the complete permutation potential of scrambling in German. This calls for an adequate structural solution. Cascading functional projections are ordered and so would be the outcome of scrambling. Scrambling would map one particular order onto another particular order. From this perspective, scrambling would not be equivalent to the permutation of arguments. It should rather behave like Scandinavian Object Shift, which is not the case, however. Cumulating scrambled items in a multiple Spec projection would not be adequate either because scrambled items may be separated by intervening adverbials. They do not come in packages.

3.3.3 Is scrambling triggered by a functional feature?

Pro:

- A syntactic trigger feature provides a grammar-internal causality for movement. This is favored by economy-based accounts.

Con:

- The various triggering properties suggested in the literature do not single out scrambled items. The alleged triggering properties are also found with phrases in situ.

This section is to complete the evidence against scrambling as movement targeting a functional projection. In section 3.2.1, evidence has been accumulated that

militates against movement to a functional Spec position. This section argues against a trigger-account in terms of feature checking.

If the proposed feature has content (in contrast to a merely technical implementation like Sauerland 1999a), the issue of optionality can be put to test easily. Let us take De Hoop's distinction between weak and strong interpretations of indefinite DPs. If scrambling were triggered by a specific interface feature, (97a) and (97b) would differ precisely to the extent defined by the presence or absence of that feature.

(97) a. daß ja Max Primaballerinas bewundert
that PRT Max primaballerinas admires
'that Max admires primaballerinas'
b. daß ja Primaballerinas Max bewundert
that PRT primaballerinas Max admires

But (97a) can receive the same interpretation as (97b), namely a generic one: if someone is a primaballerina, Max admires this person. Therefore, the claim that a strong feature 'generic' is the trigger of scrambling cannot be satisfactory, because of the licit generic interpretation of (96a). If it were indeed a strong feature, it would obligatorily trigger movement. If, on the other hand, the generic interpretation is available in situ, there is no justification for a contentful triggering feature.

The fact that there is a difference between (97a) and (97b) – the existential interpretation is lost in the scrambled order (97b) – is irrelevant in this context of argumentation. What is essential is not the loss but the exclusive gain. The loss of an interpretation in the course of movement does not differentiate between optional or triggered movement. It is simply a domain effect: if scrambling makes a DP leave the MAC, it leaves the domain of existential closure.

There is also a technical solution, of course, if one wants to enforce obligatoriness in face of optionality, namely, to stipulate some changes in the minimalist program which would bring about the 'overt' optionality in terms of invisible obligatoriness. Measures in this direction have been suggested by Haeberli (1993). He proposes that "the positions for case checking do not have to be fixed. Case checking projections are unspecified [. . .] projections in German [. . .] Thus, any NP can check its Case in any specifier position of these CasePs." The result is that argument Scrambling in German is tied to obligatory A-movement above VP into any of the CasePs. Even if one would accept this as an ad hoc measure for protecting the MP-axioms that do not admit optional movement – although it is not in any way supported by independent theoretical or empirical considerations – it is too weak: as emphasized earlier, scrambling does not single out DPs. A case-driven account is therefore bound to fail. Scrambled PPs and CPs remain unaccounted for.

Finally, if there were a triggering feature for Scrambling, this feature should be found at work in some other Germanic languages as well, for instance, in Icelandic, with its rich morphological system of case-marking and a movement

phenomenon called Object shift. This is not the case however (cf. Collins and Thráinsson 1996: 410). Although a pre-VP position is accessible for Object shift, this movement conserves the base order, both for subject-object (98a, b) as well as for double object constructions (98d, e). In German, both orders are available (98c, f).

(98) a. Í gær las Jón bækurnar ekki.
yesterday read John books-the not
'John did not read the books yesterday.'
b. *Í gær las bækurnar$_i$ Jón e$_i$ ekki.
yesterday read books-the John not not
c. Gestern las die Bücher Hans nicht. (= 98b)
yesterday read the books Hans not
'Hans did not read the books yesterday.'
d. Forstjórinn svipti mannin vinunni.
the boss deprived man-the (ACC) work-the (DAT)
'The boss deprived the man of the work.'
e. *Forstjórinn svipti vinunni$_i$ mannin e$_i$.
the boss deprived work-the (DAT) man-the (ACC)
f. Der Chef hat die Arbeit$_i$ dem Mann e$_i$ entzogen. (= 98e)
the boss has the work the man deprived
'The boss deprived the man of the work.'

If there were a trigger feature for Scrambling in German, the difference between the availability of scrambling in German and the lack of scrambling in Icelandic would have to be reduced to an accidental property; it so happens that the relevant feature is strong in German but weak in Icelandic. The difference is not accidental, however. It is a difference that relates directly to the OV vs. VO difference. So, arbitrary assignment of strong/weak values is thus but a technical option, but the relevant generalization is not to be captured.

3.3.4 Parasitic gaps as evidence for scrambling as A'-chaining?

This section provides reasons to dismiss so-called parasitic-gap evidence. The phenomena suspected to be parasitic-gap constructions in German are ellipsis constructions with properties known from coordination. Hence it need not come as a surprise that their grammatical behavior is different. The background: if scrambling licensed parasitic gap constructions, it would have to be an instance of A'-movement.

The binding data discussed in section 2.2.1. (Property (v)) suggest that Scrambling chains are A-chains rather than A'-chains (cf. Grewendorf 1989; Webelhuth 1992). But there seems to be a contradicting piece of evidence, namely, parasitic gaps apparently licensed by Scrambling. The phenomenon of parasitic gaps has been considered the cardinal evidence for A'-dependencies. However, as has been pointed out by Webelhuth (1989: 410f.), its impact is more confusing than revealing in German:

(99) a. ?Er hat jeden$_i$ Gast [ohne *pg*$_i$ anzuschauen] seinem$_i$ Nachbarn e$_i$
he has every guest [without to-look-at] (to) his neighbor
vorgestellt.
introduced
b. ?Er hat die Gäste$_i$ [ohne *pg*$_i$ anzuschauen] einander$_i$ e$_i$ vorgestellt.
he has the guests [without to-look-at] (to) each other introduced

If (99) is a parasitic gap construction, its pattern is inconsistent with standard assumptions. On the one hand, a parasitic gap needs an A'-chain for licensing, but on the other hand, A'-antecedents cannot bind anaphors and would trigger weak cross-over violations. In (99a) the scrambled quantified DP binds a pronoun without a weak crossover effect, and in (99b) the scrambled object binds an anaphor. These properties are associated with A-positions, however. Since under standard understanding a position cannot simultaneously be treated as A and A', there are either two movement steps involved (cf. Mahajan 1994b), or the dichotomy must be relaxed (cf. Déprez 1994), or the data must be re-evaluated for their validity. We advocate pursuing the last option.

At least for German, the identification of constructions like (99) as parasitic gap constructions is of questionable validity. First of all, the gaps in adverbial infinitival clauses do not have the properties of parasitic gaps in English, as the comparison between (100a–c) and (101a–c) illustrates. The typical cases of English (cf. 100d) are very marginal in German, however (cf. 101d). Parasitic gap constructions with the gap in a finite clause are ungrammatical in German. Only infinitival adjuncts (see 101a, b) seem at first glance to display a parasitic-gap-like behavior.

(100) a. *Where did Elaine work e$_i$ without ever living e$_i$? (Postal 1993: 737)
b. *What he became e$_i$ without wanting to become e$_i$ was a traitor. (p. 746)
c. *This is a topic about which he should think e$_i$ before talking e$_i$. (p. 736)
d. ?Which disease did everyone who caught e$_i$ want Dr. Jones to study e$_i$. (p. 738)

(101) a. Wo hat Elaine, anstatt mit dir zu wohnen, ihr (= 100a)
where has Elaine instead-of with you to live her
Büro eingerichtet?
office established
'Where did E. establish her office instead of living there together with you?'
b. Was er wurde, ohne eigentlich werden zu wollen, (= 100b)
what he became without really become to want
war ein Syntaktiker.
was a syntactician
'What he became without really wanting it was a syntactician.'

c. Das ist ein Thema, über das er, anstatt zu (= 100c)
that is a topic over which he instead-of to
schwätzen, nachdenken sollte.
talk think should
'This is a topic about which he should think instead of chatting.'

d. *Welches Haus wollte jeder, dem er e_i zeigte, e_i sofort kaufen?
which house wanted everyone who he showed at once buy

Furthermore, the same type of construction is found with elements that do not scramble easily. *Wh*-elements in situ license the alleged parasitic gaps, both in the function of a *wh*-interrogative (102a) and in the function of a *wh*-indefinite (102b). It should be noted that the alleged parasitic gap in (102a) must be interpreted like a bound pronoun.

(102) a. Wer hat seinem Nachbarn wen [ohne e_i anzuschauen] vorgestellt?
who has his neighbour whom [without to-look-at] introduced
'Who has introduced whom to his neighbour without looking at?'

b. Er hat seinem Nachbarn wen [ohne e_i anzuschauen] vorgestellt.
he has his neighbour whom [without to-look-at] introduced
'He has introduced someone to his neighbour without looking at.'

Fanselow (1993) adduces additional evidence against a parasitic-gap analysis for structures like (102a–b). He notes parallels between this construction and conjunction reduction and concludes that *ohne* ('without') and *anstatt* ('instead of') function syntactically like coordinating heads. The alleged parasitic gaps are rather the result of coordination ellipsis (cf. 103b) and not the result of the parasitic-gap type variable-binding mechanism. Viewed from this perspective, it is not surprising any more that the alleged parasitic-gap construction unlike the standard construction may contain more than one gap.

(103) a. daß er eine $Frau_i$ einem $Mann_j$ [anstatt e_i e_j vorzuziehen]
that he a woman a man [instead of to prefer (to)]
unterordnen wollte
subordinate wanted
'that he wanted to subordinate a woman to a man instead of preferring [her to him]'

b. daß er eine Frau einem Mann zuerst unterordnete und dann
that he a woman a man first subordinated and then
[– vorzog]
[preferred –]
'that he first subordinated a woman to a man and then preferred her to him'

Once it is realized that elliptic infinitivals are not cases of parasitic-gap constructions in German (and the very same considerations apply to Dutch), the

puzzling conflict between A- and A'-properties disappears, and so does the support for an A'-movement analysis of Scrambling in German.

3.3.5 Clause-bound scrambling as adjunction to VP?

Pro:

- Direct correlation with the headedness factor.
- Immediate account for the locality properties.

Con:

- Insufficiently developed adjunction/merge mechanisms.
- Insufficiently developed licensing system.
- Currently a minority position in the field. Caveat: the author belongs to this minority.

The previous sections provided evidence against all but one of the currently admissible options, namely A-chains within the projection of V^0. This seems to be an odd result. It may become less odd, however, once the two crucial factors are appreciated. One factor is the parameter of argument licensing; the other factor is the headedness parameter.

In a language like German with a relational system of argument identification (identification by case), the syntactic base order of arguments in syntactic structure is an immediate reflex of the ranking in the lexical A-structure. In particular, it is important to keep in mind that base-order patterns of one class may be identical with scrambling orders of another class. This presupposes that the identification of arguments is not a function of case checking in position that are unique for a given case. If the checking of a specific case is not tied to a unique structural configuration for the given case in a given language, case may be successfully checked in alternative positions. On the other hand, the base order must be projected because the arguments of a head are ranked in the A-structure, and the A-structure is mapped to the phrase structure projected by the head. A simple illustration is (104) and (105)

(104) a. V^0: $<A_1 <A_2>>$
b. $[_{VP}$ A1 $[A_2\ V^0]]$

Assume a verb with two arguments, ranked as in (104a). This A-structure projected on syntactic representation yields (104b), a VP with base order. If, on the other hand, the arguments appear in the reverse order as in (105a), and the first position is a possible checking position and the second position a possible base position (as in 105b), the relation between these two positions fulfills the requirements of an A-chain: the chain locally combines a checking license and a projection license.

(105) a. / . . . $A_2\ A_1\ V^0$/
b. $[_{VP}\, A_{2\text{-}i}\ [A_1\ [e_i\ V^0]$

This type of A-chain is possible only in the grammatical setting sketched above. In the following paragraphs it will be characterized more precisely.

- **Scrambling criterion** (observational):
  If a language L with head-final V-projections has different A-structure dependent base orders for argumental expressions, then L is also a scrambling language.

In other words, if there are A-structure dependent base orders, the given language allows for non-positional identification of arguments. This is a precondition for Scrambling. Note that this rules out Dutch and Icelandic as Dutch has positional identification and therefore no order alternation for DP arguments. Icelandic has different base orders for objects but it is a head-initial language.

- **Scrambling criterion** (technical):
  If in a language L the identification of argumental constituents in head-final projections is not subject to positionally fixed unique identification configurations, L is a scrambling language.

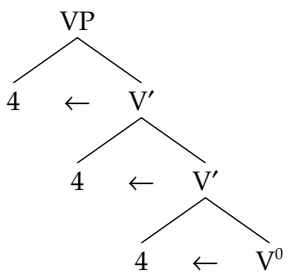
The crucial difference between a head-final and a head-initial projection is the availability of the extendable identification domain. In a head-initial projection, the extendable domain is necessarily empty; in a head-initial projection, an identification position is a position preceded by the head. So adjunction to the left creates positions that are not in the identification domain. Therefore, genuine scrambling-structures cannot arise in head-initial projections.

Excursion 2: OV vs. VO

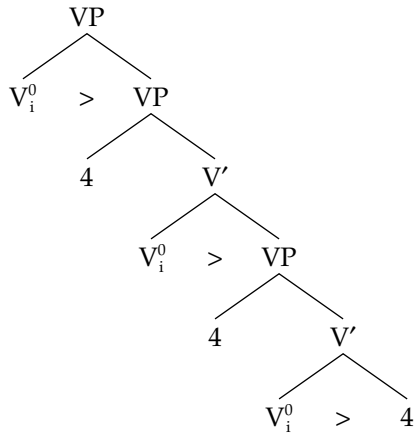
Claims:

- A head-final projection is a projection with the head in the foot position of the projection. The licensing directionality is regressive (see 1).
- A head-initial projection is a projection with an empty head in the foot position bound by the overt head in a shell projection. The licensing directionality is progressive (see 2).

(1) Head-final VP–VP



(2) Head-initial VP-shellVP



Two factors are crucial for the correlation between scrambling and headedness. First, unlike head-initial projections, head-final ones ones are simple projections, that is, binary layered structures with the head in the right foot position.

The implications for Scrambling are obvious, given that Scrambling is adjunction to the V-projection.[24] Adjunction in the structure (106a), but not in (106b), extends the identification domain of the head. Hence, left-adjoining to the projection (as in (106a)), adds one more node to the projection line and opens a position in the identification domain of the head. Left-adjunction as in (106b) creates a position that is not in the identification domain of the head of the projection. This is the basic difference between adjunction to OV and VO projections. If Scrambling structures are adjunction structures, this difference in the projection structure of head-final vs. head-initial projections entails that the grammatical properties of Scrambling in OV must be different from those that would result from an analogous operation in a VO language.

The second factor differentiates between German as a Scrambling language and Icelandic as a non-Scrambling language: the Scrambling position must be within the identification domain of the lexical head of the projection.[25] We assume that argument identification is subject to the directionality parameter. OV is – as demonstrated above – the result of regressive identification whereas VO is the outcome of progressive identification. The difference between Scrambling in an OV system, in contrast with a VO system, is illustrated in (106). In (106a) the scrambled XP is in the identification domain of V^0, but not in (106b), where it precedes a progressively identifying head:

(106) a. $[_{VP}\ XP_i\ [_{VP} \ldots [e_i \ldots V^0]]]$
b. $[_{VP}\ XP_i\ [_{VP}\ V^0\ [\ldots e_i \ldots]]]$

Arguments in positions within the identification domain of the lexical head are L-related positions. This is the reason why scrambled and non-scrambled XPs do

not differ with respect to grammatical factors conditioning opacity for extraction. It is also the reason for the lack of differences in binding. After all, a position in the identification domain of a lexical head is a position in which an XP is linked. In terms of the A'- vs. A-distinction, a linking position is an A-position. This accounts for the A-chain properties of Scrambling.

We shall have to answer the question, What determines the position of the gap in a Scrambling construction? The gap is the foot of the Scrambling chain in the base position of the scrambled element. This position is determined by the base order and hence predictable from the A-structure of the lexical head of the projection. The pertinent principle is that of the discharge of A-structure onto syntactic structure that guarantees that the ranking in the lexical A-structure is conserved in the syntactic structure:

(107) **Principle of conservative mapping of A-structure onto syntactic structure:** The A-structure ranking in the lexical A-structure of a lexical head is mapped onto a syntactic c-command hierarchy.

The lowest ranking argument in the A-structure is associated with the lowest A-position in the projection of the head, the next higher one with a position c-commanding the lower one, and so on. In terms of merging, the argument expression with which the head merges first is associated with the lowest ranking argument and merging continues in the inverse order of the ranking. The minimal domain of mapping will be referred to as Minimal Argument projection Complex (MAC).

Let us assume, for the sake of illustration, a head with a three-argument A-structure and a given ranking as in (108a). The resultant MAC, the minimal complete lexical projection that contains all A-positions, is either a structure like (108b), for head-final projections, or a structure like (108c) for head-initial ones.

(108) a. $h^0 <A_i <A_j <A_k>>>$ lexically stored information
b. $[_{HP}\ A_i\ [A_j\ [A_k\ h^0]]]$ (head final)
c. $[_{HP}\ A_i\ [\mathbf{h^0_i}\ [A_j\ [h^0_i\ A_k]]]]$ (head initial, projection shells)

An illustration for the structures (108b, c) is given in (109a, b), respectively, in the form of a German head-final and an English head-initial V-projection. For the latter we follow the standard assumption that the external argument is the only argument to the left of the head. This position is structurally a Spec position of the head-initial projection and it is identifiable as the single position to the left of the head. In head-final projections no position is singled out structurally. All positions are positions to the left of the head.

(109) a. $[_{VP}$ jemand$_i$ [jemandem$_j$ [etwas$_k$ *zeigen*]]]
someone$_{(NOM)}$ someone$_{DAT}$ something$_{ACC}$ show
b. $[_{VP}$ someone$_i$ [*show*$_q$ [somebody$_j$ [e$_q$ something$_k$]]]]

Let us now return to the question we started with, namely, the identification of the gap in a Scrambling construction like the one in (110). The gaps are identifiable in the MAC in the order of the ranking of the A-structure.

(110) daß (ja) [die Bilder$_k$ [Linguisten$_j$ [MAC niemand$_i$ [e$_j$ [e$_k$ zeigte]]]]]
that (PRT) the pictures linguists nobody showed
'that nobody showed the pictures to linguists'

The scrambled constituents are adjoined to the V-projection and thus remain in the identification domain of the head. (Note that the scrambled order could, of course, also be *Linguisten$_j$ die Bilder$_k$* since both are scrambled across the subject.) The case is checked in the overt position; linking to the A-structure position requires chain formation between the identification position and the base position. The resulting chain is thus a chain between an overt A-identification position and a covert linking position, that is, an A-chain.

In a head-initial projection, this type of structure does not give rise to A-chains for a simple reason. Positions adjoined to the MAC are positions to the left of the head position and therefore are not in the potential identification domain of the head:

(111) [$_{VP}$ something$_k$ [$_{MAC}$ someone$_q$ [*show*$_i$ [somebody [e$_i$ e$_k$]]]]] (*scrambling)

Since the position adjoined to the MAC in (111) is not in the identification domain of the lexical head because identification is subject to a directionality requirement, the chain cannot be an A-chain. It could be an A'-chain only. This is the grammar-theoretical reason for the absence of A-chain Scrambling of the German type within VO languages. The remaining possibility for scrambling within the MAC in VO languages, that is, adjunction to the left is ruled out for principled reasons as well. Adjunction to the left is not admissible in constrained phrase-structure theories as those of Haider (2000a) or Kayne (1994).

4 Conclusion: questions and answers

- What makes an SOV-language (like German, Hindi, Japanese) a scrambling language?
  - Licensing domains are non-positionally restricted.
  - V-projections are head-final.
- What prevents scrambling in SVO languages (like English, French, or Icelandic)?
  - There is no adjunction to the right (universal restriction).
  - Heads of head-initial projections do not license to the left; hence there is no adjunction to the left either.
  - Scrambling is conditioned by the headedness property (head-final). Hence a language with mixed headedness (e.g., German) does not scramble in head-initial projections (NP, PP), but only in head-final ones (VP, AP).

Typological note: VSO languages such as Tagalog allow for scrambling in the sentence domain (for Tagalog see Schachter 1996). What this indicates for our present concern is that reordering in the domain of the verb – the V-projection (plus higher functional projections) – is possible if arguments are not confined to unique licensing positions. In addition, we should take into account that languages like Polish and Russian are considered scrambling SVO languages. This is a serious challenge to the account described above, unless there is an independent factor intervening, namely, the positioning of V^0. If Slavic languages are more like Hindi (see Mahajan 1997) or Yiddish (see Haider and Rosengren 1998), the problem disappears. These languages are neither true OV nor true VO languages, but rather a combination of both OV and VO: in that the base position plus the identification directionality is OV, but the verb may move to a surface position to the left. If this characterization is correct, scrambling is possible because the identification directionality is like in an OV system. The surface position of the verb, however, masks this property.

- What prevents the permutation of DP arguments in Dutch, unlike German?
  - Positional licensing of DP objects (because of the lack of relational morphological identification).
- What is responsible for the apparent combination of A- and non-A-movement properties (crossover, parasitic gaps, etc.)?
  - (Mis)interpretation of data, (mis)interpretation of theoretical concepts.

NOTES

I want to thank Anders Holmberg and an anonymous reviewer for their valuable efforts to improve the quality and readability of an earlier version of this chapter. Please blame remaining shortcomings exclusively on the author.

1 Representative for the Scandinavian languages (Faroese, Iceandic, Norwegian, Swedish).
2 A necessary condition for scrambling within a projection P is (i) that P must be a head-final projection, and (ii) that the arguments of the head of P must be licensed relationally, that is, the identification of the given argument phrases does not depend on unique structural positions for each argument. (See Haider 1991a; Corver and Van Riemsdijk 1997; Haider 1997c; Haider and Rosengren 1998.)
3 Capitals indicate the locus of the pitch accent.
4 Stefan Heym, interview.
5 The position of a negation particle is a position that c-commands the finite verb or its trace. This is one reason why a negation particle in the role of sentence negation cannot appear in a VP-internal position in a VO language:

(i) He has talked *gently* to Mary.

(ii) *He has talked *never* to Mary.

(iii) *He has talked *not* to Mary.

But in an OV language the negation particle, just like adverbs of all semantic types, occurs VP-internally, since any VP-internal position c-commands the finite verb in its base position.

6 The MAC is the minimal projection of the head that contains all argument positions of the head. This is a modification of Diesing's (1992b) claim that the VP is the domain of existential closure. The VP in an OV language may be larger than the MAC. This is the case if scrambling is analyzed as adjunction to VP. In head-initial projections, however, the left boundary of the MAC is identical with the left boundary of the VP.

7 There are some restrictions regarding genitival objects, however (cf. Rosengren 1993). Since this is not relevant here we shall not discuss it further.

8 In the following example the subscript is the trace index; the superscript is the binding index.

9 Nominative is a bi-partite relation because the nominative DP obligatorily agrees with the finite verb. The DP and the finite verb share a feature matrix. By definition, the finite verb, as the head of the projection, c-commands all the phrases in its projection. So the feature matrix of the governor of nominative c-commands any position within the VP. If binding is defined in terms of the position of the head that agrees with the DP features rather than the DP position itself, the result is in accordance with the empirical facts. It is important to realize that overt agreement is the crucial factor and not the subject function (cf. ECM subjects).

10 'An operator A may have scope over an operator B iff A c-commands B or an A'-element coindexed with B.'

11 Nominal-case distinctions in Dutch are found only with pronouns, much as in English.

12 A derived un-accusative predicate is the passive of a ditransitive verb. An example of a primary unaccusative verb is *overkomen* ('happen to'):

(i) dat Jan boeken gegeven werden
that Jan books given were
dat Jan rampen overkomen zijn
that Jan disasters happened were

13 This is of course not the same as to say that they are informationally equivalent. The difference in position of the minimal focus exponent is of course important but not relevant in this connection.

14 Note that a reflex of this property is the fact that the verb that denotes the same concept in English – the verb *devote* – does not allow for a 'dative alternation'. An unambiguous goal relation is ranked lower than a theme argument in A-structure.

15 Note that contrary to widespread rumours there is no specificity effect in the German counterpart of the English *there*-construction:

(i) Es spielt jetzt für sie *die Academy of St. Martin in the Fields* unter Neville
there plays now for you *the Academy of St. Martin in the Fields* under Neville
Mariner.
Mariner

16 See Askedal (1986). The examples are excerpted from T. Mann, *Die Buddenbrooks* and F. Werfel, *Das Lied der Bernadette*.

17 Haeseryn et al. (1997: § 22.5.6.3) "Als lijdend voorwerp en indirect object beide een substantiefgroep zijn, moet het indirect object steeds vóór het lijdend voorwerp

staan, hoewel niet steeds vlak ervoor" ['If the direct object and the indirect object are both DPs, the indirect object must always precede the direct object, although not always immediately'].

18 Haeseryn et al. (1997: § 22.5.6.3) "dan is verplaatsing gemakkelijk mogelijk" ['then movement is well possible'].

19 Commentary (Eurosport channel, February 22, 2002) on Sarah Hughes' gold-medal-winning performance.

20 The fact that Dutch infinitival subject clauses are obligatorily extraposed supports the assumption of an IP shell for Dutch, which is confirmed by the German–Dutch contrast in the distribution of sentence internal expletive subjects discussed earlier. The Dutch restriction is the parallel of the English restriction on clause-internal clausal subjects.

21 The very same ECP effect can be seen with English VP-topicalization:

(i) a. . . . and [found a solution]$_i$ he has e_i
b. * . . . and [found a solution]$_i$ he e_i

In (b), the trace of the topicalized VP would be governed only by an empty functional head. The ECP requires a lexicalized head. Note that whatever condition is to replace the coverage of the ECP in the Minimalist Program must cover this distinction.

22 Examples such as *Who was taken advantage of?* and *Who did you give this book to?* show clearly that the verb and the preposition are not adjacent heads because in both examples the preposition is not adjacent to the verbal head.

23 *Auffallen* is a particle verb: *auf+fallen*, literally translated 'up+fall', with the meaning *to happen to notice*. The gloss uses the translational equivalent 'strike' plus a particle.

24 Adjunct(ion) is used here as a purely structural notion: the adjunction position is a position merged with the projection of a syntactic category (daughter and sister of a segment of a (maximal) projection XP), without being selected by the head. The BC (see above) allows adjunction on the left but not on the right side of a projection.

25 We assume a P-and-P-theory-checking system for overt case: a lexical head can check for a single case value per case category, that is, one structural case, one lexical case, and one oblique (e.g., prepositional) value.

4 Conclusion

1 Introduction

1.1 Wh-*expressions as diagnostics of scope*

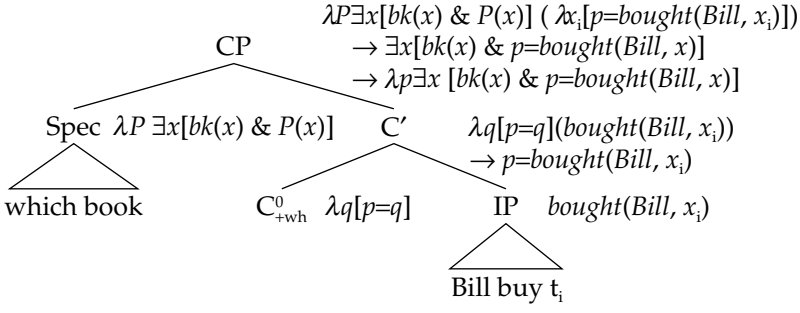
1.1.1 Fronting and possible answers as indicators of scope

I will begin this survey of multiple-*wh*-questions by outlining those theoretical claims for which the study of *wh*-dependencies has been particularly important. These include the claim that there is a level of syntactic representation intermediate between overt syntax and the interpretive module, known as Logical Form (LF), and that movement at this level is subject to the Empty Category Principle (ECP) but not Subjacency.

Wh-expressions provide a special window on the nature of syntactic dependencies because in many languages they appear at the periphery of the clause, in the position at which they are assumed to be interpreted. In this they differ from quantified expressions, for example, which also may be argued to require clausal scope for interpretation but do not seem to occur in a specially designated scope position in any language. To appreciate the diagnostic power of *wh*-expressions, consider a simple question in English, such as (1a), and one of its possible answers, given in (1b):

(1) a. Which book did Bill buy?
b. (Bill bought) *War and Peace*.

(2) a. λp ∃x [book(x) & p = bought(Bill, x)]
b. {Bill bought *War and Peace*, Bill bought *Aspects*}
c.



Intuitively, the fronted *wh*-expression is linked to the object of the verb *buy*. Syntactic tests, using agreement and binding facts, for example, can further establish the syntactic dependency between the fronted element and the gap in

argument position. In logical form this dependency is understood as an operator–variable relation. Under a standard semantics for questions such as Hamblin (1973) or Karttunen (1977), (1a) is interpreted as in (2a), yielding the set of propositions obtained by varying assignments to the variable bound by the *wh* ∃ operator.[1] In a context where the quantifier ranges over the set {*War and Peace*, *Aspects*}, we get the set of propositions in (2b) as the denotation of the question. An appropriate answer is understood to be one that picks out the true proposition from this set, specifying in effect, a value for the fronted *wh*-expression. Structure (2c) makes explicit the mapping from syntactic structure to semantic interpretation (Bittner 1994; von Stechow 1996). The crucial operation that shifts a sentence from a declarative proposition-type meaning to an interrogative set-of-propositions type meaning hinges on the propositional variable *p* over which lambda abstraction can take place. Crucially for our purposes, the fronted *wh*-expression must be interpreted outside the scope of this variable. If the +WH specification on C^0 is taken to be the position at which the propositional variable is introduced, and the fronted *wh* taken to be in [Spec, CP], the mapping from syntax to semantics is straightforwardly compositional. Thus, one might take fronting of *wh*-expressions as direct evidence of their scope position.[2]

Multiple-*wh*-questions have special syntactic and semantic properties. In English they are formed by fronting one *wh*-expression and leaving the other(s) in situ. Possible answers to such questions specify values not only for the fronted *wh*-expression but also for those in situ:

(3) a. Which student bought which book?
b. Bill bought *War and Peace*, Sue bought *Aspects*.

(4) a. λp ∃x ∃y [student(x) & book(y) & p = bought(x,y)]
b. {Bill bought *War and Peace*, Bill bought *Aspects*, Sue bought *War and Peace*, Sue bought *Aspects*}
c. $[_{CP}$ Which student$_i$ $[_{IP}$ t_i bought which book]] → $[_{CP}$ which book$_j$ Which student$_i$ $[_{IP}$ t_i bought t_j]]

If we take possible answers as a diagnostic, and assume that specification of values is due to clause external existential quantification binding variable positions inside IP, as the Hamblin–Karttunen semantics of questions suggests, multiple-*wh*-questions force us to the conclusion that there must be a way of interpreting *wh*-expressions in situ that allows them to form operator variable relations of the kind shown in (4a). Following the syntax–semantics mapping outlined above, it appears plausible to assume that the *wh*-in-situ moves covertly to a position outside C^0. A semantic argument for the existence of LF can thus be made using possible answers to multiple-*wh*-questions as indirect evidence.

1.1.2 Constraints on Scope: ECP and Subjacency

If considerations of interpretability lead us to postulate an abstract level of syntax, it should be possible to characterize it in theoretical terms. In particular, one

could ask if there are constraints on the operation of Move α at this level. In this subsection we will consider evidence that has been used to establish the status of the ECP and Subjacency as constraints on movement at LF.

To see how multiple-*wh*-questions have shaped our view of LF, consider the following questions, uttered out of the blue:

(5) a. Who saw what?
b. ?*What did who see?

(6) a. How did Bill read what?
b. *What did Bill read how?

The choice of which *wh*-expression will be fronted in a multiple-*wh*-question is clearly sensitive to the status of the argument. In (5) a subject is chosen over the object for fronting, in (6) an adjunct is preferred over the object. This phenomenon, which goes by the name of Superiority in the literature, can be accounted for by imposing syntactic requirements on traces:

(7) a. $[_{CP}\ [_{Spec\text{-}i}\ what_j\ [_{Spec\text{-}i}\ who_i]]\ [_{IP}\ t_i\ saw\ t_j]]$
b. $[_{CP}\ [_{Spec\text{-}j}\ who_i\ [_{Spec\text{-}i}\ what_j]]\ [_{IP}\ t_i\ saw\ t_j]]$

(8) a. $[_{CP}\ [_{Spec\text{-}i}\ what_j\ [_{Spec\text{-}i}\ how_i]]\ [_{IP}\ Bill\ read\ t_j\ t_i]]$
b. $[_{CP}\ [_{Spec\text{-}j}\ how_i\ [_{Spec\text{-}j}\ what_j]]\ [_{IP}\ Bill\ read\ t_j\ t_i]]$

(9) **Empty Category Principle:**
Traces must be properly governed.
A properly governs B iff A theta-governs B or A antecedent-governs B (Chomsky 1986a).

The ECP states that traces must be properly governed and an account of the Superiority effects can be given if it is assumed that [Spec, CP] carries the index of the first *wh*-expression that moves into it (Lasnik and Saito 1992). As the derivations in (7a) and (8a) show, the ECP is respected when covert movement is from the theta-marked direct object position, leaving the subject or the adjunct trace created at S-structure to be antecedent governed by the fronted *wh*-expression. In the unacceptable cases in (7b) and (8b), the situation is reversed. Though the trace created at S-structure satisfies the ECP (doubly), the trace created at LF does not.

Note that ECP as a constraint on S-structure movement can also be established on the basis of examples like (10). The explanation for the contrast between (10a) and (10b) draws on the same elements of explanation as the contrast between (7a) and (8a), and (7b) and (8b). Structure (10b) is unacceptable because an intervening complementizer blocks antecedent government of a trace in non-theta position:

(10) a. $[_{CP}\ [_{Spec\text{-}i}$ Which author$_i$] $[_{C'}$ do $[_{IP}$ you believe $[_{CP}\ [_{IP}\ t_i$ wrote the book]]]?
b. *$[_{CP}\ [_{Spec\text{-}i}$ Which author$_i$] $[_{C'}$ do $[_{IP}$ you believe $[_{CP}$ that $[_{IP}\ t_i$ wrote the book]]]?

What makes the argument from multiple-*wh*-questions for the existence of ECP effects at LF significant is that it gives content to the idea that LF is a level of syntax, with properties in common with S-structure. This result is important because it is an argument against an alternative view in which assignment of scope can be a viewed as a purely semantically driven step in the computation.

Let us turn now to constraints on scope covered by the subjacency condition. As Ross (1986) showed, though *wh*-fronting can occur across clauses, it is restricted in certain contexts:

(11) a. Which book did Mary tell John to buy t?
b. Which book does Mary think John will buy t?

(12) a. *Which book does Mary know a man who has read t?
b. Which book is such that Mary knows a man who has read it?

(13) a. *Which book does John know where Mary bought t?
b. Which book is such that John knows where Mary bought it?

Here we have evidence that *wh*-dependencies created at S-structure are syntactically constrained. In (12a), the fronted *wh*-expression associated with a position inside the complex noun phrase is clearly unacceptable (Ross's CNPC). It is easy to see that the problem is not semantic in character. Sentence (12b) shows that if the relevant dependency between the *wh*-expression and the gap inside the complex noun phrase could be established in (12a), it would be interpretable as a proper request for information. The contrast between (13a) and (13b) makes the same point for *wh*-dependencies involving embedded questions (Ross's *Wh*-Island Constraint). The two can be subsumed under the Subjacency Condition:

(14) **Subjacency Condition (Chomsky 1986a):**
If (α_i, α_{i+1}) is a link of a chain, then α_{i+1} is subjacent to α. β is n-subjacent to α iff there are fewer than n+1 barriers for β that exclude α.

Given that *wh*-in-situ in multiple-*wh*-questions moves at LF, one can test whether the Subjacency Condition also holds at that level. The following data test the relevance of the two subcases of Subjacency:

(15) a. Who knows a man who wrote which book?
b. Bill knows a man who wrote *Aspects*.

(16) a. $\lambda p\ \exists x\ \exists y$ [person(x) & book(y) & p = $\exists z$ [man(z) & wrote(z,y) & knows(x,z)]

b. {Bill knows a man who wrote *Aspects*, Sue knows a man who wrote *Aspects*, Bill knows a man who wrote *LGB*, Sue knows a man who wrote *LGB*}

(17) a. Which student knows where Mary bought which book?
b. Bill does/Bill knows where Mary bought which book.
c. Bill knows where Mary bought *Aspects* and Sue knows where Mary bought *LGB*.

(18) a. λp ∃x ∃y [student(x) & book(y) & p = know(x, λp′ ∃z [place(z) & p′ = buy(Mary, y at z)]]
b. {Bill knows where Mary bought *Aspects*, Sue knows where Mary bought *Aspects*, Bill knows where Mary bought *LGB*, Sue knows where *Mary* bought LGB}

Baker (1970) argued that the possibility of answering (17a) with (17b) or (17c) indicates a syntactic ambiguity in the scope of *wh*-in-situ. Answers like (17b), specifying values for the fronted *wh* only, can be derived if the *wh*-in-situ takes scope over the embedded clause. List answers like (17c), on the other hand, which pair students and books, indicate that the *wh*-in-situ takes matrix scope, in violation of the *Wh*-Island Constraint. A similar argument, based on possible answers, has been made for matrix scope of the *wh*-in-situ in (15), in violation of CNPC. These examples establish a difference between operator–variable dependencies created at S-structure and those created at LF. On the basis of such examples, it has been claimed that the Subjacency Condition does not hold at LF.

As in the case of the ECP, the scope of *wh*-in-situ is crucial in establishing the status of Subjacency at LF. Quantifiers, for example, do not help in this regard. Example (19) shows that a reading where for each book there is a possibly different student who thinks John will buy it is not available:

(19) Some student thinks John will buy every book.

Since we know from (11b) that this is a context which allows extraction, the inability of the ∀ quantifier to take scope over the ∃ suggests that it is a property of Quantified NPs that their scope must be clause-bounded (but see chapter 74 for discussion). The relevance of subjacency at LF, therefore, cannot be determined by examining the behavior of quantifiers, and our primary source for this claim remains the interpretive possibilities of *wh*-in-situ.

1.1.3 Alternatives to Covert Movement

We have seen that the observable syntactic structure of English multiple-*wh*-questions reveals the scopal property of one *wh*-expression directly by fronting it, while concealing that of the other(s), for which we must look to indirect evidence in the form of appropriate answers. We have also seen that these twin indicators of scope make multiple-*wh*-questions an extremely powerful diagnostic

tool. Adopting the Principles and Parameters model of grammar, I have demonstrated the power of multiple-*wh*-questions to test the syntactic properties not only of S-structure but also of LF. There are, of course, many alternative analyses of the phenomenon that have been proposed over the years and we will discuss some of them in subsequent sections. For now, I would like briefly to mention three mechanisms for interpreting *wh*-expressions which do not depend on movement, namely, Cooper-storage, Unselective Binding, and Choice Functions. My aim here is to explicate differences between them with respect to the assignment of scope as well as to note points of contact. I will not try at this point to summarize the particular arguments made or specific conclusions drawn by the proponents of each approach.

Let us take as a starting point the idea that covert movement is not essential to the interpretation of *wh*-in-situ, or other scope-bearing elements for that matter. An alternative proposed by Baker (1970) depends on co-indexation between a Q-morpheme in complementizer position and a *wh*-in-situ. His analysis of (17a), repeated below as (20a), shows the two scope possibilities discussed earlier:

(20) a. Who knows where Mary bought what?
b. $[Q_i\ who_i\ [t_i\ knows\ [Q_{j,k}\ where_j\ Mary\ bought\ t_j\ what_k]]]$
c. $[Q_{i,k}\ who_i\ [t_i\ knows\ [Q_j,\ where_j\ Mary\ bought\ t_j\ what_k]]]$

Note that given a proposal like this, the notion of LF as essential to the syntax–semantics interface can be dispensed with, but only if it is combined with an alternative way of interpreting the *wh*-expression than the one given in section 1.1. The *wh*-expression there is interpreted like an existential generalized quantifier which combines with a predicative expression built up out of the denotation of C′, the syntactic constituent it has scope over. The challenge posed by structures like (20b–c), or any other structure encoding scope without covert movement, is to find a compositional way of assigning clausal scope to expressions within the clause at the interface level.

Engdahl (1986), working within a non-derivational syntactic framework, suggests that *wh*-in-situ should be interpreted on a par with other generalized quantifiers using the storage mechanism of Cooper (1983). Briefly put, this involves interpreting the *wh* in argument position as a variable and keeping its quantificational force, the existential along with the restriction, in store till an appropriate scopal position is reached, at which point existential binding of the variable is effected. Hamblin–Karttunen denotations, equivalent to the ones derived under the movement approach, could thus be derived for multiple-*wh*-questions without having to take recourse to covert movement.[3]

A second approach for interpreting *wh*-in-situ without movement is proposed by Pesetsky (1987a) and Nishigauchi (1986, 1990). Recognizing the kinship between *wh*-expressions and indefinites, they adopt the unselective binding approach of Lewis (1975), Kamp (1981a), and Heim (1982), where the indefinite provides a variable that must be bound by sentential operators. Under this approach, we

might take the C^0_{+WH} to provide not only the propositional variable *p*, but also the existential quantifier binding the *wh*-variables. In the basic cases, the resulting set of propositions is the same as in the other proposals considered so far, but there is a crucial difference with respect to the status of the common noun inside the *wh*. In this case, it remains within the scope of the propositional variable, simply adding an additional condition on the variable:

(21) a. Which student read which book?
b. $[Q_{i,j}$ which student$_i$ [t_i read which book$_j$]]
c. $\lambda p\ \exists x\ y$ [student(x) & p = read(x,y) & book(y)]

The third approach, proposed by Reinhart (1997), is similar in that it takes the *wh*-in-situ to be an indefinite bound by existential closure. The key difference is in the interpretation of the common noun. Reinhart points to the fact that the unselective binding approach makes the wrong prediction in cases like the following:

(22) a. Who will be offended if we invite which philosopher?
b. $\lambda p\ \exists\ x\ y$ [p = [[invite(we, y) & philosopher(y)] $\rightarrow$ offended(x)]]
c. Lucie will be offended if we invite Donald Duck.

(23) a. $\lambda p\ \exists\ x\ \exists f$ [p = [[invite(we, y) & f(philosopher)] $\rightarrow$ offended(x)]]
b. $\lambda p\ \exists\ x\ \exists f$ [student(x) & p = [read(x, f(book)]]

As (22b) shows, the *wh*-in-situ is in the antecedent of a conditional. This means that any individual who is not a philosopher suffices to make the antecedent false and hence the conditional proposition true. Sentence (22c) thus qualifies as a potential answer to the question. Reinhart therefore argues for a treatment of *wh*-in-situ in terms of choice functions. Under this view the quantification ranges over functions that take a (non-empty) set and pick out an individual from that set. *Wh*-expressions, like other indefinites, do not contribute an individual variable but denote a set to which the existentially quantified function applies. The problem is resolved since Donald Duck would simply not be a possible value for *f*(*philosopher*) in (23a). For completeness I give the interpretation of the simpler case (21a) in (23b).

The availability of well-defined semantic mechanisms like Storage, Unselective Binding, and Choice Functions makes it clear that *wh*-scope phenomena are not inextricably linked to movement and successful analyses have been given which dispense with movement or combine movement with alternative scope-assignment strategies to different degrees. On the two ends of the spectrum, then, lie frameworks like the Principles and Parameters model that encode all scope relations via movement, and frameworks that eschew movement altogether, such as Head-driven Phrase Structure Grammar. For the first type of framework, alternative scope mechanisms are obviously superfluous while they are clearly essential for the second type. There are also a number of interesting possibilities that fall

between these two opposing points. One, advocated by Pesetsky (1987a), favors *wh*-movement at S-structure and LF but allows for certain (discourse-linked) *wh*-expressions to be subject to unselective binding. Pesetsky thus argues for a uniform characterization of Move α at both syntactic levels, explaining the non-standard behavior of some *wh*-in-situ as a reflection of their being a distinct phenomenon subject to distinct principles. Reinhart (1997), on the other hand, takes the possibility of covert movement to be antithetical to the basic tenets of Minimalism, and argues for a movement account for fronted *wh* only, reserving an account in terms of choice functions for all *wh*-in-situ. As is clear in even this cursory list, a number of a priori defensible positions are possible. One might wonder to what extent the issues raised by multiple-*wh*-questions, discussed within a framework utilizing movement as the sole scoping mechanism, transfer to frameworks that rely on other mechanisms. I will try to clarify below the sense in which I believe the central questions about the interface between form and meaning are maintained across these divergent views.

Consider the role of Subjacency in distinguishing between S-structure and LF in the Principles and Parameters model. As we noted, this is based on two types of evidence, evidence of Subjacency effects in fronting possibilities and absence of Subjacency effects in answers specifying values for *wh*-expressions inside islands. The first kind of evidence is direct, the second indirect in that it relies on the premise that possible answers specify values for all and only *wh*-expressions that have matrix scope. In subsequent sections we will have a chance to probe this assumption more fully. Taking it at face value for now, it can be easily shown that the descriptive generalizations revealed by multiple-*wh*-questions have equal significance in alternative models of grammar.

In a non-derivational model like Engdahl's, for example, something akin to Subjacency applies to operator–gap dependencies when *wh*-operators are in clause-initial position. The same does not apply to *wh*-in-situ, whose quantificational force can be held in store beyond the relevant bounding nodes. Approaches such as Pesetsky's, adopting unselective binding for D-linked *wh*-in-situ, or those like Reinhart's, adopting choice functions for all *wh*-in-situ, make similar distinctions. A dichotomy between two scope mechanisms is recognized, only one of which is considered sensitive to subjacency.[4] While there are substantive differences between the various positions, the point I would like to emphasize is that they share fundamental assumptions about the relation between possible answers and scope. To the extent that the argument for a particular property of abstract movement turns on the diagnostic of possible answers, and specification of values is linked to binding of a variable in argument position by an existential quantifier with scope over the propositional variable, it will also be of relevance in models employing alternative scope mechanisms. Although I will continue to talk in terms of movement much of what I say is intended to apply more generally.

1.1.4 Overview of the chapter

In the previous subsections I have tried to convey an idea of the central role that multiple-*wh*-questions play at the interface of syntax and semantics. In doing so,

I have introduced the two empirical phenomena that have been central in the analysis of multiple-*wh*-questions: Superiority effects and apparent violations of Subjacency. In the next subsection, I will broaden the empirical base by surveying languages in which multiple-*wh*-questions are formed differently from English. Section 1.2, therefore, has a primarily typological goal, after which the chapter takes up the task of examining the theoretical import of descriptive generalizations more closely. In doing so, it also tries to refine those generalizations.

Section 2 begins by noting that Superiority effects are not manifested in D-linked contexts and goes on to a survey of various accounts that have been given for the presence or absence of Superiority. It concludes by addressing the possibility of cross-linguistic variation in Superiority. Section 3 takes a closer look at subjacency violations typically associated with *wh*-in-situ. It begins by examining the nature of pair answers on which this view is based and goes on to elaborate the semantics required to derive them. It ends with a reassessment of the claims about subjacency.

It might be worthwhile, before proceeding further, to delineate the intended coverage of this survey. Using answers to questions as a guide, I confine my study of multiple-*wh*-questions to those whose appropriate answers require specification of values for more than one *wh*-expression. By this criteria, questions with the following schemata do not qualify as proper objects of this case study, if their appropriate answers give values for only one *wh*-expression:

(24) a. [. . . WH_1 . . . [. . . WH_2 . . .]]
b. [. . . WH_1 . . . [. . . WH_2 . . . t_1]]

(25) a. Who wonders when Mary will come?
b. ravi kyaa soctaa hai, ki meri kab aayegii — Hindi
Ravi what thinks that Mary when will come
(Dayal 1996a)

(26) a. Despre care$_i$ ştii [cine$_j$ t_j i-a povestit t_i]? — Romanian
about which you-know who to-him has told
'Which one do you know who told him about?'
(Comorovski 1989)
b. Ni xiang-zhidao [shei mai-le sheme]. — Chinese
you wonder who bought what (Huang 1982a)

Examples of the schema in (24a) are given in (25a–b). Example (25a) only requires information about the identity of wh_1. Example (25b) instantiates what is known as the Scope Marking or Partial *Wh* Movement construction, characterized by the fact that it appears, on surface at least, to seek for the identity of wh_2 only. The schema in (24b) is exemplified by the possibility in some languages of scoping out of a *wh*-island, whether at S-structure or LF. Sentence (26a) is a question about the fronted *wh* and although (26b) is ambiguous with regard to which *wh* takes matrix scope, only one of them can do so. Although I will mention such

cases in describing the cross-linguistic possibilities in the next section, and in other sections whenever relevant, I will not delve into issues raised by them. Scope Marking and *Wh* extraction out of islands are discussed in chapters 47 and 77, respectively, to which I refer the reader. I should also mention that this chapter should be read in conjunction with chapter 77, since there is substantial overlap between them.

*1.2 Cross-linguistic variation in multiple-*wh*-questions*

1.2.1 Non-fronting languages

English, the language I have used so far to illustrate the theoretical import of multiple-*wh*-questions, represents only one of three documented strategies for the formation of such questions. This section introduces the two other strategies, namely, the absence of fronting in some languages and the obligatory fronting of all *wh*-expressions in others. We will also briefly consider two other language types, those in which multiple-*wh*-questions are unattested and those in which *wh*-expressions are said to be optionally fronted. The section ends with a summary of some explanations that have been given for the existence of variation in (multiple) question formation across languages.

Let us begin with *wh*-in-situ languages which have played a crucial role in the development of syntactic theory. We will base our survey of such languages on Chinese and Japanese. The following illustrate simple multiple questions in the two languages respectively:[5]

(27) a. Shei mai-le sheme (ne)?
who buy-ASP what Q
b. Dare-ga nani-o katta ka?
who-NOM what-ACC bought Q
'Who bought what?'

(28) a. $[_{CP}\ WH_i\ WH_j\ [_{IP} \ldots t_i \ldots t_j \ldots]]$
b. $[_{CP}\ Q_{ij}\ [_{IP} \ldots WH_i \ldots WH_j \ldots]]$

The *wh*-expressions are in their base positions here, a fact that could be demonstrated more clearly if arguments other than the subject were being questioned.[6] Additionally, there is a morpheme identifying the clause as interrogative, either optionally or obligatorily. Broadly speaking, two proposals have been made about the interpretation of *wh* in these languages. One, schematized in (28a), treats *wh*-in-situ as moving at LF in order to be interpreted. Under this view, fronting and non-fronting languages differ only in the level at which movement takes place. The other view allows *wh*-expressions to remain in situ but interprets them via unselective binding, treating the Q-morpheme as the relevant operator. This is schematized in (28b).

I will begin by summarizing the key arguments for the movement approach, the reference point for which is Huang's (1982a) influential work on Chinese. It

is obvious that superiority effects cannot be discerned in simple questions, but Huang argued that ECP is nevertheless operative in the interpretation of *wh*-in-situ. In a context like (29a) where the matrix verb selects a +WH complement, it is possible for the object *wh*-in-situ to be interpreted with matrix scope, but not the adjunct. The availability of a wide-scope reading for the embedded object also reveals the other important property of LF movement that Huang argued for, namely, the insensitivity to syntactic islands. This is further shown by the possibility of a direct question interpretation for (29b), where the *wh*-expression is contained inside a complex NP:[7]

(29) a. Ni xiang-zhidao [Lisi zeme mail-le sheme]?
you wonder Lisi how bought-ASP what
'For what object x, you wonder how Lisi bought x?'
*'For what manner x, you wonder what Lisi bought in manner x?'
b. Ni zui xihuan [piping shei de shu]?
you most like criticize who REL book
'For which x, you like the book that criticizes x?'

Huang's characterization of the interpretive possibilities of *wh*-in-situ has been challenged on the basis of Japanese by Nishigauchi (1986, 1990) and Choe (1984). Nishigauchi argues that although the Japanese counterpart of (29b) does have a direct question interpretation, the Japanese translation for (29a) can only be understood with both embedded *wh*-elements taking narrow scope:

(30) a. Tanaka-kun-wa [Mary-ga doko-de dono hono-o katta]- ka
Tanaka-TOP Mary-NOM where which book-ACC bought Q
sitte-imasu ka?
know Q
'Does Tanako know where Mary bought which book?'
*'For which book x, does Tanako know where Mary bought x?'
b. Kimi-wa [dare-ga kai-ta] hono]-o yomi masi-ta ka
you-TOP who-NOM write book-ACC read Q
'For which x, you read the book that x wrote?'

(31) $[Q_i\ [_{DP}\ who_i\ [book\ that\ t_i\ wrote]]_j\ you\ read\ t_j]$

Nishigauchi takes (30a) as evidence that the scope of *wh*-in-situ is constrained by subjacency. This is captured in the unselective binding approach he adopts by requiring *wh*-in-situ to be bound by the closest Q-operator. The apparent wide-scope interpretation of (30b), he suggests, is due to local movement of the *wh*-in-situ to a DP adjoined position. Binding of the *wh* by the Q operator becomes possible after large-scale Pied-Piping of the DP, as shown in (31).[8]

The difference between Chinese and Japanese *wh*-in-situ has been studied by Aoun and Li (1993a) and Tsai (1994b), who argue in favor of unselective binding also for Chinese but locate the difference in the domain within which such

binding must take place in the two languages. A different account of the facts is given by Watanabe (1992a), who maintains that LF *wh*-movement is not subject to subjacency, positing S-structure movement of an abstract *wh*-element in Japanese to account for the *wh*-island effect noted by Nishigauchi.

As we see, the languages under consideration make a significant contribution to our understanding of the syntactic principles governing scope assignment for *wh*-in-situ. The issue of whether Subjacency applies to *wh*-in-situ, even in languages like Japanese, is not a settled question. Watanabe (1992a) and Dayal (1996a) both note that conclusions about subjacency have to take into account the fact that introducing a *wh* in the matrix clause in structures like (30a) has a dramatic effect. Example (32), like its English counterpart, readily allows for an answer pairing individuals with books:

(32) Dono sensei-ga [Mary-ga doko-de dono hono-o katta]- ka
which professor-NOM Mary-NOM where which book-ACC bought Q
sitte-imasu ka?
know Q
'For which professor x and book y, does x know where Mary bought y?'

In section 3 we will return to the question of subjacency effects with *wh*-in-situ, from the perspective of a more refined understanding of the role of possible answers in diagnosing scope. The brief discussion here lays out the basic facts that have been reported in the literature.

1.2.2 Multiple-fronting languages

Let us turn now to the other end of the spectrum, to languages with multiple *wh*-fronting. The primary question posed by the possibility of multiple fronting is whether all the *wh*-elements are in their final scope position in these languages or whether they move to peripheral positions within the clause. In (33a) all *wh*-expressions are in [Spec, CP] position, in (33b) they are adjoined to IP. The structure in (33c) represents a position in between where one *wh* occurs in Spec while the others are adjoined to IP:

(33) a. $[_{CP}\ WH_i\ WH_j\ WH_n \ldots [_{IP} \ldots t_i\ t_j\ t_n \ldots]]]$
b. $[_{IP}\ WH_i\ WH_j\ WH_n \ldots [_{IP} \ldots t_i\ t_j\ t_n \ldots]]]$
c. $[_{SPEC,\ CP}\ WH_i\ [_{IP}\ WH_j\ WH_n\ [_{IP} \ldots t_i\ t_j\ t_n \ldots]]]$

Various authors have argued for these possibilities, but we will base our survey of multiple-fronting languages on Rudin (1988b), who argues that multiple-fronting languages instantiate either (33a) or (33c). Her study focuses on Polish, Serbo-Croatian, Czech, Bulgarian (all Slavic languages), and Romanian (a Romance language) (see also Comorovski 1989, 1996). Rudin claims that in Bulgarian and Romanian, all *wh*-expressions move into Spec, while in Serbo-Croatian, Polish, and Czech, one *wh* moves into Spec while the others adjoin to IP. She classifies the first set as +MFS (Multiply Filled Spec) language and the second set as –MFS

language. I give examples below from Bulgarian to represent +MFS languages and Serbo-Croatian to represent the –MFS languages. I abstract away from a discussion of internal differences among the languages of each group:[9]

(34) a. Koj kogo vižda?
who whom sees
'Who saw whom?'
b. *Koj vižda kogo?

(35) Ko koga vidi?
who whom sees
'Who sees whom?'

Rudin identifies four properties distinguishing the two types of language, which she claims follow from the proposed distinction in landing sites. Only +MFS languages allow multiple *wh*-extraction from a clause and countenance *wh*-island violations. Only –MFS languages allow the insertion of clitics, parentheticals, adverbs, etc. after the first *wh*-expression and allow the *wh*-expressions to be in any order.

Consider the possibility of multiple extractions:[10]

(36) Koj_i kude_j misliš [če e ostišul t_i t_j]?
who where think-2s that has gone
'Who do you think that went where?'

(37) a. Ko_i zelite [da vam šta kupi t_i]?
who want-2p to you what buy-3s
'Who do you want to buy you what?'
b. Šta_i zelite [da vam ko kupi t_i]?
what want-2p to you who buy-3s
'Who do you want to buy you what?'

(38) $[_{CP}\ WH_i\ WH_j \ldots [_{CP}\ [_{SPEC,\ CP}\ t_i'[t_j']] \ldots t_i\ t_j \ldots]]]$

Since the matrix verb selects a –WH complement, both *wh*-expressions must take matrix scope. This happens obligatorily at S-structure in Bulgarian. In Serbo-Croatian, however, only one embedded *wh* can be fronted. The other *wh* must occur in the preverbal focus position. This is analogous to English, though it is possible to front the object *wh* as well as the subject *wh* without any apparent superiority effect. Rudin argues that languages that allow multiple *wh*s to adjoin to [Spec, CP] at S-structure (option 33a) provide an escape hatch for multiple *wh*-expressions to move through without violating subjacency, as shown in (38). Languages that adopt IP-adjunction for all but one *wh* instead (option 33c) encounter a subjacency violation if multiple *wh*s are extracted.[11]

This difference in adjunction sites, she notes, also accounts for the fact that nothing can intervene between the first *wh* and other *wh*s in Bulgarian but may

do so in Serbo-Croatian. In (39) the auxilliary obligatorily follows all the *wh*-expressions. In (40), on the other hand, it must follow the first *wh*-expression. Taking the auxiliary to be in C^0 accounts for the distribution. Similar arguments are made on the basis of adverbials and parentheticals:

(39) Koj (*e) kakvo (*e) na kogo e dal?
who what to whom has given

(40) Ko je što (*je) kome (*je) dao?
who has what to whom given
'Who gave what to whom?'

A related difference is in the order of fronted *wh*-expressions. In Bulgarian it is fixed. (39) instantiates the only permissible sequence for this sentence. In Serbo-Croatian, (40) shows one of six possible orders. Rudin points out that the restriction in fronting in Bulgarian mirrors superiority effects in English and suggests that Bulgarian *wh*-words occupy the same position at S-structure that English ones occupy at LF, namely [Spec, CP]. The first *wh* moves to Spec while the others adjoin to it, adjunction being to the right. It is therefore expected that restrictions on fronting should be correlated in the two languages even though they differ in the level at which *wh* movement takes place. The absence of superiority effects in Serbo-Croatian does not follow from its being a –MFS language (see section 2). The survey here indicates the relevance of these languages to a theory of syntactic movement.

*1.2.3 Languages without multiple-*wh-*questions*

The survey of typological variation would not be complete without noting that multiple-*wh*-questions are not universally available. The two best-known examples of languages that do not allow multiple-*wh*-questions are Irish, discussed in McCloskey (1979), and Italian, analyzed by Calabrese (1984).

McCloskey notes that (41a, b) are unacceptable in Irish and Calabrese gives (42) for Italian:

(41) a. *Cé aL rinne caidé?
who COMP did what
'Who did what?'
b. *Caidé aL thug sé do cé?
who COMP gave he to who
'What did he give to whom?'

(42) a. *Chi ha scritto che cosa?
'Who has written what?'
b. *Chi è partito quando?
'Who left when?'
c. *Quale ragazza ha dato un bacio a quale ragazzo?
'Which girl gave a kiss to which boy?'

(43) a. *MARIO ha scritto una LETTERA, (FRANCO un ARTICOLO, CARLO un LIBRO).
'Mario has written a letter.'
b. *FRANCO è partito alle CINQUE.
'Franco has left at five.'
c. *SANDRA ha dato un bacio a CARLO.
'Sandra gave a kiss to Carlo.'

According to McCloskey, multiple *wh* in Irish is impossible because Irish *wh*s are not generated in argument position. Instead they select for S' (CP), later followed by deletion of a pronoun in argument position. As he notes, however, to derive the absence of multiple-*wh*-questions, it would have to be stated that the selected S', CP be non-interrogative.

Calabrese correlates the absence of multiple-*wh*-questions in Italian with its disallowing sentences like (43), which have multiple focus and, intuitively, would form appropriate answers to (42).[12] His view is that *wh*-expressions are marked with a focus feature, which can only be assigned in the postverbal position in Italian. Thus, multiple-*wh*-questions are ruled out because such marking is necessarily restricted to one per clause.

McCloskey's and Calabrese's proposals locate the absence of the relevant forms to language specific properties (see below for Adams 1984 on this). Unfortunately, these proposals have not been pursued in subsequent literature and the theoretical implications of languages without multiple-*wh*-question remain largely unexplored. Legendre et al. 1998 discuss, for example, consequences of such languages for OT syntax. The question posed by the existence of such languages is what the optimal (hence grammatical) structure in Italian would be for the LF 'Who ate what?' They point out that the impossibility of any such structure shows that members of the candidate set are not determined on the basis of shared LFs, as in Grimshaw (1997b).

1.2.4 Optional-fronting languages

A question that might be worth addressing here is whether there are languages in which *wh*-fronting is optional. Though such languages have been reported, they do not intersect with strategies for multiple *wh*-formation in interesting ways. A familiar example of an optional-fronting language is French, but multiple-*wh*-questions in French are formed analogously to English. Furthermore, the option of having *wh*-in-situ in single-*wh*-questions is restricted to root clauses. French is therefore typically classified as a fronting language. Examples of languages considered to have true optional fronting are Bahasa Indonesian (Saddy 1991), Egyptian Arabic (Wahba 1991), and Palauan (Georgopoulos 1991b). However, the possibility of fronting in these languages is restricted to one *wh*-expression and there appear to be no superiority type effects, typical of movement to [Spec, CP]. Cheng (1997) provides evidence to argue that the apparent movement is, in fact, an instance of clefting and classifies these languages as in-situ. At any rate, no language has been reported in which there is the option of leaving all

wh-expressions in situ or moving all to [Spec, CP], that is, an optional-multiple-fronting language. We assume, therefore, that optional movement cross-linguistically is either scrambling (which can affect all *wh*-expressions) or clefting (which is restricted to a single *wh*-expression). In either case, the principles governing such movement would not be limited to *wh*-expressions but would apply to non-interrogative arguments as well.

1.2.5 Explanations for typological variation

In concluding our introduction to the multiple-*wh*-question phenomenon, let us consider how the attested variation in question formation strategies fits into the picture of universal grammar. As in other studies of typological variation, the goal is to derive differences on the basis of a few parametric choices.

The most worked out proposal has been made by Cheng (1997) and I will discuss that first. According to Cheng, all languages are required to distinguish interrogative clauses from non-interrogative ones at S-structure but they may differ with respect to how they do so. The Clausal Typing Hypothesis draws on the idea that a language may choose to mark interrogative clauses by the presence of a Q-morpheme in C^0, or by movement of a *wh*-expression to a [Spec, CP] from where C^0 can be marked +WH via Spec–Head agreement. Combined with principles of economy, this predicts that languages with Q-morphemes will be *wh*-in-situ languages since there would be no motivation for overt movement at S-structure. Languages without such morphemes would be forced to move one *wh* to [Spec, CP]. Languages like Chinese and English instantiate the two possibilities admitted by this approach. Multiple-fronting languages like Bulgarian and Serbo-Croatian, however, are not predicted by this approach since only one *wh* movement can be forced by the requirement for Clausal Typing. An auxiliary explanation is therefore called for to account for movement of the other *wh*-expressions.[13]

Cheng points to the fact that in the languages known to have multiple fronting, indefinites are formed by adding an affix to *wh*-expressions. From this she concludes that *wh*-expressions have a null interrogative determiner. Given that these languages lack Q-morphemes, one of the *wh*-expressions must move to [Spec, CP] for clausal typing. The motivation for movement of the other *wh*-elements, however, is independent of requirements of clausal typing. It is forced instead by the need for the null determiner to be licensed at S-structure, for which it must establish a local relation with the C^0_{+WH}. Adjunction to [Spec, CP] or to IP both qualify as governed positions, accounting for Rudin's distinction between +MFS and –MFS languages.

Another proposal for the existence of different strategies in question formation is presented by Adams (1984) and, following her, Rudin (1988b). This approach combines two standard views about parametric variation in *wh*-movement. One idea is that all languages require *wh* movement for interpretation but they differ in the level by which such movement must take place, an idea for which Cheng's Clausal Typing Hypothesis provides the motivation. This allows for the broad distinction between *wh*-movement and in-situ languages. The other is that

languages may or may not have a filter against multiple *wh*-words in Spec, originally formulated as the filter against Doubly Filled Comp. Though typically languages are expected to vary on this filter only at S-structure, Adams extends it further, arguing for a more general version of it: *[$_{\text{COMP/Spec, CP}}$ α COMP/Spec, CP] at level X of the grammar. By barring adjunction at LF as well as S-structure, she derives the fact that languages like Irish and Italian do not have multiple-*wh*-questions and by allowing adjunction at S-structure and LF, the fact that Bulgarian and Serbo-Croatian require multiple fronting.[14]

Rudin, adopting Adams's proposal, notes that although it works straightforwardly for +MFS languages, the status of fronting in –MFS languages requires further elaboration. She takes the fact that only one *wh* moves into Spec to be evidence that such languages are like English, and unlike Bulgarian and Romanian, in enforcing the filter at S-structure. To drive the distinction between English which leaves the other *wh*-words in situ and –MFS languages that require obligatory adjunction to IP, Rudin suggests that some languages may not allow LF movement to take place from A-positions. While this is needed to complete the account, it should be noted that this part of the proposal remains quite speculative.

In concluding this section, I would like to point out that explanations for cross-linguistic variation would have to be modified once alternative scope-assignment possibilities are admitted. For example, under Reinhart's proposal, non-multiple-*wh* languages cannot be derived by the Doubly Filled Comp Filter applying at S-structure and LF alone. Unless it is also stated that the language cannot interpret *wh*-expressions via choice functions, the possibility of *wh*-in-situ remains open. In the case of –MFS languages, Reinhart's proposal could open up an alternative explanation for obligatory IP adjunction. If such languages had the Doubly Filled Comp Filter at S-structure but not LF, it would allow movement of multiple *wh* at LF. Rudin's proposal that LF movement could only be from A'-positions, forcing partial movement at S-structure, could be motivated by positing a language specific ban against choice functions. No doubt, more work would have to be done to see whether such an approach would hold up against other considerations, such as Reinhart's theoretical objection to LF movement within a minimalist framework. And at the empirical level, it would have to be shown that regular indefinites in these languages behave differently from languages in which choice functions exist, a not too promising prospect. My goal here in making these suggestions is not to present them as serious proposals but merely to indicate how developments in the semantics of questions can impact on typological explanations.

2 Superiority effects

2.1 Amelioration under D-linking

In the previous section, I isolated two empirical properties of multiple-*wh*-questions – Superiority effects and Subjacency violations – and outlined in broad terms the possible cross-linguistic variation in the formation of multiple-*wh*-questions. I

would now like to take a closer look at these empirical properties and their theoretical import. The goal of this section is to probe the nature of Superiority effects, leaving Subjacency violations for section 3. We will begin our survey of Superiority by discussing the notion of D-linking, a condition under which such effects seem to be canceled. The impact of D-linking is shown for languages like English where one *wh*-expression is fronted, as well as for languages like Bulgarian where all such expressions move.

An important observation about Superiority is that the effects do not survive if the *wh*-expressions are changed from a monomorphemic *who*, *what*, etc. to a complex phrase of the form *which N*. These effects were noted by Katz and Postal (1964) and Bolinger (1978), but the first extensive discussion is due to Pesetsky (1987a):

(44) a. Who read what?
b. *What did who read?
c. Which book did which man read?

(45) a. Who did you persuade to read what?
b. *What did you persuade who to read?
c. Which book did you persuade which man to read?

A priori, the difference in acceptability could be due to a syntactic or a semantic difference. A possible syntactic difference might be that *which* is a specifier while *who/what* are heads. Pesetsky, however, rejects this possibility, pointing to the fact that *how many*, which would also be classified a specifier, displays superiority effects:

(46) a. I need to know how many people$_i$ t_i voted for whom.
b. *I need to know who(m)$_j$ how many people voted for t_j.

Pesetksy argues that the difference in superiority effects is due to a lexical dichotomy between *wh*-words, depending on whether they refer to a given set of entities in the context of utterance. While *which* phrases appear to bear the relevant relation to discourse inherently, monomorphemic *wh*-expressions can lend themselves to the relevant D-(discourse) reading in appropriate contexts. When they do, Superiority effects are not manifested, as shown in the following ((47a) is from Bolinger):

(47) a. I know what just about everybody was asked to do, but *what* did *who* (actually) do?
b. I know that we need to install transistor A, transistor B, and transistor C, and I know that these three holes are for transistors, but I'll be damned if I can figure out from the instructions *where* what *goes*.

The correct generalization, then, is that the Superiority condition applies to non-D-linked *wh* only or, alternatively, that D-linked *wh* are exempt from the

Superiority Condition. Pesetsky argues that the lexical distinction between two types of *wh*s correlates with a difference in methods of scope assignment. Non-D-linked *wh*s take scope via movement and are subject to the normal constraints. D-linked *wh*s get bound by unselective Q-operators (à la Choe and Nishigauchi) and are exempt from those constraints.[15] This is illustrated below:

(48) a. $[_i$ who$_i$ what$_j$ [t$_i$ read t$_j$]]
b. [Q$_i$ which book$_j$ [which man$_i$ read t$_j$]
c. **Nested Dependency Condition/Path Containment Condition:**
If two *wh*-trace dependencies overlap, one must contain the other.

In (48a) both *wh*-words move, being non-D-linked, violating (48c). In (48b), however, there is only one dependency at issue. The other *wh*-word being interpreted in situ via unselective binding. Monomorphemic *wh*-words, in contexts like (47), are interpreted similarly. Note that under this view, it is the D-linking of the *wh*-word in situ that is critical in the amelioration of Superiority effects. As pointed out to me by Chris Barker, however, (48b) is degraded if *which man* is replaced by *who*, a fact unexplained by Pesetsky's account.

Although Pesetsky's distinction has a semantic–pragmatic basis, the fact that *which* NPs are exclusively D-linked provides a diagnostic which he uses to argue for a third type of *wh*-expression. Since *the hell* in (49) is compatible with *what* but not *which* it is argued to be aggressively non D-linked:

(49) a. What the hell book did you read that in?
b. *Which the hell book did you read that in?
c. ?What the hell book did which man read?

Given his claim that only D-linked *wh* can be interpreted in situ, the fact that aggressively non D-linked *wh*-expressions exist provides a new tool for distinguishing moved vs. non-moved *wh*-expressions in languages. Sentence (49a), under this view, would be a question requiring obligatory movement. It should be noted, however, that this kind of expression does not readily occur in multiple-*wh*-questions. The question in (49c), to the extent that it is acceptable, does not lend itself to a multiple-pair answer and has the feel of an echo question. This, as far as I can see, does not follow from the account presented. Thus, some care needs to be taken in using such expressions to diagnose obligatory movement.

Pesetsky's identification of the role of D-linking in redeeming Superiority violations has been extremely influential in further developments in the theory of *wh*-scope phenomenon. It is worth noting, however, that the aspect of his account that has held up is the correlation between *which* phrases and non-canonical scope, not the claim that such expressions are interpreted in situ. A potentially important piece of evidence with regard to the status of D-linked phrases and (non)-movement comes from multiple-fronting languages. Pesetsky cites Wachowicz's (1974) discussion of Polish as corroborating the prediction made by

his theory that D-linked *wh*-expressions may be exempted from fronting. But these facts have not gone unchallenged (see Cheng 1997 for discussion).

Doubts about a non-movement analysis for D-linked *wh*-expressions surface when one considers Comorovski's (1989, 1996) discussion of multiple-fronting language. Recall Rudin's observation that +MFS languages impose a strict restriction on the order of *wh*-words (cf. 34 above) akin to the Superiority condition in English. Comorovski shows that this restriction is relaxed if the *wh*-words are D-linked. The following Romanian examples illustrate this point:

(50) a. [Pe care$_i$ cine$_j$ [t$_j$ l$_i$ a văzut t$_i$]]?
which-ACC who him has seen
'Which one was last seen by whom?'
b. *[Ce$_i$ cine$_j$ [t$_j$ a văzut t$_i$]]?
what who has seen

(51) a. [Despre care$_i$ cine$_j$ [t$_j$ ţi a vorbit t$_i$]]?
about which who to-you has told
'Who told you about which one?'
b. *[Despre ce$_i$ cine$_j$ [t$_j$ ţi a vorbit t$_i$]]?
about what who to-you has told

Comorovski also notes that in Romanian (and Bulgarian), extraction out of *wh*-islands are only acceptable under D-linking:

(52) a. [Despre care$_i$ [ştii [cine$_j$ [t$_j$ i a povestit t$_i$]]]?
about which you-know who to-him has told
'Which one do you know who told him about?'
b. *[Despre ce$_i$ [ştii [cine$_j$ [t$_j$ i a povestit t$_i$]]]?
about what you-know who to-him has told

It is clear from Comorovski's description of the facts that D-linking is a significant factor in overriding restrictions on fronting but not in making fronting itself unnecessary. This is corroborated in subsequent work on multiple fronting by Richards (1997). Of course, it should be noted that Pesetsky's claim that D-linked *wh* can be interpreted via unselective binding without movement does not commit him to a non-movement analysis. He addresses, for example, the question of why English single-*wh*-questions require fronting by appealing to a language-specific need for the Q-morpheme to be triggered by the presence of a *wh*-word in Spec. Similarly, multiple fronting of D-linked expressions could be motivated on the basis of their status as polarity items requiring a local relation with the Q-operator, as proposed by Cheng (1997). However, facts like (50–52) do strike a cautionary note against a simple correlation between D-linking and non-movement. Setting this aside, the role of D-linking as a factor in the formation and interpretation of multiple-*wh*-questions is generally accepted as having cross-linguistic validity.

2.2 Explanations for superiority

2.2.1 Within the Principles and Parameters framework

With the caveat about D-linking in place, let us turn to explanations of the basic Superiority phenomenon. The first explanation is found in Chomsky (1973), who explained it by positing the Superiority Condition. In combination with strict cyclicity, (53) derives not only the asymmetries observed in fronting but also *wh*-island effects:

(53) **Superiority Condition:**
No rule can involve X,Y in the structure . . . X . . . [$_{\alpha}$ . . . Z . . . WYZ . . .], where the rule applies ambiguously to Z and Y and Z is superior to Y.

Though the condition was essentially a description of the phenomenon in structural terms, it served to bring Superiority into theoretical center stage. Syntactic theory has since then grappled with this problem at every stage of its development. Instead of trying faithfully to summarize the many explanations that have been offered over time, I will try to highlight those analyses that have been particularly influential. Taking the Principles and Parameters model as a landmark, we can identify three distinct approaches to Superiority. As already discussed in section 1.1.2, a leading view of the phenomenon takes ECP as regulating fronting possibilities. Another proposal, discussed above (due to Pesetsky 1987a), takes the relation between two dependencies as critical to the explanation. A third approach, advocated by Aoun et al. (1987), relates superiority to Binding Theory.

The ECP-based account has already been shown to deliver the basic Superiority effect, namely, that, given a multiple-*wh*-question with one lexically governed argument and one not so governed, it is the latter that will be fronted. Here I would like to indicate some further issues that arise as a consequence. The approach predicts, for example, that a multiple-*wh*-question with two *wh*-expressions that are not lexically governed will be ungrammatical. The COMP-indexing mechanism will ensure that the overtly fronted *wh* will antecedent govern its trace but the other trace will necessarily remain ungoverned. This is shown in (54a, b):

(54) a. *How did John go where?
b. *Where did John go how?
c. Who went where?

One problem that this approach encounters is the determination of the class of *wh*-expressions that are lexically governed. In particular, the status of locative and temporal expressions, *where* and *when*, is an issue. The unacceptability of (54a) suggests that the trace of *where* could not be lexically governed, but there are other cases, such as (54c), where the explanation for acceptability turns on the trace being lexically governed. Attempts have been made to address this

question but we will not discuss them at any length here, simply alerting the reader to the fact.

An interesting problem that surfaces under this approach has to do with the effect of additional *wh*-expressions. They seem to improve the violation, even when that additional *wh* does not leave a lexically governed trace. This problem, noted in passing by Chomsky (1981), was discussed at some length by Kayne (1984a). In fact, he discussed the effect of an additional *wh* in the context of Superiority violations. (55a, b) and (56a, b) show normal constraints on fronting. The questions in (55c) and (56c) show the improvement due to the presence of an additional *wh*:

(55) a. I'd like to know who hid what there.
b. *I'd like to know what who hid there.
c. ?I'd like to know what who hid where.

(56) a. I'd like to know who hid it where.
b. *I'd like to know where who hid it.
c. ?I'd like to know where who hid what.

(57) a. Let $\beta_1 \ldots \beta_j, \beta_{j+1} \ldots \beta_n$ be a maximal set of empty categories in a tree T such that $\exists\alpha, \forall j, \beta_j$ is uniformly bound by α. Then $\{\alpha\} \cup (\cup_{1\leq j\leq n} G_{\beta-j})$ must constitute a subtree of T.
b. *[[$_\alpha$ where] [[$_1$ who] [$_2$ [hid] [it]]
c. [$_2$[$_\alpha$ where] [$_2$ [$_1$ who] [$_2$ [$_2$ hid] [$_2$ what]]

According to Kayne, what is relevant in these cases is whether the fronted *wh* and the *wh*-element(s) in situ can satisfy connectedness, as defined in (57a). The unacceptable (56b), for example, has a representation as in (57b). The *wh*-in-situ, not being canonically governed, cannot form an appropriate sub-tree with the fronted *wh*-word. The additional *wh*-word in (57c) is governed by the verb. Being governed in the canonical direction for the language, its g-projection extends upwards, connecting with the fronted *wh*-word and properly including the subject *wh*-word in-situ. This is shown in (57c).

Kayne's augmentation of the ECP-based accounts remained till very recently the primary explanation for these facts. Note that this augmentation of the theory is distinct from the one argued for by Pesetsky (1987a) in that it seeks to regulate ordinary *wh*-expressions, not a special class of D-linked expressions. Similar augmentations would be required within theories adopting the Path Containment Condition (cf. 48c).

Aoun et al. (1987) propose an account that seeks to unify explanations for standard superiority effects and their absence with D-linked *wh*. It takes as its governing principle the Generalized Binding Theory of Aoun (1986):

(58) a. An anaphor must be X-bound in its governing category.
b. A pronominal must be X-free in its governing category.
c. An R-expression must be A-free. (where X = A or A′)

According to them, the critical difference between *wh*-expressions that do and those that do not display Superiority is in their structural complexity. Arguing that QR moves only the *wh*-quantifier, not its restriction, they posit the following representations:

(59) a. *What did who buy?
b. $[[_i \text{ what}_i \text{ who}_j] [t_j \text{ AGR}_j \text{ buy } t_i]]$

(60) a. Which book did which woman buy?
b. $[[_i \text{ which book}_i \text{ which}_j] [[t_j \text{ woman}]_k \text{ AGR}_k \text{ buy } t_i]]$

Taking traces to be anaphoric elements subject to Principal A, they note an important difference between the two cases with respect to whether AGR counts as an accessible Subject for the subject trace. In (59b) it clearly does, defining the governing domain within which the anaphor-trace must be A'-bound. In (60b), however, AGR is indexed with the NP containing the anaphor trace. The trace therefore does not have a governing domain and can remain free.

The Generalized Binding Account is meant to be a purely structural account of variation in superiority effects, potentially rendering Pesetsky's empirical generalization irrelevant to movement theory. As pointed out by Comorovski (1996), is it not clear whether this is so. She notes that cases claimed to show the irrelevance of non-D-linked Superiority violations, in fact, do carry presuppositions. Though the *wh*-words in (61) may not range over a set of familiar entities of the ordinary sort, they arguably range over a set of familiar kinds. She notes that a purely structural account of the phenomenon must meet the challenge of creating contexts showing this not to be the case. Recall that (46) above, where *how many N*, though complex, is shown to display superiority effects, makes the same point:

(61) Which type of book does which type of man read?

2.2.2 Economy-based accounts

A fundamental shift in the nature of the explanation for Superiority effects occurred with the advent of the Minimalist Program (Chomsky 1993, 1995c) and Optimality Theory (Prince and Smolensky 1993). The guiding idea behind the Principles and Parameters model was that movement was always available unless such movement resulted in a structure that violated some principle of grammar. In contrast, the intuition informing Minimalism was to take movement as undesirable, unless forced by some principle. This conceptual shift is marked by the replacement of Move α by Movement as Last Resort as a central tenet of syntactic theory.

Consider the explanation for Superiority proposed in Chomsky (1993). Movement is forced only when the morphological features of an expression need to be discharged under a feature-match with a functional category, as stated in the principle of Greed. Further, Procrastinate rates covert movement less costly than

overt movement. Finally, Shortest Move requires movement to be to the closest potential landing site where Greed can be satisfied. This means that *wh*-expressions, across and within languages, can differ in whether they have strong features that would force movement or weak features that could not trigger movement. Since only one *wh*-expression is fronted in English multiple-*wh*-questions, it follows that only one *wh*-expression carries strong features. The Superiority effect, then, reduces to a question about determining why subjects, rather than objects, in the basic case, must carry strong features. Before we look at the specifics of the explanation, it may be worth noting that *wh*-expressions that do not carry strong features will still need to be interpreted, either via covert movement or via choice functions, as argued by Reinhart (1997).[16]

To return to the question of Superiority, one approach is to take Shortest Move to apply transderivationally. As elaborated in Kitahara (1994) and Oka (1995), the optimal candidate is chosen from a set of convergent derivations having the same numeration and the same LF. Under this view, (62a) and (63a) belong in the same reference set since they have identical LFs. It is obvious that Shortest Move is respected in the former but not in the latter, specially if the choice-function analysis is adopted for interpreting *wh*-in-situ. Note that this requires constraints to hold globally:

(62) a. [who$_i$ [t$_i$ saw what]]
b. [what$_j$ who$_i$ [t$_i$ saw t$_j$]]
c. [Q$_j$ who$_i$ [t$_i$ saw t$_j$]]

(63) a. *[what$_j$ did [who see t$_j$]]
b. [who$_i$ what$_j$ [t$_i$ saw t$_j$]]
c. [Q$_i$ what$_j$ [t$_i$ saw t$_j$]]

An alternative possibility, mentioned in Chomsky (1993) and developed more fully in Chomsky (1995c), is to put the burden for movement on the properties of the functional category which is the target of movement, rather than on the moved expression. Given this view, *wh*-expressions can be thought of as a morphologically unified class. We start, then, with a C^0 that needs to attract a *wh*-expression to its Spec in order to satisfy its requirements, in effect replacing the notion of Move with that of Attract. Now, there is a natural sense in which the subject can fulfil this requirement more economically than the object. The Minimal Link Condition is built into the definition of Attract in such a way as to capture this intuition. Note that this approach to Superiority does not rely on a global application of the constraints. This line of thought has been fully explored in Kitahara (1997).

Accounts of multiple questions within Optimality Theory also play on the tension between formal requirements forcing fronting, such as Op-Spec, and a general preference against movement such as Stay (Grimshaw 1997b). By ranking Op-Spec > Stay, fronting of one *wh*-expression is forced. She discusses the paradigm in (64):

(64) a. What will they put where?
b. *What will where they put?

In (64a), OP-SPEC is violated by *where* while STAY is violated by *what*. In (64b), with *where* moving to an internal specifier position, *where* violates STAY in addition to OP-SPEC. (64a) is the optimal candidate since it involves one less violation of STAY. Although Superiority effects per se are not discussed there, it should be clear how optimal candidates can be identified on the basis of ranked constraints. Some interesting correlations between Minimalist accounts and OT accounts are made in essays contained in Barbosa et al. (1998), in particular Ackema and Neeleman and Legendre et al. Ackema and Neeleman (1998), for example, derive the basic superiority effect through the interaction of three ranked constraints Q-marking (requiring a *wh* in [Spec, CP]) ≫ Stay (prohibition against movement) ≫ Q-Scope (requiring all *wh*-expressions to front). The tableau in (65) shows how the explanation works. It should be obvious how differences in ranking can result in different cross-linguistic possibilities for fronting.

(65)

	Q-Marking	Stay	Q-Scope
☞ Who has seen what		******	*
What has seen who		*******!	*
Who what has seen		*******!****	
Has who seen what	*!	***	**

There are further interesting developments within economy-driven approaches that we will discuss in section 2.3 but before doing that I would like to turn to a somewhat different view of the meaning of *wh*-expressions that has proved influential in recent literature and discuss its impact on studies of superiority.

2.2.3 *Accounts based on functional* wh

Another recent approach to Superiority effects takes its cue from the semantics of questions with quantifiers. An observation in the literature, dating back to Kiss (1993) and Comorovski (1989) is that multiple-*wh*-questions require a list answer in which every member of the subject term is paired but no such requirement is imposed on the object. Consider the following contexts given in Dayal (1996a). In (66a) the fact that there is a woman who will not get paired does not seem to affect the felicity of the question, but in (67) the fact that a man will not get paired makes the question infelicitous:

(66) a. **Speaker A:** We're organizing singles tennis games between men and women. There are three men interested in playing against women, namely Bill, Mike and John. But there are four women interested in playing against men, namely Mary, Sue, Jane and Sarah.
b. **Speaker B:** So, which man is playing against which woman?

(67) a. **Speaker A:** We're organizing singles tennis games between men and women. There are four men interested in playing against women, namely Harry, Bill, Mike and John. But there are only three women interested in playing against men, namely Mary, Sue and Jane.
b. **Speaker B:** So, which man is playing against which woman?

Though the judgments are delicate there is a clear contrast which holds up against a wide range of data. This property of multiple-*wh*-questions has been explained by Hornstein (1995), Comorovski (1996), and Dayal (1996a), working independently, in terms of Chierchia's (1993) explanation for the subject–object asymmetry in questions with quantifiers. A question with a universal quantifier in subject position allows functional answers and list answers while a question with the universal in object position allows neither:

(68) a. Which woman does every man like?
b. (Every man likes) his mother.
c. John likes Mary and Bill likes Sue.

(69) a. Which woman likes every man?
b. *His mother (likes every man).
c. *Mary likes John and Sue likes Bill.

Building on the view in Engdahl (1986) that *wh*-expressions can quantify over functions from individuals to individuals, Chierchia argues that functional *wh*-expressions leave a doubly indexed functional trace. The subscripted i-index identifying it with the *wh*-operator is the functional variable. The superscripted a-index, which can be bound by a c-commanding argument, is an individual variable. Intuitively, the a-index corresponds to the pronoun in the functional answer and may be taken as having a pronominal character. The LF and interpretation for the functional reading of (68a), under this account, is given below:

(70) a. [which woman$_i$ [every man$_j$ [t_j likes t_i^j]]]
b. $\lambda p \exists f[\forall x(\text{woman}'(f(x))) \wedge p = \forall y[\text{man}'(y) \rightarrow \text{like}'(y, f(y))]]$
$\Rightarrow$ {Every man likes his mother, Every man likes his wife, Every man likes his girlfriend}

Wh-quantification here is over variables whose possible values are functions to a set of women, such as *mother-of*, *wife-of*, etc. The functional reading of the question denotes the set of propositions, each of which states that every man likes the individual he stands in some functional relation to. One of these propositions will be the true answer in a given context. The list answer, roughly speaking, is the graph of a function, listing for each member of the domain set the individual who stands in the relevant functional relation to that individual. We will defer further details of the implementation till section 3, except to note that the universal term which provides the domain set has to take scope outside the propositional variable p.

Turning to (69), Chierchia notes that for functional binding to take place an LF like (71a), in which the quantifier c-commands the *wh* trace, would be needed. Structure (71a) is ruled out as a case of weak-crossover violation since the variable t_j is coindexed with a pronoun to its left, the a-index of the *wh*-term:[17]

(71) a. *[which woman$_i$ [every man$_j$ [t^j_i likes t$_j$]]]
b. [which woman$_i$ [t$_i$ [every man$_j$ [likes t$_j$]]]

The well-formed LF in (71b) has the quantifier adjoined to VP from which no functional binding can take place. The absence of list answers to questions with quantifiers in object position follows since list answers under this approach are derivative on functional answers. The only available answer here is therefore the individual answer.

Hornstein, Dayal, and Comorovski each point out that if multiple-*wh*-questions can encode the kind of functional dependencies that questions with quantifiers can, in a question with two *wh*-expressions, the a-index of one *wh* can be bound by the other. Taking an example like (72a), there would be two potential LFs for it, only one of which would be syntactically well-formed:[18]

(72) a. Which man saw which woman?
b. [$_{CP}$ [which woman$_j$ [$_{CP}$ which man$_i$ [$_{IP}$ t$_i$ like t^i_j]]]]
c. *[$_{CP}$ [which woman$_j$ [$_{CP}$which man$_i$ [$_{IP}$ t^i_i like t$_j$]]]]

In (72b) the subject term binds the a-index of the object term and there is no problem with this binding. In (72c) the object term binds the subject term but this involves a WCO violation since *which woman* crosses over the pronominal a-index of *which man* in order to bind it. This provides a straightforward account of why it is the subject *wh* has the 'universal force' identified by Kiss and Comorovski. Dayal (1996a) also provides evidence showing that in languages where scrambling overcomes WCO violations, it is possible to get the universal reading for the scrambled object.[19] It is against this background that Hornstein and Comorovski develop their accounts of Superiority. Hornstein presents a number of cases showing the correlation between superiority effects and WCO as support for the general approach. The explanation can be demonstrated on the basis of a basic Superiority case like (73a). Given the Minimalist framework, the fronted *wh*-word is assumed to leave a copy in base position and one of them must be deleted before interpretation:

(73) a. What$_i$ [who buy what$_i$]?
b. What$_i$ [who^i_j buy t$_i$]
c. Who$_i$ [t$_i$ buy what^i_j]

(74) a. [What [who bought what]
b. [[who bought what]
c. [who [who bought what]
d. [who [t bought what]

Hornstein assumes that *wh*-words that bind syntactic variables can be interpreted as ranging over individuals, thereby providing the domain of the function. Full copies are interpreted functionally. Translating this into the current representation, this allows for two interpretive possibilities for the structure in (73a). The possibility in (73b), where we have a function from things to individuals who bought those things is ruled out as a WCO violation. The question that remains for Hornstein is why the possibility in (73c) is ruled out. This would require the steps in (74), deletion of the moved *wh*-word (74b), movement of the in-situ *wh*-word (74c), followed by deletion of its copy (74d). But, as he notes, a structure respecting superiority would yield this result more economically since it would require only two steps (74c and 74d). Thus, (73a) is either ruled out by WCO (74b) or blocked by a more economical derivation. There are further possibilities within the minimalist assumptions for deriving this effect considered by Hornstein, which I will not go into here.

Now, consider what happens when the *wh*-expressions are D-linked. The structure in (75b) shows that deleting the copy of the fronted *wh*-element and interpreting the expression in Spec leads to the familiar WCO violation, analogous to (73b) above. The key difference here, according to Hornstein, is that D-linked *wh*s do not have to be fronted in order to be interpreted as the domain term. Thus the derivation in (76) is viable. Crucially, there is no difference in the number of steps needed to interpret the structure regardless of whether the subject or the object is fronted:

(75) a. [which book [which man review which book]]
b. *[which book$_j$ [which man^j_i review t$_j$]]

(76) a. [which book [which man review which book]]
b. [[which man$_i$ review which book^i_j]]

Comorovski starts from a different premise. She points out that a list answer to a multiple *wh* requires the members of the domain set to be given. This says, in effect, that at least one *wh*-expression must be D-linked. Two questions arise at this point. Why is there no discernible D-linking for subjects in multiple-*wh*-questions respecting Superiority? What role does D-linking play in Superiority violations? Comorovski draws on the idea in Kuno (1982) that a multiple question is a request for information about pairs, where the question provides a sorting key for arranging that information. In general, subjects tend to carry old information and are natural sorting keys.[20] Fronting of an object *wh*-word is a signal for a change in the structurally encoded criterion for sorting. In functional terms, this means that the object *wh*-word sets the domain of the function:

(77) a. Which book did which man recommend?
b. [which man$_j$ [which book$_i$ [t^i_j recommend t$_i$]
c. [Its$_i$ author] recommended each book$_i$ / Each book was recommended by its author.

It remains to be explained, then, why there is no perceived WCO effect. Comorovski notes that backward anaphora is generally possible with universals like *each N*. What *each*-universals and *which* NPs share is the fact that they both carry existential presuppositions, the intuition driving the term D-linking. Taking the presuppositional nature of a *wh*-term to be criterial in over-riding WCO, Superiority violations are claimed to be predictable on the basis of their possible functional answer.

While Hornstein and Comorovski both take the functional *wh*-approach as a key element of the explanation, they end up with very different results. For Hornstein, the subject that has been crossed over by a D-linked *wh* remains the domain term but not for Comorovski. This difference is, in principle, testable. However, it should be noted that Hornstein's conclusion about the nature of the pairings permitted in a question with two *which* Ns does not accord with the intuitions reported in (66–67) above. For him, two D-linked phrases require the members of each term to be exhaustively paired so the direction of functional dependency is not predicted to make a difference. Comorovski, however, does predict that in acceptable cases of Superiority violation, it will be the object-*wh*-word that is exhaustively paired while the subject *wh* may or may not be. In unpublished work, Dayal (1994) reported that Superiority violations do result in a requirement of exhaustivity for the object *wh* but the judgments for the subject term were unclear. Similar effects seem to obtain for scrambled versions of multiple-*wh*-questions in languages like Hindi and Japanese, which is suggestive that the same points may be at issue (Dayal 1996a). It would be fair to say, however, that the semantic consequences of Superiority violations remain an open issue in functional and other accounts of multiple-*wh*-questions.

2.3 Typological variation in Superiority effects

2.3.1 Superiority in multiple-fronting languages

Having surveyed a range of explanations for Superiorty effects in English, let us return to the issue of ordering in multiple-fronting languages. Recall that the basic generalization in Rudin was that in +MFS languages, where all movement was to [Spec, CP], there was a strict ordering among the fronted *wh*-word while in the –MFS languages the order was free. This issue is taken up in Richards (1997) who proposes an explanation within the Minimalist framework.

Richards takes Bulgarian multiple-*wh*-questions such as (34), repeated below in (78), as his starting point. As shown in (78a), the first step in the derivation involves movement of the highest *wh*-word as an instance of Attract Closest. This is analogous to the English Superiority case. The fact that the second *wh*-word, when it moves, is 'tucked in' as in (79b) rather than extending the tree with an outer specifier as in (79c), is argued to be evidence that Shortest Move is in play:

(78) a. Koj kogo vižda?
who whom sees
'Who saw whom?'
b. *Koj vižda kogo?

(79) a. [$_{Spec}$ koj$_i$ [t$_i$ vižda kogo]]
b. [$_{Spec\text{-}1}$ koj [$_{Spec\text{-}2}$ kogo$_j$ [t$_i$ vižda t$_j$]]
c. *[$_{Spec\text{-}2}$ kogo$_j$ [$_{Spec\text{-}1}$ koj$_i$ [t$_i$ vižda t$_j$]]

Bošković (1997), however, extends Rudin's paradigm by noting that although there are strict restrictions on the leftmost *wh*-word, the order of other *wh*-expressions in Bulgarian is relatively free (see also Comorovski 1996). Thus, putting the direct object before the indirect object does not lead to ungrammaticality in (80b). The order of the tucked in *wh*-expressions appears to contradict Attract Closest:

(80) a. Koj na kogo kakvo dade?
who to whom what gave
b. ?Koj kakvo na kogo dade?

Richards explains this paradigm on the basis of a Principle of Minimal Compliance which he describes using the following metaphor. In a given structure, if one expression pays the taxes imposed on movement within that structure, other such expressions are exempted from paying those taxes. In this case, the second and the third *wh*-expressions are exempted from Attract Closest since the dues are paid by the first *wh*-word. As Richards notes, multiple-fronting-languages provide strong empirical argument against the claim in Chomsky (1995c) that each overt operation must extend the tree at its root.

Given that Richards argues for 'tucking in' of *wh*-expressions, the issue of Superiority violations under D-linking becomes relevant. He posits a Topic phrase above CP and allows D-linked *wh*-expressions to optionally have matching morphological features. This makes it possible for a D-linked object to move to the left of a subject. Picking up on these issues, Pesetsky (2000) proposes further refinements in the theory. According to him, *wh*-expressions may undergo three distinct types of movement: overt phrasal movement, covert phrasal movement, and feature movement. Adopting a single output syntax, Pesetsky locates the difference between overt and covert movement in pronunciation rules which target either the head or the tail of a movement chain. Feature movement, on the other hand, is the attraction of a morphological feature from within a phrase by some category. The full phrase, because it does not undergo any movement, is necessarily pronounced in situ. Crucial evidence from ACD phenomenon is presented for this three-way distinction but for reasons of space I will not go into those arguments here, confining myself to demonstrating how typological variations in multiple-*wh*-questions are derived under this approach. There are two other pieces that play a role in the explanation. Languages can differ in having multiple- or single-Spec Complementizers; only phrasal movement can satisfy multiple-Spec requirements. In multiple interrogatives with D-linked *wh*-words, this requirement is suspended or, alternatively, D-linking is compatible with single-Spec Complementizers. Pesetsky leaves this open.

