So there is no reason to think that the verb *know* takes a PP complement in (15). It is therefore clear that the syntactic structure of the example in (15) would be either as in (17a) where *who* is in the Spec of the PP headed by *with* in [Spec, CP] or as in (17b) where the PP headed by *with* is in argument position and its argument *who* is extracted to [Spec, CP] (the . . . indicates possible material that is not relevant to our discussion here):

(17) a. John left, but I don't know [$_{CP}$ [$_{PP}$ who$_i$ [with t_i]]$_j$ [[$_{IP}$ . . . t_j]]].
b. John left, but I don't know [$_{CP}$ who$_i$ [[$_{IP}$ . . . [$_{PP}$ with t_i]]]].

The representation in (17b) is not relevant to Van Riemsdijk's claim that *wh*-phrases may be independently generated in [Spec, PP], since the *wh*-phrase is not in [Spec, PP].[3] The relevant structure is the one in (17a). If this representation is the correct structure for the Sluicing construction, then we should expect that PPs with a non-bare *wh*-phrase are possible in the same position and that PPs with a bare *wh*-phrase in its Spec are also possible elsewhere. These expectations are not borne out by the facts, however. As shown in (18), non-bare *wh*-phrases are not possible in the Sluicing context:

(18) a. *John left with some students, but I don't know [$_{PP}$ which ones$_i$ [with [t_i]]].
(cf. John left with some students, but I don't know with which ones)

b. *Mary brought in these books, but I don't know [$_{PP}$ which class$_i$ [for [t_i]]].
(cf. Mary brought in some books, but I don't know for which class)

If a bare *wh*-phrase is possible in [Spec, PP] as in (17a), then it is unclear why a non-bare *wh*-phrase may not occur in the same position. Furthermore, if we take the examples in (18) as evidence that non-bare *wh*-phrases may not be base-generated in [Spec, PP], then a problem arises as to how they may nevertheless be extracted without violating the HC, if they cannot use [Spec, PP] as escape hatch:

(19) a. Which ones/students$_i$ did John leave [$_{PP}$ t_i [with t_i]]?
b. Which class$_i$ did Mary bring in these books [$_{PP}$ t_i [for t_i]]?

The grammatical contrast in (20) shows clearly that a PP with a bare *wh*-phrase in its Spec is not possible elsewhere, casting some doubts on the claim that the *wh*-phrases in (15) occur in [Spec, PP]:

(20) a. *[$_{PP}$ who$_i$ [with t_i]]$_j$ did John go out last night t_j?
b. [$_{PP}$ with whom]$_j$ did John go out last night t_j?

Although the grammatical contrast between (15a) and (20a) does not shed much light on the analysis of Sluicing (cf. also n. 3), it seems clear that the examples in (15) by themselves are not compelling evidence for *wh*-phrases being (possibly) base-generated in [Spec, PP].

A problem of a different sort also arises in Dutch, where a non-R-pronoun appearing to the left of a P may sometimes be extracted:

(21) a. Je zei dat hij [$_{PP}$ de boom in] geklommen is. Dutch
you said that he the tree in climbed is
'You said that he climbed into that tree.'
b. Welke boom$_k$ zei je dat hij [$_{PP}$ t_k in] geklommen is?
which tree said you that he in climbed is
'Which tree did you say that he climbed into?'

There is an issue as to where the complement *de boom* occurs, specifically, whether it appears in the complement position of the P *in* 'in', i.e., a postposition, or it occurs in the [Spec, PP] position, having moved leftward from the complement position, i.e., *in* 'in' is a preposition:

(22) a. . . . [$_{PP}$ [[$_{DP}$ de boom] in]] . . .
b. . . . [$_{PP}$ [$_{DP}$ de boom]$_i$ [in t_i]] . . .

But from the perspective of the HC it does not matter whether *in* is a preposition or a postposition; extraction out of the PP is subject to the HC.

From the perspective of the HC, the *wh*-phrase *welke boom* 'which tree' in (21b) must be extracted through the [Spec, PP], either as in (23a) or as in (23b):

(23) a. $[_{DP}$ welke boom$]_i \ldots [_{PP}\ t_i\ [t_i$ in$]] \ldots$
b. $[_{DP}$ welke boom$]_i \ldots [_{PP}\ t_i$ [in t_i]$] \ldots$

But we see in (10) that non-R pronouns generally appear to the right of P, and are therefore not in [Spec, PP]. So non-R-pronoun *wh*-phrases may not be extracted through [Spec, PP], and extraction of the sort in (23) should be impossible. Van Riemsdijk (1978a) thus argues that in cases like (21) the P incorporates into V (Evers 1975b), as in (24):

(24) a. Je zei dat hij $[_{PP}\ t_j$ de boom] [in$_j$+geklommen] is.
b. Welke boom$_k$ zei je dat hij $[_{PP}\ t_j\ t_k]$ [in$_j$+geklommen] is?

As a result, the head position of the PP is empty and the HC no longer applies; the *wh*-phrase in a PP whose head position is empty can now be extracted, observing the HC, as in (24b).

The idea that the P *in* in (21) incorporates into V apparently explains two facts. First, it explains why the complement of the P ends up being to the left of P, P having moved rightward as indicated in (24a). Second, it explains why the P may (optionally) raise together with V to the right of the auxiliary:

(25) a. Je zei dat hij $[_{PP}$ de boom $t_j]\ t_i$ is [in$_j$+geklommen]$_i$.
'You said that he climbed into that tree.'
b. Welke boom$_k$ zei je dat hij $[_{PP}\ t_k\ t_j]\ t_i$ is [in$_j$+geklommen]$_i$?
'Which tree did you say that he climbed into?'

But there are some facts that do not fall under this account. As shown in (26), the P is clearly not incorporated into V; yet, the *wh*-phrase may be extracted:

(26) a. Welke boom$_k$ klom Jan $[_{PP}$ in $t_k]$?
which tree climbed Jan into
'Which tree did Jan climb into?'
b. Ik geloof dat Jan de boom$_k$ gisteren $[_{PP}$ in $t_k]\ t_i$ is geklommen$_i$.
I think that Jan the tree yesterday in is climbed
'I think that Jan climbed into that tree yesterday.'
c. Welke boom$_k$ zei je dat hij $[_{PP}$ in $t_k]\ t_i$ is geklommen$_i$?
which tree said you that he in is climbed
'Which tree did you say that he climbed into?'

Here, the head of the PP is not empty. In addition, as non-R-pronouns may not be independently base-generated in the [Spec, PP], the *wh*-phrase may not be extracted via [Spec, PP] to get around the HC.[4] So movement out of the PP in (26) should violate the HC, contrary to facts.

3 A syntactic reanalysis account for P-stranding

Hornstein and Weinberg (1981: 60–61) propose a Case-theoretic approach to P-stranding. Specifically, they claim that languages may resort to a syntactic rule of reanalysis applying to VP, and that there is a universal filter against traces with oblique Case:

(27) a. **Syntactic rule of Reanalysis:**
V → V* (where V c-commands all elements in V*)
b. **Oblique Case Filter:**
*[$_{NP}$ e]
oblique

They further assume a Case-marking rule that marks an NP with a [+oblique] Case if it is governed by P (cf. Chomsky 1980a; Rouveret and Vergnaud 1980); crucially, the Case-marking rule must apply after reanalysis. Along these lines, the syntactic rule of reanalysis would apply to the VP in (15a) to produce a complex verb like that in (28b) or (28c):

(28) a. John [$_{VP}$ [$_{V}$ talked [$_{PP}$ to Harry] [$_{PP}$ about Fred]]].
b. John [$_{VP}$ [$_{V}$ talked to] Harry [$_{PP}$ about Fred]].
c. John [$_{VP}$ [$_{V}$ talked to Harry about] Fred].

The (apparent) object of the preposition (*to* or *about*) is in fact an object of the reanalyzed verb, and the *wh*-phrase object of these reanalyzed verbs may now be extracted since it is no longer governed and Case-marked with a [+oblique] Case by P after reanalysis:

(29) a. Who$_i$ did John [$_{VP}$ [$_{V}$ talk to] t_i [$_{PP}$ about Fred]]?
b. Who$_i$ did John [$_{VP}$ [$_{V}$ talk to Harry about] t_i]?

The reanalysis rule in (27) has certain intuitive appeal since the structural relation between the trace of the extracted *wh*-phrase and the V+P complex predicate is exactly like that between the trace of the extracted object and a simple verb. The reanalysis account of P-stranding correctly predicts that P may not be stranded if it heads a PP that is not part of a VP, since the syntactic rule of reanalysis applies only to elements attaching to VP. Thus, P-heads of sentential PPs, PPs in COMP, or extraposed PPs cannot be stranded, these PPs not being (locally) c-commanded by V (Postal 1972: 213, 216):[5]

(30) a. *What time$_i$ did John arrive [$_{PP}$ at t_i]?
b. What conclusion$_i$ did John arrive [$_{PP}$ at t_i]?

(31) a. *Who(m)$_j$ do you believe Fred thinks [$_{PP}$ to t_j]$_i$ Joan talked t_i?
b. *Who(m)$_j$ do you believe [$_{PP}$ to t_j]$_i$ Fred thinks Joan talked t_i?

(32) a. Who$_i$ did John [$_V$ talk to t_i] about Harry yesterday?
b. ??Who$_j$ did John talk t_i about Harry [$_{PP}$ to t_j]$_i$ yesterday?

The grammatical contrast in (33) also follows since the reanalysis rule in (27) presumably fails to apply to V and P when the two are separated by an adverbial, the PP plausibly appearing in an adjunct position and the head P no longer being c-commanded by V:[6]

(33) a. They stepped repeatedly on the carpet.
b. *The carpet was stepped repeatedly on.

An implication of the reanalysis rule in (27a) is that the elements and the V with which they are reanalyzed must be adjacent (Hornstein and Weinberg 1981: 67), so that the rule can apply to cases like (25a), repeated in (34a), where P and V are adjacent, turning it into the structure in (34b):

(34) a. Je zei dat hij [$_{VP}$ [$_{PP}$ de boom in] geklommen] is. Dutch
you said that he the tree in climbed is
'You said that he climbed into that tree.'
b. Je zei dat hij [$_{VP}$ [$_{DP}$ de boom] [$_V$ in geklommen]] is.
c. Welke boom$_k$ zei je dat hij [$_{VP}$ t_k [$_V$ in geklommen]] is?
which tree say you that he in climbed is
'Which tree did you say that he climbed into?'

A *wh*-phrase object of the reanalyzed verb can now extract, as in (34c). The same account would work in German as well:

(35) a. . . . weil man nie [$_{VP}$ [$_{PP}$ davon [$_V$ hörte]]] German
because one never it-of heard
'. . . because one never heard of it.'
b. . . . weil man nie [$_{VP}$ da [$_V$ von hörte]]
c. . . . weil man da$_i$ nie [$_{VP}$ t_i [$_V$ von hörte]]

There are several empirical and conceptual problems with the reanalysis account of P-stranding. Empirically, if extraction of the sort in (28) is the result of P being reanalyzed with V so that the object of P would become the object of the reanalyzed V+P, then we should expect P and V to behave as a syntactic unit. The expectation is not borne out, however:

(36) a. *[$_V$ in klom]$_i$ Jan de boom niet t_i? Dutch
in climbed Jan the tree not
'Did Jan not climb into the tree?'
b. *[$_V$ von hörte]$_i$ man da nie t_i? German
of heard one it not
'Did one never hear of it?'

In addition, in cases like those in (37) where the P is clearly not adjacent to V and cannot be reanalyzed with it, the reanalysis account of P-stranding would lead us to expect that the object of P may not be extracted:[7]

(37) a. Wo$_i$ hörte man nie [$_{PP}$ t_i von]? German
what heard one never of
'What did one never hear of?'
b. Welke boom$_i$ klom Jan [$_{PP}$ t_i in]? Dutch
which tree climbed Jan in
'Which tree did Jan climb into?'

The fact that it may be extracted shows that there is an empirical problem with this account, the same problem we saw in (26).

Conceptually, insofar as the examples in (30–32) can be excluded on independent grounds, the ungrammaticality of these examples may turn out to have no bearing on the filter ruling out traces marked with oblique Case. The sentential PP in (30), the preposed PP in (31) (it is unclear, however, whether these are in COMP, i.e., [Spec, CP]) and the extraposed PP in (32) are evidently in adjoined positions, and extraction out of adjuncts is independently excluded by Huang's (1982a) Condition on Extraction Domain (CED). Therefore, to the extent that the examples in (38) do not bear on reanalysis as they obviously do not involve P-stranding, there is no reason to suppose that those in (30–32) are not ruled out by the CED, but by the filter in (27b):

(38) a. *What$_i$ did John read the newspaper [before Bill wrote t_i]?
b. *Which book$_i$ did Fred met the man [who bought t_i].
c. *About who(m)$_j$ did John claim (that) [books t_j]$_i$ many people will buy t_i?

We can conclude that the ungrammaticality of the examples in (30–32) is no evidence for the filter in (27).

The reanalysis-account of P-stranding is also inadequate from a cross-linguistic point of view. As Hornstein and Weinberg (1981: 68) note, one must assume that languages like Romance, which do not allow P-stranding at all, have no syntactic rule of reanalysis. But if no other property is brought to bear on the lack of P-stranding, then the assumption is simply a conceptually unsatisfying stipulation.

4 Government-theoretic accounts of P-stranding

We will now look at two government-theoretic accounts of P-stranding. One is related to the government and Case property of a lexical head, and the other to the direction of government.

4.1 The government and Case property of lexical heads

Kayne (1984a: 114ff) accepts the existence of a reanalysis rule in English, but what is involved is not so much reanalysis qua constituent as suggested by Hornstein and Weinberg (1981) as reanalysis in terms of government (Rouveret and Vergnaud 1980). In fact, French causatives (Rouveret and Vergnaud 1980) and complex predicates involving Ns and Vs (Pollock 1979) are two cases of reanalysis:

(39) a. faire lire 'to cause to read', laisser partir 'to let go'
b. mettre fin à 'to put an end to'

Kayne proposes a constraint on reanalysis to the effect that elements undergoing the reanalysis rule must be governed in the same way. He argues that Vs and Ps govern in the same way in English in assigning structural case, whereas in French Ps do not govern and assign Case structurally like Vs. Consequently, Vs and Ps may be reanalyzed in English, but not in French.

Kayne (1984a) points out three differences between English and French, claiming that they bear on government. First, the English prepositional complementizer (P-complementizer) *for* allows an overt subject in the embedded clause, but the French P-complementizer *de* (or *à*) does not:

(40) a. It would be a pity for something to happen to him.
b. For there to be riot would be catastrophic.

(41) a. *Ce serait dommage de quelque chose lui arriver. French
it would be pity to some thing to him arrive
'It would be a pity for something to happen to him.'
b. *D'il y avoir une émeute serait catastrophal.
to-it there have a riot would be catastrophic
'For there to be a riot would be catastrophic.'

Second, French *de* permits a phonetically empty pronominal in the embedded [Spec, IP] position, while English *for* does not:

(42) a. Ce serait dommage de PRO partir maintenant. French
it would be pity to leave now
'It would be a pity to leave now.'
b. *Ce serait dommage de Jean partir maintenant.
it would be pity to John leave now
'It would be a pity for John to leave now.'

(43) a. It would be a pity for John to leave now.
b. *It would be a pity for PRO to leave now.

Third, English generally allows a lexical subject in an infinitival complement to Exceptional Case-marking (ECM) verbs, but French permits it only to the extent that the lexical subject undergoes *wh*-movement:

(44) a. I believe John to be the most intelligent of all.
b. John considers there to be a problem.

(45) a. *Je crois Jean être le plus intelligent de tous. French
I believe John be the most intelligent of all
'I believe John to be the most intelligent of all.'
b. Quel garçon crois-tu être le plus intelligent de tous?
which boy believe-you be the most intelligent of all
'Which boy do you believe to be the most intelligent of all?'

Kayne claims that these three differences between English and French would have a unified account if in French Vs govern structurally, but Ps govern NP only in the sense of subcategorization, while in English both Vs and Ps govern structurally. That is, whereas V in the position X may govern P in both configurations in (46), but P, unlike V, does not necessarily do so, depending on the language:

(46) a. . . . [$_{XP}$ X YP] . . .
b. . . . [$_{XP}$ X [$_{ZP}$ YP [Z . . .

Specifically, P governs P from the position X in the configuration in (46b) in English, but not in French.

The assumption that French Ps do not govern structurally explains why French *de* allows a phonetically null pronominal PRO in the YP position in (46b) but not a lexical one, the position not being governed (cf. the PRO theorem, Chomsky 1981). Kayne further suggests that ECM-complements are headed by a phonetically empty P-complementizer Φ in the C position, which assigns Case to the embedded subject position by transmitting the Case it receives from V:

(47) a. I believe [$_{CP}$ [Φ [$_{IP}$ John [to be the most intelligent of all]]]].
b. *Je crois [$_{CP}$ [Φ [$_{IP}$ Jean [être le plus intelligent de tous]]]]. French

The grammatical contrast in (47) is then due to the different government property of the P-complementizer in the two languages. In English, it governs the embedded subject position and hence may assign Case to the embedded subject. In French it does not govern the embedded subject position, and hence cannot assign Case to it. An overt argument in the embedded subject position of an ECM-complement would then fail to be assigned Case, violating the Case Filter. Although the facts in (40–42) clearly indicate that English and French P-complementizers have different properties, the difference concerns only P-complementizers, not Ps in general. For Ps in PPs, French is pretty much the same as English; French Ps in PPs assign or check Case of their objects, and hence govern them, just like their English counterparts:

(48) a. J'ai voté [$_{PP}$ pour Jean].
I-have voted for John
'I voted for Jean.'
b. J'ai parlé [$_{PP}$ avec Jean].
I-have talked with John
'I talked with John.'
c. J'ai [$_{VP}$ vu Jean].
I-have seen John
'I saw John.'

At least for Ps in PPs, then, they assign or check Case of their objects the same way as Vs. Now, if Case-assignment or checking requires government, a standard assumption in the framework at the time, and Ps govern the same way as Vs, contrary to Kayne's claim, then we should expect that V and P in (49a) and (49b) may be reanalyzed as one complex verb, and that the object of P may be extracted; but the fact is that it may not:

(49) a. *Quel candidat$_i$ as-tu voté [$_{PP}$ pour t_i]?
which candidate have-you voted for
'Which candidate did you vote for?'
b. *Qui$_i$ as-tu parlé [$_{PP}$ avec t_i]?
who have-you talked with
'Who did you talk with?'
c. Qui$_i$ as-tu [$_{VP}$ vu t_i]?
who have-you seen
'Who did you see?'

It thus seems that the difference between English and French P-complementizers does not tell us much about the government property of Ps in general, and much less so whether P-stranding is related to government.

Kayne's government-theoretic account for the grammatical contrast in (45) is not without problems. If V may govern across one clausal boundary, but P may not, then a question arises as to how the trace of the embedded subject in (45b) would be (properly) governed when it is extracted, given the Empty Category Principle (Chomsky 1981):

(50) Quel garçon$_i$ crois-tu [$_{CP}$ t_i [Φ [$_{IP}$ t_i [être le plus intelligent de tous]]]]?
which boy believe-you be the most intelligent of all
'Which boy do you believe to be the most intelligent?'

Although some alternative explanation for the contrast in (45) may be provided for,[8] it seems clear that there is no good reason to suppose that the empty complementizer does not govern the embedded subject position.

From the cross-linguistic perspective, Kayne's government account of P-stranding would not work for the limited cases of P-stranding in German and

Dutch. The examples in (51) are a minimal pair, differing only with respect to whether the object of the P is an R-pronoun or not:

(51) a. Ik had er$_i$ niet [$_{PP}$ t_i op] gerekend. Dutch
I had it not on counted
'I had not counted on it.'
b. *Ik had hem$_i$ niet [$_{PP}$ op t_i] gerekend.
I had him not on counted
'I had not counted on him.'

There is no reason to think that the P *op* 'on' has different government properties in (51), as both the R- and non-R pronoun objects are assigned or check the Case of P. In fact, Kayne (1984a: 116) noted that P-stranding in these languages might not involve reanalysis, but did not elaborate on why the distinction between R- and non-R pronoun bears on P-stranding. Thus, to the extent that the grammatical difference in (51) is left unaccounted for, the empirical coverage of the reanalysis account based on government seems to be confined to English and Romance.

4.2 Directionality of government and P-stranding

Bennis and Hoekstra (1984) suggest a government-theoretic account of P-stranding, crucially without reanalysis. Essentially following Kayne (1984a), they posit the gap condition in (52) for the relation between a gap and its antecedent (Bennis and Hoekstra 1984: 34):

(52) **Gap Condition:**
A gap Z in a tree P is linked to its antecedent by a connected subtree of P which constitues a g-projection.
XP is a g-projection of the structural governor W of Z iff the head of XP c-governs Z or a g-projection of W.
X c(anonically)-governs Y iff X precedes Y in a VO language and follows Y in an OV language.

Koster's (1987) account is also along these lines, except the link between the gap and the antecedent is constrained by government harmony, requiring that the structural governors in the link between the antecedent and the gap govern in the same direction, similar to Kayne's suggestion that government in the same way is required for reanalysis.

With the Gap Condition in (52), the grammatical contrast in (51) is accounted for as follows. In the structure in (53a) for the example in (51a), the trace is linked to its antecedent by a connected subtree, the VP, which constitutes a g-projection of the structural governor *op* 'on' of the trace t_i:

(53) a. Ik had [$_{VP}$ er$_i$ [$_{VP}$ niet [$_{VP}$ [$_{PP}$ t_i op] gerekend]]]]
'I had not counted on it.'

b. *Ik had [$_{VP}$ hem$_i$ [$_{VP}$ niet [$_{VP}$ [$_{PP}$ op t_i] gerekend]]]
'I had not counted on him.'

The head *gerekend* of the VP c-governs the PP projection of *op*, and the PP in turn is a g-projection of the structural governor *op* of the trace which is c-governed by *op*.[9] By contrast, the gap in (53b) is not linked to its antecedent by a connected g-projection, the P *op* not c-governing the gap.

A major problem with these government-theoretic accounts is that they give no genuine explanation as to why P-stranding is possible in English and Scandinavian languages, while it is impossible in Romance, even though they are all VO languages, a problem also acknowledged in Bayer's (1996: 93, n. 7) account of P-stranding based on the canonical direction of government. In the English examples in (1a) and (2a), repeated in (54), the gap is linked to its antecedent by a connected g-projection:

(54) a. Which book$_i$ have they [$_{VP}$ talked [$_{PP}$ about t_i]]?
b. That book$_i$ has been [$_{VP}$ talked [$_{PP}$ about t_i]].

In the French counterparts of the examples in (54), given in (55), the gap is also linked to its antecedent by a connected g-projection:

(55) a. *Quel livre$_i$ as-tu [$_{VP}$ parlé [$_{PP}$ de t_i]]? French
which book have-you talked about
'Which book have you talked about?'
b. *Ce livre$_i$ a été [$_{VP}$ parlé [$_{PP}$ de t_i]]?
this book have been talked about
'This book has been talked about.'

But the problem remains as so why there should be a sharp grammatical difference between (54) and (55) with respect to P-stranding. Bennis and Hoekstra (1984: 35, 41) note this problem, but simply say that whether or not a specific category is a structural governor appears to some extent to be a language particular matter. This is at best a restatement of the facts.

There is also a conceptual problem with the formulation of canonical government in (52). It is not defined in terms of government, so a category may in principle be a canonical governor without being a governor, or vice versa. This problem is a technical one, and can easily be rectified with no serious consequences for the Gap Condition. A more significant conceptual problem is the notion of canonical government. To the extent that it has no bearing on other facts, it remains to be seen whether the notion of canonical government is warranted.

5 P-stranding and syntactic D-to-P-incorporation

It is a noticeable fact about Romance and German that P sometimes coalesces with the following D into a suppletive form, as illustrated in (56–58):[10]

(56) a. Jean a parlé du sujet le plus difficile. French
has talked about-the subject the most difficult
'John talked about the most difficult subject.'
b. Suppletive forms:
au=à le, aux=à les, 'to the'; auquel=à lequel, auxquels=à lesquels 'to the which'
du=de le, des=de les 'of the'; duquel=de lequel, desquels=de lesquels 'of the which'

(57) a. Gianni ha parlato del soggetto più difficile. Italian
has talked about-the subject most difficult
'Gianni talked about the most difficult subject.'
b. Suppletive forms:
al=a il, alla=a la, alle=a le, allo=a lo 'to the';
coi=con i, cogli=con gli, col=con il, colla=con la, colle=con le, collo=con lo 'with the';
dal=da il, dalla=da la, dalle=dal le, dallo=da lo 'from the';
dei=di i, degli=di gli, del=di il, della=di la, delle=di le, dello=di lo 'of the';
nei=in i, negli=in gli, nel=in il, nella=in la, nelle=in le, nello=in lo 'in the';
sul=su il, sulla=su la, sulle=su le, sullo=su lo 'on the'

(58) a. Hans war am Schalter. German
was at-the counter
'Hans was by the counter.'
b. Im Hause war keiner da.
in-the house was nobody there
'Nobody was there in the house.'
c. Suppletive forms:
am=an dem 'at/by the.MASC/NEUTER.DAT'; ans=an das 'at/by the.NEUTER.ACC';
aufs=auf das 'on the.NEUTER.ACC'; auf'n=auf den 'on the.ACC';
auf'm=auf dem 'on the.DAT'; aus'm=aus dem 'out of the.DAT';
beim=bei dem 'at the.DAT'; durchs=durch das 'through the.NEUTER.ACC';
durch'n=durch den 'through the.MASC.ACC';
für'n=für den 'for the.MASC.ACC'; fürs=für das 'for the.NEUTER.ACC';
im=in dem 'in the.DAT', ins=in das 'in the.NEUTER.ACC';
mit'm=mit einem/dem 'with a/the.DAT'; seit'm=seit dem 'since the.DAT';
übers=über das 'about the.NEUTER.ACC';
vom=von dem 'from the.DAT'; vorm=vor dem 'before the.DAT';
zu der=zur 'to the.FEM.DAT'; zum=zu dem 'to the.MASC/NEUTER.DAT'.

Intuitively, a suppletive form may be taken to indicate that two elements the suppletive form represents are no longer separable. Moreover, as P-stranding is

the result of moving the DP object of the P, the lack of P-stranding may be considered to be a consequence of P not being separable from the following D. What we need is some theoretical rationale for this intuition. But the conceptual approach should be clear. Given the independent property of having suppletive forms for the sequence P+D that Romance and Germanic share, it is natural to bring it to bear on the lack of P-stranding in these languages.

5.1 A syntax–morphology-interface condition on P-stranding

Suppose the mapping between syntax and morphology is subject to the syntax–morphology-interface condition in (59) (cf. Law 1998; Van Riemsdijk 1998b):

(59) **Syntactic constraint on suppletion:**
Elements that undergo suppletive rules must form a syntactic unit X^0.

From this perspective, then, the suppletion facts in (56–58) can be taken to be evidence that D incorporates into P in overt syntax, resulting in the configuration in (60), so that the P+D as a syntactic unit X^0 may undergo a suppletive rule:

(60) $[_{PP}\ [P^0{+}D^0_i\ [_{DP}\ [t_i\ [_{NP}\ [N^0]]]]]]$

It is now easy to see why D+NP may not be extracted in the structure in (60). Here, the incorporated D and the following NP (or DP) do not form a syntactic constituent. Consequently, P cannot be stranded by moving D+NP (or D+DP) (cf. Schwartz 1972 on constraints against moving non-constituents).

Notice that the condition in (59) does not require that elements forming a syntactic X^0 necessarily undergo suppletion. Thus, a verb with agreement and tense morphologies need not have suppletive forms, even though they sometimes do.[11] So there is no requirement that a suppletive form exist whenever D incorporates into P. Unless there is evidence to the contrary (cf. section 6), the null hypothesis is that all Ds incorporate into Ps in Romance and Germanic except English.[12]

Further facts about P-complementizers in Romance support the claim that suppletion rules may apply only to elements forming a syntactic X^0. As shown in (61), the French P-complementizers *de* and *à* (Huot 1977) do not coalesce with the following clitic pronoun *le* (homophonous with the determiner *le*), in contrast with the Ps in PPs:

(61) a. Je lui ai demandé [de le/*du lire]. French
I him have asked to it/to-it read
'I asked him to read it.'
b. Nous sommes prêts [à le/*au faire].
we are ready to it/to-it do
'We are ready to do it.'

From the perspective of the constraint in (59), the impossible suppletions in (61) have a very simple explanation: the object pronominal clitics and the P-complementizers do not form an X^0. The positioning of the clitics shows that this is correct.

In finite clauses, an object pronominal clitic occurs between the subject and the finite verb, i.e., below [Spec, IP]:

(62) a. Jean le lit. French
John it read
'John is reading it.'
b. *le Jean lit.
c. $[_{IP}$ Jean [le lit]].

Hence, there is little reason to think that in infinitivals the object pronominal clitic appears in a position higher than [Spec, IP]. If this is correct, then the object clitic, occurring below [Spec, IP], would not be in a position to incorporate into the P-complementizer to form a syntactic X^0 with it:[13]

(63) a. . . . $[_{CP}$ de $[_{IP}$ [le lire . . .
b. . . . $[_{CP}$ à $[_{IP}$ [le faire . . .

So the suppletive forms *du* and *au* cannot arise since they do not meet the required syntactic condition for suppletion in (59).

If P-stranding correlates with (the lack of) D-to-P incorporation, then we should expect that P may be stranded when D does not incorporate into P, regardless of whether the complement of P is extracted under A-bar-movement, as we have been discussing so far, or under A-movement (prepositional passive, henceforth P-passive). As we will see, the prediction is largely borne out, subject to independent constraints on A-movement.

5.2 Lack of P-stranding in Romance

If noun phrases are projections of Ds, then *wh*-items like *que* 'what' *qui* 'who' and *quel* 'which' in French or *che* 'what' *cui* 'who' and *qual* 'which' in Italian are plausibly Ds. French *que* 'what' and *qui* 'who' as well as Itatian *che* 'what' *cui* 'who' may appear by themselves:

(64) a. Que vois-tu? French
what see-you
'What do you see?'
b. Qui vient?
who come
'Who is coming?'

(65) a. Che vedi? Italian
what see.2SG
'What do you see?'

b. Chi viene?
who come
'Who is coming?'

Given that noun phrases are projections of Ds, the sole appearance of *que* 'what', *qui* 'who', *che* 'what', and *cui* 'who' implies that they must be Ds. Furthermore, as the determiner is almost always obligatory in noun phrases in Romance, the fact that a determiner does not appear (in fact, it may not) when French *quel* 'which' or Italian *qual* 'which' appears shows that *quel* and *qual* are probably Ds:

(66) a. Quel livre as-tu lu? French
which book have-you read
'Which book did you read?'
b. Quale piazza visitiamo? Italian
which square visit.1PL
'Which square are we visiting?'

French *quel* and Italian *qual* also inflect for number, just like the determiners, showing further that they are probably of the same category:[14]

(67) a. Quels/*quel enfants as-tu vu? French
which.PL/*which.SG children have-you seen
'Which children did you see?'
b. Quali/*quale monumenti visitiamo? Italian
which.PL/*which.SG monuments visit.1PL
'Which momuments are we visiting?'

If other Ds incorporate into Ps as the suppletion facts in (56–57) show, then there is no reason why the same does not hold of *que*, *qui*, *quel*, *che*, *cui*, or *qual* 'which' when they are complements to a P.

We can now understand why P-stranding under A-bar-movement of the sort in (68) is impossible:

(68) a. *Quel sujet$_i$ as-tu parlé de t_i? French
which subject have-you talked about
'Which subject did you talk about?'
b. . . . [$_{PP}$ [[de+quel$_i$] [$_{DP}$ t_i [$_{NP}$ sujet]]]]
c. Qui a parlé duquel sujet?
who have talked about-the subject
'Who talked about which subject?'
d. Duquel sujet$_i$ as-tu parlé
about-which subject have-you talked
'About which subject did you talk?'

In the structure in (68b), the head D *quel* incorporates into the P *de*, most evident in (68c) and (68d) with the suppletive form *duquel*, and hence can no longer

A-bar-move with its NP-complement, the two no longer forming a syntactic constituent. The same argument applies to cases of A-movement. As is well known, Romance is unlike English in not having P-passive, as shown in (69):

(69) a. *Le sujet a été parlé de. French
the subject have been talked about
'The subject was talked about.'
b. . . . [$_{PP}$ [[de+le$_i$] [$_{DP}$ t_i [$_{NP}$ sujet]]]]
c. Ils ont parlé du sujet.
they have talked about-the subject
'They talked about the subject.'

The ungrammaticality of the example in (69a) has exactly the same explanation. The determiner *le* incorporates into the P *de*, most evident in (69c), and hence cannot move with P as a syntactic unit to derive the example in (69a), the two no longer forming a syntactic constituent. It thus seems that relating D-to-P incorporation, as evidenced independently in the suppletive forms, we can explain in a principled way why Romance languages generally do not allow P-stranding.

5.3 P-stranding under A-bar-movement in German and Dutch

For German and Dutch, the lack of P-stranding under A-bar-movement has the same account as that for Romance. Like French *que* and *qui* and Italian *che* and *chi*, German *wer* and *was* 'what' and Dutch *wie* and *wat* may occur by themselves. On the assumption that noun phrases are headed by Ds, it must be the case that *wer* and *was* in German and *wie* and *wat* in Dutch in *wh*-phrases containing them as the sole constituent are of the category D (the example in (71a) sounds more natural with *er* 'there' in the end, a point irrelevant here):

(70) a. Wer kommt? German
who comes
'Who is coming?'
b. Was hast du gekauft?
what have you bought
'What did you buy?'

(71) a. Wie komt? Dutch
who comes
'Who is coming?'
b. Wat heb je gekocht?
what have you bought
'What did you buy?'

Moreover, as German *welche* 'which' and Dutch *welke* 'which' inflect for gender, number, and, in German, for Case as well (just like the determiner), they are plausibly of the category D (cf. n. 14):

(72) a. Ich habe dem/*den Mann geholfen. German
I have the.DAT/the.ACC man helped
'I helped the man.'
b. Welchem/*welchen Mann hast du geholfen?
which.DAT/which.ACC man have you helped
'Which man have you helped?'

(73) a. Welk/*welke boek heb je gelezen Dutch
which book have you read
'Which book did you read?'
b. Welke/*welk film heb je gezien?
which film have you seen
'Which film did you see?'

So if other Ds incorporate into P as the suppletion facts in (57) show, then there is no reason why the same does not apply to *wer*, *was*, *welche* or *wie wat*, and *welke* when they are complements to a P. We can now understand why P may not be stranded under A-bar-movement. In the example in (74a), the D *welchem* incorporates into the P, as shown in the structure in (74b); it therefore cannot move with its NP complement, since the two do not form a syntactic constituent:

(74) a. *Welchem Kerl hast du mit gerechnet? German
which guy have you with counted
'Which guy have you counted on?'
b. . . . [$_{PP}$ [[mit+welchem$_i$] [$_{DP}$ [t_i Kerl]]]] . . .

What we need to explain is why P-stranding, albeit limited, is sometimes possible with R-pronouns, as shown in the example in (6), repeated in (75):[15]

(75) a. Wo$_i$/*Was$_i$ redest du von t_i? German
what talk you.NOM from
'What are you talking about?'
b. Waar$_i$/*Wat$_i$ heb je op t_i gerekend? Dutch
what have you on counted
'What have you counted on?'

The obvious difference between *wo* and *was* and between *waar* and *wat* is that *wo* or *waar* must appear to the left of the P taking it as argument, while *was* and *wat* must occur to its right.

If we take R-pronouns appearing to the left of P to be in [Spec, PP] (cf. Van Riemsdijk 1978a and Corver 1990), from where it cannot incorporate into P (cf.

Travis's 1984 Head Movement Constraint), it then follows immediately that they may move out of PP, stranding P:[16]

(76) a. Wo$_i$ hast du [$_{PP}$ t_i [mit]] gerechnet? German
what have you with counted
'What have you counted on?'
b. Waar$_i$ heb je [$_{PP}$ t_i [op]] gerekend? Dutch
what have you on counted
'What have you counted on?'

Examples like those in (77) independently show that Dutch R-pronouns are not incorporated into P. Here, an R-pronoun is separated by an adverbial from the P taking it as argument (cf. Van Riemsdijk 1978a: 87) as in (77a),[17] and it may move together with both the adverb and the P as in (77b), or by itself, stranding P, as in (77c) and (77d):[18]

(77) a. Vlak er achter vs. er vlak achter. Dutch
right it after
'right after it'
b. [$_{PP}$ er vlak achter]$_i$ geloof ik dat Jan toen t_i stond.
it right after believe I that then stood
'I believe that Jan then stood right behind it.'
c. Ik geloof dat Jan er$_i$ toen [$_{PP}$ t_i vlak achter] stond.
d. Waar$_i$ denk je dat Jan [$_{PP}$ t_i vlak achter] stond?
where think you that Jan right after stood
'Where do you think that Jan stood right behind?'

Exactly the same account can be given to cases like (26), repeated in (78), where P is stranded as a result of extracting a non-R-pronoun:

(78) a. Welke boom$_k$ klom Jan [$_{PP}$ t_k in]? Dutch
which tree climbed Jan into
'Which tree did Jan climb into?'
b. Ik geloof dat Jan de boom$_k$ gisteren [$_{PP}$ t_k in] t_i is geklommen$_i$.
I think that Jan the tree yesterday in is climbed
'I think that Jan climbed into the tree yesterday.'
c. Welke boom$_k$ zei je dat hij [$_{PP}$ t_k in] t_i is geklommen$_i$?
which tree say you that he in is climbed
'Which tree did you say that he climbed into?'

Since the D head of the DP complement of the P *in* 'in' does not incorporate into P, as evidenced independently in (79) where it clearly is in [Spec, PP]:

(79) a. Hij klom [$_{PP}$ de boom in]. Dutch
he climbed the tree in
'He climbed into the tree.'

b. Wie klom [$_{PP}$ welke boom in]?
who climbed which tree in
'Who climbed into which tree?'

The DP complement of P can then be extracted from [Spec, PP], stranding P. The lack of P-stranding under A-bar-movement in German and Dutch thus has exactly the same account as that for Romance, P being no longer separable from D as a result of D incorporating into P. In the few cases where P-stranding is possible, it is due to the head D of the DP complement of P not incorporating into P.

5.4 P-stranding under A-movement in Germanic

If the lack of P-stranding correlates with D-to-P incorporation, then we would expect P-stranding to be possible precisely when D does not incorporate into P. We saw in the last section that the expectation is largely borne out under A-bar-movement. The question that naturally arises is whether we can reasonably expect that P-stranding under A-movement is also possible when D does not incorporate into P. The null hypothesis is that it should be, but there is a complication; as we will see presently, some general conditions may exclude A-movement. Thus, cases where P may not be stranded under A-movement may turn out to fall under the same conditions.

As we discussed in section 5.2, when D incorporates into P, the object of the P may not extract, stranding P. The ungrammaticality of the example in (80b) is thus just as expected, if D incorporates into P as in (80c):

(80) a. Es wurde völlig mit dem Kerl gerechnet. German
it became fully with the guy counted
'The guy have been fully counted on.'
b *Dem Kerl$_i$ wurde völlig mit t_i gerechnet.
the.dat guy became fully with counted
'The guy has been fully counted on.'
c. . . . [$_{PP}$ [[in+dem$_i$] [$_{DP}$ t_i Kerl]]]

As R-pronouns do not incorporate into P, they may move out of PP and thereby strand P. In this light, the facts in (81) are unsurprising:

(81) a. Es wurde völlig [$_{PP}$ da [mit]] gerechnet. German
it became fully it on counted
'It has been fully counted on.'
b. Es wurde da$_i$ völlig [$_{PP}$ t_i [mit]] gerechnet.
c. Da$_i$ wurde völlig [$_{PP}$ t_i [mit]] gerechnet.

The examples in (81) evidently do not involve movement of a *wh*-phrase, typical of A-bar-movement. One might thus be lead to suppose that movement of the

sort in (80b) and (81b) are instances of A-movement. However, for virtually all analyses of verb-second root clauses, a non-subject appearing before the verb in second position is in [Spec, CP], an A-bar position on standard assumptions (Travis 1984; Haider and Prinzhorn 1986). If this is correct there might not be any structure resulting from P-stranding under A-movement in Germanic languages other than English at all. As it turns out, English systematically differs from other Germanic languages with respect to Case and agreement in a class of constructions including the impersonal passive construction with an overt expletive. As we will see presently, in English, when the participle carries passive morphology, the logical object, which otherwise receives accusative case, generally appears in subject position with nominative Case and agrees with the finite verb in number and person. This is not necessarily so in other Germanic languages. Since P-stranding under A-movement involves passive, we may naturally wonder whether the difference between English and other Germanic languages with respect to Case and agreement in passive bears on P-passive, the result of stranding P under A-movement.

As is familiar since Aoun (1979) and Chomsky (1981), the passive morpheme on the passive participle (mostly *-ed* or *-en* in English) is commonly taken to absorb accusative Case for the object, which then has to move to a Case position, e.g., the subject position of a finite verb, where it may be assigned (or check) nominative Case:

(82) a. John and Mary$_i$ were/*was killed t_i.
b. *It/there were/was killed John and Mary.

If the object of a verb with passive morphology does not move, as in (82b), then the structure would be excluded by the Case Filter (Rouveret and Vergnaud 1980), barring overt noun phrases without Case. A distinct feature of the passive construction is that the finite verb agrees in number with the (logical) object in subject position, as shown in the contrast in (82a). The same agreement fact holds of German passives as well:[19]

(83) . . . , dass Hans und Maria getötet wurden/*wurde. German
that Hans and Maria killed became.PL/*became.SG
'. . . , that Hans and Maria were killed.'

However, there is a class of examples in which the apparent subject systematically does not agree with the finite verb. With verbs assigning non-accusative Case to the object, the finite verb in the passive shows no agreement with the (logical) object appearing in a preverbal position, as illustrated by the examples in (84) for Icelandic (Levin and Simpson 1981) and German in (85):

(84) a. Þeim var hjálpað. Icelandic
them.DAT was helped
'They were helped.'

b. Mig þyrstir.
me.ACC thirsts
'I am thirsty.'

(85) a. Ihnen wurde/*wurden geholfen. German
them.DAT became.SG/became.PL helped
'They have been helped.'
b. Mir ist kalt.
me.DAT is cold
'I'm cold.'

Agreement with the finite verb in the example in (81) turns out to pattern like that in (86). The German pronoun *da* may have a plural antecedent (cf. *einer davon* 'one of them'), and yet it may not agree with a finite verb, as shown in (86a).[20] In the Icelandic example in (86b), the (logical) object of a P assigning accusative Case appears before the finite verb, but it does not agree with it:

(86) a. Da$_i$ wurde/*wurden völlig [$_{PP}$ t_i mit] gerechnet. German
they became.SG/became.PL fully with counted
'They are counted on.'
b. Krakkana$_i$ er/*eru oftast talað vel [$_{PP}$ um t_i] Icelandic
the kids.ACC is/are usually spoken well of
'The kids are usually well spoken of.'

With respect to agreement, then, English differs from other Germanic languages in that the (logical) object (of V or of P) agrees with the finite verb when it appears preverbally in passive:

(87) a. The carpet$_i$ has/*have been stepped [$_{PP}$ on t_i].
b. The carpets$_i$ have/*has been stepped [$_{PP}$ on t_i].
c. The carpet$_i$ has/*have been sold t_i.
d. The carpets$_i$ have/*has been sold t_i.

We will later see the significance of the agreement facts, but for now let us see whether we should consider P-stranding of the sort in (84–85) on a par with P-stranding under A-bar-movement (cf. section 5.3).

Maling and Zaenen (1985) argue that Icelandic examples comparable to those in (84a) are not genuine P-passives but involve topicalization of the object of the P, i.e., *wh*-movement. They give the Icelandic examples in (88) as evidence that the fronted objects of Ps are not in subject position, since they retain the Case assigned to them in-situ:[21]

(88) a. Þessa kona$_i$ er oftast talað vel [$_{PP}$ um t_i]. Icelandic
that woman.ACC is usually spoken well of
'The woman is usually spoken well of.'

b. Þennan ref$_i$ hefur aldrei verið skotið [$_{PP}$ á t_i].
that fox.ACC has never been shot at
'That fox has never been shot at.'

Furthermore, the extracted objects of the stranded Ps exhibit no subject properties like undergoing raising, binding of a reflexive, and being subject to locality for topicalization. The dative object of a verb may appear preverbally in a complement of an ECM verb, but the object of a stranded P may not do so:[22]

(89) a. Ég tel honum hafa verið hjálpað í prófinu. Icelandic
I believe him.DAT to-have been helped in the-exam
'I believe him to have been helped in the exam.'
b. *Ég tel Vigdísi vera oftast talað vel um.
I believe Vigdis to-be most-often spoken well of
'I believe Vigdis to be most often well spoken of.'

The dative object of a verb appearing preverbally may bind a reflexive, but the object of a stranded P may not:

(90) a. Honum var oft hjálpað af foreldrum sínum/*hans.
him.DAT was often helped by parents his[+refl]/*[–refl]
'He was often helped by his parents.'
b. Hana er talað vel um í hennar eigin landu/í landi ?*sínu.
she.ACC is spoken well of in her own land/in land her[+refl]
'She is well spoken of in her own land.'

Many speakers allow topicalization in embedded *að* 'that'-clauses but not in binding domains like indirect questions, comparatives, and relatives, i.e., syntactic islands. They crucially distinguish objects of verbs and objects of Ps:

(91) a. Hann spurði, hvenær henni hefði verið hjálpað.
he.NOM asked when she.DAT had been helped
'He asked when she had been helped.'
b. *Hann spurði, hvort Vigdísi væri talað vel um.
he.NOM asked whether Vigdis was spoken well of
'He asked whether Vigdis was well spoken of.'

Maling and Zaenen thus conclude that P-stranding is not a unified phenomenon, and suggest that P-passive is possible only when there is some independent lexical process reanalyzing V and P, which turns the object of P into the direct object of the reanalyzed V+P. The difference between English and Icelandic with respect to P-passive is that English has a rule of lexical reanalysis but Icelandic does not.

They argue that prenominal modifiers of the sort in (92) constitute independent evidence for a reanalysis rule in English, and the lack thereof in Icelandic as

in (93) and (94) shows that V cannot be reanalyzed with P, even though the language allows prenominal modifiers that are related to verbs:

(92) a. a much talked about subject
b. an often alluded to problem
c. a well spoken of young lady

(93) a. **Þettaer [vel töluð um] kona. Icelandic
'This is a well spoken of woman.'
b. *þettaer [vel umtöluð] kona.

(94) a. Nýfallinn snjór.
'new snow'
b. Sokkna skipið.
'the sunken ship'
c. Mikið lesin bók.
'a much read book'

The grammatical contrasts in (92–94), and, by the same token, those in (89–91) as well, certainly call for an explanation, but it is not quite clear whether they are due to the lack of a lexical rule reanalyzing V and P in Icelandic.

In fact, if P-stranding is possible only if P is reanalyzed with V,[23] then it must be that P is reanalyzed with V in cases like (95) (Maling and Zaenen 1985: 199):

(95) Hann spurði hvern ég hefði talað við. Icelandic
he asked whom I had talked to
'He asked whom I had talked to.'

We can surely distinguish the example in (95), a result of A-bar-movement, from those in (89b) and (91b), results of A-movement, and argue as Maling and Zaenen do that the grammatical examples in (86b), (88), and (90b) are the results of A-bar-movement. What this amounts to is that P-stranding under A-movement, i.e., P-passive, requires lexical reanalysis of V and P, but P-stranding under A-bar-movement does not. Maling and Zaenen (1985: 205) attribute the requirement to the assumption that only arguments bearing the grammatical function OBJ may passivize (Zaenen and Maling 1983). Thus, unless it comes to bear the grammatical function OBJ, object of P cannot passivize, i.e., P may not be stranded under A-movement. The requirement does not hold of arguments undergoing A-bar-movement, since syntactic binding, i.e., *wh*-movement, is not restricted to arguments bearing the grammatical function OBJ.

There are three major problems with this account, however. First, there is little, if any, independent morphological evidence for P being reanalyzed with V. Morphologically, the participial suffix *-ed* occurs on V regardless of whether it is reanalyzed with P. If V is reanalyzed with P, we could reasonably expect the participial morphology to appear on the whole reanalyzed unit (e.g., [*talk about*]-*ed*).

The fact that it does not shows that there is no morphological evidence for P being reanalyzed with V. Second, there is no independent motivation for assuming that object of P may bear the OBJ grammatical function. Third, the assumption that the process of lexical reanalysis may vary from language to language is at best a restatement of the cross-linguistic variations with respect to P-passive, if the process is not shown to be related to any other processes or principles of grammar.

Questions of this kind would cease to arise if there is in fact no condition on P-stranding specific to A-movement, and the more limited possibilities of P-stranding in structures without *wh*-movement are in fact related to independent properties. I would like to suggest that the possibility of stranding P under A-movement, as observed for English, is related to Case.

The standard assumption about agreement with a finite verb is that the verb is in I^0 and the argument agreeing with it in [Spec, IP]. Along these lines, then, what the lack of agreement in (84–85) – examples without P-stranding – and in (86) – examples with P-stranding – suggests is that the preverbal argument in all these cases is not in [Spec, IP]. These examples are thus in sharp contrast with the English example in (87) where the preverbal argument appears in [Spec, IP] and agrees with the finite verb. There are two related questions that we need to address. First, why should it be that the preverbal argument in German and Icelandic is not in [Spec, IP]? Second, why should it be that the preverbal argument in English is in [Spec, IP]? These two questions lead to a third, more general, question: is there some other difference between English and other Germanic languages that bears on the anwers to the first two questions? Before considering these questions, let us note that these issues are quite independent of P-stranding; the same questions arise for the examples in (84–85) and (87c) where there is no P-stranding.

I would like to first discuss some facts related to the third, more general question, as the answers to the first two questions hinge on it. As it turns out, Germanic languages exhibit a sharp division with respect to the impersonal passive construction. All Germanic languages have it, except English (Vikner 1995: 209):

(96) a. . . . daß *pro* getanzt worden ist. German
that danced became is
'. . . that there was dancing.'
b. . . . að Það hefur verið dansað. Icelandic
that there has been danced
'. . . that there was dancing.'
c. . . . at der er blevet danset. Danish
that it there became danced
'. . . that there was dancing.'
d. *. . . that there/it has been danced.

The issue that arises for the grammatical contrast in (96) is why it is that English does not allow the impersonal passive construction, while all other

Germanic languages do. Moreover, as the same sharp division, all Germanic languages on the one hand and English on the other, also holds of agreement with a preverbal argument (as discussed above), it seems quite natural to relate these two differences.

The (abstract) passive morpheme is commonly taken to absorb Case, which explains why the object of a passivized verb in English must move to a Case position. As for German, and by extension all other Germanic languages as well, the accusative Case for the object seems to be absorbed by the passive morpheme, as evidenced in (83), where the object is in subject position where it is assigned (or checks) nominative Case and agrees with the finite verb; but the passive morpheme in these other Germanic languages need not absorb any Case if the verb itself does not assign accusative Case to the object, as in (84) and (85). Suppose the Case-absorption property of the passive morpheme varies from language to language (Baker 1988a: 345ff., refining the Case-theoretic accounts of NP movement by Chomsky 1980a and Jaeggli 1982) in that it must absorb accusative Case in some languages, e.g., English, but it does not necessarily do so in some others, e.g., other Germanic languages. Specifically, the passive morpheme must absorb the accusative Case of the verb, if there is any, but particular languages may vary, as a parametric choice, as to whether the passive morpheme must absorb Case at all. It must in English, but need not do so in other Germanic languages, which explains why a verb assigning no accusative Case in these latter languages may bear passive morphology, but not in English.

The variations with respect to impersonal passives can now be related to the Case-absorption property of the passive morpheme. Thus, the example in (96d) is excluded since the passive morpheme in English must absorb Case, and there is none for it to absorb. In the examples in (87c) and (87d), the passive morpheme absorbs the accusative Case for the object, the object must therefore move to [Spec, IP] of a finite clause where nominative Case is assigned (or checked), and where it agrees with the finite verb. This answers the second question above. By contrast, the impersonal passive construction in (96a–c) is possible in Germanic languages other than English, since the passive morpheme in these languages need not absorb Case. The same account can be given to explain why in the examples in (84) in Icelandic and those in (85) in German the object retains its (non-accusative) Case.[24] As movement to [Spec, IP] is motivated by Case, the object with Case cannot move to [Spec, IP], explaining why the preverbal object in (84) and (85) does not agree with the finite verb.[25] This answers the first question above. Thus, the answer to the third, more general, question is that P-stranding under A-movement is related to the Case absorption property of the passive morphology, which manifests itself independently in the impersonal passive construction. If a language allows the impersonal construction, i.e., the passive morpheme need not absorb Case, then it will not allow an object with Case to move to [Spec, IP], there being no motivation for movement to [Spec, IP] for Case. P-stranding under A-movement in these languages is therefore only apparent, P being stranded not by A-movement of the object of P to [Spec, IP], a Case position, but by A-bar-movement to a non-Case position.

It bears pointing out that since there is very little, if at all, Case and agreement morphology in Swedish, Danish, and Norwegian. Therefore, there are no Case and agreement facts showing that the apparent P-passive is the the result of P-stranding under A-movement. Nevertheless, as these languages allow the impersonal passive construction, just like Icelandic, it thus seems reasonable to conclude that the passive morphology in these languages has the same Case absorption property as that in Icelandic, namely, it does not necessarily absorb Case. This is what makes the impersonal passive construction possible.

Now, if the English passive morpheme must absorb Case, then one might wonder how it absorbs Case in P-passive. In an example like that in (97a), the object *the carpet* of the P *on* plausibly receives Case from the P, and it is not obvious that the verb *step* has any Case feature:

(97) a. They stepped on the carpet.
b. The carpet$_i$ has been stepped on t_i

If this is correct, then how would the Case absorption property of the passive morpheme in English be satisfied in (97b), repeated from (87a)?

Law (1998) suggests that in P-passive the Case feature of P, which is otherwise checked by its argument, moves to the verb on which the passive morpheme appears (cf. Move-F, Chomsky 1995c: 261–271), so as to satisfy the Case absorption property of the passive morpheme. As a result, the object of the P must move to the subject position where it is assigned nominative Case, and agrees with the finite verb, just like other cases of passive. On this view, the example in (97b) would have the derivation as in (98):

(98) The carpet$_i$ has been stepped [$_{pp}$ on t_i]
[Case] ←┘

If the Case feature of P must move to the participle, then we would expect it to be subject to constraints on movement. The expectation is borne out. In the example in (33b), repeated in (99a), an adverb intervenes between V and P, an indication that the PP is in an adjoined position:

(99) a. *The carpet$_j$ was stepped t_i repeatedly [on t_j]$_i$.
[Case] ←┘
b. ?*Which carpet$_j$ did they step t_i repeatedly [on t_j]$_i$?

P may not be stranded in (99a), since movement of the object of P to subject position as well as movement of the Case feature of P to the participle violate Huang's CED barring extraction out of adjuncts. It is noteworthy that the example in (99b) is slightly better than that in (99a), perhaps due to there being only one CED violation by the extraction of the *wh*-phrase. As the passive morpheme need not absorb Case in other Germanic languages, the Case feature of the P does not move to the verb that carries the passive morpheme, accounting for why the

object of the P retains the Case assigned to it by the P, and why it cannot move to [Spec, IP], a Case position.[26] In this way, with the parametric choice of Case absorption, we can relate the retention of non-accusative Case and the impersonal passive construction with an overt expletive.

6 Some remaining problems and issues

The foregoing discussion emcompasses only facts in some standard varieties of Romance and Germanic languages. The question that naturally arises is whether the analysis can be extended to other varieties. I would like to discuss two cases that appear to raise some problems for the D-to-P incorporation analysis of P-stranding. The first case concerns the lack of D-to-P incorporation, as observed in cases where an adverb intervenes between P and D, in syntactic environments where movement is possible in principle. The second case concerns D-to-P incorporation, as manifested in the D+P suppletive forms, in syntactic environments where movement is generally impossible.

6.1 Lack of D-to-P incorporation

An apparent problem for the D-to-P-incorporation analysis of P-stranding is the impossible D-to-P incorporation in examples like (100–110) across all German dialects (Van Riemsdijk 1998b: 662–663):

(100) a. von genau dem Gegenteil — German
from exactly the.DAT opposite
'from exactly the opposite'
b. *von dem genau Gegenteil
c. *vom genau Gegenteil

(101) a. zu knapp der Hälfte
to nearly the half
'to nearly half'
b. *zu der knapp Hälfte
c. *zur knapp Hälfte

Given that what follows P in (100–101) is a constituent, most clearly in verb-second main clauses, as shown in (102), the structures in (103a) and (103b) for (100a) and (100a), respectively, are perfectly reasonable:

(102) a. [Genau das Gegenteil] hat er gesagt. — German
exactly the.ACC opposite has he said
'He said the exact opposite.'
b. [Knapp die Hälfte] sind meine Freunde.
nearly the.NOM half be my friends
'Nearly half are my friends.'

(103) a. von [genau dem Gegenteil]
b. zu [knapp der Hälfte]

Conceptually, then, the problem is why D in (103) may not incorporate into P as in (104), the structures for (100b) and (101b):

(104) a. *von+dem$_i$ [genau t_i Gegenteil]
b. *zu+der$_i$ [knapp t_i Hälfte]

The impossibility of P-to-D incorporation in (104) would follow immediately if the complement of P in these cases is in fact headed by *genau* 'exactly' or *knapp* 'nearly', as movement of D to P would violate Travis's HMC. But there seems to be little independent evidence for the complement of P in (103) being headed by *genau* or *knapp*.[27] Van Riemsdijk (1998b: 654–656) suggests that contraction of P and D is a result of head adjunction of D to P. As an instance of head movement, it is subject to the head-adjacency principle in (105) (Van Riemsdijk 1998b: 644–645), particularly relevant to the D-to-P incorporation is the condition on head adjunction:

(105) **The Head Adjacency Principle** (HAP):
A transformational process that affects two head positions must be either Head Adjunction or Head Substitution.
Head Adjunction (HA):
Two phonetically identified heads are joined, yielding an adjunction structure, in which case the two heads must be strictly linearly adjacent at the moment of application of the rule.

Thus, the reason why D cannot move to P in (104) is that the two are not adjacent, there being an element intervening between them.

As it turns out, there seems to be some constraint in German barring stranding a left-modifier independently of P-stranding. As shown in (106), the R-pronoun *da* may move to [Spec, PP] or to a still higher position (cf. section 5.3). But it may not do so when a left-modifier like the adverbial *genau* 'exactly' is stranded as shown in (107) (the surface forms of the examples in (107b) and (107c) are good with the adverbial *genau* 'exactly' modifying the verb, i.e., it is not part of the PP headed by *von* 'of'. Cf. the discussion of the examples in (109–110) below):

(106) a. Hans hat [da$_i$ [von t_i]] geredet.
Hans has it of talked
'Hans talked of it.'
b. Da$_i$ hat Hans [t_i [von t_i]] geredet.

(107) a. Hans hat [von [genau diesem Thema]] geredet.
Hans has of exactly this topic talked
'Hans talked of exactly this topic.'

b. *Hans hat [da$_i$ [von [genau t_i]]] geredet.
Hans has it of exactly talked
c. *Da$_i$ hat Hans [t_i [von [genau t_i]]] geredet.

Notice that there is nothing wrong, semantically, with the adverbial *genau* appearing with the R-pronoun *da*; the position of the adverbial is crucial:

(108) a. Hans hat [genau [von [diesem Thema]]] geredet.
Hans has exactly of this topic talked
'Hans talked of exactly this topic.'
b. Hans hat [genau [da$_i$ [von t_i]]] geredet.
Hans has exactly it of talked
'Hans talked of exactly it.'
c. Da$_i$ hat Hans [genau [t_i [von t_i]]] geredet.
d. [genau [da$_i$ [von t_i]]] hat Hans geredet.

There is a complication with *genau*, however. As it may modify the verb, it is not straightforward to construct examples where it unambiguously modifies the verb or the DP that superfically follows it:

(109) a. Hans hat genau erklärt, wer dafür zuständig ist.
Hans has exactly said, who it-for responsible is
'Hans said exactly who is responsible for it.'
b. Die Details hat Hans nicht genau präzisiert.
the details has Hans not exactly specified
'Hans did not exactly specify the details.'

That is, there are alternative structures for the same surface forms of the examples in (108a–c) where *genau* is not part of the PP, but modifies the verb:

(110) a. Hans hat genau [von [diesem Thema]] geredet.
Hans has exactly of this topic talked
'Hans talked exactly of this topic.'
b. Hans hat genau [da$_i$ [von t_i]] geredet.
Hans has exactly it of talked
'Hans talked exactly of it.'
c. Da$_i$ hat Hans genau [t_i [von t_i]] geredet.

The modifier *all* 'all' is a better choice. Although it is like *genau* in that it is formally invariant and can precede a DP with different number, gender, and Case forms:

(111) a. [All der gute Wein] steht auf dem Regal.
all the.SG.NOM good.SG.NOM wine.SG stands on the shelf
'All the good wine is on the shelf.'

b. Auf dem Regal stehen [all die guten Weine]
on the shelf stand all the.PL.NOM good.PL.NOM wine.PL
'On the shelf is all the good wine.'
c. Hans hat [all den guten Wein] getrunken.
Hans has all the.SG.ACC good.SG.ACC wine.SG drunk
'Hans drank all the good wine.'
d. Hans hat [von all dem guten Wein] getrunken.
Hans has of all the.SG.DAT good.SG.DAT wine.SG drunk
'Hans drank from all the good wine.'

The modifier *all* differs from *genau* in not being able to modify a verb:

(112) a. Hans hat all sein Geld verloren.
Hans has all his money lost
'Hans lost all his money.'
b. *Hans hat all es verloren.
Hans has all it lost
'Hans lost it all.'
c. Die Politiker haben alle/*all gelogen.
the politicians have all/all lied
'The politicians have all lied.'

As shown in (113), the phrase left-modified by *all* may not be moved, leaving behind the modifier *all*:

(113) a. *[Die guten Weine] stehen [all t_i] auf dem Regal
the.PL.NOM good.PL.NOM wine.PL stand all on the shelf
'On the shelf is all the good wine.'
b. *[Den guten Wein]$_i$ hat Hans [all t_i] getrunken.
the.SG.ACC good.SG.ACC wine.SG has Hans all drunk
'Hans drank all the good wine.'

Suppose for some reason a modifier may not be left-adjoined to a category whose head is phonetically empty. The examples in (113) would then be straightforwardly excluded. So are those in (104) and (114):

(114) *von+dem [all [t_i guten Wein]]

In other words, the examples in (104) and (114) are ruled out not because P may not incorporate into D, but precisely because incorporation of D into P would give rise to structures in which a modifier is left-adjoined to a category whose head is devoid of phonetic content. This is exactly the reason why the examples in (113), which have no D-to-P incorporation, are excluded. What remains to be explained, however, is why D may have the option of not incorporating into P in (103).

There is some indication that there is a constraint that specifically bars stranding of a left-modifier. As shown in (115), a right-modifier may be stranded in German:[28]

(115) a. Hans hat [da$_i$ [von t_i [was uns übrigens auch interessiert]]]
Hans has it of what us by the way also interested
geredet.
talked
'Hans talked of it, which also interests us.'
b. [da$_i$ [von t_i [was uns übrigens auch interessiert]]] hat Hans geredet.

Notice that the examples in (115) have a non-restrictive relative clause made explicit by the expression *übrigens* 'by the way'; it is most plausibly adjoined to the DP-complement of P headed by the R-pronoun *da*. The examples in (113) show that the quantifier *all* is not part of the projection that moves leftward. The leftward movement of the R-pronoun in (115) essentially shows the same point. The bracketed phrase in (115) is thus structurally parallel to that in (113) in that the position of the relative clause in (115) is structurally comparable to that of the quantifier *all* in (113). The grammatical contrast between them shows that a left-modifier may not be stranded, while a right-modifier may. The ungrammaticality of the examples in (107b) and (107c), further instantiations of the structure in (104a), now follows since a left-modifier is stranded.

The HA clause of the HAP cannot explain why the examples in (107b) and (107c) are ungrammatical, since movement of the R-pronoun *da* is phrasal. The same also holds of the examples in (113). The constraint against stranding left-modifiers in German thus seems to have some empirical support, although it is conceptually unclear why there should be such a constraint.

The lack of D-to-P incorporation in Italian in cases like in (116) (Van Riemsdijk 1998b: 664) apparently raises a problem for the D-to-P analysis of P-stranding, as the explanation for the lack of P-to-D incorporation in German in cases like (100) and (101) cannot be carried over to Italian:[29]

(116) a. con tutta la famiglia. Italian
with whole.FEM the.FEM family.FEM
'with the whole family'
b. *con+la$_i$ [tutta [t_i famiglia]] (**colla=con la*)

As shown in (117), if the pronominal *la* 'her/it.FEM' orignates in the position to the right of the quantifier *tutta* 'all, whole' and then moves to the verb (Kayne 1975), then the resulting structure would be comparable to that in (116b), which are just like the structures in (113) in German (the combination *la ho* is phonologically [lo], orthographically *l'ho*):

(117) a. La$_i$ ho vista [tutta t_i] Italian
it.FEM have.1SG seen all
'I saw it all.'

b. Quale famiglia hai vista [tutta t_i]?
which family have.2sg seen all
'Which family have you seen all?'

The fact that the structures in (117) are possible, but those in (113) and (116b) are not calls for an explanation. To approach the solution to the problem in (116b), we need to find out what the category of the quantifier *tutta* is, what relationship it bears with the following DP, and what the head of the DP *tutta la famiglia* 'the whole family' is. These questions are largely independent from one another. Let us first discuss the issue of the category of the quantifier *tutta*.

The examples in (118) show that the quantifier *tutta* is plausibly of the category determiner; it may appear by itself, without being followed by a DP (Schwarze 1988: 29):

(118) a. Tutti sanno leggere. Italian
all can.3PL read
'All can read.'
b. Avete capito tutto?
have.2PL understand all
'Have you understood everything?'

Now, if arguments are DPs, it then follows that the quantifier *tutta* is a determiner.

Let us now turn to the issue of the internal structure of the DP consisting solely of the quantifier *tutta*. Although it is clear that the quantifier is the head, we may wonder whether it takes a null DP complement as represented in (119), or simply takes no complement, as in (120), i.e., the quantifier *tutta* is an intransitive determiner in this case:

(119) a. [$_{DP}$ tutti *pro*] sanno leggere. (=118a)
b. Avete capito [$_{DP}$ tutti *pro*]? (=118b)

(120) a. [$_{DP}$ tutti] sanno leggere. (=118a)
b. Avete capito [$_{DP}$ tutti]? (=118b)

The representation where the DP appears in subject position in (119a) is plausible, as Italian allows null subject *pro*. That in (119b) is much less so, since null object pronouns, in contrast with null subject pronoun, are restricted to having a plural, human antecedent in generic contexts (Rizzi 1986a). The context in the example in (119b) is clearly not generic, and the object need not have a human antecedent; it may refer to books. Hence, there cannot be an object *pro* in (118b). If this is correct, then the example in (118b) most naturally has the structure in (120b). (118a) can have the structure in (120a) as well.

If an appositive relative clause may appear as DP-adjunct, and a restrictive one as NP-adjunct (cf. Browning 1991; Law 1991b), then the fact that the quantifier

tutto may co-occur with an appositive, but not with a restrictive relative clause (Cinque 1995b: 479) shows that the quantifier *tutto* heads the DP, i.e., it is an intransitive determiner in this case:

(121) a. Ho preso tutto, che non era poi molto, e me
have.1SG take everything which not be that much and myself
ne sono andato, . . .
of-it am go
'I took everything, which was not that much, and I left.'
b. *Ho preso tutto che mi piaceva.
have.1SG take everything that me please
'I took everything I liked.'

The conclusion is further supported by facts about the French counterpart of *tutto*; French does not allow null arguments. As shown in (122), the quantifier *tout/toutes/tous* 'all' may appear without being followed by a DP (Grevisse 1986: 1157):

(122) a. On peut s'attendre à tout. French
one can expect to all
'One can expect everything.'
b. M. Gaston Deferre qui serre les mains de toutes et de
Mr. Gaston Deferre who shake the hands of everyone.FEM and of
tous.
everyone.MASC
'Mr. Gaston Deferre who shakes hands with everyone.'

Clearly, there is no reason to think that the DP consisting solely of the quantifier *tout/toutes/tous* 'all' takes a null pronoun as complement.

If the quantifier *tutta* in Italian and its counterpart in French are Ds, then we should expect them to be able to take an NP complement. The expectation is only partially borne out. French *tout/toute/tous/toutes* may take an NP complement, so may Italian *mezza* 'half', but *tutta* and *entrambi/ambidue/ambo/ambe* 'both' may not (Giorgi 1995: 300, Renzi 1995: 358):

(123) Toute personne; toutes les personnes; tous (les) deux. French
all person all the persons all the two
'All persons; all the people; both of them.'

(124) a. mezza (la) faccia Italian
half the face
'half (of) the face'
b. tutti *(i) ragazzi; tutta *(la) torta
all the boys all the tart
'all the boys; all the tart'

c. entrambi *(i/quei) bambini; ambo/ambe *(le) mani
both the/those children both the hand
'both children; both hands'

It is not clear why Italian *tutta* and *entrambi/ambo/ambe* differ from their French counterparts in obligatorily taking a DP-complement.

As for the structural relation between the quantifier and the following DP, there are a priori three possibilities. If the quantifier *tutta* heads the DP *tutta la famiglia* 'the whole family', then it either selects the following DP as complement as in (125a), or it projects a DP and the following DP adjoins to it, as in (125b):

(125) a. $[_{DP}$ [tutta $[_{DP}$ la famiglia]]]
b. $[_{DP}$ $[_{DP}$ tutta] $[_{DP}$ la famiglia]]

Alternatively, the DP *tutta la famiglia* is headed by the determiner *la*, and the quantifier *tutta* itself projects a DP and adjoins to the DP *la famiglia*. The representation for this last case would be just like (125b).

The structure in (125b) does not seem to be attested elsewhere, regardless of whether the first DP joins to the second, or the other way round. If it were possible, then we should expect DPs of the sort in (126) to be possible, contrary to fact:

(126) a. *[[la famiglia] [la riunione]]
the family the reunion
'the family reunion'
b. *[[il corso] [il texto]]
the course the text
'the course text'

This leaves (125a) as the only possible structure for the DP *tutta la famiglia* where the quantifier *tutta* heads the whole DP. The lack of D-to-P incorporation in (116b) is now straightforward. Movement of the determiner *la* to P in the structure in (127) violates the HMC:

(127) *P+la$_i$ $[_{DP}$ [tutta $[_{DP}$ t_i N]]]

It should be pointed out that although the example in (117a) does not bear on the account for (127) directly, there being no P-stranding, it is legitimate to ask why the structures and derivations given in (117), if they are correct, are possible at all; in particular, we may ask whether movement of the pronominal clitic in (117a) also violates the HMC, just like movement of the determiner in (127). The question is an important one, but is independent of P-stranding, as the same question also arises when the quantifier *tutta* is absent, i.e., the example in (117a) is grammatical without the quantifier. The pronominal clitic apparently moves across two lexical heads, and should violate the HMC, if it indeed undergoes

head movement. The movement of the pronominal clitic in (117a) is then clearly related to a more general pattern, quite independently of the presence of the quantifier *tutta*. What needs to be explained is, although it remains unclear, why the structure in (117a) in Italian does not obey the constraint against stranding a left-modifier in German.

6.2 D-to-P incorporation from the specifier position

Van Riemsdijk (1998b: 659) points out that in some southern German varieties, a possessive pronoun may be preceded by a full DP in the dative Case, as in (128a) and (129a), whose head D may contract with a preceding preposition, as in (128b) and (128b):

(128) a. von [[dem Bürgermeister] [seinem Gehalt]] German
of the.DAT mayor his.DAT salary
'of the mayor's salary'
b. vom Bürgermeister seinem Gehalt

(129) a. zu [[der Prinzessin] [ihrem Palais]]
to the.DAT princess her.DAT palace
'to the princess's palace'
b. zur Prinzessin ihrem Palais

Although it is not immediately obvious what structure the DP-complement of P has in these cases, it seems clear that the possessive pronoun is the head of the DP-complement of P, most evident in the Case form of the possessive pronoun when the DP complement appears as complement of verbs assigning different Cases (cf. the examples in (135) below). Now, if forming an X^0 is a necessary condition for contraction, then the head D of the DP in the specifier must move to P, in violation of Ross's (1986) Left Branch Condition (LBC) barring movement of DP from the specifier position of a DP.

The problem is even more acute for the D-to-P incorporation analysis of P-stranding in cases like (130–131), where the D contracting with P is further embedded (Van Riemsdijk 1998b: 659):

(130) a. von [[[dem Hans] seiner Mutter] ihrem Geld] German
of the Hans his.DAT mother her.DAT money
'of Hans's mother's money'
b. vom Hans seiner Mutter ihrem Geld

(131) a. von [[[[dem Hans] seiner Mutter] ihrem Freund] seinem Geld]
of the.DAT Hans his.DAT mother her.DAT friend his.DAT money
'of Hans's mother's friend's money'
b. vom Hans seiner Mutter ihrem Freund seinem Geld

The contraction facts in (128–131) thus seem to suggest that the condition for contraction is purely phonological. That is, contraction of D and P is possible as long as they are adjacent. However, there is evidence showing that syntactic structure is relevant to contraction. As shown in (132–133), P and D may not contract, even though they are adjacent (Van Riemsdijk 1998b: 655):

(132) a. von [$_{DP}$ [$_{D}$ e] [$_{AP}$ dem König treu ergebenen] [$_{N}$ Dienern]]
of the.DAT king faithfully devoted servants
'of the servants faithfully devoted to the king'
b. *vom König treu ergebenen Dienern

(133) a. zu [$_{DP}$ [$_{D}$ e] [$_{AP}$ der Direktion zur Verfügung stellenden]
to the.DAT board to availability put
[$_{N}$ Zimmern]]
rooms
'to the rooms made available to the board'
b. *zur Direktion zur Verfügung stellenden Zimmern

The obvious structural difference between (128–131) and (132–133) can be schematically represented as in (134a) and (134b) respectively (the DP in (134a) may be further embedded in the specifier of X):

(134) a. P [$_{XP}$ [$_{DP}$ . . . D . . .] [X . . .]] (D-to-P incorporation possible)
b. P [$_{XP}$ [X [$_{DP}$ . . . D . . .] . . .]] (D-to-P incorporation impossible)

In terms of government, then, D is conceivably governed by P in (134a), but certainly not in (134b) where a head X intervenes between D and P (Chomsky 1986a; Rizzi 1990b). Van Riemsdijk (1998b: 660) suggests that accessibility for government is recursively defined to the effect that a lexical head may govern the specifier position of a complement, or a specifier position of a category further embedded in the specifier of the complement. Along these lines, then, the D head of the DP in the specifier in (134a) may move to P, but that in (134b) may not. In the latter case, the D is found inside a category that is too far to be governed by P.

While the D-to-P incorporation analysis of P-stranding is entirely compatible with such a view of government, there are certain empirical predictions that I cannot verify for lack of access to speakers and detailed descriptions of these varieties of German. If government is recursively defined across all lexical categories, then V in particular in the position of P in (134a) can govern D as well, just like P. V should also be able to govern the DP projection of D, and extraction of a DP from a specifier position of a DP should be possible, in violation of Ross's LBC:

(135) a. Ich habe [[dem Hans] [seinen [Vater]]] gesehen. German
I have the.DAT Hans his.ACC father seen
'I saw Hans's father.'

b. [[Dem Hans] [seinen [Vater]]]$_i$ habe$_j$ ich t_j t_i gesehen.
c. [Dem Hans]$_i$ habe$_j$ ich t_j [t_i [seinen [Vater]]] gesehen.

(136) a. Ich habe [[[dem Hans] [seinem [Vater]]] [seinen [Chef]]] gesehen.
I have the.DAT Hans his.DAT father his.ACC boss seen
'I saw Hans's father's boss.'
b. [[Dem Hans] [seinem [Vater]] [seinen [Chef]]]$_i$ habe$_j$ ich t_j t_i gesehen.
c. [Dem Hans]$_i$ habe$_j$ ich t_j [t_i [seinem [Vater]] [seinen [Chef]]] gesehen.

The structural relation between (the trace of) the finite verb and the DP in the specifier of the object in (135–136) is exactly the same as that between P and DP in (134a). Thus, the examples in (135c) and (136c) are very crucial to the theory of recursive government.

Unfortunately, I am not able to find speakers of the dialects allowing a full DP in the dative Case preceeding the possessive pronoun as in (128a) and (129a) to check whether the examples in (135c) and (136c) are possible.[30]

7 Conclusion

I suggest to consider the suppletion facts involving Ps and Ds as evidence for Ds incorporating into Ps. A direct consequence of incorporation is that the incorporated head no longer forms a syntactic constituent with its complement, and hence may not move together with it. On this view, P-stranding does not depend on any specific assumption, such as canonical government or a reanalysis rule for V and P. Intuitively, then, P-stranding is simply the result of movement of the DP object of P. So if P and its DP object are not separable for some independent reason, then the lack of P-stranding follows immediately.

As P-stranding is simply the result of movement, it is irrelevant whether the movement is to an argument position, A-movement, or to a non-argument position, A-bar-movement. The difference between English on the one hand and other Germanic languages on the other with respect to P-passive does not warrant treating P-stranding differently in terms of A- vs. A-bar-movement. The difference can readily be accounted for by the independent Case-absorption property of the passive morpheme, which manifests itself in the impersonal passive construction independently from P-stranding.

Quite obviously, the accounts discussed above are adequate only to the extent that the empirical facts they bring to bear are correctly captured. It is almost certain that they will need to be revised when we consider languages with radically different grammatical properties. For instance, many Slavic and Asian languages have no determiner; yet, they disallow P-stranding. In fact, P-stranding is rather uncommon cross-linguistically, a fact that no theory of P-stranding to date is able to explain. To achieve explanatory adequacy, linguistic theory must capture this fact.

NOTES

I am indebted to two very helpful anonymous reviewers for their extremely insightful comments and criticisms. Parts of section 5 have been presented at Friedrich-Schiller-Universität, Jena, May 1997 and at the North Eastern Linguistics Society Conference, University of Toronto, October 1997. I would like to thank the participants in these two events, especially Henk van Riemsdijk, for discussing various issues with me, as well as Johanna Barddal, Jörg Dreyer, Andrea Moro, and Christer Platzack for their help with Icelandic, German, Italian, and Swedish. I assume responsibility for any error or inadequacy.

1 According to King and Roberge (1990), Acadian French spoken in Prince Edward Island, Canada, allows relatively free stranding of Ps:

(i) a. Quoi-ce que tu as parlé hier à Jean de? Acadian French
what-it that you have talked yesterday to John about
'What did you talk to John about yesterday?'
b. Robert a été parlé beaucoup de au meeting.
Robert has been talked a lot of at the meeting
'Robert was talked about a lot at the meeting.'

Remarkably, it seems to allow P to be stranded in an adjunct domain sometimes, impossible in English:

(ii) a. Quelle heure qu'elle a arrivé à?
what time that-she has arrived at
'What time did she arrive?'
b *Qui-ce que tu as parti après avoir vu?
who that you have left after to-have seen
'Who did you leave after having seen?'

Lack of access to more detailed description of the language prevents me from further discussing this dialect of French. I will also not discuss cases like (iii), which Zribi-Hertz (1984) argued involve a null pronoun rather than movement of the complement of P, as the apparently stranded P is in a syntactic island for extraction:

(iii) a. Je connais bien cette valise, car je voyage avec. Colloquial French
I know well this suitcase because I travel with
'I know this suitcase well, for I always travel with it.'
b. Ce banc, savez-vous qui doit sauter par-dessus.
this bench, know-you who must jump over
'This bench, do you know who must jump over?'

2 Frisian apparently permits extraction of non-R-pronouns under A- and A-bar-movement, impossible in German and Dutch (Hoekstra 1995: 97):

(i) a. Wa hast mei pratt? Frisian
who have.2SG with talk
'Who have you talked with?'

b. Hokker kandidaat stimme jimme op?
which candidate vote you for?
'Which candidate are you voting for?'

(ii) a. De bern wurdt net nei harke.
the children is not to listen
'The children were not listened to.'
b. Elkenien hat er in foto fan makke.
everyone has he a picture of make
'Has he made a picture of everyone?'

However, Hoekstra argues that the complements of P in (i) and (ii) are not extracted out of PP, but are base-generated in [Spec, CP], with the object of P being a phonetically empty resumptive pronoun, which may be overt when it and its antecedent are not in the same clause (Hoekstra 1995: 116):

(iii) Hokker famke$_i$ miendest dat er sei
which girl thought-you that he said
dat er mei har$_i$/der$_i$ met praat hie?
that he with her/there with talked had
'Which girl did you think that he said that he had talked with?'

Hoekstra's analysis predicts that the stranded P may not lie in a syntactic island, e.g., an adjunct, as the object of P is not moved out of PP. Lack of access to Frisian speakers prevents me from verifying this prediction.

3 The example in (17b) may be derived from (ia) by deleting the portion of the sentence lying between the *wh*-phrase and the P taking it as its argument, i.e., deleting the material inside the parentheses, a non-constituent (Ross 1969b):

(i) a. John left, but I don't who know (he went out) with.
b. *John left, but I don't who know with (he went out).

Notice that (ia) is independently possible with the material inside the parentheses present, so the structure in (17b) does not seem implausible, apart from the issue of deleting a non-constituent. The problem is the structure in (17a), since it would have to be derived, implausibly, from the ungrammatical example in (ib). An additional problem for the deletion account of Sluicing is that it does not explain why non-bare *wh*-phrases are impossible in the Sluice, as the examples in (18) show.

4 A similar problem arises in French for the HC as well. If the I position is filled with the verb in embedded clauses, then extraction of the object in (i) should be impossible, according to the HC, since the head of the VP is not empty:

(i) Je me demande [$_{CP}$ qui$_i$ [[$_{IP}$ tu [as [$_{VP}$ vu t_i]]]]. French
I myself ask who you have seen
'I wonder who you saw.'

One way to get around this problem would be to allow adjunction to the intervening maximal projections (Chomsky 1986a). But new problems arise. One needs to

independently justify the landing sites, given the SPC, and explain why such adjunction is not available for extraction out of PPs.

5 A reviewer points out that some speakers accept Hornstein and Weinberg's example (30a). It is not clear, however, whether there are other dialectal differences bearing on this example.

6 Anderson (1977: 373) argues that passives of apparent objects of Ps are possible just when the object in question has been affected by the action or has acquired some characteristics as a result of it. The grammatical contrast in (i) is thus presumbly due to the bed in (ia) but not New York in (ib) being affected by the act of sleeping or having acquired some characteristics as a result of sleeping, as noted by Hornstein and Weinberg (1981: 88) (see also Baltin and Postal 1996):

(i) a. The bed was slept in.
b. *New York was slept in.

But the grammatical contrast between in (ii) and (33b) clearly does not fall under this account:

(ii) The carpet was repeatedly stepped on.

The only difference between them is the position of the adverb, and there is no reason to think that *the carpet* in the two examples has different properties in terms of affectedness.

7 H. van Riemdijk (p.c.) points out that extraction of the sort in (37) may be consistent with the excorporation analysis of Roberts (1991a) in that V first incorporates into P and then V excorporates from the V+P complex to the second position. But this does not explain why V and P fail to behave like a syntactic unit.

8 One may conceivably argue that the subject trace is antecedent-governed by the trace in [Spec, CP], but this does not seem to be a possible solution in Kayne's analysis, as he explicitly states that movement into COMP is necessary in French to bring the embedded subject NP into a position close enough to V that V can govern it (Kayne 1984a: 112), apparently implying that head-government (Rizzi 1990b; Law 1991a) is required for traces. A possible solution of the government problem in (50) is to assume that French P-complementizers have no Case property, explaining why the embedded subject in (42) may not be overt, but nevertheless govern the embedded subject position, given that in (50) is grammatical. It may also be that the *wh*-phase in (50) moves through a Case position in the matrix clause, e.g., [Spec, AgrO] (cf. Chomsky 1991).

9 I assume here that negation is a VP-adjunct and that the R-pronoun *er* and the non-R-pronoun *hem* in (53) adjoin to the VP as well. The discussion in the text requires no changes if these assumptions turn out to be incorrect, e.g., negation heads a functional projection (cf. Laka 1990). The point here is that R-pronouns may move out of PP, but non-R-pronouns may not. The landing site of the R-pronoun is an independent issue (cf. Kayne 1991).

10 Schaub (1979) gives an extensive list of the *Verschmelzungsformen* 'fused forms' for P+D in German (cf. also Van Riemsdijk 1998b: 653). For cases like (i), where Ps begin with a vowel, the leftmost R-pronouns are doubled with what looks like a pronoun *da* followed by a semivowel *r* (*dar* is preferably reduced to *dr*), the same phonological reduction seen in pairs like *heraus* vs. *raus* 'from here'):

(i) a. Wo besteht er dar-auf? German
what insists he it-on
'What is he insisting on?'
b. Da habe ich dar-an gedacht.
it have I it-of thought
'I have thought of it.'

The apparent doubling of the R-pronouns may suggest that both of them are base-generated in place, but as far as I can tell, the examples in (i) arguably involve movement of the R-pronoun *wo* or *da*, since the P may not lie inside a syntactic island. Wunderlich (1984: 96, n. 21) claims that the consonant *d* to the left of a preposition is the spell-out of the trace of the R-pronoun *da* (cf. Oppenrieder 1991a for an alternative view, however). It is unclear whether the doubling of the R-pronouns has significant syntactic consequences.

11 A clear case in point is the English verbs in the present tense; most of them have the ending *-s* suffixed to the verb stem in third person singular (cf. *work* vs. *works*), while the rest have the same form as the verb stem. The remarkable exception is the copular verb *be*, which has several suppletive forms: *am*, *is*, *are*. There seems to be no generalization as to what kind of verbs undergo suppletion.

12 This assumption might seem unmotivated for Dutch, which has no D+P suppletive forms. As Dutch shares with German a large number of syntactic properties (syntax of verbs, scrambling, impersonal passives, etc.), it does not appear implausible that Dutch Ps may have the same properties as German Ps. The lack of suppletive forms for D+P in Dutch is not too surprising given the little morphology it has for other categories, e.g., Case morphologies on nouns, adjectives, and determiners.

13 In Italian (and Spanish) object pronominal clitics follow the non-finite verb or occur above the complementizer in cases of clitic climbing (cf. Rizzi 1982: 3–5):

(i) a. Piero affermava di conoscer-*la* molto bene. Italian
Peter stated of know-her very well
'Peter stated that he knew her very well.'
b. Piero *li* venne a chiamare stazione.
Peter them came to call station
'Peter came to call them at the station.'

However, they never appear in a position from which it can incorporate into the P-complementizer.

14 As a reviewer points out, a category inflected for number and gender is not necessarily of the category determiner, e.g., adjectives. But as the determiner is usually obligatory in Romance, the exceptions being cases like *prend contact avec* 'to have contact with' where the noun is a complement to a verb, it is quite plausible that French *quel* 'which' and Italian *qual* 'which' are determiners.

15 Müller (1991) argues that all XPs are barriers for extraction of the complement of X, but the barrierhood of XP can be voided if X incorporates into a higher head. P-stranding is thus possible if P incorporates into V abstractly, with the consequence that the Case-assigning capability (of the trace) if P is lost, and V with the incorporated P cannot take over the Case of P and assign it structurally to the object of P (Müller 1991: 191). As the formally invariant R-pronouns do not need Case, it follows that only these can be extracted out of PP when P incorporates abstractly into V.

Several problems arise in this analysis, however. First, there is no obvious reason for abstract incorporation of P into V. Second, to distinguish P incorporating into V with the subsequent loss of the Case assignment property and V incorporating into I without loss of the Case assignment property, Müller (1991: 180) assumes that lexical categories are opaque in that the Case property of the incorporated head is lost, while functional categories are transparent in that the incorporated head can still assign Case when it incorporates into a functional category. There is clearly no independent evidence for the lexical vs. functional category distinction regarding the Case property of the incorporated head. Third, intuitively, if a predicate assigns Case, then there must be a category that takes its Case (cf. Chomsky's 1995c feature-checking theory). In order to bring about the result that P cannot assign Case to its object when it incorporates into V, it must be assumed that V takes or checks the Case of P, for which there is apparently no independent motivation. Fourth, in a case like (i) where the PP moves to [Spec, CP] in main clause, P presumably cannot incorporate into V, because abstract (head) incorporation is subject to constraints on (head) movement:

(i) Davon hat er geredet. German
it-from has he talked
'He talked of it.'

The problem here is that the Case of the preposition *von* cannot be assigned or checked, the R-pronoun needing no Case. Fifth, as Müller (1991: 192, n. 26) notes, it must be assumed that as a parametric choice the trace of a P incorporated into V in English in p-passive can assign Case to its object, as full DPs needing Case may be extracted, stranding P. It is not clear whether this parametric choice is related to any other grammatical property.

16 It is an independent issue whether R-pronouns originate in the Spec position or move from the complement position. On conceptual grounds, one might assume the latter so that all complements originate from the same position, despite there being no empirical evidence for R-pronouns originating in a position to the right of P.

17 Note that the examples in (77) by themselves do not show that the R-pronoun *er* is in [Spec, PP]; it might very well be in an adjoined position. What these examples do show, however, is that the R-pronoun does not incorporate into P. My analysis of P-stranding needs no modification if it turns out to be adjoined to PP.

18 A reviewer points out that the temporal P *na* 'after' may not be stranded, in contrast with the locative P *achter* 'after':

(i) Ik heb (*er) Jan (??er) vlak (er) na bezocht. Dutch
I have it Jan it right it after visited
'I have visited Jan right after it.'

The PP *erna* in (i) seems to be an adjunct. Therefore, that *er* may not move out of the PP stranding P *na* (i) is plausibly due to Huang's CED, cf. the discussion of (38).

19 The reason why an embedded clause is chosen in (83) is to abstract away from the verb-second effect. The example in (i) with a matrix clause obscures the position of the logical object of the verb *Hans und Maria* 'Hans and Maria'. It is not immediately obvious that it is in subject position, i.e., [Spec, IP], even though it agrees with the finite verb:

(i) Es wurden/*wurde Hans und Maria getötet. German
it became.PL/*SG Hans and Maria killed
'Hans and Maria were killed.'

In most analyses, subject–finite verb agreement involves the configuration in which the finite verb is in I^0, and the agreeing argument is in [Spec, IP]. It then follows that the expletive *es* (phonetically identical with the third person singular neutral nominative or accusative argument pronoun) is not in subject position. Moreover, the expletive *es* cannot appear in an embedded clause with an overt complementizer, indicating that the expletive *es* in (i) is most probably not in subject position:

(ii) . . . , dass (*es) Hans und Maria getötet *wurde/wurden.
that it Hans and Maria
'. . . that Hans and Maria were killed.'

20 There is a complication with the example in (86a). The German third person pronoun *da* is formally invariant, regardless of the number, gender, and Case features. It is therefore not immediately clear that the grammatical version of (86a) with the verb in the singular shows that it really agrees with a singular *da*. The crucial point is that it cannot have the plural form, even when *da* has a plural antecedent, showing that the singular form of the verb is most likely the default form when it does not agree with an argument. Cf. the examples in (85).

21 The structures in (82) would be more closely parallel to those with *wh*-movement if they are represented as in (i), a kind of topicalization structure (Koster 1978d), where *O* is a phonetically null counterpart of an overt *wh*-phrase, known as the null operator (Chomsky 1982; Browning 1991):

(i) a. Þessa kona [O_i [er oftast talað vel [$_{PP}$ um t_i]]]. Icelandic
that woman.acc is usually spoken well of
'The woman is usually spoken well of.'
b. Þennan ref [O_i [hefur aldrei verið skotið [$_{PP}$ á t_i]]].
that fox.ACC has never been shot at
'That fox has never been shot at.'

It is not clear, however, why in structures in (i) the topicalized object has the Case assigned to the operator by P, even though it does not originate from the trace position.

22 The term raising applying to both English and Icelandic here is unfortunate. A-movement is commonly taken to be Case-motivated, which is clearly true of English, but not of Icelandic (cf. the DPs with quirky Case that retain their Case even when they do not appear in the base-position).

23 As Baltin and Postal (1996: 142) point out, it is not always possible to have the P+V combinations in P-passive as prenominal modifiers (adding an adverbial like *often* or *repeatedly* in (ib) does not seem to improve grammaticality):

(i) a. The table was jumped/leaned/sat on.
b. *Jumped/leaned/sat on tables.

What needs to be explained is why the examples in (92) are possible, but those in (ib) are not, an issue that is independent of whether the P+V combinations are the results of reanalysis.

24 Vikner (1995: 209–210) attributes the difference between English and other Germanic languages with respect to the impersonal passive construction to the different structural conditions under which Case is assigned in these languages. More specifically, he suggests that chains consisting of an expletive and a passive morpheme are subject to a condition according to which a chain not receiving a theta-role under government must receive Case under government. In his view, the passive morpheme in English is assigned a theta-role, but not under government, and the subject is assigned Case under Spec-I^0 agreement. Thus, a chain consisting of the expletive and the passive morpheme in English is impossible, since the expletive in subject position is not assigned Case under government. By contrast, Case is assigned under government from C^0 in verb-second languages; thus, a chain consisting of an expletive and a passive morpheme in the impersonal passive construction is always possible in these languages.

There are two problems with his analysis. First, it does not explain why an overt expletive is impossible in cases like (i):

(i) a. Ist (*es) getanzt worden? German
is it danced become
'Has there been dancing?'
b. *Hafur (*Það) verið dansað. Icelandic
has it been danced
'Has there been dancing?'

Second, as Vikner also notes, his account does not explain why it is also impossible to embed the impersonal passive construction under an ECM verb in English, when the expletive is assigned Case under government.

(ii) a. *I believe there to have been danced.
b. *Do you believe there to be have slept anybody here?

25 There is an independent issue as to why an argument with Case moves, if movement must be motivated. I leave this issue open here.

26 The same conclusion holds of the examples in (i) (Maling and Zaenen 1985: 207):

(i) a. Henne$_i$/*hon$_i$ skrattades det [$_{PP}$ åt t_i]. Swedish
her.ACC/she.NOM was-laughed it at
'She was laughed at.'
b. Ham$_i$/*han$_i$ blev der leet [$_{PP}$ ad t_i]. Danish
her.ACC/she.NOM was it smiled at
'She was smiled at.'

Many speakers prefer to retain the expletives *det* and *der* in (i) (Christer Platzack, p.c. and Allan et al. 1995: 161). Thus, the ungrammaticality of the examples in (ii) might very well be due to the absence of the expletive, rather than to lack of P-passive in these languages:

(ii) a. *Hon$_i$ skrattades [$_{PP}$ at t_i]. Swedish
she.NOM was-laughed at
'She was laughed at.'

b. *Han$_i$ blev leet [$_{PP}$ ad t_i]. Danish
she.NOM was smiled at
'She was smiled at.'

27 Van Riemsdijk (1998b: 662, n. 40) notes that *genau* 'exactly' in (100) and *knapp* 'nearly' (101) are really adjectives, used adverbially. They are uninflected in this use, but must be inflected when used as adjectives. The form of the adjectival inflection depends on the number, gender and Case features of the modified noun (cf. the schwa on *genau* in *das genaue Gegenteil* 'the exact opposite'). However, many, if not most, adjectives do not have the syntax of *genau* or *knapp*. As shown in (i), adjectives like *klug* 'clever', *dumm* 'dumb', *ehrlich* 'frank', and *schön* 'nice' may be used adverbially, but they cannot intervene between P and its DP-complement (note that *klug* in (id) modifies *geredet* 'talk', not *Mann* 'man', and that in (iid) *schön* modifies *geantwortet* 'answer', not *Frage* 'question'):

(i) a. Hans hat klug geredet. German
Hans has cleverly talked
'Hans talked cleverly.'
b. Hans hat von dem klugen Mann geredet.
Hans has of the.DAT clever man talked
'Hans talked of the clever man.'
c. *Hans hat von klug/klugen dem Mann geredet.
d. Hans hat klug/*klugen von dem Mann geredet.
'Hans talked of the man cleverly.'

(ii) a. Hans hat schön geantwortet.
Hans has nice answered
'Hans answered nicely.'
b. Hans hat zu der schönen Frage geantwortet.
Hans has to the.DAT nice.DAT question answered
'Hans answered the nice question.'
c. *Hans hat zu schön/schönen der Frage geantwortet.
d. Hans hat schön/*schönen zu der Frage geantwortet.
'Hans answered the question nicely.'

It is not clear why adjectives like *genau* and *knapp* may have adverbial use but many others do not.

28 Note that the degraded status of the example in (ia) is most probably due to independent factors, having to do with P being separated too far from the verb taking it as complement. The example becomes perfect if the relative clause occurs at the end of the sentence as in (ib) so that P and the verb are close together:

(i) a. ??Da$_i$ hat Hans [t_i [von t_i [was uns übrigens auch German
it has Hans of what us by the way also
interessiert]]] geredet.
interest talked
'Hans talked of it, which by the way we are also interested in.'
b. Da$_i$ hat Hans [t_i [von t_i] t_j] geredet [was uns übrigens auch interessiert]$_j$.

A similar grammatical contrast holds of the examples in (ii) where there is no P-stranding:

(ii) a. ?Da hat Hans von diesem Thema, was/das uns übrigens auch interessiert, geredet. German
there has Hans of this topic what/that us by the way also interest talked
'There Hans talked of this topic, which we are by the way also interested in.'
b. Da hat Hans von diesem Thema geredet, was/das uns übrigens auch interessiert.

The slight grammatical difference between (ia) and (iia) is perhaps due to the already (slightly) marginal status of P-stranding.

29 It is worth noting that according to Rizzi (1995: 515) contraction with *con* 'with' is optional, in contrast with the pair in (i) given by Van Riemsdijk (1998b: 663):

(i) *con la famiglia vs. colla famiglia. Italian
with the family

Renzi (1995: 410) also gives the example in (ii) where *con* is not contracted with the following determiner:

(ii) Ho comprato un quadro con la cornice. Italian
have bought a picture with the frame
'I bought a picture with the frame.'

The problem remains as to why the example in (116b) is ungrammatical.

30 In (European) Portuguese, a prepositional complementizer may contract with the D of the following subject (Van Riemsdijk 1998b: 660–661):

(i) a. Eu entrei depois do/*de o meu pai chagar do escritorio. Portuguese
I entered after of-the/of the my father arrive from-the office
b. Antes da/*de a chuvada estalar no pavimento, entrou pela vila [. . .] uma charrete.
before of-the/of the downpour to-rattle in-the soil there-entered in-the village a barrow

As subject it can at least sometimes be extracted (Zubizarreta 1982b: 82):

(ii) a. Que rapazes$_i$ acreditas que t_i tenham gasto esse dinheiro?
which children believe.2SG that have spent that money
'Which children do you believe spent that money?'
b. Que rapazes$_i$ desconfia a policia que t_i tenham roubado aquela loja?
which children suspect the police that have broken into-that house
'Which children does the police suspect broke into that house?'

The D-to-P incorporation as indicated by the P+D contraction in (i) is not totally surprising since the subject in (i) is governed in whatever way the subject in (ii) is.

Subject extraction out of an inflected infinitival, of which the examples in (i) are instances, are not always possible, however. In particular, the subject of an inflected factive infinitival complement may not be extracted (Zubizarreta 1982b: 82):

(iii) a. *Quem$_i$ preocupa-te t_i terem gasto esse dinheiro?
who worries-you have.INF.3.PL spent that money
'Who worries you in having spent that money?'

b. *Que meninos$_i$ é que tu lamentas t_i terem roubado aquela loja?
which children be that you regret have.INF.3.PL broken into that house
'Which children is it that you regret to have broken into that house?'

At first glance, the ungrammaticality of the examples in (iii) is quite unexpected. If P may govern D in (i), allowing D to move to P, then there is no reason why the matrix V in (iii) may not. The problem is aggravated by the fact that object may be extracted out of an inflected factive infinitival complement. The example in (iv) is only slightly degraded (Zubizarreta 1982b: 82):

(iv) ?Que loja$_i$ é que tu lamentas os meninos terem roubado t_i?
which house be that you regret the children have.INF.3.PL break
'Which house is it that you regret the children broke into?'

Zubizarreta (1982b: 88) suggests that movement to the Comp (=[Spec, CP]) of a factive complement is not possible, as a factive clause projects a nominal Comp (not represented in (iii)). Being governed by the verb, the object may move directly to the matrix clause, an option that is not available to the subject, since the verb does not govern it. But a subject can move out of a non-factive complement since its Comp is available as an escape hatch. The trace of the extracted phrase in subject position is presumably governed by the trace in Comp (Lasnik and Saito 1984).

Nevertheless, the government-based account for P-stranding in (i) cannot rely on Zubizarreta's analysis since there is no trace in Comp to govern the DP in subject position out of which D moves to P. It must be assumed that it is P that governs the subject. Notice that the examples in (iii) lack a complementizer, their ungrammaticality is thus expected under this account.

It should be emphasized that P does not always contract with the D head of a DP subject of an infinitive (cf. Longa 1994, cited in Van Riemsdijk 1998b: 660, n. 38). In fact, Caetano et al. (1986: 113) give some examples where P does not contract with D, in contrast with (i):

(v) a. Não há perigo de as crianças se perderem. Portuguese
not have danger of the children self lose
'There is no danger of the children getting lost.'

b. Não pude sair, por o tempo estar mau.
not could go out because the weather be bad
'I couldn't go out, because the weather is bad.'

They mention explicitly that P does not contract with a following article that is part of a subject.

  5.3 Chamorro
  5.4 Verb-initial clauses that are only apparent
6 Conclusion: VOS, directionality, and late linearization

1 Introduction

The notion of VOS language originates in Joseph H. Greenberg's work on linguistic universals and word order typology. Greenberg (1963: 76–77) observed that languages can be typologized according to what he called their dominant order: the relative surface order of subject (S), verb (V), and direct object (O) in unmarked or pragmatically neutral clauses (see also Jakobson 1963: 268–269). Greenberg claimed that almost all languages have a dominant order in which the subject precedes the direct object: SVO, SOV, or – less commonly – VSO. But even as he proposed this statistical universal, he noted the existence of languages with

a dominant order in which the direct object, exceptionally, precedes the subject (1963: 105, notes 5 and 110). Later research has established that virtually all such languages have VOS as their dominant order: the verb precedes the direct object, which in turn precedes the subject, in pragmatically neutral clauses (Dryer 1995).

For word-order typologists in Greenberg's tradition, VOS languages raise two issues. Why is VOS possible, if uncommon, as a dominant order, whereas OVS and OSV are rare or non-existent? And why do VOS languages pattern with VSO and SVO languages, as opposed to SOV languages, for the purposes of the word-order correlations uncovered by Greenberg?

Crucial information bearing on the first issue was supplied by Steele (1978), who noticed that languages whose dominant order is VSO or VOS very commonly allow the other order, VOS or VSO, as an option (see also Keenan 1978). Building on this observation, many typologists have replaced Greenberg's third dominant order with the more inclusive 'verb-initial', which is intended to encompass VOS as well as VSO (see Dryer 1992; Nichols 1999: 65; and others). As for the second issue, a goal of word-order typology since Lehmann (1973) and Vennemann (1973) has been to derive Greenberg's word-order correlations from some single, more fundamental principle (but compare Hawkins 1980 for a different approach). This effort has met with mixed success; see Dryer (1995) for a useful survey.

The issues raised by VOS languages within generative grammar are remarkably similar to those that have preoccupied word-order typologists, once two differences are taken into account. First, generative syntacticians are concerned not so much with VOS as a language type as with VOS as a clause type. Second, the generative approach to clause types represents them two-dimensionally, in terms of the interaction of hierarchical relations (dominance) and left-to-right order (precedence) in constituent structure. Within this overall framework, questions like the following arise. What are the phrase structure and derivation of VOS clauses? Why is it cross-linguistically uncommon for such clauses to be pragmatically neutral? And how is the structure of VOS clauses related to that of VSO clauses or SVO clauses?

These questions bear ultimately on the theory of phrase structure and the extent to which the theory imposes universal constraints on left-to-right order. Since Chomsky (1986a: 3), it has been standard to assume that clauses conform to X'-Theory in that they are projected from a clausal head, such as T(ense) or I(nflection), whose complement is the predicate phrase or VP and whose specifier is the subject. Kayne (1994) has developed a theory of the interaction of dominance and precedence in phrase structure in which complements are universally projected to the right, and specifiers to the left, of their heads. If Kayne's theory is adopted, then the simplest possible clause structure would be an SVO structure in which VP is projected to the right of the clausal head but the subject is projected to the left – a structure in which the subject precedes VP. Clauses with any other word order, including VOS or VSO, would have to be derived from this minimal SVO structure via movement.

On the other hand, if Kayne's theory is not adopted, then there is no need to view VOS clauses as derivationally more complex than (the simplest) SVO clauses, and a wider range of analytic possibilities opens up. One could treat

VOS clauses as clauses whose specifier is simply projected to the right rather than to the left. On this view, VOS clauses would differ from SVO clauses merely in the setting of a directionality parameter. Or one could assume that all clause types, whatever their surface word order, originate as unordered hierarchical structures which are linearized relatively late, after the derivation has left the syntax proper. (For different incarnations of the idea, see, e.g., McCawley 1968a; Bresnan 1982c; Dowty 1982a; Perlmutter and Postal 1983c; Gazdar et al. 1985; Halle and Marantz 1993; and Chomsky 1995c.) If so, VOS clauses would not differ from SVO clauses in any syntactically interesting way.

Section 2 gives an overview of the languages in which the syntax of VOS clauses has been investigated. These include languages whose dominant order is frequently or exclusively VOS (e.g., Palauan, Tzotzil), as well as languages which have VOS clauses, but not as the dominant order (e.g., Italian). Section 3 surveys the kinds of evidence that have been advanced to support the claim that VOS clauses are derived by leftward movement of VP, or some larger constituent, to a higher specifier position. Section 4 raises the issue of the motivation for this movement. Section 5 examines other evidence that suggests that not all VOS clauses are derived via leftward movement of VP. The overall picture that emerges is consistent with the idea that there are multiple syntactic routes to VOS-hood. Section 6 takes a brief look at the proposal that VOS clauses are base-generated as clauses whose specifier is projected to the right. The conclusion reached is that almost no evidence distinguishes this proposal from an approach in which precedence is simply not represented in the syntax and all clausal word orders, including VOS, are derived from unordered hierarchical structures via late linearization.

2 Some languages with VOS clauses

2.1 Overview

As Greenberg noticed, there are remarkably few languages with fixed VOS order – languages whose pragmatically neutral clauses must be VOS. It is far more common for languages to have verb-initial order, that is, to allow pragmatically neutral clauses to be VOS or VSO. Fixed VOS languages and verb-initial languages have been documented in many areas of the Pacific and in parts of North America, Central America, and South America (Keenan 1978). Although such languages have various genetic affiliations, almost all that have been studied from a generative perspective happen to come from just two families: the vast Austronesian family and the much smaller Mayan family.

Very few Austronesian languages have fixed VOS order. Among them are Malagasy (Keenan 1976b, 1978; Pearson 1998, 2000a; Paul 2000), Toba Batak (Keenan 1978; Schachter 1984), and Formosan languages such as Atayal, Seediq (Aldridge 2002), and Tsou (Chang 1998). Significantly more Austronesian languages have verb-initial order: for instance, Tagalog (Schachter 1976b, 1996; Kroeger 1993) and other Philippine languages; Standard Fijian and other Fijian languages (Dixon 1988; Kikusawa 2001); Maori (Bauer et al. 1993, 1997) and other Polynesian

languages; Palauan (Georgopoulos 1985, 1991a); and Chamorro (Gibson 1980; Chung 1990). The Malagasy examples below are representative:

(1) a. Manolotra ny vary ny vahiny aho.
offer.AT the rice the guests I
'I offer the rice to the guests.' (Keenan 1976b: 257)

b. Avy ny orana.
come the rain
'The rain is coming.' (Keenan 1976b: 254)

c. Mihevitra Rabe fa handeha ho any Antsirabe rehampitso.
thinks.AT Rabe that will.go Fut there Antsirabe tomorrow.
'Rabe thinks that he will go to Antsirabe tomorrow.'
(Keenan 1976b: 276)

Roughly as many Mayan languages have fixed VOS order as have verb-initial order. The fixed VOS languages include Tzotzil (Aissen 1987), Yukateko (Durbin and Ojeda 1978), and some dialects of Tz'utujil; the verb-initial languages include Kaqchikel, K'iche', and other dialects of Tz'utujil (England 1991). Consider these examples from Tzotzil:

(2) a. 7i-s-pet lok'el 7antz ti t'ul-e.
cp-A3-carry away woman the rabbit-cl
'The rabbit carried away the woman.' (Aissen 1987: 1)

b. 7i-bat xchi7uk s-malal li Maruch-e.
cp-go with A3-husband the Maruch-cl
'Maruch went with her husband.' (Aissen 1987: 11)

c. Ta la x-lok' ta k'ux-7ak'al ti 7antz-e jujun 7ak'ubal.
icp cl nt-leave to crunch-charcoal the woman-cl every night
'The woman went out to crunch charcoal every night.'
(Aissen 1987: 12)

In addition, there are languages whose dominant order is not fixed VOS or verb-initial by any stretch of the imagination, but which nonetheless have clauses that are verb-initial. Included here are languages that impose few if any word-order restrictions on pragmatically neutral clauses, such as Warlpiri (Hale 1983), as well as certain SVO languages, such as Spanish and Italian. Some Italian examples follow:

(3) a. Esamineranno il caso molti esperti.
will.examine the case many experts
'Many experts will examine the case.' (Burzio 1986: 21)

b. Ha parlato Giovanni.
has spoken Giovanni
'Giovanni has spoken.' (Burzio 1986: 85)

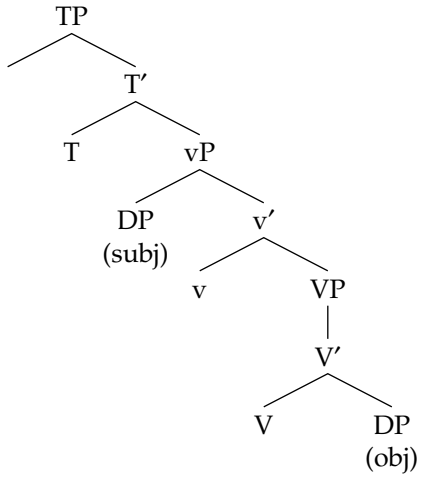
The analysis of verb-initial clauses in Spanish and Italian is discussed further in sections 3.3 and 5.4.

2.2 VOS and ergativity

Whether a transitive clause is characterized as VOS or VSO depends on which of its argument noun phrases is identified as the (surface) subject. In quite a few of the languages just mentioned, a transparent identification of the subject is complicated by morphological ergativity, and this complication should be acknowledged here. Many Mayan languages have an ergative-absolutive system of verb agreement, and many Austronesian languages have, or could be analyzed as having, an ergative-absolutive system of case marking. If the ergative noun phrase is identified as the subject of a transitive clause, then Tzotzil has fixed VOS order (Aissen 1987) and Niuean has fixed VSO order (Seiter 1980; Massam 2000). But had the absolutive noun phrase been identified as the subject, these classifications would be reversed. The issue is further clouded in some Western Austronesian languages, such as Malagasy and Tagalog, for which it remains controversial whether the noun phrase analyzed as the surface subject by Keenan (1976b), Kroeger (1993), and Guilfoyle et al. (1992) might instead be a topic (Pearson 2000a; Richards 2000), an absolutive (Aldridge 2002), or "none of the above" (Schachter 1976b; 1996).

An internally articulated phrase structure for the clause provides a way of navigating around these issues. Following Aissen (1992), Campana (1992), and many others (cf. Woolford 1991; Bittner and Hale 1996a), the discussion here adopts a view of the clause structure of ergative languages in which the ergative noun phrase originates as a predicate-internal subject – more precisely, as the specifier of v, an abstract verbal head that selects VP as its complement (Chomsky 1995c) – but does not raise in overt syntax to the highest specifier of the clause. On this view, the question of whether VOS clauses are derived via leftward movement of VP can be posed in essentially the same way for the ergative language Tzotzil as for a language like Italian. The principal difference lies in whether the subject is assumed to raise in overt syntax to the specifier of the clausal head: in Tzotzil it does not, whereas in Italian, depending on other assumptions, it might or might not (see section 3.3). See (4):

(4)



The situation is a bit different for Western Austronesian languages such as Malagasy and Tagalog. Though the clausal syntax of these languages has generated considerable debate since the mid-1970s, most of the generative analyses proposed are agreed in assuming that at some point in the derivation, the noun phrase argued by Keenan (1972) and Kroeger (1993) to be the surface subject raises to a specifier position located very high within the clause. Assuming this but remaining agnostic on all other details, the question of interest becomes whether the VOS clauses of such languages are derived via leftward movement of VP, or some maximal projection dominating VP.

It is important that there are languages in which VOS is a dominant order but none of these special considerations arise. For instance, the Fijian languages and Palauan are Austronesian languages in which the identification of the (surface) subject is completely transparent. These languages have verb-initial order: their pragmatically neutral clauses are realized as VOS or VSO. Some examples from Boumaa Fijian are given in (5):

(5) a. E rai-ca a gone a qase.
3sg see-Tr Art child Art old.person
'The old person saw the child/The child saw the old person.'
(Dixon 1988: 243)

b. Sa+na qali i Toga o Viti.
Asp+Fut subservient to Tonga Art Fiji
'Fiji would then have been subservient to Tonga.' (Dixon 1988: 41)

c. E tu'u-na mai o Tui Waini'eli ni o ira sa+na mai
3sg tell-Tr here Art Title that Art 3pl Asp+Fut come
'aba-ti Boumaa.
invade-Tr Place
'Tui Waini'eli said that they would come and invade Boumaa.'
(Dixon 1988: 243)

3 VOS as a derived clause type

3.1 Theoretical background

VOS clauses pose a challenge for versions of the theory of phrase structure in which the subject is universally projected to the left of VP. Consider, for instance, what is probably the first such theory – Emonds's (1976) attempt to impose universal restrictions on base rules. Emonds's proposal included the tentative restriction that at deep structure, a clause must either be subjectless or else have a subject NP that is a left sister of VP (1976: 18). The only way that a VOS clause could satisfy such a restriction would be for VOS word order to be derived by movement – either movement of VP or its subconstituents to the left of the subject, or else movement of the subject to the right of VP.

In the 1970s, most generative syntacticians assumed that clauses were members of an exocentric category, S, which consisted of the subject plus the predicate

phrase or VP. But since Chomsky (1986a), that assumption has been superseded by the view that clauses conform to X′ principles: they are projected from a clausal head, T(ense) or I(nflection), whose specifier is the subject and whose complement is VP. Such a view makes it possible to see Emonds's restriction as one instance of a more general requirement that specifiers must be projected to the left.

One theory that appeals crucially to this set of ideas is Kayne's (1994) theory of antisymmetry. The core of antisymmetry is the proposal that the observed order of elements in constituent structure is determined rigidly by hierarchical relations. Kayne fleshes out this proposal as follows. First, he shows that it is workable to claim that whenever a syntactic category X asymmetrically c-commands a syntactic category Y, the words dominated by X will have a single, universally fixed order with respect to the words dominated by Y. He then observes that given this claim, a head will always have its specifier, which asymmetrically c-commands it, on the opposite side from its complement, which it asymmetrically c-commands. Finally, assuming that the subject is a specifier and VP, a complement, he uses Greenberg's statistical universal concerning dominant order (see section 1) as evidence that 'specifier–head–complement, and not the reverse, is the only order available to the subcomponents of a phrase' (1994: 36).[1] His conclusion is that whenever a category X asymmetrically c-commands a category Y, the words dominated by X must *precede* the words dominated by Y.

The theory of antisymmetry has radical consequences for the analysis of VOS clauses, as Kayne's exceedingly brief discussion makes clear. He says: "From the present perspective, . . . VOS must not have S in a final specifier position, but must instead either have . . . VO moving as a unit leftward past S, or else V and O moving separately leftward past S, with the expectation, then, that such languages should show . . . VOSX orders." (1994: 36). This, then, is another theory in which VOS order would have to be derived by movement – specifically, leftward movement, since if antisymmetry is assumed, any movement to a c-commanding position must necessarily be to the left (Kayne 1994: 47).

Suppose Kayne's theory is adopted and VOS clauses are indeed derived by leftward movement. Then one question that immediately arises is whether V and the object are moved across the subject separately or as a single phrasal constituent, say, VP.

Some relevant evidence is supplied by the possibility of VP coordination. In various languages with VOS clauses, the subject can be preceded by what is evidently a coordinate VP – a phrasal constituent consisting of multiple verbs, each accompanied by its own complement and modifiers (see Keenan 1978: 319–321). Such coordinate VPs are found in fixed VOS languages, such as Malagasy, as well as verb-initial languages, such as Chamorro:[2]

(6) Malagasy:
  a. [Misotro toaka] sy [mihinam-bary] Rabe.
     drink alcohol and eat-rice Rabe
     'Rabe is drinking alcohol and eating rice.' (Keenan 1978: 320)

b. [Henon-dRabe] sy [najeren-dRakoto] ny mpihira gasy.
heard.TT-Rabe and watched.TT-Rakoto Det folk singer
'The folk singer was heard by Rabe and watched by Rakoto.'
(Pearson 1996: 119)

(7) Chamorro:
a. [Ma-yíluluk i mata-nñiha] yan [man-haha] i famagu'un.
agr-rub the eye-agr and agr-yawn the children
'The children rubbed their eyes and yawned.' (Chung 1990: 591)
b. esta ki [mam-ara mañalik] pat [mam-ara mañätfinu'] i sindalu
until agr-stop Infin.laugh or agr-stop Infin.swear the soldier
'until the soldiers stopped laughing or stopped swearing'
(Chung 1990: 592)

In languages that permit predicate phrases other than VPs, these too can precede the subject even when they are coordinate. Consider the following examples from Maori, another verb-initial language. In (8a), the subject is preceded by a coordinate DP predicate; in (8b), by a coordinate PP predicate:[3]

(8) Maori:
a. [He mahi roa], [he mahi manawanui] te whakapiata pounamu.
Pred.a work long Pred.a work patient the shine greenstone
'Working with greenstone is a long and patient enterprise.'
(Ngata 1994: 346; s.v. *polish*)
b. [Kai roto], [kai waho] rānei te tāke hokohoko i tēnei kaute?
T.at inside T.at outside Q the tax trade in this account
'Is this account G.S.T. inclusive or exclusive?'
(Ngata 1994: 137; s.v. *exclusive*)

In clauses of these types, any attempt to derive the surface word order by moving V – more generally, the predicate X^0 – separately from its dependents would violate Ross's (1986) Coordinate Structure Constraint. Therefore, if VOS order is derived by leftward movement, the entire VP must be allowed to move across the subject as a unit.

The rest of this section adopts the simplifying assumption that VOS order is *always* derived by leftward movement of the entire VP or equivalent, where 'equivalent' refers to a predicate XP or some even more inclusive category. In other words, what moves to the left is always a single maximal projection. For most practitioners of Principles and Parameters Theory (though not Carnie 1995), it follows that this VP must either raise to a higher specifier or else adjoin to a maximal projection – no other types of phrasal movement are allowed.

The analytic possibilities can be narrowed even further. It is standardly assumed in Principles and Parameters Theory that adjunction to a maximal projection is a completely free option, whereas raising to a specifier is sometimes forced – by Case, the Extended Projection Principle, and the like. As a matter of

fact, in most languages whose dominant order is VOS or verb-initial, leftward movement of VP would have to be forced. In such languages, pragmatically neutral clauses must begin with V: they are not in free variation with SVO clauses, contrary to what Greenberg (1963: 79) originally claimed (see Keenan 1978). The observation suggests that for these languages at least, VP raises to a higher specifier (see Carnie and Guilfoyle 2000).

In sum, if specifiers are universally projected to the left, then VOS clauses are derived by raising of VP to a specifier position. The precise identity of the specifier and the motivation for this movement are discussed further in section 4.

3.2 *Evidence for VP raising*

Several kinds of evidence have been advanced to support the hypothesis that VOS clauses – more generally, verb-initial clauses – are derived by VP raising. Some of the most convincing evidence involves language-specific patterns of *wh*-movement and their interaction with clausal word order. The basic form of the evidence is discussed in section 3.2.1. After a brief excursus into remnant movement (section 3.2.2), further refinements of the evidence are presented in section 3.2.3. Some additional arguments that have been offered for VP raising are surveyed in section 3.3.

3.2.1 VP raising and extraction

In Principles and Parameters Theory, every maximal projection that undergoes movement must move to a specifier or to an adjoined position. Now, adjuncts are generally assumed to be islands to extraction. So are specifiers, unless they are specifiers of complements to lexical heads (passim, but especially Chomsky 1986a). These observations create an expectation. If VOS clauses are derived by leftward movement of VP or equivalent, then the moved VP should constitute an island, and its subconstituents should be inaccessible to *wh*-movement. The subject, however, should be accessible, since any subject that originated within VP will, by hypothesis, have raised out of it before leftward movement of VP occurs.

Keenan (1972) was the first to observe that there are languages in which this expectation is realized. In many Western Austronesian and Formosan languages with VOS clauses, subjects are accessible to *wh*-movement but non-subject arguments are not. This extraction pattern is precisely what one would expect if VOS clauses are derived from an SVO structure by VP raising.

Consider, for instance, Malagasy and Seediq, both languages with fixed VOS order. (Both are also languages in which the surface subject has sometimes been analyzed as an absolutive or a topic; see section 2.2.) The examples in (9) illustrate the Malagasy clause types viewed by Keenan (1972) and others as active (9a) and one type of passive (9b). Notice that the VP is enclosed in brackets:

(9) a. [Manasa ny lamba] ny zazavavy.
wash.AT the clothes the girl
'The girl is washing the clothes.' (Keenan 1976b: 265)

b. [Sasan'ny zazavavy] ny lamba.
wash.TT.the girl the clothes
'The clothes are washed by the girl.' (Keenan 1976b: 265)

The examples in (10) illustrate analogous clause types in Seediq, a language that Aldridge (2002) treats as ergative. For her, (10a) is antipassive and (10b) transitive:

(10) a. Wada [m-ari hulama laqi] ka Ape.
Perf AP-buy treat child Abs Ape
'Ape bought the child a treat.' (Aldridge 2002: 10)
b. Wada [s-bari hulama na Ape] ka laqi.
Perf Appl-buy treat Erg Ape Abs child
'Ape bought the child a treat.' (Aldridge 2002: 6–7)

In both languages, the surface subject – more accurately, the syntactically most prominent DP, however analyzed – occurs at the right edge of the clause, outside VP. What is important is that this DP is the only argument of the clause that is accessible to *wh*-movement.

To see this, consider first relative clauses in Malagasy (Keenan 1972, 1976b, and many others), which can be assumed to involve *wh*-movement of a null operator from some clause-internal position to the specifier of C. Surface subjects can be relativized in Malagasy, whether the clause is active (11a) or passive (11b). This amounts to saying that subjects in this language can undergo *wh*-movement. (In (11) and subsequent examples, the origin site of the null operator is indicated by an underline but the moved operator itself is not represented explicitly.)

(11) a. ny zazavavy izay [manasa ny lamba] ___
the girl that wash.AT the clothes
'the girl that washed the clothes' (Keenan 1976b: 265)
b. ny lamba izay [sasan'ny zazavavy] ___
the clothes that wash.TT.the girl
'the clothes that are washed by the girl' (Keenan 1976b: 265)

Non-subjects cannot be relativized, whether they are direct objects (12a), benefactives (12b), or some other grammatical function. More generally, arguments that would normally have surfaced within VP are inaccessible to extraction:

(12) Malagasy:
a. *ny lamba izay [manasa ___] ny zazavavy
the clothes that wash.AT the girl
'the clothes that the girl washed' (Keenan 1976b: 265)
b. *ny ankizy izay [nividy ny vary (ho an) ___] ny vehivavy
the children that bought.AT the rice for the woman
'the children that the woman bought rice for' (Keenan 1972: 174)

Rackowski and Travis (2000: 124) observe that if Malagasy clauses are derived by VP raising and the moved VP is an island, this pattern follows immediately.

Essentially the same extraction pattern occurs in Seediq, although to appreciate this, it is necessary to achieve some distance from the issue of ergativity. According to Aldridge (2002), constituent questions in Seediq are clefts in which the interrogative phrase is a higher predicate and the rest of the construction is a headless relative clause. The headless relative can be assumed to involve *wh*-movement of a null operator from some clause-internal position to the specifier of C – this is the movement relevant here. Now, surface subjects (which Aldridge analyzes as absolutives) can undergo *wh*-movement within the headless relative. Such subjects can be relativized whether the clause in which they originate is active (in her terms, antipassive; see (13a)) or passive (in her terms, transitive; see (13b)):

(13) Seediq:
a. Ima ka wada [m-ari patis-ni] ___ ?
who? Abs Perf AP-buy book-Def
'Who bought this book?' (Aldridge 2002: 1)
b. Maanu ka wada [burig-un na Ape] ___ ?
what? Abs Perf buy-Tr Erg Ape
'What did Ape buy?' (Aldridge 2002: 1)

But non-subjects are inaccessible to *wh*-movement. It is impossible for the null operator within the headless relative to be the agent of a passive (in Aldridge's terms, an ergative) or any other grammatical function that would normally have surfaced within VP:

(14) Seediq:
*Ima ka wada [burig-un ___] patis-ni?
who? Abs Perf buy-Tr book-Def
'Who bought this book?' (Aldridge 2002: 1)

Ergativity aside, the point is that the null operator must be outside VP when it is targeted by *wh*-movement. (Compare the origin sites underlined in the examples above and their locations with respect to the bracketed VPs.) Aldridge (2002: 2–3) points out that this is the expected pattern if Seediq clauses have undergone VP raising and the moved VP is an island.

The absence of overt adjunct extraction in Seediq is highly compatible with this line of thought. As Aldridge shows, locative interrogative phrases in Seediq must surface in situ, within VP. Compare (15a) with the ungrammatical (15b), which can be analyzed two ways: either as a simplex sentence in which the locative has undergone *wh*-movement or as a cleft in which the moved constituent is a null locative operator within the headless relative. Either way, (15b) is ill-formed, presumably because locatives and other adverbials are inaccessible to *wh*-movement:

(15) Seediq:
a. [M-n-ari inu patis] Ape?
AP-Perf-buy where? book Ape
'Where did Ape buy books?' (Aldridge 2002: 2)
b. *Inu [m-n-ari patis ___] Ape?
where? AP-Perf-buy book Ape
'Where did Ape buy books?' (Aldridge 2002: 2)

These facts fall into place if adverbials are assumed to adjoin to VP or equivalent and, further, the VP constituent that raises in Seediq is always as inclusive as possible. More generally, the full extraction pattern of this language offers striking empirical support for the claim that VOS clauses are derived by VP raising.

The facts of adjunct extraction in Malagasy are more equivocal. Keenan (1976b: 250) observes that under certain circumstances, locative and temporal phrases in Malagasy can surface to the right of the subject, outside VP (see (16a)). This positioning is consistent with the observation that these adverbials can be clefted (16b):

(16) Malagasy:
a. [Nividy mofo ho an'ny ankizy] aho tamin'ny asabotsy.
bought.AT bread for.the children I on.the Saturday
'I bought bread for the children on Saturday.' (Keenan 1976b: 250)
b. Amin'ny Talata no [manasa lamba] Rakoto ___.
P.Gen.Det Tuesday Foc wash.AT cloth Rakoto
'It is on Tuesday that Rakoto washes clothes.' (Paul 2000: 37)

On the other hand, instrumental phrases can also be clefted (see Keenan 1976b: 268–269; Paul 2000: 37–38)), despite the fact that they evidently must surface to the left of the subject, within VP:

(17) Malagasy:
a. [Manasa ny lamba amin'ity savony ity] Rasoa.
wash.AT the clothes with.this soap this Rasoa
'Rasoa is washing clothes with this soap.' (Keenan 1976b: 268)
b. Amin'ity savony ity no [manasa lamba ___] Rasoa.
with.this soap this Foc wash.AT clothes Rasoa
'It is with this soap that Rasoa is washing clothes.'
(Keenan 1976b: 269)

How is this asymmetry in the overall pattern to be understood? Clefts such as (16b) and (17b) are analyzed by Paul (2000: 167–184) as biclausal constructions in which the focus is a higher predicate and the rest of the sentence is an event nominal, meaning roughly 'the event of Rasoa's washing clothes'. If this approach is correct, then (16b) and (17b) would not involve *wh*-movement at all, and no violence would be done to the evidence from argument extraction that

VPs in Malagasy are islands. On the other hand, if clefts are analyzed as biclausal constructions in which the focus is a higher predicate and the rest of the sentence is a headless relative, then (17b) would involve *wh*-movement of a null operator corresponding to the instrumental phrase, suggesting that VPs are not islands in this language after all. Which of these approaches is superior remains to be determined.

Finally, it is appropriate to step back and ask how strong the extraction evidence is for the VP raising analysis of VOS clauses. As mentioned earlier, many Western Austronesian and Formosan languages have an extraction pattern consistent with the VP raising analysis. For the evidence to be compelling, one would hope to find similar extraction patterns outside the Austronesian family – for instance, in Mayan languages, or in other VOS languages that have not yet been documented extensively. Investigation is needed to determine whether such patterns do, in fact, occur.

3.2.2 *Raising of remnant VPs*

Further evidence for VP raising can be found in languages whose clauses begin with V but are not rigidly subject-final. Crucial to an understanding of this evidence is the notion of remnant movement.

In theories such as antisymmetry, in which all movement is to the left, the appearance of rightward movement is achieved through multiple leftward movements. Suppose an element *X* surfaces to the right of some constituent *Y* from which it has been extracted. The relevant surface order can be derived by two leftward movements: first *X* raises out of *Y* and then the rest of *Y* raises over *X*. The key assumption is that *X* has already been extracted from *Y* at the point when *Y* raises. Movement of a constituent that some element has already been extracted from is known as remnant movement (see, e.g., Den Besten and Webelhuth 1990, the references cited below, and – for a formalization – Stabler 1999).[4]

In a series of papers, Massam (2000, 2001a, 2001b) has proposed that clauses in Niuean, a VSO language, are derived by raising of a remnant VP to a higher specifier. (See Lee 2000 for a similar proposal for Quiavini Zapotec.) Although Massam's hypothesis deals specifically with Niuean, it clearly has the potential to generalize to other languages whose clauses begin with V. The observation raises the possibility that there might be a single, universally valid derivation of VSO order, one involving raising of a remnant VP. If so, VP raising might succeed in explaining the typological links between VOS and VSO languages and their perceived similarities to SVO languages (see section 1). Pragmatically neutral clauses in all three language types would originate as SVO; then VP would move leftward, either intact or as a remnant, to produce clauses that would be VOS or VSO.

Niuean is an ergative Polynesian language. This language resembles some other VSO languages in exhibiting VSO order only in clauses containing verbs (see Chung 1990 on Chamorro, and Carnie 1995 and Doherty 1996 on Irish). Clauses with non-verbal predicate phrases – DP or PP – have a word order in

which the entire predicate XP precedes the subject. In other words, these clauses have XOS order, where X represents the predicate head:

(18) Niuean:
a. Ko e kamuta a au.
Pred Abs carpenter Abs I
'I'm a carpenter.' (Seiter 1980: 53)
b. Hā he fale a ia.
Pred in house Abs she
'She is in the house.' (Massam 2000: 105)

Like other Polynesian languages, Niuean has a construction traditionally known as noun incorporation. Massam (2001b) demonstrates that the bare object nominal in this construction is not just N, but rather a maximal projection with the internal structure of NP as opposed to DP (see also Seiter 1980: 69–71). Importantly, this object NP forms a constituent with the verb and that constituent (bracketed in the examples below) precedes the subject. The word order of so-called noun incorporation clauses, therefore, is VOS:

(19) Niuean:
a. Ne [inu kofe kono] a Mele.
Past drink coffee bitter Abs Mele
'Mary drank bitter coffee.' (Massam 2001b: 158)
b. Kua [kai ika mo e taloa] a mautolu he mogonei.
Perf eat fish with Abs taro Abs we.pl.ex at now
'We are eating fish and taro right now.' (Seiter 1980: 70)

All other Niuean clauses have fixed VSO order. Predicates that are verbs or adjectives must be separated from their complements by the subject, as (20) shows:

(20) Niuean:
a. Ko e tele e Sione a Sefa.
Pres kick Erg Sione Abs Sefa
'Sione's kicking Sefa.' (Seiter 1980: 29)
b. Iloilo lahi a ia he vagahau Niuē.
clever very Abs she at language Niuean
'She's very good at Niuean.' (Seiter 1980: 3)

Massam's account of these facts runs as follows. Because so-called incorporated nouns are NPs as opposed to Ns, they cannot incorporate via head-to-head-adjunction (see Baker 1988a, 1996) and therefore surface as free-standing complements of V. These NP complements have no Case feature and so need not raise out of VP for Case-checking purposes. DP complements of N or P check their Case feature in situ, but DP complements of V must raise out of VP to check their Case in the specifier of a functional head. Finally, every Niuean clause originates

as SVO and then undergoes raising of the predicate XP, either intact or as a remnant. These assumptions combine to derive the word-order patterns just surveyed. Examples (18–19) are produced by raising the intact predicate XP, which is a DP in (18a), a PP in (18b), and a VP in (19). Example (20a) is produced by first raising the direct object out of VP for Case-checking purposes and then raising the remnant VP around it.

Can this sort of approach be extended to other languages whose clauses begin with V? A key component of Massam's account of Niuean is the assumption that remnant VPs are created for theoretically motivated reasons (see also Lee 2000). For instance, the reason why DP complements must exit from VP is so that their Case feature can be checked. The observation suggests that in order for the remnant VP analysis to generalize to other clause types, the raising of other complements out of VP would have to be given a theoretical rationale. It is a completely open question whether this can be done. To get some sense of the issues, consider the following.

(i) In many languages whose clauses begin with V, including Quiavini Zapotec, Niuean, and Malagasy, CP complements of V must surface at the right edge of the clause, following the subject. In a remnant VP analysis, these CPs (bracketed in the examples below) would presumably have exited from VP before VP was moved leftward:

(21) Quiavini Zapotec:
B-quilly Lieeb Gyeeihlly [y-to'oh Gyeeihlly ca'rr].
Perf-persuade Felipe Mike Irr-sell Mike car
'Felipe persuaded Mike to sell the car.' (Lee 2000: 156)

(22) Niuean:
Pehe mai a lautolu [ne kaihā e koe e moa].
say Dir1 Abs they Past steal Erg you Abs chicken
'They say that you stole the chicken.' (Seiter 1980: 125)

(23) Malagasy:
Mihevitra Rabe [fa mitady ny zaza Rasoa].
think.AT Rabe that look.for the child Rasoa
'Rabe thinks that Rasoa is looking for the child.' (Keenan 1976b: 276)

What could motivate this sort of CP raising? Lee (2000: 156–158) suggests that in Quiavini Zapotec, CPs must raise out of VP in order to be licensed in the specifier of a higher functional head L(icensing). While such a suggestion leads to the desired result, its theoretical rationale is rather cloudy. Licensing in the specifier of L looks suspiciously like Case licensing – a sort of licensing that CPs are widely assumed not to need, and even to resist (see Stowell 1981; a different view is offered by Chung 1991). But if L is not a Case licenser, what exactly is it, and what other evidence supports its existence?

(ii) In fixed VSO languages such as Irish and – arguably – Niuean, PP complements of V must surface to the right of the subject. In a remnant VP analysis, these complements too would presumably have exited from VP prior to VP raising:

(24) Irish:
Rinne leannán dínn.
made lovers of-us
'We became lovers (lit. Lovers made of us).' (McCloskey 2001a: 170)

(25) Niuean:
To fanogonogo a au ki a koe.
Fut listen Abs I to Pers you
'I'll listen to you.' (Seiter 1980: 147)

Massam's (2001b) proposal with regard to examples like (25) is that Niuean simply has no complement PPs. Instead, the goal PP in (25) is an adjunct that can be stranded when the lower VP to which it is adjoined undergoes VP raising. It is not immediately obvious that such a proposal is tenable. If there were no complement PPs at all in Niuean, what could explain their systematic absence? At the same time, one would not want to claim that the PPs in (24–25) must raise out of VP for Case-checking purposes, since PPs are standardly assumed not to have Case features.

(iii) In certain verb-initial languages, such as Chamorro (Chung 1998) and Maori (Bauer et al. 1997), all complements of V – whatever their category type – are freely ordered with respect to the subject. The Chamorro examples below illustrate this for complements that are DPs (26), CPs (27), and PPs (28):

(26) a. Ha-bäba i petta si Antonio.
agr-open the door Antonio
'Antonio opened the door.'
b. Ha-bäba si Antonio i petta.
agr-open Antonio the door
'Antonio opened the door.'

(27) a. Mungnga gui' [na u-maigu' än taluani] i neni.
refuse himself Comp agr-sleep when afternoon the baby
'The baby refuses to sleep in the afternoons.'
b. Mungnga gui' i neni [na pära u-maigu' än taluani].
refuse himself the baby Comp Fut agr-sleep when afternoon
'The baby refuses to sleep in the afternoons.'

(28) a. Mamahlao nu hämi si Dolores.
agr.ashamed Obl us Dolores
'Dolores is ashamed of us.'

b. Mamahlao si Dolores nu hämi.
agr.ashamed Dolores Obl us
'Dolores is ashamed of us.'

Whether this word order could be explained in terms of remnant movement is an extremely interesting question. Suppose one were to infer from the (b) examples above that all types of Chamorro complements must exit from VP in order to be licensed. Then it would seem to follow that the predicative constituent that raises in the (a) examples is not VP but (the remnant of) some substantially larger constituent – AgrOP, LP, or even TP.[5] If so, some explanation must be found for the fact that this substantially larger constituent can undergo raising in Chamorro but not, say, Niuean. What could the explanation be?

It may well be that an overall theory of remnant movement would successfully resolve all these issues. Until such a theory is developed, it remains unsettled exactly what range of clause types beginning with V can be derived by raising of (a remnant) VP.

3.2.3 *More on VP raising and extraction*

Regardless of how the issue of theoretical motivation is resolved, a clear empirical prediction is made by the hypothesis that all verb-initial clauses are derived, one way or another, by raising of VP or equivalent: non-subject arguments that can surface outside VP, to the right of the subject, should be accessible to *wh*-movement (see Rackowski and Travis 2000: 129).[6]

The Austronesian languages with VOS clauses provide an instructive testing ground for this prediction. It has already been shown (in section 3.2.1) that two fixed VOS languages, Seediq and Malagasy, conform completely to expectations as far as extraction of arguments is concerned. In these languages, non-subject arguments must surface inside VP and are completely inaccessible to *wh*-movement. Toba Batak is another fixed VOS language that behaves as predicted (see Clark 1984; Schachter 1984). In this language, indirect objects are evidently freely ordered with respect to the subject, but direct objects must surface to the immediate right of the verb, within VP (see (29)). Therefore, both subjects and indirect objects should be eligible for *wh*-movement, but direct objects should not be. That this is so can be seen from the constituent questions in (30).

(29) Toba Batak:
a. [Mangalean missel i tu soridadu i] jeneral i.
AT.give missile Det to soldier Det general Det
'The general gave the missile to the soldier.' (Clark 1984: 12)
b. [Mangalean biang] si Torus tu si Ria.
AT.give dog PM Torus to PM Ria
'Torus is giving a dog to Ria.' (Schachter 1984: 137)
c. [Mangida si Ria] si Torus.
AT.see PM Ria PM Torus
'Torus sees Ria.' (Schachter 1984: 123)

(30) Toba Batak:
a. Isa [mangida turiturian] ___ ?
who? AT.see play
'Who is seeing a play?' (Schachter 1984: 126)
b. Tu ise [mangalean missel i] jeneral i ___ ?
to who? AT.give missile Det general Det
'To whom did the general give the missile?' (Clark 1984: 12)
c. *Aha [mangida ___] si John?
what? AT.see PM John
'What is John seeing?' (Schachter 1984: 126)

The extraction pattern is not as well-behaved in Austronesian languages with verb-initial order – languages that allow both VOS and VSO clauses. The prediction is that subjects and direct objects in these languages should be able to undergo *wh*-movement, since both can surface outside VP. Boumaa Fijian conforms to this prediction. Clauses in this language are VOS or VSO depending on context, although VOS is evidently more frequent in elicitation (see (31) and Dixon 1988: 243). Consistent with this profile, interrogative phrases can optionally undergo *wh*-movement whether they are subjects or direct objects. When the subject has been extracted, the verb continues to exhibit a proclitic subject pronoun (see chapter 14) which is probably a form of subject–verb agreement (see Dixon 1988: 33).[7] When the direct object has been extracted, the verb exhibits the form of the transitive suffix appropriate for direct objects that are common nouns as opposed to pronouns. This inflection suggests that the gap left by *wh*-movement is a trace, not a resumptive pronoun (see Dixon 1988: 170; and chapter 55). See (32):

(31) Boumaa Fijian:
a. [E rai-ca a gone] a qase.
3sg see-Tr Art child Art old.person
'The old person saw the child.' (Dixon 1988: 243)
b. [E rai-ca] a gone a qase.
3sg see-Tr Art child Art old.person
'The child saw the old person.' (Dixon 1988: 243)

(32) Boumaa Fijian:
a. O cei [e sabi-ci i'o] ___ ?
Proper who? 3sg hit-Tr you
'Who hit you?' (Dixon 1988: 170)
b. O cei [o aa rai-ca] ___ ?
Proper who? 2sg Past see-Tr
'Who did you see?' (Dixon 1988: 170)

On the other hand, Tagalog does not behave as predicted. Even though the direct object in this language is freely ordered with respect to the subject (see (33)), it is – as numerous authors have observed – completely inaccessible to extraction

(see, e.g., Schachter 1976b: 500; Kroeger 1993: 23–24). Consider the relative clauses in (34), which can be assumed to involve *wh*-movement of a null operator. Although the subject can be relativized, as (34a) shows, the direct object cannot be (34b):

(33) Tagalog:
a. [Nagbigay ng libro sa babae] ang lalaki.
AT.gave Gen book Dat woman Nom man
'The man gave the woman a book.' (Kroeger 1993: 111)
b. [Bumasa] ang lalaki ng diyaryo.
AT.read Nom man Gen newspaper
'The man read a newspaper.' (Schachter 1976b: 500)

(34) Tagalog:
a. lalaki-ng [bumasa ng diyaryo] ___
man-Linker AT.read Gen newspaper
'the man who read a newspaper' (Schachter 1976b: 500)
b. *diyaryo-ng [bumasa] ang lalaki ___
newspaper-Linker AT.read Nom man
'the newspaper that the man read' (Schachter 1976b: 500)

Other Philippine languages resemble Tagalog in permitting VSO clauses but restricting *wh*-movement to subject arguments; see Keenan (1972: 180–181).

If one steps back and reviews the Austronesian evidence just surveyed, two conclusions suggest themselves. First, there is considerable empirical support for the claim that VOS clauses in some languages – Seediq, Malagasy, Toba Batak – are derived by raising of VP or equivalent. Second, it would be far more difficult to maintain the more general hypothesis that verb-initial clauses are always derived by (remnant) VP raising. For further commentary, see section 5.

3.3 *Other evidence*

Three additional kinds of evidence that have been offered for the VP raising hypothesis are summarized below.

Lee (2000) argues that in Quiavini Zapotec, a fixed VSO language, verbs pattern with maximal projections (DPs and PPs) in their ability to be modified by modal and adverbial clitics and to serve as the target of constituent negation. She concludes that the V that surfaces at the left edge of the clause is actually a remnant VP that has raised to the specifier of T.

Rackowski and Travis (2000) use the left-to-right order of adverbials in Malagasy and Niuean to argue for iterative raising of VP. Their argument relies on Cinque's (1999) theory of adverbial placement (see chapter 4), a theory constructed to account for his claim that there is a universal left-to-right order of linguistic expressions with adverbial meaning. Cinque's theory holds that adverbials are specifiers of functional heads whose hierarchical arrangement is invariant across

languages. Rackowski and Travis observe that in Malagasy (a fixed VOS language) and Niuean (a fixed VSO language), the surface order of adverbials is roughly the mirror image of what Cinque's theory predicts. Their account of this mirror-image effect assumes that (i) adverbials in Malagasy and Niuean are heads, not specifiers, and (ii) VP raises iteratively through the specifiers of these heads, pied-piping ever larger amounts of functional structure, to produce the observed surface order. Although iterative VP raising could indeed achieve this result, it is by no means the only analytic possibility. Massam (2002) points out some difficulties with such an account of Niuean. She then advances the proposal that the surface order of Niuean adverbials is produced not by VP raising, but instead by iterative adjunction of the abstract verbal head v to higher adverbial heads.

Finally, Longobardi (2000a) uses the interpretation of unmodified bare nouns in Italian to argue that postverbal subjects in this language originate as the subjects of SVO clauses in which VP then raises leftward. The argument relies on two observations: first, bare noun subjects in SVO clauses have a generic interpretation only when they have a modifier, and second, bare nouns that serve as postverbal subjects in VOS clauses display exactly the same restriction. From this, Longobardi (2000a: 695) concludes, "Applying Occam's razor to the set of lexically ungoverned positions, . . . superficially postverbal generic subjects actually occur in the independently best known of all such positions, precisely that of preverbal subjects." The conclusion does not seem fully convincing, given that no account is offered of the restriction on bare nouns, which remains essentially unanalyzed, and given that the same restriction is evidently exhibited by bare nouns that are direct objects (Longobardi 2000a: 700–701).

4 The motivation for VP raising

What might motivate VP raising? It was observed in section 3.1 that if specifiers are universally projected to the left, then VOS clauses would have to be derived from SVO clauses by leftward movement of VP or equivalent. In the Minimalist framework (see Chomsky 1995c), overt syntactic movement is forced by a head's need to check some strong feature against a comparable feature of the category in its specifier. The natural assumption within this framework is that VP raises to the highest specifier of the clause in order to check some strong feature of the clausal head. The characterization immediately suggests the Extended Projection Principle (EPP). Originally stated as the principle that clauses must have subjects (Chomsky 1982: 9–10), the EPP has come to be understood as the requirement that the subject DP raise out of predicate-internal position to check a strong feature of T, usually identified as [D] (see Chomsky 1995c: 232) or, more simply, EPP (see Chomsky 2001b: 8–9). And indeed, several researchers have independently proposed that VP raising is driven by the need to check a strong feature of T that is, in some sense, the EPP-feature.

These proposals build on Alexiadou and Anagnostopoulou's (1998) hypothesis that in certain null subject languages with VSO clauses (such as Greek and Irish),

the EPP is satisfied by head-movement of V to the clausal head. More precisely, Alexiadou and Anagnostopoulou claim that V raises so that its agreement morphology, which is pronominal and therefore [D], can check the clausal head's strong [D] feature. In the proposals of interest here, this core intuition is recast so that the moved constituent is (a remnant) VP rather than V, and the feature to be checked is not [D] but some feature more characteristic of predicates.

For instance, Massam (2000, 2001a, 2001b) claims that the VSO clauses of Niuean arise when (a remnant) VP raises to check the [Pred] feature of the clausal head. Aldridge (2002) makes a similar proposal for the VOS clauses of Seediq.

Pearson (2000a) claims that the VOS clauses of Malagasy are produced when a maximal projection considerably more inclusive than VP (i.e., TP) raises to check the [T] feature of a higher clausal head. His proposal recalls Massam and Smallwood's (1997) earlier claim that VSO clauses in Niuean are derived by head-movement of V to T, a movement driven by V's need to check its [T] feature.

More generally, Massam and Smallwood (1997) hypothesize that the inflectional feature essential to the formation of clauses is [D] in languages like English, but [T] in languages like Niuean. This idea is taken up by Davies and Dubinsky (2001b), who propose that the EPP is parameterized to be D-prominent or V-prominent. Languages in which the EPP is D-prominent demand that a DP raise to the specifier of T; languages in which the EPP is V-prominent demand that (some projection of) V raise to T (or, presumably, to T's specifier; but see Carnie 1995).

The proposals differ in the identity of the strong feature claimed to motivate VP raising: [Pred], [T], or [V]. Although these features are all intended to pick out the predicate as opposed to the subject, they are not equivalent, empirically or theoretically. Here are some relevant considerations.

Suppose one assumes (uncontroversially) that for the strong feature to be more than a diacritic for VP raising, it must have some independent syntactic rationale. Following the example set by the original EPP-feature, [D], one might imagine that the strong feature should be a category feature of the raised VP or equivalent that can be annotated on the clausal head.

For [V], the difficulty with such a scenario is empirical. It has already been mentioned that the clauses of some languages have predicate-first order whether the predicate head is verbal or non-verbal (see section 3.2.2). Niuean is such a language; so are the other Polynesian languages and Chamorro. Assuming that clauses in these languages are derived by raising of the predicate XP, that raising could not be driven by the need to check a [V] feature of the clausal head, since predicate DPs and PPs must be forced to raise even though they are not [V].

For [Pred] and [T], the issues seem more theoretical. In most Minimalist conceptions of the clause, [Pred] is not a category feature, although such a category could certainly be given independent existence in a more finely articulated structure for the clause. As for [T], it is usually assumed to be the defining category feature of the clausal head, not a feature of VP (or, more generally, of the predicate XP). Hence, if [T] is chosen to be the strong feature, two sorts of readjustments

must be made. The raised VP or predicate phrase must have the feature [T] as well (see Massam and Smallwood 1997; Pearson 2000a), and matters must be arranged so that VP raising is not an inevitable, universal consequence of the fact that T is the head of the clause. In other words, it must remain possible for the EPP-feature on the clausal head to be [D] *or* [T].

In sum, while VP raising might well be motivated by the need to check an EPP-feature, the precise identity of that feature remains unclear.

If VP raising is motivated by the EPP, what empirical evidence could reveal that this is so? One potential line of investigation is suggested by Miyagawa's (2001) discussion of the EPP and scrambling in Japanese. Miyagawa shows that when the subject of a Japanese clause is the universal quantifier *zen'in* 'all', it must have wide scope with respect to sentential negation (see chapter 53). But, surprisingly, such a subject can have narrow scope just in case an object has been scrambled to the left. His account of this pattern runs as follows. First, in order for an element to have narrow scope with respect to negation, it must be c-commanded by Neg, a functional head located below T but above the abstract verbal head v in the structure of the clause. Second, all of the predicate's arguments originate within vP: the subject originates as the specifier of v, the object originates within the VP complement of v, and so on. Third, some DP must raise to the specifier of T to check T's EPP-feature. Miyagawa claims that when the subject raises, the result is an unmarked (SOV) clause in which the subject must have wide scope with respect to negation. But, crucially, it is also possible for the object to raise to check T's EPP-feature – a movement characterized as A-scrambling in other work. When the object raises, the result is an OSV clause in which the subject remains within vP, in a position where it can have narrow scope with respect to negation.

Two aspects of Miyagawa's account are useful here: first, the claim that maximal projections besides the subject can raise to satisfy the EPP; and second, the insight that in such cases, the subject remains within vP for scope and specificity purposes (see Diesing 1992b).[8] Generalizing these ideas to VP raising, one would expect that if this movement does satisfy the EPP, the subject should remain in situ, within vP, where it should be able to have narrow scope with respect to sentential operators such as negation or existential closure. It should therefore not exhibit the necessarily wide scope or specificity which Keenan (1976c) claims are characteristic of subjects and which Diesing (1992b) associates with higher syntactic positions in the clause (notably, the specifier of T).

It is well known that in Malagasy, the DP identified in this chapter as the surface subject exhibits some semantic characteristics of traditional subjects after all: it must be specific – in fact, definite (see Keenan 1976b: 252–254 and many others). If one assumes that VP raising in this language satisfies the EPP, the pattern seems contrary to expectations. But, given the controversy over whether so-called subjects in Malagasy should be analyzed instead as topics, and given that topics are often associated with definiteness (see section 2.2), it is difficult to know what, if anything, to conclude.

A more promising array of facts is presented by Tongan, a Polynesian language closely related to Niuean. Tongan is a morphologically ergative language. Like Niuean, it exhibits XOS order in clauses with non-verbal predicates and has object incorporation; unlike Niuean, it allows VOS as well as VSO order in clauses containing verbs. The point of interest is that subjects in Tongan need not have wide scope or be specific. (This holds true whether the absolutive or the ergative noun phrase is identified as the subject of a transitive clause.) The subject can, for instance, be a non-specific DP headed by the non-specific article *ha*, which generally has narrow scope with respect to sentential operators (see Churchward 1953).[9] Consider the following examples:

(35) Tongan:

a. ʻOku tapu ke hū ha sela tangata ki he ʼapi pōpula . . .
T forbidden T enter a warder male to the prison
'It is unlawful for a male warder to enter a prison . . .'
(Churchward 1953: 59)

b. Naʻa ku faʻo ia ki ha puha.
T I put it at a box
'I put it into a box (some box or other).' (Churchward 1953: 271)

c. He ʼikai lakasi ʼe ha taha au.
T not surpass Erg a one me
'No one can beat me.'

d. Naʻe ʼikai ke kai ʼe he tangata ha ika.
T not T eat Erg the man a fish
'The man didn't eat any fish.'

These facts are expected if Tongan clauses are derived by raising of VP, either intact or as a remnant, and VP raising satisfies the EPP.

It might be appropriate at this point to raise the possibility of a deeper connection between VP raising and ergativity. As was observed earlier, quite a few languages with VOS clauses are morphologically ergative (see section 2.2 and the references cited there). One popular approach to ergativity within Principles and Parameters Theory holds that in ergative languages, the predicate's arguments originate within vP and remain there throughout overt syntax: no DP raises to satisfy the EPP. Within the strand of research explored here, that could well be because the EPP in these languages forces raising of VP instead. Morphological ergativity might, in other words, emerge as an indirect consequence of VP raising and therefore of the EPP. The mechanisms that would achieve such a result have yet to be worked out.

Further research is needed to determine whether the subject remains within vP for scope and specificity purposes in the languages for which VP raising appears to be well-motivated – Malagasy, Seediq, Toba Batak, and Niuean. If the results are as predicted, there would be good reason to believe that VP raising is forced by some version of the EPP.

5 Are all VOS clauses derived by VP raising?

5.1 Overview

The preceding discussion leads one to expect that if a language's verb-initial clauses are derived by VP raising, it should have the syntactic profile outlined in (36):

(36) **The profile of languages whose verb-initial clauses are derived by VP raising:**
   a. VP coordination is allowed.
   b. The subject is accessible to extraction. So are other constituents which originate outside VP or which can be shown to have raised out of VP. All other subconstituents of VP are inaccessible to extraction.
   c. The subject can have narrow scope with respect to sentential operators such as negation and existential closure.

Although complete evidence is lacking for many of the languages surveyed in section 2.1, initial indications are that Malagasy, Seediq, Toba Batak, and Niuean conform quite closely to this profile (for details, see sections 3 and 4).

In view of this, one might be tempted to go further and conjecture that all VOS clauses – perhaps even all verb-initial clauses – are derived from an SVO structure by raising of (a remnant) VP or equivalent to the specifier of the clausal head. Part of the appeal of such a conjecture is its compatibility with Kayne's theory of antisymmetry and, more generally, with the proposal that specifiers are universally projected to the left (see section 3.1). So it is of some theoretical interest that the conjecture is probably not correct. There are languages whose syntactic profile deviates from (36) in ways that argue that VP raising could not be responsible for their VOS clauses. Among these languages are Tzotzil and Chamorro.

5.2 Tzotzil

Tzotzil is a Mayan language with null arguments and an ergative-absolutive system of agreement. Pragmatically neutral clauses in this language are rigidly VOS: the direct object always follows the verb and precedes the subject. PPs display a wider range of word-order possibilities, evidently being able to occur after V or any constituent further to the right (Aissen 1987: 12). Consider the following examples (more are cited in section 2.1):

(37) a. 7i-yal la ta te7 ti vinik-e.
   cp-descend cl from tree the man-cl
   'The man climbed down from the tree.' (Aissen 1987: 12)
   b. Ch-ba s-man chitom li Xun-e.
   icp-go A3-buy pig the Xun-cl
   'Xun will go to buy pigs.' (Aissen 1987: 16)

The fact that Tzotzil has fixed VOS order leads one to expect that if this word order is produced by VP raising, direct objects should be inaccessible to extraction (see (36b)). Any PPs that must surface to the left of the subject, within VP, should be inaccessible as well. However, in a detailed study, Aissen (1996) shows that subjects, direct objects, and PPs in Tzotzil are all eligible for *wh*-movement. In the constituent questions below, the interrogative phrases that have been extracted include a subject (in (38a)), a direct object (38b), and a goal PP (38c):

(38) a. Buch'u s-pas mantal ___ ?
who? A3-do order
'Who's giving the orders?' (Aissen 1996: 451)

b. K'usi av-il ___ ?
what cp.A2-see
'What did you see?' (Aissen 1996: 451)

c. [Buch'u ta s-na] ch-a-bat ___ ?
who? P A3-house icp-B2-go
'To whose house are you going?' (Aissen 1996: 470)

The significance of this extraction pattern is increased by the fact that it is clearly produced by movement as opposed to resumption (see chapter 55). Aissen (1996) establishes that when an interrogative phrase is the possessor of a DP that is a prepositional object or the subject of a transitive verb, *wh*-movement is not legal unless the interrogative phrase raises to the specifier of the PP or subject DP and the entire PP or DP is pied-piped (see chapter 50). For instance, in the examples surrounding this paragraph, the interrogative phrase has visibly moved to the left edge of the pied-piped constituent (enclosed in brackets), which is a PP in (38c) and (39a) and the subject DP in (39b):

(39) a. [Buch'u ta s-na] av-ik'ta komel l-a-bolsa-e ___ ?
who? P A3-house A2-leave Dir the-A2-bag-cl
'In whose house did you leave your bag?' (Aissen 1996: 470)

b. [Buch'u x-ch'amal] y-elk'an chij ___ ?
who A3-child A3-steal sheep
'Whose child stole sheep?' (Aissen 1996: 460)

Compare the ungrammatical examples below, in which pied-piping has not occurred:

(40) a. *Buch'u cha-b-at [ta s-na ___]?
who? icp-B2-go P A3-house
'Whose house are you going to?' (Aissen 1996: 469)

b. *Buch'u av-ik'ta komel a-bolsa [ta sn-a ___]?
who? A2-leave Dir A2-bag P A3-house
'Whose house did you leave your bag at?' (Aissen 1996: 469)

c. *Buch'u y-elk'an chij [x-ch'amal ___]?
who? A3-steal sheep A3-child
'Whose child stole sheep?' (Aissen 1996: 460)

Aissen's account of these patterns is phrased in terms of some central ideas of Principles and Parameters Theory: the Empty Category Principle, the *wh*-criterion, and abstract Agreement. For present purposes, the details of her account are less important than the observation that certain kinds of constituent questions are ungrammatical unless pied-piping has occurred. That fact reveals that constituent questions in Tzotzil do not have an interrogative phrase that is base-generated in the specifier of C and co-indexed with a null resumptive pronoun. The reason is this: were such a resumption strategy available, the questions in (40) should be grammatical. There is no reason to expect them not to be, given that comparable non-questions with null pronouns are well-formed:

(41) I-kom [ta s-na *pro*].
cp-remain P A3-house
'He remained at his house.' (Aissen 1996: 468)

Given all this, the strong ungrammaticality of (40) argues that a resumption strategy must be simply unavailable. The corresponding questions in (39) must therefore be derived via movement.

In short, direct objects in Tzotzil are accessible to *wh*-movement, even though they surface to the left of the subject, within VP. From this it follows that VPs in Tzotzil are not islands, and so could have not undergone leftward movement, contrary to what one might have assumed. The conclusion we are led to is that VOS clauses in this language are not derived by VP raising after all.

5.3 Chamorro

Chamorro is an Austronesian language with null arguments and verb-initial order. In this language, clauses with non-verbal predicates have the entire predicate phrase preceding the subject; clauses containing verbs, which are the focus of interest here, can be VSO or VOS. Consider the following examples:

(42) a. Ha-pula' i näna i patgon-ña.
agr-undress the mother the child-agr
'The mother undressed her child.' (Chung 1998: 150)
b. Ha-pula' i patgon-ña i näna.
agr-undress the child-agr the mother
'The mother undressed her child.' (Chung 1998: 151)

Now, if Chamorro's verb-initial order were produced by raising of (a remnant) VP, one would expect VP coordination to be allowed (see (36a)). This expectation

is realized: clauses can routinely have a coordinate VP preceding the subject. See section 3.1 and the examples below:

(43) a. [Mu-ma'a'ñao] ya [ha-yuti' i salappi'] i säkki.
agr-afraid and.then agr-drop the money the thief
'The thief got scared and dropped the money.' (Chung 1998: 133)
b. [Ha-dandan i gitala] ya [k*um*anta] si Juan.
agr-play the guitar and.then agr.sing Juan
'Juan played the guitar and sang.'

But implicit in the VP raising hypothesis is a further prediction: it should be impossible for a coordinate VP which is incomplete – which lacks some subconstituent of one of its conjuncts – to occur to the left of the subject. This is because the extraction that would have created such a remnant VP would violate Ross's (1986) Coordinate Structure Constraint.

Surprisingly, this further prediction is not realized. Chung (1990) shows that in clauses such as (44), the subject can be preceded by a coordinate VP that appears to be incomplete. In (44a), for instance, the right conjunct VP is missing its direct object, which surfaces after the subject. In (44b), the right conjunct VP is missing a PP complement:

(44) a. [Mu-ma'a'ñao] ya [ha-yuti'] i säkki i salappi'.
agr-afraid and.then agr-drop the thief the money.
'The thief got scared and dropped the money.' (Chung 1998: 134)
b. kao [ligát] yan [ti kontra] un lai yan Konstitusión Marianas
Q agr.legal and not agr.opposed a law with Constitution Marianas
'whether a law is legal and not in conflict with the Constitution of the Marianas' (Chung 1998: 135)

What is important is that not all types of apparently incomplete coordinate VPs are permitted. For instance, when it is the *left* conjunct VP whose direct object surfaces after the subject, the result is ungrammatical, as (45) shows:[10]

(45) *[Ha-dandan] ya [k*um*anta] si Juan i gitala.
agr-play and.then agr.sing Juan the guitar
'Juan played the guitar and sang.'

