The second most complicated of the three cuneiform scripts had about 100 different characters (none of them the same as in Old Persian), so it was not surprising when, by comparing what seemed to be the same names in corresponding Persepolitan inscriptions, it too was shown to record syllables—both CV and VC. Its language, which is today called Elamite, is still not well understood. Hincks was one of the scholars who did that work; but more importantly, he went

on to decipher the third, most complicated script, which used several hundred characters. By the time Hincks got involved, in the mid-1840s, numerous cuneiform inscriptions had been brought from the heartland, Mesopotamia, and they too were in the third script, so Hincks had a great deal of material to compare. This time, the second script did constitute a subset of the third script, but the most useful aspect of the inscriptions was their repetitiveness: what seemed to be the same formulas appeared in different texts, or even within one text, but they contained small divergences. (Some of the best examples came from an extensive inscription in what we now call Urartian, which was published in 1840.) A sequence like *A B C D E F G* might substitute for *A B H E F G*, and Hincks saw that this could mean that *C D* stood for C_1V_1–V_1C_2, while *H* stood for $C_1V_1C_2$. He also discovered patterns like *iprus–iparras*, a sure sign that the language was Semitic; we now call it Akkadian (and the words were verbs). He found, rather incredibly, that characters could have more than one pronunciation—and he suggested that this was because the pronunciations found their origin in more than one language, what we now call Sumerian alongside Akkadian. Most importantly, he realized that some of the characters were being used not for the sounds they represented, but to stand for meanings. These characters—which he initially referred to as 'ethnological boulders,' since they were like alien rocks standing in a plowed field—were remnants of Sumerian routinely used in Akkadian texts.

Thus, between 1846 and 1852, Edward Hincks provided the key to the Akkadian, Urartian, and Sumerian languages. One often hears of H.C. Rawlinson in this connection, but he was never afterward able to explain how he deciphered cuneiform; it is now known that, in his post in Baghdad, he was kept informed of Hincks's work and used it in his analysis of the great inscription on a cliff at Behistun, Iran, which he copied with great difficulty—but which became available too late to be useful in the decipherment.

Another celebrated decipherment was accomplished by Michael Ventris in 1952, when he realized that the Linear B tablets from Crete and Mycaenae on the Greek mainland were actually in an archaic form of Greek, not some unknown predecessor language. In this and several other cases, the virtual bilinguals were known place names that seemed to occur in texts found in those places; another is the decipherment of the Maya glyphs.

The Uses of Philology

It is self-evident that without philology to make texts available for study, history could not be written and historical linguistics would be limited to deductions that can be made by comparing attested languages. But philology has applications that are not so obvious: investigating the *use and distribution* of languages themselves reveals patterns in the human career that do not emerge when only the *contents* of historical documents are considered. On at least one occasion a philologist has used his professional skills in creating a fantasy universe; Tom Shippey (2003), besides introducing the work of philology to the committed reader, shows how J.R.R. Tolkien's legion of imitators generally fail for lack of the kind of profound background Tolkien created through his many invented languages—and with example after example reveals that Tolkien's deep learning in Germanic philology, as well as Celtic and Finnic, underlies feature after feature of Middle Earth.

Philosophy of Language

Rather like the scholastic philosophers of the late Middle Ages, twentieth-century philosophers have seen philosophy as linguistic analysis, as the attempt to discern the logical structure of reality through discerning the formal structures—the superficial or deep grammar—of the language in which we report or think reality. Philosophers are particularly interested in certainty, in necessary truths as opposed to mere chance events. Nineteenth-century formalist mathematicians, similarly, honed a sense of mathematics as syntactically grounded in formal language or in a consistent set of linguistic conventions. Since philosophers conceived of their enterprise as a search for helpful logical truths and *not* as dependent on any experiential truths (philosophers do not do experiments), twentieth century philosophy became logicolinguistic analysis, and hence philosophy of language became, in short and for much of the past century, philosophy.

Linguistic philosophy was not just seeing the features of language that revealed the world's categorical structure but also seeing beyond language's perhaps misleading surface features. To give a standard example, the verb *to be* in English plays three vastly different logical roles. *Is* can mean *identity,* as in 2 *is* (*the same as*) 2, *Dubya is* (*the same as*) *President George W. Bush,* or *heat is* (*the same as*) *the average motion of molecular particles. Is,* however, can also mean predication, as in *The sky is (has the property of being) blue, Roses are* (*have the property of being*) *red,* or *The earth is* (*has the property of being*) *spherical.* Finally, *Is* can mean existence, as in *There is* (*exists*) *a Santa Claus* or *God is* (*exists*) as opposed to *God is (exists) not.* Bertrand Russell (1919), while imprisoned as an antiwar demonstrator in World War I, wrote in *Introduction to mathematical philosophy* that it was important to keep these three senses wholly separate in linguistic analysis (so important that Russell added that he would declaim so even if he were 'dead from the waist down and not merely in prison'). In the mathematical logical notation that Gottlob Frege and Russell created in the late nineteenth century, these notions were indeed wholly separate and specifically represented. With a notation that puts predicates in capitals and writes names and variables for individuals in lower case, 'a = b' means two names stand for the same individual, 'Pa' means predicating P of individual a, and '∃x[Dx]' means, if D predicates *divine*, that there exists a God. Russell stressed that this notation commendably dissolved the 'ontological argument for the existence of God', which mostly simply runs, *God is that being who possesses all possible perfections; existence is a perfection; therefore, God exists.* This argument confounds the hypothetical predications 'If something is Divine, then it has various Perfections' and the existential 'Something exists that is Divine'.