Superiority effects in non D-linked questions and their absence in D-linked questions are explained as follows:

(81) a. Who $C_{m\text{-SPEC}}$ [___ saw whom] *phrasal movement of* who *due to* $C_{m\text{-SPEC}}$
b. Who whom $C_{m\text{-SPEC}}$ [___ saw ___] *phrasal movement of* whom *due to* $C_{m\text{-SPEC}}$
c. Pronunciation in English: S V O
d. Pronunciation in Bulgarian: S O V

(82) a. $C_{1\text{-SPEC(f)}}$ [f-which woman saw which man] *feature movement of* which woman *due to* $C_{1\text{-SPEC}}$
b. Which man $C_{1\text{-SPEC(f)}}$ [f-which woman saw ___] *phrasal movement of* which man *due to* $C_{1\text{-SPEC}}$
c. Pronunciation in English: O S V
c. Pronunciation in Bulgarian: O S V

In (81) phrasal movement of both *wh*-words is forced by the multiple-Spec requirement. This is suspended in the case of D-linking (82), making it possible for the subject to undergo feature movement. As would be obvious, the explanation for the absence of Superiority effects turns on the role of D-linking in allowing multiple *wh* interrogatives with single-Spec Complementizers. As noted by Pesetsky himself, one weakness in the proposal is that the crucial connection between the semantic property of D-linking and syntactic scope mechanism remains as elusive as in earlier accounts of the phenomenon.

Pesetsky also accounts for the fact that Superiority effects disappear in the presence of extra *wh*-words even without the benefit of D-linking. The relevant steps for a representative case are as follows:

(83) a. $C_{m\text{-SPEC(f)}}$ [f-who put what where] *feature movement of* who *due to* $C_{m\text{-SPEC}}$
b. What $C_{m\text{-SPEC(f)}}$ [f-who put ___ where] *phrasal movement of* what *due to* $C_{m\text{-SPEC}}$
c. What where $C_{m\text{-SPEC(f)}}$ [f-who put ___ ___] *phrasal movement of* where *due to* $C_{m\text{-SPEC}}$
d. Pronunciation in English: What did who put where?

Crucially, there are two other *wh*-expressions that can undergo phrasal movement to satisfy the $C_{m\text{-Spec}}$ requirement, leaving the subject *wh* to undergo feature movement.

More work has been done on multiple-fronting languages, such as Grewendorf (2001), that is worth exploring, but in the interest of space I will end my discussion here and turn briefly to a different problem having to do with the cross-linguistic applications of explanations for Superiority.

2.3.2 Languages without Superiority effects

As would be obvious, the new typology of *wh*-movement opens up new ways of explaining typological variation, and in this concluding subsection I will outline how languages which do not show Superiority effects are accounted for. One such case, mentioned in section 1, is the class of languages classified –MFS by Rudin; another is German. For a –MFS language like Polish, Richards (1997) takes Rudin's general approach that they do not involve movement to Spec of CP. In Richards's terms, this means that multiple specifiers at CP level, with their

characteristic 'tucking in' effect, are not created in languages like Polish. Instead, apparent cases of multiple-*wh* fronting are essentially movement to multiple specifiers of IP. Since each such position is equidistant to C, Attract Closest is satisfied by movement of any *wh* to [Spec, CP] position.

German displays a different paradigm in that both SVO and OVS order are acceptable, with S and O as *wh*-expressions, without the benefit of D-linking. Pesetsky explains this by locating the difference between English and German in the possibility of $C_{m\text{-}SPEC}$. According to him, German lacks this possibility. Then it follows that in a multiple-*wh*-question, only one *wh*-word needs to move to fulfill the requirements of $C_{1\text{-}SPEC}$. The other *wh*-word necessarily undergoes feature movement, making a derivation analogous to (82) acceptable.

This account of the absence of Superiority effects presents an alternative to an earlier proposal by Fanselow (1991, 1997). His basic idea was that the apparent Superiority violation in German OSV is preceded by scrambling of O to pre-S position. *Wh*-movement from a scrambled structure will respect economy only if the Object is moved. Fanselow draws on the following contrast as further evidence:

(84) a. Wer glaubte, daß der Peter ihr wen vorstellte.
who-ACC believed that the Peter-NOM her-DAT whom-ACC introduced
'Who believed that Peter introduced whom to her?'
b. ?*Wen glaubt wer, daß der Peter ihr vorstellte?

In (84b) the embedded object cannot occur to the left of the matrix subject. This is because to do so would first require the object to scramble long-distance to the pre-subject position and then the *wh*-element to move to [Spec, C]. Fanselow shows that such long-distance scrambling is not available out of finite clauses, providing independent evidence for the proposed reliance of Superiority violations on scrambling possibilities. This proposal has been critiqued by Pesetsky, to which I refer the reader.

We have seen that fronting possibilities in multiple-*wh*-questions have played a critical role in the development of syntactic theory. Within the Principles and Parameters model they provided evidence for the ECP and within Minimalism and Optimality Theory they are shaping the view of economy/optimality in language. While the issues touched upon in this section raise further questions worthy of exploration, we will conclude our survey of the theoretical issues related to the Superiority phenomenon and turn to the Subjacency phenomenon in the next section.

3 Subjacency and *wh*-in-situ

3.1 The diagnostic of possible answers

3.1.1 Single- vs. multiple-pair answers

In moving from a survey of issues surrounding Superiority to a survey of issues surrounding Subjacency, we shift from direct evidence in the form of grammaticality

judgments about fronting to indirect evidence about intuitions regarding possible answers. It would, therefore, be appropriate to begin by taking a closer look at the diagnostic of possible answers. As mentioned in section 1, a standard assumption in the literature is that possible answers specify values for all and only those *wh*-expressions that take matrix scope. In the case of simple single-*wh*-questions, the answer specifies values for one expression, in the case of multiple-*wh*-questions for two or more, as the case may be. Given this assumption, the fact that questions like (15) and (17), repeated below, give values for more than one *wh*-expression is indirect evidence that the *wh*-expression inside the island is able to take matrix scope in violation of Subjacency:

(85) a. Which person knows the man who wrote which book?
b. Bill knows the man who wrote *Aspects*.

(86) a. Which student knows where Mary bought which book?
b. Bill knows where Mary bought *Aspects* and Sue knows where Mary bought *LGB*.

Dayal (2002) notes that although both allow a paired answer, the form differs. (85a) lends itself only to a single-pair answer; (86a) can readily allow a multiple-pair. (It may be possible to force a multiple-pair answer to (85a) by constructing specific contexts, but nothing particular needs to be done to get such answers for (86a).) Similar scope taking mechanisms violating Subjacency could not be involved in both constructions. Before looking at the Subjacency cases, however, we will examine the distinction between single- and multiple-pair answers in the basic cases.

Multiple-*wh*-questions have been said to have three different readings: a list reading, a REF-Q reading, and an echo-Q reading. These readings were identified by Bolinger (1978), Wachowicz (1974, 1975), and Pope (1976), under various terms. The summary here is taken from Dayal (1996a), which relies on their observations as well as on the discussion in Comorovski (1989). To see the difference between the three, consider three situations in which the multiple-*wh*-question *Who cooked what?* can occur and the answers it admits in those situations.

Let us demonstrate the list reading first. Take a context in which there are several dishes on the table and the questioner knows several people who have cooked dishes. She asks (87a) and gets the response in (87b):

(87) a. Who cooked what?
b. John cooked the meat, Bill cooked the rice, and Sue cooked the vegetables.

As Wachowicz puts it, the information the questioner is interested in is the proper pairing between two given sets. This reading crucially presupposes that there will be at least two pairs in the list. This is what we are calling the multiple-pair reading.

Now, let us turn to the echo reading of the question. An appropriate context is one where the questioner only hears part of an utterance and wishes the utterance to be repeated. In the following, subscripting is supposed to indicate a string that is phonetically unclear:

(88) a. $_{\text{John}}$ cooked $_{\text{the meat}}$
b. Whó cooked whát?
c. John cooked the meat.

Echo questions can be distinguished from ordinary ones by their rising intonation.

Finally, consider REF-Questions, which ask for the identity of a unique pair of individuals, as opposed to a list of pairs. (88b), uttered in response to (88a), would have a REF-Q reading:

(89) a. He cooked something
b. Who cooked what?
c. John cooked the meat.

REF-Questions were classified by Wachowicz as a type of echo question but Pope shows that though they are similar to echo questions they are intonationally distinct. The *wh*-expressions do not need emphatic stress and are uttered with the same fall in intonation as ordinary questions. Further, they are not requests to repeat the information already provided in the discourse, but rather for an elaboration.

That REF-Questions differ from echo questions can also be shown by cases that are clearly not triggered by previous utterances. The questions in (89a) and (89b) can be asked without a particular context and be answered with just a single pair of individuals. All that is required is that the questioner know that only a single pair can be named in the answer. Question (90a), for example, pragmatically rules out a multiple-pair answer. Similarly, if there are only two individuals, only one of them can be the first to hit in (90b):

(90) a. Who killed Robert Kennedy when?
b. OK, who hit who first?

There are two approaches that have been taken to the distinction between single- and multiple-pair answers. One is to treat it as a pragmatic effect. Under this view, questions are able to yield multiple-pair answers but they are not restricted to them. Single-pair answers are simply a sub-case of the larger possibility. The other approach is to take this distinction as arising from the semantic representation of the question and in the next subsection we will look at the various proposals that have been made to derive this distinction. The reason for taking the semantic approach to this phenomenon seriously is that there are empirical effects that cannot be handled in a pragmatic approach. We have already seen evidence from two different domains about the nature of restrictions governing

possible answers. In section 2.2.3 we saw that proponents of the functional *wh*-approach have appealed to the intuition that in a multiple-*wh*-question only one *wh*-expression, the superior one, is exhaustively listed and at the beginning of this section we saw that there are constructions where a pair answer is possible, but not a multiple-pair answer. Once we understand the semantic moves involved in deriving the two possibilities, we will re-examine the phenomenon of Subjacency violations with *wh*-in-situ.

3.1.2 Deriving single- and multiple-pair answers

Higginbotham and May (1981) were the first to attempt an account of pair-list answers by proposing a semantic operation they termed 'absorption'. The goal of this operation was to provide a transition from uniqueness effects in single-*wh*-questions like (91a) to multiple-pair answers in (91b). Although their proposal has been widely accepted in the syntactic literature, the details of the semantic operation are somewhat difficult to decipher:

(91) a. Which man came to the party?
b. Which man knows which woman?

In this section I will present the account of the switch from uniqueness to list answers proposed in Dayal (1996a), which has the advantage of being embedded in the propositional theory of questions introduced in section 1.

Dayal based her account on the paradigm below, where (92a) requires a unique individual to be named in the answer, (92b), a plurality of individuals, while (92c) is neutral in this regard:

(92) a. Which man came to the party?
b. Which men came to the party?
c. Who came to the party?

(93) a. $\lambda p\ \exists x$ [man/men(x) and p = x came to the party]
b. {a came, b came, c came};
c. {a came, b came, c came, a+b came, a+c came, b+c came, a+b+c came}
d. $Ans(Q) = \iota p\ [p \in Q \wedge {}^{\vee}p \wedge \forall p' \in Q\ [{}^{\vee}p' \rightarrow p \subseteq p']]$

Adopting the view that the domain of individuals includes atomic entities as well as their sums, she makes the existential *wh*-quantifier sensitive to number morphology. Now, in the singular case, the question denotes the set in (93b), in the plural case the set in (93c).[21] Further, she defines the Answerhood operator, as shown in (93d), to pick out the maximally informative true proposition in the set, namely the one that entails all the others. In the singular case, there can be no entailment relation between the various members of the set so the question can be answered only if a unique proposition is true. In the plural case, however, there can be more than one true proposition since their conjunction can satisfy (93d). Although the semantics allows there to be only one true proposition in the

set, say *a came*, there is assumed to be an implicature that a plurality of individuals have the property in question. *Who* is taken to be like the plural case minus the plurality implicature.

Turning to multiple-*wh*-questions, it should be obvious that (93d) – if applied to the Hamblin sets – presented in section 1, for example – will yield single-pair answers. In section 2.2.3 we discussed the functional approach to multiple-*wh*-questions advocated by Hornstein (1995), Dayal (1996a), and Comorovski (1996). As argued by Dayal (1996a), the functional approach derives the intended effects only if two conditions are added to the proposal of Chierchia (1993). One is the Answerhood operation introduced above, the other is the requirement that each proposition in the set be a full graph of the function. Let us consider this with the help of a concrete example:

(94) a. Which man$_i$ likes which woman^i_j?
b. [Which woman$_j$ [Which man$_i$ [t$_i$ likes t^i_j]]]
c. $\lambda p\ \exists f_{<e,e>}$ [Dom(f) = man & Range(f) = woman & p = $\cap$ $\lambda p' \exists x$ [p'= like(x,f(x))]]
d. {a likes c and b likes d,
a likes c and b likes c,
a likes d and b likes d,
a likes d and b likes c}

The question is analyzed as involving a functional dependency respecting WCO, as in (94a). At LF we take the *wh*-in-situ to undergo A′ movement to [Spec, CP] and the logical representation is as given in (94c). Without going into the details of the derivation, a functional dependency is posited whereby the subject term sets the domain of the function, the object term its range and the propositions relate individuals in the domain set with some functionally dependent entity in the range set. Crucially, each proposition in the denotation of the question is a conjunction of the atomic propositions obtained by varying the values of x and its dependent element f(x) in the IP denotation. If the set of men = {a,b} and the set of women = {c,d}, the question denotes the set of four propositions in (94d), where each proposition is the graph of a function relating the domain and the range sets. Although the particulars of this operation differ from that proposed by Higginbotham and May, this too can be thought of in terms of Absorption of two *wh*-operators.

The Answerhood operator in (93d), when applied to sets derived via Absorption, picks out a unique maximally true proposition from the question denotation. As would be obvious, each possible answer ensures that the domain set is exhaustively paired and that the pairings are not one–one or many–one. This is because although *a and b both like c* is acceptable as an answer to (94a), *a likes c and d* is not (see Engdahl 1986 and Dayal 1996a for further discussion of this issue). The ambiguity of multiple-*wh*-questions in allowing single pair vs. multiple-pair answers, on this account, rests on the lexical ambiguity of *wh*-expressions in being ordinary individual quantifiers, or expressions that can enter into functional dependencies.[22]

Note that there are two key factors in deriving the desired effects, each proposition in the set must represent the full graph of the function and only one proposition must be picked out as a possible answer. As shown in Dayal (1996a), Chierchia's analysis of questions with quantifiers is unable to derive appropriate answers because it allows atomic propositions in the set and takes the conjunction of any subset of the question as a possible answer. This problem is inherited by Comorovski (1996), who applies Chierchia's analysis to multiple-*wh*-question:

(95) a. $\lambda p\ \exists x\ \exists f_{<e,e>}$ [man(x) & Range(f) = woman & p = x like f(x)]
b. {a likes c, a likes d, b likes c, b likes d}

Comorovski's account, like Chierchia's and Engdahl's, yields sets of atomic propositions no different from ordinary Hamblin sets and does not impose restrictions on how many of them would enter into a possible answer. This predicts, in the case of (95), for example, that *a likes c and d* will be a possible answer, contrary to the stated goals of the analysis.

Recall that Hornstein's functional account differs from Comorovski's in not requiring covert movement of *wh*-in-situ. It is a bit hard to see what question denotations are at issue since he does not give a semantics for the structures. However, let me highlight a point that may be crucial in evaluating Hornstein's account. As we saw in (94), the relevant operation that delivers multiple-pair answers is possible only if both *wh*-expressions take scope outside C^0, where the propositional variable is introduced. That is, the LF representation of the multiple-*wh*-question must be as given in (94b). In this respect, his syntax for multiple-pair answers is no different from the syntax proposed for deriving standard Hamblin sets. Single-pair answers arise when the Answerhood operator applies to question denotations derived from *wh*-expressions interpreted as ranging over individual variables, multiple-pair answers from its application to question denotations where *wh*-expressions encode a functional dependency. For Hornstein's account to be complete, a semantics deriving the intended answers has to be given, which at this point has not been done.

3.2 Pair answers across islands

3.2.1 Single-pair answers across islands

In this section we will summarize the proposal in Dayal (2002), which is partially based on Dayal (1996a), for deriving the difference between the types of pair answer possible when the *wh*-expressions are separated by an island. The primary empirical generalization there is that multiple-pair answers are restricted to *wh*-islands that conform to a particular format dubbed *the* wh-*triangle*, with single-pair answers available in the other cases. We will begin by summarizing the account for single-pair answers across islands before considering the role of the *wh*-triangle.

It might be worth recalling that the possibility for *wh*s-in-situ to take scope outside islands has been explained in a number of ways; to mention just a few,

by taking Subjacency to be inapplicable at LF (Huang 1982a), by unselective binding of D-linked *wh*-expressions (Pesetsky 1987a), and by existential closure involving a choice function interpretation for *wh*-in-situ (Reinhart 1997). None of these proposals, however, have taken the distinction under discussion into account, so it may be worth demonstrating this explicitly. While (96b) is a perfectly acceptable answer to (96a), (96c) is at least an awkward, if not a clearly unacceptable answer to it:

(96) a. Which linguist will be offended if we invite which philosopher?
b. Professor Smith will be offended if we invite Professor Brown.
c. #/*Professor Smith will be offended if we invite Professor Brown, and Professor King will be offended if we invite Professor Matthew.

This also holds of multiple-*wh*-questions such as the following, cited commonly in the literature as showing wide scope of *wh*-in-situ:

(97) a. Which student read the book that which professor wrote?
b. Which student got a headache after she read which book?

In order to account for this fact Dayal (2002) notes that the operation for forming multiple-pair answers given in section 3.1.2 must be blocked from holding across islands. She constrains the Absorption associated with functional dependencies from holding across islands by requiring movement at any level to obey standard constraints. Since the *wh*-in-situ cannot move to matrix Spec, it cannot fix the value for the range of the function and its trace cannot be functionally bound by the matrix *wh*. The question then arises how the single-pair answer can be derived without actual movement. Here Dayal appeals to Reinhart's choice-function analysis, which is designed for this very purpose:

(98) a. [Which linguist$_i$ [t$_i$ will be offended if we invite which philosopher]]
b. $\lambda p\ \exists x\ \exists f_{<<e,t>e>}$ [linguist(x) & p = x will be offended if we invite f(philosopher)]
c. {a will be offended if we invite c, b will be offended if we invite d, a will be offended if we invite d, b will be offended if we invite c}

As shown above, at the matrix level there is existential quantification over functions that yield an arbitrarily chosen entity out of the set they are applied to. Since the LFs of such questions do not have two *wh*-operators that can undergo Absorption, we get as the denotation of the question a set of atomic propositions. The Answerhood operator, when applied to such question denotations, yields single-pair answers. The choice function approach, then, derives what could be described as a non-quantificational or referential interpretation of the *wh*-in-situ (see Saddy 1991 for a similar characterization of *wh*-in-situ).

It may be worth noting that choice functions are not blocked from applying to *wh*-in-situ in simple questions or in the *wh*-island cases to be discussed below.

The claim is that they cannot be used to derive multiple-pair answers. Since a Ref-Q reading is always possible, either choice functions or ordinary existential quantifiers can be used to derive sets of atomic propositions. The usefulness of choice functions surfaces when islands are involved by providing an alternative to covert movement. Covert movement, if allowed, would open up the way for Absorption and incorrectly yield multiple-pair answers across the board.

3.2.2 Multiple-pair answers across islands

Turning to cases in which multiple-pair answers are possible across islands, Dayal notes two properties that the structure must have. One, the embedded *wh*-word whose value is given must be in a multiple-*wh*-question. Two, this multiple-*wh*-question must be a complement of the matrix verb. These two conditions result in a *wh*-triangle construction that is met in the well-known example in (99a). Sentences like (99b) – attributed by Mahajan 1990 to David Pesetsky – with an intervening clause do not allow the relevant answers, even though the intervening clause does not introduce an island, as shown by (100). Sentence (99c) is somewhat marginal since the *wh* in the embedded clause is not fronted and English does not allow *wh*-in-situ in single-*wh*-questions. Be that as it may, it still does not allow a multiple-pair answer:

(99) a. Which student knows where Mary bought which book?
b. Which student believes (that) John knows where Mary bought which book?
c. ?Which student knows that Mary bought which book?

(100) Which book does Bill believe (that) John knows Mary bought?

Dayal (1996a) treats the multiple-pair answer as relating the matrix *wh*-word to the multiple-*wh* complement rather than to the embedded *wh*-in-situ:

(101) a. $[[\text{where Mary bought which book}]_i\ [\text{which student}_j\ [t^i_j\ \text{knows}\ t_i]]]$
b. Q = {where Mary bought A, where Mary bought B, where Mary bought C}
c. $\lambda p\ \exists f_{<<<s,t>t>,e>}\ [\text{Dom}(f) = Q\ \&\ \text{Range}(f) = \text{student}\ \&\ p = \cap\ \lambda p'\ \exists q[p' = \text{know}\ (f(q), q)]]$

Here the embedded multiple-*wh*-question is interpreted as a second order question – that is, a set of questions rather than a set of propositions. Since the matrix verb is defined for questions, not sets of questions, the complement QRs take clausal scope. Semantically, it denotes the set of questions in (101b) and the full question is interpreted as a relation between the members of this set and individual students who know the answer to them.

Given the local nature of QR, this explains why the intervening clause in (99b) effectively blocks the multiple-pair answer. The explanation for the second property, the requirement that the complement question be a multiple-*wh*-

question, shown by the contrast between (99a) and (99c), turns on the possibility of a second-order interpretation for it. Independent evidence that multiple-*wh*-questions, but not single-*wh*-questions, can denote sets of questions can be seen by examining possible answers to the following echo questions:

(102) a. Mary bought whát at the store?
b. {Mary bought a book at the store, Mary bought a pen at the store . . . }

(103) a. Where did Mary buy whát?
b. {Where did Mary buy the book? Where did Mary buy the pen? . . . }

Extrapolating from echo questions to the multiple-*wh*-questions under issue, Dayal proffers a type-theoretic account of the multiple-*wh* complement requirement for multiple-pair answers across islands. Single-*wh* complements can be interpreted in situ and do not involve semantically driven QR.

One point that should be noted is that the proposed functional dependency in (101a) appears to be in violation of WCO. Dayal suggests that this is perhaps due to the D-linking of the embedded *wh*-word, are like questions with the universal *each N* rather than those with the universal *every N* in not displaying subject–object asymmetries. We will return briefly to the role of D-linking in multiple-pair answers in section 3.3.2.

To sum up, regardless of whether the particular proposals for deriving single- vs. multiple-pair answers hold up, the general point that the diagnostic of paired answers cannot be used as a simple indicator of wide scope has to be recognized. The distinction in the types of paired answers admitted by questions with *wh*-in-situ inside Complex Noun Phrases and those inside *wh*-islands shows that a uniform account of their interpretation is difficult to maintain.

3.3 Reassessing Subjacency at LF

3.3.1 The evidence for and against Subjacency

In the previous subsections the view that *wh*-in-situ have exceptional scope properties has been subjected to close scrutiny by drawing a distinction between two types of paired answers and relating this distinction to explicit claims about the semantics of questions and answers. Let us return now to the empirical motivation behind claims about the scope of *wh*-in-situ and re-examine the data which have provided the basis for those claims from the present perspective. As we will see, while some data provide definitive evidence in favor of one position, some can be shown to be consistent also with the opposite position. The three language groups which will be relevant in this process are East Asian languages, South Asian languages, and the Slavic/Balkan languages. Though the last group does not have *wh*-in-situ they provide crucial evidence on the issue under discussion.

Chinese, Japanese, and Korean, all *wh*-in-situ languages, have been key players in the debate about subjacency at LF. The earliest claims for the absence of

subjacency at LF was based on the interpretive properties of embedded questions in Chinese (Huang 1982a). And one of the earliest challenges to this position was made by Nishigauchi (1986, 1990), Choe (1984), and Pesetsky (1987a) on the basis of Japanese and Korean data. The core facts were introduced already in section 1 but I will repeat some of them to make the discussion here self-contained.

Chinese *wh*-in-situ shows neither CNPC nor *wh*-island effects:

(104) a. Ni zui xihuan [piping shei de shu]?
you most like criticize who REL book
'For which x, you like the book that criticizes x?'
b. Ni xiang-zhidao [Lisi zeme mai-le sheme]?
you wonder Lisi how bought-ASP bought
'For what object x, you wonder how Lisi bought x?'

In contrast, Nishigauchi describes Japanese as immune to CNPC alone:

(105) a. Tanaka-kun-wa [Mary-ga doko-de dono hono-o katta]-ka
Tanaka-TOP Mary-NOM where which book-ACC bought Q
sitte-imasu ka?
know Q
'Does Tanako know where Mary bought which book?'
*'For which book x, does Tanako know where Mary bought x?'
b. Kimi-wa [dare-ga kai-ta] hono]-o yomi masi-ta ka?
you-TOP who-NOM write book-ACC read Q
'For which x, you read the book that x wrote?'

Deguchi and Kitagawa (2002) challenge the judgment for (104a), however, arguing that this reading is available under an appropriate prosodic rendering of the question. Japanese would then be like Chinese, as described by Huang.

Hindi seems to fall at the opposite end of the spectrum in displaying no wide-scope effect, at least in standard cases of relativization and complementation (Davison 1984; Gurtu 1985; Mahajan 1990; Srivastav 1991c; Dayal 1996a). With non-finite complements, Hindi patterns with Chinese and Japanese:

(106) a. jaun jaantaa hai ki meri-ne kyaa khariidaa.
John knows that Mary what bought
'John knows what Mary bought.'
'What does John know that Mary bought?' [unavailable]
b. *jaun-ne vo kitaab khariidii jo kis-ne likhii?
John that book bought that who wrote
'For which x, did John buy the book x wrote?'
c. jaun-ne kis-kii likhii kitaab khariidii?
John whose written book bought
'For which x, did John buy the book x wrote?'

Although the effects noted here are not specific to multiple-*wh*-questions – they apply more generally to the scope of *wh*-expressions in these languages – the following data are critical in evaluation of specific claims. In all these languages, multiple-pair answers are readily available in the typical Baker configuration involving a *wh*-triangle:[23]

(107) a. Dono sensei-ga [Mary-ga doko-de dono hono-o
which professor-NOM Mary-NOM where which book-ACC
katta]-ka sitte-imasu ka?
bought Q know Q
'For which professor x and book y, does x know where Mary bought y?'

b. Kaun jaantaa hai ki meri-ne kahaaN kyaa khariidaa.
who knows that Mary where what bought
'Who knows where Mary bought what?'

c. Koj znae kakvo kade e kupila Mariya.
who knows what where bought Maria
'Who knows where Mary bought what?'

In fact, Dayal (1996a) notes that this configuration is sufficient to yield multiple-pair answers, even in languages like Bulgarian where both embedded *wh*-expressions have undergone overt movement, as in (107c).

Turning now to claims about Subjacency at LF emanating from such facts, both positions have been successfully defended. One way of categorizing the analyses that have been proposed is to use assumptions about the specification of values as a guide. Among those who take specification of values as evidence of matrix scope are Watanabe (1992a), Richards (1997), and Deguchi and Kitagawa (2002) in addition, of course, to Huang. Those who take pair answers to under-determine scope are Kim (1991) and Mahajan (1990), in addition to Dayal (1996a, 2002). The challenge for the first group is to find a principled explanation for why a single *wh*-word may be blocked from taking wide scope in some languages while the addition of an extra *wh*-word makes that option available in those languages. The challenge for the second group is to find principled reasons for enforcing local scope and finding plausible ways of deriving paired answers without wide scope.

Starting with the first group, Watanabe (1992a) reconciles the Japanese facts with Huang's view that *wh*-in-situ are exempt from Subjacency by arguing that Japanese, contrary to appearances, is in fact a fronting language. The distinctive feature of Japanese is that fronting involves a phonetically invisible operator, not the full phrase. This derives the absence of any phonetic impact of movement while preserving the constraints on movement typical of fronting. In order to account for paired answers in (106), then, he appeals to the fact that overt movement is restricted to one *wh*-operator, as in many languages with standard fronting. The invisible operator associated with the embedded indirect object undergoes local fronting to satisfy the Q-morpheme in embedded Comp, leaving

the direct object to undergo full-scale LF movement in violation of Subjacency. With regard to cases like (104b) he assumes pied-piping, along the lines of Nishigauchi's proposal.

Recall from the previous section the proposal in Richards (1997) that constraints only have to be met once per cycle, encoded in the Principle of Minimal Compliance. Under this view, the contrast between (105a) and (107a) can be explained in the following way. In the case of (107a), the matrix *wh*-word moves into matrix Spec in accordance with Subjacency and by 'paying the Subjacency tax' now allows the embedded *wh*-word to move to matrix Spec in violation of Subjacency. In contrast, (105a) is a structure in which the matrix Spec does not have a *wh*-word which could pay the tax, with the effect of barring the embedded *wh*-word from moving into that position. Richards's proposal, then, differs crucially from Huang and Watanabe in maintaining the relevance of Subjacency for covert as well as overt movement. He agrees with them, however, in his assumption that when pair answers are available they are due to scope in violation of Subjacency.[24]

Although these approaches are extremely innovative in resolving the apparent paradox presented by these data, it might be worth noting that they are subject to the criticism levelled by Mahajan (1990) and Dayal (1996a) against Huang's original account that they do not explain the loss of that reading when a clause intervenes between matrix and embedded *wh*-word (cf. (99b)). This is, of course, due to the fact that pair answers are tied to wide scope for the embedded *wh*-in-situ and the intervening clauses under discussion do not introduce any barrier to movement. Further, they are also open to the criticism in Dayal (2002) that they cannot distinguish between single-pair answers that hold for questions with one matrix *wh*-word and one *wh*-word inside Complex NPs or conditionals and multiple-pair answers for questions where the embedded *wh*-word is in a *wh*-island. Finally, they do not address the possibility of multiple-pair answers to cases like (107c) where the operators are moved to embedded scope positions in overt syntax.

An alternative proposal, due to Kim (1991) and Mahajan (1990), aligns *wh*-expressions with quantifiers and treats *wh*-movement as an instance of Quantifier Raising. Taking QR to be a local operation, this in effect enforces locality in the interpretation of *wh*-in-situ and the issue of Subjacency effects becomes moot. The question, of course, arises how wide-scope effects for *wh*-in-situ inside islands are to be explained. The natural move to derive such effects is to treat the containing clause as having scope, allowing pair answers to cases like (107) while still blocking them in cases like (105) and (106). The QR approach to *wh*-in-situ is very similar to the position advocated by Dayal (1996a, 2002), discussed in sections 3.1 and 3.2, but there are differences between the two positions that may be worth bringing out here.

One problem pointed out by Dayal (1996a) is that the syntactic domain of *wh*-movement and quantifier scope, in Hindi at least, are not identical. In particular, a quantifier inside a gerund cannot take matrix scope while a *wh*-expression in the same position is forced to take scope at the matrix level. Other, more

substantive differences, have to do with semantic assumptions about *wh*-expressions. If *wh*-movement is like QR it would be to a position inside C^0. It follows, then, that the relevant semantic interpretation for *wh*-expressions would have to involve choice functions. As we saw in sections 3.1 and 3.2, it is not a straightforward matter deriving the switch from uniqueness in ordinary single-*wh*-questions to multiple-pair answers in multiple-*wh*-questions. And we also saw that the distinction between single-pair and multiple-pair answers in the more complex cases is intractable for any theory that takes a uniform approach to all *wh*-expressions. These authors do not provide explicit discussion of the semantics of QR'd *wh*-expressions, and it is possible that they do not intend the co-relation between quantifiers and *wh*-expressions to be taken literally. If so, they might consider acceptable the idea proposed in Dayal (1996, 2002) that *wh*-movement is distinct from QR in terms of the landing site, but akin to it in being a semantically driven local operation.

Before concluding, I should note that the recalcitrant problem for approaches positing locality at LF is the possibility of wide scope for embedded *wh*-questions in Chinese, exemplified in (104). However, given our refined understanding of the diagnostic of possible answers the possibility of wide scope for Chinese and Japanese *wh*-in-situ should be evaluated against further data. Some of the relevant cases would be the Chinese counterparts of the examples in (108):

(108) a. Who knows how Mary bought what?
b. Who believes that John knows where Mary bought what?

If the embedded *wh*-word can indeed move to matrix Spec, we expect questions like (108b) to allow multiple-pair answers. If they do not allow such answers, it would indicate that non-local movement is not possible even in Chinese. As far as I am aware, these cases have not been discussed in the literature but the predictions of the various approaches summarized here are clear enough. We see, then, that although positing absence of Subjacency at LF provides a simple explanation for some cases, it runs into serious problems when tested across a wider set of facts. In general, it predicts a large number of unavailable readings. As highlighted in sections 3.1 and 3.2, positing mechanisms for assigning wide scope without movement, such as choice functions and deriving pair answers from them, over-generates in the same way. The most restrictive approach consistent with the data surveyed seems to be one in which covert movement is restricted essentially to local positions, and a distinction made between questions with *wh*-expressions in Spec positions and those with *wh*-in-situ at LF. As discussed here, there are problems in this approach as well that need further exploration.

3.3.2 Specification, scope, and D-linking

As would be clear from the discussion so far, broadly speaking there are two approaches one might take in analyzing questions with *wh*-in-situ in embedded clauses. One is to take specification of values in the answer for that *wh*-word as

evidence of wide scope. In the kinds of examples we have been looking at, this has the consequence of making Subjacency potentially irrelevant at LF. The other is to deny that specification of values in the answer is an absolute indicator of scope. This allows for the preservation of Subjacency at LF, requiring of course an auxiliary explanation for the form of the possible answers.[25] Here I would like to mention some facts that bear on this issue.

Kuno and Robinson (1972) challenged Baker's account of multiple-pair answers in cases like (109a) by pointing to the fact that the version in (109b) with no *wh*-in-situ also allows such answers:

(109) a. Who knows where Mary bought what?
b. Who knows where Mary bought these books?

Since questions like (109b) could not involve LF wide scope of the embedded definite, an alternative pragmatic approach must be available for such cases. But if such an account exists, why would it not extend to the cases involving *wh*-in-situ? This challenge was never answered and the status of (109b) and its implications was simply set it aside during the eighties when the theory of LF was being elaborated. In fact, even in current literature the importance of these examples remains underappreciated.

Dayal (1996a) notes that, in fact, Kuno and Robinson's point gains further weight when the following paradigm is taken into account. The question in (110a) does not allow a multiple pair reading, while (110b) does:

(110) a. Which woman knows where Mary bought these books?
b. Which woman knows where Mary bought which book?

Changing the matrix *wh*-word to a singular, which we have seen in section 3.1.2 to impose uniqueness requirements in single-*wh*-questions, leads to loss of multiple-pair answers in questions with embedded plural definites (110a). This suggests that the list answer to (109b) derives from an individual answer like *John and Bill know where Mary bought these books*. It is just a more informative rendering of this statement, as claimed by Kuno and Robinson. However, one cannot conclude the same for questions with embedded *wh*-expressions. As (110b) shows, when the *wh* is D-linked, inherently or in a given context, the possibility of multiple-pair answers survives even with a matrix singular. This raises two questions, namely, What is the structural and semantic properties at issue in such cases? and Why should D-linking make a difference? The approaches surveyed above have all been attempts to provide an account of pair answers that is not based on pragmatics. With regard to the second question, beyond an intuitive correlation between familiarity with the set of entities at issue, however, there is no formal characterization of the semantics of D-linking. The data presented here show quite clearly that if the diagnostic of possible answers is to be used seriously, more work needs to be done on the topic.

4 Conclusion

We have seen in this survey that questions in general, and multiple-*wh*-questions in particular, have been an extremely important phenomenon in the development of linguistic theory. Typologically, they are diverse enough to raise interesting questions about the nature of Universal Grammar and the ways in which individual languages can differ. Further, they lie at the interface between syntax and semantics and provide a unique window into the principles governing the assignment of scope. A particular feature of questions is that they can be analyzed on the basis of two types of evidence, direct evidence in the form of acceptability judgments about fronting and indirect evidence in the form of possible direct answers admitted by them. In doing this survey, I have tried to highlight the relevant conclusions drawn on the basis of multiple-*wh*-questions as well as to refine our understanding of the nature of the diagnostics used in arriving at those conclusions.

NOTES

I am grateful to Chris Barker and Satoshi Tomioka for very useful comments, and to Heather Robinson and Scot Zola for help with the preparation of the manuscript.

1 Karttunen differs from Hamblin in restricting the set of propositions denoted by the question to those that are true. This difference affects the precise way in which questions are related to their answers but does not affect the general point being made here. In section 3, however, the importance of using Hamblin sets as question denotations and encoding Karttunen's truth requirement in an answerhood operator will be shown to be relevant in making more fine-grained distinctions in pair answers.
2 I ignore intensional operators since they do not affect the issues under discussion.
3 Of course, it should be emphasized that frameworks with or without movement may be combined with other theories of questions, such as Groenendijk and Stokhof (1984), where questions denote propositions rather than sets thereof. The considerations that go into the choice between Hamblin–Kartunnen and G&S do not depend on the syntactic properties of multiple-*wh*-questions. I therefore do not discuss them here.
4 Note that in all models, a further distinction between the scope of *wh*-in-situ and quantified NPs also has to be made.
5 There is a typologically distinct type of *wh*-in-situ language, exemplified by many South-Asian languages. See chapter 77 and the discussion in section 3.
6 In Japanese, it is possible to scramble the *wh*-words into sentence initial positions, but this is an option that is open to all arguments and can be shown not to involve *wh*-movement.
7 Chinese does not show a subject–object asymmetry in extraction. This is explained as a consequence of the subject position being properly governed in Chinese.
8 As shown by von Stechow (1996), the syntax proposed by Nishigauchi is not adequate and yields incorrect answers unless obligatory reconstruction of the non-*wh* material is enforced.

9 The status of sentences with *wh*-in-situ in Serbo-Croatian *Ko vidi coga?* and other –MFS languages remains open. There is general unclarity whether *wh*-in-situ is possible, whether they are possible but only under a D-linked interpretation, or ruled out altogether. It can safely be assumed that there is, at the very least, a strong tendency or preference for multiple fronting in these languages.

10 In Romanian it is also possible for multiple extraction to take place from different clauses. That is, questions with the schema $[_{CP}\ WH_i\ WH_j\ [_{IP} \ldots [_{CP} \ldots t_i \ldots [_{CP} \ldots t_j \ldots]]]]$ are considered acceptable.

11 It should be obvious how multiple adjunction to Spec would account for *wh*-island violations of the kind seen in (26a).

12 It is generally accepted that this follows from the semantics of focus and questions. See Rooth (1992) for an explicit statement of the correlation between question denotations and focus in answers.

13 Cheng argues that the presence or absence of Q morphemes can be independently established on the basis of how yes–no questions are formed in a given language. Note that optional-fronting languages, as mentioned in section 1.2.4, are argued not to involve *wh*-movement at all, and are therefore not problematic for the Clausal Typing Hypothesis.

14 Adams's filter applies to COMP, Rudin's to [Spec, CP]. The differences between the two are not of direct concern here. I should also mention that the discussion of this filter has been somewhat simplified by ignoring differences between relative pronouns and interrogative pronouns and by ignoring the possibility of the constraint applying at PF, a point that is not adequately established.

15 As a consequence of this, Pesetsky argues that Subjacency can be taken to be operative at LF as well as S-structure. Apparent violations of Subjacency would be due to a D-linked *wh*-word being bound long-distance by a Q-operator. Note, though, that Pesetsky's approach goes counter to Nishigauchi's claims regarding the scope of Japanese *wh*, an issue we return to in section 3.

16 *Wh*-expressions can also be interpreted via skolem functions, which we discuss in section 2.2.3 under the term 'functional *wh*'. The functional-*wh* analysis is neutral with respect to whether it applies to fronted *wh* or to *wh*-in-situ.

17 The a-index may be anaphoric instead of pronominal in some languages. It should be noted that Chierchia's analysis of functional/list answers is not tied to any particular account of WCO. Two proposals treating it in terms of leftness and relating it to functional answers are Williams (1994) and Jacobson (1994). The latter argues for a variable-free semantics to get the same results as Chierchia. Other references for WCO are Koopman and Sportiche (1982) and Safir (1986).

18 Note that May's (1985) account of this asymmetry does not work for multiple-*wh*-questions. For him, the (im)possibility for scope permutation turns on the landing site of the scopal expressions, rather than on their base positions. Two *wh*-words, unlike a *wh*-word and a quantifier, can form a local relation in [Spec, CP] without violating the PCC. An object *wh*-word is therefore predicted to be able to take scope over the subject and (somehow) be interpreted universally. See Dayal (1996a) for discussion.

19 See also Williams (1994) for similar ideas and related discussion.

20 See also Krifka (1999) for a similar explanation of the subject–object asymmetry in questions with quantifiers.

21 See Link (1983) and the account of comparable uniqueness and maximality effects with definite determiners. This correlation between *wh*-expressions and definites

derive from an earlier version of the theory presented in Srivastav (1991c). It has also been proposed by Rullmann (1995b).

22 See also Sharvit (1997b) and Bittner (1998) for further discussion of functional dependencies in questions.

23 Watanabe (1992a) and Richards (1997) discuss differences in acceptability judgments depending on the position of the matrix *wh*-word. The examples given here are uncontroversial.

24 For Deguchi and Kitagawa (2002), of course, there is no additional *wh*-effect. The perceived contrast between (105a) and (105b) might be due to the fact that the relevant prosody is not as easily available with yes/no questions as with *wh*-questions.

25 The correlation between specification of values and scope has played a pivotal role in the analysis of the Partial *Wh*-Movement/Scope Marking Construction surveyed in chapter 47.

  5.3 Summary
6 Conclusion

1 Introduction

In this chapter we discuss the semantic and syntactic properties of a set of expressions known as *n*-words. The term is coined in Laka (1990) and is employed to refer to nominal and adverbial constituents that appear in negative-concord (NC) structures. Although the term has been quite popular, curiously, it has never been defined in the strict semantic or syntactic sense. Cross-linguistically, *n*-words form a quite heterogeneous class in terms of both their distribution and semantic properties, hence the task of assigning a clear semantic or syntactic criterion for what constitutes an *n*-word becomes rather tricky. Fortunately, there are some distributional criteria that single out *n*-words from other negation-related elements. We use these in the working definition we adopt in this chapter:

(1) ***N*-word:**
An expression α is an *n*-word iff:
   a. α can be used in structures containing sentential negation or another α-expression yielding a reading equivalent to one logical negation; and
   b. α can provide a negative fragment answer.

This definition is general enough to capture the (quite diverse) data that we will present in section 3; at the same time, it can serve as the basis for distinguishing between 'weaker' and 'stronger' *n*-words; for example, we can derive a class of stronger *n*-words by substituting the modal *can* in (1a) with *must*. *N*-words in languages that exhibit strict NC, requiring that the sentential negative marker (SN) be always present in the structure containing the *n*-word, are stronger in this sense (the relevant data will be presented in section 3). On the other hand, negative quantifiers in Germanic languages, which do not exemplify NC, do not fall under (1),[1] nor do existential polarity items (PIs) that are licensed by negation, as well as other non-veridical licensers, e.g., English *any*, or Serbian–Croatian *i*-NPIs (the terminology from Progovac 1988, 1994), since these PIs do not satisfy (1b) and cannot provide negative fragment answers. Why this is so is not pertinent to our discussion, but see Giannakidou (2000: 469, n. 6) for an explanation. Note that we refer to these items as polarity items and not 'negative' polarity items (NPIs) because, as we said, they are licensed in a (large) variety of contexts that are not negative but non-veridical (in the sense of Giannakidou 1998, 1999). The term 'NPI' will be used to only refer to PIs that are licensed by negation (or, more generally, antiveridicality). *N*-words in strict NC are in fact prototypical NPIs because they are not licensed by operators other than negation and antiveridical *without*.

NC is a phenomenon known to linguistics since Jespersen's (1917) double-attraction, Klima's (1964) neg-incorporation, and Labov's (1972) negative-attraction rule. Roughly, we talk about negative concord in situations where negation is interpreted just once although it seems to be expressed more than

once in the clause. One occurrence of negation is the sentence negation (SN), and given that *n*-words can provide negative answers in isolation, as we see in (3), we can speculate that the additional occurrence of negation is the *n*-word. Here are some examples:

(2) a. Gianni *(non) ha visto **niente**. Italian
John not have.3sg seen n-thing
'John didn't see anybody.'

b. *(No) he dit **res**. Catalan
not have.1SG said n-thing
'I didn't say anything.'

c. Balázs*(nem)látott **semmit**. Hungarian
Balázs not saw.3SG n-thing
'Balázs didn't see anything.'

d. Milan *(ne) vidi **nista**. Serbian–Croatian
Milan not see.3SG n-thing
'Milan can't see anything.'

e. Janek *(nie) pomaga **nikomu**. Polish
Janek not help n-person
'Janek doesn't help anybody.'

f. *(Dhen) ipa **TIPOTA**. Greek
not said.3SG n-thing
'I didn't say anything.'

g. John-wa **nani-mo** tabe-*(nak)-atta. Japanese
John.TOPIC n-thing eat. negation.past
'John didn't eat anything.'

(3) Q: Qui se li va apropar? Catalan
who refl him/her AUX.3SG approach
'Who approached {him/her}?'

A: **Ningú.** 'No one.'

Negative Concord is observed in many languages, among others Romance, Slavic, Greek, Hungarian, Nonstandard English, West Flemish, Afrikaans, Lithuanian, Japanese (see among others Labov 1972; Ladusaw 1992, 1994; Van der Wouden and Zwarts 1993; Bosque 1980, Laka 1990, Herburger 2001 for Spanish; Zanuttini 1991, Longobardi 1991, Acquaviva 1993, 1995a, 1997 and Tovena 1996 for Italian; Quer 1993, 1994, Vallduví 1994 for Catalan; Peres 2000, Puskás 1998, Tóth 1999, Surányi 2002 for Hungarian; Giannakidou 1997, 1998, 2000 for Greek; Haegeman 1995b, Den Besten 1986 for West Flemish and Afrikaans; Hoeksema 1997 for Middle Dutch; Progovac 1988, 1994 for Serbian–Croatian; Brown 1999 for Russian; Przepiórkowski and Kupsc 1997, 1998, Blaszczak 1999, and Richter and Sailer 1998 for Polish; Watanabe 2001 for Japanese). These are the languages we consider here, though our primary focus will be on the three large European families Greek, Romance, Slavic.

The sentences in (2) exemplify the variety known as negative concord proper: they contain sentential negative markers, which contribute logical negation ¬, and the *n*-words.[2] Uppercase letters in the Greek *n*-word in (2f) indicate that it is pronounced emphatically; henceforth we will refer to Greek *n*-words as 'emphatics'. This accent is not related to focus for reasons that have been discussed in Giannakidou (1997, 1998: 227–31; see, however, Tsimpli and Roussou 1996 for a focus-based account). Emphatic accent is a distinctive feature of NC patterns in other languages too, e.g., Hungarian (see especially Puskás 1998), and should not necessarily be collapsed with focus, as emphasized also in Szabolcsi (1981b), Vinet (1998), and Surányi (2002); see also our discussion in sections 2.3.1 and 2.3.4 on certain syntactic asymmetries between focused items and *wh*-words. (This does not mean, of course, that *n*-words cannot be focused; but indiscriminately collapsing *n*-words to focalized elements is hardly motivated, given that certain *n*-words at least exhibit the properties of topics rather than foci (cf. Giannakidou 2000 and section 2.3.4).)

As shown, the co-occurrence of the SN is obligatory; but the sentences above are interpreted uniformly as containing a logical structure with only one negation. At a general level, then, *n*-words in NC can somehow be associated with negative meaning, and the major task has been to identify what it means exactly to be able to do so. The most obvious possibility is, of course, to interpret association with negative meaning as equivalent to having inherent negative meaning. This possibility seems particularly attractive in view of the fact that *n*-words can contribute negative fragment answers; *n*-words have thus been treated as negative quantifiers, originally in Zanuttini (1991) and Haegeman and Zanuttini (1991).

In order to decide whether or not to pursue this hypothesis, we must consider one important fact: when a language actually employs a negative quantifier, NC is systematically excluded, as in languages which do not employ NC as a rule, e.g. German, Dutch, and English (West Germanic), and the Scandinavian languages. Germanic *n*-words, unlike *n*-words in NC structures, when co-occurring with a SN, yield only a double negative reading:

(4) a. Frank heeft niet **niemand** gezien. Dutch
Frank have.3sg not n-person seen
'It is not the case that Frank saw nobody.'
#Frank didn't see anybody.
b. Frank did not see nobody. English
c. Frank hat nicht niemand gesehen. German

The interpretation of these sentence is as in (5) below, which is derived by combining the meaning of a negative quantifier and negation.

(5) $\lambda P\ \forall x\ [\mathbf{person}\ (x) \rightarrow \neg\ \mathbf{P}(x)]\ (\lambda y\ \neg\ \mathbf{saw}\ (\text{Frank}, y)) =$
$\forall x\ [\mathbf{person}\ (x) \rightarrow \neg\ (\neg\ \mathbf{saw}\ (\text{Frank}, x))]$

Hence, the sentences entail that Frank did see somebody or everybody (depending on whether we exploit universal negation for negative quantifiers, as we did here, or existential negation, which is also possible; we discuss the issue later).

This reading differs clearly from the one we have without negation, illustrated below. NC structures have only this reading (e.g. 2a).

(6) a. Frank saw nobody.
b. λP ∀x [**person** (x) → ¬ **P**(x)] (λy **saw** (Frank, y)) =
∀x [**person** (x) → ¬ **saw** (Frank, x)]

Negative quantifiers in Germanic languages are thus inherently negative. Hence, when we have an additional syntactic negation coming from SN as in (5), we have a second logical negation too. The question is: are *n*-words in NC languages identical to negative quantifiers in non-NC languages? If so, why is it that we have NC in the former – with a reading not equivalent to (5) but to (6) – but not in the latter?

At this initial stage it is instructive to consider that *n*-words need not be morphologically negative either, although by employing the prefix *n-*, the term itself allows for the implication that part of the expression qualifying as an *n*-word will contain a morpheme morphologically recognizable as negative. It has often been observed in the relevant literature that this is not the case (see among others Laka 1990; Quer 1993; Déprez 1997; Giannakidou 1998, 2000; Rowlett 1998). For example, Italian *niente, nessuno*, and Serbian–Croatian *nista* do bear negative morphology but their Catalan, French, and Greek counterparts do not, or do so but not consistently. Catalan, for instance, has *ningú* 'n-person' but *res* 'n-thing', and French and Greek *n*-words lack negative morphology altogether. Negative morphology is, then, not a prerequisite for *n*-word status.

With these preliminaries, our discussion is organized as follows. In the next section the central issues of the interpretation of structures with *n*-words are presented. First I give an overview of the core puzzles, then we discuss the individual proposals. Once it is made clear what the predictions are of each individual proposal, we can proceed with the empirical complexity of NC and *n*-words in section 3. Our goal will be to test the empirical scope of NC theories and see to what extent they are applicable to certain data, and of course when they are not. In section 4 we examine the alleged negativity of *n*-words and show it to be problematic for most cases. Having reached the conclusion that *n*-words cannot be negative quantifiers, in section 5 we address the question of whether NC structures co-exist with existential polarity dependencies under negation. This question is important in trying to decide what logical structure *n*-words map onto: existential or universal negation. We will use the results of this section in order to construct a typology of *n*-words and their proper semantic characterization. We conclude in section 6 by summarizing the main findings.

2 The interpretation of negative concord and the nature of *n*-words

For a successful account of NC the proper semantic characterization of *n*-words is essential. We thus go back to the original question: should we grant negative

status to *n*-words or not? This question corresponds to the following cluster of four subinquiries:

(a) The negative 'concord' question. If *n*-words are negative, then in NC we do have more than one occurrence of negation. But why do we end up interpreting only a single negation? This situation is in sharp contrast with Germanic negative quantifiers whose inherent negativity cannot be cancelled, as we saw, and which therefore do not exhibit NC. If *n*-words in NC are indeed negative, the very phenomenon itself constitutes an anomaly and in order to explain it we must stipulate some special rule for NC languages which cancels out the extra negative meanings. We would further have to stipulate that this rule is not operative in Germanic languages since these do not exhibit NC. But why NC languages employ this rule but non-NC languages do not, does not seem to follow from something more general in the grammar of these languages and remains essentially an *ad hoc* premise.

(b) The diversity of interpretation question. If *n*-words are not negative, then what is their actual meaning and how do they end up giving negative fragment answers? It is a quite complex enterprise to try to answer the question of what the possible meanings of *n*-words are, because the set of expressions identifiable as *n*-words in various languages with NC is highly heterogeneous. Evidently, this complexity mirrors the logical complexity of general negative statements. As we see below, there are two possible logical structures that *n*-words can map onto:

(7) **Logical representations of general negative statements:**
(a) $\forall x\ [P(x) \rightarrow \neg\ Q(x)]$ (universal negation)
(b) $\neg\exists x\ [P(x) \wedge Q(x)]$ (existential negation)

The two formulae are truth conditionally equivalent; but the fact that these two options exist makes it plausible to hypothesize that some *n*-words would correspond to existential quantifiers under negation, some others to universal quantifiers, and some others perhaps to both. As we shall see, various implementations of these hypotheses have been proposed in the literature. *N*-words have been argued to be indefinites or universal quantifiers. The former alternative is explored in, among others, Ladusaw (1992, 1994); Acquaviva (1993, 1997); Giannakidou (1997); Giannakidou and Quer (1995, 1997); Piñar (1996); Déprez (1997, 2000). The latter idea that some *n*-words are universals has been put forth in Giannakidou (1998, 2000), and is further supported by literature on Hungarian (Szabolcsi 1981b; Surányi 2002 and references therein). *N*-words have also been characterized as underspecified in Van der Wouden and Zwarts (1993), being compatible with both a negative quantifier and an existential quantifier meaning. This approach, essentially, acknowledges that *n*-words may be ambiguous between negative and non-negative meanings, a position that seems unavoidable, at least for some Romance *n*-words, as we conclude later in section 4. Yet, there are empirical problems with the specific implementation in Van der Wouden and Zwarts, noted in Giannakidou (1997: 166–168), which we ignore here.

Crucially, another decisive factor is whether *n*-words may occur without the presence of the sentential negative marker, or whether the presence of the negative marker is obligatory in all contexts – the latter situation is known as 'strict' NC (Giannakidou 1998). In the non-strict varieties, and in the absence of SN, it seems reasonable to hypothesize that the negative value comes from the *n*-word itself. Interestingly, in these varieties of NC, *n*-words may give rise to double negation readings too, thereby supporting the hypothesis that they may be negative under one interpretation; but in strict NC languages double negation readings are never allowed.

(c) The locality question. A cross-linguistic feature of *n*-words and NC is that they are clause-bounded (see especially Progovac 1988, 1994; Zanuttini 1991; Déprez 1997; Giannakidou 1998, 2000). This feature inspired an analysis of *n*-words as parallel to anaphors in Progovac (1988, 1994); but, most importantly, it suggests a close similarity between NC and quantifier scope, which is also known to be clause-bounded. This characteristic is worth emphasizing because it prima facie argues against the plausibility of a non-quantificational analysis of *n*-words as indefinites.

(d) The polarity question. In the early 1990s there was a debate as to whether *n*-words are negative quantifiers or NPIs (see especially Laka 1990 versus Zanuttini 1991). This debate inspired discussions in various Romance languages, and it relied on the assumption that being an NPI means 'being existential', instead of 'being licensed by negation'. This assumption has been shown to be unfounded in more recent discussions, where NC is treated as an instance of negative polarity: *n*-words, in this view, especially those in strict NC languages, *are* NPIs since they need negation to be licensed (see especially Progovac 1988, 1994; Ladusaw 1992, 1994. Giannakidou 1997, 1998, 2000; Laka 1990 can also be seen as favoring this view). The HPSG analyses of NC (Przperkópski and Kupsc 1997, Richter and Sailer 1998) also implement directly accounts of NC in terms of polarity. We will take this position for granted in the present chapter and allow the underlying assumption that *n*-words in NC are NPIs.

The central problem is, as we said, the 'anomalous' character of NC: the fact that seemingly multiple negations are interpreted as a single negation. Ideally, we would not like NC to be an anomaly; we want to be able to derive it from other, better understood, phenomena. The same desideratum applies, at a general level, to all polarity phenomena: we do not want to posit them in the grammar as composition external filters, but we want to derive them from rules that we need independently anyway; see Giannakidou (1998, 2001) for extensive discussion; see also Tovena (1998). The reduction of NC to an indefinite or quantificational dependency should be seen as attempting to do precisely this. Another attempt, in the same spirit, is Progovac (1988, 1994), who tries to reduce the principles governing NC to the principles of Binding theory. This reduction, though at first glance appealing, does not actually afford a better understanding of NC since it reduces one mystery – NC – to another one (the Binding theory), without offering an actual semantic characterization of *n*-words. We do not address this proposal here in any detail, but we will try to integrate Progovac's

facts about Serbian–Croatian, which are in many ways significant, to the general approach we pursue in this chapter.

Given the two logical options in (7), as well the option of inherent negativity, it seems simple-minded to expect a single interpretation for NC cross-linguistically; rather, it is more reasonable to expect a family of interpretations jointly to accommodate the whole range of data. This is the stance we are taking here, in agreement with a research agenda originating in Ladusaw (1994) and further implemented in Acquaviva (1997), Giannakidou and Quer (1995, 1997), and Giannakidou (1997, 1998, 2000).

2.1 Negative absorption

Zanuttini (1991), Haegeman and Zanuttini (1991, 1996), and Haegeman (1995b) view NC as an agreement phenomenon. They proposed a quite influential account based on the assumption that *n*-words are negative quantifiers. In order to derive NC, they invoke a special rule, negative absorption, inspired by Higginbotham and May's (1981) *wh*-absorption (whose current theoretical status, let it be noted, is being reconsidered under more recent discussions of multiple *wh*-dependencies; see, e.g., Reinhart 1997). The postulation of negative absorption on a par with *wh*-absorption presumes that NC and multiple *wh*-dependencies are instances of the same phenomenon which is also highly questionable; see especially Acquaviva (1995a, 1997) and Giannakidou (1998) for discussion. At any rate, negative absorption has been proposed to allow any number of *n*-words and the SN to merge into one semantic negation (the neg-criterion; Zanuttini 1991; Haegeman and Zanuttini 1991; Haegeman 1995b; for a slightly different variant formulated in terms of 'negative void' see Postma 1995a).

(8) **Negative absorption rule:**
$[\forall x \neg]\ [\forall y \neg]\ [\forall z \neg] \rightarrow [\forall x,y,z]\ \neg$

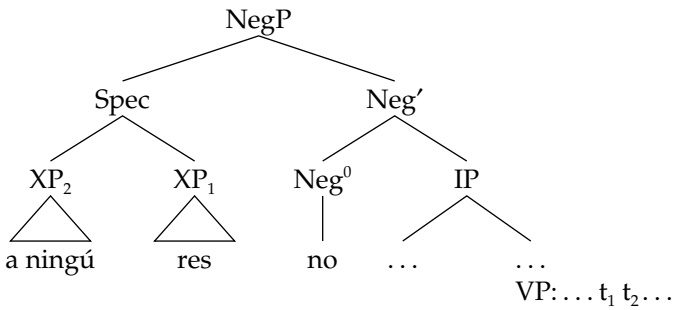
Multiple negative quantifiers amalgamate into a single negative quantifier. Syntactically, these structures contain just a single operator which can bind n-number of variables (just like in multiple *wh*-structures under *wh*-absoprtion). The neg-criterion has been restated recently in terms of feature checking in, e.g., Brown (1999), Watanabe (2001), and Progovac (2000). The idea is, for example, in Brown (1999), that *n*-words contain an uninterpretable neg feature that must be checked against the appropriate headnegation; for Watanabe, the relevant feature is a focus feature. Given that interpretability of features is still largely undefined in the current state of the theory, as well as the fact that, as we shall see later in section 5, not all *n*-word or NPI dependencies involve movement (in the sense of feature checking), I will stick here to the more classical version of the absorption approach.

Consider a sentence like the one below from Catalan with two *n*-words and SN: this sentence is assumed to contain a single negative quantifier which ranges over two variables:

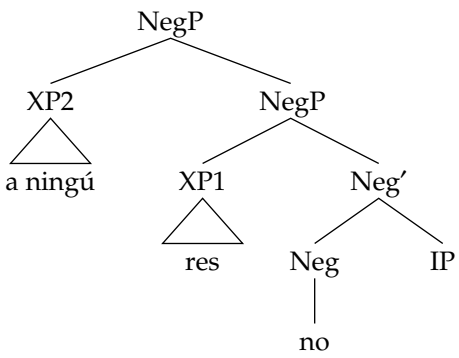
(9) a. No he dit res a ningú.
not have.1sg said n-thing to n-person
'I didn't say anything to anybody.'
b. No x, y [**thing** (x) ∧ **person** (y)] [**said** (I, x,y)]

This analysis is generalized to a number of languages. Crucial to this analysis is the assumption that *n*-words are (syntactic) negative operators, hence semantically negative items. Zanuttini (1991), Haegeman and Zanuttini (1991, 1996), and Haegeman (1995b) state that *n*-words in Romance and West Flemish are negative quantifiers. As such, *n*-words comprise a [+quantificational] and a [+negative] feature, where being [+quantificational] entails being a syntactic operator. Because *n*-words are quantifiers, their sentential scope must be syntactically derived by reaching a scope position at least by LF; being negative too, *n*-words must agree with a negative head. Both requirements are met by application of move-α, which raises *n*-words to [Spec, NegP] or adjoins them to that position either at s-structure or at LF (but see Haegeman 1995b for the stronger claim that the neg-criterion is uniformly satisfied at s-structure).[3] Once *n*-words reach [Spec, NegP] they enter a Spec–Head relation with the negative head. In this analysis, the relevant part of (9a) would look at LF as either (10) or (11) depending on whether we assume raising to [Spec, NegP] or adjunction to NegP.

(10)



(11)



The driving force for such configurations is the neg-criterion, a well-formedness condition which applies to all elements bearing the feature [+negative] and

which determines their distribution and interpretation. It requires that such expressions check their negative feature against a head endowed with it. Based on the *wh*-criterion as formulated in Cinque (1990c), Haegeman and Zanuttini state the neg-criterion in (12):

(12) **The neg-criterion:**
   a. A NEG-operator must be in Spec–Head agreement relation with an X^0 [NEG].
   b. An X^0 [NEG] must be in Spec–Head agreement relation with a NEG-operator.

Additionally, the following definitions obtain:

(13) a. NEG-operator: a negative phrase in a scope position;
   b. Scope position: left-peripheral A'-position [Spec, XP] or [YP, XP].

In fact, the neg-criterion may be regarded as a particular realization of a more general constraint, the affect-criterion (cf. Cinque 1990c; Haegeman 1992). The rule in (12) tells us nothing about the phonological realization of Neg^0, although the most plausible implementation of it would imply that the availability of NC must be linked to the realization of Neg^0 (covert or overt), as in Zanuttini (1991); see also Moritz and Valois (1994). We saw, however, in n. 2 that NC is allowed also with SN that are not heads but XPs. The negative head may be overt or covert, depending on language-specific constraints. Strict NC languages like Greek, Catalan, and Slavic (where SN is obligatory) require that Neg^0 be always overt. In languages where this does not hold, such as Italian, Spanish, and Portuguese, such a requirement is absent. Evidently, the movement involved for the satisfaction of the neg-criterion is an instance of A'-movement.

The detailed descriptions that will follow make it clear that the neg-criterion approach, posed in this generality, cannot be the correct analysis of NC. The underlying idea, which can be restated as negative quantifiers forming resumptive structures, may indeed be a useful one for a certain variety of NC negative spread, which we discuss in section 3. But there are at least three problems with the particular implementation we outlined here. First, the characterization of the general class of *n*-words as negative quantifiers will be questioned in section 4; we see there that there is very little evidence that *n*-words are negative in most variaties of NC. We can, of course, still maintain that *n*-words are quantificational without being committed to negativity. This is indeed an appealing option, and is explored in various works (Déprez 1997; Giannakidou 1998, 2000; Puskás 1998; and others).

The second problem comes from the alleged uniformity between multiple *wh*-dependencies and NC and the reduction of the latter to the former. It has been emphasized numerous times in the literature that there are significant asymmetries between *wh*-dependencies and NC (see the references mentioned earlier). The discussion will not be repeated here, but we will take it as established that NC and *wh*-dependencies are distinct. Finally, by invoking the special rule of

negative absorption, whose role appears to be particular to NC, we have not succeeded in getting rid of the anomalous character of NC. Instead, we have further established this anomalous character by reducing it to another 'special', hence also anomalous, mechanism: *wh*-absorption. Ideally, we would prefer a theory which derives the resolution of NC from a mechanism for which we have independent evidence in the grammar anyway.

2.2 N-*words as indefinites*

The indefinites approach signals the first attempt to reduce NC to an independently motivated mechanism: that of indefinite binding. The approach was initiated in Ladusaw (1992, 1994) and was further developed in Acquaviva (1993, 1997), Giannakidou and Quer (1995, 1997), Giannakidou (1997), Déprez (1997, 2000), Richter and Sailer (1998), and others. The idea is that *n*-words are open formulae with no quantificational force of their own (Kamp 1981a; Heim 1982). Like indefinites, *n*-words contribute a free variable and a predicative condition on that variable:

(14) [[uno studente]] = **student** (x)
[[nessuno studente]] = **student** (x)

N-words differ from regular indefinites in that they come with a roofing requirement (Ladusaw 1992) which must be met at the sentence level. Roofing in Ladusaw is stated as a binding requirement: *n*-words must be bound by a semantically appropriate operator. In Giannakidou and Quer (1995, 1997) and Giannakidou (1997) this requirement is generalized to non-veridical operators. Negation, of course, is not strictly speaking a variable binder since it is not a quantificational operator;[4] roofing, then, is better rephrased as a requirement that existential closure apply under negation (Giannakidou 1998). So, for the sentence we just discussed in (9a), we will have the structure in (15):

(15) $\neg\ [_{VP}\ \exists x \exists y\ (\textbf{thing}(x) \wedge \textbf{person}\ (y) \wedge \textbf{said}\ (he, x,y))]$

The *n*-word variable is existentially closed in the scope of negation, i.e., in the VP. In Giannakidou (1997) it is further noted that this is the only level for application of existential closure; *n*-words and other (negative) polarity indefinites can never be bound via text-level existential closure, as this would imply a wide-scope reading with respect to negation, with the ensuing assertion of existence, which (negative) polarity indefinites do not have. In this account, the narrow scope of polarity indefinites and their polarity requirement are collapsed into the same source.

By assuming that *n*-words denote open formulae with no inherent quantificational force, the indefinites approach seems to offer an easy solution to the problem of NC: *n*-words do not contribute negation, only the SN does. This, however, turns out to be too easy a solution. The most obvious problem is that *n*-words do

not exhibit the quantificational variability characteristic of indefinites, which are unselectively bound by quantificational (Q-) operators, acquiring thereby the Q-force of their binders. When construed with Q-adverbs, for example, *n*-words are never bound by them; instead they seem to remain existentially closed under negation in the VP domain. This is illustrated in the following example from Greek:

(16) {Sixna/Pu ke pu}, otan o Janis ine thimomenos, dhen milai me KANENAN.
'{Usually/Sometimes}, when John is upset he talks to nobody.'

(17) a. USUALLYs [$_{\text{Restr.}}$ John is upset in s] [$_{\text{Scope}}$ $\neg\exists$x (**person** (x, s) $\wedge$ **talk** (John, x,s))]
b. SOMETIMESs [$_{\text{Restr.}}$ John is upset in s] [$_{\text{Scope}}$ $\neg\exists$x (**person** (x, s) $\wedge$ **talk** (John, x,s))]

Here we have two Q-adverbs with varying Q-force, but the interpretation of *KANENAN* remains 'zero people' for each situation the Q-adverb quantifies over. Thus, the Q-adverb does not bind the *n*-word variable. If indefinite, then, in addition to the roofing requirement, *n*-words would have to have another 'special' feature: they cannot be bound by a Q-operator. But this is a striking feature, given that being bound by a Q-operator is a very basic property that indefinites generally have. PI indefinites not related to negation, such as free choice indefinites, actually do exhibit Q-variability of the standard kind (Giannakidou 2001: 701–703).

One may argue that a potential ambiguity between negative and existential interpretations is indeed a case of Q-variability. This might be, for example, a suitable analysis for Romance, as *n*-words in these languages seem to be negative under negation but existential in non-negative environments (interrogatives, conditionals, restriction of $\forall$, etc.; to be discussed in section 4). Such an analysis, however, would still have to deal with the following two problems. First, not all *n*-words exhibit this ambiguity. Greek NC *n*-words, for instance, which are only licit under negation and antiveridical operators, are never interpreted as existentials. In fact, as we will in section 4, in contexts favoring this interpretation Greek *n*-words are ungrammatical (interrogatives, conditionals, restriction of $\forall$, etc); the same holds for Slavic and Hungarian *n*-words. On the other hand, we see in section 5 that there are *n*-words which are indeed interpreted existentially, roughly equivalent to *any* under negation, but these are interpreted only existentially, hence there is no variability.

The second problem is that the derivation of the negative reading is non-compositional. If in the negative reading *n*-words involve $\forall$-force, $\forall$ must be stipulated composition-externally, because negation alone can surely not provide it. Given that $\forall\neg$ and $\neg\exists$ are truth conditionally equivalent, it makes more sense to say that there is actually no quantificational variability, and that *n*-words contribute $\exists$, which under negation, $\neg\exists$, will give the negative meaning. In a non-negative context, the existential import of $\exists$ will be preserved. This squares neatly with our previous observation that *n*-word indefinites can be bound only

by an existential quantifier under negation, and by no other Q-operator. But if this is so, then the 'indefinites' analysis is no longer about indefinites; it is about existential quantifiers, and it is this re-interpretation that we adhere to in the present chapter.

Let us finally note that an existential approach to *n*-words will have trouble handling the issue of locality arising in NC; we see in section 5 that NC cross-linguistically is generally not licensed long-distance (Zanuttini 1991; Longobardi 1991; Progovac 1994; Giannakidou 1997, 1998, 2000; Przepiórkowski and Kupsc 1997, Brown 1999, among many others). If *n*-words were indefinites/existentials, it is surprising to find such locality constraints as indefinites are generally thought to have 'unbounded' scope. In some cases even, in Polish and Russian, for instance, locality is very strict: NC is excluded from non-monoclausal domains, even if these domains are subjunctive-like or infinitival. The analysis of *n*-words as indefinites predicts that *n*-words will be licensed unboundedly as long as they remain in the scope of the licensing operator. As we shall see in section 5 this is true of existential PIs under negation, e.g., *any*, but it is clearly not true of *n*-words in NC.

2.3 N-*words and universal quantifiers*

A different line of reasoning is pursued in Giannakidou (1998, 2000). It is proposed that NC cross-linguistically must involve the two logically available possibilities: an existential and a universal construal. In a given language, the two construals may be realized by two different paradigms of *n*-words, as is the case in Greek, but in others, a single paradigm may incorporate both meanings. This picture was recently supported by work on Hungarian in Surányi (2002), where it is shown that the two paradigms of Hungarian *n*-words actually have both interpretations each. In an earlier paper by Szabolcsi (1981b), Hungarian *n*-words were uniformly analyzed as universals, which again supports the more specific argument that we need to allow for the universal quantifier option in the semantics of *n*-words cross-linguistically. Note also that certain languages, e.g., Hebrew, employ morphologically universal *n*-word *kol* 'every', e.g., *kol yeled nivdak* 'every child was examined', and *lo* (neg.) *nimce'u kol maxalot* 'no disease was found' (the data are from Mittwoch 2001: 280). The same can be said for the Japanese complex wh-*mo* which is used in NC and contains what has been analyzed as a universal marker: *mo* (see Watanabe 2001 and references therein). Obvioulsy, then, the hypothesis that there may be universal *n*-words is empirically well motivated. Significant motivation comes also from the parallelism between *n*-words and universal quantifiers in terms of their scope possibilities, which is what we consider first.

2.3.1 *Universal quantifiers and* n-*words: parallelism in scope*

In this section we examine the scope parallelisms between *n*-words and universal quantifiers that support the hypothesis that *n*-words are universal quantifiers. The locality involved in NC, clause-boundedness, will be shown to be identical

to the locality in quantificational dependencies. For simplicity, we concentrate on one language, namely, Greek.

The first observation is that *n*-words in NC are generally not licensed long-distance. This is a cross-linguistic feature of NC which we return to later (section 5.1). Greek lacks infinitives, but has three types of complement clause: *oti*, *na*, and *pu* clauses. *Oti* is the indicative nonfactive complementizer and *pu* is the indicative factive one. *Na* introduces subjunctive clauses but it is not a complementizer (Philippaki-Warburton 1994 and references therein). *Na*-domains in Greek usually behave on a par with infinitival and restructuring domains of other languages (Aissen and Perlmutter 1983), which are known to be transparent with respect to certain long-distance dependencies (for reasons immaterial here). Greek *n*-words are not accepted in indicative complements of negated matrix predicates. NC is possible only in monoclausal domains and subjuncive *na*-clauses:

(18) a. *O Pavlos dhen ipe oti idhe KANENAN.
the Paul not said.3sg that saw.3sg n-person
'Paul didn't say that he saw anybody.'
b. *Dhen lipame pu pligosa KANENAN.
not be-sorry.1sg that hurt.1sg n-person
'I don't regret that I hurt anybody.'
c. O Pavlos dhen theli na dhi KANENAN.
the Paul not want.3sg that.subj. see.3sg n-person
'Paul doesn't want to see anybody.'

This situation contrasts clearly with *wh*-dependencies which are freely allowed through *oti* complements, and partly through *pu* complements, which are weak islands (*pace* Roussou 1994; Varlokosta 1994). The details are presented in Giannakidou (1998, 2000), but the basic fact is illustrated here:

(19) a. Pjon$_1$ ipe o Pavlos oti idhe t$_1$?
who said.3sg the Paul that saw.3sg
'Who did Paul say that he saw?'
b. Pjon$_1$ xarike o Pavlos pu idhe t$_1$?
who was.glad.3sg the Paul that saw.3sg
'Who was Paul glad that he saw?'

Hence NC is clearly not a *wh*-dependency it is also not a focus dependency, as in situ focus is indeed sanctioned through *pu* and *oti* complements:

(20) a. Xarikes pu i Maria pandreftike PJON?
were.glad.2sg that the Mary married.3sg who
'You were glad that Mary married who?'
b. Akusa oti i Maria pandreftike to JANI.
heard.2sg that the Mary married.3sg John
'I heard that Mary married JOHN.'

In-situ focus in Greek is licensed also in islands, as in other languages; more detailed discussion of the asymmetries between focus and NC are found in Giannakidou (1998). What we note here is that the long-distance pattern we observe with NC cannot be reduced to that of *wh*-movement or focus. Giannakidou and Quer (1995, 1997) further show that the Greek picture describes correctly the facts in Spanish; see also Progovac (1994) for the observation that Serbian–Croatian *n*-words are licensed only in subjunctive clauses, and Zanuttini (1991) for Italian. Catalan *n*-words can be licensed in indicative clauses too, licensing existential readings; we return to the significance of this fact in section 5.1. The second thing to note is that the generalization that NC is licensed long-distance only in subjunctive complements can occasionally be violated: *n*-words may appear in the indicative complements of epistemic neg-raising verbs, e.g., in the *oti* complement of *pistevo* 'believe':

(21) Dhen pistevo oti idhes KANENAN.
not believe.1sg that saw.2sg n-person
'I don't believe you saw anybody.'

N-word licensing in the complements of epistemic neg-raising verbs is generally very weak, and subject to performativity constraints, i.e., person (the embedding predicate must be first person singular), and tense constraints (only present tense is acceptable), as is shown in Giannakidou and Quer (1995, 1997: 106–111) and Giannakidou (1997), where the availability of cases like (21) was linked to the parenthetical uses of neg-raising verbs (for a general discussion of neg-raising, see Horn 1978). If *pistevo* is modified by an adverb, neg-raising is blocked, and so is NC, because adverb modification forces the attitudinal reading. The fact was first observed by Veloudis (1982), who discusses extensively the interaction between *n*-words and neg-raising.

(22) Dhen pistevo adhikeolojita oti me apata.
not believe.1sg unreasonably that me-cheat.3sg
'I don't believe unreasonably that (s)he is cheating me.'
#I believe unreasonably that (s)he isn't cheating me.

(23) *Dhen pistevo adhikeolojita oti idhes KANENAN.
not believe.1sg unreasonably that saw.2sg n-person
'I don't believe unreasonably that you saw anybody.'

Since *adhikeolojita* in (23) is an attitude modifier, *pistevo* cannot be used parenthetically. As a result, NC is not possible; compare this sentence to (21) without the adverb.

Crucially, adverbs exhibit exactly the same blocking effect with quantifier scope. As shown in Farkas and Giannakidou (1996), *para poli* 'very much' prevents *kathe* 'every' from taking scope over *kapjos* 'some' in (24), although this is possible in (25), without the adverb; '>' reads as 'scope over':

(24) a. Kapjos kathijitis ithele para poli kathe ipopsifios s'afti ti lista
some professor wanted very much every candidate in this list
na vri dhulja.
that.subj find.3sg job
'Some professor wanted very much every candidate on this list to find a job.'
b. ∃ > ∀
c. *∀ > ∃

(25) a. Kapjos kathijitis ithele kathe ipopsifios s'afti ti lista na vri dhulja.
some professor wanted every candidate in this list subj find.3sg job
'Some professor wanted every candidate on this list to find a job.'
b. ∃ > ∀
c. ∀ > ∃

Example (25) can be true in a situation in which professors co-vary with students (e.g., if we have excellent recommendation letters for each student candidate). This indicates that *kathe ipopsifios* 'every candidate' has scope over the existential *kapjos kathijitis* 'some professor'. Sentence (25) lacks this reading: only one, very hopeful, professor is involved. Related to this is a third fact, namely, that universal quantifiers cannot scope beyond the clause they occur in, unlike indefinites, for instance, which can have scope across one or more clause boundaries, or *wh*-phrases. Universal quantifers cannot cross the tensed clause boundary (for discussion see Farkas and Giannakidou 1996; Reinhart 1997). Exceptions to this generalization were presented in Farkas and Giannakidou (1996) involving *na*-clauses, which we discuss next; the effect can be reproduced in Romance and English with restructuring or infinitival domains.

Farkas and Giannakidou observe that universal quantifiers such as *kathe* can indeed scope over an indefinite in the main clause as long as it is found in a *na*-complement. From a *pu* or *oti* complement, *kathe* cannot take wide scope:

(26) a. Kapjos kathijitis frondise kathe fititis s'afti ti lista na vri dhulja.
some professor made-sure every student in this list subj find.3sg job
'Some professor made sure that every student in this list will find a job.'
b. ∃ > ∀
c. ∀ > ∃

(27) a. Kapjos fititis lipithike pu kathe kathijitis tis sxolis apolithike.
some student was-sorry that every professor of.the dept. got-fired.3sg
'Some student regrets that every professor in the department got fired.'
b. ∃ > ∀
c. *∀ > ∃

(28) a. Kapjos fititis ipe oti kathe kathijitis tis sxolis apolithike.
some student said.3sg that every professor of.the dept. got-fired.3sg
a. 'Some student said that every professor in the department got fired.'
b. $\exists > \forall$
c. $*\forall > \exists$

The *na*-sentence in (26) has a reading in which professors co-vary with students (as in the scenario mentioned above where there are different recommendation letters for each candidate); the sentences in (27) and (28) lack this reading, as indicated. Farkas and Giannakidou propose certain semantic constraints to account for what allows for wide scope, which is not of immediate relevance here. What matters is that we may safely assume that the following holds:

(29) **Clause-boundedness of universal quantifiers**
The scope of $\forall$ is clause-bounded, except when $\forall$ occurs in an infinitival (or restructuring) domain.

But this is exactly the constraint we observed with NC in (18): NC is clause-bounded and possibly long-distance only across *na*-complements; hence NC is clause-bounded in the way the scope of universal quantifiers is. The type of locality involved in NC, then, strongly implicates a quantificational dependency. Note that this conclusion is not necessarily an argument for Quantifier Raising (QR), although it is implemented as application of QR in Giannakidou (1998, 2000). The generalization can be cast also in a system where quantifiers do not move; for an attempt to implement this idea as an instance of non-movement AGREE (Chomsky 2001b); see Giannakidou and Merchant (2002).

2.3.2 *Negative concord as a universal scoping above negation*

Greek *n*-words are universal quantifiers, which are additionally polarity sensitive – since they need negation to be licensed. In the framework of polarity we are assuming, NPI-universals come with a sensitivity requirement which makes them different from non-sensitive universals: unlike these, which can combine with both positive and negative predicates, NPI-universals can only combine with negative (i.e. antiveridical) predicates. Just like in other polarity dependencies discussed in Giannakidou (1998), this distinctive feature must be encoded in the grammar as a type difference between non-sensitive universals and their NPI-counterparts.[5]

As NPIs, NPI-universals require the presence of negation but they must move in a scope position above negation. This movement is motivated (a) by their sensitivity requirement to combine with an antiveridical predicate, and (b) by the need to yield the correct interpretation for NC as $\forall\neg$, which is the only reading NC structures have.[6]

Consider now the following core sentences, and their respective interpretations. Since Greek is a VSO language, the orders are natural and quite common.

Overt movement of emphatics is also allowed (and must be analyzed as topicalization, as we will see later in section 2.3.4).

(30) Dhen irthe KANENAS.
not came.3sg n-person
'Nobody came.'

(31) Dhen ipe o Pavlos TIPOTA.
not said.3sg the Paul n-thing
'Paul said nothing.'

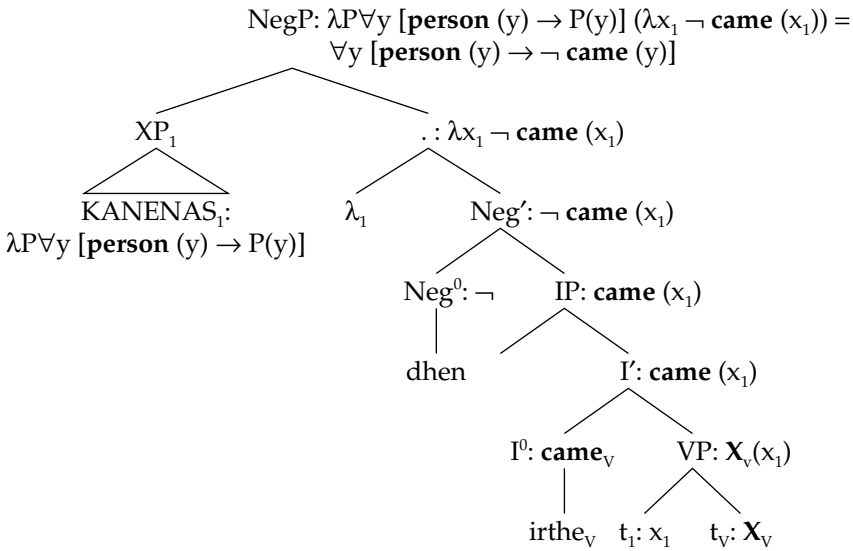
(32) $\forall x$ [**person** (x) $\rightarrow \neg$ **came** (x)]

(33) $\forall x$ [**thing** (x) $\rightarrow \neg$ **said** (Paul, x)]

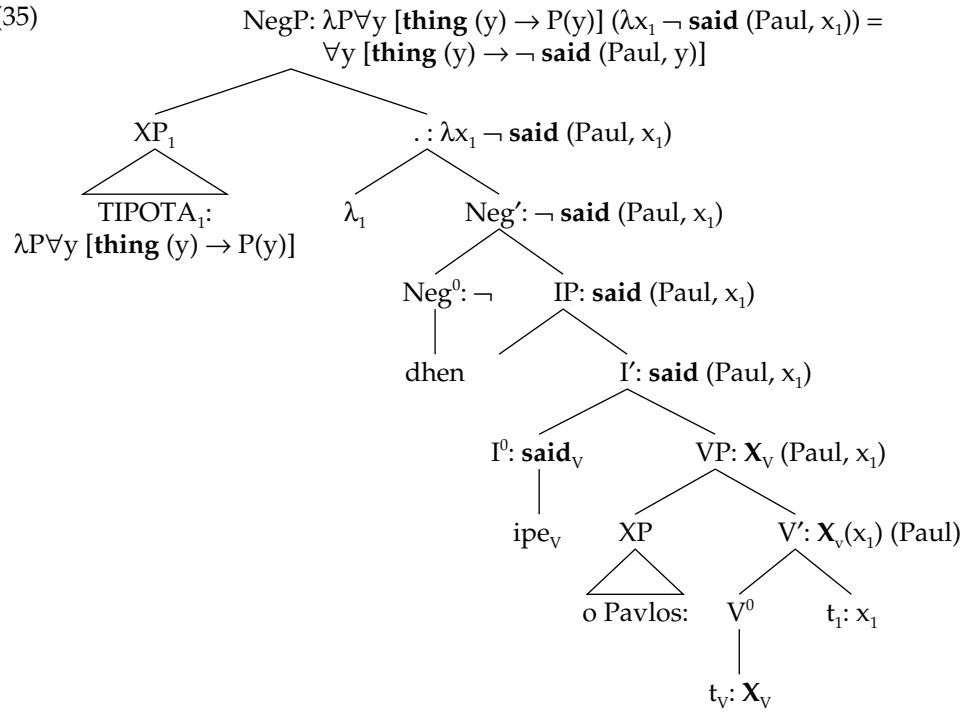
The *n*-word is interpreted above negation, resulting in a universal negative statement. Since we are dealing with quantifiers, the obvious way to derive this reading is to assume that KANENAN and TIPOTA undergo QR and scope above negation. Note that non-sensitive universal quantifiers like *kathe* 'every' cannot scope over negation from a VP-internal position. This fact has been noted for a number of languages (see Beghelli and Stowell 1997 for discussion; Giannakidou 2000: 499–501, for an explanation of the contrast by invoking the Elsewhere principle of Kiparksy 1973).

Given that negation precedes the emphatics in the linear order, we must assume that the universal-over-negation reading is achieved by QR at LF. The proposed LFs are given in (34) and (35); for the '.'convention see Heim and Kratzer (1998); some irrelevant intermediate steps are suppressed.

(34)



(35)



In such configurations, KANENAS and TIPOTA undergo QR past *dhen* and land in [Spec, NegP], though an orthodox implementation of QR as adjunction (May 1985), in this case to NegP (or just IP, if one wishes to analyze *dhen* as a clitic), is equally conceivable. In either case, emphatics are interpreted outside the scope of negation, arriving at the desired logical representations. Nothing specific to NC such as absorption needs to be stipulated. Multiple occurrences of emphatics require successive adjunctions to NegP (or multiple specifiers as in Chomsky 1995c; nothing crucial seems to rely on this choice).

The analysis presented here has one thing in common with the neg-criterion approach: it proposes movement of the *n*-word to [Spec, NegP]. Yet, unlike the neg-criterion, this analysis does not *rely* on the existence of NegP, and can be cast, as mentioned above, also in terms of adjunction to IP, if one does not want to postulate NegP, for example, or in order to account for NC with *without*, where there is no overt negation. In the context of NegP, the motivation of the movement to [Spec, NegP] in this analysis differs substantially from that in the proposals insipired by the neg-criterion. In these approaches, the *n*-word moves in order to undergo absorption (or check its negative feature). In the account presented here, *n*-word movement to [Spec, NegP] is motivated by the correct interpretation of NC. Additionally, this analysis seems to work independently of the syntactic status of the NM (whether it is the head or the specifier of NegP). Hence, unlike accounts based on the neg-criterion, this proposal captures

correctly the fact that NC arises with both X^0 and XP SNs (cf. section 1), without further adjustments.

2.3.3 Commitment of existence

The analysis of *n*-words as universal quantifiers predicts that universal *n*-words will give rise to an existential inference, just like universal quantifiers usually do. The issue is discussed extensively in Horn (1997), where it is shown that universal statements are not like regular conditionals which can be true also in case the antecedent is false. Rather, we tend to interpret universal quantifiers with non-empty restrictions: for example, we tend to evaluate *Every student left* as true only in a context where there are students; a continuation like *but there are no students* is highly disfavored (though not impossible, especially if instead of an episodic past tense we have a modal verb; see Giannakidou 1999: 401–404 for discussion). With some universals, the existence condition is a presupposition, e.g., with *both* and *each*. We need not address at present the issue of what exactly the nature of these existence inferences with universals is; we will just refer to them as existential commitments, following Horn. The presuppositional nature of existence with universals becomes visible with negation:

(36) a. #I Cleo dhen idhe kathe monokero.
the Cleo not saw.3sg every unicorn
#Cleo did not see every unicorn.
b. ¬[∀x **unicorn** (x) → **saw** (Cleo,x)]

The sentence is odd, in Greek as well as in English. The source of oddity is that we presume that the restriction of the universal is non-empty, that is, that there are unicorns in the actual world, and this is a bizarre thing to assume.

Unlike universals, existential quantifiers do not express existential commitment under negation. The sentence in (37a) is fine and can be continued with something like 'because unicorns don't exist':

(37) a. I Cleo dhen idhe enan monokero.
the Cleo not saw.3sg a unicorn
'Cleo did not see a unicorn.'
b. ¬∃x [**unicorn** (x) ∧ **saw** (Cleo,x)]

In the light of this contrast, the hypothesis that some *n*-words are universal predicts that those *n*-words will resemble other universal in presupposing, or being associated to, existence. Consider the sentences below, with an extensional and intensional verb:

(38) a. #I Cleo dhen idhe KANENAN monokero.
the Cleo not saw.3sg n- unicorn
'Cleo saw no unicorns.'
b. ∀x [**unicorn** (x) → ¬ **saw** (Cleo,x)]

(39) a. #I Cleo dhen psaxni.3sg KANENAN monokero.
the Cleo not seek.3sg n- unicorn
'Cleo seeks no unicorns.'
b. $\forall x$ [**unicorn** (x) $\rightarrow \neg$ **seek** (Cleo,x)]

These sentences are as odd as (36), and for exactly the same reason: we are forced to commit ourselves to existence of unicorns, which is of course an odd thing to do. Hence the sentences above support the assumption that emphatic *n*-words are universals and not existentials. (Note that the scope with respect to negation does not really matter, as existence commitment with regular universals survive despite the fact that the universal is interpreted under the scope of negation and not above it, as is the case with *n*-words.)

Existential PIs (called 'non-emphatics'; to be discussed more extensively in section 5), and bare NPs do not give rise to existential commitment, as expected. The following sentences are fine since we are not forced to question the speaker's grasp of the actual world:

(40) a. #I Cleo dhen {idhe/psaxni} KANENAN monokero.
the Cleo not saw.3sg/seek.3sg n- unicorn
'Cleo didn't see any unicorns.'
'Cleo isn't looking for any unicorns.'
b. #I Cleo dhen {idhe/psaxni} monokerus.
the Cleo not saw.3sg/seek.3sg unicorns
'Cleo didn't see unicorns.'
'Cleo isn't looking for unicorns.'

The contrast between emphatics and non-emphatics/bare plurals we observe is in accordance with the position defended in Giannakidou (1997, 1998) that non-emphatics are interpreted as existentials inside the scope of the licensing operator. Bare NPs too are known to take narrow scope with respect to other operators (see Carlson 1977a).

Finally, consider construals of emphatics with modal verbs like (41):

(41) Dhen epitrepete na apolisun KAMIA nosokoma.
not is.allowed.3sg subj fire.3pl n- nurse
'They are allowed to fire no nurse.'

In construals with negative quantifiers and intensional verbs, sentences like the English translation of (41) and especially their Dutch (*geen*) and German (*kein*) counterparts – are known to give rise to the three readings below (see Jacobs 1980; von Stechow 1993; Rullmann 1995a; De Swart 1996):

(42) a. For each nurse *x*, one is not allowed to fire *x*. (wide scope)
b. What one is allowed to do is not fire any nurses. (narrow scope)
c. One is not allowed to fire any nurses. (split)

The three readings are truth-conditionally distinct. The reading in (42b) is rather marginal without the appropriate context. On the wide-scope reading, we talk about a particular set of nurses and one is not allowed to fire those nurses. On the so-called split reading, on the other hand, we do not talk about a particular set of nurses. Sentences with this reading are true if firings are about some nurse or other. The availability of the split reading has been taken to argue in favor of a decompositional analysis of negative quantifiers as $\neg\exists$, as in this reading the modal operator is interpreted in between negation and the existential quantifier (but see our discussion in section 5.2.4 regarding the contrast between German and Dutch, on one hand, and English, on the other).

Crucially, the Greek sentence in (41) has only one reading: the wide-scope one. The other two readings, where negation and the intensional operator take wide scope over the quantifier, are excluded. This is precisely what the analysis of universal *n*-word predicts. (As expected, bare plural and non-emphatic construals are only interpreted narrow scope, or with the split reading.)

2.3.4 Existence, familiarity, and topicalization

In agreement with the existence commitment, universal *n*-words exhibit the property of familiarity. The notion is the one from Heim's file-change semantics (Heim 1982): a quantifier is familiar if it carries an index which is already present in the files representing the previous discourse. Familiar quantifiers are thus presuppositional, i.e., they pick up discourse referents whose existence is previously established. Definite NPs prototypically denote familiar quantifiers, but universal quantifiers have also been taken to refer to familiar discourse referents, only in their case the discourse referent is a set rather than an individual (Kamp and Reyle 1993; Szabolcsi 1997c). From a universal *n*-word, then, we expect familiarity; and this fact makes universal *n*-words prime candidates for topics, which can also undergo syntactic topicalization. These expectations are indeed borne out, as shown in Giannakidou (1998, 2000). In this section we briefly summarize the core facts, also because they make very clear predications cross-linguistically.

Consider the standard case in (43) and its assigned semantic structure.

(43) a. Dhen aghorasa KANENA vivlio.
not bought.1sg n- book
'I bought no book.' (= I didn't buy any books)

b. $\forall x$ [**book** (x) $\rightarrow \neg$ **bought** (I, x)]

Negative sentences with emphatic *n*-words have constrained distribution: they cannot be uttered just out of the blue. Those with existential/indefinite PIs, however, though truth-conditionally equivalent, can be used more freely and pose no requirement on the initial context, as we realize when we think of the respective sentence with *any*. The following two examples illustrate what it means to pose restrictions on the initial context.

Context 1.
Background: A: You were shopping all day. Did you buy anything? Clothes? Books? Records?

B: a. #A, oxi. Dhen aghorasa KANENA vivlio.
Oh, no. not bought.1sg n- book
Oh, no. I bought no book.

b. A, oxi. Dhen aghorasa kanena vivlio.
Oh, no. not bought.1sg n- book
'Oh, no. I didn't buy any book(s).'

In the background of this context, no reference to a particular set of books is established; the mentioning of books happens in a non-declarative sentence, hence no set of books is introduced in the set of files representing the common ground. In such a situation, the use of the emphatic *n*-word is totally inappropriate. Only the use an existential paradigm is felicitous – the non-emphatic *kanena vivlio*, equivalent to *any* under negation (to be discussed shortly in section 5). The contrast supports the assumption that universal *n*-words denote familiar objects, unlike indefinite *n*-words which are standardly analyzed as novel (Heim 1982).

Context 2.
Background: A: I remember you told me about those books that you saw at the *Griekse Eiland*. You wanted to buy them, right? What happened? Did you buy them after all?

B: a. A, oxi. Piga ke ta idha, ala dhen aghorasa (telika) KANENA vivlio.
'Oh, no. I went and looked at them but I bought no book after all.'

b. A, oxi. Piga ke ta idha, ala dhen aghorasa (telika) kanena vivlio.
'Oh, no. I went and looked at them, but I didn't buy any book after all.'

Unlike in Context 1, in Context 2, reference to a set of books has been established in the background. This renders the utterance with the emphatic felicitous. As expected, the statement with the existential *n*-word is fine too.

Denoting familiar entities, universal *n*-words can actually undergo topicalization. Definite NPs are what we would consider prototypical topics, since they are the prototypically familiar NPs; indefinites and weak NPs (in the sense of Milsark 1974), on the other hand, cannot be used as topics because they carry novel indices, i.e., they introduce objects in the discourse rather than presupposing them. Indefinites can be used as topics only if novelty is suspended, as happens when indefinites are interpreted as partitives.

Since universal quantifers denote familiar discourse entities they can easily be used as topics, and even undergo syntactic topicalization across languages (for discussion and references see Giannakidou 2000; Cinque 1990c; Rizzi 1997). We witness this in the clitic left-dislocation (CLLD) examples below, where the universal object quantifiers appear in a left peripheral topic position, and they are linked to clitics in the base position:

(44) Kathe dhema to paredhosa ston paralipti tu. Greek
every parcel it delivered.1sg in-the recepient his
'As for every parcel, I delivered it to its recipient.'

(45) Tutti i tuoi libri li ho rimesso al posto. Italian
all your books them have.1sg put.back in place
'As for your books, I put them back to their place.'

In the above cases, the quantifier phrase is rich in descriptive content: it is either a modifier/determiner or additional modifers are used; bare quantifiers cannot be topicalized (Giannakidou 1997, 1998; Anagnostopoulou 1997):

(46) *Kathena ton idha.
everybody him saw.1sg

The requirement for rich descriptive content is not a mystery; rich descriptive content helps us indentify the discourse referent. This seems to be necessary for universal quantifiers, because otherwise, the universal quantifier picks up a set too large for a proper discourse referent. Crucially, emphatic *n*-words can also be left dislocated and co-indexed with clitics:

(47) [KANENAN fititi]$_1$ dhen (ton$_1$) idha na erxete stin ora tu.
n- student not him saw.1sg subj. come.3sg in time his
'I saw no student arriving on time.'

(48) [KANENA apo ta vivlia]$_1$ dhen (to$_1$) aghorasa telika.
n- of the books not it bought.1sg finally
'I bought none of the books after all.'