Chung's account of these facts rests on the claim that in (44), there is no remnant VP whose creation would have violated the Coordinate Structure Constraint. Instead, the coordinate VP is intact and the subject simply surfaces within its right conjunct. As before, the exact details of the analysis are irrelevant. What matters is that if Chamorro clauses were derived by leftward movement of (a remnant) VP, (44) should be ill-formed. The fact that (44) is grammatical argues that the verb-initial order of this language is not produced by VP raising, contrary to what one might have initially supposed.

Further evidence against a VP raising analysis of Chamorro clauses is provided by the semantic characteristics of surface subjects. Recall that if Chamorro had VP raising and that movement were forced by the EPP, the subject should surface in situ, within vP, where it should be able to have narrow scope with respect to sentential operators such as negation and existential closure (see (36c)). But, contrary to expectations, there are circumstances under which the subject cannot have narrow scope. Chung (1998: 102–107, 112–117) shows that Chamorro subjects which are external arguments must be specific. This amounts to saying that any subject that originates in the specifier of v must surface outside vP, the domain of existential closure. Chung (1998: 92–99) also shows that Chamorro subjects differ from non-subjects in being unable to be negative concord items (see chapter 45). Assuming that negative concord items are interpreted as narrow-scope indefinites, this distribution strongly suggests that subjects cannot have narrow scope with respect to negation.

In short, Chamorro seems to be another language whose verb-initial clauses are not derived by VP raising.

5.4 Verb-initial clauses that are only apparent

The discussion of this chapter has so far proceeded as if the identification of VOS clauses is a straightforward matter. It should be acknowledged here that this is not always so. In some languages, clauses that appear to be verb-initial may in fact be SVO clauses in which the subject is null.

Spanish could well be a language of this type. Although Spanish is traditionally viewed as an SVO language with some verb-initial clauses (see section 2.1), some recent research has suggested that this language might not have a classical version of the EPP – a requirement forcing some DP to raise to the specifier of the clausal head. In a thoughtful study, Goodall (2001) argues that Spanish does indeed have a classical EPP requirement, one satisfied in SVO clauses by raising of the subject DP. He goes on to propose that in verb-initial clauses, the EPP is satisfied by raising of a null adverbial. In other words, these apparently verb-initial clauses have an element occupying the specifier of the clausal head, and in this sense are actually SVO. Notice that if this is so, Spanish is simply irrelevant to the issue of whether verb-initial clauses are universally derived from an SVO structure by leftward movement of VP.

Could this sort of approach to verb-initial order be used to defuse the evidence just presented (in sections 5.2 and 5.3) that VOS clauses in Tzotzil and Chamorro do not involve VP raising? Conceivably. It should be reiterated, though, that both Tzotzil and Chamorro are languages in which no pragmatically neutral clauses are overtly SVO. Consequently, in order for such an approach to get off the ground, one would need to maintain that every pragmatically neutral clause has an SVO structure in which the highest specifier is not visibly occupied. Whether evidence could be found to support such an analytic move remains to be seen.

6 Conclusion: VOS, directionality, and late linearization

The conclusion that emerges from section 5 is that not all VOS clauses are derived from an SVO structure by VP raising. Rather, it seems likely that there are multiple syntactic routes to VOS-hood: the VOS order of some clauses (e.g., in Seediq) is derived by VP raising, but the VOS order of other clauses (e.g., in Tzotzil) is not. Such a result falls in line with other research that suggests that there is no single, universally valid derivation of any given word-order type (see, e.g., Chung 1998 on VSO).

Suppose all this is accepted. Then the next question to address is how VOS order arises when no VP raising is involved.

Within some versions of Principles and Parameters Theory, the most straightforward way of answering this question is to appeal to the parametric setting of some universal principle. For instance, Georgopoulos (1991a) proposes that the X′ principle responsible for projecting the specifier has a directionality parameter associated with it. Setting that parameter to project T's specifier to the right leads to VOS order; setting it to project to the left leads to SVO order.

A directionality approach of this sort puts VOS clauses and SVO clauses on an equal footing for most syntactic purposes. Both clause types have the same hierarchical structure, neither is derivationally more complex than the other, and their linear order differences are traceable to a single parameter. The approach does not, of course, address the markedness issue of why SVO is a cross-linguistically common type of word order, whereas VOS is quite uncommon. But in this respect it does not differ much from a VP raising approach. The VP raising approach examined in section 4 claims that both VOS clauses and SVO clauses arise from a minimal SVO structure when some constituent raises to satisfy the EPP. When VP raises, the resulting word order is VOS; when the subject DP raises, the result is SVO. The initial structure of the two clause types is the same, and their derivational complexity seems equivalent. As before, the linear order differences are traceable to just one parameter – the content of the EPP-feature.

Word order is conceptualized differently in other versions of Principles and Parameters Theory and in Minimalist syntax (see, e.g., Halle and Marantz 1993; Chomsky 1995c; and others). Following a strand of thinking that goes back at least to McCawley (1968a), these frameworks assume that precedence relations are simply not represented in the syntax: clauses are unordered hierarchical structures that are linearized relatively late, after the derivation has left the syntax proper. (See the references cited in section 1.) Such an approach claims that SVO clauses and VOS clauses are syntactically identical (as long as no VP raising is involved). The two clause types are differentiated only when linear order is established, on the way to the phonology.

What matters here is that there are few if any empirical differences between a directionality approach to VOS and a late linearization approach. The two are

indistinguishable for almost all practical purposes. Consequently, much of the evidence that VOS clauses have their specifiers projected to the right need not bear on the syntax per se, since it can be recast in terms of late linearization.

For instance, Chung (1990, 1998) uses some intricate word-order evidence from Chamorro to argue that the specifiers of Chamorro clauses are projected to the right and the subject then lowers, optionally, to adjoin to some projection of [V]. In fact, many of the patterns she describes could equally well be produced via linearization – an alternative that fits more comfortably into Principles and Parameters Theory, given that lowering is not a standard type of movement. Chung does offer some evidence that the syntactic position of the lowered subject must be visible in Logical Form. It is not obvious how a late linearization approach would handle this evidence, which involves the interaction of quantification with the VP coordination pattern illustrated above in (44) (see section 5.3).

Georgopoulos (1991a) argues on the basis of cross-linguistic evidence that weak crossover effects arise in languages in which specifiers and complements are governed from different directions. Among other things, her proposal is intended to account for the absence of weak crossover effects in Palauan and other VOS languages. These languages, she claims, have no weak crossover because their specifiers and complements are both projected to the right (and, therefore, governed from the left). Crucial to the proposal is the assumption that bound pronouns observe the head government requirement of the Empty Category Principle. One current approach to the head government requirement is to relegate it to the phonology, broadly construed. If such an approach is tenable, one could conceivably restate Georgopoulos's proposal in PF terms as well.

Finally, Freeze and Georgopoulos (2000) contend that a directionality approach to word order accounts for certain differences in the expression of location, existence, and possession (see chapter 24) in languages of different word-order types. Their proposal aims to explain two descriptive generalizations. First, no verb-initial language has a lexical verb meaning 'have'; and second, no SOV language has a locative proform in existential sentences. What is of interest is that both generalizations actually concern the lexicon, not the syntax. Recent work in morphological theory (e.g., Anderson 1992; Halle and Marantz 1993) suggests that lexical insertion, like linearization, occurs late – after the derivation has branched to the phonology. If so, Freeze and Georgopoulos's account could conceivably be recreated outside the syntax proper. It should be noted, though, that the descriptive generalizations which are their point of departure might not be completely accurate. For instance, Chamorro is a verb-initial language but nonetheless has a lexical verb meaning 'have'. For discussion of the syntax and semantics of this verb, see Chung and Ladusaw (2004).

In conclusion, the VOS clauses that do not involve VP raising could be assumed to be VOS in the syntax. But most of the evidence is also compatible with the idea that the word order of these clauses – in fact, all word order – is the product of late linearization and therefore syntactically insignificant. Importantly, the two approaches that have been taken to (these) VOS clauses assume that they have the same hierarchical structure as SVO clauses.

NOTES

Thanks to Edward L. Keenan for his perceptive and spirited commentary on this chapter and to Nathan Sanders for his expert assistance with the formatting. Funding from the Academic Senate and from the Institute for Humanities Research, University of California, Santa Cruz, is gratefully acknowledged.

1 This conclusion extends to morphologically ergative languages if they are assumed to have the phrase structure described earlier in section 2.2.

2 Examples like (i) suggest that Tagalog has a pattern of VP coordination similar to that of Chamorro. See Kroeger (1993: 34–36) for discussion and a different analysis:

(i) [Huhugasan ko] at [pupunasan mo] ang mga pinggan.
Fut.wash.DV me.Gen and Fut.dry.DV you.Gen Nom Pl dish
'I will wash and you dry the dishes.' (Kroeger 1993: 34)

3 In (8a), *he* can be analyzed as an indefinite determiner or as the content of T. If the former, then each conjunct in this example is a predicate DP; if the latter, then each conjunct is T′. See Chung and Ladusaw (2004).

4 If the VP-internal subject hypothesis is adopted in one of its original forms and subjects are assumed to raise out of VP for Case or EPP reasons, then leftward movement of VP will always be an instance of remnant movement. The assumption in the text is, instead, that the subject originates within the maximal projection of v, an abstract verbal head that takes VP as its complement (Chomsky 1995c).

5 This is, in fact, the style of analysis proposed by Pearson (2000a) for Malagasy and by Aldridge (2002) for Seediq.
Examples (26–28) were provided by Chamorro consultants in Sunnyvale, California, and Saipan.

6 PP complements and adjuncts in Niuean must also surface to the right of the subject and are therefore predicted to be accessible to extraction. In fact, most of these PPs can be extracted only via a resumption strategy. See Seiter (1980).

7 Dixon (1988: 170) states that when the subject has been extracted, "the subject pronoun . . . is retained in the predicate." Since this pronoun routinely co-occurs with full DP subjects that surface to the right of VP (Dixon 1988: 33), it is arguably a form of subject agreement, not a resumptive pronoun.

8 Diesing (1992b) proposes that VP is the domain of existential closure, where the subject is assumed to originate as the specifier of V. In a theory in which the subject originates as the specifier of the abstract verbal head v, the obvious restatement of her proposal is that the domain of existential closure is vP.

An approach to scope and specificity effects different from Miyagawa's is suggested by the work of Alexiadou and Anagnostopoulou (1998). As mentioned earlier, Alexiadou and Anagnostopoulou claim that the word order of some VSO languages arises when V undergoes head-movement to the clausal head to satisfy the EPP. Their investigation leads them to recognize two subclasses of such languages: in one subclass, the subject remains within VP, while in the other, it raises to a specifier above VP but below the clausal head. If this further parameterization is adopted, the result would be that subjects could exhibit wide scope and specificity without actually having raised all the way to the specifier of the clausal head. All that would be necessary

would be for them to have raised out of VP. For various reasons, such an approach is not pursued here. The position taken in the text is essentially Miyagawa's position.

9 The Tongan negative *'ikai* in (35) is a syntactic verb that takes the negated clause as its complement (see, e.g., Churchward 1953: 62). Examples (35c–d) were provided by Tongan consultants in Los Angeles in the 1970s.

10 Examples (43b) and (45) were provided by Chamorro consultants in Sunnyvale, California, and Saipan. Thanks to David Adger for pointing out the significance of examples of type (45).

Praise for *The Blackwell Companion to Syntax*, Volumes I–V

"When I first started studying linguistics in 1960 it was possible for an assiduous student to read almost everything in the field. The success of the discipline has meant that those happy days are, happily, gone forever. Syntax is now so big that no one can read even a fraction of what is on offer. There have been two unfortunate results: first, today's syntacticians keep rediscovering old facts, often reinventing eccentric wheels; second, they keep complaining that other linguists ignore their work. The usual excuses are that the material we ought to have referred to is distributed, seemingly at random, among hundreds of books and articles; life is finite; institutional pressures are unrelenting; and it is hard enough keeping up with work done in one's own framework on one's own area of special interest, without trying to see what rival theorists in adjacent areas might have had to say on the matter at hand, however relevant in the long term their contribution might be.

Such excuses will no longer do. *The Blackwell Companion to Syntax* provides a comprehensive overview of the progress and achievements made in syntax over the last 35 years. A galaxy of international stars under the leadership of two distinguished linguists, Martin Everaert and Henk van Riemsdijk, has constructed an unparalleled and monumental survey of empirical facts and theoretical insights covering the entire field. Whether you are interested in parasitic gaps, Icelandic logophors, or quantifier scope ambiguity, you will find here the essential background to your own contribution. This is a major achievement and the Companion will rapidly become essential reading for all serious linguists."

Neil Smith, University College London

"*The Blackwell Companion to Syntax*, unique in character and designed with great skill and care, is sure to be a rich source of high-quality information on critically important topics, and an invaluable research tool for the study of language."

Noam Chomsky, Massachusetts Institute of Technology

"For any serious researcher interested in theoretical linguistics, this incredible companion will remain an important and extremely useful source of reference for years to come."

Yukio Otsu, Keio University, Tokyo

"The flow of linguistic theory is shaped by the empirical puzzles of the rocks and the banks of the river bed. Any particular rock will have different effects at different points in the river. This Companion assembles the empirical puzzles and that is an enormously valuable service: it enables readers to understand why particular puzzles were of interest at particular stages in the development of theory and it assembles the puzzles into a compendium, in the belief that puzzles need solutions at every point in the development of theory, even if the shape of the solutions changes significantly at different stages of theoretical development.

The compendium of puzzles will be a great resource for young investigators, joining the river at some point and wanting to know what was upstream as they find their way downstream."

David Lightfoot, Directorate for Social, Behavioral and Economic Sciences, National Science Foundation, Arlington, VA

"Looking for a topic to work on? Grab *The Blackwell Companion to Syntax* and read some articles there. Or you may try to think of a topic not covered (if that is possible). Either way, this five-volume set should be within your reach if you want to be an active researcher."

Akira Watanabe, University of Tokyo

"In a rapidly moving field, it is essential to have an accessible repository of the empirical generalizations that fueled the theoretical debates. These generalizations have not only a historical value. It is often the case that the latest theoretical constructs tend to focus on the most recent empirical issues being discussed and ignore the previous ones. In this respect, this book provides a constant reminder of what needs to be incorporated in the current debate. It can be considered the empirical memory of the field."

Joseph Aoun, University of Southern California

"*The Blackwell Companion to Syntax* will be an indispensable source for theoretical, descriptive, and applied linguists alike. Much of the syntactic knowledge accumulated since the *Aspects* is not easily accessible and some of it may even be in the world of oblivion for many linguists. Younger scholars may have difficulties to understand some of the work done in a by now obsolete theoretical framework. Others may want to have easy access to the analytic knowledge of earlier work in their daily research activities. Since the knowledge presented in the Companion is largely independent of the various stages of syntactic theorizing, it can profitably be used by researchers working on syntactic problems whatever their theoretical background may be. The contributions of the present encyclopedia have been written by top scholars in the field covering practically all important issues addressed in syntax during the last forty years or so. It will certainly serve as an essential research tool for a great number of linguists for many years to come."

Ferenc Kiefer, Hungarian Academy of Sciences, Budapest

"*The Blackwell Companion to Syntax* is a very important accomplishment. Everaert and Van Riemsdijk have brought together a large group of internationally reputed researchers, each of whom analyzes a particular empirical domain that has played a central role in the development of syntactic theory. It is a valuable reference and pedagogical tool. I have no doubt that this work will benefit not only undergraduate and postgraduate students of linguistics but anyone interested in syntax and in the remarkable intellectual history of the field."

M. Carme Picallo, Universitat Autònoma de Barcelona

"This is the most impressive collective endeavor in the field of syntax ever attempted. It summarizes the (basic) descriptive results obtained for a great many syntactic phenomena in the last fifty years of research in generative grammar. It is an indispensable work of reference for students and researchers alike."

Guglielmo Cinque, University of Venice

"Since the beginnings of generative grammar, our knowledge of the syntactic aspects of the human language faculty has increased exponentially, with every investigation giving rise to ever deeper investigations and to cross-linguistic research. Every time I write a paper, prepare my lectures, or advise students on their research, I am confronted with the problem of accessing a vast body of syntactic knowledge. With 77 case studies written by leading syntacticians, *The Blackwell Companion to Syntax* is certain to help address this fundamental problem."

Christopher Collins, Cornell University and New York University

"The past 30 years have seen an explosion in the breadth and depth of linguistic research, as focused theoretical perspective has sharpened empirical investigations. The Companion is a time capsule for the results of empirically significant projects, ensuring that the results of the past are not lost in the future. Any scholar who opens the volumes will find there a wealth of wide-ranging, scholarly, and theoretically informed discussion of just about every syntactic phenomenon currently known to the field – from double nominatives to topicalization; from the spray/load alternation to SOV languages. The insightful and rich chapters come from some of the extraordinary researchers of the time period. If the next generation of scholars does not utilize this marvelous resource, it will not be the fault of the editors and authors, and they can be sure that current researchers will profit immediately from this outstanding project."

Jane Grimshaw, Rutgers University

The Blackwell Companion to Syntax

Volume IV

Blackwell Handbooks in Linguistics

This outstanding multi-volume series covers all the major subdisciplines within linguistics today and, when complete, will offer a comprehensive survey of linguistics as a whole.

Already published:

The Handbook of Child Language
Edited by Paul Fletcher and Brian MacWhinney

The Handbook of Phonological Theory
Edited by John A. Goldsmith

The Handbook of Contemporary Semantic Theory
Edited by Shalom Lappin

The Handbook of Sociolinguistics
Edited by Florian Coulmas

The Handbook of Phonetic Sciences
Edited by William J. Hardcastle and John Laver

The Handbook of Morphology
Edited by Andrew Spencer and Arnold Zwicky

The Handbook of Japanese Linguistics
Edited by Natsuko Tsujimura

The Handbook of Linguistics
Edited by Mark Aronoff and Janie Rees-Miller

The Handbook of Contemporary Syntactic Theory
Edited by Mark Baltin and Chris Collins

The Handbook of Discourse Analysis
Edited by Deborah Schiffrin, Deborah Tannen, and Heidi E. Hamilton

The Handbook of Language Variation and Change
Edited by J. K. Chambers, Peter Trudgill, and Natalie Schilling-Estes

The Handbook of Historical Linguistics
Edited by Brian D. Joseph and Richard D. Janda

The Handbook of Language and Gender
Edited by Janet Holmes and Miriam Meyerhoff

The Handbook of Second Language Acquisition
Edited by Catherine J. Doughty and Michael H. Long

The Handbook of Bilingualism
Edited by Tej K. Bhatia and William C. Ritchie

The Handbook of Pragmatics
Edited by Laurence R. Horn and Gregory Ward

The Handbook of Applied Linguistics
Edited by Alan Davies and Catherine Elder

The Handbook of Speech Perception
Edited by David B. Pisoni and Robert E. Remez

The Blackwell Companion to Syntax, Volumes I–V
Edited by Martin Everaert and Henk van Riemsdijk

The Handbook of the History of English
Edited by Ans van Kemenade and Bettelou Los

The Blackwell Companion to Syntax

Volume IV

Edited by

Martin Everaert and
Henk van Riemsdijk

Preface

Generative grammar has always set its aims high. From its inception in the 1950s, the ambition has been to go beyond observational and descriptive adequacy to reach explanatory bliss. Important work would be about 'conditions on transformations' rather than on 'some properties of *wh*-movement in English', about the 'transformational cycle' rather than on verb clusters.[1] This is what science should be like. And while earlier attempts at achieving a semblance of an explanatory theory were often clumsy and inadequate, these past forty or so years have shown that truly fundamental questions can now be asked and addressed.[2] This emphasis on theory has not, of course, altered the fact that linguistics is a thoroughly empirical science, but data and analyses are seen as what they are: tools to help us understand the structure and properties of the human language faculty. It is the fate of tools that when the product is finished they are put away. When some (as it turns out controversial) data from Italian had suggested that the notion of bounding node should be parameterized, we then forgot about the Italian data and happily proceeded with the idea of parameters.[3] Numerous other examples could be added.

More generally, the data and analyses that at some point in the history of generative grammar played an important, sometimes even a crucial, role have a tendency to fade into the background rather quickly.[4] This effect is particularly strong when the piece of theorizing they helped to establish becomes obsolete, but it is even true when the theoretical insight persists over time. As time went on, and as generative grammar (using the term in the broad sense, including all its theoretical diversity), in its explosive success, expanded to dozens of countries, hundreds of universities and colleges, and many hundreds of researchers, the muckheap of once useful but then discarded empirical material continued to grow. Old hands in the field may still be served by a good memory, helping them to dig out some of these rejects if they seem useful at some later stage, but successive new generations of young linguists simply don't have access to the wealth of data, generalizations, and analyses that might be terribly important to their research if only they knew about them.

But it is not only a problem for younger generations. Researchers who like to keep track of developments, particularly (but not only) in those subfields that are not directly related to their own research, or who work in closely related disciplines such as, for instance, psycholinguistics or sociolinguistics, find it increasingly difficult to keep track. Current handbooks are often concerned with current theorizing, but only marginally with the history of the various versions of the theory and even less with the empirical generalizations underlying those theories. As a consequence, an ever smaller percentage of the potentially useful empirical material is treated in standard textbooks, and hence the rest is not part of the knowledge that researchers and students in the field may be expected to possess.

It might be objected that the articles in which all this wisdom is stored are, after all, still around in the journals, in the books, in the libraries. But given their theoretical focus, the titles are often unrevealing as far as the empirical domain is concerned, keywords are notoriously absent or unreliable, relevant data are scattered over several articles, and, most importantly, the presentation of the data in these articles is subservient to the theoretical claims that are made and hence not presented in succinct, didactically useful ways.[5] So searching for the relevant materials, even if you know what to look for, is often hard. For young researchers, such a search task is doubly difficult because very often the descriptive generalizations are presented in a jargon and formalism that were characteristic of the theoretical framework at the time, sometimes decades ago. Who thinks to look up the term 'backward equi' when looking for data relevant to what we now call exceptional case marking (ECM)?[6]

Having a good, theoretically oriented mind is not enough. You cannot gain an understanding of the abstract properties of Universal Grammar without having any ideas about interesting empirical areas that might provide the crucial evidence (or counter-evidence) for your claims. But these flashes of empirical insight can only come if you have enough knowledge in your head to start the neurons firing away. And you can only have that knowledge if you have been taught about a certain range of phenomena in a variety of languages, or if you have had access to a repository of such materials to work through by yourself. The problem is that such courses are rarely taught, the reason being more often than not that the relevant data are not available in a form that is didactically usable.

This is the lacuna that we are hoping to fill with *The Blackwell Companion to Syntax*. In these five volumes, we offer you 77 case studies of syntactic phenomena that should, at least partly, fill the gap and constitute an important research tool for the working linguist and for teachers and students of syntax (and its interfaces). In bringing these chapters together, we were guided by a working definition of what a syntactic case study was supposed to be. The following properties were thought to be central: *a well-delimited empirical area (both as to the construction(s) involved and as to the languages in which the phenomena are found) whose analysis has, at one time or another in the history of generative grammar, played an important role in the theoretical debates at that time*. More often than not, we will find that such results are relatively robust in the sense that they will stand and

be interpretable regardless of various innovations or adaptations of the version of the theory in which they first saw the light.

The so-called 'verb-raising' construction in Continental-West Germanic languages (chapter 75) will serve as an example. Much has been published on this subject, a reasonable degree of consensus exists about the most important properties of the construction, its analyses have been frequently used to support theoretical proposals, etc. Nevertheless, the existence of this complex of facts is hardly known outside the small group of specialists in this field, the main properties cannot be presupposed as common knowledge, and no one in the field can be properly held responsible for ignoring the verb-raising construction. In a situation like that, the chapter's presentation will be oriented toward combining views and formulating them in such a way that they will be accessible to researchers from various approaches to the theory of grammar.

In addition, of course, the delimitation had to be such that the empirical subdomain in question could be treated in manageable chapters. It would have been unthinkable to include a case about relative clauses: even a thick monograph would not do such a topic justice. But the subtopic of free (headless) relative clauses (chapter 27), a topic that in the late 1970s and the 1980s generated a considerable literature, is a typical example of what we had in mind.

What about the theory? We wanted to make the empirical generalizations, the insights into the properties of constructions, the main focus of each chapter. But wherever useful and possible, of course, reference can be and is made to the theoretical issues that the phenomena in question were or even are relevant to. This introduces a certain bandwidth, and indeed some of our authors stress the empirical side more strongly while others swerve more easily into theoretical discussions. With a project this size it has been impractical to impose more uniformity than we have achieved here. It was, frankly, not always easy to convince our authors to take time away from their primary theoretical research to write the chapters we asked them to. And it was also on occasion hard to curb the attention that they tended to give to theoretical issues and their own role in those theoretical developments. More generally, wherever possible we suggested that theoretical issues be addressed in robust, sustainable ways, not in terms that would reflect the fads and the terminological peculiarities typical of a specific brief period in the short history of generative grammar.

It does not take a great deal of knowledge of the field to realize that an enterprise such as the present one is a highly open-ended affair. Even if we had achieved complete coverage at the time of appearance, new cases would soon present themselves. But complete coverage is unattainable in the first place. It is always possible to come up with other potential cases, not represented in the present work. Even now we already have a number of ideas about cases that might be added and which may at some point be added to the present collection. Nevertheless, we believe that the coverage that the present collection achieves is very considerable. So much ground is covered that already it seems doubtful that future graduate students of linguistics could be expected to work through all of this material. If a student manages part of it and has the rest at his or her disposal

as an encyclopedia of linguistic phenomena, we feel certain that his or her research will greatly benefit. As teachers we are frequently confronted by a big question mark in the faces of students or even fellow faculty members when we use terms like 'contraction', 'subdeletion', or 'freezing effect'. And when asked "Where can I read up on this?" we are often faced with our own bad memory and the virtual impossibility of pointing toward one representative text that will concisely and competently explain what kind of phenomena are hiding behind these terms. This, we feel sure, is now a problem of the past.

If, as we are convinced, this *Companion* will become an important research tool in linguistics, a pressing need will also be felt for additional case studies to be added. While it may well be possible to project further volumes in the future, or an updated or extended version of the present publication, it has been clear to us from the start that the best way to make this an incremental enterprise is to publish these cases electronically. This would allow the possibility of reviewing cases now published, adding new cases relatively easily, and allowing discussion fora, etc. When that happens, the way to expanded coverage of the field will be paved. For the moment we refer you to www.syntaxcompanion.org to keep you informed on developments in this area.

One point to make about the references: every individual chapter has a reference section; the consolidated reference list is in volume V, and in the XML CD version the links are to the consolidated list rather than to the end-of-chapter lists. So in the chapter references you may find entries with a, b, etc. after the date even if there is only entry with that author and date in that chapter, because there is more than one entry in the whole five volumes with the same author and date. For example, even if there's only one Chomsky 1995 cited in any one chapter, it will appear as Chomsky 1995a or 1995b or 1995c, because there are three Chomsky 1995 entries in the consolidated references for the whole five volumes, identified as a, b, and c.

As editors of this encyclopedia of case studies, we have had to make many choices. In doing so we were greatly helped by the project group at NIAS, the Netherlands Institute for Advanced Study in the Humanities and Social Sciences, at Wassenaar, in the dunes lining the Dutch coast, in 1996/1997. The definition of what we would consider a typical case study was intensively discussed and ultimately fixed by that group: Reineke Bok-Bennema, Norbert Corver, Denis Delfitto, Joe Emonds, Martin Haiden, Itziar Laka, Eric Reuland, Tim Stowell, Sten Vikner, and, to some extent, Ian Roberts. We were also fortunate to have good input and feedback from Hagit Borer, Jan Koster, and Edwin Williams, our special outside consultants. The original list of cases was also compiled by that group. First sample chapters were produced during that year. And we brainstormed a lot about who would be the ideal author for which chapter. Nevertheless, we accept full responsibility for all the choices that were made.

We do wish to emphasize, however, that it has never been our intention to suggest that the present collection could be interpreted as a kind of canon, in the literary sense of the word (to the extent that literary scholars are still prepared to advocate such a notion). What we say above about the open-ended character of

an enterprise such as this should underline the fact that nobody could pretend that it is at all possible to establish such a canon, even if one tried to.

The first plans for this project were made in 1993. That is when we decided to apply to NIAS to see if we could get together a team of colleagues with whom to discuss the scope, the objectives, and the realization of the present work. The application was approved. We gratefully acknowledge the generous support, financial, logistic, and otherwise, of NIAS and, in particular, Dick van de Kaa and Wouter Hugenholtz, respectively the rector and the director of the institute. The group convened in the splendid isolation of NIAS in the academic year 1996/1997. There, we were happy to be able to work together with the colleagues mentioned above. Ilke van den Ende joined us as a student trainee. We were also happy to be able to organize two workshops at NIAS during that year. A third was held in Los Angeles at USC with the help and support of Hagit Borer and Tim Stowell in 2001. We wish to thank the participants at these workshops for their contributions, and LOT (the Dutch National Graduate School of Linguistics) as well as NWO and KNAW (the Netherlands Organization for Scientific Research and the Dutch Royal Academy of Sciences respectively) for financial support for these workshops. We also wish to thank the BSGM Foundation for an additional grant to the NIAS group. Last but not least we wish to thank those who have assisted us with the administration and correspondence, with the copy-editing and the HTML-conversion and the maintenance of the website: Jenny Doetjes, Bart Hollebrandse, Rob Goedemans, and Hannah de Mulder. Without them we literally and figuratively could not have managed. Thanks are due to NWO and the Utrecht Institute of Linguistics OTS (Language in Use project) for grants that made this assistance possible.

Finally we would like to thank all those at Blackwell who, over the years, have helped us realize this project – Ada Brunstein, Philip Carpenter, Sarah Coleman, Tami Kaplan – and the copy-editing team – Fiona Sewell, Anna Oxbury, Peter Kahrel – for doing such a wonderful job.

Utrecht and Tilburg
Martin Everaert and Henk van Riemsdijk

NOTES

1 Introduction

Sentences containing quantifiers, especially those containing two or more of them, like (1), are often ambiguous:

(1) Every man danced with some woman.

(1) has the two readings paraphrased under (2a) and (2b), among others:

(2) a. 'For every man in a given domain, there is at least one (possibly different) woman with whom he danced.'
b. 'There is at least one woman among the women in a given domain with whom every man danced.'

The meaning difference between (2a) and (2b) can be characterized in different terms. In (2a), in which the interpretation of the prepositional object quantifier is

dependent on the interpretation of the subject quantifier, the subject quantifier is said to have scope over the object quantifier (or to have wider/broader scope than the object quantifier). The fact that the interpretation of the object may covary with the different individuals in the domain of the subject quantifier is a consequence of the fact that the object is distributed over the subject. In the case of (2b), the relative scope of the quantifiers is the opposite of that in (2a): the object quantifier has the wider/broader scope; the subject quantifier is in the scope of the object.

A further way of interpreting (1) is to interpret the two quantifiers independently of each other, i.e., to assume that the value of neither quantifier is a function of the other.

Quantifiers enter into – possibly ambiguous – scope relations not only with quantifiers but also with other types of sentential operators, among them *wh*-operators (3a), negation (3b), and intensional predicates (3c). A quantifier can sometimes take either embedded scope or matrix scope – as happens both in (3c) and in (3d):

(3) a. Who did everybody meet?
'Which is the person that everybody met?'
'(Tell me) for everybody, which (possibly different) person he met.'
b. John didn't meet two celebrities.
'It is not the case that John met two celebrities.'
'There are two celebrities who John did not meet.'
c. John wanted to meet two celebrities.
'It was John's desire that he meet two celebrities.'
'There were two celebrities that John wanted to meet.'
d. Someone seems to deserve credit for that.
'There is someone who seems to deserve credit for that.'
'It seems that someone deserves credit for that.'

In the framework of generative grammar, where semantic interpretation is basically determined by syntactic structure, sentences displaying scopal ambiguity are believed to be structurally ambiguous. Unlike in other cases of ambiguity, however, intuition gives no clue as to how sentences like those in (1), (3a), or (3b) can be mapped on two alternative structures; at which level of representation the two alternative structures should be constructed and by what means.

Furthermore, the ambiguity expected in the case of sentences containing two scope-bearing operators is not always present. Thus the following set of examples, though parallel with those in (3a–d) in several respects, lack one of the two readings that their counterparts in (3a–d) have:

(4) a. Who met everybody?
b. Two celebrities didn't meet John.
c. John wanted to meet more than two celebrities.
d. Someone seems to himself to deserve credit for that.

(4a, b) do not have the inverse scope readings that (3a, b) have (i.e., the scope order of the two quantifiers cannot be the opposite of their surface order). In (4c) the quantifier can only have embedded scope, whereas in (4d) it can only have matrix scope. An adequate analysis of scope ambiguities should be able to predict two readings for (3a–d), and should block one of them in the case of (4a–d) in a principled way.

2 The treatment of scope ambiguities in early generative grammar

The Standard Theory of Generative Grammar, in which the deep structure of the sentence was subject to semantic interpretation, provided limited means of assigning two deep structures to a quantified sentence. What it could handle was the scopal ambiguity of sentences with negative quantifiers like *no one* (cf. Klima 1964). *No one*, e.g., that in (5a), was claimed to be the output of a *neg*-transportation transformation merging *not* with *anyone*. It was assumed that the negative particle was adjoined as a modifier to the constituent that it had scope over; hence the ambiguity in (5a) was derived from whether in deep structure the negative particle was adjoined to the matrix VP, as in (5b), or to the embedded VP, as in (5c):

(5) a. I demand that you marry no one.
    b. I not demand that you marry anyone.
    c. I demand that you not marry anyone.

As pointed out by Kayne (1998: 128), this approach cannot predict the subject–object asymmetry attested in *neg*-transportation. It remains unclear why (6a) is not ambiguous, i.e., what prevents *neg*-transportation from deriving (6a) from (6b):

(6) a. I demand that no one marry you.
    b. I not demand that anyone marry you.

In the Extended Standard Theory, and then in its Revised version, scope interpretation was referred to surface structure, which led to a theory in which the relative scope of quantifiers was determined by surface c-command (see Reinhart 1976). This approach predicted a scope ambiguity only among quantifiers mutually c-commanding each other; hence it could not handle such obvious cases of scope ambiguity as transitive clauses with a subject quantifier and an object quantifier, e.g.:

(7) In this office somebody speaks every official language of the UNO.

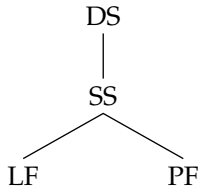
Reinhart's theory also wrongly predicts the scope interpretation of NPs containing a quantified head and a quantified PP, such as the subject of (8):

(8) Many children in every city are waiting for Santa Claus.

In the case of (8) the predicted scope order is the opposite of the attested scope order: the quantifier embedded in the PP adjunct has wider scope than the matrix quantifier c-commanding it.

Fundamental problems of these types have led to the conclusion that quantifier scope cannot be disambiguated either in D-structure or in S-structure. Logical operators should be assigned scope on a further level of representation, called Logical Form, which is to be derived from S-structure by rules not affecting phonological interpretation – see Chomsky (1975c) and May (1977). In the so-called T-model of grammar there is no direct mapping between LF and PF; their relation is mediated by S-structure, as follows:

(9)



May (1977) claims that the rule deriving quantifier scope, called Quantifier Raising (Q-Raising), applied in the course of mapping SS on LF, adjoins a quantifier to S (IP). Q-Raising is subject to the same conditions, particularly to the same island constraints, as the rules mapping DS on SS. It leaves a trace which acts as a variable. Q-Raising is triggered by the Condition on Quantifier Binding in (10), and its output is subject to the Condition on Proper Binding in (11):

(10) **Condition on Quantifier Binding:**
Every quantified phrase must properly bind a variable.

(11) **Condition on Proper Binding:**
Every variable in an argument position must be properly bound [c-commanded by a binding phrase].

The scope of a quantifier is everything which it c-commands at LF.

In sentences with multiple quantifiers, adjunction to S is iterated, and the adjunction operations are allowed to cross. Scope ambiguity arises from the fact that the quantifiers of a sentence can be subject to Q-Raising in any order, as a consequence of which an S-structure can be mapped on more than one LF. Consider the two LFs derivable from (12a):

(12) a. Some man loves every woman.
b. $[_S$ [some man]$_i$ $[_S$ [every woman]$_j$ $[_S$ t_i loves t_j]]]
c. $[_S$ [every woman]$_j$ $[_S$ [some man]$_i$ $[_S$ t_i loves t_j]]]

May's framework correctly predicts that in complex NPs containing a quantified head and a quantified NP embedded in a PP, the scope order of quantifiers is the

opposite of their surface order. Consider an instance of this construction, and the LF derived from it, displaying 'inverse linking'. (May calls pairs of quantifiers linked if one of the quantified NPs includes the other. Quantifiers binding sister variables are non-linked.)

(13) a. Everybody in an Italian city met John.
b. $[_S$ an Italian city$_i$ $[_S$ [everybody in $t_i]_j$ $[_S$ t_j met John]]]

If the quantifiers were adjoined to S in the opposite order, as in (14), then the trace of the PP-internal NP, t_i, would not be properly bound, in violation of the Condition on Proper Binding:

(14) *$[_S$ [everybody in $t_i]_j$ $[_S$ [an Italian city]$_i$ $[_S$ t_j . . .

If the quantified NP containing the PP adjunct is in object position, then, naturally, we also obtain two non-linked readings, because the PP can also be interpreted as an immediate constituent of the matrix VP:

(15) John $[_{VP}$ $[_{VP}$ met $[_{NP}$ everybody]] $[_{PP}$ in some Italian city]]

This S-structure is predicted to be ambiguous: the two quantifiers can undergo Q-Raising in any order.

Interestingly, the inverse scope attested in the case of quantified NPs containing a quantified PP is missing if the noun phrase has a *wh*-feature; such NPs are ungrammatical:

(16) a. *Which man in some city did you meet?
cf. b. Which man in Cleveland did you meet?

The ungrammaticality of (16a) is derived from the assumption that, with the *wh*-phrase moved to S', and the quantifier adjoined to S, the Condition on Proper Binding is not satisfied (the trace of *some city* is not bound):

(17) $[_{S'}$ [Which man in $t_i]_j$ $[_S$ [some city]$_i$ $[_S$ did you meet t_j]]]

In some idiosyncratic cases, quantified NPs with a quantified PP adjunct are scopally ambiguous: they can be understood to involve inverse linking, or they can be assigned direct (or natural) scope, interpreted from left to right. E.g.:

(18) Every senator on a key congressional committee voted for the amendment.

(19) a. Inverse linking:
$[_S$ a key congressional committee$_i$ $[_S$ [every senator on $t_i]_j$ $[_S$ t_j voted for the amendment]]]
b. Natural scope:
every senator > on a key congressional committee

Whether or not the natural scope reading also exists in addition to the regular inverse scope depends on several factors, among them the lexical selection of the preposition. For instance, a quantifier complementing the preposition *in* only allows inverse linking. The lexical selection of the quantifier also plays a role. Compare (18), which is ambiguous, with (20a, b), which only have an inversely linked reading:

(20) a. Each (of the) senator(s) on a key congressional committee voted for the amendment.
b. All senators on a key congressional committee voted for the amendment.

The depth of embedding of PPs also affects the scope reading. Thus, whereas (21a) is ambiguous, (21b) is disambiguated by the embedding of an additional PP under the lower quantifier:

(21) a. Every exit from a freeway is badly constructed.
b. Every exit from a freeway to some California city is badly constructed.

The idiosyncrasy of these factors is regarded by May (1977) as evidence indicating that the natural, non-inversely linked reading is not derived by the rules of sentence grammar.

In possessive constructions with a quantified genitive and a quantified complement or adjunct, e.g., in those under (22–23), the two quantifiers are not linked. They undergo Q-Raising, i.e., adjunction to S, separately, in an optional order, which yields two readings:

(22) Some company's refusal of every merger offer began a panic.

(23) Every city's destruction by some pestilence was assured by their misdeeds.

A *wh*-phrase, moved to S', on the other hand, necessarily has wider scope than a clause-mate quantifier. Thus, whereas (24), containing two clause-mate quantifiers, is ambiguous, (25a, b), containing a quantifier and a *wh*-phrase, are not:

(24) John recorded one song on every album.

(25) a. Which song did John record on every album?
b. Which album did John record one song on?

In some cases the *wh*-operator can also have narrow scope with respect to a clause-mate quantifier, e.g.:

(26) a. What did everyone order?
b. Where did everybody go?

May (1977) dismissed the unpredicted wide-scope reading of the quantifier in (26a, b) as a marked, idiosyncratic case which need not be accounted for in sentence grammar. However, it soon became clear that the phenomenon is not idiosyncratic but displays a subject–object asymmetry characteristic of sentence grammar; namely, whereas object quantifiers can have wide scope with respect to a *wh*-phrase, subject quantifiers, e.g., those in (27a, b), cannot:

(27) a. Who ordered everything?
b. Who went everywhere?

Q-Raising is a clause-bound process (as predicted by Subjacency); hence embedded quantifiers have clause-bounded scope – in the unmarked case. In certain instances, however, the quantifier can scope out of the embedded clause. For example, in (28a) *someone* can have scope over the verb *believe*, and in (28b) *too many people* can have scope over the verb *want*, as is clear from the paraphrases of the relevant readings:

(28) a. Ralph believes that someone is a spy.
'There is someone who Ralph believes to be a spy.'
b. Harry wanted us to invite too many people.
'It was too many people that Harry wanted us to invite.'

The marked readings are, again, excluded from the realm of sentence grammar by May (1977).

Raising subjects (e.g., that in (29a)) – as opposed to control subjects (e.g., that in (29b)) – can have narrow scope with respect to the matrix predicate, and even with respect to the embedded object:

(29) a. Some politician is likely to address every rally in John's district.
b. Some politician wants to address every rally in John's district.

May's theory accounts for the additional narrow scope of the subject in (29a) by allowing Q-Lowering in Raising constructions.

3 Logical Form in Government and Binding Theory

The emergence of the Empty Category Principle made May's (1977) explanation of the scope ambiguity of sentences containing both a subject quantifier and an object quantifier obsolete. It was no longer possible to Q-Raise the subject and the object quantifiers in any order. The subject trace needed a local antecedent, hence the Q-Raising of the subject had to precede the Q-Raising of the object. Furthermore, the asymmetry noticed between the scope possibilities of subject

and object quantifiers (cf. (26–27) above) also required an explanation. These problems lead to the formulation of a more sophisticated theory of Logical Form in May (1985).

In May (1985) the scope of a constituent is still identical with its c-command domain; however, the definition of c-command is modified, as follows:

(30) **C-command:**
a c-commands *b* iff every maximal projection dominating *a* dominates *b*, and *a* does not dominate *b*.

In the LF under (31b), derived from (31a), the quantifiers mutually c-command each other (the first maximal projection dominating each one is S'), so they have identical scopes, i.e., they can be interpreted in either scope order. (31c), on the other hand, is ruled out by the ECP:

(31) a. Every student admires some professor.
b. $[_S$ some professor$_i$ $[_S$ every student$_j$ $[_S$ t_j admires $t_i]]]$
c. *$[_S$ every student$_j$ $[_S$ some professor$_i$ $[_S$ t_j admires $t_i]]]$

The subject–object asymmetry attested in the scope relation of *wh*-phrases and quantifiers also falls out in the framework of May (1985). Consider again the relevant cases:

(32) a. What did everyone buy for Max?
b. Who t bought everything for Max?

The ambiguity of (32a) is unproblematic, as the Q-Raising of the subject and the *wh*-movement of the object result in an LF in which the quantifier and the *wh*-phrase mutually c-command each other:

(33) $[_{S'}$ What$_i$ $[_S$ everyone$_j$ $[_S$ t_j buy t_i for Max]]]

Owing to a technical innovation of May (1985), the explanation also carries over to the post-*Barriers* (Chomsky 1986a) framework of generative syntax, in which S is also analyzed as a maximal projection (IP); namely, a node created by adjunction to a maximal projection is not a maximal projection, but merely a segment of a maximal projection. The phrase providing the adjunction site, and the node created by adjunction to it, make up a maximal projection together. Hence the quantifier and the *wh*-phrase in (32a) will continue to c-command each other, given that the first maximal projection dominating each of them is CP.

As for (32b), neither quantifier adjunction to S nor quantifier adjunction to S' yields a grammatical output. Cf.:

(34) a. *Who$_j$ $[_S$ everything$_i$ $[_S$ t_j buy t_i for Max]]
b. *everything$_i$ $[_{S'}$ who$_j$ $[_S$ t_j buy t_i for Max]]

(34a) is out because it violates the (standard version of the) ECP, whereas (34b) is illegitimate because S' is not a possible adjunction site. However, adjunction to other maximal projections, among them the VP, is possible; hence (32b) can be assigned the following LF:

(35) Who_j [$_S$ t_j [$_{VP}$ everything_i [$_{VP}$ buy t_i for Max]]]

Assuming that S = IP is maximal, *who* in (35) asymmetrically c-commands *everything* (S, the first maximal projection dominating *everything*, does not also dominate *who*); hence (35) is not ambiguous.

Evidence for the possibility of the VP-adjunction of object quantifiers is provided by the pair of examples in (36) (cf. Sag 1980). Whereas (36a) is ambiguous, the ambiguity disappears in (36b), in which the sentence is followed by a parallel sentence involving ellipsis. In (36a) the object quantifier is bound to have narrow scope:

(36) a. Some student admires every professor.
b. Some student admires every professor, but John doesn't.

The narrow scope of the object quantifier in (36b) falls out if we assume that the elided VP is reconstructed at LF, and a reconstructed VP must not contain a free variable. Then the reconstructed VP must have the *every* phrase adjoined to it, as in (37); that is why it will necessarily have narrower scope than the subject quantifier, adjoined to S:

(37) [$_S$ some student_2 [$_S$ e_2 [$_{VP}$ every professor_3 [$_{VP}$ admires e_3]]]], but John doesn't [$_{VP}$ every professor_3 [$_{VP}$ admire e_3]]

The way May (1985) defines c-command enables a quantifier adjoined to a subject or object NP to have sentential scope (given that the quantifier adjoined to the NP will only be dominated by a segment of NP). Observe how the two readings of a quantified NP containing a quantified PP are derived. The matrix quantified NP (NP3) is adjoined to S, whereas the embedded quantified NP (NP2) is adjoined to the matrix NP. Hence both have sentential scope, and the sentence is ambiguous:

(38) a. Every exit from a freeway is badly constructed.
b. [$_S$ [$_{NP3}$ [$_{NP2}$ a freeway] [$_{NP3}$ every exit from e_2]] [$_S$ e_3 is badly constructed]]

4 Scope ambiguity or lexical ambiguity?

As discussed in detail in chapter 74, Fodor and Sag (1982) raised the possibility that the ambiguity attested in the case of indefinites like that in (39) is not scopal in nature but is a lexical ambiguity:

(39) Every professor met a student in the syntax class.

That is, the indefinite has both a quantifier interpretation, meaning that the set of students meeting every professor is not empty, and a referential interpretation. Under its quantifier interpretation the indefinite enters into a scopal relation with its clause-mate quantifiers. Thus the indefinite of (39) as a quantifier can either have narrow scope with respect to the universal quantifier ('Each professor met a possibly different student . . .'), or it can have a wide-scope interpretation ('The set of students in the syntax class that every professor met is not empty'). However, the sentence also has a third meaning, with the indefinite understood as referential: 'There was a particular student in the syntax class who every professor met.'

Fodor and Sag have the following evidence for the referential reading of indefinites:

(i) An indefinite can scope out of an island. Thus the indefinite in the complex NP in (40) and that in the *if*-clause in (41) can both refer to an individual that does not merely exist in the hypothetical world of the complex NP or the *if*-clause:

(40) John overheard the rumor that a student of mine had been called before the dean.

(41) If a friend of mine from Texas had died in the fire, I would have inherited a fortune.

If the scope of the indefinite transgresses an island, the indefinite is claimed by Fodor and Sag always to have maximal scope (a claim not generally accepted). Thus, if the indefinite in (42) has matrix scope, it is also claimed to have scope over the universal quantifier – which is only possible if it is a referential expression with a maximally wide scope existential quantifier:

(42) Each teacher overheard the rumor that a student of mine had been called before the dean.

(ii) As was discussed in connection with (36), VP deletion is blocked if the deleted VP contains a quantifier whose scope is larger than the VP. Whichever quantifier is assigned wider scope in (43a), neither quantifier will scope out of the deleted VP, hence both readings are licensed. (43b), on the other hand, has only one reading: the universal quantifier has narrow scope – or else it would have a scope wider than the deleted VP:

(43) a. Sandy thinks that someone loves each of my friends.
Chris does, too.
b. Sandy thinks that someone loves each of my friends.
Chris thinks that someone does, too.

This constraint apparently does not hold in the case of a deleted indefinite:

(44) a. Sandy thinks that every student in our class plays chess better than a guy I beat this morning.
Chris does, too.

b. Sandy thinks that every student in our class plays chess better than a guy I beat this morning.
Chris thinks that every student does, too.

The elliptical sentence (44b) is just as ambiguous as that in (44a), also meaning 'There is a guy I beat this morning such that Sandy thinks that every student in our class plays chess better than he.' This is only possible if *a guy* is a referring expression.

Fodor and Sag (1982) conclude that indefinites are lexically ambiguous. They are either quantifiers, binding a variable, entering into a scope relation with other quantifiers; or they are referring expressions which have no scope, but which presuppose, or infer, existential quantification of maximal scope. Under the latter interpretation they refer to an unidentified but identifiable individual. The initial sentences of the following dialogues illustrate this ambiguity. Whereas that in (45a) involves a referential indefinite, that in (45b) is an instance of a wide-scope existential quantifier:

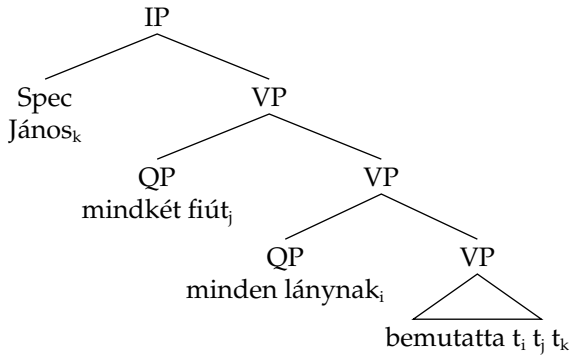
(45) a. A student in syntax 1 cheated on the exam. His name is John.
b. A student in syntax 1 cheated on the exam. We are all trying to figure out who it was.

5 Visible LF in Hungarian

In Hungarian (see Kiss 1991) – as well as in the Bantu KiLega (Kinyalolo 1990), Palestinian Arabic (Khalaily 1995), and Chinese (Bartos 2000) – quantifiers occupy a designated A-bar position in the left periphery of the sentence, after the topic but before the focus and the VP. That is, Quantifier-Raising is a visible operation: it is adjunction to the left edge of the predicate phrase. Here is a Hungarian example containing two quantifiers, and a slightly updated version of the structure assigned to it in Kiss (1991):

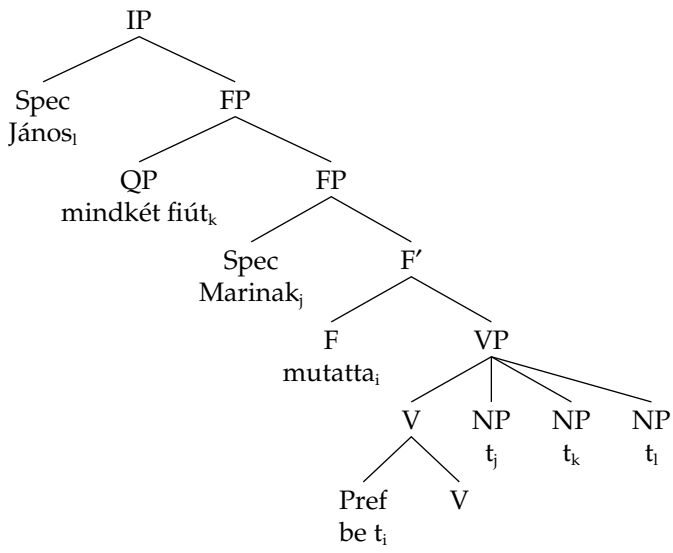
(46) a. János mindkét fiút minden lánynak bemutatta.
John both boy.acc every girl.dat introduced
'John introduced both boys to every girl.'

b.



If the sentence also contains a focus, Q-Raising is adjunction to the Focus Phrase:

(47)



Quantifiers and the focus are analyzed differently, the former adjoined to the predicate phrase (VP or FP), the latter substituted into Spec, FP so as to account for an empirical difference between their syntactic behaviors: whereas Focus Movement triggers V-to-F movement across the verbal prefix, Quantifier-Raising does not do so.

Owing to the fact that quantifiers are moved to scope positions at S-structure, Hungarian sentences with two or more quantifiers are not ambiguous; surface c-command relations, and surface order even, disambiguate them. Compare the word order and the meaning difference of the following pair of sentences:

(48) a. Jánost mindenkét lány többször is meghívta.
John.acc both girls several times invited
'It is stated about John that each of the two girls invited him on several occasions.'

b. Jánost többször is mindkét lány meghívta.
John.acc several times both girls invited
'It is stated about John that on several occasions, both girls invited him.'

In both sentences the first quantifier, asymmetrically c-commanding the second one, has scope over it, but not vice versa.

In a language like Hungarian, where scope relations are determined by surface c-command and surface precedence, the following generalizations are expected to hold: (i) a QP in the specifier position of a noun phrase cannot have narrower scope than the quantifier associated with the head; and (ii) a QP in the complement position of a noun phrase cannot have wider scope than the quantifier

associated with the head. Both predictions are borne out. The first one will be demonstrated by the examples in (49) and (50):

(49) [Minden családtag [két fényképe]] jól sikerült.
every family-member's two photos well came-out
'Two photos of each family-member came out well.'

As predicted, (49) cannot mean that 'two photos showing all the family members came out well'. The slightly marginal (49) also has a fully grammatical version, in which the possessor is case marked and extraposed, and then undergoes Q-Raising on its own. The remnant noun phrase occupies the focus slot in Spec, FP:

(50) [$_{FP}$ Minden családtagnak [$_{FP}$ két fényképe sikerült jól]]
every family-member.dat two photos came-out well

The second generalization is illustrated under (51a). The pragmatically possible scope reading, with the complement taking scope over the quantified head, cannot be derived because the complement does not c-command the quantifier of the head. The intended reading can only be achieved if the complement is realized as a genitive specifier (see (51b)), or, still better, if it is realized as a case-marked possessor extraposed and then Q-raised (see (51c)). To demonstrate that the possessor has undergone Q-Raising independently, I will supply it with the (usually optional) formative appearing on the right-hand side of distributive quantifiers:

(51) a. *[Minden [bejárat [több boltba]]] megrongálódott.
every entrance several store-to was-damaged
'Every entrance to several stores was damaged.'
b. [Több bolt [minden bejárata]] megrongálódott.
several store's every entrance was-damaged
c. [$_{VP}$ Több boltnak is [$_{VP}$ minden bejárata [$_{VP}$ megrongálódott]]]
several store.dat even every entrance was-damaged

Hungarian facts have been used as evidence in arguing for LF Q-Raising (if Q-Raising is visible in some languages, it must be covertly present in other languages, as well). At the same time, they have also been regarded as evidence for a grammatical model without LF, in which scope relations can be read off S-structure – as in Williams (1986).

6 A chain binding theory of quantifier scope

It had already been observed in May (1977), and particularly in May (1985), that the movement of a quantifier, or the movement of another operator across a quantifier, may result in ambiguity. Thus a raised quantified subject may have either embedded or matrix scope:

(52) a. A hippogryph is likely to be apprehended.
b. 'There is a hippogryph which is likely . . .'
c. 'It is likely that a hippogryph . . .'

May (1985) could only account for the narrow-scope reading of the raised quantifier by assuming Q-lowering at LF, with the output in (53):

(53) e_i is likely a hippogryph$_i$ [e_i to be apprehended]

A *wh*-phrase raised across a quantifier into a higher clause may also have either wide scope or narrow scope with respect to the quantifier:

(54) Who do you think that everyone saw at the rally?

It appeared that the wide-scope reading of the subject quantifier in (54) can only be derived at the cost of giving up the assumption that Q-Raising observes the ECP. At the same time, the ECP did not prove to be completely irrelevant; e.g., the embedded subject quantifier, capable of taking scope over the matrix *wh*-phrase in (54), cannot take scope over a matrix subject quantifier. Cf.:

(55) Some men think that everyone saw Mary at the rally.

Aoun and Li (1989) approached these problems by replacing the notion of variable binding by the notion of chain binding in quantifier scope interpretation. They sought to account for a complex set of English and Chinese data which display some unexpected differences; namely, whereas an English transitive sentence containing two quantifiers is ambiguous, its Chinese counterpart is not (as was observed by Huang 1982a) – see (56a–b). On the other hand, a Chinese passive sentence with two quantifiers is ambiguous, whereas an English double object construction is not – cf. (57a, b):

(56) a. Someone tried every dish.
b. Yaoshi liangge ren zhaodao meige xiansuo
if two men found every clue

(57) a. Yaoshi liangge xiansuo bei meigeren zhaodao
if two clues by everyone found
b. John assigned someone every problem.

Aoun and Li propose the following scope principle:

(58) **Scope Principle:**
A quantifier A has scope over a quantifier B if A c-commands a member of the chain containing B.

Q-Raising is claimed to be constrained by the Minimal Binding Requirement, which forbids stacked quantifiers, i.e., structures of the type Q_i Q_j [t . . . t], whether the quantifier-variable relations are nested or crossing:

(59) **Minimal Binding Requirement:**
Variables must be bound by the most local potential A' binder.

As a consequence of (58) and (59), LF representations of multiple quantifier constructions can be of two basic types:

(60) a. Q_i [. . . t_i . . . Q_j [. . . t_j . . .]
b. Q_i [. . . t_i . . . Q_j [. . . t_i . . . t_j . . .]

The lower t_i in (60b) does not violate the Minimal Binding Requirement because it is an NP trace, not a variable. Whereas (60a) is disambiguated, (60b) is ambiguous: both Q_i and Q_j have scope over the other, because each c-commands a trace of the chain containing the other. According to Aoun and Li (1989), a Chinese transitive sentence with a subject and an object quantifier has structure (60a). In English, on the other hand, the subject is generated inside the VP; hence an English sentence like (56a) is to be mapped on the LF in (60b). (Chinese Infl, unlike English Infl, is not lexical, and the non-L-marked VP blocks subject raising to Spec, IP.) In a Chinese passive sentence, however, the subject quantifier does bind a VP-internal trace; that is why it is scopally ambiguous. (As Hornstein 1995: 39 notes, it is unclear, though, why the non-L-marked Chinese VP does not block NP-movement in this case.) The English double object construction is claimed to be similar to the Chinese active transitive sentence in the respect that the indirect object and the direct object are claimed to form a small clause, in which the VP-external constituent has no trace in the VP.

This is the relevant section of the LF that Aoun and Li (1989) would assign to (54), given again as (61a):

(61) a. Who do you think that everyone saw at the rally?
b. Q_i [. . . [$_{CP}$ t_i [$_{IP}$ Q_j [t_j [$_{VP}$ t_j t_i]]]]]

The sentence is correctly predicted to be ambiguous: Q_i, the *wh*-operator, c-commands every member of the chain headed by Q_j, and Q_j, the embedded subject operator, also c-commands the root of the chain headed by Q_i.

(55), given again as (62a), on the other hand, is correctly predicted to be non-ambiguous, given that the lower quantifier does not c-command a member of the chain headed by the higher quantifier:

(62) a. Some men think that everyone saw Mary at the rally.
b. Q_i [$_{VP}$ t_i . . . [$_{CP}$ [$_{IP}$ Q_j [$_{IP}$ t_j [$_{VP}$ t_j]]]]]

(32a, b) appear, at first sight, to violate the Minimal Binding Requirement. These are the chains they involve:

(63) a. What did everyone buy for Max?
$Q_j\, Q_i\, [_{IP}\, t_i\, [_{VP}\, t_i\, t_j]]$
b. Who bought everything for Max?
$Q_j\, [_{IP}\, t_j\, Q_i\, [_{VP}\, t_j\, t_i]]$

Actually, the problem with the Minimal Binding Requirement is eliminated by a qualification added to the requirement, according to which *a* only qualifies as a potential A-bar binder for *b* iff *a* c-commands *b*, *a* is in an A-bar position, and co-indexing of (*a*, *b*) would not violate any grammatical principle. Auon and Li argue that the co-indexing of the *wh*-phrase (Q_j) with t_i would be a Principle C violation, hence Q_j is not a potential binder for t_i. The real problem, pointed out by Ruys (1992), is that (63b), with Q_i binding both t_j and t_i, is predicted to be just as ambiguous as (63a), contrary to fact.

In this framework, the scopal ambiguity attested in Raising structures can be accounted for without lowering. Observe the LF assigned to an English Raising structure:

(64) a. Someone seems to have attended every rally.
b. $someone_i\ [t_i$ seems $[every\ rally_j\ [t_i$ to have attended $t_j]]]$

Every rally can have scope over *someone* because it c-commands a trace of the chain containing *someone*. This approach, however, cannot solve a problem first noticed by Aoun (1981); namely, in (65a) the matrix reflexive forces the existential quantifier binding it to have matrix scope. Nevertheless, the LF assigned to (65a) by Aoun and Li, represented in (65b), is as ambiguous as any Raising structure:

(65) a. Someone seems to himself to have attended every rally.
b. $someone_i\ [t_i$ seems to himself $[every\ rally_j\ [t_i$ to have attended $t_j]]]$

A further problem is that Chinese Raising structures, e.g., that in (66), are not ambiguous:

(66) Yaoshi liangge ren keneng kandao meigeren
if two men likely see everyone

Aoun and Li explain the lack of narrow scope of the raised subject in (66) by claiming that in Chinese the raising predicate and the embedded predicate are restructured to form a single complex predicate (because otherwise the non-L-marked matrix VP, a barrier, would not let the embedded subject through).

In a revised version of the scope interpretation theory of Aoun and Li (1993b), only the bare quantifiers are Q-raised out of the quantified NPs. Hence the new theory does not refer to NP-traces any longer; the Scope Principle interprets only non-NP links of chains. That is:

(67) **The Scope Principle:**
X takes scope over Y just in case some part of X's A'-chain c-commands some part of Y's A'-chain.

Aoun and Li assume the following Generalized Binding Condition:

(68) An A'-binder B is a potential antecedent for a variable V iff indexing B and V does not violate any grammatical principle, e.g., principle C, the theta-criterion, etc.

Adopting the adjunction theory of *Barriers* (Chomsky 1986a), Aoun and Li only allow adjunction to XPs in non-theta-positions. That is, whereas the subject NP is a potential adjunction site, the object NP is not. A subject quantifier assumes wide scope by being adjoined to IP, and it assumes narrow scope by being adjoined to the subject NP, which dominated it originally. (In Aoun and Li's framework, a Q adjoined to NP does not c-command outside the NP; hence the Minimal Binding Requirement is not violated.) An object quantifier, on the other hand, takes wide scope by being adjoined to IP, and narrow scope by being adjoined to VP. Cf.:

(69) a. Some student attended every class.
b. $[_{IP}$ Every$_i$ $[_{IP}$ $[_{NP}$ some$_j$ $[_{NP}$ t_j student]] attended $[_{NP}$ t_i class]]]
c. $[_{IP}$ Some$_j$ $[_{IP}$ $[_{NP}$ t_j student] $[_{VP}$ every$_i$ $[_{VP}$ attended $[_{NP}$ t_i class]]]]]

In Chinese active sentences Spec, IP is a theta-position, hence structure (69b), in which the subject has narrow scope with respect to the object, is illicit. In Chinese passive sentences, on the other hand, Spec, IP is not a theta-position, allowing adjunction.

In Raising constructions the subject can be lowered into the embedded subject position in both languages. In English, the lowered subject can have its quantifier adjoined locally to the subject NP, which is a non-theta-position – see (70). In Chinese, where the embedded subject position is a theta-position, this move is impossible; hence the lowered subject cannot assume narrow scope with respect to the embedded object:

(70) $[_{IP}$ t_i . . . $[_{IP}$ Q_j $[_{IP}$ $[_{NP}$ Q_i $[_{NP}$ t_i N']] . . . $[_{NP}$ t_j N']]]]

The optional lowering does not take place in (71) because it would leave an unbound anaphor:

(71) Someone seemed to himself to have attended every rally.

The appeal of this approach is somewhat diminished by the fact that the Q-Raising rule it assumes is not identical any more with the visible Q-Raising of, e.g., Hungarian, which involves quantified NPs.

7 A Minimalist approach to scope ambiguities

In the Minimalist framework, the Q-Raising transformation is problematic for at least two reasons. Phrasal adjunction, in general, is an atypical operation in Minimalism. Phrasal movement should be substitution, and, furthermore, it should be motivated by the need of morphological feature checking. Quantifiers actually do bear morphological markers; so if they had an invariant landing site, it would not be inconceivable to analyze their landing site as the specifier of an abstract quantifier head with a quantifier feature to check. However, May (1985), Aoun and Li (1993), and others have convincingly shown that the English scope facts cannot be accounted for unless Q-Raising is allowed a variable landing site.

These considerations have led to new approaches to quantifier scope interpretation. Hornstein's solution is the simplest (cf. Hornstein 1995: ch. 8); he eliminates Q-Raising, and derives its effects from regular A-movement to Spec, AgrS and Spec, AgrO. His theory is based on the standard Minimalist premises that the subject moves to Spec, AgrS, whereas the object moves to Spec, AgrO, and movement is copying and deletion. He also makes the following specific assumptions:

(i) At the CI interface an A-chain has at most one and at least one lexical link (the rest of them are deleted).
(ii) A definite argument must be outside the VP shell at the CI interface (as required, e.g., by the Mapping Principle of Diesing 1992b).

In Hornstein's theory, quantifiers are moved via A-movement – which explains why quantifier scope normally cannot transgress a sentence boundary. Wide-scope quantifiers are interpreted in the head positions of their chains, whereas narrow-scope quantifiers are interpreted in the root positions of their chains. A transitive sentence with two quantifiers, like that in (72a), can be associated with four possible CI interface representations, spelled out in (72b–e). The chain links to be deleted are put into brackets:

(72) a. Someone attended every seminar.
b. $[_{AgrS}$ Someone $[_{TP}$ Tns $[_{AgrO}$ every seminar $[_{VP}$ (someone) $[_{VP}$ attended (every seminar)]]]]]
c. *$[_{AgrS}$ Someone $[_{TP}$ Tns $[_{AgrO}$ (every seminar) $[_{VP}$ (someone) $[_{VP}$ attended every seminar]]]]]
d. *$[_{AgrS}$ (Someone) $[_{TP}$ Tns $[_{AgrO}$ (every seminar) $[_{VP}$ someone $[_{VP}$ attended every seminar]]]]]
e. $[_{AgrS}$ (Someone) $[_{TP}$ Tns $[_{AgrO}$ every seminar $[_{VP}$ someone $[_{VP}$ attended (every seminar)]]]]]

(72c, d) are illegitimate representations, because they contain a definite argument (the *every* phrase) in the VP, and thereby violate the Mapping Principle of Diesing

(1992b). (72b) is the representation yielding direct scope, whereas (72e) is the representation yielding inverse scope.

In this model, a subject universal quantifier, e.g., that in (73), is bound to have wide scope, as the Mapping Principle does not allow it to be interpreted inside the VP:

(73) Every man kissed a woman.

The women kissed may be different for each man or may be the same, which looks like a difference in relative scope. Hornstein, however, is forced to deny the ambiguity, and to call the sentence vague instead.

Hornstein's theory correctly predicts the ambiguity of raising structures of the following type:

(74) a. Someone seemed to attend every class.
b. [$_{AgrS}$ Someone seemed [$_{AgrS}$ someone to [$_{AgrO}$ every class [$_{VP}$ someone attend (every class)]]]]

Since the chain headed by *someone* has members both above and below the universal quantifier in Spec, AgrO, any of which is legitimate at the CI interface, *someone* can have either wide scope or narrow scope with respect to the universal quantifier.

Hornstein's theory is successful in treating cases in which one of the scope possibilities is excluded because it does not meet some independent binding requirement. For example, the usual ambiguity of transitive sentences with two quantifiers disappears in (75a) because only the higher subject chain link, c-commanding Spec, AgrO, binds the pronoun embedded under the object:

(75) a. Someone$_i$ played every piece of music he$_i$ knew.
b. [$_{AgrS}$ Someone [$_{Tns}$ [$_{AgrO}$ every piece of music he knew [$_{VP}$ (someone) [$_{VP}$ played (every piece of music he knew)]]]]]

Raising structures in which only one of the scope possibilities meets a binding requirement are analyzed similarly:

(76) a. Every picture of his$_i$ dog seemed to someone$_i$ to be out of focus.
b. [$_{AgrS}$ (every picture of his dog) [$_{VP}$ seemed to someone$_i$ [$_{AgrS}$ every picture of his$_i$ dog to be out of focus]]]

(77) a. Someone$_i$ seemed to himself$_i$ to be reviewing every report.
b. [$_{AgrS}$ someone$_i$ [$_{VP}$ seemed to himself$_i$ [$_{AgrS}$ (someone) to be [$_{AgrO}$ every report [$_{VP}$ (someone) [reviewing (every report)]]]]]]

In (76) the matrix prepositional object can bind the pronoun only in the subject link occupying the embedded AgrS. The link in the higher Spec, AgrS is not in

its c-command domain. The link in the lower VP, on the other hand, is ruled out by Diesing's Mapping Principle (it is a definite NP, which must leave the VP). Hence the raised subject has narrow scope with respect to the matrix prepositional object. In (77), on the other hand, the matrix subject can only have wide scope because only the highest chain link c-commands the matrix anaphor.

The Chinese facts also fall out if we assume that in Chinese the subject chain has no VP-internal chain link except in passive sentences.

8 Scope interpretation constrained by economy

The approach of Fox (1995b) maintains the Quantifier Raising and Quantifier Lowering rules of May (1985), and argues that they are restricted by economy considerations. This theory is built on the insight that shorter derivations are less costly; hence, among derivations with the same semantic interpretation, that involving the least moving is the optimal one. In other words, a quantifier moves only to establish a semantically significant scopal relation. Compare the possible derivations of (78a) and (79a):

(78) a. A boy loves every girl.
b. $[_{IP}$ a $boy_1 \ldots [_{VP}$ every $girl_2$ $[_{VP}$ t_1 loves $t_2]]]$
c. $[_{IP}$ every $girl_2$ $[_{IP}$ a $boy_1 \ldots [_{VP}$ t_1 loves $t_2]]]$

(79) a. John loves every girl.
b. $[_{IP}$ $John_1 \ldots [_{VP}$ every $girl_2$ $[_{VP}$ t_1 loves $t_2]]]$
c. $*[_{IP}$ every $girl_2$ $[_{IP}$ $John_1 \ldots [_{VP}$ t_1 loves $t_2]]]$

Although the derivation in (78c) is longer than that in (78b), the two derivations have different interpretations; hence they do not belong to the same reference set, and need not be compared with respect to economy. In the case of (79), on the other hand, the additional layer in (c) does not yield a further interpretation; hence the (c) variant is less optimal than the shorter (79b).

Fox's theory provides a natural account of a wide range of problematic scope interactions. Consider first the interaction of scope and VP ellipsis, discussed above in connection with (36). Recall that the problem is represented by the lack of ambiguity in (80b), as opposed to (80a):

(80) a. Some boy admires every teacher.
b. Some boy admires every teacher and Mary does too.

The explanation quoted in connection with (36) is based on the assumption that VP reconstruction at LF requires the elided VP to contain the operator binding the VP-internal variable. This explanation, however, only works if VP reconstruction is ordered after QR in LF. What is worse, VP ellipsis does not always eliminate ambiguity. In (81) the elided object quantifier can have scope over the subject:

(81) Some boy admires every teacher and some girl does too.

That is, whereas (82a) is an impossible LF for (80b), (82b) is a possible LF for (81):

(82) a. *every teacher$_1$ [some boy admires t_1] and
every teacher$_2$ [Mary admires t_2]
b. every teacher$_1$ [some boy admires t_1] and
every teacher$_2$ [some girl admires t_2]

In the case of (80a)/(82) the derivation is interpretively identical with the derivation involving no adjunction to IP; hence, as the less econominal variant, it is discarded. In the case of (80b)/(82b) adjunction to IP elicits a meaning which is otherwise not available; hence economy considerations are irrelevant. The requirement of parallelism between elided material and its antecedent coupled with the economy principle in question yields the following generalization:

(83) **Ellipsis scope generalization:**
The relative scope of two quantifiers, one of which is in an antecedent VP of an ellipsis construction, may differ from the surface c-command relation only if the parallel difference will have semantic effects in the elided VP.

Extraction out of coordinate structures is also known to limit scope interpretation possibilities. Compare the ambiguous (84a) with (84b), in which across-the-board quantifier lowering eliminates one of the scope readings: the object quantifier within the coordinated VP cannot take scope over the subject:

(84) a. A different student likes every professor.
b. A different student [[likes every professor] and [hates the dean]].

This fact has led May (1985) and Ruys (1992) to the conclusion that QR obeys the Coordinate Structure Constraint. However, this explanation cannot be extended to cases like (85):

(85) A guard is standing in front of every church and sitting at the side of every mosque.

This sentence is understood to describe a situation in which the guard varies with the churches and the mosques. This reading can be represented by an LF involving VP-level QR in both conjunctions, and across-the-board lowering of the subject to the two coordinate VPs, as follows:

(86) – is [$_{VP}$ every church$_1$ [$_{VP}$ [a guard] standing in front of t_1]] and
[$_{VP}$ every mosque$_1$ [$_{VP}$ [a guard] standing at the side of t_1]]

The question is why the proposed derivation, i.e., across-the-board lowering, is not allowed in the case of (84b). The answer is provided by the economy principle in question, together with the following independently motivated assumptions:

(87) a. Extraction is possible out of a coordinate structure only if there are two independent structures, each composed of one of the coordinates together with material above it up to the antecedent.
b. Grammatical constraints are checked independently in the two derivative structures.

It follows from (87) that lowering is only possible if it is across the board. Furthermore, as required by economy, lowering must yield a distinct interpretation in both derivative structure. This is satisfied in (86a, b), but would not be satisfied in (84b). Consider its LF:

(88) [$_{VP}$ every professor [$_{VP}$ a different student likes]] and
[$_{VP}$ the dean [$_{VP}$ a different student likes]]

Fox's approach can also explain why Quantifier Raising is clause-bounded in most cases: because QR takes place successive-cyclically, and each step must be motivated by a shift in semantic interpretation. Compare the following minimal pair:

(89) a. One girl knows that every boy bought a present for Mary.
b. One girl knows what every boy bought for Mary.

In (89a) the universal quantifier cannot take scope over the matrix existential quantifier. The reason is that there is no motivation for the first step of successive-cyclic Q-Raising to take place. Movement in one swoop across the clausal boundary, on the other hand, would violate regular constraints of A-bar movement – hence the quantifier is stuck. In (89b), on the other hand, the movement of the universal quantifier over the *wh*-operator is semantically motivated (it provides a pair-list reading). The quantifier raised that high is available for Q-Raising into the matrix sentence.

9 The theory of relativized scope

Liu's dissertation (1990) initiated an important new line of research in the area of scope ambiguities, which has culminated so far in a volume of papers edited by Anna Szabolcsi (1997c), among them Beghelli and Stowell (1997).

Liu (1990) was among the first to point out that the scope possibilities of a quantifier also depend on its type (see also Ioup 1975a). She divided quantified NPs into two types (generalized-specific (g-specific) and non-specific NPs), but Beghelli and Stowell (1997) have argued for the necessity of a more sophisticated classification. They distinguish five types of quantified phrases:

(90) a. Interrogative QPs: *what*, *which man*.
b. Negative QPs: *nobody, no man*.

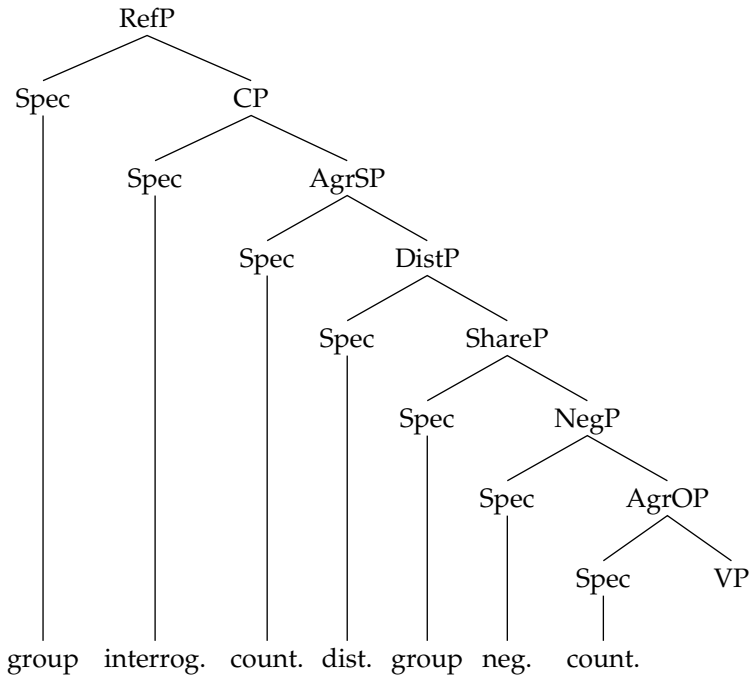
c. Distributive-universal QPs: *every/each man*.
d. Counting QPs: *few girls*, *at most three students*.
e. Group-denoting QPs: *one man*, *three men*, *a man*, *the men*.

They claim that these types of quantified phrases have their own designated landing sites in sentence structure, where they participate in feature checking. Their scope extends over the domain they c-command at LF; hence the fact that they can occupy only certain positions imposes indirectly constraints on their scope possibilities, and on their relative scope, as well.

Beghelli and Stowell argue for a much more articulated left periphery for the English sentence than was previously assumed. Although they base their claim on evidence internal to English, facts from languages with visible quantifier movement, primarily Hungarian, also support their proposal.

The structure they assign to the English sentence is represented under (91). Different types of quantifiers move to the specifiers of different projections in order to have their particular feature checked. The diagram indicates what type of quantifier each position can be filled with:

(91)



Simple indefinites of the type *a man*, *men*, can also remain in the VP as bound variables. Beghelli and Stowell are forced to analyze also *every* phrases that are in the scope of, e.g., negation (see (92)) as VP-internal bound variables:

(92) The students could not answer every question.

The proposed structure leaves room only for a few types of scope ambiguity. Thus a group-denoting QP, e.g., *two books* in (93), can have either wider or narrower scope than a distributive QP – given that it can occupy either Spec, RefP above DistP, or Spec, ShareP below DistP at LF:

(93) Each student read two books.

The system correctly predicts the lack of scope ambiguity in a wide range of cases, which remained a mystery for all previous approaches. For example, it falls out that a counting QP of object function, e.g., that in (94a, b), can never take inverse scope over a group denoting QP or distributive QP in subject position:

(94) a. Some/one of the students visited more than two girls.
b. Every student visited fewer than three girls.

An interrogative QP is predicted to take wide scope with respect to any other QP in its clause, other than a group denoting QP in Spec, RefP – which is borne out in most cases, though it is not borne out in the type illustrated in (32a) above.

Beghelli and Stowell claim that they can predict that of the seemingly similar constructions in (95a, b) and (96a, b), only the former have inverse scope:

(95) a. An American flag was hanging in front of two buildings.
b. Blossoms sprang out of two rosebushes.

(96) a. Five guards stood in front of two buildings.
b. Three blossoms sprang out of two rosebushes.

Simple indefinites (those supplied with *a/an*, and bare plurals), like *an American flag*, and *blossoms* in (95), have the possibility of a VP-internal bound variable interpretation; hence they can have narrow scope with respect to a group-denoting QP occupying ShareP. In (96a, b), however, the group-denoting subject QP will stand in Spec, RefP and the other one in Spec, ShareP; therefore inverse scope is impossible. (It is not quite clear, though, why it could not be the other way round, with the locative taking scope in Spec, RefP and the subject in Spec, ShareP.)

It also falls out from structure (91) that negation can have scope only over an object-counting QP, occupying Spec, AgrOP – see (97a) – but not over a subject-counting QP, occupying Spec, AgrSP – see (97b):

(97) a. The students didn't read two books.
b. Two students didn't read this book.

The scope of negation cannot extend over a group-denoting QP, either, unless it is a bare indefinite or an *every* phrase acting as a VP-internal bound variable, as in (98a, b):

(98) a. A student didn't write this book.
b. Every student didn't write an essay.

(91) also accounts for why an *each* QP more often takes wide scope than, e.g., an *every* QP: an *each* QP can only sit in Spec, DistP. That is why an *each* QP in the scope of negation is marginal, at best – cf.:

(99) a. John didn't read every book.
b. ??John didn't read each book.

Compare also the minimal pair in (100):

(100) a. One boy didn't read every book.
b. One boy didn't read each book.

In the case of (100a) the scope order *one>not>every* is perfectly possible, with *every* interpreted as a VP-internal bound variable. In (100b), on the other hand, the *each* QP must be raised to Spec, DistP; hence only the opposite scope order (*each>one>not*) exists.

It still remains a question why (101) is marginal:

(101) ??Every boy didn't leave.

Beghelli and Stowell claim that only *each* QPs are endowed with a [+Distributive] feature that must be checked in Spec, DistP; *every* QPs are underspecified for [Distributive]. Accordingly, *every* QPs only move to Spec, DistP if they are not bound as variables by a closer binder such as negation.

Szabolcsi (1997b) argues against semantically blind scope-assigning rules like that in (102) on a semantic basis:

(102) a $[_D \ldots b \ldots] \rightarrow$ (a scopes over b)

She provides further minimal pairs in the case of which a semantically blind rule would yield a wrong result. E.g., not all direct-object QPs can scope over the subject (cf. 103a, b), and not all direct-object QPs can scope over negation (cf. 104a, b):

(103) a. Three referees read every abstract.
every N > three N
b. Three referees read few abstracts.
*few N > three N

(104) a. John didn't read many abstracts.
many N > not
b. John didn't read few abstracts.
*few N > not

As she points out, it is not the case that the missing readings are incoherent – because they can be expressed by different constructions, such as those in (105):

(105) a. Few abstracts were read by three referees.
few N > three N
b. Few abstracts were not read by John.
few N > not

Szabolcsi claims that quantification involves a variety of distinct, semantically conditioned processes. She distinguishes two basic types of scope-taking mechanisms:

(i) The noun phrase introduces a logical subject of predication (i.e., basically a discourse referent).
(ii) The noun phrase performs a counting operation on an independently defined predicate denotation.

The two mechanisms, associated with different left-peripheral positions, result in different interpretations. These can be observed particularly clearly in Hungarian, where the left-peripheral positions in question (those identified by Beghelli and Stowell 1997) are filled visibly, at S-structure. Compare, for example, the following Hungarian examples:

(106) a. Tegnap sok diákunk meg betegedett.
yesterday many student-our PREFIX got-sick
b. Tegnap sok diákunk betegedett meg.
yesterday many student-our got-sick PREFIX

(106a), with the quantified phrase in Spec, DistP, involves a 'subject of predication' mode of operation, i.e., we take a set of students and claim that each of them fell ill. (106b), with the quantified phrase in Spec, AgrP, on the other hand, involves a counting operation: we take those who fell ill, and count our students among them.

10 The theory of overt quantifier movement

Kayne (1998) adopts Beghelli and Stowell's claim that quantified phrases occupy various designated landing sites in the left periphery of the sentence. What is new in his approach is the claim that movement to scope position invariably takes place in visible syntax; i.e., it always means the movement of phonologically realized phrases. Constructions in which an operator nevertheless does not c-command its scope at S-structure involve the subsequent movement of the phrase c-commanded by the operator into a position above the operator.

Kayne's starting point is the Norwegian construction in (107a, b), in which the negative object is assumed to occupy the specifier of NegP, a projection above VP and below CP. As shown by (107c, d), the preposing of a negative object into Spec, NegP is obligatory, and movement to Spec, NegP is restricted to negative objects:

(107) a. [$_{CP}$ Jon [$_{C'}$ leser [$_{NegP}$ ingen romaner]]]
John reads no novels

b. [$_{CP}$ Jon [$_{C'}$ har [$_{NegP}$ ingen romaner lest]]]
John has no novels read.

c. *Jon har lest inger romaner.
John has read no novels.

d. [$_{CP}$ Jon har [$_{NegP}$ ikke [$_{VP}$ lest noen romaner]]]
John has not read any novels.

Kayne claims that the movement of *no*-phrases to Spec, NegP takes place in English, as well – see (108); however, in sentences containing a lexical verb its effect is covered by subsequent VP movement into a higher specifier position – see the derivation in (109):

(108) a. [$_{CP}$ John [$_{C'}$ is [$_{NegP}$ no Einstein]]]
b. [$_{CP}$ John [$_{C'}$ has [$_{NegP}$ no car]]]

(109) John reads no novels → (neg phrase preposing)
John no novels$_i$ reads t_i → (VP preposing)
John [reads t_i]$_j$ no novels$_i$ t_j

Nobody and *somebody* do not occupy the same positions in this framework, which is also clear from the following minimal pair:

(110) a. Nobody is bound to be there.
b. Somebody is bound to be there.

Whereas (110a) cannot be assigned the interpretation in (111a), with *nobody* having narrow scope, (110b) can be assigned the interpretation in (111b), with *somebody* having wide scope:

(111) a. *'There is bound to be nobody there.'
b. 'There is bound to be somebody there.'

Nobody could only assume narrow scope in the Spec, NegP of the embedded clause. Its movement from there to the matrix subject position, however, would be improper (A'-to-A) movement; that is why its narrow-scope reading is impossible.

The asymmetrical scope possibilities of subjects and objects fall out in this theory for free. Consider again the minimal pair quoted above under (5a) and (6a), repeated here as (112):

(112) a. I demand that you marry no one.
b. I demand that no one marry you.

The negative object of (112a) assumes wide scope through the following series of movements:

(113) a. I demand that you marry no one → (neg preposing)
b. I no one$_i$ demand that you marry t$_i$ → (VP preposing)
c. I [demand that you marry t$_i$]$_j$ no one$_i$ t$_j$

The subject of (112b) cannot assume wide scope simply because a subject cannot be moved across a filled complementizer into a matrix A'-position (a constraint traditionally derived from the ECP).

A similar analysis is applied to *only* and *even* phrases, as well. The fact that these phrases follow their operator head *only* or *even* instead of appearing in its specifier position is derived by the further movement of the head to a higher W position, where it has its +w [word order] feature checked. That is:

(114) a. . . . only criticized Bill → (movement to Spec, *only*)
b. . . . Bill$_i$ only criticized t$_i$ → (raising of *only* to W)
c. . . . only$_j$ Bill$_i$ t$_j$ criticized t$_i$ → (VP preposing)
d. . . . [criticized t$_i$]$_k$ only$_j$ Bill$_i$ t$_j$ t$_k$

The theory does not appear to be particularly suitable for the handling of scope ambiguity; Kayne has to assume – in a way contradicting his program – that scope ambiguity arises from the possibility of reconstruction. Consider the following German example:

(115) weil irgendjemand auf jeden gespannt ist
because someone for everyone anxious is

Irgendjemand originates in a position below *auf jeden*, into which it can be reconstructed. (As suggested in Kayne 1998: fn. 110, the verb-final order may be the result of V movement to I, and the preposing of the verbless VP to Spec, IP. *Auf jeden* is in the specifier of a Distributive Phrase.) In (116) below, in which the universal quantifier is in an infinitival object presumably left in situ, on the other hand, *jemand*, the matrix subject, does not originate in a position below that of *jeden* – that is why *jeden* cannot have wide scope:

(116) weil jemand versucht hat jeden reinzulegen
because someone tried has everyone to-cheat

The question remains why the English equivalent of (116) is ambiguous:

(117) (since) someone has tried to cheat everyone

Cf. also:

(118) At least one student has tried to fool every professor.

In these English examples the *every* phrase is claimed to have been raised overtly into the matrix clause, followed by VP preposing. Cf.:

(119) a. Someone has tried to cheat everyone. → (distributive phrase preposing into Spec, DistP)
b. Someone everyone$_i$ has tried to cheat t_i → (VP movement to Spec, W)
c. Someone [has tried to cheat t_i]$_j$ everyone$_i$ t_j.

Kayne claims that in German, VP movement is systematically absent.

Kayne's theory of scope interpretation, eliminating post-Spell-Out A'-movement, simplifies grammar at the cost of deriving extremely complex sentence structures with projections of no independent motivation (e.g., WPs). Erteschik-Shir (1997) pursues the opposite strategy: her theory enriches grammar by introducing a level of representation marking topic-focus structure, but employs no empirically unmotivated transformations (whether quantifier movement or remnant movement).

11 Scope determined by f-structure

In Erteschik-Shir's theory of f(ocus) structure, scope is determined – and disambiguated – in the so-called f(ocus)-structure of sentences, which is an annotated S-structure with the topic and focus constituents marked (cf. Erteschik-Shir 1997: ch. 5). Topic and focus are discourse notions interpreted in the framework of a dynamic semantic model employing the file metafor. The TOPIC rule instructs the hearer to locate on the top of this file an existing card, whereas the FOCUS rule instructs the hearer either to open a new card (in the case of an indefinite) or to locate an existing card (in the case of a definite), and to put it on the top of the file.

Erteschik-Shir's premises for the derivation of scope are extremely simple. First, the topic by definition takes scope over the rest of the sentence. Sentences with an implicit stage topic (an invisible spatio-temporal argument referring to a particular location in space and time) have 'unscoped' interpretations (i.e., interpretations without any scope dependencies), in which the quantifiers are interpreted independently of each other, neither quantifier being a function of the other.

The topic of a sentence is selected from among the constituents identifying a discourse referent (i.e., basically from among the specific/generic noun phrases) by means of the following constraints:

(120) **Topic Constraints:**
a. If both the subject and another argument qualify as topics, the subject is picked as the main topic (unless discourse pushes heavily for the other f-structure).

b. A stage topic (represented by an explicit or implicit locative or temporal expression) or a subject topic is less marked than an object topic.

Sentences with two quantifiers such as (121) have two unmarked readings and a marked one. One of the unmarked options is to analyze the subject quantifier (Q1) as the topic (as in 122a); the other one is to assume a stage topic, with both quantifiers in focus (as in 122c). The marked solution is to pick the VP-internal quantifier as the topic (see 122b):

(121) Two girls arrested three boys.

(122) a. $[Q_1]_{TOP}\ [V\ Q_2]_{FOC} \rightarrow (Q_1 > Q_2)$
b. $TOP_2\ [Q_1\ V\ Q_2]_{FOC} \rightarrow (Q_2 > Q_1)$
c. $sTOP_t\ [Q_1\ V\ Q_2]_{FOC} \rightarrow$ (non-scoped reading)

Under any scope relation, both *two girls* and *three boys* allow both a D(istributive) reading and a C(ollective)/sum reading, i.e., they can be taken to denote either a set of individuals, or a single multitude: the sum (marked by the symbol +) of its members.

In the case of a stage topic, the truth of the predicate is evaluated with respect to a given time and place – that is, a single event is involved, which yields unscoped readings. (122c) actually has four unscoped readings, depending on whether the two quantifiers are assigned a D(istributive) set reading or a C(ollective) (sum) reading. The four possibilities are represented by Erteschik-Shir as follows (the symbols *s* and *o* mean 'subject' and 'object'):

(123) a. Cs Co {+(a, b)} → {+(1, 2, 3)}
b. Cs Do {+(a, b)} → 1
→ 2
→ 3
c. Ds Co a → {+(1, 2, 3)}
b →
d. Ds Do a → 1
b → 2
→ 3

In the reading under (123a) both the girls (a, b) and the boys (1, 2, 3) are looked upon collectively, as groups/sums. (123b) says that a group of two girls arrested three individual boys; (123c) says that two individual girls arrested a group of three boys; in (123d) both the boys and the girls are taken to be individuals.

The scoped readings are represented under (124):

(124) a. Ds (Co) a → [1, 2, 3]
b → [4, 5, 6]

b. Ds (Do) a $\rightarrow$ 1 b $\rightarrow$ 4
$\rightarrow$ 2 $\rightarrow$ 5
$\rightarrow$ 3 $\rightarrow$ 6

c. Do (Cs) [a, b] $\rightarrow$ 1
[c, d] $\rightarrow$ 2
[e, f] $\rightarrow$ 3

e. Do (Ds) a $\rightarrow$ 1 c $\rightarrow$ 2 e $\rightarrow$ 3
b $\rightarrow$ d $\rightarrow$ f $\rightarrow$

In the two unmarked cases (corresponding to (120a)) the subject quantifier functions as topic, and has wide scope. Depending on whether the object cardinal is looked upon collectively or distributively, the sentence means (124a) or (124b). In the case of (124a) the two girls each arrested a group of three boys, whereas in the case of (124b) the two girls each arrested three individual boys.

(124c, d), with the object quantifiers having wide scope, represent two marked readings. In the case of (124c) a possibly different group of two girls arrested each of the three boys, whereas in the case of (124d) a possibly different set of two individual girls arrested each of them.

Stage topics are ruled out for individual-level predicates; hence sentences with individual-level predicates such as (125) are predicted to have no unscoped readings:

(125) Two students speak three languages.

Indeed, (125) does not express that a group or set of two students speaks a group or set of three languages. Either each of the students speaks three languages (irrespective of whether their languages are the same or different), or each of the languages is spoken by two students (irrespective of whether the speakers of the different languages coincide or not).

Certain individual-level predicates block a reading in which the object is interpreted as the topic. E.g.:

(126) a. Two boxes contain three books.
b. Two lakes are close to three houses.
c. Two women have three husbands.
d. Two dogs require three caretakers.

Such sentences are predicted not to allow their object to take wide scope, and, as their predicates are individual-level, they cannot have a stage topic, either. Indeed, they can only be assigned the following readings:

(127) a. Ds (Co) a $\rightarrow$ [1, 2, 3]
b $\rightarrow$ [4, 5, 6]

b. Ds (Do) a $\rightarrow$ 1 b $\rightarrow$ 4
$\rightarrow$ 2 $\rightarrow$ 5
$\rightarrow$ 3 $\rightarrow$ 6

Consider also the relative scope possibilities of *some* and *every*, e.g., in (128):

(128) Everyone arrested someone.

Someone cannot be the main topic; furthermore, it is singular, hence the distributive/collective distinction is irrelevant. This leaves three readings, namely:

(129) a. sTOP_i [everyone$_D$ arrested someone]$_{FOC}$
b. sTOP_i [everyone$_C$ arrested someone]$_{FOC}$
c. Everyone$_{TOP}$ [arrested someone]$_{FOC}$

The unmarked reading that can be derived from (128a) is that in (129c). *Everyone* is nearly always understood to denote a specific set already present in the domain of discourse, and hence to bear a topic role. In this case, represented in (129c), the predicate is assessed for each individual member of this set, with the denotation of *someone* co-varying with them. In the unlikely interpretation under (129a) the sentence is assigned a stage topic; hence it describes a single event in which one person gets arrested by each member of the set defined by *everyone*. (129b) means the same except that *everyone* is viewed collectively. In Erteschik-Shir's theory the focus of a sentence can be further divided into a subordinate topic and focus, which allows for the topic to distribute over the object also in the case of a stage topic.

Each differs from *every* in that it has only a distributive reading; no collective reading is available in its case.

A scope theory based on a somewhat similar insight is that of Hunyadi (2002), who argues that relative scope is universally expressed by sentence prosody. In the type of language represented by, e.g., Hungarian, an operator has scope over the intonational phrase that it is the head of. The head of an intonational phrase is the constituent bearing primary stress; hence a stressed quantifier has scope over the unstressed quantifiers of the same intonational phrase. Operators heading separate intonational phrases are ambiguous scopally (unless they are inherently ranked, occupying different positions in a stipulated hierarchy of operators, in which the focus is preceded by quantifiers, and quantifiers are preceded by so-called sentence operators).

12 Scope and lexical semantics

Farkas (1997) claims that structural considerations underdetermine scope; they determine a necessary condition of an expression taking scope over another one, which, however, is not a sufficient condition.

Here is a case illustrating Farkas's point. The scope of universal quantifiers is usually-clause bound (unlike the scope of existentials, which is unbounded). E.g.:

(130) a. A politician said that every city should be the capital.
b. A politician said that the President lives in every city.

In these sentences, the universal cannot have 'extra-wide scope', extending over the existential in the main clause, by any means. On the other hand, its extra-wide scope is perfectly possible in the following sentences:

(131) A student made sure that every invited speaker had a ride.

The structural conditions are identical in (130) and (131); what is different is the lexical semantics of the main predicates. This is the generalization that accounts for the possibility of the wide-scope reading of the universal in (131):

(132) Extra-wide scope of a distributive universal over an indefinite is possible iff the two arguments are co-participants in some eventuality *e* in virtue of the lexical semantics of the predicates involved. In this case the two arguments are related in some relation *R*.

13 Conclusion

Questions of operator scope have been in the focus of interest in generative linguistics for at least 25 years; still, presumably not even the English facts to be accounted for are fully known yet (as recent papers such as Beghelli and Stowell 1997 and Szabolcsi 1997b revealed important new constraints on possible scope relations). Analyses of the quantifier scope phenomena of languages other than English hardly exist at all, and cross-linguistic studies are also very rare; hence very little is known of the parametric variation licensed in Universal Grammar. Hungarian, as well as Palestinian Arabic and Kinyarwanda, have been reported to display transparent, disambiguated quantifier scope relations; but it is not known how wide-spread this type of language is. In the case of languages like English the disambiguation of scope – i.e., the mapping of the non-bi-unique relation between form and interpretation on bi-unique relations – requires creative technical solutions. These are particularly sensitive to changes of linguistic theory and hence to obsolescence – so the problem of scope ambiguities is likely to stay with us also in the years to come.

1 Introduction

1.1 An informal introduction

Condition C of the Binding Theory, or some equivalent formulation, prohibits coreference between a non-pronoun (names, descriptions, etc.) and a pronoun under certain structural conditions. This prohibition is illustrated in the paradigm in (1) (underlined elements are supposed to corefer or to enter into a binding relationship):

(1) a. John said he was running for office.
b. *He said that John was running for office.
c. The office that John is running for will make him influential.
d. The office that he is running for will make John influential.

The pronoun may refer to the person designated by the name *John* in a, c, and d but not in b. This pattern shows that linear order is not at stake, or least not alone. The relevant notion involves c-command, leading to the informal formulation of Condition C in (2):

(2) **Condition C:**
A pronoun cannot corefer with a non-pronoun that it c-commands.

Only in (1b) is this principle violated under the relevant reading. In this context, (3) is surprising:

(3) a. *Whose examination of John did he fear?
b. *He feared Mary's examination of John.

In (3a), the pronoun does not c-command the *wh*-phrase, yet this sentence is deviant. This means that some modification of Condition C is needed.

A priori we may think that there are two distinct approaches to explaining this deviance: either modify the way Condition C is formulated, or keep it constant and modify how we define the kind of input that is used to evaluate whether it is satisfied or not. This is a subtle distinction. For the distinction to be real we must make sure that the two approaches are not mutually interchangeable. If we build into the formulation of Condition C a rule for evaluating the input that duplicates what we would do if we modify the input to Condition C without changing its formulation, the proposals are identical on these data and will have to be evaluated on something they truly do differently. This does not mean there is no issue, but the issue will not be relevant to the data we will look at, nor will it modify the logical structure of what ultimately needs to be said.

The second approach has always looked quite plausible, given that the deviance of (3a) seems related to the deviance of (3b): in both, the offending description is contained in the direct object of the verb *fear*, and the canonical[1] position of the direct object of *fear* is the postverbal position, a position c-commanded by the pronoun. If the direct object is treated as if it were in this canonical object position, we would have essentially manipulated the input to Condition C without reformulating it. Again, there are many different notations that can be used to construe this idea, and justifying which one should be used is a rather complex issue related to the choice of approaches discussed above, and not discussed here.[2]

Since (3a) involves a movement dependency between the clause-initial *wh*-phrase and one argument of the verb – a non-controversial claim when properly understood – we will use one current notation for this dependency in terms of traces. Accordingly, it can be represented as a binding relationship between this preposed phrase and the direct object position of this verb:

(4) [Whose examination of John]$_j$ did he fear t_j?

with t_j the trace of the *wh*-phrase. The pronoun *he* c-commands this trace t_j. If we suppose that this preposed phrase is, for the purpose of Condition C, in its trace position t_j or behaves as if it were in its trace position, the problem this sentence raises is accommodated, as it now has a structure similar to that of (3b).

Since the preposed phrase is moved, but behaves as if it had not, i.e., as if it were in the position it moved from, this process is, using the spatial movement metaphor, called reconstruction: the preposed phrase is reconstructed into its trace.

The kind of questions we will ask are: when does reconstruction take place? Is it always possible? Is it sometimes obligatory? Is it sensitive to the type of movement constructions involved? For example, we may ask of A-movement constructions whether they exhibit reconstruction effects at all (researchers are historically divided on this question) and, if they do, whether they do so in the same way as A-bar constructions.

These, however, are a small corner of a bigger problem. To provide a broader perspective, we note that the investigation of reconstruction effects is part of

increasingly larger questions, which are important but will essentially be left unaddressed here.

We may first ask whether reconstruction effects function the same way in all movement constructions. Second, we may ask a set of more general descriptive questions. Reconstruction effects can be viewed as special cases of the more general category of connectivity effects. Connectivity effects are cases in which a phrase seems to behave as if it occupied a position different from its 'surface' position, i.e., the position that it seems to be occupying in the spoken string. Such effects are found in a great variety of constructions, in particular constructions involving movement but also in constructions for which movement is not clearly or perhaps not plausibly involved.

As descriptive questions we can ask:

- Under what conditions are connectivity effects found?
- Are connectivity effects and reconstruction effects the same?
- Are connectivity effects always and only found in movement constructions?

Connectivity effects have been extensively investigated and there have been many proposals to achieve a principled understanding of their existence and their properties, with repercussions affecting core aspects of the architecture of syntactic theory. One type of construction in particular stands out as significant: (specificational) pseudocleft constructions. They exhibit connectivity effects and it is far from obvious that they involve movement (of the relevant kind). They may instead involve deletion or special interpretive rules. Recent work dealing with these questions includes Heycock and Kroch (1999); Sharvit (1999); Den Dikken et al. (2000); and Schlenker (2003b).

Finally, we ought to raise theoretical questions, i.e., questions of explanatory adequacy:

- Why do we find the answers that we do to the descriptive questions?
- How is linguistic theory organized so that connectivity effects, or the relationship between connectivity and reconstruction, fall out from the very architecture of the theory?

For example, given the current state of the research, it may well be true that connectivity effects are found only in cases of movement (reconstruction effects) or deletion (under some kind of identity). If such is the case, the existence of connectivity is related to the presence of the 'connected' phrases in positions other than where they overtly occur, at the right level of analysis. If it were otherwise, the existence of connectivity would appear more mysterious. Similarly, differences in reconstruction properties in A- and A-bar-movement constructions should follow directly from the differences between these movements, in much the same way as different projectiles (in a vacuum) follow different paths due to some difference in their initial velocity and nothing else.

Finally, before proceeding, it is worth noting that the data on reconstruction will mostly come from English, the language for which there is a systematic and deep and wide enough body of technical literature. The data are complex and non-uniform across speakers. The root of these dialectal differences is not understood. What will be presented here is what, in the author's judgment, the technical literature takes more or less to be the standard dialect. The text will contain scattered, non-systematic remarks about such variations (see Kuno 1997 and Safir 1999 for some discussion).

1.2 A more systematic introduction

1.2.1 Relevant principles

We define connectivity effects as cases in which a phrase superficially in a certain position P behaves as if it were in position Q.[3] In principle, such effects could arise and mostly do arise with respect to any principle appealing to the syntactic position of particular phrases (e.g., what it means to be interpreted as an argument of some predicate, to be inflected for a particular Case, or to show a certain kind of agreement morphology).

For the most part, we will focus on reconstruction or connectivity effects involving a few interpretive principles of binding and scope, that is, generalizations about structure-sensitive referential dependencies between phrases. The term 'reconstruction' is customarily reserved for such cases of connectivity.

For each of these interpretive principles, we provide in (5) a rough approximation of its formulation below, sufficient to illustrate the problems relating to connectivity:

(5) a. **Binding principles** (see chapter 9):
Condition A: anaphors must have a local antecedent (more or less a c-commanding antecedent in the same clause no further than the first c-commanding subject).
Condition B: pronouns cannot have a local antecedent (more or less a c-commanding antecedent in the same clause).
Condition C: pronouns cannot corefer with non-pronouns they c-command.

b. **Scope principles:**
If *X* superficially c-commands *Y*, *Y* can be interpreted in the scope of *X*. *X* and *Y* can outscope each other only if *X* and *Y* are clause mates.

c. **Pronominal binding principle** (a principle of both binding and scope):
A pronoun can behave as a variable bound by *X* only if it can be interpreted in the scope of *X*.

As we have seen above in the case of Condition C, in order to understand reconstruction effects, and beyond, connectivity effects, we need to concurrently develop first how exactly Condition C should be formulated, and second what

kind of manipulation (syntactic processes, rules of semantic interpretation, etc.) surface syntactic structures have to be subjected to in order to provide the right kind of input for the application of this principle.

The same questions arise for each of the principles above. This makes the potential complexity of the resulting system we will need to postulate increase exponentially. Thus it is conceivable that each properly formulated principle requires a different kind of manipulation of the strings we are studying. On the other hand, it is also conceivable that a unique input in conjunction with principles (not covertly encoding in their formulation any manipulation of the surface syntactic string) is sufficient. This would, for example, justify a level of Logical Form representations, that is, manipulated surface structures, which all the principles under consideration would take as input. Regardless of what the correct answer is, it is clear that it will have a fundamental bearing on the internal organization of syntactic theory and its interface with semantic theory.

We will now adopt a certain vocabulary to talk about syntactic dependencies, which is standard in the Principles and Parameters family of theoretical models and encodes various assumptions. It is important to keep in mind that this does not affect the essence of the limited data discussed here, but does affect the form in which they are presented.[4] One such assumption is the representation of predicate–argument relations as structurally local underlying relations modified by movement dependencies. Another is the representation of movement dependencies as trace-binding relations. Finally we talk about movement derivationally, mostly because standard vocabulary – invented with a derivational perspective in mind – sounds more intuitive this way.

1.2.2 Movement and pied-piping

To talk meaningfully about connectivity and reconstruction, we need basic characterizations of movement and pied-piping. This is what this section provides.

Natural languages exhibit movement dependencies. The existence of such dependencies can be simply illustrated by the distributional differences between the DPs *the boy* and *which boy* in (6) and (7):

(6) a. Jones met the boy.
    b. Who met the boy?
    c. *The boy did Jones meet.

(7) a. *Jones met which boy?
    b. Who met which boy?
    c. Which boy did Jones meet?

We want to say that regardless of the choice of determiner D in $[_{DP}$ D boy], this DP behaves as a direct object of *met* in the sense that whatever kind of semantic object this DP stands for, it is understood as bearing the same semantic relation – call it its thematic property – to the predicate *meet* in all these sentences. The

fact that D = *which* induces different distributional properties than D = *the* means that these determiners have different licensing requirements. These licensing requirements – call them quantificational in the present case – sometimes force a *wh*-D (*which*), but not a definite D (*the*), to appear sentence-initially, as in (7c).

A minimal description of these observations could take the following form: a DP – say *which boy* – encodes two set of properties (to simplify say only two, even though it may be two among others): thematic properties and quantificational properties. Its thematic properties require it to be paired to some predicate (here, *meet*). Its quantificational properties require it to be paired with some quantificational position (i.e., to be assigned scope: here the clause-initial position). The movement dependency is the dependency between the quantificational position of this DP and the predicate.

As mentioned above, we use a standard notation to express this dependency, assuming as correct the consequences that this choice carries (even though almost everything discussed here could be recast in some alternative notation). In these terms, the thematic properties of the 'object' DP in (7c) are expressed by the direct object position this DP occupies in underlying structure, or, to put it representationally, by the position of its most deeply embedded trace. Its quantificational properties are derived from the position it occupies in overt structure, i.e., by the position in which the DP is 'pronounced', namely [spec, CP]. The movement dependency is then a dependency between [spec, CP] and the direct object position. A fuller picture would take into account the fact that DPs need (and in many cases morphologically encode) Case. Current theories postulate that all DPs will also involve movement to a Case position to license their Case property.

In (8):

(8) Bill wonders $[_{CP}\ e_0\ [_{C'}\ [_{IP}\ [e_1]$ will be $[_{VP}$ sold $[e_2]]]]$
|
[which pictures]

we get three positions (e_0, e_1, e_2) where e_0 = [spec, CP] is the quantificational position, e_1 = [spec, IP] is the nominative position, and e_2 is the thematic position of the phrase [which pictures]. In this example, the *wh*-DPs must participate in a movement dependency between the thematic position and the quantificational position. What is remarkable is that the need for this movement is a property of the determiner *which*, not of the noun *pictures*. This is made clear by (6) and (7), which involve the same object noun, different determiners, and different movement possibilities. The fact that the noun *pictures* in (8) is pronounced at the front of the embedded clause is no doubt because (i) *which* needs to be linked to this clause-initial position, and (ii) *which* and *pictures* need to be closely associated. Generalizing on standard use, let us call this property pied-piping:[5] the NP *pictures* has pied-piped in the sense that it appears where it does, not by virtue of what it is intrinsically but rather because it must be closely associated with an element, *which*, which has this distributional requirement.

Now suppose that a moved XP (e.g., a DP linked to several positions) contains moved material sensitive to the position in which this DP occurs. For a given property, which one(s) of these positions is this sensitive material evaluated in? Because a given DP is only pronounced once but is associated with several positions (e.g., thematic, Case, quantificational, etc.), the overt position in which it appears is not necessarily the one in which it is evaluated. Answering these questions means answering the descriptive questions we listed about reconstruction.

More generally, suppose we have a phrase P linked by movement to several positions ordered from highest to lowest (e_1, e_2, . . . , e_n). By convention here (we only consider overt movement for the moment), this phrase is pronounced in position e_1. If this phrase P contains material that appears to behave with respect to some principle (e.g., Binding Theoretic principles) in a position, say e_{n-1}, lower than that in which it is pronounced, we say that we are observing a 'reconstruction effect'. We also say that the material 'reconstructs' into e_{n-1}.[6] As mentioned earlier, the term 'reconstruction' is customarily reserved for cases in which the principles in question are interpretive principles of binding and scope.

It is worth remarking that there is no reason to think that this is a scientifically well-founded decision: it may well be that the right approach treats in a uniform way reconstruction effects involving thematic roles (something that actually systematically takes place), morphological properties such as Case or Agreement, and every other reconstruction effect. Nevertheless it is reasonable to try to understand how reconstruction for scope and binding works before worrying about whether all reconstruction effects should be treated uniformly. In what follows, I will thus use the term 'reconstruction' to mean reconstruction for scope and/or binding.

It is in this context that the following specific questions arise immediately:

- How does the reconstruction property arise?
- What properties does it have? Is it always possible? Is it sometimes obligatory?
- Do the possibilities of reconstruction depend on the overt distribution of P (i.e., on the position in which P is pronounced?

One question we may ask that we will not investigate in detail here is the following: when a phrase is moved, can we in principle find reconstruction effects with any part of this moved phrase? The answer seems to be mostly yes, with perhaps one exception: pied-piped material clearly shows reconstruction effects, but it is less clear whether, and perhaps unlikely that, the portion of the moved phrase that induces the movement is allowed to reconstruct. In the *wh*-movement example above, a negative answer would mean that the *wh*-determiner itself does not reconstruct. We will not discuss this question here.

We will restrict our discussion throughout to the reconstruction of pied-piped material in the sense of pied-piping adopted earlier. It should be noted that it is sometimes hard to tell what is the trigger for movement and what is pied-piped, e.g., in the case of topicalization of DPs and VPs, or in the case of A-movement. With this proviso, the reconstruction problem is nearly the mirror-image of the

pied-piping problem: the pied-piping problem is the problem of how much bigger a phrase can move than seems strictly necessary, while the reconstruction problem asks how big a portion of a moved phrase can behave as if it had not moved.

The very existence of reconstruction effects may appear somewhat surprising: why should languages bother to move a phrase to some position, only to interpret a portion of this phrase in a position it has been moved from? This may be taken as a reason to reject a 'literal' reconstruction mechanism process in favor of an alternative account without any 'moving back'. But this would be an illusion, for there seems to be no account available at the moment – and perhaps in principle – which does not construe the relevant reconstructed readings differently from that gotten from a structure in which movement of the reconstructed portions would not have taken place at all. And this is precisely what needs to be explained, regardless of the notations used to do it.

By definition, pied-piped material is moved for reasons extrinsic to the movement trigger. It is thus not so surprising that this material might behave as if it had not moved. Perhaps what is really surprising is that pied-piping exists at all. So far as is presently known, it is an unexplained property of language.[7]

2 Basic reconstruction effects

We begin by illustrating reconstruction effects with each of the interpretive principles we are focusing on. In each case, the examples will show that a (portion of a) moved phrase behaves from the point of this principle as if it had not moved.

2.1 Pronominal binding

Consider (9) (where the underlined quantifier is meant to bind the underlined pronoun):

(9) a. No politician ignores many of his collaborators.
b. *Many of his collaborators ignores no politician?

(Note that (9b) shows a weak crossover effect.) The judgments are preserved under movement:

(10) a. Which of his collaborators does no politician ignore t?
(Intended answer: His main pollster.)
b. *Which of his collaborators t ignores no politician?
(Intended answer: His main pollster.)

The pronoun *his* can only be bound by the quantifier *no politician* if the trace of the *wh*-phrase containing it is c-commanded by this quantifier, i.e., if the condition on pronominal binding is satisfied if we treat the moved phrase as unmoved.

2.2 Scope

Reconstruction effects for scope can be illustrated in a variety of ways. We illustrate cases of scopal interactions between two DPs, and cases of scopal interaction between a DP and a predicate.

2.2.1 DP–DP interactions

DP–DP scopal reconstruction can be illustrated by such examples as (11):

(11) Visit some girl, Bill says every boy did t.

Such a sentence may be interpreted with the DP *some girl* in the scope of the DP *every boy,* i.e., as meaning that Bill says that each boy visited a girl different from the one the other boys visited. If this were the interpreted form, we would not expect *every boy* to be able to outscope *some girl*, since these expressions are not clause mates. This is of course a reading that is available in the unmoved counterpart of this example:

(12) Bill says every boy visited some girl.

Examples illustrating the same effect but involving *wh*-movement are given below. First consider (13):

(13) a. You convinced three friends of a friend that every member should co-opt Bill.
b. You convinced Bill that every member should co-opt three friends of a friend.

Only in (13b) is it possible to understand the phrase *a friend* as being in the scope of *every member*. In other words, in (13b), Joe should co-opt a certain number of friends of a friend of Joe's, Mary should co-opt a certain number of friends of a friend of Mary's, etc. This reading is unavailable in (13a).

These judgments are preserved under *wh*-movement:

(14) a. How many friends of a friend did you convince t that every member should co-opt you?
b. How many friends of a friend did you convince Bill that every member should co-opt t?

Only in (14b), in which the trace t of the preposed *wh*-phrase is a clause mate of the quantifier *every member*, is it possible to understand the phrase *a friend* as being in the scope of *every member*. This is consistent with the idea that the pied-piped material in the preposed phrase can be interpreted as if it were in a position (it occupies overtly or in a position) it has been moved from.[8]

2.2.2 DP–predicate interactions

Consider (15):

(15) a. How many songs will you compose?
b. How many songs will you perform?

Thinking for illustrative purposes of the meaning of the verb *compose* as *cause to be in existence*, and *perform* as *cause to be performed*, we can paraphrase (15a) by (16a), and (15b) by either (16b) or (16c):

(16) a. For what number x, you will cause there to be x many songs in existence?
b. For what number x, you will cause there to be x many songs performed?
c. For what number x, there are x many songs you will cause to be performed?
= How many songs are there that you will perform?

The difference lies in the scope of the existential quantification rendered here by *there are . . .* with respect to the expression *will cause*. The reading in (16c) is less natural in the case of (15a): we cannot assert the existence of a set of objects with certain properties if these objects do not yet exist (presuming that if the songs are not composed yet, they do not exist in the relevant sense). For ease of reference, let us call the readings in (16a) and (16b) the narrow-scope or narrow readings (since *there* has narrower scope than *will cause*). We will call the reading in (16c) the wide-scope or wide reading.

The crucial ingredient here is this: one cannot plausibly be asserting the existence of songs in (15a) because the preposed phrase is an argument of a verb of creation, namely *compose*. Thus, these two sentences behave like their unmoved counterparts in (17) and illustrate a reconstruction effect:

(17) a. You will compose three songs?
b. You will perform three songs?

2.3 Condition C

We have already illustrated Condition C effects in (3). We repeat these examples here as (18):

(18) a. *Whose examination of John did he fear?
b. *He feared Mary's examination of John.

(18b), without *wh*-movement, behaves like (18a), illustrating a reconstruction effect.

2.4 Condition A

Reconstruction for Condition A of the Binding Theory can seemingly be illustrated by cases such as the following involving the reciprocal anaphor *each other*. Consider first the paradigm in (19) without *wh*-movement:

(19) a. *She reminded each other's friends that they saw Bill.
b. They reminded each other's friends that she saw Bill.
c. She reminded Bill that they saw each other's friends.

The pattern in (20) with *wh*-movement exactly mirrors this paradigm:

(20) a. *Which of each other's friends did she remind **t** that they saw Bill?
b. Which of each other's friends did they remind **t** that she saw Bill?
c. Which of each other's friends did she remind Bill that they saw **t**?

Unless some trace of the moved phrase is c-commanded by a potential antecedent, the sentence is ill-formed: these sentences behave from the point of view of anaphor binding as if movement had not taken place. However, the anaphor *each other* is a bound variable and thus falls under the principle of pronominal binding. As a result, we need to proceed differently to illustrate a pure Condition A reconstruction effect.

Either we illustrate a Condition A reconstruction effect with an anaphor that is not a bound variable, or we check that the locality condition that Condition A imposes on the antecedent anaphor relation must be satisfied under reconstruction. It turns out not to be straightforward to perform either of these tests in a simple way. It is possible that reflexives qualify as non-bound-variable anaphors in certain conditions (with non-quantificational antecedents), but showing that this is the case is at best complicated and perhaps not really possible. Checking the locality condition may be possible in cases involving intermediate traces (that we will discuss later, in section 3.1.2) but also involves complications. We thus leave this open at this point.

2.5 Condition B

Showing that Condition B effects are found under reconstruction also requires some analysis. (21–2) show a case in which a pronoun shows disjoint reference effects in its original position and under movement (topicalization), i.e., under reconstruction:

(21) a. *Mary says he saw him.
b. He says Mary saw him.

(22) a. *Him, Mary says he saw t.
b. Him, he says Mary saw t.

Of course, we should make sure that (22a) is not independently excluded. It may be, if all traces of A-bar-moved DPs (e.g., Topicalized DPs) behave like descriptions with respect to Condition C (*wh*-traces are R-expressions subject to Condition C): t would have to be disjoint from *he* because of Condition C without reconstruction. The acceptability of (22b), however, suggests that the traces of preposed pronouns are not subject to Condition C. If they were, the object t of *saw* would have to be disjoint from *he* (a Condition C effect). We conclude that the parallelism between (21) and (22) does illustrate a reconstruction effect.

2.6 Idioms and theta-roles

It is not customary to include the checking of predicate–argument relations in a discussion of reconstruction effects, even though predicate–argument relations (theta-role assignment) are interpretive relations. We have already seen in the case of verbs of creation that it is necessary to include such checking in the description of reconstruction effects. Once this is done, we can recast trace theory (in part) as encoding the fact that reconstruction for thematic role assignment systematically takes place.

For example, in (23):

(23) a. You think I like John.
b. John, you think I like t.

the presence of the trace t encodes the observation that from a thematic point of view, *John* in (23b) behaves exactly like *John* in (23a): this is a reconstruction effect. Although it is not fundamentally conceptually different from the general case, one special subcase of this is particularly useful, namely the case of (non-compositional) idiom chunks:

(24) a. You think Mary took much care of Bill.
b. How much care do you think Mary took t of Bill?

Unlike what happens with a preposed name or description, a preposed idiom chunk receives no relevant interpretation independently of the rest of the idiom. As a consequence, it must be understood exactly as if it was reconstructed.

3 Some basic generalizations

This section is a short overview of some basic generalizations regarding reconstruction in A-bar-movement cases, which form the basis of many discussions. They will be discussed in turn. We have seen that there are reconstruction effects with respect to every principle listed in (5). Recall that a reconstruction effect is an 'as if' effect: a moved item I behaves as if it were in a different position Q from the position P in which it is 'pronounced'.

The first generalization is that Q is a position from which I has moved, and no other position: reconstruction in movement cases is into traces, including intermediate traces, and nowhere else. The second generalization is that there are reconstruction effects in every type of phrasal movement: all varieties of A-bar-movement constructions and A-movement constructions (we leave aside non-phrasal movement cases).

3.1 Reconstruction: where to?

3.1.1 No reconstruction into non-traces

Naturally, it is not possible to prove that reconstruction is possible only into traces. However, individual examples can be (and have been) provided showing that other options are unavailable. We repeat below a few such examples, making the relevant point explicit.

Consider the contrasts in (25a), in which the pronoun *he* may or may not corefer with the phrase *the typical male viewer*:

(25) a. [Whose characterization of him] does the typical male viewer like t?
b. *[Whose characterization of the typical male viewer] does he like t?

We construe this as indicating that the preposed phrase (*wh*-moved) is reconstructed in the t position. That it is the position of this trace that matters rather than the mere fact that some movement has taken place is demonstrated by the contrast in (26):

(26) a. Which examiner of a good student you know did you tell **t** that he knew the dean?
b. *Which examiner of a good student you know did he tell the dean that you knew **t**?
c. *Which examiner of a good student you know did you tell the dean that he knew **t**?

It is only when the trace t of the preposed *wh*-phrase is c-commanded by the pronoun *he* that deviance ensues. Thus, it is the position from which movement originates that is important.

The same conclusion can be reached for other principles. We can illustrate it in the case of the reciprocal anaphor *each other*. (27) shows that unless some trace of the moved phrase is c-commanded by a potential antecedent, the sentence is ill-formed:

(27) a. *Which of each other's friends did he remind **t** that they saw Bill?
b. Which of each other's friends did they remind **t** that he saw Bill?
c. Which of each other's friends did he remind her that they saw **t**?

This shows again that we are dealing with a reconstruction effect and not the effect of some movement having taken place.

Similar examples can be constructed for pronominal binding ((10), repeated here as (28), where the underlined quantifier is meant to bind the underlined pronoun):

(28) a. Which of his collaborators does no politician ignore t?
(Intended answer: His main pollster.)
b. *Which of his collaborators t ignores no politician?
(Intended answer: His main pollster.)

As seen earlier, the pronoun *his* can only be bound by the quantifier *no politician* if the trace of the *wh*-phrase containing it is c-commanded by this quantifier.

We can also illustrate this with respect to scopal interaction between quantifiers ((14), repeated here as (29)):

(29) a. How many friends of a friend did you convince t that every member should co-opt you?
b. How many friends of a friend did you convince Bill that every member should co-opt t?

As seen earlier, only in (29b) is it possible to understand the phrase *a friend* as being in the scope of *every member*. In (29b), Joe should co-opt a certain number of friends of a friend of Joe's, Mary should co-opt a certain number of friends of a friend of Mary's, etc. This reading is unavailable in (29a), and this is consistent with the idea that the pied-piped material in the preposed phrase can be interpreted in a position (it occupies overtly or in a position) it has been moved from.

3.1.2 Reconstruction into intermediate positions

When a phrase is moved several times, reconstruction appears possible, at least in some cases, in any position the phrase has moved through: reconstruction is possible into any trace. Let us examine the logic of this situation. Consider the following structure, in which each element c-commands the next one:

(30) P . . . A . . . t1 . . . B . . . t2

P is a phrase moved from t2 to the c-commanding t1 on the surface c-commanding position of P. To illustrate the existence of cases in which reconstruction is into t1, we need to look at cases in which the exact reconstructed position of a moved phrase matters. One option is to check Condition A, which imposes a locality requirement.[9]

The reconstruction properties of pied-piped anaphors is exemplified in (31):

(31) a. I wonder which pictures of each other you think they said we liked.
b. I wonder which pictures of each other [you think [t1 they said [t2 we liked t3]]].

(31a) is ambiguous as to what the antecedent of the reciprocal anaphor is. Any underlined DP qualifies ((32): contrast this with (20)):

(32) a. I wonder which pictures of the others (of you) each of you thinks they said we liked t.
b. I wonder which pictures of the others (of them) you think each of them said we liked t.
c. I wonder which pictures of the others (of us) you think they said each of us liked t.

This state of affairs finds a ready description, given the otherwise well-supported assumption that extraction out of a sequence of clauses proceeds by successively fronting the moving phrase to the beginning of each clause containing it until it finds its final landing spot. As a result, a more complete representation of (31a) is (31b). Optional reconstruction into traces can then put the moved phrase back into any intermediate t position, where it can select an appropriately local antecedent. If reconstruction in t1 or t2 were not available, neither *you* nor *they* would qualify as appropriately local antecedents. This is a reconstruction effect in 'intermediate' traces. (Note that this paradigm also illustrates a reconstruction effect for Condition A.)

3.2 Reconstruction and movement types

We now briefly address the question of whether the possibility of reconstruction is sensitive to the type of movement involved. We will show that reconstruction effects seem to be found with all types of movement.

3.2.1 A-bar movement

Reconstruction effects are not limited to direct *wh*-questions of DPs. We find the same Condition C effect as above in direct or indirect *wh*-questions or Topicalization of various phrases, such as PPs, APs, or VPs, or other types of A-bar movement of various phrases. This is illustrated in (33):

(33) a. *I wonder [whose pictures of a successful athlete] he reminded Bill that you saw t.
b. *It is incredible [how proud of a successful athlete] Mary told him you were t.
c. *[Next to a good student's locker], she always puts stickers t.
d. *[Train a successful athlete I know], he says I should t.

(34) exemplifies reconstruction effects with the anaphor *each other* in a variety of constructions:

(34) a. I wonder which of each other's comments they/*Sue reported t.
b. Which of each other's friends did they/*Bill remember t?
c. *It is incredible [how proud of each other] Mary said you were t.
d. Next to each other's starting blocks, the athletes/*she put lucky charms t.

And (35) does the same thing for bound pronouns:

(35) a. I wonder whose comments about him no one reported t.
b. Happy that he had to lie, no one thinks you are t.
c. Against his own country, no true patriot will ever fight t.

3.2.2 A-movement

We will now demonstrate that reconstruction effects are also found with A-movement. It should be noted that this is a more controversial conclusion. The reason is that reconstruction seems to fail in a variety of A-movement cases. Dealing in detail with this controversy is beyond the scope of this chapter. The preponderance of the evidence clearly supports the existence of reconstruction effects in A-movement constructions. Here, we will limit ourselves to presenting some clear cases of reconstruction effects, noting a couple of cases of reconstruction failures.

The basic problem is raised by the ambiguity of (36):

(36) A Russian seems to have won the race.

(36) can have the two paraphrases in (37):

(37) a. It seems that there is a Russian who won the race.
b. There is a Russian who seems to have won the race.

In (37a), existential quantification takes place inside the scope of the verb *seem*. In (37b), existential quantification outscopes the verb *seem*.

One standard account takes the following form:

(i) The target sentence involves raising to subject, that is, it is associated with a pair of syntactic representations, roughly (38):

(38) a. seems [a Russian to have won the race]
b. a Russian [seems to have won the race]

These two representations are technically described as respectively the underlying structure of the target sentence and the surface structure of the target sentence.

(ii) The relationship between these syntactic structures is movement: the difference between these two structures – the relative position of the constituent *a*

Russian – is formalized as a movement rule or movement dependency, the effect of which is to express the non-redundant portions of these two structures. The constituent [a Russian] is raised from the position 'subject of the embedded clause' to the position 'subject of the main clause'; everything else remains the same. This movement, called 'raising to subject', belongs to the subcategory of A-movement.

(iii) The scopal ambiguity arises from taking either of these representations as input to compute scope relations, the first one giving rise to (37a) or (37b), the second to (37b) only.

(iv) Since the first interpretation is computed on the basis of the representation of the target sentence which does not surface, it looks like this interpretation is reached by exactly undoing movement: this is a reconstruction effect.

Many authors have argued that there is reconstruction under A-movement in this sense (e.g., Barss 1986; Sportiche 1997, 1999; Romero 1997a; Lebeaux 1998; Fox 1999). Some authors (e.g., May 1985) have argued that these readings arise by a different mechanism than exact undoing of the movement (they invoke a mechanism of Q-lowering). These doubts are echoed by Zubizaretta (1982a) and Lasnik (1998) regarding whether there is reconstruction under A-movement. The form of their argumentation is as follows: if there is reconstruction, we expect it to be fully general. Whenever we have a raising-to-subject structure, we should expect all interpretations to be available that are computed on pre-movement structures. If some of these interpretations are not available, this suggests that reconstruction is not generally available.

One such case is attributed to Chomsky by Zubizarreta. It is based on the pair in (39–40):

(39) Everyone is not listening.

(40) Everyone seems not to be listening.

(39) allows a reading in which negation outscopes the universally quantified subject, yielding the meaning in (41):

(41) It is not the case that everyone is listening.

Assuming reconstruction is available in (40), it should, from the relevant interpretive point of view, be treated as in (42):

(42) It seems everyone is not listening.

and thus yield the interpretation in (43), which is not an available interpretation:

(43) It seems that it is not the case that everyone is listening.

Lasnik argues for a similar conclusion based on the available readings for (44) (and other comparable examples):

(44) Every building is 10 percent likely to collapse.

If reconstruction were available in such a case, it should behave as in (45):

(45) It is 10 percent likely that every building will collapse.

But such a reading seems unavailable. What (44) says is that each building has a 10 percent probability of behaving a certain way. If there are two buildings in total, the probability that both collapse is 10 percent of 10 percent, that is, 1 percent, not 10 percent as (45) states. In other words, *every* cannot scope under *10 percent likely*: reconstruction seems impossible.

Although such cases raise serious problems which a theory of reconstruction must address, they do not seem to undermine the availability in principle of reconstruction in A-movement cases. First, note that the reading in (41) of (39) (and many other similar cases) looks like a straightforward case of reconstruction of A-movement from VP-internal subject position:

(46) Everyone is not [t listening] → is not [everyone listening].

Second, there are many other cases that Barss (1986), Sportiche (1997, 1999), Romero (1997a), Lebeaux (1998), and Fox (2002) provide suggesting reconstruction does take place. Cases involving complex scopal interactions can straightforwardly be computed on the basis of the pre-movement structures. Consider (47):

(47) a. A southerner is predicted to win every senate race.
b. It is predicted that for every senate race, a (different) southerner will win it.
c. For every senate race, there is a (different) southerner who is predicted to win it.
d. For every senate race, it is predicted that there is a (different) southerner who will win it.

Three relevant scope-inducing elements are involved: the existential quantifier introduced by the singular indefinite subject *a southerner*, the universal quantifier *every*, and the verb *predict*. A priori this should yield six scopal readings, but the three in which *a southerner* outscopes *every senate race* are pragmatically odd (since they require the same southerner to win every senate race). The remaining three are listed in (47b, c, d). (47b) clearly is the most accessible and natural reading, and is also the most relevant for our present purposes. The readings paraphrased in (47b, c) correspond to readings in which the sentence expresses a summary of individual predictions, one for each senate race. Such readings seem difficult at best, perhaps entirely unavailable for this sentence (although

pragmatically quite plausible): the sentence in (47a) most naturally reports a unique global prediction. This means that the only way that *every senate race* can outscope *a southerner* is if both of them are in the scope of the verb *predict*. These two observations indicate that one (perhaps the only) input for scope computation is (48a):

(48) a. is predicted [a southerner to win every senate race]
b. a southerner will win every senate race

As the prominent reading of (48b) shows, within a single clause, *every senate race* can then outscope *a southerner*.

Moreover, reconstruction effects can be illustrated with binding effects. Let us begin with Condition A, and consider the well-formed examples in (49):

(49) a. Pictures of each other seemed to the boys [t to be fuzzy].
b. Pictures of each other struck them as [t rather fuzzy].
c. It seemed to each of the boys [that pictures the other boys were fuzzy].
d. It struck each of them [that pictures of the others were fuzzy].

(49a, b) are well-formed with the readings indicated in (49c, d) respectively, even though the antecedent *them* of *each other* does not c-command it. Furthermore, the presence of an acceptable (plural) antecedent seems crucial to their acceptability. A similar reading with a discourse antecedent or a singular antecedent is unavailable. Thus, (50a, b) are deviant:[10]

(50) a. *Pictures of each other seemed (to him) [t to be fuzzy].
b. *Pictures of each other struck him as [t rather fuzzy].

The interpretation of these facts is straightforward and indicates that reconstruction for binding is possible. Under reconstruction, sentences (49a, b) and (50a, b) are respectively treated from the point of view of binding as their underlying structures (in 51–52):

(51) a. seemed to the boys [pictures of each other to be fuzzy]
b. struck them as [pictures of each other rather fuzzy]

(52) a. *seemed (to him) [pictures of each other to be fuzzy]
b. *struck him as [pictures of each other rather fuzzy]

In (51), the anaphors have a local enough c-commanding antecedent, while they do not in (52). The assumption that the experiencer *them/the boys* does c-command the subject of the embedded clause can be somewhat controlled by the unacceptability of (53):

(53) *It seemed to him [that John was sick].

which follows straightforwardly from a Condition C violation if this c-command relation holds. The assumption that the experiencer *them/the boys* does c-command material in the embedded infinitive can be controlled by the unacceptability of (54):

(54) *Mary seemed to him [t to like John].

Reconstruction effects with pronominal binding can also be directly illustrated. The well-formedness of (55):

(55) a. Pictures of his child seemed to everyone [t to be good].
b. Such evaluations of his speech struck every child as [t unfair].

shows that A-movement can remove a c-commanding binder for a pronoun without creating a violation of the structural requirement for pronominal binding. This suggests that pronominal binding can be evaluated on the pre-movement (i.e., reconstructed) structures in (56):

(56) a. seemed to everyone [pictures of his child to be good]
b. struck every child as [such evaluations of his speech unfair]

We can control for this conclusion by first noting that close parallels to (56a) support the relevant interpretation (see (57)):

(57) it seemed to everyone that pictures of his child were good

Second, we can check that in the absence of a position to reconstruct the raised subject in, the relevant reading is unavailable (due to the weak crossover effect: see (58)):

(58) a. *The new friend of his father painted every child.
b. *Such teachers of her children call every mother.

Similar reconstruction effects can also be illustrated for Condition C (cf. again Sportiche 1997, 1999; Romero 1997a; Fox 1999). We present one such type of example which will become relevant later.

First note that the French idioms in (59–60) can be somewhat marginally passivized as indicated:

(59) a. Jean a pris grand soin de Marie.
'John took a lot of care of Mary.'
b. ?Grand soin de Marie a été pris (par Jean).
*'A lot of care of Mary was taken by John.'

(60) a. Dans cette conversation, Jean a pris le parti de Marie trois fois.
'In this conversation, John took Mary's side three times.'

b. ?Dans cette conversation, le parti de Marie a été pris trois fois (par Jean).
?'In this conversation, Mary's side was taken three times by John.'

The idea is to use these idioms to design examples in which movement of an idiom chunk overtly removes a Condition C configuration. Their crucial feature is the passivizable object which can contain a name, and which can then be raised across a coreferential pronoun. We get (61–62):

(61) a. ?Grand soin de Marie me semble avoir été pris t.
b. ?Grand soin d'elle$_j$ lui$_j$ semble avoir été pris t.
c. ?Grand soin de Marie$_j$ lui$_k$ semble avoir été pris t.
d. *Grand soin de Marie$_j$ lui$_j$ semble avoir été pris t.
'Good care of Mary/her seemed to me/her to have been taken.'

(62) a. ?Le parti de Marie me semble avoir été pris t trois fois.
b. ?Son$_j$ parti lui$_j$ semble avoir été pris t trois fois.
c. ?Le parti de Marie$_j$ lui$_k$ semble avoir été pris t trois fois.
d. *Le parti de Marie$_j$ lui$_j$ semble avoir été pris t trois fois.
'Mary's/her side seemed to me/her to have been taken three times.'

(Passivization followed by) raising of the embedded direct object containing a name across a co-indexed pronoun systematically yields the deviant sentences (61d) and (62d), as compared to the benchmark, in which either the direct object contains a name but is raised across a non-co-indexed pronoun ((61a, b) or (62a, b)) or the direct object contains a pronoun ((61c) and (62c)).[11]

We noted in section 2.6 that idiom chunks had to reconstruct for the purpose of idiom interpretation. The effect of idiom reconstruction is to create a configuration violating Condition C. Since the sentences are deviant, they show that Condition C has access to structures reconstructed for the purpose of idiom interpretation.

3.3 Modalities of reconstruction

Reconstruction seems to operate differently depending on the circumstances. In this section we briefly describe some observed possibilities before returning to some of them in later sections. First, we will illustrate the observation that reconstruction may appear to be obligatory, optional, or impossible. Second, we will briefly consider how much of a moved phrase can reconstruct.

3.3.1 Obligatoriness, optionality, or impossibility

We will illustrate the following basic observations. First, in the simple and general case, reconstruction for Condition A is optional, while reconstruction for Condition C is obligatory. Consider again the cases of Condition C discussed previously. Imagine the context of asking questions about, or commenting to a

person comparing and analyzing, various surveys of TV viewers. We find the following:

(63) a. *[Whose characterization of the typical male viewer does he object to t?
b. *The standard characterization of the typical male viewer, he objects to t.

It is not sufficient to say reconstruction is available; we must say it is obligatory. If the option of not reconstructing the (pied-piped portion of the) preposed phrase in its trace position were available, there would be a derivation without a Condition C violation and the sentences should be acceptable.

It is not the case, however, that reconstruction of pied-piped material is always obligatory. In some cases, it seems to be optional. Observe the contrast in (64):

(64) a. *[Whose characterization of the typical male viewer does he resent t?
b. [Whose survey describing the typical male viewer does he resent t?

This contrast is typically taken to reflect a complement–adjunct asymmetry (see Van Riemsdijk and Williams 1981; Freidin 1986; Lebeaux 1988b, 1991, 1998). The offending description in (64a) is part of a pied-piped complement of the pied-piped head N of the *wh*-phrase, while it is part of the adjunct (the relative clause) to the pied-piped head N of the *wh*-phrase in (64b). We return to discussion of these facts in section 4.2.1.

In the case of Condition A, the optionality of reconstruction can easily be illustrated. We have seen that pied-piped phrases containing anaphors may reconstruct into any of their traces, but they need not reconstruct at all. Thus (65a) is well-formed with the interpretation given in (65b):

(65) a. They wonder which pictures of each other I preferred t.
b. Each of them wonders which pictures of the others I preferred.

If reconstruction were required, we would expect this sentence to be deviant, since the only possible antecedent, *they*, for *each other* would be 'too far'. This expectation is not met.

Second, sometimes reconstruction is impossible. We have already seen such cases in A-movement constructions. For example, (44), repeated here as (66), lacks a reading in which *10 percent likely* outscopes *every*:

(66) Every building is 10 percent likely to collapse.

Other, superficially more complex cases of impossible reconstruction are illustrated in (67–68):

(67) a. Stand on every roof, a guard will.
b. A guard will stand on every roof.
c. Every roof will have a different guard on it.

(68) a. Likely to win, nobody is.
b. Nobody is likely to win.
c. It is likely that nobody will win. (= In all likelihood, nobody will win.)
d. Nobody has the property of being likely to win.

(67a) should, under reconstruction of the preposed constituent, allow all the readings allowed by (67b), and in particular, the pragmatically most plausible reading paraphrased by (67c). Such a reading seems unavailable, perhaps suggesting that reconstruction of the preposed constituent is not possible. (68a) should, under reconstruction of the preposed constituent, allow all the readings allowed by (68b), and in particular, the reading paraphrased by (68c). Such a reading also seems unavailable, only the reading paraphrased by (68d) is available. This again may suggest that reconstruction of the preposed constituent is not possible.

We will not discuss any of these extremely interesting cases any further here. Sportiche (2003) extensively discusses cases of the sort in (66). Barss (1986), Sauerland (1999c), and Sauerland and Elbourne (2002) discuss the sorts in (67–68).

3.3.2 Partial reconstruction vs. radical reconstruction

As we mentioned earlier in section 1.2.2, reconstruction typically is held to affect only pied-piped material. Whether or not this description is factually accurate depends on a fine analysis of movement triggers and targets. Superficially, however, it seems false.

First consider a *wh*-question already discussed in 2.2.1 ((14b), repeated here as (69); see also note 8).

(69) How many friends of a friend did you convince Bill that every member should co-opt t?

There does not seem to be a reading in which the *wh*-operator *how many* reconstructs. Such a question would ask, for each member, the number of friends of a friend (of his) that you convinced Bill that this member should co-opt. The unavailability of such a reading is plausible given that *wh*-operators seem to be propositional operators, which in English[12] scope over the clause in front of which they are preposed. Thus it is quite plausible to assume that they cannot reconstruct.[13] Such examples may thus involve partial reconstruction.

There are cases for which it is harder to tell. For example, in cases of 'Topicalization' such as (70):

(70) A book, it is obvious everyone will buy.

the whole of the preposed element can be under the scope of *every*, suggesting total or so-called 'radical' reconstruction. But we cannot really decide without knowing exactly what the movement trigger and targets are. In particular, when

a constituent is topicalized, there are informational properties added to the sentence (being a topic or a focus, etc.). What would it mean for these properties to be reconstructed, and are they?

Finally, there are similar cases in A-movement constructions. The reading in which the subject scopes under the raising verb in (71a) seems undistinguishable from the interpretation that (71b) – without the movement – would receive:

(71) a. A southerner will win every senate race.
b. is predicted [a southerner to win every senate race]

Such cases are also said to involve radical reconstruction. We will not discuss these questions any further here. Some issues regarding A-movement are addressed in Sauerland (1999c) and Sauerland and Elbourne (2002).

4 Accounts

We now turn to discussions of the accounts that have been given of the reconstruction effects found with each principle, accompanied by some critical remarks. We will provide a discussion of each principle and its associated reconstructed effects in turn. In the next section, we will look at how all the various conclusions reached for each individual principle can be reconciled in a coherent whole.

We begin by outlining the essential ingredients of the theoretical constructions elaborated in the Principles and Parameters framework to account for the facts above, following more or less their historical development. Again, very little that will be discussed depends on the particular notation that we use; most of what we say could readily be translated into other notations. However, we need to be rather specific about this notation to do justice to some of the proposals that have been put forth within this framework.

We assume the following:

(i) There is a level of surface syntactic structures (surface trees or, in Minimalist terms, input to spell-out). These structures are derived from underlying syntactic structures by means of movement.
(ii) There is a level of underlying structures (underlying trees). These structures are defined as representing predicate argument relations as local syntactic relations.
(iii) Movement maps underlying trees onto surface trees (spell-out trees) by successive application. Movement dependencies are represented as trace-binding relations in surface syntactic structures.
(iv) A surface structure tree can be manipulated by processes yielding its Logical Form (LF), which is the interface with non-grammatical systems of interpretation.

Note that conceptually, in such models, LF representations, which may (or may not) differ from underlying or surface representations, have their raison d'être in providing a transparent input for semantic interpretation. In effect, LFs 'are' exhaustive representations of the structure-sensitive aspects of sentence meanings. Note also that there is a priori no assumption that LFs are different from underlying structures or surface (spelled-out) structures.

4.1 Condition A

We begin with a discussion of reconstruction effects with respect to Condition A. Recall what we have established so far:

- There are reconstruction effects with respect to Condition A.
- Reconstruction for Condition A can be into any trace position of the moved phrase.
- Reconstruction is optional.

How do we account for these properties?

4.1.1 Anywhere Principle

All accounts essentially have the same structure: they simply allow a moved phrase containing an anaphor to be evaluated in any position that it is linked to by movement – its original position or any intermediate landing position. In the literature, several alternative proposals (P) are put forward to derive this result:

P1 Literal reconstruction: Condition A applies at the output of a manipulated surface structure in which pied-piped material is literally in a position in which Condition A can be satisfied. Under such a proposal, (72a) would be first manipulated to yield the LF (72b). Condition A would be applied to this LP, yielding the interpretation in (72c) or ultimately (72d):

(72) a. I wonder which pictures of <u>each other they</u> remained fond of t.
b. I wonder which <u>they</u> remained fond of pictures of <u>each other</u>.
c. I wonder for which x, <u>they</u> remained fond of x, pictures of <u>each other</u> (x).
d. I wonder for which x, each of them remained fond of x, pictures of the others (x).

P2 Modification of Condition A (Barss 1986, 1988): The binding domain of an anaphor for Condition A is by definition computed from any position that the anaphor has occupied in the course of a derivation. Thus, in (72a), the local domain of the anaphor can be computed either from the position that *which pictures of each other* occupies at surface structure or from t.

P3 Condition A as an anywhere principle (Belletti and Rizzi 1988): Condition A can be satisfied in the course of a derivation. As long as an anaphor satisfies

Condition A at any point in the course of derivation, Condition A is satisfied. Thus, (72a) is well-formed because Condition A is satisfied before *wh*-movement takes place.

P2 is stated in derivational terms while P3 is stated in representational terms (it can be seen as applying to a single level of representation). For our purposes, they are equivalent. The question, then, is whether we can distinguish P1 from P2/P3.

Consider, first, reciprocals. Recall that a reciprocal is a bound variable. As a result, it seems clear that given the shared conceptualization of LF, only P1 is acceptable for reciprocals. Indeed, since a reciprocal is a bound variable, to be interpreted as such it must be in the scope of – that is, be c-commanded by – its antecedent at LF (recall this is how LF is defined). This means literal reconstruction is required anyway for the LF of (72a). The other alternatives seem to become redundant.

It should be noted that current theoretical developments considerably narrow the difference between these two (or three) approaches. Indeed, under some recent models (Minimalist cyclic models), LF representations are constructed and interpreted cyclically from the bottom up. As a result, Condition A could reasonably be held to have to be checked at the end of each cycle, rather than only once at the end of the last cycle, giving the appearance of P2 or P3 under the guise of P1.

Turning now to reflexives, it is clear that this reasoning does not necessarily apply to them. Unlike reciprocals, a reflexive does not have to be analyzed as a bound variable. It can be thought of as a pronoun coreferential with (i.e., picking out the same referent as) its antecedent, whose selection obeys c-command and locality constraints. In other words, scope and the determination of an acceptable antecedent are perhaps divorced in the case of reflexives, and may thus provide a way to distinguish P1 from P2/P3 as they apply to reflexives. Indeed, if a phrase containing a reflexive is allowed to outscope the c-command position of the antecedent of the reflexive, P1 cannot be right, while P2/P3 may. We will leave this question open here (but see Cresti 1995 and Fox and Nissenbaum 2002 for some discussion).

4.1.2 Predicate–argument asymmetry

The statement that reconstruction for Condition A can be into any trace position of the moved phrase seem contradicted by the existence of the kind of case in (73–74), noted in Cinque (1984) and Barss (1986):

(73) a. [These pictures of each other], I think they liked t.
b. [Visit each other's parents], I think they will t.

(74) a. They think that [these pictures of each other], I like t.
b. *They think that [visit each other's parents], I will t.

In (73), the preposed phrase may reconstruct, allowing *they* to antecede *each other*. (74a, b), however, diverge: (74a) allows *each other* to take *they* as antecedent, indicating that the domain for anaphor binding is the main clause. This is not sufficient, however, for (74b), which is deviant. This suggests that predicate movement (such as VP-preposing) differs from A-bar movement of DPs: predicate movement behaves as if reconstruction is always obligatory even when anaphors are involved: if the preposed predicate must be interpreted in the position t in (74b), its deviance is derived. This generalization seems corroborated by the behavior of AP preposing:

(75) a. I wonder how fond of each other's parents (Bill thinks) they are t.
b. *They wonder how fond of each other's parents (Bill thinks) Sue is t.

As (75b) illustrates, it is not possible to select *they* as antecedent, even though it would be in the local domain of the anaphor if it could compute its binding domain from the moved position. Furthermore, when there are intermediate traces, reconstruction must be all the way down:

(76) a. *I wonder how fond of each other's parents they think [t Bill is t].
b. *Visit each other's parents, you think [t they said [t Mary and Bill did t]].

Reconstruction into intermediate trace positions would wrongly allow *they* to be antecedent in (76a) and *you* or *they* in (76b).

Descriptively, the computation of the binding domain for Condition A of an anaphor pied-piped under predicate movement must take place from the lowest possible reconstructed position. Of course, a theory of reconstruction should be able to derive why predicate movement behaves differently from other types of movement. We postpone this discussion to section 5.3, until after we have discussed reconstruction effects for Condition C.

4.2 Condition C

We now turn to a more detailed discussion of reconstruction effects with respect to Condition C. Summarizing the descriptive generalizations we have from section 3.3.1, we get:

- Reconstruction for Condition C is obligatory.
- Reconstruction for adjuncts is optional.

We will begin by examining how the second generalization should be derived. Next we will survey some proposals regarding the first generalization and proceed to discuss cases in which it appears violated. We will then return to predicate–argument asymmetries discussed in the previous section and survey how these asymmetries should be handled.

4.2.1 Argument–adjunct distinction

Recall what the argument–adjunct asymmetry is. It is based on the kind of contrast in (77a, b):

(77) a. *[Whose characterization of the typical male viewer does he resent t?
b. [Whose survey describing the typical male viewer does he resent t?

As was said earlier, this contrast is typically taken to reflect a complement–adjunct asymmetry (see Van Riemsdijk and Williams 1981; Freidin 1986; Lebeaux 1988b, 1991, 1998). The offending description in (77a) is part of a pied-piped complement of the pied-piped head N of the *wh*-phrase, while it is part of the adjunct (the relative clause) to the pied-piped head N of the *wh*-phrase in (77b).

(78) initially suggests that what is at stake in this difference is not only the degree of embedding of the offending descriptions within the preposed phrase, since they are more or less equally embedded:

(78) a. Which pictures that you had given to an actor you know did he say you wanted back t?
b. *How happy that you had met an actor you knew did he say you were t?

In both cases, the offending description is embedded inside a pied-piped clause. When this pied-piped clause is a complement of the Adjective head of the *wh*-phrase, deviance results. This seems to strengthen the conclusion that we are dealing with a complement–adjunct asymmetry. We should note, however, that this assumption is controversial (see, for example, Safir 1999; Kuno 1997; Lasnik 1998) and there seems to be some poorly understood speaker variation. In what follows, we will suppose that the relevant difference is indeed a complement–adjunct asymmetry and we will formulate the relevant generalizations in these terms.

At this point, the most mainstream idea concerning how to treat this asymmetry is the one put forward by Lebeaux (1988b, 1991). To resolve the apparent paradox caused by the difference between (77a) and (77b), Lebeaux suggests that unlike a complement to a phrase, an adjunct to a phrase – here the relative clause adjunct to the NP *survey* – can be inserted in a derivation after this phrase has moved (can be inserted acyclically).[14] Accordingly, the derivation of (77b) would have the stages in (79):

(79) a. Underlying structure: He resents whose survey?
b. *Wh*-movement: Whose survey does he resent t?
c. Adjunct insertion: Whose survey [describing the typical male viewer] does he resent t?

Since reconstruction is, descriptively, a matter of accessing a pre-movement structure to evaluate interpretation, no Condition C can arise in such cases if such a derivation is possible. Hence the complement–adjunct asymmetry that we have been assuming holds in these reconstruction cases.

Granting the correctness of the putative adjunct–argument asymmetry and Lebeaux's basic idea, several questions arise, which we address in turn. The first is why adjuncts can be inserted in this fashion while complements cannot. One idea is that relations of predicate saturation and modification must be syntactically local. A predicate needs its complement locally to be properly saturated. This means that at LF, a predicate must have its complement locally. If reconstruction is nothing but access to pre-movement structures, complements must be inserted in underlying structures. A phrase also needs its modifier locally somewhere, but this can be satisfied anywhere, e.g., after the phrase has moved. Such an idea makes sense especially for representations that are interpreted, that is, LFs. Consider now the well-formed example in (80a):

(80) a. Which [[pictures of each other] [which John likes]] does he think they like t?
b. Which [[pictures of each other] [which John likes]] does he think they like [pictures of each other]?

The head of the relative clause must reconstruct to allow *each other* to be properly and locally bound by *they*, but the relative must have been inserted late in order to avoid a Condition C violation between *John* and *he*. This means the interpreted form must be as in (80b); that is, the head of the relative clause must be present twice: once in the low position, because complements must reconstruct and because *each other* needs to be properly bound, and once high, so that the relative clause can modify it locally.

This is natural in the context of Chomsky's (1995c) proposal that traces are copies (to which we return in section 5.2.1): the second form is simply the LF representation of the first:

(81) a. Which [[pictures of each other] [which John likes]] does he think they like t?
b. Which [[pictures of each other] [which John likes]] does he think they like [pictures of each other]?

This means that we could just as well state Lebeaux's idea representationally by stating that the only requirement should be that LFs satisfy the locality requirement necessary to interpret predicate–complement (more generally predicate–argument) and modifier–modifiee relations. In such a case, the derivation of these sentences (if there is one) would be (82):[15]

(82) a. Which [[pictures of each other] [which John likes]] does he think they like [[pictures of each other] [which John likes]]?
b. Which [[pictures of each other] [which John likes]] does he think they like [[pictures of each other] [~~which John likes~~]]?

with selective LF erasure of what need not be interpreted (here the lowest copy of the adjunct).

As a last remark on this topic, it should be noted that relative clauses raise particular problems. First, it is not entirely clear that relative clauses should be treated as adjuncts. Kayne (1994), for example, argues that they should be treated as complements of Determiners. Second, there are cases which have been argued to involve raising of the head of the relative clause from inside the relative clause (cf. Vergnaud 1974; Kayne 1994). According to such proposals, the head of the relative must originate inside the relative clause. Consequently, the relative clause cannot be inserted as an instance of late adjunct insertion, which makes this derivational approach problematic. The representational equivalent does not face such a problem, however, as selective reconstruction (or partial copy erasure) is still viable.

A relevant case would be the well-formed sentence in (83):

(83) Which [[pictures of each other$_j$] [which Jane showed the boys$_j$]] does she think you like?

Since the reciprocal *each other*, as part of the head of the relative clause, is bound by the object inside the relative clause, this should be a case of a head having raised from inside the relative clause. Under a derivational approach à la Lebeaux/ Chomsky, the lower copy should at least contain the head of the relative clause, hence the relative clause itself (since this head is only introduced inside the relative clause), incorrectly triggering a Condition C violation, as in (84a). Under a representional approach, no such problem arises: portion of traces can be selectively interpreted as in (84b):

(84) a. Which [[pictures of each other$_j$] [which Jane showed the boys$_j$]] does **she** think you like [[pictures of each other$_j$] [which **Jane** showed the boys$_j$]]?
b. Which [[pictures of each other$_j$] [which Jane showed the boys$_j$]] does **she** think you like [pictures of each other$_j$]?

We leave these questions open and refer to Sportiche (2000) for further discussion.

4.2.2 Anywhere Principle

Ignoring the adjunct–argument asymmetries just discussed, the preliminary observations we have presented suggest that reconstruction is obligatory when it comes to Condition C effects. We first sharpen this observation by asking what happens when there are several traces. (85a, b) are illustrative:

(85) a. *[Whose characterization of the typical male viewer does he object to t1?
b. *[Whose characterization of the typical male viewer do you think t2 he object to t1?

(85b) is deviant.[16] If obligatory reconstruction could be done in the intermediate trace t2, no Condition C effect should arise, leaving this deviance unexplained.

We conclude that with respect to Condition C, reconstruction is mandatory in the lowest trace, all the way down.

How should these observations be handled? There are basically two proposals:

P4: Condition C is an anywhere principle: it cannot be violated at any stage of a derivation.

P5: Condition C applies at LF and literal reconstruction is obligatory: the (pied-piped portion of the) moved phrase occurs in LF in the position of the most deeply embedded trace.

P4 is put forward by Lebeaux (1988b, 1991, 1998), while P5 is proposed by Chomsky (1995c) and is defended in Fox (1999) (but perhaps undermined by Fox 2002 and by Fox and Nissenbaum 1999, as we will see below).

Comparing P4 and P5, it is easy to see that P5 is conceptually preferable: why should Condition C, a principle of interpretation, apply anywhere else but at LF? This is one of the reasons Chomsky provides for his view.[17] However, just as we have discussed in connection with Condition A, this argument loses some force in a model in which bits of LF are incrementally and cyclically calculated. P4 could, in such a model, be seen as applying at the output of each cycle. P5 could too, so that the differences between them would be much diminished, but it could also apply as originally intended by Chomsky (i.e., as last cyclic in a cyclic model).

Still, the proposals would not be identical. Are there grounds on which to decide whether P4 can be an anywhere Principle as Lebeaux defines it? Note that P4 is stronger than P5: P5 applies to a subset of cases that P4 applies to. The way to decide, then, is to find cases falling under P4 but not under P5 and see whether they are deviant or not: P4 predicts a positive answer, P5 a negative one. What we need to find are sentences in which a pre-movement structure violates Condition C, but the post-movement structure does not. P4 predicts them to be deviant, P5 does not.

One class of cases is discussed by May and Fiengo (1994) and Fox (1999, 2002), and involves Antecedent Contained Deletion (ACD). Examples are in (86):

(86) a. *If the pollsters showed him the characterizations of the typical male viewer . . .
b. If the pollsters showed him the surveys the typical male viewer would want them to . . .
c. [the typical male viewer would want them to ___]$_j$ the pollsters *showed him* t_j

(86a), a Condition C effect, shows that the pronoun *him* c-commands the second object *the characterizations of the typical male viewer*. Despite this c-command relationship, (86b) is fine. The basic reasoning proposed is the following (see the references cited for more detail): the antecedent of the missing VP in (86b) is the VP containing the relative clause. Replacing the missing VP with its antecedent would lead to infinite regress (as it still contains the missing VP). To resolve this paradox, movement of the relative to a position outside of the VP must be available

as in (86c), providing a non-paradoxical antecedent (in italics) for the missing VP. As a side-effect, this movement removes *the typical male viewer* from the c-command domain of the pronoun *him*. The fact that the sentence is fine suggests that Condition C is checked only after this movement has taken place.

However, according to Fox (2002) and Fox and Nissenbaum (1999), this last set of examples could be derived without the relative clause being c-commanded by the pronoun at any level – roughly speaking, the relative clause is merged into the tree as extraposed. Such analyses crucially rely on the adjunct–argument asymmetry (perhaps analyzed as late adjunct insertion – see section 4.2.1). Under such analyses, these examples, which involve the relative clauses as adjuncts, become irrelevant to the present point. A discussion of this proposal is important to decide the significance of examples such as (86a) and (86b), but this is beyond the scope of this chapter.[18]

There are cases, however, which seem more difficult to reconcile with P4. Consider the following examples involving A-movement, such as (87a) with (87b) as pre-movement structure:

(87) a. This picture of John seems to him [t to be fuzzy].
b. seems to him [this picture of John to be fuzzy]

Since this sentence is well-formed, it suggests that Condition C is not checked before movement, as the pre-movement structure in (87b) would otherwise violate Condition C. Lebeaux (1991, 1998), who wants to preserve Condition C as an Anywhere Principle, suggests a different theory of underlying structure to get around this problem, namely that in underlying structure, all NPs are empty slots which are allowed to be filled only after A-movement has taken place. Accordingly the underlying structure for (87a) would be:

(88) seems to him [[$_{DP}$ this [$_{NP}$ e] of [$_{DP}$ D [$_{NP}$ e]] to be fuzzy]

In this structure, it must be assumed that Names such as NPs are NPs (a non-trivial assumption) with a silent Determiner, annotated as D here. At this point, this DP would not qualify as a name or an R-expression and thus not fall under Condition C. Insertion of *John* would take place after raising to subject yielding (87a).

There are several problems with such an approach. One problem is that it is unclear exactly what the principles guiding the form of underlying structures are any more. Another is the fact mentioned earlier involving idiom chunks (which is actually a fact about scope). Recall that if an idiom chunk is (passivized and) raised, we get Condition C effects ((61–62), repeated here as (89–90)):

(89) a. ?Grand soin de Marie me semble avoir été pris t.
b. ?Grand soin d'elle$_j$ lui$_j$ semble avoir été pris t.
c. ?Grand soin de Marie$_j$ lui$_k$ semble avoir été pris t.
d. *Grand soin de Marie$_j$ lui$_j$ semble avoir été pris t.
'Good care of Mary/her seemed to me/her to have been taken.'

(90) a. ?Le parti de Marie me semble avoir été pris t trois fois.
b. ?Son$_j$ parti lui$_j$ semble avoir été pris t trois fois.
c. ?Le parti de Marie$_j$ lui$_k$ semble avoir été pris t trois fois.
d. *Le parti de Marie$_j$ lui$_j$ semble avoir été pris t trois fois.
'Mary's/her side seemed to me/her to have been taken three times.'

To get a Condition C effect, the name must be c-commanded by the pronoun either in underlying structure or at LF. If the former, a reason must be found as to why an NP object of an idiom chunk must be inserted in underlying structure. If the latter, we must suppose that we reconstruct into the trace position material that was never there in the first place. (What then is the reconstruction process?)

Similar conclusions can be reached by looking at cases (cf. Sportiche 1997, 1999; Romero 1997a; Fox 1999) in which a raised subject containing a name is understood as under the scope of the raising verb. Fox (1999), provides the following example, again going in the same direction:

(91) *For these issues to be clarified, many more new papers about Quine$_j$'s philosophy seem to him$_j$ [t to be needed].

Fox's reported judgment is as indicated. This sentence is constructed so as to strongly favor a reading in which the existence of these new papers is not asserted. In other words, it strongly favors a reading in which the subject is interpreted as reconstructed in the scope of the verb *seem*, i.e., as corresponding to the underlying representation in (92):

(92) seem to him$_j$ [to be needed many more new papers about Quine$_j$'s philosophy]

Its status ensues from the Condition C violation that is incurred.