Russell was particularly praised for his 'paradigmatic' analysis of 'definite descriptions', phrases of the form *The so and so.* Consider 'The present King of France is bald.' If you think this statement has a subject/predicate logical form, and believe that statements are either true or false, then you seem to have to say that *either* 'The present King of France is bald' is true *or* 'The present King of France is not bald' is true. The problem, of course, is that there is no *present King of France* (when Russell wrote and subsequently). It is no solution to say 'The present King of France' means *nothing,* because then 'The present King of the United States' and 'The round square' and countless other phrases would presumably also mean, or stand for, *nothing;* but it is evident that all such phrases differ in meaning. If a revolution occurred in the United States in 2084, there might then be a King of the United States, but that would not mean there would be a round square and a French King as well (or that *nothing* had changed to *something*). Russell insists that 'The present King of France' does not *mean anything* all by itself. Rather, 'The present King of France is bald' means 'There exists an *x* that bears the predicate of *being kingly of France*, and if any *y* also bears that predicate, *y = x*, and *x* is bald.'

Following Russell's lead, in the 1920s, the logical positivists of the Vienna Circle insisted that logico-mathematical truths provide the formal structure within which the observational truths of experience array themselves. *Theoretical terms,* such as 'vital spirit', 'electron', or 'virus', are only acceptable if they can be specified completely in observational terms. The Vienna Circle philosopher W.V.O. Quine (1960) of Harvard University claims that by casting science into Russell's austere predicate logic, you can most clearly determine what science says has to be real. Indeed, such a translation into predicate logic will strip off the possibly misleading superficial features of actual languages. Philosophical *linguistic analysis,* conceived in this fashion, cares nothing for the *phonology* of language, for literal physical sound streams and their transformation into the sharper, leaner, and deeper

structures that fluent speakers hear. Moreover, the exclusive concern is with the truth or falsity of sentences that describe the world, collectively feeding what scientific generalizations we can muster about the world. As Quine put it, startlingly, *all of science is held up as one sentence to nature*—but that is just to insist that we collectively assert and understand this scientific sentential consensus, not that anyone actually *says* this *one sentence*. Philosophy of language, as so understood, has little concern with *how natural language is used in the acts and interactions of everyday life.* Quine makes this clear when, at the beginning of *Word and Object*, he approvingly cites Otto Neurath's metaphorical remark that we are like seamen who must make repairs in our boat while at sea. Here, 'we' means all scientific-minded humans, and 'the boat' means whatever natural and artificial symbol systems we use in our collective scientific description of the world, with Quine highlighting the austere notation of mathematical logic.

By the mid-twentieth century, however, philosophers began to shift from a concern with the true/false logical relationship between sentences and the world to a more expansive, but also more narrowly linguistic, concern with sentences as speech actions of speakers, who carry individual responsibility *to us* for what they say, indeed for what they *do* in saying *so*. In the 1950s, the Oxford University philosopher J.L. Austin, among others, drew attention to *performatives*, sentences that, when uttered by the appropriate person in the appropriate circumstances, *do something.* If I say, 'I promise to return your $20 tomorrow', I am not describing, truly or falsely, some peculiar mental state; rather, by my speaking, *I make a promise.* If I say, 'By the power vested in me by the State of New Jersey, I appoint you Port Commissioner,' *I make an appointment.* 'I promise X' and 'I appoint Z' are *explicit* performatives, where the main verb of the sentence explicitly indicates what action is performed. However, 'I certainly will return your $20 tomorrow' will, given appropriate circumstances, constitute a promise. Similarly, if an officer says to his subordinate, 'You will move your men to that bridge,' he has given an *order.* Indeed, Austin maintained that every *use of language*, or every speech act, has a performative aspect. For example, if I say 'There's a bittern in your garden,' I should know a little something about bitterns and have had some opportunity to identify the bird. If I have no idea of what bitterns look or sound like, and indeed, have not been in or near your garden, I *have no right to say* what I did. Given that I meet those minimal requirements, I may demur if you ask, 'How do you know it's a bittern?' pleading perhaps 'Well, I don't *know* it's a bittern but it is a large, white-feathered marsh bird', or I may take a further plunge and say, 'Oh, I know it's a bittern—I got a clear view and, growing up in the Fens, I'd know that booming anywhere'. Philosophical concern with semantic, performative, and pragmatic aspects of language has meant some fruitful interaction with linguistic science, particularly given the concern with syntax and logical form stressed by Noam Chomsky and other generative linguists since the 1960s.

But still other philosophers have come to feel that philosophy is well rid of an exclusive emphasis on philosophy as linguistic analysis. In the middle decades of the twentieth century, philosophers concerned with values emphasized metaethics or the 'logic of the language of morals'; more recently, philosophers have addressed specific normative issues. Similarly, many recent philosophers have constructed rational choice, and social contract theories. Thinkers as diverse as the logician Saul Kripke and the linguist Noam Chomsky have argued that necessary truths are more central to science than the real but often trivial analytic truths of language. *Heat is the average motion of molecular particles* is not, Kripke argues, an analytic or lexical truth, but rather a scientifically discovered necessary physical truth. In the same vein, *water is H_2O* asserts a physical necessity, given the basic combinatory properties that form the fabric of atomic physics. Similarly, perhaps, the linguist's claim that natural languages are generative and transformational follows from the structural character of the human linguistic faculty as a matter of biological necessity (it certainly does not follow from a lexical entry attributed to normal speakers, most of whom do not have 'generative and transformational' in their everyday vocabulary—or 'average motion of molecular particles', for that matter). In any case, few philosophers today would be wholly content to characterize philosophy as *linguistic analysis.*

Phoneme

The phoneme [from Greek *phonema*—a sound] is recognized as the smallest abstract sound unit of a language, for example, *map* consists of three phonemes /m/, /æ/, and /p/. Each word in a given language must consist of a permitted sequence of phonemes. Phonemes may be defined as the class of sounds of a language that distinguish words from one another.