The presence of the clitic is not obligatory but in itself, the fact that emphatic *n*-word preposing allows clitics argues for a topic analysis, against an assimilation of such structures to focus preposing which, strictly speaking, requires a gap in the base position (Tsimpli 1995). The appearance of the clitic is again sensitive to the richness of the descriptive content of the preposed emphatic or the sentence predicate. As we see in (49), bare emphatics are incompatible with clitics:

(49) *KANENAN$_1$ dhen ton$_1$ idha.
n-person not him saw.1sg
'Nobody I saw.'

A parallel is observed in the preposing of Italian *n*-words. As noted in Rizzi (1997), bare *nessuno* cannot be coindexed with a clitic, but if we enrich its descriptive content and combine it with a relatively 'heavy' predicate, clitics become fine:

(50) *Nessuno l 'ho visto.
n-person him have.1sg seen

(51) Nessuno {di loro/in questo dipartimento} l 'ho visto parlare
n- student of them/in this department him have seen talk
con Maria.
with Mary
'I saw {none of them/no-one in the department} talking to Mary.'

The above contrasts are consonant with the idea that *n*-words can be used as topics. We will not pursue the matter in more detail here; see Giannakidou (1998, 2000) for additional diagnostics supporting this conclusion.

2.3.5 Summary

The theory implemented in Giannakidou (1998, 2000) proposes a 'pluralistic' view of NC, where *n*-words can be either universal or existential, or ambiguous between the two readings. A number of novel diagnostics are offered for universality, which we summarize here in points (a), (b), and (c). In section 5, we augment this list with the diagnostics in (d–f).

(52) **Diagnostics for universal *n*-words:**
A universal *n*-word has the following properties:
a. It is licensed only by local negation; long-distance licensing may be allowed only through an infinitival or subjunctive clause.
b. It expresses existential commitment, i.e., we tend to interpret it with a non-empty restriction.
c. It can be used as topic in topicalization structures. It these cases it may be coindexed with a clitic pronoun (or a pronoun performing the respective function, if a language does not employ clitic pronouns).
d. It can be modified by modifiers corresponding to *almost/absolutely*.
e. It cannot bind donkey pronouns.
f. It cannot be used as predicate nominal.

In section 5 we will further review a number of tests for the existential import of *n*-words. The predictions for other languages are, then, clear, and we should be able to use the proposed diagnostics in order to trace the relevant Q-force of a given *n*-word paradigm. Notably, the theory does not predict that all *n*-words will exhibit the features of the Greek ones – on the contrary, because we acknowledge that negative statements can also exhibit an underlying existential structure, we expect languages to realize this option too. In such languages, however, *n*-words will behave differently with respect to the diagnostics above. We see, for example, that Slavic *n*-words, exhibit a mixed behaviour in satisfying criteria (a), (d), and (e), and partly (b), but at the same time, they violate (f) and can occur as predicate nominals, or they do not always give rise to existence commitments. (The topicalization test still needs to be checked.) Surányi (2002) further notes

that Hungarian *n*-words can be presuppositional and non-presuppositional, depending on the syntactic position in which they are found, a finding also supporting the pluralistic view on NC that we presented here.

Having familiarized ourselves with the theoretical options for *n*-words and NC, we can now illustrate the empirical picture. We will see that for the correct interpretation of *n*-words we need two basic options: *n*-words can be either universal quantifiers or existential ones. In certain positions they can also receive a negative meaning, primarily in the preverbal position or in negative spread; but this happens only with a subset of *n*-words, mainly in Romance languages.

3 Two basic varieties of negative concord and the distribution of *n*-words

A central division in the description of NC is that between strict NC and non-strict NC (Giannakidou 1998). In this section we illustrate the distinction which we will use as a guide, for the taxonomy of *n*-words in section 3.2.

3.1 Strict and non-strict varieties of negative concord

Strict NC varieties always require the presence of SN; in (2) we saw examples of this variety. It does not matter whether the *n*-word is a subject, object, or adjunct, or whether it is preverbal or postverbal. In strict NC varieties, the presence of SN is obligatory. We illustrate this below with examples from Serbian–Croatian and Greek:

(53) a. Milan *(ne) vidi nista. Serbian–Croatian
Milan not see.3sg n-thing
'Milan cannot see anything.'
(Progovac 1994: 40, 41)

b. Milan nikada *(ne) vozi.
Milan n-when not drive.3sg
'Milan never drives.'

(54) a. O Petros *(dhen) idhe TIPOTA. Greek
the Peter not saw.3sg n-thing
'Peter didn't see anything.'

b. O Petros POTE *(dhen) odhiji.
the Peter n-when not drive.3sg
'Peter never drives.'

Besides Greek and Serbian–Croatian, all other Slavic languages, as well as Hungarian, Romanian, and Japanese exhibit the property of strict NC. Even in structures with multiple *n*-words is the presence of SN obligatory, as we see in the examples below (from Giannakidou 2000; Przepiórkowski and Kupsc 1998; Puskás 1998; Watanabe 2001, respectively):

(55) KANENAS *(dhen) ipe TIPOTA. Greek
n-person not said.3sg n-thing
'Nobody said anything.'

(56) Nikt *(nie) uderzył nigogo. Polish
n-person not hit.3sg n-person
'Nobody hit anybody.'

(57) Balázs *(nem) beszélt senkivel semmiröl. Hungarian
Balázs not spoke.3sg n-person n-thing
'Balázs didn't talk about anything with anybody.'

(58) Dare-mo nani-mo iwa-*(nak)-atta. Japanese
n-person n-thing say.neg.past
'Nobody said anything.'

Hence Greek, Hungarian, Japanese, and Slavic languages form a natural class in terms of strict NC, and require the SN even when more than one *n*-word occurs in a sentence. Strict NC structures never receive double negation readings, as emphasized in the studies just mentioned.

The situation in Romance is quite different. The presence of SN is not obligatory and two *n*-words may co-occur in the absence of it, as in the sentences below. This variety of NC is known as negative spread (Den Besten 1986).

(59) a. Nessuno ha letto niente. Italian
n-person have.3sg read n-thing
'Nobody read anything.'
b. Nadie dijo nada. Spanish
n-person said.3sg n-thing
'Nobody said anything.'
c. Ningú va dir res. Catalan
n-person aux.3sg say n-thing
'Nobody said anything.'
d. Ninguem viu nada. Portuguese
n-person saw.3sg n-thing
'Nobody saw anything.'

Crucially, if we insert SN in languages above we get a double-negation reading; but Romanian and Catalan seem to be an exception to this. Catalan in particular allows optionally for SN with a NC (single negation) reading:

(60) Cap estudiant (no) va dir res.
n- student not aux.3sg say n-thing
'No student said anything.'

There are more subtle details to be addressed here. The most important one to note is that although negative spread is fine with bare *n*-words, i.e., *n*-words as independent NP constituents, it seems to be disallowed when *n*-words are used as modifiers or determiners. The fact has been noted in Acquaviva (1997) for Italian (and attributed to Manzotti and Rigamonti 1991), but it has not been discussed much in the relevant literature.

(61) ??Nessuno studente ha letto nessun libro.
n- student has read n- n-thing
(Acquaviva 1997: 69)

The sentence above is reported impossible on the intended NC reading. Similarly, structures with two *n*-words functioning both as determiners are excluded in Spanish and Catalan (Josep Quer, p.c.). Compare the two sets of sentences below:

(62) a. Ningún estudiante dijo nada Spanish
b. Cap estudiant (no) va dir res Catalan
n- student (not) said n-thing
'No student said anything.'

(63) a. ??Ningún estudiante contestó ninguna pregunta. Spanish
n- student answered n- question
b. ??Cap estudiant va contestar cap pregunta. Catalan
n- student answered n- question

According to the native speaker's intuition, the unacceptable judgment in Spanish is due to the fact that it points to a double negative reading which is, however, not possible. In Catalan, on the other hand, if we add SN *non* the result is a NC reading 'No student answered any question' and not the double-negative reading 'it is not the case that no students answered any questions'. This is so because addition of SN in Catalan does not yield double negation, as we just saw (60). In the Romance languages family, the only language that does not seem to exhibit a contrast regarding the determiner or QP status of the *n*-word is Portuguese, according to Peres (2000), where equivalents of (61) are reported to be fine.

We surely want to link these facts to other distinctive feature of Romance NC regarding the position of *n*-words (preverbal or postverbal) that we tackle immediately below. Most importantly, if the relevant *n*-words were inherently negative, we would not expect to see the contrasts presented here; double-negative and NC readings should be freely allowed (depending on whether we apply the rule of negative absorption or not), contrary to fact. On the other hand, the different judgments we get between bare *n*-words and determiner *n*-words could be made to follow if we assumed that bare *n*-words are negative quantifiers, but determiner words are indefinites: the non-co-occurrence of two determiner *n*-words

would then follow as a non-licensing, since there is no negation. Two bare *n*-words, on the other hand, would form a branching negative quantifier structure yielding one negative reading. In fact, the re-interpretation of negative absorption as branching quantification seems to be a desirable move for explaining the pattern of negative spread (as suggested in Giannakidou 1997: 151; see De Swart and Sag 2002 for an implementation of this idea as resumptive quantification in French).

Going back to the comparison between strict and non-strict NC varieties, we should note again that Greek, Hungarian, and the Slavic languages do not exhibit negative spread and require SN regardless of the number of *n*-words. In the example below (from Giannakidou 2000) we see that the number of *n*-words that can occur in a sentence is unlimited, and the presence of SN is still obligatory:

(64) KANENAS *(dhen) ipe POTE TIPOTA se KANENAN Greek
n-person not said.3sg n-ever n-thing to n-person
'Nobody ever said anything to anybody.'

Given this clear empirical contrast between Romance languages and strict NC languages regarding the obligatoriness of the SN, it seems reasonable to expect that the semantic properties of *n*-words in these two core varieties will not be the same. The existence of negative spread, as well as the fact that double negation readings arise with bare *n*-words and negation indicates that these particular *n*-words may indeed contribute negation, as we just suggested; but in strict NC varieties *n*-words obviously do not convey logical negation, since they always need SN, and license only NC readings.[7]

Not all Romance languages, however, allow negative spread; recall example (60) from Catalan, which allows the SN with more than one *n*-words. Romanian forms an even stronger exception: it *requires* strict NC, and does not allow negative spread at all (data from Bernini and Ramat 1996: 176, 186)

(65) a. Nimeni *(nu) vine.
n-person not come.3sg
'No one is coming.'
b. Nimeni *(nu) vazu nimic.
n-person not saw.3sg n-thing
'No one saw anything.'

Obviously, then, the semantic content of *n*-words in Romance is not uniform. Instead we seem to have a scale which includes on the one end Romanian, which is strict NC, and on the other end Spanish, Italian, and Portuguese, which allow for negative spread. Catalan is in between the two ends. This situation clearly suggests that the semantic content of Romance *n*-words vis-à-vis negativity must be different in each variety.

Before closing this section it is worth reminding that, as noted in n. 1, negative spread patterns are marginally found in languages that typically do not exemplify NC, e.g. Dutch and German. These cases, however, are restricted to certain contexts, and exhibit special emphatic intonation which marks their exceptional use.

(66) Hier hilft KEINER KEINEM German
here help.3sg n-person n-person
'No one helps anyone here.'

Negative quantifiers can, then, occasionally form branching structures, independent of NC. It seems that almost none of the NC languages that have been thoroughly studied in the literature makes exclusive use of negative spread. French may be an exception to this generalization, as we shall see in section 3.3.

3.2 The position of n*-words: preverbal vs. postverbal*

A distinctive feature of non-strict NC varieties of Romance is that the presence of the SN may be disallowed even in structures with one *n*-word. This happens when the *n*-word is preverbal, as we see in the examples below from Spanish and Italian (Zanuttini 1991). Generally, then, while preverbal *n*-words exclude SN, postverbal ones require it. This fact is further illustrated below with data from Spanish:

(67) a. Mario *(non) ha visto nessuno. Italian
Mario not has seen n-person
'Mario didn't see anybody.'
b. Nessuno (*non) ha visto Mario.
n-person not has seen Mario
'Nobody saw Mario.'

(68) a. Pedro *(no) ha visto a nadie. Spanish
Pedro not has seen n-person
'Peter didn't see anybody.'
b. Nadie (*no) ha visto a Pedro.
n-person not has seen Pedro
'Nobody saw Peter.'

The b-sentences with preverbal *n*-words have the expected single negation NC reading only if SN is absent. The reading is illustrated below for the Spanish sentence; the universal negation is employed for uniformity, but as we said, the existential version is equivalent:

(69) $\forall x$ [**person** (x) $\rightarrow \neg$ **saw** (x, Pedro)]

If we do insert SN, we get the double negation reading:

(70) a. Nadie no ha visto a Pedro.
n-person not has seen Pedro
'Nobody saw Pedro.'
b. ¬ (∀x [**person** (x) → ¬ **saw** (x, Pedro)])

The asterisk in (67b) and (68b) is intended to show the absence of this double negation reading. Putting the facts together, we have to conclude that in preverbal position the *n*-word itself seems to contribute a negation, so that the addition of SN amounts to the addition of one more negation in the logical structure. The obvious question is: if the NC rule cancels out multiple negations in postverbal positions, why does it not apply in the case of preverbal ones? If *n*-words are negative we should expect double-negative readings to arise indiscriminately with preverbal and postverbal positions.

The best we can come up with is to stipulate an additional syntactic condition that negation must be expressed at the topmost level of the sentence, and that this can be done either by SN itself, or by an *n*-word (which is essentially the proposal in Zanuttini 1991). Once the *n*-word is inserted, the condition is satisfied, and the insertion of SN would add another logical negation; the condition would not affect the postverbal postion, obviously. Crucially, the condition would affect not only a preverbal subject, but also a topicalized preverbal *n*-word. Note also that the condition concerns exclusively the combination of a preverbal *n*-word and SN: we do not have double-negative readings with a preverbal and a postverbal *n*-word in negative spread. Apparently, this is so because with two bare *n*-words a different operation applies the formation of negative branching hence the negation-topmost condition does not apply. At any rate, to the extent we need the negation-topmost condition, and we do seem to need it, we accept that the *n*-words that the condition applies to convey, in certain positions, logical negation.

In strict NC languages such as Greek and Slavic we do not observe preverbal versus postverbal contrast; the SN is obligatory regardless of the position of the *n*-word (see Progovac 1994 and Giannakidou 1998, 2000 and works cited there).[8]

(71) a. Mario *(ne) vidi ni(t)koga.
Mario not see.3sg n-person
'Mario cannot see anyone.' (Progovac 1994: 37)
b. Ni(t)ko *(ne) vidi Mario.
n-person not see.3sg Mario
'Nobody can see Mario.' (Progovac 1994: 37)

(72) a. O Petros *(dhen) idhe KANENAN. Greek
the Peter not saw.3sg n-person
'Peter did not see anyone.'

b. KANENAS *(dhen) idhe ton Petros.
n-person not saw.3sg Peter
'Nobody saw Peter.'

Crucially, both patterns are attested in Catalan, as a preverbal *n*-word optionally allows the NM whereas a postverbal one requires it (see Quer 1993). Compare the sentence below with the ones above from Spanish and Italian:

(73) a. Ningú (no) ha vist en Pere. Catalan
n-person not has seen Peter
'Nobody saw Peter.'
b. En Pere no ha vist ningú.
Peter not has seen n-person
'Peter didn't see anybody.'

Sentence (73a) has the NC reading in (69) and not the double-negative one in (70); compare to Hungarian in n. 9. This fact correlates with the restricted negative spread observed in Catalan that we noted previously in 3.2. The correlation is supported further by Romanian, which does not tolerate negative spread and behaves just like strict NC varieties in requiring the presence of SN even with preverbal *n*-words, as we saw in (65). So, again, we are forced to conclude that it is impossible to invoke a uniform characterization for *n*-words in Romance, certainly not in terms of negativity. The implication of this is that we cannot invoke a uniform rule for NC in this language family either.

3.3 A typology of n*-words*

Having illustrated the basic patterns of negative concord, we summarize the results in this section in a typology of *n*-words. Before we present the final classification, however, there is a language that deserves special mention, and which we have not discussed so far: French.

French can be seen as a language with exclusive use of negative spread. The reason for this is that, although the French *n*-words *personne*, *rien*, etc. co-occur with the negative marker *ne*, this marker arguably does not convey logical negation:

(74) a. *Marie n'a vu Paul.
Intended meaning: 'Mary didn't see Paul.'
b. Marie n'a pas vu Paul.
'Mary didn't see Paul.'

Logical negation is expressed by *pas*; this explains the quite overwhelming tendency in colloquial French to drop *ne* altogether. Crucially, *pas* and *n*-words cannot co-occur, but two (or more) *n*-words with *ne* are fine:

(75) * Marie n' a pas rien dit.
'Mary didn't say anything.'

(76) Personne n'a rien dit.
'Nobody said anything.'

We can conclude, then, that patterns with French *n*-words and *ne* are patterns of negative spread, which squares with the observation that *ne* can also be dropped. French appears to be unique in that it employs only negative spread and strictly excludes NC proper.

French *n*-words have been treated in the literature as negative quantifiers (Corblin 1996, Larrivée 1995, among others), as quantificational elements with the force of *zero* N (Déprez 1997), as indefinites (Corblin and Tovena 2001) and non-negatives (Rowlett 1998), and as ambiguous (De Swart and Sag 2002). Note that sentences with multiple French *n*-words are systematically ambiguous between a NC and a double-negation reading (see a recent posting in the *Linguist* list 10.1799 by Misako Kitamoto with statistics on this ambiguity based on a sample of 26 speakers), which support the hypothesis that French *n*-words must be both negative and non-negative. Since we have proposed that negative spread can be analyzed as involving a branching quantifier structure, it seems plausible to say that, at least in negative spread, French *n*-words are indeed negative quantifiers. But French *n*-words can also be used in non-negative sentences, e.g., interrogatives, with existential meaning (as we shall see in section 4), hence we must also allow for a existential interpretation. In section 5, however, we see that French *n*-words do not receive non-quantificational interpretations, e.g., they cannot be used as predicate nominals, with negation. This fact is clearly problematic for the indefinite-only analysis, as this analysis predicts French *n*-words to be fine predicate nominals.

We are now in position to provide a typology of *n*-words in Romance, Slavic, Greek, and Hungarian based on the distinction between strict and non-strict NC and the empirical characteristics emanating from this distinction (see Table 45.1). We have a continuum with strict NC on the one end (rows 1–6) and negative-spread-only on the other, identified with French in row 11, which systematically licenses double-negative readings. In between we have Catalan, closer to the strict NC end, and Italian, Spanish, and Portuguese, closer to the French end. Keep in mind that the proper set of comparison here is the set of Germanic negative quantifiers which do not allow NC, and therefore answer 'no' to the three possibilities indicated in the table. French is almost identical to the Germanic situation, save for those cases where multiple occurrences of *n*-words do not allow for double-negative readings. We will compare this table to the semantic tests in section 5.3; the most important test is, as we will see, the ability to occur in non-negative contexts with non-negative readings. We will see that almost all *n*-words in the non-strict varieties (6–11) can do this; the only exception seems to be Portuguese.

Table 45.1 The distribution of *n*-words in Negative Concord

Language	PreV *n*-word+SN	PostV *n*-word+SN	Negative Spread
1. Greek	Yes	Yes	No
2. Hungarian	Yes	Yes	No
3. Polish	Yes	Yes	No
4. Russian	Yes	Yes	No
5. Serbian–Croatian	Yes	Yes	No
6. Romanian	Yes	Yes	No
7. Catalan	Yes	Yes	Yes
8. Italian	No	Yes	Yes
9. Spanish	No	Yes	Yes
10. Portuguese	No	Yes	Yes
11. French	No	No	Yes

Obviously, *n*-words in strict NC cannot be characterized as negative in any sensible way (although they can still provide negative fragment answers; we turn to this immediately). For these languages, then, an approach along the lines of negative absorption must be prima facie excluded.

4 The issue of negativity

Let us consider now in more detail the negativity of Romance *n*-words. Recall first that unambiguously negative quantifiers appear only in languages without NC, e.g., German, Dutch, and English (West Germanic). As we mentioned earlier, the standard diagnostics are two. First, negative quantifiers contribute negative meaning in the absence of SN. Second, when they co-occur, or when they co-occur with a SN, only double negative readings arise. Both facts are illustrated below.

(77) a. Heeft Frank **niemand** gezien? Dutch
have.3sg Frank nobody seen
'Is it true that Frank saw nobody?'
b. Frank heeft niet **niemand** gezien.
Frank have.3sg not nobody seen
'It is not the case that Frank didn't see anybody.'
Frank didn't see anybody.
c. Niemand zei niets. Iedereen had iets te vertellen.
nobody said nothing everybody had something to say
'It is not the case that nobody said anything. Everybody had something to say.'

In the above sentences *niemand* and its English counterpart are interpreted as negative quantifiers. The same can be said for *niets* 'nothing'. I give here the

version with ∀ without implying that this is the only option; negative quantifier construals can also admit ¬∃ readings (if this is how we chose to interpret *n*-words as predicate nominals, for example; the issue becomes relevant in 5.2).

(78) a. [[niemand]] = λP ∀x [**person** (x) → ¬ **P** (x)]
b. [[nobody]] = λP ∀x [**person** (x) → ¬ **P** (x)]
c. [[niets]] = λP ∀x [**thing** (x) → ¬ **P** (x)]

So negative quantifiers in West Germanic are inherently negative *n*-words. Crucially, languages with such *n*-words do not exhibit NC. Sentences like (77b, c) are unambiguously double negatives. The question now becomes: are Romance *n*-words, in the non-strict varieties of NC (including Catalan) identical to their counterparts in non-NC languages?

4.1 Negative meaning and ellipsis

The most popular alleged piece of evidence for the negativity of *n*-words comes from the fact that *n*-words can occur in fragment answers with negative readings (see Zanuttini 1991 for the original observation for Italian). This fact holds for strict as well as non-strict varieties, so we will address it in general terms here:

(79) Q: Who arrived?
a. Nessuno. Italian
'Nobody.'
b. KANENAS. Greek
'Nobody.'

I assume the following definition of what counts as a fragment answer:

(80) **Fragment answer:**
An answer α to a *wh*-question Q is a fragment answer iff:
a. α corresponds in form to the *wh*-XP constituent in Q; and
b. α is interpreted as a proposition.

It follows from (a) and (b) jointly that a fragment answer is an elliptical structure, since α is a non-sentential constituent which nevertheless receives the interpretation of a sentence. Hence, in the fragment answer above, *Nessuno* and *KANENAS* identify *who* arrived, and, although what appears as an answer in each case is just an NP, the fragment answer they each form is actually interpreted as a proposition meaning *Nobody arrived*. What has not been sufficiently appreciated in the literature is that the fact that *n*-words are interpreted negatively in the absence of overt negation does not prove that they are negative. Rather, negation here arises from the fact that we have ellipsis. If we were to spell out the full structure, the presence of negation would be indispensable, as indicated below; strike-through indicates elided material:[9]

(81) A: KANENAS [*(~~dhen) irthe~~].
n-person not arrived.3sg
Nobody [arrived].

There are two similar cases which might indicate that *n*-words contribute negative meaning in elliptical contexts: (a) coordinations (disjunctions, and possibly also conjunctions), and (b) some apparently equative structures which are interpreted like comparatives, invoking alternatives. We give here Greek examples (from Giannakidou 2000) but similar facts have been documented for Romance (Zanuttini 1991) and Slavic (Przepiórkowski and Kupsc 1998):

(82) Thelo na pandrefto ton Petro i KANENAN (alo).
want.1sg subj marry.1sg the Peter or n-person (else)
'I want to marry Peter or nobody (else).'

(83) O Petros ine toso psilos oso KANENAS (alos) stin taksi tu.
Peter is as tall as n-person (else) in-the class his
'Nobody else in Peter's class is as tall as Peter is.'
(Implicating that Peter is taller than anybody else in his class. Not that Peter is as tall as everybody else in his class.)

(84) i [*~~(dhen) thelo na pandrefto~~ KANENAN.
or not want .1sg subj marry.1sg n-person
. . . or I don't want to marry anybody.

(85) oso [*~~(dhen) ine~~] KANENAs alos stin taksi tu.
as not is n-person else in-the class his
'Peter is as tall as nobody else in his class.'

In these cases, the addition of *alo* 'else', which seems necessary for most speakers, signals that we are considering alternatives. Reduced co-ordinations have been argued to be an instance of clausal ellipsis by numerous authors (see Johnson 1996; the same holds for clausal comparatives, for a recent discussion see Lechner 2001).

Further evidence that we are dealing with clausal ellipsis is provided by the fact that in the coordination example (86) the preposition *me* 'with' cannot be omitted; this is in agreement with other cases of moved remnants under ellipsis, such as in gapping and sluicing, since Greek does not allow preposition stranding (see Merchant 2001 for the correlation between preposition stranding and the (un)availability of prepositions under ellipsis). On the other hand, DPs can be coordinated in general, as in (87):

(86) Thelo na miliso me ton Petro {i/ke} *(me) KANENAN (alo).
want.1sg subj talk.1sg with the Peter {or/and} with n-person (else)
'I want to talk to Peter {or/and} nobody (else).'

(87) Milisa me ton Petro ke ti Maria.
talked.1sg with the Peter and the Mary
'I talked to Peter and Mary.'

Likewise, prepositions cannot be omitted in negative answers:

(88) Q: Me pjon milises?
with whom talked.2sg
'Who did you talk to?'
A: *(Me) KANENAN.
'(To) nobody.'

Again, we see that a language which does not allow preposition stranding, Greek, does not allow omission of the preposition in a negative fragment answer; but in English, a language allowing preposition stranding, the preposition can be omitted with no cost. Hence we have to say that the negative meaning in elliptical fragments arises not as an inherent contribution of the *n*-word, but rather as the result of their being associated with negation at the level at which ellipsis is resolved. Watanabe (2001) questions the ellipsis argument by raising the problem of the antecedent. If the elliptical LF contains negation in a fragment answer, where does this negation come from? The problem is that the antecedent is actually positive; and this goes against the assumption that the ellipsis structure and that of its antecedent must be syntactically isomorphic. Syntactic isomorphism, however, is a highly controversial assumption, as shown recently in Merchant (2001), and one that Giannakidou (2000) does not share. Merchant illustrates numerous problems with the arguments for syntactic isomorphism; the problems with LF-identity were also well known in the purely semantic approaches to ellipsis, and they were even noted in more syntactic approaches like Fiengo and May (1994), where 'vehicle change' was introduced to explain away some of them.

Merchant (2001) proposes an alternative based on (a particular implementation of) semantic isomorphism: the antecedent proposition must semantically license the elliptical one. Licensing is, roughly, a relation between inferences. The elliptical proposition will be licensed only if it can be inferred by the proposition that serves as its antecedent. Following Karttunen (1977), where questions denote the set of their true answers, a negative-fragment answer is indeed licensed semantically by its antecedent in Merchant's terms. A negative answer is part of the denotation of a question, and thus a possible inference from it. A question like *Who arrived?* denotes the Q-set we see below. This set contains a negative proposition as a possible answer:

(89) Domain: {Frank, Bill}
Q: {Frank arrived, Bill arrived, Nobody arrived}

So we do have an appropriate antecedent for a negative fragment answer; but it is found in the *denotation* of the question, and need not be part of its syntax. That

it is the semantics that we need becomes evident in the fact that a plain declarative sentence, like the one below, does not serve as an appropriate antecedent for this kind of ellipsis:

(90) A: O Janis irthe.
'John arrived.'
B: #Oxi, KANENAS.
'No, nobody did.'

The denotation of an extensional declarative sentence is just a single proposition; if it happens to be positive, as in (90), it cannot license semantically an ellipsis which needs a negative antecedent.

It thus seems safe to conclude that the negative meaning in ellipsis fragments is not evidence for an inherent negative meaning of *n*-words. It is a little more complicated to trace the negative antecedent in the coordination and the comparative examples which also license the negative ellipsis; but note that these structures involve alternatives (worlds and degrees), and this may provide the basis for a successful search.

Most importantly, items which indeed have inherent negative meaning, like *udhis* 'nobody' and *udhen* 'nothing', are *not* construed with negation. *Udhis*, *udhen* are remnants from ancient Greek with very limited use in the modern language. They are negative quantifiers, and, as we see below, cannot co-occur with negation.

(91) Udhen neoteron (*dhen) exomen.
nothing new not have.1pl
'We don't have any new developments.'

Sentences such as (91) belong to a formal register, but when appropriate, they do not allow negation. The absence of NC in ancient Greek is parallel to the absence of NC in English, German, and Dutch, and due, apparently, to the fact that a negative quantifier paradigm is employed in these languages.[10] It appears, therefore, that the ellipsis facts question directly the assumption that *n*-words are negative quantifiers. True, this conclusion seems safer to make for strict NC varieties, where the SN is obligatory in every case. But what about non-strict varieties of *n*-words?

4.2 Non-negative readings of n*-words*

The decisive fact here is that most Romance *n*-words can be used in non-negative contexts without contributing negation. These contexts are typical polarity structures, e.g. interrogative sentences, conditionals, superlatives, and restrictions of universal quantifiers. The fact has been noted numerous times in the literature, and is illustrated below with examples from Catalan, Spanish, and Italian (Quer 1993; Laka 1990; and Acquaviva 1997, respectively):

(92) a. Li diràs res? Catalan
him/her tell.fut.2sg n-thing
'Will you tell him/her anything?'
b. Si aneu enlloc digueu- m'ho.
if go.2sg n-place tell.imp.2pl me
'If you go anywhere, let me know.'
c. Tothom qui vulgui res que m'ho digui.
everybody who want.3sg n-thing that me tell.3sg
'Everyone who wants something, should let me know.'

(93) a. Perdimos la esperanza de encontrar ninguna salida. Spanish
lost.1pl the hope to find n- exit
'We lost hope of finding some way out.'
b. Todo aquel que tenga nada que dicir . . .
all who that have n-thing that say
'Everyone who has anything to say. . . .'

(94) a. È venuto nessuno? Italian
is.3sg come n-person
'Has anyone come?'
b. È l'idea più stupida che abbia mai avuto nessuno.
is.3sg the idea more stupid that have.subj.3sg n-ever had n-person
'It's the dumbest idea anybody has ever had.'

In the above sentences, *n*-words are unable to contribute negation by themselves. Instead, they are interpreted merely as existential quantifiers, as evidenced by the translations. The comparison with the Germanic (77a), which is a negative question, is quite telling. We have to conclude, therefore, that these Romance *n*-words, unlike the Germanic ones, are not negative quantifiers. Note that this conclusion holds even for the most relaxed variety of French, which allows both a negative and an existential reading:

(95) Est-ce que tu a vu personne?
'Did you see anybody?'
'Is it true that you saw nobody?'

Hence, Romance *n*-words are at best ambiguous between a negative and a non-negative, existential meaning.

In contrast to the rest of Romance, Romanian and Portuguese *n*-words cannot appear in non-negative structures at all. This implies that these *n*-words apparently cannot contribute negative meaning themselves; though this does not seem to be a correct assumption for Portuguese, which, unlike Romanian, allows negative spread and *n*-words in preverbal position without negation. (We compare the two languages again in the concluding section.) Additionally, Romanian and Portuguese *n*-words seem unable to contribute existential meaning; in this they

are in sharp contrast with the rest of Romance languages, which allow existential readings with their *n*-words to varying degrees. For this purpose an unambiguously existential item is employed:

(96) a. Telefonou {*ninguém/alguém}? Portuguese
(Intended meaning: Did you call anybody?)
b. Se vem {*ninguém/alguém} estamos perdidos.
'If anybody comes, we are lost.'

(97) a. A telefonat {*nimeni/cineva}? Romanian
(Intended meaning: Did you call anybody?)
b. Dac vine {*nimeni/cineva} sîntem pierdui.
'If anybody comes we are lost.'

(There seems to be no difference between European and Brazilian Portuguese in this respect.) That these *n*-words are unable to contribute an existential quantifier also casts serious doubt on the hypothesis that they are indefinites (see e.g. Peres 2000 for Portuguese). If they were, we would expect an existential reading in non-negative contexts. *N*-words in strict NC languages exhibit exactly the same pattern: they are not licit in non-negative contexts. The point is illustrated here with interrogatives:

(98) a. Da li Milan voli nitkoga? Serbian
that Q-prt Milan love.3sg n-person
b. *Nikto zvonil? Russian
n-person called.3sg
c. *Olvassot Maria semmit? Hungarian
read.3sg Maria n-thing
d. *Idhes KANENAN? Greek
saw.2sg n-person

Greek, Hungarian, and Slavic *n*-words are ungrammatical without negation. This implies that they are unable to contribute negation on their own, as West Germanic *n*-words do, despite the fact that their morphological make-up seems to have a negative component. As previously, a plausible conclusion must be that *n*-words in strict NC are unable to contribute an existential quantifier independently of negation either. An additional conclusion for *n*-words in strict NC varieties is that they are negative PIs (NPIs), and not just PIs, as those *n*-words occurring in non-negative contexts arguably are. This claim must obviously be extended to Portuguese, excluding thereby the *n*-word from a non-negative context as a licensing failure.

The picture we draw here regarding negativity clearly supports the position that we have been arguing for all along, namely, that *n*-words do not form a semantically uniform class across languages. It also seems hard to pin down a class of *n*-words that is just negative – Portuguese may be such a case, as we

suggest later in the conclusions. Generally, when in non-negative contexts *n*-words are either interpreted existentially (Italian, Spanish, Catalan), or they cannot be interpreted at all and are thus ruled out (Romanian, and strict NC). At best, we can find only *n*-words that are ambiguous between negative and non-negative readings (French). Given that *n*-words may indeed have existential readings, we need to check, finally, what the characteristics of existential readings are, and what their impact is on the analysis of *n*-words. This is the direction we take next.

5 The possibility of having an existential polarity item under negation

Consider a language like English which employs a negative quantifier and *any* under negation:

(99) a. **Existential negation:**
I didn't buy any book(s).
b. $\neg\exists$x [**book** (x) $\wedge$ **bought** (I, x)]

(100) a. **Universal negation:**
I bought no book.
b. $\forall$x [**book** (x) $\rightarrow$ $\neg$**bought** (I, x)]

The two sentences are, of course, truth-conditionally equivalent (though there are pragmatic differences; recall our discussion in section 2.3). But crucially, the negative sentence with a PI like *any* unquestionably involves an existential under negation.[11] Standard English does not exhibit NC. But imagine that we have a language which is like English in employing an existential item like *any* under negation, but unlike English, it also has NC. In this language NC must be identified with universal negation, and the *n*-words used must correspond to a universal quantifier. In Giannakidou (1998, 2000) it is argued that Greek is such a language. On the other hand, imagine a language that has NC, but unlike Greek and English, does not exhibit a separate existential dependency under negation. If we can show that *n*-words in that language are not negative, then they must be ambiguous between the universal and existential readings we have identified here. In Giannakidou (2000) it is suggested that (a number of) Slavic *n*-words must belong to this type; we illustrate the relevant diagnostics in section 3.2. Recall from section 2.2. that we do not want to treat this as an indefinite ambiguity as there is no evidence for quantificational variability and the universal meaning cannot be introduced in this context without violating compositionality. Rather, as genuinely ambiguous, we would expect the Slavic *n*-words in question jointly to exhibit the properties of universal *n*-words that we have discussed so far, and those of existential items that we will present here.

Whether we call existential items '*n*-words' or just PIs seems a harmless terminological choice; the characterization 'PI' nevertheless reflects more accurately

the fact that these items are not strictly negative PIs and are licensed routinely in non-negative polarity environments – some existential PIs in more environments than others, *any* being very broad in this respect. *N*-words which receive existential interpretation are also licensed in non-negative environments with precisely this interpretation, as we saw in section 4.1.

The syntax of existential dependencies under negation and NC differ in one important respect, namely, locality. This basic difference manifests itself in three ways, which I illustrate in section 5.1. There are also clear semantic differences between existential PIs and *n*-words under negation, to be presented in section 5.2. The discussion will provide us with a number of diagnostics that will enable clear comparisons between languages, which we summarize in section 5.3.

5.1 Negative concord vs. existential dependencies: locality

In this section we illustrate that, unlike NC, existential dependencies under negation are not clause-bounded. The argument can be made very clearly for Greek, so I follow here closely the discussion in Giannakidou (2000). Greek has the paradigm of emphatic *n*-words that we have already been discussing; apart from that, Greek employs a homophonous non-emphatic paradigm, illustrated in (101); the English gloss here is intended to capture the semantic affinity to the existential import of *any* (but non-emphatics do not have free-choice readings):

(101) kanenas 'anyone, anybody'
tipota 'anything'
pote 'ever'
puthena 'anywhere'

Giannakidou (1998, 2000) considers emphatic accent not as focus, but as a morphological feature that distinguishes emphatics from non-emphatics.[12] That non-emphatics are interpreted existentially becomes evident when we consider their interpretation in non-negative contexts. Non-emphatics occur freely in these contexts, as the equivalents of *any*; emphatics, on the other hand, never occur in non-negative contexts:

(102) **Question:**
Pijes {pote/*POTE} sto Parisi?
went.2sg n-ever in-the Paris
'Have you ever (=sometime) been to Paris?'

(103) **Intensional verb:**
An dhis tin Elsa {puthena/*PUTHENA} na tis milisis.
if see.2sg the Elsa n-where subj her talk.2sg
'If you see Elsa anywhere (=some place), talk to her.'

(104) **Modal verb:**
I Maria bori na milisi me{kanenan/*KANENAN}.
the Mary may.3sg subj talk.3sg with n-person
'Mary may talk to anybody (=somebody).'

(105) **Imperative:**
Pare {kanena/*KANENA} milo.
take.imp.2sg n- apple
'Take any (=some) apple.'

The inability of emphatic *n*-words to occur in non-negative structures shows that they are NPIs, and not just affective polarity items (APIs), as non-emphatics have been characterized in Giannakidou (2000). APIs are interpreted existentially. Romance *n*-words take over (some of) these API-uses that Greek emphatic *n*-words cannot perform, as we saw, and when they do, Romance *n*-words are also interpreted existentially.

The licensing of emphatic *n*-words, as we saw in section 2.3, is local in the sense of clause-boundedness, but the licensing of non-emphatics is unbounded (as first observed in Giannakidou and Quer 1995, 1997). Syntactically, therefore, non-emphatic APIs behave on a par with *any* and their licensing is quite unconstrained. To appreciate the empirical extent of the freedom of licensing of existential PIs, we present here three representative differences with NC *n*-words.

5.1.1 N-*words in islands*

Non-emphatics are licensed in syntactic islands. The examples below illustrate this with a relative clause and an adjunct, but more examples are given in Giannakidou (1998). Quer (1993, 1994) reports a similar observation about Catalan *n*-words, an example of which is given in (108), from Quer (1993: 30):

(106) Dhen prodhosa mistika [pu eksethesan {kanenan/*KANENAN}].
not betrayed.1sg secrets that exposed.3pl n-person
'I didn't reveal secrets that exposed anybody.'

(107) Dhen milisa [epidhi ithela na prosvalo {kanenan/*KANENAN}].
not talked.1sg because wanted.1sg subj offend n-person
'I didn't talk because I wanted to offend anybody (but because I had to).'
SCOPE: NOT [Because . . . anybody]; # [Because . . . anybody] NOT talked

(108) a. No vindra perque vulgui fer res amb ningu.
not fut.come.1sg because want.1sg do n-thing with n-person
'I will not come because I want to do anything with anybody.'
b. No dire secrets que puguin ofendre ningu.
not fut.tell.1sg secrets that can.pl offend.3pl n-person
'I wouldn't reveal secrets that could offend anybody.'

In this respect, non-emphatics and Catalan *n*-words are like *any*, which is also fine in islands as we see in the glosses; emphatic *n*-words, on the other hand, contrast clearly with these and are ungrammatical. The fact that they occur in islands makes it hard to argue that non-emphatics and *any* are licensed by movement; rather, it seems more reasonable to say that they are licensed in situ as in Giannakidou and Quer (1995, 1997) and Giannakidou (1997, 1998). The interpretation of non-emphatics and Catalan *n*-words is identical to *any*, it is existential, as indicated in the translations. The relevant reading is always with *any* and the *n*-words under negation, in agreement with Linebarger (1980, 1987), as indicated in (107). If *any* and the *n*-words are outside the scope of negation they are illicit, a fact noted in Quer (1993). We see this in the sentence below:

(109) *Dhen milisa, epidhi ithela na prosvalo kanenan ke epidhi mu ixan apogorepsi na miliso.
*'I didn't talk; because I wanted to offend anybody and because they forbade me to talk in the first place.'
SCOPE: [*because* clauses] NOT talked

In this sentence, the *because*-clause is not in the direct scope of negation, as required for these cases (by Linebarger's *Immediate Scope Constraint*). The problem, of course, is that in this scoping the *because*-clauses are not negated at all, hence the licensing requirement that PIs be in the scope of its licenser is not met, and the PI becomes ungrammatical. Again, it is important to note that to the extent that *n*-word licensing is possible in islands, the *n*-words that successfully occur there are existentials. Negative quantifiers are of course also allowed, as in *I did not talk because I wanted to offend nobody*, but then they contribute negative meaning. Catalan *n*-words and Greek non-emphatics do not have this interpretation, and seem to behave just like existentials. Greek emphatics, on the other hand, are unacceptable in islands because they would have to move out of the island in order to scope above negation. It is important to note that *n*-words in other strict NC varieties exhibit clearly the pattern of Greek emphatic *n*-words, and not that of non-emphatics or Catalan *n*-words.

5.1.2 N-*words in embedded clauses*

The basic fact, which correlates with the observations we just made regarding *n*-words in islands, is that only items with existential meaning can be licensed long-distance. In this, non-emphatic APIs are again parallel to *any*. We have already seen in section 2.3 the locality constraints imposed on emphatics and the parallelism with quantifier scope. We provide here the relevant contrastive data.

Emphatic items are not accepted in indicative complements of negated matrix verbs. NC is possible only in monoclausal domains and *na*-clauses. Non-emphatics, on the other hand, and existential/indefinite dependencies with *any* are fine:

(110) I Ariadhni dhen ipe oti idhe {tipota/*TIPOTA}.
the Ariadne not said.3sg that saw.3sg n-thing
'Ariadne didn't say that she saw anything.'

(111) I Ariadhni dhen theli na dhi {kanenan/*KANENAN}.
the Ariadne not want.3sg subj. see.3sg n-person
'Ariadne doesn't want to see anybody.'

The embedding may not be limited to just one complement clause, as illustrated in the sentence below (from Giannakidou 1998); the translation indicates that the same holds for *any*:

(112) Dhen ipa oti pistevo oti itheles na me katigorisis
not said.1sg that believe.1sg that wanted.2sg subj me accuse.2sg
se kanenan.
to n-person
'I didn't say that I thought that you wanted to badmouth me to anybody.'

Emphatics are, of course, unacceptable in such cases. The ban on long distance licensing generalizes to a significant number of *n*-words in Romance, and strict NC varieties, as illustrated below.

(113) a. Milan ne tvrdi [da Marija poznaje Serbian–Croatian
Milan not claim.3sg that Mary know.3sg
{*ni(t)koga/i(t)koga}].
n-person
'Milan does not claim that Mary knows anybody.'
b. Ne zelim [da vidim {*ni(t)koga/i(t)koga}].
not wish.3sg that see.1sg n-person
'I do not wish to see anybody.' (Progovac 1994: 41)

We see in these sentences that so-called *i-NPI*s (the terminology is from Progovac 1994) in Serbian–Croatian are just like non-emphatics in generally being licensed long distance. *Ni-NPI*s, on the other hand, are just like emphatics and are licensed only locally. Serbian–Croatian and Greek appear to be identical in this respect: they have two *n*-word paradigms under negation, of which only one can be licensed long distance; and it happens to be existential. This direct mapping, however, breaks down when we consider clausemate negation. In contrast to Greek, the existential paradigm *i(t)koga* is not licensed with local negation (Progovac 1994: 42):

(114) *Marija ne poznaje i(t)koga.
'Mary doesn't know anybody.'

This fact generalizes over a number of languages in Slavic, and also Hungarian (see the data in Haspelmath 1997 and the works mentioned there on the individual languages). The impossibility of the existential dependency under clausemate negation clearly suggests that *n*-words must do this job. The anti-locality effect of existentials in these languages was assimilated to the anti-locality we find in pronouns in Progovac (1994); but in the context we assume here it can be seen as

a case of blocking, the existential PI is blocked by clausemate negation because the *n*-word is used to express this meaning. It seem unavoidable, then, to conclude that Slavic *n*-words do have existential meanings, a position to be supported later on by the fact that they can be used as predicate nominals and that they do not always allow presuppositional readings with negation.

5.1.3 Preceding negation

Finally, another typical characteristic of an existential dependency is that the PIs involved in it cannot directly precede negation, as indicated in (115b); non-existential *n*-words, on the other hand, can.

(115) a. KANENAN dhen idha.
n-person not saw.1sg
'I saw nobody.'
b. *Kanenan dhen idha.
*anybody I didn't see.1sg

N-word preposing is always optional. Again, we observe the parallel with non-emphatics and *any* here. The usual assumption for these items is that they must be licensed in the c-command domain of their licenser in order to be grammatical, and that c-command must hold at s-structure (though extensive arguments have also been presented recently that c-command must hold at LF; (see Uribe-Etxebarria 1994 and Giannakidou 1998; see also Hoeksema 2001 for noting the insufficiency of the s-structure conditions). We need not delve into further details. What matters is that, unlike Greek non-emphatics, *n*-words in the other languages we are considering, including of course also emphatics, can freely precede negation, hence they are in sharp contrast with existential/indefinite PIs.

To conclude this section, we saw that unlike universal *n*-word licensing, existential licensing under negation is unbounded, proceeds through islands, and is not subject to s-structure c-command. Hungarian, Slavic, and many Romance languages lacking the existential paradigm under negation obliterate the distinction overtly attested in Greek.[13] This explains, for instance, why some of these *n*-words occur in islands (recall the Catalan *n*-words), or why they receive existential interpretations in the absence of negation (recall the data in section 4).

In the next section we review some additional diagnostics which will help us further decide whether an *n*-word could be existential or not.

5.2 Existential polarity items and the semantics of n*-words*

In this section we review some central arguments in support of the observation that the semantic import of PIs like *any* and non-emphatics is existential. We contrast the semantics of the two paradigms to that of universals on the basis of a number of diagnostics.

5.2.1 Almost/absolutely *modification*

∀-quantifiers, but not indefinites or existentials (∃), can be modified by *almost/absolutely* (see Dahl 1970 and Horn 1972 for the original observation). We see below that only emphatics admit *almost/absolutely* modification.

(116) a. *Electra was willing to accept {absolutely/almost} something.
b. Electra was willing to accept {absolutely/almost} everything.

(117) a. Dhen idha sxedhon {KANENAN/*kanenan}.
not saw.1sg almost n-person
'I saw almost nobody.'
b. Dhen idha (apolitos) {KANENAN/*kanenan} (apolitos).
not saw.1sg absolutely n-person absolutely
'I saw absolutely nobody.'

N-words in the various Romance languages also admit *almost/absolutely* under negation. But, as shown in Quer (1993, 1994), *almost/absolutely* modification fails in non-negative contexts, where the *n*-words are interpreted existentially (recall the data in section 4.2). This contrast supports the view we are pursuing that Romance *n*-words in the non-strict varieties are ambiguous between existential and possibly negative readings (given that they allow negative spread and can be interpreted negatively in the preverbal postion), and are illustrated below:

(118) a. Non ho visto quasi nessuno. Italian
not have seen almost n-person
'I saw almost nobody.'
b. *Ha visto quasi nessuno?
'Did he see almost anybody?'

(119) a. Non he dit absolutament res. Catalan
not has said absolutely n-thing
'He said absolutely nothing.' (Quer 1993: 64)
b. *Li diras absolutament res?
will you tell him/her absolutely n-thing
c. *Si aneu absolutament enlloc digeu-m'ho.
if go.2pl absolutely n-where tell.IMP.it
'If you go absolutely nowhere, tell me.'

More examples are given in Quer (1993, 1994) further supporting the contrast between existential and non-existential interpretations and the possibility or not to admit *almost/absolutely* as modifiers. It has been a popular strategy in recent years to question the results of the *almost* test (e.g., Horn and Lee 1995; Déprez 1997), but see Giannakidou (2000: 472–474) for discussion of why the potential counter-arguments do not threaten the generalizations we observe here.

5.2.2 Ke-*modification*

The second difference concerns *ke*-modification. *Ke* 'and' is a modifier of existential quantifiers, and emphatics are incompatible with it. This expression is comparable to Dutch *ook maar* and German *auch nur*, which have a similar meaning. In (120) we see that *ke* and its ilk are incompatible with universals:

(120) a. Dhen ipe ke{kati/*katheti} spudheo.
not said.3sg and something/everything important
'He didn't say something important.'
b. Dhen ipe ke{tipota/*TIPOTA} spudheo.
not said.3sg and n-thing important
'He didn't say anything important.'
c. Wil jij {ook maar iemand/*iedereen} zien?
want you to particle someone/everyone see
'Do you want to see anybody?'

Emphatics, then, behave on a par with universal quantifiers as far as *ke*-modification is concerned. Non-emphatics, on the other hand, are well-behaved existentials. The test can be checked with the other languages under consideration (see Surányi 2002 for application to Hungarian).

5.2.3 Donkey anaphora

Like universal quantifiers and quantificational elements in general, universal *n*-words do not license donkey anaphora, a point extensively discussed in Giannakidou (1997, 1998):

(121) I fitites pu exun {kati$_1$/tipota$_1$} na pun, as to$_1$ pun tora.
the students that have.3pl something/n-thing subj. say let it say.3pl now
'The students that have {something$_1$/anything$_1$} to say should say it$_1$ now.'

(122) *I fitites pu dhen exun TIPOTA$_1$ na pun, as (min) to$_1$ pun tora.
'*The students that have nothing$_1$ to say, let them (not) say it$_1$ now.'

(123) I fitites pu aghorasan kathe vivlio$_1$, na to$_1$ ferun mazi tus.
the students that bought.3pl every book subj. it bring.3pl with them
'*The students that bought every book$_1$ should bring it$_1$ with them.'

In these examples we see that non-emphatics behave dynamically in that they can establish anaphoric links from a relative clause just like existential quantifiers. *Any* behaves no different in this respect. Emphatics and universal quantifiers, on the other hand, are static: they cannot bind variables outside their scope, as we see in (122) and (123), respectively. Richter and Sailer (1998) note that Polish *n*-words behave on a par with emphatics with respect to donkey anaphora, a fact suggesting that they receive universal interpretation. But they

express reservations for the validity of the test by saying that negation creates islands for anaphora anyway (see also Surányi 2002); for instance:

(124) *The students that didn't buy {any/some} book should show it now.

In this declarative sentence, negation binds off the variables contributed by *any book* and *some book* and anaphora is blocked, since there are no discourse referents to be picked by the pronoun in the main clause. However, there are declaratives which actually allow anaphora even through negation; an example is given below, attributed to Barbara Partee:

(125) This place doesn't have a bathroom, or it has it in a strange place.

Hence it is not entirely true that anaphora is blocked under negation. Even more frequently, existentials can bind pronouns under negation in directive sentences, as the examples below illustrate with non-emphatics; *any* appears to have a limited ability to do the same:

(126) a. Don't check any book$_1$ out from that (Satanic) library; reading it$_1$ might warp your mind.
b. Min aghorasis kanena vivlio$_1$; bori na apodixti *pro*$_1$ epikindino.
not buy.2sg n- book may subj. prove.3sg *pro* dangerous
'Don't buy any book$_1$; it$_1$ might prove dangerous.'

In the negated imperative-like (126a), anaphora is enabled across negation and *might* between *any book* and *it*, and the same can be said for (126b) (though in this sentence the bound reading may be not the most salient reading in English). Imagine the context of a dictatorial regime, where some books are forbidden by the government, and whoever buys them runs the risk of going to jail. In this context, (126b) can be felicitously uttered, meaning either 'buying books will prove dangerous', or 'the books that you buy may be dangerous'. The second reading is the one indicated in the indexing in (126b). Emphatics, crucially, do not allow this reading; universal quantifiers do not allow it either:

(127) Min aghorasis KANENA vivlio$_1$; bori na apodixti *pro*$_{*1}$ epikindino.
not buy.2sg n- book may subj. prove.3sg *pro* dangerous
'Buy no books; it might be dangerous (if you buy).'

(128) Min aghorasis kathe vivlio$_1$; bori na apodixti *pro*$_{*1}$ epikindino.
not buy.2sg every book may subj. prove.3sg dangerous
'Don't buy every book; it might be dangerous (if you buy them all).'

Example (127) has only the reading where buying books can prove dangerous, and likewise (128) can only mean 'buying all the books will be dangerous'. Hence directive negative sentences are indeed static for universal quantifiers and

emphatics, but still dynamic for non-emphatics and *any*. Why anaphoric links with negation are more easily established in directive sentences is a more general issue that needs to be addressed in the context of donkey anaphora, but it is not of direct relevance here.

Though the discussion above has certainly not exhausted the subtleties and variation arising with donkey anaphora, the clear contrasts we witnessed in this subsection allow us to pair emphatics with universal quantifiers, and non-emphatics with existential quantifiers. Most significantly, *n*-words in other strict NC languages, e.g., Hungarian, Polish, Serbian, and possibly other Slavic languages, and Romanian behave on a par with emphatics (Richter and Sailer 1998; Blaszczak 1999). Below we give examples supporting this point from Hungarian and Romanian.

(129) *A diakok akiknek van (sem) *semmi* (sem) mondanivalojuk most kene mondjak. Hungarian
*The students that don't have *n-thing* to say should say it now.

(130) *Studentii care nu au*nimic* de spus ar trebui s-o spuna acum. Romanian
*The students that not have *n-thing* to say should say it now.

Obviously, in these languages too, *n*-words are quantificational, hence they cannot bind pronouns outside their syntactic scope.

In some non-strict NC Romance languages, on the other hand, *n*-words behave like existentials/indefinites, can be licensed in conditionals even without negation, and can bind donkey pronouns. We illustrate below with Catalan; but Portuguese, as we see, is different:

(131) a. Si truca ningú, digues-li que no hi sóc. Catalan
if calls n-person tell him that not LOC am
'If anyone calls, tell him I'm not in.'

b. *Todo aluno que trouxe nenhum livro Portuguese
every student who bought n- book
mostrou-o para mim.
showed it to me

Italian, Spanish, etc. should be just like Catalan, since these languages too allow for existential interpretations of their *n*-words. We note again that Portuguese *n*-words form the exception which, as we saw in section 5.1, do not receive existential interpretations at all, are not licensed in non-negative contexts, thus also not in the restriction of a universal quantifier.

5.2.4 Use in predicate nominals

Existential PIs can occasionally be used as predicate nominals under negation, but non-existential *n*-words cannot. The contrast is visible again in Greek: on a par with universals and unlike non-emphatics and regular existentials, emphatics

cannot be used as predicate nominals, as shown in the examples in (132); this fact was first observed by Quer (1993) and Giannakidou and Quer (1995):

(132) Dhen ine {kanenas/*KANENAS} jatros.
not be.3sg n- doctor
'He is no doctor.'

(133) Frank is {a/*every} student.

Partee (1987) discusses restrictions on the availability of type-shifting to predicative (type <*e*,*t*>) interpretations. She argues that type-lowering from <<*e*,*t*>,*t*> to <*e*,*t*> is not allowed for universals: they must always be assigned the generalized quantifier type (<<*e*,*t*>,*t*>) – the reasons why this is so are immaterial here. The unacceptability of emphatics in predicate-nominal positions indicates that emphatics cannot be lowered to the predicative type. Non-emphatics, on the other hand, make perfectly good predicate nominals.

Admittedly, sentence (132a) differs from the corresponding one with the bare NP in (134), which is the unmarked option:

(134) Dhen ine jatros.
not be.3sg doctor
'He is not a doctor.'

The difference in Greek between the two options is exactly parallel to the one we observe with the corresponding sentences in English: the *no doctor* version is marked, and has a pejorative flavor in it. In the case of *He is no doctor* the person in question can still be a doctor, but just not a good one. *He is not a doctor,* on the other hand, states that the person in question does not have the property of being a doctor, and it is true only in this situation.

What is the situation with other *n*-words? The cross-linguistic picture seems split. On the one hand, we have *n*-words that can be used as predicate nominals; on the other, we have *n*-words that follow the Greek pattern and cannot be used for this function. French, Italian, Hungarian (see Surányi 2002), and Romanian illustrate the latter, thus confirming the quantificational pattern:

(135) a. *Non è nessun dottore. Italian
not be.3sg n- doctor
b. *Il n' est aucun docteur. French
he not be.3sg n-doctor
c. *Maria nu e nici un doctor. Romanian
Maria not be.3sg n- a doctor

(136) *Mari se orvos. Hungarian
Mari no doctor.

Hence the Greek, Hungarian, and Romanian varieties of strict NC form a natural class in this respect. The Slavic variety, however, gives a different picture. Polish, Russian, and Serbian *n*-words can indeed be used as predicate nominals (Richter and Sailer 1998; Blaszczak 1999).

(137) a. On nie jest zadnym lekarzem. Polish
he not be.3sg n- doctor
'He is no doctor.'
b. Nikakoj on ne vrach. Russian
n- he not doctor
c. Jovan nije nikakav doctor. Serbian
John not n- doctor

So there is a clear division with strict NC regarding the option of *n*-word predicate nominals, and the use of *n*-words is always a marked option, accompanied by a pejorative meaning. Catalan is in-between: in most cases it excludes *n*-words from predicate-nominal positions, but occasionally it allows them to appear there, if they are construed with abstract nouns and convey the evaluative meaning we have observed:

(138) a. No és cap geni. Catalan
not is n- genius
'He's no genius.'
b. No és cap meravella.
not is n- marvel
'He's no marvel.'
c. No és (*cap) metge.
not is n- doctor

Apparently in Catalan the noun 'doctor' is not amenable to a pejorative interpretation, thus the ungrammaticality of (138c). At any rate, the pattern confirms the observation that if a language allows for existential readings of *n*-words, as Catalan does systematically, then it will allow them to occur in predicate nominal positions.

In the same spirit, the Russian, Polish, and Serbian data seem to suggest that *n*-words in these languages are amenable to existential interpretations, at least in these cases. This conclusion would be consistent with the observation that we made earlier vis-à-vis the fact that these languages do not employ another existential PI-paradigm under negation. The question then is: if Slavic *n*-words can be existential, why does not their existential import surface in other contexts, e.g., with interrogatives and other non-negative contexts, as in the case of Catalan *n*-words? The only way to handle this question is to postulate, as we did earlier, that *n*-words in Slavic are NPIs and therefore licensed only by negation; we can content ourselves with such an answer at this stage although, surely, as with every polarity phenomenon, we would like to know what the deeper lexical semantic source of this fact is.

Going back to Romance *n*-words that do not tolerate predicate-nominal uses and comparing these to Catalan, an interesting correlation emerges. The Romance languages that disallow predicate nominal *n*-words are more limited than Catalan in licensing their *n*-words in non-negative contexts with existential readings; Catalan seems to be the most liberal case given the documented facts (Quer 1993, 1994). Since Portuguese does not license existential meanings with *n*-words, as we saw, we would expect it to block predicate nominal uses altogether; but this is not what we get:

(139) O Pedro não é nenhum médico.
the Peter not is n- doctor
'Peter is no doctor.'

If Portuguese *n*-words are negative, as we have accepted in section 4.2, these data suggest that *nenhum medico* is just like the English *no doctor*. Note that Portuguese also exhibits the unmarked pattern of negation and a (bare) infinitive that is generally available in the languages we are discussing, including English. Crucially, the very fact that negative quantifiers are used in this marked pattern as predicate nominals casts doubt on the general applicability of this test. We will discuss some more data below, and continue assuming that the possibility of a predicate nominal use may indicate existential meaning, but we should keep in mind that the predicate nominal test may actually not be one of the most reliable diagnostics.

A question arises regarding Italian and French (and also Spanish), which do seem to allow existential uses, albeit more restricted than Catalan. Why can the existential reading not arise under negation? An answer that suggests itself is the following. If we assume, as we do in this chapter, that French, Italian, and Spanish *n*-words are ambiguous between negative and existential quantifiers, and if the negative quantifier meaning is the meaning that appears with preverbal *n*-words, then, under negation postverbally these Romance *n*-words would be existentials, hence they could type-shift to a predicative type. We must assume, quite tentatively, that what blocks this shift is the fact that the unmarked option with an indefinite exists in these languages. (In Greek, presumably, the shift is not blocked because there are two series of *n*-words.)

Now, if Romance *n*-words in postverbal position are not negative quantifiers, we can explain why they are bad without negation, unlike Germanic *n*-words:

(140) a. *Gianni è nessun dottore. Italian
John is n- doctor
b. *O Pedro é nenhum medico. Portuguese
the Peter is n- doctor

(141) a. Hij is geen arts. Dutch
b. He is no doctor English
c. Er ist kein Artzt. German

In addition, Romance *n*-words are polarity sensitive: they need negation to be licensed in the postverbal position. Hence sentences like (140) are ruled out as licensing failures.

In German and Dutch, finally, negative quantifiers are the only means to express the [neg+indefinite] meaning, whereas in English there is the less evaluative option of *He is not a doctor*; hence the non-equivalence of *no doctor* to *not a doctor* that we noted. Crucially, the use of inherently negative *n*-words as predicate nominals may be an argument in favor of a decompositional analysis of negative quantifiers as $\neg\exists$ (as has actually been proposed for German and Dutch *n*-words in Jacobs 1980, von Stechow 1993, and Rullmann 1995a), only for languages that do not have the option of an indefinite and negation. Dutch/German and English/Portuguese contrast clearly in this respect, as we have seen.

5.3 Summary

Let us conclude the discussion in this section by summarizing the characteristics of existential PIs under negation that we have observed. We give the full list below, incorporating some of the contrasting observations with universal quantifiers we noted in section 2.3.

(142) **Diagnostics for existential *n*-words:**
An existential *n*-word has the following properties:
a. It is licensed freely long distance in complement clauses.
b. It can be licensed in syntactic islands, e.g., relative clauses and adjunct clauses.
c. It cannot be modified by modifiers corresponding to *almost/absolutely.*
d. It can bind donkey pronouns.
e. It can be used as a predicate nominal.
f. It need not express existential commitment, i.e., we can interpret it with an empty restriction.

These properties contrast clearly with those of universal *n*-words that we repeat here:

(143) **Diagnostics for universal *n*-words:**
A universal *n*-word has the following properties:
a. It is licensed only by local negation; long distance licensing may be allowed only through an infinitival or subjunctive clause.
b. It expresses existential commitment, i.e., we tend to interpret it with a non-empty restriction.
c. It can be used as topic in topicalization structures. In these cases it may be coindexed with a clitic pronoun (or a pronoun performing the respective function, if a language does not employ clitic pronouns).
d. It can be modified by modifiers corresponding to *almost/absolutely.*
e. It cannot bind donkey pronouns.
f. It cannot be used as predicate nominal.

Finally, we note here the properties of negative *n*-words, in order to have the full set of comparison:

(144) **Diagnostics for negative *n*-words:**
A negative *n*-word has the following properties:
a. It receives negative meaning and excludes sentential negation in the preverbal position.
b. It receives negative meaning and excludes sentential negation when it co-occurs with another *n*-word (negative spread). The first *n*-word is usually in the preverbal position (though not always, recall French).
c. It is licensed only by local negation; long distance licensing may be allowed only through an infinitival or subjunctive clause.
d. It can be used as topic in topicalization structures. It these cases it may be coindexed with a clitic pronoun (or a pronoun performing the respective function, if a language does not employ clitic pronouns).
e. It can be modified by modifiers corresponding to *almost/absolutely*.
f. It cannot bind donkey pronouns.
g. It usually cannot be used as predicate nominal.

(We need to qualify (g) with *usually*, if we want to include Portuguese *n*-words, which admit predicate nominal uses, in the class of negatives; recall also what we just noted, namely, that the predicate nominal use is not a totally reliable diagnostic.) We see that negative *n*-words have a number of properties in common with universal *n*-words, for example (c) through (g), a fact suggesting that it may be more accurate to treat a negative quantifier as having the underlying logical structure of a universal statement. Most Romance *n*-words exhibit jointly the characteristics of existential and negative *n*-words. *N*-words in strict NC varieties, on the other hand, are either only universals (Greek emphatics), or only existentials (Greek non-emphatics), or they exhibit the properties of both (Slavic *n*-words). The crucial fact will be the number of *n*-words a language allows under negation: Greek allows two and therefore splits the two readings, but Slavic languages only have one, and therefore collapse the logical distinction between a universal and an existential quantifier under negation.

6 Conclusion

Negative concord (NC) is not a uniform but a quite diverse phenomenon across languages. The primary goals of this chapter were to illustrate the empirical richeness of NC, and familiarize the reader with the various analyses that have been proposed to handle the diversity. Given the interaction between logical negation and quantifiers, we have the following five options as possible interpretative strategies for *n*-words: (a) *n*-words can be negative; (b) *n*-words can be existential; (c) *n*-words can be universal quantifiers; (d) *n*-words can be ambiguous negative and existential quantifiers; and (e) *n*-words can be ambiguous

between universal and existential quantifiers. Apart from the fact that negation with quantifiers involves two logical structures, ambiguity is expected because many languages do not employ a distinct PI with existential meaning under negation; hence *n*-words inevitably take over some of the existential functions. Crucially, option (b), that *n*-words are unambiguously existential quantifiers, was not supported by the data discussed here.

We did find convincing evidence, however, that Greek NC instantiates the universal option: *n*-words in NC are NPI-universals which must scope over negation in order to be properly interpreted. This conclusion was supported by various diagnostics: the observed locality in NC; donkey anaphora; exclusion from predicative use; scope parallelisms between NC and universal quantifiers; the availability of existence inferences under negation with both NC *n*-words and universal quantifiers ('presuppositionality'); and the possibility of topicalization. The distinctive feature of Greek NC is that Greek also employs an existential PI under negation; the *n*-word, then, is unambiguously universal.

Interestingly, the wealth of facts reviewed here questioned the viability of the negative absorption approach in its pristine form, which posits that all *n*-words are negative quantifiers. It became clear that there is no evidence that *n*-words as a general class are unambiguously negative. The only actual piece of evidence indicating inherent negativity is the fact that some *n*-words can occur preverbally without negation; in this case it is clearly the *n*-word that contributes negation. But *n*-words which do that, with the exception of Portuguese, are also admitted in non-negative polarity contexts, e.g., interrogatives, conditionals, restrictions of universals, and in these contexts they contribute not a negative but an existential quantifier. In view of this we cannot but conclude that these *n*-words are at best ambiguous between negative quantifier and existential readings – a conclusion supported also by the semantic tests we applied in section 5.2. This, then, will be our conclusion for Italian, Spanish, French, and Catalan, where, in contrast with Greek, no existential PI-paradigm other than the *n*-word is used; hence the ambiguity is not unexpected. Crucially, the ambiguity correlates with the position of *n*-words: the negative-quantifier meaning arises in the preverbal position with negation; in the postverbal position and in non-negative polarity contexts these Romance *n*-words are existential quantifiers.

Portuguese and Romanian, on the other hand, are different. We saw in section 5 that *n*-words in these two languages are not licensed in non-negative contexts. However, Romanian is a strict NC language, Portuguese is strictly non-strict; it freely allows negative spread. If negative spread indicates negative branching, we have to conclude that Portuguese *n*-words are indeed negative quantifiers; this is, then, a unique case in the sample of languages we have examined. Additionally, we must postulate that in contrast with Germanic negative quantifiers, Portuguese *n*-words (a) can form branching structures thus giving NC reading with one another, and (b) are NPIs, hence they must be licensed, and cannot occur in a non-negative context. Romanian *n*-words, on the other hand, seem to exhibit the characteristics of universal quantifiers that we discussed illustrating with Greek.

N-words in Slavic languages cannot be negative, as we saw in section 5. Given that Slavic languages employ only one paradigm of *n*-words under negation, this means that their *n*-words must be ambiguous between existential and universal meanings. This conclusion is supported by the fact that they scored well on both sides with respect to the number of diagnostics we considered. For example, Slavic *n*-words are possible predicate nominals, but exclude donkey anaphora; they allow pressuppositional readings but they are not forced to have them. Certainly, there are more subtle variations between the individual languages, but it seems relatively safe to assume that the variations will fluctuate within the two options posited here.

Hungarian *n*-words were argued to be universal quantifiers (Szabolcsi 1981b and subsequent works cited in Surányi 2002). They behave just like the Greek *n*-words; but Hungarian does not employ an existential PI under local negation, which opens up the possibility that Hungarian *n*-words perform this function too. However, their impossibility as predicate nominals and the fact that they do not allow donkey anaphora suggest clearly that they follow the universal pattern. According to Surányi (2002), Hungarian *n*-words allow both presuppositional and non-presuppositional readings with negation; if this judgment is correct, then an existential meaning would also have to be an, albeit marginal, option with these *n*-words.

In this chapter we focused on a limited number of languages and tried to show the intricacies involved in the interpretation of their *n*-words. The sample has been, of course, too small, considering the many languages that are out there exhibiting some or other form of NC. Though at present we cannot undertake the task of uncovering new varieties of NC, we must be confident that the analyses and diagnostics presented in this paper will prove helpful in the description and understanding of *n*-words in these languages too. The expected meanings and meaning shifts should be drawn from the quite exhaustive repertory we have established in this study.

NOTES

I wish to thank the editors of the *Companion to Syntax* for inviting me to write this chapter, as well as two reviewers for their helpful comments. The final stages of this research were supported by the Royal Dutch Academy of Sciences (KNAW), whose contribution is hereby gratefully acknowledged. For comments and suggestions, I wish to thank Jason Merchant, Josep Quer, and Ljiljana Progovac. I am also grateful to the following people for judgments and discussion of their native languages: Carmen Dobrovie-Sorin and Donka Farkas for Romanian; Josep Quer for Catalan and Spanish; Donka Farkas and Balázs Surányi for Hungarian; Ljiljana Progovac for Serbian; Maria Aloni, Carlo Ceccheto, and Paola Monachesi for Italian; Cristina Schmitt, João Costa, and Jairo Nunes for Portuguese; and Dave Kaiser for his assistance with the Russian data.

1 Although there is a clear divide between languages that employ NC as a standard structure and languages that do not, we should note that even languages that do not

have NC may allow it occasionally, e.g., Dutch (Giannakidou 1998: 185, Van der Wouden 1997: 245), and German (Giannakidou 1998: 185); e.g., *Je hebt NOOIT GEEN tijd voor mij* 'You never have time for me', from Dutch. These cases are admittedly quite marginal, and have a clear emphatic intonation. With this precaution, statements like 'a language has NC' should be taken to mean 'a language employs NC as a standard structure'. On this point, see also Acquaviva (1993).

2 A parenthetical note on the status of SN: SN in NC may be 'light', as in the examples in (2) or 'heavy'. Light SNs are usually argued to be heads (see Pollock 1989, and especially Zanuttini 1991, 1997). Romance, Slavic, Greek, and Non-standard English exemplify NC proper with a light SN. Heavy SNs, on the other hand, are, according to most accounts, XPs analyzed as specifiers of NegP (Pollock 1989; Bayer 1990b; Zanuttini 1991, 1997; see also Merchant 2000). Quebecois French, Bavarian, and Afrikaans exhibit NC with a heavy NM, as we see below (see Vinet 1998, Bayer 1990b, and Den Besten 1986):

(i) a. J' ai pas vu personne. Quebecois
I have.1sg not seen n-person
'I haven't seen anybody.'

b. Ich bin froh, daß ich keine Rede nicht halden brauch. Bavarian
I be.1sg glad that I no talk not hold must.1sg
'I'm glad I don't have to give a talk.'

c. Hulle het nooit gesing nie. Afrikaans
they have n-ever sung not
'They have never sung.'

Mixed cases are also possible. West Flemish forms one such case where light and heavy NMs combine with *n*-words (for details see Haegeman 1995b).

3 In Haegeman (1995b) [Spec, NegP] is assumed to be always filled at s-structure, either by a contentive element (an *n*-word) or by a phonologically null expletive neg-operator. In this context, in West Germanic languages (West Flemish, Dutch, German, Afrikaans) and in Hungarian, the neg-criterion is met via overt movement of *n*-words. In Romance (French, Spanish, Italian, Portuguese) and in English, operator-chains are invoked (in the spirit of Brody 1995b) to ensure satisfaction of the neg-criterion.

4 See Giannakidou and Quer (1995, 1997) and Giannakidou (1997) for an analysis of negation as a binary Q-operator with restriction and scope, extending a proposal made in Ladusaw (1994) that negation can be thetic (non-quantificational) or categorical (quantificational). However, the analysis of negation as a binary operator seems hard to motivate, because negation does not behave like one. With a Q-binder for instance, a variable appearing in the restriction is still affected by the Q-operator: it acquires its Q-force:

(i) a. Typhoons usually arise in THIS part of the Pacific.
b. USUALLYx [**typhoons** (x)] [**arise in this part of the Pacific** (x)]

The sentence is interpreted as 'as for typhoons, they usually arise in this part of the Pacific' (and focus actually indicates which material goes to the nuclear scope; more discussion in Krifka et al. 1995). The material in the restriction is still in the semantic scope of the Q-adverb and aquires the respective Q-force. With negation, however,

there is no way to make the distinction between restriction and nuclear scope: if material is allegedly in the restriction of negation, it is no longer affected by it and is interpreted positively, as if it is outside the scope of negation. Thus there seems to be no real motivation to impose a tripartite structure for negation.

5 Taking the opposite track, Progovac (2000) tries to reduce quantifiers in general to negative polarity items, by arguing that all quantifiers, positive or negative, have a polarity feature (positive or negative) which is responsible for their raising. The proposal should be seen as a welcome attempt to give quantifiers morphological features, which would drive their movement in a minimalist analysis, and it clearly shares with the quantificational approach to NC the main idea of reducing the two phenomena, NC and quantification, to one.

6 This has an important consequence for the definition of the syntactic domain of PI-licensing. It entails that, despite what we might be inclined to believe, this domain does not always correspond to the c-command domain of the licenser. Though in many cases licensing maps indeed onto a be-in-the-scope-of condition, this mapping is not a conceptual necessity. The type of syntax involved in licensing (or anti-licensing) will be almost exclusively determined by the semantic content of PIs. In the case of NPI-∀, the quantificational semantics and the licensing requirement that NPI-∀ combine with an antiveridical predicate leave no other option but the escape-the-scope-of-condition (for more discussion see Giannakidou 2000).

7 Despite the fact that they are not negative, *n*-words in strict NC varieties could still be argued to have a 'negative' feature, as is argued in Brown (1999) and Progovac (2000) for Russian and Serbian. The assumption here is that this feature is uninterpretable on the *n*-word itself, so the *n*-word must check it and eliminate it against negation. Even in these terms, however, *n*-words would be different from negative quantifiers, as these would have to carry an interpretable negative feature (Brown 1999).

8 Hungarian is an interesting case: it has two series of *n*-words, what Surányi (2002) calls a bare *n*-word, and a second complex one which contains a bare *n*-word and the morphological SN *sem*. With a bare *n*-word we have the standard strict NC pattern; but with the *sem*-word, addition of SN *sem* gives ungrammaticality. It is important to note the difference with Romance, where addition of SN does not give ungrammaticality, but yields a double-negation reading. For more details, including a syntactic explanation of why the double-negation reading is excluded, see Surányi (2002) and references therein.

9 As regards fragment answers in particular, consider that bare NP remnants of minimizers can also be used, as *leksi* 'word' in (i):

(i) Q: What happened? Did he say anything all night?
A: LEKSI! 'Not a word!'
word

It would be quite far-fetched to invoke inherent negative meaning for *leksi* 'word' here. Rather, the ability of *leksi* to serve as a felicitous fragment answer with negative meaning arises as a result of the fact that the minimizer is always construed with negation.

10 Notice that double-negative readings are not licensed with *udhen*. This probably has to do with the fact that these structures are not productive and belong to a very limited register. At any rate, it is worth pointing out the contrast with negative

quantifiers in Germanic languages, and the similarity with Hungarian, mentioned earlier in n. 8.

11 We need to emphasize this point because *any* allows the so-called free-choice readings too, which may give the impression of universal quantification. For extensive discussion of why free-choice *any* is not a universal quantifier, see Horn (2000) and Giannakidou (2001). Most importantly, however, even if we took *any* to be a universal, in the case of negation we would still have to exclude the scoping of $\forall\neg$, as the sequence **Anybody did not come* is ungrammatical. Therefore, even if we adopt a universal analysis of free choice, under negation we are forced to assume that *any* can only be an existential (see Linebarger 1980 for more details on this).

12 For extensive discussion see Giannakidou (2000). Here, we just note that the accent-as-morphology option is not a 'peculiarity' specific to *n*-words, but it is observed elsewhere in the grammar of Greek, for instance, to distinguish between 'few' *-LIJI-* and 'a few' *-liji-*, and 'too' *-POLI-* and 'very' *-poli-*. Using suprasegmental features to perform morphological distinctions is a common strategy across languages, for instance, stress is systematically employed (e.g., *pérmit* versus *permít* for the noun versus verb distinction in English), and tone, as in certain African languages.

13 Note that we are considering here the possibility of a (negative) polarity existential PI, i.e., a PI that will be licensed by negation (and possibly other non-veridical elements) and which will be interpreted inside negation. The languages we are considering employ occassionally indefinite paradigms other than *n*-words, e.g., free-choice items (whose semantics is considerably more complex than that of the simple existential quantifier under negation), or positive polarity existentials equivalent to *some*. The use of such existentials is not relevant because these are positive polarity items and tend to escape the scope of negation, hence the existential under negation structure would not be correct for them. Greek employs yet another indefinite for this purpose, *kapjos*. For a comparison between *n*-words and *kapjos*, see Giannakidou (2000: 480–482).

46 Object Shift

STEN VIKNER

1 Introduction
2 Differences between object shift and scrambling
  2.1 When does object shift apply?
    2.1.1 Verb movement required (Holmberg's generalization)
    2.1.2 Prepositions, particles, and indirect objects block object shift
  2.2 Parasitic gaps
  2.3 Which elements may undergo object shift?
  2.4 What is the landing site of object shift?
    2.4.1 Object shift is clausebound
    2.4.2 Is object shift movement to an adjoined position?
    2.4.3 Is object shift movement to a specifier position?
    2.4.4 Landing site between two adverbials
  2.5 Summary: object shift vs. scrambling
3 Case as the key to object shift
  3.1 Traces of case assigners are optional case assigners
  3.2 The role of morphological case
  3.3 Case assignment from I°
  3.4 Pronominal-object shift as cliticization
4 Equidistance as the key to object shift
5 Focus and interpretation as the key to object shift
  5.1 The interpretation of object shift
  5.2 Objects marked [–Focus] must be licensed by categories marked [+Focus]
6 Conclusion: a few recent accounts

1 Introduction

The definition of 'object shift' to be used here is a narrow one, covering only the kind of object shift typically found in the Scandinavian languages, following the

original use of the term in Holmberg (1986: 165). Sometimes object shift has been taken to include also at least some instances of scrambling as found in the Continental West Germanic languages (Afrikaans, Dutch, Frisian, German, and Yiddish); see among others Vanden Wijngaerd (1989), Neeleman (1994b: 408), and Bobaljik (1995: 85). For a thorough discussion of scrambling, please refer to chapter 43.

Scrambling (as in the German examples (1b, c) below) and object shift (as in Icelandic (2b, c) and Danish (3c)) have in common that both move a DP leftward, from a position inside VP to a position outside VP but inside the same clause:

(1) Scrambling (German)

a.	Peter	hat_v		ohne	Zweifel	nie	$[_{VP}$	Bücher	gelesen]	t_v.
	Peter	has		without	doubt	never		books	read	
b.	Peter	las_v	die Bücher$_i$	ohne	Zweifel	nie	$[_{VP}$	t_i	t_v	].
	Peter	read	the books	without	doubt	never				
c.	Peter	las_v	sie_i	ohne	Zweifel	nie	$[_{VP}$	t_i	t_v	].
	Peter	read	them	without	doubt	never				

(2) Object shift (Icelandic)

a.	Pétur	$hefur_v$	eflaust	aldrei	t_v	$[_{VP}$	lesið	bækur].	
	Peter	has	doubtlessly	never			read	books	
b.	Pétur	las_v	bækurnar$_i$	eflaust	aldrei	$[_{VP}$	t_v	t_i	].
	Peter	read	books-the	doubtlessly	never				
c.	Pétur	las_v	þær$_i$	eflaust	aldrei	$[_{VP}$	t_v	t_i	].
	Peter	read	them	doubtlessly	never				

(3) Object shift (Danish)

a.	Peter	har_v	uden	tvivl	aldrig	t_v	$[_{VP}$	læst	bøger].	
	Peter	has	without	doubt	never			read	books	
b.	*Peter	$læste_v$	bøgerne$_i$	uden	tvivl	aldrig	$[_{VP}$	t_v	t_i	].
	Peter	read	books-the	without	doubt	never				
c.	Peter	$læste_v$	dem$_i$	uden	tvivl	aldrig	$[_{VP}$	t_v	t_i	].
	Peter	read	them	without	doubt	never				

All the above examples are verb second (V2), i.e., the finite verb has been moved from the position marked t_v to its present position as the second constituent of the main clause. In addition, in all examples the base position of the object is inside the VP, i.e., to the right of the adverbials *no doubt* and *never*, cf. (1a), (2a), and (3a). When scrambling (1b, c) or object shift ((2b, c) and (3c)) takes place, the object moves to a position to the left of these adverbials. From these examples, which focus on the similarities between object shift and scrambling, it might appear that there are no differences. This is not so; there are many differences between the two types of movement, as object shift is much more restricted than scrambling. Only object shift requires verb movement, and only object shift is restricted to DPs (though see (82b) and (84b) below). In section 2 I will review in detail a number of restrictions that apply to object shift but not to scrambling.

There is also a difference between Icelandic object shift and object shift as found in the other Scandinavian languages, namely, the difference between (2b) and (3b). Either both full DPs and pronouns (Icelandic) or only pronouns (the other Scandinavian languages) may undergo object shift. This will be discussed further in section 3.4.

After the various empirical characteristics of object shift have been discussed and compared to those of scrambling, the discussion will turn to an analysis of the movement and its motivation (case in section 3, equidistance in section 4, and interpretational considerations in sections 5 and 6).

2 Differences between object shift and scrambling

2.1 When does object shift apply?

2.1.1 Verb movement required (Holmberg's generalization)

Object shift is blocked if the main verb which selects the object does not move out of its base position in V°. Because the Scandinavian languages (like all other Germanic languages except English) are V2, one context in which the main verb moves out of V° is a main clause where the main verb is also the finite verb; see (4) and (5).

(4) Icelandic: full DPs

a. Af hverju las_v Pétur aldrei [$_{VP}$ t_v þessa bók]?
why read Peter never this book

b. Af hverju las_v Pétur þessa $bók_i$ aldrei [$_{VP}$ t_v t_i]?
why read Peter this book never

(5) Icelandic: pronouns

a. *Af hverju las_v Pétur aldrei [$_{VP}$ t_v hana]?
why read Peter never it

b. Af hverju las_v Pétur $hana_i$ aldrei [$_{VP}$ t_v t_i]?
why read Peter it never

(6) Danish: full DPs (impossible)

a. Hvorfor $læste_v$ Peter aldrig [$_{VP}$ t_v den her bog]?
why read Peter never this book

b. *Hvorfor $læste_v$ Peter den her bog_i aldrig [$_{VP}$ t_v t_i]?
why read Peter this book never

(7) Danish: pronouns

a. *Hvorfor $læste_v$ Peter aldrig [$_{VP}$ t_v den]?
why read Peter never it

b. Hvorfor $læste_v$ Peter den_i aldrig [$_{VP}$ t_v t_i]?
why read Peter it never

This observation, that the object may move only if verb movement has taken place, goes back at least to Holmberg (1986: 165) and has been known as Holmberg's generalization, at least since Collins and Thráinsson (1993: 135). Furthermore, (5a) and (7a) illustrate the obligatory nature of pronominal-object shift (see also sections 3.4 and 5.1): If a(n unstressed) pronoun can undergo object shift, it must. This is definitely true for Icelandic and Danish, but as shown by Josefsson (2003: 200–202), e.g., object shift of pronouns in Swedish is optional rather than obligatory.

In those main clauses where the finite verb is an auxiliary verb, the main verb, *read*, occurs in a non-finite form and does not leave the VP. Consequently object shift may not take place:

(8) Icelandic

a.	Af hverju	hefur$_v$	Pétur			aldrei	t$_v$	[$_{VP}$ lesið	þessa	bók]?
	why	has	Peter			never		read	this	book
b.	*Af hverju	hefur$_v$	Pétur	þessa	bók$_i$	aldrei	t$_v$	[$_{VP}$ lesið	t$_i$	]?
	why	has	Peter	this	book	never		read		

(9) Icelandic

a.	Af hverju	hefur$_v$	Pétur		aldrei	t$_v$	[$_{VP}$ lesið	hana]?
	why	has	Peter		never		read	it
b.	*Af hverju	hefur$_v$	Pétur	hana$_i$	aldrei	t$_v$	[$_{VP}$ lesið	t$_i$]?
	why	has	Peter	it	never		read	

(10) Danish

a.	Hvorfor	har$_v$	Peter			aldrig	t$_v$	[$_{VP}$ læst	den	her	bog]?
	why	has	Peter			never		read	this		book
b.	*Hvorfor	har$_v$	Peter	den	her bog$_i$	aldrig	t$_v$	[$_{VP}$ læst	t$_i$		]?
	why	has	Peter	this	book	never		read			

(11) Danish

a.	Hvorfor	har$_v$	Peter		aldrig	t$_v$	[$_{VP}$ læst	den]?
	why	has	Peter		never		read	it
b.	*Hvorfor	har$_v$	Peter	den$_i$	aldrig	t$_v$	[$_{VP}$ læst	t$_i$]?
	why	has	Peter	it	never		read	

In embedded clauses the Scandinavian languages differ. In Icelandic the finite verb moves to I°, whereas in the other languages it seems to stay in V°; see, e.g., Holmberg and Platzack (1995: 76–77); Vikner (1995: 139, 1997b); Rohrbacher (1999: 56–80). Consequently, object shift is found in embedded clauses only in Icelandic (and only if the main verb moves out of VP, i.e., only if the main verb is finite), (12b) and (13b), and not in the other Scandinavian languages (15b):[1]

(12) Icelandic

a.	Ég spurði	af hverju	Pétur	læsi$_v$		aldrei	[$_{VP}$ t$_v$	þessa	bók].
	I asked	why	Peter	read		never		this	book

b. Ég spurði af hverju Pétur læsi$_v$ þessa bók$_i$ aldrei [$_{VP}$ t$_v$ t$_i$].
I asked why Peter read this book never

(13) Icelandic
a. *Ég spurði af hverju Pétur læsi$_v$ aldrei [$_{VP}$ t$_v$ hana].
I asked why Peter read never it
b. Ég spurði af hverju Pétur læsi$_v$ hana$_i$ aldrei [$_{VP}$ t$_v$ t$_i$].
I asked why Peter read it never

(14) Danish
a. Jeg spurgte hvorfor Peter aldrig [$_{VP}$ læste den her bog].
I asked why Peter never read this book
b. *Jeg spurgte hvorfor Peter den her bog$_i$ aldrig [$_{VP}$ læste t$_i$].
I asked why Peter this book never read

(15) Danish
a. Jeg spurgte hvorfor Peter aldrig [$_{VP}$ læste den].
I asked why Peter never read it
b. *Jeg spurgte hvorfor Peter den$_i$ aldrig [$_{VP}$ læste t$_i$].
I asked why Peter it never read

Scrambling, on the other hand, does not require the verb to be moved as it may take place regardless of whether the main verb has left its VP (16a) or not (16b):

(16) German
a. Warum liest$_v$ Peter dieses Buch$_i$ oft [$_{VP}$ t$_i$ t$_v$] ?
why reads Peter this book often
b. Warum hat$_v$ Peter dieses Buch$_i$ oft [$_{VP}$ t$_i$ gelesen] t$_v$?
why has Peter this book often read

The fact that (16b) is grammatical thus shows that scrambling does not fall under Holmberg's generalization, at least not as formulated here ('the object may only move if verb movement has taken place'), assuming that neither German nor, e.g., Dutch have finite-verb movement in embedded clauses (see chapter 43 of this volume and also, e.g., Vikner 2005). If the generalization is formulated as in Déprez (1994: 111), 'Object movement never crosses a thematic verb', scrambling does not go against the generalization, since the object does not scramble across the verb as it is base-generated in a position left of the verb (assuming that the base order of German is SOV). There are still many types of object movement that do not fall under the generalization, however, e.g., object cliticization in Romance (see section 3.4 and chapters 13 and 14 in this volume), or another case of Germanic object movement, namely, scrambling in Yiddish. Yiddish is normally taken to be an SVO language, which means that when scrambling takes place in a sentence where the main verb is not finite, the object moves across the main verb:[2]

(17) Yiddish
a. Far vos hot$_v$ Moyshe nit t$_v$ [$_{VP}$ geleyent dos dozike bukh]?
why has Moses not read this book
b. Far vos hot$_v$ Moyshe dos dozike bukh$_i$ nit t$_v$ [$_{VP}$ geleyent t$_i$]?
why has Moses this book not read

In section 3 and the following sections below, various suggestions as to why object shift (but not scrambling) requires the verb to have left its VP will be discussed.

2.1.2 Prepositions, particles, and indirect objects block object shift

Object shift is blocked if it has to cross a c-commanding preposition:

(18) Icelandic
a. Af hverju las$_v$ Pétur aldrei t$_v$ [$_{PP}$ í þessari bók]?
why read Peter never in this book
b. *Af hverju las$_v$ Pétur þessari bók$_i$ aldrei t$_v$ [$_{PP}$ í t$_i$]?
why read Peter this book never in

(19) Icelandic
a. Af hverju las$_v$ Pétur aldrei t$_v$ [$_{PP}$ í henni]?
why read Peter never in it
b. *Af hverju las$_v$ Pétur henni$_i$ aldrei t$_v$ [$_{PP}$ í t$_i$]?
why read Peter it never in

(20) Danish
a. Hvorfor læste$_v$ Peter aldrig t$_v$ [$_{PP}$ i den her bog]?
why read Peter never in this book
b. *Hvorfor læste$_v$ Peter den her bog$_i$ aldrig t$_v$ [$_{PP}$ i t$_i$]?
why read Peter this book never in

(21) Danish
a. Hvorfor læste$_v$ Peter aldrig t$_v$ [$_{PP}$ i den]?
why read Peter never in it
b. *Hvorfor læste$_v$ Peter den$_i$ aldrig t$_v$ [$_{PP}$ i t$_i$]?
why read Peter it never in

Object shift is also blocked if it has to cross a c-commanding verb particle, like *out* in *Peter threw out the old carpet*. For independent reasons (see, e.g., Taraldsen 1984; Åfarli 1985; Vikner 1987: 266; Johnson 1991; Collins and Thráinsson 1993: 163), the particle always c-commands its complement in Swedish, (22), whereas this never happens in Danish, (24). In Icelandic, (27), and also in Norwegian, the situation is parallel to the one in English in that the particle may either precede

(and c-command) a full DP complement or follow it, but a pronominal complement must precede the particle. It is therefore only in Swedish that we can observe how a particle blocks object shift, (23c):

(22) Swedish
a. Peter har$_v$ inte t$_v$ kastat bort mattan.
Peter has not thrown away carpet-the
b. *Peter har$_v$ inte t$_v$ kastat mattan$_i$ bort t$_i$.
Peter has not thrown carpet-the away

(23) Swedish
a. Peter kastade$_v$ inte t$_v$ bort den.
Peter threw not away it
b. *Peter kastade$_v$ inte t$_v$ den$_i$ bort t$_i$.
Peter threw not it away
c. *Peter kastade$_v$ den$_i$ inte t$_v$ bort t$_i$.
Peter threw it not away

In Danish, the particle has to follow its complement whether or not object shift has taken place, (24), and therefore the particle does not have any blocking effect (25c). In fact, the pronoun may not follow the particle, (25a), and has to undergo object shift, (25b, c). If the complement of the particle is a full DP, it still precedes the particle, (26a, b), but it cannot undergo object shift, (26c):

(24) Danish
a. *Peter har$_v$ ikke t$_v$ smidt ud tæppet.
Peter has not thrown away carpet-the
b. Peter har$_v$ ikke t$_v$ smidt tæppet$_i$ ud t$_i$.
Peter has not thrown carpet-the away

(25) Danish
a. *Peter smed$_v$ ikke t$_v$ ud det.
Peter threw not away it
b. *Peter smed$_v$ ikke t$_v$ det$_i$ ud t$_i$.
Peter threw not it away
c. Peter smed$_v$ det$_i$ ikke t$_v$ ud t$_i$.
Peter threw it not away

(26) Danish
a. *Peter smed$_v$ ikke t$_v$ ud tæppet.
Peter threw not away carpet-the
b. Peter smed$_v$ ikke t$_v$ tæppet$_i$ ud t$_i$.
Peter threw not carpet-the away
c. *Peter smed$_v$ tæppet$_i$ ikke t$_v$ ud t$_i$.
Peter threw carpet-the not away

In Icelandic, the particle may or may not precede its complement whether or not object shift has taken place, (27), and therefore the particle does not have any blocking effect, (28c) and (29c). Though a full DP may occur in any of the three positions, (28), a pronoun may not follow the particle, nor may it fail to undergo object shift (29a, b):

(27) Icelandic
a. Pétur hefur$_v$ ekki t$_v$ hent út mottunni.
Peter has not thrown away carpet-the
b. Pétur hefur$_v$ ekki t$_v$ hent mottunni$_i$ út t$_i$.
Peter has not thrown carpet-the away

(28) Icelandic
a. Pétur henti$_v$ ekki t$_v$ út mottunni.
Peter threw not away carpet-the
b. Pétur henti$_v$ ekki t$_v$ mottunni$_i$ út t$_i$.
Peter threw not carpet-the away
c. Pétur henti$_v$ mottunni$_i$ ekki t$_v$ út t$_i$.
Peter threw carpet-the not away

(29) Icelandic
a. *Pétur henti$_v$ ekki t$_v$ út henni.
Peter threw not away it
b. *Pétur henti$_v$ ekki t$_v$ henni$_i$ út t$_i$.
Peter threw not it away
c. Pétur henti$_v$ henni$_i$ ekki t$_v$ út t$_i$.
Peter threw it not away

In Norwegian, the situation is the same as in Icelandic as far as the particle is concerned (the particle may or may not precede its complement independently of whether object shift has taken place), but the object-shift situation is not the same in the two languages as only pronouns undergo object shift in Norwegian. Norwegian versions of the Icelandic (27), (28), and (29) would therefore basically have the same judgments as in Icelandic, with at least one major exception, namely, that (28c) would be ungrammatical in Norwegian because full DPs cannot undergo object shift (though see Nilsen 1997).

The fact that prepositions and (Swedish) particles block object shift might be related to the blocking of object shift by verbs inside VP. The generalization (first formulated in Holmberg 1986: 176, 199) could be that object shift is impossible if the object is governed (or assigned case) by an overt governor (or case-assigner) as opposed to object shift of objects which are governed (or assigned case) by the trace of a governor/case-assigner. The crucial difference would thus be that when object shift is blocked by a non-finite verb, a finite main verb in embedded clauses (except in Icelandic), a preposition, or a particle (only in Swedish), the governor/case-assigner is not a trace, but when object shift is not blocked, the

governor/case-assigner is a trace (e.g., when the main verb has undergone V2 in main clauses, or in Icelandic when the main verb has moved to I° in embedded clauses). For further discussion of this, see sections 3.1 and 5.2.

The next set of data to be considered is not covered by this generalization. Object shift of a direct object is blocked by an indirect object, (30b) and (31b), even though object shift of both objects, (30c) and (31c), or object shift of the indirect object alone, (30d) and (31d), are not blocked:[3]

(30) Icelandic

a.	Ég	lána$_v$			ekki	t$_v$	Maríu	bækurnar.
	I	lend			not		Maria.DAT	books-the.ACC
b.	*Ég	lána$_v$		bækurnar$_i$	ekki	t$_v$	Maríu	t$_i$.
	I	lend		books-the.ACC	not		Maria.DAT	
c.	Ég	lána$_v$	Maríu$_j$	bækurnar$_i$	ekki	t$_v$	t$_j$	t$_i$.
	I	lend	Maria.DAT	books-the.ACC	not			
d.	Ég	lána$_v$	Maríu$_j$		ekki	t$_v$	t$_j$	bækurnar.
	I	lend	Maria.DAT		not			books-the.ACC

(Collins and Thráinsson 1993: 149, 154, 143, 154)

(31) Danish

a.	Jeg	låner$_v$			ikke	t$_v$	Maria	bøgerne.
	I	lend			not		Maria	books-the
b.	*Jeg	låner$_v$		dem$_i$	ikke	t$_v$	Maria	t$_i$.
	I	lend		them	not		Maria	
c.	Jeg	låner$_v$	hende$_j$	dem$_i$	ikke	t$_v$	t$_j$	t$_i$.
	I	lend	her	them	not			
d.	Jeg	låner$_v$	hende$_j$		ikke	t$_v$	t$_j$	bøgerne.
	I	lend	her		not			books-the

The reason why the generalization is formulated in terms of the direct object being unable to undergo object shift across the indirect object, rather than the accusative object being unable to undergo object shift across the dative object, is that, as shown by Thráinsson (2001: 153), e.g., the generalization also holds for examples where both the direct and the indirect object are dative (for more Icelandic data with unexpected morphological cases, see (62), (63), and (64)):[4]

(32) Icelandic

	Mannræninginn	skilaði$_v$ . . .					
	Kidnapper-the.NOM	returned					
a.	. . .			aldrei	t$_v$	foreldrunum	börnunum.
				never		parents-the.DAT	children-the.DAT
b.	*. . .		börnunum$_i$	aldrei	t$_v$	foreldrunum	t$_i$.
			children-the.DAT	never		parents-the.DAT	

c. . . . foreldrunum$_j$ börnunum$_i$ aldrei t_v t_j t_i.
parents- children- never
the.DAT the.DAT

d. . . . foreldrunum$_j$ aldrei t_v t_j börnunum.
parents- never children-
the.DAT the.DAT

'The kidnapper never returned the children to the parents.'
(Thráinsson 2001: 153, his (14))

As mentioned earlier, and as discussed in section 3.1, Holmberg (1986: 176) suggests that object shift is possible only if the object is governed (or assigned case) by a trace of a governor/case-assigner. The reason is taken to be that traces (of case-assigners) do not necessarily (but only optionally) assign case. As for the double-object data in (30–32), Holmberg (1986: 206) proposes an account for them in terms of case visibility of an empty preposition which assigns case to the indirect object: If the empty preposition assigns case to the indirect object, it does so only because it is embedded under the verb, and then the verb trace must assign case to the direct object, and none of the objects may undergo object shift; see (30a, b), (31a, b), and (32a, b). If the empty preposition does not assign case to the indirect object, then the verb trace does not have to assign case to the direct object. This allows two situations, either one in which the verb trace does not assign case either, and then both objects undergo object shift; see (30c), (31c), and (32c), or one in which the verb trace does assign case, and then the indirect object undergoes object shift on its own, which is shown in (30d), (31d), and (32d). One problem here is that this empty preposition is taken to move along with the indirect object under object shift, something which overt prepositions never do, see section 2.3.