As a control, note that coreference per se is not problematic. (93), with the pronoun and the name swapped, is fine:

(93) Many more new papers about his philosophy seem to Quine$_j$ [t to be needed].

All these are cases in which movement removes an offending configuration for Condition C, and thus they argue against the idea that Condition C is an Anywhere Principle.

We conclude that Condition C applies at LF and does not apply to underlying structures.[19] This is not compatible with P4, but it is with P5 and thus favors the latter (under either construal: cyclic or last cyclic). It is less clear at this point whether P5 is correct in stating that Condition C only applies at LF rather than, say, to surface representations as well (if they are different). In a Minimalist model such as Chomsky's (1995c), given the results above, LF would indeed be the only option.

Assuming the correctness of P5 raises further problems. If the mapping from (what roughly corresponds to) surface representations to LF is not trivial, it remains to be explained why, in general, such mapping operations (*wh*-in-situ

interpretation, quantifier raising – apart perhaps from the ACD cases discussed earlier) never bleed Condition C. For example:

(94) a. A different person compared her to every picture of Jane.
b. Who told him about which picture of Bill?

In (94a), *every picture of Jane* can outscope *a different person*, but this interpretive operation (quantifier raising to a position higher than the subject) cannot remove the Condition C violation incurred if *her* and *Jane* are coreferential. In (94b), if *wh*-movement preposes *which picture of Bill* to [spec, CP], there will not be a Condition C violation at LF.

One option is to assume that there are no 'covert' operations (cf. Williams 1986; Brody 1995b); another is to assume that Condition C applies to 'surface-like' structures. In Chomsky's (1995c) Minimalist framework, the second option is unavailable and the first is not considered. This is why, talking about *wh*-in situ interpretation, Chomsky suggests that such mapping operations move only the quantifier and not the whole DP (just the D without the NP), here yielding (95), which still violates Condition C:

(95) which [who told him about t picture of Bill]

Chomsky's copy theory of traces could be construed differently to handle this general observation. Adopting for expository purposes Fox's (2002) construal of such copies as definite descriptions and assuming phrasal covert movement, the LF of (94a) would roughly be (96):

(96) for every picture of Jane [a different person compared her to this picture of Jane]

New problems of course now arise: if traces are copies, or if movement is limited to Ds, what happens in the cases of ACD discussed above? We refer to Fox (1999, 2002) and Fox and Nissenbaum (1999) for further discussion.

4.2.3 Predicate–argument asymmetry

Unlike argument preposing, predicate preposing does not seem to increase the set of possible antecedents for a pied-piped anaphor. This contrast is illustrated in (97):

(97) a. They think that [these pictures of each other], John likes t.
b. *They think that [visit each other's parents], John will t.

How should this contrast be handled?

One class of proposals (Williams 1980; Barss 1986, 1988; Huang 1993; and in part Reinhart and Reuland 1993) require (using different devices) that nothing other than the subject of a predicate can bind an anaphor inside this predicate from outside this predicate: either the anaphor is bound internally to the predicate phrase, or it is bound by the subject of this predicate. Clearly all such proposals

will be able to exclude (97b), since the only antecedent it would allow for the reciprocal would be *John.* However, most will be insufficient in general to extend to cases not involving anaphors. For example, Barss (1986) and Heycock (1995) note the ill-formedness of the type of example in (98):

(98) a. *[Bribe a Nobel Prize winner]$_k$, he did t_k.
b. *[Bribe a Nobel Prize winner]$_k$, he says you$_j$ did t_k.

The relevant factor here is that coreference between *he* and *a Nobel Prize winner* is excluded. One option for handling these facts would be to adopt Lebeaux's (1991) proposal that Condition C is an Anywhere Principle and cannot be violated at any stage of the derivation. However, we have seen that this option is not tenable. Furthermore, it would not generalize to the anaphor cases.

In effect what is needed to handle all of these cases ((97) and (98)) is some reason why reconstruction of preposed predicates to their lowest trace is required. If such is the case, examples (97b) and (98b) would respectively receive the LFs in (99):

(99) a. *They think that ~~[visit each other's parents],~~ John will [visit each other's parents].
b. *[Bribe a Nobel Prize Winner], he says you did.

whose ill-formed status follows immediately. This is exactly what Barss (1986) proposes. The question is now why it should be true that reconstruction of predicates is required.

There are two proposals in the literature. The first is an elaboration of Huang (1993) due to Takano (1995), which we will detail below. The second is due to Heycock (1995), who argues that predicates must always reconstruct for scope reasons. If we accept that predicates must (at least under normal circumstances) take narrow scope – and Heycock (1995) provides strong supporting evidence for this claim – we derive the reconstruction properties of preposed predicates. We only have an explanation, however, if we can derive the idea that predicates must have narrow scope. Otherwise, we simply have a sophisticated stipulation of the result that we want with as many stipulated properties (= predicates must have narrow scope) as results (= they must reconstruct). In other words, granting that predicates must always reconstruct for scope reasons, the question is why.

If the semantic properties of predicates somehow precluded them from being interpreted with wide scope, we would have such an explanation, but there do not seem to be reasons why failure to reconstruct a predicate should lead to semantic ill-formedness. Thus a priori there is nothing wrong with representation of the meaning of (100a) as (100b) with wide scope of the predicate:

(100) a. John will sleep.
b. There is a property P of sleeping, will (P (John)). (assuming verbs range over properties or relations)

Huang's (1993) proposal seems to be successfully extendable to all such cases, and with some explanatory power, because it seems independently plausible given general assumptions about phrase structure. Regarding anaphors, Huang suggests the preposing of predicates actually always preposes a constituent containing the subject of this predicate. As a result, the domain within which the anaphor must be bound is no larger than this preposed constituent itself.

The details of this proposal are as follows: first, the subject of a predicate is always generated internally to the projection of this predicate as specifier of this projection (this is the so-called Predicate Internal Subject Hypothesis, justified on independent grounds). In underlying structure, the subject of a verb V (or an adjective A) is always the specifier of the corresponding VP (or AP). If this subject shows up elsewhere, it has been moved. For example, (101a) has the surface structure indicated in (101b):

(101) a. John will see Mary.
b. John_j will $[_{VP}\ t_j$ [see Mary]].

The structure of the example involving VP-preposing now looks as in (102):

(102) a. Visit each other's friends, you think they said [Bill and Mary]$_j$ will t_k.
b. [t_j Visit each other's friends]$_k$, you think they said [Bill and Mary]$_j$ will t_k.

The trace t_j closes off the domain within which *each other* can look for an antecedent and thus can be the only antecedent available. Since this trace is the trace of *Bill and Mary*, *Bill and Mary* is the only allowed antecedent. One appealing aspect of this proposal is that under these assumptions about phrase structure, pied-piping of the subject trace follows from the general properties of phrasal movement: the subject trace is within the minimal phrasal constituent containing the predicate and thus must move along with it; the minimal movable projection of a predicate always contains the (trace of the) subject of this predicate.

Of course, this proposal covers (98a) but not (98b), repeated – with traces – as (103):

(103) a. *[t_j Bribe <u>a Nobel Prize winner</u>]$_k$, <u>he</u>$_j$ did t_k.
b. *[t_j Bribe <u>a Nobel Prize winner</u>]$_k$, <u>he</u>$_m$ says you$_j$ did t_k.

As we saw earlier, (98b) would also be straightforwardly handled as a Condition C effect if the VP were forced to literally reconstruct: the description *a Nobel Prize winner* would be c-commanded by the coreferential pronoun *he*, thus triggering a Condition C effect.

If we modify Huang's proposal and suppose that literal reconstruction of moved predicates is required we handle all the relevant facts. This is Takano's (1995) proposal. The Huang–Takano proposal provides a simple reason why literal reconstruction is required: traces are bound variables and must, at LF, be in

the scope of (i.e., be c-commanded by) their binders.[20] In particular, if a preposed predicate does not reconstruct, it will leave the trace of the subject that it contains without c-commanding antecedent. Thus the behavior of fronted predicates is ultimately due to the Predicate Internal Subject Hypothesis (as Huang suggested), but in two different ways: for anaphors because the predicate always has a trace subject, and for Condition C because this trace forces reconstruction of the fronted predicate.

Heycock (1995) argues not only that the Huang–Takano proposal is insufficient,[21] but also that it is too strong. We will comment on Heycock's arguments and their inconclusiveness in sections 5.3.2 and 5.3.3.

4.3 Scope

We now turn to a more systematic investigation of the interaction of reconstruction for binding and reconstruction for scope. As we will see, such considerations play a major role in determining reconstruction possibilities (as shown, for example, in Cresti 1995; Heycock 1995; Fox 1999), and lead to substantial reformulations of the problem. In this subsection, we discuss scope reconstruction. In the next section we will turn to the interaction of scope and binding reconstruction.

We have already seen all sorts of reconstruction effect for scope, e.g., cases of pronominal binding, reciprocal binding, and quantifier–predicate interactions. We now focus a bit more on the last of these. Recall that in such sentences as (15) (repeated here as (104)), in which we paraphrase *compose* as *cause to be in existence* and *perform* as *cause to be performed:*

(104) a. How many songs will you compose?
b. How many songs will you perform?

we can paraphrase (104a) by (16a) (repeated here as (105a)), and (104b) by either (16b) or (16c) (repeated here as (105b, c)):

(105) a. For what number x, you will cause there to be x many songs in existence?
b. For what number x, you will cause there to be x many songs performed?
c. For what number x, there are x many songs you will cause to be performed?
= How many songs are there that you will perform?

As outlined above, the difference lies in the scope of the existential quantification rendered here by *there are* . . . with respect to the expression *will cause*. Reading (105c) is less natural in the case of (104a): we cannot assert the existence of a set of objects with certain properties if these objects do not yet exist (presuming that if the songs are not composed yet, they do not exist).[22] We have called the readings in (105) and (105b) the narrow-scope or narrow readings (since *there* has

narrower scope than *will cause*) and the reading in (105c) the wide-scope or wide reading.

As has often been noted (see, e.g., Dobrovie-Sorin 1994b; Heycock 1995), we can unambiguously render the narrow readings of (104a, b) in French as in (106a, b).[23] The wide reading of (104b) is rendered by (106c), which also allows the narrow reading:

(106) a. Combien vas-tu composer de chansons?
how many will you compose of songs
b. Combien vas-tu chanter de chansons?
how many will you sing of songs
c. Combien de chansons vas-tu chanter?
how many songs will you sing

Call the construction exemplified in the first two sentences *combien*-split. Given that *combien* means 'what is the number (or quantity) x such that', it is natural to take the position of *de chansons* to correspond to the locus of the existential quantification 'there are x many songs'. In this way, the surface form of the French narrow-reading question seems to be exactly what we need to express its meaning, as (106a) essentially has the form of (105a). By the same token, (106c) has the form of (105c). It is thus plausible to assume that the ambiguity of the English sentence (104b) is represented at LF by varying what reconstructs:

(107) a. Reconstruction: how many will you perform songs (narrow reading)
No reconstruction: how many songs will you perform (wide reading)

This plausibility argument as to what the LF representations of such sentences are finds support from some French facts noted in De Swart (1998):[24]

(108) a. Combien de chansons les enfants ont-ils tous chanté(s)?
how many of songs the children have-they all sung
b. Combien les enfants ont-ils tous chanté de chansons?
how many the children have-they all sung of songs
c. For what number x, the children all caused there to be x many songs performed?
d. For what number x, there are x many songs the children all caused to be performed?

The sentence in (108b) has only a narrow reading, represented by (108c), with the existential quantifier (*there*) in the scope of the universal quantifier (*all*) so that the choice of the songs to be performed can vary with each child. Given that floated quantifiers always take their surface scope, this reading is predicted by

the assumed LF representation for narrow readings. The sentence in (108a) is ambiguous between the narrow and the wide reading. Under the wide reading, represented by (108d), the existential quantifier (*there*) is not in the scope of the universal quantifier (*all*) so that the choice of the songs cannot vary with each child. To make this more concrete, imagine an exam situation in which children have to sing six songs. Three of them are the exact same three for all the children (the imposed program), and the other three are freely chosen by each child (the free program). To (108a), it is possible to truthfully answer 'three' or 'six'. To (108c), only 'six' is a truthful answer.

5 Simultaneous reconstruction requirements

In this section, we discuss what happens in situations in which the requirements of several binding and/or scope principles must be simultaneously satisfied. We actually already have encountered such situations, but we now discuss them somewhat more systematically. A coherent overall theory of reconstruction should be able to handle all such cases – certainly a non-trivial task and, if achieved, a non-trivial result.

We begin by discussing interactions between Condition C and pronominal binding. Next we turn to quantifier–predicate scope and Condition C. Finally, we examine the case of predicate preposing and its interaction with scope considerations and Condition C.

5.1 Condition C, Condition A, and pronominal binding

Lebeaux (1991) reports that Condition C effects and the possibilities for pronominal binding correlate. He discusses examples similar to (109) (from Fox 1999, in which more such examples are discussed):

(109) a. *Which survey that he could show to the typical female viewer would she hope no pollster would publish t?
b. Which survey that he could show to her would the typical female viewer hope no pollster would publish t?
(Desired answer to both: 'His most embarrassing.')
c. *Quel sondage qu'il pourrait montrer à Madame toutlemonde ne laisserait-t-elle aucun journaliste publier t?
d. Quel sondage qu'il pourrait lui montrer Madame toutlemonde ne laisserait-t-elle aucun journaliste publier t?

In order for the pronoun *he* to be understood as bound by the quantifier *no pollster*, reconstruction of the relative clause must take place. However, if

reconstruction takes place, this puts the indirect object of the verb *show* in the c-command domain of the subject of the verb *hope*. If the latter is a pronoun, and the former is a name or a description, we should observe a Condition C effect, and we do, as in (109a). Otherwise we should not, as in (109b). The deviance of (109a) indicates that Condition C and the condition on pronominal binding cannot be checked on strictly different inputs. If they were, we should be able to satisfy Condition C on some input and the condition on pronominal Binding on another at which the Condition C configuration is not met. This, for example, would be the case if Condition C applied at S-structure but not at LF and pronominal binding were checked at LF but not at S-structure.[25] This reinforces the idea that Condition C applies at LF (but says nothing about whether or not, in addition, Condition C applies elsewhere, e.g., to surface representations).

The same point can be illustrated with reciprocals, which also act as variables bound by their antecedents. This also illustrates an interaction between the locality requirement of Condition A and Condition C. Contrast (110a, b):

(110) a. *Which stories *about each other's characterizations of the typical male viewer* would he conclude the journalists should publish?
b. Which stories *about each other's characterizations of him* would the typical male viewer conclude the journalists should publish?

(110a) does not seem to allow the reading in (111a), but (110b) allows the reading in (111b). Some care is needed to evaluate this contrast, as we want to make sure that the interpretation under which (110a) and (110b) are judged has the relevant distributive readings, which can (roughly) be paraphrased as (111a, b):[26]

(111) a. Which stories about the others' characterizations of the typical male viewer would he conclude each journalist should publish?
b. Which stories about the others' characterizations of him would the typical male viewer conclude each journalist should publish?

5.2 Scope and Condition C

The conclusion that the LF of the narrow and wide readings is as in (107) directly bears on the relationship between scope and binding with respect to reconstruction, as extensively discussed in Heycock (1995). She reports the contrasts (the examples are slightly changed) in (112a, b) which we will discuss in turn. For the first one, imagine the following context in which no prior virtual existence has been established for such surveys (cf. note 23): have the opinions of the typical male viewer been taken into account in designing surveys of his TV viewing habits? Should we send questionnaires out to him to help us formulate the questions? Is it worth it, given the low response rate we get? In the end, when all is counted:

(112) a. *How many surveys about the typical male viewer is he likely to help design t?
b. How many surveys about the typical male viewer is he likely to challenge t?
c. *How many is he likely to help design surveys about the typical male viewer?
d. How many surveys about the typical male viewer is he likely to challenge t?

Let us examine these sentences in turn.

5.2.1 *The wide-scope reading*

Let us first consider the meaning of (112b), repeated here. Here, we can easily imagine a context in which the surveys about the typical male viewer already exist, since he is likely to challenge them. This makes the wide reading readily available, which means that the LF (112d) (repeated here) is fine, avoiding a Condition C effect:

(112) b. How many surveys about the typical male viewer is he likely to challenge t?
d. How many surveys about the typical male viewer is he likely to challenge t?

We are now faced with an apparent contradiction. We had concluded that reconstruction of non-adjunct pied-piped material is obligatory to guarantee that we observe Condition C effects. This means that at least the nominal *surveys* should reconstruct. For scopal reasons, however, it looks as though we want the same nominal not to reconstruct.

This problem becomes more acute in (113):

(113) a. *How many pictures of a famous artist you know is he looking for t?
b. LF1: How many pictures of a famous artist you know is he looking for?
c. LF2: How many is he looking for pictures of a famous artist you know?

Clearly the sentence in (113a) can receive a wide reading and thus get the LF representation LF1 in (113b). This predicts that under the wide reading there should not be any Condition C effect. But this seems wrong: coreference between the underlined elements is blocked in (113a). To get this result, we would need to postulate instead of LF1 the logical form LF2, given in (113c). But this would wrongly claim that only the narrow reading is available for (113a).

A solution to this problem can be constructed by using Chomsky's (1995c) theory of movement traces as copies, which we have already seen helps resolve other problems.[27] According to Chomsky's proposal, a sentence like (114a) would have (114b) as surface syntactic representation, (114c) as input to phonology (Phonetic Form or PF), and (114d) as manipulated surface structure for the purpose of interpretation (LF):

(114) a. How many books are you looking for?
b. Surface Form: How many books are you looking for how many books?
c. What PF sees: How many books are you looking for ~~how many books~~?
d. What LF sees: How many ~~books~~ are you looking for ~~how many~~ books?

Chomsky's copy theory of movement has several positive aspects. First, it eliminates the need to postulate objects (traces), whose internal structure is not entirely clear (e.g., how do traces obey X-bar theory?). Second, Move is an operation of copying a moving phrase and deleting the original copy. The copy theory turns movement into a simpler operation, essentially identical to the elementary structure-building operation (*merge*). It differs only in taking as input an object that has served as input for an earlier merger – *move* is *merge-the-same-object-again*, that is, by appealing to a notion of identity of distinct syntactic objects which seem independently required by cases of ellipsis, as Chomsky (1995c) notes. The 'deletion' part is now handled independently as part of PF interpretation or LF interpretation, and there can be mismatches between what is deleted in PF and what is deleted in LF, as the paradigm in (114) makes clear.[28]

Turning back to the problem raised by (113a), we can resolve the contradiction by departing from Chomsky's proposal and assume that the LF of (113a) is not (113c) but rather a representation in which both the moved copy and the original copy are interpreted at LF.[29] In the case of a narrow reading, reconstruction must be obligatory, as we have now seen several times. In the case of the wide reading, it is important that the moved constituent be interpreted with wide scope, but nothing prevents a copy of this constituent from being interpreted in the original trace position as well. This permits a reconciliation of scope considerations with the obligatory character of reconstruction of pied-piped complements necessary to explain certain Condition C effects.[30]

The idea that both copies can be interpreted is developed in Fox (1999) for different reasons (see also Brody 1995b; Safir 1999; Rizzi 2000a). Fox suggests that the 'bottom' trace is interpreted like a definite description. Other possibilities could be contemplated (Safir 1999 treats it like a pronoun), but from now on, for ease of exposition, we will represent the lower copy as a demonstrative expression referring back to the top copy when there are two (or more) copies. For the sentence in (115a), this would yield the LF representations (115b) for the narrow reading and (115c) for the wide reading. Taking Fox's proposal into account, we will understand the LF of (115c) as (115d):

(115)	a.	The sentence:	How many pictures of *a famous artist* is *he* looking for t?
	b.	Its narrow-reading LF:	How many is *he* looking for pictures of a famous artist?
	c.	Its wide-reading LF:	How many pictures of a famous artist is *he* looking for pictures of a famous artist?
	d.	Paraphrase of the wide-reading LF:	How many pictures of a famous artist are such that *he* looking for <u>these</u> pictures of a famous artist?

The effect of interpreting both copies in the case of wide readings are clear: in all cases, we see that coreference between *he* and *a famous artist* leads to a Condition C violation.

5.2.2 The narrow-scope reading

Turning now to (112a), its reported deviance might look surprising. Since *about the typical male viewer* is an adjunct, it should be allowed not to reconstruct and thus should not have to feed Condition C. The reason for the deviance, Heycock (1995) hypothesizes for similar examples, is that the LF representation of (112a) must be (112c), with reconstruction of the restriction of *how many*. Indeed, the surveys about the typical male viewer not having been designed yet, only the narrow reading of this question is plausible. In (112b), the wide reading is plausible, thus allowing the LF (112d), which causes no Condition C violation.

Note that in such circumstances, for this reasoning to go through in the case of the narrow reading, it must not be possible to totally reconstruct the nominal head *surveys* of the preposed constituent without reconstructing the adjunct modifier *about the typical male viewer* as well. This seems reasonable: the adjunct must, by hypothesis, be predicated of some modifiee, to which it must stand in a syntactically local relation: as a result, it cannot be left stranded in a high position.

5.3 Predicate movement, scope, Condition C, and predicate-internal subjects

5.3.1 Scope reconstruction and islands

Recall that we concluded that moved predicate phrases always reconstruct. This means that predicate movement should never obviate Condition C effects or increase the set of possible antecedents for a pied-piped anaphor. These two points are again illustrated in (116):

(116) a. *[t_j Pleased with an old painter], I think he was t.
b. *[t_j Pleased with an old painter], he thinks you were t.
c. *[t_j Visit [each other]$_k$'s parents], you think they said [Bill and Mary]$_j$ will t.

In (116a, b), obligatory reconstruction will put the preposed constituent back into position t, thus triggering Condition C effects. In (116c), the presence of t_j prevents anything other than *Bill and Mary* from qualifying as antecedent for *each other*. Note that the Predicate Internal Subject Hypothesis truly derives the required reconstruction from the independent existence of a condition on pronominal and variable binding.

Heycock (1995) provides support for her observation that predicates are limited to taking narrow scope. This support is based on some extraction facts out of *wh*-islands. Several authors (e.g., Cinque 1990c, who attributes the observation

to Giuseppe Longobardi) have noted that an amount question (*how much*, *how many*) out of *wh*-islands is only possible if this question receives a wide-scope reading in the sense of the text. Thus we find the facts in (117) (e.g., with *how many*):

(117) a. *How many songs do you wonder whether Sue will compose t?
b. ?How many songs do you wonder whether Sue will perform t?

In (117a) (without context), lexical choices strongly favor the narrow reading (the wide reading, *how many songs are there such that . . .*, is implausible given that the songs are not yet composed). In (117b), the wide reading is plausible and the sentence is better (with the reading *how many songs are there such that . . .*).[31] (See chapter 64.)

Degree questions (e.g., with *how* + adjective) behave like narrow-reading amount questions (as noted in Rizzi 1990b, citing Roberts 1988b and Baltin 1992) and unlike wide-reading amount questions:

(118) a. *How intelligent did she wonder whether she was?
b. *How afraid of dogs did they ask if he was?

Heycock takes this to suggest that the only (or the only accessible) interpretation degree questions tolerate is the narrow reading; that is, that predicates must reconstruct. (If the wide reading were available, (118a, b) should have the status of (117b) and not of (117a).)

Heycock further argues (following Kroch 1989a) that the unavailability of the narrow reading in amount or degree questions out of *wh*-islands is due to pragmatic infelicity rather than semantic deviance or ungrammaticality. Questions out of *wh*-islands, they argue, require that the questioned phrase ask the identity of an entity or entities presupposed to exist.[32] In the case of the wide-reading question (117b), repeated here as (119a), the presupposition would be what is given in (119b):

(119) a. ?How many songs do you wonder whether Sue will perform t?
b. There are songs such that you wonder whether Sue will perform them.

This should make it possible to rescue narrow readings for amount and degree questions out of *wh*-islands. First, Heycock (following Kroch) argues that contexts can be constructed that make amount questions or degree questions out of *wh*-islands more acceptable. Heycock's example is (120a), with its interpretation in (120b) and it presupposition in (120c):

(120) a. How many points are the judges arguing about whether to deduct?
b. What is the number such that the judges are arguing about whether to deduct this number of points?
c. There is a certain number of points that the judges are arguing about whether to deduct.

Similar facts can be found in French. Normally, *combien*-split is sensitive to weak islands such as *wh*-islands or an intervening negation. In French, this is easier to check, since we can guarantee the narrow reading by using *combien*-split. This type of context indeed makes the approximate translation of (120a) yield the relatively acceptable (121):

(121) Combien est-ce que les juges se demandent s'il faut déduire de points?

We find similar contrasts for negative islands. (122) is hard to interpret:

(122) *Combien est ce que Jean n'a pas emprunté de livres cette année?
'How many hasn't John borrowed books this year?'

Out of context, there is no particular presupposition about there being a number of books that one should borrow. However, this sentence improves greatly if we utter it with the presupposition that there is a certain number of books that John has not borrowed this year.

Consider now (123), asked in a context (familiar to French people) in which there is a small, fixed number of competitive exams to take every year, and every student decides which ones to take and which ones to opt out of. It is then perfectly natural to ask how many competitive exams John decided to opt out of, as in (123a) (with the intended interpretation in (123b)):

(123) a. Combien est ce que Jean n'a pas passé de concours cette année?[33]
'How many hasn't John taken of competitive exams this year?'
b. What is the number/it is not the case that John took this number of exams this year.

Extraction out of *wh*-islands of degree-modified predicates can also easily be done. For example, in the following context, sentence (124a) is fine: 'According to reliable sources, Einstein's sister was just as well informed and just as smart as him and he was extremely proud of her.' Just as well informed, I can believe' but:

(124) a. This smart, I wonder whether she was t.
b. *This proud of Einstein's sister, I wonder whether he was t.
c. This proud of his sister, I wonder whether every student ever was t.

We must make sure that sentence (124a) is not a case of wide reading but rather a case of felicitous narrow reading, since predicates must always reconstruct, ruling out wide readings in degree questions in principle. First, note that (124b) is still deviant. This shows that a copy of the predicate phrase is interpreted as reconstructed, but does not exclude the presence of an interpreted copy at the top as well. The well-formedness of the third sentence (in an appropriate context) does show that such structures may be interpreted with no copy left at the top (otherwise we would have an unbound pronoun). This does not demonstrate

that wide readings are unavailable for preposed predicates, but at least it shows that such examples as (124a) can be treated as cases of narrow readings, i.e., as having the interpretation in (125):

(125) There is an amount X such that, I wonder whether she was X smart.

5.3.2 Definite descriptions, predicate-internal subjects, and partial reconstruction

Heycock also discusses the contrasts in (126):

(126) a. *[How afraid of some question Gore has not prepared for] do you think he is now?
b. [How pleased with the pictures Pollock painted long ago] do you think he is now t?

The unacceptability of (126a) is predicted. Forced reconstruction of the preposed predicate phrase puts *Gore* in the c-command domain of *he*, thus triggering a Condition C effect. The acceptability of (126b) is unexpected. To deal with this, Heycock suggests that the definite description *the pictures that Pollock painted long ago* can be assigned wide scope, deriving the representation in (127):

(127) [The pictures that Pollock painted long ago]$_k$, how do you think he was pleased with t_k?

Heycock remarks that if this wide-scope reading becomes less plausible, a Condition C effect reappears. This is the case in (126a), in which it is most natural for the relative clause not to be interpreted with widest scope. The contrast in (128a, b) is similar:

(128) a. How jealous of a girl that Mary had met at the party did she become?
b. *How eager for a friend that Mary might confide in would she become?

It is possible to interpret the underlined indefinite in (128a) as having wide scope ('There is a girl that Mary had met at the party: how jealous of her did she become?'). Such a wide-scope reading for the indefinite is far less plausible for (128b).

Let us examine how this proposal can be reconciled with earlier conclusions. Consider again (126b), repeated here as (129):

(129) [How pleased with the pictures Pollock painted long ago] do you think he is now?

We must obligatorily reconstruct the predicate and its complement, and scope out the definite description in such a way that it leaves no interpreted copy

below the pronoun *he*. In this instance, this is possible because we need not reconstruct adjuncts, and an adjunct contains the potentially offending name. This yields (130):

(130) [How the pictures Pollock painted long ago do you think he is pleased with these pictures] now?

in which the lower copy does not contain the relative clause.

That this is on the right track seems supported by the contrast between (131a) and (131b):

(131) a. [How pleased with the pictures an old painter you know painted long ago] do you think he is?
b. *[How pleased with the pictures of an old painter you know] do you think he is?

The difference between them is that the potentially offending name is contained in an adjunct in (131a), and can thus fail to reconstruct. In (131b), it is part of the complement structure and thus must be reconstructed, triggering a Condition C effect.

Similarly, it is clear why (132) is a Condition C violation, given the only possible LF representation it could have:

(132) a. I gave him this picture of Bill yesterday.
b. LF: [This picture of Bill]$_j$, I gave him this picture of Bill yesterday.

However, the lack of obviation of Condition C effects in sentences such as in (133) is problematic. They would get the corresponding representations in (134) after scoping out of the definite description (leaving only copies of non-adjunct material), and would thus be predicted to escape Condition C, contrary to fact:

(133) a. *He says that the man who an old painter met left.
b. *She considers the book a European princess wrote to be unreadable.
c. *I told him that the man who an old painter met left.
d. *He$_j$ wonders [how pleased with the pictures an old painter you know painted long ago] you are.

(134) a. The man who an old painter met [he says that this man left].
b. The book a European princess wrote [she considers this book to be unreadable].
c. The man who an old painter met [I told him that this man left].
d. [The pictures an old painter you know painted long ago] he$_j$ wonders [how pleased with these pictures] you are.

One way out could be to restrict the distance that the definite description can scope over. If, roughly, it were clause bound, all these problems would disappear.

This would predict, however, that (135a) should still be fine (viz. its representation in (135b) after scoping out of the definite description):

(135) a. Je lui ai donné la photo que le vieux peintre m'a demandée.
b. I gave him the picture the old painter asked for yesterday.
c. [The picture an old painter asked for], I gave him this picture.

The French sentence in (135a) given in English in (135b), is clearly much better than (132a) and indeed is perfectly fine, particularly if read with such an intonation that the (underlined) direct object is backgrounded. This, however, may be an effect due to 'extraposition' of the relative clause.

The examples in (136) are sharply out:

(136) a. *Il m'a donné la photo que le vieux peintre m'a demandée.
b. *He gave me the picture the old painter asked for yesterday.
c. [The picture the old painter asked for], he gave me this picture.
d. He [the picture the old painter asked for] gave me this picture.

This suggests that if descriptions can scope out within their clause, leaving a copy optionally containing adjunct material, the distance this movement can span is quite restricted. Here the definite description must stay lower than a definite subject. Note that in the initial case in (130), scoping of the definite description is from within a preposed *wh*-phrase. Clearly this is an area for further research.

5.3.3 What drives predicate reconstruction?

The structure of (126b) under Huang's (1993) proposal is (137):

(137) [How t_j pleased with the pictures Pollock$_j$ painted long ago] do you think he$_j$ is now t?

This would seem incompatible with Huang's proposal, Heycock (1995) claims. The presence of t_j coindexed with *he* should trigger a Condition C effect (whether Condition C is an Anywhere Principle or only applies at LF). Under a theory assuming that Condition C cannot be violated anywhere, such examples are clearly incompatible with Huang's proposal, since at some level, t_j c-commands *an old painter*. But this problem is more general: this sentence poses a problem for any account assuming that the preposed predicate obligatorily reconstructs in its entirety to t, putting *Pollock* in the c-command domain of *he*. To get around this problem, Heycock suggests that definite descriptions can scope out. If Heycock's proposal is on the right track and the LF representation of (137) is (138):

(138) The pictures Pollock painted long ago [how do you think he$_j$ is t_j pleased with these pictures]?

the problem Heycock points out for Huang's proposal is also solved by her proposal *under the assumption that Condition C only applies at LF*: once the definite

description has been scoped out and the adjunct is not reconstructed, there is no longer a Condition C violation, regardless of the presence of a predicate-internal subject. We conclude that the Huang–Takano proposal (see section 4.2.3) can be maintained.

In Heycock (1995), one additional problem is mentioned regarding Takano's modification of Huang's proposal that we have been discussing. The examples of degree questions in (139) allow coreference:

(139) a. How much longer than your yacht actually is did John think it was?
b. How much more intelligent than John actually is did he say he was?

Of course, this would be a problem if Condition C were an Anywhere Principle. Is it so under the assumption that Condition C applies only at LF? To decide whether this indeed constitutes a problem, we must examine what the LFs of (139) can be. In (139b), for example, the *than* clause is a dependent of *more*. (In its absence, the *than* clause could not be present). Thus, the representation in (140) of this amount question seems reasonable:

(140) What is the degree D added to the degree to which John is actually intelligent such that he said he was D intelligent?

This makes it basically a narrow-reading amount question on a degree, in which no LF violation of Condition C should occur (the *wh*-question bears on a degree increase, but the predicate *intelligent* has narrow scope). As Heycock remarks, that this is a narrow-reading amount question is corroborated by the fact that such questions become unacceptable when originating inside a *wh*-island:[34,35]

(141) *How much more intelligent than he is do you wonder whether he was?

6 Conclusion

We begin with a summary of the conclusions we reached first descriptively. Then we summarize the accounts that these descriptive generalizations seem to suggest in a Principles and Parameters type of model.

Descriptively, we concluded that:

- We find reconstruction effects for scope, pronominal binding, and all binding conditions in all types of movement constructions.
- Reconstruction for preposed predicates is always required, with consequences for all relevant conditions: Condition A, Condition C, scope, and pronominal binding.
- Regarding Condition C, reconstruction is obligatory sometimes and optional at other times. We took the relevant factor to be a complement–adjunct distinction, but it is not fully established that this is the relevant distinction.

- Reconstruction for Condition A, scope, and pronominal binding is possible but not required.
- Reconstruction effects correlate to a certain extent: reconstruction for pronominal binding and scope either both take place or both do not.
- If reconstruction for scope or pronominal binding takes place, reconstruction for Condition C does too. (This is only relevant for cases of optional reconstruction for Condition C; that is, it only relates to adjuncts.)
- Reconstruction effects, however, do not always correlate: reconstruction may take place for Condition C without doing so for scope.
- There were cases of impossible reconstruction, which we left unexplained.

We construed these descriptive generalizations as follows:

- All binding conditions and scope computation must be computed on the basis of representations that serve as input for semantic interpretation, which we define as LF. It makes little sense for scope or pronominal binding (in effect a scope principle) to be evaluated anywhere else (at best it would be redundant). We reached similar conclusions for Condition A, although it should be noted that we did not discuss potentially relevant differences between reflexives and reciprocals.
- Condition C cannot hold of underlying structures but may of surface structures (depending on the treatment of antecedent-contained deletion and the correctness of the Huang–Takano approach, among other things).
- Mismatch of scope and binding reconstruction patterns can be handled by taking traces to be copies and requiring that bottom (or bottom-most) copies always be interpreted at LF.
- The obligatoriness of reconstruction for preposed predicates can be tentatively attributed to the Huang–Takano hypothesis, and to the idea that interpreted traces (which are lower copies) behave as bound variables (and are thus subject to the condition on pronominal binding).

It is worth noting that these conclusions are consistent with Chomsky's (1995c) proposal requiring all binding conditions to be LF conditions only.

Regarding the properties of movement, we reached the following conclusion regarding how to construe the basic operation Move and its interaction with LF principles of scope:

- Movement is copying.
- Either or both copies can be interpreted at LF.
- The position determining the scope of an XP is that of its highest interpreted copy.
  - If only the lower copy of an XP is interpreted, this XP receives narrow scope.
  - If the top copy of an XP is interpreted, this XP receives wide scope.

Among the issues left unresolved are the existence and exact properties of covert movement (although we have been led to the assumption that covert scoping out is possible, e.g., for definite descriptions), the impact of the analysis of relative clauses on the theory of reconstruction, and the behavior of reflexives.

Descriptively, there are a number of questions we have not discussed. We have not talked about reconstruction effects for negative- or positive-polarity-item licensing (see Den Dikken et al. 2000 for some relevant discussion). We also have not discussed the properties of reconstruction documented in other languages (e.g., in Arabic: see Aoun and Benmamoun 1998; in British English: see Elbourne 1999; or in Japanese: see Saito 1989 on scrambling).

Theoretically, we have limited ourselves to implementing the assumed descriptive generalizations in a Principles and Parameters type of framework, but we have of course not discussed all approaches to reconstruction within it. Among recent works that were not discussed here, there are approaches assuming PF movement (e.g., Aoun and Benmamoun 1998; Sauerland and Elbourne 2002). The work of Safir (1999) incorporates ideas about vehicle change originally proposed in May and Fiengo (1994) into the treatment of reconstruction effects (by treating lower copies as pronominals, for example). Putting the burden of the treatment of reconstruction effects onto the semantic rules themselves rather than onto the syntactic input to these interpretive rules is done in flexible composition rules approaches, such as Jacobson (1999) or Sharvit (1998). More distant treatments of reconstruction effects can be found in McCawley (1999) within generative semantics. As mentioned at the outset, it remains to be seen to what extent these alternatives are truly different from what we have covered in the logical structure of the proposals that they make.

NOTES

Many thanks to the following people who listened, commented on material in here, or (non-exclusive) were endlessly tortured to give judgments: two reviewers, Leston Buell, Guglielmo Cinque, Danny Fox, Edward Garrett, Peter Hallman, Richard Kayne, Hilda Koopman, Martin Prinzhorn, Luigi Rizzi, Françoise Roth, Barry Schein, Philippe Schlenker, Michel Sportiche, Noémie Sportiche, Sophie Sportiche, Tim Stowell, Harold Torrence, Jean-Roger Vergnaud, Edwin Williams, and the audiences in my lectures at UCLA since 1994, at the Università di Venezia and the Università di Firenze in the spring of 1999, and at the GLOW summer school in Thermi in the summer of 1999. Thanks also to Howard Lasnik and Susumu Kuno for promptly providing copies of their articles.

1 This notion of canonical is far from trivial, of course. Informally, let us think of it in English as the normal immediately postverbal position of direct objects.
2 The general issue is that of how movement dependencies should be represented – antecedent trace binding relations, slash notation, feature percolation, or other possibilities.
3 This would include all cases of movement, whether overt or 'covert', as well as possibly other cases.

4 At the right level of abstraction(/formalization), it is likely that most of the superficial differences between our description of the data and others induced by the particular notation we use would disappear. Assuming that the empirical generalizations we accept are correct, this is due to the fact that the notations most often simply directly encode them (a comment about the relative theoretical shallowness of the field at the present stage of its development).

5 Standard use takes this to be a case of feature projection instead, taking the string D NP *which boy* in (7) to obligatorily be a DP (inheriting the D property), and reserves the term 'pied-piping' for cases when such feature projection is optional, as in $[_{+wh}$ which boy] and $[_{\text{Optionally }+wh}$ with [[$_{+wh}$ which boy]'s brother]].

6 Note that we use the term 'reconstruction' as meaning 'connectivity in case of movement'. In particular, we make no assumption here about the mechanism by which these reconstruction effects arise.

7 One possible reason sometimes given is that it may allow us to circumvent grammatical constraints on movement. It is also conceivable that pied-piped material may in some respect (e.g., in terms of scope, or in terms of the *de re*/*de dicto* distinction) receive different interpretations than non-pied-piped material.

8 Consistent with the idea that only pied-piped material reconstructs is the observation that it is difficult to understand the *wh*-quantifier itself as reconstructed: the number asked does not seem able to vary with the choice of member.

9 For a variety of reasons (if P reconstructs in t2, it will be in the scope of A and B), it is more difficult to illustrate this property of reconstruction into intermediate traces with other principles. One option is the following example:

(i) Which picture that John sold to <u>her</u> did you convince <u>every girl</u> t_1 that he had stolen t_2?

This sentence seems good with *her* bound by *every girl*, and *John* and *he* coreferential. Reconstruction of the relative clause *picture that John sold to her* is required to allow pronominal binding of *her* by *every girl*. If reconstruction was in t_2, it would create a Condition C effect between *he* and *John*. However, if reconstruction is in t_1, no Condition C effect is created. Note that the relative clause is an adjunct and can thus be 'late inserted' in t_1.

10 We are not considering the reading in which each picture is of the other pictures, which may be available but is irrelevant.

11 An additional control would raise a name or a pronoun across a name Experiencer, but raising across a non-pronoun is deviant in French (as in German or Dutch, unlike what happens in English):

(i) *Ma place semblait à Marie avoir été prise.
'My seat seemed to Mary to have been taken.'

This is only marginally improved by 'extraposing' the Experiencer:

(ii) *?Ma place semblait avoir été prise à Marie.
'My seat seemed to have been taken to Mary.'

12 The restriction "in English" is meant to exclude from discussion cases of partial *wh*-movement (which may also satisfy this description; see chapter 47) and cases of scrambling of *wh*-phrases.

13 There exist interesting apparent counter-examples, such as:

(i) Where do you think every kid will hide?

with the reading 'Every kid will hide in a different place. For each kid, where do you think it is?'.

14 Chomsky (1995c) has argued that to make sense of Lebeaux's proposal, we need to abandon the idea of a level of underlying structure in favor of the Minimalist cyclic MERGE approach.

15 Throughout, we ignore the lower copy of the *wh*-element itself.

16 Some authors disagree (cf. Huang 1993) and detect a significant improvement in the second member of each sentence as opposed to the first one. If this effect is real, a principle like P4 below in the text cannot be right in general.

17 This would also be necessary in treatments such as Reinhart's (1983a), which crucially appeal to the meaning of the sentence and comparisons between ways of expressing it.

18 It is not entirely clear that such an analysis is generally tenable for ACD given the availability of cases such as:

(i) I wanted everyone you did to leave.

in which Extraposition seems unavailable for the relative. If *you did* was extraposed, the infinitive would have had to extrapose too, but extraposition of infinitivals seems unavailable (viz. **I wanted you tomorrow to leave*). Moreover, there may be another difficulty found in the following type of acceptable example:

(ii) If the journalists always agreed to show him the stories about her that no model would want a known gossiper to see . . .

These are cases which have been argued to involve raising the head of the relative clause from inside the relative clause (cf. Vergnaud 1974; Kayne 1994): here the head of the relative presumably must originate inside the relative clause (so that it can reconstruct and get *her* bound by *no model*), and thus this construction cannot involve late adjunction of the relative clause in an extraposed position.

19 Note that if LF is constructed and interpreted cyclically, the span of A-movement cannot be larger than one cycle (otherwise the Condition C problems with A-movement reappear).

20 If trace are copies, such copies must be properly construed so that they are scopally dependent.

21 Apart from the arguments of the text above, Heycock argues that the following pair undermines Huang's approach:

(i) *I would never consider her Sally's worst enemy.
(ii) *Sally's worst enemy, I would never consider her.

According to Heycock, the preposed constituent in (ii) could not contain the trace of *her* because it is a DP, *a DP only can have one specifier*, and Sally occupies this specifier position. This argument seems less strong as it relies on the italicized assumption, which basically contradicts the Predicate Internal Subject Hypothesis (*her* is the subject of the predicate *Sally's worst enemy*), and should thus be taken to be incorrect,

pending strong evidence to the contrary–evidence lacking at the moment. (There is some evidence that argument DPs can have only one overt specifier, but this hardly bears on the question at hand.) Heycock also points out other arguments that we will review in section 5.3.3.

22 This is plausible without relevant context. It would be naive to conclude that the reading in (105c) is unavailable for the first question in general. Such a question can very well be asked with that reading in a context in which the songs have a virtual if not actual existence. For example, knowing that six different songs must be composed for a movie, one can ask one of the composers:

(i) How many of these songs will you compose?

with the reading in (105c). As Tim Stowell points out (p.c.), the same remark applies to examples of this sort:

(ii) I am building the house.

which seem paradoxical as the object of the verb of creation is definite (and thus referring to some pre-existing entity). Even examples similar to Heycock's (1995) below, carefully chosen to eliminate this possibility, can be circumvented in an appropriate context:

(iii) How many stories about John is she likely to invent?

could be uttered felicitously with a wide reading if we interpret this not as an actual present but as a historical present (reviewing the woman's life and knowing all the stories she invented, we can mentally place ourselves at some stage of her life and utter (iii) meaning '(Of all the stories she will invent in her life) how many of these is she likely to invent at this point)?' In what follows, we always assume that we are not in such contexts in the narrow-scope examples.

23 To the author's ear, only the narrow reading remains available even if we modify the sentence to allow for a pre-established set of songs in discourse, as in:

(i) Combien vas-tu chanter de chansons apprises l'an dernier?
how many will you sing songs learned last year

The construction *combien . . . de* differs from the (partitive) construction *combien . . . des* (where des = de +les), as in:

(ii) Combien vas-tu chanter des chansons apprises l'an dernier?

which also allows moving *combien* by itself but uses a different (extraposed) intonation and is ambiguous. See also Fox (1999: 153, fn. 20).

24 Two remarks on these data: first, the agreement on the past participle in (108a) is indicated as optional. The correct description is more complex: it depends on the reading that is assigned to the question: (impossible with the narrow reading, optional with the wide reading). See Obenauer (1994) for relevant discussion. Second, de Swart reports the French facts differently: she reports that under the wide reading, the

universal quantifier *tous* can take scope of the *wh*-word *combien* (so that the number varies with each child). I think such a reading – a pair-list reading – is impossible with a floated Q, but would be possible with a non-floated Q (i.e., in *Combien de chansons tous les enfants ont-ils chanté?*).

25 Recall that the condition on pronominal binding cannot fail to be checked at the level at which interpretation is actually performed, i.e., LF, by definition, so the only possibility for strictly different inputs for Condition C and pronominal binding is if Condition C applies to surface or underlying structures (if they are different from LF structures).

26 In particular, parasitic readings should be avoided, e.g.:

(i) Stories about each other's characterizations = Each story is about the characterization of the other stories
(ii) Stories about each other's characterizations = Each one's story about the others' characterizations

27 This idea is already present in various form in earlier literature, e.g., Burzio (1986). Chomsky, however, uses and justifies it in ways consistent with our present discussion.

28 One problem with copy theory is that portions of the resulting interface representations (in Chomsky's 1995c sense) are allowed to be ignored. This raises questions regarding the empirical content of the 'bare output' (or 'legibility') conditions crucial to Chomsky's (1995c) minimal design conjecture.

29 This proposal takes care of all the problems raised in Heycock (1995: section 6) for the idea that Condition C applies only at LF.

30 Another option would be to get the wide reading from a representation like:

(i) How many you are looking for pictures?

and let the indefinite *pictures* take wide scope by other mechanisms (e.g., choice function). Space precludes a discussion of this option. Let us remark that it would wrongly predict impossible answers to questions such as (108a).

31 It is not relevant here why such a difference is observed. For proposals, see chapter 64 and references therein.

32 There are other proposals similar in spirit if not in detail to this idea (see Szabolcsi and Zwarts 1993, for example).

33 Such facts show that there cannot be an absolute prohibition on certain types of quantifiers (*combien*) crossing over others (negation). This would call at the very least for refinements of approaches to these questions, such as Rizzi's (1990b) Relativized Minimality approach.

34 By the Heycock–Kroch proposal mentioned in section 5.3.1, these questions should improve in a context with the right presupposition.

35 Heycock mentions one more example of the same kind. She gives:

(i) *How much faster than John did he see Mary running?

but native speakers rejected even a variant of it without coreference, due to the clash between the tense of the elided VP and its antecedent (running). If the tense clash is resolved as in:

(ii) How much faster than John did does he think Mary ran?

the sentence seems fine. Note also that the underlined part would be barred from reconstructing all the way down, because it would be a paradoxical antecedent-contained deletion structure.

1 Introduction: phenomena and issues

The italicized pronouns in (1) (cited from Prince 1990, and attributed there to Tony Kroch) are conventionally known as 'resumptive' pronouns:

(1) a. There are guests who I am curious about what *they* are going to say.
    b. The only one we could see *her* figure was Number Two.

Compare the pronouns in (1) with those in (2):

(2) a. Sally said that *she* would resign.
    b. Most people think that *they* have a right to a decent job.
    c. Every kid in my class who has a VCR knows how to program *it*.

What distinguishes the two cases? The pronouns in (1) appear in positions where one would, in a certain sense, have expected to find a gap. The expectation is reasonable because the variable position in a relative clause or question in English is normally defined by the presence of a gap, as in (3):

(3) a. There are guests that everyone wants to invite ___.
b. The only one (who/that) we could see ___ was Number Two.

For the cases in (2), on the other hand, there is no sense at all in which the possibility of a pronoun alternates with the possibility of a gap.

This first contrast between (1) and (2) is closely linked with a second. The pronouns in (1) are obligatorily bound (as gaps, of course, would be in the same positions). The pronouns in (2), on the other hand, are free to find their antecedents in pragmatic or discourse context.

Putting these observations together in an initial way, then, we can say that a resumptive pronoun is a pronominal element which is obligatorily bound and which appears in a position in which, under other circumstances, a gap would appear. The binder of the pronoun is the same, apparently, as the element which binds the gap in the corresponding filler-gap construction.

I use the term 'pronominal element' in this informal definition (rather than the simpler 'pronoun') because the range of elements which can serve the resumptive function is in fact quite broad. Besides including all categories of pronoun – tonic and clitic, overt and non-overt – it also includes epithets, which seem to be sufficiently pronominal that they can serve the resumptive function in certain languages and under certain conditions. This is shown, for example, by the informal English (4) (from Kroch 1981; see also Sells 1984b; Aoun and Choueiri 1996; Safir 1996a; Aoun et al. 2001):[1]

(4) There was one prisoner who we couldn't even figure out why *the poor guy* was in jail.

Most discussion of resumption has centred on cases in which the pronoun appears in the variable position of an unbounded dependency construction – relative clauses, constituent questions, clefts, comparative clauses, infinitival null-operator constructions, and the like. The phenomenon is almost certainly broader than this would suggest, but this chapter will begin by following tradition in focusing on this set of cases.

Characterized in this way, the phenomenon of resumption is very widespread, as is illustrated briefly in (5–8):[2]

(5) an ghirseach ar ghoid na síogaí í — Irish
the girl C stole the fairies her
'the girl who the fairies stole'

(6) Es un país que hablan tanto de él. — (Informal) Spanish
is a country C they-talk a-lot about it
'It's a country that they talk a lot about.'

(7) L-kteeb yalli ʃtarayto mbeeriħ Daa‿. Lebanese Arabic
the-book C bought [S1]-it yesterday is-lost
'The book that I bought yesterday is lost.'

(8) ha-ʒiš še- raʒ ʒoto Hebrew
the-man C saw [S1] him
'the man that I saw'

Within the broad category of unbounded dependency constructions, attention has tended to focus on the case of relative clauses, but the phenomenon of resumption extends (at least in certain languages) to the entire range of unbounded dependency constructions. This is illustrated for constituent questions in two languages in (9) and (10), and for clefts in the Irish example in (11):

(9) Céacu fear ar labhair tú leis? Irish
which-of-two man C spoke you with [MS3]
'Which man did you talk to?'

(10) ʒayya rəʒʒeel χabbartu-u ʒenno . . . Lebanese Arabic
which man told [2P]-him C
'Which man did you tell that . . . ?'

(11) Tigh beag caol gur mhaireamar ann. Irish
house little narrow C we-lived in-it
'It was a narrow little house that we lived in.'

McCloskey (1990) provides a much more thorough discussion of the range of constructions in Irish in which resumptive pronouns may figure.

These initial observations are enough to set the scene for the major questions which have shaped work on the phenomenon of resumption. Since resumptive pronouns are pronouns (at least in their apparent form), a series of questions can be asked about where they fit in the context of the general theory of pronominal anaphora. To what extent do they share the properties of other classes of pronouns (those in (2), for instance)? But since they simultaneously appear in positions which are canonically associated with the appearance of gaps, one can also ask a series of questions about how resumptive elements interact with the processes which create gaps. If we follow much recent work in assuming that gaps in relative clauses and questions are always created by movement operations, this second question then becomes the following: to what extent does the relation between a resumptive element and its binder exhibit the properties of movement?

Most work on resumption attempts to answer these two questions and tries to understand the Janus-like nature of resumptive elements – one face toward the domain of pronouns and anaphoric elements, the other toward the theory of movement.

A fundamental question, which has not often been explicitly addressed, but which lies behind much of the discussion, is why resumptive elements have the form that they do. That is, resumptive pronouns simply *are* (formally) pronouns. I know of no report of a language that uses a morphologically or lexically distinct series of pronouns in the resumptive function. If we take this observation to be revealing, there can be no syntactic feature which distinguishes resumptive pronouns from 'ordinary' pronouns, and any appeal to such a feature must be construed as, at best, an indication of the limits of understanding.

2 Early treatments

Work of the 1970s (especially in the second half of the decade) addressed these fundamental questions by assuming that unbounded dependency constructions were frequently derived by way of a rule which deleted bound pronouns in certain contexts – when bound by the head of a relative clause construction, for instance (Morgan 1972; Perlmutter 1972; Bresnan and Grimshaw 1978; McCloskey 1979). An example like (12a), on this account, would derive by way of deletion of the pronoun from an underlying structure which more resembled (12b):

(12) a. the guy that I talked to ___
b. the guy that I talked to *him*

Resumptive pronouns, on this account, are the surface manifestation of the failure of this rule to apply – either because the targeted pronoun occupies a position that was inaccessible for one reason or another (possessor position, say, in most languages, or prepositional object position, or within an island), or else because the rule is optional. The synonymous Irish pair in (13), for example, would be taken to reflect optional application of the rule of bound pronoun deletion:

(13) a. an ghirseach a ghoid na síogaí ___
the girl C stole the fairies
'the girl who the fairies stole'
b. an ghirseach ar ghoid na síogaí í
the girl C stole the fairies her
'the girl who the fairies stole'

The larger framework of assumptions here is that:

(i) Unbounded dependency constructions need to contain a bound variable, to be semantically well-formed.
(ii) Pronouns are the devices which natural language canonically makes available for the expression of bound variables.
(iii) The gaps characteristic of unbounded dependency constructions can be produced either by movement or by deletion.

On this view, then, resumptive pronouns have the form of pronouns because they mark variable positions and pronouns are the canonical linguistic expression of variables (even when those pronouns are not apparent in the pronounced string). And the widely noted tendency for resumptive pronouns to appear in inaccessible positions (inside islands particularly) can be understood as reflecting the island-sensitivity of the bound pronoun deletion rule.

A core assumption, of course, was that movement and deletion are equally available in unbounded dependency constructions. On this view, for instance, (14a) in English would be derived by way of *wh*-movement, while (14c) would reflect application of a rule deleting the pronoun of (14b):

(14) a. the guy who I talked to ___
b. the guy that I talked to *him*
c. the guy that I talked to ___

Since it depended on the postulation of unbounded and island-sensitive deletion rules (as in Ross 1986, from his 1967 dissertation), this set of ideas formed one part of the debate in the second half of the 1970s about the nature of islands and the typology of transformational operations. As a consequence, as that debate moved toward resolution and as the hypothesis of successive-cyclic rule application (Chomsky 1973) came to be widely accepted, the foundation on which these ideas rested (assumption (iii) above in particular) came to seem untenable.

In the new context, the relations among (14a, b, c) look rather different. (14a) and (14c) are both derived by movement of a relative pronoun. (14c) differs from (14a) only in that the fronted pronoun is subsequently deleted (or was phonologically null to begin with). Given this, the fundamental challenge becomes that of understanding how the presence of a pronoun (as in (14b)) can serve the same function as, or in some sense stand in for, a gap derived by movement. The relation between resumption and movement – what they share and how they differ – thus becomes central.

3 Issues

Within that broad context, work on resumption can be seen as addressing the following sharper questions:

(i) What mechanisms license the appearance of resumptive pronouns, and what is the place of those mechanisms in the typology of anaphoric interactions?
(ii) How do those mechanisms relate to, and interact with, the movement mechanism?
(iii) What defines the difference between languages which make productive use of resumptive elements and those which do not? How can this difference be understood within the larger setting of work on the parameters that define differences among languages?

(iv) Is the pre-theoretical category 'resumptive pronoun' theoretically unitary? Or are there rather distinct types of elements and devices which are grouped under this rubric?
(v) In what sense (if any) is resumption a last resort mechanism?

A way of broaching these issues is to look at what have been thought to be the core properties of resumptive pronoun constructions. Looking at those properties, and the attempts that have been made to understand them, will lead us to the kind of consensus that emerged in work of the middle and late 1980s – a consensus that embodied a set of answers to questions (i–v) above. We will at that point be in a position to look at the various theoretical and empirical challenges that have arisen to subvert that consensus, or at least to bring it into question.

4 Properties

4.1 Immunity from constraints on movement

The single most celebrated property of the binding relations that resumptive pronouns enter into is that they show no sensitivity to general constraints on movement. (We will consider exceptions and objections to this very general claim shortly.) This property has been familiar at least since the work of Ross (1986), where it was discussed as a sensitivity to the difference between 'chopping' rules (movement and deletion) and 'copying' rules (those which leave a pronominal copy in the origin site).[3] I will illustrate the effect here with (attested) examples from Irish (15–20). In all cases, the resumptive element is underlined.

Examples (15) and (16) demonstrate immunity from the *wh*-island constraint:

(15) na hamhráin sin nach bhfuil fhios cé a chum iad
the songs DEMON NEG C is knowledge who C composed them
'those songs that we don't know who composed them'

(16) teach nach n-aithneochthá cá rabh sé
house NEG C recognize [COND] [S2] where was it
'a house that you wouldn't recognize where it was'

Examples (17) and (18) illustrate immunity from the Complex Noun Phrase Constraint:

(17) An fánaidhe a n-abradh daoine nár thuig é go rabh sé
the wanderer C would-say people NEG C understood him C was he
éadtrom sa cheann.
light in-the head
'The wanderer that people who didn't understand him would say that he was soft in the head.'

(18) seanchasóg ar dócha go bhfuil an táilliúir a dhein í sa chré
old-jacket C probable C is the tailor C made it in-the earth
fadó
long-ago
'an old jacket that the tailor who made it has probably been in the grave for ages'

In (19) we have a case of the cleft subcase of the *wh*-island constraint:

(19) cathracha nach sibh a chuir suas iad
cities NEG C you C put up them
'cities that it wasn't you that built them'

And in (20) we have an instance in which a resumptive pronoun appears inside an adjunct island:

(20) Nérée Caron, nach bhfuil ann ach tamall beag ó bhí sí
Nérée Caron, NEG C is in-it but time small since was she
dóigheamhail feiceálach
beautiful attractive
'Nérée Caron, who it is only a short time since she was beautiful and attractive'

The examples cited in (15–20) illustrate a lack of sensitivity to subjacency effects, but it is well known that resumptive pronouns also amnesty ungrammaticalities attributed to the Empty Category Principle (ECP), as can be seen in the (informal) English examples in (21):

(21) a. He's the kind of guy that you never know what he's thinking.
b. *He's the kind of guy that you never know what ___ is thinking.
c. They're the kind of people that you can never be sure whether or not they'll be on time.
d. *They're the kind of people that you can never be sure whether or not ___ will be on time.

4.2 Strong crossover

The relation between a resumptive pronoun and its binder, then, does not show sensitivity to the locality conditions thought to be diagnostic of the movement relation. It does, however, exhibit a number of properties characteristic of A-bar-binding. Specifically, the bound element itself behaves like a variable (understood for present purposes as being an element whose most local binder occupies an A-bar-position). There are at least two senses in which this is true.

Most fundamentally, it is the resumptive element which is the syntactic correlative of the semantic variable which is found in every A-bar-binding construction.

But there is also a more specific sense in which resumptive pronouns "behave like variables." A property of the traces left by movement to A-bar-positions is that they are subject to the strong crossover effect (Postal 1971; Wasow 1979):

(22) **Strong crossover effect:**
The trace of movement to an A-bar-position may not be anaphorically linked with a c-commanding pronoun.

In (23):

(23) *Who did she$_j$ claim [t_j had arrived earliest]?

the trace in embedded subject position is c-commanded by, and co-indexed with, the pronoun *she*, resulting in ungrammaticality. A now widely accepted proposal by Chomsky (1981) derives this effect from Condition C of the Binding Theory, which requires that a certain class of elements (non-pronominal DPs and *wh*-traces) not be bound by an element in an A-position. Whether or not this proposal is right (see Lasnik 1989b for a proposed refinement and Postal 1997b for an argument that the whole approach is misguided), the phenomenon itself provides us with a question to ask about resumptive pronouns – do they resemble *wh*-traces in giving rise to strong crossover effects?

The question has been addressed for a number of languages (those languages for which the most complete descriptions of resumptive pronouns are available), and the answer so far seems to be that resumptive pronouns do trigger strong crossover effects. Demonstrating this requires some ingenuity. One cannot simply take (23) and replace the trace with a pronoun as in (24):

(24) Who$_j$ did she$_j$ claim [that she$_j$ had arrived earliest]?

This does not provide a test case for strong crossover because the possibility remains open that the higher of the two pronouns functions as the required variable, in which case the second (lower) pronoun has the same (unproblematic) status as the pronoun in (25):

(25) Who$_j$ t_j claimed [that she$_j$ had arrived earliest]?

To overcome this difficulty, one can use, instead of the higher pronoun in (23), some element which is known to give rise to robust strong crossover effects but which cannot itself be used as a resumptive element. Epithets may be used for this purpose in many languages. Lasnik (1989b) has shown that they give rise to clear strong crossover effects (even in languages in which lexical DPs do not), and in many languages at least in which resumptive pronouns figure, epithets may not in general serve the resumptive function. McCloskey (1990) conducts this test for Irish and demonstrates that the strong crossover effect does indeed emerge:

(26) *Sin an fear ar dhúirt an bastard go maródh sé muid. Irish
that the man C said the bastard C kill [COND] he us
'That's the man$_j$ that the bastard$_j$ said that he$_j$ would kill us.'

The experiment was subsequently replicated in a number of Semitic languages – see Shlonsky (1992) on Hebrew and Palestinian Arabic, Aoun and Choueiri (1996) and Aoun et al. (2001) on Lebanese Arabic.

4.3 Weak crossover

Although resumptive pronouns share with variables a sensitivity to strong crossover, it was established early (Sells 1984a, 1984b; McCloskey 1990; Shlonsky 1992) that they quite generally show no weak crossover effects. Weak crossover (Wasow 1979) arises when a variable is coreferent with a pronoun which does not c-command it. The Irish example in (27), however, is fully grammatical (see also (17) above), in contrast with its English translation, which is degraded to some degree (Safir 1984, 1986, 1996a):

(27) an fear$_j$ ar fhág a$_j$ bhean é$_j$
the man C left his wife him
'the man$_j$ that his$_j$ wife left ___$_j$'

4.4 Antilocality and the Highest Subject Restriction

But if resumptive pronouns show some of the distinctive properties of variables, they also betray their origins by exhibiting at least one important pronominal property as well.

One of the core properties of pronouns is that their binding is subject to an antilocality requirement – a pronoun and its antecedent cannot occupy the same local domain. In the area of A-binding, this requirement is encapsulated in Condition B of the Binding Theory (Chomsky 1981), which renders ungrammatical an example like (28):

(28) a. *Charles$_j$ is proud of him$_j$.
b. *Each actress$_j$ nominated her$_j$.

Resumptive pronouns in a number of languages show what is arguably a similar kind of restriction. In these languages, a resumptive pronoun cannot occupy a subject-position immediately subjacent to its binder. This condition, known as the Highest Subject Restriction (McCloskey 1990), is illustrated with the contrasting Irish examples in (29a, b):

(29) a. *fear nár fhan sé sa bhaile
man C NEG–PAST remained he at-home
'a man that didn't stay at home'

b. fear nár fhan ___ sa bhaile
man C NEG–PAST remain at home
'a man that didn't stay at home'

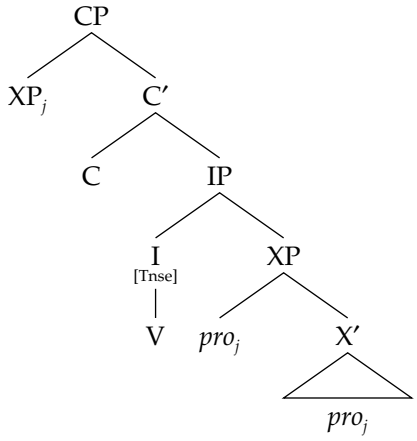
Similar facts have been documented for a variety of languages and language-types (Doron 1982; Borer 1984b; Shlonsky 1992; Ouhalla 1993; Schafer 1995).

Various approaches to the analysis of this phenomenon have been suggested. One thread that runs through many of them is that the ungrammaticality of local subject resumptives is best seen as an aspect of the kind of antilocality property typical of pronouns (Borer 1984b; McCloskey 1990; Aoun and Choueiri 1996). One way of implementing the general idea is presented in McCloskey (1990), drawing on earlier work by Aoun and Li (1989). There it is proposed that the disjointness requirement defined by Principle B of the Binding Theory (which in its original formulation governs only binding by an element in an A-position) should be extended to the domain of A-bar-binding. A formulation like the one in (30) has the required consequences (Aoun and Li 1989, 1990, 1993a; McCloskey 1990; Aoun and Choueiri 1996):

(30) **The A-bar-Disjointness Requirement:**
A pronoun must be A-bar-free in the least complete functional complex containing the pronoun and a subject distinct from the pronoun.

To see how this will work, consider the schematic structure in (31):

(31)



Assume for present purposes that the specifier of XP in (31) is the 'subject position' in the language in question. If the element in specifier of CP binds the occurrence of *pro*$_j$ within X′ (a non-subject), then the binding is not in violation of (30), since the relevant CFC in this case is IP, and the pronoun is in fact A-bar-free within IP. When the element in specifier of CP binds *pro*$_j$ in the specifier of XP, on the other hand, the structure stands in violation of (30), since here the least CFC containing

the pronoun and a subject distinct from the pronoun is the higher IP (or the root), and the pronoun is not A-bar-free in this domain.

There are numerous known difficulties for this approach,[4] but it is not irrational to hope that those difficulties could be resolved without sacrificing the essence of the proposal.

Summarizing, then, A-bar-bound resumptive elements show the following mix of properties in many languages:

(i) The binding relation they enter into shows no sensitivity to the locality constraints which characterize movement.
(ii) They share with variables the property of triggering strong crossover effects.
(iii) The binding relation they enter into does not show weak crossover effects.
(iv) The binding relation they enter into is constrained by an antilocality requirement reminiscent of Principle B of the Binding Theory.

4.5 An understanding

If these general lines of thought could be sustained, a pleasingly consistent overall view could be seen to emerge:

(i) Transformational theories of the origin of pronouns have been thought to be deeply flawed,[5]
(ii) therefore pronouns have to be regarded as base-generated rather than as being derived by transformation.
(iii) Resumptive pronouns look just like ordinary pronouns. Therefore the null hypothesis is that resumptive pronouns should also be taken to be base-generated.
(iv) The binding relation between the resumptive pronoun and its binding operator is therefore not created by movement, so
(v) no sensitivity to constraints on movement is expected in the binding of resumptive pronouns.
(vi) But it has been independently argued by Safir (1986) that the notion of 'variable' should be defined contextually (a variable is an element whose most local binder occupies an A-bar-position).
(vii) That being so, resumptive pronouns must be variables and should be subject to Condition C. We therefore expect strong crossover effects.
(viii) But resumptive pronouns are also pronouns. Therefore it is natural that they should exhibit the antilocality requirement which is a fundamental constraint on the binding of pronouns; from this we derive the Highest Subject Restriction.
(ix) The absence of weak crossover effects is also consistent with the overall conception. Safir (1984, 1986, 1996a) argues that weak crossover is to be understood as a violation of a general parallelism constraint which requires that all the variables bound by a single operator be of the same

type – all pronominal or all non-pronominal. This requirement is respected in the Irish example in (27) (since both variables are pronouns) but violated in its English translation.

Standing back from the specifics, the intuition here is that unbounded dependency constructions are characterized by the presence of a bound variable, and that natural language provides two distinct ways to realize variable binding relationships – either by way of a bound pronoun or by way of movement from the bound to the binding position. In the language of 'chains': the sense in which resumptive pronouns and traces can serve many of the same functions is that both can serve the function of being the bottom-most position in an A-bar-chain, an abstract theoretical notion which subsumes both certain movement relations and certain binding relations, both linking binding positions with bound positions.

5 Open issues

It would be an overstatement to call the understanding just sketched a 'consensus'. But something like it guided a good deal of work on resumption in the middle and late 1980s and into the early 1990s, and generated a research agenda – one that grappled with the important issues that remained unresolved even within that consensus.

One of those issues concerns the level of representation at which resumptive pronouns are defined as variables, the two candidates most often considered being S-structure and LF.[6] A second issue is whether or not the use of resumptive pronouns represents a last resort mechanism. The conception of resumption just outlined provides no reason to expect that it might in any sense represent a reach for the last resort. Resumption simply represents (on this view) one of the ways in which an A-bar-binding relation can be established. But many theoreticians have had the intuition that resumption is in fact a last resort mechanism, and have striven to design theories in which it would follow that resumption would be available only if movement (the unmarked way, on this view, to establish an operator–variable binding) were unavailable.

For anyone whose native language is English, the intuition is strong and clear that this is how things work. Resumptive pronouns in English appear – if not exclusively then at least in the general case – in positions from which movement would be impossible (see (21) above, for instance). But for many languages in which the resumptive strategy is more productively used, the situation seems to be very different.[7] The apparent fact in Irish, for instance, is that resumptive pronouns and gaps are in free variation in all positions except those from which movement is impossible (in which resumption is the only option) and those affected by the Highest Subject Restriction (see (29a, b)), in which only a gap is possible. Similar facts appear to hold in Hebrew.[8]

6 The identity of the binding element

The issues considered so far have been the focus of a great deal of discussion. In this section I want to highlight an issue which is, in my view, of central importance, but which has been less discussed.

There is strong evidence (as we have seen) that resumptive pronouns function as 'variables' in the technical sense. Given the theoretical context in which we are working, this means that they must have a binder (a co-indexed element in a c-commanding A-bar-position). There has also seemed to be strong evidence that the local binder of the resumptive element cannot be the overt element with which it is ultimately linked – the head of a relative clause, the interrogative phrase of a question, the focused phrase of a cleft and so on (Safir 1986; McCloskey 1990). The evidence seems rather to suggest that that ultimate binding is mediated by a more local binding – between the resumptive pronoun and an element in CP. The Irish evidence, as we will see below, seems to be particularly clear on this point.

But what then should the binder of the resumptive pronoun be taken to be? The answer that has usually been given is that the binding element must be a null operator base-generated in the specifier position of CP. The null operator is linked in turn with the ultimate binder by way of the relation called 'R-Binding' by Safir (1984). For the case of an interrogative structure, then, we will have the schematic structure in (32a), and for a relative clause the schematic structure in (32b):

(32) a. $[\mathrm{DP}_{[\mathrm{Q}]j}\ [_{\mathrm{CP}}\ \mathrm{Op}_j\ \mathrm{C}[_{\mathrm{IP}}\ \ldots\ \textit{pro}_j\ \ldots\ ]]]$
b. $[_{\mathrm{DP}}\ \mathrm{NP}_j\ [_{\mathrm{CP}}\ \mathrm{Op}_j\ \mathrm{C}[_{\mathrm{IP}}\ \ldots\ \textit{pro}_j]]]$

There is a worry here, though – a worry that one might label 'the problem of eternal silence'. I mean by this that there are no cases, as far as I have been able to determine, in which the postulated operator is other than null. No language, I believe, has an element *foo* such that one finds relative clauses analogous to (33):

(33) $[_{\mathrm{DP}}$ the guy $[_{\mathrm{CP}}$ *foo* that $[_{\mathrm{IP}}$ I spoke to him]]]

What one finds over and over again is some equivalent of (34), with no audible element occupying the specifier position of CP:

(34) $[_{\mathrm{DP}}$ the guy $[_{\mathrm{CP}}$ that $[_{\mathrm{IP}}$ I spoke to him]]]

The conception of resumption as we have outlined it so far has no explanation for the absence of (33) – an absence which can hardly be accidental. If invariant binding operators exist, it is not obvious what principle would force such operators to be phonologically null in *every* case.

The only set of proposals in this general family, as far as I know, which is not subject to this objection is that developed by Demirdache (1991), who argues that

the specifier position of CP is empty until LF. In the derivation of LF representations, the resumptive pronoun itself is taken to move into the specifier of CP. As long as movement between S-structure and LF is not subject to the same locality requirements as overt movement (Huang 1982a and much subsequent work), this analysis is tenable.

7 Parameterization

A remaining open issue concerns how language-particular differences in this domain are to be characterized. For some languages (Hebrew, Lebanese Arabic, Irish), resumption is a fully integrated aspect of the grammatical system. For others (English, for instance), it is typically regarded as an auxiliary phenomenon, not part of the grammar proper, but rather a device that speakers resort to under certain performance conditions (increased processing load in particular – Erteschik-Shir 1992; Dickey 1996). Chao and Sells (1983) and Sells (1984b) present evidence from English that the distinction between the two language types is necessary, delineate some of the distinctive characteristics of the two types, and introduce the term 'intrusive resumption' for the English type. They point out in particular that resumption in English relative clauses is degraded if the ultimate antecedent of the resumptive pronoun is quantificational:

(35) *I'd like to meet every linguist that Mary wondered if she should invite *him* to the party.

If this position is correct, as is widely assumed, then the theory of parameterization has to provide a way to draw a distinction between the two language types. One proposal within the larger framework just sketched is that the relevant property is a property of the functional head C. If resumptive pronouns are bound by null operators in the specifier of CP, then it is natural that the heads which host such binding operators in their specifiers should bear a distinctive morphosyntactic feature, a feature which has an overt morpho-phonological consequence in the Irish complementizer system, as seen in (13), repeated here as (36):

(36) a. an ghirseach a ghoid na síogaí ___
the girl C stole the fairies
'the girl who the fairies stole'
b. an ghirseach ar ghoid na síogaí í
the girl C stole the fairies her
'the girl who the fairies stole'

Here there are distinct complementizers (*a* versus *ar* in the case in point) depending on whether the clause contains a gap or a resumptive pronoun (see McCloskey 1990, 2001b, 2002 for discussion). If this position turns out to be defensible, then

this instance of parameterization falls into line with the emerging consensus that parametric differences derive from featural properties of functional lexical items.

8 Movement and resumption

The open issues just summarized are serious and substantial; some seem soluble, some seem deeper. Overall, though, the conception is reasonably attractive and could make some claim to cross-linguistic generality. But we must now look at a series of cases and issues which pose more fundamental problems for the conception just outlined and which ultimately threaten to subvert it completely, or at least to force radical revisons. Interestingly, all have to do with the interplay between resumption and movement. I want to look at these cases in order of ascending difficulty.

8.1 Swedish, Vata, and Gbadi

Engdahl (1985) provides one of the earliest comprehensive studies of the resumptive pronoun phenomenon in a given language – Swedish in this case. A typical example is given in (36):

(37) Vilket ord visste ingen hur det stavas ___?
which word knew no one how it is-spelled
'Which word did nobody know how it is spelled?'

Engdahl demonstrates that resumptive pronouns in Swedish have the following range of properties:

(i) They license parasitic gaps; see (38).
(ii) They give rise to weak crossover effects.
(iii) They satisfy the ATB requirement on extraction from coordinate structures; see (39).
(iv) They worsen, rather than improve, subjacency violations; see (40).
(v) They "are used systematically only in the subject position of tensed clauses" – in fact, to void what would otherwise be 'COMP-trace' violations (Engdahl 1985: 11).

(38) Vilken fånge var det läkarna inte kunde avgöra om han verkligen
which prisoner was it the-doctors not could decide if he really
var sjuk utan att tala med ___ personligen?
was ill without to talk with in-person
'Which prisoner was it that the doctors couldn't decide if he really was ill without talking to in person?'

(39) Det finns vissa ord som jag ofta träffar på ___ men inte minns
EXP are certain words that I often meet but not remember
hur de stavas.
how they are-spelled
'There are certain words that I often come across but never remember how they are spelled.'

(40) ?*Vilken bil åt du lunch med någon som körde den?
which car ate you lunch with someone that drove it
'Which car did you have lunch with someone that drove?'

Engdahl concludes from these observations that resumptive pronouns in Swedish "behave just like *wh*-traces" and are "phonetically realized traces." At about the same time, and I believe independently, Hilda Koopman (1982) (see also Koopman 1984: sections 2.3.3.2 and 6.2.4) made an almost identical set of observations and drew similar conclusions about the behavior of resumptive pronouns in two Kru languages of West Africa (Vata and Gbadi).

In the face of these observations and proposals, it is impossible to maintain the simplest view of the relation between resumptive pronouns and gaps in A-bar-binding constructions. One cannot maintain, that is, that the presence of a gap indicates that movement has applied and that the presence of a pronoun indicates that movement has not applied. Simple inspection of a string will never be enough to establish whether a given instance of A-bar-binding is established by way of movement or by way of base-generation followed by binding.

There is a sense, though, in which these results do not challenge what I have called here the consensus view in any very deep way. The two sets of properties (properties of movement-derived constructions and properties of non-movement-derived constructions) still line up in neat opposition. In Swedish, Vata, and Gbadi, those A-bar-binding relations which terminate in a pronoun show the complete constellation of properties associated with A-bar-movement. In Irish and similar languages, resumptive pronoun constructions show none of those properties. As long as we can make sense of the idea that a pronoun can be the 'spell-out' of a trace (as in the former group of languages), the larger conceptual architecture is not severely threatened.

Two points are worth making, however. The first is that, interpreted in this way, the observations imply that the phenonemon of resumption is not theoretically uniform ((iv) of p. 99 above). The second is that in the theoretical context in which such proposals were first made, it was not clear that the notion 'spell-out of a trace' made much sense. Two strands of development, however, changed that. One has to do with our understanding of the movement operation, and the other has to do with our understanding of the category 'pronoun'.

One of the innovations of the Minimalist program (Chomsky 1993, 1995c) has been to reintroduce, or re-emphasize, a certain understanding of movement which was standard in work of the 1960s and 1970s – namely that the movement operation, rather than being a primitive, is in fact a composition of two more

fundamental operations: copying and deletion. A copy of the moved element is first created; it is inserted in the target position; then the occurrence of the moved phrase in the origin site is deleted. Given this rediscovery or re-emphasis, it becomes easier to understand what it might mean to 'spell out' a trace. A trace, on this general view, is simply the silence that remains after the lowest occurrence of a copied phrase is deleted. Chomsky (1993) proposes that the deletion takes place on the 'phonological' side of the derivation (that is, in a derivational sequence which follows SPELL OUT and is inaccessible to the operations which create and interpret logical forms). Given that overall conception, it is easy to imagine that deletion of the original copy of the phrase might be partial rather than complete. That is, for a *wh*-question like (*I wonder*) *which word they are not sure how it's spelled?*, we will have a sequence of representations like that illustrated schematically in (41):

(41) a. [$_{IP}$ they are not sure [$_{CP}$ how [$_{IP}$ [$_{DP}$ *which* [$_{NP}$ *word*]] is spelled]]]
b. [$_{CP}$ [$_{DP}$ which [$_{NP}$ word]] [$_{IP}$ they are not sure [$_{CP}$ how [$_{IP}$ [$_{DP}$ *which* [$_{NP}$ *word*]] is spelled]]]]
c. [$_{CP}$ [$_{DP}$ which word] [$_{IP}$ they are not sure [$_{CP}$ how [$_{IP}$ [$_{DP}$ *which* [$_{NP}$ Ø]] is spelled]]]]
d. [$_{CP}$ [$_{DP}$ which word] [$_{IP}$ they are not sure [$_{CP}$ how [$_{IP}$ [$_{DP}$ *it* [$_{NP}$ Ø]] is spelled]]]]

In (41b), we have the immediate aftermath of movement (copying of the *wh*-phrase and its merger into the specifier position of CP). In (41c), the NP-portion of the lower copy has been deleted. In (41d), the *wh*-feature on D has been eliminated, and D is as a consequence realized as the default third singular pronoun, namely *it*.

Furthermore, given the view that pronouns are in fact determiners (Postal 1970b; Abney 1987; Koopman 1999b), it becomes easy to imagine derivations in which the NP-part of a moved phrase would be deleted stranding a D – that is, a 'resumptive' pronoun.

Two theoretical developments combine to make this set of ideas as plausible as they now are. One is the (re)introduction of the copy-and-delete theory of movement. The second is the articulation of a complex internal structure for nominal phrases – a development which in turn opens the possiblity of viewing pronouns also as having complex internal structures. This last move (on which see especially Koopman 1999b) opens up a range of new possibilities and options in debates about base-generation versus derivation by movement. The pronoun in (41d), for instance, can be said to be both base-generated *and* tranformationally derived.

Numerous difficulties and puzzles remain, of course. What mechanism forces or permits partial deletion following movement? Why exactly is it that the results of partial deletion systematically resemble pronouns? How is the theory of islandhood and of ECP effects to be rethought in this context?

However these questions are ultimately answered, the type of resumptive documented by Engdahl and Koopman (which exhibits all the properties of a

trace but involves pronunciation of D) seems to demand an understanding along these lines.

If this line of thought is roughly correct, then certain consequences follow which are unexpected within more traditional perspectives. Engdahl documents for Swedish, and Koopman documents for the Kru languages, that resumptive pronouns are found only in positions in which a trace would be in violation of the ECP. More exactly, resumptive pronouns are found in these languages only in subject positions immediately subjacent to a *wh*-phrase, much as in English examples such as (42):

(42) They're the kind of people that you never know who *they* might insult.

The ungrammaticality of the corresponding examples with gaps rather than resumptive pronouns, such as (43):

(43) *They're the kind of people that you never know who *t* might insult.

has generally been attributed to the Empty Category Principle, standardly taken to be a condition on representations at the level of Logical Form. But this interpretation cannot be right if the perspective just developed is on the right track. Given that perspective, the difference between the (Swedish equivalent of) (42) and (the Swedish equivalent of) (43) emerges only at the point where deletion applies, and the difference is a function only of whether that deletion is complete or partial. But when that conclusion is in turn embedded within the general framework of Chomsky (1993) or Chomsky (1995c: chapter 4), it follows in turn that whatever makes the difference between (42) and (43) cannot be an LF principle. Whatever it is, it must rather do its work on the 'phonological' side of the derivation (where the deletion subcomponent of movement does its work). It is only on that side of the derivation that (42) and (43) are distinguishable at all, on this view of matters. Put more crudely, it follows that subject ECP effects must be 'phonological' phenomena, in the broad sense. This conclusion in turn now makes contact with the strand of more recent work which suggests that many traditional island and ECP effects may find their explanation in the syntactic space between the syntax proper and the linearized prosodic and phonological string (Merchant 2001; Boeckx 2003).

8.2 Reconstruction

A more complex set of facts has been documented for Lebanese Arabic in an important series of papers by Joseph Aoun, Lina Choueiri, and Norbert Hornstein (Aoun and Choueiri 1996, 2000; Aoun et al. 2001).

This pattern of facts is of importance because of the complex interplay it exhibits between resumption and reconstruction. This interaction is in turn crucial in assessing to what extent resumption shows the characteristics of movement. Reconstruction is the phenomenon whereby a moved phrase exhibits properties

or interactions attributable to its occupying a syntactic position other than the one in which it is pronounced. A strong (but not universal) consensus in recent work attributes reconstruction effects in general to syntactic movement. A phrase 'acts as if' it occupies a position other than that in which it is pronounced because it has been moved from that position. One of the virtues of the copy-and-delete understanding of movement is that it provides a particularly simple understanding of the phenomenon. A phrase 'acts as if' it occupied a lower position than that in which it is pronounced because there is an occurrence of that phrase (deleted in the pronounced string but not in the representation submitted to interpretive mechanisms) in the lower position.

This account makes a very tight connection between the phenomenon of reconstruction and the operation of movement. If it is correct, then reconstruction effects constitute as reliable a diagnostic as there can be that a movement operation has applied.

The question of whether or not one gets reconstruction effects under resumption was asked early (Zaenen et al. 1981) and answered positively. The investigation was fairly brief, however, and centered on a language (Swedish) for which the movement analysis of resumptive pronouns was already well supported. The work of Aoun, Choueiri, and Hornstein is important because the investigation went farther empirically, was embedded in a richer theoretical context, and centered on a language (Lebanese Arabic) for which the movement theory of resumption was initially much less plausible because resumptive pronouns in the language appear routinely inside islands.

What emerges, briefly, from this body of work is the following. Resumptive elements (strong pronouns or epithets) which appear inside islands behave differently from resumptive elements which are not inside islands, even though the two are formally identical (Aoun and Choueiri 1996 suggest the terms 'true resumption' and 'apparent resumption' respectively for the two cases). In particular, resumptive elements which are not trapped within islands exhibit reconstruction effects, but resumptive elements inside islands show no reconstruction effects.[9] In (44), for example, in the absence of an island boundary, the clitic pronoun inside the fronted nominal phrase may be bound by the negative quantifer:

(44) **Lebanese Arabic:**
təlmiiz-a l-kəsleen ma abbarna wala m allme ənno huwwe
student-her the-bad NEG told-1.PL no teacher that he
za bar b-l-fa S
cheated-3.SG.MASC in-the-exam
'Her bad student, we didn't tell any teacher that *he* cheated on the exam.'

That is, the pronoun contained within the fronted phrase can apparently be reconstructed to the position of the resumptive pronoun, a position from which it can be bound by the negative quantifier *no teacher*. Such reconstruction, however, is systematically impossible if the resumptive element (pronoun or epithet) is contained within an island which excludes its ultimate binder.

If reconstruction is a true diagnostic for movement, then it follows from these observations that (at least in Lebanese Arabic) resumptive pronouns outside islands are formed by movement, but those inside islands are not. It follows in turn that both mechanisms (movement and base-generation) must be available within the same language, and the fact that the two outcomes are formally indistinguishable becomes very puzzling.

Further research on the interaction between resumption and reconstruction is urgently needed.

9 Conclusion

What we have called here (in a deliberate oversimplification) the 'consensus view' of resumption found in work of the 1980s and early 1990s is, then, now difficult to maintain, at least in its entirety or in its simplest form. It has been subverted by a number of developments – the rethinking of what the movement operation is, the new centrality of reconstruction as a diagnostic tool, and the ongoing rethinking of islandhood and ECP phenomena (encouraged in part by study of cases in which ellipsis makes good what would otherwise have been an island violation – Merchant 2001 and much subsequent work). It is hard to predict how of all of this will be resolved, but the area is ripe for further work, and there is a rich base of observation and analysis upon which to build.

There is also a deep mystery lying at the bottom of it all. It is known that resumptive elements may serve the purpose of marking variable positions in unbounded dependency constructions. It is known that resumptive elements may occur in positions from which movement is impossible (hence apparently allowing greater expressive power than is permitted by movement alone). It is also known that resumption imposes a considerably lighter burden on the human sentence processor than does the production and resolution of syntactic movement configurations. Why, then, is movement used at all in the creation of these structures?

NOTES

1 There is a certain sense in which it is unsurprising that this possibility should exist. Epithets exhibit a number of other 'pronominal' properties – they give rise to robust Condition C effects in languages (Thai and Vietnamese, for instance) in which only pronouns give rise to such effects (Lasnik 1989b). In addition, as noted more than once, epithets may be bound by quantifiers:

(i) Each delegation's leader spoke on its behalf.
(ii) Each prisoner's lawyer had to witness the poor bugger's punishment.

The point can only be made with examples in which the quantifer does not command the epithet (as in (ii)), since one would otherwise have Condition C effects. However,

when allowance is made for this, the effect seems clear enough. The examples in (i) and (ii) seem to be equivalent in acceptability.

2 (5) is from McCloskey (1990), (6) from Suñer (1996), (7) from Aoun and Choueiri (1996), and (8) from Borer (1984b).

3 This property of resumptive pronouns has played an important part in the investigation of weak island phenomena. Much work on the topic (see especially Cinque 1990c and Postal 1998, anticipated by Perlmutter 1972) argues that under certain conditions the apparent trace of A-bar-movement is in fact a silent resumptive pronoun. Given the amnestying effect of resumption on island violations, one can in this way understand why certain cases of (apparent) extraction from island configurations are relatively well-formed.

4 For some difficulties internal to Irish, see McCloskey (1990: fn 14). The difficulty here revolves around an equivocation in (30) concerning use of the term 'subject' – which is not well-defined. An additional concern is that languages which have the Highest Subject Restriction (HSR) in some form seem to differ in how they treat embedded subjects. In Irish, subjects of embedded clauses may freely serve the resumptive function (McCloskey 1990: 210, 240). But in Lebanese Arabic (Aoun and Choueiri 1996, 2000; Aoun et al. 2001) they cannot. Certain languages (literary Welsh, Russian) require that neither subjects nor objects in the highest clause be resumptive (Harlow 1981; Sells 1984b; Déprez and Hale 1986; Broihier 1995; Pesetsky 1998b). Finally, not all languages which exhibit resumptive pronouns exhibit the HSR effect. We will consider a suggestion about one such group of languages shortly, but that suggestion will leave a number of cases untouched (see Suñer 1996, for instance, on (informal) Spanish, and Prince 1990 on Yiddish). Perhaps in such cases, there is no A-bar-binder at all and the pronoun trivially satisfies the A-bar-Disjointness Requirement. For alternative approaches to the Highest Subject Restriction effect, see Déprez and Hale (1986); Shlonsky (1992); Pesetsky (1998b).

5 But see Kayne (2002) for an argument that this consensus view should be reconsidered.

6 Chomsky (1982) argued that resumptive pronouns in English were identified as such (by being bound) only at the level of Logical Form. McCloskey (1990) presented an argument from Irish that resumptive pronouns in that language must be distinguishable from other pronouns at the level of S-structure. Shlonsky (1992) countered the argument and suggested a return to the position of Chomsky (1982). One of the principal empirical issues at stake here is the question of whether or not resumptive pronouns license the appearance of parasitic gaps (an indicator of S-structure A-bar-binding). Sells (1984b) argued that, at least in Hebrew, resumptive pronouns do license the appearance of parasitic gaps, and concluded that they must represent S-structure variables. Shlonsky (1992) challenged both the empirical claim and the conclusion derived from it.

7 Prince (1990) cites a great number of naturally occurring data which might suggest that the usual claim is not in fact correct for English either. McDaniel et al. (1997) report experimental data suggesting that children learning English (unlike adults) accept resumptive pronouns in positions in which traces are also possible.

8 The qualifying "appear" is important here, because many of those who have argued for the last resort character of the resumption mechanism (Shlonsky 1992; Fox 1994; Pesetsky 1998b) have argued for the existence of hidden factors which block movement (and hence force the appearance of resumptive pronouns) in all the cases in which resumptive pronouns appear. I know of no suggestion about what these hidden factors might be in the case of Irish. This issue is closely connected with the issue of

how to understand the Highest Subject Restriction. If movement is freely available from subject position, and if resumption is possible only when movement is impossible, then it will follow that resumptive pronouns will never appear in subject position. See Shlonsky (1992) in particular for a development of this line of thought.

9 There is in addition a set of correlated effects involving obviation and the possibility of having quantificational antecedents.

5.3.2 An alternative line of inquiry

1 Introduction

All Romance languages have a reflexive-reciprocal clitic (*se* in French, Spanish, and Romanian, and *si* in Italian, referred to as SE henceforth). In most Romance languages, Goal/Benefactive reflexives are formally indistinguishable from Theme/Patient reflexives. In Romanian, however, Goal/Benefactive reflexive clitics are overtly marked for dative Case (*îşi*$_{\text{Dat}}$ vs. *se*$_{\text{Accus}}$). Certain Romance languages – for example, Italian, Spanish, and Portuguese (but not French or Romanian) – also have a nominative/subject SE (best translated as 'one' in English and 'on' in French).

The terms 'accusative, dative, and nominative' SE may seem somewhat surprising insofar as these three elements show no overt morphological distinctions (with the exception of Romanian dative SE). This terminology is nevertheless justified by the possibility of analyzing the three types of SE as differing with respect to abstract Case. Assuming that a given abstract Case can be assigned to only one element (or chain) inside the same syntactic domain, it is possible to infer the abstract Case of SE on the basis of the Cases of the other DPs with which SE co-occurs: thus, accusative SE may co-exist with nominative or dative DPs,

but not with accusative DPs; nominative SE may co-exist with accusative DPs; etc. The abstract Case distinctions correlate with functional distinctions only partially: nominative SE can indeed be analyzed as an arbitrary subject clitic, but accusative SE cannot be said to be an object clitic, because (i) reflexives built with accusative SE do not behave as transitives (see section 2.1.3.1) and (ii) accusative SEs other than reflexives (inherent, inchoative, passive, or middle SE) cannot even be assumed to correspond to (suppressed) arguments. Finally, theta-role distinctions are also only partially helpful: we can indeed distinguish between accusative and dative reflexive-reciprocals in terms of theta-roles (Theme/Patient vs. Goal/Benefactive), but theta-roles are irrelevant for distinguishing between accusative and dative inherent SE-verbs.

Dative and nominative SE will occupy only very few pages of this chapter (see sections 2.2 and 2.3, respectively). Starting with section 3, we will focus on accusative SE, and more particularly on its middle and passive readings. How many accusative SEs are there? What is the common feature or structure that underlies its various readings (reflexive, passive, middle, inchoative, inherent)? Is it possible to propose a unifying analysis or should we postulate several homophonous types of accusative SE?

There are many phenomena regarding *se/si* in Romance that will be left aside: (i) the intricate detail of the placement of SE in French and Italian causatives and Italian restructuring environments; (ii) the various semantic constraints on the features of the implicit Agent in passive SE configurations; and (iii) long-distance bound reflexives in Italian.[1]

2 Types of SE

The overview below is meant to illustrate the main contexts in which accusative, dative, and nominative SE can each be found.

2.1 Accusative SE

According to some GB theorists of the 1980s, reflexive, middle, and passive SE are intrinsically distinct elements (Belletti 1982; Grimshaw 1982; Zubizarreta 1987; Cinque 1988; among many others).[2] This view cannot explain why these elements systematically exhibit the same morphological form across Romance languages.[3]

Partial unification of the various readings of accusative SE goes back to Burzio (1986): inchoative, inherent, middle, and passive SEs are alike insofar as they can all be analyzed as markers of unaccusativity,[4] understood as a lexical operation that triggers the suspension of the external theta-role and of accusative Case.

Interesting evidence due to Kayne (1975), Burzio (1986), and Pesetsky (1995) suggests that the unaccusative analysis can be extended to reflexive SE. This hypothesis has been convincingly criticized by Reinhart and Siloni (2004), who argue instead that reflexive SE-verbs behave as unergatives.

2.1.1 Inherent and inchoative SE

Inherent and inchoative SE-verbs are two subclasses of unaccusatives (overt Theme, no explicit or implicit Agent), which differ from each other by the absence vs. presence of transitive alternates: inchoatives have transitive alternates, whereas 'inherent SE-verbs' do not; they are of necessity accompanied by SE, and are registered as such in the Lexicon:

(1) a. **Inherent:**
Marie s'est évanouie.
Mary SE has fainted.[5]
'Mary fainted.'

b. **Inchoative:**
La branche$_i$ s$_i$'est cassée e$_i$.
the branch SE has broken
'The branch broke.'

Building on earlier insights by Zribi-Hertz (1987), Labelle (1992) has established that French inchoatives built with SE (e.g., *s'agrandir* 'to get bigger, to enlarge') behave as unaccusatives, whereas those inchoatives that cannot be constructed with SE (e.g., *cuire* 'to cook') qualify as unergatives. The distinction was clearly established on the basis of tests such as auxiliary selection, *il*-impersonals and *en*-extraction, embedded infinitival relatives, tough-constructions, adjectival passives, and participial constructions.

The question now arises as to what determines – for a given change-of-state verb – the choice between functioning as an unaccusative (in which case it is marked with SE) or as an unergative (in which case SE is precluded). Following Rothemberg (1974), Bernard (1971), Burston (1979), and Forest (1988), the answer proposed by Labelle is that the unergative form is used with predicates that express internally driven, autonomous natural processes[6] (*vieillir*, *maigrir*, *grandir*, *grossir*, *rougir*, *sécher*, *pâlir*, *fondre*, *cuire*, *durcir*, *éclater* 'to grow old, thin, tall, fat, to go red in the face, to dry, to pale, to melt, to cook, to harden, to burst'). The processes described by these verbs may be brought about by external causes expressed by complements introduced by *de*, but such causes only constitute the initial force that induces an internally caused process. Even if such external causes are mentioned, these verbs do not allow SE: *(*se) rougir de honte*, *(*se) fondre sous l'effet de la chaleur* '(*se) go red with shame, (*se) melt with the heat'.

Many inchoative verbs – more precisely, those that may refer to natural processes as unfolding in an autonomous way (although not internally caused) – allow both constructions, with notable aspectual differences: *casser/se casser* 'break', *raffraîchir/se raffraîchir* 'cool off', *durcir/se durcir* 'harden'. In the SE-construction, the object undergoing the change of state is projected to the object position, and consequently it is used as an event-measure in the sense of Tenny (1987). Correlatively, SE-inchoatives focus on the final state of the entity undergoing the change, rather than on the unfolding of the process itself.[7] This characterization of the difference between unergative and unaccusative inchoatives constitutes a

refinement of Zribi-Hertz's (1987) claim that reflexive inchoatives are perfective or resultative. This generalization has been questioned by Lagae (1990), who argues that the focus on the final state that indeed characterizes SE-inchoatives is not to be analyzed as perfectivity, although it does explain certain restrictions on the choice of tense or the incompatibility with certain aspectual markers, e.g., *mettre le vin à raffraîchir/*se raffraîchir* 'let the wine cool'.

SE is obligatorily used whenever an external cause is implied. It is particularly striking that verbs built with causative prefixes such as *a-* or *en-*, or causative suffixes like *-ifier-* or *-iser*, require SE: *s'alléger* 'become lighter', *s'agrandir* 'to grow bigger', *s'assécher* 'to dry out', *s'amaigrir* 'to become thinner', *s'abêtir* 'become stupid', *s'allourdir* 'to become heavier', *se diversifier* 'to diversify', *s'humidifier* 'to become humid'.

There exist some verbs which, although they are not morphologically complex, require SE in order to take the inchoative reading. According to Labelle, such verbs are to be classified as "conceptually transitive," i.e., as requiring both their arguments to be projected, unless the external argument is absorbed by SE. A case in point is provided by the pair *briser/casser* 'break', which are near-synonyms, but differ regarding the use of SE: in the absence of SE, *casser* can be used both as a transitive and as an inchoative, whereas *briser* is of necessity transitive; its inchoative use requires SE. The existence of pairs of verbs such as *briser/casser* indicates that the choice between the unaccusative and unergative status may sometimes be idiosyncratic, unmotivated. This leads us to expect that the choice between SE-marking and unmarked forms for semantically close verbs may differ from one Romance language to another. Although detailed analyses exist for most Romance languages (see in particular Folli 2002a, 2002b and Masullo 1999 for Italian and Spanish, respectively), there is no comparative study of this domain of the grammar.

2.1.2 Middle and passive SE

Middle SE and passive SE are alike regarding thematic structure (the overt DP is a Theme, and the Agent is either implicit or realized as an Adjunct *by*-phrase), but differ insofar as middles are interpreted generically, as ascribing a property to the subject DP, whereas passives refer to (particular or habitual) events:

(2) a. **Middle:**
Le $grec_i$ se_i traduit e_i facilement.
the Greek SE translates easily
'Greek translates easily.'

b. **Eventive passive:**
Il_j s_i'est traduit trois $romans_i$.
it SE has translated three novels
'Three novels were translated.'

c. **Habitual passive:**
Les pommes se mangent en hiver.
apples SE eat during winter
'Apples are eaten during winter.'

Much of the literature devoted to SE has focused on various issues relating to the analysis of middle and passive SE: (i) the syntactic representation of the implicit Agent; (ii) the distribution of middle and passive SE in Italian non-finite clauses; and (iii) the correlation between the position of the subject and the reading of SE-verbs. Sections 3, 4, and 5 below are devoted to these issues respectively.

2.1.3 Reflexive-reciprocal SE

(3a–b) illustrate the reflexive and reciprocal uses of SE-verbs:

(3) a. Jean$_i$ se$_i$ lave e$_i$.
John SE washes
'John washes himself.'
b. Jean et Marie se disputent souvent.
John and Mary SE quarrel frequently

Insofar as they alternate with object clitics, reflexive and reciprocal SEs seem to have pronominal status; hence Kayne's (1975) rule of SE-placement, which leaves behind a trace of SE in an A-position. Kayne clearly showed, however, that SE-placement differs from Cl(itic)-placement (the rule that moves pronominal clitics from an A-position to a clitic position; see chapter 13) in crucial ways. Further evidence going in the same direction led Burzio (1986: 42) to the conclusion that reflexive SE is ambiguous between an object clitic and a marker of unaccusativity ("affix[es] with no other syntactic function than marking the lack of theta-role assignment to the subject position").[8] The same view was adopted in Bouchard (1984), Marantz (1984), Grimshaw (1990), and Pesetsky (1995), but Reinhart and Siloni (2004) have convincingly argued against analyzing reflexive SE-verbs as unaccusatives and have proposed instead that they behave as unergatives.

2.1.3.1 Reflexive SE-verbs are not transitives

The empirical evidence reviewed in this subsection was invoked by Burzio (1981) and subsequently by most GB theorists in favor of the unaccusative analysis. On closer scrutiny, however, these are not arguments in favor of the putative unaccusative behavior of reflexive verbs. What the facts really show is that reflexive SE-verbs do not pattern with transitives, which means that reflexive SE is not an object clitic.

Clear evidence against the pronominal status of SE is provided by French causatives. Pronominal clitics cannot attach to a verb embedded under causative *faire*, whereas this position is accessible to SE:

(4) a. *La crainte du scandale l'a fait *la* tuer.
the fear of scandal him-has made her kill.
'The fear of scandal made him kill her.'
b. La crainte du scandale l'a fait *se* tuer.
the fear of scandal him-has made SE kill.
'The fear of scandal made him kill himself.'

Consider next the paradigm in (5a–f). According to a clear empirical generalization, the underlying subject of an infinitival clause embedded under a causative *faire* must be preceded by the preposition *à* in case a direct object is present, but lacks *à* with intransitive verbs (see (5a–c)). The example in (5d) shows that pronominal clitics behave on a par with object DPs (see (5c)), whereas the grammaticality of (5e), without *à*, and the ungrammaticality of (5f), where *à* is present, indicate that SE does not function as a direct object:

(5) a. Jean a fait manger Marie.
John has made eat Mary
'John let Mary eat.'
b. *Jean a fait manger **à** Marie.
c Jean a fait manger la soupe **à** Marie.
John has made eat the soup to Mary
'John let Mary eat the soup.'
d. Jean l_i'a fait manger e_i **à** Marie.
John it-has made eat to Mary
'John let it eat to Mary.'
e. La crainte du scandale a fait *se* tuer la mère du juge.
The fear of scandal has made SE kill the mother of the judge.
'The fear of scandal made the mother of the judge kill herself.'
f. *La crainte du scandale a fait *se* tuer **à** la mère du juge.
The fear of scandal has made SE kill **to**-the mother of the judge.

The two tests just discussed for French cannot be used in other Romance languages such as Romanian or Italian: Romanian does not have counterparts of *faire*-causatives, and in Italian, *fare*-causatives block the cliticization of SE on the embedded infinitival (Burzio 1986):

(6) a. *Questo farà [$_{VP}$ pentirsi Giovanni]
This will make John repentSI
b. *Maria ha fatto [$_{VP}$ accusarsi Piero]
Mary has made accuseSE Peter
'Mary has made Peter accuse himself.'

Burzio (1986: 410) attempts to correlate the contrast between Italian and French with the difference between free subject inversion and *il*-impersonals, but the issue remains open.[9]

2.1.3.2 Reflexive SE-verbs are not unaccusatives

Burzio's (1986) data reviewed above show that SE-reflexives do not behave as transitive verbs accompanied by object clitics. Although the data are compatible with both the unergative and the unaccusative analysis, Burzio favored the unaccusative hypothesis: reflexive SE would be an unaccusative marker that suspends the subject theta-role: SE-affixation to a transitive verb, e.g., *accuse*, would be a

morphological process that gives rise to a corresponding verb, 'self-accuse', which is an unaccusative verb (1986: 415). Reinhart and Siloni (2004) argued conclusively against the unaccusative analysis of SE-reflexives. Under their view, SE-reflexives are unergatives.

Arguing in favor of the unaccusative analysis of reflexives, Burzio (1986) observed that the object of transitives and the subject of unaccusatives (cf. *arrivare* as well as SE-marked unaccusatives) can be relativized via small-clause relativization, in contrast with the subject of unergatives and transitives:

(7) a. uno studente [scPRO$_i$ invitato t$_i$ alla festa]
a student (who was) invited to the party
b. uno studente [PRO$_i$ arrivato t$_i$ ieri sera]
a student (who had) arrived yesterday evening
c. L'auto capovoltasi nell'incidente era la Ferrari.
The car (which had) rolled over in the accident was the Ferrari.
d. Un pilota accortosi dell'incidente diede l'allarme.
A driver (who had) become aware of the accident gave the warning.

(8) a. *uno studente [PRO telefonato ieri sera]
a student (who had) telephoned yesterday evening
b. *Un individuo accusatolo di aver assassinato il presidente fu creduto pazzo.
A guy (who had) accused him of having assassinated the president was thought (to be) crazy.
c. *un individuo accusato se stesso di aver assassinato il presidente
a guy (who had) accused himself of having assassinated the president

SE-reflexives behave on a par with unaccusatives:

(9) Un individuo accusatosi di aver assassinato il presidente fu creduto pazzo.
A man (who had) accused himself of having assassinated the president was believed crazy.

Reinhart and Siloni observed, however, that not all reflexives are allowed to occur in Italian reduced relatives:

(10) *L'uomo lavatosi ieri è mio nonno.
The man washed-SE yesterday is my grandfather.

Burzio himself brought up empirical evidence going against his own proposal; in particular, SE-reciprocals cannot appear in reduced relatives:

(11) ?Due amici incontratisi allo stadio non si vedevano d'anni.

A second argument in favor of the unaccusativity of SE-reflexives is based on auxiliary selection: they select the auxiliary *be*, in contrast with both transitives and unergatives, which select *have*:

(12) a. Jean s'est puni.
John SE-has punished
b. Jean s'est lavé le visage.
John SE-has washed his face
c. Il s'est mangé 300 kg de viande.
there SE-has eaten 300 kg of meat

Reinhart and Siloni observe that auxiliary selection is not a decisive argument in favor of unaccusativity, since *be* is selected by transitive verbs taking a dative SE:[10]

(13) Marie s'est envoyé une carte du Maroc.
Mary SE-has sent a postcard from Morocco

Further evidence against the unaccusativity of SE-reflexives is related to the distribution of *en*. Thus, although reflexives (marginally) allow their subject DP to occupy the postverbal position (presumably the direct object position) in French *il*-impersonals, *en*-extraction is blocked by SE-reflexives, in contradistinction to SE-unaccusatives and SE-passives, which behave on a par with unmarked unaccusatives and copula passives:

(14) a. Il s'en est cassé beaucoup dans ce lave-vaisselle. (unaccusative)
there SE of them has broken many in this dish-washer
b. Il s'en est lavé beaucoup dans ces douches publiques récemment. (OK passive; *refl.)
there SE of them has washed many in these public showers recently
c. ?*Se ne sono incontratisi due.
SE of them have met two. (Burzio 1986: 424)

Note that quite independent of the distribution of *en*, the context of *il*-impersonals does not constitute clear evidence in favor of the unaccusative analysis of SE-reflexives. As shown in (15a), *il*-impersonals are productive and perfectly grammatical with unaccusatives (be they marked with SE or unmarked) and with periphrastic as well as SE-marked passives (Burzio 1981, 1986; Pollock 1981, 1983), but examples of the type in (15b), built with SE-reflexives, are quite hard to find:

(15) a. Il s'est mangé 20 kg de viande en deux jours. (passive)
it SE ate 20 kg of meat in two days
b. ?Il s'est dénoncé trois mille hommes ce mois-ci. (reflexive)
it SE denounced 3,000 people this month (Kayne 1975: 381)

2.1.3.3 Reflexive SE and the Agent theta-role

Under later implementations of the unaccusative analysis of reflexives, reflexive SE was assumed to absorb the external theta-role (see Marantz 1984; Kayne 1988; Guéron 1991; Pesetsky 1995; Sportiche 1998), on a par with passive SE. In section 3 below, we will show that the hypothesis that accusative SE absorbs the external theta-role is problematic for passive SE. Those problems transfer to reflexive SE.

2.1.3.4 Reflexive SE-verbs are unergatives

We have so far reviewed the evidence against two possible analyses of SE-reflexives: they are neither transitives nor unaccusatives. Reinhart and Siloni (2004) propose instead that SE-reflexives are unergatives, obtained from their transitive alternates by an operation that identifies the two arguments of a two-place relation. In certain languages, e.g., Hebrew, this identification takes place in the lexicon, in which case it amounts to a lexical reduction operation that reduces a two-place relation to a property (Chierchia 1989; Reinhart 1997). In Romance languages, on the other hand, reflexivization relies on an identification operation that takes place at LF. Whereas lexical reduction is restricted to apply to co-arguments, LF-identification may apply to arguments of two distinct predicates, as in ECM constructions:

(16) Jean se considère [e intelligent].
John SE considers intelligent
'John considers himself (to be) intelligent.'

Hebrew counterparts of this kind of example are ungrammatical, because Hebrew reflexivization can only resort to lexical reduction.

2.1.4 Unifying characterizations of accusative SE

Beyond important differences, non-reflexive accusative SE-verbs (inherent SE-verbs, inchoatives, middles, and passives) can all be argued to be unaccusatives[11] insofar as the external role is suspended (i.e., not realized in the syntax), and the internal role is realized as a subject (in particular, it is assigned nominative Case).[12]

In the preceding section we have concluded, following Reinhart and Siloni (2004), that the unaccusative analysis of SE-reflexives should be discarded. And yet a unifying analysis of reflexive and non-reflexive accusative SE-verbs is desirable, due to very clear cross-linguistic generalizations: (i) Romance languages all have both reflexive and non-reflexive accusative SE; and (ii) many languages other than Romance have a non-active voice that is used both for reflexives and for inchoatives and middle-passives.

2.1.4.1 Lexical accounts

It is widely agreed that accusative SE does not function as an object clitic, but rather as a morphological marker that affects argument structure at the level of

the lexicon. This general characterization is compatible with quite different lexical rules, e.g., Inchoativization, Reflexivization, or Middle Formation (Grimshaw 1982). According to Reinhart and Siloni (2004), the SE-morphology appears when some derivational operation has taken place, be it reduction, saturation, or reflexivization (identification).[13]

One may wonder why operations as distinct as lexical reduction (which itself comes in two flavors: reduction of the external or of the internal role, corresponding respectively to unaccusatives and reflexives), LF-identification, or saturation (postulated in the analysis of passives and middles by Chierchia 1989 and Reinhart 1997) should be marked by one and the same morphological marker, SE.

Similar questions arise for other lexicalist analyses, in particular for Wehrli's (1986) view that the unifying characteristic of SE is that it absorbs an argument. According to this author, the various instantiations of SE are obtained by combining two parameters: (i) which argument is absorbed; and (ii) whether the absorption operation is lexicalized or not:

(17) a. Inherent SE: absorption of the internal argument; lexicalized
b. Unaccusative SE: absorption of the external argument; lexicalized
c. Reflexive SE: absorption of the internal argument; non-lexicalized
d. Middle SE: absorption of the external argument; non-lexicalized

But why should one and the same element absorb either one of the two arguments, despite the fact that it is uniformly marked with accusative Case?

2.1.4.2 SE as an anaphor

Dobrovie-Sorin (1994b, 1998) argues that the GB notion of anaphor (defined as an element that is subject to Principle A of Binding Theory) provides a unified characterization of the various types of accusative SE. According to a restricted theory of binding, only elements that occupy A-positions are subject to binding conditions. Under such a theory, binding conditions do not apply to clitics, but only to their traces. In particular, the anaphoric feature of SE, which is registered in the lexicon, is transferred to a designated A-position. A sentence containing SE will thus of necessity rely on the indexing configuration given in (18), where NP_i and e_i occupy respectively the subject and the object positions. The 'complete' version of the representation in (18) is (18'):

(18) $NP_i\ e_i$

(18') $NP_i\ SE_i\ e_i$

The absence of SE in (18) is only meant to indicate that the S-structure position of SE is irrelevant for Binding Theory, although, of course, the position of SE is crucial for phenomena having to do with cliticization; e.g., clitic climbing in *faire*-causatives or restructuring environments, etc.

The assignment of indices in (18–18′) characterizes reflexive as well as unaccusative uses of SE, which differ regarding thematic structure, as shown in (19a–b), or the fully developed representations in (19′a–b):

(19) a. (NP_i) (e_i)
b. $(NP_i\ e_i)$

(19′) a. (NP_i) $(SE_i\ e_i)$
b. $(NP_i\ SE_i\ e_i)$

The representation in (19b) differs from that in (19a) insofar as the two co-indexed argument positions belong to the same theta-chain. The two-chain configuration given in (19a) underlies SE-reflexives, which are characterized by an identification relation between the internal and the external arguments,[14] whereas the representation in (19b) underlies the non-reflexive uses of accusative SE-verbs (inherent, inchoative, middle, and passive SE-verbs),[15] which qualify as unaccusatives.[16]

In sum, the possibility of similar and yet distinct syntactic configurations is the result of the modularity of GB theory. The common property of SE-constructions pertains to binding theory (SE is lexically marked as an anaphor, and as such it forces the binding/co-indexation relation that characterizes both (19a) and (19b)),[17] whereas their dissimilarities pertain to theta-theory: one and the same binding relation may form one or two theta-chains, depending on the lexical properties of the predicates.

Postma (1995a) shares with Dobrovie-Sorin (1994b, 1998) the hypothesis that the unifying property of all uses of accusative SE is its being an anaphor, but proposes a different analysis. Postma assumes that the Agent role is projected in the syntax and that the various readings of SE arise as a consequence of the way in which the theta-chain corresponding to the Agent role is identified with the Theme-chain (for further details of Postma's proposal see section 3.5. below). In section 3 it will be argued that the Agent is not projected in the syntax of SE-verbs (other than reflexives), and in section 5 it will be shown that agentive or non-agentive interpretations depend on the syntactic position in which the internal argument is realized.

2.2 Dative SE[18]

In most Romance languages, dative SE is homophonous with accusative SE (cf. French, Italian, Spanish, Portuguese):

(20) a. Marie se fait des robes. French
Mary SE makes dresses
'Mary makes dresses for herself.'
b. Jean s'est envoyé des cartes postales.
John SE HAS sent postcards

In Romanian, reflexive clitics show an overt case distinction: *se* for accusatives and *îşi* for datives. The Romanian counterparts of the French examples in (20) are given in (21):

(21) a. Maria îşi face rochii.
Mary SE_{Dat} makes dresses
b. Ion şi-a trimis cărţi poştale. (*şi* is the phonologically weak form of *îşi*)
John SE_{Dat}-has sent postcards

Kayne (1975) observed that in French, dative SE cannot be bound by a derived subject, i.e., a subject that is the head of an NP-chain resulting from NP-movement (cf. passives and subject-raising configurations). Rizzi (1986b) showed that the generalization also holds in Italian ((22) for – passives, (23–24) for – subject raising):

(22) a. *Gianni$_i$ si$_i$ è stato affidato e$_i$.
John SI HAS been entrusted
'John to-himself was entrusted.'
b. *I nostri amici$_i$ si$_i$ sono stati presentati e$_i$.
our friends SI HAVE been introduced
'Our friends to-each-other were introduced.'

(23) a. *Gianni$_i$ si$_i$ sembra [e$_i$ non fare il suo dovere].
John SI seems not (to) do his duty
'John to-himself seems not to do his duty.'
b. *Le due candidati$_i$ si$_i$ risultavano [e$_i$ poter vincere].
the two candidates SI appeared (to) be able (to) win
'The two candidates to-each-other appeared to be able to win.'

(24) a. *Gianni$_i$ si$_i$ sembra [e$_i$ intelligente].
John SI seems intelligent
'John to-himself seems intelligent.'
b. *Loro$_i$ si$_i$ risultano [e$_i$ in regola con le tasse].
(they) SI appear in good order with taxes
'They to-each-other appear in good order with the taxes.'

Non-clitic anaphors such as *se stesso* or *l'uno l'altro* are not subject to this constraint:

(25) a. Gianni$_i$ è stato affidato a **se stessi$_i$**.
John HAS been entrusted to himself
b. I nostri amici$_i$ sono stati presentati l'uno all'altro$_i$.
our friends HAVE been introduced to each other

The restriction observed with passives and raising verbs also holds in adjectival constructions, as shown in the (b) examples below. The (a) examples, which contain the corresponding non-clitic anaphors, are grammatical:

(26) a. Gianni$_i$ è [e$_i$ affezionato a se stesso$_i$].
John is affectionate to himself
b. *Gianni$_i$ si$_i$ è [e$_i$ affezionato].
John SI is affectionate

(27) a. Loro$_i$ sono simili [e$_i$ l'uno all'altro].
they are similar to each other
b. *Loro$_i$ si$_i$ sono [e$_i$ simili].
they SI are similar

(28) a. Loro$_i$ sono [e$_i$ odiosi l'uno all'altro$_i$].
they are hateful to each other
b. *Loro$_i$ si$_i$ sono [e$_i$ odiosi].
they SI are hateful

The observed parallelism between A-chain configurations (passives and subject raising) and adjectival constructions is expected under the GB analysis of adjectives, going back to Couquaux (1979, 1981): the copula verb *be* is assumed to take a small-clause complement headed by the adjective; the subject position of *be*, which is empty at D-structure (because *be* assigns no theta-role) is targeted by the NP-movement of the subject of the small clause.

Verbs that are semantically close to the adjectives in (26–28) do not trigger ungrammaticality, presumably because in this case the subject is not the head of an A-chain but instead is base-generated in its S-structure position:

(29) a. Loro$_i$ si$_i$ assomigliano e$_i$.
(they) SI resemble
'They resemble each other.'
b. Loro$_i$ si$_i$ fanno e$_i$ pena/tenerezza/simpatia.
(they) SI make pain/tenderness/liking
'They make pain/tenderness/liking to-each-other.'

Kayne's (1975) account of the phenomenon relied on an extrinsic ordering of the rules of passivization and reflexive cliticization: the former applies before the latter, and the observed ungrammaticality obtains because reflexivization requires SE to be co-indexed with a subject, a requirement that cannot be satisfied: the prior application of passivization has suspended the external theta-role, and the object-to-subject NP-movement has not yet applied.

Burzio's (1986: 397–399) explanation builds on the same idea, but differs in the technical implementation. The ungrammaticality of dative SE with derived subjects would be due to the fact that the co-indexation relation between SE and a subject in Spec, IP, which defines SE, cannot be satisfied at D-structure in the relevant configurations: within the model of grammar assumed by Burzio, passives and raising verbs are generated with an empty Spec, IP position.

Rizzi (1986) rejected Burzio's account on the grounds that it stipulates an idiosyncratic property of SE, that of requiring a co-indexation with a subject at all levels of representation (in particular at D-structure), and he proposed instead an explanation relying on a Chain Condition: the chain in (30), representing a dative SE bound by a subject heading an A-chain, is ill-formed because the NP-trace (resulting from the NP-movement of the subject) is unduly locally bound by SE:

(30) *NP_i SE_i t_{NP_i}

This solution raises both empirical and theoretical problems. Note first that configurations of the type in (30) are grammatical in English, where the intervening binder is a strong dative reflexive pronoun:

(31) a. $Mary_i$ seems [to $herself_i$] t_i to have done her duty.
b. $John_i$ appeared [to $himself_i$] t_i to be capable of doing the job.

Within Rizzi's proposal one could account for the grammaticality of (31) by assuming that the reflexive pronoun, because it is embedded inside a PP, does not C-command the NP-trace, and thus does not count as a disturbing intervening binder. Pesetsky (1995: 105) observes that C-command must be postulated in exactly the same configuration in order to account for Principle C violations:

(32) *$Mary_j$ seems [to him_i] t_j to like $John_i$.

A comparable problem is raised by Romanian, a language in which the dative clitic *îşi* can be bound by derived subjects:[19]

(33) a. Ion şi Maria şi-au fost prezentați anul trecut.
John and Mary SE_{dat}-have been presented year-the last
'John and Mary were presented to each other last year.'
b. Ion îşi e recunoscător numai lui.
John SE_{dat} is grateful only to him(self)
c. Ion şi Maria şi-au devenit pur şi simplu insuportabili.
John and Mary SE_{dat}-have become purely and simply unbearable (to each other)
'John and Mary have become purely and simply unbearable to each other.'

Romanian clearly differs from French and Italian insofar as dative and accusative reflexive clitics are overtly distinguished by morphological Case: *îşi* and *se* respectively. Given Rizzi's account, one would have to say that morphological Case-marking blocks C-command. This proposal faces the problem noted above for English, regarding Principle C violations:

(34) *Maria $îi_j$ para a-l_j place pe Ion_j.[20] Romanian
$Mary_i$ to-him_j seems to [e_i] him_j like $John_j$.

It should be noted that although Rizzi's (1986) Chain Condition has the flavor of Rizzi's (1990b) Relativized Minimality Constraint, Rizzi (1990b) does not attempt to restate it. The reason might be that the Chain Condition cannot be restated in terms of relativized minimality: SE is an A'-antecedent, and as such it should not disturb the relation between an NP-trace and its antecedent, because the latter sits in an A-position.

Following a suggestion by Kayne, Pesetsky (1995: 103–105) proposes an explanation based on a Marantz–Kayne type of analysis for SE (see section 3.6): SE would necessarily be an external argument, regardless of whether it gives rise to reflexive, passive, or middle interpretations, and regardless of its Case: nominative, accusative, and dative SEs all need to absorb the external theta-role. The ungrammaticality shown in (22–24) and (26b), (27b), and (28b) would then be due to the fact that there is no external theta-role available for absorption by SE, since passives, raising verbs, and *be* do not assign an external theta-role. This solution does not explain why a dative SE that bears *morphological* dative Case, as in Romanian, does not need to absorb the external theta-role.

The problems faced by Rizzi (1986) and later proposals do not arise within Burzio's account, the only defect of which seems to be that it stipulates that the co-indexation relation required by SE (by virtue of its being an anaphor) should hold at all levels of representation, in particular at D-structure. This proposal is also confronted by a theory-internal problem, due to the evolution of the generative model: in the various versions of Minimalism, the D-structure level of representation is eliminated. It seems possible to solve this problem, while at the same time giving a conceptual justification to Burzio's proposal, by slightly modifying it: the co-indexing requirement imposed by SE would hold in the lexicon rather than at D-structure. The reason why it should hold in this component of the grammar would simply be its lexical nature: on a par with accusative SE, dative SE would be a *lexical* affix (rather than a pronominal clitic; see section 2.1.3), which as such should satisfy its anaphoric feature in the lexicon itself. This requirement cannot be satisfied if we assume that passives, adjectives, and raising verbs do not have external arguments in the lexicon. Because strong pronominal anaphors such as *l'uno l'altro* or *se stessi* are pronominal anaphors rather than lexical affixes, they do not function as anaphors in the lexicon, but only in the syntax: hence, they can be bound by derived subjects, i.e., elements that fill the (Spec, IP) position at S-structure. Similarly, we may explain the Romanian data by assuming that reflexives that are overtly marked for dative Case function as pronominal clitics rather than lexical affixes, and therefore the binding conditions are to be satisfied in the syntax rather than in the lexicon.

2.3 *Nominative SE*

Only certain pro-drop Romance languages – in particular Italian, Spanish, and Portuguese – have a nominative/subject SE:

(35) a. Non si_i e_i è mai contenti. Italian
not SI is ever satisfied
'One is never satisfied.'
b. Spesso si_i e_i è traditi dai falsi amici.
frequently SI is betrayed by false friends
'One is frequently betrayed by false friends.' (SI+passive)
c. In questa università si_i e_i studia le materie letterarie.
in this university SI teaches the humanities
d. (Le materie letterarie) le si_i e_i studia in questa università.
(the humanities) them SI teaches in this university
'(The humanities) one teaches them in this university.'

(35a–b) cannot involve an accusative SE because neither (the copula verb *be* +) adjectives nor passives can assign accusative Case. In (35c), the verb does not agree with *le materie letterarie*; therefore this DP cannot be a postverbal subject, but must instead be analyzed as a direct object; since direct objects take accusative Case, SE itself cannot be accusative. In (35d), accusative Case is assigned to the object clitic *le*, and is thus unavailable for SE itself. The examples in (35a–d) are instead compatible with analyzing SE as an arbitrary subject clitic (marked with abstract nominative Case) comparable to arbitrary *on* 'one' in French.

Romance scholars have frequently attempted to unify nominative and accusative SE (see, among others, Castelfranchi and Parisi 1976; Manzini 1986b; Guéron 1991; Kayne (class lectures in the 1980s and 1990s)). According to Manzini (1986b), what brings together all the occurrences of *si* is the fact that *si* is co-indexed with the subject NP. This suggested unification is, however, problematic, since the co-indexation convention notates here two distinct types of dependency relations. It is by virtue of being a subject clitic that nominative *si* is co-indexed with the subject position. Accusative *si*, on the other hand, is co-indexed with the subject not because it is a clitic, but rather because it is an anaphor. Since it notates two distinct types of dependency relations (a subject clitic chain and an A-chain, respectively), the co-indexation itself cannot be viewed as a common property of the two *si*s, which means that Manzini's unification attempt fails. According to Kayne (1986), the unifying property of all uses of SE is the fact that it absorbs the external role. As we will demonstrate in section 3 below, the notion of 'absorption' was used to refer to two irreconcilable operations:

(i) The external theta-role may be 'absorbed' but nevertheless projected in the canonical syntactic position of subjects. This kind of absorption characterizes nominative clitics (and agreement morphemes in pro-drop languages), in particular nominative SE, but crucially not passivizing morphemes.
(ii) The external theta-role may be 'suspended', i.e., not projected in the subject position; it remains present in argument-structure and may surface as an adjunct *by*-phrase. The suspension of the external role characterizes passivizing morphemes in general, and middle-passive SE in particular, but cannot be correct for nominative SE.

Note that a unified approach to accusative and nominative SEs would predict that these two types of SE necessarily co-occur cross-linguistically, but this prediction is incorrect. It is indeed clear that French does not have nominative SE. Moreover, Dobrovie-Sorin (1986, 1987, 1994b, 1998) has established that although it is a pro-drop language, Romanian lacks nominative SE.[21] Thus, the Romanian counterparts of the Italian examples in (35) are all ungrammatical:

(36) a. *Nu *se* este niciodată mulțumit. Romanian
not SE is never satisfied
'One is never satisfied.'
b. *Adesea *se* este trădat de prieteni falşi.
frequently SE is betrayed by false friends
'One is frequently betrayed by false friends.'
c. *În această universitate se predă ştiințele umane.
in this university SE teaches the humanities
d. *(Stiințele umane) le se predă în această universitate.
(the humanities) them SE teaches in this university

The contrast between Spanish and Romanian illustrated in (37–38) constitutes further evidence in favor of the lack of nominative SE in Romanian. Since Spanish SE may be nominative, it may co-occur with a prepositional accusative. Since Romanian SE is of necessity accusative, it blocks the occurrence of a prepositional accusative:

(37) En esta escuela se castiga a los alumnos. Spanish
in this school SE punishes *a* the students
'In this school they punish the students.'

(38) *În şcoala asta se pedepseşte pe elevi. Romanian
in this school SE punishes *PE* students
'In this school they punish the students.'

Given that all Romance languages have accusative SE, but only some of them have nominative SE, we may assume, in line with Belletti (1982), Burzio (1981, 1986), Zribi-Hertz (1982), Hyams (1986), Zubizarreta (1987), and Dobrovie-Sorin (1986, 1994b, 1998), that these two SEs are homophonous, but clearly distinct linguistic entities as different from each other as *man* 'one' and *sich* in German or *on* 'one' and *se* in French.

Although some empirical intricacies related to the distribution of SE in Italian infinitivals made Burzio (1982, 1986) wrongly believe that middle-passive SE is a particular type of nominative SE (see sections 3.4 and 4 below), Burzio proposed clearly different analyses for accusative and nominative SE, which can still be maintained modulo technical restatements due to the evolution of the GB model itself. Burzio's (1986) characterization of the distinction is stated in terms of the level at which SE is inserted: (the core cases of) accusative SEs are analyzed as

lexical affixes marking unaccusativity, which absorb/suspend the external theta-role at the level of the lexicon and are base-generated directly in their S-structure position (this is true for simple predicates; in complex predicates, e.g., causatives and restructuring environments, one must allow for clitic climbing). Nominative SE, on the other hand, behaves as a pronominal clitic: it is subject to clitic movement, and functions as an argument, being assigned a theta-role via a clitic chain.

The homonymical treatment of nominative and accusative SEs is confronted with some potential problems: auxiliary selection, relative order with respect to object clitics, and negation seem to treat the two SEs alike. Although these problems have not yet received a satisfactory solution, they do not seem to affect the view that nominative SE and accusative middle-passive SE should be treated as homonyms rather than as instantiations of the same element. This does not mean that the homonymy itself is completely accidental. It is, indeed, known that nominative SE developed via a diachronic reanalysis from accusative SE. According to Naro (1976), constructions of the type SE V NP, involving passive SE, came to be reanalyzed as an S-V-O sequence, with SE taken as a subject pronoun. This reanalysis took place in Italian, Spanish, and Portuguese, but not in French or Romanian. In sum, the existence vs. the absence of nominative SE is a parameter according to which Romance languages that have middle-passive SE vary: Italian, Spanish, and Portuguese have both nominative and accusative SE, whereas Romanian and French have only accusative SE. This variation is expected under the homonymical analysis of nominative and accusative SE, since the existence of particular pairs of homonyms is language-specific.

2.4 When SE combines with unergatives

Italian (and Spanish or Portuguese) constructions of the type *si dorme* 'SE sleeps', in which SE combines with unergatives, rely on nominative SE, but their Romanian counterparts cannot be assigned this analysis, because Romanian does not have nominative SE (see section 2.3 above):

(39) si canta/si dorme . . . /si mangia — Italian
SE sings/SE sleeps/ . . . SE eats
'one sings/one sleeps/ . . . one eats'

(40) *se* cîntă/*se* doarme/*se* munceşte/*se* mănîncă — Romanian
SE sings/SE sleeps/SE works/SE eats

According to Dobrovie-Sorin (1986, 1994b), examples such as (40) rely on a passivizing accusative SE, comparable to impersonal middle *sich* in German:[22]

(41) Es lebt sich angenehm hier. — German
it lives SICH in a pleasant way here
'Life is pleasant here.'

2.4.1 The passivization of unergatives

The passive phenomenon is currently described as involving the suspension of the external theta-role and of accusative Case; correlatively, the internal argument is NP-moved from the object to the subject position (see chapter 2). Because unergatives are currently viewed as being unable to subcategorize a direct object, Marantz (1984), Baker (1988a), and Sobin (1985), among many others, were led to modify and parameterize the analysis of passivization. The core property of passives was relaxed, merely requiring the suspension of the external role (the precise technical stipulation differs from one author to the other, and is of no interest here). This analysis of impersonal passives, described as the spontaneous demotion of the Agent by Perlmutter (1978), has become general across grammatical models. This kind of analysis stipulates two distinct rules of passivization: one for transitives and another one for unergatives. Moreover, no real understanding of the cross-linguistic variation shown by the passivization of unergatives was achieved: the impossibility of passivizing unergatives in certain languages is assumed to be due to the parameterization of either passive morphemes or unergatives, but no independent evidence can be adduced in favor of either one of these parameters.

Dobrovie-Sorin (1986, 1994b, 1998) proposed a different line of inquiry, based on the hypothesis that the passivization of unergatives relies on exactly the same rule as the passivization of transitives.[23] Under this view, the structure underlying the example in (42c), where *se* combines with an unergative, is exactly the same as that underlying (42a) and (42b), constructed with a transitive. This analysis relies on the hypothesis that unergatives may project a null cognate object:[24]

(42) a. S_i-au mîncat pro_i e_i ieri.
SE$_i$-HAVE-3RD PLUR eaten pro_i e_i yesterday
'They were eaten yesterday.'

b. S_i-a mîncat pro_i e_i bine ieri.
SE$_i$-HAS-3RD SING eaten pro_i e_i well here
it was eaten well yesterday
'We/they ate well yesterday.'

c. Se$_i$ doarme pro_i e_i bine aici.
SE$_i$ sleeps-3RD SING pro_i e_i well here
it is slept well here
'One sleeps well here.'

According to Dobrovie-Sorin's analysis, these examples rely on chains of the form *(pro, e)*, made up of a null subject (its exact position is not directly relevant here: one may assume either (Spec, VP) or (Spec, IP)) and of an empty category that occupies the direct object position; this chain is marked with the Theme role, assigned in the object position.[25] The only difference between (42a, b, and c) concerns the interpretation of this chain (referential, protoypical, and cognate objects respectively), which depends on the selectional properties of the verb.

This analysis of middle-passive unergatives seems to be facilitated by Hale and Keyser's (1993a) hypothesis that unergatives are universally transitive in their lexical relational structure; that is, they are to be represented as being derived by the incorporation of cognate objects into light verbs. Note, however, that this view on the lexical representation of unergatives does not oblige us, and perhaps does not even authorize us, to assume that the traces of the incorporated cognate objects are projected in the syntax. According to Dobrovie-Sorin (1986, 1994b, 1998), the presence of null cognate objects in the syntactic representation of passive unergatives is not induced by the lexical properties of unergatives (unergatives merely *allow* the presence of a direct object), but rather by the properties of *passive* configurations, and in particular by the properties of middle-passive SE. Note that this proposal does not entail that null prototypical and cognate objects are projected in the S-structure representation of *active* unergatives or intransitively used transitives.

2.4.2 Does SE combine with unaccusatives?

According to a well-known generalization, unaccusative verbs cannot passivize.[26] Given this generalization, we expect examples such as (43) to be ungrammatical in Italian:

(43) a. *Ritengo non essersi arrivati in sufficiente anticipo.
(I) believe not to HAVE-SE arrived sufficiently ahead of time
b. *Non essendosi morti in giovane età
not HAVING-SE died young
c. *Sembra essersi arrivati troppo tardi.
(it) seems to HAVE-SI arrived too late

These examples are ungrammatical because SE can be neither nominative (because nominative SE is ruled out in Italian non-finite clauses; see section 4 below) nor a passivizing accusative SE (because unaccusatives cannot passivize).

Quite surprisingly, however, the Romanian examples in (44) are grammatical:

(44) a. Ieri s-a ajuns la timp.
yesterday SE-has arrived in time
'Yesterday people arrived on time.'
b. La noi, se moare des din cauza cancerului şi a bolilor cardiace.
here/in our country SE dies frequently because of cancer and of cardiac diseases
'Here/in our country people die frequently from cancer and from cardiac diseases.'
c. Nu se moare din atîta.
not SE dies of that much
'One does not die from so little.'
d. In sală se amuțeste la apariția examinatorului.
in the classroom SE goes quiet when the examiner appears
'Everyone goes quiet when the examiner shows up in the classroom.'

e. Se întîrzie zilnic.
SE arrives late every day
'People arrive/are late every day.'
f. După medicamentele astea, sigur se va învia!
after (having taken) medicines-the these, for sure SE will resurrect
'People will surely be restored to life after having taken these drugs.'
g. La temperatura de –20 grade, se degeră.
at the temperature of –20 degrees, SE freezes

Given this type of data, one might be led to conclude, contra Dobrovie-Sorin, that Romanian does have a nominative SE. The solution suggested by Dobrovie-Sorin (1987, 1994b) herself is that in Romanian, the distinction between unergatives and unaccusatives is not grammatically encoded. Indeed, most of the current tests of unaccusativity cannot be used in Romanian: this language does not use *be* as a perfect auxiliary (all verbs are built with *have*), and it has no counterpart of the French clitic *en* (Italian *ne*).

One may, however, wonder whether there is any limitation on the use of passive SE with verbs that are semantically close to unaccusatives. And indeed, there exist at least two types of impossibilities (Pană-Dindelegan, p.c.). On the one hand, passive SE cannot apply to inherent reflexives. Thus, verbs such as *a se aglomera*, *a se atrofia*, *a se bifurca*, *a se bronza*, *a se caria*, *a se cicatriza*, *a se înnora*, *a se învechi*, *a se îneca* 'to get crowded, to atrophy, to bifurcate, to get tanned, to get a cavity, to scar, to get cloudy, to get old, to drown' cannot be used with an impersonal passive SE. Given that inherent reflexives are unaccusatives, they behave exactly as predicted by the hypothesis that unaccusatives cannot passivize.

The second limitation concerns the type of subject selected by the verb: a one-argument verb can be used with an impersonal passive SE only if it is construed as involving a human argument. Thus, examples such as *Vasul acostează* 'The ship is coming ashore', *Mi- a amorțit piciorul* 'My leg went numb', *Soarele apune* 'The sun is going down', *Luna asfințește* 'The moon is going down', *Pomii au înfrunzit/ înmugurit/înflorit* 'The trees grew leaves/budded/flowered', *Veniturile cresc/ descresc* 'The income increases/decreases' cannot give rise to impersonal forms. Some of these verbs may combine with impersonal SE, as shown in (45). But crucially, the implicit suspended argument can only be interpreted as human:

(45) a. După vîrsta de 60 de ani, se apune încet-încet!
after the age of 60, SE goes down slowly-slowly
'People slowly fade after reaching the age of 60!'
b. S-a acostat departe de aici.
SE-has come ashore far from here
'The landing was far from here.'
c. S-a amorțit.
SE-has come numb
'People got numb.'

d. Se creşte fără griji.
SE grows up without worries
'One grows up carefree.'

Although the constraint regarding the human feature of the implicit suspended argument of SE-passives is not well understood (see Mendikoetxea 1999), its existence supports the hypothesis that SE-passivization cannot apply to genuine unaccusatives: the human feature of the external argument makes it easier for a given verb to be construed as unergative, thus allowing for passivization.

2.4.3 Cross-linguistic variation: the passivization of unergatives and impersonal constructions

French clearly differs from Romanian in not allowing passive SE to combine with unergatives:[27]

(46) a. *Il se procédera à une enquête. French
IL SE will proceed to an inquiry
'An inquiry will be started.'
b. *Il s'aboutira à un compromis acceptable.
IL SE will arrive at/reach an acceptable compromise
'An acceptable compromise will be reached.'
c. *Il s'est tiré sur les manifestants.
IL SE-HAS shot at the demonstrators
'The demonstrators were shot at.'
d. *Il se lui a été demandé/suggéré de partir.
IL him/her$_{Dat}$ SE-has asked/ordered/suggested to leave
'He/she was asked/ordered/suggested to leave.'

Cinque (1988) explains the ungrammaticality of (46) by parameterizing the types of SE, and by assuming that the SE that is allowed to combine with unergatives (analyzed as an impersonal passivizing +arg nominative SE by Cinque) does not exist in French. This kind of account is not available for Dobrovie-Sorin (1998), who argues against the existence of a nominative +arg SE (see section 4.1 below) and assumes that unergatives may combine with an accusative middle-passive SE. Since such an element exists in French, we would expect examples such as (46) to be grammatical.

One may choose to parameterize unergatives, as proposed by Jaeggli (1986):

(47) In certain languages (see German), but not in others (see French), unergatives assign structural Case.

The first problem with (47) is that it parameterizes a property that is currently assumed to be universal, namely the possibility for unergatives to assign structural Case.

Note furthermore that the parameter in (47) cannot account for a very clear empirical generalization: languages that (do not) admit *se* V_{unerg} also (do not) admit *se* V_{trans} with a null prototypical object. Thus, the contrast between the Romanian examples in (42) and the French examples in (46) is parallelled by the contrast in (48a–b), where the verb is transitive in both languages:

(48) a. Se_i mănîncă pro_i e_i prea mult aici. Romanian
SE$_i$ eats pro$_i$ e$_i$ too much here
'One eats too much here.'
b. *Il_i se_j mange e_j trop ici. French
it$_i$ SE$_j$ eats e$_j$ too much here

Another problem raised by the parameterization of unergatives is that it cannot account for the fact that in one and the same language, French for example, unergatives may be used with copula passives, although they cannot be used with middle-passive *se*. Note indeed that the examples in (46) become grammatical if instead of the middle-passive *se* we use the copula passive:

(49) a. Il sera procédé à une enquête.
IL will be proceeded to an inquiry
'An inquiry will be undertaken.'
b. Il sera abouti à un compromis acceptable.
IL will be arrived at a compromise acceptable
'An acceptable compromise will be reached.'
c. Il a été tiré sur les manifestants.
IL has been shot at the demonstrators
'The demonstrators were shot at.'
d. Il lui a été demandé/ordonné/suggéré de partir.
IL him$_{Dat}$ has been asked/ordered/suggested to leave
'He was asked/ordered/suggested to leave.'[28]

If we tried to analyze the ungrammaticality of (46) as being due to some property of French unergatives, we would incorrectly expect the examples in (49) to be equally ungrammatical.

We are led to conclude that the cross-linguistic variation regarding the possibility or the impossibility of passivizing unergatives cannot be due to parameters bearing on either passivizing morphemes or unergatives. A possible line of investigation is to relate the possibility of passivizing unergatives to the syntactic properties of *il*-impersonals, by taking into account the constraints that bear on copula passives and on SE passives, respectively. Thus, SE is legitimate only if a binding relation can be established, but this requirement cannot be satisfied in (48b): the trace of SE and the expletive subject are contra-indexed; if these two elements are co-indexed, *il* no longer counts as an expletive, but rather as a referential pronoun, which conflicts with the selectional properties of unergatives: they select cognate objects. In sum, a violation of Principle A arises in French

il-impersonals whenever SE combines with unergatives. Romanian impersonals, on the other hand, rely on free subject inversion, the syntactic properties of which make it possible for Principle A to be satisfied: in (48a), the trace of SE is A-bound by the null subject *pro*. Turning finally to the French examples in (49), constructed with a copula passive, they do not contain any lexical anaphor, and consequently Principle A is irrelevant.

3 SE-verbs and the representation of Agentivity

3.1 Suspension of the external theta-role: suppression or absorption?

Descriptively speaking, passive configurations can be characterized as follows: the internal argument of the corresponding active verb surfaces as a subject (it is either realized in the canonical subject position or else is part of an expletive–argument chain), and this necessarily correlates with the fact that the Agent role is not realized in the subject position. In somewhat more theoretical terms, passive 'morphemes' (cf. the *-en* suffix or passive SE) can be assumed to suspend the Agent role and correlatively block the assignment of accusative Case. For this generalization, as well as for many other issues brought up below (the realization of external arguments, the relations between lexicon and syntax), see chapter 2.

One way of understanding the suspension of the external theta-role is to identify it with its suppression. It is indeed clear that in the case of inchoatives, middles, or adjectival passives, the Agent role manifests no 'syntactic activity' (see section 3.2 below), although middles (unlike inchoatives and adjectival passives) arguably involve some kind of implicit agentivity.

Verbal passives in general, and passive SE configurations in particular, differ from inchoatives, adjectival passives, and middles in exhibiting agentivity: tests such as Agent-oriented adverbs or control into purpose clauses have been recurrently invoked in favor of the hypothesis that in passive configurations, the Agent is not suppressed but, quite on the contrary, syntactically realized (see chapter 34).

What is, then, the syntactic position occupied by the Agent in passives? By the very definition of passives given above, a 'suspended' Agent is *not* projected onto the subject position. One possibility is to assume that the Agent of passives is realized as an overt or covert *by*-phrase (Chomsky 1965; Wasow 1977; Jaeggli 1986; Åfarli 1989; Schoorlemmer 1995). Other authors believe that implicit Agents are realized as pro or PRO (see chapter 34). Still other theorists propose that it is the passive morpheme itself that constitutes the syntactic realization of the Agent role (this assumption was made for passive SE by Belletti 1982 and for the past participle morpheme *-en* by Baker et al. 1989).

In what follows, we will first review the empirical evidence adduced in favor of the hypothesis that passive SE absorbs the external role (section 3.2). The various implementations of this widely assumed hypothesis[29] will then be discussed and rejected (sections 3.3–3.6). The concluding remarks (section 3.7) will establish an

essentially negative result: in passive configurations, the Agent is not projected onto a subject(-like) position; nor can passive SE itself be assumed to function as an external argument; tests such as control into adjunct clauses or Agent-oriented adverbs do not prove the existence of a syntactically realized Agent (Williams 1985).

3.2 Control

Belletti (1982) proposed that the external theta-role is *absorbed* rather than merely *suspended* by passive SE. Belletti believed that this hypothesis could explain why, in contradistinction to analytic passives (*be* + past participle), passive SE is incompatible with a *by*-phrase (e.g., *Ce poème s'est lu hier pendant la fête (*par Marie)* 'This poem SE HAS read yesterday during the party (*by Mary)'): because the Agent theta-role is realized as SE, it cannot surface as a *by*-phrase. Belletti's hypothesis was extended to analytic passives by Baker et al. (1989), who assume that the Agent role is absorbed by the passive morpheme *-en*. Under this view, the different distribution of *by*-phrases in passive SE configurations as opposed to analytic passives can no longer be explained.

Belletti (1982) assumed Agent-absorption by SE not only for passive but also for middle SE, which also implies some kind of agentivity (in clear contrast with, e.g., inchoative SE). This unifying hypothesis conflicts with a clear split between the two constructions: certain types of adjunct clauses can be controlled by the implicit Agent of (analytic or SE-marked) passives, but not by that of middles (the latter are identifiable by the property reading):

(50) a. Les livres ont été vendus pour aider les pauvres. French
'The books were sold in order to help the poor.'
b. *Les livres se vendent facilement pour aider les pauvres.[30]
'The books [SE] sell easily in order to help the poor.'

(51) a. Questi appartamenti si vendono volutamente occupati. Italian
these apartments SI sell deliberately occupied
'These apartments are deliberately sold occupied.'
b. Quell'uomo politico si può corrompere (facilmente) per dimostrare la propria influenza.
that politician SI can bribe (easily) to show one's influence
'That politician can be bribed (easily) in order to show one's influence.'
c. Il museo del campo si può visitare facilmente anche nudi.
the camping museum SI can visit even naked
'The camping museum can be visited even naked.'

(52) a. Questi appartamenti hanno il vantaggio di vendersi (*volutamente) occupati.
these apartments have the advantage of to sell-SI (*deliberately) occupied
'These apartments have the advantage of being sold (*deliberately) occupied.'

b. Quell'uomo politico ha il vantaggio di potersi corrompere facilmente (*per dimostrare la propria influenza).
that politician has the advantage of to bribe-SI easily (*to show one's influence)
c. Il museo del campo ha il vantaggio di potersi visitare facilmente (*anche nudi).
the camping museum has the advantage of to be allowed-SI to visit easily (*even naked)

The possibility of control is currently invoked in favor of the hypothesis that the Agent of passives is projected in the syntax. The passive morpheme *-en*, as well as passivizing SE (in contrast with middle SE), would instantiate syntactically projected Agents (see Jaeggli 1986; Baker et al. 1989; Hoekstra and Roberts 1993b for *-en*; and Belletti 1982a and Cinque 1988 for SE). This view has been convincingly criticized by Fellbaum and Zribi-Hertz (1989), who argued that phenomena such as control into final clauses or the possibility of Agent-oriented adverbs do not depend on the syntactic realization of the external argument, but instead should be analyzed as being sensitive to the presence of semantically implicit Agents.[31]

Important evidence against the projection of Agents in passive configurations comes from control verbs. The Spanish examples in (53) are grammatical (and so are their analogs in (85a–b)), because in Spanish and Italian, SE can be a nominative clitic which, like any other subject clitic, qualifies as a legitimate *syntactic* controller:

(53) a. En ciertos estudios basados en fenomenos linguisticos, se ha intentado reformar la historia politica y social.
in certain essays based on linguistic phenomena, SE has tried to reconstruct the political and social history
b. Se espera llegar al final del camino.
SE hopes to arrive at the end of the road

The ungrammaticality of the Romanian examples in (54) can be explained if we assume that (i) passive SE is not a legitimate syntactic controller and (ii) Romanian does not have nominative SE (see section 2.3 above):[32]

(54) a. *In unele studii s-a încercat a reface, pe baza unor fenomene lingvistice, istoria politică şi socială.
in certain essays based on linguistic phenomena, SE-has tried to reconstruct the political and social history
b. *Se speră a ajunge la capătul drumului.
SE hopes to arrive at the end of the road.
c. *S-a început a ține seama de nevoile tuturor.
SE-has started to take into account everybody's needs
d. *S-a promis a respecta dispozițiile
SE-has promised to obey the instructions

The different guises of agentivity described above can be summarized as follows:

(55) Verbal passives and middles (unlike adjectival passives and inchoatives) are semantically agentive (semantically imply an Agent-role).
   a. Verbal passives (be they analytic or marked by SE), have a *syntactically active implicit agent* (control into purpose adjunct clauses, subject-oriented adverbs).
   b. Middles (exhibiting the property reading) have a *syntactically inactive implicit agent* (their implicit Agent-role shows no syntactic activity).

(56) Neither analytic nor SE-marked passives can combine with control verbs (*try, start*, etc.), nor do they license a reflexive pronoun, in contradistinction to nominative SE.

Although Cinque (1988) advocates a unifying analysis of SE, his proposal is in fact based on postulating two homonymical morphemes, marked with distinct Cases: nominative [+arg] SE, which absorbs the external theta-role, and accusative [–arg] SE, which merely suspends it, respectively corresponding to passive and middle SE. This distinction would explain the contrast described in (55a) vs. (55b) and illustrated in (50a) vs (50b) and (51) vs. (52). The hypothesis that passive SE is a nominative clitic functioning as an argument cannot, however, account for the generalization in (56).[33] A more detailed discussion of Cinque's proposal can be found in section 4 below.

3.3 *Passive SE absorbs the external theta-role in the lexicon*

According to some authors, the absorption of the external theta-role by SE takes place in the lexicon, in which case middle-passive SE, although functioning as an Agent, bears no syntactic relation to the subject position. This type of lexical rule is, however, highly problematic. Standard lexical rules affect argument structure, by suppressing or adding a theta-role (cf. passivization and causativization, respectively), but cannot directly assign a given theta-role to a designated lexical item.[34] Theta-roles can be assigned to lexical items only indirectly: a given lexical item is assigned a grammatical function (due to the syntactic position it occupies or to the morphological or abstract Case that it is assigned), and linking rules (lexicon–syntax mapping rules) ensure the relation between grammatical functions (or syntactic positions) and theta-roles.

3.4 *Middle-passive SE absorbs the external theta-role in the syntax, via a chain with the Spec, IP position*

Let us now examine those analyses that rely on the hypothesis that passive SE is a particular type of subject clitic, which takes its external role in the syntax, via

a chain with a subject-related position (which, depending on the author, can be Spec, IP; Spec, VP; Spec, vP; or Spec, AgrP), onto which the external role is projected. The numerous implementations of this view vary depending on the Case-features attributed to SE (accusative, nominative, or even dative), the empirical motivation, and the types of accusative SE for which the absorption hypothesis is postulated (most authors assume this analysis for passive SE; certain authors extend it to middle SE).

According to Burzio (1981), middle-passive SE is a particular type of nominative-subject SE, which forms a chain with the (Spec, IP) position. This analysis is confronted with a number of problems, among which is Case-assignment: if SE itself absorbs nominative Case, there is no Case left for the overt DP, corresponding to the externalized internal argument. In order to allow nominative Case on both *si* and the preverbal DP, Burzio (1986: 47) allows for overlapping chains (see also Cinque 1988), an undesirable assumption. In (57), the chain (*gli spaghetti*, *si*), needed for the transfer of nominative Case to *si*, overlaps with the chain (*gli spaghetti*, *t*), needed for theta-role transmission. Precisely because the two chains intersect in the (Spec, IP) position, nominative Case would be assigned to both chains:[35]

(57) Gli spaghetti$_i$ si$_i$ sono già comprati t$_i$.
the spaghettis SI HAVE already bought
'The spaghettis have already been bought.'

Quite clearly, the assumptions needed in order to allow both SE and the overt DP to take nominative Case (and correlatively be in a CHAIN with Spec, IP) do not belong to core GB theory, but are in fact distortions of GB theory that are merely meant to provide a technical solution for the problems raised by the Burzio–Cinque analysis.

A further, interrelated problem is that the trigger of NP-movement is lost: an affix marked with nominative Case does not absorb accusative Case, which therefore is available for the internal argument, thus voiding the need for NP-movement. Since Cinque wants to preserve the hypothesis that passivization correlates with NP-movement, he provides the following solution (1988: 558–559): the suspension of accusative Case is triggered, due to Burzio's generalization, by the fact that nominative SE suspends/withholds the external theta-role.[36]

Another problem is that French (as well as Romanian) lacks nominative SE, and yet has passive and middle SE. This is unexpected within Burzio's assumption, according to which middle and passive SEs are particular instantiations of nominative SE.[37] Burzio (1986: 145–148) concludes his short discussion of French middle-passive SE by acknowledging that it does not show the standard properties of nominative SE; it would be a "particular, unique" manifestation of nominative SE. But then, precisely because Italian and French middle-passives behave on a par, Burzio is led to conclude that Italian has two distinct types of nominative SE: the canonical one, which qualifies as a well-behaved nominative clitic, and is absent in French, and a peculiar one, corresponding to middle-passive SE (in both French and Italian).

Burzio's problematic analysis was adopted, under Cinque's (1988) revision,[38] by the vast majority of GB theorists. Dobrovie-Sorin (1994b, 1998) argued instead that middle and passive SEs are particular instantiations of accusative SE (see section 4 below for alternative analyses of the data brought up by Burzio and Cinque). Here, we will briefly sketch an alternative account of the piece of data illustrated in (58), corresponding to Burzio's (1986: 47, example (69)):

(58) [quei libri]$_i$ si andranno . . . a comprare t$_i$

According to Burzio, examples of this kind rely on both object-preposing of *quei libri* and NP-movement (more precisely, subject raising) of *si*. Since the NP-movement of *si* can only apply to the subject clitic *si*, in contrast to accusative *si*, Burzio concludes that the *si* in (58) is a subject *si*. There is, however, no evidence in favor of the fact that in this example, *si* has undergone NP-movement. We may alternatively analyze this displacement as being due to Restructuring (Rizzi 1982a), a configuration in which the object clitics generated on the embedded verb end up cliticized on the main verb:[39]

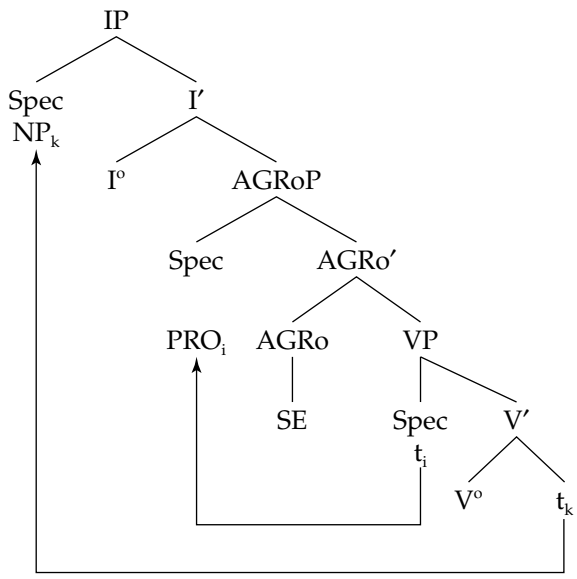
(59) Giovanni lo$_i$ va/viene a prendere t$_i$.

In sum, the position of *si* in (58) is to be accounted for in the same way as the position of *lo* in (59), which is consistent with *si* being accusative rather than nominative.

3.5 Middle-passive SE forms a chain with an A-position other than Spec, IP

The proliferation of syntactic positions that characterized late versions of GB theory made it technically possible for the external role of middle-passive verbs to be syntactically projected in positions other than Spec, IP. In their analysis of Dutch middles (which are not marked by a reflexive clitic) Hoekstra and Roberts (1993) propose that the external role is absorbed by a null subject of type pro that occupies (Spec, VP), the VP-internal subject position (see Sportiche 1988 and many others). The advantage of this proposal, which was adapted to Romance middle-passive SE in the subsequent GB and Minimalist literature, would be that the (Spec, IP) position remains available for the Theme to raise to. Note, however, that we must assume that an agentive pro in (Spec, VP) can be bypassed by the Theme-DP on its way to (Spec, IP). This is a locality problem that arises for all versions of this analysis, which essentially postulate that passive SE configurations consist of two chains: the chain of the internal argument, obtained by NP-movement from the object position to (Spec, IP), would co-exist with the chain of the external argument. The exact shape of this second chain differs from one author to the other, varying with the technical changes of the model itself. According to Postma (1995), SE heads the projection of AGRo,[40] and PRO sits in the Spec of this same projection and binds a trace in (Spec,VP):

(60)



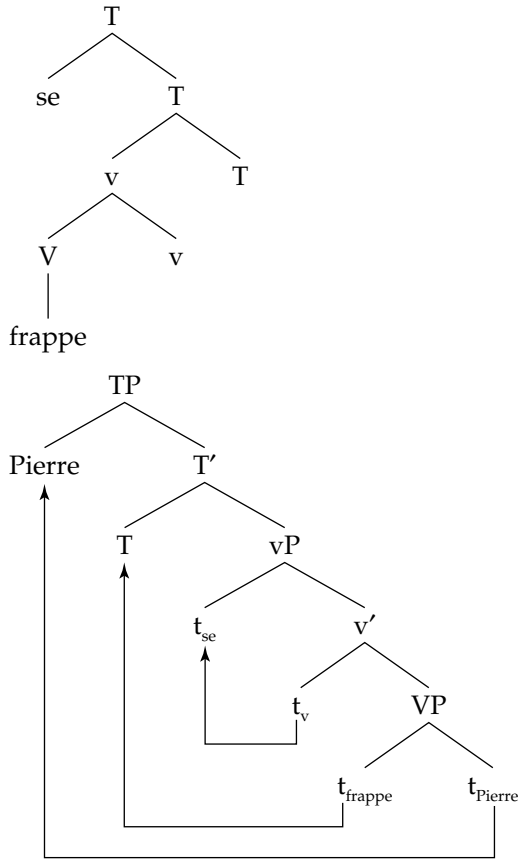
Postma assumes that this configuration underlies all uses of accusative SE, and he derives the different possible readings from differences in agreement relations: if agreement takes place in IP, we get the reflexive reading; if no agreement takes place, we get the passive reading. The reader is referred to the technical details of this quite complex analysis. Let us simply observe that any analysis that assumes that passives rely on two distinct theta-chains is confronted with the locality problem. Various technical solutions have been proposed, which remain unconvincing.

Minimalist implementations of the same basic analysis are led to stipulate that, unlike overt external arguments (see (61b)), null pronouns corresponding to the external argument (see (61a)) do not block the movement of the internal argument to the subject position (McGinnis 1998):[41]

(61) a. A good guide *pro* was recommended *t* by Susanna.
b. *A good guide *Susanna* was recommended *t*.

Similarly, the movement of the internal argument would not be blocked by the trace of se in se-passives and se-reflexives (for which McGinnis adopts an unaccusative/passive analysis). The configuration postulated by McGinnis is essentially the same as Potsma's, with AGRoP having been replaced by a light verb projection, notated vP (Chomsky 1995c: chapter 4). The replacement of AGRoP with vP triggers another technical difference: SE can no longer be assumed to head the projection, but may instead be assumed to be generated in the (Spec, vP) position, which in this model is the canonical position for external arguments:

(62) Pierre se frappe.
'Pierre slaps himself in the face.'



SE cliticizes to T° as soon as this node is filled by the raised verb, and once SE has cliticized, the object is free to raise to Spec, IP. The fact that null pronouns (see (61a)) and clitic traces allow NP-movement to bypass them, in sharp contrast with overt DPs, is explained on the basis of the assumption that once an NP has cliticized to T, it is no longer accessible for movement to Spec-TP, so this NP and its trace don't count as interveners for Shortest Move.

A still different version of the hypothesis that the external theta-role is syntactically projected in middle-passive configurations can be found in Cardinaletti's (1990) analysis of German middles. According to Cardinaletti, the *es* that shows up in *hier lebt sich es angenehm* absorbs the external theta-role. Note that unlike Italian *si*, German *sich* is uncontroversially an accusative clitic. Cardinaletti's analysis of German thus winds up postulating that an accusative middle-passivizing morpheme such as *sich* (i) does not absorb the external theta-role but (ii) does not suspend it either (since this theta-role would be linked to *es*).

3.6 SE absorbs the external theta-role and dative Case

The locality problem discussed above is avoided by a technical implementation due to Guéron (1991), who builds on Kayne's (1988) suggestion that in all its uses, including reflexive SE and subject/nominative SE: (i) SE absorbs the external role; (ii) SE absorbs dative Case; (iii) SE binds/identifies an empty category in a VP-adjoined position.[42] Although this is not explicitly stated, the Kayne–Guéron analysis is meant to solve what was taken to be a severe problem for the analysis of middle-passive SE (and for that of reflexive SE, if the latter is analyzed as unaccusative): if the empty category in object position is the trace of SE, it cannot also be the trace left behind by the A-movement of the internal argument. Note, however, that this problem only arises if one assumes the pronominal analysis of SE, according to which SE necessarily binds a SE-trace in the object position. If instead we adopt Burzio's hypothesis that accusative SE, including middle-passive SE, is a morphological marker, which as such binds no trace, the object position may host the NP-trace of the object raised to the subject position.

The Kayne–Guéron proposal is confronted with several problems. To make the discussion concrete, consider examples such as (63):

(63) Les pommes se mangent en automne.
the apples SE eat in autumn
'One eats apples in autumn.'