The phoneme is a fundamental unit of phonology—the study of the sound systems of languages and the relationships between those sounds. Different languages have various numbers of phonemes; for instance, one Brazilian language—*Piraha*—is said to have only ten phonemes, while one of the African languages—*!Xu*—is known to have 141 phonemes.

The term phoneme was introduced in the late 1870s, and the phoneme theory was first developed by Jan Baudouin de Courtenay and his pupils as a response to the need to systematize the sound patterns of the language. Since then, the phoneme and its features have been defined in various ways by different linguists. As Baudouin understood it, the term originally meant a 'mental image' of a real physical sound, and speech was the act of producing sounds as close to that mental image as possible. However, during the twentieth century, linguists came to a different view. Lev Scerba, who had initially followed Baudouin, shifted to the functional aspect of the phoneme, that is differentiating words. Daniel Jones also described a phoneme as a physical concept. If Nikolai Trubetskoy defined the phoneme as the smallest distinct unit and incapable of further subdivision, Roman Jakobson saw it as the sum of features that distinguish the phonemes from each other.

Contrastive Function

It is traditionally accepted that the phoneme functions as the minimal contrastive unit of speech. In other words, the phoneme differentiates the meaning of words. The native English speaker easily discerns the difference in meaning between the words in minimal pairs, i.e. word pairs that differ in only one sound element: *man* and *pan*, where [m] and [p] differentiate between a human and a kitchen utensil, thus indicating that they possess different phonemes; *bag* and *big*, where [æ] and [I] make possible the distinction between an object and a size; *den* and *then*, where [d] and [ð] clearly indicate that one word means a 'lair' and the other one means 'at that time'; or *man* and *men*, where [æ] and [e] identify one man as opposed to two or more of them.

Phonetic Context

Every uttered word is a particular combination of sounds and is called the phonetic context of a sound. The English phonetician Daniel Jones gives the following definition of the phonetic context:

> …phonetic context of a sound is to be understood to mean the sounds next to it or near it in the sequence of which it is a part, together with its duration (length), stress and (if voiced) voice-pitch.

Minimal pairs provide the same phonetic context with only one different phoneme, as in *bat* and *cat*; where the sounds [b] and [k] occur in the same phonetic context, they differentiate the meaning of the words, and, therefore, are two different phonemes.

Allophones

A phoneme may have several variants or *allophones*. As opposed to phonemes, allophones do not distinguish words, and they never occur in the same phonetic context. For example, *cat* and *king* possess a common sound [k]. However, the sound [k] is pronounced slightly differently: in the first instance, it is articulated—or pronounced—further back in the throat. In the second instance, the tongue—in an attempt to combine the sounds [k] and [i]—moves upward and forward producing a palatalized [k]. These two sounds vary only in the way they are articulated (pronounced); they cannot occur in the same phonetic environment, i.e. the palatalized [k] cannot occur before [æ] as in *cat* for the simple reason that our tongues are physically unable to make these two sounds together. The two sounds vary slightly in articulation; however, the difference is not significant, and may not even be picked up by a native English speaker. Thus, these two variants of /k/ are not distinctive in English; they are not different phonemes, but rather allophones of the same phoneme /k/.

Daniel Jones gives the following examples of the allophones of the English phoneme /t/:

The principal [t] is used before vowels in the strongly stressed position as in *table* or *ten*.

A dental [t] is used before [th] as in eighth.
A retracted [t] is used in [tr] as in train.
An unaspirated or barely aspirated [t] is used in weakly stressed positions as in *letter.*
A laterally exploded [t] is used in [tl] as in *kettle.*
A nasally exploded [t] is used in [tn] as in *mutton.*

For a native language speaker of a given language, it is not really important how carefully allophones are pronounced to understand what is being said. However, it is more important that phonemes are pronounced properly in order for the listener to get the correct message; instead of *My brother bought you a big present*, the speaker must not relay *My brother bought you a pig present*.

Languages differ with respect to which sounds are perceived as distinctive (phonemic) and which sounds are mere variants or allophones of phonemes. English distinguishes between [l] and [r] as in *lay* and *ray*, which make them different English phonemes. Korean does not see any distinction between these two sounds, i.e. they are perceived by Koreans as allophones of one phoneme. Moreover, although English distinguishes between [d] and [ð] as in *than*, Malay does not distinguish them as two phonemes but as allophones of one phoneme. Of course, many languages make other distinctions that an English native speaker may not be able to hear.

Distribution

Each language imposes limitations on the distribution of phonemes, i.e. each particular phoneme can occur only in certain phonetic contexts in that language. In English, there are no words that can start with the nasal [ŋ] sound. There are no such words as *ngull, ngreed, ngoose*. In Chinese or Vietnamese, however, similar sound constellations are quite possible (e.g. names such as *Ng* or *Nguyen*).

The distribution pattern of the phonemes in a language can be identified by analyzing which phonemes may occur in the following positions:

syllable-initial   syllable-medial   syllable-final
word-initial   word-medial   word-final

The English phoneme /p/ can be found in all of the above-mentioned positions, for example:

post   apt   map
packet   upper   ketchup

Other English phonemes can occur only in certain positions, for example, /æ/ as in *rat, stamp, sachet, ant* can only be found in syllable- or word-initial positions and syllable- or word-medial positions.

Phonological Opposition

The phonological opposition, developed by the Prague School, illustrates the network of connections and relations between the phonemes. For example, *proportional* opposition features two or more pairs of phonemes, such as /p/ vs. /b/, /k/ vs. /g/, which are opposed to each other on the basis of voiced features, while /r/ and /l/ are in *isolated* opposition and are opposed to each other on features that do not create a phonemic opposition in English.