In Vikner (1989: 142), the blocking effect of an indirect object in situ, (30b), (31b), and (32b), is taken to be a relativized minimality effect, assuming that the indirect object is an A-position and object shift is A-movement. Collins and Thráinsson (1993: 158) suggest an explanation within the Minimalist framework. The features of the head (AgrIO°) attracting the indirect object must be at least as strong as the features attracting the direct object (AgrO°), which means that if AgrO° has strong features (as is necessary to make the direct object move), AgrIO° must have strong features too, which will force the indirect object to move as well. Finally, Müller (2001: 288–294) suggests an account for this effect (which he refers to as an order preservation effect, cf. shape preservation in Williams 2003) by means of an optimality-theory constraint called PARALLEL MOVEMENT, which is violated every time a c-command relationship between any two arguments is not the same at all levels (i.e., before and after the various movements).

2.2 *Parasitic gaps*

A number of differences between object shift and scrambling have often been taken to illustrate that object shift is A-movement and scrambling is A-bar-movement,

e.g., in Holmberg (1986: 175) and Vikner (1989: 142, 1994b: 490). More recently, the assumption that object shift is A-movement has been questioned by, e.g., Holmberg and Platzack (1995: 147) and Holmberg (1999).

Following the analysis of Chomsky (1982: 40) and (1986a: 56), a parasitic gap may occur only in a construction where A-bar-movement has taken place. Consider the following *wh*-movement constructions in German and Danish, where parasitic gaps are possible ('t' is the trace, 'e' is the parasitic gap):

(33) German
Welches Buch$_i$ haben alle [ohne e$_i$ zu lesen] t$_i$
which book have all without to read
ins Regal gestellt?
into-the bookcase put
'Which book did everyone put on the shelf without reading first?'
(Müller 1995: 172)

(34) Danish
Hvad for en bog$_i$ stillede alle t$_i$ hen på reolen
which book put all onto bookcase-the
[uden at læse e$_i$ først]?
without to read first
'Which book did everyone put on the shelf without reading first?'

The fact that parasitic gaps may occur in scrambling constructions like (35), but not if scrambling does not take place as in (36), is often considered an indication that scrambling is an instantiation of A-bar-movement (cf., among others, Bennis and Hoekstra 1984: 65; Felix 1985: 190; Müller 1995: 172; chapter 43 in this volume):

(35) German
. . . , daß alle dieses Buch$_i$ [ohne e$_i$ zu lesen] t$_i$
that all this book without to read
ins Regal gestellt haben.
into-the bookcase put have
(Müller 1995: 173, his (74a))

(36) German
*. . . , daß alle [ohne e$_i$ zu lesen] dieses Buch$_i$
that all without to read this book
ins Regal gestellt haben.
into-the bookcase put have
'. . . that everyone put this book on the shelf without reading (it) first'
(Müller 1995: 173, his (86))

Object shift, on the other hand, does not trigger parasitic gaps, indicating that it is not an A-bar-movement (as first noted by Holmberg 1986: 225):

(37) Danish
*Alle stillede$_v$ den$_i$ straks t_v t_i hen på reolen
All put it at once onto bookcase-the
[uden at læse e_i først]
without to read first

The absence of object shift does not improve (37), see (38), whereas both (37) and (38) are well-formed without the bracketed clause introduced by *without*:

(38) Danish
*. . . at alle straks stillede den hen på reolen
that all at once put it onto bookcase-the
[uden at læse e_i først]
without to read first

2.3 *Which elements may undergo object shift?*

From the standard instantiations of A-movement (passive, raising) and A-bar-movement (*wh*-movement), we know that A-movement is movement into, but A-bar-movement out of, a case-marked position. This distinction forms the basis for some of the arguments in favor of object shift being A-movement and scrambling being A-bar-movement.

Assuming that PPs may not receive case – e.g., they are at best marginal in the subject position of tensed sentences (for English, see, e.g., Quirk et al. 1985: 736 and Stowell 1981: 268) – it is possible to account for why PPs may undergo scrambling (39b), (40b), but not object shift (41b), (42b); (43b), (44b). Object shift is movement into a case-marked position, but scrambling is not:

(39) German
a. Ich habe nicht für das Buch bezahlt.
I have not for the book paid
b. Ich habe für das Buch$_i$ nicht t_i bezahlt.
I have for the book not paid

(40) German
a. Ich habe nicht dafür bezahlt.
I have not there-for paid
b. Ich habe dafür$_i$ nicht t_i bezahlt.
I have there-for not paid

(41) Icelandic
a. Ég borgaði$_v$ ekki t_v fyrir bókina.
I paid not for book-the
b. *Ég borgaði$_v$ fyrir bókina$_i$ ekki t_v t_i.
I paid for book-the not

(42) Icelandic
a. Ég borgaði$_v$ ekki t$_v$ fyrir hana.
I paid not for it
b. *Ég borgaði$_v$ fyrir hana$_i$ ekki t$_v$ t$_i$.
I paid for it not

(43) Danish
a. Jeg betalte$_v$ ikke t$_v$ for bogen.
I paid not for book-the
b. *Jeg betalte$_v$ for bogen$_i$ ikke t$_v$ t$_i$.
I paid for book-the not

(44) Danish
a. Jeg betalte$_v$ ikke t$_v$ for den.
I paid not for it
b. *Jeg betalte$_v$ for den$_i$ ikke t$_v$ t$_i$.
I paid for it not

((39–40) and (43–44) are from Vikner 1994b: 492, his (11–14))

There are many other types of constituent which fit into the same picture in so far as they are not normally taken to be assigned case and they may not undergo object shift. One such type of constituent is the predicative adjectival, as shown in (45–47), others are, e.g., VPs. However, unlike the situation with PPs, there is no difference between scrambling and object shift here, e.g., predicative adjectivals undergo neither scrambling (45b), nor object shift (46b), (47b):

(45) German
a. Peter ist nie krank.
Peter is never ill
b. *Peter ist krank$_i$ nie t$_i$.
Peter is ill never

(46) Icelandic
a. Pétur er aldrei veikur.
Peter is never ill
b. *Pétur er veikur$_i$ aldrei t$_i$.
Peter is ill never

(47) Danish
a. Peter er aldrig syg.
Peter is never ill
b. *Peter er syg$_i$ aldrig t$_i$.
Peter is ill never

2.4 What is the landing site of object shift?

2.4.1 Object shift is clausebound

At the outset, we said that object shift was a leftward movement of a DP from a position inside VP to a position outside VP but inside the same clause. The following examples illustrate that, as opposed to scrambling in Russian, e.g., object shift may not move a DP out of a clause (49a):[5]

(48) Russian
Vy posylku$_i$ videli [kak zapakovali t$_i$].
you parcel saw how (they) wrapped
'You saw how they wrapped the parcel.' (Müller 1995: 128, his (71b))

(49) Icelandic

a.	*Ég	veit	bókina$_i$	[af hverju	þau	seldu		ekki t$_i$	].
	I	know	book-the	why	they	sold		not	
b.	Ég	veit		[af hverju	þau	seldu	bókina$_i$	ekki t$_i$	].
	I	know		why	they	sold	book-the	not	
c.	Ég	veit		[af hverju	þau	seldu		ekki bókina	].
	I	know		why	they	sold		not book-the	

'I know why they did not sell the book.'

As was illustrated in section 2.1.1, object shift moves a DP to a position which follows the subject and which in main clauses also follows the finite verb (in Icelandic it follows the finite verb also in embedded clauses). The position targeted by object shift furthermore precedes the negation and any (medial) sentential adverbial, both of which again precede all non-finite verbs (in Danish, Faroese, Norwegian, and Swedish embedded clauses, the negation and sentential adverbials also precede the finite verb).

2.4.2 Is object shift movement to an adjoined position?

In the earliest treatment of object shift, Holmberg (1986: 218, 170), the shifted object is taken to be adjoined to VP in Icelandic and to I-bar in Mainland Scandinavian (i.e., Danish, Norwegian, and Swedish). Holmberg (1986: 170, 93) is forced to assume adjunction to I-bar in Mainland Scandinavian because of his assumption that the finite verb in embedded clauses occurs in I° in all of the Scandinavian languages. Following Pollock's (1989) suggestions that finite French verbs move to I° whereas finite English verbs remain in V°, Holmberg and Platzack (1988), among others, suggested that the same difference obtains between Icelandic and Mainland Scandinavian. One of the advantages of this view was that the landing site of object shift in Icelandic could now be taken to be the same as the landing site of object shift in Mainland Scandinavian, a view followed by almost all subsequent analyses (cf. also section 2.1.1). Consequently

Vikner (1989, 1994b) takes object shift to be adjunction to (the highest) VP in all of the Scandinavian languages (as opposed to scrambling in, e.g., German, which is taken also to allow adjunction to IP). Holmberg and Platzack (1995: 142, 20) follow a very similar approach in that they take object shift to be adjunction to ActiveP, a functional projection immediately above (the highest) VP.

2.4.3 Is object shift movement to a specifier position?

Whereas most early analyses of object shift thus assume that the shifted object occurs in an adjoined position, almost all later analyses take the shifted object to occur in a specifier position, namely, the specifier position of some functional projection immediately above VP. Two of the earliest suggestions along these lines are Déprez (1989: 226) and Johnson (1991), who consider object shift movement to [AgrOP, Spec] (Johnson 1991 first refers to the landing site of object shift as μP-Spec, 1991: 606–608, but later identifies [μP, Spec] with [AgrOP, Spec], 1991: 628). This analysis is also found in, e.g., Chomsky (1993: 12–16), Bobaljik (1995: 80) and Collins and Thráinsson (1996).

As Holmberg (1999a: 6–7, 14–15) points out, the exact position of [AgrOP, Spec] with respect to, e.g., auxiliary verbs is crucial. Compare Déprez's (1989: 113) analysis in (50a) with Bobaljik's (1995: 83) in (50b):

(50) a. . . . $[_{\text{AgrOP}}$ spec AgrO° $[_{\text{V(aux)P}}$ spec V°(aux) $[_{\text{V(main)P}}$ spec V°(main)]]]
b. . . . $[_{\text{V(aux)P}}$ spec V°(aux) $[_{\text{AgrOP}}$ spec AgrO° $[_{\text{V(main)P}}$ spec V°(main)]]]

Déprez (1989: 113) situates AgrOP above all VPs in the same clause, whereas Bobaljik (1995: 83) explicitly situates AgrOP immediately above the VP of the main verb and below the VP of the auxiliary (or the VPs of the auxiliaries). Given that a shifted object always precedes negation and (medial) sentential adverbs, these two analyses then make different predictions as to whether the auxiliary V° follows or precedes negation and (medial) sentential adverbs. The fact that all non-finite auxiliaries in Scandinavian as well as all finite auxiliaries in Mainland Scandinavian embedded clauses follow rather than precede the negation and (medial) sentential adverbs is only compatible with an analysis such as (50a), where the potential landing site of object shift precedes all VPs.

In a reaction to this criticism, Bobaljik (2002: 225) explicitly assumes both that negation (and presumably also sentential adverbials) always adjoin to the highest VP of the clause and that object shift is to the specifier position of an AgrOP, which is right above the VP of the verb that selects the shifting object. In other words, only when the highest VP is also the VP of the main verb (i.e., the verb that selects the shifting object), does the [AgrOP, Spec] position targeted by object shift precede the negation (and sentential adverbials). This makes the prediction that if it should be possible to have object shift in a clause where the finite verb and the object-selecting main verb are not the same verb (something which is normally excluded, cf. (8b), (9b), and (11b) above), the shifted object (which is in [AgrOP, Spec] right above the VP of the main verb) should follow, not precede, the negation (which is adjoined to the VP of the finite auxiliary verb). As Bobaljik

(2002: 235) himself notes ("it might leave as problematic the respective order of the pronoun and negation"), this is precisely the wrong prediction for the central example of Holmberg (1999: 7), here given as (51c). The (shifted) object has to precede the negation, even though the sentence contains both a finite auxiliary and a non-finite main verb (which has been topicalized) (Example (51c) is a Danish version of Holmberg's Swedish 1999: 7, (11a)):[6]

(51) Danish

a. *Kysset$_x$ har$_v$ jeg ikke [$_{VP}$ t$_v$ [$_{VP}$ t$_x$ hende]], . . .
Kissed has I not her

b. *Kysset$_x$ har$_v$ jeg ikke [$_{VP}$ t$_v$ hende$_i$ [$_{VP}$ t$_x$ t$_i$]], . . .
Kissed has I not her

c. Kysset$_x$ har$_v$ jeg hende$_i$ ikke [$_{VP}$ t$_v$ [$_{VP}$ t$_x$ t$_i$]], . . .
Kissed has I her not
. . . bare holdt hende i hånden.
only held her in hand-the
'Kissed her, I haven't, only held her hand.'

It would thus seem that Holmberg's (1999: 6–7, 14–15) criticism of at least some [AgrOP, Spec] analyses is still highly relevant.

Even though Johnson (1991) and Chomsky (1993: 12–16), e.g., do not explicitly say where an auxiliary VP would be placed in the structure, the above criticism applies to these analyses as well because both require that all main verbs (even non-finite ones) move to AgrO°; for Johnson (1991) because non-finite main verbs, too, exhibit the positional effects he accounts for by assuming V°-to-AgrO° movement, and for Chomsky (1993: 12–16) because all main verbs must move to AgrO° to make it possible for the object in all types of clauses to undergo overt or covert object shift to [AgrOP, Spec] to have its object case checked (see also section 4 below on 'equidistance'). The point is that the main verb could not possibly move to AgrO° if an auxiliary V° would intervene between AgrO° and the main V°. On the other hand, as outlined above, the auxiliary V° must intervene between AgrO° and the main V° to produce the correct predictions for (51b, c).

Similar to the [AgrOP, Spec] analyses are the analyses of object shift as movement to (or through) [TenseP, Spec], as in Bobaljik and Jonas (1996) or Bošković (2004), or as movement to the specifier position of an IP-internal TopicP, as in Jayaseelan (2001: 71) or Josefsson (2001). However, as long as the position targeted by object shift is a position above even the highest VP of the clause, these analyses are not subject to Holmberg's (1999: 6–7, 14–15) criticism discussed above. Nilsen (1997) and Cinque (1999: 115), who assume the existence of a large number of functional projections inside IP but above VP, suggest that object shift may end in the specifier position of most if not all of these functional projections. These analyses are not subject to the criticisms voiced above as they assume that auxiliary verbs may be inserted in a large number of different functional heads, depending on the meaning of the auxiliary.

In some recent discussions of object shift, the landing site of object shift is left open, e.g., in Holmberg (1999). Similarly, whereas Chomsky (1995c: 360) suggests that object shift is movement to the outer of two specifier positions of *v*P, Chomsky (2001b: 33) makes it clear that although object shift moves through this position, it does not end there (in Chomsky 2001b: 33, two different movements, namely, Object Shift and Disl, correspond to what is normally called object shift, as also pointed out by Svenonius 2001).

2.4.4 Landing site between two adverbials

One of the reasons given by Holmberg and Platzack (1995: 152) for analyzing object shift as movement to an adjoined position rather than movement to [AgrOP, Spec] are the adjacency effects discussed by Vikner (1994b: 493–497). Here the data will first be discussed from the point of view of the adjunction analysis, and only afterwards will the specifier analysis be considered.

According to Stowell (1981: 113), case-assignment under government requires the case assigner and the case assignee to be adjacent. If object shift is movement to a case-assigned position, its landing site would have to be adjacent to a case assigner. If this case assigner is I° (or rather the verb or verb trace inside I°), the landing site of object shift would have to be adjacent to the verb or verb trace in I°. Although adjacency to a trace (including adjacency to a verb trace in I°) is impossible to see, the fact that I° itself is adjacent to the subject in [IP, Spec] (assuming that adverbials or other elements cannot adjoin to intermediate projections like I-bar) means that when I° only contains a trace, adjacency to I° results in surface adjacency to the subject in [IP, Spec]. In other words, under these assumptions an account can be made for why object-shifted objects (and also floating quantifiers referring to object-shifted objects) may not occur separated from the subject in [IP, Spec] or from the verb in I° by an adverbial (as Holmberg and Platzack 1995: 182 note, this argumentation may be seen as support of the assumption that Mainland Scandinavian has an I°-position, even though it is never overtly filled by a verb). In scrambling, on the other hand, nothing prevents the scrambled element (or a floated quantifier referring to a scrambled element) from occurring between two adverbials.

In (52c), (53c), (54c), and (55c), the scrambled or object-shifted object has been adjoined to the left of two adverbials; in (52b), (53b),[7] (54b), and (55b), the object has been adjoined between two adverbials (which prevents it from being adjacent to [IP, Spec] or I°); and in (52a), (53a), (54a), and (55a), no movement has taken place at all:

(52) German

	Gestern	hat$_v$	Peter	. . .							
	yesterday	has	Peter								
a.	. . .		ohne	Zweifel			nicht	das	Buch	gelesen	t$_v$.
			without	doubt			not	the	book	read	
b.	. . .		ohne	Zweifel	das	Buch$_i$	nicht	t$_i$		gelesen	t$_v$.
			without	doubt	the	book	not			read	

c. ... das Buch$_i$ ohne Zweifel nicht t_i gelesen t_v.
the book without doubt not read
'Yesterday Peter undoubtedly did not read this book'

(53) Icelandic
a. Í gær las$_v$ Pétur eflaust ekki t_v bókina.
yesterday read Peter doubtlessly not book-the
b. *Í gær las$_v$ Pétur eflaust bókina$_i$ ekki t_v t_i.
yesterday read Peter doubtlessly book-the not
c. Í gær las$_v$ Pétur bókina$_i$ eflaust ekki t_v t_i.
yesterday read Peter book-the doubtlessly not
'Yesterday Peter undoubtedly did not read this book'
(Examples (52) and (53) are from Vikner 1994: 493–494, his (15–16))

Neither scrambling nor object shift (of a full DP) is obligatory, cf. (52a) and (53a), though see section 5 on focus. The crucial difference is that whereas a scrambled object may land anywhere, (52b, c), an object-shifted object may only land in a position adjacent to I°, (53b, c). (Jónsson 1996: 66 finds an example of the same type as (53b) to be only marginal rather than completely ungrammatical.)

In the other Scandinavian languages, object shift may seem to be obligatory, but this is because, as mentioned above, only pronominal objects undergo object shift, and pronominal-object shift is obligatory (see section 3.4 below, and recall that Josefsson 2003: 200–202 shows object shift of pronouns in Swedish to be optional rather than obligatory). That this is a difference between pronouns and full DP objects is illustrated by pronominal data from Icelandic, compare (55) to (53):

(54) Danish
a. *I går læste$_v$ Peter uden tvivl ikke t_v den
yesterday read Peter without doubt not it
b. *I går læste$_v$ Peter uden tvivl den$_i$ ikke t_v t_i
yesterday read Peter without doubt it not
c. I går læste$_v$ Peter den$_i$ uden tvivl ikke t_v t_i
yesterday read Peter it without doubt not
'Yesterday Peter undoubtedly did not read it'

(55) Icelandic
a. *Í gær las$_v$ Pétur eflaust ekki t_v hana
yesterday read Peter doubtlessly not it
b. *Í gær las$_v$ Pétur eflaust hana$_i$ ekki t_v t_i
yesterday read Peter doubtlessly it not
c. Í gær las$_v$ Pétur hana$_i$ eflaust ekki t_v t_i
yesterday read Peter it doubtlessly not
'Yesterday Peter undoubtedly did not read it'
(Examples (54) and (55) are from Vikner (1994b: 493–494, his (17–18))

The only two possible object positions in sentences where object shift is allowed are thus the base position of the object and a position preceding all (medial) sentential adverbs and negation. In other words, the object has to be adjacent either to V° or to I°, as expected if it receives case from either V° (if object shift does not apply) or I° (when object shift has applied).

Let us now turn to similar evidence involving so-called floating quantifiers. According to Sportiche (1988), a floated quantifier (see chapter 71) may occur only in positions in which the quantified NP may occur, or through which the quantified NP may have moved. Giusti (1990) applies this analysis to scrambling and object shift, arguing that both these movements are included in those that may leave floating quantifiers behind.

As shown by the following examples, the possible positions of floated quantifiers are the same as the possible positions of the object; that is to say that any position is possible in scrambling (56), but only the position preceding the adverbials and the base position are possible in object shift (57):

(56) German

a. Peter wird die$_i$ Bücher$_i$ ohne Zweifel nie alle$_i$ t$_i$ lesen.
Peter will the books without doubt never all read

b. Peter wird die$_i$ Bücher$_i$ ohne Zweifel alle$_i$ nie t$_i$ lesen.
Peter will the books without doubt all never read

c. Peter wird die$_i$ Bücher$_i$ alle$_i$ ohne Zweifel nie t$_i$ lesen.
Peter will the books all without doubt never read
'Peter will undoubtedly never read all the books'

(57) Icelandic

a. Pétur las$_v$ bækurnar$_i$ eflaust ekki allar$_i$ t$_v$ t$_i$.
Peter read books-the doubtlessly not all

b. *Pétur las$_v$ bækurnar$_i$ eflaust allar$_i$ ekki t$_v$ t$_i$.
Peter read books-the doubtlessly all not

c. Pétur las$_v$ allar bækurnar$_i$ eflaust ekki t$_v$ t$_i$.
Peter read all books-the doubtlessly not
'Peter undoubtedly never read all the books'

(Examples (56) and (57) are from Vikner (1994b: 496, his (20), (21))

Admittedly, the ungrammaticality of (57b) is not directly explained by the adjacency requirement discussed above, as case is assigned to the NP *bækurnar* or *allar bækurnar*, which is adjacent to I° in all three cases in (57). One possible account for (57b) would be that it shows that the object cannot have moved through a position beween the adverbials on its way to its surface position, maybe because such a position would not be an A-position (making the movement an instance of 'improper movement', cf., e.g., Chomsky 1981: 195, 199), or because there would be no need for object shift to go via this position.

Summing up so far, if object shift is movement to an adjoined position, the data in (52–57) may be explained by assuming case may be assigned to an adjoined position, provided adjacency is respected.

If, on the other hand, object shift is movement to [AgrOP, Spec], then the requirements that the shifted object precede both negation and sentential adverbials must stem from [AgrOP, Spec] preceding the position of negation and medial sentential adverbials. This again would have to mean either (a) that scrambling (in Continental West Germanic) and object shift (in Scandinavian) have different landing sites (i.e., they cannot both be movement to [AgrOP, Spec]) or (b) that negation and the sentential adverbials have different positions in the two types of language. To be more precise, if object shift and scrambling target the same position (as assumed, e.g., by Bobaljik 2002: 230–233), negation and sentential adverbials in Continental West Germanic must be possible both to the left and to the right of this target [AgrOP, Spec], whereas negation and sentential adverbials in Scandinavian have to be restricted to the right of the target [AgrOP, Spec].

Notice finally that adjacency as discussed here is very different from what Bobaljik (2002: 210–221) calls adjacency, e.g., in that two elements may be adjacent in Bobaljik's sense even though an adverbial occurs between them.

2.5 Summary: object shift vs. scrambling

Throughout section 2, the properties of object shift in Scandinavian have been compared to the less restricted characteristics of scrambling in languages like Dutch and German (see (58)). Two additional differences between the Scandinavian languages were shown to follow from independent variation. First, only in Icelandic is object shift possible in embedded clauses, because only in Icelandic do all finite verbs move to I°, see examples (12) and (13b). Second, only in Swedish is object shift actually blocked by a particle, because only in Swedish does the object never precede the particle, see examples (22) and (23).

(58)

Section	Property	Object shift in Scandinavian	Scrambling in, e.g., German and Dutch
2.1.1	May take place independently of verb movement out of VP	No	Yes
2.1.2	May cross a preposition	No	Yes
	May cross a particle	No	Yes
	May cross an indirect object	No	Yes
2.2	Allows a parasitic gap	No	Yes
2.3	Moves (pronominal) DPs	Yes	Yes
	Moves PPs	No	Yes
	Moves predicative APs	No	No
2.4.1	May cross a clause boundary	No	No (Russian: yes)
2.4.4	May land between adverbials	No	Yes

One difference between the Scandinavian languages which does not follow from independent variation is that only in Icelandic do full DPs undergo object shift, see examples (4) and (5). In the other Scandinavian languages only pronominal DPs undergo object shift, see examples (6) and (7). This is further discussed in section 3.4.

Sections 2.4.2 and 2.4.3 discussed which kind of position is targeted by object shift (and scrambling), and showed that although there is no general agreement in the literature, there is a growing trend to assume the landing site to be a specifier position rather than an adjoined position.

3 Case as the key to object shift

3.1 Traces of case assigners are optional case assigners

As mentioned in section 2.1.2, Holmberg (1986: 176) was the first to suggest an analysis of object shift where case assignment by a trace is optional, as also assumed in Vikner (1994b: 500) and Holmberg and Platzack (1995: 166). This means that in structures where we would expect a DP to be assigned case by a V°, such case assignment is only obligatory if V° contains a verb. If V° does not contain a verb but only its trace, this V° assigns case optionally. In other words, if a verb has moved out of VP, it is possible for its object not to be assigned case by the verb trace, and therefore to move into a different position and be assigned case there. If an object is assigned case not by the trace of a verb, but by the verb itself (i.e., if the verb has not left VP), this case assignment is not optional but obligatory, and therefore the object is not free to move into a different position and be assigned case there. How is the shifted object assigned case, then, if not by V°? In Holmberg (1986: 208, 217), the shifted objects are not assigned case at all: because shifted objects (in Swedish only pronouns, in Icelandic all DPs) have morphological case, they do not need to be assigned case syntactically. One problem for this hypothesis is that, as illustrated in the next section, full DP objects have morphological case in Faroese, and yet they may not undergo object shift.

3.2 The role of morphological case

Morphological case is realized on all DPs only in two of the Scandinavian languages – Faroese and Icelandic.

(59)

the book	Icelandic	Faroese	Danish	Swedish	Norwegian
Nominative	bókin	bókin	bogen	boken	boka/boken
Accusative	bókina	bókina	bogen	boken	boka/boken
Dative	bókinni	bókini	bogen	boken	boka/boken

(Vikner 1994b: 502)

From the point of view of case morphology, Faroese thus patterns with Icelandic against the other Scandinavian languages, whereas as far as object shift is concerned, Faroese is more like the other Scandinavian languages, see (6) and (7), than like Icelandic, see (4) and (5):

(60) Faroese

a. Jógvan keypti$_v$ ikki [$_{VP}$ t$_v$ bókina].
Jógvan bought not book-the.ACC

b. *Jógvan keypti$_v$ bókina$_i$ ikki [$_{VP}$ t$_v$ t$_i$].
Jógvan bought book-the.ACC not

(Barnes 1992: 28)

(61) Faroese

a. *Jógvan keypti$_v$ ikki [$_{VP}$ t$_v$ hana].
Jógvan bought not it.ACC

b. Jógvan keypti$_v$ hana$_i$ ikki [$_{VP}$ t$_v$ t$_i$].
Jógvan bought it.ACC not

(Vikner 1994b: 502)

According to Sundquist (2002), a similar situation obtained in Middle Norwegian, in that morphological case was also found outside the pronominal system, and yet object shift was restricted to pronouns. In early modern English, too, we find only pronominal-object shift and not object shift of full DPs (Roberts 1995: 274–276). From the point of view of case this is less surprising, as early modern English did not have morphological case outside the pronominal system. Object shift in early modern English is of course remarkable in the fact that it shows that object shift may also be found in a non-Scandinavian language, indeed in a non-V2 language. Another potential problem related to morphological case is that in Icelandic the direct object does not always have accusative case, but may have one of the other three cases: The object is genitive in (62), dative in (63), and even nominative in (64) (where the subject is dative; see Sigurðsson 1989: 198–241; Taraldsen 1995):

(62) Icelandic

'Today you probably do not find this book amusing.'

The standard view on oblique case is that it is inherent or lexical case, which is assigned together with the thematic role (see Marantz 1984: 81 or Andrews 1990 and references there). To analyze these facts in a way compatible both with this standard view and with the analysis that object shift is movement to a case-assigned position, inherent case (i.e., case which is assigned at D-structure) would have to be licensed at S-structure, and this licensing would have to take place under conditions identical to the ones under which structural case assignment takes place.

3.3 Case assignment from I°

Holmberg's (1986: 208, 217) suggestion that shifted objects are not assigned case at all as they do not need case assignment because they have morphological case thus predicts that objects may shift if and only if they have morphological case. The ungrammaticality of full DP object shift in Faroese, (60b), was a direct counter-example to this analysis.

In Vikner (1994b: 500) and in Holmberg and Platzack (1995: 152), the shifted object is assigned case from I°. Vikner further suggests that a non-nominative case cannot be assigned by an X° which is already assigning nominative, e.g., C° in V2-languages and I° in non-V2-languages. Thus, object shift never occurs into a position preceding the verb, where C° is busy assigning nominative case

(though see note 8 on long object shift in Swedish), and object shift never occurs at all in non-V2 languages, where I° is busy assigning nominative case, although object shift in early modern English, mentioned in the previous section, is a problem for this claim because early modern English is not a V2-language. The fact that early modern English is a VO-language and that it does not allow object shift of full DPs also excludes scrambling as a possible analysis.

The formulation of Holmberg's generalization in section 2.1.1 referred to the (obligatory) movement of the selecting verb, rather than to the (obligatory) movement of the case-assigning verb. The possibility of object shift in two particular contexts, perception verbs, and causative verbs, however, indicate that case-assignment is the relevant notion rather than selection, which again lends further, if rather indirect, support to the idea that case assignment is the key to object shift. For reasons of exposition, this will only be illustrated with perception verbs. A perception verb like *see* may either select a DP or an embedded clause as its object, and if it selects an embedded clause, this may either be finite or non-finite. When *see* selects a non-finite embedded clause, as in (65–70), the subject of the embedded clause is not selected by *see* but by the verb (or the VP) of the embedded clause, *beat*. There is nevertheless a particular relation between *see* and the embedded subject, as *see* is taken to assign case to the embedded subject, so this subject is accusative in spite of its being a subject, as witnessed by its form, which is *þá* 'them.MASC' rather than *þeir* 'they.MASC' in Icelandic (66b), and *dem* 'them' rather than *de* 'they' in Danish (68b).

(65) Icelandic
a. Pétur $sá_v$ áreiðanlega $[_{VP}\ t_v\ [_{IP}$ FH vinna Hauka]].
Pétur saw presumably FH beat Haukar
b. Pétur $sá_v$ FH_i áreiðanlega $[_{VP}\ t_v\ [_{IP}\ t_i$ vinna Hauka]].
Pétur saw FH presumably beat Haukar

(66) Icelandic
a. *Pétur $sá_v$ áreiðanlega $[_{VP}\ t_v\ [_{IP}$ þá vinna Hauka]].
Pétur saw presumably them beat Haukar
b. Pétur $sá_v$ $þá_i$ áreiðanlega $[_{VP}\ t_v\ [_{IP}\ t_i$ vinna Hauka]].
Pétur saw them presumably beat Haukar

(67) Danish
a. Peter $så_v$ formentlig $[_{VP}\ t_v\ [_{IP}$ AGF slå FC København]].
Peter saw presumably AGF beat FC Copenhagen
b. *Peter $så_v$ AGF_i formentlig $[_{VP}\ t_v\ [_{IP}\ t_i$ slå FC København]].
Peter saw AGF presumably beat FC Copenhagen

(68) Danish
a. *Peter $så_v$ formentlig $[_{VP}\ t_v\ [_{IP}$ dem slå FC København]].
Peter saw presumably them beat FC Copenhagen
b. Peter $så_v$ dem_i formentlig $[_{VP}\ t_v\ [_{IP}\ t_i$ slå FC København]].
Peter saw them presumably beat FC Copenhagen

In spite of the relation between *see* and the embedded subject, *FH/þá/AGF/dem*, being one of case-assignment and not one of selection, the verb movement of *see* allows the embedded subject to undergo object shift in the usual fashion, i.e., obligatorily if it is a pronoun (66) and (68), optionally if it is an Icelandic full DP (65), and not at all if it is a Danish full DP (67).

That (65–68) are cases of object shift, i.e., that the embedded subject is moving around an adverbial of the main clause in (65b), (66b), and (68b), is supported by the fact that the adverbial in question, *presumably*, is a speaker-oriented adverbial which only occurs as a sentential adverbial in main clauses; it is ill-formed to the right of the main clause participle, *seen*:

(69) Icelandic
- a. Pétur hefur$_v$ áreiðanlega [$_{VP}$ t$_v$ [$_{VP}$ séð [$_{IP}$ FH vinna Hauka]]].
  Pétur has presumably seen FH beat Haukar
- b. *Pétur hefur séð áreiðanlega FH vinna Hauka.
  Pétur has seen presumably FH beat Haukar
- c. *Pétur hefur séð FH áreiðanlega vinna Hauka.
  Pétur has seen FH presumably beat Haukar

(70) Danish
- a. Peter har$_v$ formentlig [$_{VP}$ t$_v$ [$_{VP}$ set [$_{IP}$ AGF slå FC København]]].
  Peter has presumably seen AGF beat FC Copenhagen
- b. *Peter har set formentlig AGF slå FC København.
  Peter has seen presumably AGF beat FC Copenhagen
- c. *Peter har set AGF formentlig slå FC København.
  Peter has seen AGF presumably beat FC Copenhagen

Summarizing sections 3.1, 3.2, and 3.3, it was shown how assuming case assignment by a verb trace to be optional was an attempt to account for Holmberg's generalization. Object shift is possible only if the case-assigning verb leaves VP because only then is the case-assigned DP assigned case by a trace, which again means that only then is it possible for this DP not to be assigned case and therefore to move into a case position higher up in the clause.

3.4 Pronominal-object shift as cliticization

If case were crucial for object shift in the manner described in the previous section, we might expect that one of two situations would obtain in a given language: either all objects may undergo object shift (provided all other conditions on object shift were fulfilled), or no objects may undergo object shift at all. There would be no reason to expect pronouns (i.e., pronominal DPs) to behave any differently from full DPs, given that all DPs are alike in requiring case. However, the two types of object do behave differently with respect to object shift cross-linguistically.

In Icelandic, both pronominal objects and full DP objects may undergo object shift, see (4) and (5) above, whereas in the other Scandinavian languages (Danish, Faroese, Norwegian, and Swedish), only pronominal objects may undergo object shift, full DP objects may not, see (6), (7), (60), and (61).

Before discussing potential accounts of this difference, I shall give some further examples. 'Strong' pronouns (i.e., pronouns which are stressed, modified, or coordinated, cf. Holmberg 1986: 209) differ from pronominals which are not stressed, modified, or coordinated. As seen in (5) and (7) above, normally, pronouns obligatorily undergo object shift (though only optionally in Swedish, as mentioned in connection with (7)). Strong pronouns, however, behave like full DPs in this respect, i.e., they may optionally undergo object shift in Icelandic, see (4), and they may not undergo object shift in Danish, see (6).

The strong pronouns in (71) and (73) are stressed versions of the unstressed pronouns in (5) and (7), i.e., Icelandic *hana* and Danish *den* 'it'. The strong pronouns in (72) and (74) are Icelandic *þessa hérna* and Danish *den her*, 'this here'. The result would have been the same with expressions such as Icelandic *þessa með rauðu kápuna* or Danish *den med det røde omslag* 'the one with the red cover'.

(71) Icelandic: strong pronouns may undergo object shift

a. Af hverju las_v Pétur aldrei [$_{VP}$ t_v HANA]?
why read Peter never it

b. Af hverju las_v Pétur $HANA_i$ aldrei [$_{VP}$ t_v t_i]?
why read Peter it never

(72) Icelandic: full DPs may undergo object shift

a. Af hverju las_v Pétur aldrei [$_{VP}$ t_v þessa hérna]?
why read Peter never this here

b. Af hverju las_v Pétur þessa hérna$_i$ aldrei [$_{VP}$ t_v t_i]?
why read Peter this here never

(73) Danish: strong pronouns do not undergo object shift

a. Hvorfor $læste_v$ Peter aldrig [$_{VP}$ t_v DEN]?
why read Peter never it

b. *Hvorfor $læste_v$ Peter DEN_i aldrig [$_{VP}$ t_v t_i]?
why read Peter it never

(74) Danish: full DPs do not undergo object shift

a. Hvorfor $læste_v$ Peter aldrig [$_{VP}$ t_v den her]?
why read Peter never this here

b. *Hvorfor $læste_v$ Peter den her$_i$ aldrig [$_{VP}$ t_v t_i]?
why read Peter this here never

Let us now turn to some proposed accounts of the difference between pronominal-object shift and full DP object shift. A number of analyses take pronominal-object shift to be X°-movement along the lines of, e.g., cliticization in the Romance

languages (Holmberg 1991a: 167; Josefsson 1992, 1993; Déprez 1994: 122; Bobaljik and Jonas 1996: 207; Diesing 1996: 77, 1997: 415). The main advantage of such an approach is that the question of whether or not a language has object shift can now be turned into the question of whether or not a language has full DP object shift, and this can then plausibly be tied to whether or not I° (or T°) has strong features. I° (or T°) can be argued to have strong features in Icelandic (as reflected in the presence of V°-to-I° movement), but weak features in the other Scandinavian languages (which lack V°-to-I° movement). The main drawback, to be further discussed below, is that although it may become easier to account for whether or not a language has object shift of full DPs, it becomes much more difficult to account for whether or not a language has pronominal-object shift, as the differences between pronominal-object shift in Scandinavian and cliticization in Romance become unexpected (e.g., why do the former but not the latter observe Holmberg's generalization?).

As pointed out in Vikner (1994b: 504–506) and Holmberg and Platzack (1995: 154–156), assuming pronominal-object shift to be X°-movement is problematic for at least two reasons. One is that the object-shifted pronoun behaves differently from a Romance clitic pronoun, in that object-shifted pronouns do not occur in C° together with the finite verb, whereas Romance clitic pronouns do. If the object-shifted pronoun has incorporated into the verb, it should not only move along with the verb when the verb moves from V° to I° (which it arguably does; shifted objects occur adjacent to I°, see section 2.4.4), but it should also move along with the verb when the verb moves from I° to C°. The latter is quite clearly not the case, (75a):

(75) Danish

a. *Hvorfor [$_{C°}$ læste- den$_v$] Peter [$_{I°}$ t$_v$] aldrig [$_{VP}$ t$_v$ t$_i$]?
why read it Peter never

b. Hvorfor [$_{C°}$ læste$_v$] Peter [$_{I°}$ t$_v$- den$_i$] aldrig [$_{VP}$ t$_v$ t$_i$]?
why read Peter it never
'Why did Peter never read it?'

Not only would (75a) incorrectly be expected to be grammatical, but (75b) would also, again incorrectly, be expected to be ungrammatical. Although it should not be possible for the pronoun to be left behind in I° when the verb moves on to C° (see Kayne 1991: 649, who says a trace cannot be "a proper subpart of a X° constituent," referring to Baker 1988a: 73), this is exactly how (75b) would have to be analyzed if pronominal-object shift were X°-movement: the trace of the verb which has moved to C° is a proper subpart of I°.

It is of course possible to revise the analyses of Kayne (1991: 649) and Baker (1988a: 73), and to allow some form of excorporation, as in Roberts (1991a: 214–216). However, it is far from clear that this could be done in such a way as to rule out (75a) and rule in (75b) without doing the same to the Romance data. In French, for instance, ruling out (76a) and allowing (76b) would be problematic, as the French judgments are the exact mirror image of the Scandinavian ones; compare (76) and (75):[8]

(76) French

a. Où [$_{C°}$ l$_i$' avait$_v$]- il [$_{I°}$ t$_v$] [$_{VP}$ t$_v$ [$_{VP}$ acheté t$_i$]]?
where it- had he bought

b. *Où [$_{C°}$ avait$_v$]- il [$_{I°}$ le$_i$ t$_v$] [$_{VP}$ t$_v$ [$_{VP}$ acheté t$_i$]]?
where had he it bought
'Where had he bought it?'

Josefsson (1993: 21–22) says about the above difference that Scandinavian has weak pronouns, i.e., what she calls independent heads, whereas Romance has clitics, i.e., dependent heads. The crucial difference is that only independent heads are able to excorporate. However, the ability to excorporate is exactly the property that we are trying to account for, and so we arrive at a restatement of the problem above; if pronominal-object shift is X°-movement along the lines of cliticization in Romance, why do the two not behave alike? The other problem with the assumption that pronominal-object shift is X°-movement is connected with the fact that Scandinavian pronouns (if they should turn out to be clitics) would be clitics on the right side of their incorporating heads, as opposed to Romance clitics, which are on the left; see (76a).

If the Scandinavian pronoun were to incorporate into the verb already in the V°-position, we would expect a situation (e.g., right before verb movement to C°) in which finite tense endings would follow the compound head consisting of the verb and the incorporated pronominal object, which clearly is not the case; cf. (3c) with (77).

(77) Danish

* . . . [$_{I°}$ [$_{T°}$ [$_{V°}$ [$_{V°}$ læs-] dem] -te]] . . .
read- them PAST

(I am assuming here, along with Roberts 2001: 122, that Baker's 1988a: 13–15 mirror principle is relevant for the sequence of morphemes in complex words, even in a framework where such elements are checked in the relevant functional heads rather than base-generated there, as originally assumed by Baker 1988a.)

If on the other hand the Scandinavian pronoun were to incorporate into the verb at some point higher than V° (e.g., in T° or in I°), then it would have to be able to move at least one step as an XP since it would have to be able to move out of VP without incorporating into V°. If this were possible, however, then we would no longer have an account for Holmberg's generalization, i.e., for why it is necessary for the verb to move out of VP even for pronominal-object shift to be possible. There would in effect be no difference in this respect between an incorporation analysis of Scandinavian object shift and cliticization in Romance, where the object clearly does not incorporate into V°; the object is not incorporated into the main verb *acheté* 'bought' in (76a).

It would thus seem that there are good reasons not to take pronominal-object shift to be X°-movement along the lines of cliticization in Romance. But then, what is it? And if pronominal-object shift is no different from object shift of full DPs, we have no account of why four out of five Scandinavian languages have

the former but not the latter. Recent accounts (including the ones to be discussed in the rest of this chapter) have very little to add to this discussion; although Holmberg (1999: 22) and Chomsky (2001b: 33) both assume that pronominal-object shift is XP-movement as well, they do not attempt to account for why pronominal-object shift is also found in at least four languages that do not have object shift of full DPs.

4 Equidistance as the key to object shift

The so-called equidistance account (Chomsky 1993: 15–19) is an alternative to Holmberg's generalization. The idea is that the reason why object shift is possible only if the main verb leaves VP is that this verb movement is necessary to allow the object to move across [VP, Spec], which is where the subject is base-generated.

Chomsky (1993: 15–19) thus solves two problems at the same time. One problem is to find a reason for Holmberg's generalization, the other, to explain how object shift (as A-movement) may move across the base position of the subject in [VP, Spec] (which is an A-position), in violation of relativized minimality and/or the shortest movement condition. In other words, how can the object move from its base position, as in (78a) across [VP, Spec] into a higher specifier position, here [AgrOP, Spec], as in (78b)?

(78) a. $[_{VP}$ Subject V° Object]
b. $[_{AgrOP}$ Object AgrO° $[_{VP}$ Subject V° t_{obj}]]

Chomsky's (1993: 18) suggestion is that if and only if the verb moves from V° to AgrO° do [VP, Spec] and [AgrOP, Spec] count as belonging to the same minimal domain. If [VP, Spec] and [AgrOP, Spec] belong to the same minimal domain, they are equidistant from the object position, which means that from the point of view of the shortest movement condition, the object is free to move into either [VP, Spec] or [AgrOP, Spec]. In other words, the object is free to move into [AgrOP, Spec] even though this means moving across the base position of the subject in [VP, Spec], as in the derivational step from (79b) to (79c), as long as the verb has just moved from V° to AgrO°, as in the step from (79a) to (79b):

(79) a. $[_{VP}$ Subject $[_{V°}$ Verb] Object]
b. $[_{AgrOP}$ $[_{AgrO°}$ Verb] $[_{VP}$ Subject $[_{V°}$ t_{verb}] Object]]
c. $[_{AgrOP}$ Object $[_{AgrO°}$ Verb] $[_{VP}$ Subject $[_{V°}$ t_{verb}] t_{obj}]]

If the verb would not move, [VP, Spec] and [AgrOP, Spec] would not belong to the same minimal domain and they would therefore not be equidistant, and so the object could not leave its base position (at least not by means of A-movement).

According to Bobaljik and Jonas (1996: 202), this scenario repeats itself when the subject moves out of its base position on its way to [AgrSP, Spec] (roughly equivalent

to [IP, Spec]). The question is now how the subject may move across the object (or object trace) in [AgrOP, Spec] (which is an A-position). If we assume with Bobaljik and Jonas (1996: 198) that AgrOP is the complement of T°, then if the verb moves from Agr° to T°, as in the step from (80c) to (80d), then [AgrOP, Spec] and [TP, Spec] count as equidistant, and the subject may move across the object (or object trace) in [AgrOP, Spec], as in the step from (80d) to (80e):

(80) a. $[_{VP}$ Subject $[_{V°}$ Verb] Object]
b. $[_{AgrOP}$ $[_{AgrO°}$ Verb] $[_{VP}$ Subject $[_{V°}$ t_{verb}] Object]]
c. $[_{AgrOP}$ Object $[_{AgrO°}$ Verb] $[_{VP}$ Subject $[_{V°}$ t_{verb}] t_{obj}]]
d. $[_{TP}$ $[_{T°}$ Verb] $[_{AgrOP}$ Object $[_{AgrO°}$ t_{verb}] $[_{VP}$ Subject $[_{V°}$ t_{verb}] t_{obj}]]]
e. $[_{TP}$ Subject $[_{T°}$ Verb] $[_{AgrOP}$ Object $[_{AgrO°}$ t_{verb}] $[_{VP}$ t_{subj} $[_{V°}$ t_{verb}] t_{obj}]]]

Chomsky (1995c: 349–355) eliminates Agr categories altogether and introduces the concept of multiple specifiers, so that in effect what was described earlier as [VP, Spec] and [AgrOP, Spec] are now considered to be two different specifiers of the same VP (or of the same V°). Chomsky (1995c: 356–357) then goes on to revise the conditions on equidistance so that two specifiers of the same head are equidistant. This in turn means that equidistance no longer requires the verb to move from one head to the next higher one, and therefore the account of Holmberg's generalization is lost, as noted by Chomsky (1995c: 358) himself. The first step of object shift can now be a movement into the outer specifier of VP, and object shift is therefore able to cross the base position of the subject, which is the inner specifier of the same verb. As Chomsky (1995c: 358) said, Holmberg's generalization would have to be a property of the verb, so that it can have more than one specifier only if it is a trace. And Chomsky continues, "There is no obvious reason why this should be so."

5 Focus and interpretation as the key to object shift

The two accounts discussed so far, the one linked to optional case assignment by a trace and the equidistance account, have at least three features in common:

(i) They assume that full DP object shift is optional and they therefore have nothing to say about which full DPs undergo object shift and which ones do not.
(ii) They also both assume that pronominal-object shift is obligatory.
(iii) Finally, they both predict that non-DPs cannot possibly undergo object shift.

In section 5.1 we shall see that the first two assumptions do not hold, and in this section we will see that the prediction that only DPs undergo object shift is not quite borne out either.

When the adverb *there* is unstressed and defocused, it may undergo object shift in Icelandic, (82), and it must do so in Danish, (84) (as observed in Josefsson 1994: 117; Haider et al. 1995: 20; Thráinsson 2001: 197, n.7):

(81) Icelandic
a. Býr$_v$ Pétur ekki lengur t$_v$ í Kaupmannahöfn?
lives Peter not longer in Copenhagen.DAT
b. *Býr$_v$ Pétur í Kaupmannahöfn$_i$ ekki lengur t$_v$ t$_i$?
lives Peter in Copenhagen.DAT not longer

(82) Icelandic
a. Býr$_v$ Pétur ekki lengur t$_v$ þar?
lives Peter not longer there
b. Býr$_v$ Pétur þar$_i$ ekki lengur t$_v$ t$_i$?
lives Peter there not longer

(83) Danish
a. Bor$_v$ Peter ikke længere t$_v$ i København?
lives Peter not longer in Copenhagen
b. *Bor$_v$ Peter i København$_i$ ikke længere t$_v$ t$_i$?
lives Peter in Copenhagen not longer

(84) Danish
a. ??Bor$_v$ Peter ikke længere t$_v$ der?
lives Peter not longer there
b. Bor$_v$ Peter der$_i$ ikke længere t$_v$ t$_i$?
lives Peter there not longer

These data might seem to support the view discussed in section 3.4, that pronominal-object shift is cliticization – cliticization in Romance also affects clitic adverbials, e.g. French *y* 'there'. However, like any other kind of object shift, object shift of Icelandic *þar* and of Danish *der* 'there' underlie Holmberg's generalization, as opposed to cliticization of their Romance counterparts:

(85) French
a. Pierre n' y a jamais vécu.
Pierre not there has never lived
Danish
b. *Peter har der aldrig boet.
Peter has there never lived
c. Peter har aldrig boet der.
Peter has never lived there

As in section 3.4, the conclusion therefore remains that pronominal-object shift is not a kind of cliticization but a kind of object shift. The fact that non-DPs undergo object shift as well suggests that the key property is not case or equidistance, but something entirely different. In the next sections we shall see that the key property may be focus and interpretation.

5.1 The interpretation of object shift

From what has been said so far about full DP object shift in Icelandic, it might seem as if it is completely optional. This is not the case, however. As observed in Diesing and Jelinek (1995: 150) and in Diesing (1996: 79, 1997: 418), the interpretation of an object-shifted object in Icelandic differs from that of a non-object-shifted one, and this difference parallels the difference in interpretation between scrambled and non-scrambled objects in e.g. German and Yiddish (cf. Diesing 1992b: 129). Consider first a German example:

(86) German

a. . . . weil ich selten die kleinste Katze streichle
because I rarely the smallest cat pet

b. . . . weil ich die kleinste Katze$_i$ selten t_i streichle
because I the smallest cat rarely pet

(from Diesing and Jelinek 1995: 130, their (9a), Diesing 1996: 73, her (17), and Diesing 1997: 379, her (14a))

Diesing and Jelinek (1995) and Diesing (1996, 1997) observe that the interpretation of (86a) is that whichever group of cats I meet, I rarely pet the one which is the smallest in that particular group. The interpretation of (86b) is that there is a cat which is smaller than all others, and that cat I rarely pet. In other words, the relative scope of *rarely* and *the smallest cat* correspond to their surface order, the one furthest left has wider scope. This is also the case in Icelandic:

(87) Icelandic

a. Hann les sjaldan lengstu bókina.
he read rarely longest book-the

b. Hann les lengstu bókina$_i$ sjaldan t_i.
he read longest book-the rarely

(from Diesing 1996: 79, her (32), and Diesing 1997: 418, her (82))

According to Diesing (1996, 1997), the interpretation of (87a) is that whichever group of books he is put in front of, he rarely reads the one which is the longest in that particular group. The interpretation of (87b) is that there is a book which is longer than all others, and that book, he rarely reads. Thus also here, the relative scope of *rarely* and *the longest book* correspond to their surface order, the one furthest left has wider scope. Diesing's claim is that these interpretation differences can be derived from the Mapping Hypothesis of Diesing (1992: 10, 1997: 373); see also Diesing and Jelinek (1995: 124), i.e., the differences follow from whether the object is inside the VP and thereby part of the 'nuclear scope (the domain of existential closure)' or outside VP but inside IP and thereby part of the 'Restriction (of an operator)'. The difference in interpretation between (87a) and (87b) makes it clear that full DP object shift is not optional but that, depending on which interpretation is the target, object shift is either obligatory or impossible.[9]

Diesing and Diesing and Jelinek also point out that claiming pronominal-object shift to be obligatory is at best a gross oversimplification. The point is that there are pronouns which do not undergo object shift, namely, indefinite pronouns. They do not have wide scope, and therefore remain in their base position (both in languages with object shift, here Icelandic and Danish, and in languages with scrambling, here German):

(88) Icelandic
a. Ég á ekki regnhlíf, áttu ekki eina?
I have not umbrella have-you not one
b. *Ég á ekki regnhlíf, áttu $eina_i$ ekki t_i?
I have not umbrella have-you one not

(89) Danish
a. Jeg har ikke nogen paraply, har du ikke en?
I have not any umbrella have you not one
b. *Jeg har ikke nogen paraply, har du en_i ikke t_i?
I have not any umbrella have you one not

(90) German
a. Ich habe immer einen Regenschirm, warum hast Du nie einen?
I have always an umbrella why have you never one
b. *Ich habe immer einen Regenschirm, warum hast Du $einen_i$ nie t_i?
I have always an umbrella why have you one never
(from Vikner 1997a: 11–12, his (34–36), based on Diesing 1996: 76, her (24–25))

Actually, it can also be claimed that it is possible for definite pronouns not to undergo object shift. We have already discussed (71) and (73), where it was shown that stressed definite pronouns do not have to undergo object shift (and in languages where full DPs cannot undergo object shift, stressed definite pronouns cannot do it either). It is possible to reinterpret this kind of data to show that the interpretation depends on whether or not object shift takes place, and then the obligatory stress on definite pronouns that have not undergone object shift is a consequence of them being focused. The following is a further example from Danish:

(91) Danish
En Dag saa hun Niccolo i Gaden ... Men han saa ikke hende
one day saw she Niccolo in street-the but he saw not her
(from *Ekko* by Karen Blixen, with the original orthography, cited in Togeby 2003: 169)

As pointed out by Togeby (2003: 169), (91) requires that both the subject *han* 'he' and the object *hende* 'her' are stressed. In other words, (91) corresponds to English ... *but HE did not see HER*, where the focus is on *he* and *she* having switched roles,

from 'seer' to 'seen' and vice versa. It would not have been ungrammatical for Karen Blixen to have written . . . *Men han saa hende ikke*, but this would not have the interpretation with focus on the role switching, it would simply correspond to English . . . *but he did not see her*, where the focus is on the entire VP.

This section has shown that depending on interpretation and focus, object shift of full DPs and object shift of pronouns may or may not take place.

5.2 Objects marked [−Focus] must be licensed by categories marked [+Focus]

Here we review the analysis proposed in Holmberg (1999a), and although focus and interpretation (which were dealt with in the previous section) are central to Holmberg's (1999) analysis, this will only come in at the end of the discussion.

Holmberg (1999: 6) points out that Chomsky's (1993: 15–19) equidistance account (as presented in section 4 above) only accounts for those cases of Holmberg's generalization where the main verb leaves VP by moving into the next higher head position (i.e., the head which is the sister of the VP in question). The reason is that only by means of such a head movement do [VP, Spec] and [AgrOP, Spec] count as equidistant. If the verb were to leave VP in a different fashion, the equidistance account would predict object shift to be impossible, as [VP, Spec] and [AgrOP, Spec] would not be part of the same minimal domain and therefore not count as equidistant. Holmberg (1999) argues that this prediction is not borne out, and the example that shows this is the one already discussed earlier as (51c), repeated here as (92c) (see (ic) in n. 6 for an Icelandic version). The non-finite main verb *kysset* 'kissed' has left its VP by means not of head movement but of topicalization, and yet object shift is well-formed:

(92) Danish

a. *Kysset$_x$ har$_v$ jeg ikke [$_{VP}$ t$_v$ [$_{VP}$ t$_x$ hende]], . . .
kissed has I not her

b. *Kysset$_x$ har$_v$ jeg ikke [$_{VP}$ t$_v$ hende$_i$ [$_{VP}$ t$_x$ t$_i$]], . . .
kissed has I not her

c. Kysset$_x$ har$_v$ jeg hende$_i$ ikke [$_{VP}$ t$_v$ [$_{VP}$ t$_x$ t$_i$]], . . .
kissed has I her not
. . . bare holdt hende i hånden.
only held her in hand-the
'Kissed her, I haven't, only held her hand.'

Holmberg (1999) then goes on to discuss other data where an element blocks object shift only if this element is not a trace. One such element is the particle in Swedish. Object shift is not possible across an unmoved particle, (93b) (see also (23c) above), but it is possible across the trace of a particle even in Swedish, (93d):

(93) Swedish

	Ja ja,	jag	ska	mata	din	katt,	men . . .	
	all right,	I	shall	feed	your	cat,	but	
a.	. . .	jag_k	$släpper_v$	t_k		inte	t_v	in den.
		I	let			not		in it
b.	*. . .	jag_k	$släpper_v$	t_k	den_i	inte	t_v	in t_i.
		I	let		it	not		in
c.	. . .	IN_j	$släpper_v$	jag		inte	t_v	t_j den.
		in	let	I		not		it
d.	. . .	IN_j	$släpper_v$	jag	den_i	inte	t_v	t_j t_i.
		in	let	I	it	not		

'All right, I'll feed your cat, but I won't let it in.'

(Example (93d) is from Holmberg's 1999: 17, his (44b))

The assumption made in section 3.1, that traces of case assigners are optional case assigners, partially accounts both for object shift being possible across the trace of a particle in Swedish even though overt particles block object shift and for object shift being possible across the trace of a non-finite main verb even though overt non-finite main verbs block object shift. The account is only partial in so far as what is predicted is that case does not have to be assigned to the base position of the object, because the (potential) case assigner is a trace, but what is not accounted for is how the shifted objects are assigned case, as the case assigners have not moved through I°, for instance. As for the equidistance account discussed in section 4, it is also unclear whether it could account either for object shift being possible across the trace of a particle in Swedish or for object shift being possible across the trace of a non-finite main verb.

Another element that blocks object shift only if it is not a trace is the indirect object. Compare (30–32) above, which show that indirect objects block object shift of the direct object ((30b), (31b), (32b)) unless the two objects undergo object shift together, ((30c), (31c), (32c)). Holmberg (1999: 17) gives two Swedish examples where the indirect object has undergone A-bar-movement to [CP, Spec]: *Vem_j gav_v du den_i inte t_v t_j t_i?*, 'Who gave you it not?', i.e., 'Who did you not give it?'; and *$Henne_j$ $visar_v$ jag den_i helst inte t_v t_j t_i*, 'Her show I it rather not', i.e., 'To her, I would rather not show it'. However, because in both of these examples, both the indirect and the direct object are pronouns, the possiblity cannot be excluded that the two objects could have undergone object shift together, and the indirect object, *hvem* 'who'/*henne* 'her', could then have undergone A-bar-movement to [CP, Spec] after the object shift had taken place. This does not mean, though, that Holmberg does not have a point; it merely means that the two examples cited above do not support this point in an optimal way. Better examples are (94b) and (95b), because the indirect object that has undergone *wh*-movement to [CP, Spec], *Maria*/*Maríu*, is a full DP which at least in Danish presumably could not have undergone object shift first, cf. (6) above:

(94) Danish
a. Maria$_j$ fortalte$_v$ du forhåbentlig ikke t$_v$ t$_j$ noget.
Maria told you hopefully not anything
'I hope you did not tell MARIA anything.'
b. Maria$_j$ fortalte$_v$ du det$_i$ forhåbentlig ikke t$_v$ t$_j$ t$_i$.
Maria told you it hopefully not
'I hope you did not tell MARIA.'

(95) Icelandic
a. Maríu$_j$ sagðir$_v$-ðu vonandi ekki t$_v$ t$_j$ leyndarmálið.
Maria.DAT told-you hopefully not secret-the
b. Maríu$_j$ sagðir$_v$-ðu leyndarmálið$_i$ vonandi ekki t$_v$ t$_j$ t$_i$.
Maria.DAT told-you secret-the hopefully not
'I hope you did not tell MARIA the secret.'

It is clear that the pronominal direct object could not have moved across the full DP indirect object, *Maria*/*Maríu*, if the latter had not undergone *wh*-movement, (96b)/(97b):

(96) Danish
a. ??Du fortalte$_v$ forhåbentlig ikke t$_v$ Maria det.
you told hopefully not Maria it
b. *Du fortalte$_v$ det$_i$ forhåbentlig ikke t$_v$ Maria t$_i$.
you told it hopefully not Maria
c. *Du fortalte$_v$ Maria$_j$ det$_i$ forhåbentlig ikke t$_v$ t$_j$ t$_i$.
you told Maria it hopefully not
d. *Du fortalte$_v$ Maria$_j$ forhåbentlig ikke t$_v$ t$_j$ det.
you told Maria hopefully not it

(97) Icelandic
a. Þú sagðir$_v$ vonandi ekki t$_v$ Maríu leyndarmálið.
you told hopefully not Maria.DAT secret-the
b. *Þú sagðir$_v$ leyndarmálið$_i$ vonandi ekki t$_v$ Maríu t$_i$.
you told secret-the hopefully not Maria.DAT
c. Þú sagðir$_v$ Maríu$_j$ leyndarmálið$_i$ vonandi ekki t$_v$ t$_j$ t$_i$.
you told Maria.DAT secret-the hopefully not
d. Þú sagðir$_v$ Maríu$_j$ vonandi ekki t$_v$ t$_j$ leyndarmálið.
you told Maria.DAT hopefully not secret-the
'I hope you did not tell Maria the secret.'

The same picture appears when A-movement of the indirect object occurs, e.g., when the finite main verb is passivized in Icelandic. In (98), the indirect object *þér* 'you.DAT' has moved out of VP, and the direct object *þvílíkt tækifæri* 'such a chance' can therefore undergo object shift, (98b):

(98) Icelandic
a. Þér$_j$ gafst$_v$ oft t$_v$ t$_j$ þvílíkt tækifæri.
you.DAT was-given often such chance
b. Þér$_j$ gafst$_v$ þvílíkt tækifæri$_i$ oft t$_v$ t$_j$ t$_i$.
you.DAT was-given such chance often
'You were often given such a chance.'

In (99), the indirect object *Maríu* 'Maria.DAT' has not moved out of VP, and therefore the direct object *þvílíkt tækifæri* 'such a chance' cannot undergo object shift, (99b):

(99) Icelandic
a. Pétur gaf$_v$ oft t$_v$ Maríu þvílíkt tækifæri.
Peter gave often Maria.DAT such chance
b. *Pétur gaf$_v$ þvílíkt tækifæri$_i$ oft t$_v$ Maríu t$_i$.
Peter gave such chance often Maria.DAT
'Peter often gave Mary such a chance.'

That object shift of a direct object is possible across the trace of an indirect object but not across an overt indirect object is not expected under any of the approaches discussed so far. Insofar as any of the above approaches would predict an (overt) indirect object to block object shift, the same would be expected of the trace of an indirect object.

In order to account both for the data captured by the accounts discussed earlier and for the additional data discussed here, Holmberg (1999: 25–28) suggests that shifted objects are all marked [–Focus] and that they must be licensed by being c-commanded by a category (an X° or an XP) with the feature [+Focus]. For more discussion of the shifted objects not being in focus, see section 5.1 above, which showed that objects which are focused do not undergo object shift. The reason why objects never object shift across (overt) verbs, prepositions, and (Swedish) particles is that these are inherently marked [+Focus], and therefore they can license objects marked [–Focus], and there would be no reason and thus no justification for object shift to go any further.

Adverbials, on the other hand, are not marked [+Focus], and they can therefore not license objects marked [–Focus]. Furthermore, if an element not marked [+Focus] intervenes between the licensing [+Focus] element and the [–Focus] element that must be licensed, this licensing is blocked. These two assumptions, that an adverbial cannot itself license a [–Focus] object and that an adverbial blocks such licensing if it intervenes between a licensing category and a [–Focus] object, therefore force shifted objects to precede adverbials.[10]

6 Conclusion: a few recent accounts

Needless to say, there have been a number of other discussions and analyses of object shift in the literature than the ones that have been mentioned here. In this

final section, three recent accounts will be briefly mentioned to the almost certainly unjust exclusion of several others.

In his article about 'phases', Chomsky (2001b: 34) suggests that the crucial difference concerning Holmberg's generalization is whether or not the DP in question is properly inside the VP of the main verb, i.e., whether or not the DP is the leftmost overt element in the VP. If the DP is not the leftmost overt element in the VP, it may have either the interpretation *Int* or *Int'* (see, e.g., example (ic) in note 9, where object shift could not possibly have taken place). (*Int'* roughly corresponds to Holmberg's (1999) [+Focus], i.e., the interpretation assigned to a DP which remains in situ in an object shift context, cf. the discussion of (87a) above, whereas *Int* corresponds to Holmberg's (1999) [–Focus], i.e., the interpretation assigned to a DP which has undergone object shift; cf. the discussion of (87b) above.)

If the DP **is** the leftmost overt element in the VP, however, it may only have the interpretation *Int'* (Chomsky 2001b: 34). If a [–Focus] DP finds itself with *Int'*, an interpretation incompatible with its form, the sentence is deviant if the DP stays where it is, but a way out of the problem is for it to move to [v*P, Spec], where it will obtain the right interpretation *Int*, due to to v*'s EPP feature (the result of this is a structure with object shift, see (87b) above and (ib) in n. 9). On the other hand, if a [+Focus] object finds itself with *Int'*, there is no problem, as this is not incompatible with its form. It might move to, [v*P, Spec], but then it will be deviant, as here it will get the wrong interpretation *Int*, due to to v*'s EPP feature (the result of this is a structure without object shift even though there could have been object shift, e.g., (87a) above or (ia) in note 9). In other words, Chomsky's (2001b) phases account rests on distinguishing whether something is the leftmost overt element in VP or not.

Svenonius (2001) suggests a different account of Holmberg's generalization, also based on Chomsky's (2001b) phases. If a VP contains an overt verb, it is sent off to Spell Out and discourse-related movements (which include object shift and scrambling) are impossible. If, on the other hand, the verb has left the VP, then the VP is not sent off to Spell Out on its own, but has to wait until it can be sent to Spell Out as part of a larger XP. In this case, discourse-related movements are allowed within this XP, and so object shift is possible.

Bobaljik (2002) suggests a rather different account (already discussed in sections 2.4.3 and 2.4.4) which is based on his particular concept of adjacency, where two elements may be adjacent even though elements in adjoined positions occur between them (Bobaljik 2002: 210–221). When the main verb is finite, I° has to be adjacent to the main verb, and this blocks object shift in those cases where a shifted object would intervene between the two (Bobaljik 2002: 221–224), e.g., in those embedded clauses where the finite verb occurs in V° (i.e., in Danish, Faroese, Norwegian, and Swedish). When the main verb is a participle, it is Pple° that has to be adjacent to the main verb (Bobaljik 2002: 225), and this blocks object shift in those cases where the overt shifted object would intervene between Pple° and the main verb. One problem with this is that the landing position of object shift in a clause where the main verb is a particple would have to be lower

than Pple°, and because Pple° is below the V° of any auxiliary verb, which again is lower than negation or a sentential adverbial, the prediction would be that if object shift should be possible in a structure where the main verb is a participle, object shift would target a position lower than negation or a sentential adverbial. That this is not so, is shown in (51c)/(92c) and their discussion.

NOTES

I am very grateful to my Syncom colleagues for their help, criticism, and, not least, incredible patience. Many thanks also go to Jonathan Bobaljik, Ken Ramshøj Christensen, Molly Diesing, Anders Holmberg, Gunnar Hrafn Hrafnbjargarson, Kyle Johnson, Gunlög Josefsson, Carl Vikner, and an anonymous reviewer.

1 In Icelandic control infinitives (see Thráinsson 1986: 247; Holmberg 1986: 155–158; Sigurðsson 1989: 49–56; Johnson and Vikner 1994; Jónsson 1996: 159–166), the infinitival verb embedded under the control verb must leave VP as it must precede negation, (ia, b). Given that the verb must leave its VP, it is not surprising that object shift is possible, (ic):

(i) Icelandic

a.	*María	lofaði$_v$	[$_{IP}$	að			ekki	lesa	bókina	].
	María	promised		to			not	read	book-the	
b.	María	lofaði$_v$	[$_{IP}$	að	lesa$_v$		ekki	t$_v$	bókina	].
	María	promised		to	read		not		book-the	
c.	María	lofaði$_v$	[$_{IP}$	að	lesa$_v$	bókina$_i$	ekki	t$_v$	t$_i$	].
	María	promised		to	read	book-the	not			

'María promised not to read the book.' (Jónsson 1996: 164)

2 Den Besten and Moed-van Walraven (1986: 113), Diesing (1997: 388), and Sadock (1998) take Yiddish to be a VO language with remnants of OV, whereas Santorini (1993) classifies it as mixed OV/VO and Hall (1979), Geilfuss (1991), Haider and Rosengren (1998: 78–81), and Vikner (2001b) assume the basic order in modern Yiddish to be OV.

3 The form of an object in the Danish examples varies depending on whether or not the object in question has undergone object shift, given that only pronouns can undergo object shift and that they have to undergo it.

4 An example with the same word order as (32b) is acceptable, but with the opposite interpretation, namely, that the kidnapper never returned the parents to the children. In other words, it would have the structure of (32d) and (30d).

5 The reason why the example of non-clausebound scrambling is from Russian is that German (and Dutch) scrambling actually is clausebound, and therefore completely parallel to the object shift data in (49):

(i) German

a.	*Ich	weiß	dieses	Buch$_i$	[warum	sie			nicht	t$_i$	verkaufen].
	I	know	this	book	why	they			not		sell
b.	Ich	weiß			[warum	sie	dieses	Buch$_i$	nicht	t$_i$	verkaufen].
	I	know			why	they	this	book	not		sell

c. Ich weiß [warum sie nicht dieses Buch verkaufen].
I know why they not this book sell
'I know why they do not sell this book.'

6 Many speakers of (at least) Danish and Icelandic do not find (51c)/(ic) completely acceptable, but it would seem that there is general agreement that (51c)/(ic) is considerably less unacceptable than (51a, b)/(ia, b):

(i) Icelandic
a. *Kysst$_x$ hef$_v$ ég ekki [$_{VP}$ t$_v$ [$_{VP}$ t$_x$ hana]], . . .
kissed has I not her
b. *Kysst$_x$ hef$_v$ ég ekki [$_{VP}$ t$_v$ hana$_i$ [$_{VP}$ t$_x$ t$_i$]], . . .
kissed has I not her
c. ?Kysst$_x$ hef$_v$ ég hana$_i$ ekki [$_{VP}$ t$_v$ [$_{VP}$ t$_x$ t$_i$]], . . .
kissed has I her not
. . . bara haldið í höndina á henni.
only held in hand-the on her
'Kissed her, I haven't, only held her hand.'

7 It must be admitted that some Icelandic speakers find (53b) acceptable. Notice though that Thráinsson (2001: 162) gives the following judgment of a completely parallel example:

(i) Icelandic
*Jón las$_v$ eflaust bókina$_i$ aldrei t$_v$ t$_i$.
John read doubtlessly book-the never

It should perhaps be added that there seems to be general agreement among Icelandic speakers as to the unacceptability of the pronominal version of this kind of example in (55b).

8 To complicate matters even further, pronominal-object shift in Swedish is different both from pronominal-object shift in the other Scandinavian languages, (75), and from Romance clitic pronouns, (76), in that both options are possible. The shifted pronoun may occur either left of the subject, (ia) or right of the subject, (ib):

(i) Swedish
a. Därför ger$_v$ mig$_i$ [$_{IP}$ Tutanchamons hemska förbannelse ingen
therefore gives me Tutanchamon's terrible curse no
ro$_j$ [$_{VP}$ t$_v$ t$_i$ t$_j$]].
rest
b. Därför ger$_v$ [$_{IP}$ Tutanchamons hemska förbannelse mig$_i$ ingen
therefore gives Tutanchamon's terrible curse me no
ro$_j$ [$_{VP}$ t$_v$ t$_i$ t$_j$]].
rest

(Example (ia) is from Josefsson 1992: 65)

Example (ia) is commonly referred to as long object shift, and compared to normal or 'short' object shift, as in (ib), long object shift is subject to some additional and rather elusive restrictions. According to Holmberg (1984: 3), only weak reflexive

pronouns or weak first or second person pronouns undergo long object shift; whereas Josefsson (1992: 68) shows that all those pronouns that have different nominative and accusative forms undergo long object shift. Josefsson (1992: 65–67) also discusses certain thematic restrictions on long object shift. Finally, Thráinsson (2001: 154) points out that long object shift was also found in Danish and Norwegian in the nineteenth century.

9 If object shift is blocked (e.g., by the main verb being a participle), both the reading that is associated only with a shifted object in an object-shift construction and the reading associated only with a non-shifted object in an object shift construction are possible:

(i) Icelandic
   a. Í prófunum svarar hann sjaldan [$_{DP}$ erfiðustu spurningunni].
      in exams-the answers he rarely most-difficult question-the
   b. Í prófunum svarar hann [$_{DP}$ erfiðustu spurningunni] sjaldan.
      in exams-the answers he most-difficult question-the rarely
   c. Í prófunum hefur hann sjaldan svarað [$_{DP}$ erfiðustu spurningunni].
      in exams-the has he rarely answered most-difficult question-the
      (Vikner 2001a: 325–326)

The difference between (ia) and (ib) parallels the difference between (87a) and (87b) in the main text. The interpretation of (ia) is that regardless of which exam he is taking, he rarely answers whichever question happens to be the most difficult one in that particular exam. The interpretation of (ib) on the other hand, is that there is one particular question which is more difficult than all others (e.g., 'list all the irregular verbs in Icelandic') and which appears in most or all exams, and when he encounters this question, he rarely answers it.

In her minimalist analysis of (87a) and (87b) (and, by extension, of (ia) and (ib)), Diesing (1996: 70, 1997: 375–376) assumes the existence of a 'scoping constraint', which says that DPs should move to the position in the surface order that corresponds to their scope, and which therefore forces object shift in (87b) and (ib) and prevents object shift in (87a) and (ia). Diesing takes these examples, (87a, b) and (ia, b), to show that the scoping constraint must be a 'condition on convergence', to explain why the scoping constraint overrides 'procrastinate', an 'economy condition', which says do not move unless absolutely necessary.

Vikner (2001a: 334) argues that while these assumptions give the correct predictions concerning (87a, b) and (ia, b), they make an incorrect prediction concerning (ic). The point is that in the reading of (ic) that corresponds to (ib), the scoping constraint is overridden, *the most difficult question* has scope over *rarely* and yet does not precede it. In other words, (ic) shows that Holmberg's generalization overrides the scoping constraint, and (ib) shows that the scoping constraint overrides procrastinate. The problem is that within minimalism, for the scoping constraint to override procrastinate, it would (as Diesing 1997: 422 says) have to be a condition on convergence, but that in turn would mean that it could not itself be overriden by anything; on the contrary, a violation of a condition on convergence must lead to a crash and this would incorrectly predict (ic) to be unambiguous. On the other hand, as Vikner (2001a) shows, an analysis within optimality theory would not run into this problem. In OT it would be perfectly possible to have a particular constraint both override one constraint and itself be overridden by another.

Thráinsson (2001: 193) points to a basic problem common to the accounts of Diesing (1996, 1997), Vikner (2001a), and Chomsky (2001b). In structures where a DP is not prevented from object shift by Holmberg's generalization but nevertheless does not undergo object shift, e.g., (87a) and (ia), these accounts assume the DP to have only one interpretation, namely, the narrow scope/unfocused/weak reading. Although speakers agree that this reading is possible and preferred, it is not quite clear that the other one, the wide scope/focused/strong reading (i.e., the one that is the only reading in (87b) and (ib)), is completely excluded for all speakers; cf. De Hoop (1992: 137–139).

10 As pointed out by Holmberg (1999: 15) and Josefsson (2001: 92, 2003: 204), this account would incorrectly predict long object shift (i.e., object shift to a position left of the subject) to be impossible. See (ia) in n. 8 for a grammatical example of long object shift.

3.2 Clausal pied-piping

1 Introduction: organization of the chapter

The term 'partial movement' (PM) can be understood in at least two ways. If interpreted literally it refers to all constructions in which – by whatever criterion – a phrase 'ought' to have moved to a position P, but has in fact only been displaced to a structurally lower position. However, the generative discussion of PM often focuses on a special subcase of (apparent) scope marking for *wh*-phrases, which may or may not turn out to be a subcase of partial movement in the sense just introduced. This chapter tries to do justice to both interpretations of PM. However, most of the discussion is concerned with the scope-marking construction.

The chapter begins with a definition of PM, and then develops a simple typology. The next section exclusively focuses on the *wh*-scope-marking construction *was denkst du wer kommt* 'what do you think who comes', whereas section 3 deals with other instances of PM in the more literal sense. Apparent PM effects in child language (see, e.g., McDaniel et al. 1995; van Kampen 1997) are beyond the scope of the present chapter. In order to facilitate the interpretation of the example sentences, phrases that have undergone PM (or appear to have done so) will appear in boldface throughout this chapter. Fully moved phrases appear in italics. *Wh*-phrases in situ will be underlined.

1.1 Definitions

Partial movement (PM) contrasts with the complete execution of a movement operation. This distinction arises in the context of the idea that certain grammatical principles require the displacement of phrases from their original position to a different structural slot. This may be necessary for picking up or checking Case, for fulfilling requirements such as the Extended Projection Principle (every clause must have a subject), for reasons linked to scope, etc. Thus, in a language of the English type, a *wh*-phrase must appear in the specifier position (Spec) of the largest CP (clause) it takes scope over semantically (unless it appears in a multiple question). The *wh*-phrase has to move to its LF-scope position.

(1) a. *John believes that Mary saw who?
b. *Who* does John believe that Mary saw t?

Movement is *complete* – as in (1b) – if the phrase reaches a position in which it meets the relevant requirements (*who* has moved to its scope position); movement is *partial* whenever the phrase has been displaced but its final landing site is below the relevant position. PM is thus illustrated by Bahasa Indonesian (2b), a construction in which the *wh*-phrase *siapa* 'who' has left its base position (in contrast to (2a)), but has not moved into the matrix clause which it takes scope over (Saddy 1991, 1992).

(2) a. Bill tahu Tom men-cintai siapa.
Bill knows Tom loves who
b. Bill tahu **siapa** yang Tom cintai.
Bill knows who FOC Tom loves
c. *Siapa* yang Bill tahu Tom cintai.
who FOC Bill knows Tom loves

Of course, not every movement that places, e.g., a *wh*-phrase closer to the position corresponding to its scope is partial *wh*-movement. Thus, *wh*-phrases can be scrambled to a certain extent in German (cf. (3a–b)). *Wen* is closer to its LF-scope position in (3a) than it is in (3b) (as (3d) shows), but this movement is carried out because of whatever is responsible for scrambling – it is not related to scope taking.

(3) a. Ich weiss nicht *wann* wen wer t gesehen hat.
I know not when who-acc who-nom seen has
b. Ich weiß nicht, *wann* wer wen gesehen hat.
c. [$_{CP}$ *wann* [$_{IP}$ wer [$_{VP}$ wen gesehen hat]]]
d. [$_{CP}$ *wann* [$_{IP}$ wen [$_{IP}$ wer [$_{VP}$ t gesehen hat]]]]
'I do not know who saw whom when.'

It is thus more accurate to say that movement of Σ from A to B is an instance of partial f-movement if:

(a) B is a typical landing site for f-movement;
(b) B is the highest such position Σ reaches (in overt syntax);
(c) the requirements responsible for f-movement cannot be met by Σ in B, but would be met in C, such that
(d) C is higher than B; and
(e) B does not participate in any other type of chain-merger, at least not in overt syntax.

Condition (a) distinguishes partial *wh*-movement from, e.g., *wh*-phrase-scrambling. Condition (b) distinguishes partial *wh*-movement from intermediate steps of cyclic *wh*-movement. Condition (c) excludes complete *wh*-movement. Condition (d) is added in order to distinguish partial *wh*-movement from constructions such as German (4) discussed by Reis and Rosengren (1992), in which *wh*-phrases are moved beyond their LF-scope position, but in which they nevertheless appear in

a typical landing site for *wh*-phrases, namely, the Spec of the matrix CP. Condition (e) serves to exclude parasitic gap constructions such as (5): according to some approaches (e.g., Chomsky 1986a), parasitic gaps arise by the *wh*-movement of an empty operator to the Spec of, e.g., the adjunct clause. The two chains (of the empty operator and of the real *wh*-phrase) are, however, merged later.

(4) Wen sag mal dass sie t liebt.
who say once that she loves
'Tell me who she loves.'

(5) *Which books* did you file t? [OP without reading t]

1.2 A simple typology of partial movement

Although the movement of phrases and words may serve a multitude of purposes and ends, the generative discussion of PM has focused on constituent question formation. This appears to reflect a generalization about natural languages: there are very few or no undisputable cases of partial topicalization, scrambling, relative clause formation, raising, incorporation, etc. (see section 1.2.5). The following typological remarks thus concentrate on partial movement in question formation.

1.2.1 Simple partial movement

The construction exemplified in Bahasa Indonesian (2b) represents the simplest type of PM: the structure involves the partial displacement of the *wh*-phrase only. This construction will be called simple partial movement (SPM). SPM-structures are grammatical in other Malay languages (cf. Cole and Hermon 1998b), in Kikuyu (Clements 1984), Buli (Ferreira and Ko 2000), Slave (as illustrated in (6b), see Rice 1989; Basilico 1998) and other Athabascan languages (Western Apache, Potter 1997; Babine-Witsuwit'en, Denham 2000), and in Ancash Quechua (Cole 1982b).[1]

(6) a. Raymond [Jane judeni ri yili] kodhisho? Slave
Raymond Jane where FOC 3-be 3-know
b. Raymond [**judeni** Ri Jane yili] kodhishi?
'Where does Raymond know that Jane is?'

Other languages exemplify SPM in a restricted way only. Thus, in Iraqi Arabic (Wahba 1991), SPM is restricted to infinitive complements (7).

(7) a. Mona raadat tijbir Su'ad tisa'ad meno? Iraqi Arabic
Mona wanted to force Su'ad to help who?
b. Mona raadat tijbir Su'ad **meno** tisa'ad?
c. Mona raadat **meno** tijbir Su'ad tisa'ad?
d. *Meno* Mona raadat tijbir Su'ad tisa'ad?

Some dialects of German and Romani (see McDaniel 1989) allow SPM in complex multiple questions only: when a *wh*-phrase (from the matrix clause) occupies its scope position, another *wh*-phrase from a lower clause can or must move to the highest still vacant specifier position, as illustrated in (8b) for some versions of German (co-existing there with standard German (8a)), and (8c) for Romani.

(8) a. *Wer* glaubt dass sie wen liebt?
who thinks that she whom loves
b. *Wer* glaubt **wen** sie liebt?
who thinks whom she loves
'Who thinks that she loves whom?'
c. *Ko* vakerja **kaj** o Demiri khelja?
who said where the Demir danced
'Who said that Demir danced where?'

SPM always co-exists with full *wh*-movement and with the *wh*-in-situ strategy. We may defend generalization S1 as follows: a language that allows SPM also allows full movement to the scope position and the in situ strategy in some contexts (Russian may be an exception, though)[2] – not necessarily the one in which a SPM shows up. For the contexts in which SPM is possible, we can also defend S2 by stating that the *wh*-phrase might have also stayed in situ. The validity of S2 is supported, e.g., by the array of facts of Iraqi Arabic, where (wide scope) *wh*-elements in situ are restricted to non-finite complement clauses, just as SPM is. Of course, the reverse of S1 does not hold: there are languages like Duala in which *wh*-phrases may either stay in situ or undergo complete movement, but in which SPM is not acceptable (Epée 1976; Biloa 1993; Sabel 1996a, 2000). Likewise, the reverse of S2 does not hold: there are contexts in which *wh*-phrases are tolerated in situ but in which SPM is ungrammatical (see, e.g., Cole and Hermon 1998b).

Generalization S1:
If a language tolerates SPM, it also tolerates *wh*-elements in situ and allows full *wh*-movement.

Generalization S2:
If a construction is grammatical with SPM, it can also be constructed with a *wh*-phrase in situ.

1.2.2 Partial movement with a scope-marking particle

In Albanian (Turano 1995), the scope of *wh*-phrases is marked by a particle and the *wh*-phrase may undergo PM, as illustrated by (9):

(9) a. A mendon se Maria thotë se **çfarë** ka sjellë burri? Albanian
Q think that Mary says that what brought her husband
b. A mendon se **çfarë** thotë Maria se ka sjellë burri?
'What do you think that Maria says that her husband brought?'

This construction can be called particle-marked partial movement (PPM). PPM also exists in Iraqi Arabic if the element *sh*-appearing in front of the verb in (10) and (11) is to be analysed as a *wh*-particle. The particle is optional if *wh*-in situ is grammatical as well (as in (11)), and obligatory otherwise (as in (10)).

(10) a. Sh-tsawwarit Mona Ali raah weyn? Iraqi Arabic
Q-thought Mona Ali went where
b. Sh-tsawwarit Mona **weyn** Ali raah
'Where did Mona think that Ali went?'

(11) a. (Sh)-raadat Mona Ali ygaabal meno?
Q-wanted Mona Ali meet whom
b. (Sh)-raadat Mona **meno** Ali ygaabal?
'Who did Mona want Ali to meet?'

PPM also seems to belong to the strategies of question formation in Passamaquoddy (see chapter 4 of Bruening 2001). SPM and PPM may co-exist within a single language (Iraqi Arabic), and so can PPM and the what-construction (Passamaquoddy). The difference between SPM and PPM corresponds to the one between *wh*-in-situ-languages in which the scope of a *wh*-phrase needs to be marked by a particle (as in Japanese) and languages in which this is not mandatory (e.g., Chinese).

1.2.3 *Partial movement with scope marking by the most unmarked* wh*-word*

In a considerable number of languages, the scope marker in PM is formally identical with the most unmarked simple *wh*-phrase, as in German (12a). It is not fully accurate, though, to call *was* and its counterparts in other languages scope-markers, because they can (and, in some dialects, must) appear in all Specs of CP between the 'real' *wh*-phrase and its LF-scope position, as (12b) illustrates. Of course, in (12b) the lower *was* does not mark the scope of *wen*. Let us call this construction type the WHAT-construction (WC), and *was* (and similar items) the what-phrase (WP), because the other terms (*wh*-scope marking construction, *wh*-expletive, etc.) are not theory-neutral. WPs will appear in capitals in all subsequent examples.

(12) a. WAS glaubst du **wen** Irina t liebt?
what believe you who-Acc Irina loves
'Who do you believe that Irina loves?'
b. WAS glaubst du WAS er sagt **wen** Irina liebt?
What believe you what he says who Irina loves
'Who do you believe that he says that Irina loves?'

The WC can also be found in Frisian (Hiemstra 1986), Serbian–Croatian,[3] Czech,[4] Romani (13a); McDaniel 1989), Hungarian (13b); Marácz 1989; Horvath

1997), Finnish, Warlpiri (Dayal 1994; Legate 2002, forthcoming), and older versions of Mohawk (Baker 1996). It is absent in Dutch and English. In the WC languages just mentioned, the WC always involves the partial movement of the real *wh*-phrase.

(13) a. So misline **savo filmi** o Demiri dikhla? Romani
what you-think which film Demir saw
'Which film do you think Demir saw?'
b. MIT mondtak hogy **kit** hívott rel Mari? Hungarian
what they said that who-Acc called up Mary
'Who did they say that Mary had called up?'

A WC can furthermore be found in Hindi (14a; Srivastav 1991c; Mahajan 1990), in Bangla (14b; Bayer 1996), in Kashmiri (Wali and Koul 1997), and in Marathi. The type of WC found in the Indian languages does not necessarily involve PM of a *wh*-phrase, since these languages tolerate *wh*-in-situ (see (15)). However, PM of the *wh*-phrase is possible or necessary if, e.g., the WP *kyaa* 'what' and the real *wh*-phrase would be separated by a finite-clause boundary without movement, as in (16).

(14) a. Siitaa-ne KYAA socaa ki ravii-ne kis-ko dekhaa? Hindi
Sita-Erg what thought that Ravi-Erg who saw
'Who did Sita think that Ravi saw?'
b. Tumi KI bhebe-cho Ke baaRi kore-che
you what think who house built?
'Who do you think built the house?'

(15) Jaun kyaa soctaa hai?
John what think-PR

(16) a. Raam-ne KYAA socaa ki ravi-ne KYAA kahaa ki
Raam-Erg what thinks that Ravi-Erg what said that
kOn sa aadmii aayaa thaa
which man came
b. Raam-ne KYAA socaa ki **kOn sa aadmii** ravii ne kahaa ki aayaa thaa?

In Iraqi Arabic, WC is possibly exemplified in constructions involving *sh-(eno)* 'what' – *sheno* is used before subjects and *sh-* before verbs, so maybe WC and PPM fall together in this language. See below for more discussion of the status of *sheno*. In those contexts where there is a choice between movement and the in situ-strategy in Iraqi Arabic, WC can be used with both, a fact that supports the view that the availability of WC is independent of PM.

Russian, Polish, and perhaps also Warlpiri differ from the other languages with a WC insofar as they seem to use the equivalent of *how* as their WP. However, at least (17b) may require a different analysis. For the vast majority of Polish

speakers, the construction cannot be used for embedded questions (see (18), Adam Przepiórkowski, p.c.), and it is confined to a very small set of verbs like *think.* One may therefore wonder whether (17b) really illustrates a productive example of a WC.

(17) a. Как vy dumaete **kogo** ona ljubit? Russian
how you think who she loves
'Who do you think she loves?'
b. Jak myslisz **kto** wczoraj do nas przyszedł? Polish
how think-2sg who yesterday to us came
'Who do you think visited us yesterday?'

(18) *Zastanawiam się, **jak** sadzisz, kto przyszedł. Polish
I wonder how you think who came

The use of the WC is also highly restricted in Russian, as Stepanov (2001) points out – it is again possible with a handful of matrix verbs only. However, Stepanov argues that these restrictions may be derived from the Case-less nature of *kak*. Interestingly, according to Legate (2002), the WC is rarely used in Warlpiri as well. These observations suggest that the particular choice of the WP may be important for the grammaticality of a WC. In Passamaquoddy, the WC is also formed with a *wh*-phrase meaning 'what' (*keqsey*), but according to Bruening (2001) the default *wh*-phrase would be *tan*.

In PPM and WC, the scope of the partially-*wh*-moved phrase is marked by the particle and (the highest occurence of) the WP, respectively. In other words, in PPM/WC languages explicit scope marking is a necessary condition for the well-formedness of PM.

1.2.4 Clausal pied-piping involving partial movement

A fourth type of partial movement in question formation can be found in Basque (Ortiz de Urbina 1990: 20) and – in a very restricted way in certain varieties of German: it involves clausal pied-piping (CPP). The *wh*-phrase moves to the specifier position of the complement clause (the partial-movement part). Then, the whole complement CP rather than the *wh*-phrase moves to LF-scope position of the *wh*-phrase; see (19) for Basque and (20) for German.[5]

(19) **Nor** etorriko d-ela Bihar esan diozu Mireni? Basque
who come Aux-that tomorrow said Aux to Mary
'Who did you say to Mary t will come tomorrow?'
'that who will come tomorrow have you said to Mary?'

(20) **Wen** einzuladen würde dir Spass machen? German
who to invite would you fun make
'Who would it be fun for you to invite?'

Aniko Liptak (p.c.) points out that Hungarian allows partial movement of a *wh*-phrase in a (free) relative clause if the whole relative clause moves into the matrix Focus Phrase, as in (21). The structure is grammatical only if the *wh*-phrase moves the relative-clause internal focus position.

(21) ?Aki hány pontot ér el megy át a vizsgán? Hungarian
who how many points scores-PV goes through the exam
'Who are such that they pass the exam, who score how many points?'

A *wh*-element internal to a relative clause is also licensed in case it moves to the relative-internal FocP, and the head of the relative is a *wh*-phrase and moves to the matrix [Spec, FocP], as in (22). The head of the relative can be any *wh*-phrase, bare or complex: who, which student, etc.

(22) Ki megy át a vizsgán, aki hány pontot ér el? Hungarian
who goes through the exam who how many points scores
'Who are such that they pass the exam, who score how many points?'

There are, thus, some constructions that might be analyzed as CPP, but whether that is the optimal analysis has not yet been established.

1.2.5 Partial movement in constructions other than questions?

In the light of the fact that partial movement seems to be quite a widespread phenomenon in the context of constituent question formation, it is remarkable that there are only few convincing cases of PM in other domains of grammar. *Wh*-movement in question formation belongs to a family of operator movement dependencies, and one would expect to find close analogues of PM in these contexts. Likewise, A-movement might be carried out only partially.

Romani relative clauses such as (23a) (see McDaniel 1989) involve the partial movement of the relative pronoun. It is not easy to decide whether the element *so* that appears at the edge of the relative clause really is a WP-like element (so that (23a) would be a relative clause instance of WC) or whether it simply is the Romani complementizer (in which case (23a) would be an instance of SPM). Certain dialects of German seem to possess the same construction, but their analysis is unclear in exactly the same respect: the element marking the 'scope' of the relative pronoun could be a WP-element or the simple complementizer *wo/was* showing up in relative clauses in many dialects. So there may be instances of PM with relative clauses, but they are few, and there is no reason to assume they do not belong to the SPM type.

(23) a. Ake o ćhavo so mislinav **kas** i Arífa dikhla. Romani
here the boy what/that I think whom Arifa saw
'Here is the boy who I think Arifa saw.'
b. Ake o ćhavo *kas* mislinav so i Arífa dikhla.
here the boy whom I think that/what Arifa saw

Many southern German dialects allow constructions like (24) and (25): a clause has been moved to topic (focus) position, and within that clause a noun phrase occupies the topic position that may be considered the matrix topic or matrix focus. In this sense, the construction exemplifies CPP with topicalization. Note that most southern German dialects forbid clause-internal topicalization in an embedded clause unless that clause itself occupies the matrix topic position – a clear indication that CPP is involved. Little is known about these constructions, so I refrain from going into details.

(24) **Den Fritz** dass du kennst ist schön.
the-Acc Fritz that you know is nice
'It is nice that you know FRITZ.'

(25) **Den Fritz** wenn du triffst musst du vorsichtig sein.
the-Acc Fritz when you meet must you careful be
'You must be careful when you meet Fritz.'

English topicalization in embedded contexts such as in (26) may be taken to involve partial movement as well. One argument in favor of this position is the observation that topicalization is impossible within islands, as (26b) shows (see Ross 1986). This is reminiscent of what holds for partial *wh*-movement in Malay languages (see below), and is easily accounted for if the topicalized phrases move up into the matrix clause at LF, and cannot cross barriers in this process.

(26) a. He said that **revenooers**, he does not like.
b. *That **revenooers** he does not like is obvious.

In languages which have overt focus movement, structures reminiscent of SPM can be found more often than not. The following examples from Passamaquoddy (Bruening 2001) illustrate this point. A focus phrase can stay in situ (as it does in (27)), or it can be moved to the position corresponding to its scope (28), but intermediate landing sites as in (29) are grammatical as well, as Bruening shows.

(27) Tehpu kesiciy-uk-il wisukiluwohehtw-ac-il Maliw-ol. Passamaquoddy
only I know he-made-angry Mary-Obv

(28) Tehpu *Maliw-ol* kesiciy-uk-il wisukiluwohehtw-ac-il.
only Mary-Obv I know he-made.angry
'I only know that he made MARY mad.'

(29) Tehpu kkat kesiciy-ahq-il **Weyn-ol** kisapem-ac-il.
only Neg she-knows Wayne-Obv she-can-rely-ony
'She only doesn't know about WAYNE whether she can rely on him.'

Let us finally turn to A-movement and ask if any constructions involve partial movement here. Raising-to-subject constructions as in (30a) alternate with

expletive constructions in which *there* appears in what would be the target position of movement. Interestingly, 'partial' movement of the nominative noun phrase is impossible in these constructions, i.e., it cannot move to the subject position of the embedded infinitive in such cases, as (30c) illustrates. This fact has been the subject of much theorizing in recent years, in particular in the minimalist program (see Chomsky 1995c).

(30) a. A unicorn seems ___ to be ___ in my garden.
b. There seems ___ to be a unicorn in my garden.
c. *There seems a unicorn to be ___ in my garden.

Perhaps A-movement dependencies are not always incompatible with partial movement, however. Thus, passive formation alternates with *there* insertion, too, but now, what would be the subject in an ordinary passive does not appear in its root position (31b), but is rather fronted within the verb phrase (31c). Likewise, Exceptional Case Marking constructions such as (32) might be reconstructed as involving partial movement. Suppose the accusative case of *a unicorn* is checked in the specifier position of an Agreement-Object head (or a similar entity) in the matrix clause, and suppose it is true (in spite of the arguments brought forward by Postal 1974) that *a unicorn* has not moved to this position in overt syntax, but rather appears in the subject position of the infinitival clause. Then *a unicorn* has moved there without reaching its target A-position – a constellation that fulfills the criteria for PM. These observations possibly reflect topics of future research on partial movement but the data have rarely (if ever) been analyzed in this light.

(31) a. A moose was shot ___.
b. *There was shot a moose.
c. There was a moose shot.

(32) I expect **a unicorn** to be ___ in my garden.

The next subsection discusses some theoretical issues. Section 2 concentrates on the WHAT-construction, because it certainly constitutes the subtype of PM that has received most attention in the past. Section 3 discusses the other types of PM.

1.3 Theoretical issues

If there is partial movement in the strict sense of the term, the construction poses a problem for certain theories of grammar. The problem with PM is reminiscent of the one that arises with cyclic movement. According to Chomsky (1995c) and other work in the minimalist framework, a phrase Σ can move to a position P, the specifier of the head H, only if it is attracted to that position by H. H attracts Σ only if H possesses an (uninterpretable) feature that must be checked by Σ in a specifier–head configuration.