Since by assumption SE is dative, it is unclear how it can absorb the external role, because this role is not linked to a VP-adjoined position, or to any kind of dative-related position. The answer could be that the external role is of the Experiencer-type. This is indeed compatible with dative-marking, but crucially not with the suspended external role of passives, which is agentive. Guéron suggests that this peculiarity is due to quirky Case, but no empirical evidence supporting this proposal is provided. It is furthermore unclear why a dative-marked reflexive should trigger the absorption of accusative case, which is a defining characteristic of passives.[43]

3.7 Conclusions

Although standard GB theory (Chomsky 1981) was designed to block it, most GB analyses of passivization postulated the projection of the external role in subject-related positions by modifying those principles of GB that were meant to prevent it. But each of the particular implementations of this hypothesis is confronted with its own problems: passive SE cannot be analyzed as either a nominative clitic or a (possibly accusative) clitic associated with (Spec, IP); nor can we assume passive SE to be a pro occupying (Spec, VP) or the Spec position of some other functional projection.

This negative result calls for alternative analyses of the empirical evidence adduced in favor of the syntactic projection of the Agent in middle-passive SE constructions: (i) the intricate distribution of middle-passive SE in Italian non-finite clauses; (ii) the correlation between the (preverbal vs. postverbal) position of the subject DP and the meaning (generic/middle/stative vs. eventive passive) of SE-verbs (Ruwet 1972; Raposo and Uriagereka 1996). These two sets of data will be examined in sections 4 and 5 below.

4. The distribution of SE in non-finite Italian clauses

Because passivizing SE is illegitimate in control configurations, Burzio (1981, 1986) and all the subsequent literature assumed that passivizing SE needs nominative Case, an assumption that creates theoretical and empirical problems (see sections 4.1.3 and 4.1.4). Dobrovie-Sorin (1998) has provided new solutions to the peculiar distribution of passivizing SE in control infinitivals, based on the view that (i) passivizing SE carries accusative Case and (ii) nominative SE is banned from non-finite clauses (see section 4.2.1). The ungrammaticality of passive SE in control configurations is traced back to three distinct constraints (see section 4.2.2). Finally, it is argued that in Italian non-finite clauses, the SE that appears with unergatives is a passivizing accusative SE (see section 2.4 above).

4.1 Cinque's (1988) analysis: two types of nominative SE in Italian

4.1.1 SE with unergatives vs. SE with adjectives, analytic passives, or psych verbs

The contrast between (64) and (65) shows that the class of (presumably) nominative SEs splits in Italian infinitivals: the examples in (64), in which nominative SE combines with unaccusatives, analytic passives, and adjectival predicates, are ungrammatical, whereas the examples in (65), built with unergatives, are grammatical. The examples in this section are borrowed from Cinque (1988), but some of the glosses and the clustering of examples may be different:

(64) a. *Ritengo non essersi arrivati in sufficiente anticipo. (SE + unaccusatives in Aux-to-Comp)
(I) believe not (to) HAVE-SI arrived sufficiently ahead of time
b. *non essendosi morti in giovane età. (SE + unaccusatives in Aux-to-Comp) not HAVING-SI died young
c. *Sembra essersi arrivati troppo tardi. (SE + unaccusatives in raising configurations) it seems (to) HAVE-SI arrived too late

e. *Sembra non essersi benvenuti qui. (SE + copula in raising configurations)
it seems not (to) BE-SI welcome here
f. *Sembra non essersi stati invitati da nessuno. (SE + passive in raising configurations) it seems not HAVE-SI been invited by anybody

(65) a. Ritengo non essersi provveduto alle sue necessità con la dovuta solerzia.
(I) believe not (to) HAVE-SI taken care of his needs with due zeal.
'(I) believe his needs have not been taken care of with due zeal.'
b. non essendosi provveduto alle sue necessità con la dovuta solerzia
not HAVING-SI taken care of his needs with due zeal
'his needs not having been taken care of with due zeal'
c. Sembra non essersi lavorato a sufficienza.
(it) seems not HAVE-SI worked sufficiently
'It seems that there was not enough work.'

Given this contrast, we may conclude that the SEs that show up in the two classes of examples are of different types. This solution is compatible with several options: we may believe that (i) the two SEs are nominative and accusative, respectively, or (ii) the two SEs are both nominative, but nevertheless distinct. Building on a suggestion by Burzio (1981, 1986), Cinque argues in favor of the second hypothesis, which seems to be supported by the fact that in (65), SE combines with unergatives, a context that was believed to be compatible with nominative SE, but not with accusative SE. This hypothesis seems to be further supported by the contrast between examples such as (65), illustrating Aux-to-Comp and subject-raising configurations, which are known to be compatible with nominative Case assignment, and examples of the type in (66), illustrating configurations relying on arbitrary PRO, in which nominative Case cannot be assigned:

(66) *Sarebbe meglio lavorarsi un po' di più.
(it) would be better (to) work SI a bit more
'It would be better to be worked a bit more.'

According to Burzio (1986) and Cinque (1988), the contrast between (65) and (66) can be explained by assuming that the SE that combines with unergatives needs nominative Case: the examples in (65) are grammatical because SE can get nominative Case (Aux-to-Comp configurations allow nominative Case assignment in Italian infinitivals), whereas the example in (66) is ungrammatical because nominative Case is unavailable in controlled clauses.

4.1.2 A passivizing nominative SE

The contrast between (65) and (66) is parallelled by the contrast between (67) and (68), which shows that passive SE is allowed in Aux-to-Comp and subject-raising contexts, but disallowed in control configurations:

(67) a. Ritengo non essersi ancora scoperto il vero colpevole. **(Aux-to-Comp)**
[I] believe not to HAVE-SI yet discovered the true culprit
'I believe the true culprit has not yet been discovered.'
b. non essendosi ancora scoperto il vero colpevole **(Aux-to-Comp)**
not HAVING-SI yet discovered the true culprit
'the true culprit not having yet been discovered'
c. Sembra non essersi ancora scoperto il vero colpevole. **(Subject raising)**
(it) seems not (to) HAVE-SI yet discovered the true culprit
'It seems that the true culprit has not yet been discovered.'

(68) **Control configurations:**
a. *Sarebbe meglio scoprirsi il colpevole.
(it) would be better (to) discover SI the culprit
'It would be better for the culprit to be discovered.'
b. *Quei prigionieri$_i$ vorrebero [PRO$_i$ essersi già liberati e$_i$].
those prisoners would want have SI already released
'Those prisoners would want to have been already released.'

Although passive SE is compatible with an analysis in terms of accusative SE, the contrast between (67) – where nominative case can be assigned – and (68) – where nominative Case cannot be assigned – was interpreted by Burzio (1986) and Cinque (1988) as indicating that passive SE needs nominative Case, on a par with the SE that combines with unergatives (see again examples (65) vs. (66)).

Let us now be more specific about the details of Cinque's analysis: (i) two distinct nominative SEs are postulated, which are distinguished by different choices for the feature ±arg(ument); (ii) the SE that combines with unergatives (see (65)) may be either +arg or –arg, whereas the SE that combines with the copula, passives, unaccusatives, etc. (see (64)) can only be marked as –arg; (iii) –arg SE is disallowed in those configurations in which no overt AGR morpheme is present (hence the ungrammaticality of (64)).

(69) **Cinque's (1988) typology:**
a. –arg [nom] impersonal SE (SE + copula, SE + unaccusatives, SE + passives, SE + unergatives)
b. +arg [nom] passivizing SE (SE + transitives, SE + unergatives)
c. –arg [acc] 'pure' passivizing SE (Middle SE)

4.1.3 Theoretical problems with the ±arg(ument) distinction

As presented by Cinque himself, the ±arg distinction is an attempt to solve a theoretical problem, which had been previously noted by Burzio (1986: 45f.), Belletti (1982a: fns. 21, 37, Appendix), and Manzini (1986), concerning examples such as (70):

(70) Si parte.
'One leaves.'

The verb *partire* 'to leave' belongs to the unaccusative class, and as such assigns a theta-role to the [NP, V'] position, and leaves [Spec, IP] with no theta-role. On the assumption that *si* is an argument subject clitic base-generated in Infl (or in some Infl-related clitic position) that can take its theta-role only from the Spec, IP position, examples such as (70) violate the Theta-Criterion at D-structure. Cinque solves this problem by assuming that the *si* that appears in (71) is not an argument (hence the feature [–arg] that would characterize it). Compare an example such as (71):

(71) Si dorme.
'One sleeps.'

Since *dormire* 'to sleep' assigns a theta-role to the Spec, IP position at D-structure, it may combine with a +arg *si*. But note that under Cinque's analysis, *dormire* may also combine with a –arg *si*, on a par with *partire*. In other words, *si dorme* is systematically ambiguous in Italian, depending on the nature of *si*, whereas *si parte* unambiguously relies on a –arg nominative *si*.

Dobrovie-Sorin (1998) observes that the theoretical problem invoked by Burzio, Belletti, Manzini, and Cinque in connection with *si* in fact extends to subject clitics in general. Should we then assume a systematic ambiguity for subject clitics in general (cf. in particular the subject clitics of Italian dialects), on a par with the ambiguity that Cinque assumes for *si*? More concretely, should we assume that subject clitics may be either +arg or –arg when they combine with transitives or unergatives, but only –arg when they combine with unaccusatives?[44] Cinque does not go in this direction, and his implicit answer to the problem of subject clitics is that they should be assumed to be –arg elements, regardless of the type of verb with which they combine. It is important to stress that Cinque's –arg feature should not be interpreted as notating expletive clitics, as opposed to referential clitics, but rather as saying that nominative clitics (and clitics in general) fall outside the argument/non-argument distinction, which is relevant only for elements that occupy A-positions.

We are thus led to conclude that the [–arg] feature need not be stipulated: it is the unmarked option for clitics in general; [+arg] nominative SE, on the other hand, is an element that does not fall under the general characterization of clitics. Cinque assumes [+arg] *si* to be related to an A-position that is assigned a theta-role at D-structure, but is filled with an expletive at S-structure. Such a discrepancy between the clitic and its trace, which is unprecedented for clitics, brings to mind the current characterization of passive morphemes in general and middle-passive *si* in particular: *si* absorbs (or rather suspends) the external theta-role, and as a consequence the subject position is occupied by an expletive. In sum, the [+arg] feature of *si*, which is found with no other clitic, can be viewed as a label for passive *si*. Since passive morphemes cannot be marked with nominative Case, we are led to conclude that Cinque's +arg nominative SE is in reality a passivizing SE that absorbs accusative Case. The only genuine nominative SE is Cinque's –arg nominative SE. We thus end up with only two basic distinct types of SE, accusative and nominative.[45]

4.1.4 *Empirical problems*

Cinque's proposal is also confronted by several empirical problems:

(72) a. The hypothesis that [+arg] nominative SE is a passivizer[46] is problematic, since the occurrence of a nominative clitic marked with the external theta-role is incompatible with the passivization phenomenon. To make them compatible, one would have to allow for the double assignment of nominative Case or for overlapping CHAINS, which are undesirable on general grounds (see section 3.4. above).
b. Passive SE-verbs agree with the overt DP, on a par with reflexives and other types of accusative SE-verbs. Compare –arg [nom] SE, which triggers *lack* of agreement between the verb and the overt DP.
c. Passive SE cannot co-occur with an accusative-marked argument. This is expected if SE itself is [acc], but not if it is [nom].

In what follows, these problems will be illustrated with examples borrowed from Cinque (1988) himself. Crucial for the analysis of the data is the contrast between SE-verbs in Italian finite and non-finite clauses: whereas a truly nominative SE can appear in Italian finite clauses (see section 2.3 above), it is ungrammatical in Italian non-finite clauses. The contrast between Italian finite and non-finite clauses is parallelled by the contrast between Italian and Romanian finite SE-verbs. This is predicted by the hypothesis that Romanian does not have nominative SE.

4.1.4.1 Verbal agreement

Because the overt DP of a middle-passive SE is a subject, it triggers agreement with the verb. With nominative SE instead, the verb is in the third person singular. In Italian infinitivals, verb agreement with the postverbal NP is obligatory (the agreement can only be checked here on the past participle, since in non-finite clauses the auxiliary verb is not inflected for number and person), which supports the analysis in terms of a middle-passive SE:

(73) a. *Ritengo essersi venduto pochi automobili.
(I) esteem (to) have SI sold (sing.) few cars
b. *?essendosi venduto pochi automobili
having SI sold (sing.) few cars

(74) a. Ritengo essersi venduti pochi automobili.
(I) esteem (to) have-SI sold (pl.) few cars
'I esteem to have been sold (pl.) few cars.'
b. essendosi venduti pochi automobili
having SI sold (pl.) few cars
'having been sold (pl.) few cars'

(examples borrowed from Cinque 1988: (79–80))

As expected, the agreement pattern found in Italian non-finite *si* constructions also characterizes Romanian finite *si* constructions, because they can only rely on middle-passive *si*:

(75) a. *În această universitate se predă ştiinţele umane.
in this university SE teaches (sing.) the humanities
b. În această universitate se predau ştiinţele umane.
in this university SE teach (plur.) the humanities
'In this university are taught the humanities.'

4.1.4.2 The distribution of accusative clitics

Another piece of evidence showing that passive SE in Italian infinitivals is [acc] is provided by the distribution of accusative clitics. While [nom] impersonal SE is compatible with accusative clitics (see example (35d)), middle-passive SE is not:

(76) a. *Ritengo esserlesi vendute ad un prezzo eccessivo.
(I) esteem (to) have-them-SI sold at an excessive price
b. *essendolesi vendute ad un prezzo eccessivo
having-them-SI sold at an excessive price
(examples borrowed from Cinque 1988: (81–82))

The same type of ungrammaticality arises in Romanian finite clauses:

(77) *(ştiinţele umane) le *se* predă în această universitate
(the humanities) them SE teach in this university

4.1.4.3 *L'uno l'altro*, floating of *tutti*

Impersonal [nom] SE can serve as an antecedent for *l'uno l'altro*:

(78) Si era parlato l'uno con l'altro. Italian
SI had spoken with each other
'We/they had spoken with each other.'

But *l'uno l'altro* is disallowed in Italian infinitivals (and in Romanian finite clauses):

(79) a. (Io non c'ero, ma) *deve/sembra essersi parlato l'uno con l'altro. Italian
'(I wasn't there, but) (it) must/seems (to) have SI spoken with each other.'
b. *Ritenevo essersi parlato l'uno con l'altro.
'I deemed (to) have SI spoken with each other.'
c. *non essendosi affatto parlato l'uno con l'altro
'not having SI at all spoken with each other'

(80) *S-a vorbit unul cu altul. Romanian
'SI has spoken with each other.'

The observed ungrammaticalities can be understood if we assume that in Italian infinitivals, the SE that combines with unergatives can only be a middle-passive accusative SE (just as in Romanian finite clauses; see (82) and section 2.4 above), which induces a chain of the type (pro, e), which is assigned the theta-role corresponding to a cognate object. But cognate objects are not legitimate antecedents of *l'uno l'altro*, hence the ungrammaticality of (79a–c) in Italian and (80) in Romanian.

The same behavior is found with the quantifier *tutti*: it allows impersonal [nom] SE as an antecedent (see (81)) but not the [acc] passive SE, which occurs in Italian embedded infinitivals (see (82)) and in Romanian finite clauses (see (83)):

(81) Si è reagito a sproposito tutti. Italian
SI has reacted off the point all
'We all reacted off the point.'

(82) a. *?Sembra essersi reagito a sproposito tutti. Italian
'(It) seems (to) have SI reacted off the point all.'
b. *?Ritiene essersi reagito a sproposito tutti.
'(He) believes (to) have SI reacted off the point all.'
c. *?essendosi reagito a sproposito tutti
'Having SI reacted off the point all'

(83) *S-a reacționat prost toți. Romanian
'SE-has reacted badly all.'

4.1.4.4 Control

In Italian non-finite clauses, *si* cannot combine with control verbs:

(84) *Ritengo non essersi promesso di ottemperare alle disposizioni.
'(I) believe not (to) HAVE-SI promised to obey the instructions.'

This is still another context in which Italian non-finite clauses contrast with Italian finite clauses (85) and are parallel to Romanian finite clauses ((54), repeated here as (86)):

(85) a. In certi studi basati su fenomeni linguistici, si è cercato di ricostruire la storia politica e sociale.
in certain essays based on linguistic phenomena, SE-has tried to reconstruct the political and social history
b. Se espera llegar al final del camino.
SE hopes to arrive at the end of the road
c. Si è cominciato a prendere in considerazione le esigenze di tutti.
SE-has started to take into account everybody's needs
d. Si è promesso di seguire le istruzioni.
SE-has promised to obey the instructions

(86) a. *In unele studii s-a încercat a reface, pe baza unor fenomene lingvistice, istoria politică şi socială.
In certain essays based on linguistic phenomena, SE-has tried to reconstruct the political and social history
b. *Se speră a ajunge la capătul drumului.
SE hopes to arrive at the end of the road
c. *S-a început a ține seama de nevoile tuturor.
SE-has started to take into account everybody's needs
d. *S-a promis a respecta dispozițiile
SE-has promised to obey the instructions

The data in (84) are surprising under Cinque's (1988) analysis relying on nominative SE, but expected if nominative SE is disallowed in Italian non-finite clauses; in examples such as (84), *si* can only be analyzed as a middle-passive accusative *si*, which is not a legitimate syntactic controller.[47]

4.2 Dobrovie-Sorin's (1998) analysis

4.2.1 Nominative clitics and agreement features

According to Dobrovie-Sorin (1998), Cinque's +arg nominative SE is a passivizing accusative SE. Because passivization cannot apply to the copula, passives or unaccusatives, the examples in (64) cannot be analyzed as relying on a passivizing accusative SE, but could only rely on nominative SE (which is free to combine with any kind of verb). However, this possibility is itself ruled out, because nominative *si* is not allowed in Italian non-finite clauses, an impossibility that Dobrovie-Sorin attributes to the empirical generalization stated in (87):[48]

(87) Nominative clitics must be identified by overt subject agreement morphemes.[49]

This generalization explains why examples of the type in (64) are ungrammatical. The examples in (65), on the other hand, are grammatical, because they can be analyzed as relying on a passivizing accusative SE (which can combine with unergatives; see section 2.4 above).

4.2.2 Middle-passive SE in control infinitivals

The main empirical data that led Burzio (1986) and Cinque (1988) to believe that passivizing SE needed nominative Case was the ban on passivizing SE in control configurations ((68), repeated here as (88–89), and (66), repeated here as (90)):

(88) *Sarebbe meglio scoprirsi il colpevole.
(it) would be better (to) discover SI the culprit
'It would be better for the culprit to be discovered.'

(89) *Quei prigionieri$_i$ vorrebero [PRO$_i$ essersi già liberati e$_i$].
those prisoners would want have SI already released
'Those prisoners would want to have been already released.'

(90) *Sarebbe meglio lavorarsi un po' di più.
(it) would be better (to) work SI a bit more
'It would be better to be worked a bit more.'

Following Burzio (1986: 44), Cinque (1988) attributes the ungrammaticality of (88–90) to a violation of the Case filter: *si* requires nominative Case, which cannot be assigned in control configurations. Compare Aux-to-Comp contexts (see (67)), in which nominative Case can be assigned. This explanation is not available within Dobrovie-Sorin's (1998) analysis, according to which the *si* in (88–90) is marked with accusative Case. Dobrovie-Sorin proposes that the ungrammaticality shown in (88–90) is due to three distinct constraints, none of which requires *si* itself to be marked with nominative Case.

4.2.2.1 Case

Case assignment is relevant only in example (88): *il colpevole* is an overt DP, which as such needs Case. But nominative Case cannot be assigned in this type of Italian infinitivals; *il colpevole* cannot take accusative Case either, because it is *si* itself that needs accusative Case.

4.2.2.2 A semantic constraint on control

Nominative Case is not needed in (89), since there is no lexical DP in the infinitival clause. Dobrovie-Sorin suggests that the relevant factor is a semantic constraint, which is in fact suggested by Cinque's (1988) own observation that control is compatible with *si* if the property reading is forced:

(91) a. La luce gialla ha il vantaggio di vedersi bene anche nella nebbia più fitta.
the yellow light has the advantage of see SI well even in the thickest fog
'The yellow light has the advantage of being able to be seen even in the thickest fog.'

b. Certe lingue hanno la proprietà di impararsi con più facilità di altre.
certain languages have the property of acquire SI more easily than others.
'Certain languages have the property of being more easily learnable than others.'

(= Cinque 1988: (187a–b))

According to Cinque, the examples in (91) are grammatical because the property reading relies on middle *si*, which is accusative. Compare the ungrammaticality of (89), constructed with an impersonal passive *si*, which according to Cinque requires nominative Case. Since there is, however, no conclusive evidence in favor of the Case distinction between passive and middle *si*, Dobrovie-Sorin assumes only one type of passivizing *si*, marked with accusative Case, which allows either an eventive passive or a middle reading, depending on the position of the overt DP-argument (see section 5 below). Examples such as (89) are

ungrammatical because the verb *volere* 'want' requires the embedded clause to refer to a particular event, but the eventive passive reading of SE-verbs is blocked in controlled clauses. This constraint on the reading of SE-verbs is a particular case of a broader empirical generalization, to be examined in section 5 below: the eventive passive reading is blocked if the subject DP sits in Spec, IP.

4.2.2.3 Passive SE unergatives and the argument status of PRO

We are left with (90), repeated as (92a). Dobrovie-Sorin's explanation relies on the parallellism with (92b), the ungrammaticality of which is itself comparable to that of (93a–c) in English:

(92) a. *Sarebbe meglio [PRO_i lavorarsi$_i$ e_i un po' di più].
(it) would be better [PRO_i (to) work SI_i e_i a bit more]
b. *Sarebbe meglio [PRO piovere un po' di più].
(it) would be better [PRO (to) rain a bit more]

(93) a. *PRO to rain tomorrow would be a tragedy.
b. *PRO to arrive a man would be marvelous.
(cf. For there to arrive a man . . .)
c. *PRO being likely that . . . , we didn't go.
(cf. It being likely that . . . , we didn't go.)
d. PRO to arrive late would be an offense.
(cf. For us/you . . . to arrive late . . .)

According to Chomsky (1981: 325–327) and Rizzi (1982), the ungrammaticality of (93a–c) is due to the generalization stated in (94):

(94) [A chain headed by] arbitrary [non-controlled] PRO is necessarily an argument.

Examples (93a–c), as well as (92b), are ungrammatical because weather verbs and impersonal constructions must be constructed with quasi-argumental and expletive subjects, respectively, which conflicts with the argument status of PRO (see (94)). Compare the example in (93d), which is grammatical, because there PRO takes a fully referential reading.

This analyis also accounts for (92a): the (PRO, e) chain on which (92) relies counts as an argument, and this conflicts with the selectional requirements imposed by middle-passive unergatives (cognate objects are not fully referential arguments).

This account predicts the grammaticality of middle-passive *si* unergatives in Aux-to-Comp configurations (65a–b), repeated here as (95)):

(95) a. Ritengo non essersi provveduto alle sue necessità con la dovuta solerzia.
(I) believe not (to) HAVE-SI taken care of his needs with due zeal
'(I) believe his needs have not been taken care of with due zeal.'

b. non essendosi provveduto alle sue necessità con la dovuta solerzia
not HAVING-SI taken care of his needs with due zeal
'his needs not having been taken care of with due zeal'

Since nominative Case can be assigned here (by the Aux raised to Comp), these examples can be analyzed as relying on chains of the type (pro, e), which are not subject to the constraint in (94), and therefore can function as cognate objects, licensed by the quasi theta-role assigned by unergatives to their objects.

The distribution of SE unergatives is thus completely parallel to the distribution of weather verbs as described and analyzed by Rizzi (1982):

(96) Essendo piovuto per tutto il pomeriggio, non siamo usciti.
'Having rained for the whole afternoon, (we) didn't go out.'

(97) Suppongo [esser molto improbabile che Mario ci aiuti].
'(I) consider (it) (to) be very unlikely that Mario help us.'

In sum, the fact that *si* V_{unerg} sequences are allowed in Aux-to-Comp contexts and disallowed in control configurations is not due to the fact that *si* needs nominative Case, but rather to the interpretive constraint in (94), which holds for PRO as opposed to *pro*.

5 The interpretation of SE-verbs and the position of their subject

In this section we will examine a well-known constraint on the passive reading of SE: it can only obtain in those contexts in which the subject (corresponding to the underlying internal argument) occupies a VP-internal position; in case it occupies the canonical subject position, the passive reading is unavailable, the only possible interpretation being the middle reading. We will show that this generalization, established for French by Stéfanini (1962) and Ruwet (1972), subsumes Raposo and Uriagereka's (1996) generalization regarding European Portuguese. We will, however, question Raposo and Uriagereka's explanation, which was based on Cinque's (1988) hypothesis that passive SE is a subject-like clitic.

5.1 French: the choice between the middle and the passive readings depends on the S-structure position of the overt argument

Stéfanini (1962) and Ruwet (1972) have established that:

(98) French SE-verbs with preverbal subjects allow the middle reading, but cannot take the eventive passive reading (see (99)),[50] which is allowed only in *il*-impersonals (see (100)).

(99) a. Ce livre s'achète par correspondence.
this book SI buys by mail
'This book can be bought by mail.'
b. *Ce livre s'est acheté hier.
this book SI HAS bought yesterday
'This book was bought yesterday.'
c. *Les prisonniers se libéreront la semaine prochaine/le plus rapidement possible.
the prisoners SE will release next week/as soon as possible
'The prisoners will be released next week/as soon as possible.'

(100) a. Il se boira beaucoup de vin ce soir.
it SE will drink a lot of wine this evening
'A lot of wine will be drunk this evening.'
b. Il s'est bu beaucoup de whisky à la réception.
it SE HAS drunk much whisky at the reception
'A lot of whisky was drunk at the reception.'

The eventive meaning is indicated by the compatibility with temporal adverbials and the incompatibility with the manner adverbs characteristic of middles (Obenauer 1970: 62):

(100) c. * Il se reboise pas mal de terrains difficilement.
it SE reforests quite a number of grounds difficultly
'Quite a number of grounds are difficult to reforest.'

Since the postverbal DP of French *il*-impersonals occupies the object position, the French data can be summarized as follows:

(101) a. Subject DP in Spec, IP ⇒ middle and habitual passive readings of [acc] SE.
b. subject DP in VP-internal position ⇒ eventive passive reading of [acc] SE.

5.2 European Portuguese

5.2.1 Raposo and Uriagereka's (1996) generalization

Raposo and Uriagereka (1996) established that in European Portuguese (eventive-)passive configurations, the preverbal subject is not in (Spec, IP), but instead occupies a left-peripheral position (Topic or Focus, depending on the inherent properties of the DP):[51]

(102) a. $[_{specIP}$DP$]$ $[_{I'}$ se V . . . $]] \Rightarrow$ *passive SE.
b. $[_{specTopP}$DP$]$ $[_{IP}$ $[_{I'}$ se V . . . $]] \Rightarrow$ OK passive SE.

Inflected infinitivals provide evidence in favor of this analysis. Thus, both an analytic passive and a SE-passive may occur as inflected infinitives with the agreeing DP in the *post*verbal position (all the following examples are European Portuguese):

(103) a. Vai ser difficil [*pro* serem aceites [**os documentos**]]. (analytic passive)
will be difficult to-be-3pl accepted the documents
'It will be difficult for the documents to be accepted.' (SE-passive)
b. Vai ser difficil [*pro* aceitarem-se [**os documentos**]].
will be difficult (to)-accept-3pl-SE the documents
'It will be difficult for the documents to be accepted.'

However, an eventive-passive SE, in contrast with analytic passives, is ungrammatical if the DP is in the *pre*verbal position:

(104) a. Vai ser difficil [[**os documentos**]$_i$ serem aceites t_i]. (analytic passive)
will be difficult the documents to-be-3pl accepted
'It will be difficult for the documents to be accepted.'
b. *Vai ser difficil [[**os documentos**]$_i$ aceitarem-se t_i]. (SE-passive)
will be difficult the documents SE-to-accept-3pl

In embedded infinitivals, preverbal subjects can only occupy the Spec, IP position, since the Spec, Top position is not available there:

(105) *Vai ser dificil [[**esses documentos**], os tribunais aceitarem(-nos) *ec*].
(it) will be difficult those documents, the courts (to) accept-3pl(-them)
'It will be difficult those documents, for the courts to accept (them).'

Since the Spec, IP position, blocks the eventive-passive reading of SE-verbs (by virtue of the generalization in (102a)), this reading is unavailable in (104b).

Another relevant context is Aux-to-Comp: the position immediately on the right of Aux is of necessity Spec, IP, which can be occupied by the subject of analytic passives, but not by the subject of SE passives:

(106) a. Eu penso [terem$_j$[[os presos]$_i$ t_j sido fuzilados t$_i$]]. (copula passive)
(I) think (to)-have-3pl the prisoners been shot
'I think the prisoners were shot.'
b. *Eu penso [terem-se$_j$ [[os presos]$_j$ t_j fuzilado t_j]. (passive SE)
(I) think (to) have-3pl-SE the prisoners shot

Raposo and Uriagereka furthermore show that in eventive SE passives, the Topic DP cannot bind a trace in (Spec, IP). The argument relies on the distribution of bare NPs. As is well known, in Romance pro-drop languages, bare NPs (BNPs) cannot occupy the preverbal subject position (Spec, IP):

(107) a. O Nestor compra salsichas no talho Sanzot. (BNP in object position)
the Nestor buys sausages at-the butcher-shop Sanzot
'Nestor buys sausages at the Sanzot butcher-shop.'
b. *Salsichas sao compradas no talho Sanzot. (BNP in Spec, IP)
sausages are bought at-the butcher-shop Sanzot
'Sausages are bought at the Sanzot butcher-shop.'
c. *Salsichas custam caro no talho Sanzot. (BNP in Spec, IP)
sausages cost expensive at-the butcher-shop Sanzot
'Sausages are expensive at the Sanzot butcher-shop.'

Dislocated bare NPs are allowed only if they bind the object position (see (108a)). The ungrammaticality of (108b–c) indicates that the dislocated subjects (marked by the comma intonation) of analytic passives and of unergatives bind a trace in [Spec, Infl], which is illegitimate:

(108) a. Salsichas, o Nestor compra **ec** no talho Sanzot. (trace in object position)
sausages, the Nestor buys at-the butcher-shop Sanzot
'Sausages, Nestor buys at the Sanzot butcher-shop.'
b. *Salsichas, **ec** sao compradas *t* no talho Sanzot. (intermediate trace in Spec, IP)
sausages, are bought at-the butcher-shop Sanzot
'Sausages, (they) are bought at the Sanzot butcher-shop.'
c. *Salsichas, **ec** custam caro no talho Sanzot. (intermediate trace in Spec, IP)
sausages, cost expensive at-the butcher-shop Sanzot
'Sausages, (they) are expensive at the Sanzot butcher-shop.'

The grammaticality of (109b) indicates that the dislocated subject of SE passives does not necessarily bind a trace in (Spec, IP), but may be directly coindexed with the object position:

(109) a. Vendem-se salsichas no talho Sanzot. (BNP in obj position)
sell-3pl-SE sausages at-the butcher-shop Sanzot
'Sausages are sold at the Sanzot butcher-shop.'
b. Salsichas, vendem-se **ec** no talho Sanzot.
sausages, sell-3pl-SE at-the butcher-shop Sanzot.
'Sausages, (they) are sold at the Sanzot butcher-shop.'

Further evidence in favor of Raposo and Uriagereka's generalization is provided by parasitic gaps (which we do not review here), and by the position of the subject DP relative to other left-peripheral DPs. The left periphery of European Portuguese contains at least three positions, as indicated in (110). Each one of these slots may, but need not, be instantiated:

(110) $[_{\text{specTopP}}$ **def DP** . . . $[_{\text{specFocP}}$ ***wh*-phrases** . . . $[_{\text{specIP}}$ **canonical subject**]]]

With the eventive-passive SE, the preverbal subject cannot occupy the Spec, IP position (see (111b)); it is either in [Spec, Top], as in (111a), or in (Spec, Foc), as in (112), depending on whether it is a definite DP or a focused constituent (*wh*-phrase, emphatic operator):

(111) a. $[_{specTopP}$**[Esses livros]**$_i$ $[_{specFocP}$[so numa loja]$_k$ $[_{IP/I'}$ se vendem ec$_i$ ec$_k$]]].
those books only at-one store SE-sell-3pl
'Those books only at a (particular) store are sold.'
b. *$[_{specFP}$[So numa loja]$_k[_{specIP}$ **[esses livros]**$_i$ se vendem ec$_i$ ec$_k$]].
only at-on store those books SE-sell-3pl

(112) a. $[_{specTopP}$ A Maria, $[_{spec\ FP}$ **[quantos presentes]**$_i$ $[_{spec\ IP}$ [se deram ec$_i$]]]]?
to-the Mary, how-many presents SE-gave-3pl
'To Mary, how many presents were given?'
b. $[_{specTopP}$ A Maria, $[_{specFP}$**[muitos presentes]**$_i$ $[_{specIP}$ [se deram ec$_i$]]]].
to-the Mary, many presents SE-gave-3pl
'To Mary, many presents were given.'

The example in (111c) shows that the subject of analytic passives can occupy Spec, IP:

(111) c. $[_{specFP}$So numa loja $[_{specIP}$ **esses livros** sao vendidos]].
only at one store those books are sold (subject of copula passive SE in Spec, IP)

In sum, Raposo and Uriagereka provide clear evidence showing that the preverbal subject of eventive-passive SE does not sit in (Spec, IP), nor does it bind a trace in (Spec, IP). It sits in a left-peripheral position and entertains a direct relation with a VP-internal position. This behavior of passive SE contrasts with analytic passives, as well as with SE-reflexives.

5.2.2 Middle SE

The behavior of middle SE was not examined by Raposo and Uriagereka. One may simply guess that middle SE contrasts with passive SE and behaves on a par with reflexives. By using the tests provided by Raposo and Uriagereka themselves, it can indeed be shown that middle SE allows its subject to sit in Spec, IP.

In contrast with eventive-passive SE, middle SE allows its subject to be in the preverbal position in inflected infinitivals, and this position can only be analyzed as being Spec, IP (compare example (104b)):

(113) a. vai ser dificil esta luz ver-se de longe
(it) will be difficult this light see(inflected)- SE from afar
b. vai ser dificil este lindo vestido lavar-se facilmente
(it) will be difficult this beautiful dress wash-SE easily
(examples provided by Joao Costa, p.c.)

Note furthermore that the preverbal subject of middle SE may occur to the right of an extracted adjunct, in which case it can only sit in (Spec, IP). Middle SE thus patterns with reflexives and analytic passives and contrasts with eventive passive SE:

(114) a. [$_{specTop}$Em que momento do espectáculo] [$_{specIP}$a luz] se viu bem?
at what moment of the show the light SE saw well
(Joao Costa, p.c.)

b. [$_{specTop}$Em que momento da operaçao] [$_{specIP}$os especialistas] se consultaram?
at what moment of the operation the specialists consulted each other
≠ at what moment of the operation the specialists were consulted

Given the data just reviewed, Raposo and Uriagereka's generalization should be revised as follows:

(115) **Revision of Raposo and Uriagereka's generalization:**
a. [$_{specIP}$DP] [$_{I'}$ se V . . . []] ⇒ OK middle, *eventive-passive
b. [$_{specTopP}$DP] [$_{IP}$ [$_{I'}$ se V . . . []]] ⇒ OK eventive passive

5.3 A unifying analysis of European Portuguese and French

The data in European Portuguese summarized in (115a–b) bring to mind Ruwet's generalization (see (101)):

(116) Just as in French, a preverbal DP sitting in (Spec, IP) triggers the middle/generic reading of passive SE constructions. The eventive-passive reading is blocked.

Because European Portuguese is a pro-drop language, preverbal subjects do not necessarily sit in Spec, IP, but may be in Spec, Top or Spec, Focus instead. These positions do not induce the interpretive constraint characteristic of Spec, IP. We may thus conclude that French and European Portuguese illustrate two particular instantiations of one and the same constraint on passive SE configurations.

5.3.1 Raposo and Uriagereka's explanation

Raposo and Uriagereka's explanation basically amounts to the idea that the Spec, IP position is made unavailable by the eventive-passive SE. Raposo and Uriagereka follow Cinque (1988) in assuming that the eventive-passive SE is marked as +arg and is an '[NP, IP]' clitic, which as such fills – at some point in the derivation – the [NP, IP] position: SE goes to (Spec, v') and from there to (Spec, IP), thus rendering this position unavailable for the internal argument to raise to. This

account is problematic insofar as it basically amounts to assuming that a passivizing morpheme, here SE, is a subject clitic (see sections 3.4 and 4 above).

The contrast between the middle and the eventive-passive reading is not explicitly brought up by Raposo and Uriagereka. Within their account, the behavior of middle SE can only be analyzed as being due to its inherent features: in contrast with passive SE, middle SE does not need to go to Spec, IP. Thus, in order to account for the contrast between passive and middle SE, Raposo and Uriagereka would have to postulate lexical homophony: passive SE and middle SE would be two inherently distinct elements, much as in Cinque (1988).[52] The problem is that there is no evidence – other than the data we try to explain – in favor of a distinction between passive and middle SE. In particular, they both trigger 'agreement with the object' (this is Raposo and Uriagereka's term, which in fact refers to the overt subject, corresponding to an underlying Theme), which is the criterion that Raposo and Uriagereka choose for distinguishing eventive-passive (their 'indefinite') SE from the 'impersonal' (i.e., nominative) SE.

5.3.2 *An alternative line of inquiry*

Dobrovie-Sorin (2004, forthcoming) proposes an explanation based on the idea that the 'syntactic activity' of the Agent (which is necessary for the passive reading to obtain) of SE-verbs is possible only if the internal argument occupies the object position. Under this view, the passive reading of accusative SE is blocked not because passive SE itself goes to Spec, IP, but rather because this position must remain empty in order for the Agent to be present at Logical Form.

NOTES

1 To this day, Kayne (1975) and Burzio (1986) remain the best references on the problem stated in (i), both for the detail of the empirical description and for insights regarding the analysis. For (iii) the reader is referred to Giorgi (1991).

2 Zubizarreta (1987) and Belletti (1982) distinguish reflexives from middle-passive SE: the latter, but not the former, would absorb the external theta-role. Burzio (1986) analyzes middle-passive SE as a particular instantiation of subject/nominative SE. Cinque adopts this analysis for impersonal and habitual passive SE (*Dans cette maison, la Bible se lit tous les jours* 'In this house, the Bible SE reads every day'), but departs from Burzio in assuming that the property interpretation of middles (*Ce livre se lit facilement* 'This book SE-reads easily') relies on accusative SE. Within Cinque's typology, impersonal passives (including habitual passives) rely on a nominative +arg SE, whereas middles rely on an accusative –arg SE.

3 The morphological identity shown by passives, anticausatives, and reflexives is widespread across unrelated language families, such as Indo-European, Uto-Aztecan, Athapaskan, Turkic, Ethiopian Semitic, and Dravidian (Haspelmath 1987, 1990; Kemmer 1993; Geniušenė 1987).

4 Perlmutter's (1978) unaccusatives were called 'ergatives' by Burzio (1981, 1986). Because it may cause confusion (by unduly bringing to mind 'ergative' languages), this terminology will be avoided here.

5 In order to simplify the glosses, the verb *être* 'be' will be translated as *have* whenever it functions as a perfect auxiliary.

6 For the claim that unergatives and unaccusatives can be distinguished in terms of internal/external causation see also Levin and Rappaport (1995), who attribute the main insight to Smith (1970).

7 Labelle further assumes that in SE-inchoatives the external role (the one to which is attributed 'responsibility' for the change) is discharged by SE itself, which would be generated in the (Spec, VP) position, leaving the Spec, IP slot available for the externalization of the internal argument (1992: 395). This proposal, which suffers from the problems brought up in section 3 below, is not crucial for Labelle's main proposal.

8 Crucial to Burzio's view is the idea that SE is not a pronoun, but rather an unaccusativity marker. The 'affixal' nature of SE is less central: being an unaccusativity marker does not force a given element to be an affix (completely bound morpheme), but is compatible with it being a clitic ('semi-bound' morpheme, or 'syntactic affix' in Anderson's 1992 terms), or a weak pronoun (cf. Dutch *zich*-anaphors). Conversely, affixes (e.g., agreement morphemes on the verb) may function as pronouns, by virtue of binding an empty category of type *pro*.

9 In Italian, the embedded verb may be interpreted as reflexive in the absence of SE:

(i) Questo farà [$_{VP}$pentire Giovanni]
this will make [repent John]
'This will make John repent himself.'

(ii) Maria ha fatto [$_{VP}$accusare Piero]
Mary has made [accuse Peter]
'Mary made Peter accuse himself.'

The fact that SE cannot surface in Italian examples such as (i–ii) thus seems to be due not to a constraint on the compatibility between the syntactic operations underlying causatives and reflexives, but rather to a morphological constraint on SE-placement in Italian causatives. Pesetsky (1995: 99–100) suggests that the disappearance of SE in Italian causatives and the disappearance of SE in nominalizations (in all Romance languages) are due to the same constraint. The generalization would be that the lexicalization of the +reflexive feature is blocked by derivational morphemes. French and Spanish causatives, which allow reflexives, would have to be analyzed as syntactic causatives, whereas their Italian counterparts would be morphological causatives.

10 According to Burzio (1986: 140, 406), the verb *be* as a perfect-marker is triggered, in both French and Italian, by the co-indexation relation that holds between SE and the subject position. Because both accusative SE and dative SE are co-indexed with the subject position, *be* is used as a perfect marker in both cases. Note, however, that dative SE differs from accusative SE in not allowing agreement on the past participle, despite *be*-selection. With accusative SE, past participle agreement is *obligatory* (compare the optional agreement triggered by accusative clitics):

(i) Marie s'est décrite aux enfants.
Mary SE HAS described-femin. to the children

(ii) Marie l'a décrite aux enfants.
Mary her has described-femin. to the children

(iii) Marie s'est souvenu/*souvenue de Jean.
Mary SE-HAS recalled-unmarked/*recalled-fem. of John

(iv) Marie s'est dit/*dite qu'elle n'aimait plus Jean.
Mary SE-HAS said-unmarked/*said-femin that she no longer loved John

(v) Marie s'est maudite/*maudit d'avoir laisser mourir Jean.
Mary SE-HAS blamed-unmarked/*blamed-femin. for having let die John

The dissociation between *be*-selection and past participle agreement is analyzed by Burzio as indicating that past participle agreement is not triggered by the co-indexation between SE and the subject, but rather by the presence of an NP-chain. Accusative SE relies on an NP-movement chain, but dative SE does not (Burzio 1986: 406).

11 Burzio (1986) shows that dative SE cannot be subsumed under the unaccusative analysis, but functions instead as an object clitic.

12 According to Burzio (1986), middle-passive SE is not an unaccusativity marker, but rather a particular type of subject clitic. Evidence against this view will be presented in sections 3.4 and 4 below.

13 Zubizarreta's (1987) proposal is a mixed lexicalist-syntactic approach, according to which SE is a verbal operator that is inserted either at L-R (the lexico-syntactic level of lexical representation, to be kept distinct from the lexico-semantic level, notated S-R) or at S-structure, which would result in middle and reflexive interpretations, respectively. Although Zubizarreta herself assimilates SE to A'-operators, this hypothesis does not seem to play any role in her approach, and in fact her notion of 'verbal operator' seems closer to that of voice-marker or argument-change marker.

14 Note that given the unergative analysis of SE-reflexives advocated by Reinhart and Siloni (2004), the representations in (19a) and (19a') should be viewed as pertaining to a level of representation other than S-structure.

15 The particular choice that predicates make between (19a) and (19b) is a matter of lexical semantics: some verbs may take the option in (19a), others the one in (19b) and yet other verbs may allow either option (cf. *aimer* 'love', *casser* 'break', and *laver* 'wash', respectively).

16 Note that French *il*-impersonals do not rely on the chain configuration in (19b):

(i) Il_j s_i'est traduit trois $romans_i$.
IL SE HAS translated three novels
'Three novels were translated.'

Dobrovie-Sorin (1994b, 1998) suggests that a chain of the type in (19b) is formed at LF, after expletive replacement (required by Chomsky's 1986a Full Interpretation Principle) by the raised DP.

17 Dobrovie-Sorin (1998) suggests that her characterization of SE can be restated in reflexivity terms (Reinhart and Reuland 1993). SE can be assumed to be a reflexive marker if the definition of reflexive predicates is changed: a reflexive predicate would be one in which two argument *positions* (rather than two theta-roles) are co-indexed. This suggestion is, however, problematic, because the notions of reflexive marker and reflexive predicate are designed in such a way that they are distinct from 'simplex expression anaphors' such as *zich*. Now, although SE differs from *zich* in being unable to be long-distance bound, it resembles *zich* insofar as both SE and *zich* can be

markers of 'inherent reflexivity' (in Everaert's 1986b terms) or 'unaccusativity', unlike *zichself*. A careful rethinking of the properties of SE in terms of reflexivity theory remains to be developed.

18 We will leave aside the 'intensifying' use of dative SE, which is found in colloquial Spanish:

(i) Juan se baila tangos, rumbas, chotis: lo que sea.
John SE dances tangos, rumbas, chotis: whatever there is

(ii) Juan se escribe cien versos al dia.
John SE writes (one) hundred verses a day

This type of SE is subject to a syntactic constraint that also holds for benefactives: it can be used only if a direct object is present.

19 Note, however, that (the trace of) *îşi* cannot be bound by the subject of raising verbs:

(i) *Copiii tăi îşi păreau să fie fericiți.
your children SE_{dat} seemed that [they] be happy

(ii) ?*Copiii tăi îşi păreau fericiți.
your children SE_{dat} seemed happy

This ungrammaticality might be due to a different constraint: a reflexive dative and its antecedent must be co-arguments.

20 The Romanian data are somewhat complex, due to the use of prepositional accusatives and clitic doubling, which are both obligatory for proper names. These phenomena are irrelevant here.

21 The correlation between being a pro-drop language and having nominative SE was suggested by Belletti (1982). This correlation holds for French but not for Romanian.

22 The German example in (41) has a generic reading, whereas the Romanian examples in (40) refer to particular events. Note, however, that the impossibility of particular time reference is not peculiar to the *sich* that combines with unergatives, but characterizes the passivizing use of *sich* in general:

(i) *Dieses Buch hat sich gestern gelesen.
this book HAS SICH yesterday read

(ii) Dieses Buch liest sich angenehm.
this book reads SICH with pleasure

23 A conceptually similar analysis can be found in Perlmutter (1978), who argues against the spontaneous demotion of the Agent and proposes instead that impersonal passives rely on the advancement of a dummy, an operation that is the relational grammar counterpart of the NP-movement of a null object in GB theory.

24 Under this view, unergatives do not differ from transitives by their subcategorization properties (both types of verbs may, but are not obliged to, take a direct object), but only by their selectional requirements: unergatives select a cognate object, which as such need not be projected in the syntax, whereas transitives normally select fully referential objects, which must be syntactically realized; some transitives can be

construed as having prototypical objects (e.g., *eat*, *drink*, *write*, etc.), which are not lexicalized; those transitives that do not allow for prototypical objects must lexicalize their object (e.g., *observe*, *consider*, *discover*, etc.). In sum, the borderline between unergatives and transitives is less clear cut than is usually assumed, which explains why this distinction is not grammaticalized in well-described languages (compare the *be/have* alternation that distinguishes unaccusatives on the one hand from transitives and unergatives on the other hand).

25 Dummy null cognate objects may be assumed to be assigned a quasi theta-role (see Dobrovie-Sorin 1998).

26 Depending on the particular definition of passivisation that one may adopt, the reason may be that (i) the 'absorption' of accusative Case – which is imposed by passivisation – cannot apply vacuously (Jaeggli 1986a) – in other words, passivisation cannot apply because there is no accusative Case to absorb; or (ii) unaccusatives have no external role, and passivization can apply only if there is an external role to be suspended.

27 Similar contrasts between Romanian and French arise regarding verbs that take idiomatic and sentential complements. The French examples in (iia–c) have the same glosses as the Romanian examples in (ia–c):

(i) a. S-a luat loc imediat.
SE-has taken place immediately
'Place was taken immediately.'
b. Li s-a dat apă la moară.
to-them SE-HAS given water to the mill
'They were given favorable evidence.'
c. S-a spus/descoperit/declarat că Ion e nebun.
SE-has said/discovered/declared that John is crazy
'It was said/discovered/declared that John was crazy.'

(ii) a. *Il s'est pris place immédiatement.
b. *Il s'est donné de l'eau à leur moulin.
c. *Il s'est dit/découvert/déclaré que Jean était irresponsable.

For lack of space we restrict our attention to the contrast concerning unergatives. A detailed discussion of the other data can be found in Dobrovie-Sorin (1994b, chapter 5).

28 The reader may have noticed that the examples in (49) are constructed with unergatives that subcategorize a PrepP. With unergatives that do not subcategorize PrepPs, the passive is somewhat less acceptable (the presence of a modifier is obligatory):

(i) ?Ensuite, il a été couru jusqu'à la gare.
then, IL was run to the station

(ii) ?Mais, il a été dormi dans ce lit récemment.
but, IL has been slept in this bed recently

For discussion see Dobrovie-Sorin (1994b).

29 Haider (1985b), Haider and Rindler-Schjerve (1987), and Dobrovie-Sorin (1986, 1994b, 1998) are isolated exceptions.

30 French SE-verbs are ambiguous between passive and middle readings. Adverbs such as *facilement* 'easily' are only compatible with the middle reading, which in turn is

incompatible with control into a final clause. If *facilement* is suppressed, the example becomes grammatical, but it loses the middle reading.

31 See also Williams (1985) and Lasnik (1988), who argue that the PRO subject of final clauses need not be controlled by a DP argument, but may be controlled by an event.

32 These examples become grammatical if the embedded verb undergoes SE-passivization:

(i) În unele studii s-a încercat a se reface istoria politică şi socială.
in certain essays SE has tried to SE reconstruct the political and social history.
'In certain essays it was tried for the political and social history to be reconstructed.'

(ii) Se speră a se ajunge la capătul drumului.
SE hopes to SE arrive at the end of the road
'It is hoped that the end of the road will be arrived at.'

(iii) S-a început a se ține seama de nevoile tuturor.
SE-has started to SE take into account everybody's needs
'It was started that everybody's needs be taken care of.'

(iv) S-a promis a se respecta dispozițiile.
SE-has promised to SE obey the instructions
'It was promised that the instructions will be obeyed.'

As indicated by the glosses, both occurrences of SE are interpreted as SE-passives. No ungrammaticality arises, since the verb in the main clause does not function as a control verb: as for any passivized verb, its external argument is suspended and its only argument is the embedded clause itself. We may now wonder why a similar analysis is ruled out for the examples in (54): why is it not possible to analyze the SE in the main clause as an instance of passive SE? The answer is that the embedded verb is in the active form, and as such projects a null subject, which needs to be controlled, a requirement that cannot be satisfied because passive SE cannot function as a legitimate controller. Compare (i–iv), where the embedded clause contains a SE-passive: the external argument has been suspended, thus suspending the need for control.

33 Cinque tries to solve this problem by assuming that his [+arg] nominative SE binds a non-referential trace in Spec, IP, which as such is unable to function as a syntactic controller. This peculiarity of [+arg] nominative SE conflicts with the currently observed behavior of nominative clitics, which qualify as syntactic controllers. This is indeed what we find with Cinque's –arg nominative SE, which according to Dobrovie-Sorin (1988) is the only truly nominative SE (see section 4 below).

34 Pronominal clitics exist that are specified for a designated grammatical function (e.g., nominative, dative, or accusative), but not for a particular theta-role.

35 Adopting a suggestion by Chomsky (1986a: 217), Cinque argues that the two chains in (57) are allowed to overlap because they belong to distinct types: one of them is a theta-chain, whereas the other is an expletive–argument pair. One can thus maintain the ban on overlapping theta-chains, while allowing overlapping CHAINs (this notion covers both expletive–argument pairs and theta-chains).

36 This proposal unduly identifies the absorption of the external theta-role by a nominative clitic – which is in fact a particular kind of syntactic realization of the external

role, a process that *does not suspend* accusative Case – with the suspension of the external theta-role by a passivizing morpheme, which blocks the syntactic realization of the external role in the canonical subject position and correlates with the suspension of accusative Case. To make this point clear, consider nominative clitics or even agreeement morphemes. One may assume that they absorb/retain/withhold the external theta-role, but one must ensure that the (Spec, IP) position vacated by nominative clitics/agreement morphemes is *not* available for a DP that carries the Theme-role (correlatively, accusative Case *is* available). Otherwise, we would expect nominative clitics, as well as subject-agreement morphemes, to function (at least optionally, but maybe necessarily) as passivizing morphemes, which they do not. In sum, nominative clitics cannot be passivizers because they are syntactic realizations of the external role, which blocks the externalization (encoded as NP-movement in GB theory) of the internal role.

37 Burzio (1986: 144–148) himself observes that French middle-passive *se* contrasts with Italian nominative *si*: whereas the latter behaves as a pronominal subject clitic, the former behaves as a lexical affix (cf. inchoative and inherent SE), which as such cannot be affected by subject raising:

(i) *Il se semble construire beaucoup d'immeubles. French
it SE seems (to) build many buildings

38 A detailed review of Cinque's (1988) analysis can be found in Dobrovie-Sorin (1998). Let us simply mention here that Cinque differs from Burzio insofar as Cinque distinguishes between middle and passive SE, which would be marked as accusative and nominative, respectively.

39 Although Burzio (1986) himself is of course fully aware of Restructuring phenomena, he does not subsume examples of *si*-raising under Restructuring.

40 Mendikoetxa and Battye (1990) assume that nominative and accusative SE head AGRsP and AGRoP, respectively. However, the Spec positions of these projections are not related to SE, since these authors assume that the external role is not absorbed, but merely suspended by SE.

41 The idea that passives involve a null pronoun in Spec, VP is not integral to McGinnis's work on reflexives. In fact, she discarded this idea in later work: McGinnis (1998, 2004) does not treat passives as involving a 'pro' external argument.

42 The two authors differ regarding the nature of the empty category controlled/identified by SE (PRO for Kayne and pro for Guéron), as well as regarding the position of this empty category. Both Kayne and Guéron allow the empty category identified by SE to be VP-adjoined, but they disagree on a further possible position: according to Guéron, subject SE binds a pro in a right-hand-generated (Spec, IP) position, whereas Kayne assumes that SE may occupy (Spec, VP). Since for Kayne's views we can only rely on lectures of the 1980s and on a short (1986) abstract, we will concentrate here on the syntactic side of Guéron's (1991) analysis, leaving aside its semantic part, which was not taken up in the subsequent literature on SE.

43 The fact that a dative-marked reflexive does not trigger passivization is clearly indicated by Romanian. Examples such as (i), which contain dative reflexives, can only be interpreted as containing goal or benefactive reflexive pronouns:

(i) Ion îşi trimite cărţi poştale.
John SE_{Dat} sends postcards

Conversely, a dative reflexive cannot appear in the Romanian counterparts of French examples of the type in (63):

(ii) Merele se mănîncă toamna.
apples-the SE_{Accus} eat in [the] autumn

(iii) *Merele îşi mănîncă toamna.
apples-the SE_{Dat} eat in [the] the autumn

44 There seems to be no reason to believe that in an example such as (i), the Friulan subject clitic *al* is ambiguous (between the [+arg] and the [–arg] features), whereas in (ii–iii) it is non-ambiguous (being compatible only with the [–arg] feature). The examples are due to Poletto (1991, 1993):

(i) Al duar.
'He sleeps.'

(ii) Al ven duman.
'He will come tomorrow.'

(iii) Al e staat vist.
'He has been seen.'

The only plausible analysis is that in all these examples *al* is a referential clitic. Compare (iv–vi), where *al* is quasi-argumental or expletive:

(iv) Al pluof.
'It rains.'

(v) al par che . . .
'it seems that.'

(vi) Al ven Toni.
'There will come Toni.'

It thus seems clear that Cinque's [+arg]/[–arg] distinction cannot be identified with the well-established distinction between referential and expletive subject clitics.

45 Given this analysis, Italian examples of the type *SE* V_{unerg} (see (71)) are indeed ambiguous, as suggested by Cinque himself, but the ambiguity is not one between two types of nominative SE but rather one between a nominative SE and a passivizing accusative SE.

46 Cinque's assumption that a nominative passive *si* exists can be traced back to Burzio's (1986: 48)) proposal, to the effect that certain passive *si*s bear both accusative and nominative Case.

47 Regarding control into adjunct clauses, see section 3.2 above.

48 Existing analyses of nominative clitics, bearing in particular on Italian dialects, do not provide any counter-example to this generalization, which has, however, not been derived as a consequence of theoretical principles.

49 That overt agreement morphology rather than finiteness is required by nominative SE is clear when one considers Portuguese: it is because this language has infinitivals inflected for AGR features that the Portuguese counterparts of the examples in (64) are grammatical (see Cinque 1988: 531–533).

50 The generalization in (98) has to be qualified in view of some French examples due to Zribi-Hertz (1982):

(i) a. La question s'est discutée hier dans la salle du conseil.
the issue SE HAS discussed yesterday in the council hall
'The issue was discussed yesterday in the council hall.'
b. Le crime s'est commis ce matin.
the crime SE HAS committed this morning
'The crime was committed this morning.'
c. L'opération s'est effectuée hier.
the operation SE HAS carried out yesterday
'The operation was carried out yesterday.'
d. Le point s'est soulevé hier à la réunion.
the point SE HAS raised yesterday at the meeting
'The point was raised yesterday at the meeting.'

We will leave these exceptions aside.

51 Raposo and Uriagereka furthermore show that in order for the eventive passive reading to survive, the topicalized DP should not transit through Spec, IP.

52 Although Raposo and Uriagereka do not follow Cinque in characterizing passive SE as a nominative clitic, it is difficult to see how an '[NP, IP]' clitic, which 'must go to Spec, IP', could avoid being marked with nominative Case.

    3.3.3 Locative and directional expressions
    3.3.4 Temporal expressions
4 Conclusion

1 Introduction

1.1 Overview

Secondary predicates pose a challenge for syntactic theories because they partake in two (potentially syntactic) relationships. The first relationship is generally considered to be an instance of adjunction to a projection of V. The second relationship holds between the secondary predicate and one of the arguments of the main predicate, the controller. This relationship is usually held to be an instance of predication: the secondary predicate ascribes a condition or state to the controller. Consider the secondary predicates *alive* in (1) and *wanka* in (2), the near-equivalent of (1) in the Australian language Martuthunira. In both examples, the controller is the object, and the secondary predicate expresses a state which holds of the controller at the time of the event expressed by the main predicate (i.e., the mouse was alive when the snake ate it):

(1) The snake ate the mouse alive.

(2) Martuthunira (Ngayarda, Pama-Nyungan):
Nhula miyu mungka-rnuru wajupi-i wanka-a-l.
DEM cat(NOM) eat-PRS grasshopper-ACC alive-ACC-THEN
'That cat eats grasshoppers alive.' (Dench 1995: 182)

While both the adjunct status and the argument-oriented nature of *alive* in examples such as (1) and (2) seem obvious, no generally accepted definition of secondary predicates exists to this day. Consequently, both the range of constructions that are considered secondary predicates and their analysis vary considerably, even in the literature devoted to secondary predicates in a single language, English. For example, following Halliday (1967), both depictives (such as *alive* in (1) and (2)) and resultatives (such as *dead* in *Joy shot the bird dead*) are generally regarded as secondary predicates. However, the question of whether resultatives really fall under the same construction type as depictives has been the matter of some debate in the literature (see chapter 58). Cross-linguistically, resultative notions are often expressed by complex predicates, not adjunct constructions. This is true for the Australian language Warlpiri (Simpson 2005), and also for English and German – at least this has been argued by Dowty (1979), and is the central claim in Winkler (1997). Since the input of Australian languages into the discussion on secondary predication has mainly been in the domain of depictive secondary predicates, only this construction type will be considered here.

Controversial issues also include the level of adjunction of secondary predicates, and the grammatical and semantic restrictions on both the main predicate and the secondary predicate. Furthermore, it has been a matter of debate whether the relationship between the secondary predicate and its controller is truly a relationship of predication, and if it is, how it is to be represented (see chapter 58). Moreover, while most authors consider secondary predicates to be adjuncts,

it is often difficult to distinguish (obligatory) predicative complements – often analyzed as small clauses – from (optional) depictives (cf. Halliday 1967; Plank 1985; Aarts 1995; Schultze-Berndt and Himmelmann 2004: 65).

Another problem in the definition of depictives, which is discussed more rarely, is the word class and the internal structure of the secondary predicate. Most discussions of depictive secondary predicates in English focus on adjectival secondary predicates such as *alive* in (1). But a number of authors, including Aarts (1995: 79–80) and Nichols (1978: 124), also consider prepositional phrases such as *in tears* in (3) as depictives:

(3) We found him in tears. (Aarts 1995: 80)

Example (3) also illustrates the notorious difficulty of distinguishing depictives and adverbials. Many adjuncts, e.g., adjuncts of manner or quantification, can be given both an event-oriented and an argument-oriented interpretation, as has been pointed out by many authors including Jackendoff (1972), McConnell-Ginet (1982), Geuder (2000), and Maienborn (2001) (see also chapter 4). Consider *reluctantly* in *Joy ate the meat reluctantly*, which semantically is argument-oriented (it is Joy who is reluctant). While in English, *reluctantly* is formally marked as an adverbial by the suffix *-ly*, no corresponding formal difference exists between depictives and simple adjectival adverbs in a language like German, and in many languages, including some Australian languages, corresponding manner expressions are formally marked in the same way as depictives (see sections 2.5.3 and 3.3).

The problem of establishing a universally valid definition of secondary predicates is thus aggravated when languages with a very different grammatical and lexical structure are considered. For example, Larson (1991) proposes a unified analysis for secondary predicate constructions and serial verbs (see chapter 59). On the other hand, some authors subsume under secondary predicates noun phrases which are coreferential with pronominal arguments in head-marking languages, and therefore have a very different pragmatic function from secondary predicates in a language like English (see section 3.1). If these proposals are taken together, the range of expressions that could be identified as secondary predicates goes far beyond the clear cases that are comparable to example (1) in English.

Studies of Australian languages have made important contributions to the theory of secondary predication, but these languages also pose a number of problems which still remain to be solved, and raise the question of how secondary predicates can be delimited from other construction types. Australian languages are interesting for the theory of secondary predication in a number of ways. First, many of them have a rich case system, with secondary predicates obligatorily agreeing in case. The range of agreeing adjuncts, however, often goes far beyond the range of expressions that are generally regarded as secondary predicates in a language like English (see sections 2.5 and 3.3).

Second, some Australian languages have a lexical structure which is rather different from that of the better-known European languages, and this also has

consequences for the analysis of secondary predicates in these languages. For example, it has been claimed for some Australian languages that the restriction of secondary predicates to stage-level predicates does not hold (see section 2.5.1). It has further been reported that some languages have word classes restricted to depictive function, or a special word class of predicative elements which may be used as parts of complex predicates or secondary predicates, but not as main predicates (see section 2.5.3).

Third, many Australian languages belong to the so-called non-configurational type, and secondary predication has figured prominently in attempts to propose unified phrase structure representations for configurational and non-configurational languages (see section 3.1.1). In non-configurational languages which allow discontinuous noun phrases, the additional problem arises of whether and how these should be distinguished from secondary predicate constructions (see section 3.1.2). Australian languages often also exhibit a certain type of external possession construction involving body parts and other part expressions, for which likewise analyses in terms of secondary predication structures have been proposed (see section 3.2).

1.2 *A brief introduction to Australian languages*

It is important to note that Australian languages do not form a homogeneous group either in terms of their genetic relationship or in terms of their typological characteristics. Research on the genetic subgrouping of Australian languages is still in progress; it is made more difficult by the complete lack of records dating before the invasion of Europeans, and the scarcity of documentation of the languages in some areas. Of the estimated 200–250 Australian languages at the time of first European contact (Walsh 1991, 1997), more than half are no longer spoken, and most of the remaining languages are severely endangered, especially if they are no longer acquired by children. The number of speakers rarely exceeds a few hundred people, and often only a dozen or fewer fluent speakers remain.

The by now widely accepted genetic division (cf. Blake 1988; Evans 1988 – but see Dixon 1997, 2002) is between the relatively coherent genetic group of Pama-Nyungan (henceforth PN) languages, covering most of the continent, and around 25 other language families – each comprising only a few languages – which are subsumed under the label Non-Pama-Nyungan (henceforth NPN) languages.

With regard to their morphological structure, most Australian languages are agglutinating with varying degrees of fusional characteristics, but some NPN languages, like Mayali (see example (4)), are strongly polysynthetic. Most languages are 'non-configurational' in the sense that the order of phrases is conditioned by pragmatic rather than syntactic factors. Word order within phrases may be restricted to varying degrees (see section 3.1). Most NPN languages have bound pronominals which are prefixed to the verb. Prefixing is only attested for very few PN languages; usually, these either lack bound pronominals altogether, or feature pronominal suffixes or enclitics (see section 3.1.1).

Australian languages have played a prominent role in the debate on ergativity – cf. Dixon (1979, 1994), Silverstein (1976), Bittner and Hale (1996a, 1996b), among many others. The majority of languages are indeed morphologically (but not necessarily syntactically) ergative. However, there are also languages of the accusative type, and in polysynthetic languages like Nunggubuyu (Heath 1984), core arguments are often unmarked for case (cf. also Baker 1996: 130–131).

The discussion in the remaining sections draws on a sample of languages from several language families with varying typological characteristics. Section 2 presents an overview of the morphological and syntactic properties of depictive secondary predicates in Australian languages. Section 3 reviews the contrasting ways in which the term 'secondary predication' has been applied in the analysis of Australian languages, and outlines some of the problems of delimiting secondary predicates from other construction types.

2 Morphological and syntactic properties of depictive secondary predicates in Australian languages

In the following subsections, only depictives that are adjuncts (in the traditional sense, not in the wider sense introduced in section 3.1.1) will be considered. Note, however, that in some of the polysynthetic NPN languages of northern Australia, such as Mayali, argument-oriented elements may be incorporated into the main predicate and in this case are constituents of a complex predicate rather than adjuncts. In (4a), the predicate *nga-rrarrkid-ma-ng* is a single phonological and grammatical word consisting of the verb stem and the incorporated predicate nominal *-rrarrkid* 'alive', which semantically predicates on the object. In (4b), the nominal *yau* 'child' is incorporated and may be interpreted as a secondary predicate ('as a child'):

(4) Mayali (Gunwinyguan, NPN):
   a. Ka-rrarrkid kaluk nga-rrarrkid-ma-ng.
      3-alive FUT 1.SBJ/3.OBJ-alive-pick.up-NPAST
      'It's alive, I'll pick it up alive.' (Evans 1997: 400)
   b. an-yau-bawo-ng kure bedda
      3.SBJ/1.OBJ-child-leave-PAST.PERF LOC 3PL
      'My mother left me with them as a child.' (Evans 1997: 422)

2.1 Syntactic position

Little is known about the precise syntactic properties of depictive secondary predicates in Australian languages. While in English, depictives are usually analyzed as constituents of the VP and there is some controversy regarding the level of adjunction, e.g., of subject and object depictives (see chapter 58), many

Australian languages lack evidence for the existence of a phrasal category verb phrase, and the word order of both arguments and adjuncts is rather variable. These properties have been subsumed under the label 'non-configurationality' (see section 3.1). The lack of a fixed position of the secondary predicate is in many Australian languages compensated for by extensive agreement; that is, the depictive indicates the relationship to its controller by agreement rather than position (see section 2.2).

In any case, an analysis in terms of syntactic position can only capture the status of the secondary predicate as an adjunct, but does not directly capture the relation between the secondary predicate and its controller (although it has been claimed for English that the position varies depending on whether the controller is a subject or an object). This second relation has sometimes been described in terms of dependency, e.g., by Mel'cuk (1988), Nichols (1978), and, with reference to Australian languages, by McGregor (1997: 54–56, 2005), who regards it as an attributive relationship. The nowadays more widely accepted analysis of depictives is that developed within the framework of predication theory. Here, the relationship between controller and depictive is analyzed as an instance of predication, which is considered to be an irreducible syntactic relationship (see chapter 58).

2.2 *Agreement*

Because of their argument-oriented nature, depictive secondary predicates are reminiscent of attributive modifiers in an NP. Therefore, in many languages a marking device that is typically used to establish coherence between the constituents of a noun phrase – agreement – is used to link a depictive to its controller (which does not have to be overtly expressed; see section 2.4). This phenomenon is well known from Ancient Greek and the Slavic and Romance languages (cf., e.g., Napoli 1975; Nichols 1978; Legendre 1990).

Many Australian languages also show extensive agreement of depictives with their controllers (this type of agreement has been termed 'referential agreement' by Dench and Evans 1988: 14–16). In ergative languages like Warlpiri, the depictive takes ergative marking if the controller is an actor in a transitive clause (5a), and absolutive marking (usually zero) if the controller is an undergoer in a transitive clause (5b), or the sole argument of an intransitive clause (cf. Simpson 1991: 199–214; Hale et al. 1995):

(5) Warlpiri (Ngumpin-Yapa, PN):

a. Maliki-rli$_i$ ka marlu wajilipi-nyi mata-ngku$_i$.
dog-ERG PRS kangaroo(ABS) chase-NPAST tired-ERG
'The dog is chasing the kangaroo tired.' (Hale 1994: 192)

b. Maliki-rli ka marlu$_i$ wajilipi-nyi mata$_i$.
dog-ERG PRS kangaroo(ABS) chase-NPAST tired(ABS)
'The dog is chasing the kangaroo (and the latter is) tired.'
(Hale 1994: 192)

In accusative languages like Martuthunira, agreement distinguishes depictives controlled by the (unmarked) nominative subject, as in (6), from those controlled by the accusative object, as in (2). Agreement is also attested for depictives with controllers in oblique cases (see section 2.4):

(6) Martuthunira (Ngayarda, PN):
Manku-marni ngunhaa$_i$ pungka-lha-rru nhurnti-rru$_i$.
grab-CONTR that.NOM fall-PAST-NOW dead(NOM)-now
'I would have grabbed [it] but it fell down dead.' (Dench 1995: 264)

Since many Australian languages allow double case marking (Dench and Evans 1988; Plank 1995), case agreement is possible even if an adjunct already takes a case marker indicating its thematic role, such as the similative marker in (7). Here the phrase *dimana-marraj* 'like a horse' is marked as a depictive secondary predicate through agreement; in other words, it is construed as a predication on the man. A paraphrase that captures this relationship is 'the man eats as if he was a horse (at the time of eating)':

(7) Jaru (Ngumpin-Yapa, PN):
Jalu mawun-du mangarri ngany-an dimana-marraj-ju.
that man-ERG plant.food eat-PRS horse-SIMIL-ERG
'That man eats food like a horse.' (Tsunoda 1981: 231)

Double case marking resulting from agreement is also found on constituents which one might be inclined to analyze as adverbials, not as secondary predicates, on semantic grounds; for example, *manyi-nhingi-ngga* 'after food' in (8):

(8) Gooniyandi (Bunuban, NPN):
Yiganyi wardjawinbirra manyi-nhingi-ngga.
uncertain they:might:take:you food-ABL-ERG
'They could take you after (they have eaten) food.' (lit.: 'from food')
(McGregor 1990: 342)

Languages with extensive agreement on adjuncts thus raise the question whether agreement should be regarded as the major criterion for the status of an adjunct as a secondary predicate. In this case, even adjuncts like the one in (8) have to be regarded as secondary predicates. Alternatively, it may be possible to distinguish secondary predicates and adverbials on the basis of other formal properties (see section 3.3). A further problem arises in languages which allow discontinuous noun phrases, since depictive secondary predicates exhibiting agreement can no longer be distinguished from modifiers in a discontinuous noun phrase by word order alone (see section 3.1.2).

2.3 Secondary predication and switch-reference

Warlpiri and several other Australian languages exhibit a particular type of argument-oriented subordinate clause which has received some attention in the literature

(cf. Austin 1981b; and for Warlpiri: Hale 1982: 290–294, 1986: 245–247; Simpson and Bresnan 1983; Simpson 1988, 1991: 314ff.; Hale et al. 1995). It is headed by a non-finite verb form (see also section 2.5.2) or (more rarely) by a nominal, followed by a suffix which simultaneously encodes relative tense (e.g., a simultaneous, anterior, or subsequent/purpose clause) and serves to identify the controller of the subordinate clause. Example (9) illustrates subordinate clauses interpreted as simultaneous (SIM) to the matrix clause in Warlpiri. In (9a), the subject complementizer (SCOMP) *-karra* indicates that the controller is a subject; in addition, the complementizer is here followed by the ergative case in agreement with a transitive subject. In both (9b) and (9c) the subordinate clause is controlled by the object of the matrix clause. The subordinate clause in (9b) does not take an overt agreement suffix because the controller is an unmarked absolutive object, but in (9c), it takes dative case in agreement with the dative object. Note that the 'object complementizer (OCOMP)' suffix *-kurra* in Warlpiri is identical to the allative case. This is not an accidental coincidence, because the use of the allative as a marker of object control is an areal feature which is also found in other northern Australian languages which are not necessarily related to each other, including Wardaman (Merlan 1994: 287–289; see example (23)), Jaminjung (Schultze-Berndt 2000: 112–113), Kaititj (Austin 1981b: 326), and Bilinarra (Nordlinger 1998: 165):

(9) Warlpiri (Ngumpin-Yapa, PN):

a. Wati-ngki$_i$ marlu nya-ngu parnka-nja-karra-rlu$_i$.
man-ERG kangaroo(ABS) see-PAST run-INF-SCOMP.SIM-ERG
'The man saw the kangaroo (while the man was) running.'
(Hale et al. 1995: 1442)

b. Wati-ngki marlu$_i$ nya-ngu nguna-nja-kurra$_i$.
man-ERG kangaroo(ABS) see-PAST lie-INF-OCOMP.SIM
'The man saw the kangaroo lying.' (Hale et al. 1995: 1442)

c. Punta-rni ka-rla tala-patu [jaja-nyanu-ku
take.away-NPAST PRS-3.IO money-PL grandmother-self-DAT
wiyarrpa-ku]$_i$ [jarda-nguna-nja-kurra-ku]$_i$.
poor-DAT sleep-lie-INF-OCOMP.SIM-DAT
'He takes money from his poor grandmother (while she is) asleep.'
(Simpson 1991: 394)

Since these constructions are restricted to controllers in a specific function, they have been used as evidence of grammatical relations (subject and object) in languages like Warlpiri (see section 2.4). Moreover, the additional agreement marking suggests that subordinate clauses of the type illustrated in (9) function as depictive secondary predicates. This is indeed the analysis proposed by Simpson (1988, 1991), Laughren (1992), Hale (1994), and Hale et al. (1995). They choose the term 'eventive' secondary predicate (as opposed to stative secondary predicate) for this construction because of the additional component of relative tense (in this case, simultaneity). This component is clearly contributed by the suffix, not by the fact that the predicate is a deverbal form, as shown in (10), where the subordinate clause is headed by a nominal. Only (10a), where the

secondary predicate is unmarked in agreement with the absolutive controller, and not (10b) can be interpreted as stating that the controller (the woman) is in a sick state. The object complementizer suffix *-kurra* in (10b) enforces an 'eventive' reading, captured in the translation as 'involved with the sick one':

(10) Warlpiri (Ngumpin-Yapa, PN):
  a. Wati-ngki karnta$_i$ nya-ngu nyurnu$_i$.
  man-ERG woman(ABS) see-PAST sick
  'The man saw (that) the woman (was) sick.' (Hale et al. 1995: 1442)
  b. Wati-ngki karnta$_i$ nya-ngu nyurnu-kurra$_i$.
  man-ERG woman(ABS) see-PAST sick-OCOMP.SIM
  'The man saw the woman involved with the sick one.'
  (Hale et al. 1995: 1442)

A number of authors, including Austin (1981b), Hale (1982, 1994) and Simpson and Bresnan (1983), on the other hand, have analyzed the same set of constructions as a same-subject construction and a different-subject construction (also termed 'obviative') in a switch-reference system. The subordinate clause marked by *-karra* indicates that its controller is the main clause subject, i.e., the two clauses have the same subject, whereas the subordinate clause marked by *-kurra* has a subject which is different from the main clause subject (i.e., a main clause object). In addition, Warlpiri also has two further contrasting markers of simultaneous subordinate clauses (Hale 1986). The first (*-ngkarni/-rlarni*, here simply glossed as SIM) allows a free choice of controller, although usually the controller is not a subject or object (11a). The second (*-rlajinta*, identical to the comitative case) may have the same subject (as in (11b)) or a different subject compared with the matrix clause, but encodes a simultaneous event which is, as it were, 'accidentally' simultaneous, and not ascribed to an argument in the main clause event (Simpson and Bresnan 1983: 60). Consequently, the first but not the second construction shows (optional) case agreement with the controller (compare (11b), with no ergative agreement, with (9a) above):

(11) Warlpiri (Ngumpin-Yapa, PN):
  a. Ngarrka-ngku ka-rla kurdu-ku$_i$ karli
  man-ERG PRS-3.IO child-DAT boomerang(ABS)
  kaji-jarnti-rni manyu-ngkarni(-ki)$_i$.
  BEN-trim-NPAST play-SIM-(DAT)
  'The man is trimming the boomerang for the child (while it is) at play.'
  (Hale 1982: 299)
  b. Ngarrka-ngku-nyanu ramparl-paju-rnu karli
  man-ERG-REFL mistake-cut-PAST boomerang(ABS)
  jarnti-rninja-rlajinta.
  trim-INF-COMIT
  'The man accidentally cut himself while trimming the boomerang.'
  (Hale 1982: 292)

In functional terms, we are therefore dealing with a switch-reference system which does not just show a binary contrast between 'same-subject' and 'different-subject', but distinguishes between same-subject (*-karra*), subject = object (*-kurra*), and free-subject (*-ngkarni/-rlarni)* categories. In addition, these are in opposition to a non-controlled simultaneous clause (*-rlajinta)*. Formally, the first three categories can also be analyzed as depictive secondary predicates controlled by the subject, the object, and a free controller, respectively, while the fourth type of subordinate clause, which does not exhibit a necessary relationship to a controller, is an adverbial. Thus, the analyses of Warlpiri non-finite subordinate clauses as switch-reference constructions and depictive constructions are complementary rather than contradictory. A similar system, where a switch-reference system can be seen as emerging from the contrast of various subordinate clause types with different control properties, is described for Martuthunira by Dench (1988, 1995: 240–262).

The secondary predicate analysis of a subordinate clause of this type is only warranted, however, when it is obligatorily controlled, i.e., when it cannot have its own subject. A true same-subject construction which is not a secondary predicate but an adverbial clause is found in the central Australian language Arrernte, although arguably the same-subject marker *-le* (which is identical to the ergative marker) represents a generalized former agreement marker (Wilkins 1988). Considering only (12a), one might be tempted to analyze the subordinate predicate as a true depictive secondary predicate which is followed by the ergative marker *-le* in agreement with the subject of the clause, just as in the Warlpiri example in (9a). However, (12b) shows that the subordinate predicate is not obligatorily controlled, since in the first line of (12b) it appears with its own subject:

(12) Mparntwe Arrernte (Arandic, PN):
   a. Artwe-le [alye-lhe-me-le] kere ite-ke.
      man-ERG sing-DETRANS-SIM-SS meat(ABS) cook-PAST.PERF
      'The man cooked the meat while singing.' (Wilkins 1988: 147)
   b. [Ayenge urrkape-tyekenhe ne-me-le], the [pmere-le
      1SG.NOM work-NEG be-SIM-SS 1SG.ERG camp-LOC
      ne-rlane-me-le] ampe kweke arntarntare-tyerte.
      be-CONTIN-SIM-SS child(ABS) small(ABS) look.after-PAST.HABIT
      'When I wasn't working, I used to stay at home and look after the baby.'
      (Wilkins 1988: 153)

2.4 *The syntactic function of the controller*

In English, depictives can be controlled by the subject of an intransitive or transitive predicate and by the object of a transitive predicate (cf., e.g., Aarts 1995: 76). This has sometimes been claimed to reflect a universal syntactic restriction, or alternatively, a restriction on the thematic role of potential controllers (e.g., to theme, agent, and patient; see chapter 58). However, languages differ considerably with regard to which arguments are easily accessible as controllers. For example,

Finnish regularly allows oblique controllers (Nichols 1978: 120–121). Some variation in the restrictions on potential controllers is also found in Australian languages (cf. Dench and Evans 1988: 15), although it has to be said that in-depth research on these issues has been carried out only for very few languages. A number of Australian languages with a rich case system and obligatory agreement of secondary predicates also allow datives and other oblique arguments as controllers. In the Warlpiri example in (13), the controller is a dative object; agreement unambiguously signals that the locative phrase encodes the location of the baby, not the food (for locative phrases as secondary predicates, see also section 3.3):

(13) Warlpiri (Ngumpin-Yapa, PN):
Karnta-ngku ka-rla kurdu-ku$_i$ miyi yi-nyi
woman-ERG PRS-3.IO baby-DAT food(ABS) give-NPAST
parraja-rla-ku$_i$.
coolamon-LOC-DAT
'The woman gives food to the baby in the coolamon (carrier dish).'
(Simpson 1991: 206)

Similarly, example (14) shows that in Diyari, a locative-marked oblique argument can be the controller of a depictive: it is the child spoken to, not the speaker, that is described as having no clothes on:

(14) Diyari (PN):
Kupa-nhi$_i$ nganhi yatha-na warra-yi [kathi pani-nhi]$_i$.
child-LOC 1SG.SBJ speak-PART AUX-PRS clothes none-LOC
'I spoke to the child with no clothes on.' (Austin 1981a: 44)

In (15a), from Martuthunira, the controller is a directional adjunct marked with the allative case. Here the presence of the temporal clitic *-l* enforces a predicative reading of the phrase *kupuyu-mulyarra*; in other words, (15a) cannot just mean 'I used to go to the little town'. The controller of the manner depictive in (15b) is the demoted agent in a passive construction, as indicated by the 'effector' case which in Martuthunira marks passive agents:

(15) Martuthunira (Ngayarda, PN):
a. Ngayu puni-wayara thawun-mulyarra$_i$ kupuyu-mulyarra-l$_i$.
1SG.NOM go-HABIT town-ALL little-ALL-THEN
'I used to go to town (when it was a) small (place).' (Dench 1995: 59)
b. Nhiyu thuur.ta kanyja-rnu juwayu-la kartarr-u paju.
this.NOM fruit(NOM) hold-PASS.PART hand-LOC tight-EFF really
'This fruit has been held in hand really tightly.' (Dench 1995: 234)

Data from Australian languages thus raise problems for the claim that restrictions on the controllers of secondary predicates are universal. It seems more likely that the potential for functioning as a controller follows the accessibility hierarchy for grammatical relations (Keenan and Comrie 1977), as has been

suggested by Nichols (1978: 120). The conditions under which oblique arguments and adjuncts can function as controllers remain a matter for further investigation.

Example (15b) also shows that the controller – in this case, the demoted agent – does not have to be overtly expressed. On the basis of comparable Warlpiri data, Laughren (1992) argues that the secondary predicate does not enter a predicative relation to a surface constituent of the clause, but rather to an argument in Lexical Conceptual Structure. Note that this observation is not restricted to Australian languages; in languages like German and English, likewise, depictives without overt controllers can be found, for example when the controller is an argument in an infinitival construction (e.g., in *not to be eaten raw*).

The conclusion that the controller is a semantic rather than a syntactic argument is further supported by the observation that agreement of secondary predicates, even in the case of overtly expressed controllers, is not simply a surface phenomenon resulting in identical case marking of two surface constituents. The case marking on the depictive reflects the semantic role of the controller rather than the marking of the corresponding NP constituent. For example, since ergative marking of agents in a transitive clause is optional in Gooniyandi (McGregor 1992b, 1998), the subject NP *goornboo* 'woman' in (16) is unmarked, whereas the depictive controlled by the subject takes ergative case:

(16) Gooniyandi (Bunuban, NPN):
Goornboo$_i$ thirri gardboowoona yoowooloo-jangi-ngga$_i$.
woman fight she:belts:them man-SIMIL-ERG
'The woman fights like a man.' (McGregor 1990: 346)

Secondary predicates – more precisely non-finite subordinate clauses of the type discussed in section 2.3 – have also been used as one of the tests for the existence of grammatical relations like subject and object in the languages in question (in particular Warlpiri), including dative objects as in (9c). First, the non-finite subordinate clause is marked differently according to whether the controller is a subject, an object, or neither; and second, the non-overt, controlled argument always has to be the subject of the subordinate clause (cf. Hale 1982: 294, 1994; Simpson and Bresnan 1983; Simpson 1988, 1991: 314; Laughren 1989: 330–336, 1992: 202; Speas 1990: 160–162). Having clear syntactic tests for grammatical relations is, of course, important in languages where subject and object are identified neither by their syntactic position (because of the 'non-configurational' nature of the language in question) nor directly by case marking (because the language is, like Warlpiri, morphologically ergative).

2.5 *Word class and internal structure of depictive secondary predicates*

Depictive secondary predicates can be classified according to their marking (e.g., agreement – see section 2.2 – or marking for control and relative tense – see section 2.3), but they can also be subdivided according to their word class and

internal structure. In this respect, too, one is forced by data from Australian languages to reconsider the range of constructions to be analyzed as secondary predicates.

2.5.1 Nominal and adjectival secondary predicates

In the standard examples found in the literature, e.g. (1), depictives are simple adjectives, and occasionally adjectival phrases. Not surprisingly, in Australian languages we also find corresponding examples where the secondary predicate is adjectival in that it encodes a temporary state or condition; examples are (2), (5), and (6).

It has often been claimed that only (adjectival) predicates encoding a temporary state, not predicates encoding a permanent quality or property, may function as depictives. Following Carlson (1977a), Stump (1985), and Kratzer (1995), the two types of predicates are also known as *stage-level* vs. *individual-level predicates* (see chapter 58). Compare (17a) and (17b):

(17) a. The snake ate the mouse alive. (stage-level predicate)
b. ??The snake ate the mouse bony. (individual-level predicate)

In many Australian languages, though, there is no clear morphosyntactic distinction between adjectives, nouns, and adverbs, which are just subclasses of nominals. Consequently, both stage-level predicates and individual-level predicates, e.g., common nouns, can be used as depictives (cf. Hale 1983; Simpson 2005). In (18), the nominal *ngarrka* 'man' predicates on the object of a perception verb. As Hale (1983: 32) states, this interpretation "is perfectly natural in a variety of situations, including, for example, that in which the speaker sees a male person (formerly 'a boy') after his initiation (now 'a man'. . .)":

(18) Warlpiri (Ngumpin-Yapa, PN):
Ngarrka ka-rna nya-nyi.
man(ABS) PRS-1SG.SBJ see-NPAST
'I see him as a man.' (Hale 1983: 31–32)

In English, as the translation of (18) shows, an NP has to be marked with *as* in order to serve as a secondary predicate. According to Stump (1985: 272–277), the predicative marker *as* is an explicit device turning individual-level predicates into stage-level predicates. Warlpiri, however, appears to lack this strict stage-level/individual-level distinction. (Note that the restriction of depictives to stage-level predicates has to be given up in any case if the version of the pronominal argument hypothesis is adopted according to which all lexical expressions are secondary predicates, or if 'part' expressions are also analyzed as depictives; see sections 3.1.1 and 3.2).

In addition to simple nominals and adjectivals, there are good reasons for also analyzing many types of case-marked noun phrases and adpositional phrases as secondary predicates; these are discussed in section 3.3.

2.5.2 *Deverbal secondary predicates*

In many languages, not only nominals but also non-finite verb forms can serve as depictive secondary predicates. This is well known for the so-called participles of English and many other European languages, which function just like adjectives in that they can be used as attributes, as main predicates, and as adjuncts (consider *Joy arrived drunk*, with a past participle functioning as secondary predicate). For non-finite verb forms which are restricted to adjunct function (but which cannot be used as attributes), the term *converb* has been suggested in the literature (cf. Haspelmath and König 1995).

Some Australian languages have a wide range of converb constructions. (Other languages do not have non-finite verb forms at all.) These converb constructions include not only simple deverbal predicates, but also more complex constructions, i.e., subordinate clauses. A subset of these can be identified as secondary predicates: first, by the fact that they are obligatorily controlled, i.e., they do not allow their subject to be overtly expressed; and second, by case agreement with their controller. However, in grammatical descriptions and theoretical accounts of these deverbal constructions, they are variously analyzed as adverbials, depictive secondary predicates, or subordinate clauses with switch-reference marking (see also section 2.3).

A possible objection to the analysis of obligatorily controlled converbs and converb clauses as secondary predicates is based on the fact that these deverbal forms typically express 'relative tense', e.g., simultaneity or anteriority. Standard depictives, on the other hand, express a temporary condition or state. In order to analyze converb constructions – especially when they show agreement with a controller – as depictive secondary predicates, one therefore either has to show that they encode a state despite the relative tense marking, or extend the notion of secondary predication.

Some authors recognize certain converb clauses as secondary predicates and use the term 'eventive' secondary predicate, e.g., for subordinate clauses in simultaneous interpretation (see section 2.3). A simultaneous converb, just like the present participle *laughing* in *Joy left the party laughing*, can be interpreted as encoding a state – the state of being in the process of (simultaneously) performing an event.

Similarly, an anterior deverbal predicate (such as the English past participle *drunk*) or a clause headed by an anterior form can be regarded as encoding a post-state of the event which is denoted by the lexeme from which it derives. This post-state holds simultaneously to the event encoded by the main predicate, and it is ascribed to the controller. In many Australian languages, anterior deverbal forms (just as in Latin and other Romance languages) agree in case with a controller. For example, in Kayardild, anterior deverbal predicates are formed by adding both a resultative suffix and a nominalizer ('NR') to the verb stem. The resulting forms can be used as simple depictives, as in (19a), and as heads of non-finite clauses functioning as depictives, as in (19b) (Evans 1995: 476–480):

(19) Kayardild (Tangkic, NPN):
   a. Nga-l-da wara-tha niwan-ji dara-thirri-n-ji.
      1-PL-NOM send-ACTUAL 3SG.OBJ break-RESULT-NR-OBJ
      'We sent him away circumcised.' (Evans 1995: 333)
   b. Dathin-a dulk-a mirra-a [kajakaja-na
      that-NOM place-NOM good-NOM daddy-ABL
      wukuwa-thirri-n-d].
      work-RESULT-NR-NOM
      'That place (garden) is lovely (having been) worked on by daddy.'
      (Evans 1995: 479)

Subordinate (converb) clauses encoding subsequent or intended events which show case agreement are also found in some Australian languages, including Kayardild (Evans 1995: 419–420), Yukulta (Keen 1983: 247), Warlpiri (Hale 1982: 281–289; Nash 1986: 261), and Yankunytjatjara (Goddard 1985). Most of these languages distinguish a purposive form marking personal intent (with agreement) from a general purposive (without agreement), which is used to indicate conventional, socially recognized purposes, and which is also found in 'different subject' expressions. The difference is illustrated in (20) for Yankunytjatjara. The general purposive marker *-ku* is shown in (20a) in 'different subject' function (the people who pour the petrol are not identical with the people who intend to return). In contrast to the general purposive, the 'intentive' marker *-kitja* always triggers agreement marking with the subject in absolutive or ergative case, respectively. It is used when the purpose of an activity is ascribed to the subject, and when, at the same time, this purpose is not obvious, i.e., when it is not conventionally recognized, but rather ascribed to the personal motivation of the agent. Thus, the 'intentive' indicates that getting firewood in (20b) and taking off the water pump in (20c) are the agent's personal intentions, non-obvious for others:

(20) Yankunytjatjara (Western Desert, PN):
   a. Munu tjuti-ra yunga-nyi kurlpa-nytja-ku.
      and pour-SERIAL give-PRS return-INF-PURP
      'And he will pour (us) some (petrol) for returning (i.e., so that we can go home).' (Goddard 1985: 164)
   b. Wati ya-nu waru urra-ntji-kitja.
      man(ABS) go-PAST fire(ABS) get-INF-INTENT
      'The man went off (because he wanted) to get firewood.'
      (Goddard 1985: 159)
   c. Carburettor-rna arra-rnu water pump-kitja-ngku.
      carburettor(ABS)-1SG take.off-PAST water pump-INTENT-ERG
      'I took off the carburettor wanting the water pump (e.g., mistakenly removed the carburettor, or removed the carburettor to get at the water pump).' (Goddard 1985: 131)

The semantic contrasts involved suggest that the constituents marked by the specific 'intention' markers in Yankunytjatjara and other languages, but not those marked by the general purposive markers, are depictive secondary predicates. Semantically, it is the intention to bring about an event that is predicated on the controller, as indicated by agreement. Thus, while the event represented by the noun phrase or subordinate clause is in a sense subsequent to the event represented by the main predicate, the intention clearly holds simultaneously with the event expressed by the main predicate. The parallel behavior of nominalized verbs (20b) and underived nominals (20c) lends further support to a parallel analysis of nominal and deverbal depictives. (Note that intentive expressions of this type are analyzed as 'subject-oriented NPs' rather than as secondary predicates by Dench and Evans 1988: 17–18; however, the authors do not give clear reasons for the distinction, nor do they indicate which other expression types should be analyzed as subject-oriented NPs.)

2.5.3 Secondary predicates from other word classes

Australian languages also feature secondary predicates that are neither nominal nor (de)verbal. For some languages – e.g., Kayardild (Evans 1995: 231), Martuthunira (Dench 1995: 53), and Yankunytjatjara (Goddard 1985: 57–58) – a nonverbal word class restricted to predicative function has been described. Because its members take nominal inflections in agreement with a controller, these are sometimes subsumed under the class of nominals or adjectives. However, if nominals and adjectives are defined as a class of words that may be used in referential and attributive function, respectively, this term does not apply to the category in question, which is restricted to predicative use without showing the formal characteristics of verbs. Most of these predicates express a condition or a posture. An example from Kayardild is *mibulka* 'asleep', used as a depictive in (21) (the second depictive in this clause, *malangarrba* 'drunk', is a true adjective which may also be used attributively):

(21) Kayardild (Tangkic, NPN):
Mibulk-i kurdala-tha kajakaja-y malangarrba-y.
asleep-OBJ spear-ACTUAL daddy-OBJ drunk-OBJ
'He speared your daddy (who was) asleep and drunk.' (Evans 1995: 333)

In addition, Kayardild has a small class of lexemes which are not only inherently predicative, but restricted to depictive function. That is, words from this class are always used as adjuncts, and in this respect resemble adverbs, but they also obligatorily agree in case with one argument of the clause (Evans 1995: 227–229). Lexical items with similar properties have been described for Warlpiri (Hale 1982: 279–280) and Diyari (Austin 1981a: 107–108), although they are simply considered a subset of nominals by some authors (e.g., Hale 1983; Simpson 1991: 125–129). Semantically, they mainly comprise notions of manner. An example is *parraparra* 'loud, energetic' in Diyari, illustrated in (22):

(22) Diyari (PN):
  a. Wata yini parraparra pithi-ya.
  not 2SG.SBJ energetic(ABS) fart-IMP
  'Don't fart loudly!' (Austin 1981a: 107)
  b. Nhulu karna-li kirra parraparra-li warra-yi.
  3SG.NONF person-ERG boomerang(ABS) energetic-ERG throw-PRS
  'The man throws the boomerang energetically.'
  (Austin 1981a: 107)

A second type of nonverbal predicate constituting a distinct part of speech is also found in (mainly northern) Australian languages, including Warlpiri (Nash 1982; Simpson 1991), Jaru (Tsunoda 1981), Gija (Kofod 1996), Jaminjung (Schultze-Berndt 2000), Wardaman (Merlan 1994), and Wagiman (Wilson 1999). Predicates of this type, termed 'coverbs', 'preverbs', or 'verbal particles' in the literature, form an open class with possibly thousands of members. These differ in morphology and distribution from inflecting verbs (the latter form a closed class in most of these languages). They cannot form the main predicate of an independent main clause, and they only occur as part of a complex predicate together with an inflecting verb, or as the main predicate in a subordinate clause. Some of these subordinate clauses, in turn, can be analyzed as depictive secondary predicates. An example from Wardaman is given in (23). In (23a), the unmarked positional verbal particle *mugurn* 'lie, sleep' forms a complex predicate with an inflecting verb (which happens to be roughly synonymous). In (23b), the same verbal particle takes the allative case, which here, as in Warlpiri (see section 2.3), has an object complementizer function. The resulting expression is a subordinate clause functioning as an object-controlled depictive:

(23) Wardaman (NPN):
  a. Mugurn ya-gurrgba nana bangbun.
  lie/sleep 3SG-sleep.PRS that(ABS) woman(ABS)
  'The woman is sleeping.' (Merlan 1994: 441)
  b. Ngon-mowojba-rri mugurn-garr.
  3SG.SBJ:1SG.OBJ-sneak.away-PAST lie/sleep-ALL/OCOMP.SIM
  'He left me sneakingly (while I was) asleep.'
  (Merlan 1994: 287)

To summarize: in Australian languages, parts of speech found in secondary predicate function include not only nominals and adjectivals, but also deverbal predicates, the verbal particles (or preverbs/coverbs) found in the northern area, and, in some languages, a class of 'manner nominals' which show obligatory case agreement but only appear in adjunct position and can therefore be analyzed as a distinct part of speech restricted to depictive function. Likewise, the internal complexity of the secondary predicate may vary; there is some evidence that case-marked NPs or adpositional phrases and subordinate clauses should be considered depictives.

3 What counts as secondary predication?

3.1 Secondary predication and non-configurationality

Australian languages, and in particular Warlpiri, have played a prominent role in discussions of non-configurationality, e.g., Blake (1983), Hale (1983, 1989, 1992, 1994), Jelinek (1984), Heath (1986), Nash (1986), Laughren (1989), Speas (1990), Simpson (1991), Austin and Bresnan (1996), Baker (1996, 2001), and Austin (2001). Many Australian languages have properties which contrast sharply with the properties of configurational languages such as English: they have free word order, they freely allow zero anaphora (i.e., omission of lexical arguments), and clauses have a 'flat' syntactic structure (i.e., there is no evidence for a category verb phrase). While it has recently been recognized that non-configurationality is not a unified phenomenon (cf. Austin and Bresnan 1996; Baker 2001), these features were originally conceived of as being in correlation. The formulation of a Configurationality Parameter (Hale 1983) was based on languages like Warlpiri where these features do in fact coincide.

Jelinek (1984) proposes to link free word order and zero anaphora, as well as a number of other phenomena such as split case marking, to the presence of clitic pronominals in Warlpiri. According to Jelinek's proposal, known as the pronominal argument hypothesis, bound or clitic pronominals have argument status in non-configurational languages, while the corresponding noun phrases are analyzed as adjuncts which are licensed by the pronominal arguments but which do not have argument status themselves. Building on this analysis, it has occasionally been argued that the adjunct noun phrases are in fact secondary predicates (section 3.1.1).

Languages which exhibit another feature often associated with non-configurationality – the possibility of discontinuous expressions – pose a further problem for the theory of secondary predication. This is the problem of distinguishing between attributes in a discontinuous noun phrase and depictive secondary predicates (section 3.1.2).

3.1.1 The status of nominal expressions in non-configurational languages

Jelinek (1984) suggests that in head-marking non-configurational languages like Warlpiri, only the clitic pronominals – which in (24) are attached to the tensed auxiliary – have argument status, not the nominal expressions (e.g., *maliki ngaju-nyangu* 'my dog' and *kuyu* 'meat' in (24)). Under this analysis, a configurational structure for a clause like (24) can be maintained:

(24) Warlpiri (Ngumpin-Yapa, PN):
[Maliki ngaju-nyangu-ku] ka-rna-rla kuyu yi-nyi.
dog 1SG-GEN-DAT PRS-1SG.SBJ-3SG.IO meat(ABS) give-NPAST
'I am giving meat to my dog.' (Hale 1994: 189)

Jelinek's proposal has later been modified (e.g., by Baker 1996) to the effect that the real arguments are empty categories (*pro*) which license agreement of the bound or clitic pronominals. Under both versions of the pronominal argument hypothesis, various solutions have been proposed for the status of the overt nominal expressions. Jelinek (1984) originally analyzed them as adjuncts which are 'ad-argumental' because they are co-indexed with a (pronominal) argument. Speas (1990: 165–170) then suggests – again, with reference to Warlpiri – that they could be analyzed as secondary predicates, conceived of as modifiers undergoing theta-merger of their argument with one of the arguments in the verbal grid. This analysis relies on the presence of case markers – considered as argument-taking predicates – in Warlpiri and related languages.

Baker (2001) defends the secondary predicate analysis of overt nominal expressions in non-configurational languages, at least for languages of the Warlpiri type, which he distinguishes from languages whose non-configurational properties result from scrambling or dislocation. One of Speas's and Baker's main arguments in support of the secondary predicate analysis is that this type of structure is needed, in any case, in order to account for the use of nominals as secondary predicates in Warlpiri in examples like (18). Baker (2001: 428–433) further claims that because of the lack of a distinction between nouns and adjectives in Warlpiri (see section 2.5.1), all nominals are really adjectival, i.e., "good predicates" and "bad arguments." He explicitly recognizes that this proposal extends the notion of secondary predication far beyond the traditional notion (note that in this approach, *maliki ngaju-nyangu* 'my dog' and *kuyu* 'meat' in (24) are assigned the same status as *alive* in *the snake ate the mouse alive*). Consequently, the restriction that only stage-level predicates can function as depictive secondary predicates (see section 2.5.1) has to be given up. Baker also recognizes that in this account depictive secondary predicates in English and in Warlpiri differ strikingly in their pragmatic function and communicative effect.

Speas's and Baker's analysis therefore deviates from Hale's. Hale (1983) explicitly distinguishes the predicative and the referential or "argumental" use of nominal expressions (thus, he states that (18) also has a second reading 'I see a man'). He also states that the class of nominals/adjectives spans a continuum from items that are more likely to be used referentially (such as determiners or free pronominals) to items that are more likely to be used predicatively, even though he also remarks that the predicative use is much more pervasive in Warlpiri than in English. Nordlinger (1998: 40–41) also cites the existence of "nominals" restricted to secondary predicate function (see section 2.5.3) as evidence against the secondary predicate analysis of all nominal expressions.

Austin and Bresnan (1996), Nordlinger (1998: 34–43), and Austin (2001) raise several other objections to the adjunct analysis of overt nominal expressions. One is that in some languages at least, some types of overt nominals are obligatory (and hence cannot be adjuncts), e.g., dative indirect objects of verbs like *ayani* 'search' in Wambaya, which, as (25) shows, are not cross-referenced by a bound pronominal:

(25) Wambaya (West Barkly, Mirndi, NPN):
Ayani gi-n babanya juwa-nka.
search 3SG.SBJ.PRS-PROG sister(ABS) man-DAT
'(My) sister is looking for a man.' (Nordlinger 1998: 35)

It seems that despite the advantages of the secondary predicate analysis of nominal expressions in non-configurational languages, the ramifications of this proposal for the theory of secondary predication have to be given more careful consideration.

3.1.2 Depictives vs. attributes in a discontinuous noun phrase

Under one definition of non-configurationality, the phenomenon of discontinuous noun phrases is considered an important characteristic of non-configurational languages (cf. Hale 1983). As Austin and Bresnan (1996) have shown, though, not all Australian languages that allow free order of phrases also allow discontinuous noun phrases. In those that do, this raises a problem for the distinction between depictive secondary predicates and attributive modifiers, since it can no longer be drawn in terms of word order alone (Dench and Evans 1988: 14; Schultze-Berndt and Himmelmann 2004: 81–84).

A widely accepted proposal, at least in the Australianist literature, was pioneered by Hale (1981a). This is that attributes in discontinuous noun phrases may have either a 'merged' (i.e., restrictive) or an 'unmerged' (i.e., non-restrictive) reading. Both are illustrated in (26):

(26) Warlpiri (Ngumpin-Yapa, PN):
Maliki-rli 0-ji yarlku-rnu wiri-ngki.
dog-ERG PERF-1.OBJ bite-PAST big-ERG
a. 'The/a big dog bit me.' (merged interpretation)
b. 'The/a dog bit me and it was big.' (unmerged interpretation)
(Hale 1983: 38)

A number of authors, including Nash (1986), Simpson (1991), and Nordlinger (1998), have proposed that non-restrictive attributes should be analyzed just like secondary predicates. It is, however, also possible that the two types of constructions can be distinguished by prosodic means. Austin (1981a: 108) claims that the Diyari clause in (27) with sentence stress on *nganhthi* has the attributive reading, but with a slight intonation break after *nganhthi* and stress on *thungka*, it has the secondary predicate reading. Similar suggestions have been made by McGregor (1992a: 316) and Hale (1994: 193):

(27) Diyari (PN):
Nhawuya nganhthi thungka parni-yi.
DEM.3SG.NONF meat(ABS) rotten(ABS) smell-PRS
a. 'This rotten meat smells.' (attribute)
b. 'This meat smells rotten.' (secondary predicate) (Austin 1981a: 108)

The prosodic properties of discontinuous modifiers in comparison with depictives, and the distinction between non-restrictive modifiers and depictive secondary predicates, remain a matter for further investigation.

3.2 *Part–whole expressions*

There exists a further construction type that has been analyzed as an instance of secondary predication by some authors. In many Australian languages, the preferred way to express the idea that a body part is involved in an event is to treat its 'possessor' as a core argument, i.e., as an external possessor (cf. Dixon 1980: 293; McGregor 1985, 1999; Blake 1987: 94ff.; and several contributions in Chappell and McGregor 1996). The body part (understood in a wide sense, i.e., including other inalienable part–whole relations like names, shadows, etc.) is represented as an additional noun phrase which shows case agreement with the possessor expression. In languages with bound pronominals or pronominal clitics, the possessor can be identified as the core argument or 'syntactically active' argument in that it triggers pronominal agreement. The phenomenon is illustrated in (28) with data from Warrwa for a transitive and an intransitive verb, respectively:

(28) Warrwa (Nyulnyulan, NPN):
a. Dab nandiny-ngayu nimala.
touch 3SG.SBJ:caught-1SG.OBJ hand(ABS)
'He touched me on the hand.' (lit.: 'he touched me hand')
(McGregor 1999: 433)
b. Ngayu nga-lma bingbal nga-nyjan.
1SG(ABS) 1SG.POSS-head(ABS) sore 1SG.SBJ-say/do
'I've got a sore head.' (lit.: 'I do/am sore my-head')
(McGregor 1999: 434)

The grammatical status of the 'part' expression in constructions like these (e.g., *nimala* 'hand' in (28a) and *nga-lma* 'my head' in (28b)) has been a matter of debate in the literature. It has been described both as part of the same noun phrase as the 'whole' expression, and as a separate constituent (cf. Blake 1987: 95ff.). Of those authors who consider the 'part' expression a separate constituent, some follow Hale (1981b) in the view that it functions as a secondary predicate (e.g., Hale 1983: 39–40; Laughren 1992; Ogawa 2001). Indeed, a property that 'part' expressions in this type of construction share with secondary predicates in the narrow sense is the existence of a semantic relationship between an argument of the main predicate and the additional constituent. In the Australian languages under discussion, this semantic relationship is also formally reflected by case agreement.

However, there are also good reasons for distinguishing 'part' expressions and secondary predicates. The secondary predicate analysis has been most explicitly criticized by McGregor (1985), who raises the objection that a 'part' expression can never serve as a main predicate, and is thus not, intuitively, a predicate (the

paraphrase 'he touched me and I am a hand' is as semantically deviant in the Australian languages in question as it is in English). Moreover, what is true of the part is not necessarily true of the whole; in other words, the 'part' expression is not optional, as in the case of true secondary predication. Rather, according to McGregor (1985: 210), the 'part' expression "specifies the EXTENT or LOCUS of the argument's involvement in the action." Harvey (1996) and Schultze-Berndt (2000: 184–186) also reject the secondary predicate analysis of 'part' expressions. Dench and Evans (1988: 13–18), likewise, distinguish the two construction types, although both are subsumed under constructions showing "referential agreement."

3.3 Depictives vs. adverbials

3.3.1 Manner expressions

As shown in sections 2.1 and 2.2, the traditional notion of secondary predication has been extended in a number of ways in order to account for phenomena in Australian languages. Another problem encountered in the analysis of Australian languages is the difficulty of drawing a borderline between adverbials and secondary predicates. For example, in a number of languages expressions which would normally be classified as manner adverbials on semantic grounds belong to a word class restricted to predicative function or even secondary predicate function and show obligatory case agreement (see section 2.5.3). An example of a manner secondary predicate from Diyari is given in (22); another example, from Yankunytjatjara, is given in (29):

(29) Yankunytjatjara (Western Desert, PN):
Wati-ngku wala-ngku / puriny-tju kati-nyi.
man-ERG quickly-ERG/ slowly-ERG take-PRS
'The man is taking it quickly/slowly.' (Goddard 1985: 57)

Dench and Evans (1988: 14–15) distinguish "ascriptive" and "adverbial" secondary predicates, on the basis of the semantic type of adjunct expression and whether it can, in principle, serve as the main predicate in a non-verbal clause. Schultze-Berndt and Himmelmann (2004) and Himmelmann and Schultze-Berndt (2005) present a cross-linguistic survey of adjunct types which have the properties of depictives at least in some languages. On the basis of agreement phenomena in Australian and other languages, they conclude that many expression types may be construed as either argument-oriented (and consequently encoded as secondary predicates) or event-oriented (and consequently encoded as adverbials). In addition to manner expressions and also those types of subordinate 'adverbial' clauses discussed in section 2.3, there are several other expression types that are encoded as secondary predicates in at least some Australian languages. These include quantifiers (McGregor 2005), comitative phrases, (30–31), similative phrases, (7) and (16), locative and directional phrases, (32–33), and even

temporal phrases, (34). All examples illustrate agreement of the adjunct constituent in question with one argument of the main predicate, usually the subject.

3.3.2 Comitative expressions

Comitative expressions, when construed as secondary predicates, e.g., by agreement marking, make explicit the relationship between the comitative argument and the argument of the clause that is said to be accompanied (usually, but not necessarily the subject). An example is (30) from Warlpiri:

(30) Warlpiri (Ngumpin-Yapa, PN):
Kurdu-ngku ka ngurlu kipi-rni karnta-ngkajinta-rlu.
child-ERG PRS mulga.seed(ABS) winnow-NPAST woman-COMIT-ERG
'The child, with the woman, is winnowing mulga seed.' (Hale 1982: 272)

For Kayardild (Evans 1995: 420) and the related language Yukulta (Keen 1983: 247–248; Evans 1995: 421), agreement even extends to the 'theme' participant of verbs of transfer (i.e., the transferred entity) in some cases. The verbs of giving and deprivation in these languages allow for a number of case frames, among them one where the 'theme' takes proprietive case (a marker of concomitance). As shown in (31), this is followed by ergative marking in agreement with the transitive subject. According to Evans (1995: 420), this case frame "stresses the ownership by SUBJ of the thing transferred, either before ('give') or after ('deprive') the transfer":

(31) Yukulta (Tangkic, NPN):
Kunawuna-nganda wuu-ja kulthangarr-urlu-ya.
child.ACC-1SG.SBJ:PAST give-ACTUAL flying.fox-PROP-ERG
'I gave the child a flying fox.' (lit.: 'I presented the child with a flying fox')
(Keen 1983: 248)

3.3.3 Locative and directional expressions

The fact that locative expressions are not necessarily event-oriented (in that they indicate the location of an event as a whole), but can also have an argument-oriented reading (in that they indicate the location of only one of the arguments in an event), has occasionally been noted in the literature, e.g. by Müller-Bardey (1990), Takezawa (1993: 55), and Maienborn (2001). In Warlpiri, a locative expression may (optionally) show case agreement with a controller, as illustrated in (13) and (32). In (32), the man and the boomerang are in the same place, but the location is ascribed to the man, probably because he corresponds to the more prominent argument:

(32) Warlpiri (Ngumpin-Yapa, PN):
Ngarrka-ngku ka jarnti-rni karli ngurra-ngka-rlu.
man-ERG PRS trim-NPAST boomerang(ABS) camp-LOC-ERG
'The/a man is trimming the boomerang in the/a camp.'
(Simpson and Bresnan 1983: 57)

Not only locative expressions but also directional expressions can be understood as predicating on one of the arguments of the main predicate. In (33), the interpretation is that the man is in the state of being oriented in the direction of the sandhill:

(33) Walmatjarri (Ngumpin-Yapa, PN):
Jilji-karti-rlu ma-nya wanyjani yapa-warnti nganpayi-rlu.
sandhill-ALL-ERG AUX-3PL.OBJ leave:PAST child(ABS)-PL man-ERG
'The man left the children on his way to the sandhill.'
(Hudson 1978: 35–36)

3.3.4 Temporal expressions

Temporal expressions constitute the perhaps most puzzling case of expressions whose formal make-up, in at least some languages, suggests an analysis as depictive secondary predicates. Temporal expressions are generally considered a paradigm case of event-oriented adverbials. Still, it is well known that they may agree with an argument of the main predicate in Ancient Greek and in Latin. Some Australian languages, too, have a class of temporal nominals which, at least optionally, agree with the subject in (ergative or absolutive) case. In Warlpiri, this class contains, among others, the terms *jalangu* 'today' and *pirrarni* 'yesterday' (cf. Hale 1982: 281). The latter is illustrated in (34):

(34) Warlpiri (Ngumpin-Yapa, PN):
Ngayi luwa-rnu marlu pirrarni-rli.
just shoot-PAST kangaroo(ABS) yesterday-ERG
'He just shot a kangaroo yesterday.' (Hale 1994: 204)

With regard to Warlpiri examples such as (34), Simpson (1991: 208–209) and also Nordlinger (1998: 118–121) maintain that the temporal expressions are adjuncts which modify the whole clause and do not stand in a depictive relation to the subject. These authors claim that the ergative case on these expressions merely indicates that the clause as a whole contains an ergative subject. Hale (1982: 281), on the other hand, suggests that temporal expressions of this type could be analyzed as depictives, considering that "an entity can be located in a time as well as in a place."

4 Conclusion

If one considers all models and proposals that have been put forward in the analysis of Australian languages, the label 'secondary predicate' has been used for a wide range of construction types, including lexical nominal expressions coreferential with the 'pronominal arguments' in non-configurational languages, 'part' expressions in external possession constructions, and many types of adjuncts (including subordinate clauses) which exhibit case agreement with one

of the arguments of the main predicate. These include a number of expressions that are traditionally analyzed as adverbials on semantic grounds. Australian languages, thus, provide a good test case for any theory of secondary predication, and show particularly clearly that despite the considerable research efforts in recent years, we still lack a universally applicable definition of secondary predicates.

  4.1 General issues
  4.2 The syntactic structure of resultatives
  4.3 The 'direct object' restriction in resultatives, and non-thematic resultatives (including so-called 'fake' reflexives)
5 Conclusion: recent developments

1 Introduction: overview and historical background

1.1 Background and basic data

The study of secondary predicates is important not only because of our interest in adequate descriptive grammars, but because of its theoretical relevance to at least two areas of grammatical theory: predication relations and aspect. This chapter will focus on secondary predication in English, where the construction is constrained in such a way as to make theoretical implications explicit. Where possible, reference will be made to studies in other languages and we will formulate the questions that these studies raise.

Secondary predicates are of two kinds: the so-called depictive predicates, illustrated in (1), and resultatives, illustrated in (2) (where the terminology comes from Halliday 1967):

(1) a. John$_i$ drove the car *drunk*$_i$.
b. Mary ate the carrots$_i$ *uncooked*$_i$.

(2) a. Jane painted the house$_i$ *red*$_i$.
b. Bill wiped the table$_i$ *clean*$_i$.

A depictive predicate attributes a property to its subject which holds of that subject all the time that the event denoted by the matrix verb is going on. Resultatives attribute a property to their subject which holds of that subject at the point that the event denoted by the matrix verb ends or culminates. Thus (1a) asserts that John drove the car and was drunk all the time that the driving event was going on, while (2a) asserts that Jane painted the house and at the end of the painting activity, the house was red. It has been suggested (Simpson 1983) that there is a third kind of secondary predicate, the circumstantial, but this seems essentially to reduce to a depictive predicate under the scope of a modal operator.

Although the existence of what are essentially secondary predicates had been noticed by a variety of grammarians (see, e.g., Jespersen 1954–1958), the earliest detailed description of the phenomenon seems to be in Halliday (1967). In his taxonomy of the grammatical constituents of a sentence, Halliday lists the 'attributive element' (see section 3 of his paper), which is essentially the Adjective Phrase. Among the grammatical uses of the attributive AP that he mentions is the function of ascribing a property to a participant in a process, the nature of which is determined by the meaning of a (non-copula) matrix verb. He makes the crucial distinction, which is expressed morphologically in English by the absence or presence of the adverbial inflection, between an adverb, which gives a property of the process itself, and the attributive (usually adjectival) modifier, which gives a property of a participant in the process; contrast the depictive predicate in (3a) with the adverbial in (3b):

(3) a. John left the room angry.
b. John left the room angrily.

For (3a) to be true requires John to be angry at the time that he left the room, while (3b) is compatible with John leaving the room in an angry fashion, though not actually being angry himself. 'John left the room angrily, although he was actually faking his displeasure' is perfectly felicitous. 'John left the room angry, although he was actually faking his displeasure' is infelicitous. (Secondary predicates can also be semantically distinguished from adverbs which are oriented toward a particular thematic participant, such as *reluctantly*. See discussion in Jackendoff 1972; Napoli 1975; McConnell-Ginet 1982; Geuder 2000; Rothstein 2004.)

Secondary predicates are most characteristically APs, although PP predicates are often found, and there is a restricted set of nominal predicates (examples of both are given in (4)). However, non-adjectival secondary predicates seem more often to be found as resultatives than as depictives:

(4) a. She reached the house out of breath.
b. He left the hospital a shade of his former self.
c. John broke the vase into pieces.
d. He painted the house a violent shade of scarlet.

There appear to be no VP secondary predicates, although it has been suggested that at least some participial modifiers, such as the one in (5), should be treated as secondary predicates:

(5) She walked down the street searching for her wallet.

Depictive and resultative predicates can be distinguished from each other by several syntactic and semantic properties, and attempts to explain these properties have been at the root of most studies of secondary predication.

Depictives can be subject- or object-oriented, as the indexing in (1) indicates, while resultatives can (usually) only be object-oriented. Thus there is no resultative reading of (6) with the meaning that John painted the house and when the house was painted he was tired:

(6) John_i painted the house tired_i.

As was pointed out by Jespersen and Halliday, resultatives in English allow so called 'fake reflexives' in which both intransitive and detransitivized verbs (such as the single-argument form of *drunk*) can take a reflexive object which is not their thematic argument and which is the subject of a resultative predicate, as in (7):

(7) a. He drank himself under the table.
b. The baby cried herself asleep.

(7a) means roughly 'He drank and at the culmination of the drinking event he was under the table' (i.e., too drunk to sit on a chair), and (7b) means roughly 'The baby cried until she was asleep.' These arguments are considered non-thematic because of the ungrammaticality of (8a, b) as opposed to (9) (where (9) should be compared with the examples in (2)):

(8) a. *He drank himself.
b. *The baby cried herself.

(9) a. Jane painted the house.
b. Bill wiped the table.

Further, these non-thematic arguments need not be reflexive:

(10) a. John sang the baby asleep.
b. The audience laughed the players off the stage.

Depictive predicates cannot be predicated of non-thematic subjects; thus (11) cannot have the reading 'John drove while he/Mary was crazy':

(11) John drove himself/Mary crazy.

A fundamental question is whether secondary predication structures are derived through syntactic or lexical operations. An obvious way to describe the semantic effect of secondary predication is that it results in the formation of a complex predicate. Thus whatever operation forms the secondary predication structure in (1a), it results in the formation of a complex predicate *drive the car drunk* which is applied to the subject *John.* Similarly, in (1b), a complex discontinuous predicate *ate . . . uncooked* is applied to the argument *the carrots*, while in (2a) *painted . . . red* is applied to the argument *the house.* However, the complex predicate formation operation can in principle be a lexical or a structural operation, with the complex predicate resulting either from a word-formation rule, or from an operation on either syntactic or semantic structures, applied during the construction of the sentence. Syntacticians (with some notable exceptions, indicated below) have tended to assume a syntactic adjunction structure, based in part on the fact that verb and predicate are never adjacent and never form a constituent (unlike verb–particle pairs), in part on the data in (29a), which indicate that the secondary predicate subject-oriented depictive is not part of the V', and in part on the desire to maintain a unified analysis for all the constructions illustrated above. Semantic analyses (e.g., Dowty 1979) have often assumed a lexical predicate formation rule for resultatives, and remained agnostic about depictives, although Wunderlich (1997a) treats both kinds of secondary predicate constructions as the output of a lexical operation.

1.2 Early generative discussion of secondary predication

Resultative predication became a topic of interest for generative formal semanticists in the 1970s (see, e.g., McCawley 1970; Dowty 1972, 1979; Green 1972). Resultatives were discussed in the context of analyses of the underlying structure of accomplishment verbs. In an aspectual characterization of verbs, 'process' events were divided by Vendler (1967a) into activity verbs heading atelic VPs, such as *run* and *push the cart*, and accomplishment verbs heading telic VPs, such as *paint the room* and *build the castle*. Dowty (1979: 91–99) summarized and developed the arguments for analyzing accomplishment verbs as decomposable into an underlying logical structure [ϕ CAUSE ψ], where ϕ is an activity sentence and ψ contains a sentence embedded under the predicate BECOME. (This is the

so-called 'bisentential analysis of CAUSE'.) Under this analysis, (9a) is analyzed roughly as in (12a), and by analogy (10a) would be analyzed as (12b):

(12) a. [[Jane did some painting to the house] [CAUSE [BECOME [the house painted]]]].
b. [[John did some singing] [CAUSE [BECOME [the baby asleep]]]].

Resultative phrases in general, and non-thematic resultatives in particular, were seen to support this analysis of accomplishments, since (i) sentences such as those in (10) seem to indicate explicitly that the grammatical template ϕ CAUSE[BECOME ψ]] is available in the language, and (ii) non-thematic reflexives show that the template could be used in an overt lexical operation which derives a phrasal accomplishment from an activity verb and an independent resultative predicate.

The intuition that non-thematic resultatives involve the construction of non-lexical accomplishment verbs is at the heart of many later analyses of resultative predication, and a great deal of research into resultatives since Dowty (1979) can be seen as an attempt to make this intuition precise, and to examine its syntactic consequences. Section 3 below discusses this issue in detail.

While interest in secondary predication in the 1970s was semantic, and focused on resultative predication, syntactic interest in secondary predication built up around the beginning of the 1980s. Syntacticians analyzed depictive and resultative predication as different instantiations of the same phenomenon.

Edwin Williams's seminal (1980) paper "Predication" explicitly made the leap of recognizing secondary predication as an instantiation of the same relation that is involved in clausal predication, and opened the way for discussion of what exactly that relation is and how secondary and primary predication differ. Williams (1980) implicitly, and Simpson (1983) followed by Rothstein (1983) explicitly, followed Halliday (1967), who argued that resultative and depictive predication are themselves two instantiations of the secondary predication relation. In this they differed from, e.g., Dowty (1979, 1982a), who argued that resultative predication is the result of a lexical operation of complex verb formation, while depictive predication is adjunct predication.

The syntactic questions about secondary predication which interested syntacticians centered on questions of licensing, and for those working in a Government-Binding framework, the discussion focused, at least initially, on depictive predicates. The questions asked were: (i) where subject-oriented and object-oriented predicates are generated, and (ii) whether the predicate is a sister of its apparent subject, or whether it forms a small clause with a PRO subject, where PRO is obligatorily controlled by the apparent subject. Thus (13b, c) were competing structures for the object-oriented reading of (13a):

(13) a. John met Mary$_i$ angry$_i$.
b. John [met Mary$_i$ angry$_i$]$_{VP}$.
c. John [met Mary$_i$] [PRO$_i$ angry]$_{SC}$.

Co-indexing in (13b) indicates predication, while in (13c) it indicates obligatory control. (Since we will not discuss the issues involved in determining the categorial status of small clauses here, I purposely do not indicate either the syntactic position or the categorial properties of small clauses, but label them 'SC'. See also the discussion in section 3.1 below.)

Government-Binding theory in the early 1980s, following the lead of Chomsky (1981), essentially came down in favor of (13c), with the exceptions being the work of Williams (1980, 1983a, and succeeding papers), Rothstein (1983), and Schein (1995). The point of contention was the status of the theta-criterion, i.e., the constraint on the assignment of thematic roles. Chomsky (1981) argued that the theta-criterion was essentially to be formulated as follows:

(14) **Theta-criterion** (Chomsky 1981):
   (i) Every argument must be assigned one and only one thematic role.
   (ii) Each thematic role must be assigned to one and only one argument.

This formulation rules out the possibility of one nominal argument being simultaneously the argument of more than one lexical head, and thus (13b) is immediately an illegal structure. Linguists who argued in favor of (13b) were forced to reformulate the theta-criterion in such a way as to allow double theta-marking in the case of secondary predication. Williams (1983a) argued that the domain of the theta-criterion should be the argument structure of the lexical head, ruling out the possibility of an argument being assigned two thematic roles by a single head, but allowing two separate heads to share an argument. Similar proposals were explored by others.

Linguists who accepted the theta-criterion as in (14) and thus adopted structure (13c) were forced to deal with a different problem, namely what position in the tree would allow the PRO subject of the small clause to be ungoverned. The difficulty in answering this question led some (including Chomsky himself) to argue that there were cases in which PRO was not ungoverned. Discussion of depictive predicates focused on these structural issues, although there was some discussion also of the semantic constraints on depictive predication, in particular of the apparent constraint that the depictive has to denote a 'transitory' or possibly stage-level property (Rothstein 1983; Rapoport 1991, 1999b). For the most part, however, discussion of depictive predicates centered on the structural issues, while discussion of resultatives stayed mostly in the domain of lexical semantics. It was argued that the 'direct object restriction' on resultatives could not follow from purely structural considerations, but must follow from aspectual considerations, such as the role of the direct object in 'measuring out' or determining the telic point of the event denoted by the verb, and the role of the resultative itself in delimiting the verb. See Tenny (1987, 1994), Levin and Rappaport Hovav (1995), and others.

Work in the 1990s began to discuss the semantic relationship between depictives and resultatives, moving the discussion of secondary predication as a general phenomenon back from the domain of predication theory to the domain of theories of aspect.

The structure of this chapter is as follows. Section 2 discusses the syntactic issues raised by secondary predication. This section is largely about secondary predicates and predication theory in general. Section 3 focuses on syntactic discussion of depictive predication, and section 4 on resultatives. Section 5 discusses some more recent developments in theories of secondary predication, which bring the topic squarely back into the domain of theories of aspect.

2 Secondary predication as a form of predication

2.1 Williams's theory of predication

Williams (1980) is a crucial point in the development of the theory of predication in general. He argues that predication is a relation between a maximal projection and a nominal argument, and that the relation is to be defined in terms of thematic role assignment:

(15) A predicate α is a maximal projection which assigns an external theta-role. The subject of a predicate α is that NP which is assigned a thematic role by α.

He furthermore claims that there is a strict structural relation between subject and predicate, namely that the subject must c-command and be c-subjacent to the predicate, where α c-commands β if every branching node which dominates α also dominates β, and α does not dominate β, and where α is c-subjacent to β if β is dominated by no more than one branching node which does not dominate α. Thus, Williams proposes that the predication relation should be defined in terms of thematic relations which themselves can be regulated by configurational relations. He makes several predictions about possible distribution of secondary predicates; in particular, the configurational c-command constraint rules out the possibility of prepositional objects being the subjects of secondary predication, and thus predicts the contrasts in (16) and (17), as well as others (on the assumption, which is supported by syntactic arguments, that the secondary predicate in (16b) is not inside the PP):

(16) a. I presented it to John dead.
b. *I presented John with it dead.

(17) a. John loaded the wagon full with hay.
b. John loaded the hay into the wagon green.
c. *John loaded the wagon with hay green.
d. *John loaded the hay onto the wagon full.

Examples like (18), however, indicate that there are thematic constraints on what the subject of a depictive can be, since (18b) is as unacceptable as (18a). On the basis of this kind of example, Williams argues that within the VP the secondary predicate is predicated of the theme:

(18) a. *John gave the book to $Mary_i$ $sick_i$.
b. *John gave $Mary_i$ the book $sick_i$.

2.2 *Rothstein (1983) and syntactic predication*

Rothstein (1983) argues that the predication relation is a essentially a non-thematic relation, and that this shows up in the fact that predicates can be predicated of pleonastic subjects, as in the small clause in (19):

(19) a. John considers it unlikely that they will arrive on time.
b. They made it impossible for anyone to win the lottery.

Rothstein argues that secondary predication is an instantiation of the same relation as clausal, or primary, predication, but that for reasons to do with licensing, there must also be a thematic relation between the secondary predicate and its subject. Primary predicates form a constituent with their subjects, and this constituent is licensed either by being tensed, or by being theta-marked, as in the case of small clauses such as those illustrated in (19). Secondary predicates do not form a constituent with their subjects (following the structure in (13b)), and are essentially adjuncts. The adjunct is licensed because it is predicated of an argument which is independently licensed as the thematic argument of another head.

2.3 *Are secondary predicates constituents of small clauses?*

The general syntactic issue discussed in Government-Binding theory concerns whether or not a secondary predicate is generated as the daughter of a small clause. The issue concerns both depictive and resultative predicates, but for the most part, discussion in the GB literature has centered on depictives. Chomsky (1981: chapter 2.6) briefly discusses depictive predicates in the context of the correct formulation of the theta-criterion. As noted above, *Lectures on Government and Binding* proposes that the theta-criterion, or condition on thematic role assignment, is a bi-uniqueness condition, formulated as in (14), repeated here as (20):

(20) **Theta-criterion** (Chomsky 1981):
(i) Every argument must be assigned one and only one thematic role.
(ii) Each thematic role must be assigned to one and only one argument.

Chomsky notes that Williams's examples of secondary predicates (from Williams 1980) are a problem for this principle, and proposes that in order to maintain the bi-uniqueness of the theta-criterion, the secondary predicate should be predicated of a PRO subject, and the correct interpretation of the subject should be given by the theory of control. Examples are given in (21), where (21b) is ambiguous between a subject-oriented and an object-oriented reading:

(21) a. John [left the room]$_{VP}$ [PRO angry].
b. John [met Mary]$_{VP}$ [PRO angry].

Chomsky distinguishes structurally between secondary predicates, which occur in adjunct small clauses, as in (21), and small-clause complements, such as those in (22) where the subject of the small clause is not the thematic argument of the matrix verb, and where the subject cannot be PRO:

(22) a. John considers [Mary a genius].
b. *John considers [PRO a genius].

Since (22b) is ruled out by the condition that PRO must be ungoverned, the structures in (21) require the small clause containing the depictive to be in an ungoverned position. As section 3.1 shows, there is strong evidence that secondary predicates in general must be inside the VP, with object-oriented predicates generated under V′. This means that under standard definitions of government, in which a head α governs everything which α m-commands (i.e., which is dominated by the maximal projection which α heads), it is impossible for the small clause to be in a non-governed position (see discussion in McNulty 1988). Chomsky does not discuss this in detail, but he raises the possibility that while theta-marked small clauses are transparent for government, and thus cannot have a PRO subject, non-theta-marked small clauses are opaque for government, so that their subject position is not governed and allows PRO. The position that (21) is the correct structure for secondary predicates is held also by Safir (1983), Stowell (1983), Hornstein and Lightfoot (1987), and, more recently, Franks and Hornstein (1992), who draw on data from Russian, and Legendre (1997), who draws on data from French to argue that secondary predicates are constituents of small clauses that are projections of the functional head Gender, and that the small clause is thus a Gender Phrase.

Williams (1980, 1983a, 1987), Schein (1995), and Rothstein (1983, 1995, 2001a) all reject the structural proposal in (21), and assume that the secondary predicate is generated without a subject, as a daughter of some projection of the V. Williams (1983a) argues explicitly against small clauses in either the cases illustrated in (21) or the ECM verbs represented by *consider* in (22). Schein takes the same position, while Rothstein (1983, 1995) argues that (22) is the correct structure for thematically marked small-clause complements of ECM verbs, but that there is no small clause in the case of adjunct predicates. The authors bring several arguments in against (21). Williams (1983a) argues that the correct way to capture the thematic independence of the secondary predicate from the main predicate is not to give it a PRO subject, but to revise the theta-criterion so that it states that no argument may be theta-marked more than once by the same head. Schein (1995) argues that non-thematic resultatives such as those illustrated in (23), where the argument of the secondary predicate is not theta-marked by the verbal head, presumably form small clauses with their subjects on Chomsky's theory, yet

although these small clauses are not theta-marked, they cannot have PRO subjects, as (24) shows:

(23) a. John ran the soles off his shoes.
b. Bill sang the baby asleep.

(24) a. *John ran PRO off his shoes.
b. *Bill sang PRO asleep.

Rothstein argues that there is good reason to assume that small clauses must be licensed by theta-marking, and that in (21), there is no way to license the small clauses. She uses the structural distinction between adjunct predication and complement small-clause predication to argue for the distinction between primary and secondary predication; primary predication occurs when the subject and predicate form a constituent, and it is a condition on primary predication that the subject is not theta-marked outside the constituent in which it occurs. On this account, (21) is inadequate, since it makes it impossible to distinguish between primary and secondary predication. (She discusses the problem of how to license the small clauses in (23) in Rothstein 2001a.) Other linguists have argued for and used a non-small-clause analysis of secondary predication; these include Roberts (1988a), Napoli (1989), Speas (1990), Carrier and Randall (1992), and Neeleman (1994a), who argues that in Dutch the predicate and the verbal head form a complex predicate. Obviously, studies of secondary predication within a framework such as Lexical Functional Grammar (e.g., Simpson 1983), which do not allow empty categories, have assumed a non-small-clause analysis throughout.

3 Depictives

3.1 Where are depictive predicates located in the tree?

Early syntactic work on secondary predicates for the most part followed Halliday in identifying depictives and resultatives as instantiations of the same mechanism. (As already mentioned, formal and generative semanticists differed from this in arguing from the beginning that resultative predication is the result of a lexical word-formation rule, while depictive predication is the result of syntactic complex predicate formation during the process of derivation. See, e.g., Dowty 1972, 1979, 1982a.) However, syntacticians tended to discuss the syntax of the two phenomena independently. Studies of depictive predication centered on two questions, one syntactic and one semantic. The syntactic question concerns where depictive predicates, and in particular, subject-oriented predicates, occur in the tree (i.e., under V', under VP, or not in the VP at all), and the related issue of the relevance of the mutual c-command constraint (i.e., that subjects and their predicates must c-command each other). This question does not arise with resultatives, since they appear to be predicates of direct objects, or subjects which

have been raised from direct object position (but see the discussion in section 5 below). The issue of syntactic position is independent of the issue of whether secondary predicates have a PRO subject or not, although it is related. If the subject of secondary predicate is PRO and the predicate and subject are part of a small clause, then they by definition c-command each other, and the question of interpreting PRO reduces to control theory. For that reason, the question of whether subject-oriented predicates are within the VP and the apparent conflict between VP-internal predicates and the c-command constraint has most concerned those who argue against a small-clause approach. However, the c-command constraint is also at stake in the analysis of secondary predicates and prepositional objects, as discussed in section 3.2. below. The semantic question focuses on what the semantic restrictions on the choice of depictive predicates are, but this has so far received much less attention in the literature.

Williams (1980) argues that the structural relation between subject and (secondary) predicate is based on c-command: the subject must c-command the predicate and be c-subjacent to it, where α is c-subjacent to β iff β is dominated by no more than one branching node which does not dominate α. Rothstein (1983) argues that the relevant relation is mutual c-command. It is fairly straightforward to argue that an object-oriented depictive is generated under the V′ as a sister to the V and its direct object, as in (25):

(25) Mary $[[\text{ate}]_{V}\ [\text{the carrots}]_{DP}\ [\text{raw}]_{AP}]_{VP}$.

However, the situation is more complicated with subject-oriented predicates as in (26):

(26) John drove the car drunk.

Rothstein (1983) claims that the mutual c-command condition predicts that these subject-oriented predicates are outside the VP, and Schein (1995) proposes the same structure. Schein bases his arguments on facts about agreement in Russian, described in Pesetsky (1982), and on quantifier-variable facts. The Russian data discussed by Pesetsky show that an adjunct predicate which has instrumental case can only be predicated of a direct object, while subject-oriented predicates must be in the nominative form. Schein argues that, under the assumption that instrumental case is assigned under government by V, this implies that a subject-oriented predicate cannot be governed by V, and thus must be outside the VP. Strictly speaking, though, it shows only that instrumental case must be assigned within VP and not that nominative case cannot be assigned to a VP-internal predicate. (See also Franks and Hornstein 1992 and Filip 2001 for more discussion of case-assignment facts with respect to Russian secondary predicates.) Schein also discusses the contrasts in (27):

(27) a. Everyone$_i$ left Mary angrier at herself than he$_i$ thought.
b. *Mary left everyone$_i$ angrier at herself than he$_i$ thought.

In (27a) the pronoun can be bound by *everyone* but in (27b) it cannot, indicating that when the secondary predicate is predicated of the subject, it is higher than the direct object.

However, tests for placement of adverbials presented in Andrews (1982) indicate clearly that these secondary predicates should be part of the VP although placed higher than the object-oriented predicates. This was pointed out in McNulty (1988), Rapoport (1991), Rothstein (1995, 2001a), and others. Andrews uses VP preposing, *though*-movement, and clefting tests, and applied to secondary predicates, the tests show that the secondary predicate is part of the VP:

(28) a. John_i said he would drive the car drunk_i and drive the car drunk_i he_i did.
b. Drive the car drunk_i though he_i did . . .
c. What John_i did was drive the car drunk_i.

However, (29a) shows that subject-oriented depictives may be stranded by pseudoclefting, while (29b) shows that in object-oriented depictives, this is not possible:

(29) a. What John_i did drunk_i was drive the car.
b. *What John did raw_i was eat the carrots_i.

In sum, the data show that a subject-oriented predicate can, but need not, be stranded by pseudoclefting, while an object-oriented predicate may not be stranded. Since, as is well known, pseudoclefting can target either the VP or the V′ constituent, the conclusion to be drawn from (27–29) is that the object-oriented predicate is the daughter of V′, while the subject-oriented predicate is daughter of VP. As such, the subject-oriented predicate will be higher than the direct object and the contrast in (29) will be explained.

Roberts (1988a) uses these facts to argue for VP-internal subjects. He shows that positing the structures in (30) allows one to maintain the mutual c-command constraint on predication, and to put subject-oriented secondary predicates inside the VP, where Andrews's tests predict that they should be:

(30) a. $[\text{e } [\text{Mary}_i \text{ [left the room]}]_{V'} \text{ angry}_i]_{VP}]_{IP}$
b. $[\text{e } [\text{Mary}_i \text{ [ate the carrots}_i \text{ raw}_i]_{V'}]_{VP}]_{IP}$

Rothstein (1995, 2001a) solves the conflict between the mutual c-command condition on predication and the evidence that subject-oriented predicates are VP internal in a different way. She argues that predicates which do not c-command a subject are absorbed into the predicate which dominates them by a syntactic process of complex predicate formation. In the case of *left the room angry, angry* is absorbed into the VP headed by *left* and the whole complex predicate is predicated of the subject. She argues that this is a better solution than Roberts's (1988a), since it applies also to subcategorized predicates, as in (31), which must be included in the V′:

(31) Mary $[[\text{feels happy}]_{V'}]_{VP}$

3.2 The c-command restriction and objects of prepositions

Williams (1980) argues that the c-command restriction rules out predicating secondary predicates of prepositional objects, as in the examples given in (16–17) above and repeated here as (32–33):

(32) a. I presented it to John dead.
b. *I presented John with it dead.

(33) a. John loaded the wagon full with hay.
b. John loaded the hay into the wagon green.
c. *John loaded the wagon with hay green.
d. *John loaded the hay onto the wagon full.

Williams notes the potential counter-example in (34), and argues that in this case *think of* has been reanalyzed as a single verb:

(34) He thought of John as silly.

Since V+P reanalysis is what is assumed to take place in pseudo-passives, we might well expect to get a correlation between prepositional objects which can host secondary predicates and prepositional objects which can be passivized, as in (35):

(35) John was thought of as silly.

In case-marking languages, the restriction that (non-reanalyzed) prepositional objects cannot host secondary predicates seems to be transferred to oblique marked objects. Levin and Simpson (1981) and Pesetsky (1982) argue that oblique objects cannot host secondary predicates. Schein (1995) argues that oblique case and prepositions should thus both be represented as P, and then in case-marking languages too, the restriction will reduce to the c-command constraint. However, examples like (36) indicate that the constraint may be thematic rather than structural. (36b) is as unacceptable as (36a) (both repeated from (18) above):

(36) a. *John gave the book to Mary_i sick_i.
b. *John gave Mary_i the book sick_i.

The dative direct object in (36b) can be the antecedent for an anaphor in VP, as in (37), and this supports the hypothesis that the restriction is thematic and not structural, and indeed, Williams claims that within the VP the secondary predicate is predicated of the theme:

(37) a. ??John gave the book about herself to every girl.
b. John gave every girl a book about herself.

Demonte (1987) brings interesting data from Spanish into the discussion. She is responding to arguments by Bresnan (1982d) and Zubizarreta (1987), who claim that the distribution of secondary predicates should be reduced to the theory of control. Demonte argues that Romance, specifically Spanish, makes a distinction between true prepositions and dummy case-marking prepositions. She shows that DP complements of dummy case-marking prepositions can host secondary predicates, while complements of true prepositions cannot. She argues that this is because true prepositions head PP phrases, while dummy prepositions are invisible to X-bar theory and do not project PPs. This still does not show unequivocally that the constraint is structural rather than thematic, since it is plausible that true prepositions and not dummy prepositions introduce thematic roles. Demonte's argument is the converse of Schein's: Schein proposes that oblique case is represented as P, while Demonte argues that dummy case-marking prepositions should be invisible for the calculation of c-command relations. The discussion of oblique objects is further complicated by work by Nichols (1978) and Simpson (1991) (cf. chapter 57), who report that in Finnish and Warlpiri respectively, oblique arguments may host secondary predicates. It is clear that much more work must be done on the relation between oblique case, oblique arguments, prepositions, and thematic marking before we can make progress on understanding this issue.

3.3 What are the semantic constraints on depictives?

Rothstein (1983) points out that there are semantic constraints on depictive predicates. It seems to be the case that the depictive must express a property which is non-inherent. Thus there are contrasts such as (38):

(38) a. Mary met John drunk.
b. *Mary met John tall.
c. I eat tomatoes fresh.
d. *I eat tomatoes non-synthetic.

Clearly the restrictions are context-dependent:

(39) a. ??I bought the blouse green.
b. I bought the blouse green but then I dyed it black.

There has been some, but not much, discussion of this in the literature, mainly in the context of the investigation of the contrast between stage- and individual-level predicates (see, e.g., McNally 1993), with attempts being made to explain (38) as a restriction that secondary predicates must be stage-level. Rapoport (1991) offers an essentially semantic explanation in terms of linking event arguments of the verbal and adjectival predicates, based on Kratzer's (1995) proposal that stage-level predicates have an event argument and individual-level predicates do not (see also Rapoport 1999b). However, work on adjectival modification

(Condoravdi 1992; Greenberg 1998) has shown that the stage/individual-level distinction is unlikely to correlate with the presence or absence of an event argument. Condoravdi argues that there are individual-level predicates which can be used as secondary predicates, for example (40), and that the restriction in (38) is pragmatic rather than semantic.

(40) He was born a Republican and he died a Republican.

Another area which remains to be investigated is the relation between secondary predication and APs used as absolutives, as discussed in Stump (1985) and illustrated in the construction in (41), which are adjuncts with a much freer semantic distribution than secondary predicates:

(41) Drunk, he walked down the street.

4 Resultatives

4.1 General issues

The two crucial syntactic properties which characterize resultative predication in English are: (i) the apparent object-orientedness of the predicates, as illustrated in (42); and (ii) the fact that resultatives can be predicated of an argument which is not a thematic argument of the matrix verb, illustrated in (43):

(42) a. John painted the house$_i$ red$_i$.
b. *John$_i$ painted the house tired$_i$.

(43) a. Bill ran the soles of his shoes$_i$ thin$_i$.
b. The audience laughed the actors$_i$ off the stage$_i$.
c. John ate himself$_i$ sick$_i$.

In (43a, b) the matrix verb is an intransitive, which is nonetheless case marking the subject of the resultative (as discussed in Rothstein 1992), while in (43c) the matrix verb is a transitive verb, which is no longer assigning the normal thematic role to its syntactic object. Thus while (42a) entails that John painted the house, the examples in (43) do not entail that Bill ran the soles of his shoes, that the audience laughed the actors, or that John ate himself. An obvious syntactic question is whether transitive and intransitive (or non-thematic) resultatives have the same syntactic structure. Syntactic research into resultatives has centered on these questions, but it has been apparent from the beginning that resultative predication is an aspectual phenomenon, and that the syntactic constraints will not be understood without understanding the lexical and semantic issues involved (see, e.g., Dowty 1979 and Hoekstra 1988, who both come to this conclusion from radically different theoretical assumptions). In particular, linguists have tried to derive the so-called 'direct object restriction' and the facts about non-thematic

resultatives from intuitions about the aspectual function of resultatives, as for example in the work of Bach (1980), Tenny (1987, 1994), Hoekstra (1988), Levin and Rapoport (1988), and Rapoport (1991), to name but a few.

The first relevant fact here is that resultatives can be added freely to transitive verbs without changing their meaning or aspectual properties only if the verb is an accomplishment. Thus (42a) contrasts with (44), where the matrix verb denotes an activity where (44a) is ungrammatical and (44b) is marginal, and requires interpreting the V + resultative as a complex telic verb with the meaning 'stir *x* until *x* is liquid':

(44) a. *John pushed the cart broken.
b. ?John stirred the soup liquid.

The second relevant fact is that intransitive resultatives illustrated in (43) involve reinterpreting an intransitive atelic activity-denoting verb as a verb denoting a telic event whose end-point is determined in some sense by the resultative.

In addition to these issues, there are a number of other questions concerning resultatives which have been noted, and which it is hoped that a general theory of the construction will explain. For example, Levin and Rappaport Hovav (1995) and Tortora (1998) discuss the apparent incompatibility of resultatives with verbs of inherently directed motion, and (as discussed below) it becomes clear that in some cases there is in fact no clear agreement on whether a predicate phrase is really a resultative. Another fruitful area of research has been cross-linguistic comparison of constraints on resultatives, in particular Napoli's (1992) comparison of resultatives in Italian and English, Neeleman's (1994a; Neeleman and Weerman 1993) work on resultatives in Dutch, and Kim and Maling's (1997) papers on Korean resultatives.

4.2 The syntactic structure of resultatives

On the assumption (which has been questioned: see below) that resultative predication is restricted to taking a direct object as subject, the mutual c-command constraint causes no problems. The syntactic issue has instead revolved around what structure should be assigned to intransitive resultatives, and whether transitive and intransitive resultatives should be assigned the same structure. Prima facie, the structure of (42a) should be as in (45):

(45) John [[painted [the house]$_i$ [red]$_i$]$_{V'}$]$_{VP}$.

This structure correctly implies that the nominal *the house* is the thematic argument of the matrix verb, and that the AP is an adjunct of some kind. Dropping the adjunct does not affect the grammaticality of the structure, and this correlates with the semantic fact that (42a) entails that John painted the house. On the assumption that all resultatives have the same grammatical function, and that all are adjuncts, the structure for (43a) should be (46):

(46) Bill [[ran [the soles of his shoes]$_i$ [thin]$_i$]$_{V'}$]$_{VP}$.

But this incorrectly implies that the adjunct *thin* is optional in this structure, and that (43a) entails that Bill ran the soles of his shoes. A more convincing structure for (43a) is (47), where the resultative predicate and its subject form a small clause, indicating that the predicate is necessary to license the nominal argument:

(47) Bill [ran [the soles of his shoes$_i$ thin$_i$]$_{SC}$]$_{VP}$.

There are three possible approaches to take to this issue. One is that both transitive and intransitive resultatives have the same 'flat' structure as in (45–46) and that the difference in entailments follows from the assignments of thematic roles: in case the matrix verb does theta-mark the direct object, the entailment holds, and if the theta-marking relation doesn't occur, then the entailment doesn't hold either. This is the position adopted by Williams (1980) and succeeding papers, and, most notably, Carrier and Randall (1992). The second approach is to assign both transitive and intransitive resultative constructions the small clause structure in (47). Thus (42a) would be assigned the structure in (48):

(48) John [painted [the house$_i$ red$_i$]$_{SC}$]$_{VP}$.

This line of argument is associated with Hoekstra (1988, 1992), who builds on the similarities between the resultative construction and verb–particle constructions. He shows that the small-clause analysis he gives parallels the analysis of verb–particle constructions given by Kayne (1984a). The difference in entailments between transitive and intransitive resultatives is derived from the workings of a lexical-semantic operation which integrates the verb and the resultative predicate into a complex which denotes a single event.

The third approach is to assume that transitive and intransitive resultatives have different structures. This is argued by Rothstein (1992, 2001a), although in recent work (Rothstein 2003, 2004) she presents an analysis of the semantics of resultatives which is compatible both with her earlier assumptions and with the assumption that all resultatives have the structure in (45).

Yet another approach to the syntactic structure of resultatives is taken by Neeleman and Weerman (1993) and Neeleman (1994a), with respect to Dutch. They argue that in Dutch, resultatives are adjoined to the V at D-structure. Like Hoekstra, they observe the similarities between resultatives and particles, but they observe also differences in behavior which lead them to analyze particles as elements which are adjoined to V in the morphological component rather than the syntax. Explicit differences between the syntax of Dutch and English, such as the fact that V + resultative may move as a constituent in Dutch but not in English, mean that their analysis is not easily applicable to the English data. Yet a different approach is taken in Winkler (1997), who argues for a complex predicate analysis of resultative constructions.

4.3 The 'direct object' restriction in resultatives, and non-thematic resultatives (including so-called 'fake' reflexives)

The facts about resultatives, as has already been discussed above, are that they can normally be predicated only of direct objects and can take neither oblique objects nor sentential subjects as their subject. The exceptions have been subjects of passive sentences and subjects of verbs which have been argued to be unaccusative, such as *freeze*. On the assumption that passives and unaccusatives involve syntactic movement to subject position, leaving a co-indexed trace in object position, the relevant resultative constructions are given in (49):

(49) a. The house$_i$ was painted t$_i$ red$_i$.
b. The river$_i$ froze t$_i$ solid$_i$.

Assuming a movement analysis of unaccusatives and passives thus allows the preservation of the 'direct object' restriction; Levin and Rappaport Hovav (1995) use the distribution of 'subject-oriented' resultatives to argue for a syntactic (i.e., movement) analysis of unaccusativity. They argue that in the context of the direct object restriction, a movement account of apparently unaccusative verbs in English, together with a movement account of passive, is the best way to explain when subject-oriented resultatives are possible (but see below in section 5 for a revision of this opinion). The direct object restriction is clearly related to the distribution of so-called 'fake' reflexives, the intuition being that inserting a reflexive after an intransitive verb and predicating the resultative of this reflexive is a way to circumvent the restriction on predicating resultatives directly of subjects. This is illustrated in (50):

(50) a. *John laughed sick.
b. John laughed himself sick.

However, examples such as (51), where the non-thematic argument is not a reflexive but a nominal with independent lexical content, indicate that the fake reflexive construction is more than a 'last resort' mechanism:

(51) They laughed John off the stage.

Simpson's (1983) principle that the controller (i.e., subject) of a resultative must be a grammatical direct object at some level of structure covers the data descriptively, but does not explain why the direct object restriction holds, or how the reflexive in (50) or the accusative-marked nominal in (51) can be introduced as objects. Rothstein (1992) suggests that these objects are case-marked by the matrix verb and thematically licensed by the resultative, but this leaves open the question of why a subject-oriented resultative is not generally possible. Dowty

(1979) already made it clear that the principles governing the introduction of resultatives are to be found in an understanding of how aspectual classification works. He shows that resultatives can be introduced with accomplishment verbs, in which case they give information about the telic point of the accomplishment, or they can be introduced with activity verbs, in which case they force the derivation of a complex verb constructed out of V + resultative predicate which has the meaning of an accomplishment. Based on the templates in (12) above, a lexical accomplishment like *x build y* means roughly something like '*x* does an activity of building *y* and this causes *y* to become built' – a complex accomplishment derived out of an activity; and a resultative like *x sing y asleep* means roughly '*x* does a singing activity and this causes *y* to become asleep'. The difference between the lexical and the derived complex accomplishment is thus that in the latter the activity and the result are specified by different lexical items, while in the former both are specified by the same lexical item. Similar approaches include, e.g., Hoekstra (1988, 1992), Levin and Rapoport (1988), Tenny (1987, 1994), Pustejovsky (1991), and van Valin (1990).

Tenny (1987, 1994) is explicit about how this relates to the direct object restriction on resultatives. Following Dowty (1979, 1991), Krifka (1992), and others, Tenny discusses how the function of the direct object in accomplishments is to 'measure out' the progress of the eventuality, with the telic point being reached when the direct object, or theme, is intuitively 'used up'. Thus an event of painting a house is over when the house is all painted, and an event of eating an apple is over when the apple is eaten up. Tenny argues that themes are delimiters ('incremental themes' in Dowty's 1991 terminology), and that the restriction is that delimiters are within V'. Since the function of the resultative is also to delimit, it too should be part of the V'.

Discussion of resultatives took a new turn around 1997, with a series of works which argue against the direct object restriction on resultatives. These include Wechsler (1997), Verspoor (1997), and Rappaport Hovav and Levin (2001), who all claim that there exist some genuine subject-oriented resultatives (i.e., resultatives whose subject-orientation cannot be reduced to deep structure object-orientation). (Kim and Maling 1997 claim that subject-oriented resultatives are possible in Korean too.)

The relevant examples include the following ((52a–b) are from Wechsler 1997, (52c) from Verspoor 1997, and (52d) from Rappaport Hovav and Levin 2001, who cite similar examples from Hoekstra 1988):

(52) a. The wise men followed the star out of Bethlehem.
b. The sailors caught a breeze and rode it clear of the rocks.
c. John walked the dog to the store/across the park.
d. The elevator creaked to the ground floor.

Both Wechsler (1997) and Rappaport Hovav and Levin (1999) give explanations in terms of the relations that different types of eventualities may have to their results. Wechsler argues that only 'canonical results' may be subject-oriented,

while Rappaport Hovav and Levin argue that subject-oriented resultatives are possible only if the event denoted by the resultative and the event denoted by the matrix verb can be conflated, by which essentially they mean that the temporal development of the two events is parallel. These papers have brought to the fore a number of examples which have been insufficiently discussed in the literature, though it still remains unclear whether they are to be analyzed as genuine resultatives. Rothstein (2004), for example, argues that since all apparent subject-oriented resultatives are locative expressions (whether PPs or, much more rarely, APs), they are better analyzed as denoting incremental path arguments in the sense of Krifka (1998a). This group of papers revives the very basic issue about when a predicate is to be analyzed as a resultative, a question which is also raised by Tortora (1998), who argues that, contra Levin and Rappaport Hovav (1995), the achievement + PP in (53) should also be analyzed as a resultative:

(53) John arrived at the station.

5 Conclusion: recent developments

A relatively recent development in the study of secondary predication has been a renewed interest in attempts to give a unified explicit semantics for depictives and resultatives, and in relating this to more general constraints on complex predicate formation. This has resulted in, among others, papers by Cormack and Smith (1994, 1999) and Rothstein (2003, 2004), which analyze secondary predication as an operation of predicate conjunction, where the conjunction operation is constrained in a way in which it is not in ordinary conjunction, such as is expressed by the operator *and*. Cormack and Smith hypothesize that secondary predication is an operation which essentially shares the properties of serial verb formation, a hypothesis which is also put forward by Larson (1991) and Collins (1997a). Cormack and Smith claim that secondary predication (both depictive and resultative) and serial verb formation involve an asymmetric conjunction operator, with differing constraints on event structure deriving the differences between different constructions such as depictive and resultative predication. Collins (1997a), in the context of the debate about argument sharing in serial verb constructions, argues that serial verb formation necessarily involves internal argument sharing between predicates, and that Ewe serial verbs and English resultatives are both to be analyzed as control structures, where the second predicate incorporates into the first at LF. The difference between Ewe and English then essentially reduces to categorial restrictions on the second predicate – in English it cannot be verbal and thus the output is not, in English, a serial verb. Rothstein (2003, 2004) argues that both depictive and resultative predication are the result of a summing operation which sums a verbal and a non-verbal predicate, each denoting events, where the denotation of the predicates is related via the relation 'time–participant connected'. Two events e and e' are time–participant connected under the condition that e and e' have the same running time, and that

they share a thematic participant. Depictives differ minimally from resultatives: with depictives the two events which must be time–participant connected are the event denoted by the verbal predicate and the event denoted by the secondary predicate, while with resultatives the relation holds between the event which is the culmination of the event denoted by the verb, and the event given by the secondary predicate. The relation between this work and the papers by Cormack and Smith and Collins has yet to be explored, but the connection between serial verb formation and secondary predication seems a fruitful avenue to explore, and it places the study of secondary predication squarely in the domain of verb aspect and complex predicate formation in the verbal domain.

Another area in which much research is going on is secondary predication in languages other than English. For example, there have been a number of recent papers examining secondary predication in Japanese (Takezawa 1993; Koizumi 1994; Miyamoto 1996), in Korean (Kim 1993; Kim and Maling 1997; Washio 1997, 1999; Wechsler and Noh 2001), and in Russian (Filip 2001; Strigin and Demjjanow 2001; Demjjanow and Strigin 2003); These have of course raised the question of what properties of secondary predication in English are shared cross-linguistically, and what properties characterize secondary predication cross-linguistically which do not show up in English. The papers on Russian have raised the issue of the syntactic constraints on and semantic relevance of case assignment in secondary predicate constructions. Wechsler and Noh (2001) have argued, contra Kim and Maling (1997), that the direct object restriction does hold in Korean resultative secondary predication, and that apparent counter-examples occur because resultatives can also be expressed via a non-predicative construction involving clause linking.

The issue of whether secondary predication is the result of a lexical or a structural operation has also received renewed attention in the last few years, especially in Neeleman (1994a), Winkler (1997), and Wunderlich (1997a). Differences between Germanic (i.e., German, Dutch, and closely related languages) and English also raise the possibility that what is a structural operation in one language may be a lexical operation in the other. Further cross-linguistic work on both the syntactic structure and semantic interpretation of secondary predication constructions should deepen our understanding of these issues.

59 Serial Verbs

PIETER MUYSKEN AND
TONJES VEENSTRA

1 Introduction
2 Definition
3 Classification
  3.1 Type 1 constructions
    3.1.1 Directional
    3.1.2 Argument-introducing
    3.1.3 Aspectual
    3.1.4 Degree
  3.2 Type 2 constructions
  3.3 Type 3 constructions
  3.4 Type 4 constructions
4 Structure
  4.1 Hierarchical relations
  4.2 Concatenation principles
    4.2.1 Subordination
    4.2.2 Adjunction
    4.2.3 Coordination
5 Argument sharing
6 Parameterization and typological correlates
  6.1 Word order
  6.2 Non-distinctiveness of verbs and prepositions
  6.3 Absence of verbal morphology and separation of verbs from INFL

1 Introduction

The phenomenon of verb serialization has been informally characterized as "a row of verbs one after another . . . [in which] the verbs stand next to each other

without being connected" (Westerman 1930: 126). Serial verb constructions typically have the following format:

(1) $NP_1\ V_1\ NP_2\ V_2\ (XP_3)$ (X = N, P)

Defined in such a way, the notion of verb serialization is rather vague. Many scholars, therefore, have tried to make this notion more precise (cf. Jansen et al. 1978; Sebba 1987; Muysken 1988; Baker 1989; Seuren 1991; among many others). Several syntactic and, to a lesser extent, semantic criteria have played a role in the discussion on the definition of serial verb constructions. It must be noted beforehand that it has never led to much agreement.

Depending on the criteria chosen, serial verbs are either (i) a particular family of constructions, restricted to some language families, or (ii) a phenomenon found to some extent in all languages. Besides the classical examples in the Greenberg–Kwa languages of Niger-Congo (cf. Awóyalé 1988), and in creole languages in the Caribbean (Jansen et al. 1978; Sebba 1987), the construction is also arguably present in Chinese, Japanese, and Korean (Chinese: C. Li and Thompson 1973; Y. Li 1990b, 1993, 1998; Sybesma 1992; Zou 1993, 1994a, 1994b; J. Li 1997; Japanese: Kuno 1973c; Kageyama 1993; Nishiyama 1998; Korean: Lee 1994), and at the limit in Germanic languages (so-called fake-coordinate VPs in which both verbs agree in the tense specification without an overt subject before V2 – see for English: Carden and Pesetsky 1977; Goldsmith 1985; Lakoff 1986; Swedish: Anward 1988; Norwegian: Åfarli and Creider 1987; Den Dikken 1991a, 1991b). In addition, Schiller (1991) has found serial verb constructions in the following language families: Hmong-Mien (Court 1985), Mon-Khmer (Phillips 1973; Kuhn 1990), Oceanic (Durie 1988, 1997), Tai-Kadai (Thepkanjana 1986), Papuan (Pawley 1980), and Semitic (Hussein 1990).

To start, we confine our discussion to examples from Saramaccan, a creole language spoken in Suriname, making supplementary reference to facts from other Atlantic creoles and from some of the better-studied languages of Greenberg–Kwa.

Serial verb constructions display a wide variety of readings, as can be seen from the following illustrative examples:

(2) a. A tjá hen gó a dí dáata.
3SG carry 3SG go LOC DET doctor
'He went to the doctor with her.'
b. A sindjó nján.
3SG sit.down eat
'He sat down and ate.'
c. A náki hen kíi.
3SG hit 3SG kill
'He hit it dead.'

In (2a) the verb *tjá* introduces a comitative; (2b) expresses two sequential events; and (2c) translates as a resultative construction. Cf. the following:

(3) a. A bígi pása mi.
3SG big exceed 1SG
'He is bigger than me.'
b. A wáka lóntu dí wósu.
3SG walk surround DET house
'He walked around the house.'
c. A téi dí fáka kóti dí beée.
3SG take DET knife cut DET bread
'He cut the bread with the knife.' [approx.]

(3a) is an example of a comparative construction; in (3b) the verb *lóntu* specifies the location/direction of the event of the first verb; and in (3c) the verb *téi* introduces an instrumental adjunct. In all cases in (2) and (3) one can say that the two verbs together express a single (albeit complex) event, which is assigned one truth-value.