Bilateral opposition represents only pairs of phonemes, such as voiced–voiceless pairs /z/ - /s/, where the third element is not possible. *Multilateral* opposition, on the other hand, may have three or more elements, such as /p/, /t/, and /k/, which are all stop consonants, or /f/, /ð/, /θ/, /s/, which are all fricative consonants.

Privative opposition can be illustrated by voiced–voiceless pairs, in which one member of each pair lacks a voiced feature (/d/-/t/, /b/-/p/). *Equipollent* opposition is where voiceless /p/, /t/, /k/ each have a different place of articulation. *Gradual* opposition involves gradation of a feature in the phonemes, for example, in vowels /i/, /e/, /a/, the difference is in aperture, or close–open continuum of tongue height.

In many languages, the phonological opposition can be neutralized. For example, in English, when /s/ occurs in the word-final position, it is pronounced as [s] after a voiceless plosive: *lips, rats, sacks,* and as [z] after the voiced plosive: *dogs, bags, ribs.*

In the Russian language, a voiced consonant can never occur at the end of the word. When the voiced consonant is found at the word-final position, it must be pronounced as voiceless. Neutralization in Russian can be illustrated by the following pair: *pok* spelled as [rok] (type of music), and *poг* spelled as [rog] (a horn); both are pronounced as [rok]. In the latter instance, the voiced [g] sound is neutralized and is pronounced as the voiceless [k].

Major Early Works on the Phoneme: Baudouin de Courtenay, Lev Scerba, Ferdinand de Saussure, Daniel Jones

This section is a brief excursion into the major contributions of world linguists in relation to the notion of the phoneme only, and not phonology, which is beyond the scope of this paper.

The term phoneme was introduced in 1875 to indicate the basic unit of human speech. Although it is said that the term was first used by French linguist Dufriche-Desgenettes in 1873, it was Jan Baudouin de Courtenay and Mikolaj Kruszewsky of the University of Kazan (Russia) who, between 1875 and 1895, conducted an extensive study of sounds, and established the phoneme theory. The Kazan School focused its research on the phoneme as 'the psychological equivalent of the speech sound'. The phoneme, according to Baudouin, was impressed in the speaker's mind. In the speech process, the speaker was aiming at uttering a sound similar to the psychological impression or the mental image; however, the pronunciation was always determined by the real phonetic context.

The work of Baudouin influenced the Russian linguist Lev Scerba (1880–1944), who attended Baudouin's

lectures in St. Petersburg. Scerba accepted the psychological definition of the phoneme, but later concentrated on the functional aspect of the phoneme, i.e. the differentiation of words. Scerba also introduced such phonological notions as complimentary distribution, which is a characteristic of a sound that never occurs in the same phonetic context. This can be illustrated by allophones of a phoneme, all of which occur in different phonetic contexts but are variants of the same phoneme. Since the allophones are different realizations of the same phoneme, it can be said that they are in complementary distribution to each other.

Ferdinand de Saussure (1857–1913), a Swiss linguist, is considered the founder of modern linguistics. His main conception assumed that language is a system of mutually defining entities. He believed that language was a structured system. This view had a major impact on the later development of structuralism in linguistics, which studies the language as a system and not the individual elements of it. Structuralism was further developed in Europe by Trubetskoy and Jakobson, and in America by Sapir and Bloomfield.

Daniel Jones (1881–1967), who was a lecturer of phonetics at University College, London, favored the idea of the phoneme as a practical tool for teaching purposes. His contribution to linguistics was in developing a more practical approach to phonology. He found phonology very useful for acquiring good pronunciation by people learning a foreign language, as a basis of nonphonetic branches of linguistics such as morphology and grammar, and as an important tool for creating alphabets as simply as possible.

The Prague Linguistic Circle, which later came to be known as the Prague School, began its meetings in 1926. It consisted mainly of Russian and Czech linguists. Among them were the Russian linguists Nikolai Trubetskoy and Roman Jakobson. The contribution of Trubetskoy lies in the developing of the notion of phonological opposition, and relations between the members of an opposition. Jakobson's view of the phoneme as a sum of distinctive features led to the creation of a new approach to phonological description. This approach of distinctive features of

the phoneme was based on the structuralist ideas of de Saussure. For example, a sound can be a vowel (a, i, o, e, u) or a consonant (b, d, g, z). If the sound is a consonant, it can be voiced (b, g, d) or voiceless (p, k, t), nasal (m, n) or nonnasal (all others). *Vowel, voiced,* and *nasal* are all examples of distinctive features.

American structuralism was developed by American linguists Edward Sapir and Leonard Bloomfield. Sapir adhered to the idea that a native speaker knows the phonemic system of their language through intuition. For Sapir, the phonemic system was a mental reality that existed independently of the act of speech. Bloomfield saw the phoneme as reality, a bundle of distinctive features, but not as the intuition of a speaker. He believed that phonemic analysis was the process of isolation of its distinctive features through minimal pairs. According to Bloomfield, finding a distribution of redundant, nondistinctive features was also part of the phonemic analysis.

Phonetic Transcription

In speech, different letter(s) may represent the same sound (e.g. s*ee*, gr*ie*f, k*ey*) or the same letter may represent different sounds (e.g. b*a*d, m*a*ny, w*a*nt). In order to be able to express speech sounds of each

language known in the world in an unambiguous way, the International Phonetic Association developed a set of symbols known as The International Phonetic Alphabet (IPA). The use of sequences of phonetic

symbols to represent speech is known as phonetic transcription. The concept of a phonetic alphabet is to have one symbol for one sound. Over the years, different alphabets with modified IPA symbols have been developed for specific aims (as many symbols are not used), but the IPA is considered the standard.