For *wh*-movement, it comes close to a standard assumption that the *wh*-phrase and the Comp head of the CP which the *wh*-phrase takes scope over agree with respect to a [*wh*]-feature. In Chomsky (1995c), this feature attracts the *wh*-phrase, but it seems present in Comp only if Comp is the head of a question. In the partial-movement constructions introduced above, the *wh*-phrase ends up overtly in the specifier position of a CP that is NOT a question. Therefore the Comp head of that CP should not possess the attracting *wh*-feature. Thus, it is unclear what has triggered the partial movement of the *wh*-phrase. This (obvious) problem has been noted several times (Simpson 1995; Fanselow and Mahajan 1996; Müller and Sternefeld 1996; among many others) and a number of different solutions have been proposed. For example, the attracting feature is a categorial one that may be present independent of question semantics (see Fanselow and Mahajan 1996); the local domain for feature checking is less restricted, so a partially moved phrase may check the feature of the attracting phrase although it has not reached its specifier position (Simpson 1995, 2000); the economy condition on movement as attraction must be relaxed (Müller 1998); the attracting feature is a focus feature that is checked in the position the phrase reaches (Sabel 2000). According to Müller (1997), there is a principle that forces *wh*-phrases into specifier positions of CPs irrespective of the featural composition of Comp. While such approaches concede that the problem is a real one, and try to solve it by changing certain assumptions in movement theory, other models explain partial movement away, at least for certain instances. Thus, Fanselow and Ćavar (2000) argue that movement targets the scope position in SPM, but that the chain created by movement is not spelled out in the highest position of the chain. The approach proposed by Dayal (1994, 1996a, b, 2000) for the WC also implies that the *wh*-phrase targets its final scope position in the WC. The evaluation of these approaches depends, of course, on the array of empirical facts that need to be accounted for. We will return to the issue briefly at the end of the two following sections.

2 The WHAT-construction

This section offers a closer look at the WHAT-construction (WC) illustrated in (12). The first subsection summarizes the major competing analyses that have been proposed for the WC: the scope-marker analysis, the feature-movement analysis, and the two indirect-dependency approaches: the argumental and the *wh*-expletive version. Section 2.2 introduces a number of empirical generalizations concerning the WC. Section 2.3. attempts an evaluation of the theoretical approaches.

2.1 Competing analyses

This section is confined to a discussion of the WC, the major focus of this chapter. Most of the literature on PM restricts itself to an analysis of WC, with a certain emphasis on German, Hungarian, and Hindi. Two families of analyses for the

WC have been proposed. In what Dayal (1994) calls the direct-dependency approach to WC, the WP *was* 'what' in (12) (repeated here) is analyzed as a 'kind of scope marker' for *wen* which has undergone PM in the sense defined above: it has left its base position, but has not moved the whole way up to its LF scope position. The direct-dependency approach goes back to Van Riemsdijk (1983b) – the theory developed by McDaniel (1989) has been a very influential version of it. Direct-dependency approaches assume that the WP and the 'real' *wh*-phrase are linked to the same chain. Therefore, the featural movement theory of Hiemstra (1986) is a direct-dependency approach as well.

(12) Was glaubst du **wen** Irina t liebt?
what believe you who-Acc Irina loves
'Who do you believe that Irina loves?'

The alternative model, called indirect-dependency approach by Dayal (1994), assumes that the WP is a *wh*-phrase for propositional complements. It is linked to the *wh*-clause, in which the *wh*-phrase has undergone standard *wh*-movement to an A-bar-position that may even, in a sense to be clarified below, correspond to its (semantic/syntactic) scope. For the indirect-dependency approach, WC thus does *not* necessarily exemplify PM in a literal sense. There are two major versions of indirect-dependency approach, the one developed by Dayal (1994, 1996a, 2000), according to which the WP is argumental, and the version proposed independently by Horvath (1997), Mahajan (1996, 2000), and Fanselow and Mahajan (1996, 2000), according to which the *wh*-phrase is an expletive.

2.1.1 The scope-marking analysis

According to a standard view (Chomsky 1981), long-distance dependencies of *wh*-phrases arise in a cyclic way. On the way to their LF-scope position, *wh*-phrases pass through all intervening [Spec, CP] positions, as in (33).

(33) [*What* do you think [t_1 that she said [t_2 that Bill saw t_3]]].

In (33), the *wh*-phrase and its traces form the A-bar-chain <what, t_1, t_2, t_3>, which links the thematic position of *what* (= t_3) to the LF scope position. In a direct-dependency approach, the WC differs minimally from long distance movement. In German (34a), the A-bar-chain <wer, t_1, t_2> linking the LF scope position to the thematic position is formed by movement, whereas in (34b), only the first link of the A-bar chain arises in this way – the second link is created by the insertion of an expletive-like element, the scope marking WP *was*: <was, wer, t_2> is a chain that serves, essentially, the same function as the one created in (34a).

(34) a. *Wer* denkst du t_1 dass t_2 kommt?
who think you that comes
b. was denkst du **wer** (dass) t_2 kommt?
what think you who that comes
'Who do you think will come?'

McDaniel (1989) develops an elaborate concept of *wh*-chains, of which expletive-like elements (scope markers), *wh*-phrases, and traces of movement may be part, if they appear in that order. She also notes (1989: 581) the resemblance of *wh*-chains with A-chains. Just as the insertion of expletive *there* is an alternative to overt A-movement (see (30), (31)), the insertion of WPs can be seen as an alternative to overt A-bar-movement. At least until a few years ago, this scope-marking analysis represented the standard view for German (cf., e.g., von Stechow and Sternefeld 1988; Müller 1997; Beck and Berman 2000). In its basic version, it confines itself to stating that an A-bar-chain <was, wer, t_2> is formed in (34b) at S-structure, and keeps this chain at all further levels.

In an extension that takes over ingredients of some generative analyses for expletives in A-positions like *there*, the direct-dependency approach assumes that the *wh*-expletives that have been inserted at S-structure have to be replaced at the level of Logical Form, and that they are replaced by the 'real' *wh*-phrase moving upwards to its scope position at LF. Consequently, the LFs of a PM-construction become indistinguishable from the LFs of long distance movement constructions (cf. Müller 1997).

2.1.2 The feature-movement analysis

A very interesting version of the direct-dependency approach (anticipating some of the theoretical assumptions about movement made in Chomsky 1995c) has been proposed by Hiemstra (1986) in her analysis of Frisian. Recently, it has been revived by Cheng (2000).

Hiemstra's view can be summarized as follows. *Wh*-movement is always the movement of a *wh*-feature. Languages differ as to what needs to be pied-piped when the *wh*-feature moves. In long-distance *wh*-movement constructions, the whole feature matrix of the *wh*-phrase is moved, including the phonetic matrix. This gives rise to (34a). Alternatively, languages may allow that nothing undergoes pied-piping – then only the *wh*-feature is moved. If this option is chosen, the *wh*-feature has to be spelled out at the landing site. It will be realized phonetically as the most unmarked *wh*-expression of the language: *was* in German, *wat* in Frisian, *mit* in Hungarian, *kyaa* in Hindi, etc. This gives rise to (34b). In addition, there is an intermediate case of featural pied-piping in which person–number features (i.e., the set of formal features to which [+wh] belongs) of the *wh*-phrase are also moved: the feature complexes transported upwards like [wh, 3rd sg., acc] will then be spelled out as the corresponding *wh*-words. This gives rise to the Copy Construction CC, which can be found in Frisian (see 35a–b), German (35c–d), and a few other languages (see also Fanselow and Ćavar 2000 for a discussion).

(35) a. *Wêr* tinkst **wêr**'t se wennet? Frisian
b. WAT tinkst **wêr**'t se wennet?
where/what think-you where-Comp she lives
c. *Wo* denkst du **wo** sie wohnt German
d. WAS denkst du **wo** sie wohnt
where/what think you where she lives
'Where do you think, she lives?'

To the extent that WC and CC are related in this or a similar way, Hiemstra's approach is the most elegant one: it is hard to see how the full *wh*-phrases appearing in CC can be considered to be scope markers or expletives.

2.1.3 The indirect-dependency approaches: argumental WHAT

While the direct-dependency approach has been the standard view for German for quite some time, research on the Hindi WC has favored a very different theory, namely, the indirect-dependency approach. This analysis was proposed first by Davison (1984), and was later taken up by Mahajan (1990), Srivastav (1991c), Dayal (1994, 1996a, 1996b, 2000). See Bruening (2001), Klepp (2002), Legate (2002), and Stepanov (2001) for indirect-dependency models for Passamaquoddy, German, Warlpiri, and Russian, respectively.

In the indirect-dependency approach, the element that is a scope marker for the direct dependency account is simply the standard *wh*-word for clausal complements. Thus, (36b) is analyzed as a version of (36a): *was* is a constituent-question phrase for CPs both in (36a) and in (36b). The relation between the WP and the CP containing the 'real' *wh*-word is then assumed to be one between a sentential expletive/pronoun and its clausal associate, as we find it in (37).

(36) a. *Was* denkst du?
what think you
'What do you think?'
b. WAS denkst du **wer** gekommen ist?
what think you who come is
Who do you think has come

(37) Ich habe es bedauert dass Hans Maria eingeladen hat
I have it regretted that Hans Maria invited has
'I regretted that Hans invited Mary.'

(38) What do you think? Who came?

In other words, the WC is a monosentential counterpart of (38), a construction with which it shares a number of properties; see Dayal (1996a, 1996b, 2000) and section 2.3.1. One argument in favor of this approach is that it offers an explanation for the fact that the WP of WC is always homophonous with a word that can be used to ask for propositions. In most languages with a WC, the WP is the counterpart of English *what*, the most unmarked *wh*-item *and* the *wh*-item used for asking for propositions. However, as mentioned above, if Bruening (2001) is correct, the WP of Passamaquoddy is not the most unmarked *wh*-item, but it is still the element asking for propositions. Likewise, the use of 'how' in the Russian or Polish WC seems to be related to the fact that Russian and Polish 'how' is a possible (though apparently not a preferred) question word asking for propositions. The connection between the WP and the *wh*-phrase asking for propositions also comes out clearly in Warlpiri, which has two questions words meaning 'what', one restricted to objects and one restricted to propositions

(translated, however, as 'how' by Legate 2002). In the WC, Warlpiri uses the latter (see Dayal 1994):

(39) a. *Nyia* ka nga-rni?
what is-he eating
b. *Nyarrpa-rlu* o-ngku yimi-ngarru-rnu?
what did-he tell-you?
c. NYARRPA-RLU o-ngku yimi-ngarru-rnu **kuja-pala** kurdu
what did-he tell-you? where children
nyarrpara-kurra ya-nu?
went
'Where did he tell you that the two children went?'

The choice of the WP is a natural consequence of the indirect-dependency approach, whereas it can be understood diachronically only in direct dependency theories.

In the indirect-dependency approaches, there is no syntactic relation between the WP and the *wh*-phrase in the lower clause. Rather, the WP enters a relation with the clause that (immediately) dominates this *wh*-phrase. The synonymy of WC-questions and questions formed by long movement thus needs to be accounted for in a different way. For Dayal (1994), the WP is a standard argumental *wh*-phrase. She suggests that the *wh*-CP in (36b) restricts the domain of propositions which *was* quantifies over in the following way. Let us assume, in the spirit of Hamblin (1973), that a question semantically represents the set of answers to it. Sentence (36a) can therefore be represented as λp (∃q, q a proposition & p = ^think (you, q)), or, if we assume (as Dayal does) that quantification is always restricted in natural languages, as λp (∃q (T(q) & p = ^think (you, q)), where T is a variable for an overt or covert restrictor of the matrix *wh*-element *was*. Note that the meaning of the complement clause in (36b) is λp (∃x (p = ^has-come (x))), by an appropriate interpretation for the *was*-CP pair, this can be made the restrictor T in the interpretation of the matrix question. We then get λp (∃q ∃x (q = ^has-come (x) & p = ^(think (you, q))) as an interpretation for (36b), and this is also a representation for the meaning of *who do you think came*, as required. The synonymy of the WC-question and those formed by long movement is thus a consequence of the interpretive rule for the *was/es*-CP pair in Dayal's system, it is not a matter of shared LFs. See Staudacher (2000) for a version of Dayal's account presupposing the Groenendijk–Stokhof type of question semantics.

2.1.4 The indirect-dependency approaches: expletive WHAT

The approach proposed by Mahajan (1990, 1996), taken up in Fanselow and Mahajan (1996, 2000), and also advanced by Horvath (1997), assumes indirect-dependency, too, but differs in its treatment of the role play by the WP. As in the argumental approach, the WP is related to a question complement, but the WP is an expletive in the theory proposed by Mahajan. In the latter respect, it resembles the scope-marking approach.

Mahajan (1990, 1996) does not postulate explicit semantic rules for LF-interpretation. Rather, he assumes that the expletive WP (the *+wh*-version of sentential expletives) needs to be replaced by its associate (the *wh*-clause) at LF. Thus, the LF of (36b) will be something like (40a) – which is an instance of clausal pied-piping as we find it in Basque. Since Mahajan (1996) argues that specifiers of XP can take scope over whatever XP c-commands at LF (see also Hornstein 1995), the LFs (40a) and (40b) (for a standard question formed by movement) are not identical, but yield identical semantic values. Mahajan's approach thus presupposes that there is pied-piping at LF. Note that specifiers of DPs appear to share scopal properties of their mother categories in (41), too.

(40) a. [$_{CP}$ Wer gekommen ist] denkst du?
who come is think you
b. Wer denkst du dass t gekommen ist?
who think you that come is
'Who do you think has come?'

(41) [Whose mother] did you see t?

2.2 *Some generalizations concerning the WHAT-construction*

2.2.1 *'Anti-locality'*

The WC differs from standard scope marking in a way that has been termed anti-locality: the WP cannot appear in the clause in which the real *wh*-phrase originates, compare German (42) and Hindi (43) with Japanese (44) (where *ka* marks the scope of the *wh*-phrases). The Iraqi-Arabic *sh-/sheno* construction classified above as a PPM shares this property, a fact that suggests it may belong to the class of WC.

(42) *Was kommt wer? German
WHAT comes who
'Who is coming?'

(43) *Tum-ne kis-ko vah kitaab kyaa dii Hindi
you-Erg who-Dat that book WHAT gave
'Who did you give that book'

(44) John-ga dare-o butta ka sirinai Japanese
John-Nom who-Acc what Q know-not
'Who did you give that book'

Generalization W1:
The WP and the *wh*-phrase (indirectly) linked to it must not be in the same clause.

Anti-locality is a straightforward consequence of the two accounts that postulate an indirect-dependency – if the WP is an expletive or argumental *wh*-CP linked to a proposition, there is simply no structural slot for it in (42) and (43). The validity of W1 is not an inevitable consequence of the two direct-dependency approaches, but there are ways to describe it. Essentially, one might account for W1 by assuming that *wh*-phrases are forced into a specifier position of CP by some constraint (Müller 1997), or by assuming that the formation of a WC is a dispreferred option (as compared to movement), which can be chosen only if movement would have to cross some kind of island: scope marking is available for long, but never for short, movement.

For German or Hungarian, i.e., for languages that have a WC and allow overt *wh*-movement, a natural idea is to split the *wh*-criterion of May (1985) and Rizzi (1990b) into two separate principles; a requirement R1 that requires that a [+wh]-Comp (or a Q head with a D-feature, or a Focus head in Hungarian) must have a [+wh]-specifier (which forces *wh*-movement or WP-insertion), and a requirement R2 that implies that *wh*-phrases must appear in the specifier position of some Comp or Focus phrase if possible (a position that need not necessarily correspond to their scope) (see Müller 1997 for such a view). R2 is violated in (42), which renders the sentence ungrammatical. R2 is also violated in grammatical multiple questions such as (45). In the Optimality-Theory account developed by Müller (1997) this difference in grammaticality between W1-violations and multiple questions is due to the fact that R2 violations cannot be avoided in multiple questions (only one *wh*-phrase can go to [Spec, CP] in overt syntax), while they can be avoided by choosing the simpler question *wer kommt* 'who comes' in the case of (42). In more complex examples such as (34b), the real *wh*-phrase fulfills R2 by moving to the lower [Spec, CP] position, whereas R1 is satisfied by *was* for the higher Comp; thus, a WC arises. In other words, (34) motivates the split of the *wh*-criterion along the lines suggested by Müller (1997).

(45) *Wen* liebt wer?
who-Acc loves who-Nom
"Who loves whom?"

Brandner (1996, 2000) accounts for W1 in a different way. Note that most *wh*-expressions allow both a *wh*- and an indefinite interpretation in German, as in many other languages (see Cheng 1997). According to Brandner, the interpretation of *wen* as a *wh*-phrase (as in (45)) or as an indefinite (as in (42a)) depends on its position. If it is in situ, the indefinite interpretation is mandatory, which, on the other hand, is absent as soon as the phrase occupies [Spec, CP]. However, a *wh*-interpretation for a *wh*-phrase in situ is licensed whenever there is a further *wh*-phrase in [Spec, CP], so that (46b) is indeed ambiguous. Brandner (1996) then proposes that the ungrammaticality of (42) is a consequence of the fact that the 'scope-marker' *was* does not license the *wh*-interpretation of *wen*, so that *wen* must be interpreted as an indefinite. The expletive scope marker is then without an associate.

(46) a. Sie wird wen heiraten.
she will someone marry
'She will marry someone.'
b. *Wer* wird wen heiraten?
who will whom/someone marry
'Who will marry whom?'
'Who will marry anybody?'

The direct dependency accounts of W1 just sketched cannot be transferred easily to the Indian type of WC, as exemplified in Hindi. Here, *wh*-phrases simply do not have to appear in [Spec, CP] and *wh*-in-situ is possible. Nevertheless W1 is respected, which thus cannot be derived in the way proposed by Müller or Brandner. Note that the scope of a *wh*-phrase that is not part of a WC is restricted to the closest finite CP it sits in in Hindi (Mahajan 1990; see also Srivastav 1991c; Dayal 1996a); the same characterizes *wh*-in-situ in Iraqi Arabic (Wahba 1991) and Bangla (Bayer 1996). With the exception of Iraqi Arabic infinitives (where a WP can optionally be inserted without consequences for scope), the insertion of the WP therefore serves a function in these languages, too; the WP extends the scope of *wh*-phrases left in a finite CP.

In a direct-dependency approach, it may therefore be profitable to describe the grammar of the WP in terms of economy considerations: a WP may be inserted only if this contributes to establishing the scope of a *wh*-phrase. Given that a *wh*-phrase in situ automatically takes scope over the finite CP immediately dominating it in Hindi, the insertion of a WP into the same clause would not have any scope-taking function, and should therefore be avoided. If this is valid, we understand not only why W1 holds in Hindi and Bangla, we also understand why (nearly) all languages employing an unlimited *wh*-in-situ strategy (like Chinese) do not tolerate WC – but Latin may be an exception (Staudacher 2000).[6]

Generalization W2:
A WP can be inserted only if it has a semantic effect, that is, a scope extension.

Generalization W2 is a property that is implemented easily if the WP has expletive properties. W2, or rather what it tries to explain, namely, the near absence of WCs in languages with an unlimited *wh*-in-situ-strategy, is not very easy to account for in models in which the WP is a full argument.

2.2.2 The WP in Spec

Generalization W3 seems to be straightfoward, but closer inspection reveals that it is not. For *wh*-in-situ-languages, W3 allows WP such as Hindi *kyaa* or Marathi *kai* (47) (Pryia Bondre-Beil, p.c.) to remain in an object position. In contrast to this, Iraqi Arabic *sh*(*eno*) must appear in clause-initial position (Wahba 1991), although Iraqi Arabic is a *wh*-in-situ language. Iraqi Arabic *sh*(*eno*) thus does not show the behavior of a WC.

Generalization W3:
If *wh*-phrases cannot stay in situ in simple questions, then a WP appears in the scope position.

(47) Sita-la KAI watle (ki) Ravi-ni konala pahile? Marathi
Sita-Erg what thought that Ravi who seen-has
'Who did Sita believe that Ravi saw?'

For languages with obligatory overt *wh*-movement like German, Frisian, and Hungarian, W3 requires that the WP appears in [Spec, CP] or [Spec, FP]. *Wh*-movement is obligatory if the specifier position of a [+*wh*] CP cannot be left unfilled. If there is no second *wh*-phrase in the clause in which the WP sits, then W3 is a trivial consequence of the grammatical property that requires that [Spec, CP] be filled. W3 goes beyond a restatement of the overt nature of *wh*-movement in one context, however, namely, multiple questions. Whereas certain dialects of German exclude constructions in which a WP combines with a further *wh*-element in the matrix clause, such constructions are possible in Hindi (48) and other dialects of German (49). The insertion of *kyaa* into a multiple question that relates items of two different (tensed) clauses is obligatory in Hindi – recall that the scope of a *wh*-phrase is restricted to the minimal tensed CP it is dominated by unless *kyaa* is used. Not much else needs to be said about (48a). For many speakers of German, however, there is a strong contrast between (49a) and (49b) that W3 captures: if two *wh*-elements compete for [Spec, CP], it is the WP that must appear in that slot.

(48) a. Kis-ne KYAA socaa ki siitaa-ne kis-ko dekhaa? Hindi
who WHAT thinks that Sita who saw
b. Kis-ne socaa ki siitaa-ne kis-ko dekhaa?
who thinks that Sita who saw
'Who thinks that Sita saw who?'

(49) a. WAS glaubt wer **wen** sie einladen wird.
what thinks who whom she invite will
b. #*Wer* glaubt WAS **wen** sie einladen wird
'Who believes that she will invite who?'

Unlike W1, W3 seems to favor the direct dependency account, that is to say, if the WP *was* is a scope marker, it is hard to see how it could ever appear in an object position, as in (49b). This reasoning is too simple, however. First, this solution leaves it open as to why this scope marker need not appear in [Spec, C] in Hindi. Second, WPs are also licensed below the ultimate scope position, as (50b) shows. They can appear in lower [Spec, CP] positions as long as their scope is extended by a WP in a higher [Spec, CP] position, as in (50b). The ungrammaticality of (50a) suggests that argumental *wh*-phrases cannot, however, extend the

scope of a WP (note that this sentence is acceptable with an irrelevant interpretation, see Fanselow and Mahajan 1996, 2000). The WP must always appear in a [Spec, C] position, yet its scope can be extended – but by further WPs only. McDaniel's (1989) approach captures this most straighforwardly since for her the WP enters a chain formation process with the real *wh*-phrase. There is a well-formedness constraint on chains that requires that a sequence of WPs (if present) must constitute the uppermost part of the chain. Müller's (1997) explanation of the contrast in (50) relates to the fact that full *wh*-phrases like *wer* in (50) can mark the scope of other *wh*-phrases only if the latter are in situ in most varieties of German – this a condition that cannot be possibly met in a WC. Yet, some German dialects allow scope marking by full *wh*-phrases for *wh*-phrases in [Spec, C], and so does Romani (see (8b, c)).

(50) a. #*Wer* glaubt WAS sie meint **wen** Fritz liebt
who believes what she means who Fritz loves
b. WAS glaubt wer WAS sie meint **wen** Fritz liebt
what believes who WHAT she means who Fritz loves
'Who believes that she thinks that Fritz loves who'?

Indirect-dependency approaches, on the other hand, claim that WPs are CP-*wh*-phrases, so (49b) should be no worse than (51), clearly an incorrect prediction. There are, nevertheless, ways to capture W3. According to Fanselow and Mahajan (1996, 2000), the clause hosting the 'real' *wh*-phrase must replace the expletive WP at LF. In the position it has thus reached in (52), *wh* can take scope over CP*, because the two authors claim that the specifier of X c-commands whatever X does. If that is combined with the assumption that the expletive WP cannot move at LF in languages with overt movement, (49b) and (50a) are ruled out because the real *wh*-phrase fails to be able to take its proper scope at LF.

(51) *Wer* glaubt was.
who believes what

(52) $[_{CP*}\,[_{CP}\,wh\text{-}\ldots\,][A]]$

Thus, all approaches considered so far must make sure by one mechanism or the other that the scope of a WP either corresponds to its surface position, or can be extended by further WPs only. Such a stipulation suffices to account for W3 in Dayal's version of the indirect-dependency account, too. W3 therefore does not contribute a lot that might help to decide between the various approaches; rather, it suggests that all current theories have a certain defect since they do not predict W3 in a strict sense. We should add that according to Klepp (2001) some speakers of German accept (49b) as grammatical. It seems hard to maintain a direct-dependency approach of the type proposed by McDaniel (1989) for these speakers.

2.2.3 WP sequences

The WC does not share all properties of standard expletive constructions. Thus, one only finds *one* expletive per chain in the *there* case (53b), but more than one WP is licensed in *wh*-chains in German (53a), Hungarian, and Hindi. Such a repetition of the WP is impossible in Iraqi Arabic and any other language or dialect in which WC is restricted to matrix questions. With respect to W4, the WC resembles *it* expletives, however (see (54)).

(53) a. WAS denkst du WAS sie meint WAS Fritz sagte **wen** Julia liebt?
what think you what she means what Fritz said who Juliet loves
'Who do you think she believes Fritz said Juliet loves?'
b. *There seems there to appear there to be a man in the room.

(54) It was believed that it is likely that it seems that he will win.

Generalization W4:
The WP may appear in any clause separating the real *wh*-phrase and its LF scope position.

Generalization W4 captures a property that distinguishes WPs from standard scope markers, as mentioned above. It is not necessarily an argument against direct-dependency approaches, because the restriction of the number of expletives in A-chains to one is itself a property that calls for an explanation that seems to involve special assumptions concerning the featural composition of *there*. Indirect-dependency approaches have no problem whatsover in accounting for (53a), because these theories assume that the WP is a *wh*-CP (expletive), i.e., the *wh*-counterpart of *it*, so that the parallel we observe between (53a) and (54) is one we should expect.

There is a further difference between standard expletive constructions and WCs; economy effects favoring Merge over Move are absent in the latter. A standard expletive such as *there* must always be inserted immediately above the root position of its associate; it is then the expletive which moves up to the highest A-position in the chain. An A-chain involving expletives thus has the form <there, t, . . . , t, NP>, i.e., the lowest chain position must be filled by the full argument NP. The associate must not move to a higher position before the expletive is inserted (see, e.g., Chomsky 1995c for possible explanations), as (55) illustrates.

(55) There seems t to appear t to be a man in the garden.
*There seems t to appear a man to be t in the garden.
*There seems a man to appear t to be t in the garden.

In WC, on the other hand, the real *wh*-phrase may undergo (partial) *wh*-movement before the (expletive) WP *was* is inserted (56) – the real *wh*-phrase can move to any of the intermediate [Spec, CP] positions prior to the insertion of *was* above

the highest surface position of the *wh*-phrase. The same holds for Hungarian and Iraqi Arabic.

(56) *Wen* denkst du dass sie glaubt dass Fritz meint dass sie liebt?
who think you that she believes that Fritz means that she loves
Was denkst du **wen** sie glaubt dass Fritz meint dass sie liebt?
Was denkst du was sie glaubt **wen** Fritz meint dass sie liebt?
Was denkst du was sie glaubt was Fritz meint **wen** sie liebt?
'Who do you think that she believes that Fritz means that she loves?'

The Hindi *kyaa* construction shares this property in the following sense. If a *wh*-phrase originating in a lower clause is to take wide scope over a higher clause, the *wh*-phrase may either be scrambled into the higher clause (Mahajan 1990; Srivastav 1991c), or the scope marker *kyaa* is used. The two options can be combined, as (57) illustrates: [partial *wh*-scrambling]. Thus, W5 seems to hold in general.

(57) Raam-ne kyaa socaa ki ravi-ne kyaa kahaa ki kOn sa aadmii
Raam-erg what thinks that Ravi-erg what said that which man
aayaa thaa?
came
Raam-ne kyaa socaa **ki kOn sa aadmii** ravi-ne kahaa ki aayaa thaa?

Generalization W5:
The *wh*-phrase may move any number of clauses up before a WP appears in the structure.

Again, the grammar of WPs is different from the one of A-expletives of the *there* type. Indirect-dependency approaches have a straightforward explanation for W5: for a WC to be grammatical, the clausal associate of the WP must be a *wh*-question, and what W5 shows is that the internal make-up of the question-associate does not matter. But W5 can be captured in direct dependency accounts with equal ease. Following Müller (1997), for instance, one can assume that *wh*-movement and *wh*-expletive insertion have similar 'costs' in the languages that allow WC, so that they may be combined quite freely.

2.2.4 (Im-)Mobility

At least for some (but definitively not for all) speakers of German, the WP *was* cannot be moved itself as in (58a), in contrast to what holds for *there*. Similarly, Hindi *kyaa* must be present in any intermediate clause between the real *wh*-phrase and the clause the real *wh*-phrase takes scope over, it cannot undergo (*wh*-)scrambling itself (58b).

(58) a. #Was denkst du t dass sie meint wen Fritz liebt?
what think you that she means who Fritz loves
'Who do you think she believes Fritz loves?'

b. *Raam-ne KYAA socaa ki ravii-ne kahaa ki Hindi
Raam-Erg what thought that Ravi-Erg said that
kOn sa aadmii aayaa thaa?
which man came
'Which man did Ram think that Ravi said ___ came?'

The ungrammaticality of (58a) for some speakers of German and of its counterparts in the other languages may be related to the expletive nature of the WP, which is that expletives do not undergo A-bar-movement in general, as (59) illustrates.

(59) a. Ich glaube dass es regnet.
I believe that it rains
b. *Es glaube ich dass t regnet.
it believe I that rains
c. Ich glaube dass Maria es schon weiss dass sie schwanger ist.
I believe that Mary it already knows that she pregnant is
d. *Es glaube ich dass Maria schon weiss dass sie schwanger ist.
'I believe that Mary already knows it that she is pregnant.'

Whether what we observe in (59) is responsible for (58) as well is not immediately obvious, however. If A-bar movement leaves a semantic variable as a trace, (59b, d) are ungrammatical on obvious grounds, and (58) would be semantically ill-formed for the same reason if the WP is an expletive. The problem would then be to account for the fact that a considerable number of speakers find (58a) grammatical while (59b, d) seem to be rejected uniformly. Those approaches (e.g., Müller 1997; Fanselow and Mahajan 1996, 2000) that replace an expletive WP with the *wh*-phrase or the *wh*-clause at some late point in the derivation can also make locality conditions on this replacement operation and/or the formation of expletive association pairs responsible for what we observe in (58).

Recall that partial movement of the *wh*-phrase is optional in Iraqi Arabic in constructions involving *sh-* and *sheno*. Thus, the *wh*-phrase may be separated by any number of (infinitive) CPs from *sh-*/*sheno*. In that sense, the *sheno* construction violates the constraint discussed in this section – but only if it is an instance of WC. Given that *sh-*(*eno*) violates other constraints on the WC as well, it is presumably more profitable to take *sheno* to be a true *wh*-scope marker in the sense of PPM.

2.2.5 The nature of the associate: a ban on yes/no questions

The Hindi WC strongly contrasts with the German and Hungarian one in allowing the associate of the WP to be a simple yes/no question (60b). This property is not shared by the otherwise identical *kai* construction in Marathi ((60c, d); Bondre-Beil, p.c.), and also not by Kashmiri.

(60) a. *Was denkst du ob er kommt?
what think you if he comes
b. Tum kyaa socte ho ki kyaa vo aayegaa? Hindi
you what think be that if he will-come
do you think that he will come?
c. *Sita-laa kai watle ki Ravi yenar ka? Marathi
Sita what thinks if Ravi comes yes–no
d. *Sita-laa kai watle Ravi yenar ki nahi?
Sita what thinks Ravi come or not
'Does Sita think that Ravi comes?'

Polish (61a), Russian, Warlpiri (61b) and Passamaquoddy (61c) seem to pattern with Hindi in this respect. Therefore, it seems we cannot say much more than [W6]

(61) a. Jak mysłisz, czy Piotrek przyszedł? Polish
how think-2sg whether Piotrek came
'What do you think? Has Paul come?'
b. Nyarrpa-ngku jangala-rlu yimi-ngarru-rnu yankirri-japa Warlpiri
how-2sg Jangala-Erg speech-tell-Pst emu-Q
japanangka-rlu pantu-rnu?
Japanangka-Erg spear-Pst
'What did Jangala tell you, was it an emu that Japanangka speared?'
c. Keq itom Tihtiyas '-kisi-peskh-a-l Passamaquoddy
what say.3 T. 3-Perf-shoot-Dir-Obv
cuspes-ol kosona tan?
porpoise-Obv or WH
'What did Tihtiyas say, did she shoot the porpoise or not?'

Generalization W6:
In some languages, a WC is possible only in the context of constituent questions.

Notice, however, that we already saw that the WC is rarely used in Warlpiri, and recall that the status of the *how*-CP construction in Polish and Russian is fairly unclear. Similarly, Bruening (2001) observes that the use of (61c) is very restricted, and requires the tag *kosona al tan* 'or what?' For this reason, he considers it doubtful that (61c) is a true scope-marking construction. Instead it seems to be a sequence of questions or an appositive. At present, it is therefore difficult to determine whether one of the two options offered by W6 is less marked than the other.

Direct-dependency accounts have not encountered serious difficulties in their attempts to account for those languages (German, Hungarian) in which the WP seems incompatible with a yes/no question. After all, the WP is claimed to be a scope marker in the chain of a *wh*-phrase. If no such chain is created, a WP cannot be inserted. One (minor) point left open by such accounts is why there is

no comparable scope-marking for yes/no questions. This is surprising in the light of the fact that yes/no operators are in fact able to take scope out of the clause they appear in, as Chinese (62) taken from Huang (1982b) illustrates.

(62) Ni renwei ta xi- bu- xihuan ni?
you think he li- not li-kes you
'Do you think he likes you, or not?'

Indeed, it seems to be a language-particular property whether the scope-marker combines with *wh*-phrases in the strict sense only or not, because the well-formedness of Hindi (60b) would otherwise imply that proponents of the direct-dependency account must assume that the German and Hindi WC have radically different analyses – an assumption that Müller (1997) and Stechow and Sternefeld (1988) indeed make, but which faces the problem that Hindi *kyaa* and Marathi *kai* apparently differ with respect to (60) only. Consequently, if (60) matters so much, Hindi and Marathi WC would require completely different analyses.

As Mahajan (1996, 2000) points out, the marker for yes/no questions in Hindi is *kyaa* itself (but the same is true of Kashmiri *k'a:* cf. also Wali and Koul 1997), so that yes/no questions possibly involve an X^{max}-operator in [Spec, CP] in Hindi. In this sense, W6 could be reformulated as W6* in a much stronger form. Whether this is convincing depends on what analysis one can give to Kashmiri *k'a* and how data such as (61) should be analyzed.

Generalization W6*:
WC is possible only with questions that involve a +*wh*-specifier.

An indirect-dependency account of the type proposed in Mahajan (1996), Fanselow and Mahajan (1996, 2000), and Horvath (1997) can exclude (60a) easily. Recall that these theories assume that the WP is a sentential expletive which is replaced by its CP associate at LF. The equivalence of the WC and a corresponding long-movement construction is guaranteed by the assumption that an XP in the specifier position of Σ may take scope over whatever Σ c-commands at LF. A *wh*-phrase filling the specifier position of a CP which is itself the specifier of the matrix clause can therefore take scope over this matrix clause. If a *wh*-element is not the specifier in a CP, its scope will not be extended. The parameterization with respect to W6 can then be expressed in terms of the specifier status of the Q-morpheme in yes/no questions (as Mahajan 1996 suggests), or by allowing scope extension for specifiers and heads in certain languages.

In Dayal's version of the indirect-dependency account it is less obvious what could be responsible for the ungrammaticality of (60a, c, d). After all, the semantic function of restricting the domain of quantification of the WP-quantifier (which is central to her theory) could be fulfilled by a yes/no question as well. Thus, one option is again the assumption that while Dayal's theory is correct for Hindi, it does not cover the German WC, which needs a fairly different analysis

then, and again one needs to be aware of the fact that this forces one to assume different analyses for Hindi and Marathi, too. Pointing to the (alleged) existence of dialects of German for which (60a) or versions of it are claimed to be fine (see Brandner 1996, Staudacher 2000, and Fanselow and Mahajan 2000 for an assessment) is just half the story, because the need to account for the more restrictive dialects does not disappear because of this. Note that yes/no questions have a distribution different from the one of complement questions. There are a number of verbs which accept only the latter as complements, as (63) illustrates. Thus, there is a semantic difference between yes/no and constituent questions after all. Whether or not the relevant factor could be used to account for W6 or W6* has not been thoroughly considered in the literature so far.

(63) Ich kann mir vorstellen
I can me imagine
a. *wen* du getroffen hast.
who you met have
b. **ob* du sie getroffen hast.
if you her met have
'I can imagine who you have met/if you have met her.'

2.2.6 Infinitives

In a WC, the real *wh*-phrase must occupy [Spec, CP] if the language does not allow simple in situ *wh*-questions (see (64–65)). The CP related to the WP must be a legal constituent question (but see below). Generalization W7 captures the fact that WC does not arise with infinitives in German, as (66) illustrates, because there are no *wh*-infinitives, and it also captures the the fact that (67a) is, in contrast, possible in Iraqi Arabic because (67b) is also fine – if, to stress the point again, the construction is correctly analyzed as a WC. See section 2.3.2. for an exception to W7.

(64) a. *Was denkst du dass Maria wen liebt?
what think you that Mary who loves
'Who do you think that Mary loves?'
b. Siitaa-ne kyaa socaa ki ravii-ne kis-ko dekhaa? Iraqi Arabic
Sita-Erg WHAT thought that Ravi-Erg who saw
'Who did Sita think that Ravi saw?'

(65) a. Sh-tsawwarit Mona [Ali raah weyn]? Iraqi Arabic
wh-thought Mona Ali went where?
b. Sh-tsawwarit Mona weyn Ali raah?
'Where did Mona think that Ali went?'

Generalization W7:
The CP related to a WP must be a syntactically legal indirect question.

(66) a. *Was glaubst du **wen** eingeladen zu haben?
what think you who invited to have
'Who do you believe yourself to have invited?'
b. *Wen* glaubst du eingeladen zu haben?
who think you invited to have
c. *Ich frage mich *wen* einladen zu müssen
I ask me who invite to must
'I wonder who to invite.'

(67) a. Sh-raadat Mona Ali ygaabal meno? Iraqi Arabic
wh-wanted Mona Ali to-meet whom
'Who did Mona want Ali to meet?'
b. Mona nasat *sheno* tishtiri
'Mona forgot what to buy.'

Generalization W7 is a straightforward consequence of indirect-dependency approaches and may seem to find rather easy explanations in the direct-dependency accounts, too. It is not clear, however, whether W7 is the crucial factor for the ban on infinitives in WC: Hungarian allows *wh*-infinitives (Horvath 1997; exx. (34–35)), yet no WC can be formed with infinitival complements, as (68b) shows. Thus, with the possible exception of Iraqi Arabic (67a) that would not be exceptional at all if it is not an instance of a WC, W8 seems to hold as well, without being reducible to W7, as Hungarian shows.

(68) a. *Kivel* akarsz beszélni? Hungarian
who-with you-want-IO to talk
b. *Mit akarz **kivel** beszélni?
what you-want who-with to talk
'Who do you want to talk to?'
c. Nem tudok *mit* mondani.
not I know what to say
'I do not know what to say.'

Generalization W8:
WC do not show up with infinitival complements.

There is no account of the WC which implies W8 without further assumptions. Direct-dependency accounts might take recourse to the idea that infinitives have a CP specifier position in very restricted circumstances only (as in (63)), so that one of the key preconditions for the availability of a WC in the movement languages – namely, that the real *wh*-phrase appears in [Spec, CP] – cannot be met. For the *wh*-in-situ languages, it seems to hold that infinitives do not delimit the scope of a *wh*-phrase they contain, so that the insertion of a WP would be superfluous for, say, the scope-taking of a *wh*-phrase in a Hindi infinitive – recall we have already seen that *kyaa* insertion must have a semantic effect. Alternatively,

one might say that infinitives have a [Spec, CP] position which is not 'type-compatible' with the [Spec, CP] position of a finite clause, so that they could not form part of the same chain. See also section 2.2 for a further attempt of an explanation.

Indirect-dependency approaches with a syntactic component (Mahajan, Horvath) might restrict the replacement of the *wh*-expletive by its clausal associate to finite CPs. There is a straightforward explanation for Generalization W8 in Dayal's system for Hindi. As discussed in Dayal (1996b), Hindi does not allow indirect-question readings for infinitivals. The analogue of *You know what to do* can only be an indirect question. This account cannot be carried over to Hungarian because of (68c) – but one might take recourse to syntactic constraints on 'associate formation' in this approach, too.

2.2.7 The complement status of the associate clause: extraction and binding

Horvath (1997) has observed that the CP hosting the real *wh*-phrase in a WC (the clausal associate of the WP) is transparent for extractions in Hungarian (69). The same holds for those dialects of German which tolerate topicalization out of *wh*-islands (70). Similar constructions are ungrammatical in Hindi.[7]

(69) Itt van az a színésznő [akinek nem emlékszem hogy Hungarian
here is that the actress who-Dat not I recall that
MIT kért János hogy **kit** mutassunk be.
what asked John that who we-introduce Sub
'Here is the actress for whom I do not remember who John asked that we should introduce to her.'

(70) Den Josef weiss ich nicht WAS sie meint **wie** wir überzeugen könnten.
the Joseph know I not what she means how we convince could
'As for Josef, I do not know how she believes that we can convince him.'

Examples (69–70) not only show that the *wh*-island condition is not respected in the pertinent languages, they also suggest that the clause c headed by the real *wh*-phrase is a complement rather than an adjunct – would it be different, c should be opaque for movement, given that most theories of barriers and islands for movement imply that adjuncts cannot be extracted from. Direct-dependency accounts immediately predict this behavior – the *wh*-island condition (Ross 1986) is the only constraining factor that could be relevant.

The indirect-dependency approaches face greater problems – if the WP is a clausal expletive and the *wh*-clause its associate, it is by no means necessary that the latter occupies a complement position. If the WP is placed into the specifier position of some object agreement phrase (or the specifier position of some verbal projection), as Mahajan (1996) and Horvath (1997) assume, then the complement position of VP can still host the clause linked to the WP. One needs to keep in mind, however, that object clauses linked to a non-*wh* CP-expletive are islands for

movement, as has been observed by Bennis (1986) and others. Therefore, indirect-dependency approaches must subscribe to the view that *wh-* and non-*wh*-expletives have different effects on the transparency of their associates for movement.

(71) Den Fritz glaube ich (*es) nicht dass sie liebt.
the-Acc Fritz believe I it not that she loves
'I do not believe that she loves Fritz.'

Horvath (1997) takes the grammaticality of (69) to be one out of three major arguments against Dayal's view of the WC. If the WP is the real argument (as Dayal claims), and the *wh*-introduced clause a structural adjunct, the latter should not be transparent for extraction. Horvath's argument is convincing, but only to the extent that transparency for movement must be defined in structural terms. The associate is semantically linked to the WP so that it may have argument status in the syntax quite independent of its position, as argued originally by Herburger (1994). Note also that clauses that appear in 'extraposed' positions are structural adjuncts (they are adjoined to VP or IP), without being necessarily opaque for movement; see German (72). If the complement clause is base-generated in a preverbal position, and if its postverbal surface position comes about by adjunction to, say, the right periphery of VP or CP, then *wh*-extraction of *wen* seems to have left a structural adjunct that is a thematic complement.

(72) Wen hast du gedacht dass Irina liebt.
who have you thought that Irina loves

Fanselow and Mahajan (1996) and Horvath (1997) claim that (73–75) constitute arguments for a complement status of the CP-associate of the WP: a pronoun sitting in the clause introduced by the *wh*-question can be bound by a quantifier in the matrix clause.

(73) Kein Student$_i$ weiss WAS die Professorin sagte **wann** er$_i$ die Prüfung
no student knows what the professor said when he the test
machen muss.
make must
'No student knows when the professor had said that he needs to take the exam.'

(74) WAS glaubt jeder Student$_i$ **wann** er$_i$ geprüft wird.
what believes each student when he tested is

(75) Mit nem hisz senki hogy milyen tőrténeteket Hungarian
what not believe no one that what stories
terjeszt róla a felesége?
spreads about-him the wife-his
'What stories doesn't anyone believe that his wife spreads about him?'

2.2.8 The status of the CP-associate: Case and subjecthood

On the whole, Generalization W9 appears to be fulfilled, as (76) illustrates for Hindi and for German. For Hindi, this may be related to the fact that *kyaa* must normally appear in an immediately preverbal position (as (77) shows). It competes with the sentential expletive *yah* for the same position, as Dayal and Mahajan observe.

Generalization W9:
WC is incompatible with the presence of a sentential expletive in an object position.

(76) a. *Siitaa-ne yah KYAA socaa ki ravii-ne kis-ko dekhaa? Hindi
Sita it what thought that Ravi who saw
b. *WAS glaubte Sita es **wen** Ravi sah?
what believed Sita it who Ravi saw
'Who did Sita think that Ravi saw?'

(77) Siitaa-ne KYAA (*abhii) socaa ki ravii-ne kis-ko dekhaa?
Sita what just now thought that Ravi who saw
'Who did Sita think that Ravi saw?'

Generalization W9 is generally predicted by indirect-dependency accounts, since they assume that the WP is generated/merged in the object position, or a specifier position linked to object agreement, which cannot be filled twice. In a direct-dependency account, W9 must be analyzed as a reflection of the greater island sensitity of chain formation in a WC as compared to standard *wh*-movement (see, e.g., Müller (1997)) – after all, clausal associates of sentential expletives are islands for movement (recall ex. (71)), see Bennis (1986). Thus, (76) might be ungrammatical because no A-bar-chain can be built up that leaves the embedded clause, which is an island. This strong island sensitivity is a clear characteristic of German WC, but the situation is less clear in Hindi and Hungarian, so that recourse to island sensitivity may be justified for German, but perhaps not in general.

It has been claimed that the WC is restricted to object clauses in German (see, e.g., McDaniel 1989, where the same claim is made concerning Romani), i.e., that it is incompatible with clauses in (derived) subject positions, which would be surprising because neither Hindi (Mahajan 1996) nor Hungarian (see Horvath 1997 and (78)) share this property. Note that (78) also indicates that the formation of WC is less restrictive than overt movement in Hungarian.

(78) a. MI zavarta Marit hogy **kinek** telefonáltál? Hungarian
what-Nom disturbed Mary-Acc that who-Dat you-phoned
b. ?**Kinek* zavarta Marit hogy telefonáltál?
who-Dat disturbed Mary-acc that you-phoned
'With whom did it disturb Mary that you have telephoned?'

The claim that German disallows a WC for (derived) subject clauses (that is widespread in the literature) is based on examples such as (79), which confound derived subjecthood and factivity, another factor restricting the WC in German, but not in other languages. When one tests non-factive subject clauses as in (80) (see Fanselow and Mahajan 2000), the results are grammatical.

(79) *Was ärgert es dich **wen** sie liebt?
what annoys it you who she loves
'Who does it annoy you that she loves?'

(80) Es ist egal was in der Zeitung steht **wen** sie liebt.
it is equal what in the newspaper stands who she love
'It does not matter who the newspapers say she loves.'

Thus, we can conclude that the WC is possible – in principle – with both object and (derived) subject clauses in Hindi and German (the CP would therefore always originate in object position). Hungarian is even less restricted, as Horvath (1997) observes: the WC is possible with adverbial clauses, although these are (just like subject clauses) barriers for syntactic movement:

(81) a. Miert vagy dühös mert **kivel** találkoztál? Hungarian
why you-are angry because who-with you had met
b. **Kivel* vagy dühös mert találkoztál?
who-with you-are angry because you had met
'Lit.: 'With whom are you angry because you had met.'

In an indirect-dependency account, a simple explanation suggests itself for the restrictions on German and Hindi WCs in constrast to Hungarian: it is related to the Case born by the WP. In Hindi, CPs show up in positions only that would bear absolutive (= structural) case. In German, CPs may show up in positions only that would be assigned nominative (= structural) or accusative (= structural) Case (if filled by an NP), as Fanselow and Felix (1987) have argued, but they cannot appear in positions that receive non-structural, lexical Case. These generalizations can be derived from the Case Resistance Principle of Stowell (1981): CPs must not be assigned Case. If the assignment of structural Case is always optional, CPs may replace NPs in the corresponding positions. If the assignment of non-structural Case is mandatory, the Case Resistance Principle prevents CPs from appearing there.

Suppose that sentential expletives are like any other sentential category in being restricted to potentially Case-free positions. Then we can understand why Hindi and German WC are confined to structural Case positions. Stepanov (2001: 178) explains the restricted nature of the Russian WC in these terms as well: *jak* 'how' simply has to be Case-less. On the other hand, if a sentential pro-form happens to be compatible with lexical Case, the WC should not be restricted to structural Case positions. Consider (82) in this respect. German *was* is normally

replaced by *wo* (lit. 'where') in the complement position of PPs. The literature on German tends to consider WCs ungrammatical when the WP would be a complement in a PP, independent of whether *wo* is extracted from PP (82a) or piedpipes the preposition (82b) (e.g., Fanselow and Mahajan 2000), but Klepp (2001) points out that some speakers accept such examples. The pertinent variation among speakers of German can easily be described in terms of lexical properties of the WP (can it receive oblique Case?).

(82) a. #Wo hast du nicht mit gerechnet wem Irina schrieb?
where have you not with reckoned who Irina wrote
b. #Womit hast du nicht gerechnet wem Irina schrieb?
'Who have you not taken it into consideration that Irina wrote to?'

For Hungarian, one would assume that CP pro-forms may in general show up in all Case positions – there are no relevant restrictions on the Case the CP receives. If the restrictions on WC we focus on here are due to Case constraints, the greater degree of freedom for WC in Hungarian becomes understandable. Notice in particular that, as (83) corroborates, the Case expressed by the WP in Hungarian is identical with the Case that would be assigned to the corresponding propositional argument. This Case pattern falls out nicely in the indirect-dependency account, as Horvath (1997) stresses, because the WP is linked to the propositional complement rather than to the *wh*-phrase of this complement in these approaches.

(83) Mire számítasz hogy **melyik fiúval** fog Mari beszélni? Hungarian
what-All you count that which boy-with will Mary speak
'With which boy do you rely on it that Mary will speak?'

For direct-dependency accounts, Hungarian data such as (81) are problematic to a certain extent. That WC formation is possible for subject and object clauses in German and Hindi is unspectacular since subject clauses are transparent for movement in these languages, too, so that one should expect other kinds of chain formation like scope marking in a WC to behave similarly. Quite in line with that, both WCs and overt long movement are impossible for adjunct clauses in German and Hindi. Arguably, then, the core island restrictions on WC formation (= scope marking) and long movement are identical. For Hungarian, however, one would have to assume that chain formation by scope marking is more liberal than chain formation by movement (see also next section). However, it is by no means obvious why the 'scope marker' does not bear the case of the *wh*-phrase it is claimed to mark the scope of in Hungarian – but rather the case of the CP that dominates that *wh*-phrases. Technical solutions are certainly possible, but the data is expected in a strict sense in the indirect-dependency theory only.

2.2.9 Negative-island effects

In Hindi (84a), German (84b), Passamaquoddy (Brüning 2001), and other languages, the WP cannot appear in a negative clause or when there is a negative

quantifier in the clause. It is not likely, however, that this behavior characterizes a general property of WCs, because the WC is compatible with negation in Hungarian, as (84c) shows, and apparently marginally so in Croatian (D. Ćavar, p.c.). Example (84d) illustrates again that the WC is more flexible than movement in Hungarian, which does show the negative-island effect.

(84) a. *Koi bhii nahĩĩ KYAA soctaa hɛ ki kOn aayegaa? Hindi
no-one what thinks be-Pres that who will-come
'Who does nobody believe will come?'
b. *WAS glaubt keiner **wen** sie liebt?
what believes nobody who she loves
'Who does nobody believe that she loves?'
c. MIT nem ismert be János hogy **hányszor** Hungarian
what not admitted-Indef János that how
hamisította az aláírásodat?
forged the signature
d. **Hányszor* nem ismerte be János hogy hamisította Hungarian
how not admitted János that forged
az aláírásodat?
the signature
'In what manner did Janos not admit that she forged the signature?'

German shows comparable negative intervention effects in many contexts, as Beck (1996b) and Pesetsky (2000) observe. Thus, a negation must not c-command a *wh*-phrase in situ (85), it must not intervene in a split construction (86), and it must not show up in the so-called copy construction (87) of German (see Fanselow and Ćavar 2000 for a detailed analysis).

(85) a. Wer hat wen nicht geliebt?
who has whom not loved
b. **Wer* hat nicht wen geliebt?
'Who has not loved whom?'

(86) a. Was hat er denn für Bücher nicht gelesen?
what has he then for books not read
b. **Was* hat er denn nicht für Bücher gelesen?
'What kind of book has he not read?'

(87) a. *Wen* denkst du **wen** sie liebt?
who think you who she loves
b. *Wen* denkst du dass sie liebt?
who think you that she loves
'Who do you think that she loves?'
c. **Wen* denkst du nicht **wen** sie liebt?
who think you not who she loves

d. *Wen* denkst du nicht dass sie liebt?
who think you not that she loves
'Who don't you think that she loves?'

Example (85) suggests that a negative element cannot intervene between a *wh*-phrase and its scope position in German – for direct-dependency approaches, this assumption suffices to rule out (84b), and the same logic may also be applied in the Mahajan–Horvath–Fanselow approach. Sentence (86) shows that negation cannot intervene between a quantificational element and it restrictor either – this is sufficient for ruling out (84b) in the Dayal-approach. Thus, the negation data (and related facts involving universal quantifiers) are expected in all theories of the WC. Therefore, the data cannot be used to argue for a quasi-parenthetical status of the WC (Reis 1996), nor to establish that there is a deep link between the WC and, e.g., the copy construction (Höhle 1996; Fanselow and Mahajan 1996, 2000). It may be added, however, that structures that are closer to (84a, b) than (84c) are unacceptable in Hungarian as well, as (88) illustrates. 'Negative-island violations' are fine in Hungarian only with verbs that presuppose a pre-existing set of propositions (such as *admit*, *reveal*, *deny*, *notice*, *permit*) – they are ungrammatical with other matrix verbs (such as *think*, *say*, *feel*). The real difference between, on one hand, German and Hindi, and on the other hand, Hungarian, thus lies in the fact that structures such as (84a, b) fail to improve when the former group of matrix verbs is used. What we observe in (88) is a pragmatically caused negative island effect in the sense of Kuno and Takami (1997); see Horvath (1997) for a detailed analysis,

(88) *Mit nem gondolsz hogy **kivel** beszélt Mari? Hungarian
what not you-think that who-with spoke Mary
'With whom didn't you think that Mary spoke?'

2.2.10 Verb-class effects

In German, factive verbs do not allow WC (89). The same holds for Kashmiri (Wali and Koul 1997: 19).

(89) ?*Was bedauerte Fritz **wen** sie liebt?
what regretted Fritz who she loves
'Who did Fritz regret that she loves?'

While direct-dependency approaches explain this restriction in terms of the island status of the complements of factive verbs, indirect-dependency theories have no simple explanation for the ungrammaticality of (89) – not too bad a property, perhaps, since neither Hindi nor Hungarian (90) share the restrictiveness of German and Kashmiri. Sentence (91b) illustrates again that Hungarian overt adjunct movement is in line with the expectation that factive islands affect extraction, so that the grammaticality of (90) is a problem for at least those versions

of the direct-dependency approach that assume that chain formation in WC follows the laws of adjunct extraction.

(90) MIT felejtett el Mari hogy **kivel** beszélt már? Hungarian
what forgot Mary that with whom she-spoke already
'With whom did Mary forget that she had already spoken?'

(91) a. MIT sajnálsz hogy **hogy** viszelkedtek a gyerekek? Hungarian
what you regret that how they-behaved the children
b. **Hogy* sajnálod hogy viszelkedtek a gyerekek?
what you regret that they-behaved the children
'In what manner do you regret that the children behaved?'

Likewise, it has already been observed by McDaniel (1989) that certain volitional predicates in German are incompatible with the WC. This property is shared by the copy construction, but not by long movement. This further restriction is, however, apparently not obeyed in Hindi or in Hungarian. Likewise, Romani 'tense dependent' clauses enter WCs.

(92) a. *Wen* möchtest du dass sie liebt?
who want you that she loves
b. **Wen* möchtest du **wen** sie liebt?
c. *WAS möchtest du **wen** sie liebt?
'Who do you want that she loves?'
d. *Wen* hoffst du dass sie liebt?
e. **Wen* hoffst du **wen** sie liebt?
f. *WAS hoffst du **wen** sie liebt?
'Who do you hope that she loves?'

Fanselow and Mahajan (1996, 2000) propose an account for this data in which the additional island effects are related to the fact that the copy construction and the WC lack an overt complementizer in the complement clause, in contrast to long movement constellations. McDaniel (1989) suggests that the complements of volitional predicates are semantically close to infinitivals, so that the ban on (92c, f) can be related to the poorly understood generalization W8 which excludes WCs with infinitival complements. It is hard to see, however, why the copy construction should obey the anti-infinitive restriction. One might also suspect that volitional predicates involve or are (hidden) modal operators after all, so that what we see in (92) is simply an intervention effect of the sort discussed in section 2.2.9. This seems tenable as long as the question of whether volitional predicates trigger intervention effects is subject to parameterization.

Reis (1996) observes that one further construction, so-called extractions from verb-second complements (see, e.g., Grewendorf 1988) turns out to to share the constraints discussed above with WC and CC. In Fanselow and Mahajan's (1996,

2000) view, (93) just illustrates the importance of having an overt complementizer for not being subject to various additional constraints. This is not convincing, however, because the set of predicates that tolerate extractions from verb-second complements is more or less identical with the set of predicates that tolerates verb-second complements – and furthermore, Vikner (1995) observes that the set of predicates that tolerates verb-second complements in German is roughly identical to the set of predicates that takes verb-second complements introduced by a complementizer in the Scandinavian languages.[8] Therefore, the absence of the complementizer in the relevant complements is a spurious side-effect in German. The intervention approach is able to account for the facts in (93) in an indirect fashion: if it is true that the grammaticality of verb-second complements is linked to the availability of a matrix-like assertive component located in the complement clause (say, in terms of the feature determination of tense and mood), and if this component must be linked to the matrix clause Comp, then negative, volitional, and factive predicates may trigger intervention effects. Now for the relation between the two Comp/Infl nodes.

(93) a. *Wen* glaubt sie liebt er?
who believes she loves he
'Who does she believe that he loves?'

b. **Wen* glaubt keiner liebt er? negative islands
who believes nobody loves he
'Who does nobody believe that he loves?'

c. **Wen* bedauert sie liebt er? factive islands
who regrets she loves he
'Who does she regret that he loves?'

d. **Wen* wünscht sie liebt er? volitional islands
who wishes she loves he
'Who does she wish that he loves?'

Such an account would not be accepted by Reis (1996). She brings yet another array of facts into the discussion of WC and points out that certain types of parentheticals behave like the WC. The particular constraints on German WC – namely, negative islands and factive and volitional verbs – are respected by parentheticals of the types illustrated in (94) as well.

(94) a. *Wen* liebt sie, was glaubst du?
who loves she, what think you?

a'. *Wen* -was glaubst du- liebt sie?
'What do you think – who does she love?'

b. **Wen* liebt sie, was glaubst du nicht?
who loves she, what think you not

b'. **Wen* -was glaubst du nicht- liebt sie?
'What don't you think – who does she love?'

c. **Wen* liebt sie, was bedauerst du?
who loves she, what regret you?
c'. **Wen* -was bedauerst du- liebt sie?
'What do you think – who does she love?'
d. **Wen* liebt sie, was wünsct du?
who loves she, what wish you?
d'. **Wen* -was bedauerst du- liebt sie?
'What do you think – who does she love?'

For Reis (1996), this apparent correlation between WC, parentheticals, and verb-second complements can be explained only if we attribute a parenthetical status to both the WC and (extractions from) verb-second complements. This solution is faced with the same problem as the Fanselow and Mahajan account: It has hard to see what a parenthetical analysis could be of, e.g., Danish verb-second clauses introduced by an overt complementizer; see (95).

(95) Watson påstod at disse penge havde Moriarty stjålet. Danish
Watson claimed that this money had Moriarty stolen
'Watson claimed that Moriarty had stolen this money.'

2.2.11 Agreement

Passamaquoddy, as described in chapter 4 of Bruening (2001), allows interesting insights into the syntax of WC. Overt movement (focus movement, relative clauses, *wh*-questions) triggers participle agreement on the verb. Long-distance questions can trigger participle agreement all along the path of movement; the same holds for long-distance relativization and long-distance focalization, see (96) (= Bruening's (72a)), in which the agreement markers appear in boldface.

(96) Wen-ihi piluwitaham-oc-**ihi** Piyel Passamaquoddy
who-ObvP suspect-2Conj-PartObvP Piyel
kisi-komutonom-ac-**ihi**?
Perf-rob-3Conj-PartObvP
'Who all do you suspect that Piyel robbed?'

Focus-movement constructions and internally headed relative clauses show that covert A-bar movement can trigger participle agreement on all verbs along the movement path as well. This is illustrated in (27), repeated here as (97).

(97) Tehpu kesiciy-uk-**il** wisukiluwohehtw-ac-**il** Maliw-ol. Passamaquoddy
only I know he-made-angry Mary-Obv

In the WC, however, it is absolutely impossible for agreement to appear above the position of the contentful *wh*-phrase, as a comparison of the data in (98) reveals (= Bruening's (119)).

(98) a. Keqsey cel elitahasi-t wen-**il** Passamaquoddy
what even IC.think-3Conj who-Obv
nemiy-ac-**il**?
IC.see-3Conj-PartObv
b. *Keqsey cel elitahasi-c-**il** wen-**il** nemiy-ac-**il**?
what even IC.think-3Conj-PartObv who-Obv IC.see-3Conj-PartObv
'Who did he think he saw?'

Bruening concludes that the WC in Passamaquoddy cannot involve covert movement of the contentful *wh*-phrase – if it did, (98b) should be grammatical. The facts of Passamaquoddy suggest that the direct-dependency account is not correct for at least some languages with a WC.

2.3 Conclusions

All theoretical approaches introduced here make reference only to concepts that are independently motivated – there are clear cases of scope marking for *wh*-phrases, there are sentential expletive-associate pairs, there are clear cases of a specifier taking wider scope than its immediate c-command domain, etc. A decision among the rivaling theories of the WC, therefore cannot be taken on purely theoretical grounds.

2.3.1 A historical dimension?

The picture that emerges from the above discussion is not necessarily a clear-cut one. One or the other generalization may favor a particular type of analysis (the direct-dependency approach fares better, e.g., with respect to W3 and W6 and with immobility facts; the indirect-dependency approach fares better with W1, W9, the Hungarian Case facts, and in particular with agreement in Passamaquoddy), but with the few exceptions discussed earlier, all theories are technically capable of capturing the relevant data. If one wants to assess the evidence, then, a number of decisions have to be made, the first one concerning the plausibility of finding a syntactic analysis that is applicable to all instances of the WC. The opposing view, endorsed by Dayal (1996a, 1996b) and Reis (1996), would be that there is a spectrum of different analyses for constructions that are superficially similar but represent different stages in a historical development from a bi-clausal entity such as (99) to a scope-marking construction as in Japanese (100). These options might be ordered as indicated in Table 47.1. There seems to be a sharp difference between A and B in Table 47.1, and also between D and E, because we saw that Iraqi Arabic *sh/sheno* is exceptional in at least two respects; the WP is not really homophononous with 'what' or 'how', and the construction fails to observe a number of generalizations (W2, W3, W4, W7) that otherwise hold for the WC. It thus seems fair to conclude that the status as a WC may be more part of the history than of the current analysis of Iraqi Arabic *sh/sheno*.

Table 47.1 Types of scope-marking construction

A	Biclausal: no syntactic integration	Two CPs	English
B	'Parenthetical': some syntactic integration	WP is an argument; clausal associate is a 'modifier'	Hindi (Dayal 1994)
C	Clausal expletive-associate pair: full syntactic integration	WP is a CP-expletive; clausal associate is a complement	Hungarian (Horvath 1997)
D	Scope-marking construction: WP part of chain formation	WP is an NP-expletive	German (Müller 1997)
E	Scope-marking construction, but phonological residue of chains	WP is a scope-marking particle	Iraqi Arabic (Ouhalla 1996)
F	Scope marking	No WP left	Japanese

(99) What do you think: will she invite him?

(100) John-ga dare-o butta ka sirinai Japanese
John-Nom who-Acc what Q know-not
'Who did you give that book?'

If this assessment is correct, one has to establish whether there is compelling evidence to allow for different analyses for the WC in Hindi (and other Indian languages), Hungarian, and German (and other Germanic languages). The key differences in descriptive terms have been identified above: the WC is not restricted to constituent questions in Hindi, and there is a rich system of overt case variation of the WP in Hungarian. According to the discussion above, however, these differences are not sufficient to motivate radical syntactic differences among the three language types in question.

2.3.2 Clear arguments?

There seems to be some consensus that the Hindi WC should be analysed in terms of an indirect-dependency approach since it may seem unlikely that a scope marker for *wh*-elements appears in a preverbal position rather than in [Spec, CP]. Furthermore, as we have seen earlier, *kyaa* and the sentential expletive are incompatible with each other (see section 2.2.8), presumably because they compete for the same position, a strictly preverbal one. Note, however, that it is not uncommon that *wh*-scope markers appear on the verb. Furthermore, the *wh*-phrase can be moved into the clause it takes scope over in Hindi, as (101) shows. This "*wh*-scrambling" operation (Mahajan 1990) may indeed place the *wh*-phrase into the specifier position of a functional projection (a Focus phrase, e.g.?) – a picture that may be blurred in Hindi by extensive further options for the scrambling of other XPs – and a view that would make Hindi resemble Hungarian in

the relevant respects quite strongly. Thus, claims that the Hindi WC *could not possibly* be analyzed as a scope-marking construction are not compelling.

(101) Raam-ne **kyaa** socaa ki ravi-ne **kyaa** kahaa ki Hindi
Raam-erg WHAT thinks that Ravi-Erg WHAT said that
kOn sa aadmii aayaa thaa?
which man came
Raam-ne kyaa socaa ki kOn sa aadmii ravi-ne kahaa ki aayaa thaa?
Raam-ne kOn sa aadmii socaa ki ravi-ne kahaa ki aayaa thaa?

The situation in Hungarian may be different in this respect – Hungarian data may be the clearest one favoring a particular approach to WC. On the one hand, the Case data discussed in section 2.2.8 strongly argue in favor of indirect-dependency approaches. On the other hand, the data discussed in 2.2.7 show that the CP hosting the real *wh*-phrase is a complement. According to Horvath (1997) this implies that the WP must be an expletive. As we saw above, this conclusion presupposes a purely structural notion of argument/complement status.

Horvath (1997) brings forward two further arguments that she believes are incompatible with Dayal's version of the indirect-dependency theory. She points points out that (102a), but not (102b), can be answered by 'nothing' or 'nothing of interest', a contrast that she claims is not easy to account for if the function of the *was* in the two examples is essentially the same, as Dayal (1996a, 1996b) claims. Whether felicity conditions for question–answer pairs decide between syntactic analysis is not fully clear, though. However, as Dayal (2000) points out, questions such as *which student came?* also cannot be answered by *nobody*. The felicity of answers to questions depends on the presuppostions linked to specific forms of question, and the contrast in (102) might be captured in these terms.

(102) a. *Was* glaubt Maria?
b. Was glaubt Maria **wie** wir das Problem lösen können?
what believes Mary how we the problem solve can

The argument involving (103) may be stronger. In a Hungarian WC, the *wh*-phrase moved upwards may be included in a yes/no question:

(103) Mit kérdeztek hogy **kivel** találkozutam-e? Hungarian
what asked-they that who-with I-met-Q-Prt
'With whom did they ask whether I had met?'

According to Horvath (1997), such structures are difficult to capture in Dayal-style accounts. Recall that according to Dayal (1996a, 1996b), *mit* would simply be a *wh*-quantifier 'what' that is restricted by the meaning of its associate, which itself must be a semantically legitimate question. It may be unclear what semantic object a combination of a yes/no question and a constituent question is – such

entities do not exist outside WC. However, a sketch of how such data (and possible Hindi counterparts) might be handled even if *mit* is an argumental *wh*-phrase can be found in Dayal (2000: 188).

It seems fair to conclude, then, that a number of empirical facts from different languages favor an indirect-dependency account for the WC. The version of the indirect-dependency approach proposed by Dayal (1994, 1996a, 1996b, 2000) has the conceptual advantage that the real *wh*-phrase moves up to its scope position (in the narrow sense) in the syntax, so that the WC does not involve partial *wh*-movement from a grammatical point of view. Consequently, the theoretical problems discussed in 1.3. simply would not arise.

2.3.3 A possible compromise?

It might be added that the difference between direct dependency approaches and indirect ones of the sort proposed by Horvath, Mahajan, and Fanselow turns out to be smaller than it may seem at first glance. There is some evidence suggesting that long *wh*-movement has to pass through a specifier position linked to the VP:

(i) in Palauan (Georgopoulos 1991b; Watanabe 1996) and many other languages, the verb agrees with a *wh*-phrase that has passed the verb on its way to the scope position (e.g., with respect to number, gender, or definitiveness)
(ii) in Quechua (Lefebvre and Muysken 1982) and many other languages, a *wh*-phrase from a lower clause may pick up a Case assigned by the matrix verb.
(iii) in Dutch[9] and some varieties of German (Fanselow and Ćavar 2000), phonetic material of a *wh*-phrase having undergone long movement may be stranded[10] in the context of *wh*-movement in the preverbal position of the matrix clause.

In Chomsky (1986a) it was argued that the *wh*-phrase adjoins to VP on its way up, an idea that has been revived in Chomsky (2000), the difference being that the *wh*-phrase now moves to a specifier position of vP/AgrO. Consider now the constellation in (104), in which a *wh*-phrase taking scope over CP* has been moved to the specifier position of a lower CP. As the next step, the *wh*-phrase might be moved to [Spec, AgrO], i.e., to the position Δ, or an expletive E might be inserted into Δ. In the latter case, this expletive E should agree with the object of the verb – i.e., it should have a clausal status, bear the case of the clausal complement, etc., but it should also be able to agree with the specifier of CP with respect to the *wh*-feature – because (unlike the specifier's case) this is a feature of the CP*s specifier the verb could subcategorize for (see Chomsky 1986a). Such a line of reasoning might bring the two approaches to WC fairly close to each other, but that point has not been investigated thoroughly so far (see Fanselow and Mahajan 2000 for some discussion).

(104) $[_{CP^*} \ldots [_{AgrO\text{-}Phrase}\ \Delta\ [AgrO\ [[_{VP}\ V\ [_{CP}$ *wh*-phrase COMP']]]] . . .]

3 Other kinds of partial movement

3.1 Simple partial movement

In contrast to the considerable amount of work concerned with the WC, few studies only have dealt with simple partial movement as exemplified again in (105) for Bahasa Indonesia (Saddy 1991). A *wh*-phrase may either stay in situ, or move up to some position which is not higher than its LF scope (105a–c). Similar constructions are well-formed in Singaporean Malay (Cole and Hermon 1998b), Kikuyu (Sabel 2000), Buli (Ferreira and Ko 2000), Slave (as illustrated in (6b), see Rice 1989, Basilico 1998) and other Athabascan languages (Western Apache, Potter 1997; Babine-Witsuwit'en, Denham 2000), and in Ancash Quechua (Cole 1982b).

(105) a. *Siapa* yang Bill tahu Tom cintai? Bahasa Indonesia
who FOC Bill knows Tom loves
b. Bill tahu **siapa** yang Tom cintai?
who FOC
c. Bill tahu Tom men-cintai <u>siapa</u>?
loves who
'Who does Bill know that Tom loves?'

We argued earlier for the generalizations S1 and S2, to which we will return to below.

Generalization S1:
If a language tolerates SPM, it also tolerates *wh*-elements in situ and allows full *wh*-movement.

Generalization S2:
If a construction is grammatical with SPM, it can also be constructed with a *wh*-phrase in situ.

3.1.1 The relation to focus movement

Note that the fronting of *siapa* in (105a, b) is accompanied by the insertion of the particle *yang*, and the deletion of particles such as *men* (105c) marking transitivity. The marker *yang* may be omitted in certain varieties of Malay (Cole and Hermon 1998b). In Kikuyu, the *wh*-phrase is prefixed by a focus particle when it has undergone partial or complete *wh*-movement, as (106) shows.

(106) a. Kama.ú a-ón-'ìrɛ <u>o</u>? Kikuyu
Kamau SP-see-T who
'Who did Kamau see?'
b. **Nóo** ó-ɣw-eciìri-a [Ngoɣe a-úɣ-írɛ áte o-on-írɛ Kaanakɛ]?
FP-who you-think N. said that saw Kanake
'Who do you think Ngoɣe said that Kaanake saw?'

c. Ó-ɣw-eciìri-á [**nóo** Ngoɣe a-úɣ -íre áte o-on-íre Kaanakɛ?
d. Ó-ɣw-eciìri-á Ngoɣe a-úɣ-íre **nóo** ate o-on-íre Kaanakɛ?

If Cheng (1997) and Saddy (1991) correctly analyze Bahasa Indonesia *yang* as a focus marker (107), it is tempting to analyze (105b) as a instance of movement to an intermediate focus position, instead of partial *wh*-movement. Note that when there is full *wh*-movement (as in 105a), *yang* is inserted as well. It would thus be likely that the full movement of *siapa* goes to the specifier of a focus phrase as well, and there is no evidence that this position is not also the one *siapa* occupies at LF. Thus, there is no principled reason for not considering what we see in (105) and (106) as instances of (partial) *wh*-movement (since *wh*-phrases move to focus positions in many other languages as well). According to Saddy (1991) the absence of parasitic gaps with partial or full *wh*-movement (in line with what holds for focus movement, and in contrast to topicalization) and the absence of weak crossover effects argue against an analysis of the fronting in (105) in terms of *wh*-movement. But there are no principled grounds that would require that *wh*-movement always licenses parasitic gaps, and a lot of languages do not show weak crossover effects with *wh*-movement. So this argument is not compelling.

(107) Buku-buku yang saya cium.
books Foc I love

In contrast, the omissibility of *yang* in Singaporean Malay (see Cole and Hermon 1998b) need not be seen as a reason against analyzing relevant *wh*-frontings as being due to focus movement (rather than *wh*-movement), but the observation also certainly does not strengthen Saddy's position. Similarly, the presence of a focus particle on moved *wh*-words in Kikuyu is compatible with the idea that (partial) *wh*-movement is not necessarily *wh*-movement in a strict sense in this language. In Slave (Rice 1989: 1162, 1165), however, the marker *ri* for focus may (108) but need not (109) be present with *wh*-elements in situ and *wh*-elements that have undergone partial movement. Basilico (1998) claims it is therefore hard to maintain that the partial movement of question phrases is always focus movement in Slave – but the contrary does not follow from the facts either.

(108) a. Raymond Jane judeni ri yili kodisho? Slave
Raymond Jane where foc 3-is 3-knows
b. Raymond **judeni** ri Jane yili kodishi
'Where does Raymond know Jane to be?'

(109) a. John seya judeni ráwozée yudeli? Slave
John my son where 3-pot-hunt 3-want-4
b. John **judeni** seya ráwozée yudeli?
'Where does John want my son to hunt?'

In Babine-Witsuwit'en (Denham 2000) SPM and focus movement co-exist as well. In contrast to focus movement, no focus marker seems to appear on the

wh-phrases that have undergone partial or complete *wh*-movement. According to Denham, *wh*-movement is strictly optional in this language.

To sum up, whether or not SPM can always be interpreted as an instance of focus movement is still an open question (see Cole and Hermon 1998b and Sabel 2000 for opposing views). Likewise, it is not clear whether going for the focus movement option instead of '*wh*-movement' really makes a difference. An argument in favor of the position that the choice matters might be that focus movement does not serve the need of checking and/or licensing the *wh*-feature of the questions Comp. Rather, it serves the need of making the focal nature of *wh*-phrases explicit. For the former need, only one position is relevant (so that one might wonder why a phrases moves at all if it does not reach that position), for the latter requirement, any focus position available in the sentence will do. In any event, some explanation linking SPM to focus movement is called for, because – at least for the small sample of languages that has been investigated so far – generalization S3 appears to hold.

Generalization S3:
If a language allows SPM, *wh*-phrases can move to focus positions and can bear focus markers in that language.

If S3 is crucial for SPM, it would be difficult to integrate German and Romani (8) (partial movement of the second *wh*-phrase in a multiple question) into an analysis of SPM.

3.1.2 Locality

One important observation of Saddy (1991) is that partially moved *wh*-phrases differ from *wh*-elements in situ with respect to island sensitivity, as (110) illustrates. The presence of a negative island does not prevent a *wh*-phrase in situ from taking wide scope in (110a), but as soon as it has undergone movement, ungrammaticality arises even though the overt movement did **not** cross the island. The pair (110c–d) shows the same for adjunct islands.

(110) a. Tom tidak meng-harap Mary mem-beli apa?
Tom not expect Mary bought what
'What did Tom not expect that Mary bought?'
b. *Tom tidak meng-harap **apa** yang Mary beli?
c. Kamu men-cemburui Bill karena saya berbicara dengan siapa?
you be jealous of Bill because I spoke with who
'Who is such that you are jealous of Bill because I spoke with him?'
d. *Kamu men-cemburui Bill karena dengan **siapa** yang saya berbicara?
e. Kamu mem-cemburui Bill karena dengan Tom yang saya berbicara?
you be-jealous of Bill because with Tom Foc I spoke

Note that focus movement is possible within adjunct islands, as (110e) illustrates. Thus, if both types of attraction to a *yang* head have the same analysis, the

non-well-formedness of (110b, d) must be due to the fact that the scope of *apa/ siapa* goes beyond the island in the relevant examples.

The contrasts in (110a–d) suggest that *wh*-elements in situ and (partially) moved *wh*-phrases show different behavior in Bahasa Indonesia. *Wh*-elements in situ, it seems, are elements that need not undergo movement at all, not even in the covert component. They are bound unselectively by a *wh*-operator (see Tsai 1994a, among others). Therefore, no island effects can arise, and it is – in a sense – also expected that – according to Saddy – *wh*-phrases in situ always take wide scope: (111a) unambiguously asks for the (single) person that is loved by everybody, while (111b, c) show the scope ambiguity one is familiar with from corresponding English examples.

(111) a. Setiap orang men-cintai siapa?
every person loves who
b. *Siapa* yang setiap orang cintai?
who FOC every person loves
c. Setiap orang tahu **apa** yang Tom beli?
every person knows what Foc Tom bought

A further observation is in line with this assumption concerning *wh*-elements in situ. Example (112a) has only the indicated reading, while ambiguities arise (ceteris paribus) as soon as the *wh*-phrase is (partially) moved (112b).

(112) a. Kamu meng-gira Jon men-ceritakan Mary tahu Tom mem-beli apa?
you think John mentioned Mary know Tom bought what
'What do you think that John mentioned that Mary knows that Tom bought?'
b. Kamu gira Jon ceritakan Mary tahu **apa** yang Tom beli?
'what do you think that John mentioned that Mary knows that Tom bought?'
'You think that John mentioned what Mary knows that Tom bought?'
'You think that John mentioned that Mary knows what Tom bought?'

The clear differences Saddy observes in Bahasa Indonesia for *wh*-phrases in situ and for partially and fully *wh*-moved phrases are not visible in Singaporean Malay according to Cole and Hermon (1998b). Nevertheless, the Malay languages share what we saw in (110), i.e., they support S4.

Generalization S4:
A *wh*-phrase that has undergone (partial) *wh*-movement must not be separated from its scope position by an island for movement.

The *wh*-in-situ strategy is less restrictive than overt movement in Slave (Basilico 1998), as (113) shows: the complements of so-called 'indirect discourse verbs' are barriers for overt movement, but *wh*-in-situ is licensed (113b). In the light of S4, it is surprising that (113c) involving partial movement is grammatical.

(113) a. *?*Ode* netá nimbáa enáih?á kenéhdzáh Slave
where your father tent 3-pitch 3-tried
'Where did your father try to pitch the tent?'
b. Raymond Jane judeni ri yili kodisho
Raymond Jane where Foc 3-is 3-knows
c. Raymond [**judeni** ri Jane yili] kodisho
'Where does Raymond know Jane to be?' (Rice 1989; ex. 1875a, b)

Slave differs from the Malay dialects in a further respect; there are configurations in which partial movement is ruled out, while complete movement is not: complements of direct discourse verbs are transparent for movement, but disallow partial movement:

(114) a. John beya judeni ráwozée sudeli?
John my son where 3-Opt.hunt 3-wants-1
'Where does John want my son to hunt?'
b. *John **judeni** beya ráwozée sudeli
c. *Hodi* nurse egháuhndá néndi?
where nurse 1-Opt-see-2-Sg 3-told-2
'Where did the nurse tell you she would see you?'

Basilico (1998) suggests that complements of direct-discourse verbs lack a [Spec, CP] node (so that (113b) could not possibly arise) – the fact that the difference between direct- and indirect-discourse complements is reminiscent of the one between finite and non-finite constructions in the European languages (at least with respect to transparency) would allow us to link (114b) to the impossibility of WC with infinitival complements.

Iraqi Arabic fulfills S4 as well, but only very indirectly. Tensed clauses are not islands for full overt movement, but they are for moved *wh*-phrases (and for *wh*-in-situ) in contrast to Bahasa Indonesia – one further crucial point concerning Iraqi Arabic is that *wh*-in-situ is not possible within syntactic islands (cf. 116).

(115) a. *Sheno* tsawwarit Mona Ali ishtara?
what thought Mona Ali bought
'What did Mona think Ali bought?'
b. *Mona tsawwarit **sheno** Ali ishtara?
c. *Mona tsawwarit Ali ishtara sheno?

(116) *Mona nasat *li-meno* tinti sheno?
Mona forgot to whom to give what
'What did Mona forget to whom to give?'

The observation S4 seems to imply that the partially moved *wh*-phrase builds up a link to its scope position that is subject to subjacency or similar constraints – but that this is part of a standard chain-building process is, perhaps, a premature

conclusion. Recall that English clause-internal topicalization is subject to a comparable restriction (117), so the logic applied to S4 also forces a partial-movement account of English topicalization. Furthermore, the formation of verb-second structures is also banned within islands in the Germanic languages (see Vikner 1995) – keeping to the line of reasoning used earlier, we would need to assume some chain-formation process in, say, (118a–b) vs. (118c–d), too. Whether this is convincing or not cannot be decided now.

(117) a. I believe that revenooers, he does not like.
b. *That revenooers he does not like is believed by everybody.

(118) a. Ich glaube dass Peter ihn gesehen hat.
I think that Peter him seem has
b. Ich glaube Peter hat ihn gesehen.
I think Peter has him seen
'I think (that) Peter has seen him.'
c. Dass Peter sie liebt überrascht mich.
that Peter her loves surprises me
d. *Peter liebt sie überrascht mich.
Peter loves her surprises me
'It surprises me that Peter loves her.'

Although Passamaquoddy does not instantiate SPM in a strict sense, its PPM constructions shed an interesting light on the analysis of partial movement. Recall that Passamaquoddy has a WC, and that Bruening (2001) observed that there is no participle agreement on the verbs sitting between the 'real' *wh*-phrase and the WP. From this, he concluded that there is no covert movement of the real *wh*-phrase replacing the WP. In addition to the WC, Passamaquoddy also allows PPM. In line with what holds for the covert movement of focus operators, participle agreement is possible on any verb intervening between a *wh*-phrase that has undergone partial *wh*-movement, and the element *tan* that may be considered a scope marker. This suggests that a chain is built up between the partially moved *wh*-phrase and the scope position.

(119) Tan elitahasi-yin-(**ik**) **tan kehsi-n** Passamaquoddy
WH IC.think-2Conj-(Part3P) WH X.many-N
nemiy-oc-**ik** apiqsehsuw-ok?
IC.see-2Conj-Part3P rat-3P
'How many rats do you think you saw?'

3.1.3 Analyses

SPM constructions can be and have been analyzed in various ways. Basilico (1998) and Cole and Hermon (1998b) analyse SPM as a subcase of the WC, the only difference being that the WP is unpronounced in Slave and the Malay languages. This allows us to relate the contrast between (113a), e.g., (no long movement) and

(113c) (partial movement okay) to the situation of various German dialects that disallow long movement and use the WC instead. On its way to LF, the WP would be replaced by its associate in SPM as well. The various options for carrying this out were discussed earlier. The theoretical implications would be those of the WC.

Other approaches assume that the partially moved *wh*-phrase reaches its LF-scope position without the assistance of an overt scope marker. The position the *wh*-phrase occupies at LF would be a function of its *wh*-feature. Its overt position could be determined by the fact that it must be placed into a focus position, an analysis first argued for by Saddy (1991) and that would make SPM comparable, to, say, *wh*-scrambling or *wh*-imperatives: *wh*-phrases are displaced, but for reasons unrelated to the *wh*-feature they possess. SPM would thus fail to be an instance of PM in the strict sense. This might be an easier analysis than one in which there is true partial *wh*-movement in the strict sense.

New syntactic models such as the Minimalist Program (Chomsky 1995c) or Optimality Theory (e.g., Kager 1999) offer more flexibility. In particular, Fanselow and Ćavar (2000) take up ideas formulated, e.g., by Groat and O'Neal (1996) in their analysis of the SPM: movement is always an overt copying of a phrase from one position to another. The result of the copying operation is subject to an (economy based) set of principles that determined which of the copies so created will be spelled out eventually (see also Pesetsky 1997). Thus, for (105), one would assume that a chain with three occurences of *siapa* is formed first – as sketched in (120) – and that principles (possibly making reference to focus, an option not explicitly discussed in Fanselow and Ćavar 2000) determine which of these copies will be pronounced. In the easiest analysis of SPM, the relevant principle would not say a whole lot more than that exactly one copy has to be retained.

(120) Siapa yang Bill tahu siapa Tom cintai siapa?

One argument in favor of such a view may be found in the agreement facts illustrated in (119). Covert movement in the classical sense (following the spell-out of the whole construction, or of a phrase) may simply come too late for triggering the phonologically visible participle agreement. In the approach favored by Fanselow and Ćavar (2000), such agreement facts are expected. Cole and Hermon (1998b) argue that full overt movement theories involving separate spell-out positions cannot account for certain pecularities in the distribution of verbal prefixes in the Malay languages, but Fanselow and Ćavar (2000) claim they have developed the pertinent analysis.

The crucial differences between the analyses are therefore: (a) is a phonetically empty *wh*-expletive involved in the construction – which would make SPM and WC structurally identical – and if not: (b) does full movement to the scope position already happen in the overt component of grammar (as proposed by Fanselow and Ćavar 2000) or not (as in the focus movement accounts)? The only clear criterion we can apply seems to be generalization S3 that favors theories

which link focus movement and partial movement to each other in one or the other way – but not necessarily so by making partial *wh*-movement an instance of focus movement.

3.2 Clausal pied-piping

Notice that there is a potential further analysis of SPM that has apparently not been proposed so far; we might link it to clausal pied-piping (CPP). The only difference between Basque (121) and SPM would be the fact that the pied-piping of the CP α the specifier of which is occupied by the *wh*-phrase happens at LF and not in overt syntax. As long as LF-movement can be phrasal (and ACD-constructions show it must be able to be so; see Pesetsky 2000 for a recent discussion) such an analysis will always be possible.

(121) **Nor** etorriko d-ela bihar esan diozu Mireni? Basque
who come Aux-that tomorrow said Aux to Mary
'Who did you say to Mary t will come tomorrow?'
'That who will come tomorrow have you said to Mary.'

The analysis of (121) seems much more obvious than the one of the constructions discussed earlier. There is a clear grammatical concept of pied-piping in the course of movement. In the spirit of Chomsky (1995c), options for pied-piping can be ordered as in (122), which are (partially) illustrated in (111). Note that in such a system the interesting question is not so much why (121) is possible at all, but, rather, why clausal pied-piping seems so rare. An answer might be sought in the idea that pied-piping is always a last-resort phenomenon and should be minimal (see, e.g., Chomsky 1995c), but a thorough discussion of pied-piping is clearly beyond the scope of this chapter.

(122)	a.	*Wh*-feature	WC (according to Hiemstra (1986) LF movement
	b.	Minimal word containing *wh*-feature	Split constructions (111a)
	c.	Minimal phrase containing *wh*-feature	normal *wh*-movement (111b)
	d.	'classical' pied-piping	of PP (111c) of DP (111d) of AP (111e)

(123) a. *Wieviel* habt ihr Schweine?
how many have you pigs?
b. *Wieviel Schweine* habt ihr?
how many pigs have you
'How many pigs do you have?'

c. *Mit wem* hat sie getanzt?
with whom has she danced
'Who has she danced with?'
d. *Wessen Bruder* hat sie geküsst?
whose brother has she kissed
'Whose brother has she kissed?'
e. *Wie intelligent* ist sie?
how intelligent is she

Note, however, that CPP and WC stand in a close relation if the latter is analysed as involving a clausal expletive. Suppose S in (124) is the scope position for a *wh*-phrase moved to the specifier position of CP#. The *wh*-phrase might then move further up alone or it might pied-pipe CP#. Instead of moving CP#, an expletive (the WP) might be inserted, ending up in S, where it is finally replaced by CP# in an instance of LF clausal pied-piping.

(124) $[_{CP^*}$ S [. . . . $[_{CP}$ *wh*-phrase [. . .]]]]

Van Riemsdijk (1985) was the first to postulate such an intimate connection between CPP and the WC (although he did not express the relation in the way it was just put), and he notes that CPP and WC are in complementary distribution in German: CPP is possible with infinitives only (113) – which must not enter the WP. It is therefore tempting to account for W8 (the absence of infinitives in a WC) in terms of a blocking relation with (125). See Trissler (1999) for a recent pied-piping analysis of (125) and related constructions.

(125) Wen zu küssen würde ein Fehler sein?
who to kiss would a mistake be
'Who would it be a mistake to kiss?'

Being an instance of extended pied-piping, CPP does not fall under the term partial movement in the strict sense.

NOTES

Thanks go to Hans-Martin Gärtner, Hubert Haider, Jarich Hoekstra, Annop Mahajan, Gereon Müller, Douglas Saddy, Matthias Schlesewsky, and to the anonymous reviewer for their valuable comments on earlier versions of this chapter. Numerous other people have contributed, among them David Basilico, Rajesh M. Bhatt, Priya Bondre-Beil, Alice Davison, Jacqueline van Kampen, Peter Kosta, Anikó Lipták, Prashant Pardeshi, Adam Przepiórkowski, Gillian Ramchand, Ghanshyam Sharma, Probal Shome, Peter Staudacher, and Arthur Stepanov. The research reported in this paper was partially supported by grant INK 12 (Innovationskolleg "Formal Models of Cognitive Complexity"), financed by the Federal Ministry of Education and Science and administered by the German Research Society DFG.

1 (i) Western Apache:
John [Earl hant'é nayishniih go] nzih?
John Earl what bought that thinks
John [hant'é Earl nayishniih go nzih
hant'é John [Earl nayishniih gonzih
'What does John think that Earl bought?'
(Potter 1997, as cited in Denham 2000: 244–245)

(ii) Babine-Witsuwit'en:
George [Lilian ndittni book yik' iyelhdic] yilhni?
George Lilian which book read told
George [**ndittni book** Lilian yik'iyelhdic] yilhni
ndittni book George [Lilian yik' iyelhdic]yilhni
'Which book did George tell that Lilian read?'
(Denham 2000: 204)

(iii) Ancash Quechua:
José munan María may-man away-na-n-ta?
José wants Mary where-to go
José munan may-man María away-na-n-ta
May-man José munan María away-na-n-ta
'Where does Joseph want Mary to go?'

2 Russian examples such as (i) might refute this generalization if a clear subordination relation is involved in such structures:

(i) Ty dumaesh **kogo** Masha ljubit?
you think who Mary loves
'Who do you think Mary loves?'

3 Serbian–Croatian, from Damir Ćavar (p.c.):
(i) što ti misliš **kto** spava
what you think who sleeps

4 Czech, from Peter Kosta (p.c.)
(i) chtel bych rad vedet co myslis **kdo** prijede
I would like to know what you-think who comes

5 The CPP analysis for German and Basque is contested. Arregi (2003) argues against it, showing that *wh*-phrases in Basque go to focus positions. For German, see Haider (1985a) and Van Riemsdijk (1985).

6 Cicero, *De officiis* 2, 25: *Quid enim censemus superiorem illum Dionysium quo cruciatu timoris angi solitum?*

7 Ungrammatical extraction crossing *kyaa* in Hindi:

(i) ???*kis-ko* siitaa-ne kyaa socaa ki ravii-ne _ kyaa ciiz dii
who-Dat Sita-Erg what thought that Ravi-Erg what thing gave

8 See, e.g., this Danish example:

(i) vi ved at denne bog har Bo ikke læst
we know that this book has Bo not read

9 I learnt about this in a talk given by Sjeff Barbiers at a workshop at the University of Potsdam in July 1999.

10 A German example would be (the split phrase appears in italics, its base position is marked by _):

(i) Was hast du *für Frauen* gedacht dass er _ einladen wird?
what have you for women thought that he invite will
'What kind of women have you thought that he will invite?'

5 Conclusion

1 Introduction: past participle agreement as Spec–Head agreement and clause structure

One of the most influential developments of recent syntactic theory is the articulated and abstract conception of clause structure first inspired by Pollock's (1989) article. Functional categories constitute the skeleton upon which clause structure is built up. Although abstract in a certain way, this conception can in fact be seen as very 'concrete' as it explicitly translates into syntactic positions features which can be overtly realized in the inflectional morphology (or are indirectly signaled by the (fixed) position of different classes of adverbs; Cinque 1999). The Infl node of Chomsky (1981) has been internally analyzed in several distinct syntactic (morpho) heads. Typical labels for these heads directly mirror

their morphological feature content: Agr(eement), T(ense), Asp(ect), M(ode), Voice, and Fin(itness) for those related to verbal morphology, and Neg(ation), Foc(us), Top(ic), and Force for those related to the informational content of the clause (cf. Belletti 1990, Zanuttini 1997, Rizzi 1997, among many others of a quite extensive literature, according to the different aspects treated; and see chapters 26 and 45). A central role is played in the clause structure by Agr nodes and their projections, which constitute a kind of bridge between the purely lexical content of verbs and the nominal content of the arguments: they are the reflection of nominal features in the verbal morphology (on the role and status of Agreement projections, see Belletti 2001).

Although in the most recent developments of the Minimalist Program (MP) the status of Agr nodes in the functional (minimal) clause structure has been questioned as their feature content is not 'interpretable' in the relevant minimalist sense (Chomsky 1995c, 2000, 2001b), positions that (preminimalist) Agr nodes designate, although possibly differently labeled, should be preserved in order to account for the morphosyntactic interaction which agreement processes display. With this qualification in mind, we can continue to use the label Agr in the traditional way to refer to the syntactic position(s) where agreement relations are established between a nominal element projection and heads connected to verbal inflectional morphology.[1]

Between the late 1980s and mid 1990s, especially under the impulse of Kayne's (1989a) article on Romance past participle agreement and Chomsky's first formulations of the Minimalist Program, the idea was put forth that clause structure should contain not only Agr-type projections related to the preverbal (high) subject position, but also other positions of this type in the lower part of the clause, closer to the VP area (see Belletti 1994, 2001; Cardinaletti 1997; Cardinaletti and Roberts 2002; for the proposal that the upper part of the clause could contain more than one single Agr-type position hosting the preverbal subject in its Spec). One of these positions, initially identified with the so-called object Case/agreement projection (AgrOP), later distinguished from it and sometimes labeled AgrPstPrtP, is the one where past participle agreement obtains (Belletti 2001; Friedeman and Siloni 1997).

Under the view that agreement processes can be taken to be the reflex of an established Spec–Head relation inside an Agr projection, as revealed by (preverbal) subject agreement, Kayne (1989a) has proposed that past participle agreement is no exception to this general characterization. As a first illustration, take the case of past participle agreement in structures containing an object clitic in Italian:

(1) L' ho conosciut**a** ieri.
her (CL) (I) have known (Fem, Sing) yesterday
'I knew her yesterday.'

Here, the past participle agrees with the moved object clitic. This agreement can be assumed to be obtained through the Spec–Head relation in the relevant low Agreement projection related to the past participial morphology,

labeled AgrPstPrtP. The relation is established in the course of movement of the clitic to its final landing site in some (functional) head in the upper part of the clause. So, past participle agreement is a reflex of the displacement of the nominal projection determining agreement. Note, incidentally, that past participle agreement gives an interesting hint as to the way the process of cliticization takes place. The process must involve a first part of movement as a maximal projection of the projection containing the clitic, passing through the Spec of the relevant agreement projection. It is only toward the end of the process, and anyway after the passage through the Spec of the projection responsible for past participle agreement that the clitic can accomplish its movement as a head, ultimately incorporating into the (finite) verb (Kayne 1989a; Rouveret 1989; Sportiche 1996b; Belletti 1999b; Rizzi 2000b; see section 3.3, for a discussion of the cases of object agreement which constitute apparent exceptions to this general pattern).

2 Past participle agreement in Romance: basic data

Past participle agreement phenomena are widespread in Romance, with differences among the various languages and dialects. Some of these will be mentioned in the course of the discussion. The Romance languages most widely discussed in the literature in this connection are standard Italian and standard French. These two languages will also constitute the central focus of the following discussion.

2.1 Standard Italian

Past participle agreement holds in the following syntactic contexts:[2]

(a) With unaccusative verbs:

(2) Maria è partit**a**.
Maria is left (Fem, Sing)
'Mary has left.'

(b) With passive morphology, both on the passive auxiliary and on the lexical verb:

(3) Maria è stat**a** assunt**a**.
Maria is been (Fem, Sing) hired (Fem, Sing)
'Mary has been hired.'