In most studies, the underlying assumption has been that verb serialization is a unified phenomenon. This is, however, not an entirely uncontroversial position (cf. Veenstra 1989; Den Dikken 1991a, 1991b). The question is whether verb serialization as such constitutes a valid domain of investigation. Muysken (1988: 65) observes that it may be the case that "in the face of new and apparently contradictory data sets on serial verb constructions becoming available, . . . a unified phenomenon is fractured into odd bits and pieces."

The most interesting question serial verb constructions pose for grammatical theory is, in our opinion, how their lexical and syntactic properties interact. On the one hand, they appear to be lexically determined: (i) the combinatory possibilities are partly lexically restricted, e.g., only verbs of movement can be followed by *gó* 'go' and *kó* 'come' expressing direction away from or toward a point of reference established in the discourse; (ii) they can form idiomatic expressions, e.g., the combination *láfu* NP *kíi* 'laugh DP kill' takes on the meaning of 'deride DP'; and (iii) they often appear to undergo thematic restructuring to form complex predicates (which in most cases give rise to the phenomenon of 'argument sharing'), a potential example being (2c). On the other hand, the individual verbs are clearly separate verbs assigning cases and thematic roles to intervening arguments. Also, the different verbs may denote different subevents, as in (2b). Several interrelated issues, therefore, arise in the analysis of serial verb constructions, among which the following will be touched upon in this chapter:

(4) a. **Lexicon/syntax and argument sharing:** Is verb serialization a syntactic process or should it be accounted for by lexical operations on argument structure? How to account for 'argument-sharing' effects?
b. **Concatenation:** If serial verb constructions form chains, what are their concatenation principles, and what is the structural configuration involved?
c. **Correspondence:** To which constructions in non-serializing languages do serial verb constructions correspond?

d. **Typological correlates:** How do we account for the difference between serializing and non-serializing languages?

Crucial to (4a) is the issue of argument sharing. Is argument sharing taken care of in the lexicon, as it would be in a lexical analysis, or is the argument-sharing effect mediated through empty categories in serial verb complements, as it would be in a syntactic analysis?

With respect to (4b), three possible concatenation principles are suggested in the literature: coordination (e.g., Hale 1991), subordination (e.g., Jansen et al. 1978; Sebba 1987), and adjunction (e.g., Bickerton and Iatridou 1987; Larson 1991; Law and Veenstra 1992).

The correspondence issue of (4c) has received ample attention. Possible candidates that have been mentioned are asymmetric coordinations (e.g., Den Dikken 1991a, 1991b; Déchaine 1993; Corne et al. 1996), verb–preposition combinations (e.g., Muysken 1988), and secondary predication constructions (e.g., Muysken 1988; Den Dikken 1991a; Larson 1991; Law and Veenstra 1992).

If there exists something like a serializing language type (4d), we would expect a number of typological correlates (i.e., co-occurring linguistic features) of serial verb constructions. The following have been put forward as possible correlates: absence of verbal (derivational or inflectional) morphology; non-distinctiveness of verbs and prepositions (in terms of verbs as either additional Case markers – e.g., Bickerton 1981; Byrne 1987 – or additional markers of thematic roles – e.g., Sebba 1984), and separation of verbs from INFL (e.g., Muysken 1988; Larson 1991; Law and Veenstra 1992; Déchaine 1993).

In addition, does the difference between serializing and non-serializing languages come about by means of different options of a single parameter or through different ways of doing syntax and morphology? The parametric option is argued for by Baker (1989, 1991b) and Collins (1995a), while Larson (1991), Law and Veenstra (1992), and Déchaine (1993), among others, argue for a modular approach to verb serialization.

Here we will try to give a first inventory of these constructions and of the analytical problems that they raise, and discuss some of the analyses proposed so far. In section 2 we present a first definition, and in section 3 an enumeration of frequently occurring types of serial verb constructions. In section 4 we discuss the different possible structures proposed for the serial verb constructions and section 5 is dedicated to the problem of 'shared arguments': one noun phrase sometimes appears to belong to different verbs. Section 6 is aimed at the problem of typology and parameterization: what makes serial verb constructions possible in a language?

2 Definition

In the study of serial verb constructions, several criteria are implicitly used for what a serial verb construction really is. Generally they amount to something like the following. A serial verb construction contains two verbs which have:

(5) a. only one grammatical subject;
b. at most one grammatical object;
c. one specification for tense/aspect:
– often only on the first verb;
– sometimes on both verbs, but agreeing in the specification given;
– sometimes only on the second verb;
d. only one possible negator;
e. no intervening coordinating conjunction;[1]
f. no intervening subordinating conjunction;
g. no intervening pause.[2]

We will illustrate each characteristic with examples from Saramaccan.

(5a) says that only one NP in the verbal chain that can be interpreted as a subject, i.e., is overtly realized in a subject position. (5b) refers to the 'object-sharing' phenomenon first observed by Stewart (1963) on the basis of Twi. This is exemplified in (6):

(6) Dí kambósa bì tá sibá dí óto wán kíi.
DET concubine TNS ASP curse DET other one kill
'The concubine was calling down a curse upon the other concubine.'

The DP *dí kambósa* is interpreted as the subject of both verbs and the DP *dí óto wan* is interpreted as the object of both verbs, although both DPs are only (overtly) realized as the argument of the first verb.

Patterns of tense and aspect marking in serial verb constructions in Saramaccan are quite complex. We first discuss tense marking and then aspect marking.

In Saramaccan (but not in all languages with serial constructions) tense is marked only once in the string. It can only occur in front of the first verb, as shown in (7a–b). Consecutive tense marking is also not grammatical (7c):

(7) a. A bì jáka en púu.
3SG TNS chase 3SG remove
'He had chased him away.'
b. *A jáka en bì púu.
3SG chase 3SG TNS remove
c. *A bì jáka en bì púu.
3SG TNS chase 3SG TNS remove

Aspect normally is only marked on the first verb (8a). It then expresses non-punctual – i.e., durative, habitual, or iterative – aspect and has scope over all subevents. If aspect is only marked on the second verb, as in (8b), it expresses durative aspect and has scope only over the second subevent. If, on the other hand, aspect is marked on both verbs, it can express durative and iterative aspect (8c). The iterative reading is preferred, however:

(8) a. A tá fáa páu túe.
3SG ASP chop tree throw
'He is felling a tree/the tree/trees.'
b. A fáa páu tá túe.
3SG chop tree ASP throw
'He is felling the tree (i.e., at this very moment the tree is falling).'
c. A tá fáa páu tá túe.
3SG ASP chop tree ASP throw
'He is (constantly) felling trees.'

Of these three ways of marking aspect in a serial verb construction, the second option, in which aspect is marked only on the second verb, is the least common.

Negation can be marked only once in the string and appears in front of the first verb and not in front of the second verb. This is shown in (9):

(9) a. De á bì héngi en peeká a dí lakwa-páu.
3PL NEG TNS hang 3SG nail LOC DET cross
'They didn't crucify him.'
b. *De bì héngi en á peeká a dí lakwa-páu.
3PL TNS hang 3SG NEG nail LOC DET cross

If an overt coordinating conjunction is present, not only the subject in the second conjunction has to be present but also the 'shared' object. This is impossible in serial verb constructions (cf. criteria in (5a–b)). The set of coordinating conjunctions includes *hén* 'and' and *ma* 'but'. Relevant examples are given below:

(10) a. A náki en hén a kíi en.
3SG hit 3SG and.then 3SG kill 3SG
'He hit it and he killed it.'
b. *A náki en hén kíi en.
3SG hit 3SG and.then kill 3SG
c. *A náki en hén a kíi.
3SG hit 3SG and.then 3SG kill

Negation can occur in front of the second verb in this case:

(11) A náki en ma á kíi en.
3SG hit 3SG but 3SG=NEG kill 3SG
'He hit it, but he didn't kill it.'

Furthermore, the subject of the second conjunct does not have to be coreferential with the subject of the first conjunct. In other words, subject sharing is not obligatory:

(12) A náki en hén mi kíi en.
3SG hit 3SG and.then 1SG kill 3SG
'He hit it and (then) I killed it.'

A subordinating conjunction also cannot appear in the string. If it is present, an overt subject is possible before the second verb (cf. also Bickerton and Iatridou 1987); either referential as in (13b), or disjoint in reference from the matrix subject as in (13c):

(13) a. A téi fáka u kóti dí beée.
3SG take knife FOR cut DET bread
'He took the knife in order to cut the bread.'
b. A téi fáka faa kóti dí beée.
3SG take knife FOR=3SG cut DET bread
'He took the knife in order to cut the bread.'
c. Dí wómi téi fáka fu dí mujée kóti dí beée.
DET man take knife FOR DET woman cut DET bread
'The man took the knife for the woman to cut the bread.'

Examples (13a–b) show that the subject in front of the second verb can be optionally realized.

Semantic criteria have received much less attention in the study of verb serialization than the syntactic ones. One (obvious) reason for this is that, as we will see below, serial verb constructions do not form a homogeneous class from a semantic point of view.

Because they are by definition monoclausal, serial verb constructions necessarily express one proposition, assuming that a proposition is a (simple or complex) predication linked up to a single tense (cf. Rothstein 1983). Thus, a predication is the core of a proposition, as in *Mary walks*, where *walks* is predicated of *Mary*. Here *walks* is the (primary) predicate of the clause, and is anchored by the finiteness of the verb (in this case present tense).

An argument often cited in the literature (e.g., Jansen et al. 1978) for this assertion is the fact that a serial verb construction has one truth-value assigned to it, and no subpart of the construction can be independently negated by means of an adversative tag. Thus, the classical contrast is the following:[3]

(14) a. *A téi fáka kóti dí beée ma á kóti en.
3SG take knife cut DET bread but 3SG=NEG cut 3SG
'He took a knife and cut the bread (but he did not cut it).' [approx.]
b. A téi fáka fu kóti dí beée ma á kóti en.
3SG take knife FOR cut DET bread but 3SG=NEG cut 3SG
'He took a knife (in order) to cut the bread (but he did not cut it).'

In sentences containing a subordination conjunction (14b), it is possible to negate the second VP independently. In a serial verb construction, on the other hand, it is not, as can be seen in (14a).

Serial verb constructions display a variety of readings, ranging from conjunctive and modificatory to causative (Muysken 1988; Larson 1991). It is possible to construct a scale of readings which runs from coordination to subordination (based on Fugier 1988):

(15)	Coordination	Enumeration of two distinct events
	I	Two distinct events in tight juxtaposition
	II	One event and its consequence
	III	One event and the aim toward which it tends
	IV	Two concomitant events
	V	One event and its reformulation
	VI	One event and the way it is realized
	Subordination	One event, and the second one on the occasion of the first one

A similar classification can be found in the work of Bámgbósé (1974, 1986).

Although interesting in themselves for descriptive purposes, such schemes in general lack explanatory power. Awóyalé (1988) underscores this observation and makes a case for a semantic template of event composition that underlies and, in part, determines the limits on verb serialization in Yoruba. This template consists of three terms: a core event predicate that can be modified by modality and state predicates (Awóyalé 1988: 9). Modality predicates indicate how events are carried out or the manner in which events occur, and state predicates signify the outcome of events:

(16) MODALITY* EVENT* STATE*

The following combinations are predicted to exist by the template: [modality event], [event event], [event state], and [state state] (see Awóyalé 1988: 20–25 on the non-availability of [modality modality] and [modality state]). The following Saramaccan examples are given to clarify the different possibilities:

(17) a. A [$_M$ tjá en] [$_E$ gó a dí dáata]. (modality event)
3SG carry 3SG go LOC DET doctor
'He went to the doctor with her.'

b. A [$_E$ sindjó] [$_E$ nján]. (event event)
3SG sit.down eat
'He sat down and ate.'

c. A [$_E$ náki en] [$_S$ kíi]. (event state)
3SG hit 3SG kill
'He hit it dead.'

d. A [$_S$ bígi] [$_S$ pása mi]. (state state)
3SG big exceed 1SG
'He is bigger than me.'

Although this is the most useful division so far into different semantic types of serial verb constructions, it remains to be seen what the implications are for the (structural) analysis of the construction. Is there one (semantic) analysis for the whole class of serial verb constructions or does every semantic type require its own analysis? Likewise, does every single semantic type correspond to a distinct syntactic structure, or is there one syntactic structure underlying all semantic types?

3 Classification

As noted above, the principal problem that serial verb constructions seem to pose for grammatical theory is how their lexical and their syntactic properties interact. On the one hand, they are clearly lexically constrained: verbs in a serial chain are in part lexically restricted, and they often appear to undergo thematic restructuring to form complex predicates. On the other hand, the individual verbs in the chain are clearly separate verbs assigning cases and thematic roles to intervening objects. What are the semantic relations between the verbs? How do the different verbs in the chain interact? Two possibilities come to mind:

(18) a. The verbs undergo thematic restructuring and become one predicate semantically.
b. All verbs in the chain are separate predicates and the relation between them is one of adverbial modification.

There are several ways in which to approach this issue. On the basis of a surface-oriented taxonomy about the number of Infls in serial verb constructions, Awóyalé (1988) proposes to set up a division between (i) languages with clausal serial verb constructions (IP-serials), exhibiting relatively more independence between the different subevents denoted by the separate verbs and free lexical selection, and (ii) languages with phrasal serial verb constructions (VP-serials), exhibiting relatively less independence or thematic restructuring and a limited set of participating verbs. The set of languages with clausal serial verb constructions would include Saramaccan and Berbice Dutch. The set of languages with phrasal serial verb constructions would include Haitian and Papiamentu (cf. Déchaine 1993 on Haitian, Bendix 1972 on Papiamentu):

(19) a. IP-serializing: Igbo, Izi, Anyi, Ijo, Saramaccan, Berbice Dutch
b. VP-serializing: Yoruba, Igala, Ogori, Ebira, Ewe, Igede, Twi, Haitian, Papiamentu

There are two observations to make with respect to this division. First, languages with clausal serial verb constructions also have phrasal serial verb constructions. Thus, Saramaccan-type languages constitute a superset, exhibiting both types (phrasal, clausal) of serial verb constructions, and Haitian-type languages are a subset, exhibiting only one type (phrasal) of serial verb constructions. The set of serializing languages with only the clausal type is not attested in the literature.

Second, the two factors to distinguish the different types of serial verb constructions – i.e., more vs. less independence between the different subevents, and free vs. restricted lexical selection – should give rise to four logically possible types of serial verb construction instead of the two mentioned. These four logical possibilities are schematically represented in (20):[4]

(20)

	Less independence between subevents	More independence between subevents
Lexically constrained	Type 1 (phrasal)	Type 2
Lexically free	Type 3	Type 4 (clausal)

The notion 'restricted lexical selection' refers to the fact that in many cases of verb serialization, we tend to find that one verb in the construction is drawn from a certain semantic or aspectual class and occurs in a 'fixed' position. The notion 'free lexical selection' refers to constructions in which there are no such restrictions.

The rather vague notion 'more or less independent subevents' refers to the event composition of the construction. Couched in Awóyalé's (1988) terms, it means that 'less independent subevents' involve combinations of modality or state predicates and event predicates and also combinations of two state predicates, while 'more independent subevents' involve combinations of event predicates only.

Within type 1/type 2 serial verb constructions, four major groups of meanings can be distinguished: directional, argument-introducing, aspectual, and degree-marking serial verbs. These four are arranged very roughly in the order of frequency in which these semantic categories are marked by serial verbs in different groups of creole languages. Then, within each semantic category, the typical verbs are listed, again in order of frequency, which encode a specific type of meaning. In the overview in (21) only the 'fixed' verb in serial verb constructions is mentioned:

(21)

Function	**Verb**	**Meaning**
Directional	go	Direction away
	come	Direction toward
	surround	Around
	be	Locative
Argument-introducing	give	Benefactive, dative
	take	Instrumental, comitative, object
	say	Finite complementizer
Aspectual	finish	Perfective
	return	Iterative
	be	Continuative
Degree	pass	Comparative, too much
	suffice	Enough

Next to the specific verbs in (21), in different languages yet other verbs can occur sometimes in serial verb constructions.

We will now turn to a description of the four types of serial verb constructions in Saramaccan.

3.1 Type 1 constructions

With regard to type 1, the following verbs in Saramaccan can be used non-initially in this sense:

(22)

Type	Token	Gloss	Meaning
Directional	gó	go	Direction away
	kó	come	Direction toward
	lóntu	surround	Circumvention
	kumútu	come out	Origin
	dóu	arrive	End-point
Argument-introducing	dá	give	Goal/recipient, benefactive, experiencer, source
	táa	say	Finite complementizer
Aspectual	kabá	finish	Completive
	káá	finish	Already
Degree	pása	pass	Comparative
	móo	more	Comparative
	pói	spoil	Excessive

Most of these verbs (the directionals are a notable exception) are susceptible to grammaticalization and/or reanalysis.

3.1.1 Directional

The verbs *gó* 'go' and *kó* 'come' in non-initial position are used to mark direction away from or toward a point of reference established in the discourse, which in most cases happens to be the speaker (Sebba 1987). They are in most cases used in combination with verbs of movement, Yoruba being a notable exception (cf. Awóyalé 1988). They can be accompanied by a locative PP, but need not be:

(23) a. A kúle gó
3SG run go
'He ran away.'
b. A wáka kó a mi písi
3SG walk come LOC 1SG yard
'He walked to my yard.'

There is no restriction on the type of verb they combine with. In addition to non-ergative verbs (as in the previous example), ergative and transitive verbs can also occur in this position:

(24) a. A kaí gó a dí baáku.
3SG fall go LOC DET hole
'He fell into the hole.'

b. A túe dí súndju gó a dí mátu.
3SG throw DET dirt go LOC DET woods
'He threw the dirt into the woods.'

The verb *lóntu* also specifies the direction of the action of the first verb:

(25) a. Mi wáka lóntu dí wósu
1SG walk surround DET house
'I walk around the house.'
b. A bì hái dí dóti zuntá lóntu dí kólo gogó
3SG TNS haul DET dirt bring together surround DET cabbage base
'He had put earth around the base of the cabbage.'

The verb *kumútu* marks the location where the participant comes from. The verb *dóu* signifies the termination and/or the end-point of the action described by the foregoing verbs. The usage of these verbs is exemplified in (26):

(26) A wáka kumútu a mi písi gó a fóto dóu
3SG walk come.out LOC 1SG yard go LOC city arrive
'He walked out of my yard to the city (and arrived there).'

Although direction is prototypically expressed by general movement verbs of the ergative type, like *gó* and *kó*, other verbs, specifically transitive ones, can also indicate direction. In those cases the direction expressed is more specific. For illustration, consider the following examples:

(27) a. A kándi dí wáta gó
3SG tilt DET water go
'He poured the water.'
b. A kándi dí wáta túe a dí fája
3SG tilt DET water throw LOC DET fire
'He poured the water onto the fire.'
c. A kándi dí wáta butá a dí báta
3SG tilt DET water put LOC DET bottle
'He poured the water into the bottle.'

Different verbs in the second position are used to distinguish different senses of the notion 'pour'. Thus, the notion 'pour' in a general sense is expressed with *gó* as the second verb, the more specific notion 'pour onto' with the transitive verb *túe* as the second verb and 'pour into' with the locative verb *butá* in second position.[5]

3.1.2 Argument-introducing

The argument-introducing group consists of two verbs: *dá* 'give' and *táa* 'say'. They always appear in non-initial position.

Dá 'give' can introduce Goal/Recipient (GOAL), Benefactive (BEN), Experiencer (EXP), and Source (SOURCE) arguments. This is shown in the next set of examples, respectively:

(28) a. A tjá sondí kó dá dí Faánsi sèmbè GOAL.
3SG carry thing come give DET French man
'He presented something to the Frenchman.'
b. Séi wan ijsie dá mi! BEN.
sell DET ice-cream give 1SG
'Sell an ice-cream for me!'
c. De maá dí fáka dá mi EXP.
3PL sharpen DET knife give 1SG
'They sharpened the knife for me.'
d. De píndja dí móni dá hen pikí-pikí SOURCE.
3PL pinch DET money give 3SG small-small
'They cheated a little money out of him.'

Táa, the suppleted form of the verb *táki* 'say', introduces finite clauses. It follows verbs of speech, cognition, and perception:

(29) a. A táki táa á búnu.
3SG say say 3SG=NEG good
'He said that it is not good.'
b. Mi sábi táa á búnu.
1SG know say 3SG=NEG good
'I know that it is not good.'
c. Mi sí táa dí wómi kumútu a dí wósu.
1SG see say DET man come.out LOC DET house
'I saw that the man had come out of the house.'

It can also mark direct speech:

(30) Mi táki táa sáka hen búta!
1SG say say lower 3SG put
'I said: put it down!'

In addition, it can be followed by *fu* 'for', as in the following example, which may be best characterized as a subjunctive complementizer:

(31) I táki táa faa náki dí dágu.
2SG say say FOR=3SG hit DET dog
'You told him to hit the dog.'

3.1.3 Aspectual

The aspectual subgroup consists of two elements: the verb *kabá* 'finish' and *káá*, a suppletive form of *kabá*. They both come as the non-initial verb in the construction. *Kabá* marks completive aspect. *Káá* has been reanalyzed as an adverb meaning

'already', and always appears at the right (most) periphery of the clause/sentence, the prototypical position for adverbs in Saramaccan:

(32) a. Mi jabí dí dóo kabá.
1SG open DET door finish
'I have finished opening the door.'
b. Mi jabí dí dóo káá.
1SG open DET door finish
'I already opened the door.'

3.1.4 Degree

The degree subgroup has three members: *pása* 'pass', *moó* 'more', and *pói* 'spoil'. *Pása* and *moó* are used in comparative constructions and *pói* is used to mark excessive degree.

Pása as well as *moó* in the comparative construction can be combined with both intransitive and transitive verbs, with no (detectable) difference in meaning:[6]

(33) a. A fátu pása/moó mi.
3SG fat pass/more 1SG
'She is fatter than me.'
b. A bebé daán pása/moó mi.
3SG drink rum pass/more 1SG
'He drinks more rum than me.'
c. A bebé daán pása/moó watá.
3SG drink rum pass/more water
'He drinks more rum than water.'

It depends on the object of *pása/moó* whether the subject or the object of the higher verb is the object of comparison, as can be seen from (33b, c).

If *pása* follows a verb of movement, it retains its original meaning:

(34) Mi wáka pása hen.
1SG walk pass 3SG
'I walked past him.'

Arguably, these constructions are instances of directional serial verb constructions.

Moó, in addition, can also be used as a degree modifier inside DPs:

(35) Dí moó hánse wan mi ké.
DET more beautiful one 1SG want
'The more beautiful one I want.'

Pói 'spoil' mainly functions as a degree marker:

(36) A fátu pói dá mi.
3SG fat spoil give 1SG
'She is too fat for me.'

When combined with transitive verbs it can, in addition, retain more of its original meaning, as shown in (37):

(37) De bì náki hen pói.
3PL TNS hit 3SG spoil
A: 'They had beaten him excessively.'
B: 'They had beaten it and it turned bad.'

The structure that makes the B-reading possible presumably is a type 3 construction.

The comparative construction with *pása* and *móo* has been fully grammaticalized and the verbs have lost most (if not all) of their verbal characteristics.

3.2 Type 2 constructions

Turning now to type 2 serial verb constructions, they also have a verb in a fixed position, but in contrast with type 1 constructions their event composition is more loosely interpreted. In Saramaccan such constructions are formed with causative verbs used in non-initial position, and the verb *téi* 'take' is used in first position:

(38)

Type	**Token**	**Gloss**	**Meaning**
causative	mbéi	make	(Direct) causation
	dá	give	(Indirect) causation
argument-introducing	téi	take	Instrument, direct object, comitative

Like type 1 serial verb constructions, these are also susceptible to grammaticalization. Causative verbs *mbéi* and *dá* have been reanalyzed as complementizers. *Téi*, on the other hand, has not been reanalyzed.

The verb *téi* can introduce Instrumental, Comitative, and Theme arguments of the following verb. This is shown in (39):

(39) a. A téi dí páu náki hen gbóó túe káá.
3SG take DET stick hit 3SG ideophone throw finish
'He already had taken a stick and beaten him down with it.'
b. Mi téi hen gó a dí sikóutu.
1SG take 3SG go LOC DET police
'I took it and went to the police with it.'
c. Me téi dí búku butá alá.
1SG=NEG take DET book put there
'I didn't take the book and put it there.'

Causative constructions with *mbéi* 'make' as the second verb express direct causality:

(40) Dí tjúba tá kái mbéi hen uwíi munjá tooná kó bè.
DET rain ASP fall make 3SG hair wet turn come red
'It is raining so that her hair becomes wet and turns red.'

(41) Egbert bebé daán hía pói mbéi a fiká a wósu.
Egbert drink rum much spoil make 3SG stay LOC house
'Egbert drank too much rum, so that he stayed home.'

Thus, in (40) the fact that her hair becomes wet (and subsequently turns red) is caused (directly) by the rainfall. In all these cases, *mbéi* links two events each of which is expressed by a verb.

Causative constructions with *dá* as the second verb express indirect causality:

(42) a. Dí mujée mbéi te dá dí míi bebé.
DET woman make tea give DET child drink
'The woman made tea for the child to drink.'
b. A butá hen-seéi dá a fón ku schaak.
3SG put 3SG-self give 3SG beat with chess
'He let himself be beaten by her at a game of chess.'

The action of the first verb creates a situation in which the action of the verb following *dá* can occur. Like *mbéi*, it also links two events.

3.3 Type 3 constructions

Resultative serial verb constructions constitute type 3 constructions. They partly correspond to particle–verb combinations in Germanic languages (cf. Sebba 1987). Although the position of the result-denoting verb is also more or less fixed (a non-initial position), they differ from type 1 constructions in that the list of participating verbs is (in principle) open-ended.

A non-exhaustive list of verbs that can occur in this position is: *kíi* 'kill', *fáu* '(make) unconscious', *téi* 'take', *túe* 'throw', *butá* 'put', *hói* 'hold', *púu* 'pull', *paajá* 'separ- ate', *jabí* 'open', and *kísi* 'catch'. Some illustrative examples are:

(43) a. De hói hen butá.
3PL hold 3SG put
'They kept him under control.'
b. AIDS kísii hen kíi.
AIDS catch 3SG kill
'He died from AIDS.'
c. Mi kísi dí fii otó téi a mámate.
1SG catch DET FOR=2SG story take LOC morning
'I recorded your story in the morning.'
d. A boóko hen púu.
3SG break 3SG pull
'He broke it off.'

Although the list of lexical verbs that participate in the construction is in principle open-ended, there is a kind of parallellism constraint on the transitivity of participating verbs, i.e., only the combination of two transitive or unaccusative verbs is possible (Veenstra 2004). The generalization with respect to possible verb combinations in the resultative construction in Saramaccan amounts then to the following:

(44) a. NP_1 V_{TRANS} NP_2 V_{TRANS} (= 45a)
b. *NP_1 V_{TRANS} NP_2 V_{UNACC} (= 45b)
c. *NP_1 V_{UNACC} V_{TRANS} (= 45c)
d. NP_1 V_{UNACC} V_{UNACC} (= 45d)

(45) a. De sikópu hen kíi.
3PL kick 3SG kill
'They kicked him dead.'
b. *De fáa dí páu kaí.
3PL chop DET tree fall
c. *De kaí kíi.
3PL fall kill
d. Dí wósu boóko kaí.
DET house break fall
'The house is fallen apart.'

This type of constraint has not been documented for any of the serializing Kwa languages (see for Edo: Stewart 1998; Ewe: Collins 1993; Yoruba: Déchaine 1993; Akan: Campbell 1996a).

3.4 Type 4 constructions

In type 4 (*clausal*) constructions, anything goes as long as it is semantically and/or pragmatically apt. There are no restrictions on the list of participating verbs or on their position in the string:

(46) A kísi dí fou náki kíi limbó bói njan.
3SG catch DET bird hit kill clean cook eat
'He caught the bird, struck it dead, cleaned, cooked, and ate it.'

(47) A súti hen fulá pása gó náki dí sitónu hén mi téi hen.
3SG shoot 3SG pierce pass go hit DET wall and.then 1SG take 3SG
'He shot him and the bullet went through him and into the wall and then I took it.'

(46) illustrates a quite complex sequence of (five) events in which all the verbs share their arguments with the first verb (and with each other). This argument sharing is not obligatory, as shown by (47), which describes a shoot-out in

Saramacca Street between a police officer and a criminal and the picking up of the bullet by a by-stander. Although the bullet is only overtly realized as the object of *téi*, it is interpreted as the subject of the verbs *pása*, *gó*, and *náki*.

4 Structure

4.1 Hierarchical relations

The hierarchical relations between the different NP arguments in a serial verb construction have received little attention so far and the discussion has been based only on data from Haitian. In this section we present data on the three types of serial verb constructions to show that the same hierarchical relations hold between the NPs in Saramaccan as in Haitian. But first we discuss the Haitian facts.

Veenstra (1997), partly based on Déchaine (1988b), discusses the relation between NP_2 and XP_3 in serial verb constructions in Haitian, and shows that this relation is asymmetrical: NP_2 asymmetrically c-commands XP_3. The tests to show the relation between the arguments are taken from Barss and Lasnik's (1986) seminal paper on double object constructions in English. They involve anaphor binding, quantifier binding, and the so-called 'each . . . the other' construction.

The first test involves anaphoric binding.[7] In the following examples an asymmetry arises. The NP in the NP_2-position can bind an anaphoric element in the XP_3-position. The reverse, however, is not possible:

(48) a. M pran $Mari_i$ montre tet-li_i/li_i nan glas la.
1SG take Mary show HEAD–3SG/3SG LOC mirror DET
'I showed Mary herself in the mirror.'
b. *M pran tet-li_i/li_i montre $Mari_i$ nan glas la.
1SG take HEAD-3SG/3SG show Mary LOC mirror DET

The upshot is that the difference in grammaticality is due to the asymmetrical c-command relation that holds between NP_2 and XP_3.

The second test involves quantifier binding and gives the same result. In order for a pronoun to be bound by a quantified NP, it must be in the structural domain of that NP. Otherwise we have a weak crossover configuration and the bound pronoun reading is not possible:

(49) a. M pran chak liv_i montre mèt l_i.
1SG take each book show owner 3SG
'I showed each book to its owner.'
b. *M pran liv l_i montre chak $elev_i$.
1SG take book 3SG show each student

The last test, based on the 'each . . . the other' construction, only reinforces the point made above that there is an asymmetrical relation between the two object

positions. The NP containing 'the other' must be in the domain of the NP containing 'each'. The reverse is ungrammatical (cf. Déchaine 1988b):

(50) a. M pran chak timoun voye paran lot la.
1SG take each child send parent other DET
'I sent each child to the other's parent.'
b. *M pran chek lot la voye chak neg.
1SG take check other DET send each person

The tests above all point toward the same conclusion, namely that XP_3 is in the domain of NP_2 and that NP_2 is outside the domain of XP_3. In other words, an asymmetrical c-command relation holds between the two object positions in serial verb constructions (of the *take*-type) in Haitian.

Turning now to different types of serial verb constructions in Saramaccan, we show that the same generalization holds for all types. The test that we use in each case involves quantifier binding. In the following examples it is shown that a quantified NP occupying the NP_2-position can bind a pronoun in the XP_3-position (the (a)-examples). The reverse situation is not possible (the (b)-examples). (51) is a directional serial verb construction:

(51) a. Mi mandá híniwan ómi-miíi$_i$ gó a dí tatá f'én$_i$.
1SG send each man-child go LOC DET father for=3SG
'I have sent each son to his father.'
b. *Mi mandá hén$_i$ tatá gó a híniwan ómi-miíi$_i$.
1SG send 3SG father go LOC each man-child

The following examples are both *take*-serials. In (52) the object of *téi* is the Theme argument of the second verb, and in (53) it is interpreted as the Instrument of the second verb:

(52) a. Mi téi híniwan búku$_i$ mánda gó a dí sikífi-ma f'én$_i$.
1SG take each book send go LOC DET write-MA FOR=3SG
'I have sent each book to its writer.'
b. *Mi téi hén$_i$ búku mánda gó a híniwan sikífi-ma$_i$.
1SG take 3SG book send go LOC each write-MA

(53) a. Mi téi híniwan búku$_i$ náki dí sikífi-ma f'én$_i$.
1SG take each book hit DET write-MA FOR=3SG
'I took each book and hit its writer with it.'
b. *Mi téi hén$_i$ búku náki híniwan sikífi-ma$_i$.
1SG take 3SG book hit each write-MA

The conclusion we draw from these data is that in serial verb constructions the different arguments stand in an asymmetric relation to one another, in a left-to-right fashion, i.e., NP_2 (asymmetrically) c-commands XP_3.

4.2 Concatenation principles

Three possible concatenation principles involved in the analysis of serial verb constructions have been formulated in the literature: subordination, adjunction, and coordination.[8]

4.2.1 Subordination

The possibility that verb serialization involves some form of subordination was mentioned as early as the mid-1970s. Schachter (1974), Jansen et al. (1978), and Sebba (1987), among others, couched their analysis in terms of subordination. More recent analyses, like Baker (1989, 1991b), Lefebvre (1991), and Sybesma (1997), also adhere to this way of relating the different VPs in serial verb constructions. Arguments for this supposition are the extractability of arguments and the (sometimes) close semantic relationship between the verbs in serial verb constructions, which quite often seems to be comparable to the relation between verbs and prepositions in [V PP]-constructions.

An argument against this hypothesis is constituted by the arrangement of the verbs in a serial verb construction. How are the verbs in the chain placed in a specific order? In the case of subordination an arrangement determined by the Head Parameter would be a plausible answer. The comparison of serial verb constructions in Sranan and Ijo suggests that the matter must be more complicated. (54) shows that Ijo is head-final:[9]

(54) a. keni bila eri mi [[NP V] I]
an elephant see TNS
'saw an elephant'

b. bele bi o nama tua mi [[[[NP P] NP] V] I]
pot DET in meat put TNS
'put meat in the pot'

c. Ari u di yo-koo bo mi. [[[IP C] V] I]
1SG 3SGM look.at in.order.to come TNS
'I came in order to see him.'

The same direction holds for [NP V] in (54a), for [[PP NP] V] in (54b), and for [CP V] in (54c). Note also that temporal marking is completely to the right in all cases, thus [VP I].

Sranan is a strict head-initial language:

(55) a. koti a brede [V NP]
cut DET bread
'cut the bread'

b. poti a brede a tafra tapu [V [NP [P NP]]]
put DET bread LOC table top
'put the bread on the table'

c. Eddy e koti a brede fu nyan en [I [V [C IP]]]
Eddy ASP cut DET bread FOR eat 3SG
'Eddy is cutting the bread in order to eat it.'

Nonetheless it turns out that the order of the verbs in serial verb constructions in both languages is the same, in a number of constructions. Take first of all the *take* serial verb constructions in (56) and (57), which also illustrate the very extensive possibilities of use of this construction:

(56) aki V Ijo

a. Ye aki u bee.
thing take 3SGM say
'Say something to him.'

b. Aru bi aki tin kaka.
canoe DET take tree tie
'Tie the canoe to a tree.'

(57) teki V Sranan

a. No teki baskita tyari watra.
NEG take basket carry water
'Don't carry water with a basket.'

b. Teki dia poti na brakoto.
take deer put LOC barbecue
'Put the deer on the grill.'

The same holds for the *give* serial verb constructions in (58) and (59):

(58) V piri Ijo

a. Duma tun-ni a piri.
song sing 3SGF give
'Sing a song for her.'

b. Egberi gba-ni u piri.
story sing 3SGM give
'Tell him a story.'

(59) V gi Sranan

a. Seni wan boskopu gi tigri.
send DET message give tiger
'Send a message to Tiger/send Tiger a message.'

b. prani a karu gi yu
plant DET corn give 2SG
'plant the corn for you'

Furthermore, degree-marking serial verb constructions, such as the comparative serial, involve the same order of the verbs in both languages:

(60) V deni Ijo

bani saramo tobou demi mi
run fast child surpass TNS
'ran faster than the child'

(61) V moro/pasa Sranan
Kofi bigi moro Kwasi.
Kofi big surpass Kwasi
'Kofi is bigger than Kwasi.'

Finally, directional serial verb constructions involve the same order as well:

(62) V bo Ijo
Eri waii bo mi.
3SGM turn come TNS
'He returned, he came back.'

(63) V kon Sranan
A waka kon.
3SG walk come
'S/he walked this way.'

The fact that the arrangement of the elements in the serial construction is independent of the Head Parameter suggests that there is no relation between the verbs stated in terms typical of subordination.

In addition, in a subordination-type analysis the first verb would select the second VP. Thus, a semantic relationship should hold between V_1 and VP_2. But with respect to resultative serial verb constructions, it is not all clear how the first verb in any relevant way would semantically select the second VP. We here revert to Saramaccan examples:

(64) a. Mi náki hén kíi.
1SG hit 3SG kill
'I struck him dead.'
b. Mi sáka dí lái butá alá.
1SG lower DET load put over.there
'I have put the load over there.'

It is difficult to conceive of the type of semantic role that *náki* in (64a) or *sáka* in (64b) would assign, respectively, to *kíi* or to *butá alá*. Moreover, such a move would mean that practically all verbs in Saramaccan (or any other serializing language for that matter) have the ability to select a predicate in addition to a nominal argument, presumably an unwarranted complication of the lexicon (and grammar) of serializing languages.

If one assumes that the first verb selects a constituent consisting of NP_2 and VP_2 (cf. Den Dikken 1991a; Sybesma 1997), moreover, several other problems arise:

(65) A téi [dí beée kóti].
3SG take DET bread cut
'He cut the bread.'

Semantically, the verb *téi* 'take' (in the sense of *seize* and *physically grasp*) does not take a proposition-denoting category as a complement. One does not seize or physically grasp a proposition. Although some verbs may take an argument that has some specific semantic property, regardless of its category, the verb *téi* 'take' in Saramaccan is arguably not one of them. For example, the verb *ask* in English takes either a clausal or a nominal argument, and both of them are of the same semantic type, namely a question (cf. Grimshaw 1979) (*the time* in (66) is also known as a concealed question):

(66) a. John asked Mary what time it was.
b. John asked Mary the time.

The verb *téi*, in contrast, can syntactically take a nominal argument, as shown in (67) (in which it is not a serial verb construction):

(67) A téi dí fáka.
3SG take DET knife
'He took the knife.'

but the nominal argument of the verb *téi* is clearly not something that denotes a proposition. Therefore, if the verb may take an XP which is either a VP as suggested in (65) or an NP as in (67), with the two categories being of different semantic types, then it seems unavoidable that we have to posit two different verbs *téi* in the lexicon of Saramaccan.

4.2.2 Adjunction

The second possible candidate is adjunction. In this type of analyses the second VP is adjoined to the first. Such structures have been proposed by Bickerton and Iatridou (1987), Larson (1991), Seuren (1991), and Law and Veenstra (1992).

Evidence for the adjunct status of the non-initial VP is its optionality, as shown below:

(68) a. A téi dí páu tjá gó butá a dí wósu.
3SG take DET stick carry go put LOC DET house
'He took the stick, carried it away and put it in the house.'
b. A téi dí páu tjá gó.
3SG take DET stick carry go
'He took the stick and carried it away.'
c. A téi dí páu.
3SG take DET stick
'He took the stick.'

Hence, the third VP is not selected by the second verb and the second VP is not selected by the first verb.

Larson (1991) also makes some semantic observations that lend plausibility to analyses that treat serial verb constructions as adjoining structures. In particular, he notes that serial verb constructions in many cases form series of secondary predications with a basic modificatory status, and have similar readings as adverbial conjuncts involving 'until' or expressing purpose and temporal adverbials. Adverbials presumably have an adjunct status. Moreover, he notes that such structures can accommodate the semantic templates of Awóyalé (1988).

Veenstra (1993) builds an argument for adjunction on patterns of argument and adjunct extraction. In contrast to arguments, adjuncts cannot be extracted from the non-initial VP in serial verb constructions (cf. also Lawal 1993 on Yoruba). He shows that these facts can be accommodated in an adjunction structure without the need of additional assumptions, unlike an analysis in term of subordination. Moreover, he shows that serial verb constructions pattern differently than small clause and perception verb complements (instances of subordination structures) with respect to *wh*-extraction. In conclusion, a good case can be made for adjunction as the guiding principle for the stacking of VPs in serial verb constructions.[10]

4.2.3 Coordination

Coordination structures come in four varieties. Two factors discriminate the four varieties: syndetic vs. asyndetic and symmetrical vs. asymmetrical.

Syndetic coordinations contain a conjunction and asyndetic coordinations do not. As already shown in section 3, serial verb constructions cannot contain (coordinating) conjunctions. This rules out the possibility that serial verb constructions are instances of syndetic coordinations. It leaves open the possibility, however, that they are asyndetic coordinations.

Symmetrical coordinations do not show sequential effects and asymmetrical ones do. A frequently cited argument in favor of a coordination analysis is that in (some) serial verb constructions there is a temporal ordering between the different actions (or subevents):

(69) a. Mi wáka gó a dí wósu.
1SG walk go LOC DET house
'I walked to the house.'
b. *Mi gó a dí wósu wáka.
1SG go LOC DET house walk

(70) a. Mi téi dí fáka kóti dí beée.
1SG take DET knife cut DET bread
'I took the knife and cut the bread.'
b. *Mi kóti dí beée téi dí fáka.
1SG cut DET bread take DET knife

(71) a. Mi náki hén kíi.
1SG hit 3SG kill
'I struck him dead.'

b. *Mi kíi hén náki.
1SG kill 3SG hit

The sequential effect shows up in all three types. These data rule out an analysis of serial verb constructions in terms of symmetrical coordination. They leave open the possibility that these constructions are asymmetrical coordinations. The conclusion, therefore, is that if serial verb constructions have a coordinate structure, they are asyndetic asymmetric coordinations (cf. Déchaine 1993).

A coordinate analysis has been argued against by Jansen et al. (1978) and Sebba (1987). They show that serial verb constructions never show the island effects that have been associated with coordinate structures since Ross (1986). In particular, all the VPs in serial verb constructions are transparent with respect to argument extraction:

(72) Na-un-sé$_i$ a wáka gó t$_i$?
LOC-Q-side 3SG walk go
'Where did he walk to?'

(73) a. Andí$_i$ a téi t$_i$ kóti dí beée?
what 3SG take cut DET bread
'What did he cut the bread with?'
b. Andí$_i$ a téi dí fáka kóti t$_i$?
what 3SG take DET knife cut
'What did he cut with the knife?

(74) Ambé$_i$ a náki t$_i$ kíi?
who 3SG hit kill
'Who did he strike dead?'

However, the argument is not as strong as it appears to be at first sight. The Coordinate Structure Constraint (CSC) of Ross (1986) is enforced for those coordinations that are (semantically) symmetric. No extraction is allowed out of the conjuncts, unless it is in an Across-the-Board (ATB) fashion, i.e., simultaneous extraction out of all conjuncts. We have already pointed out above that if serial verb constructions are anything like coordinations, they are asymmetric coordinations. Thus, the absence of island effects is not a direct argument against an analysis in terms of asymmetric coordination.

The pattern of extraction out of asymmetric coordinations is as follows (cf. Williams 1994). Extraction out of the second conjunct is allowed. Extraction out of the first conjunct is not possible, unless it happens in an ATB fashion. Relevant examples from English are given in (75):

(75) a. What$_i$ did John go to New York and buy t$_i$?
b. *What city$_i$ did John go to t$_i$ and buy a gun?

An example of an ATB extraction out of an asymmetric coordination structure in English is (76):

(76) Who_i did you see t_i and imitate t_i?

Schematically, we can represent the different extraction possibilities out of asymmetric coordination structures and serial verb constructions as follows:

(77) **Asymmetric coordination:**
a. WH_i $[_{VP1}$ V XP$]$ $[_{VP2}$ V $ec_i]$
b.* WH_i $[_{VP1}$ V $ec_i]$ $[_{VP2}$ V XP$]$
c. WH_i $[_{VP1}$ V $ec_i]$ $[_{VP2}$ V $ec_i]$

(78) **Serial verb construction:**
a. WH_i $[_{VP1}$ V NP$]$ $[_{VP2}$ V $ec_i]$
b. WH_i $[_{VP1}$ V $ec_i]$ $[_{VP2}$ V XP$]$

In an asymmetric coordination analysis of serial verb constructions, the pattern in (78b) constitutes the problem. Contrary to our expectations, you can extract out of the first conjunct.

Suppose now that we reduce this pattern to the pattern in (77c) by positing an empty category in the non-initial conjunct coreferent with the object in the initial conjunction. Then, (78b) rewrites as (79):

(79) WH_i $[_{VP1}$ V $ec_i]$ $[_{VP2}$ V ec_i XP$]$

Thus, what looks like extraction out of the first conjunct only is in fact a form of ATB extraction. The conclusion, therefore, is that serial verb constructions can be reduced to asymmetric coordination structures iff there is an empty category present in the second VP coreferent with the object of the first verb.

Arguments for the presence of an empty category inside the non-initial predicate of serial verb constructions have been presented by Bickerton and Iatridou (1987), Carstens (1988), Larson (1991), Law and Veenstra (1992), DeGraff (1993), Collins (1993, 1997a), Veenstra (1993, 1996), Da Cruz (1994), Campbell (1996a), Stewart (1998), and Hagemeijer (2000).

Munn (1992) argues that ATB constructions should be reduced to parasitic gap constructions. Although coordinate structures behave differently from structures supporting parasitic gaps, the point he makes is that multiple gap constructions in both structures are best analyzed in terms of null operator binding and chain composition. He notes that a consequence of such an analysis is that "coordinate structures are in fact adjunction structures with a hierarchical and therefore asymmetric structure" (Munn 1992: 1). This conception of coordinate structures tallies nicely with the analyses of serial verb constructions put forward by Larson (1991) and Law and Veenstra (1992), in which the second predicate is an adjunct to the first predicate and in which the argument-sharing effect is obtained through null operators.

The conclusion, therefore, is that a good case can be made for the analysis of serial verb constructions in terms of asyndetic asymmetric coordination structures (cf. Corne et al. 1996 for a similar conclusion), with coordination being syntactically analyzed in terms of an adjunction structure, with the provision that it can be shown that an empty category is present inside the non-initial predicate that is adjoined to the first predicate.

5 Argument sharing

An observation that goes back to Stewart (1963) is that overt objects in serial verb constructions are semantically related to both verbs, i.e., the verbs share their internal arguments. Thus, in (80a) the object *dí búku* 'the book' is an object of *téi* 'take' as well as of *léi* 'show':

(80) a. Mi téi dí búku léi dí wómi.
1SG take DET book show DET man
'I showed the book to the man.'
b. Mi téi dí fáka kóti dí beée.
1SG take DET knife cut DET bread
'I cut the bread with the knife.'

For example, in (80b) it has been argued that *dí fáka* 'the knife' is the Instrument object of the second verb *kóti*.

The question is whether the (semantic or syntactic) sharing of arguments is obligatory in verb serialization. Sebba (1987) discusses the following minimal pair and argues that only if the verbs share their object is it possible to speak of a serial verb construction:

(81) a. A náki hén kíi.
3SG hit 3SG kill
'She hit him dead.'
b. A náki hén kíi hén.
3SG hit 3SG kill 3SG
'She hit him and killed him.'

Sebba argues at length that (81b) involves a coordinate structure and displays a distinct behavior from that of (81a).

The most explicit answer to the question of the obligatoriness of object sharing has been formulated in the work of Baker (1989, 1991b). For him, the sharing of arguments is one of the defining properties of the construction. Moreover, this sharing is not at random, but is thematically restricted; i.e., in serial verb constructions with more than one internal argument, as in (80), the order in which arguments appear obeys the following thematic hierarchy:

(82) Ag < Instr < . . . < Th < Go < Loc

If the second verb selects a Theme and an Instrument, it is only the Instrument that can be shared with the first verb. Similarly, if the second verb is a regular triadic verb, it is the Theme that is shared with the first verb rather than the Goal. This restriction might cover in principle the observed facts for some serializing languages, such as Yoruba and Gokana. Relevant examples are given in (83) and (84), taken from Baker (1989) and Wagner (1985), respectively:

(83) a. Olú mú òbe gé búrédi.
Olu take knife cut bread
'Olu cut the bread with the knife.'
b. *Olú mú búrédi gé òbe.
Olu take bread cut knife

(84) a. mín è tú kpá nè pábia.
child TNS take book give woman
'The child gave the book to the woman.'
b. *mín è tú pábia nè kpá.
child TNS take woman give book

On the other hand, it is too restrictive for other languages, such as Haitian, Sranan, and Saramaccan (cf. Law and Veenstra 1992; Veenstra 1993). The following data, which are direct counter-examples to the thematic restriction on argument sharing in verb serialization, suffice to make the point:

(85) a. Mi téi dí fáka kóti dí beée.
1SG take DET knife cut DET bread
b. Mi téi dí beée kóti ku dí fáka.
1SG take DET bread cut with DET knife
'I cut the bread with the knife.'
c. *Mi téi dí beée kóti dí fáka.
1SG take DET bread cut DET knife

(86) a. A téi dí fóto léi hen.
3SG take DET picture show 3SG
a. A téi hen léi dí fóto.
3SG take 3SG show DET picture
'He showed the picture to him.'

Thus, it appears that the cross-linguistic variation with respect to the ordering of arguments in serial verb constructions is rather due to language-specific constraints than to universal ones on the process of serialization.

6 Parameterization and typological correlates

As noted in section 1, if there exists something like a serializing language type we would expect a number of typological correlates (i.e., co-occurring linguistic

features) of serial verb constructions. The following have been put forward as possible correlates: word order, non-distinctiveness of verbs and prepositions, absence of verbal (derivational or inflectional) morphology, and separation of verbs from INFL.

6.1 Word order

This is not promising. The Caribbean creole languages are all SVO languages, but many West African serializing languages are underlyingly SOV (as shown in work inspired by Koopman 1984), and some are SOV on the surface as well, like Ijo. Malagasy is verb-initial, and in the Pacific and Sino-Tibetan cases we find both SOV and SVO languages.

6.2 Non-distinctiveness of verbs and prepositions

Proposals that verb serialization is correlated with non-distinctiveness of verbs and prepositions come into two guises: verbs are seen either as additional Case markers (e.g., Bickerton 1981; Byrne 1987) or as additional markers of thematic roles (e.g., Sebba 1984). With respect to the latter proposal, Bruyn et al. (1999) have shown that (virtually) all creole languages have double object constructions, thereby casting doubt on Sebba's (1984) claim that verbs in serializing languages can select only one internal argument at the time. The former proposal assumes that serializing languages do not have prepositions and that this gap is taken over by verbs. Problems with this type of approach are manifold. First, serial verbs allow stranding, just like verbs; prepositions (in Sranan and Haitian) generally do not:

(87) a. San Edgar **koti** ___? Sranan
what Edgar cut
'What did Edgar cut?'
b. San Edgar **teki** ___ koti a brede?
what Edgar take cut DET bread
'What did Edgar cut the bread with?'
c. *A nefi san a e koti a brede **nanga** ___?
DET knife that 3SG ASP cut DET bread with

Second, (some) serial verbs allow predicate cleft, just like verbs, and prepositions never do:

(88) a. Na **koti** Edgar **koti** a brede. Sranan
BE cut Edgar cut DET bread
'Edgar really cut the bread.'
b. Na **teki** Edgar **teki** a nefi koti a brede.
BE take Edgar take DET knife cut DET bread
'Really with the knife Edgar cut the bread.'

c. *Na **nanga** Edgar koti a brede **nanga** a nefi.
BE with Edgar cut DET bread with DET knife

Third, some creole languages (e.g., Principense) distinguish oblique (assigned by P) from objective case (assigned by V). Fourth, all creole languages have a number of prepositions without verbal properties. Finally, serial verbs are also used non-prepositionally.

6.3 Absence of verbal morphology and separation of verbs from INFL

For Saramaccan, and creole languages in general (for West African languages the issue is not as clear), we want to suggest that absence of verbal morphology (or the inertia of it, if present, as in some West African languages) and the separation of verbs and INFL are interrelated. In general, creole languages lack verbal morphology (i.e., verbs do not inflect for tense, number, and person). They also lack V-to-I movement. It could be argued that the absence of V-to-I movement sets serializing languages, apart from non-serializing languages, which have V-to-I movement in overt syntax or at LF.

The discussion in section 4 led to the conclusion that all serial verb constructions are to be analyzed as right-adjoined structures, i.e., the second predicate is adjoined to the first predicate. If there is no verb movement to INFL in serializing languages because of the lack of tense/agreement morphology on the verb, then, as a result, the verb in the second predicate of a serial verb construction need not move to INFL. In other words, the structure of serial verb constructions, as given in (89), is legitimate in serializing languages (omitting details irrelevant for the discussion at hand):

(89) $[NP_i\ [t_i\ V_1\ [_{VP1}\ NP_2\ t_1\ [_{VP2}\ V_2\ XP_3]]]]$

The question of why non-serializing languages like English and French do not have serial verb constructions now hinges on the question of why they disallow the structure in (89). Notice that non-serializing languages usually have richer inflectional morphology in terms of tense, number, and person agreement than serializing languages. Suppose that the verb in languages with some verbal inflection must move to INFL (via Tense) to pick up inflectional morphology in overt syntax or at LF, then in the structure in (89), movement of the second verb out of the second predicate would violate Travis's (1984) Head Movement Constraint (HMC):

(90) **Head Movement Constraint:**
An X^0 may only move to the Y^0 which properly governs it.

In the structure in (89), the second verb heads a complement neither to the first verb nor to Tense. Therefore, there are two possible reasons why serial verb

constructions are not possible in non-serializing languages: either because the second verb fails to get inflectional morphology, if it does not move out of the second VP, or because the movement of the second verb to INFL to get inflectional morphology would violate the HMC, since the trace left by movement of the second verb is not properly governed.

This account of the availability of serial verb constructions in languages fares better than the account given by Larson (1991). He proposes that serializing languages differ from non-serializing ones in that in the former set of languages, secondary predicates are essentially non-nominal (either [–N] or [+V] but not [+N, –V]) in nature, while in the latter set, secondary predicates are non-verbal (either [+N] or [–V] but not [–N, +V]) in nature (see Larson 1991: 205–207 for more details and argumentation). One clear-cut prediction of his proposal is that serializing languages do not have secondary predicates headed by nouns, e.g., NP predicates in small clauses. (91) gives direct counter-examples:

(91) a. Mi féndi en bumbúu sèmbe.
1SG find 3SG good person
'I consider him a good person.'
b. A tá lúku mi ógi-wójo.
3SG ASP look 1SG evil-eye
'She looks at me angrily.'

These accounts (i.e., Larson 1991; Law and Veenstra 1992) assume a modular solution to the issue of why certain languages have serial verb constructions and others do not have them.

Baker (1989, 1991b), on the other hand, opts for a parametric approach. He starts out by discussing the Head-Licensing Condition (HLC) of Chomsky (1986b). The HLC requires a head to be linked to a single maximal projection. This gives way to the possibility of one maximal projection licensing two head positions. Consequently, Baker proposes that the key difference between serializing and non-serializing languages lies in the exploitation of this possibility. He recasts it in the following parameter (Baker 1989: 519):

(92) **Generalized Serialization Parameter:**
VPs {can/cannot} count as the projection of more than one distinct head.

Languages such as Saramaccan and Haitian allow for a positive value of this parameter and, therefore, have serial verb constructions, while languages such as French and English do not and, as a consequence, do not have serial verb constructions. One of the main problems of this approach is that it has to posit parametric differences in specific phrase structure rules, contra the spirit of Stowell (1981) and later work.

Collins (1995a) relates the possibility of having serial verb constructions to a parameter on the feature-specification of Tense. If the V-feature of Tense is [+multiple], it is a serializing language. The V-feature of Tense in non-serializing languages is

[–multiple]. Such an approach would account for the same range of facts as the approach advocated by Law and Veenstra (1992). It would lose the correlation with lack of verb movement (in overt syntax and at LF), however. In a multiple feature-specification type of analysis the verb still has to move at some point in the derivation to Tense to check off the V-feature.[11]

It appears, then, that the difference between serializing and non-serializing languages derives from differences between languages with respect to the availability/richness of tense/agreement morphology. In this way parametric variation is reduced to different properties of functional categories and their interaction with independently motivated assumptions concerning verbal syntax, a desirable result in view of the task of acquiring language (Ouhalla 1991).

NOTES

1 Williams (1971: 48–9) observes for Krio that "a large number of serial strings . . . [can] occur with an inserted conjunction . . . [with] little or no apparent difference in meaning." Dudley Nylander (p.c.), on the other hand, disclaims Williams's observation for Krio. Hyman (1971) and Déchaine (1989) cite examples from Igbo of serial constructions containing a 'consecutivity' marker. Lord (1975), on the other hand, argues that such consecutive constructions differ from serial verb constructions. As will be shown below, the presence or absence of coordination markers is relevant for serial verb constructions in Saramaccan. See Sebba (1987) on Sranan, Déchaine (1988a) on Haitian, and Veenstra (1990) on Jamaican Creole for its relevance for serial verb constructions in these languages.

2 See Givón (1991) for a comprehensive study on pause phenomena in serial verb constructions. We will not go into a discussion of this matter.

3 In some (West African) languages the contrast is not as clear. Thus, although the result of this negation test is denied for Yoruba by Bámgbosé (1986), Awóyalé (1988: 3, fn. 3) points out that all actions expressed in serial verb constructions are already performed.

4 Déchaine (1993) also comes to a division into four types of serial verb constructions on the basis of a comparative study of Yoruba, Haitian, and Igbo: dative, instrumental, resultative, and multi-event serial verb constructions. Her classification comes close to the one presented here, though it is not identical in spirit.

5 It may be the case that the latter two instances are type 3 serial verb constructions. If that is the case, it only shows that strict boundaries between different types of serial verb constructions are hard to draw.

6 Byrne (1987) notes two examples in which *pása* and *moó* cannot be used interchangeably: *A píki moó/*pása mi* 'He is smaller than me', and *A kóni moó/*pása dí wómi* 'She outsmarted the man.'

7 Binding facts are rather complex in Haitian due to competing forms of anaphoric elements (*tet-li* HEAD–3SG, *ko-li* BODY–3SG, *li* 3SG) and dialectal variation (cf. Carden and Stewart 1988; Déchaine and Manfredi 1994). The form *li* can be an anaphoric element as well as a pronominal element and accordingly may be either bound or free in its local domain. The body part reflexives sometimes retain their literal meaning in addition to their reflexive interpretation. Which form of the reflexive is chosen depends on the verb it is the object of, among other things.

8 In Chomsky's (2001a) terminology, subordination is created by the operation *set–merge*, while adjunction and coordination are created by the operation *pair–merge*.

9 We do not assume the antisymmetry framework of Kayne (1994), in which there is only one branching direction (leading to languages being analyzed as uniformly head-initial).

10 This proposal is different from the adjunction analysis by Awóyalé (1988), which requires two direction of adjunctions (leftward as well as rightward). The data in (52) and (53) above show that 'precondition states' (instrumentals) and 'postcondition states' (resultatives) pattern alike with respect to the hierarchical relation between the different arguments in serial verb constructions. As such, this argues against assigning these two types of serials a different syntactic structure. See Veenstra (1997) for elaboration of this point.

11 We could speculate that there are actually two types of serializing languages. In one type serialization is the result of lexicalization of INFL and absence of verbal morphology (Law and Veenstra 1992), while in the other type it is the result of the feature-specification of the Tense node in INFL (Collins 1995a). In the latter type, there would still be verbal morphology and V-to-I movement, but not in the former. Creole languages may be examples of the first type, while Akan, for instance, may be one of the second type. Akan has tense morphology on both verbs in serial verb constructions (cf. Schachter 1974):

(i) Mey*EE* adwuma mem*aa* Amma.
1SG=do=TNS work 1SG=give=TNS Amma
'I worked for Amma.'

We leave this speculation for future research, but note that it is not a priori necessary that all serializing languages should form a natural class.

  3.2 Movement approaches
4 Puzzles and prospects
  4.1 Sluicing-COMP generalization puzzles
  4.2 Sluicing in clause-internal *wh* languages
  4.3 Multiple sluicing
  4.4 Swiping
5 Conclusion

1 Introduction

Sluicing is the ellipsis phenomenon illustrated in (1), in which the sentential portion of a constituent question is elided, leaving only a *wh*-phrase remnant:

(1) a. Jack bought something, but I don't know what.
  b. A: Someone called.
    B: Really? Who?
  c. Beth was there, but you'll never guess who else.
  d. Jack called, but I don't know {when/how/why}.
  e. Sally's out hunting – guess what!
  f. A car is parked on the lawn – find out whose.

The sluices in (1) should be compared to their non-elliptical counterparts in (2), with which they are synonymous:

(2) a. Jack bought something, but I don't know what he bought.
  b. A: Someone called.
    B: Really? Who called?

c. Beth was there, but you'll never guess who else was there.
d. Jack called, but I don't know {when/how/why} he called.
e. Sally's out hunting – guess what she's out hunting!
f. A car is parked on the lawn – find out whose is parked on the lawn.

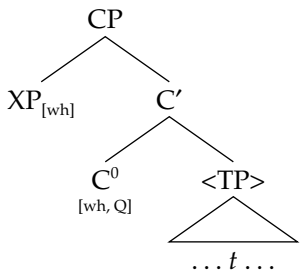
Sluicing appears to be widespread cross-linguistically (unlike VP ellipsis), and may in fact be found in some form or another in every language (like nominal ellipses, gapping, stripping, and fragment answers). It is found in at least English, Frisian, Icelandic, Swedish, Norwegian, Danish, Irish, Greek, German, Dutch, Russian, Polish, Bulgarian, Serbo-Croatian, Slovene, Persian, Hindi-Urdu, Catalan, Spanish, French, Italian, Romanian, Hebrew, Arabic, Basque, Japanese, Chinese, Korean, Finnish, and Hungarian.

Situated as it is at the intersection of two of the best-studied and most intriguing areas of generative research, namely ellipsis and *wh*-movement, it comes as no surprise that sluicing has been extensively discussed since it was first investigated (and named) in Ross (1969b). Following the divisions in general for the analysis of ellipses, there are two general schools of analysis for sluicing: either the understood material is present at some level of syntactic structure or it is not. The first school, which takes sluicing to be a subspecies of ellipsis, is represented by the majority of analyses, beginning with Ross (1969b), and continuing with Chao (1988), Lobeck (1991, 1995), Chung et al. (1995), Lasnik (2001), and Merchant (2001), among several others. Non-structural analyses of sluicing in particular have been pursued by van Riemsdijk (1978a) and Ginzburg and Sag (2000), who posit that a clausal node immediately and exhaustively dominates the *wh*-phrase.

2 Movement vs. non-movement approaches

Among the analyses that posit structure internal to the ellipsis site, two approaches can be identified. The first, originating with Ross (1969b) and pursued more recently by Lasnik (2001) and Merchant (2001), among others, analyzes sluicing as involving movement of a *wh*-phrase out of a sentential constituent (S, IP, or TP), followed by deletion of that node. This derivation is schematized in (3), where angled brackets represent deletion (or, more neutrally, enclose unpronounced material):

(3)



For an example like (1a), then, the structure would be the following:

(4) Jack bought something, but I don't know [$_{CP}$ what$_1$ C^0 <[$_{TP}$ he bought t_1]>].

The primary support for such a derivation comes from connectivity effects. The *wh*-phrase 'remnant' in sluicing shows similar behavior across a wide range of grammatical dependencies to its *wh*-phrase counterpart in fully sentential, non-elliptical structures. These connectivity effects range from case-matching effects and preposition-stranding parallelisms to binding phenomena.

First, as noted in Ross (1969b), the sluiced *wh*-phrase must bear the case that its counterpart in a non-elided structure would bear. This is illustrated for German below:

(5) Er will jemandem schmeicheln, aber sie wissen nicht, {*wer / *wen / wem}.
he wants someone.DAT flatter but they know not who.NOM who.ACC who.DAT
'He wants to flatter someone, but they don't know who.'

(6) Er will jemanden loben, aber sie wissen nicht, {*wer / wen / *wem}.
he wants someone.ACC praise but they know not who.NOM who.ACC who.DAT
'He wants to flatter someone, but they don't know who.'

Compare these to their non-elided counterparts:

(7) Sie wissen nicht, {*wer / *wen / wem} er schmeicheln will.
they know not who.NOM who.ACC who.DAT he flatter wants
'They don't know who he wants to flatter.'

(8) Sie wissen nicht, {*wer / wen / *wem} er loben will.
they know not who.NOM who.ACC who.DAT he praise wants
'They don't know who he wants to praise.'

Similar facts are found in all case-marking languages that relevant data are available for: English, Greek, Dutch, Finnish, Hungarian, Russian, Polish, Czech, Slovene, Hindi, Basque, Turkish, and Korean.

Second, there is a correlation between the availability in a given language for preposition-stranding *wh*-movement and the possibility for sluicing a *wh*-phrase without a preposition which corresponds to a correlate marked by a preposition. In general, a language *L* will allow preposition stranding under sluicing if *L* allows preposition stranding under regular *wh*-movement. The relevant facts are given here for selected languages of both kinds.

Preposition-stranding languages:

(9) English:
a. Peter was talking with someone, but I don't know (with) who.
b. Who was he talking with?

(10) Frisian:
a. Piet hat mei ien sprutsen, mar ik wyt net (mei) wa.
Piet has with someone talked but I know not with who
b. Wa hat Piet mei sprutsen?
who has Piet with spoken

(11) Norwegian:
a. Per har snakket med noen, men jeg vet ikke (med) hvem.
Per has talked with someone but I know not with who
b. Hvem har Per snakket med?
who has Per spoken with

(12) Danish:
a. Peter har snakket med en eller anden, men jeg ved ikke (med) hvem.
Peter has talked with one or another but I know not with who
b. Hvem har Peter snakket med?
who has Peter spoken with

Non-preposition-stranding languages:

(13) Greek:
a. I Anna milise me kapjon, alla dhe ksero *(me) pjon.
the Anna spoke with someone but not I.know with who
b. *Pjon milise me?
who she.spoke with

(14) German:
a. Anna hat mit jemandem gesprochen, aber ich weiß nicht, *(mit)
Anna has with someone spoken but I know not with
wem.
who
b. *Wem hat sie mit gesprochen?
who has she with spoken

(15) Yiddish:
a. Zi hot mit emetsn geredt, ober ikh veys nit *(mit) vemen.
she has with someone spoken but I know not with who
b. *Vemen hot zi mit geredt?
who has she with spoken

(16) Russian:
a. Anja govorila s kem-to, no ne znaju *(s) kem.
Anja spoke with someone, but not I.know with who
b. *Kem ona govorila s?
who she spoke with

(17) Slovene:
a. Anna je govorila z nekom, ampak ne vem *(s) kom.
Anna AUX spoken with someone but not I.know with who
b. *Kom je govorila Anna s?
who AUX spoken Anna with

(18) Bulgarian:
a. Anna e govorila s njakoj, no na znam *(s) koj.
Anna AUX spoken with someone but not I.know with who
b. *Ko e govorila Anna s?
who AUX spoken Anna with

(19) Serbo-Croatian:
a. Ana je govorila sa nekim, ali ne znam *(sa) kim.
Ana AUX spoken with someone but not I.know with who
b. *Kim je govorila Ana sa?
who AUX spoken Anna with

(20) Persian:
a. Ali ba kasi harf mi-zad, ʔama ne-mi-dan-am *(ba) ki.
Ali with someone talk PROG-hit.3sg but not-PROG-know-I with who
b. *Ki Ali ba harf mi-zad?
who Ali with talk PROG-hit.3sg

(21) Hebrew:
a. Dani katav le-mishehu, aval ani lo yode'a *(le-)mi.
Dani wrote to-someone, but I not know to-who
b. *Mi Dani katav le?
who Dani spoke with

(22) Basque:
a. Ana-k norbait-ekin hitzegin zuen, baina ez dakit nor- *(ekin).
Ana-ERG someone-with talk.to AUX but not know who- with
b. *Nor hitzegin zuen -ekin?
who talk.to AUX with

Third, binding of elements in *wh*-phrase remnants is possible, as Lasnik (2001) shows:

(23) Every linguist$_1$ criticized some of his$_1$ work, but I'm not sure how much of his$_1$ work <every linguist$_1$ criticized *t*>.

(24) Each of the linguists criticized some of the other linguists, but I'm not sure how many of the other linguists <each of them criticized *t*>.

These parallels in distribution are immediately and straightforwardly accounted for by the deletion theory of sluicing, since the grammatical constraints that regulate case on *wh*-phrases, the possibility of extracting a *wh*-phrase from a PP, binding into *wh*-phrases, and scope will be operative uniformly in both elliptical and non-elliptical structures.

The second strand of analyses of sluicing which posit structure internal to the ellipsis site is represented by Lobeck (1995) and Chung et al. (1995). For these authors, ellipses consist of a designated null category drawn from the lexicon which is replaced after S-structure/Spell-Out by a phrase marker copied from the antecedent by LF. For an example like (1a), then, the derivation would contain the following structures, where the elliptical *e* in (25a) has been replaced by the boldface material in (25b):

(25) a. At Spell-Out:
Jack bought something, but I don't know [$_{CP}$ what C^0 [$_{TP}$ *e*]].
b. At LF:
Jack bought something, but I don't know [$_{CP}$ what C^0 [$_{TP}$ **Jack bought something**]].

These analyses posit no movement of the *wh*-remnant: it is base-generated in Spec, CP and comes to bind a variable (supplied by the indefinite internal to the copied TP) only at LF. The primary motiviation for such a movementless approach comes from the fact, noted by Ross (1969b), that sluicing appears not to respect islands – more accurately, that the *wh*-phrase in sluicing can be associated with (bind) a variable which corresponds in position to a correlate internal to an island in the antecedent TP.

Examples for the major kinds of syntactic islands are given (occasionally with non-elliptical controls) in (26–34):

(26) **Relative clause island:**
a. They want to hire someone who speaks a Balkan language, but I don't remember which.
b. *I don't remember which *(Balkan language) they want to hire someone [who speaks___]*.

(27) **Left-branch (attributive adjective case):**
a. She bought a big car, but I don't know how big.
b. *I don't know how big *she bought [a ___ car]*.

(28) **Derived position islands (subjects, topicalizations):**
   a. A biography of one of the Marx brothers is going to be published this year – guess which!
   b. *Guess which *(Marx brother) [a biography of ___] is going to be published this year.*

(29) **COMP-trace effects** (cf. Chung et al.'s 1995: (90), (91a); Perlmutter 1971: 112):
   a. It appears that someone will resign, but it's not yet clear who.
   b. Sally asked if somebody was going to fail Syntax One, but I can't remember who.

(30) **Coordinate Structure Constraint:**
   a. They persuaded Kennedy and some other Senator to jointly sponsor the legislation, but I can't remember which one. (Chung et al.'s 1995: (88b))
   b. Bob ate dinner and saw a movie that night, but he didn't say which.

(31) **Adjuncts:**
   a. Ben will be mad if Abby talks to one of the teachers, but she couldn't remember which.
   b. *Ben will be mad if Abby talks to one of the teachers, but she couldn't remember which *(of the teachers) Ben will be mad [if she talks to __].*
   c. Ben left the party because one of the guests insulted him, but he wouldn't tell me which.

(32) **Complement to nouns** (Chung et al.'s 1995: (84c)):
The administration has issued a statement that it is willing to meet with one of the student groups, but I'm not sure which one.

(33) **Sentential subject** (Chung et al.'s 1995: (84b)):
That certain countries would vote against the resolution has been widely reported, but I'm not sure which ones.

(34) **Embedded question** (Chung et al.'s 1995: (84a)):
Sandy was trying to work out which students would be able to solve a certain problem, but she wouldn't tell us which one.

In (26a), for example, the *wh*-phrase *which* has moved out of the relative clause, interpretationally parallel to its unelided but ungrammatical counterpart in (26b). Similar remarks apply to the remaining islands.

If island sensitivity arises only from movement structures, as is usually assumed, the non-movement approaches (employing either LF-copying as above or eschewing structure at all, as Ginzburg and Sag 2000 do) have an immediate account of the absence of islands effects in sluicing.

3 Theoretical consequences

It is fair to say that the greater part of the work on sluicing has been devoted to various attempts to make theoretical sense out of the conundrum presented above: how to account for the connectivity effects (which seem to implicate movement structures) as well as the lack of island effects (which seem to implicate the opposite). The following two subsections explicate the tacks that have been taken.

3.1 Non-movement approaches

For non-movement approaches such as Lobeck (1995), Chung et al. (1995), and Ginzburg and Sag (2000), the primary explicandum is the connectivity effects, since the absence of island effects is directly captured. Chung et al. (1995) propose that at LF, a kind of co-indexing applies to the *wh*-phrase in Spec, CP and the correlate inside the copied TP, yielding structures like the following:

(35) Jack bought something, but I don't know [$_{CP}$ what^{x} C^{0} [$_{TP}$ **Jack bought something**^{x}]].

If this co-indexing can be made to impose case uniformity, then the case connectivity effects can be accounted for. The P-standing facts are more problematic: it is unclear just how to rule out the following:

(36) *I Anna milise me kapjon, alla dhe ksero [$_{CP}$ pjon^{x} [**i Anna milise me kapjon**^{x}]].
the Anna spoke with someone but not I.know who

One possibility, explored in Merchant (2000), is to require movement in the antecedent clause, prior to LF-copying: scoping the correlate (here *kapjon* 'someone') would require stranding a preposition at LF, and if Bayer (1996) is correct, this is impossible in these languages, so the requisite structure for resolution of the ellipsis at LF would be unavailable. Such a solution requires positing an additional Chain Uniformity condition that imposes category uniformity on all elements in a chain (even derived); see Merchant (2000) for the definition of such a condition.

Similar remarks hold for Ginzburg and Sag's (2000) account of the connectivity effects. For them, sluices like the ones discussed thus far are introduced by the phrasal type *sluiced-interrogative-clause*, which is a subtype of *headed-fragment-phrase* (among others). Such phrases are subject to a constraint (call it the 'uniformity' constraint; Ginzburg and Sag 2000: 304, (17)) that they dominate a phrase (the *wh*-phrase) whose CATEGORY and CONTENT values are the same as (are co-indexed with) the CATEGORY and CONTENT values of a phrase (the correlate) provided by the context. (The grammatical information of the correlate is introduced into the sign of the fragment phrase by a feature designed for this purpose, called SAL-UTT.) Since case and phi-features are subsorts of CATEGORY and CONTENT respectively, this constraint will ensure that the case and phi-features of the

remnant and the correlate match. Ginzburg and Sag's uniformity constraint and Merchant's Chain Uniformity condition are quite comparable in formulation and functioning. Neither condition, however, straightforwardly rules out (36). For Merchant's condition, this is because nothing rules out co-indexing *pjon* with *kapjon*, the latter embedded unmoved in a PP (it is for this reason that the correlate must be assumed to move as well). Similarly, nothing in Ginzburg and Sag's formulation rules out *pjon* being the head of a *hd-frag-ph* whose SAL-UTT value is the local value of *kapjon*. There is no obvious way to state the requirement that in some languages (e.g., Greek) but not others (e.g., English), correlates cannot be DPs selected by Ps.

3.2 Movement approaches

Movement approaches deal easily with the connectivity facts, since nothing novel need be said. For them, however, the lack of island sensitivity is the primary explicandum. We can identify two main approaches to dealing with this fact. The first is to reanalyze the movement involved in sluicing as one that does not in fact cross an island boundary. This strategy is pursued for those islands which include a propositional proper subdomain, such as relative clauses, clausal adjuncts, and sentential subjects, by Merchant (2001) (see also Baker and Brame 1972 for a related suggestion, and Fukaya 2003). On this view, the apparent extraction out of an island such as the relative clause in (37a), with the putative (ill-formed) source in (37b), does not in fact occur:

(37) a. They want to hire someone who speaks a Balkan language, but I don't remember which.
b. *I don't remember which *(Balkan language) they want to hire someone [who speaks___]*.

Instead, the extraction is local, and the desired reading is generated by interpreting the elided pronoun (whose correlate is the trace of the relative operator) as an E-type pronoun:

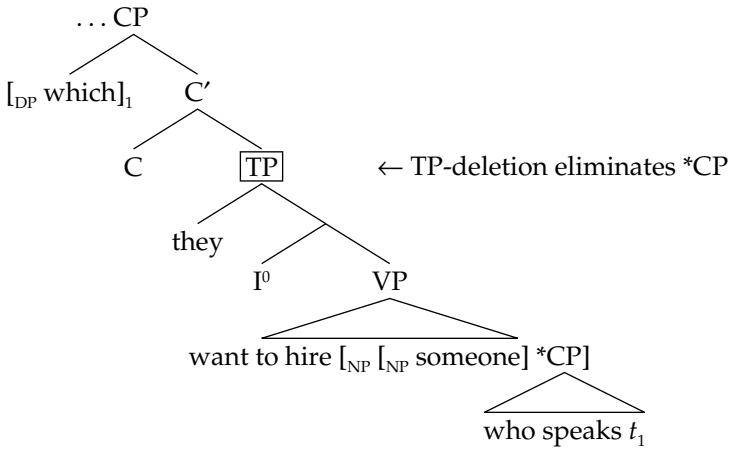
(38) They want to hire someone who speaks a Balkan language, but I don't remember which$_1$ <he$^{E\text{-}type}$ should speak t_1>.

Even if such an approach works for propositional islands (though Lasnik 2001 presents evidence that raises certain difficulties), there remains a subset of islands that are unaccounted for: left-branch extractions, derived-position islands, COMP-trace effects, and coordinate structures. For these, movement approaches from Ross (1969b) and Chomsky (1972b) to Lasnik (2001) and Merchant (2001) have posited that the source of the island violation is the pronunciation of the island. For Ross, this meant that island violations were calculated across the derivation, with island violations that remained at surface structure relatively worse than those that were targeted by deletion. Chomsky (1972b) proposed that crossing an island left a feature (a '*') which could be eliminated by a later

deletion operation. Lasnik and Merchant pursue this idea in various forms, essentially reviving the idea and coding it as a feature of crossed island nodes or of traces (non-head copies in a *wh*-chain): deletion, however construed (either as an operation, as in older accounts, or as a mere reflex of the PF-interpretation of the featural content of the ellipsis-licensing head), will have the effect that at PF, the offending feature will not be present in the representation. These two latter possibilities are illustrated in the two trees in (39) and (40), respectively:

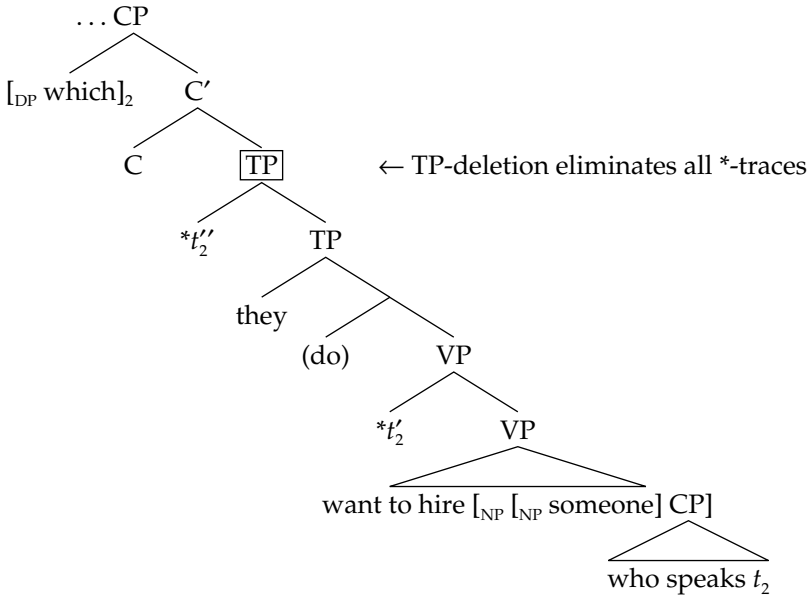
(39) a. They want to hire someone who speaks a Balkan language, but I don't remember which.

b.



(40) a. They want to hire someone who speaks a Balkan language, but I don't remember which.

b.



The central idea in both these implementations is that islands are essentially a PF phenomenon, and that ellipsis can repair an otherwise grammatically deviant structure. This notion is has proven fruitful in a number of other domains in ellipsis, and in sluicing in particular.

4 Puzzles and prospects

The domain of sluicing, more so perhaps than any other ellipsis construction, seems to have more open questions than widely accepted conclusions. Far more so than with nominal ellipses or VP-ellipsis in particular, the data that fall under sluicing give rise to a host of puzzling phenomena, the majority of which have never received systematic attention in the literature, let alone theoretically satisfying explanations. This last section is devoted to enumerating these puzzles, along with various approaches to them, and in showing where fruitful areas for further research may be found.

Broadly speaking, the puzzles divide into two kinds: movements or elements which exceptionally *cannot* occur in the presence of sluicing (the sluicing-COMP puzzles), and movements which exceptionally *can* occur with sluicing (sluicing in *wh*-in-situ languages, multiple sluicing, and swiping).

4.1 Sluicing-COMP generalization puzzles

Given the most generally accepted picture of sluicing, namely that it consists of a *wh*-phrase remnant in Spec, CP with the sentential constituent (TP) unpronounced, several puzzles emerge immediately, which can be grouped under the following generalization:

(41) **The sluicing-COMP generalization:**
In sluicing, no non-operator material may appear in COMP.

The term 'operator' here refers to the phonological exponence of the *wh*-phrase itself, and 'COMP' means, as usual, all material dominated by CP but not dominated by TP. The generalization in (41) rules out any elements in sluicing that are not part of the *wh*-phrase itself: moved elements like clitics, auxiliaries, etc. (whether they attach to C or to the *wh*-phrase) as well as base-generated elements like complementizers themselves.

The first set is illustrated by the lack of subject–auxiliary inversion in matrix sluicing in the Germanic languages, as in (42), which gives the data from English, Frisian, German, Dutch, Danish, Norwegian, Swedish, Yiddish, and Icelandic, in that order:

(42)	a.	A: Max has invited someone.	B: Really?	Who (*has)?
	b.	A: Jelle hat ien útnoege.	B: Soa?	Wa (*hat)?
	c.	A: Max hat jemand eingeladen.	B: Echt?	Wen (*hat)?
	d.	A: Max heeft iemand uitgenodigd.	B: Ja?	Wie (*heeft)?

e.	A: Max har inviteret en eller anden.	B: Ja?	Hvem (*har)?
f.	A: Anna har invitert noen.	B: Ja?	Hvem (*har)?
g.	A: Anna har bjudit någon.	B: Ja?	Vem (*har)?
h.	A: Moyshe hot emetsn ayngelodn.	B: Nu?	Vemen (*hot)?
i.	A: Anna hefur boðið vini sínum.	B: Er að?	Hverjum (*hefur)?
	Anna has invited friend her	is that?	who has

A simple solution to this fact would be to order T-to-C movement after sluicing: the deletion of the TP node would bleed the raising of the auxiliary into C. Approaches that eschew additional structure under the CP node also fare well with these facts. For other approaches, these facts are taken as a window on the mechanisms of satisfaction of feature strength: Lasnik (2001) and Merchant (2001) suggest that these facts indicate either that feature movement alone is possible (just in case the host is deleted, avoiding a PF crash) or that the strong feature that drives T-to-C movement is located on T: a strong feature internal to an ellipsis site need not move, since, by economy, it will not trigger a PF crash due to the deletion of a constituent containing it.

A similar puzzle comes from the Wackernagel clitics in South Slavic languages such as Slovene; these clitics are usually argued to cliticize onto the (first) *wh*-phrase in Spec, CP, as in (43a). Under sluicing, however, such clitics are obligatorily absent, as seen in (43b):

(43) a. Peter se je spraševal, [$_{CP}$ kako$_1$ je$_2$ [$_{TP}$ Špela t_2 popravila t_1]].
Peter REFL AUX asked what AUX Špela fixed
'Peter wondered what Špela fixed.'

b. Špela je popravila nekako, a nisem vprašal,
Špela AUX fixed something but NEG.I.AUX asked
[$_{CP}$ kako (*je) <>].
what AUX
'Špela fixed something, but I didn't ask what.'

Lobeck (1995: 59) shows that parallel facts hold for complementizer agreement in Germanic varieties such as Bavarian, where subject features can be found as a clitic on material in COMP, unless sluicing applies:

(44) Du woidd-st doch kumma, owa mia wissn ned wann-st (du)
you wanted-2sg PRT come but we know not when-2sg you
kumma woidd-st.
come wanted-2sg
'You wanted to come, but we don't know when you wanted to come.'

(45) Du woidd-st doch kumma, owa mia wissn ned wann (*-st).
you wanted-2sg PRT come but we know not when -2sg
'You wanted to come, but we don't know when.'

The range of solutions possible for accounting for such facts seems to be similar to those proposed for the lack of subject–auxiliary inversion in Germanic.

The second set of facts that fall under the sluicing-COMP generalization concern base-generated elements, in particular complementizers. These are found in many languages, including Danish, Norwegian, Frisian, Dutch varieties, Slovene, and Irish. I give the data here from Irish only:

(46) Cheannaigh sé leabhar inteacht ach níl fhios agam céacu
bought he book some but not.is knowledge at.me which
ceann (*a / *ar).
one C_{trace} / C_{pro}
'He bought a book, but I don't know which.'

Although a complementizer (either *aL* or *aN*) is obligatorily present in non-elliptical contexts in Irish, complementizers are obligatorily absent in sluicing. Two possibilities arise: first, there may be no structure other than the *wh*-phrase present, or second, the complementizer may have been incorporated into the sentential domain prior to deletion. The second possibility can be fleshed out in a variety of ways: several authors have proposed that complementizers (at least in Irish and Hebrew) cliticize onto a host internal to TP – such cliticization, clearly, would feed deletion.

Finally, I note that there are apparent exceptions to the sluicing-COMP generalization as stated, in particular from Hungarian and Japanese. It is surely no accident that these languages are commonly analyzed as not having movement into Spec, CP overtly in questions, an issue we turn to now.

4.2 Sluicing in clause-internal wh *languages*

If sluicing is contingent upon *wh*-movement into Spec, CP, then it comes as some surprise that what appears to be sluicing is found in languages in which *wh*-phrases do not front to Spec, CP, including both *wh*-in-situ languages like Japanese, Chinese, and Korean, and languages in which *wh*-phrases surface in a designated clause-internal position (often a focus position preceding the verb), such as Hungarian, Turkish, and Hindi. I give here data from Japanese and Hungarian:

(47) Abby-ga dareka-o mi-ta ga, watashi-wa dare ka wakaranai.
Abby-NOM someone-ACC see-PAST but I-TOP who Q know.not
'Abby saw someone, but I don't know who.'

(48) A gyerekek találkoztak valakivel de nem emlékszem, hogy
the children met someone.with but not I.remember that
kivel.
who.with
'The kids met with someone, but I don't remember who.'

The Japanese data in particular have been the subject of a number of studies. Two approaches can be identified. The first, proposed by Takahashi (1994), is to claim that Japanese sluicing involves a kind of movement to a clause-peripheral position (perhaps *wh*-movement to Spec, CP, perhaps merely a kind of A'-scrambling), followed by deletion of the sentential node, as in English. The second assimilates the Japanese facts to a kind of reduced cleft structure, a structure I have called 'pseudosluicing'; under these approaches (found in Shimoyama 1995; Kuwabara 1996; Nishiyama et al. 1996; Merchant 1998; Kizu 2001; Hiraiwa and Ishihara 2002; Fukaya 2003; and for another sort of sluicing, Fukaya and Hoji 1999), the unpronounced material in (47) is not due to ellipsis of a TP, but rather simply to the fact that Japanese allows a null copula and a null 'expletive' subject:

(49) watashi-wa [$_{CP}$ [$_{TP}$ *pro* dare *copula*] ka] wakaranai
I-TOP it who Q know.not
'I don't know who <it was>.'

Such a pseudosluicing analysis has many merits for the Japanese facts, but it has never been pursued for the Hungarian-type languages. For these languages, one suggestion that has been made is that a scrambling-type movement may create the input structures for deletion, or that whatever constraint prevents overt movement into Spec, CP is ameliorated by the deletion itself, however such an idea is implemented. (One possibility, following the reasoning concerning T-to-C movement above, would be to claim that the traces of *wh*-movement in these languages would trigger some kind of PF crash that deletion repairs, for example.) Another possibility, following recent work by Simpson and Bhattacharya (2003) on Bangla, is that these languages in fact do have *wh*-movement to Spec, CP, but that other factors in their grammars mask this movement; if such an analysis is correct, the fact that sluicing is possible would indicate that deletion can bleed the other movements involved in non-elliptical clauses.

4.3 Multiple sluicing

Multiple sluicing refers to structures in which more than one *wh*-phrase form remnants of sluicing, as in (50):

(50) ?Everyone brought something, but I couldn't tell you who what.

While such examples have a marginal status in English for some speakers (and even for those who accept them, such as myself and Bolinger 1978, they require a generator in the antecedent, giving rise to an obligatory pair-list reading: *Someone hit someone first, but we couldn't determine {who hit who first/*who who}.*), they appear to be fully acceptable in a number of other languages, including German, Dutch, and Greek:

(51) a. Jemand hat was gesehen, aber ich weiß nicht, wer was.
someone has something seen but I know not who what
(lit.) 'Someone saw something, but I don't know who what.'
b. Iemand heeft iets gezien, maar ik weet niet wie wat.
someone has something seen but I know not who what
(lit.) 'Someone saw something, but I don't know who what.'
c. Kapjos idhe kapjon, alla dhe ksero pjos pjon.
someone.NOM saw someone.ACC but not I.know who.NOM who.ACC
(lit.) 'Someone saw someone, but I don't know who whom.'

The immediate question that such structures give rise to concerns the nature of the movement involved in fronting the *wh*-phrases out of the clause, given that these languages allow only a single *wh*-phrase to front in non-elliptical contexts. It seems most plausible that the application of deletion to the clausal host of multiple *wh*-movement in these cases repairs whatever goes wrong in the non-elliptical cases; essentially, one would like to give an analysis to multiple sluicing that is parallel to the analysis of multiple *wh*-fronting in languages like Bulgarian, which permit it in non-elliptical contexts. Expectedly, then, the analytical options that have been pursued run the gamut of those that have been proposed for multiple *wh*-fronting. These are the following: (i) either all *wh*-phrases front by *wh*-movement into Spec, CP (adjoining to each other there or tucking in; Rudin 1986; Richards 2001), or (ii) the initial *wh*-phrase moves by *wh*-movement into Spec, CP with the non-initial *wh*-phrases moving to distinct clause-peripheral positions (Rudin 1986; Bošković 2002; Grohmann 2003), or (iii) the *wh*-phrases form a *wh*-cluster and front together (Grewendorf 2001).

Multiple sluicing gives rise to superiority effects, which is expected under all three of the options above (illustrated here for English and Greek); these facts are more puzzling for base-generation accounts of sluicing:

(52) a. *Everyone brought something (different) to the potluck, but I couldn't tell you what who.
b. *Kapjos idhe kapjon, alla dhe ksero pjon pjos.
someone-NOM saw someone.ACC but not I.know who.ACC who.NOM
(lit.) 'Someone saw someone, but I don't know whom who.'

There are restrictions on the *wh*-phrases that can be found in multiple sluicing that do not follow merely from positing movement, and which support options (ii) and (iii) above over (i). In particular, multiple sluicing is more sensitive to locality than simple *wh*-movement is: the initial and non-initial *wh*-phrases must be local to one another, where 'local' is roughly equivalent to 'clause mate', as pointed out in Takahashi (1994), Nishigauchi (1998), Heck and Müller (2000), and Merchant (2001: 113):

(53) *Everybody said Lucy'd bring something different to the potluck, but I can't remember who$_1$ what$_2$ <t_1 said Lucy'd bring t_2 to the potluck>.

'Clause mate', however, is not exactly the right notion; cross-clausal multiple sluicing in German is much better across restructuring verbs like *versuchen* 'try' than across non-restructuring verbs like *zögern* 'hesitate' (Sauerland 1999b):

(54) Irgendjemand hat {versucht /?*gezögert} irgendetwas zu klauen, aber
someone has tried hesitated something to steal but
ich weiss nicht, wer was.
I know not who what
(lit.) 'Someone {tried/hesitated} to steal something, but I don't know who what.'

In fact, even finite, tensed, non-restructuring CP boundaries can sometimes be crossed in multiple sluicing, as long as the embedded subject is bound by the matrix subject:

(55) Everybody$_i$ said he$_i$'d bring something different to the potluck, but I can't remember who$_1$ what$_2$ <t_1 said he$_1$'d bring t_2 to the potluck>.

This set of restrictions is highly reminiscent of the set found in gapping, as discussed in detail by Johnson (1996), and to the availability of multiple-pair answers to multiple questions in English, as Dayal (2002) discusses. All of this evidence seems to point to locality restrictions on the movement found in multiple sluicing, a movement which is possible only if the host of movement is subject to ellipsis (parallel, in other words, to the repair effects found for the scrambling-like movements posited by Johnson 1996, 2001, and Richards 2001 for gapping and pseudogapping). This is not to say that multiple sluicing is a subspecies of gapping, of course, since gapping is restricted to local conjunctions and disallows backwards application in right-branching languages, while multiple sluicing is not limited to conjunctions (Romero 1997b) and does occur preceding its 'antecedent' clause (as Hoyt and Teodorescu 2003 show: *I don't know who with who, but I am sure everyone will get hooked up with someone*).

Multiple sluicing is also found in Japanese, Bulgarian, Turkish, and Romanian, among other languages:

(56) a. Sono toki, dareka-ga nanika-o (Nishigauchi 1998: 146, (70))
that time someone-NOM something-ACC
mise-ta. Sikasi, dare-ga nani-o ka omoidase-nai.
showed but who-NOM what-ACC Q remember-not
'At that moment, someone showed something (to me). (lit.) But I can't remember who what.'

b. Njakoj e vidjal njakogo, no ne znam koj kogo.
someone AUX seen someone but not I.know who whom
'Someone saw someone, but I don't know who saw who.'

c. Biri bir şey gördü ama, kim ne bil-mi-yor-um.
someone something saw but who.NOM what.ACC know-NEG-PROG-1sg
(lit.) 'Someone saw something, but I don't know who what.'

d. Ion a dat cuiva ceva (Hoyt and Teodorescu 2003: 2, (7a))
Ion has given someone something
şi vreau să ştiu cui ce.
and I.want SUBJ I.know whom what
(lit.) 'Ion gave something to someone and I want to know what to whom.'

The analytical questions raised by these languages are somewhat different than those above. For multiple *wh*-fronting languages like Bulgarian, Russian, Serbo-Croatian, and Romanian, the existence of multiple sluicing is expected. In Japanese, the same questions arise as did in the previous section; because Japanese allows multiple focus structures with the copula, however, a solution similar to that proposed for single sluicing seems possible. There is reason to believe that these apparently similar facts across these languages do not submit to a uniform analysis, however: see Hoyt and Teodorescu (2003) for a careful examination of the differences between multiple sluicing in Romanian and that in Japanese.

4.4 Swiping

Monomorphemic *wh*-words selected by certain (generally 'simplex') prepositions can undergo a surprising inversion in sluicing, as illustrated by the following data:

(57) a. Abby was talking, but I don't know who to.
b. They were arguing; God only knows what about.
c. A: She got a package in the mail.
B: Really? Who from?
d. He'll be at the Red Room, but I don't know when till.
e. Bees are getting into the house, but we can't figure out where from.

This phenomenon, known as *swiping* (for sluiced *wh*-word inversion with prepositions (in Northern Germanic)), has been discussed by Ross (1969b), Rosen (1976), Van Riemsdijk (1978a), Chung et al. (1995), Culicover (1999), Richards (2001), Merchant (2002), and Van Craenenbroeck (2004). It is also found in Danish, and, for about 50 percent of speakers consulted, in Norwegian; it is found too, with variations, in some Dutch dialects, as described in Van Craenenbroeck (2004):

(58) a. Danish:
Per er gået i biografen, men jeg ved ikke hvem med.
b. Norwegian:
% Per gikk på kino, men jeg veit ikke hvem med.
Per is gone/went to cinema but I know not who with
'Per went to the movies but I don't know who with.'

Swiping exhibits a number of puzzling properties. It is limited to a small set of *wh*-words (*who*, *what*, *where*, *when*, and variably across speakers, *how long*, *how much*, *how many*), excluding all phrasal *wh*-XPs as well as *which* and *whose*. It is found only in sluicing (not gapping or pseudogapping, for example). And though aggressively non-D-linking modifiers such as *the hell* or *on earth* are generally excluded from sluicing (**Somebody broke it and I want to know who the hell!*), these modifiers become possible just in case swiping applies: *They were arguing, but God only knows what the hell about.*

Ross (1969b) (and Rosen 1976 following him) analyzed swiping as a result of a non-constituent deletion rule, formulated in (59):

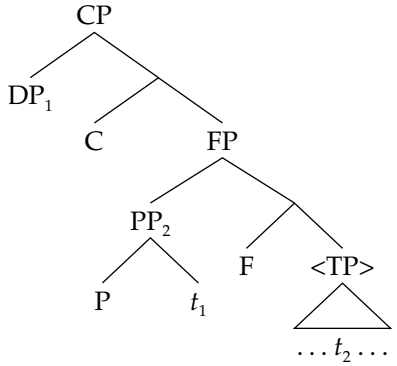
(59) $\ldots [_{CP}\ XP_{[+wh]}\ [_{IP}\ \alpha - (P) - \beta] \ldots$
$\Rightarrow_{OPT}$
1 2 3 4
1 Ø 3 Ø

Van Riemsdijk (1978) proposed to assimilate swiping to R-pronoun inversion, found in Dutch and other continental West Germanic varieties (an idea endorsed in Lobeck 1995 and Chung et al. 1995 as well):

(60) Waarmee wou je het doen?
wherewith wanted you it do
'What did you want to do it with?'

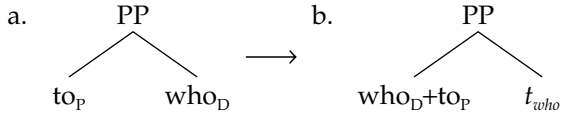
Richards (2001: 139–140) suggests that swiping is a case of stranding in an intermediate Spec, FP, an analysis championed on new and persuasive cross-linguistic grounds in Van Craenenbroeck (2004):

(61)



Merchant (2002) analyzes swiping as head-to-head movement of the *wh*-word into P^0, a kind of incorporation during the derivation from Spell-Out to PF:

(62)



Finally, Culicover (1999) claims that swiping is "*sui generis*," and that the PP is exhaustively dominated by a CP node ("radically violating standard X'-theory" 1999: 138).

All of these proposed analyses succeed in capturing some but not all of the relevant facts, and several require fairly substantial departures from widely accepted tenets of grammatical analysis as well. As such, swiping remains one of the more recalcitrant puzzles in the sluicing arena.

5 Conclusion

Sluicing remains an area of active research, primarily for two reasons: first, it sits at the intersection of ellipsis and *wh*-movement, two areas which continue to generate enormous research activity, and second, it raises so many fascinating puzzles. Some of these puzzles were illustrated in the last section, which was concerned primarily with the curiosa from sluicing's cabinet, phenomena which occur in conjunction with sluicing and which are anomalous from a variety of perspectives. As such, they form part of the outstanding issues for future work to address, and it can be hoped that they might shed light on other areas of the grammar, in particular on the nature of repair and the PF interface.

61 Specificational Copular Sentences and Pseudoclefts

MARCEL DEN DIKKEN

1 Introduction: types of copular sentences
  1.1 Copular sentences: preliminaries
  1.2 Types of copular sentences (I): a basic two-way split
  1.3 Types of copular sentences (II): more fine-grained typologies
  1.4 Reducing the typology
  1.5 A typology of copulars?
2 Types of pseudocleft sentences
  2.1 Pseudocleft sentences: preliminaries
  2.2 Types of pseudocleft I: a basic two-way split
  2.3 Types of pseudocleft II: more fine-grained typologies
  2.4 The scope of the term 'pseudocleft'
3 Specificational copular sentences and pseudoclefts: an inventory of properties
  3.1 Characterizing specificational pseudoclefts
    (i) Connection between specificational pseudoclefts and question-answer pairs
  3.2 Properties distinguishing specificational from predicational copular sentences
    3.2.1 Syntactic properties
      (ii) reversibility
      (iii) connectivity/connectedness effects
      (iii.a) reflexive connectivity
      (iii.b) reciprocal connectivity
      (iii.c) Principle C connectivity ('anti-reconstruction')
      (iii.d) negative polarity item connectivity

This is a case study on specificational copular sentences, including specificational pseudoclefts. Before we can embark on a discussion of the specifics of these constructions, we first of all need to delineate a number of terminological domains. Section 1 will address the typology of copular sentences in some detail, laying out the various types of copular constructions identified in the literature and highlighting their properties and differences. Section 2 will repeat the typological exercise of section 1 with specific reference to a subtype of copular sentence referred to as the pseudocleft construction. Sections 3 and 4 will subsequently home in on specificational copular sentences (pseudocleft and non-cleft alike) and discuss their characteristics, sections 5 and 6 addressing questions arising specifically in the context of specificational pseudoclefts and discussing the various analyses proposed in the literature.

1 Introduction: types of copular sentences

1.1 Copular sentences: preliminaries

In this work, by copular sentence in the broad sense of the term we understand any sentence type of the general schema in (1):

(1) *General format of copular sentences:*
XP *be* YP [where YP ≠ participial VP]

The schema in (1) gives us a variety of different types of copular sentences, some examples of which are given in (2–12) (see Blom and Daalder 1977: 115; Safir 1983; Den Dikken 1987; Neeleman 1997: 106–110 on examples of the type in (5–7), featuring what Safir has called 'Honorary NPs'; Blom and Daalder and Den Dikken propose to analyze such subjects as elliptical NPs, but we will not take a stand on this matter, which is orthogonal to our concerns in this work):

(2)	My colleagues are nice people.	XP = NP	YP = NP
(3)	My colleagues are nice.	XP = NP	YP = AP
(4)	My colleagues are at the office.	XP = NP	YP = PP
(5)	Under the bed is a good hiding place.	XP = PP	YP = NP
(6)	Down the hill is easier than up the hill.	XP = PP	YP = AP
(7)	Bashful is a terrible thing to be.	XP = AP	YP = NP
(8)	That they lost is an unfortunate thing.	XP = CP	YP = NP
(9)	That they lost is unfortunate.	XP = CP	YP = AP
(10)	What happened was they lost the game.	XP = CP/NP	YP = IP
(11)	What they did was lose the game.	XP = CP/NP	YP = VP
(12)	Lose the game is what they did.	XP = VP	YP = CP/NP

Exemplification is not exhaustive here, and certain non-trivial questions are raised already at this elementary stage – for instance, concerning the analysis of constructions like (10–12), particular types of pseudocleft construction; and about the accidental or principled non-existence of certain XP/YP combinations in some or all languages. (In particular, we need to exempt from the schema in (1) constructions in which YP is a participial VP – these are either passives (if the

V-head is a past participle) or progressives (where the V-head is a gerund or present participle), neither 'auxiliary construction' generally being included in the set of copular sentences; we will follow standard practice here.)

At this elementary stage in the discussion these questions need not concern us. We will return to the former question (sections 3 and 6); the latter will not play a role in the discussion to follow at all.

Note that although the schema in (1) is presented as a linear string, we make no *a priori* claims here about the word order of copular sentences. Indeed, one of the things we will have occasion to discuss in great detail in this work is the fact that a specific subtype of copular sentence, the specificational copular sentence, allows its major constituents to 'change places': one often finds that in such sentences each can be on either side of the copula.

Specificational copular sentences are just one of a variety of copular sentence types distinguished in the literature on copular sentences. Before we will be able to properly address the specifics of these specificational constructions, we will first of all need to outline the typology of copular sentences, which will serve as a backdrop to the discussion to follow. Thus, in sections 1.2 and 1.3 we will go through increasingly more detailed typologies of (largely double-NP) copular sentences, then proceeding to attempts at reducing the fine-grained typologies to a simpler pattern (section 1.4), and finally (section 1.5) raising the question of whether the typology of copular sentences (however coarse- or fine-grained) should be given shape: in terms of properties of the copula or in terms of properties of the structure/derivation/major constituents of the constructions in question.

1.2 Types of copular sentences (I): a basic two-way split

That not all copular constructions are of the same type is not a contentious claim. There is a general consensus that at least two types need to be distinguished. Basing themselves typically on the referentiality of the second, or post-copular noun phrase in a 'straight' or 'canonical' double-NP copular sentence of the general format NP_1 *is* NP_2 (cf. (13) for an example), scholars have made a general distinction between double-NP copular sentences in which NP_2 is non-referential and ones in which NP_2 is referential. Even when it comes to this simple two-way split, however, terminological proliferation is rampant. The overview in (14), which aims to be representative rather than exhaustive, gives the reader a glimpse of the kinds of labels assigned to the two types of copular sentence, with references to their inventors in the right-hand column. In what follows we will use the boldface labels **predicational** (*food for the dog* in (13) predicates a property of *his supper*) and **specificational** (*food for the dog* specifies what *his supper* consists of), due to Akmajian (1979):

(13) His supper is food for the dog.
  a. **predicational**: 'His supper serves as food for the dog.'
  b. **specificational**: 'He eats food for the dog for his supper.'

(14) A basic two-way split:

a. NP_2 = non-referential	b. NP_2 = referential	
classifying	identifying	Kruisinga and Erades (1953)
intensive	extensive/ equative	Halliday (1967), Huddleston (1971)
non-equational	equational	Bolinger (1972b)
ascriptive	equative	Lyons (1977)
attributive	identificational	Gundel (1977)
predicational	**specificational**	Akmajian (1979)
predicational	specificational(ly identifying)	Declerck (1988)

All scholars referred to in (14) essentially agree that the difference between the two types of copular sentences in (14a, b) turns on the referentiality of the post-copular noun phrase, though individual authors disagree on the precise notion of referentiality that they avail themselves of (see Keizer 1992: ch. 2 for a detailed précis).

1.3 Types of copular sentences (II): more fine-grained typologies

While the Greek philosophers of classical antiquity (Aristotle, Plato) already recognized the versatility of the copula and the many sides of 'being', it was not until Higgins (1979) that the linguistics literature was introduced to syntactic and semantic grounds for distinguishing more than just the two basic types of copular sentence in (14). Higgins (1979) proposed a four-way distinction in the realm of copular sentences, adopting the basic split in (14) and enriching it with two additional types (of which the fourth is often referred to as the equative construction as well). In his reappraisal of Higgins's seminal work on copular sentences, Declerck (1988) once again recognizes four basic types (though the criteria used for distinguishing them differ from those employed by Higgins, and concomitantly the definitions of the various types are not exactly the same either). Declerck also considers the possibility that there might be even more types of copular sentences, highlighting in particular the 'definitional copular sentence' in (16e):

(15)

		NP_1	NP_2
a.	predicational	referential	predicational
b.	specificational	superscriptional	specificational
c.	identificational	referential	identificational
d.	identity statement	referential	referential

(Higgins 1979)

(16)				
	a.	predicational	referring	non-referring
	b.	specificational(ally identifying)	weakly referring (attributive)	strongly referring
	c.	descriptionally identifying	strongly referring	strongly referring or non-referring
	d.	identity statement	referring	referring
	e.	definitional	non-referring	?

(Declerck 1988)

For both Higgins and Declerck, the typology of double-NP copular sentences is in large measure a function of the referentiality of the two noun phrases that constitute them, as well as the discourse function of the various copular sentences (usable as answers to questions, list readings, focus/presupposition), their syntactic properties (reversibility etc.; see section 4) and their intonational properties. Higgins and Declerck disagree on the proper definition of 'referential', however. Higgins follows Strawson (1950) and Geach (1970b) in taking 'referentiality' to be about 'what a proposition is about'. Declerck, on the other hand, avails himself of a subtler approach to referentiality, making distinctions not just between referring and non-referring NPs but also, within the set of referring NPs, between weakly and strongly referring NPs (the former corresponding to Donnellan's 1966 'attributive'). (Declerck does not make the referential status of NP_2 in definitional copular sentences explicit.)

Higgins explicitly rejects a classification of the NP_1 of specificational copular sentences (his 'superscriptional' NP) as 'attributive' in Donnellan's sense (but see Declerck 1988: 48–49 for a repartee of Higgins's counterarguments). For Higgins neither NP_1 nor NP_2 of a specificational copular sentence can be referential (since specificational copular sentences are not 'about' either of the two NPs); he therefore needs to introduce additional terminology to label the constituents of specificational sentences (as 'superscriptional' (defining the heading of a list) and 'specificational' (specifying the content of the list)). Apart from drawing a connection with lists (or 'colon constructions'; cf. *the winner is: John Johnson* or *the winners are: John Johnson, Jack Jackson, Dick Dixon, . . .*), however, Higgins never makes it entirely clear what it means for an NP to be 'superscriptional'.

Examples of the various types of copular sentences distinguished in (15) and (16) are given in (17–21), along with a summary of their most important characteristics (largely adapted from Declerck 1988, to whose work the page references in (17–21) refer; cf. also Keizer 1992: ch. 2):

(17) *Predicational double-NP copular sentences:*
   a. John is a teacher
   b. Mary is a pretty girl
      - are "not felt to answer a question asking for specificational (identifying) information"; in fact, "not felt to answer a question at all" (p. 55, *q.v.* for further discussion);

- do not alternate with *it*-clefts (**It is a teacher that John is*), which are "always specificational" (p. 69);
- are not reversible (**A teacher is John*).

(18) *Specificational(ly identifying) double-NP copular sentences:*
a. The bank robber is John Thomas.
b. The only people that can help you are the Prime Minister and the Queen herself.
- exhaustively specify the candidates ("values") for the "variable" (*the bank robber* in (18a)); "list reading," "exhaustivity" – section 3.2.2;
- alternate with *it*-clefts (*It is John Thomas that is the bank robber*) and put focus on the "value" NP (*John Thomas* in (18a));
- are reversible (*John Thomas is the bank robber*).

(19) *Identificational/descriptionally identifying double-NP copular sentences:*
a. That (man) is John's brother.
b. That (place) is Boston.
- are not meant to specify a value for a variable (p. 95) and are not exhaustive or contrastive;
- do not alternate with *it*-clefts (**It is that (man) that is John's brother*, **It is John's brother that is that (man)*);
- are not reversible (**John's brother is that (man)*).

(20) *Identity statements:*
a. The Morning Star is the Evening Star.
b. Dr Jekyll is Mr Hyde.
- are typically used to correct the hearer's assumption that two different descriptions apply to two different referents;
- do not alternate with *it*-clefts (**It is the Morning Star that is the Evening Star*);
- are reversible (*The Evening Star is the Morning Star*).

(21) *Definitions:*
a. A motor car is a vehicle that has four wheels and is propelled by an internal combustion engine.
b. A pyramid is what the Egyptians built to bury their pharaohs in.
- though a paraphrase of the form "NP_1 is the following: NP_2" ("list") is possible, they lack the exhaustivity typical of specificational sentences;
- do not alternate with *it*-clefts (**It is a vehicle that has four wheels and is propelled by an internal combustion engine that a motor car is*);
- are not reversible ("That is to say, switching the places of the subject NP and the predicate nominal in [(21a, b)] results in a sentence that is not ungrammatical, but which no longer counts as an example of a definition" – p. 113).

Copular sentences are often several ways ambiguous on paper. Thus, Higgins (1979: 266–267) presents the example in (22) as a three-ways ambiguous copular construction:

(22) The girl who helps us on Friday is my sister.

a.	*Predicational*	Answers the question of how the referent of NP_1 is related to the speaker; no exhaustivity implied.
b.	*Specificational*	Provides an exhaustive list in answer to the question *Who is the girl who helps you on Friday?*
c.	*Identificational*	Identifies the referent of NP_1 as the speaker's sister (cf. *That is my sister*).

1.4 Reducing the typology

Higgins (1979) notes that his identity statements and identificational copular sentences are potentially reducible to one single type, depending on one's interpretation of 'referentiality': if one insists "that referentiality is a property of expressions, not of the use of expressions, then one might also want to insist that [an identificational copular sentence] is an identity statement" (p. 263). (He himself uses 'referentiality' with reference to the use of expressions, however, so he keeps the two types of copular sentence distinct.)

Taking Higgins's typology as her starting point, Verheugd (1990) has attempted to reduce the four types of copular sentence in (15) to the two basic ones in (14), once again making crucial use of the notion 'referentiality'. Verheugd's objective is to reduce Higgins's five NP types (referential, specificational, superscriptional, predicational, identificational) to just two: referential and non-referential. With particular reference to specificational copular sentences and Higgins's notion of superscriptional NPs, she argues that such NPs can be treated as underlying predicates. She thus treats specificational sentences like *The culprit is John* as inverse copular sentences: copular sentences with a surface word order derived via inversion of the underlying subject-predicate order (see sections 4.2 and 4.3 below for details concerning the properties of copular inversion).

In the principles-and-parameters framework, Moro (1987, 1988) was the first to attempt a reduction of Higgins's typology of copular sentences, proposing an analysis of specificational sentences as inverse copular constructions (see Moro 1997 for a fully developed analysis along lines originally laid out in Moro 1987, 1988). Heggie (1988) took the same tack in her study of the syntax of copular sentences. Heggie and Moro present a variety of syntactic arguments to support a transformational derivation of such inverse copular sentences – though they differ with respect to the way they implement the analysis. We will return to the details in the discussion of inversion (once again, see sections 4.2 and 4.3 below).

By analyzing specificational copular sentences as inverse copular constructions, the principles-and-parameters analyses by Verheugd, Heggie, and Moro continue the line of thought initiated by Blom and Daalder (1977), who likewise claim that there are just two types of copular sentence (the predicational and

specificational types) and that as far as the underlying relationship between two NPs in predicational and specificational copular sentences is concerned there is no difference between the two sentence types: in both, one of the two NPs is the predicate of the other; underlyingly, then, both types of copular construction are predicational. Blom and Daalder take their cue from the intonational contour of copular sentences (focal stress in particular), and give the following characterizations of specificational and predicational copular sentences:

(23) a. In a *specificational* copular sentence, the *focused* element is contained in the *hyponym = Theme = deep structure subject*.
b. In a *predicational* copular sentence, the *focused* element is **not** contained in the *hyponym = Theme = deep structure subject*.

Of these two claims, the former is undisputed; that predicational copular sentences demand that the focus not be on/in the subject is a controversial claim, however (see Heycock 1994a, 1998).

Blom and Daalder (1977) (who express their indebtedness to Den Hertog 1973) are perhaps the most rigid and explicit champions of the idea that all copular sentences are underlyingly represented as predications, with one of the two NPs functioning as the hyperonym (Lyons's 1977 'superordinate'; cf. 'predicate') of the other (the hyponym). They even extend their hyponym/hyperonym (or subject/predicate) approach to identity statements of the type in (20), saying that the post-copular noun phrase in such constructions is the hyponym of the pre-copular NP. They argue as follows (p. 76; my somewhat liberal translation):

> In an example such as [(20a)], [*the Morning Star*] is presented as the more narrowly described element, while [*the Evening Star*] is a non-directly-identifying expression. Put differently, "being the evening star" is a property which is ascribed to something, in this case to what is referred to as [*the Morning Star*].

Since this treatment of identity statements entails that of the two NPs in (20) only the pre-copular one is referential, they add (p. 77, translation mine; original italics):

> The necessary "referential" knowledge, the knowledge that we are dealing here with what are called "definite descriptions", can be taken to be of a different nature than knowledge of the content of a grammatical construction. We would therefore like to claim that the referential knowledge in the case of an interpretation which goes beyond the grammatical interpretation is *added* to the hyperonym relationship expressed in the grammatical construction.

For Blom and Daalder, in other words, 'referentiality' is less basic when it comes to the *grammatical* classification of copular sentences than it is for the other scholars referred to in the foregoing: a predicate nominal, while quintessentially non-referential, can nonetheless be interpreted referentially on the basis of the language user's non/extra-grammatical knowledge.

Blom and Daalder's predicational approach to equative copular sentences/identity statements is controversial;[1] and since, as far as their syntactic properties are concerned, identity statements have more in common with (inverse) specificational copular sentences than with their predicational counterparts (cf. especially Heycock and Kroch 1999; also Guéron 2001; cf., e.g., section 4.3.2 below), it may be better (if one wants to treat them as underlyingly predicational in the first place) to try to analyze equatives along the lines of inverse specificational constructions. Be that as it may, even when we confine our attention to specificational copular sentences (for which inversion accounts have been proposed not just by Blom and Daalder but by Heggie, Moro, and Verheugd as well) the idea that the relationship between the two NPs is one of hyponym/hyperonym or subject/predicate is controversial.

Thus, Declerck (1988: 93) dismisses the approach, stressing that "[s]pecificational sentences do not express a hyponymy relation." In defense of his position, Declerck draws on Higgins (1979) and Halliday (1967, 1968): Higgins points out that the essence of the specificational relationship is that the contents of the concept expressed by the superscriptional NP are specified, which "naturally means that the NP denoting the concept and the NP specifying its contents cannot differ in generality or specificity" (Declerck 1988: 92–93); and Halliday argues that the two NPs of specificational sentences have "the same degree of specificity, and that this is precisely the reason why such sentences are reversible" (Declerck 1988: 93, n. 98).[2]

In what follows, we will not take a stand on the question of whether the four or five types of copular sentences enumerated in (15) and (16) qualify as primitives or whether they are instantiations of two or even just one 'macrocategory' of copular constructions, noting simply that if one wants to reduce the various types of copular sentence to one underlying structure, this will be the structure most directly represented by copular sentences of the *predicational* type: a subject-predicate structure (cf. Blom and Daalder 1977; Heggie 1988; Verheugd 1990; Moro 1997 for representatives of this general perspective).

1.5 A typology of copulas?

In sections 1.2 and 1.3 we have seen that there is good reason, at least descriptively (for the possibility of reducing the typology from a theoretical perspective, see section 1.4), to distinguish between a number of different types of copular construction (cf. (14–16)). There are two ways, in principle, of thinking of such a typology of copular constructions (cf. (24)). We refer to Keizer (1992: section 2.1) and Moro (1997: Appendix) for careful discussion, which we will summarize briefly in this section.

(24) a. *One 'be', different structures/derivations*
[e.g., Montague 1973; Stowell 1981; Dik 1983; Partee 1986, 1999; Heggie 1988; Moro 1997]

b. *Multiple 'be's*
[e.g., Huddleston 1971; Akmajian 1979; Safir 1985b; Seuren 1985; Rapoport 1987; Higginbotham 1987; Zaring 1996]

The 'classical' position in this debate is the one represented by Aristotle and Plato – the idea that 'be' is a polysemous lexical item with a variety of different meanings (corresponding to the different types of copular sentence enumerated in the foregoing). Modern philosophers have generally followed this venerable tradition in assigning *be* a variety of different meanings (cf., e.g., Mill 1856: 86; Russell 1903: 64).

In early generative work, the multiplicity of the copula seems to have been assumed more or less as a matter of course: thus, Huddleston (1971: 241), in making a distinction between predicational and specificational pseudoclefts, refers to the dichotomy in terms of the different types of *be* used in them: 'intensive *be*' vs. 'equative *be*'; elsewhere in the book he also distinguishes an identificational *be*. In making this three-way distinction among types of *be*, Huddleston follows Halliday's (1967: 66) typology of copulas. Likewise, Bolinger (1972b: 98) casts his typology of copular constructions in terms of a typology of *be*'s, recognizing an equational *be*, a locational *be* and a non-equational *be*. Akmajian (1979) similarly talks in terms of two species of *be*, as does Higgins (1979: 191) ("the verb *be* is the identity"); but Higgins (1979: 161–163) also takes care to point out that "other verbs that permit a meaning relation similar to speci- fication," like *lie in*, *consist in*, *constitute*, *amount to*, *entail*, *involve*, *have to do with* (also *justify*) behave the same way when it comes to one of the key properties of specificational sentences: connectivity.

More recently, Seuren (1985b: 299) has also felt the need to "begin by distinguishing a separate verb *be*, distinct from the ordinary predicative *be* . . . and distinct also from the *be* of identity" – a type of *be* that he labels 'specifying *be*', used in specificational pseudoclefts. And in the principles-and-parameters framework, Safir (1985b: 116) stands out as an example of the multiple-*be* approach, distinguishing at least two lexical entries for *be*: an identificational and a predicational one. In a rather different vein, Guéron (1992) argues that, while otherwise meaningless, the copula is an 'identificational operator' in inverse (specificational) copular sentences at the level of *commentaire*.[3] For a recent principles-and-parameters study of copular constructions (with special reference to Hebrew), the use of *be* in predicative and identity sentences in English, and the meaning of 'the verb *be*', see Rothstein (2001a).

The generative literature has generally tended, however, toward the one-*be* approach, ascribing the semantic variability of copular sentences to the structures involved, not to the semantics of *be*.[4] In fact, most authors in this framework agree that a key property of *be* is that it has no meaning at all – it is a functional element, linking the major constituents of copular sentences (cf. Stowell 1981; Heggie 1988; Den Dikken 1995b; Moro 1997). Even generativists who believe in the existence of a separate category of equative copular sentences alongside predicative copular constructions (cf. Heycock and Kroch 1999 for a recent

defense of this position; see also Adger and Ramchand 2003 and Pereltsvaig 2001 for discussion) routinely hasten to add that they do not take this to imply the existence of a separate 'equative *be*': there is only one copula, a 'linker', as its name suggests; the difference between equative and predicational copular sentences lies in the structures of the constructions (for Heycock and Kroch 1999, the internal structure of the small clause in the complement of *be* – see section 4.1.1 for brief discussion; for Pereltsvaig 2001, the distinction between *be* as a realization of I or *v*).

In denying the copula a meaning of its own and assigning it the status of a semantically void functional category (Partee's 1999 'non-lexical *be*'), the generative work referred to in the previous paragraph is in perfect agreement with Dik (1983), which represents a Functional Grammar perspective (for more FG-based studies on copular sentences, see Hengeveld 1992 and Keizer 1992; we will not address these further here).

In what follows we will follow (24a), the one-*be* approach to copular constructions – in the light of Higgins's (1979: 161–163) point about equivalents of *be*, and the fact that in the absence of an explicit demonstration of the polysemy (or, in fact, the 'semy', i.e., the meaningfulness) of the copula, one should proceed on the assumption that all of the semantics of copular sentences derives from (i) its major constituents and (ii) their syntactic structure and derivation.

2 Types of pseudocleft sentences

2.1 *Pseudocleft sentences: preliminaries*

A particular kind of copular sentence which has attracted a great deal of specific attention in the generative linguistic literature is the so-called pseudo(-)cleft construction.[5] Quintessential representatives of the class of pseudoclefts are copular sentences featuring a *wh*-clause, typically with *what* (less often *where*, *when*, *why*, *how*; even more rarely *who*), as one of their major constituents. Examples of such pseudoclefts are given in (25–33) (cf. esp. Akmajian 1979: 18–19):[6]

(25) What John does not eat is food for the dog.

(26) What John is is a good teacher.

(27) What John is is tall.

(28) What we need is Jerry drunk.

(29) Where John finally ended up was in Berkeley.

(30) When John arrived was at five o'clock.

(31) Why John went to the bookstore was to buy a book about pseudoclefts.

(32) How John did it was by using a decoder.

(33) %Who John visited was Bill.

Not all types of specificational pseudocleft illustrated in (25–33) are found in all languages (Ross 1999 notes, for instance, that Japanese and Kitchangana (Bantu) seem not to have the counterpart of (27)). Even in English, as Akmajian (1979: 83, n. 1) notes, "[m]any speakers find sentences such as [(33)] unacceptable (or less acceptable than sentences [(25–32)]) but judge as acceptable sentences [(25–32)]." In his corpus-based study, Collins (1991) found not a single example of a *who*-cleft, while of all the tokens of pseudoclefts with *wh*-words other than *what*, only one had the order illustrated in the examples above (with the *wh*-clause preceding the copula – see also Geluykens's 1984 corpus-based study for the rarity of this type, attested just once in his corpus as well; cf. also Heggie 1988: 352–353), all other cases involving the reverse order – but even then, their total incidence is not anywhere near that of *what*-clefts. Higgins (1979: 2) explicitly sets aside all pseudoclefts with *wh*-elements other than *what*; we will not, though most of our examples will indeed be of the *what* type.

The unbalanced distribution of *what* vs. pseudoclefts with other *wh*-words disappears once we include in the class of pseudocleft constructions examples featuring a headed relative instead of a *wh*-clause, illustrated in (35–39). All examples on this list are equally acceptable.

(34) The things John does not eat are food for the dog.

(35) The place where John finally ended up was in Berkeley.

(36) The time at which John arrived was at five o'clock.

(37) The reason why John went to the bookstore was to buy a book about pseudoclefts.

(38) The way John did it was by using a decoder.

(39) The {%one/√person} who John visited was Bill.

Most scholars agree that '*th*-clefts' (to borrow Collins's 1991 term; see also his '*all*-clefts': *All John ever eats is food for the dog*) should be treated on a par with '*wh*-clefts' (an alternative for the term 'pseudoclefts') – but Hankamer (1974) warns that the two, though similar, should not be identified (on account of the fact that "the allowable subjects of ['*th*-clefts'] are very restricted"; Hankamer 1974: n. 9); see also (175–176)). In this work, we follow the general trend of assimilating '*th*-clefts' to '*wh*-clefts'.

The term 'pseudocleft' seems to be a terminological innovation that we have generative linguistics to thank for – as Higgins (1979: 1) puts it, "this term is relatively new and seems to have arisen within the transformational-generative tradition, its formation emphasizing the formal and semantic kinship of the construction concerned to what Jespersen termed the 'cleft' construction". Jespersen's (1909) term 'cleft sentence' applies to such constructions as *It was Bill that John visited yesterday*, featuring the pronoun *it* in pre-copular position and a relative clause to the right of the copula. In early work on '*wh*-clefts', they occasionally were referred to simply as 'clefts' (cf. Jacobs and Rosenbaum 1968: 39). The parallels and differences between *it*-clefts and pseudoclefts will not be discussed here in any detail; that the two cannot be identified is clear, for instance, from the fact that there is no *it*-cleft counterpart to our earlier example in (28) (cf. **It is Jerry drunk that we need*).[7]

2.2 Types of pseudocleft I: a basic two-way split

Just as there are several types of copular sentence, the literature has also found occasion to distinguish different kinds of pseudocleft construction – where 'pseudocleft' is understood in the sense of section 2.1: as a copular sentence featuring a *wh*-clause or a corresponding (light-)headed relative clause construction as one of its major constituents (on a substantially narrower interpretation of the term 'pseudocleft', see section 2.4). Thus, Higgins (1979) distinguishes between two types, as in (40) (cf. the typology of copular sentences in (14)). The difference between the two can be illustrated with the aid of the ambiguity of the example in (25) (adapted from Clifton 1969; cf. (13), above): here *food for the dog* may be taken to denote a property ascribed to the referent of *what John does not eat* ('the things that John does not eat serve as food for the dog'), in which case we are dealing with a predicational pseudocleft; alternatively, we can take *food for the dog* to be a specification of what it is that John does not eat ('John does not eat the following: food for the dog'), in which case we are confronted with a specificational pseudocleft:

(40) *A basic two-way split* (Higgins 1979):
   a. predicational (25): 'The things John does not eat serve as food for the dog.'
   b. specificational (25): 'John does not eat (the following:) food for the dog.'

2.3 Types of pseudocleft II: more fine-grained typologies

In section 1.3 we have seen that a more microscopic investigation of copular sentences has turned up a number of additional types of such constructions (cf. (15) and (16)). In the light of the proliferation of copular sentences in general and the fact that pseudoclefts are unquestionably copular sentences themselves, one might therefore reasonably expect there to exist more than just two types of pseudocleft construction. And indeed, a more elaborate typology of pseudoclefts has been argued to exist. The one in (41) is due to Declerck (1988: 70):

(41) *A more refined typology of pseudoclefts:*
a. predicational
b. specificational
c. identity
d. definitional

(41a, b) are familiar from the foregoing discussion; examples of pseudoclefts identity statements and definitional pseudoclefts are given in (42) and (43), respectively (from Declerck 1988):

(42) *Pseudocleft identity statements:*
a. What I did was what you told me to do.
b. The one who is drinking the martini is Mr Brown.

(43) *Definitional pseudocleft sentences:*
A pyramid is what the Egyptians built to bury their pharaohs in. (cf. (21b))

Declerck's (1988) typology of double-NP copular sentences in (16) raises the expectation that a fifth type of pseudocleft construction might exist: descriptionally identifying pseudoclefts (cf. (16c); or Higgins's 1979 identificational pseudoclefts, (15c)). Though Declerck does not discuss this, it does indeed seem possible to find pseudocleft counterparts to examples of the type in (19) above: sentences of the type in (44) would appear to instantiate this type:

(44) *Identificational/descriptionally identifying pseudoclefts:*
a. That is what I need.
b. This is how I did it.

The examples in (44) seem parallel to the examples of identificational/descriptionally identifying double-NP copular sentences given in (19) – a parallelism which extends to the fact that reversal of the word order of (44b) is impossible (**How I did it is this*).[8] Collins (1991) includes (44) type examples in his set of specificational pseudoclefts and consequently finds overwhelmingly more XP < *wh* orders than *wh* < XP cases in his corpus.

For constructions of the type shown in (44b), with proximal *this* rather than distal *that*, it does not seem generally impossible, however, to reverse word order: with 'colon intonation' following *this* and a following specification, examples like *What I'm looking for is this: a crowbar and a wrench* are perfectly acceptable. Constructions such as this are most certainly specificational (as is revealed by their characteristic 'colon intonation' and their 'list reading'; cf. Higgins 1979 on the latter as a defining property of specificational sentences). One might actually go so far as to hypothesize that this *this* is a quintessential ingredient of specificational copular sentences: one might suggest that it is this *this* (which would have a null incarnation in all specificational sentences in which it does not surface overtly) that functions as the predicate of specificational sentences,

with the other two major constituents functioning as subject and 'specifier' of this predicate.

The typology in (41)/(44) mimics the typology of copular sentences presented in section 1.3. A more microscopic typology (developed in Declerck 1988: 220ff.) zooms in on specificational 'clefted sentences' (a cover term for *it*-clefts and specificational pseudoclefts), and primarily uses the information-structural properties (for more on these, see section 3.2.2, below) and concomitant intonational characteristics of the constructions as diagnostics:

(45) *A typology of* ***specificational*** *pseudoclefts:*
   a. contrastive pseudoclefts (or 'stressed-focus') (cf. (46))
   b. unaccented-anaphoric-focus pseudoclefts (cf. (47))
   c. discontinuous pseudoclefts (cf. (48))[9]

(46) a. Who broke the window? – The one who did it was John.
   b. Who broke the window? – John was the one who did it.

(47) a. It turns out that there is interesting independent evidence for that rule, and that evidence is what we must now turn to.
   b. Why is everybody so interested in uranium? – Because uranium is what you need to produce atomic power.

(48) a. My dear friends, what we have always wanted to know but what the government has never wanted to tell us, is what exactly happens at secret conferences like the one you have been reading about in the papers this week; there is one man, however . . .
   b. Those apples are good, aren't they? – So they are! What keeps me from eating all of them is that mother would be furious if I left none for the others.

These three types of specificational clefted sentences have the following key properties (cf. Declerck 1988: 224):

(49)

	(45a)	(45b)	(45c)
New/old info	focus new; clause old	focus old; clause new but represented as old	both focus and clause new
Accent	focus: heavy; clause: weak	focus: weak; clause: normal	both focus and clause normal
Contrast focus	strongly	not strongly	not strongly
Word order	both orders good	*wh*-clause post-copular	both orders good

As far as word order is concerned, Declerck's (1988) 'unaccented-anaphoric-focus' pseudoclefts (45b) are special in that they allow only the XP < *wh* order – cf. the 'identificational/descriptionally identifying pseudoclefts' of (44); see also Collins

(1991) on the differences between pseudoclefts with *wh* < XP word order and their congeners with XP < *wh* orders. What this shows is that, when one is talking about pseudoclefts, one should be careful to keep an eye on their word order.

The role of word order is also emphasized by Den Dikken *et al.* (2000), who make a distinction, within the class of specificational pseudoclefts, between 'Type A' and 'Type B' constructions:

(50) *Den Dikken et al. (2000):*
  a. 'Type A' specificational pseudoclefts
    - feature as their major constituents a *wh*-clause and a **full IP** (which is subject to optional ellipsis);
    - have *wh* < XP orders only;
    - exhibit connectivity effects for negative polarity.
  b. 'Type B' specificational pseudoclefts
    - feature as their major constituents a *wh*-clause and some XP (X ≠ I);
    - have XP < *wh* orders;
    - do not exhibit connectivity effects for negative polarity.

As the characterizations of the two types in (50) suggest, Den Dikken et al.'s (2000) two-way split within the class of specificational pseudoclefts is based largely on the behavior of pseudoclefts with full-IP 'value-XPs'[10] (cf. (51); see, e.g., Ross 1972a for discussion) and pseudoclefts featuring connectivity effects with respect to the licensing of negative polarity items in the 'counterweight' of the *wh*-clause (cf. (52)):

(51) a. What John bought was he bought some wine.
  b. *He bought some wine was what John bought.

(52) a. What John didn't buy was (he didn't buy) *any* wine.
  b. **Any* wine was what John didn't buy.

We will have occasion to discuss these two properties of ('Type A') specificational pseudoclefts in more detail further below. (See especially section 3.4 for discussion of the role of word order in the domain of specificational pseudoclefts.)

In what follows, we will not be concerned in any detail (except when it comes to contrastive analyses) with pseudoclefts of any type other than the specificational ones.

2.4 The scope of the term 'pseudocleft'

There is considerable confusion and disagreement in the literature on pseudocleft constructions concerning the meaning and scope of the term 'pseudocleft'. To quote Higgins (1979: 1–2) on this point:

> Unfortunately, the domain of application of the term is not completely clear, and there is much confusion in the literature. There are two features of the pseudo-cleft construction which are by many authors taken as defining features: (i) a semantic

> kinship to cleft sentences, and a consequent semi-formal requirement that pseudocleft sentences should have a bipartite form, looking like a broken-up form of a simple sentence, with a "focal" constituent which in some sense is being emphasized, and a remainder; (ii) a formal requirement that the sentence is a copular sentence having a subject that consists of a clause introduced by a *Wh*-item, usually *what*, this subject clause constituting the remainder of the simple sentence, and a portion which follows the copula and constitutes the focal constituent, the constituent which is being emphasized.

While some scholars use 'pseudocleft' as a cover term (in the way we did in section 2.1; cf. also Declerck 1988), others confine its reference in one or more of the following ways:

- to distinguish between examples with a *wh*-clause and examples featuring a headed relative (with *the one/thing/reason/time/way/ . . .* [cf. (33–39)], or *all*, as in *All John eats is food for the dog*; cf. Prince 1978, who uses the term '*wh*-cleft' in this narrow sense);
- to single out one particular type of pseudocleft construction: the specificational pseudocleft (see, e.g., Akmajian 1979, who uses the term 'pseudocleft' in this narrow sense);
- to single out pseudocleft constructions with *wh* < XP word orders (see the above quote from Higgins 1979 – these are Den Dikken et al.'s 'Type A' pseudoclefts).

Following, for instance, Akmajian (1979) and Collins (1991), we will include in this study not just (i) those pseudoclefts featuring a *wh*-clause ('*wh*-clefts') but also what Collins (1991) calls (ii) '*th*-clefts' and (iii) '*all*-clefts'. Unlike Akmajian (1979), but instead following, for instance, Higgins (1979) and Declerck (1988), we will not confine the term 'pseudocleft' to specificational constructions; to refer to such pseudoclefts we will use the term 'specificational pseudoclefts'. Though the emphasis will be on specificational pseudoclefts in what follows, we will contrast these with their predicational congeners in various places to properly delineate the set of specificational pseudoclefts.

3 Specificational copular sentences and pseudoclefts: an inventory of properties

3.1 Characterizing specificational pseudoclefts

What unites the examples in (25–39) (with (25) read specificationally) and sets them apart from other copular sentences is (as Akmajian 1979: 19 puts it) "that the initial clause of the pseudo-cleft contains what is essentially a semantic variable, a semantic 'gap' which must be 'filled' or specified by the focus item." Even pseudoclefts with a headed relative as NP_1 are different from specificational copular

sentences of the type discussed in section 1: they "contain relative clauses whose heads function as variables ranging over given semantic classes." We may therefore rephrase our characterization of specificational pseudoclefts as follows:

(53) *Specificational pseudoclefts* consist of:
- a constituent containing a variable (also called identified (Huddleston 1971));
- a constituent (exhaustively) specifying the value for that variable (also called identifier (Huddleston 1971), focus (Akmajian 1979, Higgins 1979), highlighted constituent (Collins 1991), counterweight (Heycock and Kroch 1999));
- a form of the copula linking the two major constituents.

In what follows, we will refer to the constituent containing the variable simply as 'the variable' (or 'the *wh*-clause', in the discussion of pseudoclefts), and to the constituent specifying the value as 'the value-XP'.

(i) *Connection between specificational pseudoclefts and question-answer pairs* The recipe in (53) is advantageous in two respects. First of all, it allows us to see the connection between specificational pseudoclefts and question-answer pairs (cf. (54)).[11] In both we find a constituent containing a variable (the *wh*-clause in (54i)) and a constituent (exhaustively) specifying the value for that variable (the focus of the post-copular constituent/answer in (54ii)); the two construction types are obviously different in that the copula is obligatorily present in the former, but absent from the latter:

		(i)		(ii)
(54)	a.	what John did	was	(John) read the newspaper
	b.	what did John do? –		(John) read the newspaper

The links between specificational pseudoclefts and question-answer pairs are stressed in many works on pseudocleft constructions (cf., e.g., Clifton 1969; Faraci 1971; Huddleston 1971; Ross 1972a, 1997, 1999; Akmajian 1979; Higgins 1979; Seuren 1985; Declerck 1988; Den Dikken et al. 2000). We will return to them in detail in section 5.

3.2 *Properties distinguishing specificational from predicational copular sentences*

3.2.1 Syntactic properties

(ii) *Reversibility* The second respect in which the recipe in (53) is beneficial is that it makes no reference to word order. And indeed, a key property which specificational pseudoclefts share with specificational copular sentences (cf. section 1.3) is their reversibility (cf. (55–56)):

(55) a. What John contributed to the conference was his best speech ever. (ambiguous: predicational or specificational)
b. His best speech ever was what John contributed to the conference. (specificational only)

(56) a. John's contribution to the conference was his best speech ever. (ambiguous: predicational or specificational)
b. His best speech ever was John's contribution to the conference. (specificational only)

While the a-examples in (55) and (56) allow a reading for *his best speech ever* according to which it predicates a property of the pre-copular constituent alongside a specificational reading which says that John contributed his best speech ever to the conference, only the latter reading survives in the b-examples.

It should be borne in mind that reversibility is not a foolproof diagnostic for specificational status – there are specificational copular sentences that are not reversible. The restrictions on reversal are largely of a categorial nature:

- if the value is an adverbial, the value < variable order is typically poor (though not entirely impossible); cf. (57) (Declerck 1988: 40; Heggie 1988: 371; Collins 1991):

  (57) a. The usual method of solving this problem is by firing the coach.
  b. ??By firing the coach is the usual method of solving this problem.

- if the value is not an expression containing an iota operator, a variable and a domain of individuals, it cannot precede the variable; cf. (58) (Guéron 1992 has the most explicit discussion of this constraint):[12]

  (58) a. Bill is {captain of the team/a doctor/a friend of mine/the best doctor in town/my best friend}.
  b. {*Captain of the team/*a doctor/*a friend of mine/the best doctor in town/my best friend} is Bill.

- if the value is a full IP (possible only in pseudoclefts), it cannot precede the variable if the verb in the *wh*-clause is substantive (rather than *do*); cf. (59) (Ross 1999, 2000; Den Dikken et al. 2000):[13]

  (59) a. What John {did/bought} was he bought some wine.
  b. He bought some wine was what John {did/*bought}.

- if the value is an AP and the verb in the *wh*-clause (of pseudoclefts) is not the copula, it must precede the variable; cf. (60) (Heggie 1988: 352–353):[14]

  (60) a. *How John likes his women is rather plump.
  b. Rather plump is how John likes his women.

Most of these constraints on reversal are not very well understood. These constraints aside, the general rule is that specificational sentences are reversible.[15] This seems to lead to a paradox when combined with the parallel between specificational sentences and question-answer pairs highlighted under (i), above. After all, question-answer pairs are not reversible (i.e., the answer does not normally precede the question). Den Dikken et al. (2000) address this question and distinguish two types of specificational pseudocleft, 'Type A' and 'Type B' constructions (cf. (50), above): it is only the 'Type A' cases that (thanks to their full-IP 'value') are on a par with question-answer pairs; and concomitantly, a hallmark of 'Type A' constructions is that they are not reversible (cf. (59b)).

With these caveats in place, we will now continue down the list of definitional properties of specificational copular sentences (see Akmajian 1979; Higgins 1979; and Declerck 1988 for the provenance of many of the following arguments, acknowledged wherever distinctive).

(iii) *Connectivity/connectedness effects* A property of specificational constructions which has preoccupied much of the discussion of these sentences in the generative literature is the fact that they exhibit connectivity/connectedness effects (cf. (61) for initial illustration). (The terms 'connectivity' and 'connectedness' are used interchangeably, the latter being the older term (cf. Akmajian, Higgins); however, to avoid confusion with the technical term 'connectedness' introduced by Kayne (1984a), in what follows we will avail ourselves of the label 'connectivity'.)

(61) a. What *John* treasures most is a book about *himself*/**him*.
b. *John*'s greatest treasure is a book about *himself*/**him*.

As (61) shows, connectivity (here with respect to anaphor–antecedent relationships) is a property of specificational sentences in general, not just specificational pseudoclefts. Indeed, "[s]pecificational sentences are the only type of copular sentences that show 'connectedness'" (Declerck 1988: 51) – as a consequence, connectivity effects can be used as a disambiguator of otherwise ambiguous pseudoclefts, as Higgins shows: while (62) is ambiguous between a specificational and a predicational reading, (63a) with anaphor connectivity is unambiguously specificational and (63b) is predicational only.

(62) What John is is important.
a. specificational: 'John is important.'
b. predicational: 'What John stands for is important.'

(63) a. What *John* is is important to *himself*. (specificational (Higgins))
What *John* is is important to *him*. (predicational)

Connectivity effects come in a variety of subtypes, listed and briefly discussed here.

(iii.a) *Reflexive connectivity* (See (63); cf. Higgins 1979).

(iii.b) *Reciprocal connectivity* (See (64); cf. Declerck 1988: 52)):

(64) a. What *they* did was kiss *each other*. (specificational)
b. *What *they* did was surprising to *each other*. (*predicational)

Reflexive and reciprocal connectivity, taken together, have served from the very beginning of the theoretical discussion of pseudocleft constructions as a key argument for somehow relating the specificational pseudocleft to the simple clause that paraphrases it (for (64a): *they kissed each other*, with *in situ* focus). The argument is simple and clear: specificational pseudoclefts reproduce 'across the copula' the binding properties characteristic of simple clauses.

The argument has never been water-tight, however. As Blom and Daalder (1977: 54) point out (cf. (65)), anaphor connectivity breaks down in Dutch when the anaphor is itself the post-copular constituent of the pseudocleft (rather than being contained in it); note, though, that English examples rendering things like (65a) are generally judged grammatical in the literature – see, e.g., Akmajian's 1979: 125 *The one that I shaved was myself* and *The one that you cheated was yourself*, and below on emphatic reflexives in English; we are not aware of any reported English counterparts to Dutch (65b), featuring the reciprocal, but they seem perfectly grammatical: *What they most detested was each other* (Caroline Heycock, p.c.)).

(65) a. ?*Wie *hij* op het oog heeft is *zichzelf*.
who he on the eye has is se-self
'Who is *he* thinking of is *himself*.'
b. *Wie *zij* tartten was/waren *elkaar*.
who they pestered was/were each other

Note also that pseudoclefts (and *it*-clefts as well) behave 'anomalously', from the simple clause perspective, in a number of contexts, as noted by Akmajian (1979: 125) and Hankamer (1974: 231–2, n. 6) (cf. also Sharvit 1997a; Den Dikken et al. 2000: 74, n. 29) – see (66a), from Akmajian, and (66b), adapted from an example of Hankamer's attributed to Stephen Anderson. Akmajian points out in a footnote (n. 10 on p. 153) that the reflexives used in examples of this kind "cannot be interpreted as normal reflexives, since they form the *foci* of their containing sentences" (original emphasis); this is certainly true, but the fact remains that the non-cleft counterparts of example like (66a, b) remain unacceptable even with heavy focal stress on the reflexive; cf. (67):

(66) a. The one who *John* claimed had been cheated was *himself*.
b. What was staring up at *John* out of his soup was *himself*.

(67) a. **John* claimed that *himself* had been cheated.
b. **Himself* was staring up at *John* out of his soup.

The status of anaphor connectivity as an argument for a transformational relationship of some sort between specificational pseudoclefts and their corresponding non-cleft paraphrases is less than crystal clear, therefore.

We note here that anaphor connectivity is unaffected by the linear word order of specificational sentences: that is, (63a) and (64a) remain grammatical with the relative order of variable and value inverted, as in (68):

(68) a. Important to *himself* is what *John* is.
b. Kiss *each other* is what *they* did.

In this respect, anaphor connectivity effects in specificational sentences are different from a third case of binding connectivity attested by specificational constructions (iii.c).

(iii.c) *Principle C connectivity ('anti-reconstruction')* (See (69); cf. Heycock and Kroch 1999; Den Dikken et al. 2000: 84, n. 35):

(69) a. *What *he* had said to Mary was that she had been lying to *John*. (specificational)
b. What *he* had said to Mary was an embarrassment to *John*. (predicational)

The facts in (69) are as expected, in the light of the anaphor connectivity effects noted above. Interestingly, however (cf. Den Dikken et al. 2000: 84, n. 35), (70), which has XP < *wh* order, is grammatical, in contradistinction to the *wh* < XP case in (69a):

(70) *Peter*'s picture of Mary is what *he* covets most.

Den Dikken et al. suggest that perhaps "such sentences are not SPCs [specificational pseudoclefts, MD] at all, or are ambiguous between an SPC and some other sentence type, e.g. an equative sentence."

(iii.d) *Negative polarity item connectivity* (See (71); cf. Ross 1972a; Halvorsen 1978; Akmajian 1979):[16]

(71) a. What I have *never* noticed is *any* signs of dissatisfaction. (specificational)
b. *What I had *never* noticed was noticed by *any* of us. (*predicational)

(72) a. What John hasn't done is leave *yet*/**already*.
b. What I doubt is that *anyone*/**someone* needs this money.
(cf. What I don't doubt is that **anyone*/*someone* needs this money.)
c. What John doesn't want is *ever* to be left alone.

Higgins (1979: 23–24) acknowledges the NPI connectivity effect noted by Ross and Akmajian (along with a number of other connectivity effects listed here) but

decides not to address it, saying that of the connectivity effects canvassed by Akmajian "the only one . . . that carries any great weight is the reflexive pronoun case." His rationale is as follows: "the rule is more clearly defined and the phenomenon better understood than, for instance, that governing *some/any* alternations." Heggie (1988: 325, n. 5) also explicitly sets aside NPI connectivity in her otherwise detailed discussion of specificational pseudoclefts. As Den Dikken et al. (2000) argue in detail, however, the distribution of NPI connectivity effects does indeed give us clear insights into the analysis of (a subtype of) specificational pseudoclefts.

We note in the context of negative polarity connectivity in specificational pseudoclefts that Blom and Daalder (1977: 24–25) present two types of example, from Dutch, in which such connectivity breaks down in these constructions. (They in fact draw the general conclusion that specificational pseudoclefts exhibit no NPI connectivity effect (in Dutch), but this is too strong a claim: Dutch counterparts to examples of the type in (71a) are grammatical, as shown in (73).)

(73) Wat ik nog *nooit* opgemerkt heb is *ook maar enig* teken van
what I yet never noticed have is also but any sign of
ontevredenheid.
dissatisfaction
'What I have never noticed is any sign of dissatisfaction.'

The first type of example discussed by Blom and Daalder is illustrated by the pair in (74). Blom and Daalder note (with a reference to the discussion of *any* in Klima 1964) that (74a) allows for a (salient) reading in which *ieder* behaves like English *any*: what (74a) then says is that he refused and would refuse any medicine at all that one offered or would offer him. That reading (which we may call the polarity reading of (74a))[17], Blom and Daalder point out, is unavailable for the pseudocleft in (74b); the example in fact has no reading at all: it is unacceptable as a reflex of a general ban on QPs as the post-copular constituent of pseudoclefts (be they predicational or specificational; see also the text accompanying (115) below for discussion).

(74) a. Hij weigerde ieder geneesmiddel.
he refused every medicine
b. *Wat hij weigerde was ieder geneesmiddel.
what he refused was every medicine

The lack of connectivity in (74b) is paralleled by the unavailability in (75b) of the inference which presents itself in (75a): that he gets upset about *any* joke at all (cf. Fauconnier 1975; like (74), we present this under the rubric of 'negative polarity' – cf. n. 17). We share Blom and Daalder's judgment; though we are not aware of any discussion of this phenomenon in the literature on English pseudoclefts, the facts seem transposable to English, with the same net result: a lack of parallelism/connectivity between specificational pseudoclefts and their simple clause counterparts.

(75) a. Hij trekt zich het onschuldigste grapje aan.
he pulls se the most-innocent joke prt
'He gets upset about (even) the most innocent of jokes.'
b. Wat hij zich aantrekt is het onschuldigste grapje.
what he se prt-pulls is the most-innocent joke
'What gets him upset about is the most innocent of jokes.'

The failure of polarity connectivity in examples of the type in (75b) is presumably connected to the fact that, systematically, NPI connectivity breaks down in specificational pseudoclefts whenever special NPIs (like *not . . . until*; Clifton 1969; Higgins 1979: 44; Sternefeld 1997) and idiom chunks are involved:

(76) a. *What John did*n't* do was (he did*n't*) leave *until 6 p.m.*
b. *What did*n't* John do? – (he did*n't*) leave *until 6 p.m.*

(77) a. *What John did*n't* have was (he did*n't* have) *a red cent*.
b. *What did*n't* John have? – (he did*n't* have) *a red cent*.

Den Dikken et al. (2000: 80) address this point and observe (i) that the ban on special NPIs and negatively polar idiom chunks as the 'value'-XP of specificational pseudoclefts rears its head in question-answer pairs as well (cf. the b-examples in (76) and (77)), and (ii) that this ban manifests itself even when the 'value'-XP or answer is a full IP containing a local licenser for the negative polarity item. The deviance of the examples in (76) and (77) (and presumably that of (75) on its idiomatic reading as well) should be sought, Den Dikken et al. suggest, in the lack of interpretive parallelism between the *wh*-clause and the 'value'/answer (manifest also in the oddity of a question-answer pair such as *What did John take? – ??He took a picture*): while the 'value'/answer is idiomatic, there is no choice but to read the *wh*-clause literally, which yields a clash.

(iii.e) *Quantifier connectivity* (See (78); cf. Hankamer 1974: 223):

(78) a. What *the little bastards* did was *all* get in the tub at the same time.
b. *What *the little bastards* did was *all* surprising to us.

This once again highlights the parallel between specificational pseudoclefts and their simple clause paraphrases (cf. *The little bastards all got in the tub at the same time*). If 'floating quantifiers' (like *all* in (78a)) are taken to be stranded by movement of the quantified noun phrase (cf. Sportiche 1988), the distribution of *all* in (78) might be construed as an argument for a transformational analysis of specificational pseudoclefts (cf. section 6 for discussion of transformational approaches). The stranding analysis of floating quantifiers is controversial, however (see Bobaljik 1998 for a critical assessment).

(iii.f) *Scope connectivity* (See (79); cf. Declerck 1988: 53; Den Dikken et al. 2000):

(79) a. ?What I *want* to marry is *a Swedish girl*.
b. What he *wanted* to find was *a nice Swedish girl* to marry.

An example of the type in (79) allows a reading of *a Swedish girl* on which it is in the scope of the intensional verb *want*, but such a reading is available only on the specificational reading of the sentence, not on the predicational one.

Scope connectivity also comes to the fore in the examples in (80), which show that the 'value'-XP of a specificational pseudocleft allows for the same *de dicto/de re* ambiguity (customarily treated in terms of scope) as does the object of the corresponding simple clause:

(80) a. What John seeks is a unicorn. (*de dicto* or *de re*)
b. John seeks a unicorn. (*de dicto* or *de re*)

(iii.g) *Selectional connectivity* (See (81–82); cf. Peters and Bach 1968; Hankamer 1974; Heggie 1988):

(81) What John counted was the pigeons/*the pigeon.
cf. John counted the pigeons/*the pigeon.

(82) a. What John wondered was whether/*that it was raining.
cf. John wondered whether/*that it was raining.
b. What he's {asking/not saying/*saying} is whether there will be any beer.
c. What {that depends/*John counts} on is whether there is enough beer.
d. What she wouldn't say (*to me) was why she ate them all at once.[18]

For reasons inherent in the lexical selectional properties of the verb *count*, a plural countable object (or a mass term, not illustrated here) is needed in combination with this verb. As (81) shows, this selectional restriction imposed by *count* carries over into specificational pseudoclefts featuring this verb in the *wh*-clause. Likewise, the fact that *wonder* selects a *wh*-clause complement asserts itself in the pseudocleft in (82a) as well. (Of course, (82) involves specificational pseudoclefts for trivial reasons, *wh*-questions not being construable as predicates.)

(iii.h) *Emotive should connectivity* (See (83–84); cf. Higgins 1979: 139–140; Bošković 1997a; Heycock and Kroch 1999.) Another reflex of selection which we may mention here under the general rubric of connectivity effects is what we will call 'emotive *should* connectivity':

(83) a. The *odd* thing is that he *should* have managed to do this all by himself.
b. What is *odd* is that he *should* have managed to do this all by himself.

(84) It is *odd* that he *should* have managed to do this all by himself.

As Higgins (1979: 139–140) first noted, the 'value'-XP of a specificational copular sentence may contain so-called 'emotive *should*' as a reflex of a selectional

property of a subconstituent of the 'variable' constituent. Predicates like *odd* can trigger the use of *should* in the clause that they select (cf. (84)); this selectional property of the predicates in question is preserved in specificational copular sentences, despite the fact that a direct link between *odd* and the clause containing *should* is not establishable in (83).

We add in the context of 'emotive *should*' (even though this does not obviously have anything to do with connectivity) that the presence of 'emotive *should*' in specificational pseudoclefts may also be triggered by a predicate outside the pseudocleft construction altogether – and that, when this happens, 'emotive *should*' will show up either in the root clause or in the *wh*-clause if the word order of the pseudocleft is XP < *wh* but may surface only in the *wh*-clause if the order is *wh* < XP (see Higgins 1979; also Bošković 1997a: 271; Heycock and Kroch 1999):

(85) a. It is a pity [that [proud of himself] *should* be [what John is]].
b. It is a pity [that [proud of himself] is [what John *should* be]].

(86) a. *It is a pity [that [what John is] *should* be [proud of himself]].
b. It is a pity [that [what John *should* be] is [proud of himself]].

For Bošković (1997a) and Heycock and Kroch (1999) the facts in (86) are an indication that specificational pseudoclefts of this type are 'reconstructed' into their simple clause counterparts in the semantic component of the grammar. See especially Bošković (1997a: 271) for careful discussion, as well as for the observation that the distribution of 'emotive *should*' is a diagnostic for distinguishing specificational and predicational pseudoclefts: in the latter, 'emotive *should*' never shows up in the *wh*-clause in such contexts as (87):

(87) a. It is a pity [that [what John is] *should* be [worthwhile]].
b. *It is a pity [that [what John *should* be] is [worthwhile]].

(iii.i) *Case connectivity* (See (88–90); cf. Bošković 1997a; Iatridou and Varlokosta 1998). One last connectivity effect that we will discuss here involves Case. Iatridou and Varlokosta (1998) point out that the 'value'-XP of specificational pseudoclefts is Case-dependent on the verb in the *wh*-clause; that of predicational pseudoclefts is not. The German pair in (88) shows this most clearly, thanks to the morphology on the post-copular noun phrase:

(88) a. Was Hans essen wollte war *einen* Apfel.
what Hans eat wanted was an(acc.) apple
b. Was Hans essen wollte war *ein* Apfel.
what Hans eat wanted was an(nom.) apple

Den Dikken et al. (2000: 73, n. 27) point out that Iatridou and Varlokosta have overstated the case: (88b) is not unambiguously predicational; it allows a specificational

interpretation as well (as is shown by connectivity effects, which are reproducible in these kinds of sentences; see Sharvit 1997 for a similar observation about Hebrew). Be that as it may, (88a) is certainly unambiguously specificational (moreover, it is grammatical only with a *wh* < XP word order, a 'Type A' diagnostic; see Den Dikken et al. 2000 for discussion). It shows that the 'value'-XP can get its Case from the verb in the *wh*-clause: a case of Case connectivity.

That the 'value'-XP is Case-dependent on the verb in the *wh*-clause is shown also by facts presented by Bošković (1997a: 250). While *ask* and *wonder* both semantically select a question, it is only *ask* which allows this question to take the form of a noun phrase; this follows from the fact that only *ask* is a Case assigner. The distribution of CP and DP complements seen in the simple clauses in (89) is mimicked perfectly in the corresponding specificational pseudoclefts in (90).

(89) a. I asked {what the time was/the time}.
b. I wondered {what the time was/*the time}.

(90) a. What I asked was {what the time was/the time}.
b. What I wondered was {what the time was/?*the time}.

(Bošković 1997a: 253 presents similar facts for *hope* and *inquire*.)

The examples in (91) and (92) (both taken from corpus-based studies: Geluykens 1984: Appendix and Collins 1991: 45, respectively) make a similar point. In both cases, the fact that the post-copular 'value'-XP does not want Case seems to be responsible for the absence of the preposition which the verbs in the *wh*-clauses would select in the presence of a Case-dependent DP. Bošković's (1997a: 253, n. 20) constructed examples in (93) (which he calls "degraded" yet better than the corresponding *wh*-questions: **What is John afraid?*, **What does it seem?*) fit into this general picture as well. (See Bošković 1997a: 253, n. 20 for discussion of why his examples in (93) are degraded.)

(91) What I am convinced is that we shall not do anything unless departments cooperate.

(92) Now what I'm fascinated is to know that communists and fascists are such bad shots.

(93) a. ??What John is afraid is that Mary will leave.
b. ??What it seems is that Mary will leave.

For Bošković, the above examples show, in addition, that the *what* inside the *wh*-clause apparently is not Case-dependent. This seems to be contradicted, however, by familiar facts of the type in (94–96) (cf. Heggie 1988: 340, 343). Here, the distribution of *of* indicates that *what* does indeed demand Case – the *what* of specificational pseudoclefts imposes the exact same restrictions on the complement of the verbs in these examples which unmistakable DPs also impose:

(94) a. What did you persuade him *(of)?
b. You persuaded him (*of) [that he should try harder]/[to try harder].
c. What you persuaded him *(of) was [that he should try harder]/[to try harder].

(95) a. What did he agree *(to)?
b. He agreed (*to) [that he would work harder].
c. What he agreed *(to) was [that he would work harder].

(96) a. What are you wondering (about)?
b. John is wondering *(about) DP.
c. What John wonders (about) is [whether he can succeed].

Notice that these data seem to confirm the parallelism between specificational pseudoclefts and question-answer pairs (cf. (i), above; also see section 5, below), while the ones in (91–93) seem to pose a problem for such a connection.

(iv) *Agreement effects* The whole battery of connectivity effects reviewed in the foregoing as a group sets apart specificational sentences (double-NP as well as pseudocleft varieties) from predicational copular sentences. Similar in spirit and effect are the (iv) agreement effects. These come in three types, the third of which deserves comment here (on (iv.a) see section 4.2).

(iv.a) *Phi-feature agreement* (See (97); cf. Declerck 1988: 79):

(97) a. What you have bought *is* fake jewels. (specificational)
b. What you have bought *are* fake jewels. (predicational)

(iv.b) *Aspectual agreement* (See (98); cf. Declerck 1988: 52):

(98) a. What he was do*ing* was work*ing* in the garden.
b. *What he was do*ing* was work in the garden.
c. *What he did was work*ing* in the garden.

(iv.c) *Temporal agreement/congruence* (See (99); cf. Akmajian 1979: 168–169):

(99) a. What you are holding in your hand *is* a small brown butterfly. (pred/spec)
b. What you are holding in your hand *was* a small brown butterfly. (predicational)
c. What you are holding in your hand *will be* a small brown butterfly. (predicational)

As Akmajian points out (p. 169), of the examples in (99) only the a-sentence has a specificational reading; the other two are unambiguously predicational. In concert

with this observation, Akmajian also shows that of these three examples only the a-example is reversible (cf. (100); see property (ii)):

(100) a. A small brown butterfly *is* what you are holding in your hand.
b. *A small brown butterfly *was* what you are holding in your hand.
c. *A small brown butterfly *will be* what you are holding in your hand.[19]

Akmajian (1979: 169–170) points out that "while the phenomenon illustrated by the sentences of [(99)] has been viewed in terms of tense agreement, it is in fact part of a deeper phenomenon," characterizable as "temporal congruence": cf. the fact that it rears its head also in non-cleft specificational copular sentences of the type in (101), conditioned by the adjective *old* in the pre-copular NP:[20]

(101) a. His old job *was* building radars at Lincoln Labs.
b. *His old job *is* building radars at Lincoln Labs.
c. *His old job *will be* building radars at Lincoln Labs.

This once again confirms the intimate connection between specificational pseudoclefts and specificational copular sentences in general.

While the preceding examples suggest that tense agreement/congruence is obligatory in specificational pseudoclefts, we should note that Declerck (1988: 81–82) points out that tense in specificational pseudoclefts is "determined by two different and independent systems": (i) "the tense depends on the relation between the chosen deictic centre and the time implied by the variable NP," or (ii) "the tense of the copula is neutralized" (with the copula systematically occurring in the present tense). We have come across examples illustrating (i) in the foregoing; examples of the second type are given in (102) (from Declerck 1988: 82), which are grammatical only "if there is 'present tense relevance', i.e., if the past act of specification is still felt to be relevant" (p. 83):

(102) a. The reason he did it *is* that he is a coward.
b. What he would not say *is* when it will happen.