History

In 1886, the International Phonetic Association was founded in Paris by language teachers who wanted phonetic notation to be used in schools, as a method of acquiring a realistic pronunciation of foreign languages. In 1897, it was named L'Association Phonétique des Professeurs de Langues Vivantes or the International Phonetic Association in English. The IPA is used, among other things, to indicate pronunciation in a dictionary, to record a language, and to transcribe speech for automatic speech recognition. The IPA is based on the Roman alphabet, but other symbols have been included to cover the wide variety of sounds found in the languages of the world. Phonetic transcription is placed between square brackets [ ] and there is no capitalization or punctuation. An overview of the different characters and symbols of the IPA is given in various charts elsewhere. The symbols will be discussed in more detail after highlighting some of the principles underlying the phonetic alphabet.

Phonetic transcription does not only vary from language to language but also from speaker to speaker. Depending on dialect, fluency, etc., the same word can be transcribed differently. Speech segments can be divided into two major categories: consonants and vowels. They are described with reference to how they are produced and their auditory characteristics. It requires considerable skill to transcribe an unknown language. During speech production, the vocal tract varies continuously and the division between subsequent speech sounds may not be clear.

Only linguistically relevant speech sounds are transcribed, not personal voice quality. A separate sign exists for each distinctive sound (e.g. /k/ for cat, track, kite, quick, monarch). The IPA also provides symbols for suprasegmental information (word boundaries, stress, intonation) and for refining the pronunciation of an utterance (e.g. aspiration).

IPA charts

The IPA charts give an overview of the different vowels, consonants, clicks, and other sounds occurring in the languages of the world. The charts are more than a list of symbols; they show how the different types of sounds can be classified. Consonants

can be distinguished with regard to voicing, manner, and place of articulation. Voicing refers to the presence or absence of vocal fold vibration (/b/ versus /p/, /d/ vs. /t/). Manner of articulation refers to the way in which speech sounds are produced (stop, fricative, nasal, trills, etc.), and place of articulation indicates the place of constriction in the vocal tract (lips, alveolar ridge, velum, pharynx, etc.). Some languages in the world contain nonpulmonic sounds, sounds that are not produced through air from the lungs: clicks and voiced implosives are indicated by special symbols, while ejectives are indicated by a plosive and an apostrophe. From an articulatory point of view, vowels can be classified according to the features 'open', 'close', 'front', and 'back'. A vowel is considered 'open' when the space between the tongue and the roof of the mouth is large and 'closed' when the tongue is near the roof of the mouth. In front vowels, the tongue is fronted and raised toward the alveolar ridge; in back vowels, the tongue is near the back of the mouth (palate). Although the vowel space is continuous, most vowels are placed in relation to one of the eight cardinal (=reference) vowels: /i, e, ɛ, a, ɑ, ɔ, o, ʊ/.

Several symbols are foreseen to designate suprasegmental information, i.e. intonation groups (‖), duration (ː), stress ('), and to distinguish between words in tone languages (e.g. Chinese, Thai). Some of these symbols are iconic in the sense that the shape of the line indicates the height and possible movement of pitch. For example, [maꜜ] with falling intonation means 'to scold' and [maꜛ] with fixed high intonation means 'mother' in standard Chinese. However, it is also possible to transcribe pitch height by adding diacritics to existing segments, e.g. [ó bà] meaning 'it perched' vs. [ó ba] 'he or she hid' in the West African language Yoruba. In this transcription, the symbols are not iconic, i.e. the accent does not indicate a rising or falling pitch, it means 'high' 'mid', or 'low'.

Another set of marks, called diacritics, has been included to further refine the transcription of phonation. This has been done to restrict the total number of characters. Diacritics are used to indicate aspiration, e.g. [pʰaɪ] 'pie', to indicate vowel centralization [ë] relative to the cardinal vowels, breathy and/or creaky voices, nasalization [fɛ̃] 'fin', meaning 'end' in French, and many other features.

Broad and Narrow Phonetic Transcription

Speech sounds can be transcribed 'broadly' or 'narrowly'. A broad transcription is a phonemic transcription, while a narrow transcription captures more phonetic details of the speech sounds. For instance, the word 'toast' can be transcribed phonemically as

[təʊst] or phonetically as [tʰɵ̆ʊst]. Both types of transcription require some knowledge of the phonology of the language to solve ambiguities related to the segmentation of utterances. And even when the likeliness of occurrence of certain (combinations of) phonemes is known, the alignment between the physical speech sounds and the phonetic transcription can still be problematic. Phonetic transcription has proved to be a very useful skill, but it cannot be done automatically. A proper analysis of the speech signals requires considerable knowledge about the segmental and suprasegmental aspects of a language.

Phonetics

Phonetics is the scientific study of speech. It is concerned with all aspects of the production, acoustics, and perception of speech in the languages and dialects of the world. The starting point for almost any phonetic investigation is the identification of certain landmarks from a cross-sectional view of the vocal tract from which both consonants and vowels of the languages of the world can be classified (see the section on Basic Classificatory Principles). The classificatory system can be used to describe both the various types of speech sounds that occur in different languages and their dialects, as well as those aspects of pronunciation that are used contrastively, that is, to signal differences of meaning (see the section on Phoneme and Phonetic Variation). Phoneticians also analyze how languages make use of pitch, duration, and loudness to communicate meaning distinctions at both the level of the word and the utterance (see the section on Prosody).

Phonetics is concerned with the way in which spoken communication is accomplished between speakers and hearers. This includes both the relationship between speech sounds and the neurological, physiological, and neuromuscular aspects of speech (see the section on Speech Motor Control and Physiology), as well as the resulting acoustic signal that is decoded by the listener (see the section on Speech Acoustics and Speech Perception).