(c) Under direct object cliticization:[3]

(i) obligatorily for the third person:

(4) a. L' ho vist**a**/*o
her (CL) (I) have seen (Fem, Sing/*NonAgr[4])

b. Le ho vist**e**/*o
them (Fem, Pl) (I) have seen (Fem, Pl/*NonAgr)
c. Li ho vist**i**/*o
them (Fem, Pl) (I) have seen (Masc, Pl/*NonAgr)
'I have seen her/him/them.'

(ii) optionally with the other persons:

(5) a. Mi/ti ha vist**a/o/o**.
me/you (CL) (he) has seen (Fem, Sing/Masc Sing/NonAgr)
b. Ci/vi ha vist**e/i/o**.
us/you (he) has seen (Fem Pl/Masc Pl/NonAgr)
'He has seen me/you/us/you.'

(d) With reflexive/reciprocal clitics (including the inherent reflexive/ergative *si*-constructions of Burzio (1986)):

(6) a. Mi sono guardat**a** allo specchio.
me (Refl, CL) (I) am watched to the mirror
b Ci siamo guardat**e** allo specchio.
us (Refl, CL) are watched to the mirror
'I/we have watched myself/ourselves in the mirror.'

(e) With impersonal (passive) *si*:

(7) Ultimamente si sono costruit**e**/*o molte case.
lately SI have been built many houses
'Lately, many houses have been built.'

2.2 *Standard French*

Past participle agreement holds in similar contexts in French, with the following qualifications distinguishing it from the Italian paradigm:

(a) With unaccusative verbs taking *être* as aspectual auxiliary (hearable in some regional varieties; same constraint as in standard Italian except that *être* is not the only auxiliary taken by unaccusative verbs in French; see section 3.4):

(8) Elles sont venu**es**.
they (Fem, Pl) are come
'They have come.'

(b) With passive morphology on the lexical verb only:

(9) Ces sottises ont été fait**es** par les
these stupid things (Fem, Pl) have been done (Fem, Pl) by the
élèves de cinquième.
students from 5th grade

(c) Under direct object movement, via cliticization and *wh*-movement, optionally in both cases:[5]

(10) Ces sottises, Jean ne les a jamais
these stupid things (Fem, Pl) Jean not them (CL) has ever
fait**es/-**.
done (Fem, Pl)
'These stupid things, John has never done them.'

(11) Voilà les sottises que Jean n'aurait jamais
here are the stupid things (Fem, Pl) that Jean wouldn't have ever
fait**es/-**.
done (Fem, Pl)
'These are the stupid things that John would never have done.'

(d) With reflexive/reciprocal clitics (including the inherent reflexive/ergative *si/se*-constructions of Burzio (1986), the so-called pronominal verbs of normative descriptions, both requiring *être* as aspectual auxiliary, hence falling under case (a):

(12) Elles se sont repris**es**.
they themselves have recovered
'They have recovered.'

Beside these basic data there are other domains where past participle agreement gives rise to various complications. Let us consider standard Italian, where the phenomenon is clear as it always has a phonetic correlate. In transitive structures containing an overt direct object and a reflexive clitic corresponding to an indirect object (benefactive/dative), the past participle obligatorily agrees with the indirect reflexive clitic, hence with the subject:

(13) a. Maria si è lavat**a**/*o i capelli.
Maria (to) herself is washed the hair
'Maria washed her hair.'
b. Gianni e Mario si sono stretti la mano.
Gianni and Mario (to) themselves are shaken the hand
'Gianni and Mario have shaken hands.'

However, if the direct object of sentences like (13) is cliticized, past participle agreement is with the direct object clitic:

(14) a. Maria se li è lavat**i**.
Maria (to) herself them (CL, Masc, Pl) is washed (Masc, Pl)
'Maria washed it.'
b. Gianni e Mario se la sono
Gianni and Mario (to) themselves her (Fem, CL, Sing) are
stret**t**a.
shaken (Fem, Sing)
'Gianni and Mario have shaken it.'

A hierarchy seems operative according to which past participle agreement with the direct object clitic necessarily takes priority over agreement with the indirect object (reflexive) clitic. The same paradigm is preserved if the reflexive clitic corresponds to a benefactive:

(15) a. Maria/io si/mi è/sono lett**a** questi libri
Maria/I (to) herself/myself is/are read (Fem, Sing) these books
volentieri.
gladly
'Maria/I has/have read these books gladly for herself/myself.'

b. Maria/io se/me li è/sono
Maria/I (to) herself/myself them(CL, Masc, Pl) is/are
lett**i** volentieri.
read (Masc, Pl) gladly
'Maria/I have read them gladly for herself/myself.'

Burzio (1986) states the operation of a hierarchy of this sort leaving the reasons for its existence as an open question. See section 5 for further discussion and a proposal.

Finally, past participle agreement with a direct object clitic is preserved and obligatory in standard Italian, also in so-called A(bsolute) S(mall) C(lauses):

(16) a. Conosciut**a**la, . . .
known (Fem, Sing) her (CL) . . .
'Having known her . . .'

b. Incontrat**a**la, . . .
met (Fem, Sing) her (CL) . . .
'Having met her . . .'

c. *?Conosciut**o**la, . . .
known her (CL)

d. *?Incontrat**o**la, . . .
met her (CL)

Note that here the clitic is an enclitic on the past participle.[6]

3 Past participle agreement as Spec–Head agreement

As mentioned earlier, a partial reformulation of Kayne's influential approach to past participle agreement (PPA), originally formulated in terms of the relation government, interprets the occurrence of PPA as a consequence of passing through the Spec of the past participle projection of an element, typically the direct object, moving to some other position in the clause: the preverbal subject position in the

case of unaccusatives and passives;[7] the clitic landing site in the case of cliticization; the (left) periphery of the clause in the case of *wh*-movement. Clearly, the most salient and interesting feature of this approach is its unifying character which drastically simplifies the understanding of a complex pattern. Let us concentrate more closely on the agreement occurring under cliticization and *wh*-movement, leaving for section 3.3 the discussion of some (apparent) cases of object agreement. Section 3.4 addresses the issue of the (apparent) correlation between auxiliary selection and past participle agreement.

3.1 Cliticization

The described approach to past participle agreement requires a movement analysis of cliticization.[8] The clitic projection in its movement to its final landing site in the upper part of the clause, passes through Spec of AgrPstPrt and triggers agreement in a way parallel to the one assumed for the case of preverbal subject–verb agreement in finite clauses. The only difference between the two cases is related to the nature of the past participial morphology which only manifests gender and number features and no feature person. Kayne's original account, as well as the subsequent literature on the topic, has typically left unexplained why such agreement process should be obligatory in some cases and optional in other cases which would otherwise meet the relevant configuration. Consider the difference in Italian, presented in section 2, between third-person clitics on the one side, obligatorily triggering past participle agreement, and first- and second-person clitics, doing so only optionally on the other. This pattern seems to identify an area of genuine optionality, also systematically manifested in the French paradigm of cliticization with clitics of all persons and numbers.

The question is a complex one. Occurrence vs. non-occurrence of past participle agreement could in fact be a sign of different types of derivation: one involving passage through the Spec of the past participial projection, one not involving it (see Sportiche 1998: ch. 3). Alternatively, the different agreement pattern could be related to other independent differences, internal to Italian and between Italian and French. The system elaborated in Guasti and Rizzi (2002) can provide a way of making the relevant distinction. In that work, the proposal is put forth that overt manifestation of agreement should in general be correlated to morphological checking taking place in the syntax; in particular, as far as verbal agreement is concerned, to syntactic Verb movement. Suppose that the hypothesis is made that the internal structure of the Agr past participial projection is more articulated than hypothesized so far in that it could involve different designated positions for clitics of different persons, with first and second person higher than third person. A way of accounting for the way the optionality is manifested in Italian suggests itself. If syntactic V movement implementing morphological checking takes place obligatorily in the first Agr head, but only optionally in the others, past participle agreement is expected to be obligatory with third-person clitics only. The difference internal to Italian could thus find a reasonable account.[9] As discussed in Guasti and Rizzi (2002), this approach can

also provide a way of accounting for the difference between Italian and French in this connection. As has been known since Pollock (1989) and Belletti (1990), the verb only moves optionally with non-finite morphology in French, while Verb movement is generalized in Italian. The optionality of past participle agreement with object clitics of all persons in French could then be reduced to a further manifestation of the optionality of non-finite Verb movement in this language.

3.2 Wh-*movement*

As illustrated in section 2, a similar issue arises in the case of *wh*-movement. Taking into consideration standard French, this language optionally manifests past participle agreement under *wh*-movement ((10), (11)). In standard Italian, this type of agreement is never manifested, as the following contrasts indicate:

(17) a. *I libri che ho letti.
the books (Masc, Pl) that (I) have read (Masc, Pl)
b. I libri che ho letto.
the books that (I) have read
c. *Quanti libri hai letti?
how many books have you read (Masc, Pl)
d. Quanti libri hai letto?
how many books have you read

The contrast between French and Italian does not go in the usual direction in this case in that Italian does not manifest agreement in cases where French does. French does not seem to make any distinction between cliticization and *wh*-movement, past participle agreement being optional in both cases. Indeed, this could ultimately be viewed as an indirect consequence of the relative poverty of French (past participial) morphology whose structural correlate could be a (relatively) flat projection for the past participle. In the spirit of the discussion in section 3.1, optionality of past participle agreement should then be expected across the board in French as a function of the optionality of non-finite V movement, independently of the kind of movement involved.[10] For Italian, the proposal should be that the verb never reaches the (by hypothesis) high(est) head in the richly articulated past participle projection, whose specifier hosts the passage of the *wh*-phrase. Lack of agreement with *wh*-movement would then follow in the way discussed in section 3.1.

Contrasts arising in standard French in the domain of *wh*-movement are particularly interesting in this connection. As past participle agreement is normally optionally admitted in this language, cases where it is impossible must reveal the operation of some principled source of their ungrammaticality. The relevant contrasts are those in (18), discussed in Rizzi (1990b) and Obenauer (1994).

(18) a. Combien de voitures a-t-il conduit**es**?
how many of cars has he driven (Fem, Pl)

b. *Combien a-t-il conduit**es** de voitures?
how many has he driven (Fem, Pl) of cars

In (18a) the whole direct object is *wh*-moved (into CP), while only the quantifier is moved in the ungrammatical (18b). The possibility in French of moving only the *wh*-quantifier, leaving the rest of the phrase containing the nominal projection behind, is shown by the grammaticality of sentences like (19) which in fact differ from (18b) only in that they do not display past participle agreement:

(19) Combien a-t-il conduit de voitures?
how many has he driven of cars

This is a straightforward indication that the source of the ungrammaticality of (18b) is solely to be found in the illegitimate past participle agreement.

Adapting Rizzi's discussion, the impossibility of (18b) can be interpreted as a case of improper movement ultimately induced by Relativized Minimality (RM). Assume that, due to RM, the derivation of sentences like (19) involves movement of the *wh*-quantifier to and from the same syntactic position in the VP area also available for the adverbial modifier *beaucoup*, illustrated by sentences like (20):

(20) Il a beaucoup consulté ces livres.
he has much consulted these books

The same position is also used as landing site for movement of the QP in sentences like (21b), related to (21a):

(21) a. Il a consulté beaucoup de livres.
he has consulted many of books
b. Il a beaucoup consulté de livres.
he has much consulted of books
c. Il a beaucoup conduit**es** de voitures.
he has much driven (Fem, Pl) of cars

The relation of sentences like (21b) and (20) is pointed out in Obenauer (1994) and discussed in Rizzi (1990b). This adverbial position is considered an A′-position, as adverbial positions in general. The impossibility of (18b) can then be attributed to the fact that, in order for past participle agreement to obtain, passage to the Spec of the past participial morphology should be necessary. It seems natural to consider this position an A-position, as specifiers of agreement projections are in general.[11] If the adverbial position is located lower than the past participle projection, the resulting derivation would constitute a case of improper movement involving the illegitimate step A′ > A, crucial in order for past participle agreement to be triggered. Note that interaction between *combien* extraction and the adverb *beaucoup* in the pre-VP position of (20) is confirmed by

the following paradigm, first discussed in Obenauer (1976) and interpreted by Rizzi (1990b) as a typical instance of the operation of the RM principle:

(22) a. Combien de livres a-t-il beaucoup consultés?
how many of books has he much consulted
b. *Combien a-t-il beaucoup consulté de livres?
how many has he much consulted of books

If, contrary to the hypothesis just explored, we were to assume that the past particle projection is lower in the clause structure than the adverbial position (the speculative proposal of section 5 would probably lead to this conclusion), agreement could take place and *combien* could subsequently move into the adverbial position with no improper movement step being created. The alternative explanation suggested in Rizzi (1990b) could then be accepted. According to this interpretation, movement of *combien* to the Spec of the past participial projection should be excluded in principle under structure preservation, as this position should be reserved to noun phrases, hence excluding QPs.

3.3 Object agreement

As seen in the previous sections, past participle agreement is possible and/or obligatory with direct objects under the particular structural conditions created by DP movement, clitic movement, and *wh*-movement, with the described asymmetries. It appears to be the case that past participle agreement can sometimes occur with a direct object which, at least apparently, fills the regular direct object position, linearly following the verb. This is neither true in standard Italian nor in standard French. However, it is true in some dialect varieties of (southern) Italian, in some other Romance languages (e.g., Occitan), and also in a somewhat more literary Italian.[12] The question then arises as to how the Kaynean approach can account for these cases, which correspond to sentences like (23), using an Italian example (marginally possible at the relevant stylistic level):

(23) Maria ha conosciut**e** le ragazze.
Maria has known (Fem, Pl) the girls (Fem, Pl)

There seem to be two solutions to this pattern. The first is to assume that the direct object is only apparently a regular direct object in (23); in these cases it actually fills a position different from the canonical position of direct objects (e.g., it could be dislocated, see below). The second solution is to assume that there is more structure defining the past participle area with at least one further position higher than the projection of the past participle; the past participle has to move into the head of this higher projection, while the direct object moves to and remains in Spec of AgrPstPrt. Under the first approach, tentatively adopted in Kayne (1989a), the kind of position the direct object fills should be made clear. Kayne suggests that it fills the right-dislocated position. Presence of a silent clitic

is assumed as the real trigger of agreement. A proposal along these lines does not seem adequate to account for those varieties where agreement appears to be obligatory: after all, why should a direct object systematically be right dislocated? Moreover, how could the presence of the silent clitic be independently justified? Under the second approach, one should clarify what kind of further functional projection would dominate the past participle agreement projection as well as what would force the verb to move into its head.[13] Hence, both approaches are tentative and leave a number of open questions. This second approach would probably provide a more natural way to account for the difference among languages. Presence vs. absence or optional presence of object agreement could be viewed as a function of object movement and syntactic verb movement (both allowing for an amount of optionality which may vary along the lines reviewed in section 3.1 for the case of non-finite V movement). Agreement would result from the combination of both object movement and syntactic verb movement. The difference among the various languages could be phrased in terms of whether movement of the object goes further than the VP area, as in the case of DP movement (in passives and unaccusatives), cliticization and *wh*-movement, or not. Some languages (standard Italian, French) would allow object movement only in the former case, others would extend the process to all cases.[14]

As discussed in Belletti (1990, 1992), standard Italian has past-participial small clauses, referred to as absolute small clauses (ASC). These display a special agreement pattern. The past participle is the first constituent of the small clause, followed by the subject in the case of unaccusative verbs, and by the direct object in the case of transitive verbs.[15] In both cases, past participle agreement is obligatory:

(24) a. Arrivat**a** Maria, . . .
arrived (Fem, Sg) Maria, . . .
'Having Maria arrived, . . .'
b. Conosciut**a** Maria, . . .
known (Fem, Sg) Maria, . . .
'Having known Maria, . . .'

If the agreement in (24a) appears to be a standard case – as the past participle always agrees with the postverbal subject in unaccusative structures – the same is not true for (24b); as discussed earlier, transitive past participles do not normally agree with the direct object in standard Italian. The idea of analyzing (24b) as a passive past participle, thus reducing this kind of agreement to the standard case of past participle agreement under passive morphology, ultimately equivalent to the unaccusative structures, does not appear to be empirically correct, as discussed in detail in the references quoted. The most direct indication is provided by the fact that the nominal following the past participle is marked with accusative case, visible when it is a (first- or second-person) personal pronoun (cf. *Conosciuta me/*io*). ASCs like (24b) are better dealt with as transitive structures with a control PRO filling the subject position. Past participle agreement in (24b) is then a genuine case of agreement with the direct object. Various ideas

come to mind to express this pattern. Notice that the second analysis hinted at above for cases like (23) can provide a fairly straightforward account: the direct object moves to Spec of the past participle agreement projection and the past participle moves higher (maybe to C; see the references quoted). Word order is obtained. The necessity of agreement in this case, contrary to regular full transitive clauses of standard Italian, should be due to special properties characterizing ASC, possibly crucially related to Case requirements. As proposed in the works quoted, agreement here provides a device to assign Case to the direct object.[16]

3.4 On auxiliaries and past participle agreement

The widespread co-occurrence of past participle agreement and presence of auxiliary *essere* might lead one to think that the two processes are strictly dependent on one another. In particular, selection of *essere* as aspectual auxiliary could be taken to be the crucial factor forcing agreement. However, the simple correlation between auxiliary selection and presence or absence of agreement is empirically incorrect in both directions. There are cases where *avere* is selected, e.g., with transitive verbs, and agreement is manifested (see the discussion in connection with (23)); furthermore, there are Romance varieties where *avere* is selected with unaccusatives and still agreement is manifested.[17] On the other hand, there are cases where *essere* is selected in standard Italian and yet agreement is impossible. Compare the impersonal SI construction with intransitives and transitives, also pointed out in Burzio (1986) in this connection:

(25) a. Si è telefonato/*i.
one is called (*Masc, Pl)
'Someone rang.'
b. Si è mangiato/*i due castagne.
one is eaten (*Masc, Pl) two chestnuts
'Two chestnuts were eaten.'

It can be suggested that selection of *essere* is due to the presence of the impersonal SI in these cases, but as no movement is involved here from the VP-internal/object position, contrary to, e.g., the impersonal passive of examples like (7), no past participle agreement is produced. This indicates that movement from the VP-internal (object) position, and not the kind of auxiliary selection, is the crucial step triggering agreement.

Lack of past participle agreement in (25) is also interesting in comparison with (26), where the adjective agrees in gender and number with the arbitrary plural impersonal SI – third person singular on the verb is often interpreted as the unmarked person agreement, the only one compatible with the impersonal subject (cf. Belletti 1982, Burzio 1986):

(26) Si è felic**i**/*e.
one is happy (Masc, Pl/*Sing)

This contrast may indicate that the AP involves a different internal representation than the intransitive or transitive past participle. Its representation is possibly, closer to the one of the past participle of unaccusatives which systematically manifest agreement (cf. *Si è partit**i*** 'someone left'). See section 5 for a proposal concerning unaccusatives which could extend to this case.

4 On some cases of past participle agreement in French and the comparison with Italian

4.1 On the A- vs. A'-status of the specifier of the past participle projection

Kayne (1989a) discusses impossible cases of past participle agreement in *wh*-constructions involving an expletive subject:

(27) a. Quelle chaleur atroce il a fait/*e.
what heat terrible it has done
'What a terrible heat!'
b. Je me demande combien de chaises il sera
I to me wonder how many of chairs (Fem, Pl) it will be
repeint/***es*** cette année.
repainted (*Fem, Pl) this year
'I wonder how many chairs will be repainted this year.'
c. Les chaises qu'il m'aurait fallu/***es***.
'The chairs which I would need.'

The account proposed by Kayne (1989a) crucially relies on the assumption that the Spec position of the past participle projection is an A'-position. Assuming that at LF the expletive must be eliminated through substitution from the associate (Chomsky 1986b), the impossibility would follow from the fact that the LF movement at work for substituting the expletive would imply an illegitimate A' > A step, from Spec of the past participle projection to the subject position in Spec of IP. However, the hypothesis that the Spec of the past participle projection is an A'-position does not look plausible, both on theoretical and empirical grounds.[18] From the theoretical point of view, the specifier of the past participle projection would constitute an isolated exception to the general A status of the specifiers of agreement projections. This is an implausible conclusion which is not independently justified. On the empirical side, consider the following pair (presented in Ruwet 1982, Grevisse 1986, and Kayne 1989a):

(28) a. *Une femme qu'on aurait dit**e** ne pas être belle.
'A woman that one would have said (Fem, Sing) not to be beautiful.'
b. Une femme qu'on aurait dit**e** belle.
'A woman that one would have said (Fem, Sing) beautiful.'

If *wh*-extraction in (28a) requires passage through the CP of the subordinate infinitival clause (Kayne 1984a), the impossibility of past participle agreement here can directly follow from the assumption that the specifier of the past participle projection is an A-position in the following way. The derivation would imply an improper movement in one of its steps: the step from [Spec, CP], an A'-position, to [Spec, AgrPstPrt], an A-position. On the other hand, if the small clause in (28b) is not a CP projection, no passage through this position is ever at work, hence the *wh*-phrase can directly move to the specifier of the past participle projection and from there into the CP position of the relative clause. No improper movement is involved in any step of the derivation. This is the interpretation proposed for contrasts of this type in Belletti and Rizzi (1996b), which crucially requires that the specifier of the past participle projection be an A-position.

4.2 Past participle agreement and inherent Case

In the same work the impossibility of past participle agreement in expletive constructions like (27) is interpreted as due to the unavailability in French of (past participle) agreement with indefinite postverbal subjects, under the hypothesis that they be marked with inherent Case in these constructions (Belletti 1988; see also Sportiche 1998: ch. 3). These examples would then fall under the often observed lack of agreement triggered by nominal expressions marked with inherent Case.[19] Indeed, if the assumption is made that agreement with inherently Case-marked noun phrases is systematically excluded in French, three apparently unrelated cases of impossible agreement – some having passed unnoticed in the theoretical literature – are attributed a unified interpretation (cf. Belletti and Rizzi 1996b, where it is also pointed out that the data on psych verbs are implicitly noted in Grevisse 1986).

(a) The impossibility of agreement under *en* cliticization (where *en* realizes partitive case, possibly assigned by the indefinite quantifier here: cf. Cardinaletti and Giusti 1992):[20]

(29) Il en a repeint /***es** deux.
he of them (CL) has repainted /*(Fem, Pl) two
'He has repainted two of them.'

(b) The impossibility of agreement with psych verbs of the *worry* class:[21]

(30) a. Cela l' a surpris /***e**.
this her (CL) a suprised /*Fem, Sing
'This has surprised her.'
b. La fille que ton départ /ce spectacle a profondement
the girl that your departure /this show has deeply
supris /***e**.
surprised /*Fem, Sing

(c) The impossibility of agreement with the postverbal subject in subject inversion structures:

(31) Il a été repeint /***es** trois voitures.
it has been repainted /*Fem, Pl three cars

This case of impossible agreement can be seen as the same lack of agreement systematically manifested in this type of structure, independent of the presence of a past participle:

(32) Il arrivera /*arriveront trois filles.
there will arrive /*Pl three girls

Note that lack of agreement in (31) and (32) cannot be related to presence of the expletive. The same impossibility is preserved in Stylistic-Inversion structures containing a semi-idiomatic expression V+N where the expletive can be absent, as first pointed out in Kayne and Pollock (1978):[22]

(33) a. Le jour où a été mis /*mise fin au conflit.
the day where has been put /*Fem, Sing end to the conflict
'The day when the conflict was ended.'
b. J'exige que soit mis /*mise fin au conflit.
I pretend that be put /*Fem, Sing end to the conflict
'I pretend that the conflict has ended.'

The comparison with standard Italian is interesting in that all the data where a comparison is directly possible have an opposite shape: past participle agreement is possible and obligatory under *ne* cliticization, with psych verbs of the *worry* class, and in subject inversion structures, including those containing a semi-idiomatic V+N expression:

(34) a. Ne ho comprat**e** /*comprato molte.
of them (CL) have bought (Fem, Pl) /*bought many
'I have bought many of them.' (cf. (29))
b. Questo l'ha sorpres**a** /*sorpreso.
this her (CL, Fem, Sing) has suprised (Fem, Sing) /*suprised
'This has surprised her.' (cf. (30))
c. Sono entrat**i** /*entrato due ladri dalla finestra.
are entered (Masc, Pl) /*entered two robbers from the window
'Two robbers have entered through the window' (cf. (31))
d. Esigo che sia mess**a**/ *?messo fine al conflitto.
(I) pretend that be put (Fem, Sing) *?put end to the conflict
'I pretend that the conflict was ended.' (cf. (32))

(The last example is slightly more acceptable than the other impossible cases. The marginal possibility of lack of agreement here could reflect the fact that the

expression is analyzed as fully non-compositional.) The proposal sketched in Belletti and Rizzi (1996b) to deal with the French–Italian contrast is that a parameterization is possible for the availability of agreement with inherent Case. Italian admits (and requires) it, French does not (cf. also Mahajan (1990) for a similar proposal in the context of a comparison between Hindi and closely related languages).

It should be pointed out that (past participle) agreement is systematically excluded with dative case, a general fact in Romance, illustrated here for Italian in the context of cliticization:

(35) *Le ho parlat**a**.
to her (I) have spoken (Fem, Sing)
'I have spoken to her.'

One possibility to capture the difference between dative and inherent case is that, as witnessed by the presence of a preposition, datives imply a further level of structure, namely, a PP level. P being incompatible with phi-features, agreement is excluded in principle when this level is activated. The hypothesis should then be that inherent Case is not prepositional.[23]

In those cases where *ne* corresponds to an adnominal complement, past participle agreement is optional (see also Lepschy and Lepschy 1977):

(36) a. Ne ho lett**a** /?letto la metà.
of it (CL) (I) have read (Fem, Sing) /?read the half
'I have read half of it.'
b. Ne ho consultat**a** /consultato l'opera.
of it (CL) (I) have consulted (Fem, Sing) consulted the work
'I have consulted his work.'

A possible interpretation here is that *ne* is ambiguous here between being inherently case-marked and as a PP.

4.3 Past participle agreement and effects on the interpretation

As first pointed out in Obenauer (1992, 1994) and discussed in Déprez (1998), the optionality of past participle agreement in *wh*-structures in French is not without consequences from the point of view of the interpretation. The distinction is particularly clear in *wh*-structures involving *combien*. Consider (37).

(37) a. Combien de fautes a-t- elle fait**es**?
b. Combien de fautes a-t- elle fait?
how many mistakes has she made? (Fem, Pl) /-

In the agreeing case a set of specific typical mistakes is presupposed, while there is no such presupposition in the non-agreeing case, at least not necessarily.

The two interpretations can be linked to different syntactic positions: the presuppositional (D-linked) interpretation to a VP-external one, the non presuppositional (non-D-linked) one to a VP-internal one. [24] In the spirit of the discussion in section 4.2, a possible interpretation of the contrast could then be the following. Assume that the *wh*-moved direct object is marked with structural accusative case in (37a) and with inherent case in (37b). Assume furthermore that the inherent case, which is available VP internally by assumption, is only compatible with weak, non-presuppositional, indefinite objects, while no such limitation constrains structural accusative case, which is assigned and checked in some functional projection outside the VP projection. The contrast in (37) is then directly accounted for. In the derivation of (37b) the inherently case-marked object does not trigger agreement in its passage through the Spec of the past participle agreement projection on its way to the CP area, as is generally the case with inherently case-marked phrases in French; in (37a) the direct object does not carry inherent case, but structural accusative case, hence in its passage through the same Spec position it does trigger agreement.

As discussed in section 2, agreement is usually optional in *wh*-constructions in French. This also implies that a structurally case marked *wh*-object can avoid triggering agreement. Hence, lack of agreement can derive from two distinct factors: either from inherent case marking or from optional agreement with an accusative case marked indefinite object. This in turn implies that the presuppositional interpretation, only compatible with accusative case, can also be available in the non-agreeing form. Obenauer's data confirm this prediction. As noted above, the presuppositional reading is not impossible also in the non-agreeing form.

5 Conclusion

A crucial observation concerning the phenomenon of past participle agreement in Romance is that no variety allows the past participle to agree with the subject of intransitive/unergative and transitive verbs. This fact is illustrated in (38) with Italian examples.

(38) a. *Maria ha parlata.
Maria has spoken (Fem, Sing)
b. *Maria ha letta un bel romanzo.
Maria has read (Fem, Sing) a nice novel

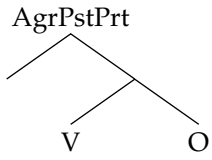
Any treatment of the computation involved in past participle agreement must account for this fact. In particular, any account should explain the difference between the impossible cases in (38) and all the possible cases discussed so far.

Following Burzio's original fundamental insight, the appropriate generalization seems to be that past participle agreement involves arguments belonging to the lowest level of the VP projection, typically the direct object (on the agreement

cases involving indirect object reflexive clitics as in (13), see below). It does not involve external arguments (in Williams's original 1981a terminology which, taken literally, is not appropriate once all arguments are projected VP internally, given the VP internal subject hypothesis of Koopman and Sportiche 1991b). The external argument is in fact the argument which is merged as the highest one within the VP (Chomsky 2000, 2001b). In what follows, a possible line of explanation of this fundamental pattern is suggested.

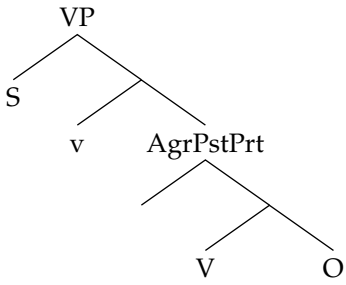
A straightforward way of excluding the highest VP argument (S) of intransitive/unergative and transitive verbs from triggering past participle agreement consists in assuming that this argument cannot pass through the Spec position of the past participle projection (on its way to the preverbal subject position). The most direct way of excluding this possibility, in turn, is to assume that this is so because the relevant agreement projection is located in a position lower than the base position of S. This amounts to claiming that the relevant agreement projection is in fact VP-internal. According to this hypothesis, past participles always correspond to unaccusative and passive structures: they are VPs with no external argument (not including the argument which is merged last). The idea is schematized in (39) (where the label O stands for the typical internal argument, i.e., the direct object).

(39)



The internal structure of an intransitive/unergative or of a transitive VP should correspond to a projection along the lines of (40).

(40)



Only O, the argument merged first filling a low position within the VP, has access to the specifier of the past participle projection in its movement(s). The hypothesis schematized in (40) directly derives the basic data presented in section 2 as well as the impossibility of (38), with the supplementary assumption that, systematically in standard Italian and less so in other Romance languages,

the auxiliary *essere* selects projections like (39), *avere*, those illustrated by (40) (on sentences involving impersonal SI, see below).[25]

Some of the data in section 2 require more discussion. Consider structures involving a reflexive clitic like (6), repeated in (41).

(41) Mi sono guardat**a** allo specchio.
myself (Refl, CL) (I) am watched (Fem, Sing) to the mirror
'I have watched myself in the mirror.'

Here, agreement is obligatory. The idea of relating this agreement to movement of the direct object reflexive clitic as in standard clitic constructions leaves its obligatoriness unexplained. It contrasts with the general optionality of past participle agreement with first- and second-person clitics in Italian, noted in section 2 and discussed in section 3.2. Hence, past participle agreement in (41) must be due to the reflexive nature of the construction. Following the spirit of one of Kayne's original proposals, it can be assumed that reflexive clitics are generated outside the VP projection (possibly as a kind of agreement marker within the clause functional structure). Structures like (41) can then be considered on a par with unaccusative structures: what actually moves here is not the clitic, but the internal argument of the unaccusative construction (in this case a silent first-person singular pronoun with feminine reference). The same analysis would be used for unaccusative structures involving an inherent reflexive.

Now consider structures containing a reflexive (indirect object, benefactive) clitic and a full direct object, like those in (13), repeated here in (42):

(42) a. Maria si è lavat**a** i capelli.
Maria (to) herself is washed (Fem, Sing) the hair
'Maria has washed her hair.'
b. Maria si è lett**a** questo libro.
Maria (to) herself is read this book
'Maria has read this book.'

The VP in (42) is transitive, projected as in (40). The reflexive clitic (indirect object, benefactive) is generated outside the VP as in the preceding discussion. But suppose that a further Agr projection above the transitive VP is selected in these cases.[26] Now, when the subject *Maria* moves out of the VP to reach the preverbal subject position in the high portion of the clause structure, it passes through the specifier of the further, higher (past participle) Agr projection and triggers past participle agreement. According to this proposal, past participle agreement is triggered here by movement of the subject, not of the reflexive clitic (a necessary conclusion, given the assumed line of analysis for reflexive clitics). The object does not move in this case. When the object moves, e.g., to cliticize, past participle agreement is triggered in the lower agreement projection:[27]

(43) a. Maria se li è lavat**i**.
Maria (to) herself them (Masc, Pl, CL) is washed (Masc, Pl)
'Maria washed them.'
b. Maria se lo è lett**o**.
Maria (to) herself it (Masc, Sing, CL) is read (Masc, Sing)
'Maria has read it.'

Note that in order to exclude the impossible examples of (25) of section 3.4, projection of the further past participle agreement projection above VP should not be allowed with impersonal (non-passive) SI, even if *essere* is the selected auxiliary. If movement of a null subject (linked to SI) from the highest merged VP-internal position to the preverbal subject position is at work, as seems natural to assume, if the further higher agreement position were made available, past participle agreement would be expected, contrary to fact. Consider now that impersonal (non-passive) constructions corresponding to (25) involve the subject clitic *on* in French which does not require selection of auxiliary *être*, contrary to the various instances of *se* (*se moyen*, reflexive; see chapters 42 and 56). This may be relevant for the Italian paradigm. It suggests that *essere* with impersonal (non-passive) SI in standard Italian is more akin to *avere* than to *essere* of structures involving true reflexives as those in (41) and (42).[28] Hence, only in the latter case should the further higher past participle projection be activated. On the strict relation between auxiliaries *avere* and *essere*, see Kayne (1993a); see also Cocchi (1995), Vikner and Sprouse (1988).

The (tentative) proposal sketched here has a feature which deserves some closer discussion. In current treatments of past participles, the agreement projection related to the past participial morphology is generally assumed to be (immediately) outside the VP projection. In the proposal outlined here, it may be located in the lexical projection of V.[29] This allows a simple account of a complex pattern. Is the assumption plausible and well grounded? At this stage we can only speculate. Let us assume that the plausibility of such a low location of the past participle agreement projection could come from the consideration that the past participle typically constitutes part of the periphrastic passive morphology in Romance. Keeping the focus on standard Italian and French, passive morphology involves auxiliary *essere/être* + past participle. It is not unreasonable to identify the passive past participle projection with (or at least strictly to link it to) the projection of a Voice head (cf. Sportiche 1996b and Cinque 1999 in particular). Cinque (1999) proposed that the Voice projection is located in a very low position in the clause structure; it may be the lowest functional projection in the functional architecture of the clause, possibly VP-internal. Interesting empirical evidence indicating the low location of the passive voice/past participle is provided by contrasts like the one in (44), presented in Cinque (1999) (see also chapter 4).

(44) a. Hanno **accolto bene** il suo spettacolo solo loro.
(they) have received well (the) his show only they
'Only they received his show well.' (Cinque (1999, (79a), (102))

b. *Hanno **bene accolto** il suo spettacolo solo loro.
(they) have well received (the) his show only they
(Cinque (1999, (79b), (102))

c. Questo genere di spettacoli è sempre stato **bene accolto**.
this kind of show is always been well received
'This kind of show has always been well received.'

Following Cinque's insight, the contrast in the relative order of the past participle and the low adverb *bene* in (44a) (active) and (44c) (passive) indicates that the passive past participle can remain low in the structure, lower than the active one.[30] The reason for that could be that the passive past participle does not (have to) move higher than the low Voice head. The proposal outlined in this section identifies the passive voice/past participle with the structure in (39). No further landing sites are available for the lexical verb. Active past participles necessarily involve more structure, at least as much as in (40); hence the verb moves higher in an active past participle anyway.

NOTES

1 To the extent that agreement is also seen as possibly a long-distance process (Chomsky 2001b), the relevant Agr positions should be identified with (some of) those filled by V+agr features. In this chapter I will not attempt to translate the more traditional, Kaynean, approach into the long-distance procedure.

2 See Burzio (1986) for the first systematic presentation and account in GB terms of the Italian and French paradigms, linking the presence of past participle agreement to the geometry of the tree requiring and/or allowing it in the presence of an antecedent–trace relation between the moved agreeing argument and its original position within the VP. Part of more recent accounts inspired by Kayne's approach, summarized in section 1, preserves Burzio's intuition, which was phrased within a functionally impoverished clause structure. See in particular Sportiche (1998: ch. 3) for a thorough development of Kayne's approach; see also Perlmutter (1989) and La Fauci (1994) for treatments of the phenomenon of past participle agreement pursued in Relational Grammar terms, and, for a fine-grained typology in the same perspective, taking into account different Romance languages, Loporcaro (1998).

3 Both under cliticization and under passive morphology, past participle agreement is preserved with complex predicates as those arising from causativization and restructuring (Rizzi 1982a, Burzio 1986, Guasti 1993 among others, and chapter 13).

(i) Maria è stat**a** fatt**a** assumere.
Maria has been made(Fem, Sing) to assume

(ii) Mario li ha volut**i** conoscere.
Mario them (cl) has wanted (Masc, Pl) to know

As for the interaction of agreement and unaccusatives in restructuring contexts, consider the following contrast, discussed in Burzio (1986):

(iii) a. Noi avremmo volut**o/*i** andare.
we would have wanted/*Masc, Pl) to go
b. Noi saremmo volut**i/*o** andare.
we would be wanted(Masc, Pl)/*- to go

In (iiib) restructuring has taken place, as signalled by use of *essere* as an aspectual auxiliary with the matrix verb *volere* (taking *avere* otherwise), conditioned by the presence of the unaccusative *andare* in the embedded infinitival. Past participle agreement is consequently obligatory as it usually is with unaccusatives.

4 The gloss 'nonagr' here stands for non-agreeing. The non-agreeing form of the past participle also corresponds to the masculine singular ending. Thus, a sentence like (4a) is grammatical if the clitic is a masculine singular third-person pronoun. The past participle ending is then interpreted as masculine singular.

5 Normative grammars indicate agreement as obligatory in both cases, which in fact appears to be optional in colloquial French (with some possible consequences in the interpretation to be discussed in section 4.3).

6 On ASC, see Belletti (1990, 1992), Kayne (1989a), and Belletti (1999b) in the context of the discussion of cliticization and enclisis. See also Egerland (1996), who studies the construction in old Italian, where it was more widespread with partially different properties, probably due to presence of a richer functional structure, as in Egerland's account.

7 With the difference between Italian and French according to whether the relation is established in every single past participle projection including those of the auxiliaries (Italian) or not (French) (cf. (3) and (9)). The difference could stem from an impoverished functional structure of the French past participle projection for auxiliaries. The question would then be whether this difference relates to other differences between the two languages. See Burzio (1986), who relates it to the differences in the selection of the aspectual auxiliary, and, more recently, Richards (1998).

8 This is compatible with Sportiche's (1996b) indirect-movement analysis of cliticization, where the moving element is not the clitic projection generated in the final clitic position, but a silent *pro* agreeing with it originating in the argument position inside the VP.

9 Hence, Italian would also manifest an amount of optionality in verb movement, normally obscured and undetectable in other domains. Given the proposed account, one might expect to find different distributions in the location of some adverbs according to whether past participle agreement occurs or not with first- and second-person clitics. However, differences do not appear to be detectable. It seems likely that agreement projections in general should not contain adverbial modifiers internal to the projection, as they should not count as possible modification domains. The idea that first- and second-person clitics could be higher in the Agr past participle internal structure can be supported indirectly by the observation that they are usually more external (hence, higher) than third-person clitics in clitic clusters. Compare the examples in (i) and (ii).

(i) Mi/ti ci manda.
to me/you (CL) there (CL) (he) sends

(ii) Ce lo manda.
there (CL) him (CL) (he) sends

See also Zanuttini (1997) for converging evidence from Italian dialects showing the different distribution of negation and first- and second-person clitics, on one hand, displaying the order Cl+NEG, and third person clitics, on the other, displaying the order NEG+Cl.

10 DP movement with passives and unaccusatives gives rise to obligatory past participle agreement in French. Possibly, there is a low DP-related position internal to the past participial projection that DPs pass through (but not necessarily clitics); the verb should be taken to move to the head of this position obligatorily in French as well. This position could be the same that quantified noun phrases must pass, given the obligatory nature of past participle agreement under quantifier floating combined with cliticization, detected by some speakers of French:

(i) Il les a tout**es** pris**es**/*-.
he them (Fem, Pl, Cl) has all (Fem, Pl) taken (Fem, Pl)

In this case, the usual optionality of past participle agreement under cliticization would otherwise (surprisingly) be suspended. Hence, there seems to be a portion of obligatory V-movement with the non-finite past participle in French as well. This portion concerns a very low area, possibly the lowest in the past participial projection.

11 Déprez (1998); Sportiche (1998: ch. 3), Rizzi (2000b). In Kayne (1989a) a different assumption is made which will be partly reviewed in section 4.1.

12 See the discussion in Lepschy and Lepschy (1977), Kayne (1989a), and the overview in Loporcaro (1998). Past participle agreement with (apparently) unmoved direct objects is also attested in early stages in the acquisition of standard Italian (cf., in particular, Antinucci and Miller 1976, Borer and Wexler 1992, McKee and Emiliani 1992, Schaeffer 1996).

13 It could be a perfective aspectual head with enough morphological attracting capacity. See section 5 on that and the presentation of Cinque's (1999) evidence, possibly relevant in this respect.

14 Cf. Richards (1998) for a suggestion on past participle agreement which seems to exclude the possibility of languages of the latter kind in principle, possibly not a desirable conclusion. The picture could also be more complex in that object agreement does not necessarily seem to correlate with agreement under overt syntactic movement, e.g., wh-movement. See Kayne (1989a) and his reference to Calabrese's judgments on Salentino, and Miremont (1976) on Occitan. Kayne (2000: ch. 8) observes that optionality of agreement with first- and second-person clitics becomes almost impossibile under restructuring. In the spirit of the hypothesis suggested in the text, this could indicate that modals have a less richly articulated past participle functional structure. See Kayne (2000) for a different proposal.

15 The construction has several peculiarities which are not all relevant here. See the references quoted, and also the discussion in Kayne (1989a) and the observations in Cinque (1990b).

16 See Belletti (1992) for an implementation of this idea according to which accusative case would here be assigned through agreement. The hypothesis can be phrased in the following terms. The past participle morphology blocks the case assignment ability of V; the direct object is then case-licensed through agreement. In full clauses containing a (transitive) auxiliary and a past participle, a crucial role in the assignment of accusative case should then be attributed to the auxiliary, which accounts for lack of obligatory past participle agreement. When the direct object is a clitic, past participle

agreement in ASC takes place as it always does in full clauses. However, the clitic is an enclitic on the past participle in ASC (cf. (16)), contrary to full clauses, where it is a proclitic on the auxiliary. This indicates that further processes are at work in ASC; see Belletti (1999b) for discussion on enclisis and proclisis in this area.

17 Compare section 3.3 for object agreement and the cases of agreement under cliticization and *wh*-movement discussed in section 3.1 and section 3.2 for cases of the former type. Compare the Altamura dialect, described in Loporcaro (1998), for cases of the latter type.

18 See Belletti and Rizzi (1996b), Déprez (1998) Sportiche (1998: ch. 3); section 3.2, n. 11.

19 Compare Icelandic, where agreement never arises with quirky subjects. But see the parameterization hypothesis below.

20 There seems to be some variation among speakers as to the impossibility of past participle agreement in (29). Some speakers allow agreement here. This might suggest that *en* is not necessarily taken to realize (partitive) inherent case by these French speakers. It could be analyzed as a possible realization of (structural) accusative as well. Note that no variation is ever found among Italian speakers in this domain.

21 Under Belletti and Rizzi's (1988) analysis the object of this class of psych verb is inherently case marked with accusative case. Interestingly, when the verb *surprendre* is used in its non-psych interpretation but as a regular transitive verb with the object marked with structural accusative, past participle agreement becomes possible again:

(i) Cette fille, le proviseur l'a surpris**e** en train de fumer.
this girl, the director her (cl) has surprised (Fem, Sing) while smoking
'The director surprised the girl while she was having a smoke.'

As for the impossibility of agreement with *falloir* (cf. (27c)), the account implies that the accusative available with this verb is an inherent accusative (cf. *Il me* le *faut*). A plausible assumption, since *falloir* would otherwise constitute an isolated exception to Burzio's generalization.

22 See Kayne and Pollock (2001) for a new analysis of this type of structure, where *au conflit* is taken to fill the subject position (as a quirky subject) and no (covert) expletive is assumed to be present. The proposal is framed within the general analysis of Stylistic Inversion (SI) as involving Remnant IP movement across the (here quirky) subject. As J. Y. Pollock has pointed out (p.c.), past participle agreement becomes possible in SI sentences similar to (33) if the postverbal subject is made heavier:

(i) Le jour où a èté mise au conflit la fin que tout le monde esperait.
the day where has been put to the conflict the end that everybody hoped

Note that the postverbal subject *la fin* contains an overt definite determiner. I take this to suggest that it should not be analyzed as being inherently case-marked. Agreement here could follow from the familiar mechanisms discussed, that is, the heavy DP moves from the original object position to the preverbal subject position where it is assigned nominative case, as in regular passive structures. The processes at work yielding SI structures would then take place (e.g., Remnant IP movement across the subject as in Kayne and Pollock 2001; but note that here *au conflit* would not be treated as a quirky subject). As the noun *fin* is inherently case marked in the idiomatic

reading, no past participle agreement should take place anyway in (33) (regardless of the adopted analysis of SI). Note that no improvement is brought about by heaviness in subject inversion structures containing expletive *il*. Compare (32) with the equally bad (ii):

(ii) *Il arriveront trois des plus belles filles que j'ai jamais rencontrées.
it will arrive (Pl) three of the most beautiful girls I have ever met

In the analysis adopted here, this is due to the fact that the postverbal subject has access only to inherent (partitive) case marking in these structures.

23 It could realize a KP level; see, e.g., Giusti (1993). A possible partially different implementation of the parameterization proposal could focus on the way in which inherent case is realized in Italian and French. It could systematically be a PP in French (with an empty P) and a NP or DP in Italian, explaining lack of agreement in French. This implementation could receive support from the fact that partitive case involves the presence of the preposition *de* with the indefinite quantifier *beaucoup*, which could be the overt trace of a general PP realization. This alternative is left as an open option here.

24 This adapts part of the spirit of Déprez's (1998) discussion, formulated in terms of different sites of reconstruction for the two *wh*-phrases, with the agreeing one being reconstructed outside the VP and the non-agreeing one inside it, assuming Diesing's (1992b) Mapping Hypothesis.

25 In the dialect referred to in n. 17, *avere* too should be allowed to select a past participle like (39). A possible characterization of French, where *avoir* is often the auxiliary with unaccusatives, and past participle agreement is nevertheless never realized in these cases, could be that a whole VP projection is always selected by *avoir* and that the nominal argument fills the highest (Spec) position of the VP projection. Hence, in its move to the preverbal subject position it does not pass through the specifier of the past participle projection. The difference with respect to intransitive VPs should stem from the fact that the argument in this case must be assumed to fill this highest position derivatively, after moving from the VP internal (object) position. This is the source of the unaccusativity of the VP. Crucially, the assumption should be that this movement be presyntactic or lexical (Hale and Keyser 1993a). As for Spanish, which lacks past participle agreement under cliticization, *wh*-movement, and with unaccusatives, and which does not have auxiliary alternation (Lois 1990) it could be assumed that the AgrPstPrt projection is altogether absent VP-internally. Interestingly, past participle agreement is manifested in Spanish only with the passive auxiliary *ser*, which, in the spirit of the proposal sketched out here, should select a past participle analyzed as in (39).

26 This could be linked to the presence of *essere*, which is always the designated auxiliary in structures involving a reflexive clitic.

27 Note that the ungrammaticality of (i), also pointed out in Burzio (1986), could be due to a violation of strict cyclicity under the proposed account:

(i) a. *Maria se li è lavat**a**.
(Maria (to) herself them (CL) is washed (Fem, Sing)
b. *Maria se lo è lett**a**.
(Maria (to) herself it (CL) is read (Fem, Sing)

Movement of the subject (activating the upper agreement projection) should be completed before object cliticization (which activates the lower agreement projection). This could provide a reason for the hierarchy of past participle agreement suggested and left unexplained by Burzio (1986). Furthermore, some principle of morphological well-formedness should be assumed to rule out the possibility of activating the higher Agr projection with different phi-features than the lower one, when the latter is activated (i.e., through object movement). Thus, a derivation not violating strict cyclicity would be ruled out by the principle of morphological wellformedness as well. The principle should be restricted to operate within the set of Agr heads belonging to the same morphological checking domain, here the domain of AgrPstPrt heads.

28 This amounts to assuming that both the impersonal and reflexive constructions determine the selection of *essere* in Italian, independently of the shape of the past participial projection.

29 This idea shares some similarities with the proposal in Collins and Thráinsson (1993), which also assumes an Agr-type projection generated VP-internally. However, the kind of Agr projection is different in the two cases. In Collins and Thráinsson it is crucially related to case assignment/checking; in the proposal in the text it is assimilated to Voice, see further the main text.

30 According to Cinque's proposal this must be related to a perfect head, located higher in the clause functional structure. This is compatible with the hypothesis in the text, although not necessary. A movement of the same sort should be allowed, without it being obligatory, also for the passive past participle if the also possible order in (i) is to be derived through V-movement:

(i) Questo genere di spettacoli è sempre stato **accolto bene**.
this kind of show is always been received well

5 Where does the NSR apply?
6 Conclusion: some final remarks

1 Introduction

It has been observed that in many languages of the world there is a correlation between prosodic prominence and the informational structure of the sentence. Much current work attempts to determine the laws that govern this correlation. Although we have made some progress, a lot remains unknown factually and therefore our understanding of the phenomenon is still precarious.

On the factual side, the difficulty lies in the nature of the data itself. Much of it is based on introspective judgments. Although this is common practice in linguistics, it is not without problems, especially in the area under discussion, which consists of native speakers' intuitions about the contextual appropriateness of a sentence with a certain prominence pattern. The delicate nature of the judgments is twofold. On the one hand, within impressionistic phonetics, the level of stress of a vowel in a given utterance can be a rather elusive feature. It is certainly a difficult feature to identify in complex utterances. It has no unique correlate, such as pitch level, vowel duration, amplitude, or a combination of these.[1] And while speakers are generally good at identifying the syllable with the highest pitch, they often lack linguistic awareness of the other acoustic properties. As it turns out, the perception of relative prominence is really bound to the perception of the groupings determined by the surface structure of the utterance.[2] The particular difficulty in the case of the association of stress with focus is that the information structure of the utterance is only partially governed by the rules of syntax. Thus, the determination of stress as a function of the information structure of the utterance or vice versa does not have the automatic character that its determination as a function of constituent structure has (see n. 2).

The second problem with judgments concerning the appropriateness of a certain prominence pattern is that it is very hard to control for context. Strictly speaking, there is no context-neutral sentence because speakers tend (un)consciously to add background information. In other words, speakers tend to provide a context for isolated sentences because this is the way that they are naturally used. Furthermore, we need to elucidate which aspect of the relation between prosodic prominence and informational structure is grammatically relevant. Numerous disparate notions and much terminology have been brought to bear on this issue (for a review, see Vallduví and Engdahl 1996), sometimes giving this area an aura of confusion.

Despite the above shortcomings and while awaiting new experimental tools better to elucidate the facts and define the object of study,[3] there are some preliminary core data which have given rise to interesting questions and theoretical debates. The present chapter intends to discuss some of these.

2 The relation between phrasal prominence and the focus structure of the sentence

Let us begin by briefly defining the notion of focus (on the notion of focus, see Chomsky 1971; Jackendoff 1972; Szabolsci 1981b; Rooth 1985; Rochemont 1986; Kiss 1998; among others). According to Chomsky and Jackendoff, the sentence is partitioned into two complementary parts, the presupposition and the focus. The focus is then understood to be the non-presupposed part of the sentence. The most reliable (although not infallible) test that we have at our disposal to determine the partitioning of the sentence into focus and presupposition is the question–answer pair.

In a question like *What happened?*, the presupposition is that there is an *x*, *x an unspecified event*, *such that x happened*. Roughly speaking, the *wh*-phrase in the question stands for the focus variable and the corresponding answer provides a value for that variable.[4] This is illustrated by the examples below, where the focus is the material contained within brackets. In (1), the focus is the TP, in (2), the focus is the VP, in (3), it is the DP object, and in (4), the DP subject. We use the term wide focus for the largest focus structure, namely (1) below, and narrow focus for all others, namely (2–4).

(1) Q. What happened?
A. [$_{TP}$ The cat in the blue hat has written a book about rats].

(2) Q. What did the cat in the blue hat do?
A. The cat in the blue hat [$_{VP}$ has written a book about rats].

(3) Q. What has the cat in the blue hat written?
A. The cat in the blue hat has written [$_{DP}$ a book about rats].

(4) Q. Who has written a book about rats?
A. [$_{DP}$ The cat in the blue hat] has written a book about rats.

In general, then, one can adopt the following operational definition:

(5) In a sentence S = α *X* β, *X* is a possible focus just in case *S* would count as a felicitous answer to the question *Q* = *wh-X* $\alpha\beta$.

One must distinguish two types of focus: informational focus (i-focus) and contrastive focus (c-focus). It is the property of exhaustivity that distinguishes the two: an i-focus is non-exhaustive, while a c-focus is exhaustive. The above *wh*-fronted questions allow for answers with i-focus interpretation, while the clefted questions in French give rise unambiguously to a c-focus type.

(6) Q. C'est qui qui a écrit un livre sur les rats?
'It is who that wrote a book about rats?'
A. C'est [$_{DP}$ le chat] qui a écrit un livre sur les rats.
'It is the cat that wrote a book about rats.'

(7) Q. C'est quoi que le chat a écrit?
'It is what that the cat wrote?'
A. C'est [$_{DP}$ un livre sur les rats] que le chat a écrit.
'It is a book about rats that the cat wrote.'

The difference between the two types of focus with respect to exhaustivity can be seen in the following contrast:

(8) Q. Who wrote a book about rats?
A. [$_{DP}$ The cat] wrote a book about rats, and [$_{DP}$ the bat] did too.

(9) Q. C'est qui qui a écrit un livre sur les rats?
'It is who that wrote a book about rats?'
A. *C'est [$_{DP}$ le chat] qui a écrit un livre sur les rats, et c'est aussi [$_{DP}$ la chauve-souris].
'It is the cat that wrote a book about rats, and also the bat.'

Vergnaud and Zubizarreta (forthcoming) suggest that because contrastive focus is exhaustive in nature, it requires uniqueness of description. And it is precisely this requirement that is violated in the answer form in (9), since the focus value is given in two separate (conjoined) clauses (the second of which has undergone conjunction reduction). On the logical structures of i-focus and c-focus, see Vergnaud and Zubizarreta (forthcoming).

3 Phrasal prominence and informational focus (i-focus) in Germanic

3.1 The classic view: the Nuclear Stress Rule-based account (Chomsky 1971; Jackendoff 1972)

From the earliest work on focus, researchers have noticed that there is a correlation between the locus of main prosodic prominence and the focus structure of the sentence; cf. Chomsky (1971); Jackendoff (1972). Thus, a transitive sentence like (10a), with main prominence on the object, can have the DP object, the VP, or the TP as its focus, but not the DP subject. In other words, it is an appropriate prominence pattern in the discourse context (1–3), but not in context (4). The sentence in (10b), on the other hand, is only appropriate in the discourse context (4), i.e., the DP subject is unambiguously the focus in that sentence.

(10) a. The cat in the blue hàt has written a book about ráts.
b. The cat in the blue hát has written a book about ràts.

From such observations, Chomsky (1971) and Jackendoff (1972) concluded that a constraint like (11) was at work:[5]

(11) The focused constituent must contain the intonational nucleus of the intonational phrase, where the intonational nucleus is identified as the syllable that bears main phrasal prominence.

In the above-mentioned works, it was assumed that main phrasal stress is assigned by the Nuclear Stress Rule (NSR), as formulated by Chomsky and Halle (1968). This version of the NSR basically states that:

(12) The rightmost word-level stress of a phrase bears main stress within that phrase.

If a bottom up, cyclical application of the NSR is assumed, then the rule can account for both primary and secondary phrasal stress in examples like (10a). In this example, the NSR assigns phrasal stress to *hat* and *rats* at the DP cycle. It reapplies to the VP and TP cycles, assigning primary phrasal stress to *rats* and demoting the stress level on *hat* to secondary prominence (by convention). In the case of (10b), the constraint in (11) requires that the prosodic pattern be reinterpreted at the TP cycle, shifting main prominence to the DP subject and demoting NS on the DP object to secondary status.

The formulation in (12) raises a number of questions, which we consider briefly in the next section before continuing the discussion of (11).

3.2 Some general remarks on the Nuclear Stress Rule (NSR)

3.2.1 The algorithm

For the purpose of analyzing the formulation in (12), it will be convenient to adopt the terminology in Chomsky and Halle (1968). Accordingly, we shall call the main stress within some phrase α the primary stress within α. The next level of stress below the primary stress, we shall call secondary stress, etc. The formulation in (12) can be viewed as a rule applying to the surface structure of an expression and assigning relative prominence within all the phrases. Within the derivational framework assumed in Chomsky and Halle (1968), this could be done in one of two ways. The prominence assignment could be a one-step process, with the rule (12) applying to all the phrases in a simultaneous fashion. Call this the one-step algorithm. Alternatively, rule (12) could be defined as a cyclical rule applying in a bottom-up fashion, first to the smallest phrases in the structure, then to the next bigger ones and so on and so forth (see Chomsky and Halle 1968: ch. 2 and pp. 340–350 for discussion). Call this the cyclical algorithm. It is clear that the one-step algorithm will yield the right result for subordinate stresses only if, for each subordinate stress, it includes a device that registers the number of domains in which subordination takes place, some function of the depth of embedding. To illustrate, consider the structure in (13), where *t*, *u*, *v*, *w* are words and α, β and γ phrases:[6]

(13) $(_{\alpha}\ (_{\beta}\ (_{\gamma}\ t\ u)\ v)\ w)$

The neutral stress contour for (13) is the one in (14), where stress levels are indicated by numerals, with 1 representing primary stress, 2, secondary stress, etc. (following the convention adopted in Chomsky and Halle 1968):

(14) $t^4\ u^3\ v^2\ w^1$

To derive the contour in (14) by the one-step algorithm, it is necessary to have a counter that indicates the number of phrases containing each subordinate stress in (13). The formal difficulty arises from the conjunction of the two facts in (15):

(15) (i) A 'level of stress' is a feature (of words and, ultimately, of vowels or syllables).
(ii) A level of stress is relative to a phrasal domain. Thus, a given word-stress may at the same time be the main stress within a phrase β and a subordinate stress within another phrase α.

The cyclical algorithm provides an elegant resolution of the tension between (15i) and (15ii). In (16–17) we give the formulation put forth in Chomsky and Halle 1968 (see Chomsky and Halle 1968: 16–18):[7]

(16) Assign primary stress to a primary-stressed word w^1 in the context
$w^1 \ldots — \ldots]_\alpha$
where α is a nonlexical category

(17) When primary stress is placed in a certain position, then all other stresses in the string under consideration at that point are automatically weakened by one.

Rule (16) assigns primary stress to a primary-stressed vowel which is preceded by another primary-stressed vowel in a phrase α. Both rule (16) and convention (17) apply cyclically. The cyclical application of (16–17) to the structure in (13) yields a natural derivation of the contour in (14). Facts of this kind constitute empirical evidence in support of the principle of the transformational cycle, stated as follows in Chomsky and Halle:

(18) it is natural to suppose that in general the phonetic shape of a complex unit (a phrase) will be determined by the inherent properties of its parts and the manner in which these parts are combined, and that similar rules will apply to units of different levels of complexity. (Chomsky and Halle 1968: 15)

The conjunction of (16–17) and of the principle of the transformational cycle constitutes a particular formalization of rule (12). Recent work within the framework of the Minimalist Program suggests that the derivational history of a sentence and its constituent structure are really two alternative ways of analyzing the sentence; see Chomsky (1994), Epstein (1999). For concreteness, we shall postulate the following (see Freidin and Vergnaud 1999):

(19) The structural description of a sentence ω is an abstract analysis Ω which can be interpreted either as a derivational history or as a phrase marker.[8]

Assuming (19), we are led to conjecture that there should be a nonderivational correspondent to the cyclical derivational implementation of (12) above. In fact, the proposal in Liberman (1979) appears to be just that. This proposal requires that the notion of stress be generalized so that not only words (and phonemes), but also every lexical or phrasal category, will be marked for stress:

(20) 'Level of stress' is a feature of phonemes, words, and categories.

Given the more abstract notion in (20), the formulation in (12) can be replaced by that in (21), which is essentially the formulation of the NSR in Liberman (1979):

(21) The rightmost immediate constituent of a phrase bears main stress within that phrase.

The formulation in (21) should be construed as a well-formedness condition on surface constituent structure. Quite obviously, that condition must be supplemented by a convention that relates the level of stress of a category to those of its constituents, since stress is ultimately realized on words and, as a phonetic feature, on vowels (or syllables). Such a convention is provided in Halle and Vergnaud (1987), where it is defined in terms of the X-bar theoretic constructs 'head' and 'projection'. Specifically, one may postulate the following corres- pondence between the notion 'main stress' and the X-bar notion of head:[9]

(22) Given a category α, let $H_m(\alpha)$ be the category or word immediately dominated by α that has main stress within α. The interpretation of the abstract feature 'level of stress' is governed by the following convention:
For any category β that dominates α, the levels of stress of α and of $H_m(\alpha)$ within β are defined to be equal.
Correspondingly, $H_m(\alpha)$ is defined as the *metrical head* of α and α, as the *metrical projection* of $H_m(\alpha)$.

The 'head-of' and 'projection-of' relations defined in (22) are transitive in the following sense:

(23) Let α be a category with metrical head $H_m(\alpha) = \delta$. If δ is itself a category, then, by definition, the metrical head of δ $H_m(\delta) = H_m(H_m(\alpha))$ has the same level of stress as α in any category that dominates α.

Accordingly, the definitions of metrical head and metrical projection can be generalized by transitivity as in (24):

(24) Given a sequence $\alpha_1, \alpha_2, \ldots, \alpha_i, \alpha_{i+1}, \ldots, \alpha_n$ such that, for $1 \leq i \leq n - 1$, α_{i+1} is the metrical head of α_i in the sense of definition (22), $\alpha_{i+1} = H_m(\alpha_i)$, then α_n is defined to be a metrical head of α_1 and, correspondingly, α_1 is defined to be a metrical projection of α_n.

The conventions in (21–23), which account for the location of the main stress in each constituent, will in general fail to determine the hierarchy of subordinate stresses in a direct or complete fashion. It is instructive, in that respect, to compare the way these conventions apply to a left-branching structure such as that in (13) with the way they apply to a right-branching structure such as that in (25):

(25) John liked ET.

In the case of the structure in (13), the conventions in (21–23) fully determine the stress levels of all the words, yielding the contour in (14). But in the case of (25), these conventions, while assigning a subordinate stress to each of the two words *John* and *liked*, fail to define any relative ranking between them. Note that the transformational algorithm in Chomsky and Halle (1968) (see (16–17)) generates the contour in (26) below for (25), assigning more stress to *John* than to *liked* (see, for example, Chomsky and Halle 1968: 89–91 and Halle and Vergnaud 1987: 265).

(26) John[2] liked[3] ET[1]

It is of course an empirical issue whether a unique stress contour is manifested in the right-branching structure in (25) and, if so, whether that contour is the one in (26).[10] Since this chapter is concerned with the location of main stress within the sentence, in particular in relation to the information structure of the sentence, we will not consider any further the question of stress subordination.[11] But a few remarks on the nature of secondary stress are in order.

3.2.2 *Secondary stress and eurhythmicity*

Secondary stress (with the exception of echo accent discussed below) is fundamentally different from primary stress in that it is sensitive to factors such as length, a phenomenon known as eurhythmicity, rather than to discourse-related factors such as focus.[12] As an illustration of this phenomenon, see the examples below (due to Bruce Hayes, p.c.). There are two possible loci for the secondary stress: it may surface on the rightmost edge of the DP subject or specifier (as predicted by the classical NSR) or it may appear at the leftmost edge of the DP subject or specifier (contrary to what is predicted by the NSR). In the case of (27) the second option is preferred, while in the case of (28) the first option is preferred. It seems that the difference in preference between the two cases is due to the presence or absence of a break following the DP in question. More precisely, it is more natural to have secondary stress on the right edge of the DP if there is a bit of a break after it, but not otherwise. And it seems that it is more natural to have a bit of a break between the verb and its nominative subject than between the noun and its genitive specifier.

(27) a. nineteen hundred lìnguists' dógs
b. nìneteen hundred linguists' dógs

(28) a. Nineteen hundred lìnguists sáng.
b. Nìneteen hundred linguists sáng.

Note furthermore that a heavier VP has the effect of blocking secondary stress on the right edge of the DP subject, as shown in (29a). Again this is probably due to the fact that a longer VP calls for an obligatory break immediately following the subject.

(29) a. *Nìneteen thousand linguists sang the Marseilláise.
b. Nineteen thousand lìnguists sang the Marseilláise.

Main phrasal prominence, on the other hand, is never affected by factors such as length; it is only sensitive to discourse-related factors. If main phrasal stress falls within the DP subject (as is necessarily the case if the subject is the focus of the sentence), then phrasal stress within the DP is obligatory where the NSR predicts it should be, namely, at the rightmost edge of the phrase. In effect, while both options in (28) are possible as an answer to the question *what happened?*, only (30a) is possible as an answer to the question *who sang?*. Sentence (30b) is possible only if it is understood as introducing a contrast with some other number of linguists.

(30) a. Nineteen hundred línguists sàng.
b. Níneteen hundred linguists sàng.

For this reason, we will ignore secondary stress in this chapter, except when a secondary stress is of the echo-accent type.

In certain cases, secondary stress is an echo of the most prominent pitch accented syllable in the context question, and for this reason it is referred to as echo accent by Zubizarreta (1998). Secondary stress in (10b) as an answer to (4) (repeated in (31)) is a case in point. (We underline words with an echo accent, as well as their source in the context question.) The focus in the answer-statement in (31) is the DP subject; therefore main phrasal prominence falls within the subject. Secondary stress within the defocalized VP is in this case a remnant (or an echo) of primary stress in the context question.

(31) Q. Who has written a book about ráts?
A. [The cat in the blue hát] has written a book about ràts.

Note furthermore that:

(32) A word that bears an echo stress within a phrase is rhythmically subordinate to the word that bears a non-echo stress within the same phrase.

In fact, (32) follows from a more general intonational principle to be discussed below (see (49)). We can see that the echo accent in the answer part in (31)

originates in the NS of the context question because its displacement does affect the focus structure of the sentence. Thus, secondary stress in the answer part in (33) signals the c-focus status of *book*, as it does in the context question where it originates.

(33) Q. Who has written a BOOK about rats? (not a squib)
A. [The cat with the blue hát] has written a bòok about rats.

3.3 *Cases not covered by the classical view: in search of a new generalization*

While the classical formulation of the NSR accounts for the prominence patterns in (10), it fails to account for several others. As shown by Schmerling (1976), Gussenhoven (1984), Selkirk (1984, 1995), in Germanic (including English) not all cases of widest focus take a rightmost stress. We will review many of these cases in section 3.3. In fact, the version of the NSR in (12) even fails to account for some basic cases in German (and Dutch), namely, verb-final transitive structures where main stress falls on the direct object, rather than on the final verb:

(34) Hans hat ein Búch gelesen.
Hans has a book read

Note that if we can come up with a successful version of that rule, then we should be able to deduce the scope of the i-focus solely from the locus of the primary nuclear stress. Consequently, we would not need to annotate the syntactic structure with a focus feature. This would indeed be a desirable result to the extent that such a feature does not have any independent justification in the grammar. We will return to this point in the last section.

An NSR-based theory intends to account only for the relation between prominence and i-focus. Therefore, this theory must assume the existence of an independent phrasal stress rule that places main prominence on the c-focus constituent. This rule, generally referred to as emphatic or contrastive, not only serves to identify the c-focus, but also has metalinguistic functions such as correction; cf. *I said CONfirmation, not Affirmation*. The contention that c-focus is or can be identified by emphatic stress (generated by the emphatic stress rule rather than by the NSR) is justifiable on several grounds. Function words are invisible for the computation of the NSR (as we shall see in section 3.3) and NS never surfaces on a function word. On the other hand, contrastive stress can surface on a function word; cf. John *DID leave*. Furthermore, contrastive stress is always associated with an audibly higher pitch level than nuclear stress and it is strictly narrow in scope. Compare (4), with NS on *hat,* and (35), with contrastive stress on *blue* (as indicated by capitals).

(35) The cat in the [$_{\text{ADJ}}$ BLUE] hat wrote a book about ràts (not the one in the RED hat).

In what follows, we will center the discussion only on nuclear stress and its relation to the i-focus structure of the sentence.

3.3.1 Wide i-focus structures

Schmerling (1976) noted that phrasal prominence in Germanic is sensitive to argument structure. This point was further reinforced in work by Gussenhoven (1984) and Selkirk (1984, 1995). Typically, in non-V-final structures in German and in English, NS goes on the rightmost word irrespective of transitivity. See the examples below:

(36) a. Hans arbeitet an einem Papíer.
b. Hans is working on a páper.

(37) a. Hans arbeitet an einem kleinen Tísch.
b. Hans is working on a small táble.

(38) a. Hans arbeitet an einem Papier in seinem Zímmer.
b. Hans is working on a paper in his róom.

(39) a. Das Taxi kommt spät.
the taxi is-coming láte
b. The mail arrived láte.

On the other hand, in V-final structures, an approximate generalization that seems to emerge is that phrasal prominence is sensitive to the transitive–intransitive distinction and that within the intransitive class, the unaccusatives behave differently from unergatives. In German, in a transitive structure like the one in (34a), repeated below, NS goes on the direct object. (This form is non-existent in Modern English since this language is head initial.)

(40) Hans hat ein Búch gelesen.
Hans has a book read

Within the class of intransitives, we find that unaccusatives behave differently from unergatives. In unaccusative structures, NS falls unambiguously on the subject. Compare (41) with (39a).

(41) Das Táxi kommt.
the taxi is-coming

Although there are German speakers that have a preference for the verb in V-final structures to be unstressed (see more on this below), it appears that in the case of unergatives NS may go either on the subject or on the verb (in wide focus structures):

(42) a. Es heisst, dass ein Júnge gelacht hat.
it is-said that a boy laughed has.
b. Es heisst, dass ein Junge gelácht hat.

Compare (42) with the unaccusative example in (43), where NS falls unambiguously on the subject in wide focus contexts:

(43) Es heisst, dass ein Júnge kommt.
It is-said that a boy comes

Similarly, in English, Schmerling notes that unergatives (in V-final contexts) allow NS on the subject. But as noted by Selkirk and Gussenhoven, NS may also fall on the verb. Of course, this does not mean that both prosodic patterns are used in the same context. In effect, it would appear that some speakers have a preference for using the pattern in (44) in a surprise context or in order to highlight a certain aspect of the information being conveyed, namely, the subject of the action. The point is that both options are possible as an answer to *What is the matter?*, indicating that both prominence patterns are compatible with a wide focus structure. This shows that prominence has multiple discourse and grammatical functions, one of which is to prosodically identify the scope of the focus.

(44) a. The báby is crying.
b. The báby is laughing.

(45) a. The baby is crýing.
b. The baby is láughing.

On the other hand, in comparable structures with an unaccusative verb, NS falls unambiguously on the subject:[13]

(46) a. The máil arrived.
b. The sún came out.
c. My bág has disappeared.

Suppose we were to put aside the pattern of unergatives with initial stress (as in (44)). To account for the unambiguous initial stress in (46), we might capitalize on the fact that the surface subject in unaccusative structures is an object at a deeper level of representation.[14] But the data is in fact more complex, as noted in Gussenhoven. While NS is unambiguously on the subject in (46c), the presence of an adverb between the subject and the verb pulls the NS onto the verb:

(47) The dog mysteriously disappéared.

Another grammatical distinction that is relevant with respect to the computation of the NSR is the complement–adjunct distinction in V-final structures; cf.

Gussenhoven op.cit., Selkirk op.cit., and also Krifka (1984). This is illustrated by the following examples (from Krifka 1984, cited in Truckenbrodt 1993), in which a complement left adjacent to the verb attracts NS (see (48a)), but not an adjunct in the same position (compare (48b) with (37b)):

(48) a. Peter hat an einem Papíer gearbeitet.
Peter has on a paper worked.
'Peter worked on a paper.'
b. Peter hat an einem kleinen Tisch geárbeitet.
Peter has on a small table worked
'Peter has worked on a small table.'

As can be easily appreciated, the NSR in (12) does not cover the distinctions discussed above. That formulation of the NSR wrongly predicts main phrasal stress on the verb across V-final structures. Another problematic case for the NSR is that of wide-focus structures that contain anaphoric material. Anaphoric material is generally pronounced with a reduced pitch range, an intonational property that is often referred to as 'de-accenting'.[15] Furthermore, we have the general intonational property in (49) (due to Selkirk 1984, Gussenhoven 1984).

(49) De-accented material is perceived as less prominent than accented material.

It follows from (49) that main phrasal prominence cannot fall on anaphoric material in Germanic (unless it is contrastive). A few examples are given below, but see Gussenhoven (1984) for many more (de-accented material is highlighted with italics):

(50) Q: Mary walked in. And then what happened?
A: John kíssed *her.*

(51) Remember John? Have you héard from *him*?

(52) A bill was sent to Congress today by President Carter which would require peanut butter sandwiches to be served at all government functions. At a press conference today, a group of Senators led by Republican Barry Goldwater of Arizona denóunced *the measure*. (Ladd 1980)

Like anaphoric elements, defocalized material is also de-accented in Germanic. Therefore (32) also follows from (49). In effect, since echo accents are contained within defocalized constituents and given that defocalized material is pronounced with a reduced pitch range (i.e., it is de-accented), then it follows from (49) that an echo accent will be perceived as subordinate to an accent contained within the focused phrase.

In (50)–(52), as well as in (31), the NSR would have to appeal to an extra mechanism that shifts main phrasal stress to the left sister node. The problem is

that this solution misses an important generalization. As we will see in the next section, patterns with de-accented material by and large fall under the same generalization as other patterns. Appending the NSR with a mechanism that shifts stress to the left fails to account for this observation.

3.3.2 *Narrow i-focus structures*

The prosodic pattern of narrow i-focus structures follows the same generalization as the wide i-focus patterns. To illustrate this point, we will examine some examples from German (discussed by Höhle 1982). In the answer in (53), the DP subject *Karl* is defocalized; it is therefore de-accented (as well as the auxiliary *hat*, given its status as a function word). This example with narrow focus on the fronted DP object and the verb (*den Húnd geschlagen*) follows the typical pattern for transitives discussed in the previous section: main phrasal stress falls on the DP object.

(53) Q: What did Karl do?
A: Den Húnd *hat Karl* geschlagen.
the dog (ACC) has Karl (NOM) beaten

Of particular interest are the examples where the object is defocalized, as illustrated in (54). The pattern we see in the answer form A_1, with main prominence on the subject, suggests that transitive structures with a defocalized object behave like intransitives (more precisely, like unergatives). In effect, for speakers that dislike main prominence on the verb when it is in final position, this is the only pattern available (these are the same speakers that dislike (42b)). Such speakers allow prominence on the final verb only if the subject is anaphoric (i.e., if it has been previously mentioned) and is therefore itself de-accented. But, interestingly, there are speakers that lack this restriction. These speakers allow the pattern in (42b) alongside (42a) and they also accept the prosodic pattern A_2 in (54). Thus, although there are idiolectal differences, the data seem to be coherent.

(54) Q: Why is Hans happy?
A_1: Weil *ihn/Hans* ein Verwándter angerufen *hat*.
A_2: Weil *ihn/Hans* ein Verwandter ángerufen *hat*.

The following empirical generalization seems to emerge:

(55) Transitive structures with a defocalized object behave like unergative structures and not like unaccusative structures.

The above generalization is also supported by the following paradigm. Although some speakers strongly prefer for defocalized objects to undergo scrambling, others lack any strong preference. The latter allow the word order in (56), where the object is defocalized, and NS is either on the subject or on the verb:

(56) Q: What happened to the book?
A_1: Ich glaube, dass ein Júnge das Buch genommen hat.
I believe that a boy the book taken has
A_2: Ich glaube, dass ein Junge das Buch genómmen hat.

Note that the classical NSR (even if amended with a stress-shifting mechanism that moves NS to the left when it falls on de-accented material) cannot account for the difference in behavior between the different verb classes in wide focus contexts, nor can it account for the generalization in (55).

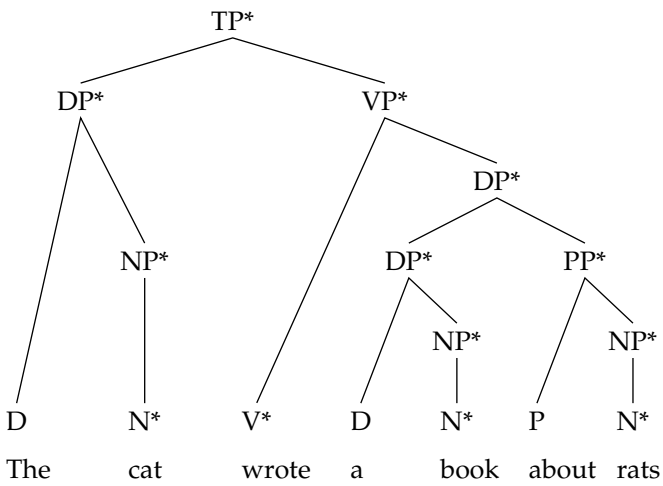
3.4 Cinque (1993)

Cinque (1993) puts forth a revised NSR that is both conceptually and empirically different from the classical NSR. Like the classical NSR, Cinque's theory assumes that the syntactic tree is the object on which the NS is computed. But his theory of phrasal stress is even more syntax-dependent than the original NSR. It is designed to capture the following basic generalization:

(57) NS falls on the most embedded element on the recursive side of the tree.

Cinque builds upon the metrical version of the classical NSR put forth by Halle and Vergnaud (1987). In a nutshell, like the classical NSR, the metrical NSR applies to the syntactic tree in a bottom-up, cyclical fashion and derives a metrical grid as output by assigning an asterisk to each syntactic node.

(58)



The most prominent word within a domain is the one that is dominated by the greatest number of asterisks. Like the classical NSR, *cat* is assigned NS within the DP subject domain and *rats* is assigned NS within the VP domain. We know

that *rats* is more prominent than *cat* and that this is achieved by the classical NSR by assigning main prominence to the rightmost category (this time at the TP cycle).

Cinque's theory, which is sensitive to depth of embedding (as encoded by the number of asterisks stacked up on a word), and not to linear order, needs yet another ingredient in order to account for the following generalization: irrespective of the degree of embeddedness within a specifier, main prominence is contained within the sister category of the specifier; cf. *The cat that chased the ràt won a príze*. To address this issue, Cinque introduces a distinction between major and minor paths of embedding and proposes that the algorithm be sensitive to that distinction. Informally, the major path of embedding within some tree *U* is the tree obtained by stripping *U* off all the specifiers and adjuncts in it. Thus, the major path of embedding within *U* is the connected set of categories which includes the head of *U* and is such that, if it includes a head *H*, it also includes the projections of *H* and the categories governed by *H* (in the sense of GB theory) together with their heads, but excludes the non-governed categories. Formally, the notion major vs. minor path of embedding is defined relative to a given maximal projection *XP* (or, equivalently, relatively to a given head *X*). To make explicit the relative character of the notion, we reformulate the definition in Cinque (1993) as in (59), where the clause in (i) defines the primitive notion and that in (ii) extends it by transitivity:[16]

(59) (i) Given some head category *X*, the major path of embedding with respect to *X* is primitively constituted by *X* and the projections of *X* together with the head of the complement of *X* and the projections of that head. The minor path of embedding with respect to *X* is primitively constituted by the head of the specifier of *X'* and the projections of that head.

(ii) Given heads *X*, *Y* and *Z* such that *X* belongs to the major path of embedding with respect to *Y*, whatever status *Y* has with respect to *Z* is extended to *X*: if *Y* belongs to the major (resp. minor) path of embedding with respect to *Z*, then, by extension, *X* is defined to belong to the major (resp. minor) path of embedding with respect to *Z*.

When there is no ambiguity, we shall refer to "the major (resp. minor) path of embedding with respect to *XP*" simply as "the major (resp. minor) path of embedding." The convention that Cinque (1993) postulates to account for the metrical asymmetry between the specifier and its sister is the following:

(60) **Convention:**
When the minor path joins the major path, the cycle corresponding to the minor path is visible in the form of one asterisk.

Cinque's algorithm delivers one very important result. Unlike the classical NSR, it is able to account for the presence of NS on the object in German V-final

transitive structures. In effect, the head of the complement phrase is more deeply embedded than the head of the verb phrase and therefore it is dominated by a bigger number of asterisks. But as it stands, Cinque's theory, like the classical NSR, fails to account for the data discussed in section 3.3.

3.5 Zubizarreta (1998)

This work is an attempt to meet descriptive adequacy while keeping alive the basic insight in Cinque's theory: NS falls on the lowest element in the (visible part of the) syntactic tree. We begin by presenting some basic assumptions about this analysis.

3.5.1 Some assumptions and a revision of the NSR

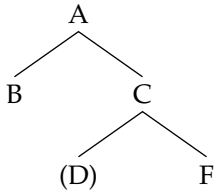
In the spirit of Liberman (1979), the NSR applies to sister nodes and it assigns relative strength to them (i.e., weak vs. strong); see (20–22) above.

NSR applies to a metrical interpretation of the syntactic tree, rather than to the syntactic tree itself. In other words, metrical sisterhood and syntactic sisterhood do not always coincide. The reason is that anaphoric, defocalized, and functional categories are pronounced with a reduced pitch range, an intonational property, which, as mentioned earlier, is referred to as de-accented. And as stated in (49), it is a fact that de-accented material is always perceived as less prominent than any accented material. Consequently, the algorithm that determines which element is the most prominent in the string can only apply to accented material. It therefore follows that:

(61) A syntactic category that fully dominates anaphoric or defocalized material, a functional word, or an empty category is invisible to the application of the NSR.

To illustrate, consider the following tree, where the parenthesized node (D) is metrically invisible because it dominates de-accented material. We then say that in this structure, C and F are metrically non-distinct. Therefore, B and F, as well as B and C, count as metrical sisters.

(62)



Based on the data discussed in section 3.3, the following approximate generalization is assumed. NS in V-final and non V-final structures in Germanic follow two distinct patterns (putting aside the cases of intransitives with NS on the verb, such as (45) and (47)):

(63) In V-final structures NS falls on the right-most selected visible element in the tree
In non-V final structures, NS falls on the right-most visible element in the tree.

Suppose we adopt the essential ideas on phrase structure proposed by Kayne (1994). First, syntactic trees are universally right-branching, i.e., they conform to the X-bar form $[_{XP}$ ZP $[_{X'}$ X^0 YP]]. Second, languages universally obey the Linear Correspondence Principle (LCA), a weaker version of which is given in Chomsky (1995c) and reads as follows:

(64) a. Given two constituents A and B, if A asymmetrically c-commands B, then every terminal node that A dominates precedes every terminal that B dominates.
b. A asymmetrically c-commands B iff. A c-commands B and B does not c-command A.[17]

It then follows that the right-most (visible) element in the tree is also the lowest one. As mentioned at the beginning of this section, Zubizarreta's analysis preserves the basic insight of Cinque's algorithm, in that NS attaches to the lowest (metrically visible) element in the tree. Embeddedness and ordering coincide, and for present purposes they are indistinguishable.

The ordering relevant for the notion 'lowest' may be defined along two distinct dimensions of the tree: either with respect to the subpart that defines selectional relations (giving rise to selectional ordering) or with respect to the constituent structure irrespective of selectional considerations (giving rise to asymmetric c-command ordering). For ease of exposition, we depart with respect to a number of details from the analysis in Zubizarreta (1998).[18] The notion of asymmetric c-command-ordering is defined in (64). Selectional ordering relative to some head *H* is then defined as the restriction of the asymmetric c-command-ordering to the set of constituents directly or indirectly selected by *H*:

(65) Let *H* be a head and let K_H be the set of constituents selected by *H* or a projection of *H*. Given two constituents C_i and C_j in K_H such that C_i asymmetrically c-commands C_j, then C_j is lower than C_i in the selectional ordering.

The NSR is then modularized in terms of these two types of orderings:

(66) **Revised NSR:**
S-NSR: Given two metrical sister-categories C_i and C_k in which one is selectionally dependent on the other, assign main prominence to the dependent category if it is the lowest in the selectional ordering.
C-NSR: Given two metrical sister-categories C_i and C_k, assign main prominence to the category that is lowest in the asymmetric c-command ordering.

Note that the context to which the S-NSR applies is a proper subset of the context to which the C-NSR applies. The S-NSR will then get a chance to apply only if it is ordered before the C-NSR (cf. the 'Elsewhere Condition' on the application of phonological rules put forth by Kiparsky 1973). It is therefore assumed that the order of application is as stated in (66).

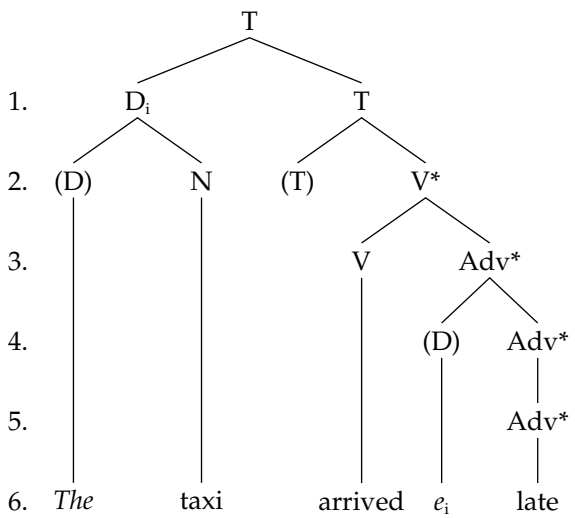
We have two tree structures: a metrical tree (which is the syntactic tree with the de-accented nodes omitted) and the full-fledged syntactic tree; see (62) above. When applying the NSR, one of the two structures, the metrical tree or the fully fledged syntactic tree, is selected and the ordering relations are assessed within the selected structure, and solely within that structure. It is suggested below that the cases of stress ambiguity (like (44–45)) are due precisely to this option.

In the next section we illustrate how the rule works with some of the basic examples discussed in section 3.3. As we shall see, the analysis sketched here accounts not only for the cases that fall under the approximate generalization given in (63) above, but also those that fall outside of it (such as examples (45) and (47)).

3.5.2 The basic examples

Recall that in non V-final structures, such as (36–39), NS falls systematically on the right-most element. Let us examine (39). As we have seen in section 3.3, the position of NS in unaccusative structures varies when other material such as adverbs is added on. The English example in (39) may be assumed to have roughly the structure below, where the parenthesized nodes are metrically invisible because they dominate de-accented or phonologically empty material. (The asterisks encode main prominence among metrical sisters, as assigned by the revised NSR. It is equivalent to the 'S' label in Liberman 1979.)

(67)

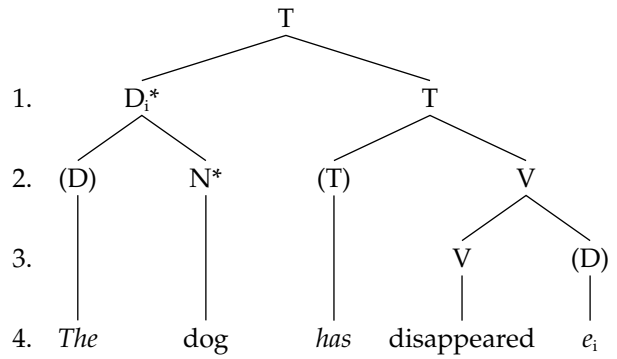


Consider a step-by-step (top-down) application of the rule (a bottom-up application would give the same result):

(i) D in line 1 and N in line 2 are metrically non-distinct. Therefore any rule application to D in line 1 extends to N in line 2. D and T are sisters but not selectionally related. Therefore, C-NSR applies, instead of the S-NSR. Since D asymmetrically c-commands T, T is assigned main prominence.
(ii) T in line 1 and V in line 2 are metrically non-distinct. Consequently, D in line 1 and V in line 2 count as metrical sisters. There is no selectional relation between them; therefore S-NSR fails to apply to these metrical sisters. Instead C-NSR applies and assigns main prominence to V in line 2, given that D in line 1 asymmetrically c-commands V in line 2.
(iii) V and Adv in line 3 are (metrical) sisters. There is no selectional relation, therefore S-NSR does not apply. Instead, C-NSR applies and assigns main prominence to the Adv since V asymmetrically c-commands Adv.
(iv) Since the Adv node in line 3 is metrically non-distinct from the Adv node in lines 4 and 5, V in line 3 counts as metrical sisters to Advs 4 and 5. Again, S-NSR fails to apply in each of these cases; C-NSR applies instead to the lowest node in the asymmetric c-command ordering, namely to Adv in lines 4 and 5.

Consider next the unaccusative structures without the adverb in final position. In this V-final unaccusative structure, NS falls on the subject (cf. (41)). The structure is as follows:

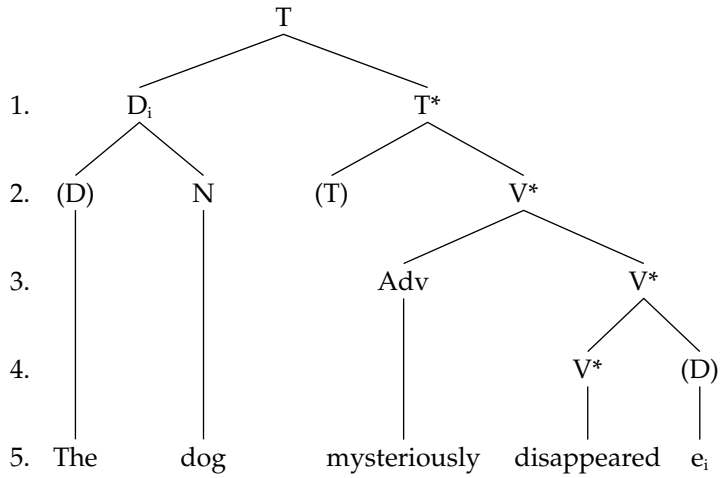
(68)



As before, D in line 1 and N in line 2 are metrically non-distinct. T and D in line 1 (and therefore N) are (metrical) sisters. Since T in line 1 and the Vs in lines 2 and 3 are metrically non-distinct, D in line 1 (and the N it dominates) function as a metrical sister of the Vs as well. Since these are selectionally related, the S-NSR applies and assigns main prominence to D (and N).

We now compare the above unaccusative structure with one which contains an adverb between the subject and the verb (cf. (47)):

(69)



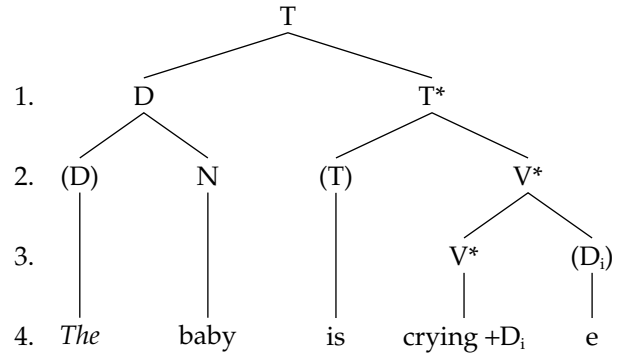
This metrical structure differs with respect to the previous one in a crucial way. The D in line 1 and the Vs in lines 3 and 4 are not metrical sisters. In this structure, D in line 1 and V in line 2 are metrical sisters but they are not selectionally related. Therefore, the C-NSR applies and assigns main prominence to V in line 2. Adv in line 3 is a metrical sister of the Vs in line 3 and in line 4 (the two Vs being metrically non-distinct). Again, since there is no selectional relation between the Adv and the Vs, the C-NSR applies and assigns main prominence to V.

The last two examples are very relevant to evaluate Cinque's system. The case of (68) is problematic because in that system we do not expect the minor path of embedding to receive NS. Recall that within that system the non-recursive side of the tree is visible only in the form of one asterisk. We could amend his system to account for this case by appealing to the presence of the subject's trace within the VP. In other words, we could say that the subject receives NS not by virtue of its surface position but by virtue of being a copy of the DP in object position, which is the most embedded node in the tree. But (69) shows that this cannot be the case. In effect, if the trace of the displaced object plays a role in determining the location of NS in (68), we would not expect the presence of a preverbal adverb to pull NS to the right, as is the case in (69). We conclude therefore that the notion of minor vs. major path of embedding is not the right notion to compute NS.

We turn next to the unergative structures. These are particularly challenging because NS may appear either on the subject or on the verb with a wide focus interpretation (e.g., (44) and (45)). Let us assume, following Hale and Keyser (1991), that unergatives are covert transitives. They have a cognate object which may be syntactically incorporated into the verb. Cf. *John slept* vs. *John slept a long sleep.* We show below that the NSR generates two distinct patterns in the case of unergatives depending on whether the full-fledged syntactic tree or the metrical tree (which is a subpart of the syntactic tree) is used to compute ordering.

If ordering is computed on the basis of the fully fledged syntactic tree, the trace of the cognate object that has been incorporated into the verb counts for the computation, more specifically it counts for the computation of selectional ordering. In this case, the pattern in (45) is obtained: NS falls on the verb.

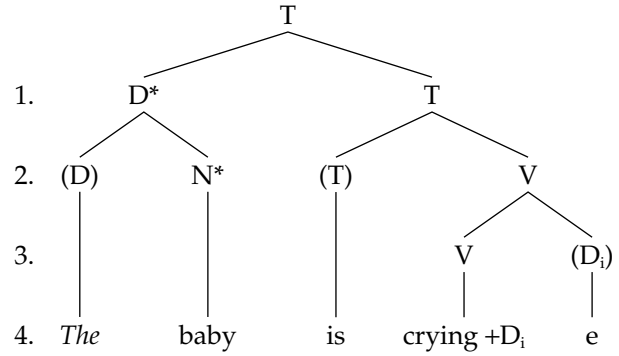
(70)



The computation in (70) proceeds as follows. As in the structures examined earlier, D and T in line 1 are sisters; C-NSR applies and assigns main prominence to T. T in line 1 is metrically non-distinct from the V nodes in lines 2 and 3. Therefore D in line 1 and the V nodes in lines 2 and 3 are metrical sisters. While D in line 1 and the Vs are selectionally related, D in line 1 is not the lowest element in the selectional ordering; D in line 3 is the lowest element in the selectional ordering. Therefore NSR fails to apply; C-NSR applies instead and assigns main prominence to the V nodes in lines 2 and 3, since these nodes are asymmetrically c-commanded by D in line 1.

If ordering is computed solely on the basis of metrically visible nodes, then the trace of the incorporated object does not count for the computation. The pattern in (44) is obtained: NS falls on the subject (as in the unaccusative structure in (68)).

(71)



In (71), as in (70), T in line 1 and the Vs in lines 2 and 3 are metrically non-distinct; D in line 1 and the V nodes are therefore metrical sisters. The two sets

of nodes are selectionally related. Given that the silent object is invisible to the computation, D in line 1 counts as the lowest selected node in the tree. The S-NSR therefore applies and assigns NS to it.

The analysis sketched above for English readily extends to German V-final and non-V-final structures. Recall that not all German speakers accept the unergative structure with NS on the final V-node; see the discussion with respect to (42a) and (42b). Given the above analysis, we can account for this idiolect by assuming that for such speakers ordering relations is unambiguously determined in terms of the metrical tree.

An interesting contrast that surfaces in German V-final structures and which is unavailable in English is the one in (48), repeated below.

(72) a. Peter hat an einem Papíer gearbeitet.
Peter has on a paper worked.
'Peter worked on a paper.'
b. Peter hat an einem kleinen Tisch geárbeitet.
Peter has on a small table worked
'Peter has worked on a small table.'

In (72a) the PP immediately preceding the lexical verb is selected by the verb and therefore the S-NSR assigns it main prominence. On the other hand, in (72b) the PP that immediately precedes the lexical verb is an adverb which bears no selectional relation with the verb. Consequently, the S-NSR does not apply; the C-NSR applies instead assigning main prominence to the verb, the lowest node in the asymmetric c-command ordering.[19]

3.5.3 Beyond the basic examples: the cases of narrow i-focus

The case of (53), repeated below, is straightforward.

(73) Q: What did Karl do?
A: Den Húnd *hat Karl* geschlagen.
the dog (ACC) has Karl (NOM) beaten

The subject that intervenes between the fronted object and the verb is metrically invisible. Therefore the fronted object and the verb are metrical sisters. The S-NSR applies and assigns main prominence to the object.

The case of (54) and (56) are more challenging. We repeat (54) below.

(74) Q: Why is Hans happy?
A_1: Weil *ihn/Hans* ein Verwándter angerufen *hat.*
A_2: Weil *ihn/Hans* ein Verwandter ángerufen *hat*.

In transitive structures where the object is defocalized, NS falls either on the subject or on the verb, as in the unergative structures examined earlier. Why should this be the case? The analysis of unergatives suggested above provides a

straightforward answer. Unergatives are covert transitive structures. And, as in the case of unergatives, if ordering is assessed on the fully fledged syntactic tree (including the defocalized object and its trace), then the S-NSR fails because the subject is not the lowest selected element in the tree. The C-NSR applies and assigns main prominence to the verb. Alternatively, if ordering is assessed with respect to the metrical nodes (which exclude the defocalized object and its trace), then the S-NSR applies. The subject is the lowest selected element in the metrical tree and is therefore assigned main prominence.

Recall that there is an idiolect of German that dislikes NS on the verb in cases like (74). As mentioned earlier, these seem to be the same speakers that reject NS on the verb in unergative structures like (42b) (unless the subject itself is defocalized). The same explanation applies in both cases. These speakers compute ordering relations solely on metrically visible nodes; therefore the subject will inexorably be assigned main prominence by the C-NSR in such structures.