We note also that there may be an effect of word order on the temporal agreement facts: though this does not seem to have been discussed in detail in the literature, Heggie's (1988) pairs in (103–104) suggest that it is only specificational pseudoclefts with *wh* < XP order which are subject to strict tense agreement restrictions:

(103) a. Where John met Mary *was* in the park.
b. In the park *is* where John met Mary.

(104) a. Who I gave the book to *was* John.
b. John *is* who I gave the book to.

Under the rubric of temporal agreement/congruence, we may also draw attention to a number of restrictions on specificational sentences in general, and specificational

pseudoclefts in particular, when it comes to tense. The reader familiar with Higgins (1979) may have assumed that Akmajian's examples reproduced here as (99c) and (100c) are ungrammatical (as specificational pseudoclefts) regardless of tense agreement/congruence – after all, Higgins (1979: 310) claims that the tense of the copula in specificational pseudoclefts may only be simple present or past tense (see also Heggie's 1988: 315 statement that "sentences like *The boss must be Joe Horn* are always equative"). Declerck (1988: 81) takes issue with Higgins's claim, however, pointing out that a specificational pseudocleft of the type in (105a) is grammatical. Ross (1999) gives additional examples (cf. (105b–d)) that contradict Higgins's claim in this domain, and help further emphasize the requirement of temporal agreement. The facts in (105c, d) are complicated, and will not be dissected in detail here; what (105c) shows particularly clearly, however, is that the agreement requirement refers to tense, not aspect: the perfect in the *wh*-clause need not be matched in the copular main clause, but the present tense form of *has* in the *wh*-clause *must* be matched by a present tense form in the matrix:

(105) a. The one who *will* win *will be* one of us.
b. What Sandy *might have been* reading {*might have been/might be/*has been*} Tolstoy
c. What Sandy *has been* reading {**might have been*/?**might be/has been/is/*was*} Tolstoy.
d. what *could have been* happening {*could have been/could be/*was/is*} that she {**has been/could have been/was/is*} working at home.

Declerck (1988: 85) also dismisses Higgins's (1979: 242) statement that *used to be* can replace *be* in predicational sentences only (a statement which is apparently correct for sentences like (106)) with reference to the grammatical examples in (107):

(106) (The one who was) the murderer of Tom *was/*used to be* John.

(107) a. The colour that she preferred *used to be* blue.
b. The one who did most of the work *used to be* John.

Declerck (1988: 85) concludes that (107) is grammatical since "the variable NP is such that different values can be assigned to it at different times," while such is impossible in (106). Even with this correction to Higgins (1979) in place, though, it remains true that with respect to the restrictions on tense (including *used to*), all specificational copular sentences (cleft and non-cleft alike) behave on a par and are to be distinguished from their predicational counterparts.

(v) *Extraction restrictions* (See (108–109); cf. practically all of the literature on specificational sentences – in particular, Heggie 1988; Moro 1997; Heycock and Kroch 1999). This is another important property covering the entire spectrum of specificational sentences.

(108) a. I believe that the cause of the riot was a picture of the wall.
b. *Which picture do you believe that the cause of the riot was *ec*?
c. *Which wall do you believe that the cause of the riot a picture of *ec*?
d. *Which riot do you believe that the cause of *ec* was a picture of the wall?
e. *The cause of which riot do you believe *ec* was a picture of the wall?

(109) a. I believe that what caused the riot was a picture of the wall.
b. *What do you believe that what caused the riot was *ec*?
c. *What do you believe that what caused the riot was a picture of *ec*?
d. *What do you believe that what caused *ec* was a picture of the wall?

Grosu (1972) presents the opacity of the post-copular 'value' constituent of specificational pseudoclefts as an argument for the so-called extraction analysis of these constructions (see section 6.2, below); however, the fact (which he notes himself) that specificational copular sentences generally have this property makes it highly unlikely that the extraction restrictions in (109) constitute an argument for an analysis of specificational pseudoclefts that derives them from their corresponding simple clause counterparts (or vice versa; on the latter, see Bošković 1997a, and the discussion in section 6.4.1). What is needed is an account of the data in (108) and (109) which generalizes over all specificational copular sentences and sets them apart from predicational copular sentences (which do allow extraction from and of the post-copular constituent; cf. (110)):

(110) a. I believe that the cause of the riot was a big surprise to us all.
b. How big a surprise do you believe the cause of the riot was *ec*?
c. Who do you believe that the cause of the riot was the biggest surprise to *ec*?
d. *What do you believe that the cause of *ec* was a big surprise to us all?

The above five traits of specificational copular sentences (including specificational pseudoclefts) are the most important syntactic distinctive features of these constructions (on interpretive hallmarks of these constructions, see section 3.2.2 below). In addition to these, we may mention a number of somewhat more microscopic ways in which predicational and specificational copular sentences differ.

(vi) *Negation* (See (111); Higgins 1979: 321; Declerck 1988: 166):

(111) a. What John is isn't important to him. (predicational)
b. *What John is isn't important to himself. (specificational)
c. *Smith's murderer isn't John.

As Higgins (1979: 321) points out, "the copula in a Specificational pseudo-cleft cannot have a 'straight' negation of the predicate, but at best only some kind of contradiction negation" – that is, (111b), while bad in isolation, could be salvaged

by contrasting *important to himself* with some other value of the variable in the *wh*-clause (cf. *What you need is not a doctor but a wife*; see also Ross's (2000) *Though what I like is not pizza, what he likes is*, which is likewise contrastive, though not with respect to the value). Declerck (1988: 166) broadens the scope of Higgins's observation to include specificational copular sentences in general; cf. (111c), which likewise is good only on a 'contradiction reading'. (On restrictions on adverbial modification other than negation, see (xx), below; this is a domain in which the facts are substantially less clear, and where, moreover, specificational pseudoclefts diverge from other specificational copular sentences.)

(vii) *Copula contraction* (See (112); cf. Kaisse 1979: 708–709). This is another domain in which all specificational copular sentences differ *en bloc* from their predicational pendants:

(112) a. What I eat's important to me. (predicational)
*What I want's an avocado. (specificational)
c. *The culprit's Chuzzlewit.
cf. Chuzzlewit's the culprit.

As (112) shows, only predicational copular sentences allow the copula to contract onto the pre-copular constituent.

(viii) *Degree modification of the post-copular term* (Cf. (113); Akmajian 1979: 164; Heggie 1988).[21] Predicational copular sentences are also singled out by restrictions on degree modification of the post-copular term.

(113) What *John* is is **somewhat/very/more** important to *him*/**himself* (than . . .).

For both Akmajian and Heggie, the impossibility of this kind of construction counts as evidence that the post-copular AP in specificational pseudoclefts like this is not a predicate – modification is a property limited to predicates.

(ix) -ever *and quantificational restrictions* (Huddleston 1971: 242; Heggie 1988; Declerck 1988.) A further peculiarity of pseudoclefts which has been made out to be reducible to a property of predicates (predicate nominals, to be more specific) concerns *-ever* and quantificational restrictions:

(114) Whatever she wrote was a novel. (predicational/*specificational)

(115) a. *John is every teacher.
b. *Bill's tie is whatever Mary hates.

The example in (114), from Bolinger (1972b), is unambiguously predicational, whereas its counterpart without *-ever* is perfectly ambiguous between a predicational and a specificational interpretation.[22]

Heggie links the unavailability of a specificational reading for (114) and the ungrammaticaticality of her (115b) to a general ban on predicate nominals: they resist universal quantification, as is shown by Williams's (1983b) example in (115a). Iatridou and Varlokosta (1998) take essentially the same tack, analyzing the ungrammaticality of examples like (115b) by analyzing the *wh*-clause of specificational pseudoclefts as a free relative functioning as a predicate nominal. Heggie and Iatridou and Varlokosta thus construe the facts in (114) and (115) as an argument for an analysis of the *wh*-clause of specificational pseudoclefts as an underlying predicate.

Their point is not well taken, however. For in specificational sentences *both* major constituents are in fact subject to quantificational restrictions – not just the *wh*-clause (as the *-ever* facts show) but the 'value' NP as well (cf. Gundel 1977; Seuren 1985: 297; Declerck 1988: 87–88; Moro 1997; Heycock and Kroch 1999); cf. also Blom and Daalder's 1977: 24–25 discussion of (74), above), as (116) and (117) show:[23]

(116) What Henry sold was
- a. a postcard
- b. a few postcards
- c. *few postcards
- d. *many postcards
- e. *most postcards
- f. *every postcard

(117) The problem/cause of the riot was
- a. English hooligans
- b. a few English hooligans
- c. *few English hooligans
- d. *many English hooligans
- e. *most English hooligans
- f. *every English hooligan

If Heggie's and Iatridou and Varlokosta's interpretation of (115) were correct, the facts in (116–117) would imply (in combination with their conclusion based on (115)) that specificational copular sentences have *two* predicative constituents – and that would not make any sense. We therefore refrain from drawing hasty conclusions concerning predicativity on the basis of quantificational restrictions of the type just illustrated.

3.2.2 Interpretive properties

Two interpretive properties of specificational constructions, closely related to one another, are worth drawing special attention to.

(x) *Information structure* There is a strong tendency for the 'value'-XP of a specificational sentence to be the focus of the construction, and to convey new

information. Blom and Daalder (1977) effectively use this fact as the key distinguisher between specificational and predicational copular sentences. The following definitions have been adapted from Blom and Daalder's work ('value'-XP replaces their 'hyponym'; see (23), section 1.4):

(118) a. In a *specificational* copular sentence, the focused element is contained in the 'value'-XP.
b. In a *predicational* copular sentence, the focused element is **not** contained in the 'value'-XP.

To illustrate, in a specificational pseudocleft such as (119), the information structure (or theme-rheme structure) of the sentence is partitioned in such a way that the *wh*-clause expresses old information while the 'value', which specifies the variable in the *wh*-clause, supplies new information. Concomitantly, the 'value'-XP in examples of this sort receives focal stress.

(119) What John bought was a book.

However, while there is indeed a strong tendency for the variable to merely express old information and for all the new information to be packaged into the value, one cannot strictly correlate the variable/value (or identified/identifier) dichotomy with the new/given information split, as Halliday (1967: 226) already pointed out. As Collins (1991: 82–83) puts it, "the two are independenty variable; the association of new information with the highlighted element may be overriden by marked focus." An example of such an override is Collins's (120):

(120) a. Tom offered Sue a sherry.
b. No, the one who poured the sherry was Tom.[24]

Although, therefore, "in the majority of basic pseudo-clefts the relative clause/theme [i.e., variable] contains (at least some) new information . . . there are several factors which work together to attenuate the newness of the item or items so marked intonationally" (Collins 1991: 119).

Declerck (1998: 13) makes a more general point of the same general nature, observing that there are essentially four ways of focusing in specificational sentences:

- focus can be on the value as a whole (the 'standard' case),
- focus can be on a subpart of the value,
- focus can be on the entire pseudocleft (in which case information in the *wh*-clause is also new; cf. Erades 1962; Prince 1978),
- focus can be on two value parts, one of which appears in the *wh*-clause (cf. (121), adapted from Declerck's cleft example).

(121) (Why did you hit Mary? – I beg your pardon!) She was the one who hit me!

We refer the reader to Collins 1991: 133, 145 for lucid summaries of the information-structural properties of pseudoclefts with *wh* < XP and XP < *wh* orders.)

(xi) *Exhaustivity* Exhaustivity (or exclusivity or uniqueness, as it has also been called) is another interpretive property peculiar to specificational copular sentences, closely related to the information structural properties of these constructions. It is an implicature (cancelable by 'particularizers' like *not only, mainly, especially, primarily*), not overly robust at that – as Collins (1991: 32) points out, "the types of sentences one may construct to test the exclusiveness implicature elicit variable responses when submitted to the judgment of native speakers": examples of the type in (122c, d), while "rejected by many" once the parenthesized material is included, apparently are not deemed as awkward as the relevant variants of (122b, e, f).

(122) a. The car needs a new battery (amongst other things/and it needs a new alternator too).
b. The car only needs a new battery (*amongst other things/and it needs a new alternator too).
c. It is a new battery that the car needs (?amongst other things/and it needs a new alternator too).
d. What/the thing the car needs is a new battery (?amongst other things/and it needs a new alternator too).
e. All/the only thing the car needs is a new battery (*amongst other things/and it needs a new alternator too).
f. It is only a new battery that the car needs (*amongst other things/and it needs a new alternator too).

Still, the fact that many speakers do indeed reject (121c, d) with the parenthesized material included "can only be attributable to the exclusiveness implicature associated with cleft and pseudo-cleft constructions" (Collins 1991: 33).

This implicature is a sufficient but not a necessary condition for specificationality – that is, any copular construction that has an exhaustiveness implicature is specificational; but not every specificational copular sentence necessarily has this exhaustiveness implicature. As Declerck (1988) points out, this implicature "can only arise if the variable is uniquely defined" (i.e., if the variable is *definite*, which it is when it is a definite noun phrase or the *wh*-clause of a specificational pseudocleft). As a consequence, in cases in which the variable happens not to be "uniquely defined," no uniqueness/exhaustiveness implicature presents itself (see Declerck's examples on p. 31, reproduced here):

(123) a. An example of this kind is World War II.
b. Typical instances of this are Julius Caesar and Napoleon.
c. Something that I don't understand is how the thief managed to get in.

There are cases in which exhaustiveness is not merely an implicature but actually an entailment of the singularity and definiteness of the variable.[25] In such cases,

adding *only* to the focus will block the specificational reading (Declerck 1988: 32): (124b) can only receive a predicational reading ('Smith's murderer is not someone with whom I have close relations').

(124) a. The one who murdered Smith is my neighbor. (ambiguous)
b. The one who murdered Smith is *only* my neighbor. (predicational only)

In a similar vein, Seuren (1985) points out that there are contexts in which the interpretive difference between (pseudo)cleft sentences and their simple counterparts is not merely pragmatic but in fact truth-conditional (cf. (125), (126)): "if in a situation where nobody laughed [(125a)] is uttered it will simply be (minimally) false and its negation [(125b)] will be true, but if [(126a)] is uttered it will be (radically) false and its negation [(126b)] will still fail to be true."[26]

(125) a. Harry laughed.
b. Harry didn't laugh.

(126) a. The one who laughed was Harry.
b. The one who laughed wasn't Harry.

3.3 *Properties peculiar to specificational pseudoclefts*

Now that we have essentially covered the list of syntactic and interpretive properties which unite all specificational copular sentences and set them apart from their predicational congeners, let us make a list of a number of characteristics peculiar to specificational pseudoclefts.

(xii) *The form of the value-XP* (Bolinger 1972b: 98–100; Hankamer 1974; Heggie 1988: 371; Declerck 1988):

(127) a. The way he spoke to me was flatteringly. (specificational)
b. The way he spoke to me was flattering. (predicational)

(128) The best way to categorize them in fact is historically. (Geluykens 1984)

(129) a. When/the day they're coming for the box is Friday. (Hankamer 1974)
b. When she waters them is weekends.

Given that (127a) and (128–129) (the latter due to Hankamer 1974; these are good in certain dialects only) are unambiguously specificational, one expects (cf. property (ii) above) that this kind of pseudocleft should be reversible – and indeed, grammatical and somewhat marginal cases of this kind have been reported in the literature (cf. (130a), due to Radford 1981, and (130b, c), from Heggie 1988: 371). As Heggie points out, "it appears that to the extent that an adverb may be easily

predicated of a human subject (i.e., PRO), the sentence is grammatical" (while "those adverbs which must be predicated of a clause are completely ungrammatical"; cf. **Apparently is how John left early*).

(130) a. A little too casually seems to have been how he addressed the judge.
b. ?Very quickly seems to be how she ran the race.
c. ?Very reluctantly is how we all left.

(xiii) *PP pied-piping* (cf. esp. Heggie 1988: 360–363)

(131) a. *With whom he goes to the cinema is with Mary/important to himself. (specificational)
b. ?With whom he goes to the cinema is important to him. (predicational)

In English it is generally impossible to perform PP pied-piping in a specificational pseudocleft (though pied-piping is possible in predicational pseudoclefts, to the same extent that PP pied-piping is ever felicitous in English). Notice, however, that Heggie (1988: 360–363) has found that pied-piping of a dative or *of*-PP does not seem impossible in specificational pseudoclefts: the examples in (132) and (133) are "simply awkward," not ungrammatical, according to her:

(132) a. ?To whom I gave the book was John.
b. ?John is to whom I gave the book.

(133) a. ?Of what Mary was convinced was that Bill would succeed.
b. ?That Bill would succeed is of what Mary was convinced.

(134) a. ?A person to whom I sent a report without notifying *pg*.
b. ?A person to whom I spoke without kneeling in front of *pg*.
c. ?To whom did John speak without being able to see *pg*?

She notes in this connection that *to whom* can also (marginally) license an NP parasitic gap (as in (134)), which suggests that the PPs in (132) and (133) can exhibit 'NP-like' behavior. If so, (132) and (133) are not genuine exceptions to the generalization that English specificational pseudoclefts disallow PP pied-piping.

Languages differ on this point, however: Higgins (1979: 41) notes Spanish examples of specificational pseudoclefts with PP pied-piping (due to Jespersen 1969: 78–79) which are grammatical (cf. (135)):

(135) a. De un rey es de quién hablamos.[27]
of a king is of whom we speak
b. Con quién hablaba es contigo.
with whom I/he was talking is with you

Similarly, Den Dikken et al. (2000: 72) report that Dutch and German allow PP pied-piping in specificational pseudoclefts as well; but see Blom and Daalder

(1977: 9) for an example of PP pied-piping in Dutch which they judge to be unacceptable (?**Waar Jan op wacht is op de uitslag* 'What Jan is waiting for is for the result'; to our ear, this example does not sound crashingly bad). See also section 5.2, below.

(xiv) '*P-drop*' (Higgins 1979: 303–304):

(136) a. Where John is going *to* is a nice place. (pred/spec)
b. Where John is going is a nice place. (predicational)

Higgins claims that not realizing the preposition *to* delivers an exclusively predicational interpretation of the pseudocleft in (136). It is unclear what should explain this fact[28] – especially from the perspective of the parallels between the *wh*-clause of specificational pseudoclefts and *wh*-questions in question-answer pairs, one might have expected non-realization of *to* to be perfectly compatible with a specificational interpretation of the pseudocleft: the question *Where is John going (to)?* is perfect both with and without *to*.

(xv) *Tag questions* (Higgins 1979: ch. 6, (85)/(87); Bošković 1997a: 272):

(137) a. *What John is is proud, isn't it? (specificational)
b. ?What John is is proud, isn't he?

(138) a. What John is is lucrative, isn't it? (predicational)
b. *What John is is lucrative, isn't he?

Bošković (1997a: 272) notes that, while in predicational pseudoclefts the choice of pronoun and verb in a tag question is determined wholly at the root level (a copular sentence with a free relative subject, resulting in *is* and *it*), in specificational pseudoclefts (at least the ones with *wh* < XP word order; we are not familiar with facts of this nature reported for XP < *wh* pseudoclefts) such is entirely impossible (see (137a)). Instead, the tag may marginally skip the copular root clause altogether and relate itself to the clause contained in the *wh*-constituent.

Sentences of the type in (137b) are certainly not brilliant (Bošković actually assigns (137b) two question marks), but they are attested in spontaneous speech – Geluykens (1984) found (139) in a corpus of spoken English (from the *Survey of English Usage*):

(139) What you're meaning, Joey, is what caused the bolus, aren't you?

The following are two restrictions on the *wh*-clause constituent of pseudoclefts.

(xvi)*Predication restrictions* (Akmajian 1979: 165; Heggie 1988: 351):

(140) a. He is tall. (predicational)
b. He is the man who robbed the bank yesterday. (specificational)

(141) a. What he is is tall.
b. *What he is is the man who robbed the bank yesterday.

In a *wh*-cleft whose *wh*-clause has the form *what X is*, the 'value'-XP must correspond to the *predicate* of the copular *wh*-clause: specificational copular sentences do not serve as input to specificational pseudoclefts whose *wh*-clause has a post-copular gap (cf. (141b), due to Akmajian 1979: 165).

This is clearly not a case of matching across the matrix copula – that is, it is not the case that the gap in the copular *wh*-clause must be a predicate in order to match the predicativity of the post-copular constituent in the matrix: after all, the latter is *not* a predicate. This is shown most directly, perhaps, by the fact that *though*-movement (an operation singling out predicates) fails in specificational pseudoclefts (as Ross 2000 has pointed out):

(142) a. Harmless old duffer though Al was, he won.
b. *Harmless old duffer though what Al was is, he won.
cf. Though what Al was is a harmless old duffer, he won.

While (141a) is grammatical (with *tall* functioning as a predicate inside the *wh*-clause), specificational pseudoclefts with a 'value'-AP "obtain freely only when the verb of the CP-predicate is the copula" (Heggie 1988: 351) – the examples in (143) and (144) are ungrammatical. Contrast these with the grammatical example in (145) (= (60b); see n. 14 on speaker variation with respect to the reverse order of (147), irrelevant here):

(143) a. *How Mary shook John was awake.
b. *Awake is how Mary shook John.

(144) a. *How Tom hammered the nail was flat.
b. *Flat is how Tom hammered the nail.

(145) Rather plump is how John likes his women.

The same problems found in (141b) and (143–144) rear their heads in question-answer pairs: while the *wh*-questions in (146a–c) are good in isolation, they cannot receive the answers provided on the right. (146d) (corresponding to (145)) once again behaves differently:

(146) a. What is he? – *The man who robbed the bank yesterday.
b. How did Mary shake John? – *Awake.
c. How did Tom hammer the nail? – *Flat.
d. How does John like his women? – Rather plump.

This enhances the parallel between specificational pseudoclefts and question-answer pairs (see section 5; cf. Den Dikken et al. 2000 for an analysis of specificational pseudoclefts exploiting this parallel).

(xvii) *Combining clefts and pseudoclefts I* (Blom and Daalder 1977; Akmajian 1979: 89; Declerck 1988):

(147) a. Whatever it was that he got from her was expensive.
b. *What it was that he got from her was expensive.

(148) a. Ik weet niet wie (het is die) daar staat.
I know not what it is that there stands
b. Ik doe wat (*het is dat) de directeur mij opdraagt.
I do what it is that the manager me assigns
c. Wat (*het is dat) hij eet is een banaan.
what it is that he eats is a banana

(149) *The thing that it was that was in the car was my hat.

Declerck (1988: 73) points out that clefting inside the *wh*-clause of a predicational pseudocleft is possible (as in (147a)), though only if *wh-ever* is used (cf. (147b)), for reasons unclear. Blom and Daalder (1977) make the converse claim: clefting inside the *wh*-clause of a specificational pseudocleft is impossible (cf. (148)). Similarly, Akmajian (1979: 89, n. 11) draws attention to the ill-formedness of his (149).

We should point out immediately, however, that the claim that the *wh*-clause of a specificational pseudocleft may not contain a cleft is not uncontroversial. Thus, Faraci (1971) points out that (at least in his variety of English) (150) is grammatical. Akmajian (1979: 74), who includes this example in his discussion, adds that "for my own speech sentences such as [(150)] are more or less marginal":

(150) %What it was that John bought was a car.

(xviii) *Combining clefts and pseudoclefts II* (Heggie 1988). A second way in which combining clefting and pseudoclefting is restricted was first noted by Heggie (1988), who draws attention to the paradigm in (151):

(151)	a.	It's coconut that is what Mary hates.	cf.	It's John that is the teacher.
	b.	*It's what Mary hates that coconut is.		*It's the teacher that John is.
	c.	*It's what Mary hates that is coconut.		*It's the teacher that is John.
	d.	*It's coconut that what Mary hates is.		*It's John that the teacher is.

As the parallelism between the left-hand and right-hand paradigms shows, specificational pseudoclefts behave like double-NP specificational copular sentences in this respect; (151) is strictly speaking out of place in this subsection, therefore, but we included it here for presentational purposes. We will return to this restriction in section 4.1.2, in the discussion of the arguments for a predicational approach to the underlying representation of specificational sentences.

3.4 Properties peculiar to specificational pseudoclefts with wh < *XP word orders*

So far we have found that specificational pseudoclefts show a superset of the restrictions on specificational copular sentences per se. All cases in which specificational pseudoclefts exhibited properties of their own involved peculiarities of their *wh*-clause, not reproducible in double-NP specificational copular sentences for obvious reasons. What we have not found yet is cases in which properties which *are* in principle reproducible throughout the class of specificational constructions are nonetheless specific to pseudoclefts. Such cases do exist, however – and systematically, whenever we find such cases, it is specificational pseudoclefts with a word order in which the *wh*-clause precedes the 'value'-XP which are subject to the constraints in question; their XP < *wh* counterparts are immune to them.

(xix) *Raising/ECM constructions* (Hankamer 1974; Higgins 1979; Williams 1983b; Heggie 1988):

(152) a. ?I consider important to *himself* what *John* is. (specificational; XP < *wh*)
b. *I consider what *John* is important to *himself*. (*specificational; *wh* < XP)

The minimal pair in (152) (taken from Den Dikken et al. 2000: 86, who refer to Williams 1983b) emphasizes the sensitivity to word order of ECM constructions embedding specificational pseudoclefts. In this respect, specificational pseudoclefts are like specificational copular sentences in general: no such construction with 'variable < value' order is ever embeddable under ECM and raising verbs (cf. Moro 1997 for extensive discussion; see also section 4.3.1 below):

(153) a. I consider John the best candidate.
b. *I consider the best candidate John.

Declerck writes in connection with the examples in (154): "In a copular sentence in which *to be* is preceded by *seem*, the copula can never be deleted on a specificational reading" (cf. Den Dikken 1995b; Moro 1997); he then goes on to point out that "WH-clefts like [(154a, b]) are not ambiguous between a predicational and a specificational reading but can only be interpreted predicationally."

(154) a. What you are working on seems an interesting subject. (predicational only)
b. What he suggested seemed a difficult thing to do. (predicational only)

The way Declerck presents this observation, one gets the impression that once *to be* is added to the examples in (154), they will allow a specificational reading – on a par with the grammatical specificational copular sentences in (155). Declerck never makes this explicit; and as a matter of fact, the empirical status of specificational pseudoclefts of the type in (156) (from Higgins 1979), (157) (all from Hankamer 1974), (158a) (from Halvorsen 1978: 34) and (158b, c) (from Ross 1999, 2000) is a contentious issue in the literature:

(155) a. The best candidate seems *(to be) John.
b. The cause of the riot seems *(to be) a picture of the wall.

(156) a. What John is tends to be boring. (predicational only)
b. What he is pointing at seems to be a kangaroo. (predicational only)

(157) a. *What he was doing turned out to be washing himself.
b. *What they were doing seems likely to be claimed to be washing each other.
c. *What the little buggers did happens to have been (to) all get in the tub at the same time.
d. *What she never wants to hear again appears to be any more WH Cleft sentences.

(158) a. What John wants seems to be never to be left alone.
b. What he likes seems *(to be) tofu.
c. What Al is seems *(to be) a harmless old duffer.

Most authors seem to agree that specificational pseudoclefts cannot participate in the raising-to-subject construction; but Hankamer (1974: 231–232, n. 6) points out that "there are some speakers who do not find all of these sentences [i.e., all of (157)] ungrammatical, particularly the ones involving reflexivization." Hankamer suggests linking this case of speaker variation to that surrounding (66b), repeated here:

(66) b. What was staring up at *John* out of his soup was *himself*.

This suggestion will not cover the entire range of speaker variation, however: no peculiarities of reflexives could be at issue in (the relevant variants of) the examples in (158).

Like raising-to-subject, raising-to-object (or ECM) seems to give rise to variable judgments in the domain of *wh* < XP specificational pseudocleft constructions – though, once again, there is no variation on this point when it comes to double-NP inverse specificational copular sentences:

(159) a. I believe the best candidate *(to be) John.
b. I believe the cause of the riot *(to be) a picture of the wall.

(160) a. *We believe what he likes to do to be (to) kiss monkeys.
b. *We believe what he is to be proud.
c. *We found what the theory depends on to be how clefts work.
d. *I believe when she waters them to be weekends. (cf. (129))

(161) a. We believe what John wants to be never to be left alone.
b. I consider what he likes *(to be) tofu.

The examples in (160) are once again due to Hankamer (1974), the one in (161a) to Halvorsen (1978) (as quoted in Declerck 1988: 91), and (161b) is from Ross (1999). The scope of Hankamer's acknowledgement of speaker variation (see above) includes these examples as well. (Blom and Daalder 1977 present grammatical Dutch examples of specificational pseudoclefts with *wh* < XP orders embedded under ECM verbs – but these require a special 'colon intonation'; we address this in section 4.1.2 below.)

Whatever the ultimate fate of specificational pseudoclefts in raising-to-subject and ECM constructions, and notwithstanding Declerck's (1988: 91) observation that the acceptability of *The murderer seems/is unlikely to be John* is "more doubtful" than that of their congeners without raising, it seems clear enough that fewer people will gladly accept examples of the type in (158) and (161) than the ones who find the variants of (155) and (159) featuring *to be* acceptable. This, then, is one context in which *wh* < XP specificational pseudoclefts differ from inverse copular sentences, fellow instantiators of the class of specificational copular sentences.[29]

This turns out not to be the only context in which *wh* < XP specificational pseudoclefts behave in a special way. There are three further restrictions on *wh* < XP specificational pseudoclefts not shared with their reverse or double-NP relatives. We sum them up below, and comment on them briefly.

(xx) *Restrictions on adverbial modification* (See (162); Higgins 1979: 318–320; Declerck 1988; Bošković 1997a):

(162) a. *What John is is probably angry with himself.
b. ??What John is probably is angry with himself.

(163) a. Angry with himself is probably what John is.
b. Angry with himself probably is what John is.

Higgins was the first to point out that specificational pseudoclefts with *wh* < XP orders permit no adverbial modifier to the right of the copula. (Higgins makes the same point with reference to the adverb *also*; see Declerck 1988: 33–34 for critical discussion.) Bošković (1997a: 268, n. 35) adds that placing the adverbial modifier in pre-copular position delivers a "slightly better" result. In this respect, specificational pseudoclefts differ not just from XP < *wh* specificational pseudoclefts (cf. (163)) but also from double-NP specificational sentences with 'variable < value' orders:

(164) a. The cause of the riot was probably a picture of the wall.
b. The cause of the riot probably was a picture of the wall.

The robustness of Higgins's observations is not crystal clear, however. Thus, Huddleston (1971: 341) presents (165a) as an example (culled from a corpus of scientific English) of a specificational pseudocleft; if indeed that is what it is,[30] it flatly contradicts (162a). Another such example taken from a corpus is (165b) (Geluykens 1984). Similarly, Declerck (1988: 91) offers (165c), featuring *perhaps* in post-copular position, as a perfectly well-formed specificational pseudocleft. Since the facts in the general area of adverbial insertion often tend to be somewhat less than clear-cut, we will not dwell on these data in any further detail here.

(165) a. What happens at the anode is probably the conversion of chloride ions into hypochlorite and hydrogen ions.
b. The thing to do is obviously to swing the PhD subject 'round to something nearer what I'm being paid to do.
c. What they need is perhaps a hammer.

(xxi) *Restrictions on gapping/ellipsis* (See (166–171); Higgins 1979: 305; Williams 1983b: 249; Heycock and Kroch 1996: 32; Ross 1999, 2000; Den Dikken et al. 2000: 67–70):

(166) a. What Bill is is important to himself, and what Sue is is important to herself.
b. *What Bill is is important to himself, and what Sue is ___ important to herself.

(167) a. Important to himself is what Bill is, and important to herself is what Sue is.
b. Important to himself is what Bill is, and important to herself ___ what Sue is.

(168) a. What Bill is is important to him, and what Sue is is important to her.
b. What Bill is is important to him, and what Sue is ___ important to her.

(169) a. The best candidate is John, and the runner-up is Bill.
b. The best candidate is John, and the runner-up ___ Bill.

Higgins (1979) has noted that in specificational pseudoclefts with a word order in which the *wh*-clause precedes the copula and the constituent specifying the 'value', it is impossible to gap the copula linking the *wh*-clause to the 'value' constituent – (166b) is ungrammatical. In this respect, constructions of the type in (166) differ strikingly from all other English copular sentences, including predicational pseudoclefts (168), double-NP specificational copular sentences with 'variable < value' orders (169), *and* specificational pseudoclefts with XP < *wh* orders (167).

The contrast between (166) and (167) shows that the ban on gapping of the root copula in the second conjunct of a specificational pseudocleft is a property peculiar to constructions with the word order *wh* < XP. Once the order of the two major constituents is reversed, gapping is perfectly possible (cf. (167b); see Den Dikken et al. 2000: 69). Not surprisingly, gapping continues to be possible once the order in (170) is reversed; and since reversibility is not a property of predicational pseudoclefts to begin with, there are no grammatical counterparts to (168) at all in which the *wh*-clause follows the AP):

(170) a. John is the best candidate, and Bill is the runner-up.
b. John is the best candidate, and Bill ___ the runner-up.

Ross (1999) notes that, in the domain of specificational pseudoclefts with *wh* < XP word order, ellipsis ('VP deletion' in Ross's terms: with the copula analyzed as a verb raising, when finite, from V to I, the ellipsis in (171) is a case of deletion of the beheaded VP) succeeds marginally when the post-copular constituent is nominal but fails completely when it is clausal; cf. (171).[31]

We add that such ellipsis comes out uniformly ungrammatical when specificational pseudoclefts have a XP < *wh* order (cf. the primed examples in (171)).[32] Note also that ellipsis is grammatical in reverse specificational sentences that are a pre-copular NP (cf. (172)).

(171) a. ?What Bill made was popcorn, and what Terry made was too.
a'. *Popcorn was what Bill made, and fudge was too.
b. *What Mary thinks is that Mars is a star, and what Sue thinks is too.
b'. *That Mars is a star is what Mary thinks, and that Venus is a planet is too.

(172) a. Bill's biggest desire was popcorn, and Terry's was too.
a'. *Popcorn was Bill's biggest desire, and fudge was too.
b. Mary's opinion is that Mars is a star, and Sue's is too.
b'. *That Mars is a star is Mary's opinion, and that Venus is a planet is too.

The same grouping of subcases of copular sentences seen in (166–172) is attested another area of the grammar in which reference is made to the copular element in the root of the construction:

(xxii) *Subject-auxiliary inversion* (See (173) vs. (174); cf. Ross 1999; Den Dikken et al. 2000: 62–63):

(173) a. What John didn't buy was any wine.
b. ?I don't know whether what John didn't buy was any wine.
c. *Was what John didn't buy any wine?

(174) a. The cause of the riot was a picture of the wall.
b. I don't know whether the cause of the riot was a picture of the wall.
c. Was the cause of the riot a picture of the wall?

The example in (173a) is unambiguously a specificational pseudocleft – it exhibits NPI connectivity. Embedding such a pseudocleft in an embedded yes/no-question with *whether* is possible; but performing subject-auxiliary inversion in the root question in (173c) results in ungrammaticality. No such ungrammaticality results, however, in the example in (174c), involving an inverse specificational copular sentence with two NPs.[33]

Once again it should be noted that the ban on subject-auxiliary inversion is at least to some degree specific to specificational pseudoclefts with variable < value-XP word order. Examples of the type in (175a) do allow the formation of a root question with subject-auxiliary inversion (cf. Declerck 1988: 45, n. 44):

(175) a. Boring is something John has always been.
b. I was wondering whether boring is something John has always been.
c. Is boring something John has always been? (cf. *Is something John has always been boring?)

It should be pointed out in this context, however, that this triplet involves a *th*-cleft, not a *wh*-cleft; that this may be important is suggested by Ross's (1999) observation that (176c) is entirely impossible (and substantially worse than *Was beans what he ate?* or ?*Was in Londen where they lived?*). For true *wh*-clefts, therefore, the category of the value-XP seems to matter when it comes to subject-auxiliary inversion.

(176) a. Afraid of colons is what Jeremy has been for many years.
b. I was wondering whether afraid of colons is what Jeremy has always been.
c. *Is afraid of colons what Jeremy has been for many years?

The facts discussed in this subsection are a clear indication that we should be careful to look at the word order of specificational pseudoclefts – while it is generally true that specificational sentences (including specificational pseudoclefts) are reversible (cf. property (ii), above), we should not therefore assume that the properties of specificational pseudoclefts with '*wh*-clause *be* XP' word order are necessarily identical with those of their counterparts with 'XP *be wh*-clause' order (see section 2.3 above: Den Dikken et al.'s 2000 split between 'Type A' and 'Type B' specificational pseudoclefts). We will address this issue in more detail in the next section, which takes a closer look at reversibility (property (ii), above). (See also section 5.2 and the beginning of section 5.3 for further divergences of specificational pseudoclefts with *wh* < XP and XP < *wh* orders.)

4 Reversibility

The question as to how to best analyze the reversibility of specificational sentences, and the restrictions on this reversibility, is intimately related to the question

of what the underlying representation of specificational sentences should be assumed to be. In abstract terms, when it comes to the question of how to analyze the word order alternation exhibited in (177), one has three options, *a priori*. These are summed up in (178a–c).

(177) a. XP *be* YP
b. YP *be* XP

(178) *Theoretical possibilities:*
a. (177a) and (177b) are unrelated, each having a different underlying structure.
b. (177a) is basic, (177b) being transformationally derived from it.
c. (177b) is basic, (177a) being transformationally derived from it.

And once the score has been settled for one particular type of instantiation of the pattern in (177), one should repeat this exercise for each additional instantiation. That is, if we were to decide, for instance, that the alternation in double-NP specificational sentences is an instance of (178b), this need not entail that the apparently similar alternation in specificational pseudocleft constructions should necessarily be analyzed along the same lines. In addition, any analysis will also need to take a decision on the question (related to the ones raised above) of whether one of the two major constituents, XP and YP, is a predicate of the other in the underlying representation of the construction at hand, and if so, which.

This said, a wealth of theoretical possibilities presents themselves. It is not surprising, therefore, that there are quite a number of different proposals available in the literature – and that there is a substantial amount of confusion around in this domain as well. In what follows we will endeavor to elucidate the issues and the positions taken in the literature.

4.1 Predicational and non-predicational approaches

In our discussion of approaches to the underlying structure and derivation of specificational sentences, we will make a basic split between two types of accounts: predicational and non-predicational approaches. The non-predicational approaches assume there to be no underlying relationship of predication between the two major constituents of specificational sentences; predicational approaches, on the other hand, do assume such an initial predicational structure.

- *Non-predicational* approaches (cf., e.g., Akmajian 1979; Heycock and Kroch 1999)
- *Predicational* approaches (cf., e.g., Blom and Daalder 1977; Higgins 1979; Heggie 1988; Declerck 1988; Moro 1997)

Non-predicational approaches are most strongly represented in the traditional analyses of specificational pseudoclefts and other specificational copular sentences;

recently, Heycock and Kroch (1999) have reinvigorated this kind of approach. The principles-and-parameters literature has brought forth a number of detailed analyses of specificational sentences which treat them as underlyingly predicational – an analysis that has an important precursor in the pre-GB era in Blom and Daalder's (1977) analysis of specificational sentences.

Largely for presentational efficacy, we will first go through the non-predicational approaches to specificational sentences (section 4.1.1), addressing the predicational approaches in section 4.1.2.

4.1.1 Non-predicational approaches

The most explicitly non-predicational approach to specificational sentences (which in their account form a subgroup of the class of 'equative' constructions; cf. 'identity statements' in sections 1 and 2) is Heycock and Kroch (1999). They treat the relationship between the major constituents of specificational and equative sentences in terms of *equation*. One of the claims of their work, therefore, is that the theory should recognize "equation as distinct from predication" (p. 375).

With specific reference to specificational pseudoclefts (one of the foci of this case study), Heycock and Kroch draw attention to the fact that if one denies that there is a grammatical ('deep') distinction between equation and predication and treats specificational pseudoclefts as underlyingly predicative, one needs to allow free relatives (which is what they take the *wh*-clause of specificational pseudoclefts to be; see section 5) to be ambiguous with respect to their semantic type: in *Honest is what I want a man to be*, the free relative would have to be of type <<*e*,*t*>,*t*> (denoting as it does a second-order property: a property of properties), while in *John is what I want a man to be (i.e., he's honest)*, the free relative should be of type <*e*,*t*>. Moreover, in order to be able to handle tautologies like *(when it comes down to it,) honest is honest*, a predicational approach would need to both type-raise *honest* from <*e*,*t*> to <<*e*,*t*>,*t*> and attach a change in meaning to this type raising operation: *honest(x)* changes into *be identical to honest(x)*. Heycock and Kroch conclude, therefore, that "in other words, if equation is removed from the syntax, it has to be put back into the semantics" (p. 375). An equative approach to specificational sentences, by contrast, will be able to characterize free relatives as being of type <*e*,*t*>, and will not need to resort to type raising operations and concomitant meaning changes.

Heycock and Kroch's approach to specificational copular sentences thus treats these as equivalent to equative constructions – or 'identity statements', in the terminology of Higgins (1979) and Declerck (1988). There certainly are parallels between equative and specificational copular sentences – for example, both behave identically when it comes to embedding under ECM verbs like *consider*, *believe*, in the absence of a copula: both (179) and (180) are ungrammatical (cf. Heycock and Kroch 1999: 374 for the equative cases; cf. Moro 1997 for the original observation concerning specificational or 'inverse copular' sentences):

(179) a. I consider John the best candidate. (predicational)
b. *I consider the best candidate John. (specificational)

(180) a. *I consider your attitude towards Jones my attitude toward Davies. (equative)
b. *I consider my attitude towards Davies your attitude toward Jones. (equative)

In equative constructions, both orders of the two NPs deliver ungrammaticality in the complement of *consider* (180); neither order hence seems to be syntactically representable as predicational (cf. the grammaticality of (179a); recall, however, Blom and Daalder 1977: 76 – discussed in section 1.4 above). It does not seem unreasonable, therefore, to deny predicate status to *both* NPs of an equative construction – equative constructions would be radically non-predicational from such a perspective. Whatever the merits of such an analysis of equatives, however, it has no logical implications when it comes to the analysis of specificational copular sentences: typologies of copular sentences routinely distinguish between identity statements and specificational copular sentences on account of the fact that their properties are not identical (see section 1.3). Heycock and Kroch's (1999: 375) remarks about tautologies like *honest is honest*, which instantiate equatives, not specificational constructions, therefore are strictly speaking beside the point when it comes to the analysis of specificational copular sentences.

Their objection to an underlyingly predicational approach to a pseudocleft like *Honest is what I want a man to be* (cf. above) is more to the point, in the present context – we are dealing here with a specificational copular sentence. But this objection of Heycock and Kroch's is based entirely on the premise that the *wh*-clause of specificational pseudoclefts like this is the same as that of the *wh*-clause of *John is what I want a man to be (i.e., honest)* (which is presumably not a pseudocleft construction to begin with): a free relative. This is by no means an uncontroversial point, however: several scholars have sought to analyze the *wh*-clause of specificational pseudoclefts as a *wh*-question instead (see section 5 for discussion). Heycock and Kroch's objection will be valid only to the extent that one accepts a free relative approach to the *wh*-clause of specificational pseudoclefts; as soon as one denies this, their point is entirely moot.

Heycock and Kroch (1999: 381–382) stress that their recognition of a separate class of equative copular sentences (alongside predicative ones) need not imply the recognition of (at least) two separate types of copular *be* – one may, instead, encode the difference between the two types of copular sentence entirely in the syntactic structure of the small clauses participating in them: there are two types of small clause, equative and predicative ones (the former involving "some functional head," the latter not); the copula *be* can take either as its complement.

(The fact that Heycock and Kroch assume that equative constructions feature a small clause, and that they say explicitly that the only difference between a predicative and an equative small clause lies in the presence in the latter of an additional functional head of sorts, may suggest that Heycock and Kroch do, after all, adopt a type of predicational approach to specificational/equative sentences – if the only difference between equative and predicative small clauses lies in a functional (i.e., non-lexical, non-predicating) head, and if – as is clear – predicative

small clauses involve predication, then how can equative small clauses *not* involve predication? The answer to this question is not given by Heycock and Kroch. They do stress, however, that in equative constructions it is impossible "to interpret one of the noun phrases as less referential/more predicative than the other" (p. 374). This is why we have classified the Heycock and Kroch approach to specificational sentences (which they subsume under their rubric of 'equatives') as a representative of the group of non-predicational analyses.)

By not making a distinction between different types of *be*, Heycock and Kroch's "one *be* but more than one type of copular sentence" approach differs from Akmajian's (1979) account of specificational sentences (pseudoclefts in particular). Akmajian (1979: 162) draws a distinction between "two fundamental senses of the copula, namely, the *specificational* sense as opposed to the *predicational* sense" (original emphasis); the former he later calls a "specification operator [=]" and the latter a "predicational operator [is]" (p. 217) – and it is the former that establishes the relationship between the two major constituents of specificational copular sentences.[34] The constituent harboring the variable and the value-XP are both referential (cf. his ch. 3, section 2.2); neither functions as a predicate of the other.[35] In essence, then, in Akmajian's analysis the 'specification operator [=]' serves as a two-place predicate in specificational sentences – though Akmajian never spells this out in detail, [=] may be taken to take the two major constituents of a specificational sentence as its arguments. The syntactic structure of base-generated specificational sentences is simple: the pre-copular *wh*-clause (treated as a free relative) occupies the subject position of the clause, the 'specification operator [=]' projects a VP and takes the post-copular 'value'-XP as its complement, as in (181):

(181) $[_S\ [_{NP}$ *what there was in the car*$]\ [_{VP}\ [=]\ [_{NP}$ *the jack you gave me/my hat*$]]]$

(Akmajian actually assigns the same syntactic structure (*modulo* the nature of the linking operator) to predicational pseudoclefts, saying that the ambiguity of a sentence like *What John does not eat is food for the dog* is "not associated with the specific derivation of clefted sentences . . . but rather . . . is a function of the general phenomena of referentiality of nominal expressions" (p. 178). We take it, though, that Akmajian would assume that *food for the dog* on its non-referential interpretation functions as a predicate of the pre-copular constituent, and that the 'predicational operator [is]' is not a two-place predicate in its own right.)

Akmajian (1979) argues for a dual approach to specificational pseudoclefts: one analysis generates the specificational pseudocleft in the base, the other deriving them transformationally from their simple clause counterparts (via extraction; see section 6.2 for discussion). We have focused here on the base generation analysis (though for the extraction derivation Akmajian assumes a structure that is underlyingly almost identical, once again featuring the 'specification operator [=]'). As Akmajian stresses several times, "there is no non-ad hoc way of preventing" this duality of sources (p. 32; also cf. p. 38). In a similar vein, Den Dikken et al. (2000) also argue for a dual analysis of specificational pseudoclefts – but this

time, the two structures are radically different, one involving predication, the other not.

The non-predicational analysis is proposed by Den Dikken et al. for a *subset* of specificational pseudoclefts – in particular, those specificational pseudoclefts which feature a word order in which the *wh*-clause precedes the copula and the 'value'-XP, and in which we find connectivity effects involving negative polarity items (their so-called 'Type A' specificational pseudoclefts). For pseudoclefts of this type, Den Dikken et al. propose a 'topic-comment' structure of the type schematized in (182), where the *wh*-clause is a *wh*-question finding itself in a left-peripheral topic position, and the 'value'-XP is represented as a full IP (from which material may be elided, subject to general restrictions on ellipsis) which functions as the root clause:

(182) [$_{\text{TopP}}$ [$_{\text{CP}}$ *wh*-clause = *wh*-question] [$_{\text{Top}'}$ *be* [$_{\text{IP}}$ 'value', either full or elliptical]]]

The structure in (182) straightforwardly captures the connection between specificational pseudoclefts and question-answer pairs (see section 5, below) and topic-comment constructions (cf. also Seuren 1985: 303), the ban on subject-auxiliary inversion, and the possibility of including a negative polarity item in the 'value', apparently licensed by a negation in the *wh*-clause – in actual fact, what happens in examples of this type is that the negative polarity item is licensed *within its own clause* by the negation in the elliptical root-IP:

(183) a. What he didn't read was any book about clefts.
b. [$_{\text{TopP}}$ [$_{\text{CP}}$ *what he didn't read*] [$_{\text{Top}'}$ *be* [$_{\text{IP}}$ ~~*he didn't read*~~ *any book about clefts*]]]

The topic-comment structure in (182) is available only for specificational pseudoclefts with a word order in which the *wh*-clause (the comment) precedes the 'value' – inversion of topic and comment is impossible, given the general impossibility of extraction across a topic (the 'topic island effect'). For specificational pseudoclefts with NPI connectivity, the analysis hence – correctly – predicts that they will feature only *wh* < XP orders. For the alternative XP < *wh* order of specificational pseudoclefts, a different analysis needs to be proposed: these cannot be derived from (182) via some transformation. Den Dikken et al. (2000) thus propose an analysis of the two-word order variants of the specificational pseudocleft in which they are structurally unrelated.

Den Dikken et al. (2000) assume that specificational pseudoclefts with XP < *wh* order, as well as double-NP specificational sentences, feature a small clause structure that includes the 'value'-XP as the subject. Discussion of this kind of structure properly belongs in section 4.1.2, on predicational approaches – to which we now turn.

4.1.2 Predicational approaches

In Higgins's (1979) characterization of specificational sentences, neither of the two constituent NPs receives the qualification 'referential' or 'non-referential';

instead, Higgins assigns NP_1 the label 'superscriptional' (paraphrasable as 'providing the heading of a list') and NP_2 the label 'specificational' (i.e., 'specifying the contents of the list'). Translating these labels into the familiar syntactic functions 'subject' and 'predicate' is not straightforward: Higgins is the only one to use these terms, and he himself is not particularly explicit when it comes to their mapping to underlying syntactic relationships. He does say, however, that the *wh*-clause of a pseudocleft is the subject of the pseudocleft. And in his discussion of the semantic representation of specificational pseudoclefts like *What we saw in the park was a man and a women* (unambiguously specificational unless reference is being made to a hermaphrodite), he writes that whereas "the subject clause specifies a set in terms of a property, the predicate expression constitutes an explicit listing of the members of the same set, and the verb *be* is the identity" (p. 118). Thus, Higgins seems to partition the specificational pseudocleft into a subject, a predicate and a copula of identity (annotated as '=', as in Akmajian's 1979 treatment of specificational sentences); cf. the semantic representation in (184b):

(184) a. What we saw in the park was a man and a woman.
b. {x: we saw x in the park} = {a man, a woman}

Yet, elsewhere in his discussion of the underlying syntactic representation of specificational pseudoclefts, Higgins (1979: 226ff.) brings up a number of syntactic tests (mostly concerning word order in questions) which lead Declerck (1988: 46) to conclude "there appears to be ample evidence that in specificational sentences it is the NP representing the focus [i.e., the 'value'-XP] that is the (underlying) subject." For Declerck, therefore, in a specificational sentence like *The best candidate is John* the post-copular NP *John* (the 'value'; cf. Huddleston's 1971 'identifier'), which is referential (either weakly or strongly), functions as the underlying subject of the construction. The pre-copular constituent (the 'identified' in Huddleston's 1971 terms), which is 'weakly referring' ('attributive' in the sense of Donnellan 1966), is the 'subject complement' (a term largely equivalent to 'predicate') in the underlying representation.

On the *surface*, however, things are governed (in Declerck's analysis) by a principle which says that "the initial NP of a specificational copular sentence is always interpreted as the theme and therefore as the syntactic subject of the clause" (p. 201), regardless of the order of the two NPs. On the surface, then, whichever of the major constituents of a specificational sentence occupies the pre-copular position (in declarative sentences not involving topicalization, that is) is the subject.

Even though Declerck (1988) explicitly does not avail himself of any particular theoretical framework (so that the precise theoretical status of terms like 'underlying', used by Declerck in various places, remains rather difficult to determine), it seems reasonable, in the light of the foregoing, to summarize Declerck's perspective on the underlying syntax of specificational sentences as in (185). Declerck identifies the variable (the *wh*-clause of specificational pseudoclefts) as the 'subject complement' in the underlying representation. With 'subject complement' read as 'predicate', Declerck's approach matches that of Moreau

(1971), Blom and Daalder (1977), Heggie (1988), Verheugd (1990), Heycock (1994a), Den Dikken (1995b), and Moro (1997) (see also Den Dikken et al. 2000 for 'Type B' specificational pseudoclefts) when it comes to the status of the 'variable' in the underlying representation of specificational constructions.

(185) *Blom and Daalder (1977); Declerck (1988); Heggie (1988); Moro (1997) etc.:*
- variable/identified = underlying predicate
- value/identifier = underlying subject

With the exception of Moreau (1971) (who only shares the 'underlying predicate' part of (185), adopting an extraction analysis; see section 6.2) and Blom and Daalder (1977), who avail themselves of a pre-p&p transformational framework, all of the aforementioned generativists assume a small clause structure for this underlying subject-predicate relationship, as illustrated in (186):

(186) . . . *be* [$_{SC}$ [$_{Subj}$ XP] [$_{Pred}$ *wh*-clause]]

It is especially Heggie (1988) who provides a range of syntactically based arguments for an underlying subject-predicate analysis of specificational sentences, with particular emphasis on pseudoclefts. Some of her arguments are intended to support the predicative nature of the *wh*-clause; others seek to vindicate the underlying subject status of XP. We will go through her arguments briefly in what follows, after which we turn to the question of how to derive the surface word order in which the 'variable' precedes the 'value'.

(i) *Quantification restrictions* (cf. section 3.2) Heggie's first argument for the predicativity of the *wh*-clause, based on facts of the type in (187), was also discussed in section 3.2 above. The upshot of it is that the impossibility of *-ever* in the *wh*-clause of specificational pseudoclefts (of whichever order; cf. (187a)) can be likened to the ungrammaticality of (187b) on the assumption that the *wh*-clause of specificational pseudoclefts is a predicate (like the post-copular noun phrase in (187b)):

(187) a. *Whatever Mary hates is Bill's tie.
*Bill's tie is whatever Mary hates.
b. *John is every teacher.

As was argued in section 3.2, this argument has no force: combined with the quantificational restrictions on the 'value'-XP of specificational sentences, it would lead to the nonsensical conclusion that *both* major constituents of specificational pseudoclefts are underlying predicates.

(ii) *ECM* (cf. section 3.4) The second indication that the *wh*-clause of specificational constructions (with 'variable < value' order) is a predicate, according to Heggie, comes from constructions of the type in (179): ECM complements (see our section 3.4 above). Heggie points out that it is impossible to embed a specificational pseudocleft (with *wh* < XP order) under verbs like *consider*:

(188) a. I consider important to himself what John is.
b. *I consider what John is important to himself.

The essence of this argument is that small clauses (like the tenseless complements of *consider* in the examples in (179) and (188)) do not make space available to perform inversion of subject and predicate; the grammatical examples in (179a) and (188a) must hence feature subject and predicate in their base order – hence, the *wh*-clause of (188) must be a predicate in the underlying representation of specificational pseudoclefts.

Once again, however, the argument is not foolproof. A clear indication that something more needs to be said about these data is that adding *to be* renders (179b) grammatical while, for most speakers at least (cf., however, Faraci 1971; Hankamer 1974), (188b) is irremediably bad:

(179) b′. I consider the best candidate *to be* John.

(188) b′. %I consider what John is *to be* important to himself.

(The fact that Blom and Daalder (1977) give examples of specificational constructions with predicate-initial order embedded under ECM verbs does not refute Heggie's argument: see section 4.2 below for discussion.)

(iii) *Combining clefts and pseudoclefts* II (cf. section 3.3) Heggie's third argument (see our section 3.3, above) makes inventive use of the combinability of clefting and pseudoclefting, as in (151a). The argument kills two birds with one stone: for alongside arguing for the predicativity of the *wh*-clause, it also confirms the subjecthood of the 'value'-XP. Heggie observes that, of the four possible outputs of a combination of a cleft and a pseudocleft in (151), only the a-example actually comes out grammatical:

(151)	a.	It's coconut that is what Mary hates.	cf.	It's John that is the teacher.
	b.	*It's what Mary hates that coconut is.		*It's the teacher that John is.
	c.	*It's what Mary hates that is coconut.		*It's the teacher that is John.
	d.	*It's coconut that what Mary hates is.		*It's John that the teacher is.

The force of the argument here comes from the independent fact that in predicate nominal constructions like *John is the teacher* or *the teacher is John*, only the non-inverted subject can be clefted (cf. the examples in the right-hand column). The parallel behavior of *what Mary hates* and *the teacher* in the two paradigms then suggests that the former, just like the latter, is a predicate in the underlying representation of copular sentences – if one assumes, of course, that *the teacher* in

John is the teacher (a non-inverted specificational copular sentence) is in fact a predicate nominal. If one accepts the latter claim (cf. Moro 1997; but see Heycock and Kroch 1999 for a different perspective), the facts in (151) argue for the predicativity of the *wh*-clause of specificational pseudoclefts.

Notice that if this argument goes through, it at the same time argues that *coconut* (the 'value') in the left-hand examples is like *John* in the right-hand cases in being an underlying subject. This is confirmed further by a variety of additional arguments provided by Heggie, the first of which concerns gapping.

(iv) *Gapping* (cf. section 3.3) This argument is originally due to Higgins (1979), and discussed also in Heycock and Kroch (1999) and Den Dikken et al. (2000) (see section 3.3, above). The key point for Heggie is that gapping of the copula linking the *wh*-clause and the 'value' fails in (189b) (while it succeeds perfectly well in (189a), featuring non-inverted XP < *wh* order):

(189) a. Important to himself is what John is, and important to herself ~~is~~ what Mary is.
b. *What John is is important to himself, and what Mary is ~~is~~ important to herself.

Heggie makes the interesting suggestion that the ungrammaticality of (189b) reduces to the general ban on gapping in constructions featuring *movement across the subject*, as illustrated in (190):

(190) *Which man did Bill see, and which man ~~did~~ Gary ~~see~~?

Notice, though, that while (190) involves gapping of two non-contiguous elements, (189b) incurs no such discontinuity problems; the causes of the ungrammaticality of the two examples may well be unrelated, therefore. At the very least, it is not clear that they *are* related.

(v) *Comparatives* (cf. section 3.2) Noting that comparatives of the type in (191a) are "limited to predicates," Heggie goes on to construe the ungrammaticality of (191b) (also brought up in section 3.2, above) as evidence that *important to himself* is **not** a predicate, hence must be a subject:

(191) a. X is more important than Y is.
b. *What John is is more important to himself than what Bill is is.

This argument will only go through if one accepts the premise that specificational pseudoclefts are *predicational* constructions – otherwise there is no implicational relationship between the non-predicatehood of *important to himself* and its subjecthood.

(vi) *Raising* (cf. section 3.4) Heggie seeks to derive further evidence for the subjecthood of the 'value' from raising (cf. Williams 1983b): (192a) is grammatical,

which shows that *important to himself* behaves like subjects in allowing for raising-to-subject. However, the raising argument presents a problem for Heggie's other claim: that the *wh*-clause is a predicate. For notice that (192b) is rejected by most speakers (but cf. Faraci 1971 and Hankamer 1974), which exposes the *wh*-clause as a creature with properties distinct from those of inverted predicates in double-NP specificational copular sentences – after all, inverted predicate nominals *can* undergo raising, as (192c) shows:

(192) a. Important to himself seems to be what John is.
b. *What John is seems to be important to himself.
c. The best candidate seems to be John.

The grammaticality of (192c) flatly contradicts Heggie's (1988: 301) claim that "only subjects may undergo raising," unless one is willing to treat *the best candidate* in (192c) as a subject, a view which would fatally undermine the parallelism arguments in favor of the predicativity of the *wh*-clause reviewed in the foregoing (cf. esp. (151)).

(vii) *Language variation* A last argument for the subject–predicate relationship expressed in (186) comes from interesting observations that Heggie (1988) makes about certain differences between French and English. She observes that English is reasonably flexible in the types of 'honorary NP' subjects (to borrow Safir's 1983 term) that it allows (cf. (193)), while French is much more restricted – crucially, not just in (194a) but in (194b) as well, regardless of the relative order of the *wh*-clause and the 'value'-XP. The PP 'value' of (194b) thus behaves exactly like the subject of a predicative copular sentence, and the *wh*-clause behaves just like the predicate of a copular sentence.

(193) a. In the park is a good place to have a picnic.
b. In the park is where John met Mary.
Where John met Mary was in the park.

(194) a. *Dans le parc est un bon endroit pour un pique-nique.
in the park is a good place for a picnic
b. *Dans le parc est où Jean a rencontré Marie.
in the park is where Jean has met Marie
*Où Jean a rencontré Marie est dans le parc.
where Jean has met Marie is in the park

Heggie's last argument, (vii), is presumably the most convincing – especially the fact that *surface* word order is inconsequential indicates that what is at issue will in all likelihood be a property peculiar to *underlying* subjects of predicates. If this argument stands up to closer scrutiny, it shows that specificational pseudoclefts – regardless of surface word order – feature a subject-predicate structure. If this is right, it also disconfirms Den Dikken et al.'s (2000) tentative suggestion that their 'Type B' specificational pseudoclefts, whose underlying structure is as in (186), do not allow inversion.

In the foregoing, we reviewed a number of syntactic considerations which have led several scholars to assume an underlying predication relationship between the two major constituents of specificational sentences. There are two further batteries of facts which have been advanced in this connection, concerning the *distribution of the copula* in and the *extraction restrictions* on inverse specificational constructions. But since these arguments are based specifically on inverse copular sentences, we will discuss them in section 4.3, which addresses the analysis of inversion from the perspective of analyses based on a predicational approach to specificational sentences.

4.2 Inversion

If one assumes a non-predicational approach to specificational sentences, one needs to spend little time on the question of how the reversibility of these constructions is to be looked upon analytically: any non-predicational analysis will assume that the two major constituents of such copular sentences are 'on an equal footing'; neither is predestined to take precedence when it comes to occupying the (surface) subject position.

If, on the other hand, one bases oneself on a predicational approach to specificational sentences, one of the two word orders of reversible copular constructions will more or less directly reflect the underlying representation, the other being derived from it via some sort of syntactic transformation. The question that arises then is what kind of transformation derives the other order.

The predicational analyses reviewed in section 4.1.2 agree that the underlying relationship between the two major constituents is such that the 'variable' is a predicate and the 'value' functions as its subject. Deriving the word orders reflected in (195) will hence be straightforward: starting out from the base structure in (186), all one needs to do is raise the underlying subject of the small clause (which may be of a variety of category types, subject to some language variation; cf. (193) vs. (194), above) to the subject position of the clause.

(195) a. John is the best candidate.
b. Under the bed is the best hiding place.
c. Important to himself is what John is.
d. Write novels is what John does for a living.

(196) a. The best candidate is John.
b. The best hiding place is under the bed.
c. What John is is important to himself.
d. What John does for a living is write novels.

(186) . . . *be* [$_{SC}$ [$_{Subj}$ XP] [$_{Pred}$ *wh*-clause]]

To get from (186) to the word orders reflected in (196), one will need to do either or both of the following two things:

(i) maneuver the predicate into a position to the left of the subject, and/or
(ii) maneuver the subject into position to the right of the predicate.

Whichever (combination) of these tacks one takes, inversion in copular sentences will come down to the reversal of the underlying subject-predicate word order – an example such as (196a) thus represents an inverse construction.

(We note in passing that there is considerable confusion in the literature about the contents of the terms 'inversion' and 'reversal': while Blom and Daalder (1977), Declerck (1988) and all principles-and-parameters studies use it in the way we are using it here (see also Quirk et al. 1972: 954), Prince (1978) and Collins (1991) refer with the term 'reverse/inverse' construction precisely to the word order pattern which, when viewed from a predicational base perspective, corresponds to the underlying subject-predicate order.)

All three tacks (i.e., (i), (ii), or (i) and (ii)) have actually been taken in the literature on copular inversion. Most authors have opted for (i) (cf. Declerck 1988; Heggie 1988; Verheugd 1990; Heycock 1994a; Den Dikken 1995b; Moro 1997), though there is disagreement among those authors when it comes to the type of position that the pre-copular predicate finds itself in: for Blom and Daalder (1977) and Heggie (1988), this is an A'-position (COMP/SpecCP), while for Heycock (1994a), Den Dikken (1995b), and Moro (1997) it is crucial that this be an A-position (the subject position of the clause, SpecIP; cf. also Den Dikken et al. 2000 for an analysis of this type for what they call 'Type B' specificational pseudo-clefts). As far as option (ii) is concerned, it has been argued by Blom and Daalder (1977) that it exists as an alternative to leftward displacement of the predicate; and Guéron (1992, 1993) argues that both the underlying predicate and the subject are displaced, the latter to a right-peripheral focus position. ("Displacement" here, as well as "maneuver" in (i) and (ii), are meant to be theoretically neutral with respect to the question of whether there is movement involved or not.) The literature can hence be summarized as follows:

(197) *Blom and Daalder (1977):*
Inversion = topicalization/left-dislocation of the base predicate to COMP, or extraposition/right-dislocation of the base subject.

(198) *Guéron (1992, 1993):*
Inversion = leftward A'-movement of the base predicate into a position adjoined to an empty-headed subject, and rightward A'-movement (focus movement) of the base subject.

(199) *Heggie (1988):*
Inversion = leftward A'-movement of the predicate to COMP/SpecCP.

(200) *Heycock (1994a), Den Dikken (1995b), Moro (1997):*
Inversion = predicate raising to subject position (SpecIP).

Since Blom and Daalder's (1977) analysis is the oldest and also represents a superset of the (i)-type approaches, let us take theirs as a starting point for the discussion. For Blom and Daalder, when what is in pre-copular position corresponds to the underlying subject, the pre-copular constituent finds itself in subject position of the clause, where it is base generated (cf. (201), which uses a verb-final word order; recall that Blom and Daalder are exclusively concerned with Dutch, an OV language). However, when the *wh*-clause (the deep predicate) surfaces in pre-copular position, it is not the surface subject – it either raises to a left-peripheral A'-position (via topicalization; cf. (202a)) or it stays put and sees the deep subject extrapose around it (extraposition/right-dislocation; cf. (202b)).

(201) $[_{S}$ Subject $[_{VP}$ Predicate *be*$]]$

(202) a. $[_{S'}$ $[_{COMP}$ Predicate$]$ *be* $[_{S}$ Subject $[_{VP}$ ___ $]]]$
b. $[_{E}$ $[_{S'}$ COMP $[_{S}$ ___ $[_{VP}$ Pred *be*$]]]$ Subject$]$

Blom and Daalder stress that both topicalization/left-dislocation and extraposition/right-dislocation are independently available mechanisms in the grammar of a language like Dutch. The status of the former is indisputed and will not be commented on further; that of the latter, Blom and Daalder argue, is confirmed by the existence of constructions of the type in (203):

(203) a. ___ belde ineens aan: de pianostemmer
'___ suddenly rang the doorbell: the piano tuner'
b. ___ is erg lekker: aardbeien met slagroom
'___ is very nice: strawberries and cream'

It is interesting to note that what (203) and specificational sentences share in common is their list reading and colon intonation (cf. Higgins 1979). (It should be noted, however, that such examples have a stylistically restricted ring to them; they certainly are not as natural as specificational sentences in which the variable precedes the value.)

Blom and Daalder's approach to inversion in specificational sentences thus takes the 'value < variable' order as basic (subject < predicate) and derives the other order from it in either of two ways: (202a) or (202b). The former will be unavailable in embedded contexts – Blom and Daalder thus predict that in embedded clauses the only way in which the inverted order can be derived is via the (rather marked) strategy of extraposition/right-dislocation. In support of this prediction, Blom and Daalder (1977: 111) mention the contrast between (204a) and (204b): even though Dutch embedded clauses are normally verb-final, in embedded specificational sentences in which the predicate precedes the subject, the latter must surface all the way at the end of the clause, to the right of the verbal cluster. Just like the examples in (203), the inverse construction in (204b) must have the special colon intonation characteristic of (202b):

(204) a. *Het bleek dat nog veel hoger de aankoopsom was.
it turned-out that still much higher the buying-sum was
b. Het bleek dat nog veel hoger was: de aankoopsom.
it turned-out that still much higher was the buying-sum

The problem with this kind of approach to inversion in embedded contexts, however, is the fact that in genuine specificational copular sentences (which (204a, b) are not), it *is* in fact perfectly possible to invert the relative order of hyponym and hyperonym in such a way that the former ends up to the *left* of the verbal cluster – that is, (205b) is grammatical (alongside the stylistically marked (205c), with its characteristic colon intonation):

(205) a. Het bleek dat de sollicitant uit NY de beste kandidaat was.
it turned-out that the applicant from NY the best candidate was
b. Het bleek dat de beste kandidaat de sollicitant uit NY was.
it turned-out that the best candidate the applicant from NY was
c. Het bleek dat de beste kandidaat was: de sollicitant uit NY.
it turned-out that the best candidate was the applicant from NY

Since (205b) clearly is not the product of a type (ii) analysis, and since topicalization (type (i)) is entirely impossible in embedded clauses in Dutch, Blom and Daalder (1977) seem at a loss to account for the grammaticality of this example. *Mutatis mutandis*, Heggie's (1988) analysis of inversion (phrased solely in terms of movement to SpecCP) faces the same problem – a problem that presents itself not just for Dutch but for English as well: in English, too, inversion is perfectly possible in embedded specificational copular sentences (even those not embedded under bridge verbs); no 'colon intonation' is required. (See also Heycock 1994b for discussion of this point.)

(206) a. It turned out that the applicant from New York was the best candidate.
b. It turned out that the best candidate was the applicant from New York.

Blom and Daalder (1977) also mention the ungrammaticality of inversion in yes/no-questions as an argument in favor of their approach to inversion. A paradigm first highlighted by Merckens (1961), in the classic '*kooplieden* discussion' in the Dutch linguistic literature in the fifties and sixties (cf. Bos 1961; Droste 1962 for other contributions to this discussion, brought together in Hoogteijling 1969), will serve to illustrate this point:

(207) a. Kooplieden zijn dat.
merchants are that
'That's what merchants are (viz., clever/thrifty/successful/mean/ . . .).'
b. Dat zijn kooplieden.
that are merchants
'That's what merchants are.'/ 'Those are merchants.

(208) a. Zijn kooplieden dat?
are merchants that
'Is that what merchants are?'
b. Zijn dat kooplieden?
are that merchants
'Are they merchants?' (*'Is that what merchants are?')

The example in (207b) is ambiguous between a reading in which *dat* 'that' is the subject of the sentence and *kooplieden* 'merchants' is its predicate (cf. English 'they/those are merchants'; for reasons that need not concern us here, Dutch systematically has the finite verb agree with the predicate nominal in such cases), and one which is the inverse counterpart of the example in (207a), in which *kooplieden* is the subject of pro-predicate *dat*. For Blom and Daalder, the latter reading of (207b) is derived via topicalization of *dat* to COMP/SpecCP (with concomitant raising of the verb; Dutch is a Verb Second language). Interestingly, now, the example in (208b), the yes/no counterpart of (207b), is not ambiguous: it only has a reading corresponding to a structure in which *dat* is the underlying subject.

The unavailability of the 'is that what merchants are?' reading for (208b) will follow if both (i) and (ii) can be blocked. For (i) this is unproblematic: topicalization is impossible in yes/no-questions. Extraposition/right-dislocation of the deep subject around the predicate is less easy to block, however – especially in the light of Blom and Daalder's (1977: 111) own examples in (209), which show that yes/no-questions do not in general block the 'colon construction'. In the light of the acceptability of (209) with 'colon intonation', one would minimally expect (208b) to improve once the requisite intonation contour is superimposed on it. Making the clause-final subject heavier will facilitate this – but (210), with a heavy clause-final NP and 'colon intonation', is simply bad, and definitely lacks the desired inverse predication interpretation:

(209) a. Is hier misschien voor handen: een oude damesfiets?
is here perhaps available an old ladies' bike
b. Heb jij soms gevonden: de sleutels van mijn auto?
have you perhaps found the keys of my car

(210) *Zijn dat: kooplieden uit Amsterdam?
are that merchants from Amsterdam

The radical unavailability of the inverse predication reading in Dutch yes/no-questions of the type in (208b)/(210) thus comes as a partial surprise from Blom and Daalder's (1977) dual approach.

From examples of the type in (208b) we should not draw the general conclusion, however, that inversion of subject and finite verb is never possible in inverse copular sentences (see also item (xxii) in section 3.4, above). Examples of

the type in (212b), derived from the inverse construction in (211b), are grammatical. Since topicalization is impossible in yes/no-questions in English as well, Heggie (1988) has no way of deriving (212b) at all. The well-formedness of this example hence stands out as an insurmountable obstacle for Heggie's analysis. Blom and Daalder (1977) would still have option (ii) at their disposal, though – and even though they do not discuss this kind of example, they might adduce the fact that (212b) seems best on a contrastive reading (cf. *or the dog*) in support of a (ii)-type analysis of this kind of example.

(211) a. (When we go on a holiday,) the cat is our biggest worry.
b. (When we go on a holiday,) our biggest worry is the cat.

(212) a. Is the cat your biggest worry?
b. Is your biggest worry the cat (or the dog)?

Dutch behaves like English when it comes to (212b). But it may be interesting in this context to note that when subject and predicate disagree in number features, as in (213), subject-predicate inversion in a yes/no-question still seems possible in English while in Dutch it is poor:

(213) a. The children are our biggest worry.
b. Our biggest worry is the children.
a.' De kinderen zijn onze grootste zorg.
b.' Onze grootste zorg zijn de kinderen.

(214) a. Are the children your biggest worry?
b. Is your biggest worry the children?
a.' Zijn de kinderen je grootste zorg?
b.' ??Zijn je grootste zorg de kinderen?

The difference between Dutch and English in (214b, b') seems to be related to the difference in finite verb agreement between the two examples (cf. also (213b, b')): while in English it is the inverted predicate that determines agreement (*is*), in Dutch agreement is triggered by the underlying subject in both 'canonical' and 'inverse' copular sentences. (We will not address the question of how the difference between Dutch and English in (214b, b') can be related to the agreement difference.)

Moro (1997) and Heycock (1994b) discuss the agreement facts in detail (see also section 3.2, above; Moro's work presents a perspective on language variation (English vs. Italian) in this department – see Den Dikken 1997 for a critique with particular reference to Dutch). And of course the fact that in English it is the inverted predicate that triggers agreement with the finite verb in (213b) (*Our biggest worry is/*are the children*) stands out as an important additional argument against a topicalization approach to inverse copular sentences *à la* Heggie (1988) (as Heycock 1994b also stresses).

The agreement facts, when carried over into the realm of specificational pseudoclefts, appear to furnish an argument in favor of an inverse predication approach to such constructions featuring *wh* < XP word order. Thus, consider the minimal pair in (97) (from Declerck 1988: 80). As Declerck notes, agreement serves to disambiguate *wh*-clefts – singular agreement, as in (97a), yields a specificational reading, while plural agreement, as in (97b), enforces a predicational interpretation. Of note in this connection is also Declerck's (1988: 79) example in (215a), which can only be assigned a specificational reading (due to the presence of the negative polarity item *any* in the 'value' constituent) – concomitantly, only singular verb agreement is possible.

(97) a. What you have bought is fake jewels. (specificational)
What you have bought are fake jewels. (predicational)

(215) a. What the book does not offer is/*are any solutions to the problems that are noted.
b. What you wanted was two things. (Geluykens 1984)

We should note in this context, however, that the agreement facts in specificational copular sentences in general are not as categorical as especially Moro makes them out to be. Despite the fact that there certainly are strong tendencies of the type just illustrated, Declerck (1988: 79–80) points out that "in specificational sentences the number of the copula can apparently be determined by that of either the superficial subject NP or the variable NP." He quotes the following examples to illustrate:

(216) a. The aim of our policy is/*are improved relations with the Soviet Union.
b. Improved relations with the Soviet Union is/?are the aim of our policy.

(217) a. More books is/?are what I need.
b. What I need is/??are more books.

(218) a. Theft and robbery is/are what I despise most.
b. What we can't have here is/?are theft and robbery.

Verb agreement is not a foolproof diagnostic, therefore; but at the very least, what we may conclude is that the very ability of the pre-copular predicate in inverse specificational sentences to trigger agreement on the finite verb is an indication that a pure topicalization analysis of inversion, *à la* Heggie (1988), is presumably untenable.

Blom and Daalder's two-pronged approach to the derivation of inversion in specificational constructions is no better equipped to account for the English agreement facts.[36] An analysis of inverse copular sentences which treats the pre-copular variable constituent as a surface subject, by contrast, is eminently fit to

explain the fact that the inverted predicate can trigger agreement on the finite verb in English examples of the type in (213b).[37] Likewise, it will straightforwardly accommodate the fact that inverted predicates of specificational sentences can undergo *raising* to ever higher subject positions, as shown in examples such as (219).[38]

(219) a. The best candidate could be John.
b. ?The best candidate is likely to be John.
c. ??The best candidate seems to have turned out to be John.

Examples of this type get less and less brilliant as the length of the raising trajectory increases (cf. also Declerck 1988: 91), but they are certainly not ungrammatical. A raising-to-subject analysis of inversion predicts their grammaticality straightforwardly. A topicalization analysis, by contrast, cannot account for the fact that a whole string of (raising) verbs can squeeze itself in between the inverted predicate and its subject, unless, in addition, the analysis resorts to extraposition/right-dislocation of the subject. In other words, to accommodate (219), an A′ predicate movement instantiation of option (i) would necessarily need option (ii) *at the same time*, and would need to apply both operations simultaneously.

Guéron (1992, 1993) presents an analysis that does indeed combine both options, taking (i) to involve A′-movement into a position adjoined to an empty-headed noun phrase base-generated in subject position (cf. (220)):

(220) $[_{IP}\ [_{DP0}\ [_{DP0}\ \textit{pro}]_i\ [_{QP}\ Op_i\ Q\ [_{DP2}\ t_i\ D\ NP_{[+Q]}]_k]]\ [I\ [_{VP}\ [_{VP}\ t_j\ [be\ t_k]]\ DP1_j]]]$

The key asset of Guéron's analysis, with its special articulation of the complex noun phrase structure in the subject position resulting from the predicate inversion operation, is that it can make sense of the quantificational restrictions on inversion, illustrated in (58), repeated here:

(58) a. Bill is {captain of the team/a doctor/a friend of mine/the best doctor in town/my best friend}.
b. {*Captain of the team/*a doctor/*a friend of mine/the best doctor in town/my best friend} is Bill.

For Guéron, these quantificational restrictions are part and parcel of the QP-structure which the raised predicate-DP ends up embedded under.

The rightward movement of the base subject (DP1) into a VP-adjoined position (Guéron's version of (ii)) also gives Guéron a window on the fact that the post-copular subject of an inverse copular sentence is *focused* – on the assumption that the right-peripheral VP-adjoined position is a focus position, this falls out straightforwardly. Less clear, however, is how Guéron's (1992, 1993) analysis would make sense of the agreement facts discussed above. For Guéron, the output of adjunction of the predicate to the *pro*-headed subject is essentially a free relative configuration (with the raised noun phrase coming to serve as a predicate

of the *pro* heading the complex noun phrase resulting from the adjunction operation). Agreement of the copula with the raised predicate should then be mediated by *pro*, which should be made to agree in number with DP2. Guéron does not address this issue; we will not attempt a formal account here. In closing the discussion of Guéron's proposal, we add that the fact that inversion of DP2 around DP1 'creates' a free relative structure in the subject position establishes a direct parallel between inverse copular sentences and specificational pseudoclefts with *wh* < XP orders (on an account of the latter, that is, which takes the *wh*-clause of specificational pseudoclefts of this type to be a free relative; see section 5 for critical discussion of this point).

All in all, the fact that the topicalization and extraposition/right-dislocation analyses stay empty-handed when it comes to a variety of properties of inverse copular sentences stands out as a strong argument for the view that the pre-copular constituent of inverse specificational sentences finds itself in subject position. This is guaranteed by the analyses proposed by Moro (1997), Heycock (1994b) and Den Dikken (1995b) (all involving predicate raising), possibly by that of Guéron (1992, 1993) (though the agreement facts remain to be worked out for that analysis), and also, of course, by accounts which treat these constructions as equatives (cf. Heycock and Kroch 1999). The fact that (as (97) and (215) illustrate) the agreement behavior peculiar to inverse specificational sentences seems to be shared by specificational pseudoclefts with *wh* < XP orders is a potential argument for an analysis of the latter along the same lines as that of the former (cf. Heggie 1988; Guéron 1992, 1993); but the topic-comment analysis of *wh* < XP (or 'Type A') specificational pseudoclefts proposed in Den Dikken et al. (2000) accommodates the facts in (215) as well: the copula, on their analysis (cf. the structure in (182), above), is a linker between the topic in SpecTopP and the comment in the complement of Top, entertaining a Spec–Head agreement relationship with the (singular) *wh*-clause in SpecTopP. (See Den Dikken et al. 2000 for more discussion of Spec–Head agreement in TopP, in connection with the tense agreement/congruence effects noted in section 3.2.) The fact that specificational pseudoclefts with *wh* < XP orders fail to *systematically* exhibit the same set of properties as inverse specificational sentences (cf., e.g., the difference between (219) and a pseudocleft like %*What John does seems to be write novels*, which is impossible for the majority of speakers), suggests that a full assimilation of such pseudoclefts to inverse specificational sentences may not be on the right track.

At this point, we may conclude that analyses of inverse specification constructions (i.e., specificational copular sentences in which the 'value'-XP follows the 'variable') in terms of topicalization (A'-movement to a left-peripheral position; COMP/SpecCP in Blom and Daalder 1977; and Heggie 1988) or extraposition/right-dislocation both face problems, and that an analysis which places the pre-copular 'variable' in SpecIP is preferable on a number of counts. This said, we still need to determine whether the pre-copular 'variable' ended up in SpecIP via movement or whether it was base generated there. In the next subsection we will present the arguments which have been brought up in support of a movement approach, considering their pros and cons.

4.3 Evidence for inversion as movement to subject position?

4.3.1 Embedding under ECM and raising verbs

Both Heggie (1988) and Moro (1997) have drawn attention to the fact that it is impossible for the 'variable' to precede the 'value' in the verbless (small clausal) complement of ECM verbs like *consider*; cf. (221) (see also section 3.4). Similarly, raising verbs like *seem* do not allow the predicate of their small clause complement to invert with its subject – (222b) is bad even for those (largely British English) speakers who accept (222a):

(221) a. We consider John the best candidate.
b. *We consider the best candidate John.

(222) a. %John seems the best candidate.
b. *The best candidate seems John.

This follows straightforwardly from a movement analysis of inverse specificational constructions: successful movement is dependent on the presence of a landing-site for the moved element; but the structure of the small clause complement of *consider* and *seem* is not large enough to make such a landing-site available.

The argument for a movement approach to inversion based on (221) and (222) will go through regardless of whether one assumes (with Heggie 1988) an A′-movement derivation or (with Moro 1997, etc.) an A-movement one. The argument becomes more specific, however, once we consider the fact that there is a way of salvaging the ungrammatical b-examples – by inserting *to be* in the complement of the ECM/raising verb (something which Heggie 1988 overlooks):

(221) b′. We consider the best candidate *to be* John.

(222) b′. The best candidate seems *to be* John.

Moro (1997) and Den Dikken (1995b) argue in detail that the distribution of the copula in these contexts is an argument in favor of an A-movement analysis of inversion in specificational constructions.

Of course the negative argument (against the A′-movement approach) is easy to make on the basis of (221b′) and (222b′) – the A′-movement analysis simply makes no appropriate landing-site available in the infinitival complement: we know that topicalization in ECM and raising infinitivals is generally impossible (cf. **We consider the best candidate, John to be*). Moreover, even if we could somehow allow topicalization in such infinitivals under limited conditions, we would still face difficulty accounting for the surface word order of the examples – how does

one maneuver the infinitival copula into a position in between the topic and the subject, given that there is no subject-auxiliary inversion in infinitives (cf. **We were wondering when to be eventually/finally/ultimately there* and *When were you eventually/finally/ultimately there?*)?

The positive side of the argument (showing how an A-movement analysis can account for the distribution of the copula in this context) involves a particular outlook on the functions of the copula, in combination with a minimalist theory of locality (cf. Den Dikken 1995b). In a nutshell, the analysis runs as follows. A-movement of a predicate around its subject would – nothing else done – incur a violation of the minimalist theory of locality (based on Rizzi's 1990b Relativized Minimality): in (223), the predicate, on its way to the higher A-position, skips an intermediate A-position (that of its subject):

(223) $*[_{FP}\ \text{pred}_i\ F\ [_{SC}\ \text{subj}\ H\ [t_i]]]$

To remedy the locality problem, one must ensure that the first position that the predicate can land in and the position that the predicate skips on its way there be rendered *equidistant* (cf. Chomsky 1995c). The way to do this is to perform an operation of domain-extending head movement – some head which has the position of the subject in its minimal domain should raise to a higher head ("F" in (223)) which has the landing-site of the raised predicate in its minimal domain. (See Den Dikken 1995b for further details.) The moving head in question is the functional head of the small clause ("H") in (223).[39] The resulting derivation is schematized in (214).

(224) $[_{FP}\ \text{pred}_i\ F{+}H_j\ [_{SC}\ \text{subj}\ t_j\ [t_i]]]$

This structure is well formed: the subject and the landing-site of the raised predicate are now equidistant, hence predicate raising is in conformity with the Minimal Link Condition ("make the shortest move").

To link the obligatory head movement of (224) to the obligatoriness of the copula in (221b′) and (222b′), Den Dikken makes the additional assumption that the result of domain-extending head movement of H to F is the emergence of the copula *be*. The copula, in constructions of the type at hand, is hence an overt signaler of the application of predicate raising and its concomitant domain-extending head movement.

The account of the distribution of the copula in ECM/raising complements just sketched is crucially based on the A-movement analysis of predicate raising – if either the predicate did not raise to SpecFP but was base generated there, or the predicate did so raise but not via A-movement, the obligatoriness of the copula could no longer be derived from the theory of locality along these lines. Thus, the facts in (221) and (222) provide us with an argument for an A-movement analysis of inversion in specificational constructions.

Heycock and Kroch (1999: 373ff.) raise a number of objections to this argument in favor of an A-movement account of inversion in specificational copular

sentences. First, they note that there are surface subjects which, even though they cannot be analyzed as inverted predicates, do trigger the obligatory presence of *to be* in ECM and raising contexts. Consider the following examples:

(225) a. One hundred yen is the best value for the dollar.
b. The best value for the dollar is one hundred yen.

(226) a. The banks consider one hundred yen the best value for the dollar.
b. *The banks consider the best value for the dollar one hundred yen.

(227) a. The best value for the dollar has changed –
b. – it used to be one hundred and thirty yen, but now it is only one hundred.

The distribution of the copula in (226) is the same as in the above examples; yet to analyze *the best value for the yen* as an inverted predicate on account of its 'non-referential' interpretation would seem to commit one to a predicational analysis of this noun phrase in (227a), where it likewise receives a non-referential interpretation. Heycock and Kroch (1999: 373) admit that this batch of facts "does not, of course, entail the absence of predicate raising (i.e., 'inversion') in the copular examples, but it does greatly weaken the motivation for it." True equatives like *the Morning Star is the Evening Star* weaken it further, they go on to point out – for these, too, require the presence of *to be* in ECM/raising constructions, yet there seems to be no referentiality difference between the two NPs in equative constructions (or 'identity statements').[40]

The previous two arguments are at best circumstantial evidence against a predicate raising approach to inverse specificational constructions. A potentially much stronger argument (cf. Heycock 1994a; Heycock and Kroch 1999: 381) comes from ECM/raising examples featuring unquestionably specificational constructions with a variable < value order which, unlike the ones in (221b, b') and (222b, b'), do *not* trigger the presence of *to be*, as seen in (228a–c):

(228) a. If what you say is true, that would make the real murderer John!
b. The best solution remains instant retreat.
c. At this point our real problem becomes John.
d. *I guess that makes one good doctor John.
e. *An example of this kind becomes World War II.

The verbs *make*, *remain*, and *become* behave differently from *consider* and *seem* when it comes to their interaction with predicate raising. Heycock (1994a, 1998), Den Dikken (1995b), and Guéron (2001) all seek to relate this to the aspectual properties of the constructions involved; Guéron, in particular, argues that the verbs *make*, *remain*, and *become* take a small clause complement containing an abstract BE, an analysis which, if correct, would render (228) directly compatible

with the Moro/Den Dikken analysis. Whatever the fate of such analyses, however, we should note that the verbs in question do not simply accept *any* inverse copular sentence in their complement: while *One good doctor is John* and *An example of this kind is World War II* (cf. (123a)) are grammatical, the examples in (228d, e) (due to Jacqueline Guéron) are bad. Further research into constructions of the type in (228) is clearly called for. But at least on its face, the difference between (228a–c) and the ones brought up originally in support of the 'predicate raising as A-movement' analysis raises some questions.

Further questions are raised by an observation made by Blom and Daalder (1977: 113), in connection with their dual account of inversion in specificational sentences. They point out that their analysis allows, in principle, for inversion in ECM contexts – even though a derivation along the lines of (202a) (topicalization/left-dislocation) is unavailable, there is nothing, in principle, that would block an extraposition/right-dislocation analysis *à la* (202b). And indeed, Blom and Daalder (1977: 113) point out that (229) is grammatical (with the same characteristic colon intonation that products of (202b) have in general); and they claim that (230) is ambiguous between a reading in which *een geboren leider* is the value and one in which it is the variable (with intonation serving as a disambiguator):

(229) Het blijkt dat hij belangrijk vindt: een goede maaltijd.
it turns-out that he important finds a good meal

(230) a. Ik vind een geboren leider de aangewezen persoon.
I find a born leader the appropriate person
hyponym/subject hyperonym/predicate
b. Ik vind een geboren leider: de aangewezen persoon.
I find a born leader the appropriate person
hyperonym/predicate hyponym/subject

(230b), with its characteristic colon intonation, is derived via (202b). Blom and Daalder's discussion of inversion thus indicates that a categorical rejection of inversion under ECM verbs would be too strong. The asterisk on examples such as (221b) should hence be taken to mean that, in the absence of special intonation ('list' or 'colon' intonation), these sentences are unacceptable.

On a more general plane, the movement analysis of inverse copular sentences raises questions about the *trigger/motivation* for movement (at least, if one seeks to embed the analysis in a theoretical framework like that of Chomsky 1995c). For Guéron (1992, 1993), for whom the raised predicative noun phrase adjoins to a base-generated subject noun phrase headed by *pro*, one could speculate that the motivation for movement lies in the licensing (for content, at the very least) of this *pro*; that, however, would be a trigger for movement alien to the types of triggers identified in Chomsky (1995c). Moro (2000) takes the satisfaction of Kayne's (1994) Linear Correspondence Axiom to be the motivation for movement of either of the two constituents of the small clause in the copula's complement – when the subject moves, the result is a canonical copular sentence; when the predicate

moves, an inverse copular sentence results; the choice between the two options is free in principle, but one of the two constituents has to move, or else PF would be presented with a structure (the small clause) whose subconstituents (subject and predicate) entertain a relationship of symmetric c-command, a structure which cannot be linearized. Once again, this would locate the trigger for movement outside the bounds of the set of possible triggers in Chomsky (1995c). A third option (taken in Den Dikken 1995b) is to assume that Case is what drives movement: the subject needs to check its Case-feature but is not in a configuration, prior to movement, which would facilitate a checking relationship with Infl; movement of either the subject itself or its predicate would create such a checking relationship. For movement of the subject itself, this needs no discussion; that movement of the predicate also creates a configuration in which the subject can get its Case-feature checked will follow on the assumption (made independently in Den Dikken 1995b) that subject and predicate are co-indexed,[41] and that Spec–Head agreement in IP is a case of coindexation as well: as a result (given uniqueness of indexation), raising of the predicate to SpecIP creates a syntactic configuration in which the *in situ* subject is coindexed with Infl; checking of the subject's features against those of Infl thus becomes possible.

This Case-based account of the trigger of predicate raising has the advantage of capturing the fact that the post-copular subject receives/checks the Case assigned by Infl without further ado. Other possibilities exist, however: one would be to assume that the copula is a Case-assigner (either of an inherent (partitive) Case, *à la* Belletti 1988, or of a structural one); another would be to assume that the post-copular subject does not need Case because it is a focus (cf. Guéron 1992; Kayne 1994 on Heavy NP Shift as a case of *in situ*, non-Case checking noun phrases). We leave this issue open here.

4.3.2 *Extraction restrictions*

Already in Grosu (1972) it was noted that in specificational pseudoclefts with *wh* < XP order, extraction from the post-copular 'value'-XP is impossible (cf. 3.2 above). He also notes that the same is true for specificational copular sentences in general. The example in (231b) illustrates this for double-NP inverse specificational sentences. Moro (1997) points out, in addition, that not just extraction *out of* but also extraction *of* the post-copular 'value'-XP is impossible in inverse specificational sentences:

(231) a. I think that the cause of the riot was a picture of the wall.
b. *What do you think that the cause of the riot was a picture of *ec*?
c. *Which picture do you think that the cause of the riot was *ec*?

These two extraction restrictions have been brought up as definitional properties of inverse specificational constructions. Italian exhibits cliticization facts which parallel the *wh*-extraction data presented here; see Moro (1997: 28–29) for discussion. Note that Moro (1997: 59) claims that the predicate of canonical (i.e., non-inverted) copular sentences is also unextractable – but Heycock and Kroch (1999: 377)

point out that this claim runs counter to the general facts (his particular example being unacceptable for reasons tangential to the subject/predicate issue).

For Heggie (1988), the ungrammaticality of (231b) (and, by the same token, although she does not discuss this explicitly, of (231c) as well) fits in with her topicalization analysis of inverse specificational constructions – the deviance of these examples will then illustrate the familiar 'topic island' effect (cf. Ross 1986). However, the degree of deviance of the examples in (231b, c) is substantially stronger than that of a garden variety topic island effect (cf. ??*What do you think that to Mary, John would never give?*). It is likely, therefore, that the deeper roots of the ungrammaticality of these examples has to be sought elsewhere.

One possibility would be to look for the deeper roots in the domain of focus. What inverse specificational constructions all share in common is the fact that the post-copular constituent (or a subconstituent thereof) is in focus. One may wish to translate this structurally into the hypothesis that it is in a special, right-peripheral focus position, and that it is this which blocks extraction of and from the post-copular noun phrase. Guéron (1992, 1993) presents an analysis along these lines (see also Heggie 1988 for the suggestion that the post-copular noun phrase is in some sort of 'constructional focus' position in at least some inverse specificational sentences; also cf. Blom and Daalder's 1977 extraposition/right-dislocation approach to these constructions). The assumption that the post-copular constituent is in a focus position (an A' island position) will readily make sense of the ban on *sub*extraction from it. It is less clear, however, that it will also successfully rule out *wh*-extraction of the *entire* constituent: *wh*-constituents are themselves foci, and in languages (like English, unlike Hungarian) in which they must raise to SpecCP they may well do so, systematically, via a stop-over in the focus position (which is the surface position of *wh*-constituents in languages like Hungarian) along the way, to check their focus feature. If so, movement from the focus position on to SpecCP should be allowed in general; it will then be unclear why the post-copular focus of inverse copular sentences should be unable to undergo *wh*-movement.

Moro (1997) presents an alternative account of these facts which capitalizes on his raising-to-subject analysis of predicate inversion. Den Dikken (1995b) presents a variant of this account, based on the same overall analysis of inversion in specificational sentences. The key to both analyses is that the post-copular constituent in an inverse specificational construction is a structural *subject* – i.e., finds itself in a specifier position. We are familiar from early transformational work (cf. Ross 1986) with the fact that specifiers (left branches) are strong islands – the 'subject condition' severely penalizes extraction from subjects. The ungrammaticality of (231b) then follows, from the subject condition (Subjacency). That of (231c) can also be made to follow from the subject status of the post-copular deep subject, if one assumes that in its base position, the trace of the extracted 'value'-NP in (231c) cannot be properly governed, which causes an ECP violation. Den Dikken (1995b) presents a different analysis of (231c), one which does not resort to the ECP but capitalizes on the co-indexation of subject and predicate and the

Principle C effect (strong crossover) resulting from extraction of the subject across its A-raised predicate (but see n. 40).

Central to the account of (231b, c) sketched in the previous paragraph is the idea that the post-copular constituent in inverse specificational sentences is in a subject position. It is in this respect that this account rests crucially on the movement analysis of inversion in specificational constructions: if this order were base generated, the post-copular NP would not be a subject. Den Dikken's (1995b) crossover approach to the ungrammaticality moreover capitalizes on the idea that the fronted predicate lands in an A-position (rather than some A'-position).

Heycock and Kroch (1999: 376–378), in their repartee of the raising analysis of specificational sentences, object, however, that "true equative sentences" exhibit the same extraction restrictions, despite the fact here there is no sense in which one of the two NPs can be singled out as an underlying predicate (but cf., once again, Blom and Daalder 1977: 76 for a different perspective):

(232) a. *Who is your attitude towards Jones my attitude towards?
b. *Whose attitude towards Davies would you say that your attitude towards Jones is?

They go on to point out that "in inverse (and equative) sentences the extraction of the surface subject is just as ungrammatical as the extraction of the post-copular noun phrase" (p. 377) – a point overlooked by Heycock (1994a); Den Dikken (1995b); Moro (1997) and others.

(233) a. *Which of the themes do you think *ec* is that phrase of music?
b. *Whose opinion of Edinburgh do you think *ec* is your opinion of Philadelphia?

Heycock and Kroch are right to point out that these facts seriously undermine the extraction argument.

While they do not present a new account of the extraction facts, Heycock and Kroch (1999: 378, n. 9) do make a potentially interesting suggestion which needs to be looked into in future research. They suggest that it might be fruitful to look for an account of the extraction restrictions in the domain of "the only other symmetric constructions in natural language syntax: coordination." The following examples show that there is indeed a close parallel between coordination constructions and equatives – even in the domain of across-the-board extraction:

(234) a. *Which city is your opinion of *ec* my opinion of Philadelphia?
b. *Which city is your opinion of Edinburgh my opinion of *ec*?
c. Which city is your opinion of *ec* my opinion of *ec*?

(235) a. *Which city does John love *ec* and Mary despise Philadelphia?
b. *Which city does John love Edinburgh and Mary despise *ec*?
c. Which city does John love *ec* and Mary despise *ec*?

This parallel suggests that what we are dealing with in the domain of extraction restrictions is constraints on 'symmetric constructions'. If this is right, it strongly enhances an account of inverse specificational sentences as equative sentences, not as inverse predicational constructions.

4.4 Reversibility: concluding remarks

In this section we have discussed approaches to what is perhaps the most conspicuous earmark of specificational copular sentences: the reversibility of their major constituents. There are two basic questions that come up in the accounts of reversibility offered in the literature:

- Does reversal involve movement or not?
- If so, is it movement of the 'variable' to the left or of the 'value' to the right (or both), and what kind of movement (A or A') are we dealing with?

Approaches which take inverse specificational sentences to be a subtype of equative copular sentences (or 'identity statements') answer the first question negatively. Underlyingly predicational approaches to inverse specificational sentences of necessity give a positive answer to this question, and have come up with a variety of ways of deriving the surface word order from an underlying subject-predicate base. Evidence has been presented in the literature in favor of the underlying predicativity of inverse specificational sentences, as well as for leftward predicate movement and rightward subject displacement accounts of the inverted order. None of these accounts is flawless, however: many of the individual arguments face difficulties, as we have seen. This raises questions about the transformational account, and, concomitantly, about the predicational base of inverse specificational sentences as well.

The predicativity of the pre-copular constituent is also potentially called into question by the fact that there are severe restrictions on what qualifies as an 'invertible predicate' (cf. (58), above). Heycock and Kroch (1999: 379–380) review these restrictions (see also Declerck 1988; Guéron 1993, 2001) and conclude that what they show is "that it is not possible to treat any constituent appearing in [SpecIP] as predicated of a postcopular argument." This stands out as perhaps the most serious obstacle to a predicate raising analysis of inverse specificational sentences. Guéron (1993, 2001), however, presents a concrete perspective on how to analyze these restrictions (which are mostly of a quantificational nature) from a perspective of an approach which starts out from an underlying subject-predicate relationship.

On the other hand, an analysis of inverse specificational sentences which treats them on a par with equative copular constructions (or 'identity statements') will need to face the fact that, despite their similarities in the domains highlighted by Heycock and Kroch, there are differences between the two as well – see section 1.3.

With these conclusions concerning the analysis of specificational copular sentences drawn, we have now reached the final destination of the code-share

flight operated by double-NP specificational sentences and specificational pseudoclefts. From this point on, we will leave constructions of the type *The best candidate is John* behind, and focus instead on two questions arising specifically in the context of specificational pseudoclefts, concerning:

- the status of the *wh*-clause,
- the relationship between specificational pseudoclefts and their simple clause counterparts.

We will address these two questions in turn, in sections 5 and 6, respectively.

5 The *wh*-clause: Question or free relative?

We are gradually making our way towards a discussion of the theoretical approaches to the relationship between specificational pseudoclefts and their simple clause counterparts. But before we can assess these, we will need to address another question: what is the status of the *wh*-clause of specificational pseudoclefts? Since *wh*-clauses with *what* as their first constituent (the canonical realization of the *wh*-clause of specificational pseudoclefts; on the limited possibility of other *wh*-elements, see section 2.1) without subject-auxiliary inversion come in two general varieties, what we need to determine is which of the two, if either, we are dealing with in a specificational pseudocleft:[42]

(236) *The* wh-*clause of specificational pseudoclefts:*
  a. a free relative,
     (cf. *What John did is a disgrace*.)
  b. an embedded *wh*-question,
     (cf. *I wonder what John did*.)
  c. a third type.

In the literature on specificational pseudoclefts, both positions in (236a, b) have in fact been taken – see Akmajian (1979), Blom and Daalder (1977), Heggie (1988), Declerck (1988), Guéron (1992), and references cited there for proponents of (236a); see Clifton (1969), Faraci (1971), Ross (1972a), Seuren (1985), Den Dikken et al. (2000), and references cited there for adherents of (236b).

The issue is certainly not straightforwardly settled. The fact that it has turned out to be extremely contentious finds its roots in the fact that neither (236a) nor (236b) fits the bill like a glove – on both sides there are familiar properties which fail to be matched by the *wh*-clause of specificational pseudoclefts. We will structure the discussion as follows. Section 5.1 will discuss general theoretical and conceptual arguments in favor each of the two approaches in (236a) and (236b). Section 5.2 is subsequently devoted to specific empirical pros and cons of the free relative approach, which, as we will see, typically can be cashed in as arguments in favor of the *wh*-question analysis. Section 5.3 then presents a list of

problems for the *wh*-question approach, which, conversely, fall into place on the free relative approach. Finally, section 5.4 addresses problems shared by both approaches, and considers option (236c).

5.1 General theoretical and conceptual issues

For proponents of a predicational approach to specificational pseudoclefts (of all sorts) according to which the *wh*-clause functions as a (small clause) predicate (cf. section 4.1.2 above for discussion), a free relative approach to the *wh*-clause is of course the only option – we are not aware of any *wh*-questions being used predicatively:

(237) a. Home is where the heart is.
b. *Home is whether you like it there.

On the other hand, for those who do not subscribe to a predicational analysis, there is no argument here in favor of a free relative approach to the *wh*-clause.

Adherents of the free relative approach may also capitalize on the fact that the *wh*-clause of specificational pseudoclefts typically alternates with a headed relative, with heads like *one/thing/reason/time/way*, etc. (the '*th*-clefts' of Collins 1991). The properties of such '*th*-clefts' are very similar to those of specificational *wh*-clefts; as a result, scholars have generally analyzed them on a par. If they are indeed identical in their distribution, this may be taken as an argument to liken the *wh*-clause of *wh*-clefts to a relative clause construction. Hankamer (1974) stresses more than once, however, that the two, though similar, are not identical, saying that the headed relative cases "*identify* rather than predicate; and that the allowable subjects of these constructions are very restricted, and do not include [headed relative] clauses" (n. 9). It may be wrong, therefore, to attach too much weight to the fact that there are contexts in which the *wh*-clause of a specificational pseudocleft can be replaced with a headed relative.[43]

As for the *wh*-question approach, its general advantage is that it captures the connection between specificational pseudoclefts and question-answer pairs, which many scholars have drawn a good deal of attention to (see Faraci 1971; Ross 1972b; Akmajian 1979; Higgins 1979; etc., and more recently, Ross 1999; Den Dikken et al. 2000; and Schlenker 2003b); cf. (238). Ross (1999) points out specifically that the *wh*-clause of a specificational pseudocleft corresponds to what he calls a 'conjunctive question', as distinct from a 'disjunctive question' – these are different in that the answer to the former "is presupposed to be known to someone in the sentence . . . whereas for disjunctive questions, no answer is known" (Ross 1999).

(238) a. What John does for a living is write novels.
b. What does John do for a living? – Write novels.

Of course, the connection between specificational pseudoclefts and question-answer pairs can in principle be established in ways other than one which takes

the *wh*-clause of the former to be a *wh*-question: the link could, for instance, be established at the level of semantics or even pragmatics.

Akmajian (1979: 78ff.) argues, however, that exactly when it comes to the semantics, the *wh*-clause of specificational pseudoclefts is in fact *not* identical with *wh*-questions in one important respect: referentiality. He makes this point – that the *wh*-clause of specificational pseudoclefts is referential while a *wh*-question is not – on the basis of empirical arguments which we will address in more detail below. On a higher theoretical plane, however, matters of referentiality are extremely contentious precisely in the domain of specificational copular sentences (cf. the discussions in Blom and Daalder 1977; Higgins 1979; Declerck 1988; and Keizer 1992; see section 1, above, for an overview).

In themselves, these broad theoretical or conceptual arguments will not tip the balance in favor of or against either of the two approaches in (236a) and (236b). What we need is explicit empirical arguments for or against them. This is what we turn to next.

5.2 *Empirical evidence against free relatives and in favor of* wh-*questions*

(i) *The ban on* -ever (cf. section 3.2) One respect in which the *wh*-clause of specificational pseudoclefts differs empirically from free relatives, and instead patterns with *wh*-questions, concerns the distribution of *-ever*. We have come across this fact in section 3.2: while free relatives freely allow the addition of *-ever*, the *wh*-clause of specificational pseudoclefts does not (cf. (239) with (241)); in this respect it is like a *wh*-question (cf. (240)):

(239) What(ever) John does is interesting. (free relative)

(240) I wonder what(*ever) John does. (*wh*-question)

(241) What(*ever) John does is write novels. (specificational pseudocleft)

Heggie (1988) and Iatridou and Varlokosta (1998) seek to derive this fact from a predicate approach to the free relative, but as was discussed in section 3.2, this line of thought is problematic. As far as we can tell, the ban on *-ever* stands out as an unresolved problem for an analysis of the *wh*-clause as a free relative. (See also Dayal 1997 for an attempt at empirically undermining the problem; her examples do not successfully alleviate the problem, however: see n. 22 for discussion.)

(ii) *PP pied-piping* (cf. section 3.3) Another property of the *wh*-clause of specificational pseudoclefts that has been noted before in this work (cf. section 3.3, above) and which plays a role in the debate concerning the analysis of the *wh*-clause is the fact that PP pied-piping is allowed inside this clause in some languages (though not in all), crucially despite the fact that those languages

strictly forbid pied-piping in free relatives (cf. esp. Den Dikken et al. 2000: 72 for discussion).

(242) *Free relative:*
*Mit wem Maria gesprochen hatte kam gerade ins Zimmer.
with whom Maria spoken had came just into-the room

(243) *Wh-question:*
Mit wem hat Maria gesprochen?
with whom has Maria spoken

(244) *Specificational pseudocleft with* wh < *XP order:*
Mit wem Maria gesprochen hatte, war mit Peter.
with whom Maria spoken had was with Peter

It should be pointed out, however, that PP pied-piping works only in those specificational pseudoclefts that have a word order in which the *wh*-clause precedes the 'value'-XP. (245) is ungrammatical:

(245) *Specificational pseudocleft with XP* < wh *order:*
Mit Peter war mit wem Maria gesprochen hatte.
with Peter was with whom Maria spoken had

This is one of a variety of ways in which specificational pseudoclefts with *wh* < XP order are different from their congeners with XP < *wh* order. We will encounter more of these in what follows. For Den Dikken et al. (2000) these mismatches are an important argument for an analysis which assigns different underlying syntactic structures to the two types of specificational pseudocleft: a topic-comment structure for *wh* < XP and a free relative structure for XP < *wh*. The latter analysis will of course straightforwardly relate the ill-formedness of (245) to that of the free relative construction in (242), while a topic-comment structure in which the *wh*-clause is analyzed as a *wh*-question accommodates the link between (243) and (244).

(iii) *Multiplicity* Free relatives in languages like English do not allow multiple *wh*-elements inside them – (246) is ungrammatical. Multiple interrogation, on the other hand, is perfectly possible in such languages, as shown in (247). The distribution of multiple *wh*-elements thus constitutes another testing ground for the hypotheses in (236a) and (236b).

(246) *[Who ordered what] should come fetch it at the counter. (free relative)

(247) I would like to know [who ordered what]. (*wh*-question)

Testing the hypotheses against this criterion actually turns out to be somewhat tricky, however. What one needs here is examples involving a rather complex

'value'-XP: one which contains values for all the *wh*s in the *wh*-clause. The kinds of pseudoclefts one is then confronted with are the kinds of cases which involve a full-clausal post-copular constituent (which, if the conditions are met, may undergo some degree of ellipsis). Such pseudoclefts (illustrated in (248)) do not meet with general enthusiasm among native speakers, however: while Ross (1972a) accepts them, Akmajian (1979) does not like them, and Higgins (1979: 86) finds them "irremediably anacoluthic." In (249), we present some attested examples from Geluykens's (1984) corpus-based study of English clefted sentences.[44]

(248) %What Tom ordered was Tom ordered a beer.

(249) a. All you do is you turn it in to the red mark.
b. All I did was I did Montaigne.
c. What you do is you look at the return.
d. What you do is you go.

In the light of this (see also section 6.1, below), it therefore will not surprise the reader that Ross's judgment of multiple *wh*s in specificational pseudoclefts differs from that reported by Akmajian and Higgins – the following examples reproduce their respective illustrations:

(250) a. %Who ordered what was Tom (ordered) a beer and Jim a watermelon flip.
b. %Who ate what was Jane ate spaghetti and Chica (ate) hamburger.
(Ross 1999)

(251) *Who kissed whom was John kissed Mary. (Akmajian 1979: 76)

(252) *What Mary gave who was John a book. (Higgins 1979: 67)

It may well be that there is substantial dialectal and idiolectal variation when it comes to multiplicity. Thus, while for Dutch, Blom and Daalder (1977) report that it fails (cf. (253)), Meinunger (1997) presents grammatical examples for German (cf. (254)):[45]

(253) *Wat zij waar gekocht heeft zijn twee aandelen Haagse Hopjes op
what she where bought has are two shares 'Haagse Hopjes' on
de beurs.
the stock-exchange

(254) ?Wer hier wem geholfen hat war die Hilde dem Heinz (und nicht
who here whom helped has was the Hilde the Heinz and not
umgekehrt).
reversed

The variation among speakers certainly raises questions. But what one may conclude at the very least is that multiplicity is not universally rejected in

specificational pseudoclefts – at least, not in those with *wh* < XP word order; it is entirely impossible in XP < *wh* cases (cf. (255), (256)). When one compares this to the fact that there is no variation among speakers at all when it comes to the ungrammaticality of multiplicity in free relatives in the languages considered (English, Dutch, German), examples like (250) and (254) present us with at least a weak case against the free relative approach to the *wh*-clause of specificational pseudoclefts with *wh* < XP order. At the same time, the categorical unacceptability of (255) and (256) tells us that specificational pseudoclefts with the order XP < *wh* do not feature a *wh*-question; the properties of their *wh*-clause are in fact similar to those of free relatives. (See Den Dikken et al. 2000 for discussion.)

(255) *Tom (ordered) a beer and Jim a watermelon flip was who ordered what.

(256) *Die Hilde dem Heinz war wer hier wem geholfen hat.

(iv) *Topicalization inside the* wh-*clause* Free relatives categorically disallow topicalization – regardless of whether the topic is placed to the left or to the right of the *wh*-word (cf. (257)). English *wh*-questions, on the other hand, have been noted to be compatible with topicalization – and as Pesetsky (1989) notes, the position of the topic is different in root and embedded *wh*-questions: in the former, the topic must precede the *wh*-phrase, while in the latter, the topic follows the *wh*-phrase (cf. (258) and (259)). The *wh*-clause of specificational pseudoclefts differs radically from free relatives: it allows topicalization. As a matter of fact, it allows it on either side of the *wh*-word (cf. (260)). This was first pointed out in Den Dikken et al. (2000: 71).

(257) a. *[To Mary, what he gave] caused a scandal. (free relative)
b. *[What to Mary, he gave] caused a scandal.

(258) a. ?To Mary, what will he give? (root *wh*-question)
b. *What <will> to Mary, <will> he give?

(259) a. *He is wondering [to Mary, what he will give]. (emb. *wh*-question)
b. ??He is wondering [what to Mary, he will give].

(260) a. ?[To Mary, what he will never give] is any wine. (spec. pseudocleft)
b. ??[What to Mary, he will never give] is any wine.

Interestingly, then, while the *wh*-clause of specificational pseudoclefts certainly does not behave like a free relative when it comes to topicalization, it seems to blend the properties of root and embedded *wh*-questions. Den Dikken et al. conclude from this that the *wh*-clause of specificational pseudoclefts is indeed a *wh*-question – but it is neither a root question nor an embedded question; it is a hybrid case with properties of both types of question.

We stress this here because most of the arguments against the *wh*-question analysis have been directed specifically towards an analysis of the *wh*-clause of specificational pseudoclefts as an *embedded* question, as we will see in the next section.[46]

5.3 *Empirical evidence against* wh*-questions and in favor of free relatives*

(v) *Determiners* (Izvorski 1997; Alexiadou and Giannakidou 1998; Ross 1999) While the previous section concerned itself with problems for a free relative approach to the *wh*-clause of specificational pseudoclefts, something which seems to stand out as a strong recommendation for such an analysis is the fact that in languages like Bulgarian (Izvorski 1997), Greek (Iatridou and Varlokosta 1998; Alexiadou and Giannakidou 1998; the latter also refer to Spanish and Catalan), and Portuguese (Ross 1999), the *wh*-clause of these constructions is obligatorily adorned with an affixal definite determiner (cf. (261) for Bulgarian, (262) for Greek, (263) for Portuguese). Such an affixal determiner is typical of free relatives in these languages; on the other hand, it never occurs on *wh*-questions in Bulgarian and Greek (though it does in Portuguese: *O que é que aconteceu?* 'What happened?').

(261) Kakvo-*(*to*) *pro* kaza bese ce Maria e umna.
what-def said was that Maria is smart
'What he said was that Maria is smart.'

(262) Afto pu ipe o Kostas ine oti i ji ine epipedi.
this that said the Kostas is that the earth is flat
'What Kostas said is that the earth is flat.'

(263) O que Boris roubou foi o Lavoris.[47]
the what Boris stole was the Lavoris
'What Boris stole was the Lavoris.'

As Den Dikken et al. (2000: 71, n. 23) point out, however, specificational pseudoclefts in these languages are characterized by two further properties which make them different from their English congeners: (i) they never allow full-IP 'values', and (ii) they never exhibit connectivity with respect to negative polarity item licensing. They might hence instantiate their 'Type B'.[48]

(vi) *No yes/no-questions* (Huddleston 1971: 243; Akmajian 1979: 76) The second problem for an assimilation of the *wh*-clause of specificational pseudoclefts to (embedded) *wh*-questions springs to mind immediately. While *wh*-questions come in two flavors (constituent questions and yes/no-questions), the *wh*-clause of specificational pseudoclefts comes only in one:

(264) a. What John did was unclear.
b. Whether John did it (or not) was unclear.

(265) a. What John did was kiss Mary.
b. *Whether John did it (or not) was {yes/he did}.
*Whether John did it (or not) was {no/he didn't}.

From the perspective of proponents of the view that there is a close syntactic relationship between question-answer pairs and specificational pseudoclefts (with *wh* < XP orders), the ungrammaticality of (265b) is surprising – after all, yes/no question-answer pairs of the type in (266) are perfectly well formed. (Notice, though, that (266) involves a *root* question, not an embedded question.)

(266) Did John do it (or not)?
a. (Yes,) he did.
b. (No,) he didn't.

Of course, a free relative approach to the *wh*-clause of specificational pseudoclefts encounters no difficulty accounting for the deviance of (265b): there are no free relatives with *whether* (for the same reason that there are no relative clauses with *whether* either).

That *if* does not occur in the *wh*-clause of specificational pseudoclefts either is less of a surprise: *if* is ruled out as the complementizer of subject questions as well:

(267) *If John did it (or not) was unclear.

(268) *If John did it (or not) was {yes/he did}.
*If John did it (or not) was {no/he didn't}.

(vii) *No adverbs* (Blom and Daalder 1977: 22; Akmajian 1979; *contra* Faraci 1971) Faraci (1971), who is an early champion of the *wh*-question analysis, mentions as one of the arguments in its favor the fact that adverbs like *exactly* can be added to both the *wh*-clause of specificational pseudoclefts and *wh*-questions, but not to free relatives. Akmajian (1979: 75) points out, however, that he does not accept Faraci's pseudocleft example in (269); likewise, Blom and Daalder (1977: 22) present a Dutch triplet which makes the pseudocleft pattern with free relatives rather than with *wh*-questions (cf. (272–274); in (273) we have corrected a word order mistake in Blom and Daalder's original example):

(269) %What, exactly, John bought was a car.

(270) What, exactly, John bought is not clear.

(271) *I threw out what, exactly John bought.

(272) *Wat ik precies gezegd heb was dat samenwerking niet meevalt.
what I exactly said have was that cooperation not with-falls
(i.e., isn't easy)

(273) Ik herinner me niet wat ik precies gezegd heb.
I recall me not what I exactly said have

(274) *Wat ik precies gezegd heb gelooft hij niet.
what I exactly said have believes he not

(viii) *No clefting inside* wh-*clause* (Blom and Daalder 1977: 22; Akmajian 1979; *contra* Faraci 1971) (cf. section 3.3) Faraci (1971) also claims that the *wh*-clause of specificational pseudoclefts can contain a cleft. But most authors (cf. Akmajian 1979 for English, Blom and Daalder 1977 for Dutch) disagree and find such combinations impossible.

(275) %What it is that John bought was a car.

For those speakers (the vast majority) for whom (275) is bad, it appears at first sight that there is a difference between the *wh*-clause of specificational pseudoclefts and *both wh*-questions *and* free relatives (*contra* Blom and Daalder 1977: 22) – (276) is grammatical, and so are the free relative examples in (277) (cf. Akmajian 1979: 80):

(276) I don't know what it is that John bought.

(277) a. Whatever it was that John bought cost him a lot of money.
b. She threw away whatever it was that John bought.

Thus, while Faraci (1971) construes (275) (which he finds grammatical) as an argument in favor of a *wh*-question approach, and while Blom and Daalder (1977: 22) bring up a Dutch example like (275) (which they find ungrammatical) as evidence in favor of a free relative approach to the *wh*-clause of specificational pseudoclefts, neither argument goes through unscathed: as Akmajian points out, the *wh*-clause of specificational pseudoclefts is identical neither with *wh*-questions nor with free relatives.

As Akmajian goes on to point out, however, it is not just any free relative that accepts internal clefting: replacing *whatever* with *what* in (277) delivers a substantially degraded result. The generalization seems to be that "*non-referential* clauses may occur in clefted form" (Akmajian 1979: 81; original emphasis); and addition of *-ever* makes free relatives non-referential. If this is correct, the fact that clefting inside the *wh*-clause of specificational pseudoclefts is impossible will reduce to the same factor that is responsible for the impossibility of *-ever* in such clauses: their referentiality (see also (ix), immediately below). In having the ability to be referential, the *wh*-clause does indeed pattern with free relatives rather than with *wh*-questions, which obviously cannot be referential in any context.

(ix) *Appositive relative clauses* (Akmajian 1979: 80) In the same context in which he assesses the cleft-*cum*-pseudocleft argument, Akmajian (1979: 80) also brings

up an additional argument (original with him) that casts doubt on the *wh*-question status of the *wh*-clause of specificational pseudoclefts, and enhances their free relative-hood. The argument is based on the fact that appositive relative clauses can be added to the *wh*-clause of specificational pseudoclefts but not to *wh*-questions (cf. (278) vs. (279)). The same argument can be built on the distribution of parentheticals (cf. Akmajian 1979: 102, n. 28); this will not be shown here.

(278) What John got from his father yesterday, which was very expensive, was that Jaguar XKE.

(279) *What John got from his father yesterday, which was quite expensive, is a mystery.

(280) What John got from his father yesterday, which was very expensive, was broken two days later.

Once again, the *wh*-clause of specificational pseudoclefts patterns with free relatives (see (280)) rather than with *wh*-questions – as a function of its referentiality, according to Akmajian.

(x) *Else/ever* (Akmajian 1979: 75) Problematic for the question analysis of the *wh*-clause of specificational pseudoclefts as well is the fact that, pointed out by Akmajian, that *else* and *ever*, while fine in *wh*-questions, are impossible in pseudoclefts:

(281) a. *What else he bought was a car.
b. *What he ever worked on was his thesis.

(282) a. What else he bought is not clear.
b. What he ever worked on is simply not known.

(283) a. *What else he bought was very expensive.
b. *What he ever worked on took him a long time to finish.

Though Akmajian does not provide free relative examples, the sentences in (283) show that what we are dealing with here is another property of the *wh*-clause of specificational pseudoclefts which makes it pattern with free relatives and not with *wh*-questions.

(xi) *Any* (Akmajian 1979: 76) Akmajian makes a similar point by drawing attention to the distribution of negatively polar *any* – it is found in *wh*-questions but not in the *wh*-clause of specificational pseudoclefts, nor (though Akmajian does not show this himself) in free relatives:

(284) *What makes any sense is not John's theory.

(285) What anyone can do about the war is unclear.

(286) *What anyone can do about the war is not important.

This argument is dependent more on the relationship between the *wh*-constituent and the external negation, it seems, than on the internal syntax of the *wh*-constituents themselves (cf. the fact that even (285) becomes unacceptable when *unclear* is replaced with *clear*). It may be important in this context that *unclear* in (285) is an ergative adjective (cf. Cinque 1990b), hence will c-command the *wh*-clause in the underlying representation of this example; in (284) and (286) we presumably do not find such a c-command relationship at any point in the derivation. The force of this particular argument is therefore less than crystal clear.

Be that as it may, in the foregoing we have found that there are a number of reasons to use care when assessing the claim that the parallelism between question-answer pairs and specificational pseudoclefts suggests an analysis of the *wh*-clause of the latter as a *wh*-question. There are a number of respects in which the two differ; and in some of those cases we actually find that there is in fact a closer kinship between the *wh*-clause of specificational pseudoclefts and free relatives (though the relationship between those two is by no means one of identity either).

5.4 *Problems either way*

No matter which tack one takes when it comes to the analysis of the *wh*-clause, one inevitably runs up against the problem that there at least two respects in which it behaves neither like a free relative nor like a *wh*-question.

(xii) *No complementizers* (Blom and Daalder 1977: 22) While, as we saw in (267–268), English *if* does not occur in subject questions and the *wh*-clause of specificational pseudoclefts alike, its cognate *of* in Dutch does occur in subject questions. But according to Blom and Daalder (1977: 22) it still fails to rear its head in the *wh*-clause of Dutch specificational pseudoclefts – interestingly, not just when it is 'on its own' (in a yes/no-question) but also when it follows a *wh*-word (in constituent questions, which in spoken varieties of Dutch allow sequences of a *wh*-word/phrase and the complementizer *of*; see e.g. Zwart 1997 for exemplification):

(287) a. Wat Jan gedaan had was onduidelijk.
what Jan done had was unclear
b. Of Jan het gedaan had was onduidelijk.
if Jan it done had was unclear
c. Wat of Jan gedaan had was onduidelijk. (= (287a))
what if Jan done had was unclear

(288) a. Wat Jan gedaan had was Marie kussen.
what Jan done had was Marie kiss
b. *Of Jan het gedaan had was {ja/inderdaad}.
if Jan it done had was yes/indeed
c. ?*Wat of Jan gedaan had was Marie kussen.
what if Jan done had was Marie kiss

Blom and Daalder (1977: 22), who draw attention to the deviance of (288c), point out that in this respect the *wh*-clause of specificational pseudoclefts bears a resemblance to free relatives, which likewise do not allow *wh- of* sequences:

(289) *Wat of ik zeg valt niet in goede aarde.
what if I say falls not in good earth

However, while we agree that (288c) is deviant, it does seem that it is noticeably less bad than the free relative case in (289), which is entirely impossible. If this is right, it makes the *wh*-clause of specificational pseudoclefts a kind of hybrid of free relatives and embedded *wh*-questions.

It is important to point out at this time that Blom and Daalder's argument based on (288) is built on the premise that, if the *wh*-clause of a specificational pseudocleft is to correspond to a *wh*-question to begin with, it should resemble an embedded *wh*-question rather than a root *wh*-question – a premise which, in its turn, is based on the impression that the *wh*-clause finds itself in clause-internal position, hence cannot itself be a root clause.

But we have seen in the examples in (262) (from Den Dikken et al. 2000) that the *wh*-clause of specificational pseudoclefts is neither a pure embedded clause, nor a perfect copy of a root clause: it has properties in common with both (in particular, it allows topics to be positioned either to the left or to the right of the *wh*-element in English). *Tertium datur*, in other words: there seem to be *wh*-questions which are neither root nor embedded clauses, thanks to their unique position in the syntactic tree structure (the SpecTopP position of Den Dikken et al. 2000). In this respect, option (236c) is presumably closer to the truth than pure versions of (236a) or (236b).

This said, the fact that the complementizer *of* is not perfect in Blom and Daalder's example (288) is less of a surprise than Blom and Daalder made it out to be. In effect, we may want to liken the *wh*-clause of specificational pseudoclefts to echoic *wh*-questions of the type illustrated in (290b), which likewise seem to have a status in between root and non-root clauses – non-root when it comes to word order; root with respect to the fact that it does not appear to be embedded under any predicate. In both these respects, it matches the *wh*-clause of pseudoclefts on the analysis of 'Type A' specificational pseudoclefts propounded in Den Dikken et al. (2000). It may be interesting to note, therefore, that adding *of* to (290b) seems somewhat less felicitous than it is in run-of-the-mill embedded *wh*-questions:[49]

(290) a. Speaker A: Wat heb je gedaan?
what have you done
b. Speaker B: Wat (?of) ik gedaan heb? – De auto gewassen.
what if I done have the car washed

Whatever the precise outcome of this discussion, it seems clear that, if the *wh*-clause of specificational pseudoclefts is to be likened to *wh*-questions at all, it must be assumed to be a cross-breed of a root and a non-root question. Possibly, this hybrid root/non-root clause could embody precisely those properties of free relatives that are shared by the *wh*-clause of specificational pseudoclefts. It seems unlikely, though, that it will also help us explain one other respect in which the *wh*-clause of specificational pseudoclefts is like no other *wh*-construction in the grammar:

(xiii) *Restrictions on* wh (cf. section 2.1) Most speakers do not accept *who* – or at least not very readily – as the *wh*-element of the *wh*-clause of specificational pseudoclefts; the only exception is constituted by pseudoclefts featuring *that* in pre-copular position (*That's who I meant*). Likewise, the *wh*-words *why* and *how* are severely restricted in pseudoclefts, as noted in section 2.1. All of these three *wh*-elements occur readily, however, in free relatives with *-ever* (though the presence of *-ever* seems essential here). We are not aware of any approach to the syntax of the *wh*-clause of specificational pseudoclefts which has succeeded in accounting for the restrictions on the form of the *wh*-element.

This concludes our discussion of the vicissitudes of the free relative and *wh*-question analyses of the *wh*-clause of specificational pseudoclefts. On balance, the following tentative conclusions seem legitimate:

- The *wh*-clause of specificational pseudoclefts of 'Type A' (see section 2.3) is a hybrid type of *wh*-question, with properties of root and embedded *wh*-questions combined.
- The *wh*-clause of specificational pseudoclefts of 'Type B' is a free relative (see esp. the facts from Bulgarian and Greek discussed at the beginning of section 5.3).

Clearly, though, neither free relatives nor *wh*-questions fit the bill perfectly. Further research will be needed to clarify the precise status of the *wh*-clause of specificational pseudoclefts. (For completeness' sake, we note in passing that for *predicational* pseudoclefts there is no doubt about the fact that the *wh*-clause of these constructions is a free relative.)

6 Analyses of the relation between specificational pseudoclefts and simple sentences: transformation or base generation?

The reason why generative linguists became interested in specificational pseudocleft sentences in the early days of transformational grammar is not difficult to

see – specificational pseudoclefts have a close relationship with their simple clause counterparts, and it seemed clear that a transformational theory of grammar should somehow be able to capture this relationship in transformational terms. The urge to meet this desideratum led to two competing types of transformational approach to specificational pseudoclefts:

- the deletion analysis (Peters and Bach 1969; Clifton 1968b; Emonds 1970; Ross 1972a; Seuren 1985; Kayne 1998: 26; Schlenker 2003b; Den Dikken et al. 2000),
- the extraction analysis (Chomsky 1972; Akmajian 1979; Moreau 1971; Grosu 1972, 1973; Verkuyl 1972: 146).

In response to these two transformational analyses, for which he listed a variety of problems, Higgins (1979) defended a non-transformational account, adopted also by Blom and Daalder (1977):

- the base generation analysis (Higgins 1979; Blom and Daalder 1977).

In the more recent principles-and-parameters literature, the restrictions on movement transformations are substantially stricter than they were in the sixties and seventies. Not surprisingly, therefore, the extraction analysis (which picks the 'value'-XP up from out of the *wh*-clause and raises it to post-copular position) has been abandoned in current GB-based work almost without exception – a notable non-conformist approach being presented by Bošković (1997a), which in a sense reverses the classic extraction analysis by lowering the 'value'-XP into the *wh*-clause (in covert syntax), thereby creating the simple sentence covertly out of its complex overt counterpart. Heycock and Kroch (1999) propose a different type of covert operation (later in the covert component, beyond LF 'proper') with the same effect of covertly reshaping the pseudocleft into its simple sentence paraphrase. We may refer to these two approaches jointly as follows:

- the covert reconstruction analysis (Bošković 1997a; Heycock and Kroch 1999).

All the various approaches to the (overt and covert) syntax of specificational pseudoclefts are meant to serve, in one way or another, the general purpose of accounting for the parallels between these and their simple clause counterparts – especially when it comes to connectivity/connectedness effects, which have played a major role in the discussion throughout the decades.

It is our purpose in what follows to give brief outlines of the various types of analysis of specificational pseudocleft constructions summed up in the previous paragraphs, with short discussions of their pros and cons (as they have been noted in the extensive literature on the construction). For detailed discussions, we refer the reader to the references provided at each point.

6.1 Deletion analyses

We will start our discussion with some remarks about the deletion analysis. It was first proposed by Peters and Bach (1968), and also adopted by Emonds (1970), Ross (1972a) and Seuren (1985); in recent years, Ross (1997), Den Dikken et al. (2000), and Schlenker (2003b) have revamped the account (the last-mentioned only for one particular subset of specificational pseudoclefts: their 'Type A' cases, which feature *wh* < XP exclusively, and are characterized by the fact that they and only they allow for NPI connectivity between the *wh*-clause and the post-copular 'value').

The deletion analysis is easy to describe in general terms. It assumes that the post-copular constituent of a specificational pseudocleft such as *What John read was novels* is a full-fledged clause corresponding to the clause contained in the *wh*-constituent in pre-copular position. Ellipsis rules subsequently come in to reduce the underlying full clause to that subpart of it which is pronounced on the surface:

(291) [[*What John read ec*] [*was* [~~*John read*~~ *novels*]]].

Ellipsis inside the full-clausal post-copular constituent is optional in principle: when it does not apply, the result is a specificational pseudocleft of the type in (292b), which, as Ross (1972a: 89, 1999) has stressed in particular (see also Clifton 1969: 38; Kayne 1998: 26; Den Dikken et al. 2000; Schlenker 2003b), is acceptable in spoken varieties of English – though this is a topic of some debate in the literature. To Higgins (1979: 86) these sentences sound "irremediably anacoluthic" (see also Blom and Daalder 1977: 20 for the claim that they are impossible in Dutch; but see Drubig 1997 for attested examples from German). But Seuren (1985: 297) declares in characteristically eloquent terms that "this construction type is extremely common in spoken English of all sociolinguistic levels, even though some who frequently use it will hotly deny that they do." See also the spontaneously produced examples in (249), from Geluykens's (1984) corpus-based study.[50]

(292) a. What John read was novels.
b. What John read was he read novels.

(249) a. All you do is you turn it in to the red mark.
b. All I did was I did Montaigne.
c. What you do is you look at the return.
d. What you do is you go.

The occurrence of full-clausal 'values' in specificational pseudoclefts serves as one of the key arguments for the deletion analysis.

Blom and Daalder's (1977) attempt as discrediting this argument for the deletion analysis based on the fact that the post-copular clause may not contain a complementizer (cf. **What John read was that he read novels*) has little force – it seems to be built on the premise that the only thing the post-copular clause could be is an *embedded* clause; but on Den Dikken et al.'s (2000) deletion analysis, it actually functions as the *root* of the pseudocleft construction as a whole.

Another argument that has been taken to recommend this analysis is the fact that it straightforwardly captures the links between specificational pseudoclefts and question-answer pairs. We discussed these links in section 5, above; see especially Den Dikken et al. (2000) for a detailed investigation of the parallels between the two construction types.

Apart from these considerations, Peters and Bach (1968) mention the grammaticality of such specificational pseudoclefts as (293) as a further argument in favor of the deletion analysis:

(293) What I saw was Mary.

On the deletion analysis, the selectional restrictions of the verb are met in both the *wh*-clause (by *what*) and the (underlyingly clausal) post-copular 'value' (by *Mary*); no clash in features will arise between *what* and *Mary*, simply because *what* is not actually a 'replacement' of *Mary* on the deletion analysis (it *would* be on the extraction analysis – see (309) below).

Blom and Daalder (1977: 17–18) (who also refer to Daems 1974: 85 in this context) take care to reject this argument for the deletion analysis, however. They stress that for them, the Dutch counterpart of (293) fails (cf. (294); note that Akmajian 1979: 99, n. 18 also notes that (293) for him is not perfect), and that even in English it is by no means generally possible to use *what* as the *wh*-word of specificational pseudoclefts with a [+human] 'value' (cf. (295)). What the facts show, according to Blom and Daalder, is that *what* works well in specificational pseudoclefts with a [+human] 'value' *only* on a 'non-specific' interpretation of the 'value' NP (paraphrasable as 'anyone who . . .' – see (296); cf. also Akmajian 1979: 100, n. 18: "*Mary* . . . is abstract in that particular context"). Blom and Daalder suggest (without elaborating) that this non-specific interpretation neutralizes the feature [+human] for the NP in question; and they then go on to point out that, if this is right, Peters and Bach's original argument in favor of the deletion analysis actually mutates into an argument *against* it: if we do find, after all, that there are general correspondences (when it comes to the feature [+human]) between the *wh*-word and the 'value', such is unexpected on a deletion approach to specificational pseudoclefts.

(294) *Wat we zagen was je moeder.
what we saw was your mother

(295) *What I amazed was Mary.

(296) a. Wat ze moeten zien te vinden is iemand met een rijbewijs.
what they must see to find is someone with a driver's license.
'What they will need to find is someone with a driver's license.'
b. Wat we nodig hebben is iemand met geld.
what we needy have is someone with money
'What we need is someone with money.'

So we see that one of the arguments presented in favor of the deletion analysis may actually turn against it in the end. Other problems for the account that have been noted include:

- *there*-sentences (cf. (297); Blom and Daalder 1977; Akmajian 1979):

  (297) a. What there was in the car was my hat.
  b. *There was my hat in the car.

- *do* (cf. (298); Blom and Daalder 1977):

  (298) a. What he did was kiss Mary.
  b. *He did kiss Mary.

These two arguments both assume that the post-copular 'value'-clause is identical in all respects with the *wh*-clause – it contains exactly the same lexical material found in the *wh*-clause. There is no *a priori* reason to expect, however, that semantically meaningless material in the *wh*-clause should be represented in the post-copular clause as well – once one assumes that the post-copular clause in (297a) and (298a) lacks the dummies (*there*, *do*) found in the *wh*-clause, the problems highlighted by the deviance of the b-examples do not present themselves. (See also Den Dikken et al. 2000: section 1.5 for discussion of 'indirect answer' pseudoclefts, in which there is no direct match between the IP in the *wh*-clause and the post-copular IP.)

(In connection with the *do* used in specificational pseudoclefts of the type in (298a) one may wonder whether it is a dummy verb or the lexical verb *do*. The fact that it combines with the dummy *do* in negative *wh*-clauses of specificational pseudoclefts and cannot itself host the negation shows that it is not the dummy *do*; on the other hand, the fact that – contrary to what is claimed in Collins 1991: 128 – it can combine with stative 'value'-VPs, as in Higgins's 1979: 194 (299), Heggie's 1988: 346 examples in (300), and Geluykens's 1984 (301), raises questions about the status of *do* as a lexical ('activity') verb:

(299) The very first thing he did when he got there was *be* rude to the chairman.

(300) a. What John did was *be* pampered by his mom.
b. What John did was *be* sick all day.

(301) The thing to do seems to me is to *be* eminently reasonable.

We leave the status of *do* in the *wh*-clause of specificational pseudoclefts for further research.)

An argument that is related to the previous one based on the distribution of *do* is the following, which concerns the possible occurrence of the infinitival marker *to* in the 'value' of specificational pseudoclefts with *do* in the *wh*-clause:

- *to* (cf. (302b); Heggie 1988: 346ff.):

  (302) a. What he did was write a letter.
  b. What he did was *to* write a letter.

From a deletion perspective, the occurrence of *to* in (302b) is unexpected: **He did to write a letter* is impossible. Plausibly, however, the *to*-infinitive in post-copular position in (302b) should be analyzed as a *nominal infinitive* (as in *To err is human, to forgive divine*). The categorial status of the 'value'-XP (the remnant of ellipsis) in the examples in (302a, b) would then be different; the former would involve a bare VP while the latter would feature a nominal *to*-infinitive. Analyzing the *to*-infinitive as a nominal infinitive still would not help one out on a 'pure' deletion approach to specificational pseudoclefts (*do* does not take nominal *to*-infinitival complements); but a deletion analysis is never forced for pseudoclefts whose 'value'-XP is nominal, on the assumption that a base-generation analysis is always available as an alternative in such cases (cf. the discussion in section 6.3, below): nominal constituents can readily be base generated across the copula.

Another objection that has been levelled at the deletion analysis in the literature concerns

- disagreement (cf. (303); Blom and Daalder 1977):

  (303) a. Wie daar staat ben ik.
  who there stands am I
  b. * Ik staat daar.
  I stands there

Here again (as in the case of *there* and *do*), the premise on which the argument is based is that there is complete formal identity between the *wh*-clause and the post-copular clause, and that hence an agreement problem arises in the latter (in the light of the deviance of (303b)). Agreement is a surface phenomenon, however. Even if verbs enter the syntactic derivation fully inflected (Chomsky 1995c), agreement will involve a checking operation that is performed late enough in the derivation to cause no trouble in (303a): by the time feature checking should be executed, the verb in the post-copular clause will already have been elided (cf. Lasnik 1995 on similar cases of avoidance of checking clashes as a result of ellipsis).

- lack of ambiguity (cf. (304); Blom and Daalder 1977):

(304) a. Wat hij zich aantrekt is het onschuldigste grapje.
what he se onpulls is the most-innocent joke
'What gets him upset is the most innocent joke.'
b. Hij trekt zich het onschuldigste grapje aan.
he pulls se the most-innocent joke on
'He gets upset by the most innocent joke.'

The upshot of this argument is that the fact that (304a) is not ambiguous (cf. section 3.2, above) while (304b) is, is unexpected if the post-copular constituent in the pseudocleft is in fact identical with (304b). This argument is valid in principle; but conceivably, the breakdown of ambiguity in (304a) could be blamed in its entirety on the *wh*-clause in pre-copular position, with reference to the fact that (for obvious reasons) *Wat hij zich aantrekt* 'What gets him upset' is not ambiguous in the way that (304b) is.

All in all, then, the empirical arguments concerned specifically with the *deletion* part of the deletion analysis are not overwhelming. What remains is the general question of the robustness of the connection between question-answer pairs and specificational pseudoclefts (see section 5, above); if, as proponents of the deletion analysis claim, this is indeed robust, it serves as an important argument in favor of this analysis – along with the fact that it provides a straightforward account of the connectivity effects characteristic of specificational pseudoclefts (which reduce to the dependencies found in simple clauses).

Some of the counterarguments that have been leveled at the deletion analysis are shared by the other transformational approach to specificational pseudoclefts, to which we turn next.

6.2 Extraction analyses

The extraction analysis of specificational pseudoclefts was first proposed by Chomsky (1972) (which first appeared in 1970) and Emonds (1970). The key ingredient of this analysis is the idea that the 'value'-XP of a specificational pseudocleft starts out as a constituent of an NP-dominated clause base generated in the subject position of the pseudocleft construction as a whole, and is raised into a post-copular position, which is generated empty. The analysis is schematically presented in (305):

(305) a. $[_S\ [_{NP}$ *it* $[_{S'}$ *that* . . . $[_{XP}$ 'value'] . . .]] $[_{VP}$ *be* ___]] → extraction →
b. $[_S\ [_{NP}$ *it* $[_{S'}$ *that* . . . [+PRO,+WH] . . .]] $[_{VP}$ *be* $[_{XP}$ 'value']]] → wh-fronting →
c. $[_S\ [_{NP}$ *it* $[_{S'}$ [+PRO,+WH] (= *what*) . . . ___ . . .]] $[_{VP}$ *be* $[_{XP}$ 'value']]]

The process of extraction of the 'value'-XP leaves behind a *wh*-pronoun (cf. [+PRO,+WH] in (305b)), the same kind of creature which early transformational

analyses of relativization postulated; this *wh*-pronoun is ultimately fronted to a position at the left edge of the NP-dominated S', replacing the complementizer *that* (cf. (305c)).

The extraction analysis runs up against a variety of theoretical and empirical problems, which have been duly noted in the literature (cf. esp. Higgins 1979; Blom and Daalder 1977). One clear theoretical difficulty concerns the cycle (though see Hankamer 1974 for the view that whatever derives specificational pseudoclefts must be a *post*cyclic rule: it does not feed raising, for example); but we will not belabor this point here (depending as it does on assumptions concerning the cycle and the nature of transformations which are specific to the theory in vogue at the time at which the extraction analysis was first proposed). Instead, we will draw attention to a theoretical issue which Blom and Daalder (1977) stress in their discussion of the vicissitudes of the extraction analysis: the fact that the extracted element is raised to a position which is not structurally superior to its extraction site, hence does not c-command the extraction site. This problem is insurmountable unless 'sideways movement' is allowed as a theoretical option (see Nunes 1995; Bobaljik and Brown 1997; Kayne 1999 for the suggestion that such movement is indeed feasible).

Moreau (1971) presents a variant of the extraction analysis which avoids this c-command problem, by reversing the underlying hierarchical relationship between the major constituents – rather than placing the 'variable' in subject position and base generating an empty slot in the complement of the copula, she generates the 'variable' in post-copular position, as the predicate of the construction. This allows her to raise the 'value'-XP out of the *wh*-clause into a position that does indeed c-command the extraction site: the subject position of the matrix clause. (Note that by generating the 'variable' in post-copular position as a predicate, Moreau's analysis is a precursor of Blom and Daalder's 1977 and Heggie's 1988 analysis of specificational pseudoclefts.)

Whatever the theoretical (de)merits of an analysis along the lines of (305) or its reverse counterpart (i.e., one in which 'NP' is the predicate in post-copular position), however, there are certain empirical properties of specificational pseudoclefts which threaten an analysis of these constructions strictly in terms of extraction. One is the fact that there are specificational pseudoclefts for which there simply is no simple clause counterpart – because of the fact that the *wh*-clause contains material which cannot occur in the simple clause paraphrase of the pseudocleft. Examples of this type typically involve *about*-PPs (cf. Green 1971; Higgins 1979; Heggie 1988):

(306) a. What I like *about Sara* is her courage.
b. *I like <*about Sara*> her courage <*about Sara*>.

An extraction analysis of specificational pseudoclefts would have to start out from the ill-formed (306b) and transform it into the grammatical surface output in (306a). (As long as it is less than crystal clear, however, what exactly is responsible for the deviance of (306b), it is difficult to assess the strength of this kind of

objection. Note, in any event, that the deletion analysis is immune to it: the post-copular IP would simply lack the *about*-PP from the start.)

Other threats to the extraction analysis are posed particularly by specificational pseudoclefts which, while exhibiting connectivity effects (which serve as an important argument for any transformational account), do not seem to make an extraction analysis available on theoretical grounds. Akmajian (1979), Higgins (1979), and Blom and Daalder (1977) draw attention to such constructions as (307–308) (cf. Akmajian 1979: 47 and 118):

(307) a. What there was next to *Bill* was {the/that} photograph of *himself* which was taken last summer.
b. *There was {the/that} photograph of *himself* which was taken last summer next to *Bill*.

(308) a. The one who has to protect {**myself*/*himself*} is *me*.
b. *I* have to protect {*myself*/**himself*}.

The problem with (307a) is that the 'value'-XP, because it is definite, would not seem to be generable inside the *wh*-clause; and (308) presents a clear person agreement problem: while the 'value' in (308a) is first person singular, the anaphor in the pre-copular 'variable' clause may only be third person singular. These facts are unexpected from an extraction perspective.

Higgins (1979: 121–122, n. 7) is "not convinced of the cogency" of the argument against extraction based on the *there*-sentences in (307). As he points out, "the 'picture-noun' *photograph* brings with it added complications. It seems to me to be equally acceptable if *himself* is replaced by *him*." Akmajian (1979: 93–98, n. 16) also suggests a possible ground for setting (307) aside as a problem for the extraction analysis: one might (as Ken Hale pointed out to Akmajian) want to assimilate (307a) to *there*-sentences with a 'list reading', which likewise form an exception to the indefiniteness requirement on *there*-sentences (cf. the fact that (307b) with a word order in which the associate of *there* is clause final and set off from what precedes it by 'colon intonation' is grammatical). Akmajian ultimately rejects this option, but in the light of the close kinship of specificational sentences and lists (cf. Higgins 1979), it would certainly be worth investigating further. At the very least, we should conclude from the above that the problem for an extraction analysis posed by *there*-sentences of the type in (307a) is not insurmountable.

Perhaps more interesting is the problem posed by (308), which concerns agreement in phi-features between the anaphor and the 'value'-XP. If the post-copular focus in (308a) were to be base generated inside the relative clause and raised to post-copular position via extraction, one would not expect the anaphor to be *himself*; instead, one would expect *myself* (but *myself*, while good in (308b), is entirely impossible in (308a); cf. Akmajian 1979: 119). The force of this argument is substantially reduced, however, by Akmajian's (1979: 120–121) observation that when the order of examples such as (308a) is *reversed* the anaphor *can* agree in all phi-features with its clause-external antecedent (though it does not have to):

(308) a'. *I* am the one who has to protect {*myself*/*himself*}.

There are three different reflexivization patterns, therefore: the one represented by the simple sentence in (308b) (with full phi-feature agreement as the only option), the one seen in the specificational pseudocleft with a post-copular 'value' in (308a) (with obligatory person disagreement), and the one found in pseudoclefts with a sentence-initial 'value' such as (308a') (where both possibilities deliver a grammatical result). Akmajian (1979: 121) takes these facts to "suggest that the reflexive forms in [(308)] arise under certain surface structure conditions" (which, he adds on p. 123, he does not understand). If he is right that we are dealing here with a surface phenomenon, the reflexive agreement facts tell us little if anything about the underlying representation of specificational pseudoclefts – they would be compatible, therefore, with an extraction approach. We will take the reflexive agreement argument to be moot, therefore – though it may ultimately support Akmajian's dual analysis of specificational pseudoclefts like (308a'): person agreement would be obtained via extraction, lack of agreement via base generation.

More importantly, however, there is one clear indication that an extraction analysis – whatever its merits for those cases to which it is indeed applicable – will not be sufficient for the entire battery of specificational constructions. In particular, it will fail to capture the parallelism between specificational pseudoclefts and other specificational copular sentences. This point is raised by Akmajian (1979: 51–52), Blom and Daalder (1977: 59–60), and Heggie (1988), among others (cf. also Higgins 1979: 145–149). Consider the following pair:

(309) What *John* contributed was a poem about *himself*.

(310) *John*'s contribution was a poem about *himself*.

As is clear from the examples, simple specificational copular sentences exhibit the same connectivity effect with respect to anaphors which pseudoclefts display. If one believes that connectivity effects are an argument for an extraction analysis, therefore, one seems forced to adopt a complex clausal analysis of nominalizations like *contribution* in (310). Chomsky (1970), however, has presented cogent evidence against such an approach to nominalizations. An extraction approach to (310) will hence be unavailable; consequently, anaphor connectivity cannot be used as an exclusive argument for an extraction analysis.

It is particularly in the light of the parallel between (309) and (310) that Akmajian (1979) comes to the conclusion that a base generation analysis for specificational sentences should be available as well. We will turn to this kind of analysis in the next section.

6.3 Base generation analyses

Throughout the decades, the base generation analysis has served as a home base for scholars who found that transformational approaches to specificational

pseudoclefts fail to be descriptively and explanatorily adequate. Higgins (1979) adopts such an account, and so do Blom and Daalder (1977); both also mention the similarities between their base-generated structures of specificational pseudoclefts and the structure of specificational copular sentences in general. As Akmajian (1979), who adopts the base generation analysis for a subset of specificational pseudoclefts, points out in various places, the base source is a structure which "there is no non-ad hoc way of preventing" (p. 32; also cf. p. 38) in any event; so one would certainly expect it to exist.

Akmajian (1979) argues for a dual approach to specificational pseudoclefts: one analysis derives them transformationally from their simple clause counterparts (via extraction; see section 6.2, above), the other generates the specificational pseudocleft in the base. The base generation analysis is argued to be required for those kinds of specificational pseudoclefts for which an extraction analysis would run into trouble:

- [±human] clashes (cf. (293)),
- *there*-sentences (cf. (307)),
- agreement clashes (cf. (308)).

For Akmajian, specificational pseudoclefts with 'value'-XPs whose categorial status is NP are always ambiguous in principle between an extraction analysis and a base-generated structure. But specificational pseudoclefts with non-NP 'values' are not derivable via base generation, according to Akmajian: there are no non-cleft specificational sentences with non-NP post-copular constituents:[51]

(311) a. What John did was kiss Mary.
b. *John's action was kiss Mary.

When it comes to the analysis of connectivity effects (the key argument for transformational approaches), Higgins's (1979: ch. 3) base generation approach looks for the account in the realm of 'the meaning of specification' (rather than in the workings of some transformation), and points out that such an approach has the advantage of predicting, correctly, that connectivity arises in specificational constructions regardless of the verb used (mentioning the occurrence of connectivity with *lie in*, *consist in*, *constitute* in support of this prediction; p. 99). Faced with this, a transformational analysis would need to mention explicitly a list of verbs which 'trigger' the transformation involved; and that list would be arbitrary, according to Higgins, unless the meaning of specification can somehow be referred to – but once one needs to refer to the meaning of specification anyway, one might as well derive the connectivity effects directly from it *without* postulating a transformation to derive the pseudocleft construction, so Higgins's argument goes. In other words, "a transformational analysis would be not merely clumsy but also unnecessary" (p. 117).

Higgins's own attempt to account for them purely in terms of the semantic notion of 'specification' remains rather vague, however. He states explicitly (p. 97)

that when it comes to the analysis of reflexive connectivity, at least two factors are involved:

(i) "the establishment of some designated noun phrase in the subject clause which can act as a controller (in Postal's sense (1970: 443))";
(ii) "the application of the properties of specification to the semantic reading so that the controller is specified as the understood subject of the predicate complement phrase."

But when it comes to "devising mechanisms for establishing understood subjects in the complements to nominalizations" (p. 98), he leaves the details open. Blom and Daalder (1977) are quite a bit more explicit in this regard. They develop an analysis which, recast in present-day theoretical terminology, hinges on postulating a null subject PRO inside the post-copular constituent:

(312) a. What *John* should do is [PRO protect *himself*].
b. What *John* was reading was [a PRO story about *himself*].

Assigning specificational pseudoclefts structures of this type will make it possible to use the pro subject of the 'value'-XP as an intermediary in the establishment of the interpretive relationship between subconstituents of the *wh*-clause and the post-copular XP.

It predicts, at the same time, that the only contexts in which specificational pseudoclefts could feature connectivity effects are the ones in which these effects can be mediated by a PRO. Blom and Daalder themselves present this as a correct prediction: they point out that anaphor connectivity breaks down in examples in which the 'value' is *constituted* by the anaphor itself (cf. their examples in (313)); and they also claim that connectivity with respect to negative polarity item licensing is impossible (at least in Dutch; cf. their (314) and (304), the latter repeated from section 6.1):

(313) a. ?*Wie hij op het oog had is *zichzelf*.
who he on the eye had is himself
b. *Wie zij tartten was/ waren *elkaar*.
who they pestered was were each other

(314) a. Hij weigerde *ieder* geneesmiddel.
he refused every medicine
b. *Wat hij weigerde was *ieder* geneesmiddel.
what he refused was every medicine

(304) a. Wat hij zich aantrekt is het onschuldigste grapje.
what he se onpulls is the most-innocent joke
'What gets him upset is the most innocent joke.'
b. Hij trekt zich het onschuldigste grapje aan.
he pulls se the most-innocent joke on
'He gets upset by the most innocent joke.'

As we pointed out in section 3, however, each of these empirical claims is problematic – it is not in general impossible for anaphors to constitute the 'value' of specificational pseudoclefts; and connectivity effects exist for a variety of phenomena other than anaphora. And even if Blom and Daalder's (1977) claims about Dutch were entirely accurate, one would still be in need of some other approach to connectivity for languages other than Dutch.

We should mention here as well that Higgins (1979) explicitly takes issue with an Equi-NP Deletion (i.e., Control) approach to anaphor connectivity effects in specificational sentences. Referring to Chiba (1971), he states that it would be impossible to postulate a PRO subject for the post-copular constituents in the examples in (315):

(315) a. *John*'s biggest worry is having to photograph *himself* without a tie on.
b. The greatest source of embarrassment that *John* has to endure is having to photograph *himself* without a tie on.

If Chiba and Higgins are right on this score, the prospects for a control approach to anaphor connectivity in specificational copular sentences are gloomy – and at best, a control approach would be a way of moving the problem into a different department anyway: after all, once one postulates a PRO subject inside the 'value'-XP, one will need to face the question of how this PRO, in turn, could be controlled by a subconstituent of the 'variable'.

If a syntactic approach along the lines of control fails, therefore, other ways of capturing the connectivity effects on a base generation analysis should be found outside the syntax. Higgins (1979) makes vague suggestions along these lines (as we have seen); more specific proposals are found in Jacobson (1995) and Sharvit (1997a), where connectivity in specificational pseudoclefts is treated as a purely interpretive phenomenon, arising wholly without syntactic c-command. In their approach, binding dependencies and other such dependencies involved in the domain of connectivity are viewed as side effects of semantic composition – an area in which the semantic properties of *what* and *be* play a key role. (We refer to section 1.5, above, for remarks about the semantic vacuity of the copula. If the discussion there stands up to careful scrutiny, it counts as an argument against semantic approaches which attribute an important role to the semantic properties of *be*.) We will not discuss these semantic accounts to the general problem of connectivity any further here.

6.4 Reconstruction analyses

Recent (principles-and-parameters) approaches to specificational pseudoclefts have largely adopted a base generation analysis (see Heggie 1988; Iatridou and Varlokosta 1998; Alexiadou and Giannakidou 1998; also the semantically oriented, syntactically simple approaches in Jacobson 1995; Sharvit 1997a), eschewing the postulation of movement operations which would raise the 'value'-XP from out of the *wh*-clause into a position on the other side of the copula – operations which

would contravene broadly accepted views on what constitutes possible movement (but cf. the discussion in section 6.1, above, on the possibility of 'sideways movement'). Apart from the re-emergence of the deletion analysis (in Den Dikken et al. 2000; Schlenker 2003b), however, there are two noteworthy exceptions to the base generation approach in the recent literature – Bošković (1997a) and Heycock and Kroch (1999). Both propose a kind of analysis which we may characterize as the reconstruction approach – the simple sentence paraphrase is 'reconstructed' out of the complex surface construction. In a sense, these reconstruction approaches (esp. Bošković's) are the opposite of the early transformational analyses. But even though they are motivated by the same overall desire (viz., to capture the connectivity effects manifest in specificational pseudoclefts), in the details of their execution they are quite different – both from the early transformational accounts and from one another. We will discuss them one by one.

6.4.1 Move at LF (Bošković 1997a)

Bošković (1997a) presents an analysis of specificational pseudoclefts which is based on the idea that the *wh*-element in the *wh*-clause is replaced with the 'value'-XP at LF as a result of Move.[52] Replacement of *what* is triggered by the assumption that what *what* is is a 'surface anaphor' in the sense of Hankamer and Sag (1976) – an anaphor that has to be replaced by its linguistic antecedent at some level of representation. (See Lødrup 1994 for related discussion of Norwegian *det*.)

(316) a. Hankamer: I'm going to stuff this ball through the hoop.
Sag: I don't think you'll be able to do *it*/*so*.
b. [Hankamer is trying to stuff a ball through a hoop]
Sag: I don't think you'll be able to do *it*/**so*.

Just like *so*, but unlike *it*, the *what* of a specificational pseudocleft needs a linguistic antecedent, and must be replaced by this antecedent by the end of the derivation. Bošković takes the point at which such replacement obtains (in any event in pseudoclefts) to be LF. At LF, therefore, the representation of a specificational pseudocleft will no longer contain *what* – in its place we find the 'value'-XP which appeared on the other side of the copula in the overt syntactic structure; this XP is moved into the *wh*-clause via Move.

With the 'value' at LF inside what used to be the *wh*-clause, the connectivity effects will follow, so the argument goes. But note that for NPI connectivity, things seem to happen 'too late': negative polarity items generally want to be c-commanded by their licensors at S-structure – cf. the ungrammaticality of (317a), from Den Dikken et al. (2000: 50): though reconstruction is possible in this kind of context (cf. the grammaticality of (317b)), negative polarity item licensing nonetheless fails here.[53]

(317) a. *Which charges that he_i concealed *anything* would every $President_i$ *deny*?
b. Which charges that he_i concealed something would every $President_i$ deny?

One of Bošković's (1997a) key arguments for the idea that the 'value' is actually moved via an instantiation of the syntactic operation Move is the fact that extraction of and from the 'value' is impossible (cf. section 3.2 for discussion):

(318) a. I think that what caused the riot was a picture of the wall.
b. *What do you think that what caused the riot was *ec*?
c. *What do you think that what caused the riot was a picture of *ec*?

For Bošković, the cause of the ungrammaticality of (318b, c) lies in a general restriction on Move: it is impossible, in general, to have Move apply either to a trace or to a constituent containing a trace. (318b, c) fall under this restriction – at LF, Move will need to replace the *what* of the pre-copular *wh*-clause with the 'value'-XP; but at that time, the 'value'-XP has already been reduced to either a trace (318b) or a constituent containing a trace (318c), as a result of overt-syntactic *wh*-extraction. The ban on movement of (constituents containing) traces thus makes it impossible for the *what* of the pseudocleft to be replaced in (318a, b), which is why these examples are ungrammatical.

Den Dikken et al. (2000: 64) find fault with this account of (318) (which, in any event, is by no means an exclusive argument in favor of the Move analysis; see section 4.3.2 for other approaches) by pointing out that *covert* extraction from the 'value'-XP is also impossible in specificational pseudoclefts:

(319) a. *Who thinks that what caused the riot was which picture of the wall?
b. *Who thinks that what caused the riot was a picture of which wall?

Here, there has been no overt-syntactic extraction from the 'value'-XP: the *wh in situ* will not move toward the overtly extracted *wh*-element *who* until LF. There should be no problem, therefore, with a derivation of (319) which first has the intact 'value' replace *what* (by which the pseudocleft is reshaped into a simple clause) and subsequently performs LF *wh*-movement on (a subconstituent of) the 'value'. Hence there is no reason, on Bošković's analysis, to expect there to be anything wrong with (319) – contrary to fact.

The ban on movement of a constituent containing a trace, Bošković argues, is also responsible for the ungrammaticality of the examples in (320) (cf. also Higgins 1979: 67):[54]

(320) a. *What John gave was Mary a book.
b. *What John gave was a book to Mary.

Bošković follows Larson (1988b) in assigning a structure to triadic constructions according to which they contain two VPs, the lower one of which includes the direct and indirect objects and *a trace of the verb*. It is precisely this lower VP that one would need to move into the *wh*-clause to derive the examples in (320) – and since one is not allowed to move a constituent containing a trace, the ungrammaticality of these examples follows directly.

Once again, however, this argument for a Move derivation overlooks an essential fact. For, as Den Dikken et al. (2000: 78) point out, examples of the type in (320) become grammatical once the *wh*-clause of the pseudocleft is given *two* variables – one corresponding to each of the two post-copular objects:

(321) ?What John gave to whom was (John gave) a book to Mary and a CD to Sue.[55]

The ungrammaticality of (320) thus turns out to have nothing to do with restrictions on Move – instead, it is a consequence of the lack of parallelism between the *wh*-clause and the post-copular 'value' (see also Boeckx 1998). In this respect, (320) seems to be on a par with Akmajian's (1979: 26) examples in (322b, c):

(322) a. What I forced Bill to do was leave.
b. *What I forced was Bill to leave.
c. *What I forced Bill was to leave.

Den Dikken et al. (2000: section 4.2) draw attention to a variety of other 'parallelism effects' in specificational pseudoclefts, largely shared by question-answer pairs. (320) thus by no means stands on its own.

As far as we can see, there are no properties of specificational pseudoclefts which argue unambiguously in favor of a LF Move approach to these constructions as proposed by Bošković (1997a). On the other hand, there do exist some general considerations which suggest that such an approach (regardless of the theoretical vicissitudes of the instantiation of Move that this analysis needs to invoke) is presumably not on the right track. These considerations are all concerned with the fact that Bošković's analysis turns on an instance of Move which is triggered by a property of the *wh*-element *what*, which he treats as a surface anaphor in the sense of Hankamer and Sag (1976).