Phonetics is a highly interdisciplinary field and is informed by theory and methodology from Linguistics, Cognitive Science, Computer Science, Electronics, Signal Processing, Acoustics, Neurology, Anatomy, and Physiology. Within Linguistics, Phonetics overlaps most directly with Phonology, Psycholinguistics, Sociolinguistics, and Dialectology and also with Syntax, Semantics, and Pragmatics in modeling the prosodic aspects of speech.

Phonetics is relevant to disorders of speech communication and to speech pathology. In the last quarter of the twentieth century, phonetics has contributed in various ways to the field of speech technology, which is concerned with the development of computer systems for the automatic generation (synthesis) and recognition of speech.

Basic Classificatory Principles

The range of possible sounds that can occur in the world's languages and from which a language makes a selection can be described in terms of various interactions between the vocal organs (Figure 1). The great majority of speech sounds are produced when air is expelled from the lungs, passing through the larynx between two shelves of muscular tissue known as the vocal folds (Figure 2). When the vocal folds are apart, as they are in quiet breathing, they do not obstruct the passage of air from the lungs. Many speech sounds are produced with open vocal folds and they are known as voiceless. In many other speech sounds, including all vowels, the vocal folds can be drawn together and made to vibrate very rapidly, that is, they repeatedly alternate between being open and closed—such sounds are voiced. There is a direct relationship between the rate at which the vocal folds vibrate and the sound's pitch. In most languages, there are pairs of
Figure 1. A cross-sectional view of the vocal tract of an adult male taken from an X-ray image (adapted from Laver, J, 1994). Upper lip (1), lower lip (2), upper front teeth (3), alveolar ridge (4), hard palate (5), velum or soft-palate (6), uvula (7), tongue tip (a), tongue blade (b), tongue front (c), tongue back (d), tongue root (e), nasal cavity (A), oral cavity (B), pharyngeal cavity (C), larynx (D), and trachea (E). The places of articulation are obtained from the following combinations: bilabial (1+2), labiodental (2+3), dental (a+3), alveolar (a+4), apical postalveolar (a+5), laminal postalveolar (b+5), palatal (c+5), velar (d+6), uvular (d+7) and pharyngeal (e+C).
Figure 2. A photograph of the vocal folds taken from above (from Ladefoged, 2001b). The space between the vocal folds is called the glottis. Here the vocal folds are apart allowing the air to pass from the lungs through the trachea into the rest of the vocal tract.

sounds that differ only in whether or not the vocal folds vibrate, such as [f] (in 'fan', voiceless) and [v] (in 'van', voiced). Voiced sounds are usually accompanied by vibrations that can be felt by placing a hand at the level of the throat and then switching voicing on and off as in a repeated production of [fffvvvfffvvvf-fvvv].

The air from the lungs can be made to pass out of the vocal tract either through the mouth (the oral cavity) or the nose (the nasal cavity) depending on the
Figure 3. The configuration of the vocal organs for the production of [n]. The direction of the air from the lungs is shown by the lines and arrows. The velum is lowered allowing air to enter the nasal cavity and pass out through the nose.

actions of the velum or soft palate (Figure 3). When the velum is raised, the air passes out of the mouth or oral cavity and sounds produced in this way are said to be oral. When the velum is lowered, the air enters and passes through the nasal cavity and exits through the nose: such sounds are nasal. Many languages have pairs of sounds that are distinguished only by whether or not the velum is raised. For example, in English [b] in 'bad' and [m] in 'mad' are produced in the same way, except that [b] is oral and produced with a raised velum while [m] is nasal and produced with a lowered velum.

Within the oral cavity, there are three other important landmarks: the upper front teeth, and behind them the alveolar ridge, which extends in an arch into the hard-palate (Figure 1).

The tongue is a highly flexible and mobile vocal organ that has a very dense concentration of different muscles. The tongue is subdivided into the tip, blade, front, and back; in the rest position, these four landmarks lie roughly below the alveolar ridge, the back of the alveolar ridge, the hard palate, and velum, respectively. The tongue is attached to the epiglottis just above the vocal folds and includes a near-vertical section in the pharynx, the root.

The upper and lower lips are involved in various ways in speech production: they may be protruded as in the vowel of 'soon' or completely closed as in [b] and [m] in '*b*ad' and '*m*ad'.

In producing any consonant, there is a point in the vocal tract at which there is the greatest degree of narrowing and therefore the greatest obstruction to the

flow of air: its location is the consonant's place of articulation and it can vary anywhere between the lips and vocal folds (Figure 1). Three commonly occurring places of articulation are: bilabial (e.g. [p], [b], [m] in 'pan', 'ban', 'man'), **alveolar** (e.g. [t], [d], [n], [l] in 'tie', 'die', 'nine', 'lie), and **velar** ([k], [g], [ŋ] as in 'cot', 'got', 'sing').

For any place of articulation, there can be variations in stricture, which defines the extent to which the flow of air out of the mouth is obstructed. When the obstruction is complete, as in [b d g p t k m n ŋ] in the above examples, the consonant is phonetically a stop. A fricative is produced when the air is forced through a very narrow opening at high speed, often producing a hissing sound due to the air becoming turbulent: examples are [s] ('sip') and [ʃ] ('ship'). If the obstruction is further reduced, the flow of air is no longer turbulent but laminar. A consonant produced in this way is an approximant; examples in English include [w] ('we'), [j] ('you'), [l] ('led') and in some English dialects [ɹ] ('red'). [l] in 'led' is also a lateral, in which the air flows over the side of the tongue, and is distinguished from central sounds in which the air flows over the center of the tongue.

The two principal features for describing vowel production are height and backness. Height is analogous to stricture and defines the degree of opening in the mouth. The smallest opening, which is never less than for approximants, occurs in high or close vowels as in 'heed' while the greatest opening is in low or open vowels like 'had'. Backness is analogous to the place of articulation defined earlier: vowels can vary between front, in which the narrowing occurs at the hard palate, and back in which the greatest point of narrowing is often in the pharynx.