4 A typologically different way of identifying the intonational nucleus: Bengali and Romance

We know that main phrasal stress plays a crucial role in identifying the intonational nucleus of the intonational phrase (or I-phrase) and that the intonational nucleus is the center around which the intonational contour is organized. The studies that assume the classical NSR, as well as some of those that have attempted to revise it (e.g., Cinque 1993, Zubizarreta 1998), have recognized that syntactic information plays a crucial role in the computation of main phrasal prominence (and therefore of the intonational nucleus) in the Germanic languages. But this does not seem to be universally true. A case in point is Bengali, described by Hayes and Lahiri (1991).

In Bengali, as in Germanic, the locus of NS plays a role in determining the possible scope of the focus. But the syntax does not play any direct role in the computation of NS (and therefore of the intonational nucleus). Instead, NS in Bengali is computed in terms of prosodic phrasing, which itself is constrained by the syntax (see further below).

In Bengali, there are two types of prosodic phrases, as identified by Beckman and Pierrehumbert (1986) for Japanese and English; the intermediate prosodic phrase (also referred to as phonological phrase or P-phrase) and the intonational phrase or I-phrase, mentioned earlier. The I-phrase is composed of one or more P-phrases. Hayes and Lahiri (p. 57) identify the following phrasal stress rules:

(75) **Bengali P-phrase stress:**
Within the P-phrase, the leftmost non-clitic word is the strongest.

(76) **Bengali I-phrase stress:**
a. A P-phrase bearing narrow focus receives the strongest stress of its I-phrase.

b. Under wide focus, the rightmost P-phrase within the I-phrase is the strongest.

Furthermore, Hayes and Lahiri show that:

(77) In Bengali a P-phrase boundary must be inserted at the right edge of the focused constituent.

Given (77), we may rephrase (76) as follows:

(78) Within the I-phrase, NS falls on the right-most P-phrase, the right edge of which must coincide with the right-edge of the focused constituent.

In the case of wide-focus structures and in the case of a narrow focused constituent in final position, NS will fall within the last P-phrase of the I-phrase. In these cases, the last phrasal stress will be the strongest. In cases where the narrow focused constituent is internal within the I-phrase, the NS will not be rightmost.

To repeat, in Bengali, the position of nuclear stress is not sensitive to syntactic structure; instead it is sensitive to prosodic phrasing. On the other hand, syntactic structure is relevant in constraining the formation of P-phrases. Hayes and Lahiri (p. 91) report that:

(79) a. Two constituents X and Y may be grouped into a single P-phrase only if X c-commands Y.
b. The verb, which is in final position, is phrased separately.

We may think of Romance languages as belonging to the same typological class as Bengali. But unlike Bengali, the P-phrase in Romance is not relevant for the computation of the NS. More precisely,

(80) In Romance, NS falls on the rightmost accented word within the I-phrase.

Zubizarreta (1998) shows that languages such as Spanish and Italian do not de-accent anaphoric and defocalized constituents. On the other hand, these languages (like Germanic and Bengali) comply with the focus–prosody correspondence principle in (11), which we repeat here:

(81) The focused constituent must contain the intonational nucleus of the intonational phrase, where the intonational nucleus is identified as the syllable that bears main phrasal prominence.

Zubizarreta (1998) argues that Spanish and Italian resolve cases in which (80) and (81) clash by movement (which she terms p-movement, meaning that it is a

type of movement that is prosodically motivated). More precisely, when the last constituent in the I-phrase is defocalized, the defocalized constituent is fronted in order for NS to be able to fall on the right-most constituent within the I-phrase, while complying with the requirement in (81). An example is provided below (where the focused constituent is the direct object). The canonical word order SVOPP is not acceptable in this context, as shown in A1 and A2. The focused direct object must appear at the right-most edge of the I-phrase to receive NS. For this reason the defocalized PP must be fronted, as shown in A3. Alternatively, the PP may be right-dislocated, in which case it is outside of the I-phrase, as shown in A4.[20]

(82) Q: Qué puso Juan sobre la mesa?
what put Juan on the table
'What did Juan put on the table?'
*A1: Juan puso el pán sobre la mesa.
Juan put the bread on the table
*A2: Juan puso el pan sobre la mésa.
A3: Juan puso sobre la mesa el pán.
A4: Juan puso el pán # sobre la mesa.

Note that the Germanic NS algorithm share something with the Bengali type system at a more abstract level. In Bengali and Romance it is the linear notion 'right-most' within the I-phrase that counts. In Germanic, it is 'being the lowest' within the syntactic tree or a subpart of it that counts. Interestingly, the LCA (stated in (64)) establishes that the phonological notion of right-most and the syntactic notion of lowest coincide. In fact, in Romance the rightmost node in the I-phrase and the lowest node in the asymmetric c-command ordering are indistinguishable. But why do Germanic and Bengali differ? Recall that in Bengali the focused constituent is obligatorily flanked by a P-phrase boundary. On the other hand, in English, as shown by Beckman and Pierrehumbert (1986) the focused constituent is not systematically followed by a P-phrase boundary. If that turns out to be the case for German as well, then we could advance the hypothesis that that is the source for the divergence between the two language types. More precisely,

(83) A system in which a focused phrase is not systematically flanked by a prosodic boundary computes prominence in terms of the syntactic notion of 'lowest', rather than in terms of its phonological counterpart, namely the notion of 'rightmost'.

Future research on prosodic prominence, prosodic phrasing, and their relation to syntactic structure should say whether or not (83) is on the right track. If (83) turns out to be correct, it would lend support to the hypothesis that rightmost and 'lowest' are the two sides of the same coin, as suggested by the LCA.

5 Where does the NSR apply?

It has been suggested above that there are two typologically distinct classes of language: one (like Germanic) in which the metrical interpretation of the syntactic tree is relevant in computing NS and another one (like Bengali and Romance) in which NS is computed strictly in terms of prosodic phrases. What can we infer from this conclusion regarding the locus of application of the NSR? Does it mean that NS applies within the syntax in Germanic and within the phonological component (or PF) in Bengali and Romance? While tempting, this conclusion cannot be correct under the standard assumption that PF and Logical Form (LF) are systematically mediated by syntax. First, as we have seen, prominence plays a fundamental role in identifying the focus domain of a sentence in both language types (cf. the principle stated in (11), repeated in (81)). To the extent that focus is part of the logical representation of a sentence (see Vergnaud and Zubizarreta (forthcoming)), it follows that information regarding prominence must be available at LF in both types of language (i.e., in Germanic as well as in Bengali and Romance).

Second, Zubizarreta (1998) has argued that the formulation of p-movement in Romance (see section 4) is intimately related to the NSR; therefore, they must both apply at the same point in the derivation. (For details on the formulation of p-movement, see Zubizarreta op. cit.: sec. 3.5.1.) Furthermore, Suñer (2000) has shown that p-movement in Romance affects binding relations. If binding relations are determined in the LF component of the grammar, then p-movement must feed LF, and so must the NSR.

Third, it was shown above that NS in Bengali (and in Romance) is computed in terms of prosodic boundaries, while in English, NS is computed on the basis of metrically interpreted syntactic structures. Nevertheless, even in English, a sentence may be composed of more than one intonational phrase, with each intonational phrase containing a NS (as required by the principle in (11)). See, for example, the famous example from Chomsky and Halle (1968):

(84) (This is the cát) (that chased the rát) (that stole the chéese).

The implication is that information regarding prosodic boundaries must be available at the point where the NSR applies – even in English.

Our conclusion is that prosodic information (such as prosodic boundaries and main phrasal prominence) must be present at the stage in the derivation where LF is constructed. That conclusion appears to be broadly in line with the standard derivational architecture. Within that architecture, PF interpretation (Spell-out) applies at the level of S-structure, from which LF is also derived (see Chomsky and Lasnik 1993; Zubizarreta 1998). Zubizarreta (1998) develops a particular version of the standard model in which prosodic information is incorporated into S-structure. In particular, prosodic structure in Germanic-like languages is presented as an annotation of S-structure, which is produced by interpretive

principles that apply to local configurations of the constituent structure (see section 3.5). But we saw earlier that a constituent structure is a derivation in a different guise (cf. (19) and n. 8 in section 3.2.1). So the account in Zubizarreta (1998) can presumably be recast and be embedded in an architecture in which PF interpretation is cyclical (see Frampton and Gutmann 1999; Uriagereka 1999; Chomsky 2001b). We sketch this alternative rendering below.

Chomsky op. cit. outlines a particular cyclical architecture, in which the cycles are called *phases*. To illustrate the workings of a derivation by phase, let us consider the structure in (85):

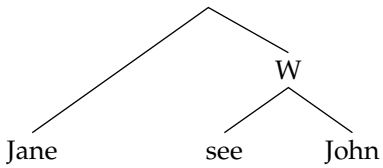
(85) [Jane saw John]

We assume that that structure has five primitive constituents, namely those given in (86), where *C* is a (silent) complementizer:

(86) {Jane, John, see, Past, C}

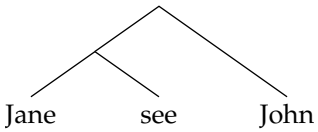
This is an oversimplification but it will do for our purpose. The first cycle may be represented as the derivation-marker in (87):

(87)



That is, Merge first applies to the pair {*John*, *see*}, then to the pair {*Jane*, *W*}, where *W* is the product of the application of Merge to {*John*, *see*}. Constituents can be described as sets and Merge can be defined as set union, so that *W* is the set {*John*, *see*}, formed from the union of {*John*} and {*see*}. And the outcome of the complete derivation in (87) is the set {*Jane John*, *see*}. Of course, that set could also be generated by the derivation in (88), since set union is associative:

(88)

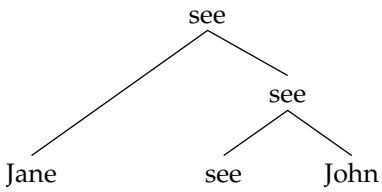


The derivations in (87) and (88) define different constituent analyses based on the same array of syntactic primitives.

A syntactic set created by Merge has a very special feature: among its elements, it counts one which may be taken to stand for the whole set. That element is called the head of the set. In the particular derivation in (87), the head of the first constituent created by Merge is *see*, which is also the head of the final outcome.

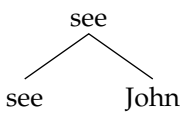
Then, the description of the derivation in (87) can be simplified as follows. Merge first applies to *John* and *see*, then it applies to *Jane* and *see*. This is represented in (89):

(89)



The derivation marker in (89) constitutes the first phase. Spell-out applies to that first cycle. Following Chomsky (2001b), we assume that the interpretively relevant part of the phase does not include the highest specifier in it. In the case of (89), it is then the submarker in (90):

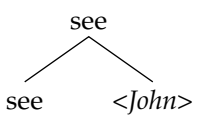
(90)



One may distinguish three functions or components of Spell-Out. The first component (SO^{I}) defines the primitive domains of PF interpretation. These are the minimal syntactic collocations which can be translated into assemblages of morphosyntactic and, ultimately, PF features. Call these primitive domains morphosyntactic domains (MSDs). An MSD is a local object: it may be a syntactic head or a short continuous sequence thereof, but nothing bigger than that. The second component of Spell-Out (SO^{II}) determines how the MSDs are strung together. In particular, SO^{II} delimits the prosodic domains and assigns relative prominence to the various MSDs within these domains. The third component (SO^{III}) actually effects the translation of MSDs into morphosyntactic and, ultimately, PF representations. The theory of SO^{III}, we assume, is Distributed Morphology (DM) (see Halle and Marantz 1993). SO^{III} treats the MSDs created by SO^{I} as independent domains and applies to these domains in an unordered fashion. From the point of view of the cyclical architecture, the critical parts of Spell-Out are then SO^{I} and SO^{II}.

The output of SO^{I} is not an independent 'PF derivation marker', but merely an annotated version of the syntactic derivation marker, in which MSDs are identified. SO^{I} converts the derivation marker in (90) into the tree in (91), where < . . . > represents an MSD:

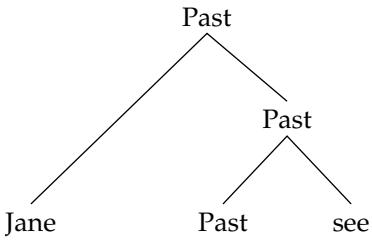
(91)



A verbal head can be identified as an MSD only in combination with the *T*(*ense*) head. This is why there is no MSD corresponding to *see* in (91). The SO^I interpretation of the first phase in (89) then reduces to the marking of *John* as an MSD (the constituent *John* is assigned Case in the first phase in (89), so it is a complete MSD by the end of that phase).

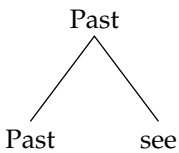
The array for the next phase includes the primitive element *Past* together with the elements at the 'margin' of the previous phase, i.e., the phasal head and its specifier. The second phase has the structure in (92):

(92)



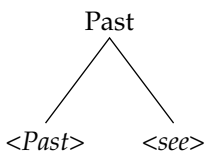
The interpretive domain in (92) is the marker in (93):

(93)



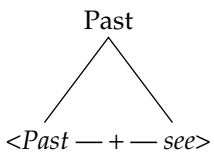
SO^I transforms this marker into the tree in (94):

(94)



In isolation, each of the MSDs <*Past*> and <*see*> would surface as *did* and *see*, respectively – more exactly, as the PF representations corresponding to *did* and to *see*. On the other hand, since <*Past*> and <*see*> are adjacent in the structure in (94), a more economical interpretation is to fuse the two MSDs into a single one, ultimately giving rise to the PF corresponding to *saw*. So the image of (93) by SO^I is the tree in (95):

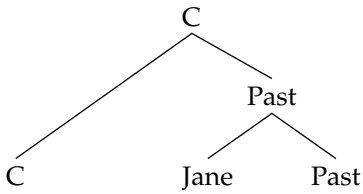
(95)



The transformation of (94) into (95) is the rule of Affix-Hopping.

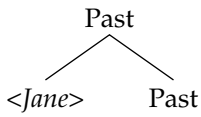
The array for the third and final phase includes the primitive element *C* together with the head of the second phase and its specifier. The final phase has the structure in (96):

(96)



The interpretive domain in (96) is the whole marker. The application of SO^I to (96) yields the tree in (97):

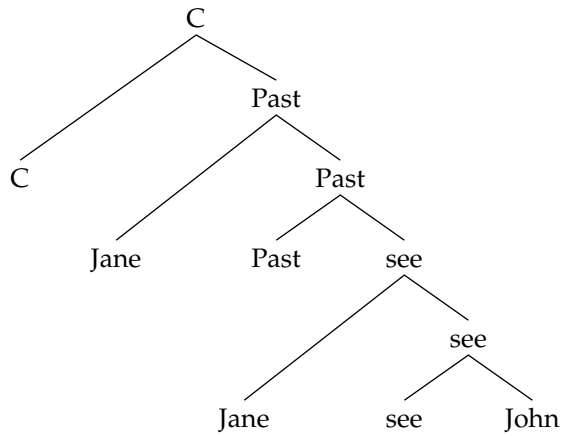
(97)



The complementizer *C* has no morphosyntactic translation. Furthermore, a functional head such as *Past* cannot be identified as an MSD unless it is combined with some verbal projection (this is the converse of the situation in (91)). The SO^I interpretation of the final phase in (96) then reduces to the marking of *Jane* as an MSD.

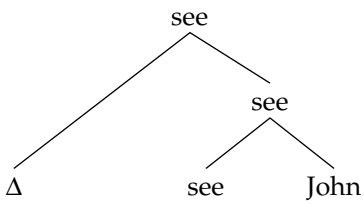
Note that we are assuming that the derivation of the stucture in (85) involves three phases, a departure from Chomsky (2001b). The latter postulates two phases, a first phase associated with the verb domain and a second one, with the complementizer domain. The difference between the two analyses rests on the status of the functional category *T*. Implicit in our proposal is the assumption that *T* is a complementizer-like category and *C* a higher complementizer. Hence the additional phase. The question at this point is how the various phases are formally linked together. How does one know that, e.g., *see* in the phase in (89) is the same element as *see* in the phase in (92)? A natural approach is to try to incorporate all the phases into a single connected derivation marker. To that effect, we capitalize on the fact that a syntactic head may represent several levels of constituency at the same time. For example, *see* in (92) can represent the head in the phase in (89) or it can represent any projection of that head. The derivation markers in (89), (92), and (96) were defined with the first interpretation in mind. If, on the other hand, we assume the second interpretation, it becomes possible to join the three markers into a single one describing the whole derivation, as shown in (98) (note that the two overlapping markers in (96) and (92) have been unified in the sense that the common subtree is represented only once):

(98)

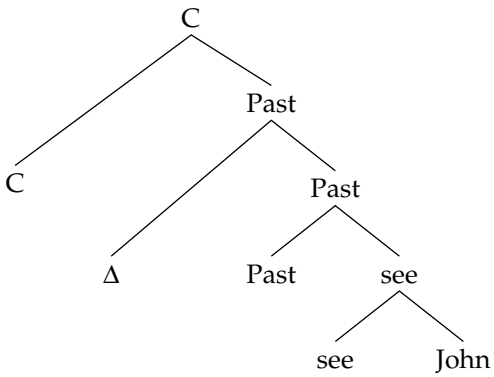


There remains a problem, though, common to the new integrated representation in (98) and to the disconnected one displayed in (89), (92), and (96). Both fail to identify the multiplicity of occurrences of *Jane* as a *chain*, i.e., as the same constituent partaking of separate phases. A chain is the association of a constituent α with a list of contexts K_α for α (see Chomsky 1995c). For any given α, the derivation may then be equated with the generation of K_α. Under the simplest definition, a context for α identifies only one occurrence of α (thus, X — U — W is not a context in that restricted grammatical sense). The pair of derivation markers in (99), where Δ is a fixed dummy symbol, is a description that identifies the chain of occurrences of *Jane* so defined:

(99) (i)



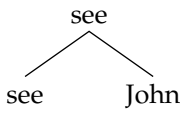
(ii)



(iii) Δ = *Jane*

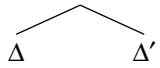
We note that there is a second constituent that shows up in two contexts, namely, the structure in (100):

(100)

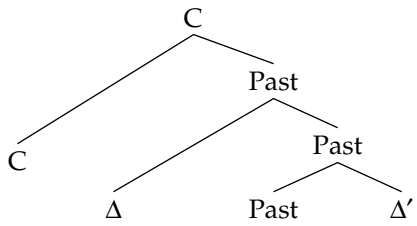


The verbal structure in (100) has two distinct grammatical roles in the sentence in (85); predicate of the constituent *Jane* and complement of the functional head *Past*. The two occurrences of (100) in (99) then also constitute a chain. Accordingly, we revise (99) to (101), where Δ and Δ′ are two distinct dummy symbols:

(101) (i)



(ii)



(iii) Δ = *Jane*
(iv) Δ′ = ($_{see}$ *see John*)

The whole description in (101) can legitimately be identified as the LF of the sentence in (85). In some sense, we are back to the two phase theory in Chomsky (2001b), with the diagram in (101i) representing the first phase and that in (101ii) the second phase. There are differences, though. The derivation described in (101) goes like this. First, a small clause is assembled, with a verb, a subject, and an object. The small clause is then separated into two parts, its subject (*Jane*) and the predicate cycle (*see John*). At this point, the derivation starts afresh, using the parts from the disassembled first phase as well as new material. The cycle [*see John*] from the first phase is plugged in the second phase at the stage where the functional category *T* is merged with its verbal complement. Following this, the subject *Jane* is merged as the specifier of *T*. In general, the LF of a sentence will have the following structure:

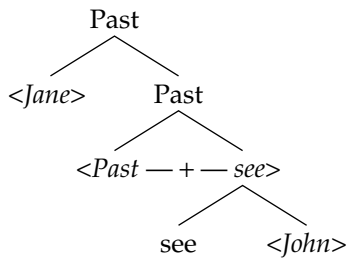
(102) An LF representation is a partially ordered set of derivation markers, where the ordering is defined in (i):
  (i) The derivation marker *p* precedes the derivation marker *q* $=_{\text{def}}$ the lexical items in *p* form a subset of those in *q*.

Note that one effect of disassembling the first phase before starting the second one in an LF such as (101) is what has been called trace deletion (see Chomsky

1995c, for example). Assuming this as a general mechanism, no phase will ever include any trace (at least, of A-movement).[21] A trace is now viewed as a derived construct: a constituent in a phase p_i is a trace to the extent that it partakes of a more inclusive phase p_j.

Within the above execution of phase theory, it is not necessary for Spell-Out to go by the same phasal 'clock' as LF. In particular, a single LF phase might correspond to a multiplicity of PF phases (see Megerdoomian 2002 for a discussion of this issue). We will assume that this is indeed the case. For example, we will maintain the PF analysis of the structure in (101) (the description of the sentence in (85)) in three phases, displayed in (91), (95), and (97). Linking these SO^I phases together yields the tree in (103):

(103)



The PF linear sequence of MSDs mirrors the derivational ordering.[22] That is, the sequence of MSDs is that in (104), where ^ is the concatenation operator:

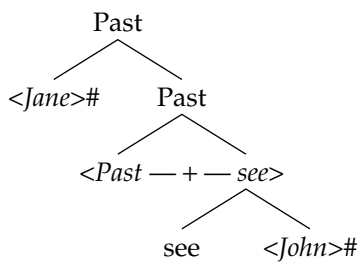
(104) <Jane> ^ <Past+see> ^ <John>

Determining the string of MSDs from the SO^I derivation marker is one of the roles of SO^{II}. In addition, SO^{II} defines prosodic domains, assigning stress at the boundaries of these domains. Concretely, we shall assume the following rule:

(105) Let μ be a sequence of MSDs (possibly reduced to one) such that μ corresponds to an LF phase. A prosodic boundary (denoted by #) is inserted after μ, unless one already exists within or after μ (having been inserted in a prior phase).

Furthermore, we assume that any DP is an LF phase by itself (on par with CP).[23] In the derivation in (103), SO^{II} will then insert # after the MSDs <*John*> and <*Jane*>:

(106)



The only other string in the representation in (106) that corresponds to an LF phase is the whole string itself (neither [*see John*], nor [*Past see John*] are phases in the analysis in (101)). The string of MSDs is then parsed as in (107):

(107) <Jane> # ^ <Past+see> ^ <John> #

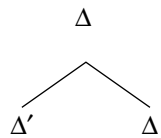
We assume that some principle subordinates *<Jane>#* to *<John>#*.[24] Thus, main prominence is assigned at the last (rightmost) boundary within the sequence.

Now consider the sentence in (108) (cf. the discussion of (68) above):

(108) Jóhn disappeared

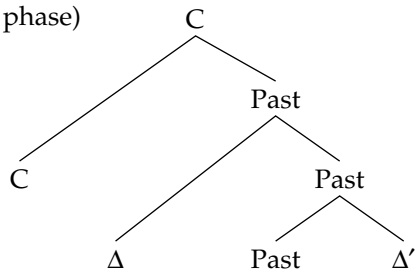
The neutral stress contour is the one indicated, with main stress on *John*. The LF description of the sentence is given in (109):

(109) (i) (1st phase)



(ii) (2nd phase)

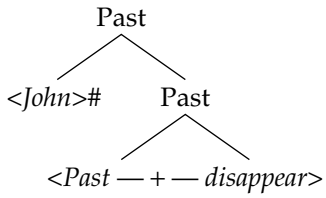
(iii) (3rd phase)



(iv) (identification of the dummy symbols)
Δ = *John*, Δ′ = *disappear*

One difference between the structure in (109) and that in (101) is that, whereas the object of the verb in (101) gets Case in the second phase, the object in (109) does not get Case until the last phase. As a consequence, the object in (109) is not interpreted as an MSD by SO^I until that final phase, once it has moved to subject position. The prosodic boundary # is then inserted after the subject. We display in (110) the image of (109) by SO^I, together with the prosodic boundary inserted by SO^{II}:

(110)



The corresponding string is that in (111):

(111) <John> # ^ <Past+disappear>

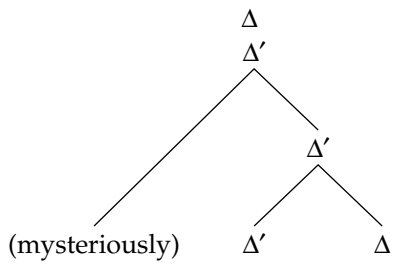
Compare next the sentence in (112) (cf. the discussion of (69)):

(112) John mysteriously disappéared.

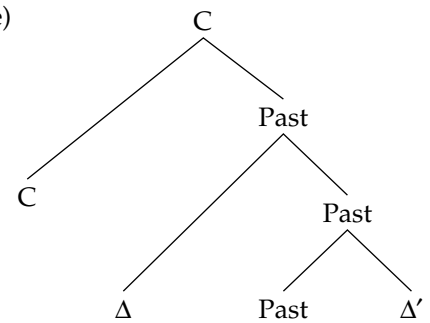
In the sentence in (112), the neutral intonation is with main stress on *disappear*. The essential difference between (112) and (108), of course, is the presence of an additional constituent in (112), namely the adverb adjoined to the verb phrase. We analyze the structure as in (113):

(113) (i) (1st phase)

(ii) (2nd phase)



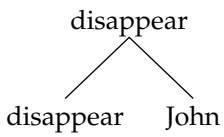
(iii) (3rd phase)



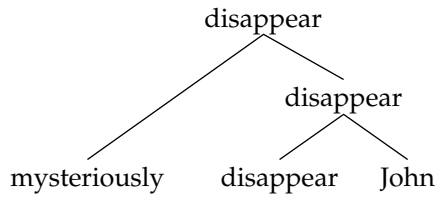
(iv) (identification of the dummy symbols)
Δ = *John*, Δ′ = *disappear*

The parentheses around the adverb *mysteriously* in (113ii) indicate that the second phase really is an abstract construct made up of two actual phases: one phase has the adverb *mysteriously* in it, the other lacks it. In other words, the second phase is a pair of 'parallel' derivations, a short one, represented in (114), and a long one, represented in (115):

(114) Short derivation:

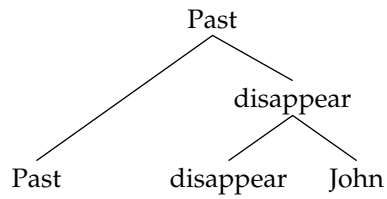


(115) Long derivation:

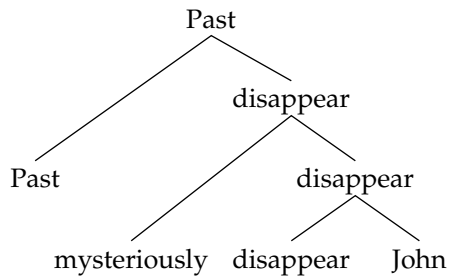


The two derivations in (114) and (115) have different outcomes, the short one yielding the set {*disappear*, *John*} and the long one, the set {*disappear*, *John*, *mysteriously*}. That difference affects later cycles. For example, consider the stage at which *Past* is brought into each derivation. The two parallel cycles that constitute the second phase give rise to the two parallel derivations in (116) and (117):

(116) Short derivation:

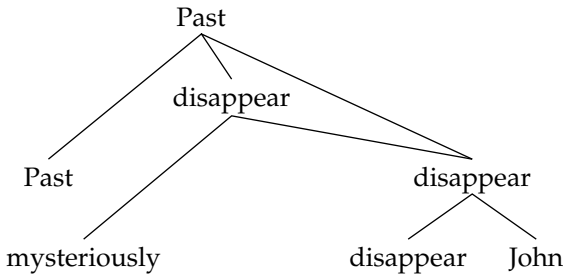


(117) Long derivation:



The two parallel derivations above may be combined into a single complex marker:

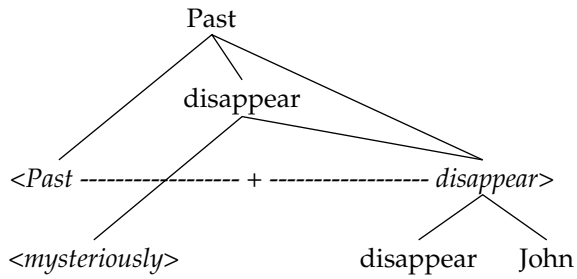
(118)



The double connection between *Past* and *disappear* in (118) reflects the constituent analysis distinction between *category* and *segment* introduced in May (1985). We take this derivational ambiguity to be characteristic of adjunction.

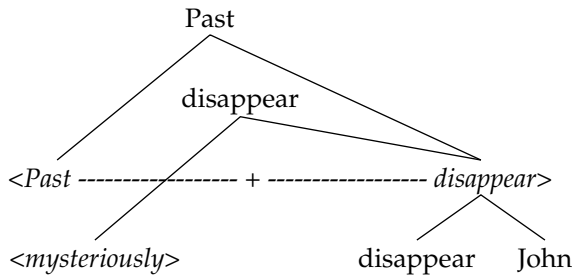
The diagram in (118) is the LF representation generated by the derivation up to the stage where *Past* is merged with the outcome of the second phase in (113ii). The SO^1 image of that stretch of the derivation is as in (119):

(119)



One issue is how the PF ordering of <*mysteriously*> and of <*Past+disappear*> is determined. One may again appeal to the principle that the PF ordering mirrors the derivational one (cf. the structure in (103) and the comment that follows it). Specifically, we will assume that the PF ordering of the MSDs displayed in (119) is determined at the combined derivational stage represented in (120):

(120)



The diagram in (120) represents the combination of the following cycles from the two parallel derivations. The cycle in the long derivation in which the verb *disappear* is merged with *mysteriously,* and the cycle in the short derivation in which it is merged with *Past*. Each cycle immediately follows that in which *disappear* is merged for the first time in each derivation. At the combined stage depicted in (120), *disappear* both precedes *mysteriously* and *Past* in the derivational ordering, while *mysteriously* and *Past* are unordered with respect to each other. Since *Past* is incorporated with *disappear* into a single MSD, the unique PF ordering compatible with the derivational ordering defined by (120) is that in (121), where <*mysteriously*> precedes <*Past+dispappear*>:

(121) <mysteriously> ^ <Past+disappear>

We see that using the complex cycle in (120) to determine the PF ordering of MSDs has the same effect as having Affix-hopping lower the inflection onto the verb. If we now assume that the combination of an adverb with the verb phrase

it modifies constitutes an LF phase, a prosodic boundary will be inserted after *disappeared*. The result is the form in (122):

(122) <John> ^ <mysteriously> ^ <Past+disappear> #

We have illustrated the cyclical framework in some detail to show that, within such an architecture, PF interpretation raises issues which are conceptually analogous, or even identical, to those arising within the standard architecture. The solutions proposed in the literature can often be translated quite directly into the cyclical format. Obviously, there are differences. Indeed, the cyclical theory allows for a more felicitous definition of 'depth of embedding' in the sense of Cinque (1993) or the revised sense of Zubizarreta (1998). A maximally embedded constituent within some structure *K* is one that constitutes a primordial LF phase in the cycle corresponding to *K*. As a consequence of the derivational approach, the interplay of structural and selectional ordering in Zubizarreta (1998) may have to be revised, possibly to be replaced by some interplay of structural and linear ordering. This would leave the logic of the parametric account unaffected, though.

6 Conclusion: some final remarks

While we have chosen to focus on a certain view of the world in this chapter, it is certainly not the only one around. The view assumed here and captured by the principle in (11) is that the possible scopes of the focus are determined by the location of the intonational nucleus. There is an alternative view, the pitch-accent-based theory of focus, put forth by Gussenhoven (1984) and Selkirk (1984, 1995). These authors propose that in Germanic pitch-accent assignment and predicate–argument relations are mediated by focus-projection rules (or focus-domain formation rules). Selkirk (1995) proposes the following rules, where the feature F is a diacritic for annotating syntactic structure (this is a non-technical rephrasing of her rules:)

(123) a. **F-marking rule:**
An accented word must be marked in the syntactic structure with the feature F.
b. **F-projection rule:**
F-marking may project upward within the syntactic structure from a head or its internal argument.

A late rhythmic rule ensures that the last accented word receives main prominence, but it plays no role in determining the possible F-structures of the sentence:

(124) **Nuclear Stress rule:**
The most prominent syllable of the rightmost constituent in a phrase P is the most prominent syllable of P.

The F-marked structures are related to the informational structure of the sentence by the following rules:

(125) a. The Focus of a sentence (FOC) is defined as an F-marked constituent not dominated by any other F-marked constituent.
b. F-marked constituents which are not a Focus are interpreted as new in the discourse, while a constituent without F-marking is interpreted as given. A Focus constituent, on the other hand, may be interpreted as either given or new in the discourse.

We will not attempt to evaluate here the empirical success of the pitch-based theories of focus. (For some discussion, see Zubizarreta 1998: section 3.5 and Ladd 1996.) We simply note here that this theory must make use of an ad hoc feature F to annotate the syntactic structure. This feature is undesirable because it lacks independent justification. It is only needed to establish the relation between pitch accent and the informational structure of the sentence. An NSR-based theory of focus does not require such a feature. In this theory, focus is directly identified by prosodic notions such as relative prominence. Other grammatical means for focus identification are also available. For example, contrastive focus may be associated with logical operators such as *only*. Some languages may make use of a bona fide syntactic position or it may make use of a particular morphological marking. But these are all independently justified notions. F-marking is not.

While some progress has been made in our understanding of the relation between prosody, focus, and syntax, much remains to be done. In effect, we have only scratched the surface of it. More typologically different languages need to be studied. In particular, it would be useful to learn the exact correlation between focus and prosody in tone languages, in particular those in which pitch is distinctive. It has been claimed that certain African languages (such as Chadic; see Tuller 1992) resort to morphology and syntactic position rather than to pitch to mark the focus of the sentence. It may be premature to draw such a conclusion before we have more in-depth studies of the phonology and phonetics of such languages. As we said in the introduction, prominence is a rather abstract notion for which there is no unique phonetic correlate. In fact, there may be relevant phonetic cues other than pitch accent (such as other aspects of the intonational contour). It is precisely this type of language that we need to investigate further in order better to understand the relation between prosody, focus, and syntax.

NOTES

1 The most consistent acoustic correlate in a language like French or English may be the amplitude and sharpness of fundamental frequency (F_0) variation associated with a given syllable (see Martin 1975, 1982).

2 The following quotation from Chomsky and Halle (1968) is relevant here:

> We do not doubt that the stress contours and other phonetic facts that are recorded by careful phoneticians and that we will study here constitute some sort of perceptual reality for those who know the language in question. In fact we are suggesting a principled explanation for this conclusion. A person who knows the language should "hear" the predicted phonetic shapes. In particular, the careful and sophisticated impressionistic phonetician who knows the language should be able to bring this perceptual reality to the level of awareness, and there is ample evidence that phoneticians are capable of doing this. We take for granted, then, that phonetic representations describe perceptual reality. Our problem is to provide an explanation for this fact. Note, however, that there is nothing to suggest that these phonetic representations also describe a physical or acoustic reality in any detail. For example, there is little reason to suppose that the perceived stress contour must represent some physical property of the utterance in a point-by-point fashion; a speaker who utilizes the principle of the transformational cycle and the Compound and Nuclear Stress Rules should "hear" the stress contour of the utterance that he perceives and understands, whether or not it is physically present in any detail. In fact, there is no evidence from experimental phonetics to suggest that these contours are actually present as physical properties of utterances in anything like the detail with which they are perceived. Accordingly, there seems to be no reason to suppose that a well-trained phonetician could detect such contours with any reliability or precision in a language that he does not know, a language for which he cannot determine the surface structure of utterances.
>
> Considerations of this sort lead us to suspect that the question of how highly differentiated the stress contours in a representation should be is of little significance. In a complex utterance with a rich surface structure, the rules outlined in the preceding section will lead to a stress contour of many levels. There may be no empirical sense to the question of whether the resulting representation is correct in full detail. Because of the completely impressionistic character of judgments of relative stress, decisions over a broad range are of little value. It is not at all surprising that there should be great difficulty, within impressionistic phonetics, in determining how many stress levels should be marked and how they are distributed in utterances that exceed a certain degree of complexity. The shape and the degree of differentiation of a stress contour are largely determined by obligatory rules and are therefore below the level of systematically significant representation. Once the speaker has selected a sentence with a particular syntactic structure and certain lexical items (largely or completely unmarked for stress, as we shall see), the choice of stress contour is not a matter subject to further independent decision. That is, he need not make a choice among various "stress phonemes" or select one or another "superfix." With marginal exceptions, the choice of these is as completely determined as, for example, the degree of aspiration. Similarly, a hearer who has grasped the structure and morphemic constitution of an utterance from a rough sampling of the physical input need not attend to stress variation, to whatever extent this may actually be a physical property of utterances.
>
> It is to be expected that determined phonetic features should be quite difficult for the user of the language to learn to identify, whether they involve stress or degree of aspiration (where undoubtedly there are many levels, predictable, at least roughly, by general rules). The apparent ease with which phoneticians

> trained in the same conventions can, to a large extent, agree on the assignment of four or five stresses in utterances may very well be traceable to their ability, as speakers of the language, to grasp the syntactic structure of utterances and to assign to them an "ideal" stress contour by the rules of the transformational cycle. Such an achievement may have little to do with any physical fact. This is, incidentally, a matter which should be subject to experimental investigation. (Chomsky and Halle 1968: 25–26)

3 There is promising work coming out of Laboratory Phonology that might pave the way toward remedying this state of affairs. See, for example, Godjevac (2000) and references cited therein.

4 This test, of course, works only to the extent that the form of the answer respects the form of the question and the relation between the two is not mediated by any hidden inferences. It is precisely for this reason that the question–answer test is not an infallible one for determining the focus structure of a sentence. See Zubizarreta (1998: 161, n. 6).

5 See also Liberman (1979); Ladd (1980); Pierrehumbert (1980); Culicover and Rochemont (1983); Halle and Vergnaud (1987); Cinque (1993); Zubizarreta (1998).

6 For example, this could be the structure for the sentence *John's son's baby cried*.

7 Chomsky and Halle (1968) actually formulate the NSR as a rule assigning stress to vowels, with the structural description in (i):

(i) $V^1 \ldots — \ldots]_\alpha$

Thus, the text formulation is more abstract since it involves the notion of stress of a word relative to other words, while stress is perceived as a phonetic property of vowels. See the text below. Nothing in our development hinges on the particular choice of formulation in terms of word stress or of vowel stress.

8 One may recall that in a constituent-analysis (i.e., context-free) grammar of the standard type, a phrase marker *is* a derivation (more exactly, a class of derivations); see Chomsky (1957: 26–33). The equivalence postulated in (19) in the text can then be viewed as a generalization of this definition to derivations involving transformations. In a sense, the duality between constituent structure and derivation manifests the compositional nature of language. The duality would break down if language structure were to display properties of a global type. A full discussion of the duality would have to address the issue of cyclical interpretation. We briefly return to this question at the end of section 5. Note that compositionality holds even when the operation involved (say Merge, or Concatenate) is associative. That the operation is associative means that all constituent structures of a given string are equivalent.

9 The convention in (22) in the text is a partial reformulation of the mechanisms postulated in Halle and Vergnaud (1987); see in particular Halle and Vergnaud (1987: 263–266).

10 An account of the contour in (26) in the text could be given within the text formalization (20–23) by recording the depth of embedding. Thus, given a category α with immediate metrical head $H_m(\alpha)$, a sister of $H_m(\alpha)$ has secondary stress within α. A sister of the immediate metrical head of $H_m(\alpha)$ has tertiary stress within α, as does a sister of the immediate metrical head of a sister of $H_m(\alpha)$. And so on and so forth. We encounter here the same unwieldiness that was noted in the text for the case of the one-step derivational algorithm, and for an obvious reason. Indeed, one should view

the natural implementation of a one-step procedure to be an interpretive system such as that in (20–23) in the text, and not a transformational algorithm. The question is then whether the interpretive algorithm just defined and the cyclical transformational algorithm in (16–17) in the text are empirically distinguishable.

11 The question of stress subordination has two distinct, but related, aspects. First, we have the question of the preservation of stress contours under embedding. To illustrate, consider the structure in (i):

(i) John's baby liked ET.

At issue here is whether the internal relations of stress in the phrases *John's baby* and *liked ET* are the same in the sentence *John's baby liked ET* as in isolation. We note that all three algorithms mentioned in this paper, the cyclical transformational algorithm of Chomsky and Halle (1968), the algorithm in Halle and Vergnaud (1987) and the interpretive algorithm discussed in note 8, assign the same stress contour to the structure in (i); namely, primary stress is assigned to *ET*, secondary stress to *baby*, and the same tertiary level of stress to *John* and *liked* (see Chomsky and Halle 1968: 90). Thus, the three algorithms presented here all imply that the internal relations of stress in the phrase *John's baby* are the same in the sentence *John's baby liked ET* as in isolation, while those of *liked ET* differ. However as Chomsky and Halle (1968) note (p. 90, n. 43), there is really no evidence bearing on the matter.

This leads to the second general question concerning stress subordination, namely, the question whether there exists any perceptual relation at all between the stress level of *John* and that of *liked* in a structure like (i). It may very well be the case that stress levels are comparable only to the extent that they independently relate to the same main stress. This is the case in (25) in the text, where *liked* and *John* are directly subordinated to the same main stress in distinct phrases. The text discussion in section 3.2.2. provides some indirect support for that view, as it suggests that the distribution of secondary stresses may be ruled by a different set of principles. If this turned out to be true, it would constitute evidence in favor of the interpretive approach.

12 For a detailed discussion of eurhythmicity in French, see Dell (1984).

13 Tokizaki (2000) argues that the stress pattern in (44) corresponds to a thetic-judgment interpretation, while the stress pattern in (45) corresponds to a categerical-judgment interpretation. While this may very well be the case, the point is that the unaccusatives in (46) give rise to an unambigous stress pattern. Main stress on the verb gives rise to a contrastive focus interpretation.

14 Bresnan (1971b) attempts to do just this by proposing that the NSR applies cyclically. For a critique of Bresnan's data, see Bolinger (1972a).

15 The term is a misnomer since de-accented words are in many cases associated with miniature but quite audible pitch accents.

16 The notion is defined as follows in Cinque (1993):

(i) a. The major path of embedding is constituted by nodes on the X-bar axis (X, X', XP) and the nodes on the recursive side of the tree.
b. The minor path of embedding is constituted by nodes on the nonrecursive side of the tree.

However, the notion 'recursive side' used in that definition is somewhat infelicitous, since both the complement of *X* and the specifier of *X'* are recursive nodes. Furthermore, the definition should make explicit the fact that the distinction major vs. minor path

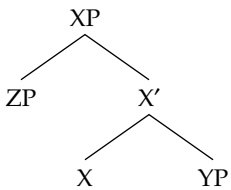
of embedding is relative to a maximal projection *XP* (or, equivalently, relative to a head *X*). This is why we have replaced Cinque's original formulation by the one in the text. Note that the notion of 'major path of embedding' has a natural interpretation in the theory in Kayne (1994), which assumes that specifiers are adjuncts.

17 The definition of c-command proposed by Zubizarreta departs slightly from the standard one. It distinguishes direct and indirect c-command:

(i) A directly c-commands B iff A and B are heads or maximal projections (excluding segments) and (a) A and B are sisters or (b) there exists a node C such that A and C are sisters and C dominates B.
(ii) If A directly c-commands B, then A indirectly c-commands C, C a projection of B that does not contain A.

According to the definition in (i), the Specifier ZP in the structure in (iii) *directly c-commands* the head X and its complement YP (as in the standard definition of c-command), but it does not directly c-command its sister X′ (because X′, being neither a head nor a maximal projection cannot be in a direct c-command relation with any category). According to the definition in (ii), ZP *indirectly c-commands* X′ by virtue of the fact that X′ is a projection of X and ZP directly c-commands X. It is this latter extension of the c-command relation that goes beyond the classical one.

(iii)



18 In Zubizarreta (1998), selectional ordering was defined on a separate, more abstract, tree. Here we assume that the syntactic tree encodes both selectional ordering and constituent ordering in terms of asymmetric c-command.

19 We see that the interplay of C-NSR and S-NSR yields the effects of the English Compound Stress rule (cf. Chomsky and Halle 1968), thus preserving an important result of Cinque (1993). To illustrate, consider the compound [*kitchen* [*towel rack*]], with the bracketing indicated. In the inner constituent [*towel rack*], *rack* is analyzed as a head taking *towel* for argument (heads are always on the right in words). Relative prominence is then determined by S-NSR, which assigns main stress to *towel*. In the higher constituent, no argument relation holds and C-NSR applies, assigning main prominence to the constituent [*towel rack*].

20 Arguably, a similar process is at play in the preposing of IP and VP with respect to selecting particle-type functional heads in Chinese. See Simpson and Wu (1999, 2000).

21 Obviously, this imposes a contraint on the relation between phases and movement; movement may never be internal to a phase.

22 Of course, the derivational ordering is a partial one. Suppose, for example, that the subject of the sentence contains more than one MSD. We will adopt the following rule:

(i) Let . . . *C* . . . be some structure, where *C* is a constituent ultimately interpreted as the sequence of MSDs $\mu = ({}_C\ m_1\hat{}m_2\hat{} \ldots \hat{}m_s)$, '^' the concatenation operator. Let *h* be the head of *C* and <*h*> be the MSD in μ associated with *h* (<*h*> is some m_i). The PF ordering of μ with respect to the context . . . — . . . is the same as that of <*h*> in isolation.

The complex formal issues which arise in connection with the projection of the partial ordering of constituent structure onto the total ordering of the time axis are discussed in great depth in Kayne (1994).

23 The LF description in (101) in the text will then have to be revised accordingly. Note that there must be some subordination principle that ensures that the boundaries introduced in previous phases do not interfere with current ones.

24 The principle might be formulated in terms of a *last* vs. *first* (*rightmost/leftmost*) parameter or, alternatively, in terms of depth of embedding (as in Halle and Vergnaud 1987, Cinque 1993, and Zubizarreta 1998).

  6.2 Phrasal movement vs. head movement, large-scale pied-piping, and the elimination of feature movement

1 Introduction

The notion of 'pied-piping' has been an integral part of all versions of the theory of generative grammar that assume transformational movements since it was first introduced by Ross (1986, from his 1967 dissertation). The term itself – attributed by Ross to Robin Lakoff – refers to the phenomenon whereby some particular movement operation T, designated to displace an element A, in fact displaces additional elements together with A; more specifically, pied-piping is involved when an application of T ends up moving some constituent B that properly contains A. Ross's Pied-Piping Convention was originally meant, for instance, to extend the application of the Relative Clause Formation transformation, so that it is able to move more than just the NP immediately dominating the relative pronoun in cases such as shown in (1–2), where (1b, c) and (2a) represent, according to Ross (1986), instances of pied-piping by the relative *wh*-pronoun.

(1) a. reports [*which*] the government prescribes the height of the lettering on . . .
    b. reports [the covers of *which*] the government prescribes the height of the lettering on . . .
    c. reports the [lettering on the covers of *which*] the government prescribes the height of . . .

(2) a. the boy [*whose* guardian's employer] we elected president
    b. *the boy [*whose*] we elected guardian's employer president

From its inception until now the existence of pied-piping has uniformly been assumed in the literature, and it has provided a widely used descriptive tool. Yet until recently, the pied-piping phenomenon itself received surprisingly little attention as a research topic in its own right. Thus, while the closely related topics of the proper formulation of, and constraints on, transformational movement operations have always been central to research in syntactic theory, even the most basic questions regarding pied-piping were not raised and addressed in any systematic fashion at least until the early 1990s. A possible reason for this may be the highly theory-dependent nature of pied-piping, namely, the fact that by its very definition, instances of pied-piping can be identified only relative to a particular formulation of the movement operation involved.

Thus, in any theoretical framework in which various movement transformations are formulated in a construction-specific manner, as was the case in the early stages of generative syntax up to the mid 1970s, a general theory of pied-piping could hardly be contemplated. Due to the excessive power of the formalism of transformations, the descriptive effects attributed by Ross to pied-piping could often be easily incorporated into the formulation of the movement transformation

itself. There were major discrepancies even involving the best-studied case, namely that of *wh*-movement, for instance between Ross's (1986) and Emonds's (1976) conception of the phenomenon of pied-piping. Under Ross's notion (see section 1.1), both cases like (1b, c) as well as cases like (2a) were analyzed as instances of the Pied-Piping Convention (given in (8) below); however, under Emonds's alternative proposal, only cases like (1b, c) were such, while those like (2a) were taken to be due to the particular formulation of the *wh*-movement transformation itself, and were claimed to involve no pied-piping. (See the formulation of *wh*-movement as moving an NP, AP, or PP with a *wh*-morpheme at its left periphery, and the analysis of the residue of Ross's pied-piping as a 'stylistic' process in Emonds 1976; on the latter idea, see also section 3). Bresnan (1976c) departs from Ross's hypothesis of pied-piping even more radically; her X-Bar theory-based, category-neutral statement of the transformation forming relative clauses eliminates the need for a stipulated pied-piping convention, not only with respect to examples of the type of (2a), but also with respect to examples like (1b, c) since it specifies the constituent that the movement operation applies to as any XP with the categorial feature [–V] (hence any NP or PP) that contains a *wh*-morpheme.

In the Principles and Parameters (P&P) framework of the 1980s, involving the reduction of the transformational component of the model to the universal Move α schema, and the development of X-Bar theory, as a uniform theory of phrase structure extending to all phrase types, it became possible to ask more general questions regarding the range and properties of pied-piping phenomena; namely, it became in principle feasible to start exploring how general pied-piping behavior is across different constructions, different category types, and across languages, and what its properties and distribution derive from. Yet, possibly due to the highly theory-internal nature of pied-piping, such issues remained essentially uninvestigated during the 1980s as well.

It was only in the 1990s that the general issue of pied-piping started to receive some more comprehensive treatment (e.g., Webelhuth 1992). General questions like the following were raised: What is it that makes pied-piping in individual constructions and with particular phrase types possible while in other cases impossible, and what factors can make it obligatory? What makes it stylistically marked in some particular cases? What is the source of some observed cross-linguistic and cross-categorial discrepancies? What are the structural and possibly non-structural conditions on pied-piping?

In accordance with the modular approach to accounting for syntactic phenomena in terms of interacting principles and parameters of UG, ideally one would like to make the various observed pied-piping options, or lack of those, also fall out of independent properties of UG. Attempts in this direction have been made in the past decade, e.g., by Webelhuth (1992), Moritz and Valois (1994), Chomsky (1995c), Koopman (1997).

The literature on pied-piping up until recently has concentrated mostly on particular cases of A-bar movement, primarily on *wh*-movements and marginally

on some other operator movements, such as negative preposing and quantifier raising. The set of languages investigated, at least with respect to overt pied-piping, has traditionally been limited to mainly English and a few other Germanic languages. Unavoidably, this will be reflected in our discussion as well: it will deal most extensively with *wh*-constructions, and will use Germanic, and primarily English, data; only some limited amount of comparative material drawn from other languages will be included where relevant.

It needs to be noted here that in the past few years, the above state of affairs started to change, mainly due to two recent developments. One of these, already referred to earlier, was the assumption of movement being feature-driven in the version of the MP presented in Chomsky (1995c), which as a consequence made all cases of movement of elements larger than the "driving" (attracted) features themselves be manifestations of pied-piping. The other factor contributing to the broadening of interest in pied-piping in recent years has been the body of research inspired by Kayne's (1994) Antisymmetry framework, which involves significantly increased reliance on the pied-piping mechanism in the analysis of a variety of languages (see, e.g., Koopman 1996, 1997; Koopman and Szabolcsi 2000; Nkemnji 1995; Pearson 2000b).

Given the sporadic and highly theory and analysis-specific nature of the claims about pied-piping in the literature, the following discussion does not purport to be exhaustive in any sense, and will address only some of the more prominent and influential observations, proposals, and directions for research. The organization of this chapter is as follows.

Section 2 provides a historical perspective on approaches to pied-piping and on the role it played at successive stages in the theory, from Ross (1986) and the Standard Theory (Chomsky 1965) to the current MP framework. Section 3 presents the various descriptive dimensions that pied-piping phenomena manifest, as observed with respect to the best-studied case, namely, instances of *wh*-movement. It demonstrates the existence of apparent variation according to construction-type based on (restrictive and non-restrictive) relatives, interrogatives, and free relatives, it examines the relevance of the position of the pied-piper within the larger phrase, and it outlines some observed differences relating to category type. Section 4 outlines the major directions and proposals towards a modular, comprehensive, structure-dependent view of pied-piping. Proposals to account for some apparent discrepancies between construction types and for cross-categorial differences will be presented and evaluated. The discussion will include the divergent behavior of PP pied-piping and the controversial issue of clausal pied-piping, as well as some cases of pied-piping under movements other than *wh*-movement. Section 5 will address the question of LF-pied-piping, that is, the issue of whether or not there is any evidence for the assumption that covert movements may also involve pied-piping. Section 6, finally, outlines the status of pied-piping and what may permit, and in fact force, it within versions of Chomsky's minimalist framework and in other current directions of research, addressing its relation to the PF-interface, to principles of economy and to the phrasal movement vs. head-movement distinction.

2 A historical overview: pied-piping and theories of movement

2.1 *The Standard Theory and Ross's Pied-Piping Convention*

The hypothesis of pied-piping by movement operations and the corresponding Pied-Piping Convention was originally introduced by Ross (1986) as part of his proposal to replace Chomsky's (1964a) A-over-A Principle – see (3) below, accounting for contrasts such as (2a) vs. (2b) – by a set of other constraints on the application of transformations, due to various empirical inadequacies he observed with respect to the former. A classic set of data Ross pointed out as crucial evidence in favor of introducing the option of pied-piping as opposed to maintaining the A-over-A Principle were the set of alternative options shown in (4–5) involving NPs contained within larger NPs moved by the Relative Clause Formation transformation:

(3) **A-over-A Principle:**
In a structure . . . $[_A$ . . . $[_A$ . . .] . . .] . . . , if a structural description refers to A ambiguously, then that structural description can only analyze the higher, more inclusive, node A.

(4) Reports [*which*] the government prescribes the height of the lettering on the covers of are invariably boring.

(5) a. Reports [the covers of *which*] the government prescribes the height of the lettering on almost always put me to sleep.
b. Reports [the lettering on the covers of *which*] the government prescribes the height of are a shocking waste of public funds.
c. Reports [the height of the lettering on the covers of *which*] the government prescribes should be abolished.

Examples (5a–c) involve movement of larger NPs than just the relative *wh*-pronoun itself that is designated by the Relative Clause Formation transformation to undergo preposing, and at the same time, examples (4) and (5a, b) demonstrate that these data are not attributable to the A-over-A Principle since they in fact violate it. Ross's proposal, beyond his independently argued move to eliminate the A-over-A Principle, was to introduce the Pied-Piping Convention to deal with the facts in (4–5). His actual formulation of the pied-piping option was shaped by some further cases indicating that in contrast to the examples of the type in (5b, c), in certain other configurations the element designated by the transformation to move cannot carry with it, i.e., cannot pied-pipe, a larger phrase containing it. The relevant observations made by Ross, involving coordinate NPs and clauses, are illustrated in (6) and (7) respectively.

(6) *The boy [Bill and *who*(*m*)] I watched was vain.

(7) a. They will give me a hat [*which*] I know that I won't like.
b. *They will give me a hat [that I won't like *which*] I know.

Accordingly, Ross states the Pied-Piping Convention, intended as a universal convention for the application of transformations, as follows:

(8) **The Pied-Piping Convention:**
Any transformation which is stated in such a way as to effect the reordering of some specified node NP, where this node is preceded and followed by variables in the structural index of the rule, may apply to this NP or to any non-coordinate NP which dominates it, as long as there are no occurrences of any coordinate node, nor of the node S, on the branch connecting the higher node and the specified node.

It needs to be noted here that the Pied-Piping Convention was crucially stated as taking along a larger phrase only optionally. This was appropriate for cases such as (4–5). However, in a well-defined set of instances, pied-piping seemed to apply obligatorily, as shown by (9a, b):

(9) a. *the boy [*whose*] we elected guardian's employer president
b. *the boy [*whose* guardian's] we elected employer president
c. the boy [*whose* guardian's employer] we elected president

It is this phenomenon – being essentially a residual A-over-A effect – for which Ross proposed the Left Branch Condition (10); this condition renders the application of pied-piping in such cases in effect obligatory.

(10) **The Left Branch Condition** (LBC)
No NP which is the leftmost constituent of a larger NP can be reordered out of this NP by a transformational rule.

Ross's statement of the Pied-Piping Convention, as well as the LBC, refer only to the category NP. But at the time, his category NP crucially included also PPs; PPs were considered by Ross as NPs immediately dominating P and NP, so movements carrying along Ps were analyzed as cases of pied-piping under this formulation as well. Furthermore, APs and AdvPs too were taken by Ross to be derived from or dominated by NPs, hence their obligatory pied-piping effects were also assumed to be covered by this formulation of the convention and of the LBC. The marked increase of category types in the course of the evolution of the theory in subsequent decades had an obvious impact on the issue of identifying the set of categories involved in pied-piping.

Unlike the highly construction-specific transformations themselves characteristic of the Standard Theory of the 1960s assumed also by Ross, the Pied-Piping Convention clearly was conceived as applying in a general way, to all transformational

movements, and irrespective of construction type. In addition to examples involving the Relative Clause Formation transformation, Ross (1986) demonstrated the pied-piping phenomenon, and the effects of conditions on its application, with respect to transformations such as the *wh*-movement rule forming interrogatives (his Question Rule), Topicalization and Heavy NP Shift (the latter two cases are exemplified in (11) and (12), respectively).

(11) a. The boy's guardian's employer we elected president.
b. *The boy's guardian's we elected employer president.

(12) a. We elected president the boy's guardian's employer.
b. *We elected employer president the boy's guardian's.

As for the issue of the universal status of the convention and cases of apparent cross-linguistic variation with respect to pied-piping phenomena, Ross noted problems at least in two major areas. One such case involved the LBC, which turned out not to apply in some languages, as for instance Russian and Latin; hence Ross proposed that it is a condition specified in particular grammars. The other area that posed important problems for the Pied-Piping Convention was the variation among languages with respect to PPs: stranding vs. pied-piping of Ps seemed not to be a free choice in particular languages as would be expected based on the convention. The stranding of Ps was known to be prohibited in a variety of languages (e.g., German, French, Italian, Russian), i.e., pied-piping of P was obligatory. On the other hand, in languages like Danish and English, pied-piping of Ps was claimed to be prohibited in some specific environments, as exemplified below for English by (13a, b) (=Ross's (4.211b, c)).

(13) a. ?*Did you notice of which difficulties she made light?
b. *Of whom are you trying to get hold?

Ross incorporated these cases of variation as separate stipulated conditions on pied-piping that appear in individual grammars, and left the original formulation of the convention in UG. Most of the empirical issues involved remain essentially unresolved until today.

2.2 *Pied-piping in the GB model: X-Bar Theory and Move α*

The major shift in the theory that took place in the 1980s GB era, replacing the Standard Theory's assumption of language-particular grammars with the Principles-and-Parameters theory, naturally resulted in a change in the view of the pied-piping mechanism as well. One factor that had an important impact on the kinds of questions that could be raised with respect to pied-piping was the development of a full-fledged X-Bar theory of phrase structure. A relevant aspect of this development was the postulation of new phrasal categories with a

uniform X-Bar structure for categories that previously either had been neglected – as for instance the category PP, as distinct from NP, and the subsequently introduced DP, projected by D(et) (see, e.g., Brame 1982; Szabolcsi 1983; Abney 1987) – or had been assigned an exocentric structure, radically different from the rest of the phrasal categories, such as the clausal categories S and S', which have become known since Chomsky (1986a) as IP, headed by I, and CP, headed by C. This in turn resulted in an increased number of category types which exhibited a uniform, precisely articulated internal hierarchical structure, with structurally defined relations such as Spec–Head and Head–Complement, and for which cross-categorial generalizations were expected to hold in principle, and had in fact been observed with respect to various empirical domains. Given this, the issue of whether the pied-piping phenomenon is category-neutral or not and if not, why not, became an obvious subject for empirical inquiry.

This direction leading towards the need for a more general, non-stipulative theory of pied-piping was further reinforced by the elimination of individual transformations in favor of the universal maximally general 'Move α' schema for transformational movement, permitting in principle free movement of any category to any position. With construction-particular statements of transformations gone, the task of accounting for observed properties of and limitations on actual movement options got assigned to universal constraints and principles, with a limited number and kinds of open parameters, within UG. UG acquired a rich modular structure consisting of a variety of subsystems of principles (e.g., theta theory, Case theory, binding theory, locality conditions); it was the interaction of these that was supposed to derive the actual clusters of empirical phenomena recognized descriptively as 'constructions', which had earlier been accounted for by stipulating various individual construction-specific transformations. Since under Move α any size constituents could undergo movement in any construction, unless it resulted in violation of a UG principle or condition, the challenge with respect to pied-piping in this framework became quite different from the situation in Ross's time. For Ross, what needed explanation in the first place, and what led him to introduce the Pied-Piping Convention, was the existence of cases when a 'larger-than-expected' constituent moved; in contrast, in the GB era, what was in need of an account was the large set of cases where pied-piping seemed to be impossible, for apparently no known reason. In other words, movements in effect became completely unlimited under the Move α schema, making the Pied-Piping Convention as such entirely redundant, and just like other instances of overgeneration by movements, cases as, e.g., those in (14–16), involving apparently illegitimate pied-piping effects, needed to be excluded in new, non-stipulative ways.

(14) *We wondered [the rumors about *whom*] shocked Mary.

(15) *[Some *how* old boys] have you met?

(16) *[Read *what*] has John?

The first systematic investigation into the nature and limitations of what pretheoretically continued to be referred to as pied-piping phenomena in the GB framework was presented by Webelhuth (1992: ch. 4). Webelhuth's study explored *wh*-movements in the Germanic languages, and arrived at a set of important structure-dependent descriptive generalizations about what positions in terms of X-Bar theory and in what types of phrases can serve as pied-pipers. His actual account of the generalizations he uncovered was based on a modular view of UG, and involved the interaction of independently motivated principles, such as the theta criterion, the definition of syntactic operator, the Bijection Principle, the definition of the modification relation, and others. (For a discussion of Webelhuth's analysis, see section 4.)

Other work on pied-piping during the GB period concentrated on more limited issues, such as the existence of clausal pied-piping and the severe restrictions on it in languages like English and German, studied, e.g., in Nanni and Stillings (1978), Ishihara (1984), and Van Riemsdijk (1985). (On CP pied-piping see also section 4.5 below.) Another specific aspect of pied-piping addressed in the 1980s was the issue of LF-pied-piping, debated primarily (a) in relation to apparent violations of Subjacency in cases of (alleged) covert *wh*-movement of in situ *wh*-phrases by Choe (1987), Nishigauchi (1990), Pesetsky (1987a), Fiengo et al. (1988), and (b) in relation to May's (1985) QR-based account of antecedent-contained deletion (ACD). (See also chapter 77 and a general overview of LF-pied-piping in section 5.) Some more general remarks about S-structure pied-piping phenomena involving *wh*-movement were presented by Kayne (1984a: ch. 8) with reference to his notion of g-projection set.

2.3 *A Minimalist perspective: feature movement and the status of pied-piping*

One major innovation that characterized the emerging Minimalist research program of the 1990s involved a change in the conception of movement operations. The minimalist framework (Chomsky 1995c) incorporated in a strict and systematic way the earlier idea of movement having a last-resort character. This was made precise by claiming that movement in the syntactic derivation, i.e., in the computational system (CS), must always be 'driven', and specifically, it is possible only for the satisfaction of abstract morphological requirements, namely, for the checking of uninterpretable formal features (such as Case, phi-features, etc.) occurring on lexical items. The assumption that all movements are feature-driven led directly to the proposal that the movement operation Move/Attract applies only to the formal features themselves. In other words, movement in the MP framework of the 1990s was conceived of as feature movement, rather than movement of full categories (but see Chomsky 2000 for a revision of the idea of feature movement). If so, as argued by Chomsky (1995c), any case in which more than just the formal features of items move is an instance of the application of pied-piping. Thus any displacement of overt material is construed in this

framework as a case of pied-piping. (On what forces such pied-piping, related issues of economy and predictions regarding LF-pied-piping, see Chomsky 1995c and section 6 below.) This extended notion of pied-piping is referred to in the MP literature as generalized pied-piping.

Observe here the contrast arising between the status of pied-piping in GB theory and pied-piping in the above version of the MP framework. While anything could in principle move under 'Move α', so the crucial question in the GB frameweork was how to exclude – usually by various well-formedness and interpretive conditions – unwanted instances of pied-piping, the issue is exactly the reverse under Chomsky's (1995c) MP. Other things being equal, nothing can move, in accordance with the notion of derivational economy, apart from formal features, and those move only when needed for feature checking. Hence the actual occurrence of any movement of elements 'larger' than such features not only constitutes pied-piping in this version of the MP, but more importantly, pied-piping itself needs to be accounted for in terms of what forces it under the MP notion of economy.

Chomsky (1995c) suggests the strong hypothesis that all pied-piping is forced by needs of the PF-interface. Bare feature movement results in scattered, isolated features, which as such are uninterpretable for the PF component, i.e., they cannot be pronounced. So pied-piping of (at least) the full lexical item bearing the relevant feature would be forced to take place in order to repair this, and thus to prevent the derivation from crashing at PF. The empirical challenge such a proposal faces is of course to find motivated PF-based reasons for the observed pied-piping of various larger than minimal pronounceable constituents (e.g., various phrasal categories). This unified PF-interface hypothesis of (generalized) pied-piping opens up some intriguing questions for future research, such as the problems raised by the existence of both head movement and phrasal movement in the theory, when both are assumed to be feature-driven, or for instance the question of the proper analysis of apparent cases of large-scale pied-piping and of the coexistence of alternative pied-piping options with respect to the same element (see also section 6).

3 Descriptive dimensions of pied-piping: *wh*-movement

The main body of phenomena considered as uncontroversial cases of pied-piping in the literature of the past three decades manifests variation along a number of different dimensions. Using the best-studied case, namely, pied-piping under *wh*-movement, the following subsections will sort out and organize the observed pied-piping phenomena along these distinct but interrelated dimensions. Each subsection will discuss one such dimension, keeping the rest of the factors of variation constant as much as possible. This outline of the relevant descriptive dimensions will be providing the empirical foundation and frame of reference for the discussion of proposed accounts in section 4.

3.1 Construction-specific variation

Contrary to what might be expected (other things being equal) under the conception of pied-piping as a unified property of movements, it turns out that at least prima facie, pied-piping applies differently to different construction types. Thus, three core cases of *wh*-movement construction of English, each involving an overt *wh*-morpheme, exhibit three distinct patterns of possible pied-piping. One such unexpected contrast holds between pied-piping options in relative clauses – of the type that led Ross to propose the Pied-Piping Convention in the first place – and pied-piping options in *wh*-questions. As will be demonstrated in section 3.1.1, a specific set of pied-piping cases exist in English with respect to relative clauses formed by *wh*-movement but not with respect to corresponding interrogatives being formed by *wh*-movement. In addition to this apparent relative–interrogative *wh*-movement contrast, a third distinct pattern of pied-piping options is attested in the case of *wh*-movement forming free relatives. As will be shown in section 3.1.2, pied-piping effects in free relatives are even more limited than they are in the case of *wh*-interrogatives. In a set of well-defined subcases, pied-piping by the *wh*-word seems impossible in free relatives while the same phrase can be pied-piped both in (restrictive and non-restrictive) headed relatives and in *wh*-questions.

3.1.1 Restrictive and non-restrictive relative clauses vs. wh-questions

Pied-piping under *wh*-movement has been observed to be most permissive in the case of relative clauses, and especially in non-restrictive relatives (on a contrast observed between pied-piping in restrictive and non-restrictive relatives, see the discussion of (21a, b) and (21c) below, as well as section 4.3.1). Consider first the kind of relative clause data (discussed also by Webelhuth 1992) that was used by Ross as the initial motivation for the Pied-Piping Convention.

(17) a. Reports [the height of the lettering on the covers of *which*] the government prescribes should be abolished.
b. He is a linguist [articles by *whom*] the editors always reject.
c. This is the kind of woman [proud of *whom*] I could never be.

Crucially, it turns out that the corresponding *wh*-questions are unacceptable. (The unacceptability of such pied-piping is even sharper in embedded interrogatives than in matrix ones, possibly due to interference from echo questions in the latter cases, as noted in Kayne 1994.)

(18) a. *[The height of the lettering on the covers of *which* reports] did the government prescribe?
b. *We don't know [articles by *whom*] the editors have rejected.
c. *I asked Bill [proud of *whom*] he has always been.

Descriptively speaking, what seems to characterize the *wh*-phrases that manifest contrasting pied-piping options in relatives vs. in *wh*-questions in English is that the *wh*-word itself in these types of phrases is located to the right of the head of the phrase (this will be made more precise in section 3.2). The cross-linguistic status of the above type of data suggests that it is the possibility of such (apparent) pied-piping in English relatives, rather than its unavailability in English *wh*-questions, that is special in some way, i.e., that is the unexpected aspect of the contrast. The reason is that relative clauses in the other Germanic languages uniformly fail to permit such instances of pied-piping, as shown for instance by Webelhuth's (1992: 129) examples for German, Dutch (see (19–20)), as well as for Swedish, Danish, and Norwegian.

(19) *der Präsident, [ein Bild von *dem*] an der Wand hing German
the president a picture of whom at the wall hung

(20) *de president, [een foto van *wie*] aan de muur hing Dutch
the president a picture of whom at the wall hung

Observe furthermore that such cases of pied-piping in English relatives as in (17) contrast not only with corresponding English *wh*-interrogatives, and not only are they ungrammatical in the other Germanic languages, but they also vary in acceptability among themselves. A systematic aspect of the latter kind of variation is pointed out by Emonds (1985: 304, n. 20).

Emonds claims that the marginal status and variability of judgments hold for pied-piping of this type specifically within restrictive relatives, indicating that such cases when acceptable, are only 'derivatively' generated, on the model of non-restrictive relatives. He bases this claim on restrictive relatives such as in (21a, b), where interference from non-restrictive relatives is reduced by the choice of the heads of these relatives (which would be inappropriate as heads of non-restrictive relatives), and on their contrast with the non-restrictive relative (21c). (Emonds's judgments below are not uniformly shared by speakers.)

(21) a. ?We should visit only the city [a favorable report on *which*] Jack received.
b. *Most students are interested in any professor [a security file on *whom*] the government won't release.
c. Most students are interested in Prof. Rotestern, [the security file on *whom*] the government won't release.

He concludes that pied-piping by a post-head *wh*-word is a legitimate, though stylistically literary, option only for non-restrictive relatives.

In sum, pied-piping (by a *wh*-word) in English has been shown to be more limited in questions than in relatives, or at least than in non-restrictive relatives.

3.1.2 Free relatives

Consider next the following contrast between *wh*-questions and headed relatives on the one hand and free relatives on the other, involving a type of pied-piping not discussed in section 3.1.1, namely, pied-piping when the *wh*-word occurs to the left of the head of the relevant phrase:

(22) ***Wh*-questions:**
a. I wonder [*what*] you bought.
b. I wonder [*whose* picture] you lost.
c. I wonder [*whose* mother's picture] is hanging on the wall.

(23) **Relatives with an overt head:**
a. the picture [*which*] you bought
b. the person [*whose* picture] you lost
c. the person [*whose* mother's picture] is hanging on the wall

(24) **Free relatives:**
a. I like [*what*] you bought.
b. *I admire [*whose* picture] you lost.
c. *[*Whose* mother's picture] is hanging on the wall should be fired.

The impossibility of pied-piping within free relatives demonstrated in (24b, c) above, and their striking contrast with the perfectly grammatical corresponding *wh*-questions and overtly headed relatives (as in (22b, c) and (23b, c)) was first pointed out and analyzed in Grosu (1989). As demonstrated by Grosu, this severe limitation on free relatives with respect to pied-piping effects is not specific to English, but holds for the full range of languages (e.g., also in German, Romanian, Finnish, Latin, Classical Greek), and is independent of where the particular free relatives fall in terms of the matching parameter (see also Grosu 1994 and chapter 27). The proposed account, based on the need of local identification for the *pro* head of the free relative, will be discussed in section 4.3.2.

3.2 The phrase-internal position of the pied-piper

The phenomena introduced in section 3.1.1 already suggested that the position of the potential pied-piper within a phrase is a relevant factor in determining whether that particular phrase will or will not undergo pied-piping. Specifically, we have seen that with the exception of some relative clauses in a literary register of English, pied-piping in the Germanic languages under *wh*-movement is possible only if the *wh*-word occurs to the left of the head of the phrase (see, e.g., (18), (19), and (20)). This observation needs to be made more precise by exploring the exact nature of the apparent constraint on the position of the pied-piper within the relevant phrase. Consider first the contrast shown in (25) and (26) regarding pied-piping options for DPs in English:

(25) a. I wonder [*whose* articles] they read.
b. I wonder [*which* airport] is the busiest.

(26) a. *I wonder [articles by *whom/which* linguists] they read.
b. *I wonder [the airport *where*/in *which* city] is the busiest.

Descriptively speaking, the relevant generalization in this set of examples is that a DP can get pied-piped under *wh*-movement only when the *wh*-word is either to the left of the head, more precisely, as suggested by (29–30) below, occupying its Spec position (as in (25a)) or is the head D itself (as in (25b)). When it follows the head of the phrase, specifically, when it is a complement of the lexical head or a modifier (adjunct), as in (26a, b), then it cannot induce pied-piping of the phrase. A similar pattern is observed also in the case of pied-piping of APs.

(27) I wonder [*how* proud of his achievements] your brother is.

(28) *I wonder [very proud of *what/whose* achievements] your brother is.

At this point one may still assume that the observed generalization about the pied-piper's phrase-internal position involves linear order with respect to the head, rather than notions of hierarchical structure and corresponding grammatical relations within the phrase. But consider the following relevant data from English and German DPs, as well as APs in German, discussed in Webelhuth (1992):

(29) a. *[The/Some *how* old books] has John lost?
b. *[Die *wie* alten Bücher] hat Hans verloren?
the how old books has Hans lost

(30) *[Auf *wen* sehr stolz] ist Hans?
of whom very proud is Hans

In (29a, b) the *wh*-word is to the left of the lexical head of the phrase, yet it cannot induce pied-piping. But this is precisely what one would expect if the correct generalization was based on hierarchical position in terms of X-Bar theory: unlike in (25) and (27), here the *wh*-word is not in the Spec position of the pied-piped phrase, but is in an adjunct of the noun phrase, namely, in an attributive-adjective phrase. The example in (30) provides even stronger evidence against a linear precedence-based generalization for what can be a pied-piper in a phrase. It shows that even though in German PP-complements of adjectives are possible both to the right and to the left of the head A (see Webelhuth 1992: 122), pied-piping of the AP by a pre-head *wh*-complement is still impossible, just like it is with post-head ones. Again, this suggests that it is being a complement rather than a Spec of the AP that is the crucial factor blocking pied-piping by the *wh*-word here, and not linear position.

Finally, one might perhaps try to claim at this point that all the above cases where the *wh*-word could not act as a pied-piper, (26), (28), (29), and (30) are due to a requirement that the pied-piper needs to be adjacent to the left periphery of the phrase, i.e., needs to be in absolute initial position. But notice that this amended linear alternative turns out to be inadequate as well, in light of the following evidence from pied-piping data involving Hungarian DPs (on a detailed analysis of the latter see Szabolcsi 1983 and subsequent work). The Hungarian facts indicate that in fact the pied-piper need not be initial in the pied-piped phrase.

(31) a. [János *melyik* fiát] szereted legjobban? Hungarian
John which son-3Sg Poss-Acc like-2Sg best
'Which son of John's do you like most?'
b. [Az anyád *hány* barátnőjének]
the mother-2Sg Poss how many woman-friend-3Sg Poss-Dat
telefonáltál?
phoned-2Sg
'How many of your mother's friends did you call?'

The type of facts presented in this subsection leads to the conclusion that the position of the (potential) pied-piper in the relevant phrase is a major factor in determining whether pied-piping will or will not be possible. Furthermore, the descriptive generalization emerging from the data so far is that specifiers and heads of phrases are able to induce pied-piping, whereas complements and adjuncts are not pied-pipers. (For further elaboration of this generalization and for proposed accounts, see Webelhuth 1992: ch. 4 and sections 3.3 and 4.)

3.3 Category type of the pied-piped phrase

An additional dimension of variation with respect to pied-piping phenomena involves the category type of phrases undergoing pied-piping. Even if we limit ourselves to the core set of category types that were assumed already during the GB period, we find that not all phrasal categories undergo the same range of pied-piping phenomena; rather there seem to exist some category-specific differences in pied-piping under *wh*-movement.

The case of DPs, APs, and AdvPs is the most straightforward. They can get pied-piped under *wh*-movement, as expected based on what we saw in sections 3.1 and 3.2. Specifically, the general case of pied-piping attested both in *wh*-questions and in relatives shown in section 3.1 (where the pied-piping *wh*-word is a specifier or a head) occurs consistently with all three of these categories. Furthermore, in languages like English, which exhibit Left Branch Condition effects, they get pied-piped obligatorily.

(32) **Pied-piping of DP:**
She wondered [*whose* closest friends] you had invited to the party.

(33) **Pied-piping of AP:**
I wonder [*how* proud of his achievements] is your brother?

(34) **Pied-piping of AdvP:**
I wonder [*how* well] she remembers her early childhood.

The cases of PPs and of clausal projections with respect to pied-piping options are far more complex, and they exhibit some patterns that are unexpected under the generalizations reached in section 3.2 above.

Regarding PPs, the major phenomenon to observe involves the existence of standard (not stylistically restricted) pied-piping of PP by a *wh*-word or phrase in its complement position, instantiated in *wh*-questions as well as in the various types of relatives; this is in contrast with the case of the other phrase types discussed, where complements were not pied-pipers. The pied-piping of Ps involves significant language particular variation: some languages, such as those permitting preposition stranding (see chapter 50), e.g., the Scandinavian languages and (colloquial versions of) English, exhibit pied-piping by the complement of P only optionally, and in certain cases not at all, whereas in a wide variety of other languages, including German, French, Spanish, and Russian, complements of P pied-pipe obligatorily under *wh*-movement. Pied-piping of PP by a *wh*-complement is illustrated below from German and Dutch.

(35) **PP-pied-piping by complement:**
a. [Mit *wem*] hat Hans gesprochen? German
with whom has Hans spoken
b. [Van *wie*] heb je die schaar gekregen? Dutch
from whom have you those scissors gotten
(Webelhuth 1992: 124)

Beyond the surprising behavior of complements of P, pied-piping by *wh*-elements in Spec is possible (though contrary to Ross's Left Branch Condition, is not obligatory), and pied-piping by modifiers is impossible, as expected based on the discussion in section 3.2:

(36) **PP-pied-piping by Spec:**
[*How many* feet behind the house] should I put the table?
Cf. [*How many*] feet should I put the table behind the house?
(Emonds 1976: 184)

(37) **PP-pied-piping by Modifier:**
a. *[Where into the kitchen] did John go?
Cf. He went [downstairs [into the kitchen]].
b. *[Wohin in die Küche] ist er gegangen?
where into the kitchen is he gone
(Webelhuth 1992: 125)

What is left to examine now is the behavior of the extended projections of V (in the sense of Grimshaw 1991), i.e., VP and the clausal functional projections postulated above VP. With respect to these clausal projections, we will limit our discussion here to the highest canonical clausal projection, namely to CP. (On proposals involving pied-piping of IP, in particular to Spec of CP, see, for instance, Sportiche's 1995 argument from French intonational yes–no questions, and Koopman's 1996; 1997 IP-pied-piping account of subject-*wh* extraction in English.)

Let us consider first the question of whether VPs undergo pied-piping under *wh*-movement. Notice that under the VP-internal subject hypothesis, the external argument of V originates in the Spec of VP and it undergoes A-movement to Spec of IP (at least in languages like English). This means that the Spec of VP is filled by a trace, hence it cannot be tested for whether a *wh*-element in it could or could not pied-pipe the VP under *wh*-movement. As for other positions in the VP, consider the set of data given below in (38) and (39) (Webelhuth 1992: 123–124); what it demonstrates is that neither a *wh*-complement nor a *wh*-adjunct may induce pied-piping of a VP.

(38) a. *[Read *what*] has John?
b. *[*Was* gelesen] hat Hans?
what read has Hans

(39) a. *[*How* closed the door] has John?
b. *[*Wie* die Tür geschlossen] hat Hans?
how the door closed has Hans

The issue of pied-piping of clauses under *wh*-movement presents a less uniform situation; in the literature there are some well-known, though controversial, claims regarding particular languages, e.g. Basque and German, permitting some varieties of clausal (CP) pied-piping. In this section we will present only the basic cases, focusing on English, and return to discuss some further more controversial, and language-specific cases in the overview of CP-pied-piping in section 4.5.

As noted in Webelhuth (1992: 126) based on examples from English (non-echo) *wh*-questions with a finite CP complement, such as (40) below, pied-piping of CP by a *wh*-element in its IP complement is impossible, irrespective of whether the *wh*-phrase occupies Spec, complement or adjunct position in the IP.

(40) a. *[That *who* met John] did Mary know?
b. *[That John met *who*(*m*)] did Mary know?
c. *[That John left *when*] did Mary know?

Similarly, pied-piping of infinitival CPs by a *wh*-element in IP is also impossible, as shown below by the (non-echo) question in (41). The same is true for standard (not stylistically marked) relative clauses as well. (On the case of non-standard extensive pied-piping in the stylistically marked, literary versions

of relatives in English introduced in section 3.1.1 above, which includes also certain instances of clausal pied-piping, see section 4.3.1.)

(41) *[To meet *who*(*m*)] would Mary be very happy?

Finally, turning to the important issue of whether a *wh*-element occupying the Spec position in CP may or may not act as a pied-piper for the whole CP, consider the following:

(42) **CP-pied-piping by Spec:**
a. *[*Which* boys to invite] did John suggest?
b. *[*Wer* ein Buch gelesen hat] wusste Hans?
who a book read has knew Hans
(from Webelhuth (1992: 127))

This type of data seem to indicate clearly that no CP pied-piping is possible under *wh*-movement, at least in English, and according to Webelhuth's (1992) claim, in the other Germanic languages either (on a controversial case of clausal pied-piping in German by a relative pronoun, see section 4.5). However, it is worth noting here that English still exhibits a construction which at least prima facie suggests that this statement may turn out to be too strong. Thus, although subject to a number of hitherto unexplored limitations, the sentence-type exemplified in (43) below might appear to instantiate CP-pied-piping by a *wh*-specifier in English (this case was originally pointed out by Anna Szabolcsi (p.c.), and was referred to in relation to the analysis of so-called partial *wh*-movement constructions in Horvath (1998, n. 10) and Kayne (2000: ch. 13, n. 107).

(43) a. [*Where* did he go], do you think?
b. [*Who* left last night], do you think?

Whether cases like (43a, b) indeed instantiate CP-pied-piping is however far from unequivocal. The presence of main clause properties in the allegedly pied-piped embedded CP, such as the requirement of being tensed (cf. (42a) and (43)), and most prominently the obligatory application of subject-auxiliary inversion (as in (43a)), suggests an alternative analysis involving no clausal pied-piping (on 'root phenomena' in embedded vs. main clause contexts, see chapter 23). Under the latter alternative, the bracketed clause in (43a, b) is the main clause, and the rest of the sentence (*do you think*) would be taken to be a parenthetical. However, until an in-depth systematic investigation of the topic is undertaken, no firm conclusion can be reached regarding the proper analysis of this curious construction type.

4 Issues and proposed analyses

In this section we will approach the various observations regarding pied-piping effects under *wh*-movement reviewed in section 3 in a systematic theory-bound

manner. The section will present and discuss proposals aimed at developing a comprehensive account that could integrate the descriptive generalizations reached with respect to *wh*-movements, together with other known pied-piping phenomena, into a general theory of pied-piping, possibly involving the interaction of several independent modules of UG. Within the framework of the P&P conception of UG, and in particular, assuming versions of this theory that have emerged since the early 1990s, it is helpful to organize the discussion of the observed pied-piping effects and the proposed accounts around the following two general questions:

(i) Given that by definition, any movement potentially involving pied-piping is (under current assumptions) driven by the need for some element smaller than the pied-piped phrase (e.g., a lexical item, or a formal feature) to be placed in a new position, what are the conditions that enable the pied-piping operation to take place, i.e., what makes movement of the larger constituent containing the element actually driving the movement operation possible in the first place?
(ii) How does the particular structure arising from the application or non-application of a pied-piping operation satisfy or violate assumed general well-formedness conditions on the output of syntactic computations (such as the requirements on operator-variable chains, the Bijection Principle, the theta criterion, or the identification of phonologically null elements)?

The primary focus of our discussion below will be question (i), and aspects of question (ii) will be brought in only to the extent that they directly bear on the particular empirical phenomena under discussion. Otherwise, issues such as for instance what mechanisms are needed for assigning correct interpretations at the LF-interface (with respect to anaphor binding, scope, etc.) to elements within pied-piped structures, and specifically the issue of the need for and the nature of a reconstruction mechanism, will not be addressed (on the latter, see chapter 54).

Based on the facts presented in section 2, it is clear that the answer to question (i) cannot be that pied-piping is free, i.e., that any moving element can pied-pipe any phrase dominating it. But at the outset, it also needs to be noted that the patterns of occurrence of pied-piping do not seem to be adequately accounted for based on the initially appealing idea that it is a default mechanism, namely, that pied-piping applies if and only if extraction of the smaller element driving the movement is prohibited. This type of hypothesis turns out to run into problems when we consider, for instance, cases where either a *wh*-element in Spec position of a phrase or the whole phrase itself may undergo the same movement operation, without resulting in any stylistic markedness; see, e.g., the case of English PPs with a *wh*-specifier as [[*how many* feet] behind *the house*] in example (36) above, or pied-piping options of DPs by *wh*-specifiers in languages such as Russian, where the Left Branch Condition seems not to apply, and extraction of the specifier is permitted. Furthermore, the above idea of 'free pied-piping as

default' is also shown inadequate by cases where, although the *wh*-elements occur within extraction islands such as, e.g., complex-NPs, coordinate structures, adjuncts, etc., yet the dominating large phrase cannot get pied-piped, in spite of the unavailability of *wh*-extraction (see e.g. (44b)):

(44) **Adjunct island:**
  a. *They knew *what* he felt guilty [after saying *t*].
  b. *They knew [after saying *what*] he felt guilty.

Thus, there clearly seem to be some substantive structure-sensitive prerequisites for pied-piping to take place.

4.1 What can pied-pipe a phrase?

A logical starting point for the exploration of the essence of pied-piping, and one that also reflects the main direction of current research on the subject (such as in Webelhuth 1992: ch. 4; Koopman 1996, 1997) is provided by the initial descriptive generalization (see (45)) reached in section 3.2 regarding the structural position of pied-pipers vs. non-pied-pipers within their phrase (manifested most transparently in the case of DPs and APs, as, e.g., (25a, b), (27) vs. (26a, b), (28–30)):

(45) Given a phrase XP,
  a. the head X and the specifier YP are pied-pipers for XP;
  b. complements of X and modifiers (adjuncts) are not pied-pipers for XP.

Some of the empirical phenomena reviewed in section 3 represent apparently major deviations from this primary generalization. Such are, obviously, the stylistically marked heavy pied-piping cases attested in relative clauses in English (shown in section 3.1.1), more importantly, the widely attested case of PP pied-piping by a complement of P, and also the case of CPs (shown in section 3.3), as well as the case of DPs in free relatives (in section 3.1.2), both of which appear not to get pied-piped even by their specifier. Each of these apparent deviations from the generalization in (45) will be reexamined and dealt with in sections 4.3, 4.4, and 4.5.

Further exploration of the statement in (45), reveals that it is not fully adequate in its present form even for the apparently straightforward DP and AP cases that it was primarily motivated by. Beyond examples such as (25a, b) and (27) representing cases of legitimate pied-piping, consider data of the following type, manifesting additional pied-piping options; such data argue for making the statement of (45) somewhat more general.

(46) They wondered [*whose* daughter's teacher] the school had fired.

In the above cases the pied-piped phrase, namely a DP, has a *wh*-word in it (*whose*), however this itself is neither the head nor the specifier of the moved

phrase. In (46), the pied-piper *whose* is the specifier of the specifier of the moved DP. What this suggests is that being a pied-piper for a phrase via the specifier relation, as stated in (45), is a transitive relation, so that also a Spec of a Spec (of a Spec) of a phrase can act as a pied-piper for the phrase. In the following section we will elaborate the core pied-piping generalizations presented above, and discuss proposals for the underlying mechanism from which they may derive.

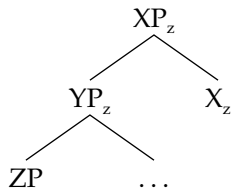
4.2 *The core cases: projection and the Spec–Head relation*

Conceptually, the generalizations summarized in (45) and amended above based on (46) seem reasonable, given what is known about the various structural positions within phrase structure. Heads project their features, thus giving rise to higher (phrasal) categories, and, consequently, phrases by definition exhibit features of their heads. Thus any feature on a head that may be driving a movement operation is available on the phrase projected from that head, hence the particular movement operation may in principle move the phrase itself, resulting in 'pied-piping' of a phrase by (features of) its head. The only other feature-sharing (agreement) relationship permitted in restrictive theories of phrase structure since Chomsky's *Barriers* (1986a) is between the specifier and the head of the phrase. This Spec–Head agreement relation offers an obvious account for pied-piping of a phrase by its Spec, provided the additional assumption that this agreement relation is dynamic in the sense that features of a specifier that the head does not possess may be inherited by this head under the Spec–Head agreement relation. (For some empirical consequences of this latter assumption, see the discussion of operator features and CP-pied-piping by *wh* under Webelhuth's (1992) analysis in section 4.5, as well as Grosu's (1994) 'anti-pied-piping' effects presented in 4.3.2.)

Koopman (1997) explicitly formulates the hypothesis that the pied-piped category inherits the feature relevant for the checking relation driving the movement through projection from the head. Furthermore, according to Koopman's hypothesis, as well as to Koopman and Szabolcsi (2000), a head can acquire such a feature in two ways (or through a combination of these two ways): the feature may originate in Spec position, and a head may inherit it through (a series of) Spec–Head agreement relations, assumed to involve a 'dynamic' type of agreement (as illustrated in (47)); alternatively, the head may inherit a feature through head movement, i.e., through a lower head bearing the feature being raised to it (this latter way will be presented in section 4.4, in the context of PP-pied-piping by a complement of P).

(47) **Pied-piping via Spec–Head agreement:**
XP inherits a feature from its *specifier (where '*specifier' is the transitive closure of the specifier relation).

E.g.:



(Koopman 1997 and Koopman and Szabolcsi 2000: 41)

In this case, ZP, being the specifier of YP, agrees with the head Y; Y's features are the features of its maximal projection YP. YP itself, being the specifier of XP, agrees with the head X, and features of X are features of its maximal projection XP. Hence XP is able to get pied-piped under movement applying to phrases bearing the feature z.

This type of account, based on mechanisms of feature inheritance and projection, is relevant for all movement operations that are driven by the presence of some syntactically active (formal) feature; its consequences extend both to A-bar movement (operator–variable) constructions, like the case of *wh*-movement under discussion, as well as to cases of A-movement, where there is no operator, and the features involved are inflectional ones, such as, e.g., Case and phi-features. What is important to note here though is that the above proposal for deriving the observed core pied-piping generalizations makes sense only if the movements involved are feature driven. If on the other hand, the overt movement of phrases were not driven by needs of feature checking, but rather for instance by an EPP property of some functional heads requiring the merger of a Spec (as proposed in Chomsky's 2000 version of the MP which assumes an operation Agree), then the pattern of pied-piping facts above might not be accounted for by the applicability/inapplicability of the movement operation itself, since the latter would not depend on the moved phrase having acquired any particular feature. Thus it would be unclear why the kind of structural position occupied by the *wh*-morpheme within the moved larger phrase turns out to make a difference for grammaticality. So under the assumption of non-feature-driven movement, the observed differences, such as for instance the well-formedness of a *wh*-element in the Spec but not in the complement position of the phrase moved to Spec of CP, would have to receive an alternative account.

A possible attempt at such an account, namely, an attempt to derive the pied-piper status of the Spec (of Spec) position in phrases without relying on features, may be based on some independent proposals made with respect to the c-command and binding properties of the Spec position by Kayne (1994), and further elaborated by Hornstein (1995). In Kayne's (1994) Antisymmetry theory, specifiers are taken to be an instance of adjunction. This assumption about specifiers, together with a definition of c-command crucially formulated in terms of exclusion (see (48), Kayne (1994: 24), has the consequence that a specifier will c-command out of the phrase it is the specifier of. In contrast a complement, as before, will not c-command out of its phrase.

(48) X c-commands Y iff X and Y are categories and X excludes Y and every category that dominates X dominates Y.

This will immediately account, for example, for the traditionally problematic cases of bound interpretation of the pronouns (discussed by Reinhart 1983a: 177) in examples like *Everyone's mother thinks he's a genius,* or *Nobody's students should respect him,* where the quantifier appears in Spec of the subject DP. It will predict the contrast with the unavailability of a bound interpretation for the pronoun in otherwise similar cases when the quantifier is in complement position within the subject DP, as in cases like *A small part of every article undermined it,* or *The election of no one to the Hall of Fame hindered his career* (from Hornstein 1995: 107). Now notice that the above assumption, namely, that specifiers, and no other positions in the phrase are able to c-command, and hence bind, some element out of that phrase could potentially provide a non-feature-based account for the specifier vs. complement distinction between pied-pipers of *wh*-moved phrases. The reason is that irrespective of the issue of *wh*-feature-checking on C, the *wh*-operator dominated by the phrase moved to Spec of CP position, such as, e.g., *whose* in *Whose article have you read?* needs to bind a variable; it needs to bind a corresponding trace within the IP. Assuming the copy theory of movement, such a 'trace' would indeed be available within the lower copy of the moved phrase. Whether this trace can or cannot be bound by the *wh*-operator dominated by the pied-piped phrase in Spec of CP depends now on whether the position of the *wh*-operator is such that it c-commands out of the Spec of CP, and hence binds the trace within the IP-internal copy. Assuming, crucially, that no additional (covert) raising of the *wh*-operator itself is stipulated, a *wh*-operator appearing in the Spec position of the pied-piped phrase will still be able to bind the corresponding trace in the copy, whereas a *wh*-operator occurring as a complement of the same phrase will clearly fail to satisfy the requirement of binding the trace in IP, due to failure of c-command.

However, some immediate empirical problems arise in relation to this notion of c-command and its use as an alternative to feature-inheritance accounts for the observed distinctions between positions of *wh*-pied-pipers vs. *wh*-non-pied-pipers within phrases. One of these is the fact that, based on Kayne's (1994) notions of specifier and c-command (48), DP specifiers would be expected to give rise to Condition C effects (in the sense of Chomsky's 1981 Binding Theory), namely, disjointness of reference in cases such as (49), and strong crossover, rather than merely mild weak crossover, effects in cases such as (50a). But the (underlined) specifiers of the DPs in (49) and (50a) in fact fail to induce Condition C and strong crossover effects. The absence of strong crossover is demonstrated by the relative acceptability judgment on (50a) contrasting with an uncontroversial strong crossover case (50b) (on the variability and mildness of weak crossover effects manifested by restrictive relative clauses such as (50a), see Lasnik and Stowell 1991).

(49) [His$_i$ mother] thinks that John$_i$ is a genius.

(50) a. ??the girl who$_i$ [[her$_i$ brother] has hit t_i]
b. *the girl [whose$_i$ brother] [she$_i$ has hit [t_i [ ]]]

The facts in (49–50) thus raise serious doubts about these specifiers of DP being able to c-command into the clause, and, more generally, about the claim that specifiers can c-command outside of the maximal XP that they are specifiers of. Incidentally, in contrast to this 'c-command out of Spec' proposal, the feature-inheritance account formulated in (43) for pied-piping may also provide a way to approach the problematic discrepancy noted here between the variable-binding behavior of quantificational specifiers (as in *Everyone's mother thinks that he is a genius*), on the one hand, and the lack of A-binding behavior of non-quantificational specifiers (see (49)), on the other. A potential account reconciling the two structurally parallel cases may be based on the reasonable assumption that while operator features – such as [*wh*] or [Distributive] – can be freely inherited by the dominating XP via the Spec–Head configuration (as in (47)), referential properties of a DP in Spec, such as those relevant for Condition C effects, cannot be inherited since the dominating DP has independent referential properties of its own.

Another empirical problem arising with respect to the purely operator binding-based (i.e., c-command-based) account of the pied-piping generalizations (45) considered above involves the unexpected discrepancy manifested by adjuncts (modifiers) of DP between the possibility of binding a pronoun and being a pied-piper (see (51a, b)); this is in contrast to the parallel we noted in the case of specifiers (being both binders of pronouns outside of DP and pied-pipers of DP) and complements (being neither binders of pronouns outside of DP nor pied-pipers). While in (51a) the adjunct in the DP seems to be able to bind a pronoun outside its phrase, in a parallel configuration in the embedded clause of (51b), pied-piping by the same adjunct in DP is still not acceptable.

(51) a. [Someone from *every small town*] hates *it.* (Hornstein 1995: 107)
b. *We wondered [[someone from *which small town/where*] Bill met].

Some general questions to consider regarding this alternative, non-feature-based, account explored above are these. Is it actually sufficient for a fuller range of pied-piping cases, and, in particular, for *wh*-adjuncts (see the contrast in (51a, b)), which were shown to act systematically as non-pied-pipers? Are the assumptions made earlier regarding the way operator–variable chains are created independently supported? Do they indeed make the feature-inheritance hypothesis of pied-piping redundant, or do these two mechanisms coexist, at least in some of the constructions? Answers to these questions would need to be established based on further investigation and broader theoretical considerations, most of which are beyond the scope of this study.