Interestingly, *what* is the *wh*-counterpart of *it* – and *it*, unlike *so* (which does have the property of being a surface anaphor), is not a surface anaphor (but a 'deep' one instead): as (316b) shows, *it* can take a situation as its antecedent; it does not need a linguistic antecedent, hence does not need to be (in fact, cannot be) replaced at LF. Given the morphological link between *it* and *what*, it is at the very least surprising that (if Bošković's approach to *what* is right) the two should part ways so radically when it comes to the 'deep/surface anaphor' dichotomy.

Surprising as well is the fact that, even though it is true that *what* is by far the most common *wh*-element in specificational pseudoclefts, it is not just *what* that can be used in these constructions – see section 2.1 for examples featuring *wh*-words other than *what*. Though in actual fact it is basically only *who* that is practically impossible in specificational pseudoclefts, Bošković predicts that only *what* should be permissible.

Even more importantly, the fact that Bošković's analysis of specificational pseudoclefts is built entirely on a property of the *wh*-element *what*, which is absent from non-cleft specificational sentences, prevents it from extending to the larger set of specificational copular sentences. Such an extension is nonetheless

called for, in the light of the syntactic and semantic parallels between specificational pseudoclefts and their non-cleft congeners (see the discussion in section 3 for a list of such parallels).

It is in the light of general considerations like this that we should conclude that an LF Move analysis of specificational pseudoclefts along the lines of Bošković (1997a) must be rejected.

6.4.2 *Iota reduction (Heycock and Kroch 1999; cf. also Partee 1986; Guéron 1992, 1993)*

Recall from section 4.1.1, above, that for Heycock and Kroch (1999), specificational pseudoclefts are equative copular constructions (cf. 'identity statements'). Such an approach to their deep and surface syntactic structure does not give one a handle on the connectivity effects exhibited by these constructions, it would seem. So, Heycock and Kroch (1999: 388) argue, "the connectedness effects in pseudoclefts are evidence that neither surface structure nor anything close to it can be the level at which crucial aspects of semantic interpretation are determined." They postulate "a quite abstract level of logical form" at which "pseudoclefts must have a structure identical in relevant respects to that of their canonical paraphrases."

The essence of Heycock and Kroch's (1999) analysis is aptly summarized with the aid of the above quotations. What is left to be determined is how the surface syntactic form of specificational pseudoclefts can be converted into a 'logical form' representation which is similar to that of their simple clause paraphrases, such that the connectivity effects can be accommodated.

Heycock and Kroch propose a semantic representation of specificational pseudoclefts which is obtained via 'iota abstraction'. In this regard, their approach is very similar to that of Guéron (1992, 1993), which also postulates an iota operator in the *wh*-clause of specificational pseudoclefts,[56] and has this variable replaced (just as in Heycock and Kroch's approach) at a very late and abstract point in the derivation (her metalinguistic level of the *commentaire*). Though different in detail, the Guéron and Heycock and Kroch approaches are of kindred spirit; we will key the discussion to the latter, more readily accessible paper.

Following Jacobson (1995), Heycock and Kroch take the *wh*-clause of a specificational pseudocleft to be a noun phrase with the semantic denotation of an individual rather than a set – in particular, the *wh*-clause/free relative *what Fiona bought* in the specificational pseudocleft in (323) is taken to "denote the maximal individual (a plural individual in the sense of Link (1983)) of which the sentence *Fiona bought y* holds." The semantic representation of *what Fiona bought* thus reads as in (324), and the concomitant semantic representation of the entire pseudocleft in (323) as in (325):

(323) What Fiona bought was that ancient dictionary.

(324) ιy[Fiona bought y]

(325) ιy[Fiona bought y] = 'that ancient dictionary'

Crucially, now, the Russellian 'iota operator' used in (324), defined as in (326), will allow us to alter the structure in (325) by applying the definition in (326) to the equative formula. Via this procedure (dubbed 'iota reduction' by Heycock and Kroch), the iota operator is eliminated from the representation in (325), and the iota-bound variable is replaced with the 'value' of the pseudocleft. The result is as in (327):

(326) ιy[f(y)] denotes a iff f(a) and ($\forall z$)(f(z) iff $z \leq a$)

(327) Fiona bought that ancient dictionary and ($\forall z$)(Fiona bought z iff $z \leq$ 'that ancient dictionary').

What we now have is a representation of (323) which, as its first conjunct, contains precisely the simple clause of the pseudocleft's paraphrase. (327) which will therefore allow us to capture the connectivity effects of specificational pseudoclefts – *if* we can ensure that the dependency relations involved in the relevant set of connectivity effects all apply no sooner than at the level of the grammar at which (327) is obtained (and if the second conjunct of (327) can be eliminated from the logical form relevant for connectivity; but as Heycock and Kroch point out later in their discussion, that second conjunct is actually unnecessary, so we need not be concerned with this condition).

It should be noted that 'iota reduction' must be taken to be obligatory – for pseudoclefts feature no 'antireconstruction effects': Principle C effects are not circumvented in these constructions (cf. **What he_i had said to Mary was that she had been lying to $John_i$*; see section 3.2). The same is true for specificational sentences in general. One must assume, therefore, that (i) 'iota reduction' applies to all specificational sentences (regardless of whether they feature a *wh*-clause or not; i.e., noun phrases like *Fiona's purchase* must have a representations of the type in (324), which 'iota reduction' takes as its input); *and* (ii) the only representation of specificational sentences which is available at the interface with the conceptual system is the one obtained by 'iota reduction'.

The point at which 'iota reduction' takes place is a very late one – it must be, according to Heycock and Kroch, since its effects are noticeable even across stretches of discourse (cf., e.g., question-answer pairs; see Heycock and Kroch 1999: 390–391, and also section 5, above). In other words, "the syntactic derivation of the LF interface representation relevant for such phenomena as binding follows operations that are part of discourse interpretation" (Heycock and Kroch 1999: 391).

Heycock and Kroch's (1999) approach to connectivity effects thus relegates them to a late stage in the derivation of the semantic representation of specificational sentences. The desired connection with the simple clause paraphrases of specificational pseudoclefts is obtained as a result of the operation of 'iota reduction' performed on the logical formula of equation that is part of the semantic representation of all specificational sentences – *all* specificational sentences, regardless of their surface word order.

This account of connectivity effects in specificational copular sentences (and across discourse chunks as well; cf. Heycock and Kroch's 1999: 390–391 discussion of question-answer pairs) hence predicts that such effects should be totally oblivious to linear order. As Den Dikken et al. (2000) stress, however, there are connectivity effects in these constructions which are highly sensitive to the relative order of the 'variable' and its 'value' – NPI connectivity effects, to be specific: *What nobody bought was any wine* is grammatical while **Any wine was what nobody bought* is not.[57] It is true, of course, that not all connectivity effects in specificational sentences are sensitive to word order; in fact, the bulk of them are not. But an overall approach to connectivity effects in specificational sentences which relegates *all* of them exclusively to a late discourse-semantic level of representation will not be able to make the desired cut.

Of course, the lateness of 'iota reduction' also makes Heycock and Kroch's (1999) analysis run up against the same problem which we noted in the previous subsection for Bošković's (1997a) approach: the fact that, in general, NPIs need to be c-commanded by their licensors at S-structure (see (317)).

Thus, while it seems likely that many of the connectivity effects known from the literature could and probably should be dealt with at a semantic level of representation, semantic accounts of connectivity will need to be supplemented by a (presumably syntactic) analysis of the fact that some of these connectivity effects (notably, NPI connectivity) have a much more limited distribution than a general 'reconstruction' or 'iota reduction' approach would lead one to expect. A dual, syntax-and-semantics analysis of specificational pseudoclefts along such lines is the ellipsis approach proposed in Den Dikken et al. (2000). It makes immediate sense of the contrast in (328) (on account of the fact that full-clausal 'values' are systematically impossible in the pre-copular position of specificational pseudoclefts), and relegates order-insensitive connectivity effects to a semantic (or even 'metalinguistic') level – perhaps indeed via something like Heycock and Kroch's 'iota reduction', or for that matter Bošković's LF reconstruction (Jacobson 1995; and Sharvit 1997a present alternative semantic perspectives).

ACKNOWLEDGMENT

The author would like to thank Jacqueline Guéron and Caroline Heycock for their detailed comments on a previous manuscript.

NOTES

1 Blom and Daalder (1977: 77) seek to support their approach with reference to the claim that the post-copular noun phrase of such constructions is *pronominalized* with *it* rather than *(s)he* – a claim which they illustrate for Dutch with the aid of (i), which, however, is not an unequivocal case of an identity statement. The argument fails to be convincing, therefore.

(i) Is hij de burgemeester van Amsterdam? Nee, maar hij wordt *het*/**hij*/**hem*.
Is he the mayor of Amsterdam? No but he becomes it/he/him.

2 Declerck also claims that the Blom and Daalder type approach to specificational sentences (which treats them as predicational underlyingly) is incompatible with Givón's (1973: 119) universal that "a predicate may never be less general than its subject" – but this is a mistake on Declerck's part: for advocates of the inversion approach to specificational copular sentences, the pre-copular NP_1 (the hyperonym) is indeed the predicate underlyingly, with the post-copular NP_2 (the hyponym) being its subject.

3 Guéron (1992) makes a difference between the *récit* and the *commentaire*, two levels of interpretation (a distinction which does not correspond to that between overt syntax and LF). In the *récit* of an inverse (specificational) copular sentence like *The culprit is John*, the copula is a part of the predicate, along with the non-verbal part; in the *commentaire* (a "metalinguistic" level, according to Guéron) it is an identificational operator.

4 As Partee (1999) points out, "in the Slavic literature, it has long been noted that insofar as differences in the semantics of different copular sentences can be predicted from differences in the semantics of the 'arguments' of the copula, it should not be necessary to posit ambiguities in the copula itself"; she refers to Chvany (1975) and Padučeva and Uspenskij (1979) in this context.

Irrelevant in the context of specificational copular sentences and pseudoclefts but significant in the broader context of copular sentences in general is the fact that languages may use different linker elements in copular sentences with an individual-level predicate (like *intelligent*) and ones with a stage-level predicate (like *sick*). Spanish and Portuguese are such languages (cf. the *ser*/*estar* distinction, where *estar* goes back to the Latin verb *stare* 'stand'). We will not be concerned with this question here. See Schmitt (1996) and references cited there for discussion of the distribution of *ser* and *estar*.

5 The term is spelled variably as "pseudo-cleft" (cf., e.g., Huddleston 1971; Akmajian 1979; Higgins 1979) or "pseudocleft" (cf. more recent work); we will use the non-hyphenated spelling in what follows.

6 (28) is taken from Ross (1999), where the 'nouniness' of *Jerry drunk* is noted (cf. Safir's 1983 'Honorary NPs').

7 On the scope of the term 'pseudocleft' (or '*wh*-cleft'), see section 2.4.

8 Reversal of the order of (44a) is not ungrammatical, however; but when reversed (*What I need is that*) it takes on the guise of a specificational pseudocleft, and is not identificational/descriptionally identifying anymore.

9 The term 'discontinuous pseudocleft' is adapted from Declerck (1988: 222), who uses 'discontinuous cleft'; the adjective 'discontinuous' does not refer to discontinuous constituency; though Declerck does not elaborate on the rationale for using this adjective to define pseudoclefts of the type in (48), what seems to be behind this term is the fact that in these constructions *both* the focus *and* the *wh*-clause are accented and represent new information, as indicated in (49).

10 For the meaning of this term and other names for the relevant constituent, see (53) and the text immediately following it.

11 Note in this context that it is precisely the link between specificational pseudoclefts and question-answer pairs that has led Declerck 1988: 8 to call the answer clause of a question-answer pair such as *Who opened the door? – John opened the door* a 'specificational sentence' (i.e., for Declerck, the scope of the term 'specificational sentence'

includes non-copular answers to questions; see also Akmajian 1979: 178–180 for a wider application of the term 'specificational' than the one used here). Declerck's extension of the term 'specificational' mistakes the 'value'-XP (the answer) for an entire 'variable-value' pair – *John opened the door* is not a specificational sentence per se: it is the 'value' of a specificational question-answer pair.

12 A problem arises here only for specificational readings of (58a); predicational and identificational copular sentences never invert to begin with (cf. (17) and (19) above). Declerck treats (58a) with *captain of the team* as a specificational copular sentence and has no answer to the question of why (58b) is ungrammatical; Higgins (1979) analyzes the same sentence as an *identificational* copular sentence; a third (and plausible) option is to treat it as a garden-variety predicational copular sentence.

13 Den Dikken et al. (2000) give XP < *wh* pseudoclefts with full-clausal 'values' a * uniformly (though they do not mention cases with *do* in this context). Ross (1999, 2000) notes the contrast between *bought* and *did* in (59b), and points out furthermore that not all speakers seem to reject (59b) even with *bought* (though it does seem to be substantially worse than both (59b) with *did* and (59a)). Ross (1999) makes the further observation that, for those speakers for whom (59b) with *bought* is good, the construction can be input to Sluicing as well, yielding sentences like (i), which are "used only in colloquial spoken English".

(i) %He bought some wine, is what.

14 The contrast in (60) is due to Heggie (1988). Not all speakers find this contrast equally strong, however – some, in fact, find it very weak at most. Pseudoclefts with *how* are usually not very good to begin with; for many speakers the choice of word order does not seem to add further complications above and beyond the use of a *how*-pseudocleft.

15 When reversed, specificational copular sentences (double-NP and pseudocleft alike) resist deletion of the pre-copular constituent (Ross 1999): **even if ___ tofu, what he likes is interesting*; **even if ___ John, the best candidate is not very intelligent*.

16 The data in (71–72) are from the published sources mentioned; many speakers find (72b) with *someone* grammatical, on a par with *I doubt that someone needs this money* – positive polarity items like *someone* are generally allowed to scope below extraclausal NPI-licensers like *doubt* (cf. Von Fintel 1999). The key fact in (72b), however, is the grammaticality of *anyone*.

17 Though more like a 'free choice item' (FCI) than like an NPI, this reading qualifies as a polarity reading on the understanding (see Giannakidou 1998) that FCIs are polarity items.

18 The contrast between *say* and *say to me* is reported in Hankamer (1974); not all speakers share this judgment, many finding the example perfectly acceptable with *to me* included. It remains unclear how to account for the contrast if it is real.

19 In Akmajian (1979: 169), the asterisk on (100c) has inadvertently been omitted.

20 The a- and b-examples in (101) are taken from Akmajian (1979); (101c) was added here, for the sake of completeness.

21 The examples and judgments here are taken from the sources given; not all speakers seem to agree.

22 Dayal (1997) presents the grammaticality of ?*Whatever she bought was not Barriers* to refute the claim that the *wh*-clause of specificational pseudoclefts does not allow *-ever*. Her example does not seem to instantiate a specificational pseudocleft, however: (i) it features sentential negation, which is otherwise impossible in specificational

pseudoclefts (cf. (111)); (ii) it is irreversible (cf. **Barriers was not whatever she bought*); and (iii) it is uniformly deemed unembeddable under ECM-verbs taking *to*-infinitival complements (cf. **I consider whatever she bought not to be Barriers*, to be contrasted with %*I consider what John is to be important to himself*, which, though judgments vary substantially, is acceptable to at least some speakers; see item (xix) in section 3.4, below).

23 See Seuren (1985: 297) for the observation that the same quantificational restrictions hold of *in situ* foci: *Henry sold (*few) postcards*; and see Declerck (1988: 87–88) for contexts in which these restrictions on specificational sentences can be alleviated.

24 Collins capitalizes both *poured* and *Tom*, but this reflects an intonation contour which seems very awkward for (120b). We assume the capitalization of *Tom* was an error and have taken the liberty of correcting it here.

25 The text discussion reproduces Declerck (1988: 32), where the definiteness and singularity of the variable is capitalized on. Notice, however, that adding *only* to the examples in (123), which do not have definite singular variables, is equally bad with the word order given there (**An example of this kind is only Word War II*). When reversed, (123) does allow the addition of *only* to the 'value' (cf. *Only World War II is an example of this kind*). Here is where a difference between (123) and (124) continues to manifest itself: **Only my neighbour is the one who murdered Smith* is impossible.

26 Note, however, that Seuren's (126b) is a marked construction: as Higgins (1979: 321) points out, root negation in specificational pseudoclefts triggers a 'contradiction negation' reading; it is this which may be responsible for the truth-conditional effect noted by Seuren with reference to negated pseudoclefts. See item (vi), example (111), above.

27 One might question the status of these Spanish examples as genuine pseudoclefts. An alternative analysis of them as cleft sentences (with a null counterpart of *it*; Spanish is a *pro*-drop language) is readily conceivable; cf. Higgins's translations in terms of *it*-clefts.

28 If indeed it is a fact – the specificational reading, while perhaps dispreferred, does seem to be available for (136b): cf. *Where John is going is that city over there*, which seems acceptable, features P-drop, but cannot be predicational.

29 Ross (1999) mentions in the context of (158) and (161) the impossibility copula-drop in absolutive constructions with *wh* < XP pseudoclefts (cf. (i) below). Double-NP specificational copular sentences seem to be grammatical with copula-drop in these contexts only on their canonical order (cf. (ii)). This potentially enhances a parallel treatment of *wh* < XP specificational pseudoclefts and inverse specificational copular sentences (cf. Heggie 1988):

(i) a. With what he likes *(being) tofu, I doubt that he'll pass.
b. *What he likes tofu?!

(ii) a. With John (being) the murderer, . . . with the murderer *(being) John, . . .
b. John the murderer?! *The murderer John?!

30 Notice, though, that inserting *only* in front of *the conversion of chloride ions into hypochlorite and hydrogen ions* is grammatical. In the light of the discussion under item (xi), above, this would seem to indicate that (165a) is not (necessarily) a specificational pseudocleft.

31 Related to this case is the one in (ib) below, also from Ross (1999), involving comparative ellipsis. Ross also mentions the ungrammaticality of subject deletion (**Even if* __

tofu, what he likes is interesting; **Though __ a drunk, what he was is well-known*); this is common to reverse specificational copular sentences as a class (**Though ___ John, the best candidate is intelligent*); n. 15.

(i) a. Barbara is more often a sadist than Bartholomew is.
b. *What he writes is more often that he is brilliant than what he says is.

32 The ungrammaticality of the primed examples in (170) and (171) is not surprising in the light of the exhaustiveness reading which characterizes specificational sentences; see item (xi) above.

33 The status of *?Is your best friend John?* seems to be somewhat degraded, however (Jacqueline Guéron, p.c.; she suggests that the difference between (174c) and the example just mentioned may have to do with the animacy of the first of the two NPs).

34 Akmajian points out, though, that his 'predicational operator [is]' occasionally links the variable and the focal material of specificational pseudoclefts as well.

35 It should be noted, however, that in the tree structures in his first chapter Akmajian does systematically label the post-copular node 'Pred' – cf., e.g., pp. 27, 40.

36 It should be noted, of course, that their analysis was exclusively designed for Dutch; it is only in a brief appendix that they consider the possibility of extending it to English.

37 See Moro (1997) for discussion of the difference between English and Italian; see Den Dikken (1997) for a critique with reference to Dutch.

38 Note that, for most speakers in any event, specificational pseudoclefts with *wh* < XP orders behave differently in this respect (cf. Hankamer 1974; Halvorsen 1978); see section 3.4 above for illustration and discussion.

39 Den Dikken identifies this head as Agr; Moro (1997) objects that if the functional head of small clauses is Agr, one would not expect it to be possible to find disagreement in phi-features between subject and predicate – but such disagreement is in fact possible: cf. the examples in (213), for instance. We will leave the question concerning the nature of 'H' open here.

40 See, however, Blom and Daalder's (1977: 76) predicational analysis of equatives, mentioned in section 1.4 above.

41 But see Postal (1971), Guéron (1992) for arguments against this; for Guéron, subject and predicate are counter-indexed in the *récit* and co-indexed in the *commentaire* (a metalinguistic level which is created out of the *récit* in the covert component): "une chaîne non pas syntaxique mais sémantique. Deux NP non coindicés sont mis dans un rapport d'équivalence" ["not a syntactic chain but a semantic one. Two non-co-indexed NPs are put in a relationship of equivalence"; p. 90].

42 Ross (1999) points out that in Brazilian Portuguese ("though apparently not in all varieties of Portuguese"), constructions of the type in (i) below are found. These superficially look like pseudoclefts from which the *wh*-element has been deleted. If that is what they are, they may be brought to bear on the question of the status of the *wh*-clause of specificational pseudoclefts. Ross himself does not assume an approach to (i) which derives it from (ii) via deletion. We cannot go into the issue here.

(i) Boris roubou foi o Lavoris.
Boris stole was the Lavoris

(ii) O que Boris roubou foi o Lavoris.
the what Boris stole was the Lavoris

43 See also Den Dikken et al. (2000: section 4.3) for a way of extending the *wh*-question analysis to '*th*-clefts', by treating examples like *The (one) thing he didn't do was drink any wine* as reduced variants of *wh*-clefts of the form *What the (one) thing he didn't do was, was drink any wine* (see also Ross 1999 on what he calls 'nominalised questions'); as they point out, such an analysis may afford one a perspective on the 'double *is*' phenonemon in sentences like %*The reason is is (that)* . . . We will not discuss these issues any further here.

44 Notice that these corpus examples all involve *do* in the *wh*-clause; pseudoclefts with full-IP counterweights whose *wh*-clause features *do* rather than a substantive verb are much more widely accepted, and, as was pointed out in (59), also behave differently when it comes to reversibility.

45 It may be important that the 'counterweight' in (253–254) features only a *single* pair of values for the *wh*-phrases in the *wh*-clause, whereas in Ross's examples in (250) a pair list is provided in the 'counterweight'. The difference between Dutch (253) and German (254) may then be related to that between Hungarian (i) and (ii) below (cf. Kiss 2002): in (i), regular multiple *wh*-questions with fronting of all the *wh*-phrases to a left-peripheral focus position, the *wh*-constituents do not have to operate on the same domain (e.g., humans) and a pair-list answer is required; in (ii), only one *wh*-constituent fronts, the other remaining *in situ*, and here the *wh*s must operate on the same domain (e.g., humans) and a pair-list answer is not required. Going back to (253) vs. (254), we note that in the former the *wh*-constituents ('what' and 'where') do not operate on the same domain, whereas in the latter they do; in the light of the Hungarian facts, only the latter will hence be compatible with a single-pair 'counterweight'.

(i) a. Ki kivel verekedett? (pair-list required)
who who-with fought 'Who fought with whom?'
b. Ki mit mondott?
who what said 'Who said what?'

(ii) a. Ki verekedett kivel? (single-pair possible)
who fought who-with
b. *Ki mondott mit?
who said what (Hungarian; adapted from Kiss 2002)

46 Before moving on to the next section, we add here one further respect in which the *wh*-clause of specificational pseudoclefts seems to pattern with *wh*-questions rather than free relatives. When free relatives undergo coordination, it is possible (as Jespersen 1909: vol. III, p. 61) points out, for the *wh*-element of the second conjunct to be *which* rather than *what* (cf. (i) below). When, on the other hand, the *wh*-clause of a specificational pseudocleft is conjoined with another *wh*-clause, it seems impossible to use *which* in the second conjunct, *what* being the only possibility. The examples in (ia, b) with *what* are taken from Declerck (1988: 220) and Geluykens (1984), respectively (the latter being a corpus-based study); replacing *what* with *which* in these examples seems to render the sentences ungrammatical, just like it would in coordinated *wh*-questions:

(i) To assert what cannot be proved and *which*, were it true, annihilates all hope of existence after death. (Percy B. Shelley)

(ii) a. What we have always wanted to know but *what*/**which* the government has never wanted to tell us is what exactly happens at secret conferences.
b. What they are thinking of and *what*/**which* they will probably come up with at the end of the day is a proposal for a cassette tape of the whole bloody issue.

47 In Brazilian Portuguese, *o que* can be left out in constructions of this type, yielding *Boris roubou foi o Lavoris*; see n. 42 above, and Ross (1999) for discussion – Ross argues against the hypothesis that this construction literally results from (263) via deletion of *o que*.

48 Note, though, that the *wh* < XP word order that these pseudoclefts display would be incompatible with a 'Type B' analysis on Den Dikken et al.'s (2000) assumption that 'Type B' pseudoclefts can only have a XP < *wh* word order.

49 The parallelism between (288c) and (290b) can presumably be strengthened by considering the distribution of the complementizer *dat* 'that' in combination with (*of* and) *wh*-phrases: *Wat of dat ik gedaan heb* 'What or that I done have' is good in embedded questions (in those varieties that allow these constructions to begin with), but it seems impossible in a context such as (290b) or in specificational pseudoclefts. These data have not, to our knowledge, been discussed in the literature before; further research is called for.

50 Recall the differences between such examples (with *do*) and ones with a substantive verb in the *wh*-clause; cf. e.g. (59).

51 Higgins (1979) seeks to counter Akmajian's claim about the non-ambiguity of specificational pseudoclefts with non-NP 'counterweight'/'value' by drawing attention to the existence of non-cleft specificational copular sentences with a gerund as post-copular constituent (such as *John's biggest worry is having to photograph himself without a tie on*), which he claims feature a VP to the right of the copula. Higgins's point is not well-taken, however: these gerunds arguably are NPs.

52 Guéron (1992) seems to be a predecessor of this approach, though she does not conceive of the operation that reconstructs the focus into the *wh*-clause as a syntactic movement operation: for her, it is an operation ensuing in the mapping of the *récit* onto the *commentaire*, the latter a metalinguistic level of representation. To quote her directly (p. 103): "Le focus remplace la tête de la relative . . . Ensuite le focus est *reconstruit* à la place de la variable dans DP2 [i.e., the free relative which includes the *wh*-clause]" [original emphasis; "The focus replaces the head of the relative . . . Subsequently the focus is reconstructed into the position of the variable in DP2"]. By taking the reconstruction to happen *beyond* syntax Guéron is in fact closer to Heycock and Kroch (1999).

53 We refer the reader to Den Dikken et al. (2000) for discussion of cases in which the point at which NPI licensing takes place is indeed LF; these cases behave in interesting ways when converted into specificational pseudoclefts.

54 The ungrammaticality of (320a) is also noted in Ross (1999), who blames it on the non-constituency of *Mary a book*; on approaches to double object constructions *à la* Kayne (1984a) or Larson (1988b), however, this sequence *is* a constituent (see the main text immediately below for discussion of Larson's account, invoked by Bošković). Ross contrasts the ungrammaticality of (320a) with the well-formedness of (i) (= (28) from section 2.1, above). Here, *Jerry drunk* is unquestionably a constituent – an Honorary NP in the sense of Safir (1983):

(i) What we need is Jerry drunk.

55 See the discussion in section 5.2 for other examples of multiplicity in specificational pseudoclefts. Not all authors find such examples grammatical (see Higgins 1979: 67 for explicit rejection of an example with a structure similar to that of (321)); the point, however, is that for those speakers for whom multiple *wh*s are possible in the *wh*-clause of specificational pseudoclefts to begin with, examples of the type in (321) are acceptable.

56 In fact, Guéron's approach is more general in that it postulates such an operator in the representation of inverse specificational copular sentences of the double-NP type (like *The best candidate is John*) as well: see (220) in section 4.2, above.

57 They also point out that the restrictions on gapping in specificational pseudoclefts (which played a role in an earlier manuscript version of their paper, Heycock and Kroch 1996; see section 3.4) are another context in which linear order effects play a key role, without the Heycock and Kroch approach managing to accommodate them.

8 Conclusion: outlook

1 Introduction

Over the past decades, Split Topicalization (ST) has attracted an increasing amount of attention. And sometimes, this construction, which used to be considered only a marginal phenomenon, even figured in important theoretical debates, as for instance whether German is configurational (cf. Fanselow 1987; Webelhuth 1990) or whether extraction should be assigned a derivational or representational analysis (cf. Van Riemsdijk 1989a; Brody 1995).

1.1 Some general remarks about Topicalization

Since ST forms a special kind of Topicalization (T), some general remarks about (unsplit) Topicalization are in order. The term 'Topicalization' was introduced by Ross (1986, originally a 1967 dissertation) as a name for a transformation that fronts a non-*wh*-constituent to the left-periphery of the clause. Nowadays, the minimal assumption is that the topicalized constituent is located somewhere in the IP/CP-domain and is coindexed with an empty category inside the clause:[1]

(1) a. $[[_{NP}$ Beans$]_i$ $[_{IP}$ I don't like [e]$_i]]$. (Ross 1986: (5.68))
b. $[[_{AP}$ Proud of him$]_i$ $[_{IP}$ I've never been [e]$_i]]$. (Ross 1986: (5.69))

T creates an unbounded A-bar-dependency relation with island and connectivity effects. The term 'Topicalization' refers to the intuitive information-structural function of this preposing transformation, which is to mark the fronted constituent as a sentence topic, i.e., as the entity the sentence is about. In this most frequent use of T, the primary accent is on a constituent within the clause, while the topicalized constituent bears a somewhat weaker accent.[2]

(2) BEANS, I don't LIKE.

ST – the topic of this chapter – forms a special kind of T. The languages in which ST is attested form a subset of the languages that have T. The phenomenon of ST has been investigated most extensively with respect to Split Noun Phrase Topicalization and Split Verb Phrase Topicalization (SVPT) in German.

1.2 Different categorial types of Split Topicalization

ST gives rise to a split-constituent dependency of the following kind: a constituent's core is extracted to the pre-field while leaving its non-core behind in the middle-field of the clause:[3]

(3) $[[_{X'} \ldots X^0 \ldots]]_i \ldots [_{XP}$ YP [e]$_i$ (ZP)]

The most frequent categorial type of ST in German is Split Noun Phrase Topicalization (SNPT). The German example in (4) forms a case in point:

(4) [$_{CP}$ [$_{TOP}$ Bohnen] [$_{C'}$ mag$_i$ er nur [$_{REM}$ grüne ___]t$_i$]].
beans likes he only green
'As for beans, he likes only green ones.'

In (4), not the entire direct object has been topicalized, as in (1a), but only its core: the adjectival modifier of the topicalized noun has been stranded within the clause. The topicalized part of a ST will be referred to as TOP and the stranded part as REM.[4] TOP and the gap in REM always corefer and must therefore be co-indexed.

By what syntactic criterion does an instance of T become classified as an instance of ST? For example in (5), part of the embedded clause has been topicalized. Does this instance of subextraction (see chapter 66) count as an instance of ST?

(5) [$_{CP}$ [Grüne Bohnen]$_i$ [$_{C'}$ glaube ich, [$_{CP}$ dass er gerne mag [e]$_i$]]].
green beans believe I that he very much likes
'Green beans, I think he likes very much.'

In order to determine the class of STs cross-categorially, the notion of extended projection (cf. Van Riemsdijk 1998a and the references therein) comes into play. Without going into the technical details of this notion, it will be assumed that an extended projection consists of the lexical projection plus its functional extensions. The categorial features of all the projection nodes in an extended projection have to be identical. So, while an incomplete nominal extended projection has been topicalized in (4), in the T in (5) it is a full extended nominal projection (NP) that is extracted out of CP in (5), and not an incomplete CP. So, the subextraction in (5) is not an instance of ST. One could say that in ST, a single (extended) projection is scattered over different positions in the clause.[5]

Besides the ST of arguments, which mainly comes about by SNPT, predicates can also undergo ST. The main categorial type of split predicate T is Split Verb Phrase Topicalization (SVPT) in German and Dutch. (6) provides a clear example of this second type of ST, which matches the scheme in (3):

(6) [$_{CP}$ [Gegessen] [$_{C'}$ hat [$_{IP}$ er [$_{VP}$ nur grüne Bohnen ___]]].
eaten has he only green beans
'He has eaten only green beans.'

However, also AP predicates can undergo ST, resulting into Split Adjective Phrase Topicalization (SAPT) (cf. Corver 1997a; Müller 1998; De Kuthy and Meurers 2001), which will further be ignored here:[6]

(7) [Stolz] ist er vor allem [$_{AP}$ ___ auf seine Kinder].
proud is he especially on his children
'He is especially proud of his children.'

Finally, yet another type of ST can be discerned, namely Mixed Split Topicalization (MST), which seems to be a blend of SVPT and SNPT:

(8) [$_{CP}$ [Mädchen verführt] [$_{C'}$ hat er schon [viele ___]]].
girls seduced has he already many
'He has already seduced many girls.' (Fanselow 1987: 102)

MST seems to pose a tough problem for most analyses proposed in the relevant literature because it is unclear how TOP can form the core part of REM, as the actual split seems to occur at the N-bar-level and not at the level of V-bar.

1.3 Interesting problems

Until now, the syntactic literature on ST has mainly focused on the nature of the A-bar-dependency relation between TOP and REM. Since T is usually analyzed in terms of direct movement, the most straightforward analysis for ST seems to be an analysis in which a main constituent's core (i.e., a subconstituent) is moved into a left-peripheral position. However, this analysis faces particular problems. First, it violates the descriptive generalization that only major, single constituents can be topicalized in German (cf. Thiersch (1978)), which will be dubbed the Single Constituent Condition (SCC) here. The theoretical counterpart of this generalization can be called the Structure Preservation Condition (SPC). The SPC, which has its roots in Emonds (1970), has been reformulated in Chomsky (1986a). It says that maximal projections can only be moved into positions that are apt to host them, such as specifier positions, and that heads can only be moved into X^0 positions. Since it is usually assumed that T targets Spec, C, a movement analysis of ST would violate the SPC. In addition, a subphrasal movement analysis faces problems having to do with unexpected overlaps between TOP and REM, which become visible when TOP and REM are concatenated into a single constituent. A telling example is the SNPT with "determiner overlap" in (9a):

(9) a. [$_{CP}$ [Eine Lösung] [$_{C'}$ hat er [$_{NP}$ eine bessere ___] als ich]].
a solution has he a better (one) than I
'As for solutions, he has a better one than I have.'
b. *[$_{NP}$ eine bessere eine Lösung]. (Van Riemsdijk 1989a: 107)

In order to deal with such movement paradoxes (cf. section 2.2), the subphrasal movement analysis has to be supplemented with additional mechanism which will be dealt with in section 3.1. However, different analyses have been proposed to deal with this problem as well (cf. section 3).

With respect to examples like (9a), yet another interesting and complicating aspect of ST deserves to be noticed, namely the considerable amount of dialectal variation with respect to the possible syntactic realizations of TOP and REM. For example, the SNPT with determiner overlap in (9a) is not accepted by all speakers

of German that allow for SNPT, but is usually only acceptable for speakers who hail from the south of Germany, or from Switzerland or Austria.

Yet another interesting aspect of this construction, which has remained almost unnoticed so far, is formed by its striking information-structure properties. One should be aware of the fact that ST is a construction that is stylistically marked and occurs almost exclusively in colloquial language (cf. Kniffka 1996).

STs are mostly characterized by two informational peaks. These two information units are intonationally marked by a rising (L*H) and a falling (H*L) pitch accent respectively and they form a rise-fall contour (RF-contour) (cf. Féry 1993; Van Hoof 2003). The rising pitch accent is marked as '/' and the falling accent as '\' in front of the accented word, which are written in SMALL CAPS. The intonational description in (10) is consistent with the prosodic description that has been provided in (2) for unsplit T. Although the difference in strength between the rising and the falling pitch accent has not been specified in (10), the falling accent is perceived as more prominent than the rising one:[7]

(10) [A: Dieses Lehrbuch fand ich ziemlich schlecht. Es gab zwar viele Beispiele . . .]
'This textbook, I found rather bad. It contained many examples, though . . .'
aber [/ERKLÄRUNGEN] gab es dazu [\KEINE ___].
but explanations gave it to that none
'but explanations, it contained none.' (Van Hoof forthcoming)

The rising and the falling pitch accent of the RF-contour signal two foci of attention. The first focus, which is marked by the rise, is located on an element in TOP and the second one, marked by the fall, is often realized on an element in REM, but can be realized on another constituent in the clause, too. TOP mostly contrasts with an entity in the context that differs from TOP with respect to the meaning that is conveyed by the element with the rise and REM sometimes contrasts with another discourse entity as well. Although the examples of ST in this article have not been augmented with a contrast-facilitating context, it is important to be aware of the specific semantico-pragmatic meaning of this construction in German.

Another intriguing but also difficult problem of ST forms its restricted cross-linguistic distribution in comparison with unsplit T. For example, SNPT leads to ungrammatical results in Modern English, Standard Dutch and Scandinavian, which all have (unsplit) T at their disposal.

As becomes clear from (11a), the SNPT in (4) does not have a direct counterpart in English. A well-formed English translation of (4), is provided by (11b):

(11) a. *[[Beans], [he likes only [green ___]]].
b. [[Beans], [he likes only [green ones]]].

In (11b), the left-peripheral NP corefers with the indefinite pronoun *ones* and not with an empty category. (11b) forms an instance of Hanging Topic Left Dislocation

(HTLD) (see chapter 37), a construction in which the left-peripheral constituent does not show connectedness effects with a sentence-internal anaphor.

Although English has VP-preposing, as illustrated in (12), this construction cannot strand arguments. So, SVPT of the German type is excluded in English (cf. (13)):

(12) They all said that Harry had been eating green beans and . . .
[eating green beans], [he must have been ___]!

(13) They all said that Harry had been eating something and . . .
*[eating], [he must have been ___ green beans].

Of course, the restricted cross-linguistic distribution of ST compared with (unsplit) T can be related to many factors. Ideally, an answer to such a deep question should follow from the proposed analysis. But a lot of hypotheses deserve to be tested before it can be answered in a more than speculative way.

The literature on ST has grown most extensively for German. The emphasis of this article will therefore be on ST in this language (but see section 7 for related phenomena in other languages). Since the two main types of ST, i.e. SNPT and SVPT, have not been treated on a par in the previous literature, the different subtypes of ST will be dealt with separately here as well.

2 Syntactic properties of Split-NP Topicalization

2.1 A-bar-characteristics

As demonstrated in detail in Van Riemsdijk (1989a), SNPT exhibits the diagnostic properties of an A-bar-dependency relation. SNPT triggers V-second and leaves behind a gap in REM. Furthermore, the relation between TOP and REM is island sensitive. The latter is illustrated by the examples in (14). (14a) demonstrates that SNPT is unbounded in principle and (14b) shows that SNPT is sensitive to the Complex-NP Constraint:[8]

(14) a. [Augen] sagt er, [$_{CP}$ dass sie [schönere ___ t_i] hat [als ich]$_i$].
eyes says he that she more beautiful (ones) has than I
'As for eyes, he says that she has more beautiful ones than I have.'

b. *[Augen] kenne ich ⟦$_{NP}$ keine Frau, [$_{CP}$ die [schönere ___ t_i]
eyes know I no woman who more beautiful (ones)
hat [als ich]$_i$]].
has than I
'As for eyes, I know no woman who has more beautiful ones than I have.'

In addition, SNPT shows connectivity effects with respect to binding and morphological case. (15) shows this with respect to Binding Condition A:

(15) [Bücher von einander$_i$] sind uns$_i$ [keine ___] bekannt.
books of each other are us none known
'As for books of each other, none are known to us.'
(Van Riemsdijk 1989a: 115)

Another important property showing that TOP and REM are A-bar-related is formed by the preservation of ordering restrictions among prenominal adjectives (cf. Van Riemsdijk 1989a). Although the grammatical contrasts shown in (16) are not absolute – for (16b) can be saved by a strong RF-contour and a context in which both TOP and REM can contrast with another discourse entity[9] – a clear contrast can be observed if the minimal pair (16a, b) is uttered 'out of the blue'. Since a similar contrast cannot be diagnosed for the corresponding HTLDs (see chapter 37), as can be derived from the translations of the examples in (16), the contrast in (16) can be interpreted as a connectivity effect:

(16) a. [Ein amerikanisches Auto] kann ich mir [kein neues ___] leisten.
an American car can I me no new (one) afford
'As for an American car, I cannot afford a new one.'
b. * [Ein neues Auto] kann ich mir [kein amerikanisches ___] leisten.
a new car can I me no American (one) afford
'As for a new car, I cannot afford an American one.'
c. Base order: [$_{NP}$ ein [$_{N'}$ [$_{AP}$ neues] [$_{N'}$ [$_{AP}$ amerikanisches]$_{N'}$ [$_{N}$ Auto]]]].
(Van Riemsdijk 1989a: 122)

Another indicator for an A-bar-dependency relation between TOP and REM is provided by the fact that TOP in SNPT can licence parasitic gaps (cf. Van Hoof 1997b):

(17) [Briefe] hat sie [ohne zu Ende *e* zu lesen] noch [keine ___] weggeworfen.
letters has she without to end to read yet none away-thrown
'As for letters, she has not thrown any away yet without finishing reading them.'

Van Riemsdijk (1989a) attributes yet another well-known A-bar property to SNPT, namely the occurrence of Empty Category Principle (ECP) effects (cf. Chomsky 1981), which states that an empty category has to be properly governed. The following tendency is observed: the tighter the structural relation between REM (containing the gap) and the verb, the more easily SNPT can apply. Under the assumption that an accusative object and the main verb have more structural cohesion than a dative object or an unergative subject and the main verb, this tendency is illustrated by the paradigm in (18):

(18) a. [Einen Wagen] hat er sich [keinen ___] gekauft.
a car has he himself none bought
'As for a car, he bought himself none.'

b. ?? [Einem älteren Mann] bin ich [keinem ___] begegnet.
an older man have I none met
'As for an older man, I've met none.'
c. ?* [Ein Experte] hat [keiner ___] den Schaden geprüft.
an expert has none the damage inspected
'As for an expert, none has inspected the damage.'

However, since ECP effects do not show up as clearly in German as they do in English, it is more appropriate to speak of ECP-*like* effects in this language. Since these effects can only be perceived if the examples are uttered with the neutral stress pattern (see chapter 49) and can be repaired with the aid of narrow focus on REM (cf. Pafel 1993; Van Hoof 1977a), this A-bar-diagnostic has to be applied with care. ECP-like effects of a similar kind have also been diagnosed for *what-for* subextraction (see chapter 66) (cf. Oppenrieder 1991b). On the other hand, Pafel (1995) has shown that the syntactic position of REM in SNPT and of the source category in *what-for* split is more constrained in comparison with the syntactic position of the source category of other split constructions, such as Quantifier Floating or Partitive Split (cf. section 2.3). Therefore, in spite of the ameliorating effect of focus, the pattern outlined in (18) can be interpreted as an indicator for the existence of an A-bar-relation between TOP and REM.

2.2 Movement paradoxes

In general, A-bar-constructions are derived by syntactic movement. However, certain syntactic properties of the internal syntactic make-up of TOP and REM in SNPT seem to demonstrate that it is highly improbable that TOP has been moved directly out of REM. Most paradoxes, however, are dialectally constrained.

The first movement paradox that can be observed if the syntactic realizations of TOP and REM are compared with their combination is determiner overlap (cf. (9), repeated in (19)):

(19) a. [$_{CP}$ [Eine Lösung] [$_{C'}$ hat er [$_{NP}$ eine bessere ___] als ich]].
a solution has he a better (one) than I
'As for solutions, he has a better one than I have.'
b. *[$_{NP}$ eine bessere eine Lösung].

The so-called continuatives, i.e., bare plurals and mass nouns, are the most unmarked TOP forms (cf. Van Riemsdijk 1989a; Kniffka 1996). Although they cannot cause a determiner overlap if they are split (cf. the SNPT in (20a)), a non-matching effect with respect to adjectival inflection can appear, as shown in (20b):[10]

(20) a. [Geld] hat er glaube ich [keines ___].
money has he believe I none
'As for money, I believe he has none.'
b. [kein(*-es) [Geld]].

The strong adjectival inflection on the quantifier is required as soon as the NP in (20) is split. This phenomenon can be explained in the following way: the gap in REM has to be licensed by overt nominal features on the syntactic category that precedes and c-commands the gap. This requirement can be satisfied by the presence of an overt functional head or by inflectional morphology on a preceding adjective. Probably, the head features of the nominal gap have to become visible through the overt part of REM. Exactly the same syntactic conditions appear to hold for the remnant of NP ellipsis (see chapter 22).

Similar mismatches have been observed with respect to the inflectional morphology on adjectives, where one can make a distinction between weak and strong adjectival inflection. This is so because both TOP and REM are inflected as if they were two independent NPs.

(21) and (22) demonstrate that the adjectival inflections within the split NPs do not always match with the adjectival inflections within the corresponding unsplit NP:

(21) a. [Polnisch-e Gänse] hat sie [kein-e ___] gekauft.
Polish-STRONG geese has she no-STRONG bought
b. *[Polnisch-en Gänse] hat sie [kein-e ___] gekauft.
Polish-WEAK geese has she no-STRONG bought
'As for Polish geese, she has bought none.'

(22) a. Sie hat [kein-e polnisch-en Gänse] gekauft.
she has no-STRONG Polish-WEAK geese bought
b. *Sie hat [kein-e polnisch-e Gänse] gekauft.
she has no-STRONG Polish-STRONG geese bought
'She has bought no Polish geese.' (Fanselow 1988)

The so-called number-disagreement facts, i.e., examples in which TOP and REM do not agree in number, form a subphrasal movement paradox, too. Note however, that TOP and REM can disagree only one way: a plural TOP can take a singular REM, but not the other way around (cf. (23)):

(23) a. [Autos] hat er nur [eins ___].
cars has he only one
'As for cars, he has only one.'
b. *[(Ein) Auto] hat er sogar [zwei ___].
(a) car has he even two
'As for (a) car, he has even two.'

Other examples feeding the movement paradox are SNPTs with a REM that simply cannot be a source for subphrasal movement because of its specific lexical content. They constitute a so-called non-source for subphrasal movement.

SNPTs containing a non-source are, for example, SNPTs with the non-interrogative quantifier *welch-* ('some') as a REM. This quantifier is only licit if it c-commands an empty category that refers to a continuative:[11]

(24) a. [Pflanzen] hatte sie immer [welche ___] im Angebot.
plants had she always some to offer
'As for plants, she always had some to offer.'
b. *[$_{NP}$ welche Pflanzen]

A completely different kind of non-source REM, which is also dialectally constrained, is formed by SNPTs with so-called full-NP remnants:[12]

(25) a. [Raubvögel] glaube ich kennt Gereon nur [Bussarde].
birds of prey believe I knows Gereon only buzzards
'As for birds of prey, Gereon knows only buzzards.'
b. *[$_{NP}$ Raubvögel Bussarde] (Fanselow 1993: 63)

According to Fanselow and Ćavar (2002), another non-source can be found in SPPT, which occurs in certain dialects of southern German:

(26) a. [In Schlössern] habe ich noch [in keinen ___] gewohnt.
in castles have I yet in no (ones) lived
b. *[$_{PP}$ In keinen in Schlössern ___] habe ich noch gewohnt.
in none in castles have I yet lived
'I have not yet lived in any castles.' (Fanselow and Ćavar 2002: 69)

2.3 Different kinds of split

TOP in SNPT is a non-quantificational indefinite and refers to a property or a kind.[13] REM restricts the TOP set by introducing some properties that can be attributed to it, so that the anaphoric relation between TOP (antecedent) and REM (anaphor) forms a proper subset relation. As a consequence, the 'whole-to-part' relation, that is also encoded in unsplit modified NPs, becomes expressed prominently in SNPT.

SNPT can also apply to pseudo partives (cf. (ia) in note 12, which is repeated in (27a) and (27b)):

(27) a. [Wein] habe ich nur [zwei Flaschen ___] dabei.
wine have I only two bottles with me
'As for wine, I brought only two bottles.'
b. [Flaschen Wein] habe ich nur [zwei ___] dabei.
bottles wine have I only two with me
'As for bottles of wine, I brought only two.'

In both split pseudo-partitives, NP1 (REM) functions as a (complex) quantifier to NP2 (TOP), like in ordinary SNPTs with a quantificational REM. However, preposings that split a real partitive clearly differ from SNPT of pseudo partitives. While in SNPT, a quantificational REM quantifies over an unrestricted set of entities in TOP, the quantifier in "real" partitive constructions quantifies over

a contextually restricted set of entities. But definite or specific TOPS are not allowed for in SNPT.

Real split-partitive constructions are, for example, Quantifier Floating (cf. (28)) and Partitive Split (cf. (29)):

(28) [Die Solisten] haben [___ alle] viel Beifall bekommen.
the soloists have all much applause got
'The soloists all got much applause.'

(29) [Von uns] hat sich [niemand ___] freiwillig gemeldet.
of us has himself nobody voluntarily announced
'None of us volunteered.' (Pafel 1995: 146)

In Quantifier Floating, the fronted NP has to target an A-position before it can target an A-bar position. In Partitive Split, the preposed PP targets an A-bar position. In both constructions, the NP within the preposed PP is definite. Therefore, both Quantifier Floating and Partitive Split are constructions that differ substantially from SNPT. Another difference between Quantifier Floating and Partitive Split, on the one hand, and SNPT and *what-for* subextraction, on the other hand, is that the source category of the former group of constructions is not subject to the ECP, as becomes apparent from the examples in (28).[14]

Yet another kind of T that seems to break up NPs is NP-PP Split (cf. De Kuthy 2002). (30) shows that NP-PP Split can go in two ways: either the NP is preposed and the PP stays behind or vice versa:

(30) a. [Über Syntax] hat er [ein Buch ___] ausgeliehen.
about syntax has he a book borrowed
b. [Ein Buch] hat er [___ über Syntax] ausgeliehen.
a book has he about syntax borrowed
'He borrowed a book about syntax.' (De Kuthy 2002: 5–7)

In principle, the preposed NP in (30b) could be the underlying core part of the nominal extended projection that is extracted from, as required by our (working) definition of ST (cf. section 1.2). On the other hand, the remnant in NP-PP Split differs from REM in SNPT because the gap in the remnant of NP-PP Split is not licensed by overt agreement morphology. In addition, NP-PP Splits do not give rise to non-matching effects like those in SNPT (cf. De Kuthy 2002: 36).

NP-PP Splits like those in (30a) have been analyzed in terms of subphrasal movement, and NP-PP Splits like those in (30b) in terms of subphrasal movement in combination with remnant movement (cf. Müller 1998) or in terms of phrasal movement preceded by reanalysis (cf. Fanselow 1987; Grewendorf 1989; De Kuthy 2002).[15]

In this section, a number of constructions that at first sight seemed to be highly similar to SNPT were listed. However, they appeared to be different from SNPT both on syntactic and semantic grounds. This conclusion is supported by the fact that in contrast with SNPT, Quantifier Floating, Partitive Split and NP-PP Split

Table 62.1 NP-Split types and properties

	SNPT	NP-PP Split	Q-Floating	Partitive Split
A′-preposing	+	+	–	+
Non-specific TOP	+	–	–	–
Non-specific REM	+	–	–	–
ECP-effects	+	+	–	–
Inflected REM	+	–	–	–

are also grammatical in English. Table 62.1 summarizes their main similarities and differences. A more exhaustive list of the grammatical properties of SNPT will be provided in section 3.4.

3 Syntactic analyses of Split-NP Topicalization

This section provides an overview of the different syntactic analyses that have been proposed in the literature so far and reviews some of their problems.[16] The analyses are subdivided into three groups: (i) subphrasal extraction analyses; (ii) verbal complex extraction analyses; and (iii) phrasal extraction analyses. Although relatively many analyses for SNPT in German are available, fully worked-out proposals are pretty rare. Therefore, the analyses will only be discussed with respect to the core data of SNPT, excluding the data to be presented in section 6.

3.1 Subphrasal extraction analyses

Subphrasal movement analyses form the main type of subphrasal extraction analysis for SNPT.[17] Apart from the movement paradoxes listed in section 2.2, this analysis type must say something extra about the SPC on Move α (cf. section 1.3). Then according to this condition (cf. Chomsky 1986a), only heads and maximal projections can be moved, but no intermediate projections. The first subphrasal movement analysis (cf. Van Riemsdijk 1989a), which was developed at a time nominal functional categories had not yet really arrived, does not derive this property from a restriction on the application of Move α, but from a well-formedness condition on S-structure representations. Subphrasal extraction analyses stemming from a more recent date (cf., for example, Tappe 1989; Haegeman 1995b; Kniffka 1996) simply do away with the problem by appealing to the modern version of X-bar-theory that divides constituents into maximal lexical and maximal functional projections.[18] The movement-and-regeneration analysis (M&R analysis) proposed in Van Riemsdijk (1989a) supports a derivational analysis of SNPT in which the movement of intermediate projections is not precluded in principle. Instead of Chomsky's SPC on Move α, van Riemsdijk assumes a well-formedness condition on X-bar-structure representations. The filter dismisses S-structures containing intermediate TOP projections that are not dominated by another intermediate or maximal projection of the same category and calls into existence some mechanisms of repair that regenerate and relexicalize missing structure in turn. Van Riemsdijk assumes that only languages that allow missing structure to be

regenerated can move intermediate projections. In some languages with regeneration, a grammatical formative in TOP can become relexicalized too. However, the lexical spell-out of regenerated structure is subject to a strict recoverability condition: only words or morphemes that are fully determined by the inherent grammatical features of the nominal lexical head, such as number, gender, and case, can be relexicalized in their unmarked form. (31b, c) demonstrate the effects of regeneration and relexicalization after the A-bar-movement of an intermediate projection to Spec, C has been completed (cf. (31a)):

(31) a. $[_{CP}\ [_{N'}$ Definitiver Beweis$]_i$ $[_{C'}$ ist bis jetzt $[_{NP}$ keiner $t_i]$ gefunden worden]].
definitive proof has until now none found
been

b. *Regeneration*: $[_{CP}\ [_{NP}\ [_{N'}$ Definitiver Beweis$]_i]$ $[_{C'}$ . . .

c. *Relexicalization*: $[_{CP}\ [_{NP}$ Ein $[_{N'}$ definitiver Beweis$]_i]$ $[_{C'}$ . . .

As becomes apparent from (31), the possibility of determiner overlap between TOP and REM in certain varieties of German is accounted for by the possibility of regeneration and relexicalization. The non-matching effects of weak and strong adjectival inflection can only be explained if the spell-out of weak vs. strong inflection is not caused by specific lexical-grammatical features, but is postponed after A-bar-movement has been completed. The same solution, however, cannot be offered for the non-source *welche*. In order to derive SNPTs with this REM, Van Riemsdijk (1989a: 110) has to make the somewhat dubious assumption that lexical meanings do not have to remain constant throughout the derivation. Also the number-disagreement facts, that are quite common among the different varieties of SNPT, do not follow in a straightforward way from this analysis. Furthermore, an explanation for the existence of full-NP remnants and SPPT would certainly overstrain the mechanisms of regeneration and relexicalization. The existence of MST remains mysterious, too, under this analysis, as Van Riemsdijk (1989a) admits himself in his note 29.

Another subphrasal movement analysis is suggested in Haegeman (1995b: 173–178). Haegeman assumes that the nominal projection consists of different functional layers and that TOP, being an intermediate maximal projection of REM, can be extracted via the outer specifier of REM. According to Haegeman, the advantage of this implementation of the subphrasal-movement analysis is that the mechanisms of regeneration and relexicalization become superfluous because a layered-NP structure allows NPs to have more internal structure than becomes apparent from surface structure. For instance, the layered-NP structure in (32a) can be used to explain the phenomenon of determiner overlap (cf. (32b)):

(32) a. $[_{QP}$ keinen $[_{DP}$ einen Wagen]]
no a car

b. $[_{DP}$ Einen Wagen$]_i$ hat er sich noch $[_{QP}\ t_i$ keinen $t_i]$ leisten können.
a car has he himself yet none afford can
'As for cars, he has not been able to afford one yet.'

Although the NP in (32a) does not form a well-formed NP in German, the order 'quantifier – determiner' is possible in unsplit NPs in West Flemish and in some other varieties of West Germanic, according to Haegeman:

(33) $[_{QP}$ gen $[_{DP}$ eenen $[_{NP}$ boek]]] West Flemish
no a book

(Haegeman 1995b: 173)

Haegeman considers *eenen* in (33) and *einen* ('one') in (32a) to be a singular indefinite determiner. She argues that both the negative quantifier and the indefinite singular determiner can be spelled out in unsplit NPs in West Flemish, but that this is impossible in German because of a surface condition. After splitting of the unsplit NP in (32a) has occurred, however, the indefinite determiner would pop up overtly in some dialects (cf. (32b)) that do not allow the indefinite determiner to be spelled out in the same configuration in unsplit NPs.[19]

Although the determiner overlaps with an indefinite determiner in TOP and an indefinite determiner or numeral in REM can be analyzed in the same way, this kind of proposal is hardly extendable to data such as (34), as Haegeman notices herself, since NPs of the form *eine bessere eine Lösung* ('a better a solution') are not attested in any variety of Germanic.

(34) [Eine Lösung]$_i$ hat er [eine bessere t_i als ich].
a solution has he a better (one) than I
'As for solutions, he has a better one than I.' (Van Riemsdijk 1989a: 107)

In order to motivate a structure for German in which adjectives take NP complements, Haegeman (1995b: 305ff. note 11) suggests a parallel with the phenomenon of double definiteness in Hebrew and Modern Greek (cf. section 7.1).

A subphrasal-movement analysis combined with a base-generated TOP is sketched in Giusti (1993: 148–154). Giusti suggests an extension of the Contrastive Left Dislocation (CLD) analysis of T (see chapter 37) to SNPT.[20] In this analysis, TOP is base-generated in left-dislocated position and is co-indexed with a moved empty operator in Spec, C that binds an empty category in REM:

(35) $[_{CP}\,[_{F}\,[_{NP}\,NP]]_i\,[_{CP}\,Op_i \ldots [_{VP} \ldots [_{QP}\,Q^0\ t_i] \ldots]]]$

Giusti assumes that the moved empty NP-operator has been assigned partitive case by Q^0 and can be lexicalized as *da* ('there') or *solche* ('such') in German. The empty operator in Spec, C and the variable in REM have the same categorial and projectional features because this chain results from movement. The left-dislocated TOP and the movement chain become co-indexed through binding and, therefore, no full identity of categorial and projectional features is required. As a consequence, this analysis opens perspectives to explain SNPTs with determiner overlap or number-disagreement. It remains unclear, however, how SNPTs

with full-NP remnants could be accounted for. On the other hand, if the moved empty operator is assumed to be *pro* (cf. Cardinaletti 1986), the generalization that the licensing conditions for the empty nominal part in REM are identical to the ones for the gap in elliptic NPs follows as a matter of fact. Giusti's analysis also complies with the SCC and with the SPC. For a slightly different CLD-analysis for SNPT, see Van Hoof (1997a).

3.2 Extraction of a verbal complex from VP

In one of the first analyses for SNPT (cf. Fanselow (1987: 98–107)), the operation of T is preceded by a process of reanalysis between the object and the verb. In this reanalysis-and-movement analysis (R&M analysis), SNPT and MST are analyzed in the same way. The preconditions for the application of reanalysis are that the to-be-reanalyzed NP is adjacent to the verb and that the NP is dominated by VP. The process of reanalysis is illustrated in (36):

(36) a. *D-str1*:
$[_{VP}\,[_{NP}$ viele Mädchen$]$ $[_{V}$ verführt$]]$
b. *D-str2 after reanalysis*:
$[_{VP}\,[_{NP}$ viele $t_i]$ $[_{VC}$ Mädchen$_i$ verführt$]]$

The SNPT and the MST in (37) are derived by A-bar-movement of the verbal complex (VC) to Spec, C:

(37) a. $[_{VC}$ Mädchen$]_i$ hat er schon [viele t_i] verführt.
girls has he already many seduced
'As for girls, he has already seduced many.'
b. $[_{VC}$ Mädchen verführt$]_i$ hat er schon [viele t_i].
girls seduced has he already many
'As for having seduced girls, he has already seduced many.'
(Fanselow 1987: 102)

Since reanalysis can only apply to VP-internal constituents that are left adjacent to the verb, this analysis predicts that SNPTs with dative and nominative REMS are generally less well-formed than SNPTs with accusative REMS. Therefore, the contrast between passivized and ergative-subject REMS, which can form a REM easily, and agentive-subject REMS, which can only form a REM if they are focused (cf. section 2.1), is predicted by this analysis under the assumption that passivized, ergative and focused agentive subjects are realized VP-internally (cf. Diesing 1992b).

Unfortunately, this proposal has not been worked out in every detail. For instance, Fanselow remains vague about the syntactic category of the verbal complex in (36b). Is it a complex word or a phrasal constituent? Related to this problem, the projectional feature of the incorporated part of the NP is left unspecified, too. It is also not clear how the empty category in (36b) can be

bound, since it c-commands its antecedent after reanalysis, but this is a general problem for certain analyses of N-incorporation. Fanselow (1987) does not describe either how the SNPT in (37a) can be derived. If it is indeed the verbal complex that has been preposed to Spec, C, the verb *verführt* ('seduced') must probably have been extracted to the right before T applies.

A serious problem for this analysis is that the linear adjacency condition on reanalysis is not always respected. If, as suggested by (36b), only the second half of the source NP, i.e., the part that is adjacent to the verb, can be reanalyzed, we would expect *Bücher von Chomsky* to be the only possible TOP-candidate in (38) (cf. (38a)), but this does not turn out to be the case (cf. (38b)):

(38) a. [Bücher von Chomsky] hat er [keine ___] gekauft.
books of Chomsky has he none bought
'As for books of Chomsky, he bought none.'
b. [Bücher] hat er [keine ___ von Chomsky] gekauft.
books has he none of Chomsky bought
'As for books, he bought none of Chomsky.'

Apart from these problems, this analysis fails to solve the same problems that were problematic for derivational N-bar-movement analyses, too. A similar analysis that overcomes some of these problems has been presented in Fanselow (1993).

In order to derive SNPT and MST on a par, Fanselow (1993) proposes the base-generated-VP-plus-chain analysis, in which a base-generated VP is co-indexed through a binding chain with an empty category in the middle-field. MST and SNPT are assigned the same underlying structures as shown in (39a, b):

(39) a. *MST*:
$[_{CP}\ [_{VP1}\ \textsc{top}_{NP}\ V1]_i\ [_{C'} \ldots [_{VP2} \ldots \textsc{rem}_{NP} \ldots [_{VP1}\ e]_i\ V2]]]$.
b. *SNPT*:
$[_{CP}\ [_{VP1}\ \textsc{top}_{NP}\ [_{V1}\ e]]_i\ [_{C'} \ldots [_{VP2} \ldots \textsc{rem}_{NP} \ldots [_{VP1}\ [_{NP}\ e]\ V1]_i\ V2]]]$.

In SNPT (cf. (39b)), the verbal head of the VP projection in Spec, C is represented by an empty category, and is overtly realized in the middle-field instead. Unlike in the former split-VP analysis, i.e., the R&M-analysis of Fanselow (1987), $\textsc{top}_{NP}$ and $\textsc{rem}_{NP}$ are base-generated as two independent NPs in the sentence.

The advantages of a base-generation analysis are clear: split NPs do not have to constitute a continuous NP in underlying structure. Therefore, both variants in (38) are predicted to be grammatical. The existence of non-sources, including full-NP remnants, follows as a matter of fact.

How does this analysis fare with respect to the theta-criterion? The standard solution GB-theory has to offer for similar phenomena, like clitic doubling (see chapter 14), is that theta-roles are not assigned to syntactic constituents, but to syntactic chains. But this procedure of theta-role-assignment cannot be adopted for $\textsc{top}_{NP}$ and $\textsc{rem}_{NP}$ in (39a, b) because the split NPs do not form an NP-chain, since they are included in constituents that form links of a VP-chain. Nevertheless,

the split NPs form different instantiations of the same argument. Therefore, Fanselow (1993) adopts a more refined version of the theta-criterion than is usually assumed in GB-theory:

(40) In the extended projection of a (base-generated) VP, an argument license can be issued only once.

The notion *argument license* in (40) does not only cover theta-assignment, i.e. the closing of an argument position, but also its modification. It is also assumed that although an argument slot can be closed only once, it can be modified repeatedly before closure. In the representational chains of co-indexed VPs in (39), TOP_{NP} receives a modification license from the (c)overt verb V1 that heads the topicalized VP, while REM is assigned a theta-role by the (c)overt verb V2 in the predicating clause. In this way, TOP and REM form two different realizations of one and the same argument of the complex predicate that is formed by V1 and V2.

In these two proposals of Fanselow, the similarities between SNPT and MST are captured by means of an almost identical structural representation. But this analysis may well turn out a means too powerful to express the common properties between SNPT and MST. Intuitively, SNPT seems to be a more basic kind of ST than MST. But in these two analyses, SNPT ends up with an analysis that is at least as intricate as the one for MST.

3.3 Phrasal extraction analyses

Fanselow (1988) proposes an analysis in which two NPs are base generated in the middle-field and one of them is topicalized. In the base-generated structure (cf. (41a)), REM is in a VP-internal A-position and TOP, an indefinite property-denoting NP, is adjoined to V^0. The corresponding S-structure that is derived after T is specified in (41b):

(41) a. Sie hat $[_{VP}$ $[_{NP}$ keine *pro*] $[_{V^0}$ $[_{NP}$ polnischen Gänse] $[_{V^0}$ gekauft]]].
she has none Polish geese bought
'She didn't buy any Polish geese.'

b. $[_{CP}$ $[_{NP}$ Polnische Gänse]$_i$ $[_{C'}$ hat sie $[_{VP}$ $[_{NP}$ keine *pro*] $[_{V^0}$ t_i $[_{V^0}$ gekauft]]]]].
Polish geese has she none bought
'As for Polish geese, she bought none.' (Fanselow 1988: 103f)

It is assumed furthermore that only REM, which is base-generated in the regular A-position outside of the domain of V^0, is assigned a theta-role. In order to satisfy the Principle of Full Interpretation (cf. Chomsky 1986b), which says that every link in a chain must make its own contribution to the meaning of a sentence, it is assumed that TOP modifies REM by binding *pro* in REM. In this way, the fronting of TOP out of the complex verb into Spec, C is forced to apply and *pro* can only be bound by the preposed TOP and by no other c-commanding constituent in the sentence.

The idea to treat REM as an elliptic NP in which the elided site is represented as a pronominal category was newly introduced in Fanselow (1988), who adopted the analysis of Olsen (1987) for ellipsis in German NPs. Similar ideas were substantiated and became more influential by the work of Lobeck (1995) (see chapter 22).

Fanselow's (1988) proposal, which has been adopted recently in Van Geenhoven (1998) and Krifka (1998b), avoids many problems that are inherent to subphrasal-movement analyses. The paradox that SNPT shows properties of movement and of base-generation at the same time receives a straightforward explanation by the two independently base-generated NPs representing the same argument and of which only one is A-bar-moved.

However, some details in the analysis remain obscure. Although Fanselow (1988: 105) states that not only non-referential NPs but also directional PPs can be adjoined to V^0 in German, he remains silent about the details of a deep structure for a VP in which both types of predicative constituents occur at the same time. Another problem for this analysis is that usually only bare nouns, i.e. bare plurals, mass nouns, or bare count nouns, take part in word formation processes and that, therefore, singular-count TOPs with a lexicalized indefinite determiner are not predicted by this analysis. A general problem for analyses that allow one argument to be represented by more than one syntactic constituent is that they do not have a straightforward answer as yet to the question of how adjectival ordering restrictions holding in the corresponding unsplit NP are preserved among TOP and REM.

Fanselow and Ćavar (2002) offer yet another phrasal-movement analysis for SNPT in German, i.e. the so-called copy-and-distributed-deletion analysis (C&DD analysis). In the Minimalist Program (cf. Chomsky 1995c), movement is analyzed as a combination of two distinct operations, i.e. Copy and Delete (C&D). According to Fanselow and Ćavar, one of the advantages of a movement analysis in which deletion does not form an automatic sequel of copying, is that the existence of a construction like SNPT comes more or less for free. They propose to derive SNPT by a special application of C&D, in which the deletion operation does not affect the entire downstairs copy, but the upstairs and the downstairs copy in a partial and complementary way. This is what they call "distributed deletion." (42) compares an instantiation of unsplit movement (42a) with an instantiation of split movement in terms of C&D (the phonetically deleted parts have been struck out):

(42) a. [viele Birnen]$_2$ . . . [~~viele~~ ~~Birnen~~]$_1$ . . . (unsplit movement)
many pears . . . many pears
b. [~~viele~~ Birnen]$_2$ . . . [viele ~~Birnen~~]$_1$ . . . (split movement)
many pears . . . many pears

Both phrasal-movement types are assumed to be licit because in both cases, i.e., in (42a) and (42b), the economy Principle of Pronunciation, saying that material should not be pronounced twice, has been respected. It is also assumed that only those syntactic categories of the copy have to be visible in the upstairs copy

whose features are checked there, and that the remaining part can be deleted in accordance with the Principle of Pronunciation. Furthermore, the C&DD-analysis is enriched with additional principles that can be ranked differently for the different varieties of German. In the analysis of Fanselow and Ćavar, split-constituent movement is marked because C&DD violates the Principle of Contiguity, which says that material that has been merged as a single phrase should remain contiguous at spell-out. However, a violation of the Principle of Contiguity is possible in German, because this language still has another principle, which is higher ranked and which allows a single constituent with two or more syntactic features to check its features with different heads before spell-out.

SNPT is further assumed to be information-structure driven. The authors assume that the information structure of SNPT in German is determined in the following way: REM has to be focused and TOP has to be a topic or a secondary focus. In addition, these information-structural requirements of TOP and REM are assumed to be encoded as strong semantico-pragmatic operator features that have to be checked by two different functional heads: a focus head F1 and a topic (or secondary-focus) head F2 (cf. also Krifka 1998b). So the to-be-split phrase XP first moves into Spec, F1, where the focus feature is checked and then into Spec, F2 where the other pragmatic feature is checked.[21] (43a) specifies the result after the two subsequent copying operations have applied, and (43b) after distributed deletion. It is assumed that the operations of distributed deletion do not apply before the copying operations have been completed.

(43) a. $[_{FP2}\ [_{XP}\ a_{topic}\ [b\ c]_{focus}]\ [F2 \ldots [_{FP1}\ [_{XP}\ a_{topic}\ [b\ c]_{focus}]\ [F1 \ldots [_{XP}\ a_{topic}\ [b\ c]_{focus}]]]]]$

b. $[_{FP2}\ [_{XP}\ \sout{a_{topic}}\ [b\ c]_{focus}]\ [F2 \ldots [_{FP1}\ [_{XP}\ a_{topic}\ \sout{[b\ c]_{focus}}]\ [F1 \ldots [_{XP}\ \sout{a_{topic}}\ [b\ c]_{focus}]]]]]$

(Fanselow and Ćavar 2002: (67))

For a great part, the explanatory force of this analysis stems from the different possible rankings of principles. For example, the phenomenon of determiner-overlap, which violates the Principle of Pronunciation, is viewed as a natural consequence of a principle that requires the phonetic string dominated by an NP to meet the lexical and morphological well-formedness conditions for NPs. Since determiner overlap violates the Principle of Pronunciation, this principle is assumed to be ranked higher than the Principle of Pronunciation in a minority of dialects. The number-disagreement facts are accounted for in a similar way. So, many problems that have been identified as movement paradoxes in section 2.2 receive an optimality-theoretic explanation in this analysis. The C&DD-analysis suggests a 'regeneration and relexicalization'-like solution for the possibility of SPPT, but it has no explanation to offer for the possibility of full-NP remnants in some dialects. Furthermore, this analysis provides no explanation for MST.

Yet another phrasal-movement analysis for SNPT, which – like any phrasal-movement analysis – obeys the SPC as a matter of fact, is an analysis that base-generates split NPs as members of a paratactic NP, i.e., the apposition analysis.

This analysis is discussed in Van Hoof (1997b, forthcoming) for German and Brabant Dutch.[22] Van Hoof relates SNPT with a complex-NP construction, named Restrictive Elliptic Appositive (REA) in Van Riemsdijk (1998a), which is attested in some colloquial varieties of German.

(44) [[Unterhosen] [dreckige]] solltest du waschen.
underpants dirty should you wash
(Van Riemsdijk 1998a: 19)

According to Van Riemsdijk (1998a), a REA forms a complex NP consisting of two independent NPs, of which the second one is elliptic. Van Hoof observes that in REAs, the second NP modifies the first one by specifying a subkind. Therefore, the antecedent/anaphor relation between the two NPs in a REA is of the same semantic type as between TOP and REM in SNPT (cf. section 2.3). Van Hoof argues that in SNPT, the split NPs are base-generated as a REA headed by the first NP. As shown in (45), the individual members of a REA form two autonomous NPs, for both NPs need a lexical determiner if they are headed by a singular count-noun:

(45) [$_{NP1}$ [$_{NP1}$ eine Unterhose] [$_{NP2}$ *(eine) saubere *pro*]].
an underpant a clean (one)

SNPT is derived by fronting the first NP into the pre-field, as illustrated in (46):

(46) [$_{NP1}$ Eine Unterhose]$_i$ habe ich glücklicherweise doch noch [$_{NP1}$ t_i [$_{NP2}$ eine
an underpant have I fortunately AFF still a
saubere *pro*]] gefunden.
clean (one) found
'As for underpants, I have fortunately still found some clean ones.'

Many grammatical properties of SNPT can be derived correctly by the apposition analysis, such as the possibility of determiner overlap, non-source and full-NP REMS as well as the possibility of number-disagreement facts.

However, some problems still remain. For example, this analysis does not predict the possibility of bare singular count-noun TOPS (cf. note 10).[23]

On the other hand, the apposition analysis is one of the very few analyses that predicts the possibility of SPPT, at least in some dialects of German. Van Riemsdijk (1998a) provides an example of a REA that consists of two PPs (cf. (47)). By splitting up the REA in this example, the SPPT in (48) can be derived:

(47) [$_{PP}$ [$_{PP}$ Auf einen Drink] [$_{PP}$ auf einen kurzen]] komme ich gern
on a drink on a short (one) come I gladly
schnell hinüber.
quickly over
'For a short drink, I'd like to come over quickly.'

(48) [$_{PP}$ Auf einen Drink]$_i$ könnte ich nur [$_{PP}$ t_i [$_{PP}$ auf einen kurzen *pro*]]
on a drink could I only on a short (one)
hinüberkommen.
come over
'As for a drink, I could only come over for a short one.'
(Van Riemsdijk 1998a: 21)

The apposition analysis can also derive MST by extraposing NP_2 from a NP-REA to VP, as demonstrated in (49) for the REA in (45). From the structure in (49), the MST in (50) can be derived:

(49) Ich habe hier noch nie [$_{VP}$ [$_{VP}$ [$_{NP1}$ [$_{NP1}$ eine Unterhose] t_i] gefunden]
I have here still never an underpant found
[$_{NP2}$ eine saubere *pro*]$_i$].
a clean (one)
'I still have not ever found clean underpants here.'

(50) [$_{VP}$ [$_{NP1}$ [$_{NP1}$ Eine Unterhose] t_i] gefunden]$_k$ habe ich hier noch nie
an underpant found have I here still never
[$_{VP}$ t_k [$_{NP2}$ eine saubere *pro*]$_i$].
a clean (one)
'As for having found underpants, I still have not ever found clean ones here.'

3.4 Summary

Although the analyses developed for SNPT in the past can be characterized as highly inventive, none of the analyses can account for all the different possible syntactic realizations of TOP and REM. Table 62.2 provides a bird's-eye view of the

Table 62.2 Analyses and properties of SNPT

VH97	Possibility of REAs

Note: See table 62.2 for abbreviations.

different grammatical properties of SNPT, as discussed in section 2, as well as a list of the most important analyses of this grammatical construction, as discussed in this section.

In relation to the restricted cross-linguistic distribution of SNPT within the Germanic language family, another interesting point of comparison has a bearing on the factor(s) that are held responsible for the occurrence of this construction in a particular language variety. Table 62.3 lines up the parameters that are implied by the different proposals.

4 Syntactic properties of Split-VP Topicalization

In SVPT, a core part of a complex verbal predicate (i.e., TOP) is extracted to the pre-field, where it is immediately followed by the fronted finite verb, while at least one of its verbal dependents, forming REM together with the c-commanded gap, is stranded in the clause. This is illustrated by the contrast between the well-formed SVPTs in (51) and the ill-formed ones in (52):[24]

(51) a. [Verkaufen] [wird er das Pferd ___ müssen].
sell will he the horse have to
'He will have to sell the horse.'
b. [Verkaufen müssen] [wird er das Pferd ___].
sell have to will he the horse
(De Kuthy and Meurers 2001)

(52) a. *[Das Pferd müssen] [wird er ___ verkaufen ___].
the horse have to will he sell
b. *[Müssen] [wird er das Pferd verkaufen ___].
have to will he the horse sell
'He will have to sell the horse.'

In a way, the syntactic properties of SVPT are reminiscent of SNPT. The X-bar-status of the fronted split VPs in (51) has been left unspecified. Under a

direct-movement analysis, the topicalized constituents cannot be maximal extended verbal projections, at least not without an additional stipulation. Therefore, SVPTs pose the same problems to the SPC and SCC as SNPT.

An analysis for SVPT must also be compatible with a plausible structural representation for the complex verbal predicate in the middle-field before the application of T. T is often used as a constituent test. However, it appears impossible to draw any firm conclusions about the constituency of complex verbal predicates on the basis of SVPT. For example, on the basis of (51a), one would conclude that the embedded verb combines with the direct object before it combines with other verbs. However, (51b) contradicts this conclusion. It shows that the main verb can also be combined with other verbs before it combines with the direct object. So on the basis of SVPT, it can only be concluded that there is no single bracketing available for the deep structure of the predicating clause. This seems to be an undesired result and has become known as the problem of spurious ambiguity (cf. Nerbonne 1994).

4.1 A-bar-properties and movement paradoxes

SVPT is island-sensitive, as briefly shown by (53), which violates the Complex-NP Condition, and by (54), which constitutes a violation of the Subject Condition:

(53) *[Gelesen] kenne ich $[\![_{NP}$ keinen Mann $[_{CP}$ der diese Bücher ___ hat]].
read know I no man who these books has
'I know no man who read these books.'

(54) *[Lesen] ist $[\![_{IP}$ $[_{IP}$ dieses Buch ___ zu müssen] schwer].
read is this book to have to difficult
'To have to read this book is difficult.'

So SVPT also creates an A-bar-relation between TOP and REM. Movement paradoxes are not that numerous as with SNPT, though they do occur. Haider (1990) brings up an example set with argument clauses that can be interpreted as a movement paradox. In German, non-topicalized argument clauses have to be realized in the post-field and cannot appear in the middle-field at surface structure, as shown in (55). However, the two SVPTs in (56) can only be derived if the transformational rules T and extraposition are not ordered. Then, in (56a), extraposition must have applied after T and in (56b), extraposition must have applied before T, at least under the assumption that SVPT is derived by direct movement:[25]

(55) a. dass er wohl fragen müssen wird, [ob wir einverstanden sind].
that he surely ask have to will whether we agreed are
b. *dass er wohl fragen [ob wir einverstanden sind] müssen wird.
that he surely ask whether we agreed are have to will
'that he surely will have to ask whether we agree.'
(Haider 1990b: 95)

(56) a. [Fragen, ob wir einverstanden sind] [wird er wohl ___ müssen].
ask whether we agreed are will he surely have to
b. [Fragen] wird er wohl ___ müssen, [ob wir einverstanden sind].
ask will he surely have to whether we agreed are
'He will surely have to ask whether we agree.'

Weerman (1989) and Zwart (1993) note that in some VPTs the dummy verb *to do* shows up naturally in the second position of a topicalized sentence, though it is really awkward in a stylistically unmarked declarative sentence. A similar contrast can be constructed for SVPT, too:[26]

(57) a. [Kochen] [tut er nur vegetarische Gerichte ___].
cook does he only vegetarian dishes
'As for cooking, he cooks only vegetarian dishes.'
b. *Er tut nur vegetarische Gerichte kochen.
he does only vegetarian dishes cook
'He cooks only vegetarian dishes.'

In spite of these movement paradoxes, the relation between TOP and REM can be characterized as of the A-bar-type.

4.2 The gap is governed by a restructuring verb

A fundamental observation about SVPT is that this construction requires a complex VP consisting of at least two verbs (cf. Haider 1990b). In addition, the governor of the gap of the preposed split VP has to be a restructuring verb (see chapter 75).

The individual verbs in a restructured complex VP are more cohesively connected than verbs that form part of a verbal complex that includes non-restructuring verbs. The cohesion property of restructured VPs becomes apparent from a number of grammatical properties,[27] among others the possibility of SVPT (cf. (58)). In SVPTs, the gap corresponding to TOP has to be governed by an (optional) restructuring verb (cf. Müller 1998 and the references therein). For instance, *wollen* ('to want'), which governs the gap in (58a), forms an obligatorily restructuring verb, *versucht* ('to try') in (58b) an optionally restructuring verbal participle and *abgelehnt* ('refused') in (58c) an obligatory non-restructring verbal participle:[28]

(58) a. [Lesen] [hat keiner das Buch ___ wollen].
read has no one the book want
'No one has wanted to read the book.'
b. [Zu lesen] [hat keiner das Buch ___ versucht].
to read has no one the book tried
'No one has tried to read the book.'
c. *[Zu lesen] [hat keiner das Buch ___ abgelehnt].
to read has no one the book rejected
'No one has rejected to read the book.'

4.3 The division of arguments among TOP and REM

If SVPT were really similar to SNPT, one would expect that the base order of arguments of a restructured VP would be reflected in the division of arguments among TOP and REM, by analogy with the preservation of adjectival ordering restrictions in SNPT. As argued in Haider (1993), the base order of arguments in non-topicalized sentences is determined by the rank of argument variables in the lexical argument structure of a verb. So, one would predict the effect of a condition like that in (59) to become perceivable somehow:[29]

(59) **No-Theta-Crossing Constraint (NTCC):**
Argument *A* cannot be in TOP if there is an argument *B* in REM and *A* >>> *B* in the argument structure of the restructured VP.

Clear contrasts with respect to the NTCC can be observed for restructured VPs that select a direct object and a dative or genetive object. As can be viewed from the base order in (60a), the genetive object must be ranked lower in the lexical argument structure of the complex VP than the direct object. The contrast between (60b) and (60c) shows the effect of the NTCC:[30]

(60) a. Man sollte seinen Vater nie eines Mordes
one should his father never the-GEN murder-GEN
beschuldigen. (Base order)
accuse
'One should never accuse his father of murder.'
b. [Eines Mordes beschuldigen] [sollte man seinen Vater nie ___].
the-GEN murder-GEN accuse should one his father never
c. *[Seinen Vater beschuldigen] [sollte man nie eines Mordes ___].
his father accuse should one never a-GEN murder-GEN
'One should never accuse his father of murder.'

However, the ungrammaticality in (60c) is not absolute, for this SVPT improves in a contrastive context with a strong rise-fall contour, as shown by the examples in (61):

(61) [Seinen /VATER beschuldigen] [sollte man nie eines \MORDES ___]
his father accuse should one never a-GEN murder-GEN
und seine /MUTTER nie eines \VERBRECHENS.
and his mother never a-GEN crime-GEN
'One should never accuse his FATHER of MURDER and his MOTHER of CRIME.'

So, ordering restrictions among arguments are preserved, although not in an absolute way, as has also been concluded with respect to the preservation of the ordering restrictions of prenominal adjectives in SNPT (cf. section 2.1).

Although it was initially believed that only indefinite subjects of passive participles and ergative verbs can be preposed along with the verb in SVPT (cf.

Thiersch 1985b; Grewendorf 1989), as illustrated in (62), Haider (1990b: 97) and Webelhuth (1990) observe that indefinite unergative subjects can also appear in TOP if the middle-field is filled by at least one verbal dependent (cf (63)):

(62) [Fehler unterlaufen] [sind meinem Lehrer noch nie ___].
mistakes occurred have my teacher yet never
'My teacher has never made any mistakes yet.'

(63) [Ein Aussenseiter gewonnen] [hat da noch nie ___].
an outsider won has there yet never
'An outsider has never won there yet.'

Haider (1990b: 97) notices that subjects of transitive VPs cannot appear in TOP if the direct object is in REM (cf. (64)), a result that corroborates the NTCC in (59):[31]

(64) *[Ein Aussenseiter gewonnen] [hat da noch nie das Derby ___].
an outsider won has there yet never the Derby
'An outsider has never won the Derby yet.'

4.4 An asymmetry between Topicalization and Scrambling

Müller (1998: 24, 215) observes that although split VPs can be topicalized (cf. (65a)), they cannot be scrambled, as shown in (65b) (cf. Fanselow 1989; Haider 1993: among others for similar observations):

(65) a. [Zu lesen] [hat das Buch keiner ___ versucht].
to read has the book no one tried
'No one has tried to read the book.'
b. *dass [zu lesen] [das Buch keiner ___ versucht hat]
that to read the book no one tried has
'that no one has tried to read the book'

However, a similar asymmetry between T and scrambling cannot be observed with the preposing of unsplit VPs, for the examples in (66) show that unsplit VPs can be scrambled:

(66) a. dass [das Buch zu lesen] keiner ___ versucht hat
that the book to read no one tried has
'that no one has tried to read the book'
b. dass [dem Matthias den Drucker zu reparieren] der Frank ___
that the Matthias the printer to repair the Frank
versprochen hat
promised has
'that Frank has promised to Matthias to repair the printer'

(Müller 1998: 215)

These contrasts show that T, as opposed to Scrambling, can also apply to partial VPs. However, the contrast between (65) and (66) can only be obtained if the examples are uttered with a flat intonation contour. So, the type of Scrambling that is not allowed to apply to parts of a restructured VP is the neutral kind of Scrambling (see chapter 43).[32]

5 Syntactic analyses of Split-VP Topicalization

The following two main types of analysis have been proposed for SVPT in German in the past: (i) the remnant-movement (RM) analysis, and (ii) extraction of a VP shell. Both analyses somehow build a bridge between the phenomenon of Scrambling and the possibility of SVPT. The fact that SVPT only occurs in the Germanic languages with Scrambling, such as German and Dutch, hints at this correlation.[33] The two analyses capture this correlation in slightly different ways.

5.1 The RM analysis

The RM analysis for SVPT was launched in Thiersch (1985) and developed further by den Besten and Webelhuth (1990) and by Müller (1998). The analysis proceeds in two steps: (i) an internal argument is scrambled (i.e., moved) out of a dominating VP, and (ii) the VP is topicalized (i.e., moved directly) into Spec, C:

(67) $[_{CP}\ [_{VP}\ t_1 \ldots V^0]_2\ [_{C'}\ V_{fin} \ldots NP_1 \ldots t_2 \ldots]]$.

In this way, the SPC is satisfied and also the spurious-ambiguity problem is solved.

In the RM analysis, it is assumed that the domain of the restructured VP also delimits the syntactic domain for Scrambling (cf. (i) in note 28), as also becomes apparent from the minimal pair in (68):

(68) a. [[t_i Zu lesen]$_k$ versucht]$_j$ hat keiner [$_{NP}$ das Buch]$_i$ t_j.
to read tried has no one the book
'No one has tried to read the book.'

b. *[[t_i Zu lesen]$_k$ abgelehnt]$_j$ hat keiner [$_{NP}$ das Buch]$_i$ t_j.
to read refused has no one the book
'No one has refused to read the book.'

(cf. Müller 1998: 19)

A theoretical problem for this analysis is the problem of unbound traces. According to the Proper Binding Condition (PBC), traces have to be c-commanded by their antecedent. Since TOP in SVPT contains an unbound trace, the PBC is expected to preclude SVPT under this analysis.

Den Besten and Webelhuth (1990) propose to alleviate the effect of the PBC for SVPT by allowing unbound argument traces in TOP to be reconstructed into

their base position and as a consequence, to become invisible for the PBC.[34] Contrasts like those in (69) are explained in this way:

(69) a. $[t_i$ Gelesen$]_j$ [hat Hans $[_{NP}$ das Buch$]_i$ nicht $t_j]$.
read has Hans the book not
'Hans has not read the book.'
b. *$[[_{PP}$ t_i Mit] gerechnet$]_j$ [hat Hans da_i nicht $t_j]$.
with counted has Hans there not
'Hans has not counted with that.'
(Den Besten and Webelhuth 1990: 78)

Müller (1998) argues that the PBC can be fully dispensed with in a strictly derivational theory of movement that adopts the main premises of the Minimalist Program (cf. Chomsky 1995c).[35]

Another theoretical problem for the RM-analysis is formed by the so-called 'anti-freezing' effects. The Freezing Principle (see chapter 28) states that extraction of a phrase α from another phrase β is only possible if β occurs in situ and is not a moved category itself. Therefore, extraction from the (overt) scrambled REM in SVPT is predicted to be always ungrammatical, contrary to fact. For example, the Freezing Priniciple correctly rules out the SVPT in (70a), but incorrectly excludes the SVPT in (70b):

(70) a. *$[t_j$ Gerechnet$]_k$ [hat da_i wie immer $[_{PP}$ t_i mit$]_j$ keiner $t_k]$.
counted has there as always with no one
b. $[t_j$ Gerechnet$]_k$ [hat da_i wie immer keiner $[_{VP}$ $[_{PP}$ mit $t_i]_j$ $t_k]]$.
counted has there as always no one with
'No one counted with that, as always.' (Müller 1998: 203)

Given the sum of facts in (70), it cannot be claimed that every scrambled phrase forms an island for extraction, since the string-vacuously scrambled REMs do not. Therefore, Den Besten and Webelhuth (1990) propose that the general ban against extraction from adjoined phrases can be alleviated if the PP is adjacent to the reconstructed verb.

Müller (1998: 205ff.) provides a different account for the contrast in (70). According to him, the REM PP in (70b) must have undergone a different kind of movement in this example, namely 'string-vacuous' extraposition, that exempts it from inducing a freezing effect. However, as Müller admits himself, this solution does not seem to be fully satisfactory either.

Müller (1998) explains the asymmetry between topicalized and scrambled split VPs (cf. section 4.4) – i.e., that split VPs can be topicalized but cannot be scrambled – by the Principle of Unambiguous Domination (PUD). The PUD says that remnant XPs cannot undergo a particular type of movement if the antecedent of the unbound trace in XP has undergone the same type of movement (Müller 1998: 241).

We will now focus on a different problem for the RM-analysis, namely on its tenet that REMs are evacuated from VP by a movement type that equals Scrambling. The strongest possible prediction of the RM-analysis is that elements that can be scrambled can be stranded as REMs and vice versa. But it can be argued that this premise cannot be upheld for at least three reasons: (i) the NTCC does not comply with it; (ii) certain elements cannot be scrambled, but can still be stranded as REMs; and (iii) certain stranded elements that can be scrambled can also be stranded with an 'in situ' interpretation.

Although different types of Scrambling can be distinguished in West Germanic (see chapter 43), most Scrambling types change the base order of arguments. Therefore, the effect of the NTCC (cf. (59)) comes somewhat as a surprise, since in the RM analysis Scrambling precedes T. The proponents of the RM analysis do not specify which Scrambling type is supposed to be relevant for their analysis. The type of Scrambling that can apply after T has been completed, on the other hand, is allowed to permute arguments (cf. note 29).

A constituent type which it is generally assumed cannot be scrambled, but that can still be stranded as a REM, is formed by negated indefinites, as shown in (71):

(71) a. dass der Fritz niemanden küsst (Base order)
that the Fritz no one kisses
'that Fritz kisses no one.'
b. ?*dass niemanden$_i$ der Fritz t_i küsst (Scrambled order)
that no one the Fritz kisses
c. [t_i Geküsst]$_j$ [hat der Fritz niemanden$_i$ t_j]. (SVPT)
kissed has the Fritz no one
'Fritz has kissed no one.' (Fanselow 2002: 99–100)

Another example is formed by non-d-linked w-indefinites, whose VP-internal position is generally believed to be fixed. Haider (1993) provides the following example:

(72) [Gelungen] [ist hier selten wem was auf Anhieb ___].
succeeded is here rarely someone something off straight
'Rarely has someone succeeded something straight off here.'
(Haider 1993: 281)

If non-specific w-indefinites are immovable, the RM analysis does not predict that they can be stranded. The SVPT in (72) can only be derived if the type of Scrambling that evacuates VP also subsumes a string-vacuous type of Scrambling.[36]

Another point that weakens the RM analysis is that in this analysis any VP node can form the target of remnant T, which makes it hard to falsify the analysis. As a consequence, the preposed remnant VP is labeled 'α' in order to remain uncommitted about the categorial features of the remnant VP (cf. Müller 1998: 214).

An HPSG analysis that resembles the RM analysis in many respects has been proposed by Hinrichs et al. (1994).

5.2 *Extraction of a VP shell*

Another possible way by means of which a movement analysis can meet the requirements that are set by the SPC and the spurious-ambiguity problem is to conceive a maximal (complex) VP as a cascade of layered VPs and by extracting one of the VP shells, as proposed for instance in Frey and Tappe (1991), Fanselow (1993), Haider (1993, 1994a):

(73) weil [$_{VP}$ jemand [$_{VP}$ einem Mädchen [$_{VP}$ einen Blumenstrauss
because someone a girl a bunch of flowers
verspricht]]] (base order)
promises
'because someone promises a girl a bunch of flowers.'

This type of analysis assumes that theta-roles cannot only be assigned in a head–sister configuration, but in a V^{max}–sister configuration as well. In addition, it is assumed that the arguments are merged in the same order as in the lexical argument structure of the main verb.

In the analysis of Frey and Tappe (1991), elements that are theta-marked in the head–sister configuration are restricted to non-depictive predicative elements, resultatives and directional PPs. The syntactic position of these elements is relatively fixed, which appears from the fact that they cannot be scrambled with a flat intonation. According to Frey and Tappe, the fact that these elements cannot be stranded in SVPT (cf. (74)) is predicted by their analysis. However as shown by (75), these SVPTs become perfectly grammatical if the predicative element is made heavier, for instance by means of focus:

(74) *[Gegessen] [hat er den Teller leer ___].
eaten has he the plate empty
'He has eaten the plate empty.'

(75) [Gegessen] [hat er den Teller nur HALB leer ___].
eaten has he the plate only half empty
'He has eaten the plate only HALF empty.'

In the analysis of Haider (1990b, 1993, 1994a), TOP is base-generated as a (small VP) in Spec, C and co-indexed with an empty category in the clause with identical categorial but with not necessarily identical level features (cf. note 17 for a reference to a similar analysis of SNPT, which violates the Chain Uniformity Condition as well).

Haider (1993, 1994a) assumes that in restructured VPs, the argument structures of the individual verbs have been unified and that the restructured VP has a complex projection base. A complex projection base contains more than one lexical head in the syntactic projection, which comes about through head-to-head

adjunction, while the arguments of the verbal complex form segments of the maximal projection of the complex head.

Given this structural representation of restructured VPs, the SVPT in (76a) can be derived. However, the derivation in (76b) is problematic because of a conflict of requirements (cf. also Haider 1993: 282). On the one hand, TOP has to be a maximal projection – not only because of the SPC, but also since it contains a direct object – while on the other hand, the empty category bound by TOP has to be a head, since it must form a complex head with the fronted restructuring verb *haben* ('to have'):

(76) a. $[_{VP}$ Versprochen$]_i$ $[hat_j$ er $[_{VP}$ einem Mädchen $[_{VP}$ einen
promised has he a girl a
Blumenstrauss e_i $e_j]]]$.
bunch of flowers

b. $[_{VP}$ Einen Blumenstrauss $[_{VP}$ versprochen$]]_i$ $[hat_j$ er $[_{VP}$ einem
a bunch of flowers promised has he a
Mädchen e_i $e_j]]$.
girl
'He has promised a girl a bunch of flowers.'

A similar kind of analysis within the framework of HPSG has been proposed in Nerbonne (1994) and De Kuthy and Meurers (2001). They propose an analysis that makes use of an argument-raising mechanism encoded in lexical rules.

A modernized version of the VP-shell movement analysis is proposed in Fanselow (2002) and is called the predicate-raising analysis (PR-analysis). In this analysis, a maximal VP is directly moved into Spec, C and each VP shell is dominated by its own lexical head. The traditional assumption that theta-roles of X^0 must be assigned to elements within XP has also been dismissed. By this move, the contents of the base-generated VP become variable, so that not only the structure in (77a), but also the structures in (77b, c) are base-generated candidates for the sentence *dass sie dem Fritz ein Buch geschenkt hat*:

(77) a. dass $[_{IP}$ sie $[_{VP2}$ $[_{VP1}$ dem Fritz ein Buch geschenkt$]$ hat$]]$
that she the Fritz a book given has

b. dass $[_{IP}$ sie $[_{VP2}$ dem Fritz $[_{VP1}$ ein Buch geschenkt$]$ hat$]]$
that she the Fritz a book given has

c. dass $[_{IP}$ sie $[_{VP2}$ dem Fritz ein Buch $[_{VP1}$ geschenkt$]$ hat$]]$
that she the Fritz a book given has
'that she gave a book to Fritz (as a present)' (Fanselow 2002: 94)

Fanselow (2002) considers theta-assignment a consequence of feature checking and assumes that the theta-features do not have to be checked before LE. As a consequence, theta-checking is not restricted to the lexical domain of a verb but is extended to the domain of dominating restructuring verbs. It is assumed that

the verbs in a restructured VP can be related by incorporation at LF, i.e. *geschenkt* in (78) can be copied to the auxiliary at LF (cf. (78e)). This does not imply that the theta-features can only be checked after incorporation at LF: some theta-features can be checked before and some theta-features have to await verb incorporation. The PR-analysis of SVPT is demonstrated in (78):

(78) a. Structure generated by Merge:
C^0 sie $[_{VP}$ dem Fritz $[_{VP}$ ein Buch geschenkt] hat]
she the Fritz a book given has

b. Movement of V_{fin} to C^0:
$[_{C^0}$ hat] $[_{IP}$ sie $[_{VP}$ dem Fritz $[_{VP}$ ein Buch geschenkt] ~~hat~~]]
has she the Fritz a book given has

c. Preposing of lower VP into Spec, C (= spell-out):
$[_{CP}$ $[_{VP}$ ein Buch geschenkt] $[_{C'}$ hat sie $[_{VP}$ dem Fritz ~~$[_{VP}$ ein Buch~~
a book given has she the Fritz a book
~~geschenkt] hat~~]]]
given has

d. Reconstruction of VP:
$[_{CP}$ ~~$[_{VP}$ Ein Buch geschenkt]~~ $[_{C'}$ hat sie $[_{VP}$ dem Fritz $[_{VP}$ ein Buch
a book given has she the Fritz a book
geschenkt] ~~hat~~]]]
given

e. Predicate raising:
$[_{CP}$ ~~$[_{VP}$ Ein Buch geschenkt]~~ $[_{C'}$ hat sie $[_{VP}$ dem Fritz $[_{VP}$ ein Buch
a book given has she the Fritz a book
~~geschenkt~~] geschenkt ~~hat~~]]]
given given has

(Fanselow 2002: 97)

In these three variants of the VP-shell-extraction analysis, there is a direct link between SVPT and the base-generated structure for restructured VPs (see chapter 75). The fact that German (and Dutch) allow for SVPT, but English does not (cf. the VPT in (12) vs. the ungrammatical SVPT in (13)), is attributed to the German-specific middle-field structure in which arguments can be base-generated as sisters of a VP. A clear advantage of these analyses is that stranded arguments are not predicted to be islands a priori because they can be in base-generated position. For the same reason, the concept of 'string-vacuous' Scrambling comes more or less for free in these analyses, so that they do not imply a mismatch between stranding and Scrambling. However, the latter point does not pertain to the PR analysis, since in this analysis free word order is base generated. Therefore, this analysis does not make a distinction between 'string-vacuous' Scrambling and Scrambling that permutes arguments, just like the RM analysis. Fanselow (2002: 105ff.) appears to draw this conclusion himself.

Table 62.4 shows in a nutshell to what extent the syntactic characteristics of SVPT are accounted for by three representative analyses of SVPT.

Table 62.4 Analyses and properties of SVPT

	M98	FT91	F02
A'-properties	+	+	+
Movement paradoxes	?	?	?
Gap is governed by a restructuring verb	+	+	+
Stranding of VP-internal arguments	−	−	+
Anti-freezing effects	?	+	+
Obedience to NTCC	−	+	−
No neutral Split-VP Scrambling	+	+	+

Note: M98, FT91, and F02 refer to Müller (1998), Frey and Tappe (1991), and Fanselow (2002) respectively.

6 Different landing sites for Split Topicalization

Until now, we have only taken into account STs in which the split constituent has been extracted to a position right in front of the finite verb in main clauses. However, ST can also target different positions, which this section will pass in review.

6.1 Split Scrambling

It has been noted in Grewendorf (1989) and Neeleman (1994a) that split NPs can also be preposed in embedded clauses, a type of ST that will be referred to as Split Scrambling. (79) and (80) provide some examples of Split-NP Scrambling:

(79) a. weil er [Kleider] immer [dreckige ___] anhat
because he clothes always dirty (ones) wears
b. weil [Kleider] er immer [dreckige ___] anhat
because clothes he always dirty (ones) wears
(Grewendorf 1989: 27)

(80) a. dass [Bücher solcher Autoren] selbst Hans seinem Sohn nicht
that books of such authors even Hans his son not
[viele ___] gibt.
many gives
b. dass Hans [Bücher solcher Autoren] selbst seinem Sohn nicht
that Hans books of such authors even his son not
[viele ___] gibt.
many gives
'that Hans does not give many books of such authors even to his son'
(Neeleman 1994: 86)

(79) and (80) show the split-scrambled NP can either precede or follow the definite subject. According to Neeleman (1994a), the examples in (80) form instances of Focus Scrambling, an A-bar-kind of Scrambling that triggers the rise-fall contour with a rise on the preposed phrase.[37]

Although split VPs, like split NPs, are not allowed to undergo neutral Scrambling (cf. section 4.4), they can undergo Focus Scrambling, again with the rise-fall contour, giving rise to Split-VP Scrambling:

(81) dass [so geliebt] [die Maria nur er hat]
that so loved the Maria only he has
'that only he loved Maria to such a degree' (Hinterhölzl 2002: 140)

Like the unsplit type of Focus Scrambling, Split Scrambling shows connectivity effects and can straddle a clause-boundary, as becomes apparent from (82):

(82) Ich hab' gehört, dass ['ne /LÖSUNG für sein$_i$ Problem] wohl \NIEMAND
I have heard, that a solution for his problem surely nobody
glaubt, dass er$_i$ [eine ___] finden wird.
believes, that he one find will
'I have heard that nobody believes that he will find a solution for his problem.'

6.2 Split Contrastive Left Dislocation

Van Hoof (1997a, 1997b) demonstrates that in Brabant Dutch split NPs cannot only undergo ST to the position right in front of the finite verb, but Contrastive Left Dislocation (CLD) (see chapter 37) as well. This type of ST, in which the finite verb ends up in third position, is named Split-CLD. As shown in (83), SNPT and Split-NP CLD (SNPCLD) occur side by side in Brabant Dutch:

(83) Brabant Dutch:
[Koeien] (die) heeft-ie [een helehoop ___] in de achterste wei.
cows D-pr has-he a whole heap in the rearmost meadow
'As for cows, he has quite a lot in the rearmost meadow.'
(Van Hoof 1997a: 280)

As becomes apparent from (83), SNPCLD differs from SNPT by a right-adjacent d(emonstrative)-pronoun (i.e. a so-called d-pronoun) whose ϕ-features agree with TOP. As shown in Van Hoof (1997a), TOP and REM are A-bar-related through the D-pronoun. Except for the presence of the D-pronoun, SNPT and SNPCLD in Brabant Dutch roughly have the same grammatical properties as SNPT in German.[38]

Examples of Split-VP CLD (SVPCLD) have also been observed for different varieties in West Germanic. Zwart (1993) provides an example for Dutch (84) and Fanselow (1993) mentions similar examples for German (85):

(84) [Gekust] [(dat) heeft Jan Marie niet ___].
kissed D-pr has Jan Marie not
'Jan hasn't kissed Marie.' (Zwart 1993: 109)

(85) a. [Schenken], [das wird Peter mir das Buch zwar nicht ___].
give D-pr will Peter me the book actually not
'Peter will actually not give the book to me.'
b. [Einem Kind schenken], [das sollte man solche Bücher besser
a child give D-pr should one such books better
nicht ___].
not
'One should better not give a child such books.'
(Fanselow 1993: 13)

According to Müller (1998: 221ff.), SVPCLD is ungrammatical in German. It has to be concluded, therefore, that Split-CLD is a variant of ST that is dialectally restricted. The question arises why this is the case (cf. Van Hoof forthcoming for discussion).

6.3 Split Topicalization and Split Scrambling

Split-NP Scrambling is also possible in combination with SNPT. These recursive splits induce the rise-fall contour with a strong rise on the split-scrambled NP:

(86) [Fehler] sind ihm [so richtig dumme ___] noch [keine ___]
mistakes are him such real stupid (ones) still none
unterlaufen.
happened
'As for mistakes, he hasn't made any real awful ones yet.'
(Pafel 1995: 66)

Given the fact that there are two different possible landing sites for ST, it does not come really as a surprise that multiple SNPT is possible, too:

(87) [Sonaten]$_j$ haben [Frauen]$_i$ bislang nur [wenige ___]$_i$ [welche ___]$_j$
sonatas have women up to now only few some
geschrieben.
written
'As for sonatas: up to now, only few women have composed some.'
(Fanselow and Ćavar 2002: 67)

Split-NP Scrambling can be combined not only with SNPT, but with SVPT and MST, too, as shown by the examples in (88) and (89):[39]

(88) [Gelesen] [hat er [/SOLCHE Bücher] \BESTIMMT noch [keine ___]].
read has he such books surely yet none

(89) [/BÜCHER gelesen] [hat er [/SOLCHE ___] \BESTIMMT noch [keine ___]].
books read has he such (ones) surely yet none
'He surely hasn't read such books yet.'

7 Work on related phenomena in other languages

Within the generative framework, SNPT and related split-NP-preposing constructions have been investigated in some depth for Modem Greek, Polish, Serbo-Croatian, and Russian. These constructions are typical of two registers, namely literary prose and spoken language. Most studies take into account only the latter variety, and so does this section. These languages also allow for split-NP preposings that seem to be of a slightly different type, since not the constituents' core but their left branch are preposed. In this type of split-NP preposing, for example, an adjective can be preposed, while the noun stays behind. Fanselow and Ćavar (2002) introduce the term pull split for this kind of split-NP preposing, a term that will be adopted here.

7.1 Split-NP preposing in Modern Greek

Androutsopoulou (1998) proposes a RM analysis for split-NP preposing in Modern Greek. Androutsopoulou only discusses split-NP preposings of the pull-split type with a definite TOP (cf. (90b)). The unsplit variant is provided in (90a):

(90) a. Idha [to kokkino forema].
I saw the red dress
'I saw the red dress.'
b. [To KOKKINO] idha [___ forema].
the red I saw dress
'It is the RED dress that I saw.' (Androutsopoulou 1998: 2)

Androutsopoulou demonstrates that the relation between TOP and REM exhibits properties of A-bar-movement. She proposes the analysis in (91) for the split-NP preposing in (90b):

(91) $[_{FocP}\,[_{DP}$ To kokkino $t_i]_j$ $idha_k$ $[_{XP}\,[_{NP}$ forema$]_i$ X^0 $[_{VP}\,t_k$ $t_j]]]$.
the red I saw dress
(Androutsopoulou 1998: 9)

According to the derivation depicted in (91), firstly the overt part of REM, apparently remaining in situ in (90b), is scrambled as a subconstituent out of the unsplit NP to the specifier of a verbal functional head, i.e. X^0, which hosts a clitic

in clitic doubling constructions. In a second step, TOP – i.e., the remnant DP containing the trace of *forema* 'dress' – is moved in its entirety into the specifier of a left-peripheral focus phrase (FocP). In this way, a potential violation of the Left Branch Condition (see chapter 66) is avoided. The island and connectivity effects are caused by the second step of remnant movement.

Although Androutsopoulou explicitly notes that the preposed NP remnant, i.e., TOP, has the syntactic appearance of an independent elliptic NP, the relation between the gap in TOP and its antecedent REM is one of movement in this analysis. However, exactly this observation and the fact that REM can also be preceded by a determiner (cf. (92)), as in independent NPs, lead Mathieu and Sitaridou (2003) to adopt an analysis that departs from a base-generated paratactic NP "[[to forema] [to kokkino]]" (cf. also Devine and Stephens 2000 for a similar analysis of split NPs in Ancient Greek):[40]

(92) [To KOKKINO] agorase [to forema ___].
the red bought the dress
'She bought the RED dress.' (Horrocks and Stavrou 1987: 91)

Mathieu and Sitaridou (2003) relate the phenomenon of determiner spreading (or: 'double definiteness' (cf. section 3.1)) in Modern Greek to split-NP preposing in this language. They propose that the two paratactic NPs in a determiner-spreading structure form a small clause. One NP forms a referential elliptic DP-predicate; the other NP, which is of the category NP and may contain an expletive determiner, forms its subject. The predicate DP of the small clause undergoes predicate inversion and raises to an outer specifier position in order to be licensed. (93) shows the determiner-spreading structure for the paratactic NP '[[to forema] [to kokkino]]' as proposed by Mathieu and Sitaridou (2003: (25)):[41]

(93) $[_{DP}\ [_{DP}$ To kokino $e]_i\ [_{SC}\ [_{NP}$ to forema] $t_i]]$.

The structure in (93) forms the point of departure for the derivation of split-NP preposing in (90b).[42]

7.2 Split-NP and split-PP preposing in Slavic languages

Most Slavic languages have split-NP and split-PP preposing. Fanselow and Ćavar (2002) propose an analysis for split-NP and split-PP preposing in Polish and Croatian; Franks and Progovac (1994) discuss split-PP preposing in Serbo-Croatian; Siewierska (1984) describes information-structural aspects of these two split preposings in Polish; and Sekerina (1997a, 1997b) takes into account information-structural and syntactic aspects of split preposing in Russian.

Two types of split preposing can be distinguished for Slavic: (i) a type that is similar to SNPT in German, in which fronting brings about an inverse scope relation between the two base-generated parts of an unsplit NP, and (ii) a pull-split preposing comparable to split-NP preposing in Modern Greek, in which the

scope relation of the split parts are the same as in the unsplit constituent. The two types of split-NP preposing are illustrated in (94) and (95). Split-PP preposing (cf. (96)), can only be of the pull-split type in Croatian; the inverted type is not allowed:[43]

(94) Croatian:
[Knijge] mi je Marija [zanimljive ___] preporučila.
books me has Mary interesting recommended
'Mary has recommended interesting books to me.'

(95) [Crveni] je Ivan [___ auto] kupio.
red has Ivan car bought
'Ivan has bought a red car.'

(96) [Na veliko] se Ivan [___ drvo] popeo.
on big self Ivan tree climbed
'Ivan climbed on a big tree.'
Fanselow and Ćavar 2002: (5b), (14a), (22e))

According to standard assumptions, pull PP-splits cannot be submitted to a subphrasal movement analysis because the modifier of the NP cannot form a constituent with the determiner. Therefore, Franks and Progovac (1994) propose a RM-analysis for the split-PP preposing in (97). As a first step, the NP moves out of the PP and right-adjoins to IP. Subsequently, the remnant PP topicalizes into Spec, C:[44]

(97) Serbo-Croatian:
$[_{CP}\ [_{PP}$ U $[_{DP}\,[_{AP}$ veliku $t_i]]]]_j\ [_{C'}$ je $[_{IP}\ [_{IP}$ Jovan t_j ušao] $[_{NP}$ sobu $]_i]]]$.
into big CL J. walked room
'Jovan walked into this big room.' (Franks and Progovac 1994: 71)

One of the problems that this analysis faces is that the structure gained after the first movement operation never occurs at the surface in this language. For example, NPs can neither be topicalized, nor be scrambled out of PPs (cf. (98)):

(98) Croatian:
a. *$[\text{Drvo}]_i$ se Ivan popeo $[_{PP}$ na veliko $t_i]$.
tree self Ivan climbed on big
b. *Ivan se $[\text{drvo}]_i$ popeo $[_{PP}$ na veliko $t_i]$.
Ivan self tree climbed on big
'Ivan climbed on a big tree.' (Fanselow and Ćavar 2002: 72)

Franks and Progovac suggest that the ill-formed examples in (98) stem from a violation of a scope-preservation principle that makes surface word order strive to reflect the scope relations in base-generated structure as much as possible.

These problems motivate Fanselow and Ćavar (2002) to extend their C&DD-analysis they propose for SNPT in German (cf. section 3.3) to split-NP and split-PP preposing in Croatian and Polish.

Sekerina (1997a, 1997b) observes that split-NP preposing and split-PP preposing in Polish and Russian have some striking similarities. Four grammatical properties identified for split preposing in Polish by Siewierska (1984), hold for split preposing in Russian, too: (i) split-PP and split-NP preposing tend to involve phrases containing a noun and just one adjective; (ii) in the majority of cases, phrases are split into two parts that end up at the edges of the clause; (iii) PPs can only be split if the prepositional object is modified and no part of the prepositional object precedes the preposition; (iv) there can be only one split per clause.

Also in Russian, split preposings go hand in hand with a contrastive reading for at least one split constituent. In the wake of Androutsopoulou (1998a, 1998b) (cf. section 7.1), Sekerina (1997a, 1997b) proposes a focus-driven movement analysis for split-NP Scrambling in Russian, too. Different possible outcomes of split-NP Scrambling in Russian together with their prosodic structures are shown in (99) and (100) (cf. also Mehlhorn (2001) for a detailed information-structural description of split-NP preposing in Russian):

(99) Russian:
  a. [Cernyj] on ljubit [___ KOFE].
  black-ACC he-NOM likes coffee-ACC
  'It is coffee that he likes to take black.'
  b. [CERNYJ] on ljubit [___ kofe].
  'He likes to take his coffee black.'

(100) a. [Kofe] on ljubit [CERNYJ ___].
  'He likes to take his coffee black.'
  b. [KOFE] on ljubit [CERNYJ ___].
  'It is coffee that he likes to take black.' (Sekerina 1997a: 384)

In contrast to Polish, where both split parts are focused in the majority of cases, resulting in a double-focus construction (cf. Siewierska 1984), both split parts can be focused only rarely at the same time in Russian (cf. Sekerina 1997a: n. 9). In general, split-NP preposing in Russian is appropriate in more contexts than in Polish. A contrastive context is no absolute desideratum and initial opening utterances of the discourse with split constituents are quite common (cf. Sekerina 1997a, 1997b).

Sekerina (1997b) proposes a double-movement analysis for split preposing in Russian: an unsplit DP or PP first scrambles into the specifier position of a higher FocusP (above IP and below CP). As a second step, a subconstituent is extracted out of it and becomes right-adjoined to FocP. Sekerina adduces two putatative causes for the fact that split phrases in Russian and Polish tend to appear at the peripheral edges of the clause (a descriptive generalization that is named

'Periphery-Constraint'). One pragmatic driving force for split-NP preposing is formed by the purpose of focus assignment to one of the two subparts of the discontinous constituent by moving it into FocP. Another information-structural force for split preposing is formed by deaccentuation as defined by the nuclear-stress rule as formulated in Cinque (1993) (see chapter 49).

7.3 Split topics 'Chinese-style'

Chinese-style topics are typical of topic-prominent languages, such as Japanese, Chinese, and Korean (see chapter 73). One type of whole-to-part relation exploited by this topic construction is the kind–subkind relation. The most famous Japanese example stems from Kuno (1973c) and is represented in (101):

(101) Japanese:
[Sakana -wa] [tai -ga] oisii.
fish TOPIC redsnapper NOM delicious is
'Speaking of fish, red snapper is the most delicious one.'
(Kuno 1973: 62)

As opposed to SNPT with a full-NP REM in German, Chinese-style topics in Japanese are not island-sensitive, as shown in (102) for the Complex-NP Constraint and in (103) for the Coordinate Construction Constraint:

(102) Japanese:
[Hon -wa] [[$_{NP}$ [shoosetu] sika yoma nai hito] -wa baka da
books TOPIC novels only read NEG person CONTR stupid is
'As for books, a person who reads only novels is stupid.'
(Van Riemsdijk 1989a: 119)

(103) Japanese:
[Isu -wa] [Peter -wa kinoo [rampu -to [kurashikku -no-o
chair TOPIC Peter TOPIC yesterday lamp and classical ACC
___]]] kat-ta
bought
'Peter bought a lamp and a classical chair yesterday.'
(Fanselow and Ćavar 2002: 77)

Although it is almost unanimously agreed upon that the topic in these constructions does not bind an empty site, but is base-generated in situ, transformational analyses have been suggested, too (see chapter 73).

7.4 Miscellanea

A construction that seems to be somewhat reminiscent of the double-subject construction in (101) is the existential construction in Malagasy, a topic-prominent language (cf. Pearson 1996). Existential clauses in Malagasy are headed by the

verb *misy*, which takes a small-clause complement. Existential clauses are used to introduce new referents or situations into the discourse.

Besides other 'part-to-whole' relations, *misy* can express a superset–subset relation between the outer subject (or 'topic' in Pearson's terms), located at the right-edge of the clause, and a predicate-internal argument:

(104) Malagasy:
[$_{\text{PredP}}$ Misy [maro ___ ao an-tokotany]] [ny raozy].
exist many DEIC LOC-garden DET-DEF rose
'Of roses, there are many in the garden.'
('Many of the roses are in the garden.') (Pearson 1996: 115)

In (104), the topic *ny raozy* 'roses' denotes a set or a kind of which the NP *maro ao an-tokotany* 'many in the garden' forms a subset (or 'subtype') or instantiation. Pearson (1996) assumes that an abstract unaccusative light verb be takes a small-clause complement DomP, whose head (Dom^0) takes a nominal complement and assigns a Domain (or 'superset' theta-role) to a DP that is base-generated in its specifier position, in order to establish the superset–subset relation between the predicate-internal and the predicate-external argument. Finally, it is argued that Dom^0 raises and incorporates into be and that the result of this process is spelled out as *misy*.

A construction that seems only remotely to be similar to SVPT in German and Dutch is the so-called predicate cleft (P-cleft) construction occurring in many West African languages. An example is Vata, a language of the Kru family (cf. Koopman 1984, 2000b). P-clefts involve two overt copies of the finite verb: one in sentence-initial position and one in the regular clause-internal position. The preposed verb is focused and contrasts with some other verb in the discourse that may be implicit:

(105) Vata:
a. [*Lē*] [à *lē* sȧ́ká].
eat we eat rice
'We are (really) EATING rice.'
b. [*Lī*] [Ȯ dā sȧ́ká *lī*].
eat s/he Perf-Aux rice eat
'S/he has EATEN rice.'
c. [*Lī*] [Ȯ *lì* sȧ́ká].
eat s/he ate rice
'S/he ATE rice.' (Koopman 1984: 38)

As shown by the examples in (105), the preposed focused verb is a segmental copy of the verb in clause-internal position. The fronted focused verb merely consists of the segmental specifications of the verb, i.e., without tonal specifications. Since elements with no associated tone surface with a mid tone, the focused verb invariably surfaces with a mid tone. The focused verb can be inherently

marked for aspect, too, as in (105a). However, the imperfective aspect is the only kind of aspect that may appear on the focused verb. And tense morphology cannot appear on the focused copy either. So in a way, the clause-initial copy is bare. In principle, any verb that may serve as the input for a morphological process can be clefted, but auxiliaries and other semantically defective verbs cannot undergo P-cleft, as they do not have enough semantic content to be focused. Koopman (1984) demonstrates that the dependency between the two verbal copies created by P-cleft is an A-bar-dependency.

In Koopman (1984), it is argued that the focused verb is moved to a clause-initial position (i.e. C^0) by head movement of the *wh*-type. It is argued that an overt copy of the fronted verb must be left behind, in order to prevent a violation of the ECP, since otherwise the clausal-internal verbal *wh*-trace is not properly governed.

Koopman (2000b) proposes a completely different analysis in which P-cleft involves remnant-XP movement. As a consequence, P-cleft is considered to be A-bar-movement of the usual kind, i.e., of an XP (and not of a head). Whereas in the head-movement analysis (cf. Koopman 1984), it is the spell-out of the clause-internal verbal copy that has to be explained, it is the spell-out of the copy in focus position that asks for an explanation in the RM-analysis. According to Koopman (2000b), the clefted verb must be overt because it is included within the fronted VP that cannot form a chain with the clause-internal verb, which is assumed to be in I^0.[45] So, the spell-out of the focused verb is required by reasons of recoverability and by the fact that only overt copies can be focused.

An analysis of the P-cleft data in (105) in terms of the C&DD-analysis is tempting (cf. section 3.3), since this analysis conceives movement as a process consisting of two separate operations, whose noncomplementary effects could somehow surface in this verb-fronting construction. However, also under this movement analysis, many questions remain open, at least at first glance. For example, why does the 'partial' or 'imperfect' copy appear in sentential-initial position and not in clause-internal position? However, in the traditional movement analysis, in which movement leaves an empty category, the P-cleft construction gives rise to completely different questions. For example, why does this construction leave more or less an exact replica of the fronted verb instead of a resumptive pronoun as usual in a resumptive-pronoun strategy? See Koopman (1984: ch. 6) for discussion.

8 Conclusion: outlook

In sum, a problem for all syntactic analyses of SNPT is that they cannot offer a straightforward solution for the full range of different possible realizations of TOP and REM. As soon as analyses aim to take into account all the possibilities in different varieties, they either overgeneralize or have to appeal to *ad hoc* mechanisms. Since there exists a considerable amount of dialectal variation with respect to the possible syntactic realizations of TOP and REM, the possibility that SNPT is not a unitary phenomenon should not be lost sight of. Most analyses exclusively

concentrate on SNPT, sometimes in combination with MST, but they have completely ignored split NPs in Split-NP Scrambling and in Split-CLD until now. Another issue that remains to be explored concerns the possible syntactic realizations of TOP in the alternative target positions of ST.

The analyses for SVPT also appear to be confronted with quite a different problem. Then, apart from the problem that is posed by movement paradoxes, both types of analysis face the problem of relating TOP to the free order of arguments within the extended, restructured VP in the predicating clause.

These investigations lead to the ultimate question of parameterization, i.e. the determination of the necessary conditions for SNPT (cf. also table 3) and SVPT to occur in a particular language. It has been suggested more than once in the past literature (cf., for example, den Besten and Webelhuth 1990) that the existence of ST correlates with the availability of Scrambling. But although both German and Dutch are Scrambling languages that allow for SVPT, not all varieties of these languages have SNPT as well.

Gouskova (2001) argues that split preposing results from the interaction of violable constraints with opposing demands. Her optimality-theoretic approach adopts a set of information-structural requirements that potentially conflicts with barrier constraints for different categorial types. Since these barrier constraints are ranked in a particular order, extraction from VP is predicted to be more likely than extraction from NP.

Fanselow (1988: 97ff.) observes two correlations for languages with discontinuous NPs, such as German, on the one hand, and non-configurational aboriginal Australian languages on the other hand: (i) if a language has discontinuous NPs, adjectives and determiners can also form NPs by themselves, i.e., the language has elliptic NPs; (ii) if a language allows for discontinuous NPs, it also has rich overt agreement morphology within NP.

In determining the relevant factors for the possibility of split NPs in a language, the possibility of NP ellipsis (see chapter 22) appears to be a relevant factor indeed (cf. also Van Hoof 1997b, forthcoming; Kuhn 1999; Mathieu and Sitaridou 2003; emphasizing this point). Also other languages with clause-internal split NPs, such as Latin, Finnish, Hungarian and West Greenlandic, allow for NP ellipsis, too. Furthermore, it has become clear from investigations in the more recent past (cf. Lobeck 1995); Kester 1996) that correlations (i) and (ii) are related too, since elided nominal catagories need agreement morphology on the overt nominal remnant to be licensed.

Also in non-configurational languages, the correlation between strong agreement morphology and the occurrence of split NPs appears to be valid. As shown by the example set in (106–107) originating from Nash (1986), NPs can only be split if each of the individual members is marked for case and agreement, although this is not required for the unsplit NP (cf. (106b)):

(106) Warlpiri:
a. [Kurdu-ngku wita-ngku] ka maliki wajilipi-nyi.
child-ERG small-ERG AUX dog chase-AGR

b. [Kurdu wita-gku] ka maliki wajilipi-nyi.
child small-ERG AUX dog chase-AGR
'The small child chases the dog.'

(107) a. [Kurdu-ngku] ka maliki wajilipi-nyi [wita-ngku].
child-ERG AUX dog chase-AGR small-ERG
b. *[Kurdu] ka maliki wajilipi-nyi [wita-ngku].
child AUX dog chase-AGR small-ERG
'The small child chases the dog.' (Fanselow 1988: 96)

Furthermore, the similarity of discontinuous NPs and elliptic NPs does not only become apparent from the obligatory agreement morphology on the adjective licensing the gap in both types, but also from the specific semantic class of the adjective, which has to be a predicative one. Mathieu (2003) reaches this conclusion for split NPs and elliptic NPs in Romance, Van Hoof (forthcoming) independently with respect to German and Brabant Dutch, and Partee (2001) reports a similar result for split NPs in Polish.

On the other hand, it cannot be claimed that a language is parameterized to have split-NP preposing if this language allows for elliptic NPs. Then, although NP ellipsis is probably a necessary condition it cannot be a sufficient one. For example, Spanish and Swedish are languages with NP ellipsis (cf. Kester 1996), but they do not have split-NP preposing with connectivity effects.

Fanselow (1988) argued that discontinuous NPs in non-configurational languages do not differ from split NPs in configurational languages. In his view, the base-generated VP structure underlying SNPT in German, which contains two independent argument NPs with the same theta-role (cf. section 3.3), also suffices to account for discontinuous NPs in non-configurational languages. Van Geenhoven (1998) provides additional semantic support in favor of this view. She shows that N-incorporation structures in West Greenlandic that occur together with a VP-internal doubling argument (cf. (108)) can be unified with the base-generated structure for SNPT in German (cf. (109)):

(108) West Greenlandic:
Jensi [$_{V'}$ marlun-nik [$_{V}$ manni-tu-ssa-a-q]].
Jensi-abs two-inst.pl egg-eat-fut-ind-[tr]-3sg
'Jensi will eat two eggs. / # Jensi will eat two of the eggs.'

(109) [$_{NP}$ Eier]$_i$ hat Jensi [$_{V'}$ [$_{NP}$ zwei] [$_{V}$ [$_{NP}$ t$_i$] gegessen]].
eggs has Jensi two eaten
'As for eggs, Jensi ate two.' (Van Geenhoven 1998: 44)

Van Geenhoven (1998) argues that both the incorporated noun in West Greenlandic and the to-be-fronted NP in German SNPT are property-denoting NPs that cannot gain wide scope because they are semantically incorporated into the verb (cf. Mathieu and Sitaridou (2003) for a similar explanation).

One more common property between SNPT and discontinuous NPs in (some) non-configurational languages deserves to be mentioned. Some incorporation languages allow an incorporated noun to appear together with an external full object NP, whereby the incorporated noun includes the reference of the external noun. Such an example is provided by Mithun (1984) for Mohawk:

(110) Mohawk:
Sha'te:ku snikú:ti rabahbót wahu-tsy-ahní:nu ki rakeniha.
eight of them bullhead he-fish-bought thus my father
'My father bought eight bullheads.' (Mithun 1984: 870)

Of course, examples like (110) are highly reminiscent of the occasional occurrence of full-NP REMS in German.

Fanselow's (1988) hypothesis that discontinuous NPs in non-configurational languages do not differ from split NPs in configurational languages is countered by the 'Pronominal Argument Hypothesis', according to which overt NPs in non-configurational languages function as modifiers or adjuncts to VP instead of VP-internal arguments. Since non-configurational languages are often characterized by a rich case or agreement system, it has been hypothesized that in these languages, the agreement morphemes or clitics satisfy a predicate's argument slots. Therefore, the overt (split) NPs do not really count for the Projection Principle. Under this hypothesis, discontinuous NPs are expected to be of quite a different type than split NPs in configurational languages. For example, the number of discontinuous NPs in non-theta-marked positions modifying a particular argument slot are predicted to be unlimited. Split NPs in configurational languages appear to be stylistically marked, for they can only occur in certain contexts, although their exact information-structural interpretation varies from language to language, perhaps because split-NP preposing in these languages constitutes a marginal phenomenon. The question arises whether split NPs in non-configurational languages are information-structurally restricted, too. This and many other questions require further research.

NOTES

This chapter received an important impulse from relevant work by Werner Abraham. It would not exist in its present form without the Sonderforschungsbereich 441 'Linguistische Datenstrukturen' at the University of Tübingen, which provided a stimulating environment for writing, and without the moral support of the editors and their assistants. Thanks are also due to an anonymous reviewer and to Edward Göbbel for making valuable comments and improving the English. The usual disclaimers apply.

1 Different syntactic analyses for T have been proposed in the past, but will largely be ignored here. For instance, it has been proposed that the topicalized constituent is directly moved into the specifier of S-bar or CP (cf. Thiersch 1978), or to the specifier of a subprojection thereof (cf., for example, Müller and Sternefeld 1993) or adjoined to IP (cf. Lasnik and Saito 1992) or is base-generated as an adjunct to S-bar or CP (cf. Chomsky 1977b, Zwart 1993, and others).

2 It has been observed by Gundel that the topicalized constituent can also receive the main sentence accent, while the remaining part of the sentence is deaccented. In this case, the topicalized constituent seems to be the focus of the sentence:

(i) BEANS$_i$ I don't like [e]$_i$ (not LENTILS).

Gundel calls this prosodic realization of T 'Focus Topicalization'.

3 In this chapter, the notion of extraction is theory neutral between a derivational and a representational analysis. In addition, it is assumed that the V-second transformation leaves a trace of movement, as can be seen in (4). In subsequent examples, the traces of V-second will be ignored. In addition, the nature of the gap caused by ST often remains unspecified and is indicated by a dash. The main structure of German sentences is often described in terms of topological domains: (i) pre-field ('Vorfeld'); (ii) middle-field ('Mittelfeld'); (iii) coda ('Koda'); (iv) post-field ('Nachfeld'). These topological domains correspond to the following structural domains:

(i) [$_{CP}$ pre-field] [$_{C'}$ middle-field] [$_{V}$ coda] [post-field].

The exact landing position of the topicalized phrase will be left unspecified. A (split) topicalized constituent is assumed to end up in a specifier or adjunct position within the CP/IP domain (cf. also note 1).

4 With the labels TOP and REM, we wish to remain neutral with respect to the syntactic or information-structural status of these constituents. While TOP hints at 'topic' and REM suggests 'remnant', of course, they cannot be equated with these suggestive notions. For example, note 7 puts in doubt the hypothesis that topicalized constituents are sentence topics, a view that is often implicitly assumed in the literature. For a more general critique on this view see Prince (1998). The notion 'remnant' has not been adopted here because this notion figures prominently in remnant-movement analyses (cf. especially section 5.1) and plays a different role in these analyses, since remnants end up as fronted constituents.

5 We refrain from referring to the functional extensions of lexical projections by their functional-category labels. So in general, the functional extension of a lexical NP projection will simply be referred to as NP. However, if the bare, lexical NP projection is at stake, it will be made explicit in the text.

6 Cf. section 2.2 for an example of Split Preposition-Phrase Topicalization (SPPT) in German and section 7 for split-PP preposing in other languages.

7 SNPT is also compatible with the prosodic pattern for Focus Topicalization (cf. note 2), as shown in (i):

(i) A: Mag er nur grüne Bananen?
'Does he like only green bananas?'
B: Nein, [BOHNEN] mag er nur [grüne ___].
No, beans likes he only green (ones)

8 It should be noted, however, that long extractions out of a subordinate clause introduced by the lexical complementizer *dass* ('that') (cf. (14a)) are judged grammatical only by speakers of High German. The double bracket '⟦' in (14b), as well as in (53), (54), (102), and (103), indicates a syntactic island.

9 For example, (16b) clearly improves in the following context (with a steep rise on TOP and a steep fall on REM):

(i) a. A: Was für Auto kannst du dir nicht leisten?
'What kind of car can't you afford?'
b. B: [Ein /NEUES Auto] kann ich mir [kein \AMERIKANISCHES ___] leisten und
a new car can I me no American (one) afford and
[ein /ALTES] [kein \FRANZÖSISCHES].
an old no French
'As for an AMERICAN car, I cannot afford a NEW one and as for an OLD one, not a FRENCH one.'

10 Some dialects allow bare singular count-nouns to be split topicalized, as illustrated in (i):

(i) [Anzug] hab' ich auch noch [einen ___].
suit have I also still one
'As for a suit, I still have one, too.'

Tops of this type cannot give rise to determiner overlap either.

11 The same phenomenon has also been observed with similar quantifiers in other dialects of German. For example, in Swabian and Bavarian, the numeral *ein* ('one') can fulfill the same function as *welch-* in northern varieties. Abraham (1995: 519) provides (i), an example from a southern Bavarian dialect spoken in Carinthia:

(i) a. [Zuckerln] ham-ma gestern a: scho [a ___] ghopt.
bonbons have-we yesterday also already one become
'As for bonbons, we got some yesterday, too.'
b. *[A Zuckerln] ham-ma gestern a: scho ghopt.
one bonbons have-we yesterday also already got
'Some bonbons, we got yesterday, too.'

12 A SNPT kind that is highly reminiscent of a SNPT with a full-NP REM is formed by the ST of pseudo partitives (cf. Selkirk 1977). However, unlike SNPT with a full-NP REM, TOP and REM can still be concatenated into a single complex NP in this kind of SNPT, as shown in (i):

(i) a. [Wein] habe ich nur [zwei Flaschen ___] dabei.
wine have I only two bottles with me
'As for wine, I have only two bottles with me.'
b. Ich habe nur $[_{NP}\ [_{NP1}$ zwei Flaschen$]\ [_{NP2}$ Wein$]]$ dabei.
I have only two bottles of wine with me
'Ich habe nur zwei Flaschen Wein dabei.' (Van Riemsdijk 1989a: 120)

13 As shown by (i), TOP must have a *de dicto* interpretation and does not carry an existential presupposition:

(i) [Einhörner] sind mir noch [keine ___] über den Weg gelaufen.
unicorns are me still none across the way walked
'As for unicorns, I've met none yet.'

14 Pafel (1995) argues that the difference in sensitivity to restrictions like the ECP between the two groups can be explained by a difference in their internal NP-structure:

only in the latter group is the element to be extracted included by all maximal-projection nodes of the NP source.

15 (ia) presents the remnant-movement analysis of (30b) (see chapter 28), (ib) shows the analysis of Fanselow (1987), which is based on the fronting of an independent NP object after reanalysis of the complex NP, and (ic) shows the more refined reanalysis process proposed by Grewendorf (1989), which not only breaks up the NP, but forms a complex verbal expression with the head NP and the verb before the NP is preposed:

(i) a. $[_{NP}$ Ein Buch $t_i]_j$ hat er $[_{PP}$ über Syntax$]_i$ t_j ausgeliehen.
a book has he about syntax borrowed

b. $[_{NP}$ Ein Buch$]_i$ hat er t_i $[_{PP}$ über Syntax] ausgeliehen.
a book has he about syntax borrowed

c. $[_{NP}$ Ein Buch$]_i$ hat er t_i $[_{PP}$ über Syntax] $[_V$ t_i ausgeliehen.
a book has he about syntax borrowed

16 For a more extended overview, see Van Hoof (forthcoming). In this section, we stick to the terminology that has been developed in the preceding sections as far as possible. Whenever necessary, however, the terminology of the analyses under review will be adopted.

17 In this chapter, 'extraction' is used theory-neutrally between a derivational and a representational approach. A representational X-bar-chain analysis for SNPT has been sketched in Tappe (1989) and Haider (1990b). The problem for this type of analysis is that it violates the Chain Uniformity Condition (cf. Chomsky 1995c), which requires that the different links in a chain should not differ with respect to their phrase-structural status.

18 The X-bar-preposing analysis Van Riemsdijk (1989a) can also be enriched with functional categories as described in Van Riemsdijk (1998a). This view roughly implies that although intermediate projections 'old style' have become maximal projections 'new style', they still count as intermediate extended projections. Therefore, SNPT still poses a problem for the SCC in that only maximal constituents can be topicalized and its theoretical counterpart, the SPC (cf. section 1.3) if maximality is conceived of as a relational notion, i.e., a projection Y of X^0 is maximal if the mother of Y is not a projection of X^0.

19 However, both Abraham (1996) and Van Hoof (1997b) cast doubt on this analysis for comparable data in Bavarian and Brabant Dutch in which the counterparts of West Flemish *eenen* in (33) seem to be a cardinal quantifier, not an indefinite determiner.

20 The left-dislocation analysis of T was originally proposed in Chomsky (1977b) for English and transformed into a covert CLD-analysis for T in German and Dutch by Koster (1978b) and Cardinaletti (1986). According to the covert CLD-analysis of T, the fronted d(emonstrative)-pronoun in CLD is either phonetically deleted or substituted for by an empty operator in T.

21 See Van Hoof (forthcoming) for a critique of the information-structural part of this analysis and the syntactic implementation thereof.

22 Mathieu and Sitaridou (2003) propose a similar analysis for split-NP preposing in Modern Greek (cf. section 7.1).

23 One might think that the apposition analysis violates the Left Branch Condition (see chapter 66). But as pointed out by Edward Göbbel, similar facts occur with

relative-clause extraposition in English, i.e., 'relative-clause stranding', if a strictly right-branching structure is assumed (cf. Kayne 1994), as illustrated in (i):

(i) $[_{NP}$ A man$]_i$ arrived $[_{NP}$ t_i $[_{NP}$ who I met in London]].

24 Although SVPT is also possible in Dutch, only German examples are presented in this section. In the literature, examples like (i) are usually not subsumed under ST, but are considered to be Ts of an unsplit VP (cf., for example, Müller 1998):

(i) $[_{CP}$ $[_{VP}$ Grüne Bohnen gegessen] $[_{C'}$ hat $[_{IP}$ nur er ___]]].
green beans eaten has only he
'As for having eaten green beans, only he has.'

However, in accordance with the extended-projection-based definition for ST adopted in section 1.2, it could be argued just as well that IP in (i) forms an extended verbal projection that is headed by the participle *gegessen* 'eaten' and that the topicalized phrase forms a split VP (cf. Van Riemsdijk 1998a: 12, n. 11, for a suggestion along these lines). However, here we only deal with the clear examples or SVPT, in which an extended verbal projection has been split in such a way that at least one argument of the split VP in TOP has been stranded in the clause. Note furthermore that, unlike for the examples of SNPT, no stylistically precise translations are rendered for the SVPT examples for complexity reasons.

25 Still one other option is available, however. The VPT in (55) and the SVPT in (56) can be derived if the extraposition of a CP argument is obligatory, but not before PF. The same kind of movement paradox can also be constructed for SNPT (cf. Fanselow and Ćavar 2002: 97).

26 For a slightly different view on the status of grammaticality of sentences like (57b), see Grohmann (2000b) and Erb (2001). According to Grohmann (2000b: 189), sentences like (i) are grammatical in some varieties of colloquial German and Dutch:

(i) Meine Freunde tun nicht viel arbeiten, die gehen lieber feiern.
my friends do not much work, they go preferably party
'My friends don't like to work very much, they'd rather go partying.'

27 For example, in restructured VPs, the arguments of the different verbs are permutable, as shown by the contrast in (i), the verbs can undergo V-raising and operators can have scope over the entire complex VP (cf. Fanselow 1989; Meurers 1999); (chapter 75, this volume):

(i) a. dass [das Buch]$_i$ keiner t_i zu lesen versucht hat
that the book no one to read tried has
'that no one has tried to read the book'
b. ?*dass [das Buch]$_i$ keiner t_i zu lesen abgelehnt hat
that the book no one to read refused has
'that no one has refused to read the book' (Müller 1998: 17)

28 (58b, c) have been borrowed from Müller (1998: 18). An anonymous reviewer points out that the SVPTs in (58b, c), as well as the SVPTs in (68), can also be derived from an underlying Third-Construction variant (cf. (i)), which is often analyzed in terms of 'remnant extraposition' (cf. Den Besten and Rutten 1989; Broekhuis et al. 1995):

(i) dass keiner das Buch$_i$ abgelehnt hat [t_i zu lesen]
that no one the book refused has to read
'that no one has refused to read the book'

However, see Müller (1998: 18, n. 17) for a reason why *das Buch* 'the book' cannot have been locally scrambled within the domain of the infinitive α in (ii), which is the underlying structure of (i):

(ii) *[$_{VP}$ t_i Zu lesen]$_j$ hat keiner [$_\alpha$ [$_{NP}$ das Buch]$_i$ t_j] abgelehnt.
to read has no one the book refused

29 Note that the permutation of arguments within TOP and within REM, after SVPT has been completed, is allowed for, however (cf. Haider and Rosengren 1998: 8 for a similar observation):

(i) a. Der Grossvater hat am Sonntag dem Enkel ein Pferd
the grandfather has on Sunday the grandchild a horse
versprochen. (base order)
promised
b. [Ein Pferd$_i$ dem Enkel e_i versprochen] [hat der Grossvater
a horse the grandchild promised has the grandfather
am Sonntag ___].
on Sunday
c. [Ein Pferd versprochen] [hat der Grossvater dem Enkel$_i$
a horse promised has the grandfather the grandchild
am Sonntag e_i ___].
on Sunday
d. [Ein Pferd versprochen] [hat dem Enkel$_i$ sogar der GROSSVATER
a horse promised has the grandchild even the grandfather
am Sonntag e_i ___].
on Sunday

30 However, no clear NTCC can be derived for the alternation between direct and indirect objects. In the restructured VP, whose main verb is *hinterlassen* ('to bequeath'), the dative argument is ranked higher than the accusative object (cf. Thiersch (1985), Müller (1998) for the same observation):

(i) a. Er hat der Kusine das Schloss hinterlassen. (Base Order)
he has the-DAT female cousine the castle bequeathed
b. [Das Schloss hinterlassen] [hat er der Kusine ___].
the castle bequeathed has he the-DAT female cousin
c. ?? [Der Kusine hinterlassen] [hat er das Schloss ___].
the-DAT female cousin bequeathed has he the castle
'He bequeathed the cousin the castle.'

31 According to Haider (1990b), the ungrammaticality in (64) vanishes if the direct object is represented by a weak pronoun or by a deaccented NP, as becomes apparent from (i):

(i) [Ein Aussenseiter gewonnen] [hat [es/das] da noch nie ___].
an outsider won has it/that there yet never
'An outsider has never won it/that yet.' (Haider 1990b: 97)

However, the status of the grammatical contrast between (64) and (i) is still rather unclear at this moment.

32 However according to Müller, Scrambling of split VPs is sometimes possible, namely if the stranded argument in REM is represented by a weak pronoun or a clitic:

(i) dass [zu lesen] [es/'s keiner ___ versucht hat]
that to read it no one tried has
'that no one has tried to read it' (Müller 1998: 227)

Note that pronoun movement and cliticization in Germanic are generally not believed to be instances of Scrambling, but instances of a different movement type (see chapter 13).

33 Still more analyses of SVPT can be distinguished, but they are mere suggestions that have not been worked out so far. Discussion of them will therefore be omitted. For example, Van Riemsdijk (1989a) considers extending his X-bar-movement analysis for SNPT to SVPT in German, but since there is no real evidence for relexicalization in TOP of German SVPT, which makes regeneration visible, this possibility has not been pursued. Weerman (1989) and Zwart (1993) suggested the LD-cum-operator analysis for SVPT in Dutch. Hinterhölzl (2002) argues that the C&DD-analysis (cf. section 3.3) is inappropriate for SVPT and provides an alternative analysis based on a strictly right-branching structure (cf. Kayne 1994) combined with RM-movement.

34 See Huang (1993) for another technical solution to the problem of unbound traces in TOP of SVPT.

35 Müller (1998) refers to SVPT by the name of Incomplete Category Fronting. Since this term also subsumes NP–PP Split, it does not equal the notion of ST used here.

36 Note that the neutral type of Scrambling that is triggered by the referentiality or definiteness property of arguments (see chapter 43) cannot be at stake in (71) and (72) because the stranded arguments are nonspecific indefinites. Hinterhölzl (2002), who assumes a VO-based restructuring account, introduces yet another type of clause-internal movement, called 'licensing movement', which can apply to all verbal dependents irrespective of their referential status. This type of movement precedes Scrambling and empties the to-be-topicalized VP in remnant T. It is assumed that this movement type does not create freezing effects.

37 In Haider and Rosengren (1998), this type of Scrambling is called Topic Scrambling and it is assumed to target a position directly below C^0. The question of which term is more on the right track will not be answered here, and neither will the question of whether this Scrambling type can be equated with embedded Topicalization in English (see chapter 23).

38 Some speakers of Brabant Dutch also allow for the split variant with a D-pronoun in situ:

(i) Brabant Dutch:
[Koeien], hij heeft die [een helehoop ___] in de achterste wei.
cows he has D-pr a whole heap in the most behind meadow
'As for cows, he has quite a lot in the rearmost meadow.'
(Van Hoof 1997a: 280)

39 Additionally, Split-NP Scrambling can also occur together with different types of Split-CLD in Brabant Dutch (cf. Van Hoof forthcoming).

40 Besides the pull-split type of split-NP preposing, Modern Greek also allows for the inverted (German) type of split NPs, as illustrated in (i), an example that originates from Horrocks and Stavrou (1987):

(i) [To FOREMA] idha [___ to kokkino].
the dress saw-I the red
'I saw the red DRESS.' (Mathieu and Sitaridou 2003: (17))

41 In (93), 'e' denotes a null-head modifier, i.e., an elided nominal head.

42 Mathieu and Sitaridou (2003) and Mathieu (2003) apply this analysis to a split-NP-preposing construction that is attested in some varieties of Romance, too:

(i) French:
a. Je préfère [la chemise rouge].
I prefer the shirt red
'I prefer the red shirt.'
b. Je préfère [$_{DP}$ [$_{DP}$ la rouge *e*]$_i$ [$_{SC}$ [$_{NP}$ de chemise] t_i]].
I prefer the red of shirt
'I prefer the RED shirt.'
c. [La ROUGE], elle te va bien [___ de chemise].
the red it you goes well of shirt
'The RED shirt suits you.' (Mathieu and Sitaridou 2003)

In passing, Grewendorf (1995) also proposes an underlying small-clause structure for SNPT in German, in which REM forms the subject and TOP the predicate of a base-generated small clause in the middle-field (cf. Grewendorf 1995: 1299).

43 The discussion of split preposing in Slavic languages sometimes also includes (pull-split *wh*-phrases (cf., for example, Fanselow and Ćavar 2002), a split type that is not considered here. As becomes apparent from the main text, Franks and Progovac (1994) provide examples from Serbo-Croation, while Fanselow and Ćavar (2002) offer examples from Croatian. Although Serbian and Croatian are very similar, they are still considered to be two different languages. The (artificial) language Serbo-Croatian was brought into existence for political reasons in the past. Probably, Serbo-Croatian examples are grammatical both in Serbian and in Croatian, but we stick to the language terminology employed by the authors here.

44 Note that Franks and Progovac (1994) base-generate NP as a complement of A^0 (cf. Abney 1986). They also suggest the RM analysis as a viable alternative for pull-split-NP preposing.

45 Both Koopman (2000b) and Pearson (1996) adopt a strictly right-branching base structure (cf. Kayne 1994) and the constituent order at spell-out is derived by successive leftward movement.

63 The Spray-Load Alternation

MAYA ARAD

1 Introduction: spray-load verbs – the data and the problem
2 Accounting for the spray-load alternation
  2.1 Thematic roles (Levin and Rappaport 1988)
  2.2 The Aspectual Interface Hypothesis
  2.3 The role of syntax
3 The semantic properties of spray-load verbs
4 Conclusion

1 Introduction: spray-load verbs – the data and the problem

The spray-load alternation, better known in the literature as the locative alternation, is exemplified in the sentences (1–5):

(1) a. Lucy sprayed the paint on the wall.
    b. Lucy sprayed the wall with paint.

(2) a. Ben loaded hay on the truck.
    b. Ben loaded his truck with hay.

(3) a. Jan plant bomen in de tuin.
       John plants trees in the Garden.
    b. Jan beplant de tuin met bomen.
       John be-plants the garden with trees.

(Dutch; Dik 1980)

(4) a. kabe ni penki o nuru
       wall on paint ACC Paint (VERB)
       'smear paint on the wall'

b. kabe o penki de nuru
wall ACC paint with Paint (VERB)
'smear the wall with paint' (Japanese; Fukui et al. 1985)

(5) a. János rámázolta a festéket a falra.
John onto-smeared-he-it ACC Paint-ACC the wall-onto
'John smeared paint on the wall.'
b. János bemázolta a falat festékkel.
John in-smeared-he-it ACC The wall Paint-with
'John smeared the wall with paint.'
(Hungarian; Moravcsik 1978)

Verbs such as *spray* and *load* appear in two different syntactic structures: each of their internal arguments may be realized as a direct object. The other argument is then realized as a goal (the truck in 2a) or a locatum (the entity that is being applied or located, like the hay in 2b). In this, they differ from other verbs that have two internal arguments, but which do not participate in that alternation:

(6) a. Lucy covered the towel with sand.
b. *Lucy covered sand on the towel.

(7) a. Ben poured water into the glass.
b. *Ben poured the glass with water.

Even from this limited set of data in (1–5), two characteristic properties of the alternation are evident. First, this alternation exists in a number of unrelated languages. Second, it is roughly the same types of verbs that participate in that alternation. The two facts combined suggest that there may be something about the lexical properties of certain verbs which enables them to be realized in two different ways.

The existence of such cases as (1–5) raises several related questions. First, noting that only a particular group of verbs undergo the locative alternation, the question arises:

- What are the lexical properties of the verbs that participate in that alternation?

Second, it has been noted by many that there exists also a difference in the interpretation of the two variants in (1a, b) (cf. Rappaport and Levin 1988 and references therein). It is always the argument that is realized as a direct object, which is interpreted as wholly affected by the action of the verb. In (1a) it is understood that the whole amount of paint involved has been sprayed on the wall (although it is not specified whether the wall is now entirely covered with paint). In (1b) it is understood that the wall is completely covered with paint (but nothing is specified as for whether the whole amount of spray has been used). This difference in interpretation raises the following question:

- How can the difference in interpretation between the two variants be accounted for?

In addition to these empirical questions, the locative alternation also raises a theoretical challenge to any theory of the syntax–lexicon interface:

- How can the two argument structures associated with spray-load verbs be accounted for?

It is worth explaining, perhaps, why this is a problem at all. Work on the syntax–lexicon interface has established a robust correlation between verbs' lexical properties and verbs' argument structure. Within generative grammar, specifically within the GB framework, this correlation is captured by the Projection Principle, which ensures that all of verbs' lexical properties are encoded at the beginning of the derivation (i.e., at D-structure). The projection of verbs is mediated via the thematic roles that each verb specifies: agent, theme, benefactor, etc. Each case of alternation poses a challenge to projection: does the verb have two lexical entries, each specifying different thematic roles, and associated with a different syntactic structure? Or is there a single lexical entry, associated with one structure only, and the other syntactic structure is derived from it?

Argument structure alternations are not a homogeneous group. Consequently, the analyses that have been suggested for different alternations vary from one class to another. Cases of the causative-inchoative alternation (e.g. *Lucy broke the glass* vs. *The glass broke*) are standardly analyzed as an instance of unaccusativity (in the case of the inchoative verb), involving a single lexical entry. (Levin and Rappaport Hovav 1995; Reinhart 1996.)

Cases such as the dative alternation (e.g., *Lucy gave a book to Ben* vs. *Lucy gave Ben a book*) have been argued by many to be a *syntactic* alternation, in which one structure is derivationally related to the other (Larson 1988b).

The locative alternation is thus an intriguing case, which does not lend itself easily to any of the above accounts (lexical operations or syntactic derivation). This question crosses theoretical boundaries: no matter what your theoretical assumptions are, there has to be a way to allow for such verbs to appear in two syntactic structures.

Cases such as the spray-load alternation can be used, therefore, as a probe into the relation between the syntax and the lexical semantics of verbs. It is precisely by looking at such phenomena that we gain insight regarding the syntax–lexicon interface.

2 Accounting for the spray-load alternation

While all accounts of the locative alternation aim to answer the three questions posed above, theories differ with regard to their theoretical focus. We shall review here three types of theories based on: thematic roles; the role of aspect in

mediating between syntax and semantics; and the role of the syntactic construction itself.

2.1 Thematic roles (Levin and Rappaport 1988)

Working within the theory of thematic roles, Rappaport and Levin (1988) concentrate on the challenge that spray-load verbs pose for the theory of thematic roles. Thematic roles, under their view, do not interface directly with the syntax. Rather, they are specified at an initial level of representation called Lexical Conceptual Structure (LCS). Part of the lexical information verbs include at that level is the thematic roles they take:

(8) LOAD: <Agent, Locatum, Goal>

Thematic roles are then associated with another level of representation, which is syntactically relevant – Predicate Argument Structure (PAS). This level specifies argument *slots*, distinguishing between internal and external arguments, but is blind to specific thematic representation such as Agent, Theme etc. The linking rules from LCS to PAS ensure that the Agent argument ends up at the position of the external argument, and never as an internal argument (and, similarly, that the Theme argument is associated with the direct internal argument). Projection from PAS to the level of D-structure then proceeds according to the well-known projection rules (external argument realized as a subject, direct internal argument realized as an object, other arguments realized as indirect objects or objects of prepositions). Levin and Rappaport assume that from the single entry of *load* type verbs at LCS, there arise two different argument structures at PAS (in the following example the external argument, *x*, is marked as being outside the scope of the internal arguments. The direct internal argument, *y*, is underlined, and the preposition present in each alternant is specified at the level of PAS):

(9) a. LOAD: x <$\underline{y}$, $P_{loc}z$>
b. LOAD: x <$\underline{y}$, $P_{with}z$>

From these two argument structures, the two syntactic structures associated with *load* are projected. The problem is how to get from the single LCS entry in (8) to the two structures in (9).

Rappaport and Levin note that the locative variant (2a) is easy to account for, if we allow the Locatum argument to be interpreted as a Theme. This ensures that the argument bearing this role ends up in the direct object position. The problem starts when we try to account for the other alternant, the '*with*-variant' (2b). Here, it is the Goal argument that is linked with the position of the direct internal argument. Goals generally tend to be linked with the position of indirect internal argument. To account for this alternation, it is necessary to postulate a linking rule specific to these cases – an undesirable thing to do. In addition, to account for the difference in interpretation between the two variants, an ad hoc

rule assigning a holistic interpretation to a direct internal argument bearing a Goal role would be required. Another possibility to associate *load*-type verbs with two argument structures would simply be to assume that they include two LCS entries, each specifying different thematic roles:

(10) $LOAD_a$: <Agent, Locatum, Goal> (locative variant)
$LOAD_b$: <Agent, Theme, Locatum> (*with*-variant)

A Theme is an entity that undergoes change of state, while a Locatum undergoes a change of location. Each of these verbs is then uniquely associated with an argument structure of its own.

However, Rappaport and Levin point out that associating *load*-type verbs with two different thematic roles raises three serious problems. First, without a definition of a Theme, labeling arguments as 'Locatum' and 'Theme' seems like a restatement of the fact that either the goal or the locatum may be associated with the direct internal argument. The question is, how do we get two different argument structures from a single lexical entry? In addition, this approach does not explain the interpretative difference between the two variants. More importantly, it also masks the connection between *load*-type verbs and another group of verbs, *clear*-type verbs, that seems like their mirror image:

(11) a. Lucy cleared dishes from the table.
b. Lucy cleared the table of dishes.

Such verbs seem to share the thematic structure of *load*-type verbs, except for their second internal argument, which bears the role of a Source rather than a Goal:

(12) $CLEAR_a$: <Agent, Theme, Source>

In the *of*-variant, the list of thematic roles is identical to that of the *load*-type verbs:

(13) $CLEAR_b$: <Agent, Theme, Locatum>

Such an approach does not distinguish between *clear*-type verbs and *load*-type verbs at the level of LCS. To summarize, the single-thematic-structure approach fails to provide linking rules and account for the affected interpretation. The double-thematic-structure approach fails to account for the near-paraphrase interpretation of the two alternants.

Cases such as the spray-load alternation clearly indicate the problems with the standard view of thematic roles (which successfully accounts for other types of alternations, such as the causative-inchoative alternation). Based on this case, Rappaport and Levin propose a finer-grained semantic representation of verbs. This view makes use of a decomposition of the meaning of load into argument variables and a number of primitive meaning components. The verb *load* has two LCSs:

(14) a. LOAD: [*x* cause [*y* to come to be at *z*] / LOAD]
b. LOAD: [[*x* cause [*z* to come to be in a STATE]] BY MEANS OF [*x* cause [*y* to come to be at *z*]] / LOAD]

(14a) is associated with the locative variant (load hay on the cart), and (14b) – with the *with*-variant (load the cart with hay). Note that the same variables occur in the main clause and in the subordinate MEANS clause in (14b) – ensuring identification of the participants in both events. Such an analysis captures the fact that the *z* variable has both undergone a change of state, and served as a goal for a change of location of the *y* variable. As Levin and Rappaport point out, this would not have been possible to capture in an approach that is based solely on thematic roles. Such an approach also captures the fact that *load* verbs make it possible for both their internal arguments to be understood as affected (by virtue of undergoing a change of state). The fact that verbs' meaning may be semantically decomposed also captures the similarity between *load* verbs and *clear* verbs. The directionality of causation is different – *load* specifies causing to come to a certain location, while *clear* specifies causing to go away from a location, but the two verbs involve the same variables and the same matrix of event structure. This, again, is impossible to capture in a thematic-roles-based approach.

Note that on this view the locative alternation is not an 'alternation' in the syntactic sense – involving a derivation of one structure from the other, as in the case of the dative alternation. Rather, the relation between the two variants occurs at an initial lexical level, where the same verb, *load*, is associated with two different, but related, LCSs.

While the model proposed by Rappaport and Levin elegantly accounts for the empirical facts related to the locative alternation, other accounts question the theoretical mechanism behind that analysis. The two types of theories that will be reviewed question the rich lexical representation that Levin and Rappaport associate with verbs. The first approach suggests that a coarser-grained criterion, based on aspect, mediates between lexical semantics and syntax. The second approach questions the very idea that the meaning of verbs resides in fully specified lexical entries.

2.2 *The Aspectual Interface Hypothesis*

Over the past 15 years, a number of linguists have emphasized the role of aspect in determining the correlation between the syntax and the lexicon (see Tenny 1987, 1992, 1994; Borer 1994; Van Hout 1996; Arad 1998). The Aspectual Interface Hypothesis (originating with Tenny 1987) argues that aspect mediates the mapping from thematic structure (or any level of lexical semantic representation) and the syntax. In particular, Tenny draws attention to the property associated with direct objects, of measuring out the event denoted by the verb: "The internal argument of a simple verb is constrained so that it either undergoes no change or motion, or it undergoes change or motion that 'measures out the event' over time" (Tenny 1992: 3). The object can be seen as a scale on which the event

proceeds over time. As the event advances, so is the change of state undergone by the agent. For example, in an event of eating an apple, the apple is gradually consumed, indicating the progress of the event. Once the apple is consumed completely, the event is terminated. The same holds for objects such as 'knit a sweater' – when the sweater is completed the event is terminated – 'read a book' or 'perform a sonata'. Other direct objects may not be as gradual, or incremental, but they serve to measure out the event as well: fix the car (the event ends once the car is fixed), solve a problem, find a book. By making the two assumptions regarding the role of aspect and the properties of the direct object, the Aspectual Interface Hypothesis gives a unified explanation of several cases of verb alternations. Let us see how this approach deals with the locative alternation.

Tenny notes that the verbs that participate in the locative alternation share a specific semantic property: they specify one argument which is a well defined location (flat surface or container) and the other, which is a material that is applied to (or removed from, in the case of *clear* verbs) that location. Like Levin and Rappaport (1988), Tenny notes that a thematic-role-based account is problematic: why would certain verbs containing a Theme and a Goal (*load*, *spray*) but not others (*push*) allow both their Theme and Goal arguments to be realized as direct objects? According to Tenny, the Aspectual Interface Hypothesis provides a simple explanation of this phenomenon. *Load* verbs denote an event that can be measured out in two different ways – both by the Theme and by the Goal. Since measuring out is associated with direct objects, either the Theme or the Goal may be realized as direct objects. The advantages of this approach are twofold: first, it captures the lexical class of verbs that participate in this alternation, and accounts for them in a unified way, using their aspectual properties. Second, it derives the subtle differences in interpretation associated with each variant. Because the direct object measures out the event, it turns out that the event terminates when the object is completely affected. In the locative variant (load the hay on the truck), the hay is realized as a direct object, and therefore the event terminates when the total amount of hay is loaded. In the *with*-variant (load the truck with hay) it is the truck that is realized as the direct object of the verb, and therefore the event terminates when the truck is full.

Note that Tenny's approach is similar in many respects to the approach advocated by Levin and Rappaport Hovav. Both approaches assume an initial lexical level where verbs' lexical properties are specified, and both believe that not all the information specified at that level is relevant for the syntax. They differ regarding the type of semantic information that is visible to the syntax. Levin and Rappaport postulate an intermediate level, PAS, mediating between the lexicon and the syntax, while Tenny takes aspectual properties to be the crucial mediator between the two.

2.3 The role of syntax

Tenny's work associates a specific semantic interpretation with the direct object position. This association is captured through linking rules, postulating that the

argument that measures out the event is lexicalized as the direct object of the verb. Borer (1994 and consequent work) points out that while the observations regarding the role of aspect are robust, the *direction* of the correlation may be opposite to that postulated by Tenny. Her approach thus turns the traditional view of argument structure upside down: it is not the case that arguments are labeled in the lexicon as Agent, Patient (or any other specification, such as event measurer), following which projection rules determine their syntactic position. Rather, it is the syntactic positions themselves that are associated with semantic interpretation: an external argument position endowed with agent-like properties, and an internal argument position, associated with the property of measuring out the event. The arguments of the verb do not bear any specifications in the lexicon. They acquire their interpretation as agents and patients only once they move into a syntactic projection associated with such an interpretation. We can define this view as the construction-based approach to argument structure (for a similar view see Van Hout 1996, as well as, somewhat differently formulated within the framework of Construction Grammar, Goldberg 1995).

The motivation behind Borer's approach is, first and foremost, economy. Instead of rich lexical specifications, followed by linking rules that ensure mapping of the 'right' argument (i.e., the one that was originally labeled as 'Agent' in the lexicon) to the external argument position, she simply postulates that projection of argument takes place freely, and whatever argument happens to end up at the higher position will be interpreted as an agent (and, similarly, the one that ends up at the lower position is interpreted as measuring out the event). This way, the theoretical machinery needed for projection is considerably reduced. There is no need for rich lexical representations, nor for linking rules. All that verbs specify is their number of arguments.