Height and backness together form a two-dimensional space that defines the ranges within which vowel production (Figure 4) occurs. The edges of the vowel space are marked by the cardinal vowels, defined by the phonetician Daniel Jones in 1918 at the University
College of London. The Height × Backness space is used to define the phonetic differences between vowels of different languages and dialects. There is independent experimental evidence to show that the extent to which listeners judge two vowels to be similar depends to a large extent on the distance between them in this space. Various acoustic analyses in the last 40 years have shown that height and backness are correlated, respectively, with the first two resonances or formant frequencies of the vocal tract.

Vowels can also vary in whether they are rounded (produced with protruded lips) or unrounded (the lips are unprotruded). There is a preference across languages for front vowels to be unrounded (e.g. 'heed', 'head', 'had' have unrounded front vowels) and back vowels to be rounded (e.g. 'hoard', 'who' have rounded back vowels). But there are many languages with front rounded (French, German) and back unrounded vowels (Japanese, Vietnamese) and in some languages, the presence or absence of lip-rounding may be the only feature that distinguishes between vowels (e.g. in French: high, front, unrounded [vi] ('vie', 'life') vs. high, front, rounded [vy] ('vu', 'seen')).

The International Phonetic Alphabet provides a set of symbols for transcribing the sounds of the world's languages based on classificatory labels or features of the kind discussed above. Each symbol therefore provides information both about the sound that is produced and its relationship with other sounds. For example, [p] is a voiceless bilabial oral stop, which means that like [f] and [t], it has open vocal folds (voiceless), like [m] and [b] it has a constriction at the lips (bilabial), like [b], [f], and [t] it has a raised velum (oral), and like [b], [m], [t], and [d] the passage of air through the mouth is completely obstructed at some stage during its production (stop).

The set of features and their relationships with each other have been considerably informed by a detailed instrumental analysis of the sounds of the world's languages in the last 40 years (e.g. Ladefoged and Maddieson 1996). Other research seeks to understand why certain feature combinations tend to be preferred by languages, whether babies are born with detectors for identifying features, and the extent to which listeners make use of features in perceiving speech.

Phoneme and Phonetic Variation

The consonants at the beginning of the words 'pin' and 'bin' are different from each other not only phonetically (the first is voiceless, the second voiced) but also in a more abstract phonological sense: they communicate a difference of meaning and are allophones of separate phonemes. The two 'p' sounds in 'pin' and 'spin' are also phonetically very different from each

Figure 4. The vowels and their phonetic symbols of the international phonetic alphabet. The vertical dimension is Height, the horizontal dimension is Backness. When the symbols appear in pairs, the one to the right represents a rounded vowel.

other in most accents of English: the one in 'pin', transcribed as [pʰ], is aspirated and produced with a puff of air that can be felt by saying the word and holding a hand near the lips, whereas the one in 'spin', transcribed as [p], is unaspirated and is produced without any puff of air. But while [pʰ] and [p] are phonetically very different, they do not communicate a difference in meaning and are allophones of the same phoneme /p/. The fact that these sounds do not distinguish between meanings in English can be shown by saying the word 'spin' but with an aspirated [pʰ]—the pronunciation might be unusual, but native speakers of English would nevertheless still identify the word 'spin'. Allophones of the same phoneme occur predictably in different contexts: whereas [p] occurs in the context after /s/ ('spin', 'spoke', 'spring', etc.), [pʰ] occurs in a different context at the beginning of stressed syllables ('pin', 'pan', 'put', etc.).

A type of transcription that makes use of only the phonemes of a dialect or language is known as a broad transcription: in such a transcription, all the phonetic characteristics that are predictable from context, and, therefore, redundant for distinguishing between meaning, are filtered out. A narrow transcription is one that includes some phonetic detail, usually at least all the allophones that are common to the speakers of a particular dialect.

Every language has a finite number of phonemes out of which it assembles its words to construct differences of meaning. An important goal in phonetics and phonology is to establish both the phoneme inventory of a language and the relationships between the phonemes and their allophones. All of these differ markedly between languages and dialects. For example, while [p] and [pʰ] are allophones of the same phoneme in English, in Korean they are allophones of separate phonemes: as a result, exchanging them can produce a meaning difference in Korean but not English. The same phonemic opposition is nevertheless likely to give rise to phonetic differences between two languages. For example, both English and French create differences of meaning by distinguishing between two phonemes /b/ and /p/ ('bin' vs. 'pin' in English; 'beau' ('beautiful') vs. 'peau' ('skin') in French). But in French the corresponding phonetic distinction is between a fully voiced [b] (the vocal folds vibrate while the lips are closed) and an unaspirated [p], whereas in English the distinction is between a devoiced [b̥] (the vocal folds only start vibrating after the lips come apart) and an aspirated [pʰ].

Not only languages but dialects of the same language can differ in their phoneme inventory and how these phonemes are produced, or realized phonetically. Whereas most English dialects have a phonemic difference between /u:/ in 'pool' and /ʊ/ in 'pull', in

Scots English there is no such phonemic opposition and so these words are indistinguishable. And while most English dialects have two very different allophones of /l/ depending on its position in the syllable, Southern Irish English makes no such distinction. Therefore, /l/ in 'leaf' and 'feel' are phonetically very similar in Southern Irish English but quite different in most other dialects.

Phonetic variation occurs at the level of the individual speaker. This variation is not simply due to the anatomical differences between speakers (which is responsible for considerable acoustic differences in the speech of men, women, and children) but also because speakers may have developed an idiosyncratic speaking style: a given speaker might have excessive nasalization or a tendency to protrude the lips during speech production. Developing a model that can represent speaker-specific aspects of pronunciation is part of voice quality research and it has important applications both in disorders of voice and speech as well as in the forensic analysis of speech that is increasingly used in criminal investigations.