Returning to the main line of investigation of the core pied-piping generalizations (45), namely, to the one based on the hypothesis of feature-driven movement together with feature 'inheritance' via the Spec–Head relation such as

formulated in (47), let us consider a related empirical issue not addressed so far. Other things being equal, the proposal predicts that all specifiers will be able to pied-pipe the phrase they are specifiers of. However, Webelhuth (1992, p. 133), in his influential work on pied-piping, calls attention to a set of facts that pose a particularly striking problem for this prediction. It involves the pied-piping behavior of English gerundive nominals with a *wh*-element in the Spec of DP position, and their contrast with parallel non-gerundive DPs, such as derived nominals, whose lexical head is N (such data were originally observed by Ross (1986: section 4.4.2)). After presenting the relevant facts (see (52–53)), we will discuss some major aspects of Webelhuth's theory of pied-piping which enabled him to derive this phenomenon, as well as could be extended to some of the other known pied-piping generalizations.

(52) a. The boy [*whose* loud playing of the piano] I disliked was a student.
b. *The boy [*whose* playing the piano loudly] I disliked was a student.

(53) a. I wonder [*whose* harsh attack on Dukakis] the Democratic voters resented most.
b. *I wonder [*whose* harshly attacking Dukakis] the Democratic voters resented most.

As shown by the unacceptability of (52b) and (53b), DPs that contain gerundive nominals cannot get pied-piped by their *wh*-specifier. This is a puzzling phenomenon in light of the fact that specifiers were found to be the prototypical pied-pipers, and the theoretical proposals outlined above had conceptually plausible ways of incorporating this (apparent) generalization. The impossibility of pied-piping manifested by gerundive nominals is more surprising than some other known deviations from the core generalizations given in (45), since unlike, for instance, the case of PPs being pied-piped by complements of P, in cases like (52b–53b) we are dealing with a DP, which is the very category that provided the primary motivation for the pied-piping generalizations. Notice also that their derived nominal counterparts in (52a) and (53a), i.e., parallel DPs but, crucially, exhibiting a lexical N as their head, do get pied-piped by the same *wh*-specifier (*whose*).

In view of these facts, Webelhuth (1992: ch. 4) develops the hypothesis that the crucial distinction between specifiers (of non-clausal categories) that are pied-pipers and those that are non-pied-pipers is a consequence of the theta criterion. In fact, Webelhuth proposes and derives the following broader descriptive generalization within his modular approach to pied-piping.

(54) A theta-marked phrase is not a pied-piper.

This hypothesis has obvious potential consequences also for the (non-)pied-piper status of complements, but here we will concentrate on (a) how (54) itself is claimed to be derived from Webelhuth's feature percolation or projection mechanism in

interaction with principles of the GB theory, and (b) how it is claimed to account for the gerund–non-gerund contrast with respect to pied-piping by specifiers. (We will return to the consequences of (54) for complements in section 4.4.)

Webelhuth's proposed account of pied-piping is presented in the general context of his theory of syntactic saturation, more specifically, of the projection of the complementation, specification, and modification relations. In this broader framework dealing with the projection of syntactic properties in phrase structure, he also postulates conventions of feature percolation or inheritance (similarly to Koopman 1997 and Koopman and Szabolcsi 2000). However, unlike the more restrictive exclusively Spec–Head relation-based mechanism in (47) above, Webelhuth's theory stipulates that (operator) features can be inherited not only from specifiers but also from complements. Notice that since no features are assumed to be inherited under the modification relation in Webelhuth's theory, the fact that modifiers can never be pied-pipers is predicted in this system too. What is relevant for us at this point is that specifiers are assumed to be able to percolate their features to their mother nodes, unless the head projection of the phrase (i.e., X′) has that particular feature (possibly inherited from the complement). Importantly, the descriptive generalization (54) is based on the output representations of this feature-percolation process being 'filtered' by independent principles of UG, and, in particular, the Theta Criterion; Webelhuth's formulation of the relevant principles makes use of the notion of 'syntactic argument', which in turn involves the notion 'operator feature' (crucially, the latter is used also in the definition of 'syntactic operator').

(55) **The Theta Criterion** (Webelhuth 1992: 148)
- (i) Every syntactic argument occurs in exactly one chain that terminates in a theta position.
- (ii) Every theta position terminates a chain that is headed by exactly one syntactic argument.

(56) α is a *syntactic argument* only if
- a. α is a maximal projection
- b. α is not expletive, and
- c. α does not carry any operator features.

(57) α is an operator feature iff $\alpha \in$ {[+WH], [+Rel]}.

Based on the above assumptions, Webelhuth's account for the (alleged) generalization (54) goes as follows. The basic condition for a phrase to get pied-piped (under A-bar movements, like *wh*-movement, which his discussion is concerned with) is that it has to receive an operator feature by percolation from its specifier or complement. So in order to be a pied-piper, a specifier (say the DP *whose*) would need to percolate an operator feature ([+WH]) up to its mother node (e.g., to the nominals in (52–53)). But no specifier or complement that is able to do that, namely, no specifier or complement that carries an operator feature, can be

a member of a theta chain according to Webelhuth's formulation. The reason is that the Theta Criterion (55) requires that heads of theta chains be syntactic arguments, and according to his definition of syntactic argument in (56), a syntactic argument must not carry any operator feature. Thus, he concludes that no phrase that receives a theta role can be a pied-piper (since it cannot bear an operator feature without violating the Theta Criterion).

Given these assumptions, Webelhuth accounts for the observed contrast in the pied-piping options of DPs with gerundives vs. DPs with lexical NPs on the basis of the independently motivated (though not uncontroversial) claim that, while the specifier of a gerundive DP is theta-marked, the specifier of a derived nominal, or any other non-gerundive DP, crucially, is not theta-marked. Webelhuth supports his claim about this theta-marking distinction between gerunds and non-gerunds by observations such as for instance the contrast between *[*yesterday's attacking Dukakis*] and [*yesterday's attack on Dukakis*] (for further relevant discussion of theta-marking in nominals, see, e.g., Abney 1987; Grimshaw 1990; Kratzer 1996). So the unacceptability of the pied-piping of gerunds by a *wh*-Spec illustrated in (52b) and (53b) is attributed by Webelhuth to a violation of the Theta Criterion; the external theta role assigned by the gerund is associated with no well-formed theta chain (due to the lack of a syntactic argument heading the chain).

The way generalization (54) follows in Webelhuth's system is not very natural conceptually; for instance, the reference to "not carrying any operator features" in the definition of "syntactic argument" (see (56c)) is quite ad hoc, since apart from aiming to derive (54), it may just as well be replaced by 'not being a syntactic operator' (being a syntactic operator and being an element carrying an operator feature are crucially kept distinct in the proposed system). If (56c) were restated this way, the Theta Criterion would no longer have the consequence that a theta-marked phrase cannot be a pied-piper. Thus the real issue to consider is whether the generalization in (54) is correct empirically, i.e., whether theta-marked phrases indeed never act as pied-pipers. In section 4.4 we will return to the issue of the putative correlation between theta-marking and being/not being a pied-piper, in the context of a discussion of pied-piping by complements.

Regarding the specific account Webelhuth's hypothesis offers for the contrast between gerundive and non-gerundive nominals, one relevant consideration in favor of finding an alternative, non-theta-theory-based account (see the discussion of (58) below) is that the degree of unacceptability of examples like (52b) and (53b) reported by speakers is very different; it is far less severe than in other cases standardly attributed to violations of the Theta Criterion, specifically, e.g., when a theta chain is headed by an expletive.

Finally, consider an additional set of relevant observations about pied-piping of gerunds, cited in an unrelated context by Culicover (1999: 97); these data represent judgments distinct in a suggestive way from those in (52b–53b):

(58) a. *[*Who* solving the problem] were you thinking about?
Cf. We were thinking about [Mary solving the problem]

b. [*Whose* solving the problem] were you thinking about?
c. [*Whose* solving of the problem] were you thinking about?

The acceptability of pied-piping in (58b) indicated by Culicover contradicts the judgments that Webelhuth cites for parallel gerunds with a possessive (*whose*) as their specifier. What is more revealing is that gerunds do exhibit a prohibition against being pied-piped by a *wh*-specifier in Culicover's dialect too, as shown by (58a). However, this holds only for accusative-marked subjects of gerunds but not for the possessive ones. This difference represented in (58a) vs. (58b, c) suggests that at least in this variety of English, and perhaps more generally, the non-pied-piper behavior of specifiers of gerunds may be related to these specifiers occurring lower in the functional layer of the nominal than the Spec of the top (DP) projection.

Possessive specifiers of non-gerundive nominals occur in all dialects as the Spec of the top functional projection of the nominal (DP), hence their ability to percolate their *wh*-feature to the DP node. In contrast, at least accusative marked, i.e., non-possessive, specifiers of gerunds, and possibly in some dialects also morphologically possessive specifiers of gerunds, would appear as the Spec of a functional projection that is not the topmost one in the nominal. Specifically, either gerunds have an additional outer layer of projection compared to non-gerundive DPs (as suggested in Kayne 1994: 135, n. 18), or the specifier *who/whose* of gerunds is a Spec of some functional complement of D. In either case, the *wh*-feature of such a specifier could not be inherited by the maximal nominal phrase under the restrictive feature inheritance mechanism based on Spec–Head agreement.

4.3 Some other effects

This section will address two types of pied-piping phenomenon, introduced earlier in sections 3.1.1 and 3.1.2, which prima facie constitute major deviations, in two opposing directions, from the core pied-piping generalizations and the corresponding theoretical proposals presented in section 4.2 above. The discussion will demonstrate, however, that, arguably, each of these cases is attributable to the effects of independent factors and does not stem from the pied-piping mechanism itself.

4.3.1 Relative clauses and the topicalization proposal

As shown in section 3.1.1, English (lexically headed) relatives, and in particular non-restrictive relatives, seem to permit a curious, much more extensive pied-piping process than what one finds in other *wh*-constructions and in other Germanic languages. Among the relevant data we find, for instance, complements of DPs and APs that are able to pied-pipe their phrase (see (59), reproduced from section 3.1.1). Such pied-piping is not possible in the rest of *wh*-constructions (*wh*-interrogatives, exclamatives, etc.), and indeed it would be excluded both under the Spec–Head agreement based feature inheritance hypothesis (47) of

Koopman (1997), and also under Webelhuth's (1992) system (in the latter, due to the theta marked nature of these complements).

(59) a. Reports [the height of the lettering on the covers of *which*] the government prescribes should be abolished.
b. He is a linguist [articles by *whom*] the editors always reject.
c. This is the kind of woman [proud of *whom*] I could never be.

In spite of the fact that this type of data include the cases that led Ross (1986) to propose the Pied-Piping Convention in the first place, already as early as Emonds's (1976) it was suggested that these particular instances of apparent pied-piping constitute a special, stylistically marked phenomenon which, contrary to Ross's view, should in fact not be taken to be derived by the same grammatical device as the other cases of *wh*-pied-piping, which occur irrespective of construction type. Specifically, Emonds (1976: 187) claimed that these cases (like (59)) fall outside the domain of grammar proper and proposed that the pied-piping processes involved in them belong to the stylistic component (as defined in Banfield 1973). As a reason for this claim, he points to the "marginal" acceptability status of this particular subtype of pied-piping data. (On the occurrence of such pied-piping in non-restrictive and restrictive relatives, see the discussion of examples (21) in section 3.1.1, and for the proposal of topicalization as the source for these, see Emonds 1979.)

Later, in the context of his general account of pied-piping presented within the framework of the GB theory, Webelhuth (1992) followed a conceptually similar path regarding these stylistically marked pied-piping cases. Recall that pied-piping of a phrase by its theta-marked complement (as, e.g., in (59)) or specifier was hypothesized by Webelhuth to be excluded, as we noted in our discussion of gerunds in section 4.2. Webelhuth's considerations in favor of analyzing cases like (59) as irrelevant for the theory of pied-piping, and hence in favor of maintaining his pied-piping theory excluding them, were the following: (a) the phenomenon is English-particular, i.e., is limited to only one among all the Germanic languages; (b) it is attested in only one construction type, namely, in relative clauses (and for some speakers only in non-restrictive ones); and (c) it belongs to a "literary" style of English and is felt to be "foreign to natural colloquial speech" (pointed out by Webelhuth, citing Jespersen). Given his conclusion that the pied-piping mechanism should not be extended to derive these "unusual" cases, to avoid the obvious overgeneration problem, Webelhuth develops an account for these stylistically marked sentences with apparent pied-piping based on a topicalization analysis, suggested originally by Emonds (1979). According to Webelhuth, these phenomena fall outside the core grammar (in the sense of Chomsky's 1981 core vs. periphery). He claims that the large phrase containing the *wh*-relative pronoun undergoes topicalization, and furthermore that this *wh*-word occurring within this preposed phrase receives interpretation as an indexical pronoun in these "exceptional" constructions. This option is available, he claims, due to the basic similarity in the semantic effects of relative and indexical pronouns (both

may involve the formation of an open sentence and its predication of a referent). Thus the analysis draws a parallel between the relation of the relative pronoun (*whom*) to the head of the relative (*his wife*) in (60a) and that of the personal pronoun (*her*) to its discourse antecedent (*his wife*) in (60b) (see Webelhuth 1992: 131). It should be noted here that Webelhuth's proposal fails to offer an account for the impossibility of using a non-*wh* pronoun (*her*) instead of *whom* in English relative clauses such as (60a), and, even more significantly, the impossibility of using a *wh*-form (*whom*) as an alternative for the definite pronoun (*her*) in cases such as (60b) (the latter option appears to be excluded cross-linguistically). These distributional facts would need to be regarded as manifestations of some hitherto unspecified purely morphological variation in the realization of pronouns.

(60) a. *His wife* [proud of *whom*] he has never been.
b. *His wife* is intelligent. But [proud of *her*] he has never been.

Under this proposal, the reason why such "exceptional" pied-piping may arise in the case of relatives but not, for instance, in interrogatives is that the *wh*-words in the latter are logical operators that restrict the range of a variable, not variables that get bound. Hence they are not able to take on the function of anaphoric pronouns, in contrast to relative pronouns, for which this is more feasible.

As for the observed preference – and, according to Emonds (1979, 1985), the actual limitation – for this kind of pied-piping to occur only in non-restrictive, rather than restrictive, relatives (see (21a, b, c)), there are at least two approaches to be considered. Assuming the topicalization-based account of non-core pied-piping, Emonds (1979) attributes its non-occurrence in restrictive relatives directly to the (alleged) root nature of topicalization (on root transformations, see Emonds (1976) and chapter 23). Since under his approach non-restrictive relatives are root clauses, he predicts that these, but not restrictive relatives, will permit topicalization and hence the occurrence of the above pied-piping phenomenon. Another proposal that can draw the relevant distinction between non-restrictive and restrictive relatives, and moreover, do so without resorting to the problematic claim of topicalization being a root phenomenon, may be based on Lasnik and Stowell's (1991) findings regarding weak crossover effects in various A-bar movement constructions. They observe a contrast between the presence of weak crossover effects – i.e., the unavailability of a bound variable construal for a pronoun – in restrictive relatives (as e.g. in *the/every man*$_i$ *who*$_i$ *his*$_i$ *mother loves* t_i) and the absence of weak crossover in non-restrictive relatives (as, e.g., in *Gerald*$_i$, *who*$_i$ *his*$_i$ *mother loves* t_i). Crucially for us, their study motivates an account for the presence vs. absence of weak crossover effects in different A-bar constructions that is based on the logical status of the local A-bar binder of the pronoun: only a true quantifier (ranging over a possibly non-singleton set) gives rise to weak crossover effects, while non-quantificational A-bar binders do not. Given this, notice first that the observed inability of the *wh*-element of non-restrictive relatives to induce weak crossover effects reinforces Webelhuth's proposal of deriving the non-core pied-piping cases under discussion from the pronoun-like,

i.e., non-quantificational, nature of the *wh*-element involved, though only as far as non-restrictive relatives are concerned. Furthermore, in light of (a) the presence of weak crossover effects in restrictive relatives, indicating under Lasnik and Stowell's theory that the *wh*-element in the latter is in fact quantificational and (b) Webelhuth's topicalization-based analysis for pied-piping cases as in (59–60) above, we can make sense of the contrast observed by Emonds between the availability of non-core pied-piping in non-restrictive relatives and its unavailability in restrictive relatives.

In sum, the proposed analysis derives this exceptional pied-piping construction, not as a true relative clause involving (pied-piping) *wh*-movement, but by the independent operation of topicalization, and, crucially, assigns an interpretation to the resulting structure in analogy to sentences with anaphoric pronouns. As the reason for their stylistically highly marked nature, Webelhuth points to the mismatch that arises between "the form of these structures as relative clauses and their interpretation, which applies a semantic rule of discourse anaphora to relative pronouns that usually exclusively fall into the domain of sentence grammar" (Webelhuth 1992: 132).

As evidence for his topicalization proposal, Webelhuth mentions the prediction that if topicalization of a phrase is impossible in a particular clause, then that phrase will not to be able to undergo stylistically marked pied-piping in the corresponding relative clause. This prediction seems to be borne out indeed, as shown by his data demonstrating the correlation between the unacceptability of topicalization in examples like *[*To leave*] *I want* and the unacceptability of the corresponding relative clause **his wife* [*to leave whom*] *he wanted* (see Webelhuth 1992: 131). However, beyond the above type of correlation that may suggest that topicalization is involved in the appearance of stylistically marked pied-piping in relatives, the proposed account, as it stands, makes some broader, and more problematic predictions as well.

Webelhuth's hypothesis of the interpretation of the relative pronoun in the preposed phrase taking it to be an indexical pronoun with a discourse antecedent suggests that no extra structural or other grammatical constraints will limit its possible positions within the topicalized phrase, and it will occur as freely as an ordinary pronoun would (as, e.g., in (60a) vs. (60b)). Thus, based on the proposal, one would expect that in English any phrase that (a) can undergo topicalization in a clause and (b) contains a relative *wh*-word should be able to undergo the exceptional pied-piping process under discussion, resulting in a well-formed relative clause in the literary style. However, contrary to this expectation, a variety of phenomena have been observed in the literature indicating the existence of further clear and specific restrictions of an obviously grammatical nature that determine the acceptability status of stylistically marked pied-piping. Thus, consider for instance the contrasts between (61a, b) and (62a–d) from Nanni and Stillings (1978), involving pied-piping data of the stylistically marked kind where it is a preposed clausal constituent, such as an infinitival (vs. finite) CP, a gerundive or an absolute, that contains the relative pronoun (the position of the relative pronoun is varied). Incidentally, notice that these data would uniformly

be excluded by Ross's (1986) formulation of the Pied-Piping Convention (given in section 2.1).

(61) a. The elegant parties, [to be invited to one of *which*] was a privilege . . .
b. The strange man [upon seeing *whom*] Mary called the police . . .

(62) a. *The men, [for *whom* to be invited to the elegant parties] was a privilege . . .
b. *The strange man [upon John's seeing *whom*] Mary called the police . . .
c. *The elegant parties, [for us to be admitted to one of *which*] was a privilege . . .
d. *The car [(the idea) that their son might drive *which*] surprised them . . .

The descriptive generalizations that emerge from the above data are that the relative pronoun in the preposed 'pied-piped' constituents cannot be a subject, but seems to have to be a complement, and that the preposed constituent itself cannot have a lexical subject, and possibly in addition it cannot have finite Tense (as suggested by Cinque 1982 and Kayne 1984a: 86).

Such data are not discussed at all in Webelhuth (1992), even though the existence of this type of clausal pied-piping effects are actually predicted in his system, since clausal arguments as well as adjuncts (such as the ones preposed in (61) and (62)) are able to undergo topicalization. He considers only clausal pied-piping outside of the context of stylistically marked relatives, and based on that concludes that it does not exist in Germanic (see our discussion in sections 3.3 and in 4.5). The apparently 'pied-piped' clauses above indeed involve no true instances of pied-piping by *wh*-movement; being stylistically marked and construction specific, they fall under the hypothesis presented above for cases like (59). What is relevant in the present context is that their existence, and, crucially, some specific structural constraints on them (illustrated above) were observed and analyzed in the earlier literature, in particular by Nanni and Stillings (1978), Cinque (1982), Hendrick (1982), Kayne (1984a: 186), and Ishihara (1984). Furthermore, it is worth noting that Italian, a language that has been shown in Cinque (1982) to exhibit pied-piping phenomena in relatives parallel to the stylistically marked cases of English mentioned earlier, also turns out to manifest the structure-based grammaticality contrasts with respect to 'pied-piped' elements in relatives shown above for English.

While the facts in (61–62) demonstrate that the interpretation of the relative pronoun (occurring within a topicalized phrase) in analogy to indexical pronouns proposed by Webelhuth is clearly not sufficient to account for the stylistically marked pied-piping phenomenon, the source of the constraints manifested is not well understood. There have been several attempts in the literature to treat (at least part of) the relevant phenomena, among them Kayne's (1984a: 185) proposal based on defining a '*wh*-phrase' that can occupy the COMP (i.e., [Spec, CP]) of the relative clause in terms of the notion of g-projection set of a *wh*-phrase, Cinque's (1982) anaphor hypothesis, Ishihara's (1984) account based on

LF-raising of the *wh*-word and the ECP, and Safir's (1986) proposal of LF-raising of the relative *wh*-word to satisfy a locality requirement on R-binding by the head of the relative. However, no comprehensive adequate account has emerged so far, and this stylistically marked pied-piping phenomenon with its pattern of robust grammaticality constraints obviously calls for further investigation of the underlying mechanism(s) that may be responsible for it.

4.3.2 Free relatives and the identification of a pro *head*

The *wh*-pied-piping phenomena in (finite) free relatives introduced with respect to English in section 3.1.2 represent another initially surprising case of deviation from the pied-piping generalization stated in (45). This deviation involves the opposite direction from the deviation found in the case of overtly headed stylistically marked relatives (discussed in section 4.3.1): the possible range of pied-piping effects in such free relatives is more restricted than what one would expect of pied-piping by a *wh*-element based on the other *wh*-constructions. Specifically, the latter construction type was claimed in Grosu (1989) not to permit pied-piping even by a *wh*-specifier (of specifier) of a DP, as shown in (24); in contrast, such pied-piping occurs freely both in interrogatives, and overtly headed relatives.

Notice that the unacceptability of cases like (24b, c) cannot be attributed to some limitation on the 'size' of the preposed *wh*-constituent permitted in free relatives, in view of the perfect acceptability of examples such as (63), where the *wh*-element is the head of the preposed 'large' DP:

(63) Mary will buy [[*whichever* portraits of friends of hers] we can find *t* for her].

Neither can we dismiss the observed extra restriction on pied-piping in free relatives by attributing the observed unacceptability simply to a Case mismatch, as, e.g., between the possessive form *whose* in (24b, c) and the free relative itself, the latter needing to be accusative (in (24b)) or nominative (in (24c)). The reason is that the same anti-pied-piping effect shown in (24) is attested also (a) in cases where the Case matching requirement known to hold in free relatives is clearly satisfied (as in the German example (64) cited in Grosu 1994: 30), as well as (b) in free relatives permitting non-matching, which occur in particular positions in languages such as Romanian (see example (65), cited by Grosu 1994: 34).

(64) *Ich bedarf [pro_{Gen} [wessen$_{Gen}$ Bildes]$_{Gen}$ du auch bedarfst]. German
I need whose picture you also need
'I need (the person) whose picture you also need.'

(65) *[Al cui cîine muşcă trecătorii] trebuie amendat. Romanian
whose dog bites the-passers-by must fined
'(The person) whose dog bites those who walk by must be fined.'

According to Grosu (1994: ch. 3), this anti-pied-piping phenomenon is found universally across languages in realis free relatives, and is limited to this construction type. Since it cannot be dismissed as some peripheral idiosyncratic phenomenon, the question arising is, Does this apparent inability of the *wh*-specifier to pied-pipe its phrase (i.e., the DP) indicate a need to revise the general feature-inheritance mechanism based on the Spec–Head relation (see (47)) postulated in Koopman's (1997) and Webelhuth's (1992) system as the central mechanism underlying pied-piping, or, alternatively, is there some independent factor that creates the special limitations on the output of pied-piping in free relatives? In view of the fact that the apparent impossibility of pied-piping of DP by its specifier is limited to a specific subclass of free relatives (in contrast to all other varieties of *wh*-constructions), it seems obvious that the more promising option of the two is the latter one, that is to say, finding an account that can derive the phenomenon from independently motivated properties of realis free relatives and general principles of UG, while leaving the pied-piping mechanism itself unaffected.

This was the kind of approach taken by Grosu (1994: ch. 3). In the context of a comprehensive study of the various subtypes of free relative, Grosu developed an account the essence of which is that the *wh*-element coindexed with the *pro* head of the free relative needs to locally identify this *pro*, but being in the Spec of the pied-piped DP, rather than being the Spec of CP itself, it is unable to do so. Grosu's proposal is based on the widely accepted assumptions that (a) realis, i.e., finite, free relatives have a phonologically null head, *pro,* and (b) the feature-content of *pro* needs to be identified. It is argued in the study that the only possible identifier for this *pro* is internal to the free relative; it is the *wh*-phrase (within the Spec of CP) that serves as its antecedent. Furthermore, the relation between the *pro* and its identifier in the clause is claimed to be subject to a strict locality requirement. Specifically, it is assumed that only the CP, i.e. the free relative itself, is local enough structurally to be able to identify the *pro* head, where identification is assumed to involve the set of phi-features of the *wh*-antecedent being conveyed to *pro*. Given this, the (anti-)pied-piping effects observed in free relatives above can be derived directly from the existence of a *pro* head in these structures in conjunction with the same feature-inheritance mechanism that we presented as the core mechanism underlying pied-piping in section 4.2 (based on Webelhuth 1992 and Koopman 1997).

In order for the identifying features of the *wh*-antecedent to reach the actual local identifier (the CP) according to Grosu's proposal, feature inheritance and/or percolation needs to take place; features of the *wh*-antecedent can be transmitted to C by Spec–Head agreement and from C to CP by percolation. Thus any case where the Spec of CP position is occupied by the *wh*-antecedent itself, as in (63), satisfies the requirement of *pro* identification. But, crucially, *pro* identification seems to fail in cases where the *wh*-antecedent of *pro* occurs in the Spec (of Spec) position of the preposed DP, as in (24b, c). The reason for this under Grosu's proposal is that the phi-features of the *wh*-specifier (*whose*) needed for the identification of *pro* cannot get to the entire DP occupying Spec of CP by Spec–Head agreement because the DP itself has inherent features of the same kind as

the *wh*-specifier, and an arguably independently motivated property of feature inheritance blocks transmission of these features. (A similar convention of priority of feature-percolation from the head over transmission of the same feature from the specifier is postulated in Webelhuth's 1992: 147 system in relation to operator features; this is of empirical significance with respect to his account of CP-pied-piping, to be discussed in section 4.5). Since the phi-features of the *wh*-specifier of DP cannot reach DP nor, consequently, CP, they fail to identify the head *pro*. (It would also need to be the case that C, in contrast to D, has no comparable features that would block transmission of the identifying features from its Spec in cases like (63).)

In sum, it appears that it is not pied-piping of a DP by its *wh*-specifier that is ruled out for some reason in realis free relatives. Rather, the unacceptability of free relatives like (24b, c), (64), and (65) is attributable to the presence of an improperly identified *pro*. Notice that in contrast to the case of phi-feature transmission, *wh*-feature transmission via the Spec–Head relation to DP, as used in the derivation of *wh*-pied-piping itself, would pose no problem of 'blocking' since this feature is not an inherent feature of D in cases such as [*whose* picture]). Supporting evidence for the *pro*-identification account of anti-pied-piping effects in realis free relatives is provided by Grosu's (1994: 142) observation regarding the contrast with irrealis/infinitival free relatives. The latter have various properties indicating that they are bare CPs, i.e., that they have no head *pro*. As expected, based on the above hypothesis for deriving the anti-pied-piping effects, these in realis free relatives turn out to manifest no such effects (see, e.g., (66) from Romanian); they in fact display the same pattern of pied-piping phenomena as infinitival embedded questions do.

(66) Maria nu are [la fotografia cui să se uite]. Romanian
Maria not has at picture-the whose SP self look
'Maria doesn't have (anyone) at whose picture to look.'

4.4 PP pied-piping

The widely attested phenomenon of pied-piping of PPs by their complements (as shown with respect to *wh*-movement in section 3.3) seems to represent a substantive problem for the basic pied-piping generalization stated in (45). Complements of other categories fail to act as pied-pipers while the complements of P can, and in a large number of languages must, pied-pipe the PP. Combined with the fact that this takes place irrespective of construction type, indicates that the phenomenon can potentially have important implications regarding the adequacy of suggested mechanisms of pied-piping (such as the feature percolation mechanism being limited to Spec–Head agreement and projection from the head) and/or regarding constraints affecting its output (such as Webelhuth's 1992 formulation of the Theta Criterion and the notion of syntactic argument).

The question of how the complement of P can act as a pied-piper for the PP has been addressed in the literature by several different proposals, though at this

point none of these seem to be supported by truly compelling empirical evidence. These proposals – to be outlined below – fall into two basic subtypes. One general direction, represented by Webelhuth's (1992: sect. 4.4.3) and Grosu's (1994: sect. 1.4.1) proposals, involves the crucial claim that the category P is not a lexical head at all but is uniformly a non-theta-marking functional category, parallel to inflectional categories and in particular to Case. Such theories also presuppose a somewhat less restrictive version of the feature percolation/inheritance mechanism than the one outlined in (47), assumed for pied-piping in work such as Koopman (1997) and Koopman and Szabolcsi (2000). The other direction of thought, manifested for instance in Kayne's (1994) and Koopman's (1997) work, involves the internal syntax of PPs and in particular the idea that what looks like a complement of P is actually not in complement, but in Spec position, at least in derived structure.

Webelhuth's assumption about operator-feature percolation (see section 4.2) permits features to percolate up to their mother node not only from specifiers, but crucially also from complements. Given this, his system has no problem predicting that *wh*-complements of P will be able to pied-pipe the PP. However it would also predict, other things being equal, that *wh*-complements of other categories, e.g., N, A, or V, will be pied-pipers as well. To avoid this incorrect prediction, Webelhuth proposed to draw the relevant distinction between complements of P and complements of the other (lexical) heads from the conjunction of the following two assumptions: (a) a particular formulation of the Theta Criterion making crucial reference to the head of a theta chain not carrying any operator feature (see (55) and (56) above), from which he derived the generalization (stated as (54)) that no theta-marked phrase can be a pied-piper, and (b) the claim that while N, A, and V theta-mark their complement, the category P is not a theta-marker, i.e., Ps, including the semantically contentful ones, take complements yet do not assign theta roles to them. These assumptions, if tenable, would yield a distinction between P-complements being pied-pipers and complements of theta-marking heads (claimed to be V, N, and A) not being pied-pipers. The operator feature [*wh*] could percolate up from a *wh*-complement in all phrase-types under Webelhuth's theory; however, due to the way the Theta Criterion is stated, all cases of pied-piping by complements that are theta-marked by the head would be ruled out as Theta Criterion violations (similarly to pied-piping by specifiers of gerundive DPs discussed in section 4.2).

Webelhuth's arguments for the claim that the category P is never a theta-marker for its complement – at most it can 'solicit' a theta role from some theta-marking head – are based on observed differences between prepositions and the other lexical heads, and on some parallels between prepositons and (oblique) inflectional Case affixes. He notes, for instance, the functional equivalence between idiosyncratically selected Ps and case affixes in languages like German, both used, according to Webelhuth, as purely formal markers (e.g., the verbs *begegnen* 'meet' and *finden* 'find' require dative or accusative case-marking on their internal argument, and parallel to this, some other verbs, e.g., *hoffen* 'hope' and *abhängen* 'depend', require particular prepositions as formal markers for

their internal argument, namely *auf* 'on' and *von* 'of', respectively). Other properties pointed out by Webelhuth are the tendency of Ps, in contrast to members of other lexical categories, to lose their meaning in the course of diachronic change, and the fact that while the theta-marking heads N, V, and A can all be stranded by their complement across languages (for instance in all the Germanic languages), stranding of prepositions by a (non-pronominal) complement is impossible in many languages, including German. The latter cases are claimed to be due to an ECP violation (Chomsky 1986a) that results from P not being a theta-governing lexical head for a trace in its complement position (on alternative accounts of P-stranding, see chapter 51). Based on these and similar observations, he concludes that prepositions are "syntactic heads with the non-thematic marking function of affixes". (For a detailed study establishing the status of P as a uniformly non-theta-marking functional category, see Botwinik-Rotem 2004.)

Accepting the well-motivated assumption that P is not a theta-assigner, Webelhuth's theory correctly yields the possibility of PP being pied-piped by its complement, while excluding pied-piping by complements of theta-marking V, N, and A heads. However, notice that this approach – in particular the idea of free feature-inheritance from complements, and the filtering of the resulting pied-piping cases only by the Theta Criterion (55–56) – makes a broader, arguably problematic, prediction. Specifically, it predicts (for operator movement cases, such as *wh*-movement) that for any head X, if X fails to theta-mark its complement YP, then YP will be able to pied-pipe XP. But is this prediction empirically justified?

First of all it appears to face some difficulty already in the case of the category P itself, in light of certain colloquial varieties of English. It is noted by Kayne (1994: 25) that for some speakers, in colloquial register, PP-pied-piping is unacceptable (see Kayne's examples (25), including, e.g., **Nobody knows to what school he goes*, **Tell us from where you got that*.) If this indeed is a systematic dialect, Webelhuth's view of pied-piping by complements would not provide a plausible way to account for it. Under Webelhuth's theory, one would have to say either that this colloquial dialect has a different feature-percolation mechanism – i.e., a different projection mechanism for the complement relation – prohibiting feature-inheritance from complements, or that Ps in this variety of English are in fact theta-assigners for their complements. Clearly, neither of these are reasonable claims.

A different, more significant kind of counter-evidence for the above prediction is provided by the case of a subset of N heads, and their minimal contrast with locative Ps. Consider the type of nominals – such as *a picture of John, the legs of the chair, a gift to Mary* – that Grimshaw (1990) refers to as "result" or "simple" nominals. As is argued extensively by Grimshaw, although such Ns are able to take complements, they have no syntactic argument structure, and, crucially for us, are not theta-assigners for their complement. (They contrast with so-called complex event nominals, which are theta-assigners, exhibiting an argument structure similar to Vs.)

Given Grimshaw's (1990) theory, there is no theta-related difference between this set of Ns and Ps to rely on: neither are theta-assigners for their complement. Hence, based on Webelhuth's mechanism of feature percolation, we would expect complements of simple nominals and result nominals to act as pied-pipers for their phrase just like Ps do. As shown by the contrast between (67a, b) and (68a, b), this prediction turns out to be wrong.

(67) a. *I wonder most pictures of whom John liked.
b. *Tell me a leg of which chair we should try to fix.

(68) a. I wonder under whom John put some pillows.
b. Tell me near whom you saw a gun.

It is also worth noting here that the choice of locative Ps – rather than idiosyncratic (inflection-like) Ps considered by Webelhuth – is significant for the comparison (67–68) above, since they constitute a more minimal contrast with the Ns being tested than other kinds of P would. Locative Ps are parallel to the Ns involved in that (a) they clearly have semantic content, and (b) they constitute independent binding domains for Condition B effects, i.e., in terms of Reinhart and Reuland's (1993) Reflexivity framework, they, just like Ns, can form a semantic predicate of their own (see the possibility of a pronoun in (69a, b)).

(69) a. John$_i$ put some pillows under him$_i$/himself.
(Cf. John$_i$ explained Mary to *him$_i$/himself.)
b. John$_i$ liked most pictures of him$_i$/himself.

In view of the pied-piping contrast between complements of result Ns and complements of Ps exhibited by (67) and (68), we can discard the above free feature-percolation approach to pied-piping by complements.

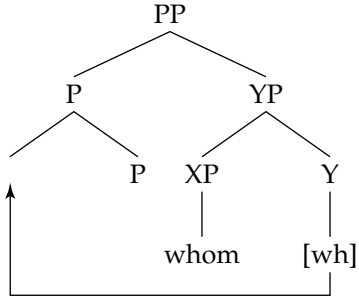
Returning now to Webelhuth's argumentation regarding the parallelism between Ps and inflectional (case-marking) affixes, what it amounts to conceptually comes very close to saying that P is a functional, rather than a lexical, head. Grosu (1994) makes this claim explicitly, and based on it, puts forth an alternative, empirically superior, account of PP-pied-piping by complements. He motivates his conclusion by pointing out various parallelisms between the behavior of Ps and of case affixes, in particular in free relatives in a variety of languages.

Importantly, given his assumption that P is a functional head, i.e., the top layer in the extended projection of N, Grosu's proposed account does not have to rely on the Theta Criterion (as in Webelhuth's version) to exclude feature percolation from complements of V, N, and A, while permitting percolation from complements of P. Instead it utilizes a different feature-percolation mechanism that is more restrictive than the one assumed by Webelhuth. Following Grimshaw (1991), Grosu proposes that aside from Spec–Head agreement, features can percolate up from complements too, but, crucially, only from within the same extended projection, not from outside of it. Hence, no percolation of *wh* or other features is possible from the complements of lexical heads, for instance to NP

(and DP) from the complement of N, or to VP from the complement of V. In contrast, percolation is possible from the NP complement of the functional head D to DP, and, crucially for our case, from the DP-complement of the functional head P to the whole PP, since in these cases, the features involved, namely both the [*wh*] feature (inducing PP pied-piping under *wh*-movement) and the phi-features (needed to identify the *pro* head of free relatives) would be staying within the same single extended projection.

Another type of approach to deriving the pied-piper status of complements of P is proposed in Koopman (1997). This alternative is compatible with an even more restrictive feature-inheritance mechanism, which limits percolation to take place via Spec–Head agreement and only within a single, non-extended, maximal projection, from a head X up to the lowest maximal projection XP (as shown in (47) of section 4.2). Importantly, no feature-percolation from any kind of complement is permitted. Instead, the proposal invokes (strictly local) head movement (see (70)). (Factors like no theta-marking by P, or P having to be a functional rather than a lexical head, play no role in the account).

(70) Head movement (and Spec–Head agreement):



Koopman's claim is essentially that a complement of P is able to pied-pipe the PP, i.e., the whole extended projection of P, due to this *wh*-complement coming to occupy actually the Spec of some head Y, which receives the *wh*-feature from it via Spec–Head agreement; crucially, this head then raises to the head of the extended projection of P, i.e., adjoins to the topmost head (the next head above it), and as a result the latter head, and hence the whole PP, receives the *wh*-feature (which originated in the complement of P). (For more on the specific assumptions regarding the internal structure and syntax of PPs, see Koopman 2000a.)

A variant of this type of movement-based approach to pied-piping by the complement of P that had been proposed occasionally earlier (see, e.g., Kayne 1994: 25) assumed that in languages that permit or require PP-pied-piping by a complement, the *wh*-complement undergoes covert movement to the Spec of the top layer of PP. The overt counterpart of the same movement had been assumed to exist too, as an intermediate step in the derivation of P-stranding, which is, as mentioned earlier, required in some versions of colloquial English. (The idea of the complement of P moving to a Spec-like position in PP when being extracted by *wh*-movement is due originally to Van Riemsdijk's 1978a work on Dutch PPs.)

These movement-based analyses of the pied-piper status of the complement of P do not need to make the problematic connection between the lack of theta-marking and being a pied-piper, as Webelhuth's account does, and, furthermore, they are not forced to claim that P is necessarily a functional head, as under Grosu's proposal. However they would still need to address this question: Are the postulated PP-internal movements unique to this category, and if so, why? If they were not, then one would expect the same option of pied-piping by a complement to arise – as a result of phrase-internal overt/covert movement 'delivering' the operator feature of the complement, as in (70) – also in projections of other lexical categories (V, N, A). This however is not attested, at least not in the well-studied Germanic case. Thus the movement postulated in the account of PP-pied-piping would have to be considered unique to this category-type. But then one is still left with the question, What makes the same movements – specifically, the head movement in (70) – available to projections of P and yet unavailable to projections of V, N, or A? A likely answer to this will presumably lead us back to the functional–lexical distinction between P and the other three heads.

4.5 Clausal pied-piping

The mechanisms proposed to underlie pied-piping considered in the above subsections, namely, versions of a feature-percolation-based account, as well as the proposal based on c-command (binding, therefore) from the Spec of a phrase to outside of that phrase, would lead us to expect that the Spec position of CP could in principle act as a pied-piper for the CP. The questions for empirical study in this respect, then, are (a) whether Spec of CP indeed can pied-pipe the CP and (b) to the extent that it cannot, in particular languages at least, what the reason for this is.

Notice first that the empirical issue of clausal pied-piping was raised and discussed in the early GB framework with respect to English by Nanni and Stillings (1978) and Ishihara (1984). However, the clausal pied-piping cases these studies discussed were of the stylistically marked variety of pied-piping we discussed in section 4.3.1. These cases are limited to relative-clause constructions whose *wh*-element occupied an IP-internal argument position; they are not part of normal colloquial English. This construction arguably involves some mechanism other than pied-piping under *wh*-movement, and is therefore not relevant for the issue of CP-pied-piping (see our discussion in section 4.3.1, based on Webelhuth's (1992) arguments for such cases of apparent pied-piping being derived by topicalization and involving a way of interpreting the *wh*-relative pronoun that falls outside of core grammar).

Regarding English, Webelhuth concludes that it permits no CP pied-piping, based on the ungrammaticality of the following type of data:

(71) a. *[*Who* [John met *t*]] did Mary know *t*?
b. *[Who [to talk to *t*]] did she forget *t*?

(Webelhuth 1992: 152)

This indeed seems to be correct; English embedded CPs with a *wh*-element occupying their Spec cannot get pied-piped to the matrix Spec of CP position under *wh*-movement no matter whether the clause is finite or infinitival. In such cases the *wh*-element in the lower Spec of CP position has only two options: either it is extracted from the embedded clause (successive cyclic movement), resulting in a matrix question, or it may stay and get interpreted in the embedded CP, provided that the selecting predicate permits an embedded question.

The explanation proposed by Webelhuth appears to attribute the ungrammaticality of examples like (71) to a property of feature percolation we already referred to in section 4.3.2 as part of Grosu's (1994) account for why the specifier of a *wh*-moved DP in free relatives cannot identify the head *pro*, in other words, why it cannot percolate its phi-features up to the DP. The relevant assumption is that a particular feature (independently of the value specified for it) that is borne both by a specifier YP and by the head projection X′ of a phrase XP can percolate to XP only from X′; feature percolation from Spec (normally available, via the Spec–Head relation) is blocked in such cases. Thus, according to Webelhuth, pied-piping of a CP by its Spec is excluded whenever the sister node of the Spec, namely C′, is marked for the feature [*wh*], since then the *wh*-element in Spec is unable to percolate its *wh*-operator feature up to the CP, and hence this CP cannot turn into an operator itself; as a result it cannot form a well-formed operator chain with the syntactic variable it binds (i.e., with its own trace) and, consequently, movement of such a CP would be ruled out. The specific stipulation Webelhuth makes in order to account for the (alleged) lack of CP-pied-piping in Germanic languages is that the (embedded) complementizer C is marked [–*wh*], and it is due to this property of C that the [+*wh*] feature of the phrase in Spec of CP cannot reach the CP. But in fact, given his particular definition of the notion 'syntactic operator', even if the [+*wh*] feature of the preposed *wh*-phrase were permitted to percolate up to the CP, the derivation would still fail to result in well-formed CP-pied-piping. As pointed out by Webelhuth (1992: 152), if *who* in a case like (71a), for instance, were to percolate its operator feature to the CP, then it would cease to qualify as a syntactic operator, and consequently, its trace in the clause would constitute a syntactic variable that is not bound by a syntactic operator, thus violating Webelhuth's (p. 143) version of the Bijection Principle (adapted from Koopman and Sportiche 1982).

However, when we go beyond the Germanic languages, Webelhuth's specific assumptions about the role played by the *wh*-feature of C and the reference of the Bijection Principle to syntactic operator preventing CP-pied-piping by its Spec appear to be challenged empirically, for instance, by the case of Basque as reported by in Ortiz de Urbina (1990). (See also Cole 1982a on CP-pied-piping in Imbabura Quechua.) Basque interrogatives exhibit *wh*-movement to the left periphery of the clause to a position that is immediately followed by the finite verbal element (allegedly a V2 phenomenon). Furthermore, Basque has two distinct overt complementizers; one -(*e*)*n* for interrogative, i.e., [+*wh*] complements, and another, -(*e*)*la*, for non-interrogative, i.e., [–*wh*], complements. Consider now the following data suggesting the existence of CP-pied-piping, pointed out by

Ortiz de Urbina with respect to Basque interrogatives (corresponding to his examples (15i) and (17)):

(72) [*Nor* etorriko d-ela bihar] esan diozu Mireni? Basque
who come Aux-that tomorrow said Aux Mary-Dat
'Who have you told Mary will come tomorrow?' (Lit. 'That who will come tomorrow have you told Mary?')

(73) [*Nor* etorriko d-ela] esan du Mirenek *t* uste du-ela Peruk?
who come Aux-that said has Mary think Aux-that Peter
'Who did Mary say that Peter thinks will come?' (Lit. 'That who will come has Mary said (that) Peter thinks?')

Example (72) is taken to demonstrate the option in Basque for the *wh*-element (*nor*) preposed within the embedded clause to pied-pipe the whole embedded CP whose Spec position it came to occupy (the alternative option being to get extracted from it). Notice that the *wh*-phrase in the embedded CP as well as the whole pied-piped complement CP in the main clause occupy a clause-initial and immediately pre-verbal position characteristic of *wh*-moved interrogatives in Basque. Example (73) shows that the pied-piped CP can itself be extracted from the embedded Spec, i.e., move successive cyclically, to form a matrix question, in the same way as nonclausal *wh*-constituents can. Such evidence from Basque leads Ortiz de Urbina to claim that, contrary to Webelhuth's claims, *wh*-operator features can percolate from Spec of CP to the CP itself, and by this turn the CP into a *wh*-operator which after undergoing movement to Spec of CP, is able to bind a syntactic variable from there, just like any other *wh*-phrase would.

Thus, Ortiz de Urbina (1990) proposes a radically different view of the status of CP-pied-piping across languages. Revising Webelhuth's assumption of C being uniformly marked [–*wh*], he assumes – in the spirit of the *wh*-criterion – that only a [+*wh*], i.e., interrogative C, can, and in fact must, have a *wh*-operator in its Spec. Given the option of operator-feature percolation from Spec to CP (ignoring the convention blocking percolation if the head has the relevant feature too), Ortiz de Urbina claims that a *wh*-phrase in Spec either percolates its feature to the CP, which would result in CP pied-piping, and will crucially make this *wh*-phrase lose its operator status, or it fails to percolate its feature to CP, hence it remains an operator itself, and no CP pied-piping will be licensed. From these assumptions he derives the prediction that CPs that are complements to [–*wh*] (i.e., non-interrogative) selecting heads, as well as non-selected (i.e., adjunct) CPs, may be pied-piped by their *wh*-Spec, whereas CP complements of [+*wh*] (i.e., interrogative) selecting heads cannot get pied-piped since they need a *wh*-operator present in their Spec. This appears to work well for Basque (see (74a) and (74b)), at least as far as the data considered by Ortiz de Urbina are concerned (for some further relevant facts, see Echepare's 1997 alternative analysis referred to below).

(74) a. [*Nor* etorriko d-ela bihar] esan diozu Mireni? Basque
who come Aux-that tomorrow said Aux Mary-Dat
'Who have you told Mary will come tomorrow?' (Lit. 'That who will come tomorrow have you told Mary?')

b. *[*Nor* etorriko d-en] galdetu duzu?
who come Aux-comp asked Aux
(Lit. 'Who will come have you asked?')
Cf. the corresponding ungrammatical English *Who have you asked will come?

As for the case of Germanic, such as the examples in (71) from English, Ortiz de Urbina needs to say something additional in order to account for the fact that they are impossible even though the selecting verbs *know* and *forge*t do permit a [–*wh*], i.e., a non-interrogative CP complement. The solution he proposes for this problem relies on the difference between Germanic and Basque with respect to whether C is empty or not. Specifically, he suggests that the Germanic cases of CP-pied-piping are ruled out by the ECP (Chomsky 1981, 1986a) due to the lexically ungoverned nature of their empty C in the output structure, i.e., that the unacceptability of examples like (71) has nothing to do with *wh*-pied-piping per se. While it is clear that some parameter distinguishing Basque and Germanic must be involved, it seems doubtful that it could simply be the emptiness of C in Germanic preposed CPs violating the ECP. If this were so, one would not expect any possibility of a CP in a left-peripheral A-bar or subject position, having a *wh*-element in its specifier and an empty C. But such cases clearly are attested, as shown by fully acceptable topicalized *wh*-CPs, such as *Who Mary invited*, *I would never reveal to you*, or subject clauses, such as *What you got from whom doesn't interest me*. A different approach that can provide a reasonable alternative way to derive the apparent cases of CP-pied-piping in Basque, and can also account for the distinct behavior of the English-type languages, is proposed by Echepare (1997) based on some novel data and generalizations he points out regarding Basque interrogatives.

Echepare's major observations leading to the reassessment of the alleged CP-pied-piping phenomenon of Basque are the following: (a) a pied-piped *wh*-CP cannot satisfy selection for a *wh*-interrogative, i.e., it can occur only in the Spec of a matrix question but not in an embedded one (see (75)) and (b) the set of *wh*-words that can pied-pipe a CP is limited to arguments and referential adjuncts, while non-referential *wh*-adverbials, like 'why' and 'how', are not able to appear in pied-piped CPs, and can take matrix scope only by extraction (see (76)):

(75) *Mikelek galdetu du [$_{CP}$ [*nor* etorriko dela]$_i$ esan Basque
Mikel ask Aux who come Aux-Comp say
duten t_i].
Aux-Comp
'Mikel asked who they said will come.' (Lit. 'Mikel asked who will come said they.')

(76) *[*Zergatik* aspertu zela]$_i$ uste duzu t_i?
why bore Aux-Comp think Aux
'Why do you think she/he got bored?' (Lit. 'Why she/he got bored think you?')

These properties are completely unexpected under a hypothesis of CP-pied-piping by *wh*-movement (as, e.g., Ortiz de Urbina's 1990 *wh*-feature-percolation-based proposal above). Echepare (1997) interprets the property demonstrated by (75) (see generalization (i) above) as indication that in fact the preposing of apparent *wh*-CPs in Basque interrogatives is not due to *wh*-movement at all, and argues that these CPs are not located in Spec of CP, but rather are topicalized phrases appearing in a projection higher than CP. Furthermore, along the same lines, the impossibility of examples like (76), i.e., 'pied-piped' CPs being acceptable only when their wide-scope taking *wh*-element is an argument or referential adjunct, is taken as indication that the *wh*-words of Basque are not operators. Echepare argues that they undergo neither overt nor covert *wh*-movement to Spec of CP; instead, he claims, *wh*-interrogatives in Basque should be analyzed as in situ *wh*-questions of the Chinese type, and receive wide-scope construal via unselective binding, since it is this type of *wh*-construction that is known to exhibit the referentiality restrictions manifested in (76) (see chapter 77). Thus, under Echepare's analysis, Basque would not instantiate *wh*-movement pied-piping a CP. If apparent CP-pied-piping constructions such as (72) and (73) indeed turn out to involve simply a topicalized CP that in these particular cases just happens to contain an in-situ *wh*-phrase, then Basque interrogatives would be consistent with Webelhuth's operator-feature-based theory of pied-piping that systematically excludes the possibility of clausal pied-piping.

Finally, there is one slightly different potential instance of CP-pied-piping by Spec within Germanic not addressed in Webelhuth (1992). This is the somewhat controversial case of pied-piped infinitivals occurring in relative constructions of German (see, e.g., Van Riemsdijk 1985 and Grewendorf 1986). Unlike the clausal pied-piping cases of the English stylistically marked, literary kind discussed in section 4.3.1, these sentences in German (such as in (77)), arguably involve overt movement of the relative pronoun within the pied-piped infinitival, as argued by Van Riemsdijk (1985, 1993), namely, movement to the Spec position of the infinitival CP.

(77) das Buch, [*das* PRO *t* zu lesen] er uns empfohlen hatte
the book which to read he us recommended had
('the book, to read which he had recommended to us')

Apparently, this kind of alleged CP-pied-piping is induced only by the Spec position of the CP, and, consequently, it is a reasonable initial assumption that it involves feature percolation to the CP. Yet it is also possible that this case should be considered nevertheless as a counterpart of the stylistically marked pied-piping cases of English discussed in section 4.3.1; the latter were claimed by

Webelhuth (1992) to involve simply topicalization of the constituent, rather than actual pied-piping by movement of a *wh*-operator. The reason is that it shares two important properties with the latter cases: (a) it is limited to occur only in relative clauses, and is impossible in interrogatives, suggesting that the process actually might not involve quantificational operators, and (b) it is excluded in the case of tensed clauses, which makes it similar to the English clausal-pied-piping cases shown in (61–62) of section 4.3.1. If analyzed in this latter way, one would then need to address the question of what forces the overt preposing of the relative pronoun within the infinitival, and why no such preposing is required (or in fact permitted) within the English cases such as those of Ishihara (1984), shown in section 4.3.1.

On the basis of these observations we can only conclude that no uncontroversial evidence is available in favor of the existence of true CP-pied-piping under *wh*-movement, in the same sense as there is uncontroversial evidence for DP-pied-piping under *wh*-movement. Even the strongest candidate discussed in the literature, namely, the case of Basque interrogatives, raises some serious doubts due to evidence internal to the language. Furthermore, it would leave open the issue of the relevant parametric difference between Basque-type languages and languages where interrogatives do not manifest CP-pied-piping.

*4.6 Pied-piping in non-*wh*-constructions*

So far our discussion has been focusing on *wh*-constructions and specifically, on accounting for the pied-piping ability of *wh*-words occupying various structural positions in their phrases. This reflects the orientation of the pied-piping literature itself, at least until recently. The obvious reason for the predominance of studies on pied-piping by *wh*-morphemes is the overtly detectable nature of this particular morpheme, and the wide range of movement operations it is involved in. Yet an uncontroversial assumption in the literature, shared by all accounts of *wh*-pied-piping reviewed above, is that the mechanisms proposed for *wh*-pied-piping generalize (at least) to the whole set of operator features in UG. Some better known cases of such operator features involved in movement, beyond [+*wh*], are the [+neg] feature of negative morphemes, central to Rizzi's (1991b) Negative Criterion (see also Haegeman and Zanuttini 1991), and within the framework of a systematically checking theory-based account of quantifier scope put forth in Beghelli and Stowell (1997), also quantificational features, such as [+Dist(ributive)], [+Univ(ersal)], and others, corresponding to individual clausal functional heads and QPs. (Another potentially relevant operator feature, namely, the feature [+Focus], proposed in Horvath 1986, and used as a crucial part of Brody's 1990a Focus Criterion, is reexamined and eliminated as such in Horvath 2000, in part based on considerations of pied-piping under overt Focus-movement as manifested in Hungarian.)

These operators are commonly assumed to involve covert (LF) movement, at least in languages like English (however, for an alternative treatment making use only of overt movements, see Kayne 2000: ch. 13). Thus, for instance, QR of the GB

framework, as well as its reanalyzed minimalist versions, such as those proposed by Hornstein (1995), Beghelli and Stowell (1997), or the movement of negative phrases to enter into a Spec–Head relation with the clausal head Neg^0 to satisfy the Negative Criterion (or to check the [+Neg] feature) are assumed to take place after Spell Out in languages such as English and French (the status of pied-piping under covert movement will be addressed in section 5). Here, however, we will consider pied-piping by such non-*wh* operators in languages and constructions where these operators undergo uncontroversially overt movements. Such cases are, for example, QR in Hungarian (Kiss 1992), movement of negative phrases to Spec of NegP in Italian and West Flemish (Haegeman and Zanuttini 1991; Haegeman 1995b), and also the Negative Inversion construction in English.

To demonstrate the ability of non-*wh* operator features to pied-pipe in a way consistent with what we found with respect to *wh*-movement, first consider examples from Hungarian involving overt Quantifier Raising of the universal quantifier *minden* 'every' to the position of Spec of DistP (postulated in Beghelli and Stowell 1997):

(78) a. [*Mindenkinek*] vettünk valamit *t*.
everyone-Dat bought-1Pl something-Acc
'We bought something for everyone.'
b. [*Minden* vendégnek] vettünk valamit *t*.
every guest-Dat bought-1Pl something-Acc
'We bought something for every guest.'
c. [[*Minden* vendég] gyerekének] vettünk valamit *t*.
every guest's child-Dat bought-1Pl something-Acc
'We bought something for every guest's child.'

Similarly, the pied-piping generalizations found in relation to *wh*-movements are attested also in the case of overt movements involving a negative constituent. This can be seen based on the following Negative Inversion examples from English, where, unlike in other instances involving negative phrases in the language, the overt nature of the movement of the [+neg] element (to the Spec of CP) is transparent. (On the question of how to derive their need for aux-inversion, i.e., for I-to-C movement, see Rizzi's 1991b discussion of the Negative Criterion, on a par with his *Wh*-Criterion.) Consider the pied-piped phrases and the [+neg] morpheme within them in (79), as well as the contrasting pairs (80a)–(80b) and (81a)–(81b); examples (80a, b) show the negative morpheme being able to pied-pipe its DP when occurring in Spec but not when occurring in complement position, and the contrast in (81) shows that when the head of a phrase is [+Neg], it can pied-pipe the whole DP, including a complement, but when the [+Neg] feature is on the complement in a DP, the whole phrase cannot be pied-piped by it.

(79) a. [*Never*] have I witnessed such behavior.
b. [Under *no* conditions] will I leave this city.
c. [[*No* student's] thesis] have they read so thoroughly.

(80) a. [[*No* young girl's] participation in the game] can they permit.
b. *[The participation [of *no* young girl] in the game] can they permit.

(81) a. [*No* articles by such a reporter] will they agree to publish.
b. *[Such articles [by *no* reporter]] will they agree to publish.

In some of the recent literature, inspired by Kayne's (1994) Antisymmetry framework, pied-piping of large, clausal and other functional projections (both in the nominal and in the verbal extended projections) is postulated on a much larger scale than in earlier work. The empirical evidence for such analyses often comes from surface discrepancies of word order (e.g., the appearance of head-final phrases in head-initial languages) or from various agreement phenomena, which under the restrictive theoretical assumption that agreement holds only in Spec–Head configurations, imply that large phrasal categories – possibly remnants appearing to be no more than just heads – move to Spec positions, as instances of pied-piping by the relevant agreeing feature(s). The existence of such 'heavy' pied-piping is discussed from a conceptual point of view by Koopman (1996). In addition to giving a general perspective on a theory with heavy pied-piping, Koopman also reviews some supporting empirical evidence from a variety of languages based on earlier studies (e.g., Nkemnji's 1995 analyses of Nweh (Grassfield Bantu)). To the extent that these large-scale movements are indeed driven by the need for feature-checking and/or agreement (which in these analyses is not always obvious), they would constitute true cases of pied-piping and would raise the obvious question of what induces the apparent language-particular variation with respect to this option, or at least what the properties and mechanisms are that make such heavy pied-piping more easily detectable in some languages than in others.

Most of the earlier literature on pied-piping considered cases of operator movement. Yet there is clearly no reason not to expect pied-piping also when the feature/morpheme-triggering movement is inflectional or categorial in nature rather than an operator; in other words, one may in principle expect pied-piping to occur under A-movements as well. Finding appropriate test-cases for A-movement pied-piping, however, is indeed more difficult, at least in the obvious canonical A-movement cases, such as noun phrase movements to A-positions (e.g., to Spec of IP). One factor limiting the range of testable cases is that having no Case, or in MP terms, having an unchecked Case feature, is a necessary condition for a DP to be eligible for A-movement (see Chomsky 1995c, 2000). However, DPs occurring, for instance, within the Spec position of a larger DP such as *some student* in [*some student's parents*] (see (82a)) are already Case-licensed inside the DP; the same is true for complements of N, which bear inherent Case. Thus these DPs cannot undergo A-movement to begin with, hence obviously could not be expected to be potential pied-pipers of their phrase. Another factor that might reduce cases of A-movement pied-piping is that, in contrast to operator movements, the types of features triggering classical A-movements (familiar from Raising or Passive constructions) are precisely those

known independently not to be inheritable via the Spec–Head relation, at least when the head is marked for the same features (see section 4.3.2 on *pro* identification by phi-features inducing an anti-pied-piping effect in free relatives, as well as Webelhuth 1992 on *wh*-feature percolation). So under a feature-percolation-based view of pied-piping, commonly assumed for operator movements, one would not expect a DP in Spec of DP position to be a pied-piper for its phrase under A-movement.

What we find when turning to the assessment of the actual empirical facts is that pied-piping indeed is attested, in the canonical A-movement cases examined, only when the pied-piper is the head of the phrase, as in (82a) and (82b) below. DPs in Spec of DP position can get pied-piped by the head, but they themselves cannot act as pied-pipers (see (82b)). (Feature inheritance from the head, and hence pied-piping of the maximal projection, is unproblematic, as expected.)

(82) a. [Some/no student's [parents]] are waiting in the office.
b. *[Some/no student's [parents]] is waiting in the office.

This is contrary to what we find in the case of operator movements such as *wh*-movement. But as pointed out above, the apparent impossibility of pied-piping by Spec under A-movement in (82b) is in fact independent of the pied-piping mechanism itself, since such DP specifiers cannot undergo A-movement at all as shown in (83) below. (Note that under *wh*-movement, possessive Spec of DPs in English pied-pipe the rest of the DP obligatorily, putatively for PF-related reasons, discussed in section 6.1).)

(83) *Some/no student('s) are [*t* ('s) parents] waiting in the office.

The ungrammaticality of (83) cannot be attributed simply to the lack of phi-feature checking (i.e., lack of appropriate agreement) on the clausal head I and of Case on the DP [. . . parents], since such phi-feature-checking by a Case-bearing DP would be possible without movement, i.e., when the relevant phrase is in post-V rather than in Spec of IP position (see Chomsky 2000 on Agree). This possibility is demonstrated in *there* expletive constructions, such as (84):

(84) There are some student's parents waiting in the office.

Some versions of the earlier GB theory though would indeed have excluded cases such as (83) above by the lack of Case on the post-V DP in (83), while permitting examples like (84) via expletive replacement.

A distinct contrast of interest involving DP-pied-piping (pointed out by an anonymous referee) is provided by the post-nominal possessive construction of English. The construction exemplified in (85) may represent an instance of DP-pied-piping by its Spec under A-movement (a case we failed to find with pre-nominal possessives as in (82–83)).

(85) a. [Some students of John's] are waiting in the office.
b. *[Some students] are [*t* (of) John's] waiting in the office.

Pied-piping here is obligatory – i.e., (*of*) *John's* cannot be left stranded by the preposed phrase (85b). Naturally, if the string *some students* in this construction does not form a constituent, we would not expect it to be able to move independently, and thus strand the rest of the DP. But if Kayne's (1994: 86) analysis of this construction – shown schematically in (86) – is right, then *some students* is clearly a constituent, one that has been preposed to the Spec of the topmost DP in the structure.

(86) [some students$_i$ [[$_D$ of] [John ['s [t_i]]]]]

Thus, assuming the structure (86) motivated by Kayne, pied-piping of *of John's* by the phrase *some students* occupying the Spec position of the highest DP projection is predicted to be possible, and this indeed seems borne out by (85a). Such examples may, under the above analysis, instantiate the case we have been searching for, namely, pied-piping of a DP under A-movement by a phrase in its Spec position. The question remaining under the above analysis is: why is pied-piping obligatory here (see 85b)? The reason for this may have to do with the fact that the preposed phrase in Spec of DP (*some students*) in this construction is arguably not a DP, but rather a QP/NP (see Kayne 1994). If the EPP driving movement to Spec of IP is in fact a requirement of checking an uninterpretable D feature of the head I (as proposed in Chomsky 1995c), then this would automatically explain why the phrase *some students* itself could not satisfy the EPP, and hence could not move by itself, only the whole DP could, as shown in (85a, b). (If so, then, technically, the movement would again be DP-pied-piping by its head D, not by its Spec.) However, according to an alternative, more recent, conception the EPP-requirement is not construed as categorial feature-checking, but as the need of the I (=T) head to have a Spec position realized (see Chomsky 2000). Under this approach, there appears to be no obvious reason for the impossibility of (85b), given that the phrase in Spec of DP is a maximal projection (QP or NP) which is demonstrably able to undergo movement by itself in Kayne's account. Possibly, however, this problematic phenomenon could fall together with some observations made in relation to the notion 'phase' in Chomsky (2000) involving the impossibility of extracting substantive, i.e., 'non-phase', categories from within their functional layer constituting a phase (i.e., from their extended projection). For instance, finite IPs cannot strand their C, and similarly, an NP/QP would not be able to strand its DP layer. (On Spec and obligatory pied-piping, see also section 6.)

A related question of obvious significance is whether A-movement can pied-pipe non-nominal projections, such as VP and various clausal functional projections, by their DP specifier. A case in point would be, for instance, if instead of the subject DP being moved from its VP-internal base position to Spec of IP, as in an English-type SVO language, the same feature-checking and EPP requirement

driving the movement of the DP could be satisfied, at least in some languages, by preposing the whole VP/*v*P or other clausal projection whose Spec position the relevant DP occupies. Notice that being (extended) projections of V, these categories would be less likely to block feature-inheritance from a DP in Spec by their head-projection than nominal projections. (Percolation of non-operator features from the complement would be excluded under (47), just like percolation of operator-features is.) A concrete test case of the above kind from English would be, for instance, the raising construction in (87a, b), where the (bare) IP complement of the raising predicate has a DP in its Spec position. The question is: can this DP pied-pipe the IP, instead of being extracted from it?

(87) a. *[The students to enjoy the lecture] are likely [*t*].
b. The students are likely [*t* to enjoy the lecture].

Pied-piping of IP under A-movement turns out to be clearly impossible in the case of (87). The reason for this again appears to lie in the nature of the category moved (see (87a)). In this case it is a defective IP – i.e., one without a full set of phi-features – in terms of Chomsky (2000). Such IPs, occurring in raising and ECM constructions, are known not to exhibit phonetic autonomy like, e.g., CPs or verb phrases do; specifically, they are unable to move or occur as elliptical answers on their own (e.g., **it's* [t *to enjoy the lecture*] *that John seems*). While English, at least in the above type of case, does not exhibit the relevant pied-piping option, empirical work on a variety of languages has uncovered putative motivation for assuming pied-piping of VPs and various clausal functional projections by their specifiers under A-movements (see, e.g., Koopman and Szabolcsi 2000 for relevant analyses and references).

5 LF-movements and pied-piping

Within the GB model of UG, it was assumed that the same operation Move α involved in mapping D-structures to S-structures also applies to S-structures, and derives from S-structures another level of syntactic representations, namely, LF. These post-S-structure applications of Move α became known as LF-movements, and were also referred to as covert movements, since they had no phonological effects, due to the architecture of the grammar (the T-model). Within such a model, the null hypothesis seems to be that all properties of LF-movement, including in particular the options of pied-piping, will be parallel to those found in the case of overt (i.e., pre-S-structure) movement, apart from any possible properties of overt movement that are imposed by phonological (PF) requirements.

The existence of pied-piping by LF-movements was thus taken for granted in the GB framework. The first actual empirical issue involving pied-piping and LF-movement arose in connection with the assumed LF-movement account of *wh*-in-situ constructions in languages such as Chinese and Japanese, and also of multiple *wh*-questions in English-type languages. Specifically, a problem for the

expected parallelism between overt and LF-movement operations appeared to exist in relation to the application of Subjacency (Huang 1982a). It was observed that in-situ (non-D-linked) *wh*-elements, assumed to undergo covert *wh*-movement, actually permitted certain island violations, and this raised the possibility that LF-movement was not subject to Subjacency. In an attempt to show that LF-*wh*-movement, too, obeys Subjacency, as one would expect, based on the null hypothesis, an interesting type of proposal was made independently in work by Choe and by Nishigauchi (published as Choe 1987 and Nishigauchi 1990); the analysis was further elaborated by Pesetsky (1987a). The proposal was based on the hypothesis of large-scale pied-piping by the LF-*wh*-movement involved, and it claimed that the suspected island violations are only apparent, since although the *wh*-element itself occurs within an island, such as a complex NP or an adjunct, what actually moves at LF is the island itself, in other words, the complex NP or the adjunct gets pied-piped. This movement, unlike extraction of the *wh*-in-situ element itself, would not violate Subjacency. Both Choe and Nishigauchi provided the type of evidence illustrated in (88), involving the felicity of answers to *wh*-questions, in support of their claim (example (88) is adapted from Pesetsky 1987a: 113):

(88) Q: Mary-wa [$_{DP}$ [$_{CP}$ John-ni nani-o ageta] hito-ni] atta-no? Japanese
Mary-Top John-Dat what-Acc gave man-Dat met-Q
'What did Mary meet the man who gave to John?'
A1: */?? Konpyuutaa desu.
computer Cop
'It's a computer.'
A2: [$_{DP}$ [$_{CP}$ Konpyuutaa-o ageta] hito-ni] desu.
computer-Acc gave man Cop
'It's the man who gave a computer (to him).'

As shown in (88), only the whole complex NP can be a felicitous answer to the in-situ *wh*-question. These types of facts are taken to show that the pied-piping of the island by the *wh*-in-situ element is the only possible derivation in the prima facie problematic cases. Hence, the apparent discrepancy between overt and LF movements with respect to the application of Subjacency would be eliminated. It must be noted here that the above covert pied-piping proposal fails to account for the fact that a certain subset of *wh*-elements, in particular non-referential adjuncts such as 'why' (reason) and 'how' (manner), are unable to take wide scope out of islands in such *wh*-in-situ languages as well (see chapter 77).

Apart from several empirical problems involved in the proposed evidence, such as those pointed out, e.g., in Fiengo et al. (1988), the above account is undesirable from the point of view of the assumptions it makes about LF-pied-piping itself. Crucially, notice that, based on what is known about overt pied-piping, the same *wh*-in-situ structures that in the above proposal are assumed to undergo LF-pied-piping would obviously not be able to undergo pied-piping by overt *wh*-movement. Under accounts of overt pied-piping based on variants of a

reasonably restrictive and empirically motivated feature percolation or inheritance mechanism (reviewed in section 4), the relevant [+*wh*] feature would clearly not be able to percolate to the complex NP in cases like (88), and, consequently, pied-piping would be impossible. This problem is best shown by the contrasts in English between overt *wh*-movement and *wh*-in-situ (alleged to involve LF-*wh*-movement) in the case of various islands, such as in (89a, b):

(89) a. *[The man [who bought what]] did Mary know?
b. Who knew [the man [who bought what]]?

LF-pied-piping by *wh*-in-situ, then, as formulated in the Choe–Nishigauchi–Pesetsky analysis, seems to resolve the non-uniformity of overt and covert movement with respect to Subjacency only at the cost of introducing another non-uniformity between overt and covert movements, namely, one with respect to the application of pied-piping. This is a serious problem since there is no plausible reason why covert movement should permit 'heavier' pied-piping than overt movement. Notice that if any needs of PF (relevant for the output of overt but not covert movement) have any impact on pied-piping options at all, these would presumably go in exactly the opposite direction; they would potentially force pied-piping rather than prevent it, e.g., in case the moved element was too 'small' to be pronouncable, such as a feature or a bound morpheme (on such effects of PF, see Chomsky 1995c, discussed in section 6).

Some problems with this LF-pied-piping proposal from the point of view of interpretation were noted by von Stechow (1996) (see also chapter 77). Von Stechow's objections may be resolved under a conception of reconstruction involving the copy theory of movement, combined with appropriate deletion conventions, of the kind suggested in Chomsky (1995c). However, it is important to note at this point that in spite of the inadequacies of this particular account for *wh*-in-situ and Subjacency, the general idea behind the proposal, namely, LF-pied-piping providing the account for what appear to be various potential island violations, is arguably on the right track. This kind of account, in a slightly amended form, in fact received some striking confirmation in the domain of the LF-movement of negative phrases in French, studied in Moritz and Valois (1994). In this work on French sentence negation, LF-pied-piping was shown not only to exist but to obey the familiar configurational requirements attributed to the restrictive feature-percolation mechanism underlying overt pied-piping.

After establishing that French negative phrases (such as *personne*) undergo LF-movement to Spec of NegP (not just chain formation with the head of NegP), Moritz and Valois (1994) proceed to explore cases where *personne* occurs within some larger phrase that can be shown (based on overt *wh*-movement) to constitute an island for extraction. The pattern of grammaticality they find is that the negative element *personne* gives well-formed negative sentences in some of these cases, but results in ungrammaticality in another subset of the cases. The mixed pattern suggests first of all that Subjacency is relevant for the LF-movement of negative phrases, and more importantly, that contrary to assumptions of the

proposal for *wh*-in-situ reviewed above, LF-pied-piping cannot apply freely, making all island effects disappear; rather, only certain kinds of configurations can result in LF-pied-piping.

The crucial claim made by Moritz and Valois on the basis of a variety of arguments is that the particular cases where an island can be pied-piped by *personne*, and thus a Subjacency violation by LF-raising to Spec of NegP can be avoided, are precisely the cases where *personne* contained in the larger phrase (i.e., in the extraction island) is able to move (covertly) to the highest Spec position of that phrase. Consider, for instance, the contrast between (90) and (91), representing one type of evidence used by Moritz and Valois.

(90) a. *l'homme dont$_i$ Lise a vu [$_{DP}$ sa (*agent*) photo t$_i$ (*theme*)]
the-man of-whom Lise has seen his picture
'the man of whom Lise saw his picture'
b. *Lise n'a vu [$_{DP}$ sa (*agent*) photo de *personne* (*theme*)].
Lise Neg-has seen his picture of nobody
'Lise did not see his picture of anybody.'
(Adapted from Moritz and Valois (1994, (49b) and (50b)))

(91) a. *De qui$_i$ Louise est-elle partie [$_{PP}$ avec [$_{DP}$ l'amie t$_i$]]?
of whom Louise is-she left with the-friend
'Whose friend did Louise leave with?'
b. Louise n'est partie [$_{PP}$ avec [$_{DP}$ l'amie de *personne*]].
Louise Neg-is left with the-friend of nobody
'Louise did not leave with anybody's friend.'
(Adapted from Moritz and Valois (1994, (58a, b)))

The (a) sentences demonstrate the impossibility of extraction from the DP in (90) and the PP in (91). Given this, the crucial evidence regarding LF-pied-piping is provided by the contrast between the negative sentences (90b) and (91b), both of which exhibit *personne* in a position prohibiting extraction. Apparently, the island effect in (91) can be voided via LF-pied-piping by *personne* in (91b); since the sentence is well-formed, a [+Neg] phrase must have moved covertly to the Spec of NegP to license the negative head. In contrast, sentence (90b) is ungrammatical, indicating that no movement of a [+Neg] phrase to the Spec of NegP could take place in it. Hence it must be the case that in (90b), not only extraction but crucially, also LF-pied-piping of the whole DP by *personne* is blocked. This fact about examples like (90b) is related by Moritz and Valois to a constraint widely observed in studies of extraction out of DP in Romance; it limits which argument of an N may move to the Spec of DP, and hence get extracted from DP. Crucially, it has the effect that when a noun phrase has both an agent and a theme, only the agent is able to move to the Spec position of the DP, and possibly get extracted further (this effect is shown overtly by the ungrammatical (90a)). The important point of the above argument is then that the impossibility of LF-piped-piping by *personne* (a theme) in (90b) and the contrast with the possibility

of LF-pied-piping by *personne* in (91b) would follow if the LF-pied-piping option were dependent on the ability of *personne* to move to the Spec position of the phrase to be pied-piped (in our cases, the phrase constituting an island for it); in other words, the evidence suggests that *personne* can pied-pipe the DP by LF-movement only if it comes to occupy the Spec of DP position. Notice that this finding of Moritz and Valois (1994) falls in place immediately in light of the two major conclusions we reached earlier on the basis of overt pied-piping: namely, (a) that pied-piping is possible only as a result of the 'pied-piped' phrase acquiring the feature that drives the particular movement (in the above case [+Neg]), and (b) that the feature-percolation mechanism is limited to Spec–Head agreement and to projection from the head of a phrase to the maximal projection (see (47) in section 4.2). Thus, Moritz and Valois's analysis seems to strongly support the assumption that, beyond Move α itself being uniform before and after S-structure/Spell Out, so are the mechanisms that regulate the possibility of pied-piping.

Within some versions of the MP, introducing feature movement to replace the traditional GB conception of Move α, and principles of derivational economy to limit movements strictly to operations necessary to ensure convergence, the very existence of covert phrasal movement was called into question. In particular, Chomsky (1995c) proposed that movement of any material beyond just the formal features themselves is an instance of pied-piping (referred to as "generalized pied-piping") and furthermore, according to an economy condition postulated, it can take place only when forced by needs of the PF interface, i.e., when the output without it would be 'unpronounceable'. (On this conception of pied-piping, see also section 6.) Under this strong hypothesis, all covert movements would necessarily be pure feature movements; only overt movements could be phrasal. In the context of this prediction, the evaluation of empirical evidence apparently pointing to the existence of covert phrasal movement, i.e., to the possibility of pied-piping under LF movement, becomes even more important than it was in earlier frameworks.

A particularly important kind of evidence in favor of LF-pied-piping is provided by the phenomenon of antecedent-contained deletion (ACD). The case of ACD constructions, exemplified in (92), is of special interest because the evidence it provides is very different in nature from the more common kind discussed above. In the above types, LF-pied-piping was inferred based on the observed bypassing of particular island effects. However, in the case of ACD, the evidence for LF-pied-piping involves interpretability, namely the resolution of VP anaphora.

(92) John [$_{VP}$ met [$_{DP}$ everyone that I did [$_{VP}$ e]]].
(Interpreted as *John met everyone that I met* t.)

The essence of the argument from ACD is based on the fact that the elided VP in cases like (92) needs a linguistic antecedent in order to get interpreted, but its antecedent is the matrix VP that the elided VP is contained in. Thus, in the

surface representation given in (92) there is no way to assign an interpretation to this null VP, since the process of VP-anaphora interpretation – the copying of the antecedent (the matrix VP) into the null VP – would reintroduce the VP gap itself, resulting in an infinite regress. This problem of regress can be eliminated, however, if there is some independently motivated process removing the elided VP from within the larger VP before the application of the interpretive (copying) procedure of VP-ellipsis. As was originally proposed by May (1985), and elaborated further, for instance, in Larson and May (1990), Fiengo and May (1994), and Fox (1999), precisely such an independently motivated process is QR, applying to the quantified head of the relative clause containing the elided VP. Thus if QR can move not only the quantifier, or the quantificational feature, but can pied-pipe the whole complex noun phrase, including the relative clause with the elided VP in it, to a position outside of the VP that contained it, then ACD interpretation would automatically become unproblematic. The LF-representation provided by QR under the assumption that it can involve pied-piping is given in (93).

(93) $[_{DP}$ everyone$_i$ that I did $[_{VP}$ e]] [John $[_{VP}$ met t_i]]

This covert pied-piping would leave behind a VP of the form [*met t*] which could now constitute an appropriate antecedent to be copied into the VP gap and provide the proper interpretation for the ACD construction in (92) (on the compatibility of this account with the copy theory of movement in the MP, see Fox 1999):

(94) $[_{DP}$ everyone$_i$ that I $[_{VP}$ *met* t_i]] [John $[_{VP}$ *met* t_i]]

Hornstein (1995) proposes a Case-driven, rather than a quantifier-driven, view of the movement involved, but this account, too, relies on the assumption of covert pied-piping – specifically, on pied-piping under covert A-movement. (For proposals using overt movements in the account of ACD, see Baltin 1987 and Kayne 2000: ch. 13.)

6 The Minimalist Program and further current directions

As reflected in the discussion of the above sections, the status of pied-piping in the theory has undergone substantial changes since its introduction in the late 1960s until current times, in accord with the evolution of the model of UG in general, and with the shifts in the conception of movement operations in particular. Here we will consider briefly the way pied-piping is conceived in current syntactic theorizing and sketch the role it plays and the issues it raises in Chomsky's (1995c, 2000) MP framework and other varieties of contemporary MP-related research.

6.1 Feature movement, economy, and generalized pied-piping

From the perspective of the GB framework, the major issue regarding pied-piping was to determine when it has the option to take place and when it is impossible. This in turn was due to the underlying assumption that, just like movement itself, pied-piping has no cost, and that therefore its application does not need to be (though of course may be) forced by some particular structural or other circumstance. In sharp contrast to this, Chomsky's (1995c) MP conception of pied-piping is based on the view of movement operations as involving, ideally, movement of no more than just the formal features of lexical items needed for the checking of corresponding uninterpretable features on some functional head. As pointed out already in section 5, the need for feature checking itself could not drive movement of any extra material beyond the feature itself. In the spirit of the economy of derivation adopted in the MP framework, this is taken to imply that movement of any lexical material, i.e., any pied-piping of material by the attracted or moved feature, referred to by Chomsky as generalized pied-piping, will be possible only to the extent that it is required for the convergence of the derivation at one of the interfaces. Furthermore, given that the most obvious problem with displacing isolated features seemed to be 'unpronouncability' – namely the lack of proper interpretation at the PF interface – Chomsky (1995c: 262–263) suggested a stronger version of the above hypothesis, according to which it is only PF needs, such as morphological and phonological properties determining PF convergence, that can induce (generalized) pied-piping. On this conception, pied-piping is viewed as a repair strategy imposed on the computational system by factors external to the system itself.

This PF-based hypothesis works adequately in some cases, as exemplified by the way *wh*-feature attraction applies to a *wh*-phrase like *whose book* (where *who* is assumed to be in the Spec of DP and *'s* is a possessive D, heading the DP). The attracted *wh*-feature cannot raise by itself since it would result in a crash at PF. So at least the whole lexical item *who* must be pied-piped; but in the present case, this would leave behind *'s book*, a form that would also cause a crash at PF; furthermore, *whose* (at least in English) cannot raise either, since being made up of the Spec of DP (*who*) and the head D (*'s*) it is a non-constituent, i.e., it is not a syntactic object at all, so it cannot be affected by a movement operation. Consequently, the smallest element that can legitimately be raised by Attract/Move [wh] according to Chomsky's (1995c) hypothesis is predicted to be the phrase *whose book.* It would furthermore be predicted that unless justified by additional PF needs, this would also be the maximal phrase that gets pied-piped; thus, e.g., phrases like *read whose book* and *an article about whose book* cannot get pied-piped under *wh*-feature movement.

Although the PF convergence hypothesis correctly derives pied-piping and, moreover, also the Left Branch Condition effect in the present case, it obviously faces some serious conceptual and empirical challenges. On the conceptual side,

the proposed economy condition involving the PF interface means that the determination of how much material is pied-piped each time when Attract applies to some feature in a derivation would involve significant look-ahead, a property known to result in sharply increased computational complexity. However, it is unlikely that such complexity is indeed inherent in overt movements, which manifest no corresponding special difficulty in production and processing (on the elimination of similar computational complexity with respect to Procrastinate and 'strong' features, see Chomsky 1995c: 228). One obvious empirical challenge for a purely PF-convergence induced view of pied-piping would be the apparent optionality of some cases of pied-piping, i.e., its alternation with extraction. This is the case, for instance, in *wh*-phrases in the Spec of DP in Russian-type languages, which permit Left Branch Condition violations, or in the case of Hungarian DPs with dative-marked possessors in the top Spec position (analyzed in Szabolcsi 1983). It is unclear how the larger phrases would be able to get pied-piped in such cases without violating the economy principle of carrying only the minimal amount of material sufficient for PF convergence.

These problems would not arise in the same way under Chomsky's (2000) version of the MP since it gives up the view of overt movement as generalized pied-piping, treating it as a 'repair strategy' for (pre-Spell Out) feature movement. It reanalyzes feature movement as long-distance agreement via the operation Agree and separates the case of overt movements from this feature-checking process in a way that makes overt movement essentially independent of the need of eliminating uninterpretable features. Instead, all overt movements are viewed as satisfying a further requirement imposed by particular functional heads to have a specifier projected (similarly to early versions of the EPP). Under this view the movement of overt material, namely, of a phrase, would no longer be a case of pied-piping induced by PF convergence. However, the empirical problem of how 'big' the moved phrase can be, i.e., what constituent can be legitimately moved to satisfy these 'EPP' requirements, is still a major issue.

It might be possible to deal with the problems of PF-convergence-induced pied-piping while maintaining the assumptions of feature movement and the economy principle of 'carry as little as possible' in some form. This involves trying to attribute the existence of phrasal movements not exclusively to the needs of PF convergence, but at least in part to the interaction of the above economy principle, requiring movement of the minimal element, with a major independently motivated economy principle of Chomsky (1995c: 297) built into the Attract operation. The latter condition requires Attract to target the closest feature that can enter into a checking relation with a feature of the attracting head (exemplified, e.g., in Superiority effects). Given that a feature (say, [*wh*]) occurring, for instance, on a morpheme in the Spec of a Spec of DP, such as in [*whose friend's mother*], would be further away (under an appropriate definition of 'closeness') from the *wh*-attracting C-head of the clause than the whole large DP itself, the condition 'closest' on Attract would force it to target the large DP, rather than the *wh*-morpheme *who*. This assumes that the *wh*-feature was present not only within the Spec of the Spec of the DP, but – due to feature percolation

(motivated earlier) – also on the large DP itself. Such a proposal would have the further advantage of being able to maintain the desirable empirical results of the earlier feature-percolation based accounts of pied-piping with respect to the possible phrase-internal positions of pied-pipers, as discussed in section 4. In a framework permitting feature-movement, this proposal would of course still need to avoid movement of just the bare *wh*-feature that percolated to the large DP in the case under discussion, and induce raising of that whole DP instead. But this would follow as before; bare feature movement prior to Spell Out would be excluded by the assumption that features displaced from their lexical item cause a PF-crash (Chomsky 1995c). This type of conception of phrasal movement is explored in Pesetsky (2000), where the option of phrasal vs. feature or morpheme movement is seen as moving the closest bearer vs. the smallest bearer of the relevant feature, both being considered ways of satisfying derivational economy.

6.2 *Phrasal movement vs. head movement, large-scale pied-piping, and the elimination of feature movement*

The empirical issue of correctly accounting for how big a constituent bearing the relevant feature ends up moving can be – in other words, what constituent gets pied-piped by the minimal element needed for feature-checking – arises independently of whether the theory postulates feature movement per se and whether one assumes an economy-based preference for moving the smallest element possible (as Chomsky's 1995c version of the MP did). Notice, for instance, that given the well-motivated feature-percolation mechanism underlying pied-piping, the problem of determining the choice between moving a head and moving the whole phrase (both bearing the same features) may arise in any framework in which movement is driven by feature-checking, even in one stipulating that features cannot move, i.e., that movements apply only to categories (as under Move α of the GB framework).

Notice that in GB theory this problem did not seem to arise. In that framework, movements were stipulated to involve requirements of individual Spec positions vs. requirements of particular heads, e.g., in the case of the *Wh*-Criterion, or the affix triggering V-to-I. This property, in conjunction with the structure preservation hypothesis (Emonds 1976; Chomsky 1986a), fully determined which movement will be phrasal movement and which will be head movement. Under the MP checking theory, however, this is no longer true, since the feature in need of checking (attracting to itself an element with a matching feature) always occurs on a functional head; specifiers as such are designated to play a role only in the more recent, EPP-based version of overt movement suggested in Chomsky (2000) (see section 6.1).

Empirically, the issue of head vs. phrasal movement calls for further investigation. Yet, based on the range of cases studied, it appears that feature-checking, if

it induces overt movement at all, induces pied-piping of a phrase rather than just the head (for evidence see, e.g., Koopman and Szabolcsi's 2000 study of verb-raising structures). This may in turn follow automatically if head movement is in fact not an option in the computational system at all, only at PF (a hypothesis suggested recently on the basis of a variety of independent considerations for instance by Chomsky 2000, Boeckx and Stjepanović 2001 and others). If so, head movement could provide no alternative to feature-checking via phrasal movement.

Yet, a similar issue of whether or not a larger constituent XP gets pied-piped in the case of a phrase YP occurring in the Spec of XP remains an empirical problem, as it was for the previous hypotheses. The Spec position has been seen to be a position potentially permitting pied-piping of the phrase (given the Spec–Head agreement based feature percolation or inheritance mechanism). The question of when this option is taken and when the element in Spec extracts rather than pied-pipes the larger phrase would seem *a priori* to be subject to variation both within and across languages. In fact it is precisely this choice between extraction from Spec and pied-piping of the whole phrase by Spec provided by UG that is claimed in Koopman and Szabolcsi (2000) to provide the basis for cross-linguistic as well as language-internal variation observed in the cases they studied.

An alternative, more challenging, hypothesis regarding pied-piping options is proposed in work by Koopman (1996, 1997). In exact opposition to Chomsky's (1995c) economy principle minimizing the amount of pied-piped material, the hypothesis developed in this direction of research, conceptually inspired by Kayne's Antisymmetry framework, is that massive large-scale pied-piping is in fact the core operation by which derivation proceeds. This line of research makes use of no economy principles and stipulates no feature movement; instead it argues that large-scale pied-piping of different projections by feature-driven 'licensing' movements within the functional layers of lexical categories is common, and, possibly, is the only option permitted by UG. Although these may be harder to detect than 'smaller', e.g. DP or PP, pied-piping, they can be argued for on empirical grounds, such as various agreement phenomena (for references, see Koopman 1996). The reason given for why the alleged cases of large-scale heavy pied-piping escaped notice is that in structures with multi-layered functional projections above each lexical head (forming an extended projection in Grimshaw's 1991 terminology) the movement of large constituents (e.g., various clausal projections) to nearby Spec positions is hard to overtly detect, especially when the head of the phrase it lands in is null. In fact, Koopman (1997) suggests that contrary to standard assumptions (see above), extraction from Spec is prohibited, and what appears to be extraction from Spec is actually pied-piping of the whole phrase that happens to be a remnant, containing overt material only corresponding to its Spec. Thus, the multiplicity of a universal set of functional categories generated above each lexical head assumed in current versions of the MP, in conjunction with the extensive use of remnant movement assumed in the above line of research, give a rather different picture of the pied-piping issue than previous theories did. Instead of a limited, relatively insignificant, property

of movements, pied-piping in such a framework of assumptions is a major syntactic device that is a concomitant, essentially, of all movement. What forces such large-scale pied-piping is less clear; it obviously is not an economy condition that serves to maximize pied-piping. It appears that extensive heavy pied-piping is induced in the above version of the theory by directly eliminating potential alternatives from UG, for instance, by stipulating that bare feature-movements and extraction from Spec position do not exist.

In view of the emerging diverse hypotheses and research sketched above, what seems clear at this point is that pied-piping will be an important focus of attention and empirical investigation in the coming years of work in syntactic theory.

6 Some remaining problems and issues
  6.1 Lack of D-to-P incorporation
  6.2 D-to-P incorporation from the specifier position
7 Conclusion

1 Introduction

Ross (1986: 138) uses the term 'preposition stranding' (henceforth, P-stranding, to include cases of stranding of postpositions) to refer to cases where a preposition is stranded as a result of its object having been extracted, as illustrated in the English examples in (1) and (2):

(1) a. Which book$_i$ have they talked about t_i?
    b. Which carpet$_i$ did they step on t_i?

(2) a. That book$_i$ has been talked about t_i.
    b. This carpet$_i$ was stepped on t_i.

Extraction of the sort in (1) generally shows different properties than that in (2), and has come to be known as A-bar-movement, in distinction from the latter, which has been given the name A-movement.

From a typological perspective, languages exhibit a range of variation with respect to P-stranding. On the one extreme lie languages like English and Scandinavian, where P-stranding is possible under both A- and A-bar-movement:

(3) a. Vad$_i$ talade du om t_i? Swedish
what talked you about
'What did you talk about?'
b. Denna bok blev talad om t_i
this book become talked about
'This book has been talked about.'

On the other extreme are languages like Romance, where P-stranding is simply impossible in general:[1]

(4) a. *Q$_i$'as-tu parlé de t_i? French
what have-you talked about
b. *Che$_i$ hai parlato di t_i? Italian
what have-you talked about
'What did they talk about?'

(5) a. *Ce livre$_i$ a été parlé de t_i. French
this book has been talked about
'This book has been talked about.'
b. *Questo libro è stato parlato di t_i. Italian
this book has been talked about
'This book has been talked about.'

Somewhere in between these two extremes are Dutch and colloquial German, where movement of an R-pronoun (German *wo* 'where/what' and *da* 'it'; Swiss German *waas* 'what'; Dutch *er* 'there/it', *daar* 'there', *waar* 'where/what', *ergens* 'something', *nergens* 'nothing', and *overal* 'all') stranding P is possible:[2]

(6) a. Wo$_i$/*Was$_i$ redest du von t_i? German
what talk you from
'What are you talking about?'
b. Waar$_i$/*Wat$_i$ heb je op t_i gerekend? Dutch
what have you on counted
'What have you counted on?'

(7) a. Da/*Dieses Buch$_i$ wurde von t_i geredet. German
it/this book became about talked
'It/this book has been talked about.'

b. Daar/*deze man is op t_i gerekend. Dutch
it/this man is on counted
'It/this man has been counted on.'

To my knowledge, there are no languages that allow P-stranding under A-movement, but not under A-bar-movement. At least superficially, then, the four logical possibilities for P-stranding can be summarized in (8):

(8)

P-stranding under A-movement	P-stranding under A-bar-movement	
+	+	English
−	−	Romance
+	−	?
−	+	German/Dutch/Scandinavian

But as we will see, P-stranding under A-movement in German and Dutch and Scandinavian languages is only apparent; there are fairly good reasons to think in fact it falls under A-bar-movement. If this is correct, then languages either allow P-stranding or not, with type of movement being irrelevant.

From the grammatical theory perspective, the patterns of variation with respect to P-stranding in (8) raise a fundamental theoretical question as to what grammatical principles sanction P-stranding. An adequate answer to this question must shed light not only on the empirical question of whether P-stranding correlates with other grammatical properties, but also on the conceptual issue of whether the type of movement should bear on P-stranding.

In what follows I will examine these issues closely and argue that there is no grammatical principle specifically sanctioning P-stranding. Rather, P-stranding is related to the independent grammatical property of D incorporating into P. It thus does not bear on the type of movement, i.e., A- vs. A-bar, but is contingent on D not incorporating into P. The table in (8) thus gives a skewed impression of P-stranding under A-bar-movement being more common than P-stranding under A-movement, but in fact has no independent theoretical significance. It is simply a reflection of the general grammatical principles and other properties in particular languages that make P-stranding possible.

2 Syntactic constraints on extraction and P-stranding

Van Riemsdijk (1978a: 160) suggests that P-stranding as a result of extraction is subject to the same general constraint on extraction in (9):

(9) **The Head Constraint** (HC):
No rule may involve X_i/X_j and Y_i/Y_j in the structure
$\ldots X_i \ldots [_{H^n} \ldots [_{H'} \ldots Y_i \ldots H \ldots Y_j \ldots]_{H'} \ldots]_{H^n} \ldots X_j \ldots$
(where H is the phonologically specified (i.e., non-null) head and H^n is the maximal projection of H (H‴ in our framework))

Thus, movement out of PPs, like out of other categories, must move through the Spec position to avoid a violation of the HC if the head H is non-empty (cf. also Koopman and Sportiche 1991b).

In Dutch, R-pronouns must appear to the left of Ps, while non-R-pronouns like *hem* 'him' *die* 'that one', and *wie* 'who' must appear to the right (Van Riemsdijk 1978a: 37):

(10) a. erop/*oper 'on it'; daarop/*opdaar 'on there'
b. op hem/*hem op 'on him', op wie/*wie op 'on whom'

If we take the left-complement of a P as appearing in the [Spec, PP] position (cf. Van Riemsdijk 1978a; Corver 1990), then we would expect that from the perspective of the HC R-pronouns may be extracted out of PPs, stranding Ps. The expectation is borne out by the facts:

(11) a. Ik had niet [$_{PP}$ er$_i$ [op t_i]] gerekend. Dutch
I had not it on counted
'I had not counted on it.'
b. Ik had er$_i$ niet [$_{PP}$ t_i [op t_i]] gerekend.

Moreover, if movement is further subject to the structure-preserving constraint (SPC, Emonds 1976: 5) restricting movement of a phrase to a position where it can be generated independently, then non-R-pronouns may not use the [Spec, PP] as escape hatch for extraction out of PP, since they cannot be independently generated there:

(12) a. Ik had niet [$_{PP}$ [op hem]] gerekend. Dutch
I had not on him counted
b. *Ik had niet [$_{PP}$ hem$_i$ [op t_i]] gerekend.
c. *Ik had hem$_i$ niet [$_{PP}$ t_i [op t_i]] gerekend.

The same explanation can be given for the lack of P-stranding in Romance. The complement of P never appears to the left of P, i.e., it never shows up in the [Spec, PP], as shown in the ungrammatical contrast in (13):

(13) a. J'ai parlé à Jean. French
I have talked to Jean
'I talked to John.'
b. *J'ai parlé Jean à.

Therefore, movement of the complement of P, stranding P, would violate either the SPC if it moves through [Spec, PP], or the HC if it moves directly out of PP:

(14) a. *Qui$_i$ as-tu parlé [$_{PP}$ [à [t_i]]? French
who have-you talked to
'Who did you talk to?'
b. *Qui$_i$ as-tu parlé [$_{PP}$ t_i [à [t_i]]?

Given these P-stranding facts in Dutch and French, it must be the case that in English when a *wh*-phrase object of a P is extracted, it moves through [Spec, PP] so as not to violate the HC. From the perspective of the SPC, a question that immediately arises is whether there is independent evidence showing that a *wh*-phrase may be independently generated in [Spec, PP]. Van Riemsdijk (1978a: 226ff) argues that Sluicing (Ross 1986) is evidence that a *wh*-phrase may independently appear in [Spec, PP]:

(15) a. John left, but I don't know [$_{PP}$ who$_i$ [with t_i]].
b. Mary bought some apples, but I don't know [$_{PP}$ what$_i$ [for t_i]].

If this is correct, then it is just as expected that a *wh*-phrase may move out of PP using [Spec, PP] as escape hatch. But it is far from obvious that the *wh*-phrase in (15) is in the [Spec, PP] position since it depends very much on the derivation and representation of Sluicing. We need not consider in detail the analysis of Sluicing in order to see that the examples in (15) do not in fact constitute evidence that *wh*-phrases may independently be generated in [Spec, PP].

The verb *know* may take either a DP or a CP complement, but, crucially, not a PP complement:

(16) a. I knew John.
b. I knew when John was in the class.
c. *I knew in the class.