While this approach may prove too coarse-grained in dealing with the variety of argument structure alternations that exist in language (e.g., psychological verbs, the dative alternation), it is very fruitful in dealing with cases of multiple realization of arguments, such as the locative alternation. Let us see how this approach deals with the locative alternation. *Load* verbs are listed in the lexicon as taking three (unlabeled) arguments. These arguments are then freely projected into the available argument positions: AspOR (for *originator* of event), AspEM (*event measurer*) and prepositional object (leaving aside, for the moment, how the identity of that preposition is determined):

(15) a. [$_{\text{AspOR}}$ Lucy [$_{\text{VP}}$ loaded [$_{\text{AspEM}}$ hay [$_{\text{PP}}$ *on* the truck]]]]
b. [$_{\text{AspOR}}$ Lucy [$_{\text{VP}}$ loaded [$_{\text{AspEM}}$ the truck [$_{\text{PP}}$ *with* hay]]]]

The argument that is projected into the AspEM position is interpreted as the measurer of the event.

Note that Borer's approach is primarily concerned with the interface of the lexicon and the syntax, rather than with internal lexical properties. Questions such as the identity of the lexical properties that are unique to *load* verbs or the distinction between *load* verbs and *clear* verbs fall outside its scope.

3 The semantic properties of spray-load verbs

So far we have been primarily concerned with the syntactic realization of spray-load verbs. There remains, however, the first question we raised here:

- What are the lexical properties of the verbs that participate in that alternation?

The data discussed so far provide some cues regarding the answer. It has been observed by a number of linguists that such verbs require both a locatum (an entity that is located or put somewhere) and a location that is either a container (e.g., the truck) or a flat surface (e.g., the wall). However, this is obviously not a sufficient condition for a verb to undergo this alternation.

Dribble, for example, takes both a location and a surface, yet fails to undergo the alternation:

(16) a. Lucy dribbled paint onto the floor.
b. *Lucy dribbled the floor with paint.

Similarly, *pour* specifies a locatum and a container, but does not allow the *with*-variant:

(17) a. Lucy poured milk into her glass.
b. *Lucy poured her glass with milk.

Conversely, certain verbs that take a locatum and a location allow the *with*-variant, but not the locative variant:

(18) a. *Lucy coated lemon icing onto the cake.
b. Lucy coated the cake with lemon icing.

(19) a. *Lucy seasoned lemon rind into the cake.
b. Lucy seasoned the cake with lemon rind.

Some finer-grained semantic criteria are required to distinguish these cases from *load*-type verbs, which participate in the alternation. Such a semantic account is offered by Pinker (1989), based on earlier work by Rappaport and Levin (1985). Pinker notes, first, that the location verbs are not a homogenous class. The first principal division holds, according to him, between content-oriented verbs and container-oriented verbs. Content-oriented verbs obligatorily take a locatum argument, while their location argument is optional (20). Container oriented verbs obligatorily take a location, while their locatum argument is optional (21):

(20) a. Lucy piled the books (on the shelf).
b. Lucy piled the shelf *(with books).

(21) a. Lucy stuffed the turkey (with breadcrumbs).
b. Lucy stuffed the breadcrumbs *(into the turkey).

Pinker assumes that the optionality of arguments tells us about the direction of the derivation. When the locatum argument is obligatory (in the case of *stuff* verbs) the derivation proceeds from the *with*-variant to the locative variant. When the locative variant is obligatory (as in the case of *pile* verbs) the derivation proceeds from the locative variant to the *with*-variant. When both arguments are optional (cf. *load*, as in *load the gun* and *load the bullets*), the verb could in principle belong to either class, although, as Pinker notes, one interpretation is more salient, or basic (in this case, the container-oriented, *load the gun*. *Load the bullets* seems like a truncated form).

Having established the basic distinction between content-oriented and container-oriented verbs, Pinker offers detailed characterizations of the different semantic classes found within each group. What is striking is that there is a robust correlation between the different semantic classes he notes and the groups of verbs that participate or do not participate in that alternation.

Content-oriented verbs (verbs taking the locative-variant) include the following classes:

Alternating:

(i) simultaneous forceful contact and motion of mass against a surface (*smear*, *smudge*, *spread*, *rub*, *dab*, *daub*);
(ii) vertical arrangement on a horizontal surface (*heap*, *pile*, *stack*);
(iii) force is imparted to a mass, causing ballistic motion in a specified spatial distribution along a trajectory (*splash*, *spray, inject*, *splatter*, *sprinkle*);
(iv) mass is caused to move in a widespread or nondirected distribution (*seed*, *scatter*, *sow*).

Non-alternating:

(v) a mass is enabled to move via the force of gravity (*dribble*, *drip*, *ladle*, *pour*, *spill*);
(vi) flexible object extended in one dimension is put around another object (*coil*, *chain*, *spin*, *whirl*);
(vii) mass is expelled from inside an entity (*spit*, *exude*, *secrete*, *vomit*).

Container-oriented verbs (verbs taking the *with*-variant) include the following classes:

Alternating:

(i) a mass is forced into a container against the limits of its capacity (*pack*, *cram*, *jam*, *stuff*);

(ii) a mass of a size, shape or type defined by the intended use of the container (and not purely by its geometry) is put into the container, enabling it to accomplish its function (*load*, *pack*, *stock*).

Non-alternating:

(iii) a layer completely covers the surface (*inundate*, *bandage*, *blanket*, *cover*, *pave*, *smother*, *tile*);
(iv) addition of an object or mass to a location causes an esthetic or qualitative, often evaluative, change in the location (*adorn*, *burden*, *clutter*, *dirty*, *embellish*, *garnish*, *soil*, *stain*);
(v) a mass is caused to be coextensive with a solid, liquid or layer-like medium (*interlace*, *lard*, *soak*, *drench*);
(vi) an object or mass impedes the free movement of, from, or through the object in which it is put (*block*, *choke*, *clog*);
(vii) a set of objects is distributed over a surface (*bombard*, *coat*, *speckle*, *spot*, *stud*).

This characterization of classes may seem too fine-grained, perhaps almost arbitrary. Pinker notes that there are wider semantic motivations behind them, related to the core they specify. Content-oriented verbs thus share the property of naming the specific *manner* of applying the content (the kind of force exerted or the direction of motion according to which the Theme moves). The motion may be forced against something (*smear*), around something (*wrap*), or all over the place (*scatter*), due to gravity (*dribble*) or against gravity (*pile*). Container-oriented verbs specify the change of state resulting from the addition of material: *adorn*, *load*, *clock*, *pollute* etc.

The ability of verbs to alternate results, according to Pinker, from two factors. First, types of actions whose goal argument can be more easily construed as undergoing change are more likely to realize their goal argument as a patient and participate in the alternation (note that Pinker's analysis is formulated in terms of thematic roles; his assumption is that thematic roles mediate between the initial level of lexical representation and syntactic projection). Loading a truck or cramming a jar means that the truck or the jar are filled to their capacity, thus affected. Pouring liquid into a glass does not entail similar affectedness of the glass. The second factor has to do with the specific content of verbs. As Pinker points out, container-oriented verbs (those taking the *with*-variant) must specify not only that a change of state has taken place in the container, but also *what* the change of state is. Otherwise, all such verbs would be synonymous with *fill* or *cover*. Content-oriented verbs (those taking the locative variant) must not only specify movement of substance into a location, but also what is the *specific* manner of the movement of that substance. Otherwise, they would all be synonymous with *put*.

Therefore, container-oriented verbs that alternate must specify not only the change of state in the container, but also the manner in which the substance is moved into the location. Similarly, alternating content-oriented verbs must specify not only the manner in which the substance is moved, but also the change of state in the location. As Pinker points out, in the *smear* class, "the moved substance and the container simultaneously feel the force of the action, and in

the *spray* class, the force imparted to the object can aim it in a direction. This contrasts with the *pour* class, where gravity is a force mediating between the immediate effect on the moving object and the effect on the destination" (Pinker 1989: 128).

Furthermore, as Pinker notes, in the case of alternating content-oriented verbs, the manner of applying the substance enables us to predict the distribution of material on the surface of the location: *smear*, *dab*, *spray*, etc. For alternating container-oriented verbs, the specified state of the container imposes constraints on the manner in which the substance is moved.

4 Conclusion

The spray-load alternation proves an interesting case study both for theories of lexical semantics and for theories of the syntax–lexicon interface. The different accounts reviewed here are complementary: each takes as its focus a different aspect of the alternation. Rappaport and Levin (1988) and Tenny (1992) are primarily concerned with the *linking* problem of alternating verbs, offering two different perspectives of the rules governing mapping between syntax and semantics. Borer (1994) uses the alternation as a case study pointing out the role of syntax in determining the semantic properties of verbs: information contained in syntactic positions (e.g., measuring out) is assigned to verbs by virtue of occupying those positions. Borer's theory draws on Tenny's observation, regarding the role of aspect in mediating between syntax and semantics. Tenny's account thus aims both to characterize alternating verbs (verbs whose Theme and Goal argument can both be construed as measuring out the event named by the verb) and explain their linking properties (by postulating that the argument that measures out the event is linked with the direct object position). Pinker's account offers the most detailed semantic characterization of alternating verbs, accounting for subtle differences between seemingly similar verbs that behave differently with respect to that alternation. Note that Pinker's characterization of alternating verbs is compatible with Tenny's. Specifying a change of state in the location entails that the goal can be construed as measuring out the event (the event proceeds along with the change of state in the container, e.g., until the truck is full). Pinker assumes some general principles that mediate between lexical semantics and the syntax. Tenny's Aspectual Interface Hypothesis may be such a coarser-grained general rule.

There remain a number of interesting questions, which cannot be addressed here for lack of space. The first question regards the acquisition of locative verbs. The second question is about the morphological marking of this alternation. In English there is no morphological marking of any of the variants, but in other languages (German, Hungarian) there is different morphological marking of the alternants (specifically, an affix on the *with*-variant). Finally, there arises the question regarding the universality of the alternation. We saw that this alternation exists in a number of unrelated languages – but does it exist in all languages? If not, what are the semantic or syntactic criteria that govern the availability of the

alternation? Within languages that allow this alternation, is the set of alternating verbs similar in each? If some languages are more 'permissive' with respect to the number and type of verbs that alternate, what factors govern this variation?

For a detailed discussion of the acquisition question, see Gropen (1989) and Brinkmann (1997). Brinkmann (1997) also offers some discussion of *be-* prefixation of the *with*-variant in German (for Hungarian see Moravcsik 1978). The last question, regarding variation between languages, must await further research.

1 Introduction

The fundamental work on islands is Ross (1986, originally a 1967 dissertation). Ross distinguished between transformations that move a constituent and leave behind a pro-form (i.e., a resumptive pronoun) and ones that 'chop' a constituent and move it without leaving anything behind. An example of the former is left dislocation (that is, in Ross's analysis left dislocation is not base generated). An example of chopping is topicalization. Of the two, only chopping operations are constrained by islands. Islands will be enclosed in angled brackets:

(1) This kid, I must call <the teacher who punished him>.

(2) *This kid, I must call <the teacher who punished ___>.

Diagnosing islands has become more complex since Ross because it is assumed that there exist invisible pro-forms (empty resumptive pronouns), in addition to overt ones. I will use 'gap' as a pretheoretical term that covers both traces and empty pronouns.

Islands come in two main varieties: weak and strong. Note that the weak/strong qualification does not correspond to degrees of ungrammaticality.

(3) **Strong islands:**
No extraction is allowed (constructions with an appropriate resumptive pronoun may be allowed).

(4) **Weak islands (WI):**
Some phrases can extract, others cannot.

The focus of this chapter is weak islands (WI). Strong islands are considered only to set the stage for the discussion of WIs.

Up until the late 1980s nothing much beyond *wh*-islands had been thought to be a weak (selective) island. Beginning with Relativized Minimality, however, an ever growing range of weak islands have been recognized. Thus, theories of weak islands have mushroomed, each coming with a significant set of new data and important new connections to other domains. The review of weak islands will emphasize the correspondence between data sets and theories. Less attention will be given to proposals that primarily recast the theoretical account of some narrow range of data.

2 Absolute vs. selective islands

Although the notion of strong vs. weak islands as defined in (3) and (4) seems like a simple descriptive one, it is not. Consider the following examples involving *wh*-islands and adjunct islands:

(5) a. *About which topic did John ask <who was talking ___>?
b. *?Which topic did John ask <who was talking about ___>?
c. *How did John ask <who behaved ___>?

(6) a. *About which topic did you leave <because Mary talked ___>?
b. *Which topic did you leave <because Mary talked about ___>?
c. *How did you leave <because Mary behaved ___>?

These two sets might suggest that both *wh*-clauses and adjunct clauses are strong islands: the extraction of three different types of phrase was attempted and failed. On the other hand, it is easy to construct other examples in which some, but not other, phrases can extract. The percentage sign % indicates that there is variation among the speakers of English:

(7) a. %About which topic did John ask <whether to talk ___>?
b. Which topic did John ask <whether to talk about ___>?
c. *How did John ask <whether to behave ___>?

(8) a. *About which topic did you leave <without talking ___>?
b. Which topic did you leave <without talking about ___>?
c. *How did you leave <without behaving ___>?

The difference between the two sets involves Tense in the first place. While tensed clauses are themselves not islands, cf.

(9) Which topic do you think that I talked about ___?

we see that the presence of Tense may considerably strengthen other islands. This fact must be systematically controlled for in the evaluation of various islands.

(Chomsky 1986a briefly touches upon the role of Tense. Cinque 1990 uses it as an important test, and Manzini 1992 proposes a theory of its behavior.) Thus, the specific constructions in (5–6) may preclude the presence of any gaps, but this in itself does not mean that *wh*-complements and adjuncts per se are totally impenetrable. Shall we conclude now that *wh*-clauses and adjuncts per se are merely weak islands? Note a fine distinction: while adverb extraction is blocked in both, the infinitival *whether*-clause allows the extraction of both DPs and PPs (at least for some speakers), while the gerundival adjunct clause allows only DP-extraction.

The interpretation of this situation is a theoretical, rather than descriptive, matter. Making the implicit assumption that the PP vs. DP facts are highly consistent in each island type. Cinque (1990) argues that this difference warrants radically different analyses because a DP gap may be an empty resumptive pronoun but a PP gap cannot be. *Wh*-islands are indeed weak (selective); adjunct-islands on the other hand are strong (absolute) and the DP-gap that they may contain is an empty resumptive pronoun.

Cinque's distinction will serve as a basic organizing principle in this chapter because it is typically taken for granted in the weak island literature: theories of weak islands do not try to account for the islands that Cinque classifies as strong.

(10) **Cinque's diagnostic of strong vs. weak islands:**
Among the domains that do not allow all standard extractions, those that allow a PP-gap are weak islands, and those that can at best contain a DP-gap are strong islands (and their DP-gap is an empty pronoun).

This is not the only possible way to cut the cake. For instance, Postal (1997a, 1998), who uses the terms locked (absolute) and unlocked (selective) island, does not attribute this much significance to PP vs. DP. Following Ross, he assumes that extraction from unlocked islands always involves empty resumptive pronouns and subsumes Cinque's weak islands under this rubric.

A note on the data: question formation, relativization, and topicalization are all instances of *wh*-movement. Because the bulk of the literature to be surveyed focuses on examples involving question formation, this chapter follows the same practice, unless the discussion of a particular work requires us to do otherwise.

3 Strong islands

3.1 Classical strong islands

While recent literature has identified a host of weak islands, the classical inventory, with the exception of certain *wh*-islands, consists of strong ones. What follows is a list, sometimes interrupted by comments.

Complex DP (with relative clause):

(11) *Which kid must you call <the teacher who punished ___>?
*Where must you call <the teacher who put the book ___>?

(12) *This kid, you must call <the teacher who punished ___>.
*On the table, you must call <the teacher who put the book ___>.

(13) *What size shoes did you call <the man who wears ___>?

(14) *How did you call <the man who behaved ___>?

Complex DP (with complement clause):

(15) *Which man did you hear <the rumor that my dog bit ___>?
*Where did you hear <the rumor that I put the book ___>?

(16) *This man, I heard <the rumor that my dog bit ___>.
*On the table, I heard <the rumor that you put the book ___>.

(17) *What size shoes did you hear <the rumor that I wear ___>?

(18) *How did you hear <the rumor that I behaved ___>?

But just as it was possible to arrange for a DP-gap in adjuncts by removing Tense, the same is possible with Complex DPs if the definiteness of the head is removed. (Pollard and Sag 1994 assume, for this reason, that there is no need for a Complex DP constraint.) PP-gaps remain practically excluded.

(19) a. ??What the police arrested <everyone who saw ___> was this video. (Postal 1998)
b. *I know in which building the police arrested <everyone who lives ___>.

(20) a. ??Which man did they consider <rumors that Bob would betray ___>? (Rothstein 1988)
b. *About which man did they consider <rumors that Bob would talk ___>?

In distinction from Tense, definiteness may create an island by itself (Fiengo and Higginbotham 1981; Manzini 1992):

Definites:

(21) *Which man did you discover <Mary's poem about ___>?

(22) ??Which man did you discover <the poem about ___>?

(23) Which man did you discover a poem about ___?

Subjects:

(24) *Which man did <his visiting ___> shock you?

(25) *Which book do you believe <the first chapter of ___> to be full of lies?

(26) *Which man does <everyone who knows ___> admire his sincerity?

Adjuncts (see the discussion of Tense above):
(27) *Which topic did you leave <because Mary talked about ___>?

(28) a. Which topic did you leave <without talking about ___>?
b. *About which topic did you leave <without talking ___>?

Authier (1991) argued that adjuncts can contain CP gaps besides DP gaps; for an alternative analysis, see Postal (1994):

(29) We suggest ___ to our employees, <without actually requiring ___ of them>, that they wear a tie.

Coordinate structures, unless extraction is across-the-board:
(30) *Which man did you invite <Mary and ___>?

(31) *Which man did you invite <Mary and a friend of ___>?

(32) Which man did you invite <a friend of ___ or a brother of ___>?

However, DP-gaps are acceptable under various circumstances (see Postal 1998 for detailed discussion):

(33) This is the beer that I <bought ___, loaded ___ into the car, went home, and then fell asleep>. (Jacobson 1996)

The status of tensed constituent *wh*-complements seems to vary cross-linguistically. Some speakers of English reject extractions from them entirely, whereas others find them tolerable. Likewise, they are rejected by speakers of Dutch, whereas they are acceptable in Scandinavian languages (see Engdahl and Ejerhed 1982) and in Hungarian. (Hungarian has object pro-drop, but only for singulars, thus we know that the gap in (34c) is not a dropped pronoun.) This variation is not well understood (though see Bayer 1984, 1996: section 6.6.4).

Tensed constituent *wh*-complements (in some languages/dialects):
(34) a. %Which man did John ask <who invited>?
b. *Welke man heb jij je afgevraagd <wie – gezien heeft>? Dutch
which man have you self asked who seen has
c. Mely fiúkat találgattad, hogy <ki látta ___>? Hungarian
which boys were-guessing-you that who saw

Left branches:
(35) *Which (man's) did you see <___ picture>?

As (35) shows, it is often difficult to extract from the left branch of a structure (Ross 1986). But comparable examples are perfect in other languages:

(36) Combien as-tu lu <___ de livres>? French
how many have-you read of books

(37) Cuius legis <___ librum>? Latin
whose read-you book

(38) Kinek olvastad <___ a könyvét>? Hungarian
who-dative read-you the book + agr

Whether all the counter-examples are well understood, the Left Branch condition seems like a less plausible generalization than the others. See Corver (1990).

Finally, some islands constrain left-extraction but not Right Node Raising, indicating that the latter may not be an extraction (Bouma 1987; Postal 1998):

(39) I patted <the dog that bit ___> and hit <the dog that adored ___> the man who stole my beloved cat.

We will not discuss the relation between *wh*-in-situ and islands; for discussion, see chapter 77.

3.2 Types of explanation

The standard explanation of the islandhood of Complex DPs, Subjects, *Wh*-complements, and Left Branches is in terms of Subjacency: movement out of them results in ungrammatical sentences because movement crosses more than one bounding node (barrier); see sections 3.4 and 7.1. Adjunct islands are standardly explained by Huang's (1982a) Condition on Extraction Domains, hence by the Empty Category Principle: an extraction domain needs to be properly governed. Likewise, Pesetsky (1982) subsumes the Coordinate Structure Constraint under the path containment version of the ECP (see section 7.1). Manzini (1992) is the only attempt to unify the effect of Definiteness and Tense with other locality phenomena: D and T block dependencies based on Case-addresses, which, in her theory, DPs otherwise rely on to escape from islands.

3.3 Ways of salvaging strong island violations

As has been mentioned, a strong island violation can sometimes be salvaged by resorting to the resumptive pronoun strategy (whether the pronoun is overt or empty). In addition, the gap in the island may be parasitic on a well-behaved trace of movement, e.g.:

(40) Which papers did you file ___ <without reading ___>?

(41) He is a man who <everyone who knows ___> admires ___.

See also Engdahl (1983), Kayne (1983), Chomsky (1982, 1986a), Cinque (1990), among others.

Finally, the island itself may be pied-piped, overtly or at Logical Form:

(42) a. *Whose did you visit <___ brother's sister>?
b. <Whose brother's sister> did you visit?

Pied-piping at LF has been proposed for apparent violations of Complex DPs in *wh*-in-situ languages in Pesetsky (1987a), and for apparent violations of a single adjunct island in among others, Cinque (1990). These matters are not discussed here further; see chapters 50 and 55 for details.

3.4 More on Subjacency

Subjacency is classically understood as a condition on movement and requires that movement not cross more than one bounding node. Bounding nodes were originally defined as a list: NP and S (= DP and IP) in English (Chomsky 1973b, 1977); NP and S' (= DP and CP) in Italian (Rizzi 1978b). Chomsky (1986a) redefines bounding nodes as barriers. An XP is a blocking category for α iff it is not theta-marked by a sister lexical head and dominates α. β is a barrier for α iff (i) β is a blocking category for α but not IP, or (ii) β is the first XP that dominates a blocking category for α. Chain-formation (which takes the place of movement) requires 1-subjacency: no more than one barrier may be crossed. (For an excellent introduction to *Barriers* as well as other theories of locality, see Roberts 1997a.)

Adopting Rizzi's (1990b) Relativized Minimality (the pertinent aspects of which will be discussed when we turn to Weak Islands), Cinque (1990) proposes two important changes in the understanding of strong islands: (i) strong islands constrain binding chains, not necessarily movement, and (ii) not only government but also binding chains require 0-subjacency (no barrier may be crossed).

3.4.1 Cinque (1990)

We now take a closer look at some aspects of Cinque's proposal, because they are fundamental in defining the division of labor between theories of strong and weak islands as assumed in most of the literature. Following Obenauer (1984/1985), Cinque observes that both parasitic gaps and gaps inside strong islands are restricted to the category DP and takes this to indicate that these gaps are not variables, but A-bar bound empty pronominals: pro. These pros are not moved in syntax but must move at LF (like some kind of abstract *wh*-phrase). But instead of moving on its own, it pied-pipes the minimal island it is contained in. This accounts for the fact that, if all goes well, one strong island can be evaded.

Now recall the contrast between tensed and gerundival adjunct islands:

(43) *Which topic did you leave <because Mary talked about ___>?

(44) Which topic did you leave <without talking about ___>?

Bona fide cases of pied-piping are also constrained by Tense (Nanni and Stillings 1978):

(45) *They bought a car that their son might drive which was a surprise to them.
'they bought a car and the fact that their son might drive it was a surprise to them'

(46) The elegant parties, to be admitted to one of which was a privilege, had usually been held at Delmonico's.

Cinque stipulates that Tensed Inflection weakly blocks the upward percolation of features. Thus, even one island cannot be pied-piped by pro if it is tensed. Cinque predicts that at most one island can be evaded: strong islands cannot be compounded:

(47) *the book that we left Russia <without being arrested <after distributing ___>>

The reason is that the movement of the pied-piped domain continues to be sensitive to islands (can at best be parasitic on overt movement). Postal (1998) notes, though, that an adjunct island can be compounded with a complex DP (see further section 3.4.3):

(48) It was Lucille that Mike went home <without criticizing <anyone who defended ___>>.

(49) It was Lucille that Mike criticized <everyone who went home <without defending ___>>.

To summarize, the observation that certain islands only contain DP gaps leads Cinque to a theory according to which these islands are strong, and the DP gap is not a trace of movement but A-bar bound pro. This contrasts with Weak Islands, which may also contain PP gaps. The latter must be traces since, according to Cinque, human languages generally lack resumptive pronouns of category PP. The behavior of weak islands is explained by considerations that do not apply to strong islands in Cinque's work and in the many other proposals this chapter will review. Thus, the DP–PP distinction carries a great burden in deciding which data are to be accounted for by each theory.

3.4.2 Some intriguing similarities between SIs and WIs

While the division of labor so determined has proven very useful in the literature, it may be worth pointing out some intriguing similarities between the phrases that may or may not escape from the two types of islands. First, there is dialectal variation among speakers of English regarding the acceptability of PP-extraction out of *wh*-islands (one of the weak islands). Unfortunately, no systematic empirical

study of this variation exists, to my knowledge, wherefore it is difficult to assess its significance for Cinque's theory.

Second, consider the following contrast:

***Wh*-phrase associated with pro in a strong island:**

(50) Which politician did you go to England <after meeting ___>?

(51) *How much water did you make the pasta <after boiling ___>?

***Wh*-phrase associated with a variable in a weak island:**

(52) a. Which politician did John ask <whether to worry ___>?
b. *About which politician did John ask <whether to worry ___>?

(53) a. *How much gravy did John ask <whether to cook ___>?
b. *With how much gravy did John ask <whether to cook ___>?

In both cases the *wh*-phrase needs to be referential in some sense. But the reasons are different. In the case of strong islands, the *wh*-phrase needs to be of the kind that resumptive pronouns tend to associate with; in the case of weak islands, it has to carry a referential index and corefer with its variable (see in section 7.2). Cinque (1990) characterizes the suitable *wh*-phrases rather similarly in the two cases, but neither this book nor any subsequent work known to me addresses the question whether the two requirements are exactly identical. Cinque (p.c., 1998) has kindly suggested the following contrast between a weak and a strong island:

(54) ?Quanti pazienti volevi sapere <se ogni dottore avesse potuto visitare ___>?
'How many patients did you want to know whether each doctor had been able to examine?'

(55) *Quanti pazienti vuoi incontrare <ogni dottore che abbia visitato ___>?
'How many patients do you want to meet each doctor who examined?'

But the exact generalization remains an open question. One proposal that attempts to unify weak and strong islands is Starke (2001).

3.4.3 Postal (1998)

Perlmutter (1972) proposed that all extractions leave invisible resumptive pronouns, whether they are from islands or not. Obenauer (1984/1985) proposed that all extractions from islands involve empty resumptive pronouns. Cinque (1990) developed a specific resumptive pronoun theory of apparent strong island violations. Postal (1998) proposes to generalize Cinque's idea to all islands and introduces many novel pieces of data.

Postal (1997a) asks the fundamental question whether or not constituents are islands by default. The standard answer is that by default they are not, which is

why theories attempt to characterize islands as a natural class. In contrast, he argues that non-islands form a small natural class, characterizable in Arc-Pair Grammar.

Postal (1998) distinguishes locked (absolute) and unlocked (selective) islands. Locked islands permit only left dislocation (or operations that are like LD in the relevant respect). Unlocked islands permit some gaps and comprise both strong and weak islands in Cinque's terms: interrogative clauses, complements of factive verbs like *regret*, rationale clauses (*go home* (*in order*) *to* . . .), clausal complements of certain nouns (*formulate a plan to prove* . . .), adjuncts, relative clauses with quantifier heads, subjects, and certain coordinate structures (Postal's list is not intended to be exhaustive). On Postal's analysis, every extraction from an unlocked island contains an invisible resumptive pronoun (RP). Such islands are unlocked because they permit the extraction of an RP. The mechanism is in many respects like Cinque's. The invisible RP in question requires control, hence it extracts to a position sister to the fronted phrase. This derives island-sensitivity. The reason why limited island violations are possible is that an RP controls a secondary invisible resumptive pronoun, notated as RPx, which extracts only to the left boundary of the lowest island from which the primary RP extracts. Tertiary RPs are excluded.

Postal assumes that RPs in unlocked islands are DPs. The fact that some selective islands permit PP gaps is acknowledged (n. 15 to ch. 3) but not addressed in any depth. But, unlike Cinque, Postal does not derive his reason for adopting an RP-analysis from category restrictions. Instead, the differential ability of phrases to occur in what he calls 'anti-pronominal contexts' plays a major role.

Anti-pronominal contexts are ones that do not allow weak definite pronouns. An example is the object of *tell* (as opposed to *determine*):

(56) Mike was a spy. We could easily determine/*tell it.

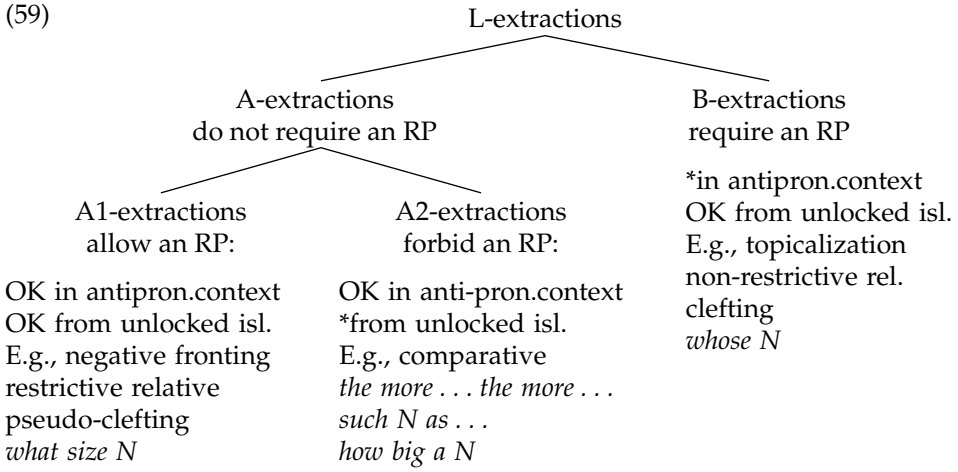
A pseudo-clefted phrase can, but a topicalized one cannot, be linked to a gap in an anti-pronominal context:

(57) What we could easily tell was that Mike was a spy.

(58) *That Mike was a spy, we could easily tell.

This is explained if topicalization requires an RP, independently of whether it is from an island, whereas pseudo-clefting does not require one. Assume further that pseudo-clefting allows, but comparative extraction forbids an RP. Then, if extraction from an island invariably involves an RP, one arrives at the typology in (59).

(59)



Note that A1-extractions are linked to an RP when escaping from an unlocked island, and they are not linked to an RP when occurring in an antipronominal context.

This typology predicts that when an anti-pronominal context is embedded in an otherwise unlocked island, no extraction is possible since the two ingredients impose contradictory requirements. Consider, for instance, the existential *there* context. The examples indicate that it is antipronominal; it disallows topicalization, it permits negative fronting, but when embedded in a factive island, it disallows negative fronting even though the latter is otherwise possible from a factive island:

(60) *There are them in the bottle.

(61) *Such chemicals, he thought there were ___ in the bottle.

(62) No such chemicals did he think that there were ___ in the bottle.

(63) *No such chemicals did he regret that there were ___ in the bottle.

(64) No such chemicals did he regret that we used ___.

Postal identifies the following further antipronominal contexts (illustrated with the impossibility of topicalization):

(65) **Existential there:**
No such chemicals did he believe that there were ___ in the bottle.
*Such chemicals, he believed that there were ___ in the bottle.

(66) **Change of color:**
*Green, he never painted the car ___.

(67) **Name position:**
*Raphael, I would not name anybody ___.

(68) **Inalienable possession:**
*His ear, I never touched him on ___.

(69) **Predicate nominals:**
*That kind of surgeon, Frank never became ___.

(70) **Adverbial NPs:**
*That reason, he resigned for ___.

(71) **Extraposed PPs:**
*Such a scurrilous review, they published ___ last year of his book.

(72) **Infinitival extraposition:**
*A definite wish, I did not perceive ___ in Sylvia to retire.

(73) **Exceptive shifting:**
*Something dangerous, he might have handed ___ to Rita other than the gun.

(74) **Temporal NPs:**
*That much time, Frank could never stay ___ in Italy.

(75) **Idiomatic V+NP:**
*That much headway, which they made ___ on the job, . . .

(76) **Place name as locative:**
*Argentina, our president is said to have been born in ___.

Postal remains non-committal as to why each extraction type allows, forbids, or requires an RP. It would clearly be desirable to identify syntactic or semantic properties that entail either that an RP is forbidden or that an RP is required, and to analyze the permissive type as syntactically or semantically ambiguous. This would be especially tempting in connection with the *wh*-phrases *how big a N* (RP forbidden), *whose N* (RP required), and *what size N* (RP permitted), whose divergent behavior Postal notes. Postal's data, whether well understood or not, provide some novel counter-examples to certain claims in the literature. Although many of the anti-pronominal contexts involve adjuncts or non-referential expressions, many others are argumental and/or referential, i.e., their island sensitivity is surprising. On the other hand, while Cinque takes the island-sensitivity of Italian negative phrases to support the referentiality generalization, (64) shows that negative fronting in English is not blocked by weak islands.

As was mentioned at the outset, Postal lumps all unlocked islands together and does not distinguish between Cinque's two subtypes, weak islands and single

strong islands. The restricted viability of such a position is in fact implicit in Cinque's work. The DPs that can escape from weak islands are described quite similarly to those that can escape from strong ones. If this is correct, then, as long as only DP-extraction is considered, we do not expect to be able, or need, to distinguish between the two subtypes. Recall that Cinque distinguishes the two subtypes with reference to the possibility of PP-extraction. In support of his unitary analysis, Postal (p.c.) notes that (77b, c) pose a problem for Cinque's dual analysis. Only one of the gaps being inside an island, the two members of the conjunction in (b) and the two individuals that make up the plural in (c) need to participate in two different filler–gap relations:

(77) a. Which cop/1 did Lucy believe Sam called ___/1 and May faint after meeting ___/1?
b. Which cop/2 and which nurse/3 did respectively Lucy believe Sam called ___/2 and May faint after meeting ___/3?
c. Which two cops/3i,j did respectively Lucy believe Sam called ___/3i and May faint after meeting ___/3j?

The island sensitivity of an extraction may not be fully equated with its inability to link to an RP, however, whether the latter property be a primitive or a derived one. As will be detailed in section 5.6, collectively interpreted arguments of one-time-only predicates are sensitive to weak islands (in the sense that extraction out of a WI forces a multiple events reading on the naturally one-time-only predicate):

(78) Which relatives do you <regret that you heard this rumor from ___>?

(79) ??Which relatives do you <regret that you got this present from ___>?

The same collective arguments can nevertheless antecede resumptive pronouns, in contrast to some amount phrases, for example:

(80) a. These relatives of mine, they gave me this present.
b. These relatives of mine, I got this present from them.

(81) *This much pain, Mary endured it.

Whether or not the unification of all unlocked islands that Postal proposes is eventually viable, in the rest of this chapter, I follow standard practice in excluding the islands that Cinque calls strong from the discussion of weak (selective) islands.

4 Weak islands: a preview

The historical starting point is the assumption, made in Huang (1982a), Lasnik and Saito (1984, 1992), Chomsky (1986a), that the paradigmatic (if not the only)

case of weak (selective) islands is *wh*-islands, and the expressions whose extraction is sensitive to WIs are adjuncts, as opposed to arguments. Since *Barriers*, a number of new theories of weak islands have appeared in quick succession. What makes this process especially interesting is the fact that practically each theory comes with a significant new set of data. The survey below will reflect this spirit. The critical data come in two dimensions:

(A) What extractions are sensitive to WIs?
(B) What induces a WI?

Much of the literature can be conveniently surveyed along the dimensions in (A) and (B). I will thus begin by drawing ever-widening circles of data, first for (A), then for (B). The third part of the discussion will review what theories account for what data sets. Sections 5 and 6 are not simple data surveys, though. Detailed and often theoretical arguments will be put forth as to why exactly the proposed generalizations hold. Also, when certain pieces of literature offer important analyses of WI-phenomena without proposing their own overall theory of WI, they will be summarized in these sections. In both these sections and in section 7, where we turn to theories, we will see that the proposals are less and less syntactic. Some of them include pragmatic or semantic factors in the description of what expressions are WI-sensitive or WI-inducers, although they formulate the explanation in syntactic terms. Others even derive the explanation from semantics.

The data to be discussed are as follows:

Ad (A) What extractions are sensitive to WIs:
(A1) Arguments vs. adjuncts.
(A2) Referential vs. non-referential.
(A3) Re-evaluating the role of D-linking.
(A4) Individual vs. non-indvidual, and *how many*-phrases.
(A5) Functional readings and event-related readings.
(A6) Individuals: is it being type e that matters?
(A7) Split constructions.
(A8) Negative polarity item (NPI) licensing.
(A9) Cross-sentential anaphora.
(A10) Elements of anti-pronominal contexts.

Ad (B) What induces a WI:
(B1) *Wh*-islands.
(B2) Negatives and other affective operators.
(B3) Response stance and non-stance vs. volunteered stance predicates.
(B4) Extraposition islands.
(B5) VP-adverbs.
(B6) Scope islands.

Section 7 presents the theories that account for these data and generalizations. To anticipate, the division of labor is as follows: when a theory accounts for only some of the data falling under some generalization, the generalization is marked with a percentage sign (%):

- ECP and Subjacency for (A1)–(B1)
- Relativized Minimality for (A2, A7)–(B1, B2, B3%, B4, B5%)
- Monotonicity for (A3, A4, A7%)–(B1, B2, B3%, B5%)
- Scope Theory, algebraic version for (A3, A4, A5, A6, A7%)–(B1, B2, B3, B5, B6)
- Scope Theory, dynamic semantic version (A4, A5, A7, A8, A9)–(B1, B2, B3, B5, B6)

5 What extractions are sensitive to WIs? (A)

Here we survey the main distinctions that have been found useful in describing what extractions are sensitive to WIs. To keep new information manageable, *wh*-islands will be used to illustrate the phenomena. Two other familiar WIs, negative and factive islands, will be added where necessary (e.g., because subject extraction out of a *wh*-island may be independently ungrammatical). The full set of WIs is much greater, though, and will be presented when dimension (B) is addressed.

5.1 Arguments vs. adjuncts (A1)

Huang (1982a), Lasnik and Saito (1984, 1992), and Chomsky (1986a) draw the distinction between arguments (claimed not to be sensitive to WIs) and adjuncts (claimed to be sensitive to them); see (82) and (83).

(82) Which problem did John ask <how to phrase ___>?

(83) *How did John ask <which problem to phrase ___>?
'what is the manner such that John asked which problem to phrase in that manner'

In addition to *how*, *why*, and, to a somewhat lesser extent, *when* are WI-sensitive adjuncts.

(84) *Why did John ask <whether to fire him ___>?
'What is the reason such that John asked whether it is a good reason for firing him'

(85) ??When did John ask <whether to fire him ___>?
'What is the time such that John asked whether it is a good time for firing him'

Where does not fit the picture very well because its WI-sensitivity does not depend much on whether it is subcategorized for (as with *put*) or not (as with *read*):

(86) ?Where did John ask <whether to put/read this book ___>?
'What is the location such that John asked whether to put this book there/ whether to read this book there'

The morphological constitution of these *wh*-words may also play a role. It has been noted that when counterparts of *why* and *when* have an articulated PP structure in a language, they extract better. Korean, Japanese, and Hungarian are cases in point.

5.2 *Referential vs. non-referential/Existential presupposition (A2)*

A major revision of the argument/adjunct distinction is prompted by observations by Ross (1984), Kroch (1989a), Comorovski (1989), Rizzi (1990b), Cinque (1990), Obenauer (1992), and Kiss (1993). In a nutshell, the claim is that originating in an argument position is not enough: a successful extractee must also be referential in some sense. Some subcategorized for, and thus, presumably, argumental, XPs are unexpectedly WI-sensitive:

(87) *What did John ask whether these pearls cost ___? (Ross)
cf. *These pearls cost.

(88) *How did John ask whether to behave ___? (Rizzi)
cf. *John behaved.

According to Rizzi (1990b), amount and manner phrases may be arguments but they do not have the theta-roles of event-participants (referential theta-roles). On the other hand, as events take place in time and space, Rizzi surmises that the event specification may license a temporal and locative index that accounts for the fact, noted above, that such phrases are less sensitive to WIs than manners and reasons.

On the basis of the fact that expletive *wh*-phrases do not have referential theta-roles, Rizzi (1992) extends this reasoning to partial *wh*-movement, which is blocked by a negative island (for cross-linguistic variation, see Dayal 1994):

(89) Was glaubst du (*nicht), mit wem Jakob jetzt spricht?
what think you (*not) with whom Jacob now talks
'With whom do(n't) you think Jacob is talking now?'

Drawing from work by Kroch and Comorovski, Cinque (1990) makes a finer distinction that involves pragmatics: a referential *wh*-phrase, in addition to having

a referential theta-role, needs to be Discourse-linked, i.e., drawn from a pre-established set.

Some of the most persuasive examples involve *how many*-phrases:

(90) *How many books are you wondering <whether to write ___ next year>?

(91) How many books on the list are they wondering <whether to publish ___ next year>?

(92) *How many points are you wondering <whether to earn ___>?

(93) How many points are the jurors debating <whether to take off ___>?

The good examples involve a contextually established set of books or a specific range of points that figure skating jurors conventionally assign to mistakes in the program. Similar contrasts are easy to construct with other *wh*-phrases, including adjuncts. For instance, although *how*-extraction out of a *wh*-island or a negative island is by default bad, it becomes rather acceptable given a contextually specified checklist of ways to solve the problem:

(94) How are you wondering <whether to solve the problem ___>?
(OK when choosing from salient checklist)

(95) How did <no student solve the problem ___>?
(OK when choosing from salient checklist)

In a similar spirit, Kiss (1993) assumes that specificity in the sense of Enç (1991) is a prerequisite for extraction out of a *wh*-island.

We might say that these proposals define WI-sensitivity in terms that combine syntax with pragmatics. In the name of philological correctness it should be mentioned that Kroch's influential paper apparently had more than one version, and the 'official, unpublished' version gives a different explanation than the one Cinque relies on. According to Kroch, what saves (91) is not that the *how many*-phrase is D-linked but, rather, the fact that the context licenses the existential presupposition that there is a particular amount such that you are wondering whether to publish that amount.

A similar interpretive contrast is pointed out in Obenauer (1992). He characterizes it in terms of specificity and correlates it with a difference in agreement with the past participle. The split construction (*combien . . . de fautes* 'how many . . . errors') never allows agreement and only the non-specific reading is available. In the non-split construction, on the specific reading agreement is optional: *Dis-moi combien de fautes tu as fait/faites* 'Tell me how many (of the typical, expected) errors you made', and on the non-specific reading, which asks about the number of errors, participle agreement is excluded.

5.3 Re-evaluating the role of D-linking (A3)

The pragmatic argument is very powerful: indeed, almost any *wh*-phrase (save for *why*, perhaps) can be made immune to WIs by D-linking. But it has been argued that D-linking is not the discriminating factor. Szabolcsi and Zwarts (1990, 1993) argue that the moral of the salient-checklist examples is different from what Kroch and Cinque draw from them. The checklist in effect turns elements of a non-individuated domain into discrete individuals. D-linking may thus play an important role in transforming a domain but, they claim, it is not D-linking itself but the emergent set of individuals that is decisive. Likewise, the pragmatic approach predicts that *wh-the-hell* can never be extracted out of a weak island, because it is aggressively non-D-linked, in the words of Pesetsky (1987a). Szabolcsi and Zwarts (1993) submit that it is an independent property of *wh-the-hell* that makes it difficult to extract from WIs. For example,

(96) Who the hell saw John?

Unless it is a rhetorical question, (96) is felicitous only if we have unquestionable evidence that someone saw John and merely wish to identify the person. The requirement of unquestionable evidence is often difficult to fulfil in the complex situations described by WI-violations:

(97) ??Who the hell are you wondering <whether to invite ___>?

On the other hand, when such evidence is available, a WI-violation by *wh-the-hell* is acceptable. E.g., seeing someone rifling through a dictionary, we may felicitously ask,

(98) What the hell do you still <not know <how to spell ___>>?

Perhaps the clearest example demonstrating the significance of individuals, in distinction to D-linking, comes from Dobrovie-Sorin (1994c). Clitic doubling in Romanian signals D-linking, and indeed, it enables a *how many*-phrase to extract from a factive island:

(99) Pe cîte femei regreţi <că le ai iubit ___>?
'how many (of the) women are such that you regret having loved them'

On the other hand, *cîte femei* 'how many women' can be extracted even if it is not doubled by *le* and, consequently, is not D-linked. It turns out that the critical factor is whether it is interpreted as quantifying over numbers of women (case (i), which is bad) or over individual women (case (ii), which is OK):

(100) Cîte femei regrei <câ ai iubit ___>?
(i) *'for what number, you regret having loved that number of women'
(ii) 'how many women are such that you regret having loved them'

These data lead to the conclusion that semantics, rather than pragmatics, plays the real role in the characterization of WI-sensitivity. (On the other hand, the WI-sensitivity of certain expressions in anti-pronominal contexts, e.g., place names in (76) remains a mystery.)

5.4 *Individual vs. non-individual, and* how many-*phrases (A4)*

Szabolcsi and Zwarts argue that the individual/non-individual distinction is what sets apart WI-escaping *which/what*-phrases from manners, reasons, amounts, and other WI-sensitive expressions (when the latter are not individuated by contextual brute force). A very similar conclusion is reached by many authors, specifically in connection with the ambiguity of *how many*-phrases. Dobrovie-Sorin proposes to split QR into two Logical Form operations: NPR (the raising of noun phrases with a quantifier feature) and DR (the raising of determiners). The first leaves an individual variable and is immune to WIs. The second leaves a higher order, determiner-type variable and is sensitive to WIs. (NPR may be followed by DR but that does not matter in relation to island escaping.) The distinction is of course highly reminiscent of the contrast between overt *combien* extraction and *combien de N* extraction (Obenauer 1984/1985):

(101) Combien as-tu (*beaucoup) consulté ___ de livres?
how many have-you (*a lot) consulted ___ of books

(102) Combien de livres as-tu (beaucoup) consulté ___?
how many of books have-you (a lot) consulted

The overt extraction of *combien* 'how many' is blocked by WIs, whereas the overt extraction of the full noun phrase (generally) is not; see also Rizzi (2000a) for a similar case of 'splitting' in Italian, involving *wh-d'altro 'wh* else'. The finer point that Dobrovie-Sorin makes is that *combien de livres* is in itself ambiguous between an amount and an individual reading, and the amount reading is absent when *combien de livres* is (grammatically) extracted out of a WI, exactly as was observed in connection with *cîte femei*:

(103) Combien de livres as-tu consulté ___?
ambiguous (DR/NPR)

(104) Combien de livres as-tu beaucoup consulté ___?
not ambiguous (*DR/NPR)

In fact, even overt *combien de N* extraction out of a WI may be ungrammatical when, as the object of a verb of creation, the phrase can only have an amount reading (Szabolcsi and Zwarts 1993). The contrast between this and grammaticality of (102) is taken to show that *combien de livres* is ambiguous:

(105) Combien de cercles as-tu (*beaucoup) dessiné ___?
how many circles have-you (*a lot) drawn

The same interpretive contrast holds for non-*wh* numeral phrases whose amount reading is produced by DR, and whose individual reading is produced by NPR, at Logical Form (Dobrovie-Sorin 1994c):

(106) John read fifty books.
(i) 'John read books. Their number was fifty.'
(ii) 'There are fifty books such that John read them.'

(107) John didn't read fifty books.
(i) *'John didn't read books. Their number was fifty.'
(ii) 'There are fifty books such that John didn't read them.'

Agreement facts in Italian clefts appear to support the claim that the amount/individual distinction has its own independent existence: amount readings, as opposed to individual readings, lack number agreement (F. Beghelli's observation, quoted in Szabolcsi and Zwarts 1993):

(108) È cinque donne che (*non) ho invitato. (amount)
is five women that (*not) have-I invited

(109) Sono cinque donne che (non) ho invitato. (individual)
are five women that (not) have-I invited

It is interesting to note that mass expressions are more irrevocably WI-sensitive than count ones, and abstract ones are more WI-sensitive than concrete ones. Thus, the following have no individual readings.

(110) a. How much milk did(*n't) you spill on your dress?
b. How much pain did(*n't) you suffer?

The pragmatic proposal would make this natural (mass and abstract denotations are difficult to D-link), but once we saw that D-linking is not a panacea magna, the explanation must lie elsewhere. Dobrovie-Sorin (1994c) proposes a thorough analysis of the amount–individual ambiguity of *how many*-phrases in terms of distinguishing the raising of determiners (DR) and the raising of noun phrases with a quantifier feature (NPR). But she does not develop a new theory of WIs; rather, she simply assumes that DR, unlike NPR, is sensitive to WIs. Other authors who identify individuality as the crucial factor are Aoun (1986), Frampton (1990), Rullmann (1993), and Cresti (1995).

An important difference between the approaches of Dobrovie-Sorin and Szabolcsi and Zwarts on the one hand, and Frampton, Rullmann, and Cresti, on the other, is that the former posit an amount–individual ambiguity even in

sentences where *how many N* does not interact with another scopal expression, whereas the latter do not. Cresti addresses the ambiguity manifested in what Longobardi (1987) called scope reconstruction facts:

(111) How many people do you think I should talk to ___?
  (i) 'For what number n: you think it should be the case that there are n-many people that I talk to.'
  (ii) 'For what number n: there are n-many people x such that you think I should talk to x.'

Cresti (and in a very similar proposal, Rullmann 1993) derives the two readings without actual reconstruction. In the derivations below, x is a trace of type e (individuals), and X is a trace of the same type as *N-many people* (intensionalized generalized quantifiers). Working bottom-up, each trace is bound by a lambda-operator to allow the next trace or the moved phrase itself to enter the chain. The lowest, argument, position of the chain is always occupied by a trace x of the individual type, but intermediate traces may make one switch to the higher type X. The scope difference with respect to *should* is due to the fact that in (i), the switch from x to X takes place within the scope of *should*, whereas in (ii), *should* has a trace x of the individual type within its scope.

(112) (i) Narrow scope (amount):
  $[_{CP}$ how many people $\lambda X[_{IP} \ldots$ think $[_{CP}$ X $\lambda X[_{IP} \ldots$ should $[_{VP}$ X $\lambda x[_{VP} \ldots x \ldots]]]]]$
  (ii) Wide scope (individual):
  $[_{CP}$ how many people $\lambda X[_{IP}$ X $\lambda x[_{IP} \ldots$ think $[_{CP}$ x $\lambda x[_{IP} \ldots$ should $[_{VP} \ldots x \ldots]]]]]$

If *wonder whether* replaces *think that*, in derivation (i) it inescapably has a higher type trace X in its scope; in derivation (ii), it can have a trace x of the individual type in its scope. Cresti stipulates that when CP constitutes a *wh*-island, the trace adjoined to CP must be of the individual type. This rules the *wonder*-version of (112i) out.

(113) (i) *Narrow scope (amount):
  $[_{CP}$ how many people $\lambda X[_{IP} \ldots$ wonder $[_{CP}$ X $\lambda X[_{IP} \ldots$ should $[_{VP}$ X $\lambda x[_{VP} \ldots x \ldots]]]]]$
  (ii) Wide scope (individual):
  $[_{CP}$ how many people $\lambda X[_{IP}$ X $\lambda x[_{IP} \ldots$ wonder $[_{CP}$ x $\lambda x[_{IP} \ldots$ should $[_{VP} \ldots x \ldots]]]]]$

Cresti (1995) proposes a novel analysis of scope-reconstruction facts related to *how many*-phrases and extends it to a new domain: functional readings. But she does not develop a new theory of WIs: she simply stipulates that only a variable of type e may be adjoined to a CP that constitutes a *wh*-island. The question as

to why this is so and how this proposal might extend to WIs other than *wh*-islands is not addressed by Cresti.

5.5 Functional readings and event-related readings (A5)

Cresti (1995) adds a set of novel data to the inventory of WI-sensitive expressions: *wh*-phrases on the functional reading, which obtains in a quantificational context, illustrated in (114i).

(114) Which book did no student read?
  (i) 'Which f, f a function from people to books, no student x read f(x)?'
  Answer: No student$_i$ read her$_i$ mother's book.
  (ii) 'Which y, y a book, no student read y?'
  Answer: No student read *War and Peace*.

When the *wh*-phrase contains a reflexive, only the functional reading is possible:

(115) Which book about herself did no politician read?
  (i) Answer: No politician$_i$ read the book her$_i$ aide wrote.
  (ii) Answer: *No politician read this book.

The functional reading (116i) is sensitive to *wh*-islands, whereas the non-functional reading of the same *wh*-phrase (116ii) is not:

(116) I know which book you wonder whether no/any student read.
  (i) *I know that you wonder whether no/any student$_i$ read her$_i$ mother's book.
  (ii) I know that you wonder whether no/any student read *War and Peace*.

This would be impossible to explain on the earlier, syntactic or pragmatic, theories. Cresti argues that on the functional reading, the trace of *which book* (*about herself*) must be of a higher order, functional type, as opposed to the individual type. Functional readings neatly fall under the individual vs. higher order generalization.

Another set of new data that might be accounted for along these lines involves event-related readings (Krifka 1990). Notice that on reading (117ii), each ship counts as many as the number of times it passes through the lock:

(117) Four thousand ships passed through the lock last year.
  (i) Object-related: 'there are 4,000 distinct ships that passed through the lock'.
  (ii) Event-related: 'there were 4,000 lock traversals by ships'.

Doetjes and Honcoop (1997) observe that the event-related reading is sensitive to WIs, negative islands among them:

(118) How many ships <___ didn't pass through the lock>?
(i) Object-related: okay.
(ii) Event-related: ungrammatical.

The authors analyze event-related readings as quantification over <event, object> pairs. The WI-sensitivity of such pairs might be explained with reference to the fact that they are not of type e – although Doetjes and Honcoop themselves offer a different explanation, namely, one in terms of an algebraic notion of individuals.

5.6 Individuals: is it being of type e that matters? (A6)

The contrasts above can indeed be accounted for by defining the critical property in terms of logical type: type e (the type of individuals) versus higher types (the types of determiners, generalized quantifiers, functions from sets to sets, event-object pairs, etc.). The following data, however, are not easily amenable to this account.

Szabolcsi and Zwarts (1993) observe that arguments and adjuncts of non-iterable ('one-time-only') predicates must denote collectives. The absence of the distributive interpretation is indicated by the unacceptability of distributing the preposition or *did* over the members of the conjunction:

(119) Which relatives did you hear this rumor from?
From my aunt and from my uncle.

(120) Which relatives did you get this present from?
From my aunt and (*from) my uncle.

(121) Which soldiers visited this house?
Jones and Smith did./Jones did and Smith did.

(122) Which soldiers destroyed this house?
Jones and Smith did./*Jones did and Smith did.

Surprisingly, these collectives are sensitive to weak islands. Example (124), which involves extraction from a factive island, is acceptable only if we are willing to give up the natural 'one-time-only' interpretation of the predicate and assume that the same present (token) was given to you several times by different relatives. Likewise, (126) is acceptable only if we assume that the same house can be destroyed more than once:

(123) Which relative(s) do you <regret that you heard this rumor from ___>?

(124) ??Which relative(s) do you <regret that you got this present from ___>?

(125) Which soldier(s) <didn't visit this house ___>?

(126) ??Which soldier(s) <didn't destroy this house ___>?

These contrasts are problematic for all the accounts reviewed above. *Which N(s)* in the non-iterative context is clearly an argument, not an adjunct. It is an event-participant. It is in all probability D-linked. Finally, it ranges over things of the same logical type as it does in the iterative context.

There are two standard approaches to collectives. According to Link (1983), collectives are plural individuals. They are entities of the same type e as singular individuals, but they have an internal part-whole structure. According to Scha (1981), collectives are sets of individuals (type <e,t>) – but singular individuals like John are also treated as sets, namely, singletons. In other words, logical type does not discriminate between WI-sensitive and WI-immune *which N(s)*. Either both are type e or both are type <e,t> (or fancier reincarnations thereof). Thus, a different definition of the pertinent notion of individualhood is needed; one that singles out almost, but not exactly, the same things as the type theoretic one. This need is underscored by the fact that the relevance of being type e is merely stipulated, but not explained, in Cresti's work. An alternative proposal in terms of algebraic structure is made by Szabolcsi and Zwarts (1993) (see section 7.5.1).

5.7 Split constructions (A7)

Obenauer (1984/1985) demonstrated that one kind of split construction, *combien*-extraction, is sensitive to WIs. The same holds for Dutch *wat voor-* and *wat aan*-split and their German counterparts, in the judgment of Beermann (1997), Corver (1990), and Honcoop (1998). (M. den Dikken (p.c.) informs me that minor additions may improve the examples, e.g., *wat . . . voor een soort boek*.)

(127) Wat voor een boek heeft Jan gelezen ___?
what for a book has John read

(128) Wat heeft Jan ___ voor een boek gelezen?
what has John for a book read

(129) ??Wat voor een boek vroeg jij je af <of je ___ moest lezen>?
'What kind of book did you wonder whether you should read?'

(130) *Wat vroeg jij je af <of je ___ voor en boek moest lezen>?
'What kind of book did you wonder whether you should read?'

(131) a. Wat heb jij ___ aan boeken gelezen?
what have you on books read
b. Alles wat jij ___ aan boeken hebt gelezen past op één klein plankje.
everything what you on books have read fits on one small shelf

(132) *Wat vroeg jij je af <of Jan ___ aan boeken heeft gelezen>?
what wondered you if John on books has read
'What books did you wonder whether John has read?'

Because *combien*-extraction inescapably yields an amount as opposed to an individual interpretation, this datum falls under the proposed generalizations earlier. The same may hold of the WI-sensitivity of *wat voor*-split, on the assumption that kinds are not individuals. But *wat aan*-phrases have an individual reading. Thus, *wat aan*-split suggests that split constructions are WI-sensitive, over and beyond whether they range over individuals or not. See also chapter 66.

5.8 Negative polarity (NPI) licensing (A8)

It has been known since Linebarger (1987) that the licensing relation between negative polarity items and their triggers is blocked by a variety of interveners. Honcoop (1998) argues that it is blocked by the same interveners that create WIs.

(133) John didn't give the beggar a red cent.
trigger: *not*; NPI: *a red cent*

(134) *Mary didn't ask <whether John gave the beggar a red cent>.

(135) *Mary didn't regret <that John gave the beggar a red cent>.

The *wh*-island and factive island tests give the desired result but, as Honcoop points out, the results may be irrelevant. To make sure that the NPI is not licensed by the intervener itself, a 'sensitive' NPI like *a red cent* needs to be used; but *a red cent* may require a clause-mate trigger, and these contexts block Neg-raising (Neg-lowering) as well. Thus, the conclusive demonstration of the WI-sensitivity of NPIs comes from a less-known set of WIs: scope islands. Scope islands will be detailed in (B6).

(136) *John didn't give <every beggar a red cent>.

(137) *John didn't give <at most three beggars a red cent>.

(138) *John didn't give <exactly three beggars a red cent>.

Honcoop's proposal that the blocking of NPI-licensing is a WI-phenomenon is very interesting for two reasons. One, this is the very first systematic explanation of the NPI-blocking facts. Two, the WI data base is now extended in a substantial and exciting manner. (P. Postal (p.c.) points out to me that Ross (1986, originally a 1967 dissertation) characterized NPIs as island-sensitive.)

5.9 Cross-sentential anaphora (A9)

Honcoop (1998) also observes an uncanny similarity between the expressions that create WIs and those that block cross-sentential anaphora when they take scope over the indefinite, e.g.:

(139) I saw a man$_i$ in the park. He$_i$ was tall.

(140) *I didn't see a man$_i$ in the park. He$_i$ was tall.

The pertinent data will be surveyed in section 7.5.2. We might list them here, along with the data in (A8), as new WI facts, but because Honcoop's proposal is to reduce the explanation of WI effects to that of the anaphora facts, it is expedient to discuss them along with his theory.

5.10 Elements of anti-pronominal contexts (A10)

The anti-pronominal contexts discussed in Postal (1993, 1994, 1997a, 1998), reviewed in section 3.4.3, in effect involve a set of WI-sensitive expressions. Some of these expressions clearly do not have individual reference. If this is correct, then their WI-sensitivity can be accounted for along the lines reviewed above, and if pronouns need to refer to individuals in the sense outlined above, the pronominal correlation might be predicted. To what extent one can make good on these suggestions remains to be investigated.

6 What contexts constitute weak islands? (B)

As was mentioned earlier, *wh*-islands are the classical WIs. Relativized Minimality revolutionized the study of WIs by bringing a host of further WIs within the scope of the theory. These include negative and factive islands, affective (downward entailing) operators, extraposition islands, etc. But this was only the beginning.

It is important to ask whether WI-sensitive extractions and WI-inducers are uniform in the sense that if a particular extraction is blocked by some weak island, it is blocked by all weak islands. The answer is generally assumed to be yes, as long as the relevant constructions can be checked at all. Therefore, in demonstrating what contexts constitute WIs, I will not check the effect against the full range of WI-sensitive extractions reviewed above. I will always pick one case that seems convincing enough. I assume that the choice is by and large arbitrary.

6.1 Wh-*islands (B1)*

As was mentioned in section 3.1, infinitival, modal, or subjunctive, *whether*-complements are the weakest islands, as illustrated by English below. Tensed constituent *wh*-questions are often strong islands. The cross-linguistic and cross-dialectal variation is poorly understood.

(141) a. Which man are you wondering <whether to invite ___>?
b. *How are you wondering <whether to behave ___>?

6.2 Negatives and other affective operators (B2)

That negatives block extraction was observed as early as in Williams (1974), together with the fact that only unstressed negatives do (the latter remains unaccounted for in the literature):

(142) *I asked how John <didn't behave ___>.

(143) I asked how John did NOT behave ___.

The island-inducing effect of negatives was analyzed systematically in Ross (1984), who called them Inner Islands:

(144) What did <no imitation pearls touch ___>?

(145) *What did <no imitation pearls cost ___>?

Rizzi (1990b) observes that the generalization extends to all items that are affective operators (i.e., NPI triggers) in the sense of Klima (1964).

(146) *How did <few men think that you behaved ___>?

(147) *How did <only John think that you behaved ___>?

(148) *How did <you deny that you behaved ___>?

In terms of Ladusaw (1980), affective operators are downward entailing (on the whole, or have such a component, as is the case with *only*). Compare:

(149) No one/Few men/Only John had ever been here.

(150) I deny that you have ever been here.

How does double negation behave in this context? Does it cancel out? Szabolcsi and Zwarts (1993) observe that in at least one case it does, but generally not. (The island-sensitivity of *as*-extraction comes from Rizzi 1990b.) See also Kuno and Takami (1997):

(151) John is our hero, as no one denies ___.

(152) *How did <no one deny that you behaved ___>?

Rullmann (1994, 1995) proposes a semantic explanation of the blocking effect of downward entailing operators. Because this theory is not intended to extend to other WIs (Rullmann regards those a matter of syntax), it is reviewed here, rather than in the theory section.

The proposal is essentially a generalization of Rullmann's account of maximality and intervention effects in comparatives. To see that comparatives give rise to maximality effects, consider (153), which means that John swam faster than the maximal speed at which Bill can run.

(153) a. John swam faster than Bill could run.
b. John swam faster than MAX({d: Bill could run d-fast})

where MAX is defined as the least upper bound of the set it operates on (i.e., MAX({1,2,3,4,5}) = 5, etc.). This account of the semantics of comparatives almost immediately explains the following contrast:

(154) a. John weighs more than Bill weighs.
b. John weighs more than everybody else weighs.
c. John weighs more than most people weigh.
d. John weighs more than many people weigh.
e. John weighs more than at least five people weigh.
f. John weighs more than Bill always/often weighs.

(155) a. *John weighs more than Bill doesn't weigh.
b. *John weighs more than nobody weighs.
c. *John weighs more than few people weigh.
d. *John weighs more than fewer than five people weigh.
e. *John weighs more than at most five people weigh.
f. *John weighs more than Bill never/seldom weighs.

The account essentially runs as follows. In both (156a) and (157a) the sets of degrees are finite and contain a maximum. However, their complements in (156b) and (157b) are infinite, and therefore do not contain a maximum. The set denoted by (157b), for example, contains all the degrees of weight d such that nobody weighs (exactly or at least) d-much. This set obviously does not have a maximum member.

(156) a. {d: at least five people weigh d-much}
b. {d: fewer than five people weigh d-much}

(157) a. {d: somebody weighs d-much}
b. {d: nobody weighs d-much}

Rullmann then argues that *wh*-questions in general give rise to maximality/exhaustivity effects as well. For example, a question that asks us to specify the maximal speed at which John can run is informally represented as follows:

(158) a. How fast can John run?
b. which d [d = MAX({d': John can run d'-fast})]

If so, then the ill-formedness of the following, for example, can be explained along the same lines as the ill-formedness of the examples above.

(159) *How fast can't John run?

What explains then that *wh*-adjuncts such as *how* and *why* are also sensitive to WIs? Consider first the examples in (160), which show that *who*, contrary to *how* and *why*, is not sensitive to WIs. Given maximality/exhaustivity, (160a) asks for the maximal plural individual that attended the party (i.e., the sum of all the people who attended the party). Question (160b) then asks for the sum of all people who were not at the party. To exclude irrelevant individuals such as Aristotle and Yeltsin from consideration, *who* must be D-linked.

(160) a. Who was at the party yesterday?
b. Who was not at the party yesterday?

The fact that *how* and *why* cannot be extracted across negation and quantificational expressions follows from the fact that *how* and *why* cannot be D-linked.

6.3 Response stance and non-stance in contrast to volunteered stance predicates (B3)

That factive contexts are WIs is well known from Cinque (1990). This is just a special case, though, as Hegarty (1992b) points out. The full picture is presented in Cattell (1978). Cattell distinguishes response stance, non-stance, and volunteered stance predicates. Reponse stance includes, alongside *deny*, items like *accept*, *confirm*, *verify*, *admit*, and others. Non-stance includes a big class of factives: *realize*, *know*, *regret*, *remember*, *surprise*, *notice*, etc. Finally, volunteered stance includes *think*, *believe*, *suspect*, *allege*, *assume*, *claim*, etc. Cattell's generalization is that the first two classes generally block adjunct extraction:

(161) *How did you accept that he behaved ___?
also: deny, confirm, verify, admit, . . .

(162) *How did you realize that he behaved ___?
also: know, regret, remember, surprise, notice, . . .

(163) How did you think that he behaved ___?
also: believe, suspect, allege, assume, claim, . . .

6.4 Extraposition islands (B4)

Again, this is one of the cases discussed in Cinque (1990). Whether extraposition islands constitute a separate case is not immediately evident, since they are overwhelmingly also factive islands, e.g.:

(164) *How <is it a scandal that he behaved ___>?

But here is at least one extraposition island quoted by Cinque that is not factive:

(165) *How <is it time to behave ___>?

On the other hand, the following extrapositions involve non-factive, non-negative predicates and do not appear to create islands (P. Postal, p.c.).

(166) How much wine is it possible/legal/fun/dangerous to drink ___ at a party?

This seems to indicate that extraposition per se is not the culprit. It is unclear to me exactly what makes *it is time to . . .* an island. Further relevant examples can be drawn from Heavy NP Shift.

6.5 VP-adverbs (B5)

Obenauer (1984/85) examines the following pattern:

(167) J'ai beaucoup conduit [___ de camions].
I have a lot driven of trucks.
'I drove many trucks.'

Although the phrase *beaucoup de camions* would be grammatical, Obenauer argues in careful detail that VP-initial *beaucoup* is not an extracted determiner but a VP-adverb. The quantified interpretation 'many trucks' is obtained through quantification of V in terms of 'many times'. He calls this phenomenon QAD (quantification at a distance). The presence of the adverb nevertheless blocks *combien*-extraction:

(168) *Combien as-tu <beaucoup consulté [___ de livres]>?

The analysis according to which a VP-initial quantifier renders split constructions ungrammatical without being derivationally related to the empty determiner slot of the DP is corroborated by the fact that iterative adverbs also block *wat voor* split (De Swart 1992):

(169) *Wat heb je <twee keer [___ voor boeken] gelezen>?
what have you two times for books read

It may be interesting to point out that these adverbs block *how*-extraction as well:

(170) *How did you <behave a lot ___>?
*How did you <behave twice ___>?

6.6 Scope islands (B6)

At least one important subset of the islands above, namely, *wh*-islands, negative (affective) islands, and adverbial islands, can easily be described as intervention islands: the WI is induced by the intervention of a certain element between the final locus of the extracted phrase and its extraction site. The intervention of other operators seems harmless, e.g., *every boy* may intervene between *how* and its extraction site, without making the sentence ungrammatical.

(171) How did every boy behave ___?

As we shall see, Rizzi's (1990b) generalization is that bad interveners are A-bar specifiers. Expressions in A-specifier or adjoined position do not matter. Universals are adjoined to some projection by QR, hence they cannot matter. But it turns out that the grammaticality of (171) type extractions is misleading. *Every boy* is an operator that may scope either below or above a *wh*-phrase; it may even be scopally independent from it. Let us illustrate the three possibilities with an example where the *wh*-phrase is immune to WIs:

(172) Which book did every boy read ___?
- (i) every > wh
  'For every boy, which book did he read?'
- (ii) wh > every
  'Which book is such that every boy read it?'
- (iii) independent scope (uniformity presupposition)
  'Taking for granted that every boy read the same book, what was this book?'

Reading (i) is often called a pair-list reading: it is answered by a list of pairs: 'Bill read *Magic Mountain*, Jim read *The Russia House*, . . .'. Readings (ii) and (iii) both ask for a single book that was read by every boy, but differ as to the possibility of what else each boy may have read. For instance, if Bill read *Jurassic Park* and *Tom Jones*, Jim read *Jurassic Park* and *Airframe*, and so on, reading (ii) is felicitous and the answer is '*Jurassic Park*'. Reading (iii) is not felicitous in the same situation: it presupposes that each boy read just one book, moreover, the same one, and merely asks to identify the book. The question is, are these three readings equally possible when *every boy* interacts with a WI-sensitive expression, rather than a *which*-phrase.

De Swart (1992) and Kiss (1993) make the fundamental observation that universals are harmless only when they (i) scope above or (iii) independently of the sensitive *wh*-phrase. When they scope below it (ii), they induce a WI. Kiss states the generalization for non-specific extractees, De Swart for split constructions:

(173) How did every boy behave ___?
- (i) every > *wh*
  'For every boy, how did he behave?'

(ii) *wh* > every
*'What was the common element in the boys' non-uniform behavior?'
(iii) independent
'Taking for granted that every boy behaved the same way, what was it like?'

(174) Combien ont-ils tous lu ___ de livres?
(i) *'For each of them, how many books did he read.'
(ii) *'For what n, they all read n or more books.'
(iii) 'They all read the same number of books; what (which) number was it?'

Because (174) contains a floated quantifier, it lacks an every > *wh* reading (i). It does have an independent reading (iii), especially if there is a contextually salient list of numbers. But crucially, it lacks reading (ii) where the universal would be scoping under *wh*. (I thank D. Sportiche and M. Starke for discussion regarding (174).) In sum, the fundamental observation is that it is not so much the nature of the syntactic position (A-bar specifier vs. other) but the scope of the intervener that matters: an operator that scopes between the WI-sensitive extractee and its extraction site blocks the extraction.

Why does the mere presence of the previously reviewed operators induce a WI? Because, for reasons of their own, they are unable to scope above (or independently of) the extracted phrase. For instance, *no one* or *twice* never induce pair-list questions at all:

(175) a. Which book did no one read?
*'For no one, tell me which book he/she read.'
b. Which book did you read twice?
*'For two occasions, tell me which book you read then.'

Following Kiss's and De Swart's insight, this point is demonstrated systematically in Szabolcsi and Zwarts (1993). Some further descriptive caution is in order, however. Based on a detailed investigation of pair-list readings, Szabolcsi (1997a) shows that the same quantifier may or may not induce a WI, depending on the syntactic context. *Fewer/more than five boys* blocks *how*-extraction in a matrix question and in a complement of *wonder* or *ask*, but not in a complement of *find out*. The presence of *only* in (178) enhances the felicity of this reading.

(176) *How did fewer than five boys behave ___?

(177) *I wonder how fewer than five boys behaved ___.

(178) I only found out how fewer than five boys behaved ___.
'I only found out about fewer than five boys how each behaved'

(179) ??How did more than five boys behave ___?

(180) ??I wonder how more than five boys behaved ___.

(181) I found out how more than five boys behaved ___.
'I found out about more than five boys how each behaved.'

These data correlate with the fact that these quantifiers are only capable of inducing a pair-list reading in *find out*-complements (irrespective of WIs):

(182) Which book did more than five boys read?
*'For more than five boys, tell me which book each read.'

(183) I wonder which book more than five boys read.
*'For more than five boys, tell me which book each read.'

(184) I found out which book more than five boys read.
'I found out about more than five boys which book each read.'

If inducing a pair-list reading can be described as the quantifier scoping above the *wh*-phrase, the WI data fall out. *More/fewer than five boys* can scope above the *wh*-phrase in *find out*-complements, hence it does not induce a WI. It cannot scope above the *wh*-phrase in the matrix or in *wonder*-complements, thus it causes a WI.

In what follows, the designation scope island will be used to refer specifically to the above data, although Szabolcsi and Zwarts (1993) argue that the scope generalization can be extended to most of the other island-inducers as well.

Finally, I note that quantifier intervention data discussed in Beck (1996b) and Kennedy (1997b) are, plausibly, special cases of weak islands, although the authors do not relate them to the weak island phenomenology. One reason may be that they are not aware of the exact range of interveners that create weak islands.

7 Theories

7.1 ECP and Subjacency for (A1)–(B1)

The historical starting point is the assumption, made in Huang (1982a), Lasnik and Saito (1984, 1992), Chomsky (1986a), that the paradigmatic (if not the only) case of weak (selective) islands is *wh*-islands (A1), and the expressions whose extraction is sensitive to WIs are adjuncts, as opposed to arguments (B1).

(185) Which problem are you wondering how to [t' [phrase t]]?

(186) ?Which student did he wonder whether to [t' [consider [t intelligent]]?

(187) How have you [t‴ [decided [t″ to [t′ [phrase the problem t]]]]]?

(188) *How are you [t″ wondering [which problem to t′ [phrase t]]]?
'what is the manner such that you are wondering which problem to phrase in that manner'

In all four examples, the lowest trace t is properly governed by t′, an intermediate trace adjoined to the closest VP. The distinction between arguments and adjuncts is drawn in the following way. An empty category that is in argument position is indelibly marked as to whether it is properly governed at S-structure. Thus in (185–186), t is marked as properly governed. Trace t′ itself is not properly governed when it is separated from its antecedent by a *wh*-island (since government requires 0-subjacency). However, intermediate traces can delete before Logical Form, because they are not needed for interpretation. Thus in (185–186), the only trace that must appear at LF is t, which is legitimate. On the other hand, non-argumental (adjunct) empty categories are marked for proper government as late as at LF, therefore intermediate traces need to be re- tained. In (187), the antecedent government chain <how, t‴, t″, t′, t> is unbroken by any subjacency violation. But in (188), t″ does not govern t′, since they are separated by a *wh*-island. Trace t′ cannot be deleted as t would then not be governed. Thus, on the whole, the extraction of an adjunct out of a *wh*-island inescapably involves an empty category that is not properly governed. As Cinque (1990) puts it, this theory forces adjuncts to move strictly successive cyclically, whereas arguments may, in effect, undergo long movement.

We see that this theory of weak islands is purely syntactic. The extraction of a phrase is sensitive to *wh*-islands simply because it originates in a non-argument position. Likewise, a moved *wh*-phrase creates an island purely with its bulk – by occupying the specifier position of CP and thus preventing the non-argument extraction from proceeding through that position.

7.2 Relativized Minimality for (A2, A3)–(B1, B2, B3%, B4, B5%)

The fact that a fronted *wh*-phrase blocks certain extractions can be attributed to the fact that, by occupying an escape hatch, it gives rise to a subjacency violation. But this explanation does not extend to negation or VP-adverbs, for instance: they do not occupy any escape hatch whatsoever. Relativized Minimality (Rizzi 1990b, Cinque 1990) is a particularly exciting theory because it pulls together a host of new islands and seeks to provide a unified account. Specifically, it seeks to account, besides *wh*-islands (B1), also for negative and affective islands (B2), factive islands, a subset of those discussed in (B3), extraposition islands (B4), and the islands created by VP-adverbs (B5). The expressions that are sensitive to WIs are defined as non-referential, as in (A2), which includes split constructions, as in (A3).

Rizzi (1990b) builds primarily on the theoretical analysis of QAD in Obenauer (1984/1985). Obenauer's insight is that a local relation between an operator and its variable is blocked by the intervention of any third party that may be derivationally totally unrelated to them but is sufficiently similar to the operator. In the same spirit, Relativized Minimality is a representational theory of 'like' intervention. This is the basic intuition as to what expressions create WIs. (For recent versions of Relativized Minimality, see the Minimal Link Condition in Chomsky 1995c and its revision in Manzini 1998.)

The assumption that WI-sensitive operators need to be connected to their variable by a series of local relations, while WI-immune operators may be linked to their variable long-distance is retained and is recast in the following way. Rizzi assumes that there are two (non-exclusive) ways to connect an operator and its variable:

(i) binding;
(ii) a chain of government relations.

Binding is an arbitrarily long-distance relation that requires the identity of referential indices; consequently, only operators that are referential can use it. Non-referential operators need to rely on a government chain. Rizzi makes intervention relevant specifically for government. Consequently, 'like' interveners block the government relation between a non-referential operator and its variable. This is the basic intuition as to what expressions are sensitive to WIs. Rizzi (1990b) defines referential operators as those that bear an event–participant thematic role like Agent, Patient, etc. Cinque (1990) adds the requirement that the operator must also be Discourse-linked. Non-referential *wh*-phrases are those that bear a role like Reason, Manner, Measure, etc. or are not D-linked.

The role of intervention is technically explicated as follows. *Barriers* incorporates a notion of minimality: a governor cannot govern into the domain of another, closer governor. Minimality is defined rigidly: only an intervening head governor counts, and it blocks both head and antecedent government. Rizzi proposes to relativize minimality to the kind of relation that obtains between governor and governee:

(189) **Relativized Minimality:**
X α-governs Y only if there is no Z such that
(i) Z is a typical potential α-governor for Y, and
(ii) Z c-commands Y and does not c-command X.

Rizzi finds it useful to distinguish four kinds of value for α: head government, antecedent government in an A-chain, antecedent government in an A-bar chain, and antecedent government in a head-chain. Since we are concerned with chains headed by a *wh*-phrase in A-bar specifier position, all and only A-bar specifiers are relevant interveners.

Rizzi analyzes *whether*, *who*, *beaucoup*, *not*, *no one*, *only John*, and *deny* as A-bar specifiers, at S-structure or at LF. In contrast, he points out that *everyone* and *two men* acquire their scope by adjunction, according to May (1985), so they are predicted not to block non-referential extraction. Extraposition islands and factive islands (and the other islands noted by Cattell, not mentioned by Rizzi or Cinque) are not covered by these considerations. To account for these, Cinque adds that the clause from which extraction occurs must be a sister of a theta-marking [+V] head.

While the general idea is very insightful, there are some analytical problems with this execution. One is the movement of *deny*, a head, to an A-bar specifier position at LF, and the assumption that the complement of *regret* is not a sister to the verb. These have an alternative solution within Relativized Minimality, however: the adoption of Progovac's (1988) and Melvold's (1991) proposals to place empty operators in the [Spec, CP] of the complements of *deny* and *regret*, which then serve as standard interveners.

More important perhaps is the problem posed by the cross-linguistic variation in the syntax of negation, attributed to the fact that the negative particle may be a head, a specifier, or an adjunct. This would suggest that the island-creating effect of negation varies accordingly, but it does not: we are not aware of any language in which negation does not create a weak island. Rizzi (1992) proposes to solve this problem by assuming an empty A-bar specifier when NEG is a head, and an empty head when NEG is a specifier. This proposal may well be correct, but it makes the original distinction of Relativized Minimality vacuous: how do we tell the effects of a head from a specifier? But there is a more important problem. The class of WI-inducers cannot be identified as intervening A-bar specifiers. This is highlighted by briefly considering another proposal that is closely related to Relativized Minimality. We turn to this proposal in section 7.3.

7.3 *Monotonicity for (A3, A4)–(B1, B2, B3%, B5%)*

Szabolcsi and Zwarts (1990) propose to recast Relativized Minimality in semantic terms. They argue against the pragmatic notion of referentiality in the analysis of WI-sensitivity. They propose that WI-sensitive expressions denote in a partially ordered domain, whereas WI-immune expressions range over discrete individuals (A3, A4).

As regards WI-inducers, the main proposal is that the interveners that create WIs share a semantic property: they are not upward monotonic but downward monotonic or non-monotonic. Specifically, *wh*-expressions (B1), negative and other affective expressions (B2), factive and negative predicates (a subset of those in (B3)), and certain VP-adverbs (a subset of those in (B5)) fit this semantic generalization; in other words, pretty much all the data discussed by Rizzi and Cinque, save for extraposition islands of the *it is time to . . .* type (B4).

The connection between the definitions of WI-sensitive expressions and WI-inducers is this. For a function to be upward monotonic means, precisely, that the partial ordering in the argument is preserved in the function value. In contrast,

a downward monotonic operator reverses, and a non-monotonic operator obliterates, partial ordering.

(190) Let ≤ be a partial ordering (e.g. the subset relation), and let A ≤ B.
If the function f is upward monotonic, then f(A) ≤ f(B).
If the function f is downward monotonic, then f(B) ≤ f(A).
If f is non-monotonic, neither entailment holds.

Extractees that denote in partially ordered domains require, for some reason, the preservation of this ordering, hence their WI sensitivity. On the other hand, discrete individuals cannot possibly be interested in the preservation of partial ordering, hence their immunity to WIs. The claim that it is the individual versus non-individual distinction that characterizes WI-immune vs. WI-sensitive extractees seems like a step in the right direction. But, as Szabolcsi and Zwarts (1993) explain in detail, the characterization of WI-inducers in monotonicity terms is seriously flawed. The main problem is that it seeks to provide a semantic definition of the class of interveners that Relativized Minimality finds relevant, and that is not the right class.

7.4 From Relativized Minimality to a scope theory

7.4.1 A major problem with Relativized Minimality

Recall a crucial background assumption of Relativized Minimality. The theory of LF that it relies on is that of May (1985). According to this theory, structure (usually) does not disambiguate scope. Example (191), for instance, is assigned a single structure in which *how* is higher than *everyone*, but they govern each other, so they can be interpreted in either scope order or even independently. The adoption of this theory for the purposes of Relativized Minimality results in the assumption that it does not matter which reading of the sentence we are considering; all we have to know is that *everyone* is in an adjoined position, so its intervention between *how* and its trace must be harmless. The question (192) is also assigned a single structure, but *no one* occupies an A-bar specifier position in it, whence it must block *how*-extraction.

(191) How did everyone behave?

(192) *How did no one behave?

Szabolcsi and Zwarts (1990) followed Relativized Minimality in this respect. The claim that certain interveners harm extraction because, being A-bar specifiers, they break a government chain was replaced by the claim that they harm because non-upward monotonic paths do not preserve partial order – but the assumption that upward monotonic interveners qua interveners are harmless became part and parcel of the theory.

As seen in section 6.6, results by Kiss (1993) and De Swart (1992) indicate that this assumption is wrong. For instance, sentences like (193) are ungrammatical on the reading where the universal takes narrower scope than the *wh*-phrase.

(193) Combien ont-ils tous lu de livres?
how many have-they all read of books
*'For what number n, they all read n or more books.'

7.4.2 Scopal intervention

Kiss (1993) and De Swart (1992) propose that any operator that scopes between the sensitive expression and its trace blocks the relation. Kiss identifies the class of sensitive expressions as non-specifics in the sense of Enç (1991), including nominals and adverbials. (See also Frampton 1991.) De Swart identifies sensitive expressions as those whose operator part is split off from the restrictive clause:

The Scope Generalization:

(194) Specificity Filter: if Op_i is an operator which has scope over Op_j and binds a variable in the scope of Op_j, then Op_i must be specific. (Kiss)

(195) A quantifier Q_1 can only separate a quantifier Q_2 from its restrictive clause if Q_1 has wide scope over Q_2 (or is scopally independent from Q_2). (De Swart)

These generalizations put the WI phenomenon in an entirely new light. Just as Relativized Minimality was based on the observation that the range of WI-inducers is much wider than Subjacency can account for, the Scope Generalization expresses the observation that both the range and the nature of WI-inducers is different from what Relativized Minimality (in its original form or in its monotonicity reincarnation) can take care of. We come back to the possible theoretical explanation of the generalization in section 7.5.

What is the coverage of these proposals? As regards island-sensitive expressions, Kiss's proposal that non-specific operators are island-sensitive essentially covers the classical data (A3, A4, A7) and event-related readings (A5), but it is not easy to see how functional *wh*-phrases (A5) and collectives (A6) can be said to be generally non-specific, since their determiner may be *which*; also, why the trigger – NPI relation (A8) might fall under the generalization is not obvious. De Swart's generalization is stated with reference to splitting: here the question is what data, beyond the classical ones (A7) might be analyzed as involving splitting. Many pieces of data involving anti-pronominal contexts (A10) fall outside both proposals.

As regards WI-inducers, it is easy to see that, with the obvious exception of purely syntactic WI-inducers like *it is time to* . . . extraposition and some of the constructions discussed by Postal, the known WI-inducers are scope-bearing operators and thus fall under the Kiss/De Swart proposal. The problem may be, rather, that there are expressions that some well-established theory or other

classifies as scope-bearing operators which nevertheless do not induce WIs. Examples are indefinite DPs and intensional verbs like *want*:

(196) How did a boy behave ___?

(197) How do you want me to behave ___?

Clearly, there are two ways out. One is to adopt analyses according to which indefinites and intensional operators are not scopal. Another is to draw some principled demarcation line between scopal expressions, predicting some of them to be innocuous.

7.4.3 Prospects for a revision of Relativized Minimality

We have seen that in order to capture the Scope Generalization, LF ought to disambiguate scope. But according to May (1985) it does not. Although this feature played a major role in diverting attention from some critical data, it is not very difficult to fix. It is not too difficult to imagine a scope theory which produces disambiguated LFs.

A second, more serious, aspect of the problem is that, if the spirit of Relativized Minimality is to be maintained, QR cannot be an adjunction rule. In Rizzi's proposal, movement to an A-bar specifier position is hindered only by an intervening A-bar specifier. QR should move the quantifier into an A-bar specifier position. This in turn requires that quantifiers all have designated landing sites. This requires a much more radical departure from May (1985). A theory that at least partially fulfils this expectation has been proposed recently, namely, by Beghelli and Stowell (1997). According to this theory, quantifier scope is a by-product of feature checking. Definites and specific indefinites check features in positions called RefP and ShareP; distributive universals check features in DistP. But Beghelli and Stowell argue, with equal force, that modified numeral (counting) QPs do not have comparable features and never move beyond their Case position. This accounts for the fact that they only marginally take inverse scope. This is a major stumbling block in the way of a revision of Relativized Minimality, because, as we saw above, *more/fewer than five boys* is as much of a WI-inducer as narrow scope *every boy*. But then it is difficult to see how the positions of, say, universals and modified numerals can be brought under a single heading. Likewise, if one goes beyond quantifiers, it is not obvious how all of Cattell's WI-creating predicates (B.3) can be placed in a position (or can be associated with an operator in a position) that falls under the same generalization. In other words, the Scope Generalization implies a radical widening of the set of WI-inducers, and it is not at all clear how all these might fit a single syntactic recipe.

The syntactic recipe does not necessarily have to make reference to A-bar specifier. But the beauty of Relativized Minimality was that it established a very tight connection between the properties that make extractees WI-sensitive and the properties that make interveners WI-inducers. The revision should recapture this explanatory connection. In fact, it is also not obvious how all WI-sensitive

expressions will fit a single syntactic recipe. Note that, alongside non-individual *wh*-phrases, WI-sensitive expressions include the amount and the event-related readings of numerical QPs, functionally interpreted *which*-phrases, definite dependents of one-time-only predicates, and negative polarity items. A somewhat different version of Relativized Minimality is to be found in Rizzi (2000a).

7.5 The Scope Theory

Kiss's and De Swart's generalizations suggest that the explanation of WI-phenomena should, at least to a great extent, be semantic. They themselves do not propose such explanations: as we saw above, the proposals are presented in terms of filters.

There have been two different lines of research that attempted to explain the Scope Generalization in formal semantic terms. Szabolcsi and Zwarts (1993) can be viewed, to some extent, as an attempt to provide a formal semantic explanation of Kiss's generalization. Honcoop (1998), on the other hand, can be viewed as an attempt to provide an extension and a formal semantic explanation of de Swart's generalization.

Szabolcsi and Zwarts (1993) was reprinted, with the addition of a handful of useful notes, as Szabolcsi and Zwarts (1997). In the discussion below, the latter, slightly expanded, version is assumed.

7.5.1 An algebraic approach to scopal intervention, for (A3, A4, A5, A6, A7%)–(B1, B2, B3, B5, B6)

The main contribution of Szabolcsi and Zwarts (1993, 1997) is an explanation of why certain expressions (the WI-sensitive ones) are unable to scope above certain others (the WI-inducers). They argue that scope assignment can go wrong in a directly semantic way, namely, it may produce a result that is strictly incoherent. They assimilate the ungrammaticality of *How much milk didn't you drink?* to the combination of a numeral with a mass noun, as in *six airs*. In both cases, interpreting the construction requires us to perform an operation, counting, or complement formation on a denotation which does not lend itself to that operation.

The article explicates a denotational semantic limitation on scope interaction using some simple notions of lattice theory. The nature of the argument can be best illustrated by way of an example. Overt *wh*-extraction creates a syntactic configuration with an extraction domain D containing a gap α. Let D contain another scopal element β, which the filler of the gap is supposed to scope over.

(198) [which books$_i$ [$_D$ did [$_\beta$ n't] you read [$_\alpha$ –$_i$]]]

(199) [how much milk$_i$ [$_D$ did [$_\beta$ n't] you drink [$_\alpha$ –$_i$]]]

To calculate the denotation of the whole sentence, the denotation of D needs to be calculated. The question is whether this is possible, in view of what α and β are.

The kind of denotation D has is determined to a large extent by what kind of gap it contains. *You read* [gap *of which books*] denotes a set of individuals, i.e., books. But *you drink* [gap *of how much milk*] arguably does not denote a set of amounts; Szabolcsi and Zwarts argue it denotes an amount. The reason why they find this distinction to be relevant is as follows. The claim is that the narrow-scope element β is interpreted by cashing out its contribution in terms of some operation(s) over the denotation of D minus β. For instance, *n't* in the examples above requires us to take the complement of that denotation. Sets of individuals form Boolean algebras. A Boolean algebra is a structure on whose elements the three well-known set-theoretic operations union, intersection, and complement – are defined. Therefore, if D minus β denotes an element of a Boolean algebra, the complement of this denotation is well-defined and is readily calculated. The segment *n't you read* [gap *of which books*] is coherent and denotes the complement of the set of things you read. Amounts, on the other hand, form structures in which complements, and probably also intersection, are not defined (these are called lattices and join semi-lattices, respectively). Now, interpreting *n't you drink* [gap *of how much milk*] should denote the complement of the amount (of milk) you drank. But the complement of an amount is not defined. The requisite denotation cannot be calculated, the string is incoherent.

How does this work with quantifiers as WI-inducers? Take, for example, universals. In Boolean terms, universal quantification is cashed out as performing intersections. Suppose there are altogether three girls, Kati, Mari, and Juli. In the course of interpreting *Which book did every girl read?* we need to intersect the set of books that Kati read with the set of books that Mari read and the set of books that Juli read. Precisely because *girl* A *read* [*gap of* which books] denotes a set of books, and intersection is defined for sets, the denotation of *every girl read* [gap *of which books*] can be calculated. But what happens when we try to interpret the following? Take (200) and (201):

(200) [how much milk$_i$ [$_D$ did [$_\beta$ every girl] drink [$_\alpha$ –$_i$]]]

(201) [how$_i$ [$_D$ did [$_\beta$ every girl] behave [$_\alpha$ –$_i$]]]

What girl *A* drank and how girl *A* behaved are not a set of amounts or a set of manners: D minus β denotes an amount and a manner, respectively. As noted above, amounts and manners arguably form join semi-lattices on whose elements not only the complement but also intersection is not defined. If so, the denotations of *every girl drink* [gap *of how much milk*] and *every girl behave* [gap *of how*] cannot be calculated. Thus, the essence of the proposal is this. An expression E can scope above an operator O if all the operations necessary to calculate the semantic effect of O can be performed in E's denotation domain. An expression E cannot scope above O and thus cannot escape the weak island induced by O if at least one operation necessary to calculate the semantic effect of O cannot be performed in E's denotation domain. It is further proposed that the relevant operations are the Boolean ones: complement, intersection, and union.

Recall the claim (A3, A4) that expressions that escape WIs are individuals, and those sensitive to WIs are non-individuals. Szabolcsi and Zwarts argue that the relevant notion of individuals is algebraic: individuals are discrete entities that can be collected into sets that form Boolean algebras. Non-individuals, in turn, are expressions that cannot be collected into such sets, either because they are non-referential, like expletives and idiom chunks, or because they denote entities that form operationally poorer structures: lattices (with union and intersection), join semi-lattices (with union), or simply partially ordered sets not closed under any of these operations.

Szabolcsi and Zwarts argue, often on the basis of independent proposals in the literature, that the whole gamut of WI-sensitive expressions that Relativized Minimality brought to light (reasons, manners, amounts, non-referential expressions, (A3, A4)) are non-individuals in this sense. Likewise, the collective arguments of one-time-only predicates discussed in (A6) are non-individuals: according to one standard analysis, collectives form join semi-lattices. Recall that the WI-sensitivity of these expressions was problematic for all other theories: they have referential theta-roles, can be definite and D-linked, and are of type e. Going beyond those data, Doetjes and Honcoop (1997) argue that the <event, object> pairs relevant in event-related readings (A5) form join semi-lattices: events are standardly thought to form such structures (there is no empty event that would turn semi-lattice into a Boolean algebra), and the pairs inherit this structure from the event component. A similar reasoning is applied to functional readings in Honcoop (2000).

Turning to WI-inducers, Szabolcsi and Zwarts argue that the calculation of the semantic effect of all the relevant WI-inducers involves, possibly in combination with union and other non-Boolean operations, the formation of complements and/or intersections. Specifically, the calculation of the semantic effect of *wh*-expressions, response stance and non-stance predicates, universal and numerical quantifiers (whether DPs or adverbs) involves at least intersections, and that of negative and other affective operators involves at least complements. This covers the data of B1, B2, B3, B5, and B6. In other words, it is argued that all these islands are scope islands (this means that the label used for (B6) is in fact too narrow).

On the other hand, plain indefinites like *a man* rely only on union, the operation that even join semi-lattices have, and is thus predicted not to cause trouble although it may well be analyzed as scopal. Intensional operators like *want* and *should* are also scopal, but their contribution is not in Boolean terms so they do not matter either. In other words, because this theory does not take the notion scopal to be an unanalyzed primitive, it is capable of distinguishing between scopal elements that are WI-inducers and ones that are not.

7.5.2 *A Dynamic Semantic approach to scopal intervention (A4, A5, A7, A8, A9)–(B1, B2, B3, B5, B6)*

Honcoop (1998) proposes an alternative account of the Scope Generalization. This account is based on a novel empirical observation. The observation is that

almost the same scopal interveners that create WIs also make an indefinite within their scope inaccessible to non-c-commanded pronominal anaphora. To see what inaccessibility is, compare (202) and (203). In (202), the non-c-commanded pronoun can refer back to the indefinite. In (203), where the indefinite is crucially within the scope of negation, the pronoun cannot refer back to it:

(202) I have a new coat$_i$. It$_i$ is blue.

(203) *I don't have a new coat$_i$. It$_i$ is blue.

Note that modal subordination improves the examples, e.g.,

(204) I don't have a new coat$_i$ yet. But I know that it$_i$ will be blue.

This, however, is an independent phenomenon that should be abstracted away from when constructing the basic data.

Now consider the following sets of examples.

The indefinite is within the scope of a *wh*-phrase, cf. (B1):

(205) *Who has a new coat$_i$? It$_i$ is blue.

(206) *Do you have a new coat$_i$? It$_i$ is blue.

The indefinite is within the scope of negation or some other affective operator, cf. (B2):

(207) *I don't have a new coat$_i$. It$_i$ is blue.

(208) *Nobody has a new coat$_i$. It$_i$ is blue.

(209) *Less than two people have a new coat$_i$. It$_i$ is blue.

(210) *I deny that I have a new coat$_i$. It$_i$ is blue.

(211) Only John has a new coat$_i$. It$_i$ is blue.

The indefinite is within the scope of a VP-adverbs, cf. (B5):

(212) *I twice had a Norwegian boyfriend$_i$. He$_i$ was tall.

The indefinite is within the scope of a quantifier (which does not fall under the above), cf. (B6):

(213) *Every kid has a new coat$_i$. It$_i$ is blue.

(214) *Most kids have a new coat$_i$. It$_i$ is blue.

(215) *More than one kid has a new coat$_i$. It$_i$ is blue.

(216) *Exactly five kids have a new coat$_i$. It$_i$ is blue.

(217) Exactly one kid has a new coat$_i$. It$_i$ is blue.

Only John and *exactly one kid* appear to go against the rule but it can be argued that in these cases, anaphora is based on an inference facilitated by unicity, not on the same mechanism that accounts for (202).

The domain within which there are indeed great differences is that of intensional operators and (non-affective) response-stance, non-stance, and volunteered-stance predicates (B3). Here, operators that do not induce WIs may create an inaccessible domain for anaphora, and vice versa. For example:

(218) *I regret that I have a new coat$_i$. It$_i$ is blue.

(219) I confirmed that he had a new coat$_i$. It$_i$ was blue. (*confirm* induces a WI)

(220) I remember that he had a new coat$_i$. It$_i$ was blue. (*remember* induces a WI)

(221) I know that he had a new coat$_i$. It$_i$ was blue. (*know* induces a WI)

(222) *I believe that he had a new coat$_i$. It$_i$ was blue. (*believe* induces no WI)

(223) *I imagined that he had a new coat$_i$. It$_i$ was blue. (*imagine* induces no WI)

(224) *I want to have a new coat$_i$. It$_i$ is blue. (*want* induces no WI)

Honcoop argues that the striking similarity between the two sets of troublemakers calls for a unified theory. (Naturally, the last set needs an explanation.) Inspired by De Swart (1992), Honcoop takes split constructions to be the paradigmatic WI-sensitive expressions and proposes an analysis for them that relies on particular assumptions of Dynamic Semantics (Groenendijk and Stokhof 1990; Dekker 1993; Chierchia 1995b). In what follows, the basic idea is presented without the formalism.

Just like Discourse Representation Theory (DRT: Kamp 1981a; Kamp and Reyle 1993), Dynamic Semantics seeks to account for the ability of indefinites to antecede non-c-commanded pronouns. But while DRT does so by interpreting indefinites as variables that pronouns may corefer with, Dynamic Semantics maintains that indefinites are existentially quantified noun phrases and bind the pronoun, although in a logically novel (dynamic) fashion. How this works does not concern us here. Relevant to us is the problem posed by pairs like those in (225).

(225) a. Usually, a new coat is expensive.
b. Most new coats are expensive.

The (a) sentence can be interpreted as the (b) sentence, which shows that an indefinite can apparently act as a variable bound by an adverb of quantification. This is not a problem for DRT but it is for Dynamic Semantics. If indefinites are existentially quantified, such binding is possible only if the existential quantifier can be removed. What is needed is an operation that removes the existential quantifier and turns *a new coat* into an expression denoting the property of being a new coat; a property that *usually* can take as its restriction much like *most* does. The operation that performs the trick is called Existential Disclosure (ED). How ED works is important to us. Roughly, it maps (226a) to (226b), the set of x's such that each x is identical to some new coat or other. In turn, (226b) is equivalent to (226c), the set of new coats:

(226) Existential Disclosure (ED):
a. there exists a new coat $\Rightarrow_{ED}$
b. {x: there exists a new coat_i and it_i is identical to x}
c. {x: x is a new coat}

It is crucial in the mapping from (a) to (b) that the proposition *it is identical to x* is added and *a new coat* binds *it*. Clearly, *a new coat* does not c-command *it*. Therefore, this binding and, consequently, the applicability of ED can only be well-formed in contexts that allow cross-sentential anaphora. If the indefinite is inside an inaccessible domain and the pronoun is outside, binding, and ED, are not possible:

(227) *{x: . . . OP [. . . indefinite_i . . .] and it_i is identical to x}

where OP creates an inaccessible domain for anaphora.

Honcoop's insight can now be summarized as follows. The operator in split constructions is related to the indefinite in the same way as an adverb of quantification is related to the indefinite it binds. In other words, *voor een boek* needs to be turned into a property that serves as the restriction of *wat*, to yield the interpretation 'what kind of book':

(228) Usually, *a new coat* is expensive.

(229) Wat denk jij dat Peter *voor een boek* heeft gelezen?
what think you that Peter for a book has read
'What kind of book do you think Peter read?'

But then ED is needed in both cases. Furthermore, in both cases ED is blocked if an expression that creates an inaccessible domain for pronominal anaphora intervenes scopally between the operator and the indefinite.

To summarize, given the reasonable assumption that the operator in split constructions uses the indefinite as its restriction, Dynamic Semantics augmented with Existential Disclosure automatically predicts that interveners that create inaccessible domains make splitting ungrammatical. Therefore, if the differences between the sets of WI-inducers and inaccessible domain inducers can be explained away, the Scope Generalization for classical split constructions falls out. Furthermore, any other construction that can be assimilated to splitting in the relevant respect is predicted to be subject to the same constraint.

Honcoop's work goes beyond De Swart's in two important respects: (i) the fatal effect of scopal intervention between the operator and its restriction is explained, not just stipulated, and (ii) it is argued that the same explanation carries over to various constructions that are not trivially split: at least to partial *wh*-movement, event-related readings, and NPI licensing.

To demonstrate the applicability of his proposal, Honcoop (1998) offers a series of innovative semantic analyses that would be difficult to do justice to here. Only the gist of some analyses is given and the reader is referred to the book for further details. Event-related readings (A5) involve quantification over event–object pairs. But both event arguments and indefinites come with their own existential quantifiers. These need to be removed in order for the pair to be formed. Removal is by ED. NPI licensing (A8) cannot be directly assimilated to splitting: although NPIs themselves may be treated as indefinites, not all licensors can be analyzed as unselectively binding them. However, all NPIs are associated with a scalar implicature. This requires computing entailment relations between alternative propositions, and the formation of these alternatives requires an application of ED.

The discrepancy between the inducers of WIs and inaccessible domains, surveyed in (218–224), is resolved by (i) providing an intensionalized version of ED; (ii) assuming that volunteered stance predicates introduce the meaning of their complement as a 'discourse referent'; and (iii) offering an E-type analysis of the anaphoric pronouns whose antecedent is in a response stance or non-stance context.

Pesetsky (2000) points out a further intriguing connection, arguing that *wh*-in-situ can be linked to a [+wh] complementizer in two distinct ways: by covert movement and by feature movement. He observes that the cases that he classifies as feature movement are vulnerable to intervention effects of the sort described in Beck (1996b). Pesetsky construes feature movement as an instance of an operator getting separated from its restriction, and refers to Honcoop (1998) as a theory that predicts that such a constellation will be sensitive to intervention. Since in Honcoop's theory, split constructions are sensitive to weak islands irrespective of whether they receive non-individual interpretations, if Pesetsky is correct, his book adds a whole new set of data to support this feature of Honcoop's theory.

7.5.3 How do the two scope theories compare?

In the cases where they are applicable at all, both the algebraic approach and the Dynamic Semantic (ED) approach get the weak island effects for free. This is

because they both reduce the effect to independent semantic facts. Providing that the proposals are internally logically correct, the semantic facts they point out will constrain the range of expressible meanings, irrespective of whether their consequences overlap with those of other syntactic or semantic considerations. It is thus possible for both theories to be correct at the same time, and their correctness is also compatible with the correctness of some other, say syntactic, explanation of some of the data.

With this important methodological comment in mind, let us ask how the two theories compare in coverage. There are data that both theories can account for, and there are data that only one or the other can. Let us start with WI-sensitive expressions. The algebraic approach can explain the WI-sensitivity of *how* (and probably, of *why* and other comparable expressions), while there seems to be no reason to assimilate them to split constructions under the ED-approach. There are expressions that denote amounts but are – at least overtly – not split: for instance (105) *Combien de cercles as-tu* (**beaucoup*) *dessiné?* and (110) *How much pain did*(**n't*) *you suffer?* These fall naturally under the algebraic approach, and also under the ED-approach if the latter assumes that they involve covert split into 'for what number n/degree d' and 'n many/d much NP'. The ED-approach is clearly good at accounting for their overtly split counterparts; the algebraic one is burdened with a need to explain why splitting forces an amount reading even on otherwise potentially ambiguous phrases.

Honcoop argues that *wat voor een boek* and *wat . . . voor een boek* have exactly the same readings, but that the non-split version is never WI-sensitive. These data fall only under the ED-theory, and so do the *wat aan*-facts, because this construction has only an individual reading. Of the more exotic data, event-related readings can be equally well accounted for in both approaches (both analyses are due to Honcoop). The WI-sensitivity of collective arguments and adjuncts of one-time-only predicates is predicted only by the algebraic approach. The fact that WI-inducers block NPI-licensing is accounted for by the ED-theory alone.

Turning to WI-inducers, islands caused by a +wh XP can, in principle, be accounted for by both theories but, as Honcoop points out, the tentative analysis in Szabolcsi and Zwarts (1997) does not extend to *whether*-islands. Both proposals account for the fact that response stance and non-stance, but not volunteered stance predicates induce WIs, but Szabolcsi and Zwarts offer only suggestions regarding the analysis. The observation that a set of quantifiers and other operators induce WIs is at the heart of both theories: naturally, both account for it equally well. The more interesting question is a deeper one: why is it that precisely those expressions whose algebraic semantic definition involves intersection and/or complement-formation create inaccessible domains for cross-sentential anaphora? Honcoop addresses this question and proposes, although in a preliminary fashion, that the algebraic properties can be used to explain the relevant Dynamic Semantic properties. If this line of reasoning is correct, the two theories may be viewed, to some extent, as two sides of the same coin.

8 Conclusion

There are two points that I would like to highlight in conclusion. The first point is that *wh*-islands are the classical example of weak islands, and adjuncts are the classical example of expressions that cannot escape from weak islands. The initial account of the facts was purely syntactic. But it has been demonstrated, first by Relativized Minimality and then by the Scope Theory, that huge sets of further data pattern along the same lines, calling for a unified explanation. Although we still do not have a fully unified theory at our disposal, it seems true beyond reasonable doubt that a substantial portion of this large phenomenon is genuinely semantic in nature.

The second point is that there is some syntactic residue: at least some extraposition islands and some of the anti-pronominal context data do not fall under the Scope Theory. Moreover, as was pointed out in section 3, in retrospect it does not seem entirely clear whether the presupposed demarcation line between weak and strong islands is as solid as one might want it to be.

It is to be hoped that further research will resolve the relation between these sets of data. One proposal that attempts to unify weak and strong islands is Starke (2001).

NOTE

I wish to thank Marcel den Dikken and Jenny Doetjes for comments. 10 Conclusion

1 Introduction[1]

Stylistic Fronting is a phenomenon, known mainly from Icelandic, Faroese, and Old Scandinavian, where a category is moved to what looks like the subject position in finite sentences with a subject gap; that is, subject relatives, embedded subject questions, other embedded sentences with the subject extracted, and various types of impersonal sentences. The examples in this chapter are all Icelandic, except where indicated otherwise.[2]

(1) Þetta er versta bók sem **skrifuð** hefur verið. (J)
this is worst book that written has been
'This is the worst book that has ever been written.'

(2) Þeir voru að tala um hvað **hægt** hefði verið. (M)
they were to talk about what possible had been
'They were talking about what had been possible.'

(3) Ef **gengið** er eftir Laugaveginum . . . (RT)
if walked is along the Laugavegur
'If one walks along Laugavegur . . .'

(4) **Fram** hefur komið að **fiskað** hefur verið í leyfisleysi á chílensku
forth has come that fished has been illegally in Chilean
fiskisvæði.
fishing zone
'It has been revealed that illegal fishing has taken place in the Chilean fishing zone.'

In Maling (1980) this movement is called Stylistic Inversion. In more recent work (including the reprinted version of Maling 1980) it is mostly called Stylistic Fronting. I will henceforth use the abbreviation 'SF'. The attribute 'stylistic' is appropriate since the movement is optional in a sense to be detailed below, subject only to stylistic variation. This is most clearly the case in Icelandic; in Faroese SF is obligatory in most cases (see Barnes 1987). It is stylistic in a different sense than for example topicalization or heavy NP shift, since, unlike these operations, SF does not even seem to have any discourse semantic effects. In connection with subject extraction, as in (1) and (2), the alternative to SF is no movement, leaving the subject position (the position immediately preceding the finite verb) empty:

(5) a. Þetta er versta bók sem ___ hefur verið skrifuð.
this is worst book that has been written
b. . . . hvað ___ hefði verið hægt
what had been possible

In impersonal clauses, embedded as well as main, the alternative to SF is insertion of an expletive pronoun (EX = expletive pronoun):

(6) a. Ef **það** er gengið eftir Laugaveginum . . .
if EX is walked along the Laugavegur
b. **Það** hefur komið fram að . . .
EX has come forth that

In the context of generative grammar the key questions are: What kind of movement is SF? Does it fall into any of the established types of movement (A-movement, A-bar movement, head movement), or or is it a distinct, new type of movement? Is it movement in the phonological component? What function does it have, or, in other words, what is the movement trigger? Are there similar movements in other languages?

One of the things that makes SF interesting is that it looks like movement to a vacant subject position, but the categories that are moved are most of the time not at all subjectlike. In fact, in many cases they look like heads, and the movement has, indeed, been analyzed by some as head movement. The categories which may undergo SF include participles, infinitives, predicative adjectives, verb particles, adverbs, the negation, PPs and DPs. That phrases such as PPs and DPs may undergo SF is somewhat controversial, but as will be shown below, they do indeed undergo SF.

In the literature SF has been discussed in relation to V2 and the subject position (Maling 1980/90; Barnes 1987; Rögnvaldsson and Thrainsson 1990), null subjects, verb movement and the role of agreement (Platzack 1987; Falk 1993; Holmberg and Platzack 1995), locality (Jónsson 1991; Richards 1998), optionality (Poole 1996), the syntax-phonology interface (Holmberg 2000; Hrafnbjargarson 2004; Burton-Roberts and Poole forthcoming).

Broadly speaking, SF relates to the complex of problems concerning the 'subject position'. Looking at cases like (1), it might relate to the notorious *that-trace (that-t)* phenomenon: SF has the effect of masking a *that-t* configuration. On the other hand, looking at cases like (3) and (4), where SF alternates with an expletive pronoun, it seems to relate to the EPP, or, especially in the case of (4), the Germanic V2 condition. In many languages, including the Scandinavian languages, the subject position has to be filled, either by a thematic subject or, in the absence of a subject, an expletive pronoun. In Icelandic and some other languages it looks like SF is another way to fill that position.

In the following I will review some important works, each of which discusses the properties of SF in detail, and offers its own analysis of the construction/operation (sections 2–7). In sections 7 and 8, I discuss some alternatives that have not been seriously considered in the literature: that SF is a PF operation; and that SF is remnant XP-movement. Section 9 is a discussion of SF-like phenomena in other languages, and section 10 the conclusions.

2 Maling (1980/90)

This article, the first work discussing SF in a generative framework, was first published in *Islensk Mál* (1980), and later reprinted in Maling and Zaenen (1990).[3] I will discuss what I take to be the four most important findings of Maling (1980/90): the distinction between topicalization and SF, the characterization of the contexts of SF, the so-called accessibility hierarchy, and the partial complementary distribution of SF and the expletive pronoun.

2.1 Topicalization vs. SF

In her paper, Maling "[argues] for a distinction between two kinds of fronting processes, *topicalization* and another kind of movement referred to as *stylistic fronting*" (p. 71). Maling summarizes the differences between topicalization and SF as follows:

(7) **Topicalization:**

- applies to NPs, PPs, etc.,
- emphasis or focus on fronted constituent,
- uncommon in embedded clauses,
- judgments vary on fronting in relatives, questions, etc.,
- unbounded,
- subject gap not required.

Stylistic Fronting:

- applies to past participles, adjectives, some adverbs, particles, etc.,
- emphasis or focus on fronted constituents not necessarily present,
- common in embedded clauses,
- accepted by all speakers,
- clause bounded,
- subject gap required.

Maling's characterization of the dichotomy has by and large been confirmed by later research, except for one property: It appears that NPs and PPs, too, can undergo SF, as there are instances of NP or PP-fronting which exhibit all the other properties listed by Maling as diagnostic of SF, plus some other SF-like properties which are not on the list (but will be discussed below). This is most easily determined with regard to the subject gap condition. Consider first the following set of sentences, illustrating the subject gap condition (for expository reasons the category fronted by SF will be in bold type throughout the paper):

(8) a. hún sem var fyrst til að lýsa stílfærslu
she that was first to investigate Stylistic Fronting
b. hún sem **fyrst** var til að lýsa stilfærslu

(9) a. afleiðslan sem hún var fyrst til að lýsa
the derivation that she was first to investigate
b. *afleiðslan sem hún **fyrst** var . . .
c. *. . . sem **fyrst** hún var . . .
d. *. . . sem **fyrst** var hún . . .

Fronting the predicative adjective is possible in the subject relative (8) but not in the object relative (9), due to the presence of the (overt) subject in the latter. (10) and (11) present another example:

(10) a. Hver heldur þú að hafi stolið hjólinu? (J)
who think you that has stolen the bike
'Who do you think has stolen the bike?'
b. Hver heldur þú að **stolið** hafi hjólinu?

(11) a. Hvaða hjól heldur þú að hann hafi stolið?
which bike think you that he has stolen
'Which bike do you think that he has stolen?'
b. *Hvaða hjóli heldur þú að **stolið** hann hafi?
c. *. . . að hann **stolið** hafi?
d. *. . . að **stolið** hafi hann?

Fronting the participle is possible in the complement clause if the extraction gap is a subject gap, not if it is an object gap.

Now consider (12) and (13):

(12) a. Þeir sem hafa búið í Ósló segja að . . .
those that have lived in Oslo say that
b. Þeir sem **í Ósló** hafa búið segja að . . .

(13) a. Hver heldur þú að verði að taka þessa erfiðu ákvörðun?
who think you that has to take this difficult decision
b. Hver heldur þú að **þessa erfiðu ákvörðun** verði að taka?
who think you that this difficult decision has to take
'Who do you think has to take this difficult decision?'

(12) is a subject relative, where in (12b) the locative verb complement, a PP, has been fronted. (13) is a case of subject extraction from a complement clause, where in (13b) the object has been fronted. Now compare (12) with (14), and (13) with (15):

(14) a. vinnan sem hann hefur haft í Ósló
the job that he has had in Oslo
b. *vinnan sem hann **í Ósló** hefur haft
c. *vinnan sem **í Ósló** hann hefur haft
d. *vinnan sem **í Ósló** hefur hann haft

(15) a. þegar hann hafði tekið þessa erfiðu ákvörðun
when he had taken this difficult decision
b. *þegar hann **þessa erfiðu ákvörðun** hafði tekið
c. *þegar **þessa erfiðu ákvörðun** hann hafði tekið
d. *þegar **þessa erfiðu ákvörðun** hafði hann tekið

The generalization that emerges is: a PP or object DP can be fronted in embedded clauses only if there is a subject gap.[4] Later on we will see other evidence that fronting of PPs and object DPs in subject gap clauses has the properties of SF.

It is important to note that Topicalization and SF do not operate on disjunctive sets of categories. If they did, they could plausibly be two special cases of a more general phenomenon, the differences being explained by the choice of category.

As it is, the sets of categories which Topicalization and SF operate on are partially overlapping: predicative adjectives can undergo topicalization as well as SF. So can many adverbs, and as shown above, so can DPs and PPs.

2.2 The two contexts of SF

Maling (1980/90) showed that SF applies in two types of finite sentences: (i) sentences where the subject has moved out (subject extraction sentences), and (ii) impersonal sentences, which either have no (visible) subject at all (impersonal passives and sentences with a generic subject), or where the subject is realized in postverbal position (existential and presentational sentences and extraposition sentences). Maling only discussed embedded sentences. However, as pointed out by Rögnvaldsson and Thrainsson (1990) among others, SF occurs in impersonal main clauses as well (see section 10 on the stylistic status of the construction).

(16) **Keypt** hafa þessa bók margir stúdentar. (RT)
bought have this book many students

This sentence has the properties of SF, not Topicalization: the moved category is not among the categories which can be topicalized, there is a subject gap, and there is no focus or emphasis on the fronted category.

SF is not found in main clause subject questions:

(17) a. *Hver **lokið** mun hafa verkefninu á morgun?
who finished will have the assignment tomorrow
Intended meaning: 'Who will have finished the assignment tomorrow?'
b. *Hver mun **lokið** hafa verkefninu á morgun?
who will finished have the assignment tomorrow

(17a) may be ruled out as a 'violation of the V2 condition', but why is (17b) ill formed, if main clause questions have a subject gap, as is generally assumed for the Scandinavian languages?[5]

It is also noteworthy that SF is not found in control infinitivals, although they have a subject gap in the sense that there is no visible subject in the structure. This is all the more noteworthy since Icelandic control infinitivals have a word order which is superficially similar to that of finite clauses: the verb seems to move to a position in the I-field, in front of the negation and other sentential adverbs (see Sigurðsson 1989; Rögnvaldsson and Thráinsson 1990; Johnson and Vikner 1994).

(18) a. Ég ætla að hafa lesið þessa bók á morgun.
I intend to have read this book tomorrow
b. *Ég ætla að **lesið** hafa þessa bók á morgun.
c. *Ég ætla **lesið** að hafa þessa bók á morgun.

2.3 The accessibility hierarchy

Only one category per clause can be moved by SF. If there are several candidates for SF in the same clause, they move according to an 'accessibility hierarchy', as first observed by Maling (1980/90). Her formulation of the hierarchy is the following:

(19) *ekki* > predicative adjective > past participle/verbal particle

(20) and (21) illustrate this hierarchy:

(20) a. Það fór að rigna, þegar **búið** var að borða. (M)
EX went to rain when finished was to eat
'It began to rain when we had finished eating.'
b. . . . þegar **ekki** var búið að borða.
when not was finished to eat
c. *. . . þegar **búið** var **ekki** að borða.
when finished was not to eat

In the embedded clause in (20a), an impersonal passive, the participle has been fronted by SF. In the negative counterpart (20b) the negation has been fronted (the finite verb normally precedes the negation in Icelandic finite clauses). (20c) shows that the participle cannot be fronted if the negation is present (the fronted category as well as the blocking negation is in boldface):

(21) a. Þetta er nokkuð sem **hægt** er að gera við. (M)
this is something that possible is to fix PRT
b. . . . sem **ekki** er hægt að gera við.
that not is possible to fix PRT
c. *. . . sem **hægt** er **ekki** að gera við
that possible is not to fix PRT

In the relative clause in (21a), a predicative adjective is fronted by SF. In (21b), the negation is fronted. (21c) shows that the negation blocks fronting of the adjective.

(22) a. fundurinn sem **fram** hefur farið (J)
the meeting that forth has gone
b. fundurinn sem **farið** hefur fram
the meeting that gone has forth
'the meeting that has taken place'
c. fundurinn sem **ekki** hefur farið fram
the meeting that not has gone forth
d. *fundurinn sem **fram** hefur **ekki** farið
e. *fundurinn sem **farið** hefur **ekki** fram

(22a, b) show that either the verb particle or the verb (a participle) may undergo SF. (22c) contains a negation, which has been fronted. (22d, e) show that the negation blocks fronting of the particle as well as the verb.

The formulation of the hierarchy is controversial, however. To begin with, not only the negation, but any sentence adverb (or any adverb which can occur in preverbal position) blocks SF of any lower category (as observed by Jónsson 1991). Consider (23), which is like (21) except that the negation is substituted by the adverb *sennilega* 'probably'. As shown, the adverb undergoes SF (optionally; the usual position for adverbs in Icelandic is following the finite verb):

(23) a. . . . sem **sennilega** er hægt að gera við
that probably is possible to fix PRT
b. *. . . sem **hægt** er **sennilega** að gera við
that possible is probably to fix PRT

Second, the reason why Maling places adjectives higher than participles in the hierarchy is based on pairs such as (24b, c):

(24) a. Þeir voru að tala um hvað hefði verið hægt.
they were to talk about what had been possible
b. . . . hvað **hægt** hefði verið.
what possible had been
c. *. . . hvað **verið** hefði hægt.
what been had possible

The participle of *vera* 'be' does not block movement of the adjective, and does not itself undergo SF. But there is good reason to think that this is something special for *vera*, or more generally, for *vera* 'be' and auxiliary *hafa* 'have' (I will return to these later). Consider, for example, (25):

(25) a. maðurinn sem er talinn ríkur
the man that is considered rich
b. maðurinn sem **talinn** er ríkur
the man that considered is rich
c. *maðurinn sem **ríkur** er talinn
the man that rich is considered

Here the participle can undergo SF, but the predicative adjective (the head of a small clause) cannot. So adjectives are not in general 'higher on the accessibility hierarchy' than participles. As will be discussed in more detail later, the reason why the predicative adjective cannot undergo SF here is the fact that the participle is another candidate for undergoing SF, and being closer to the SF target, blocks SF of the adjective. In (24), the auxiliary *vera* is not a candidate for SF (for some reason), and hence does not block SF of the adjective.

Third, the generalization that the verb particle and the verb are equally accessible to SF is probably a special case of a more general phenomenon: a head and its complement are equally accessible to SF. Consider (26):

(26) a. þeir sem **búið** hafa í Ósló
those that lived have in Oslo
b. . . . **í Ósló** hafa búið
c. þeir sem **hitt** hafa konuna sina í Óslo
those that met have wife their in Oslo
d. *. . . **í Ósló** hafa hitt konuna sina

In (26a, b) the locative is a complement of the verb (selected by the verb), and either the verb or the locative may undergo SF. In (26d, e) the locative is an adverbial, not selected by the verb, and here the locative cannot undergo SF. Consider also (27) (N = nominative, A = accusative):

(27) a. hundurinn sem hefur drepið minkinn
the dog.N that has killed the mink.A
b. hundurinn sem **drepið** hefur minkinn
the dog.N that killed has the mink.A
c. hundurinn sem **minkinn** hefur drepið (M)
the dog.N that the mink.A has killed

The object *minkinn* is a complement of the verb/is selected by the verb. Again either the object or the verb may undergo SF.[6]

In the light of recent work on locality conditions on movement (Relativized Minimality, Shortest Move, the Minimal Link Condition) it seems fairly obvious that the accessibility hierarchy falls under some such general locality condition. This will be discussed in more detail in the next section. Meanwhile, note that the accessibility hierarchy provides another useful criterion to distinguish between SF and Topicalization, since the latter is not sensitive to the presence of an adverb, adjective, or participle, etc. between the launching site and the landing site of the movement.

2.4 SF and the expletive pronoun

As discussed by Maling, there are contexts in Icelandic where the expletive pronoun *það* and SF have complementary distribution, and other contexts where SF is possible but not *það*. In general impersonal sentences, main or embedded, accept *það* or SF, and furthermore must have one or the other:

(28) a. Ef **gengið** er eftir Laugaveginum . . . (RT)
if gone is along Laugavegur
b. Ef **það** er gengið eftir Laugaveginum
if EX is gone along Laugavegur
c. *Ef er gengið eftir Laugaveginum

(29) a. Ég veit að **ekið** er vinstra megin í Ástralíu. (M)
I know that driven is left side in Australia
b. . . . að **það** er ekið vinstra megin í Ástralíu
that EX is driven left side in Australia
c. *. . . að er ekið vinstra megin í Ástralíu.

Sentences where the subject gap is the result of movement generally accept SF or a gap, but not *það*:

(30) a. Hver heldur lögreglan að ___ hafi framið glæpinn? (M)
who think the police that has committed the crime
'Who do the police think committed the crime?'
b. Hver heldur lögreglan að **framið** hafi glæpinn?
c. *Hver heldur lögreglan að **það** hafi framið glæpinn?

Maling suggests that (30c) falls under a general prohibition against extraction from a clause headed by *það*. But as noted by Rögnvaldsson and Thrainsson (1990) and Jónsson (1991), extraction is marginally possible, subject to idiolectal variation, from *það*-headed clauses, as long as the extracted phrase is not the subject, as in (30c).

3 The analysis and function of SF

Maling does not actually present an explicit analysis of either SF or Topicalization, but Platzack (1987) does, based on her observations: SF is movement of a category to Spec,IP, while Topicalization is movement of a category to Spec,CP. Movement of non-subject categories to Spec,IP, normally the place where the nominative-marked subject is found, is possible in Icelandic, but not, for instance, in Swedish, since the nominative case normally assigned to Spec,IP is absorbed by an abstract pronominal element postulated in C in Icelandic but not in Swedish. (In Holmberg and Platzack 1995: ch. 5 the element absorbing the nominative case was redefined as AgrS, the contrast between Icelandic and Swedish being related to richness of agreement morphology – Icelandic, Faroese, and Old Scandinavian have rich agreement morphology compared with the Mainland Scandinavian languages.) This accounts for the subject gap condition, straightforwardly in the sense that if the subject is itself in Spec,IP there is no vacant target position for SF. One or more auxiliary assumptions are necessary, however, to account for subject extraction sentences, where Spec,IP would seem to be occupied by the trace of the nominative subject. Given that Spec,CP, but not Spec,IP, is associated with "emphasis and focus" it also follows that Topicalization but not SF will be different in this respect, and that Topicalization but not SF will be found mainly in main clauses.

As for the 'function' of SF, or (in derivational terms) the trigger of SF, Maling assumes that it is related to the V2 condition: "this kind of fronting can therefore

be viewed as a generalization of V2 to clauses that would otherwise begin with the finite verb" (p. 71). Maling does not discuss the ontological status of the V2 condition, but the idea is presumably that there is a global V2 condition which (in terms of a standard C-I-VP analysis of finite sentences) requires the filling of Spec,CP in case the finite verb happens to be in C, or Spec,IP if the finite verb happens to be in I, a condition which would hold in some languages but not others. Those who do not accept the idea of such a condition may prefer the following: the trigger is whatever it is that requires the Spec,IP position of finite clauses to be filled, where the filler may be the thematic subject, or an expletive pronoun, or a category fronted by SF, all subject to cross-linguistic variation. In other words, the trigger is (some version of) the EPP. This idea is elaborated in Holmberg (2000), and discussed below in section 6.

In either case, the optionality of SF, in those cases where it is optional, presents a complication. Recall the facts: In impersonal clauses SF has complementary distribution with the expletive *það*, but either SF or insertion/merge of an expletive pronoun must apply. In that sense SF is obligatory. In subject extraction clauses, on the other hand, SF alternates with an empty subject position. Assuming that the trace of the extracted subject counts as a filler for the purposes of the EPP, why does SF apply at all? Assuming that the trace does not count as a filler, how come SF is not obligatory?

Rögnvaldsson and Thráinsson (1990) take issue with Platzack's (1987) analysis of SF and Topicalization, and argue instead that both are movement to the same position, namely Spec,IP, construed as an A-bar position, or perhaps a mixed A and A-bar position along the lines of Diesing (1990b) and Rizzi (1991a). They conclude that "[topicalization and SF] are *syntactically* a unified process, even though they are certainly different *functionally* . . ." (p. 28, original emphasis). They do not, however, make any suggestions regarding how the observed differences between Topicalization and SF could be explained in functional terms. They do note another difference, though, between SF and Topicalization: SF in an embedded clause does not block extraction out of that clause, but Topicalization does (see also Jónsson 1991). (31a) exemplifies extraction across a category fronted by SF, and (31b) extraction across a category fronted by Topicalization (D = dative):

(31) a. Þennan mann$_i$ hélt ég [að **farið** hefði verið með t$_i$ á sjúkrahús]. (RT)
this man think I that gone had been to hospital
'This man, I thought had been taken to hospital.'

b. *Maríu$_i$ veit ég [að **þessum hring**$_j$ lofaði Ólafur t$_i$ t$_j$]. (RT)
Maria.D know I that this ring.A promised Olaf.N
'I know that Olaf promised Maria this ring.'

This clearly supports assigning different structures to the embedded clauses, along the lines of Platzack (1987). Topicalization blocks extraction by virtue of occupying or creating an A-bar position, namely Spec,CP, which extraction cannot skip, either because the movement needs Spec,CP as an escape hatch (following

Chomsky 1977b), or because some version of Shortest Move prohibits extraction (A-bar movement) across the A-bar position Spec,CP. SF, being movement to Spec,IP, does not have any such effect.[7] This difference can thus be used as another diagnostic to distinguish between SF and topicalization in critical cases.

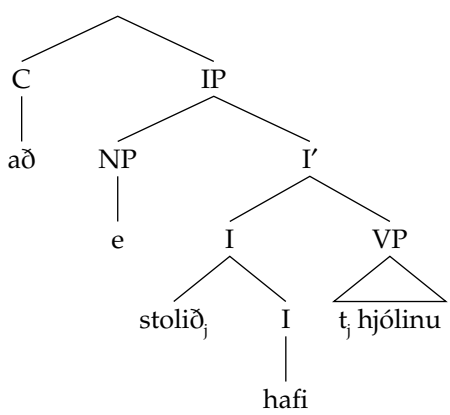
Let us summarize the diagnostic properties identified so far. The following is our revision of Maling's list of properties characteristic of SF:

(32) (i) It requires a subject gap.
(ii) It alternates with the expletive pronoun in impersonal clauses, it is optional in subject extraction clauses (in Icelandic but not in Faroese, to the same degree).
(iii) The categories which can undergo SF include nonfinite verbs, adverbs (including the negation), adjectives, particles, DPs, and PPs.
(iv) No emphasis or focus on the fronted category is necessary.
(v) Found in Icelandic, Faroese, and Old Scandinavian but not Mainland Scandinavian.
(vi) Locality: only the closest candidate for movement to an SF target T may move to T.
(vii) Extraction is possible across an SF target.

4 Jónsson (1991): SF as head movement vs. SF as XP-movement

The most detailed study of SF in Icelandic after Maling (1980/90) is Jónsson (1991), unfortunately published only as a working paper. Jónsson argues that SF is head-to-head movement: the moved participle, adverb, adjective, etc. does not land in Spec,IP but adjoins to I. The same hypothesis is elaborated in Holmberg and Platzack (1995) and Poole (1996). I will refer to it as 'the head movement hypothesis'. According to it the analysis of for example (10a) is roughly (33):

(33) hver . . .



Given that SF of participles, adverbs, adjectives and particles is indeed movement of a head, the analysis according to which the target is Spec,IP (as in Platzack 1987; Rögnvaldsson and Thráinsson 1990; and implicitly Maling 1980/90) obviously violates standard assumptions regarding movement and phrase structure within Principles-and-Parameters theory, according to which XPs move to Spec-positions or adjoin to XPs, while heads adjoin to heads. The head movement hypothesis does not have this problem. The other advantages of the head movement hypothesis discussed in the references mentioned are the following:

(i) The lack of emphasis or focus follows since the moved category is a form of clitic; clitics are generally not focused or emphasized.
(ii) The accessibility hierarchy can be subsumed under (an appropriate version of) the Head Movement Constraint (HMC; Travis 1984, 1991). Consider (34) (= (20c)), for example:

(34) a. *. . . þegar **búið** var **ekki** að borða
when finished was not to eat
b. [$_{IP}$ var+I [$_{NegP}$ Neg [$_{VP}$ búið . . .]]]

Given that the negation is a sentential head, as in (34b), it will block head movement of the participle to I by virtue of the HMC, which requires head movement to target the closest c-commanding head position.
(iii) Extraction is predicted to be possible across an SF target.
(iv) The fact that Mainland Scandinavian, in contrast with Icelandic, Faroese, and Old Scandinavian, does not have SF follows from the fact that Mainland Scandinavian has no general V-movement to I. Therefore there is nothing in I in these languages to which a head moved by SF could adjoin, assuming that adjunction/cliticization to an empty category is not possible. This point is elaborated in Holmberg and Platzack (1995 1f., 115ff.). It is consistent (by and large) with the findings of Falk (1993: 178ff.), who showed that SF disappeared from Swedish in connection with the loss of embedded V-to-I.

However, the head movement hypothesis of SF is obviously inconsistent with the observation that DPs and PPs may undergo SF: XP cannot adjoin to/be incorporated in X°. Jónsson 1991 as well as Holmberg and Platzack (1995) simply follow Maling (1980/90) in assuming that fronting of DPs and PPs falls under Topicalization (or possibly some other type of XP-movement) but not SF. Since the head movement hypothesis has been influential in recent years (see Poole 1996; Richards 1998), let us dispel any doubts that the cases of DP and PP movement discussed earlier have the properties expected of SF. Consider again (12), repeated here as (35):

(35) a. þeir sem hafa búið í Ósló segja að . . .
those that have lived in Oslo say that
b. þeir sem **í** **Ósló** hafa búið segja að . . .
c. þeir sem **búið** hafa í Ósló segja að . . .

According to the head movement hypothesis (c) is SF but (b) is something else. So let us see whether they differ from each other in any relevant respect. I will go through the properties listed in (32) one by one.

(i) *The subject gap condition*: It was shown in section 1 above that fronting of the locative PP requires a subject gap.

(ii) *Optionality*: A comparison of (35a, b) shows that fronting the PP is optional, in the subject extraction context. A comparison of (36a, b, c) shows that it is obligatory, in the relevant sense, in impersonal sentences:

(36) a. Hann spurði hvort **það** sé búandi í Ósló.
he asked whether EX is living in Oslo
'He asked whether one can live in Oslo.'
b. ?. . . hvort **búandi** sé í Ósló.
c. ?. . . hvort **í Ósló** sé búandi.
d. *. . . hvort sé búandi í Ósló.

Merger of *það* may be preferred to SF here, but crucially (36b) and (36c) are equally good, while (36d) is out.

(iii) *Categories*: This is what we are trying to establish.

(iv) *Focus*: (35b, c) or (36b, c) do not necessarily differ in terms of focus or other discourse semantic properties.

(v) *Distribution among the Scandinavian languages*: Constructions such as (35b, c) occur in Faroese and Old Scandinavian, represented here by Old Swedish:

(37) a. Tey sum **verið** hafa í Danmark, siga . . . (Faroese; Barnes 1987)
those that been have in Denmark say . . .
b. Tey sum **í Danmark** hafa verið, siga
c. En [. . .] som **likir** var enom hofman
one that alike was a courtier

On SF of PP's in Old Swedish, see Falk (1993: 181, n. 13). Constructions such as these are ill formed in the Mainland Scandinavian languages, though, represented here by Norwegian:

(38) a. de som har bodd i Oslo
those that have lived in Oslo
b. *de som **bodd** har i Oslo
c. *de som **i Oslo** har bodd

(vi) *Locality*: If the accessibility hierarchy of SF is explained by the HMC, the prediction is that movement of a PP or any other XP should not fall under it. However, fronting of a PP in a subject gap sentence is blocked by, for instance, a negation: the only category which can be fronted in (39) is the negation itself:

(39) a. þeir sem hafa ekki búið í Ósló
those that have not lived in Oslo
b. þeir sem **ekki** hafa búið í Ósló
c. *þeir sem **búið** hafa ekki í Ósló
d. *þeir sem **í** **Ósló** hafa ekki búið
e. tey sum **ikki** hafa verið í Danmark (Faroese; Barnes 1987)
those that not have been in Denmark
f. *tey sum **í** **Danmark** hafa ikki verið (Faroese; Barnes 1987)

This confirms on the one hand that fronting of the PP is indeed SF, and on the other hand that SF is not head-to-head movement. Consequently the accessibility hierarchy does not fall under the HMC, but under some more general locality condition.

(vii) *Extraction*: If PP-fronting in cases like (36c) is SF it is predicted that extraction across a fronted PP should not be any more marked than extraction across a fronted participle. Again the prediction is borne out:

(40) a. Hversu lengi heldur þú að **búið** hafi verið í Ósló?
how long think you that lived has been in Oslo
b. Hversu lengi heldur þú að **í** **Ósló** hafi verið búið?
how long think you that in Oslo has been lived
'How long do you think that people have lived in Oslo?'

(40b) should be compared with, for example, (41), where there is no subject gap, and the fronting accordingly has the properties of Topicalization:

(41) *Hversu lengi heldur þú að **í** **Ósló** hafi hann búið.
how long think you that in Oslo has he lived

We may safely conclude that fronting of the PP in (36b), (40b) and similar examples is a case of SF. Consequently, unless we are willing to accept adjunction of phrases to heads, SF cannot be derived by adjunction to I, at least not universally.

It could still be maintained that SF is sometimes adjunction to I, namely in those cases where the moved category is a head (in spite of the complications that this entails for stating the locality conditions on the movement). However, another serious drawback with the hypothesis that SF is adjunction to I is that within this theory there is no non-ad hoc explanation of the subject gap condition (as discussed in Holmberg 2000). The explanation that is given in Jónsson (1991), Holmberg and Platzack (1995), and Poole (1996) is that the head adjoined to I gets in the way of a crucial relation between I and Spec,IP, either Case (Jónsson and Poole) or agreement (Holmberg and Platzack). Therefore SF is impossible if Spec,IP is filled by a lexical (phonetically realized) DP. The only category which can occupy Spec,IP would be expletive *pro*, which does not need Case and does

not induce agreement. But there is no reason to expect adjunction of a verb, adverb, or adjective, etc. to I to have that effect. Consider a head-adjunction configuration such as (42):

(42) $[[_{H2}\ \alpha\ H1]\ [t]]$

The derived category H2 resulting from adjunction of α to H1 has all of the features of H1 (except possibly those which are checked by α). This is standard X-bar and movement theory. But then there is no reason why, say, a verb, adverb, or adjective adjoined to I would affect the Case-checking or agreement-checking properties of I, since they do not themselves check either Case or agreement. See Holmberg 2000 for additional arguments against the head movement hypothesis.[8]

We may conclude that the head movement hypothesis of SF has serious disadvantages.

5 Auxiliaries and locality

The role of the auxiliaries *vera* and *hafa* in SF was briefly noted above in section 2.3. Discussing Maling's accessibility hierarchy, Jónsson (1991) observed that SF of the copula verb *vera* 'be' is restricted.

(43) a. *Þeir töluði um hvað sem **verið** hefði hægt að gera.
they talked about what that been had possible to do
b. *Þetta er versta bók sem **verið** hefur skrifuð.
this is worst book that been has written
c. ??Þeir sem **verið** höfðu að mála voru orðnir þreyttir.
those that been had to paint were become tired
'Those who had been painting were tired.'
d. *Hetta er brotsmaðurin ið **verið** hefur dømdur.
this is the criminal who been has condemned

(Faroese; Barnes 1987)

This illustrates three uses of *vera* 'be': predicative, passive, and progressive, respectively. None of them undergoes SF. Instead, the next category down the tree may undergo SF, if it is a category of the right sort (which the infinitive *að mála* in (43c) is not).[9]

(44) a. Þeir talaði um hvað sem **hægt** hefði verið að gera.
they talked about what that possible had been to do
b. Þetta er versta bók sem **skrifuð** hefur verið.
this is worst book that written has been

c. Hetta er brotsmaðurin, ið **dømdur** hefur verið
this is the criminal who condemned has been
(Faroese; Barnes 1987)

Holmberg 2000 observed that the same is true of auxiliary *hafa* 'have':

(45) a. Þeir sem munu hafa skrifað verkefnið á morgun
those that will have written the assignment to morrow
b. *Þeir sem **hafa** munu skrifað verkefnið á morgun
c. Þeir sem **skrifað** munu hafa verkefnið á morgun

As shown in (b) the auxiliary cannot itself undergo SF, but allows the participle to be fronted instead.

Jónsson (1991) proposed that the reason why the copula is transparent to SF in this way is indeed that it cannot itself undergo SF. Essentially, in a configuration [X . . . Y . . . Z], where Y c-commands Z but not X, Y will block movement of Z to X only if Y can itself move to X.[10] Jónsson expressed this formally as a modification of Rizzi's (1990b) Relativized Minimality. The same idea is later codified by Chomsky (1995c: ch. 4) as the Minimal Link Condition within a theory where movement is triggered by properties of the target: a functional category C which has a feature F that needs to be checked will always attract the closest category capable of checking F. In that sense the closest category with F will block movement of a more distant category with F to C.

Whether or not all movement is triggered by properties of the target (by *Attract*, in terms of Chomsky 1995c: ch. 4) is an open question. However, in the case of SF there is little doubt that the trigger is some property of the target, not a property of the category that is moved. This is indicated by the fact that SF affects such a wide range of categories which on the face of it have virtually nothing in common apart from being in the 'domain of I' (leaving it open what this means exactly), having phonetic content, and (as indicated by the auxiliary facts discussed above) having semantic content. There is nothing about these properties that, in itself, would trigger movement.

As noted in Holmberg (2000), it is not even clear that the categories moved under SF have any discourse semantic feature in common. As shown by (46) the fronted category may be contrastively focused:

(46) a. . . . sem hafa GERT eitthvað, en ekki bara talað.
that have DONE something and not only talked
b. . . . sem **GERT** hafa eitthvað, en ekki bara talað. (S)

On the other hand, there is some evidence that the fronted category, if it is a DP, cannot be nonspecific. I will return to this question in section 7.

The generalization concerning auxiliaries is complicated by the fact that some occurrences of *vera* can undergo SF. Jónsson (1991) gives (47a, b) as well formed and (c) as marginal. See (37a) for an example from Faroese.

(47) a. Jón var í burtu meðan **verið** var að mála. (J)
Jon was way while been was to paint
b. þeir sem **verið** hafa veikir. (J)
those that been have ill
c. ?Völlurinn er mjög blautur þegar **verið** hefur rigning. (J)
the field is very wet when been has rain

As an additional complication, there seems to be considerable dialectal/idiolectal variation regarding these data.

6 Holmberg (2000): SF as expletive movement

An additional weakness of the head movement hypothesis of SF is that it is unclear what the trigger for SF could be. In Holmberg (2000) I reject the head movement hypothesis of SF, and propose that SF is triggered by a condition that Spec,IP must be overtly filled. This condition, formalized as a feature [P] in I, is taken to be one half of the Extended Projection Principle (EPP), the condition which, in its original form in Chomsky (1981) required every sentence to have a subject. The other half is a condition, formally a feature [D], which requires a nominal category in the checking domain of I. Together the two conditions (i.e., the two features) trigger the movement of a subject NP to Spec,IP in most transitive or unergative active clauses, or insertion of an expletive pronoun in clauses where the subject is, for various reasons, not available as a filler of Spec,IP.

In some languages the feature [D] can be checked by the agreement features on the finite verb (following Alexiadou and Anagnostopoulou 1998). In at least some of these languages this means that the expletive merged to check the feature [P] need not have nominal features. All that is needed to check [P] is an overt category, that is a category with a phonological matrix. This is, then, what SF does: it moves a category with a phonological matrix to Spec,IP to satisfy the 'phonological half' of the EPP. The claim is, therefore, that the category fronted by SF is an expletive in its derived position. This hypothesis is, furthermore, embedded in a theory assuming feature movement, along the lines of Chomsky (1995c: ch. 4). The claim is that just as formal (syntactic) features can move without pied-piping the rest of the category, including the phonological matrix (pp. 261ff.), the phonological matrix can move without pied-piping the formal features. The latter would be the case in SF. In this sense the fronted category is, indeed, a pure expletive, a piece of pure form moved to satisfy the phonological half of the EPP.

Let us see how this accounts for the properties of SF.

(i) *The subject gap condition*: This follows straightforwardly: A subject moved overtly to Spec,IP will check the feature [P], excluding SF. On SF in connection with subject extraction, see below under 2:

(ii) *Optionality*: It follows that SF alternates with the expletive pronoun in impersonal constructions; SF is just another form of expletive. More needs to be said about the optionality of SF in subject extraction contexts, though. The following is a possibility: there are two routes for subject extraction – either the extracted subject moves via Spec,IP, in which case it will check the feature [P] once it reaches Spec,IP, or the subject moves directly from its base-position, say Spec of vP, to Spec,CP, skipping Spec,IP. In the latter case the feature [P] has to be checked by an expletive, provided by SF (why the expletive pronoun will not do in that case is another problem to which I will return briefly, below).

(iii) *Distribution of SF among the Scandinavian languages*: Essentially following Platzack (1987) and Holmberg and Platzack (1995), I assume in Holmberg (2000) that the finite verb in Mainland Scandinavian does not have the nominal features it takes to check the [D]-feature in I. Therefore these languages have to have a nominal, D-marked category moved to or merged in Spec,IP, that is either the subject DP moves to Spec,IP, or a nominal expletive is merged in Spec,IP. SF is never an option (as will be discussed in section 9, this may actually be too strong a statement, though).

(iv) *Categories that undergo SF*: This theory predicts that, in fact, any category which is accessible for movement to Spec,IP at all (that is not, for example, too deeply embedded) can undergo SF, since the movement only affects the phonological matrix of the category anyway. That the range of categories affected by SF is so wide is therefore expected. The problem is, instead, that in fact not quite any category can undergo SF. As mentioned, the auxiliaries *vera* and *hafa* do not undergo SF, nor do infinitival clauses.

(v) *Absence of focus*: Since the fronted category is an expletive, it is predicted not to have any focus or emphasis.

(vi) *Locality*: The prediction is that SF should affect the closest category with a phonological matrix. More exactly, the feature [P] in I will attract the closest category with a phonological matrix. If it is the subject, then the subject moves, if it is the negation, then the negation moves, if it is a participle, then the participle moves, etc. If two categories are equally close to the target, as in the case of a verb and its complement PP or DP, either may move. Hence the fact that, for instance, the negation blocks movement of a participle as well as a PP is accounted for. What need to be explained away are all those cases where the category which undergoes SF to target T is not strictly the closest phonologically realized category to T (cf. the problem of the auxiliaries). For example, it is predicted that a verb and its complement are equally good candidates for SF since they are equally close to the target T. But in fact, without additional assumptions, the theory predicts that neither should undergo SF separately, but instead the VP containing both the verb and its complement should do so, being closer to T than its constituent parts.

(vii) *Extraction*: Since SF is movement of an expletive to Spec,IP it is predicted that it should not affect extraction. The theory does not, however, predict a difference between SF and expletive pronoun insertion with regard to extraction.

As noted by Jónsson 1991, not only does SF not affect the discourse-semantic properties of the sentence, but SF also does not affect the scopal properties of the category moved. For instance SF of the negation has no effect on the scope of the negation. From the point of view of LF, or more generally, semantic interpretation, it is as if SF had not occurred. This is consistent with the idea that the moved category is an expletive, and as such invisible at LF.

Why, however, if the moved category is an expletive, is an expletive pronoun not an alternative to SF in subject extraction sentences? In Holmberg (2000) I note that some languages in fact have an expletive subject pronoun in subject extraction sentences. The following is an example from the Romansh dialect Vallader, provided by Taraldsen (2002):

(48) a. Qual giat crajast **chid** es gnü per prüm?
which cat think-you that is arrived first
b. [CP ch- [IP id es+I VP]]

As Taraldsen shows, the form *chid* is a contracted form of the complementizer *ch(a)* and the expletive pronoun *i(d).*This form is used only when there is a subject gap, that is in subject extraction sentences and impersonal sentences. Taraldsen's analysis of (48a) is shown in (b): the expletive pronoun occupies Spec,IP. This suggests that the absence of the expletive pronoun option in the Icelandic subject extraction sentences is a historical accident, or an effect of some relatively superficial parameter: see Holmberg (2000) for discussion and references.

7 SF as a PF-operation

The fact that SF appears to have no effect on the semantic interpretation of the sentence suggests that SF does not belong to 'narrow syntax' (in Chomsky's 2000 terminology) but to the phonological component, following spell-out.[11]

This hypothesis is rejected in Holmberg (2000), for reasons which I will comment on below. There is a problem, however, pertaining to the theory in Holmberg (2000), concerning SF in connection with subject extraction, which disappears if SF is relegated to the phonological component. Assume, for the sake of argument, that SF is a movement in narrow syntax, prior to spell-out. By standard assumptions the underlying order of the embedded sentence in (10), repeated here as (49a) is (b), prior to SF and *wh*-movement: the agentive *wh*-phrase is merged as a specifier of V (or perhaps more precisely the functional verb *v*, in a multiheaded VP; see Hale and Keyser 1993b; Chomsky 1995c, ch. 4; and others).

(49) a. Hver heldur þú að stolið hafi hjólinu?
who think you that stolen has the bike
b. [IP hafi+I [VP hver [V′ stolið hjólinu]]]

Assuming a derivational theory observing strict cyclicity,[12] at the point when SF applies, the closest visible category to the SF target is the as yet unmoved *wh*-phrase, which therefore should block movement of any lower category, which apparently it does not do in (49a) (but perhaps does do in subject extraction clauses where SF has not applied, for instance (5a, b)).

This problem disappears if SF is considered as an operation of the phonological component, following spell-out. Given that *wh*-movement is an operation in narrow syntax, we do not expect any interaction between *wh*-movement and SF: at the point when the structure is spelled out, there is only the trace of *wh*-movement in Spec,VP, which does not count as a visible category.

This will also solve a related problem pertaining to theories where SF is movement to Spec,IP: by standard assumptions the relativized subject or extracted *wh*-phrase moves through this position (to trigger agreement and be assigned nominative case). But if SF is movement to Spec,IP in narrow syntax, it will erase the trace, which arguably should not be allowed (alternatively it will block *wh*-movement to Spec,IP, depending on which applies first). In the phonological component the trace of *wh*-movement is invisible/not represented, and hence cannot prevent SF to Spec,IP.[13]

Finally, the fact that SF appears to be interested only in whether a category is overt (has a phonological matrix) or not, paying virtually no attention to its syntactic categorial features, is consistent with the hypothesis that it belongs to the phonology rather than narrow syntax. But, as discussed, SF is not totally blind to non-phonological features: in particular, the fact that the auxiliaries *hafa* 'have' and *vera* 'be' do not undergo SF seems to show that SF is sensitive to the presence or absence of semantic features. This is one of the arguments in Holmberg (2000) against locating SF in the phonological component. Another argument is that SF clearly is sensitive to syntactic hierarchic structure, not just to linear order. Consider for example the fact that either of two sister categories may undergo SF, while a (visible) category c-commanding the two sisters will block movement of either of them.

We may conclude that if SF applies in the phonological component, as part of the derivation of PF, then the phonological component must have a subcomponent with operations which are syntactic in the sense that they operate on syntactic categories (words and syntactic phrases), are dependent on syntactic hierarchic structure, and have access maybe not to individual semantic features but to the presence or absence of semantic features. They would differ from the operations of Narrow Syntax in that they have no effect on LF: they affect only form, not content. In this sense (only) they are phonological. Chomsky (2000, 2001b) argues that head movement in general may belong to such a component, as suggested by the fact that it is typically triggered by morphological needs (the need to merge an affix and a head) and does not affect the scope or other semantic properties of the moved head. See also Aoun and Benmamoun (1998), who argue for a distinction between syntactic movement and post-spell-out PF-movement.

As we have seen, in impersonal constructions SF alternates with expletive insertion. Apparently they satisfy the same condition. If SF is phonological, then expletive insertion is too, presumably. If the conclusion is that the trigger of SF and expletive insertion is the EPP, then the EPP is phonological. The consequences of locating SF in the phonological component are thus far-reaching, but certainly worth investigating in greater detail.

The following is an exception to the generalization that SF has no semantic effect: in the following example it looks as though a nonspecific DP does not undergo SF, while the specific counterpart does:

(50) a. hundurinn sem minkinn/*minka drap (M)
the dog.N that the mink/minks.A killed
b. hundurinn sem drap minkinn/minka
the dog.N that killed the mink/minks.A

The example is from Maling (1980/90), where it is classified as a case of Topicalization. However, it has the diagnostic properties of SF: it requires a subject gap (see (51)); it is optional (see (52)); it is not found in Mainland Scandinavian (see (53)); it is local in the manner of SF, being blocked by an adverb (see (54)); and it permits extraction, at least marginally (see 55)):

(51) *hundurinn sem hann minkinn sýndi
the dog.D that he the mink.A showed
Intended reading: 'The dog that he showed the mink to.'

(52) hundurinn sem drap minkinn/minka
the dog that killed the mink/minks

(53) *hunden som minken bet (Swedish; *with the interpretation shown)
the dog that the mink bit
'the dog that bit the mink'

(54) *?hundurinn sem minkinn hefur sennilega drepið
the dog.N that the mink.A has probably killed

(55) ?Hvaða hundur heldur þú að minkinn hefur drepið?
which dog.N think you that the mink.A has killed
'Which dog do you think has killed the mink?'

The specificity effect is not predicted under the expletive movement hypothesis of Holmberg (2000), nor under the hypothesis that SF is part of the phonology.[14] It is compatible with either hypothesis, however, under an analysis where (50) is derived by first applying object shift (see chapter 46), followed by SF. (56) is an example of object shift (see Holmberg and Platzack 1995: ch. 6; Holmberg 2000):

(56) Hundurinn drap minkinn/*minka ekki.
the dog.N killed the mink/minks.A not

Like object shift (scrambling) in Dutch and German, Scandinavian object shift moves only specific DPs, to a high position in the sentential middle field, left of the negation and other sentence adverbs. However, it cannot move an object across a (visible) verb, which is to say that it is found only in sentences where the main verb itself has moved to I or C:

(57) *Hundurinn hefur minkinn ekki drepið.
the dog.N has the mink.A not killed

This obviously complicates the hypothesis that (50) is derived by first applying object shift, followed by SF. Furthermore, since object shift moves the object higher than the negation (or other sentence adverbs), we would not then expect the negation to block SF of the object. The prospects do not look good for the hypothesis that (50) is derived by a combination of object shift and SF, and so this remains a problem for a theory where SF is part of phonology, unless the scope of phonology is widened even more to also include operations like object shift and scrambling.

8 SF as remnant movement

We have shown that SF is not restricted to heads, but moves (some types of) phrases to Spec,IP. According to Holmberg (2000), following Platzack (1987), all SF is movement to Spec,IP, which violates standard assumptions about movement and landing sites in those cases where the moved category is a head. We should therefore seriously consider the possibility that all of the categories moved by SF are, in fact, phrasal, but that some of them consist of nothing but a head.

The categories moved by SF include nonfinite verbs, adverbs, predicative adjectives, prepositions, and verb-particles. The hypothesis that SF moves heads is primarily based on the case of the non-finite verbs, since only in that case does the movement leave behind a complement of the head, as in (58) (= (10b)):

(58) Hver heldur þú að **stolið** hafi hjólinu?
who think you that stolen has the bike

In all the other cases the fronted category may well be a complete maximal phrase, but consisting of just a head. In the case of adverbs this is entirely uncontroversial; adverbs, including the negation adverb, are known to undergo movement to Spec,CP, triggering V2 in Icelandic and the other Scandinavian languages.[15]

(59) Ekki kann ég að tala rússnesku.
not can I to speak Russian
'I certainly can't speak Russian.'

(60) Loksins kom Jón.
finally came Jon
'Finally Jon came.'

In the cases where a preposition has undergone SF it is very likely that we are dealing with PP-movement:[16]

(61) a. maðurinn sem **um** var rætt.
theman that about was talked
'the man that was talked about'
b. *þeir sem **í** hafa búið Ósló
those that in have lived Oslo

According to Sigurðsson (1997), a preposition can undergo SF if and only if the complement of the preposition is itself extracted, as in (61a), unlike (61b). This suggests that the analysis of (61a) is (62):

(62) maðurinn$_i$ sem [$_{IP}$ [$_{PP}$ um t$_i$]j var rætt t$_j$]

The situation for particles is similar. It seems that the particle can undergo SF only if the verb-particle complex is intransitive or passive. Cf. (63a), where the verb-particle complex is passive, (63b) where the sole argument is an extraposed clause, and (63c) where the verb-particle complex is transitive:

(63) a. Verðbólgan varð verri en **við** hafð verið búist. (M)
the inflation was worse than PRT had been expected
b. **Fram** hefur komið [að fiskað hefur verið í leyfisleysi á
forth has come that fished has been illegally in
chílensku fiskisvæði]
the Chilean fishing zone
c. *stelpan sem **út** hefur sloppið kettinum
the girl that out has let the cat

This follows if the particle head cannot undergo SF on its own. What does undergo SF is a Particle Phrase, consisting of just the particle and in some cases the trace of an extracted or extraposed object.

It is not inconceivable that even SF of a participle is derived by first evacuating the VP by movement of the object and other VP-constituents to a position just outside VP, and then moving the remnant VP to Spec,IP, by SF. See Hinterhölzl (1999) and Hróarsdóttir (2000) for theories where remnant XP-movement is used extensively to account for the word order of Germanic languages.[17]

Once it is recognized that SF can move phrases, a crucial and interesting question is: Why is it that SF can move for instance a DP which consists of a string of words and has a fairly complex internal structure, as in (13b), for example, but cannot move a VP or a PartP, unless it consists of a single word (under the remnant movement hypothesis)?

(64) a. *sá sem **skrifað þessa** **bók** hefur
he that written this book has
b. *stelpan sem **út** **kettinum/kettinum** **út** hefur sloppið
the girl that out the.cat/the.cat out has let
c. *kosningarnar sem **farið** **fram** hafa
the elections that gone forth have

9 SF in other languages

Most linguistic research today, certainly within generative grammar, assumes as a guiding principle that languages are more alike than they appear to be on the surface. So an obvious question to ask at this point is, do other languages than a few Scandinavian ones have something corresponding to SF?[18] There is one phenomenon, quite extensively studied in the context of European languages, which resembles SF at least superficially, namely Long Head Movement (LHM). There is another phenomenon or set of phenomena which also resembles SF, but in a different way, namely phenomena related to *that-trace*. I will deal with LHM first.

9.1 LHM

LHM is the name of a construction/operation known from various South and West Slavic languages, Old Spanish, pre-twentieth-century European Portuguese, and Breton, characterized by Borsley et al. (1996) as "a process which moves a verb directly to C over certain intervening heads" (p. 53; all the examples of LHM are from Borsley et al. unless stated otherwise).

(65) a. Napisal som list. Slovak
written have.1SG letter
'I have written a letter.'
b. Lennet en deus Yann al levr. Breton
read 3SGM has Yann the book
'Yann has read the book.'
c. Dar-te he un exemplo. Old Spanish
give you will.1SG an example
'I will give you an example.'

In the literature on LHM, Scandinavian SF is never counted as LHM, due to some obvious differences, mainly the fact that SF applies in embedded clauses, while

LHM is a root phenomenon (Luisa Rivero, p.c.; see also Jónsson 1991). But as noted, SF applies in main clauses, too, and when it does, the resemblance is striking. LHM and SF have at least the following properties in common:

(i) The moved category is generally a one-word expression (hence looks like a head).
(ii) The movement has no effect on the semantic interpretation. LHM and SF both have the character of last resort movement in order to fill a 'first position', unlike Topicalization.
(iii) They are clause bounded.
(iv) They are blocked by a negation.
(v) They are blocked by a fronted XP, for instance a *wh*-phrase or a fronted subject.

Property (iv) is exemplified by (66a, b), and property (v) by (67a, b):

(66) a. Ne sum procel knigata. Bulgarian
Neg have.1SG read the.book
b. *Procel ne sum knigata.

(67) a. Al levr en deus lennet Tom. Breton
the book has read Tom
b. *Al levr lennet en deus Tom.

In the Slavic and Romance languages LHM is associated with 'second position clitics'. The movement can be seen as triggered by the need to find a lexical host for an enclitic moved to sentence-initial position, either C or I – although for instance Borsley et al. do not adopt this view. The explanation why LHM is not found in embedded clauses would then be that the complementizer is a licit host for the clitics, and the reason why the negation blocks LHM is that the negation is also a licit host for the clitic.[19] Breton does not have second position clitics, though, so at least in the case of Breton the trigger cannot be the need to find a host for a clitic. This makes the comparison of Scandinavian SF and Breton LHM particularly interesting. The impression one gets from Schafer (1995) is that LHM of a nonfinite verb in Breton is a last resort operation used when no other category is available as a filler of the highest Spec in root clauses, presumably Spec,CP (although Borsley et al. argue that the movement targets C, not Spec,CP). This seems to hold true of SF in main clauses as well, except that Icelandic and Faroese (but not Old Scandinavian; see Falk 1993; Rögnvaldsson 1996) also have the option of inserting an expletive pronoun. That Breton does not have LHM in embedded clauses is then not surprising, in view of the fact that Breton is strictly verb-initial in embedded clauses. Effectively, Breton does not have a Spec,IP position which embedded LHM could target – assuming that it targets a Spec-position.

This suggests that LHM and SF may after all be varieties of the same movement, with Breton the missing link, as it were, between Slavic-Romance LHM and Scandinavian SF (see Jouitteau 2005 for recent work).

9.2 That-trace *phenomena*

The effect of SF in embedded clauses is to mask or obliterate (depending on the analysis) a *that-t* configuration. If we ignore SF in main clauses, we might indeed regard this as the function of the movement, in some sense.[20]

Languages resort to a variety of means to avoid *that-t*. As already mentioned, there are languages where an expletive pronoun appears in what looks like the position of the subject gap (see (48)). Other languages resort to a resumptive pronoun, for example Northern Norwegian, according to Fiva (1991):

(68) Han Paul trur æ ikke at han har læst denne søknaden.
he Paul think I not that he has read this application
'I don't think that PAUL has read this application.'

And then there are languages where the *that-t* effect disappears if an adverb appears between the complementizer and the verb. In connection with English this is known as the adverb effect (see Culicover 1992; Browning 1996). Consider standard Norwegian, where there is a fairly clear contrast between (69a, b):

(69) a. ?Hvem sa du at ville komme.
who said you that would come