Prosody

The same utterance can be said in many different ways to communicate paralinguistic effects of emotion such as happiness, sadness, surprise, anger, and so on. These paralinguistic effects are usually brought about by manipulating the prosody or the timing, pitch, and loudness of an utterance. But these manipulations can be used linguistically to distinguish either between words (word-level prosody) or between utterances (sentence- or utterance-level prosody). Prosodic effects usually extend over, and modify, more than a single consonant or vowel; this is why the units of prosody are sometimes called suprasegmentals.

Word-level prosody includes differences due to quantity that are largely communicated by timing differences (these are marked phonetically by a colon: thus, [t:] is a long version of [t]). Quantity differences can occur in the consonant (e.g. Italian: [fato], 'fact' vs. [fat:o], 'done') or in the vowel (German: [lam] ('lamb') vs.[la:m] ('lame')) or in both (Finnish: [mut:a] ('but') vs. [mu:ta] ('other') vs. [mu:t:a] ('to change')). Word-level prosody also includes tone differences in which word distinctions are based on pitch: for example, in Thai, the syllable [na] has different word meanings depending on whether it is produced with a high-falling pitch (when it means 'face'), a low-falling pitch (when it is a name), or a high-rising pitch (when it means 'aunt')—see Ladefoged (2001a) for examples and sound files.

The syllable and word-stress are part of word-level prosody. Almost all languages organize their phonemes

into syllable units and there is psycholinguistic evidence to show that children can identify syllables from a very early age. Much of the phonetic variation (such as the two types of /l/ discussed above) can be attributed to the structural position of a sound in the syllable. In many languages, consonants at the end of a syllable are phonetically much weaker than at the beginning of a syllable. This is the source of many sound changes in which syllable-final consonants weaken or delete completely (e.g. Latin 'septem' > French [set] ('sept', 'seven'), processes that also occur synchronically (e.g. the /t/ of 'fast' is perhaps never pronounced in a context like 'fast speech', so that 'fast' rhymes with 'pass').

Word-stress has to do with the relative prominence or salience and, to a certain extent, the relative loudness of syllables: for example, in the word 'abracadabra', the first and fourth syllables are more salient than the others and are said to be stressed, while the others are unstressed. In English, the position in the word of the syllable with the strongest word-stress, known as the primary stressed syllable, can vary (e.g. '*patt*ern' vs. 'ad*mit*'), whereas in other languages like Icelandic and Polish it has a delimitative function and occurs at a fixed position in the word. In some languages, there are a handful of words that differ only in their word-stress pattern: German 'übersetzen' means 'to transport' (e.g. by ferry) when it has primary stress on the first syllable but 'to translate' when it has primary stress on the third syllable. In English, unstressed syllables (and the sounds within them) can be considerably shortened and often completely deleted (e.g. the second unstressed syllable in 'Tower Bridge' can be deleted resulting in a pronunciation close to 'Tar Bridge'). This very clear phonetic difference between stressed and unstressed syllables that affects vowels and consonants in English is much less is evidence in languages such as French and this is one of the attributes that contributes to the very differently sounding rhythm of these two languages.

Utterance-level prosody includes intonation and accentuation, both of which can be used linguistically to provide a range of different meanings. Intonation depends phonetically on the rise and fall in pitch and can mark syntactic differences in many languages such as distinguishing a statement from a question. Languages, and indeed dialects of a language, have quite different associations between meaning and intonation. For example, whereas in most accents of English, the intonation falls toward the end of a statement, in Belfast-English it usually reaches a plateau and may rise; and whereas English, in common with many languages, has a rising intonation in questions requiring a 'yes—no' answer ('Did Marianna make the marmalade?'), the intonation of such 'yes–no' questions in Greek, Hungarian, and Romanian usually falls.

In the same way that word-stress concerns the relative prominence of syllables in a word, accentuation has to do with the relative prominence of words in an utterance. In many, but by no means all, languages, shifting the accentuation can evoke a different meaning that depends on the discourse structure of a dialogue. Consider that when said in isolation, the most prominent or accented word of the sentence 'I don't like classical music' is usually 'music'. But if the same sentence were said in reply to: 'Have you ever listened to Beethoven?' then the accent in the same reply would shift to 'like' to indicate that 'classical music' is part of the background or old information in the dialogue that is shared between the speaker and listener.

Accented words tend to be produced with greater clarity precisely because they often carry new information and are therefore much more difficult to predict from the context in which they occur. For a related reason, function words, which rarely carry new information and which are therefore much less likely to be accented, are less clearly produced and may be entirely deleted: consider that 'the man in the moon' can be understood as such simply by lengthening the [n] of 'man' and deleting the vowel in 'in' entirely.

Speaking style can have a considerable influence on the utterance's prosody. At faster rates of speech, or in a more casual conversational setting, many of the types of weakening and deletion discussed in this section are likely to be in greater evidence.

Speech Motor Control and Physiology

Speech motor control is concerned with the neurological and physiological bases of speech production. Investigations in this area are directly relevant to articulatory synthesis in which the aim is to be able to synthesize speech using a model of the speech production mechanism.

Studies of speech motor control make extensive use of instrumentation for the analysis of the vocal organs including: laryngography and direct fiberoptic laryngoscopy for measuring and viewing the activity of the vocal folds; aerodynamic techniques for measuring airflow and air pressure at various points in the vocal tract; and electropalatography, which records the pattern of contact between the tongue and the roof of the mouth. Midsaggital electromagnetic articulometry (EMA) has been in use for about 15 years for recording the movement and velocity of the jaw, the lips and the tongue; this technique has to a certain extent replaced electromyography, which measures the electrical activity associated with muscle contraction. Considerable progress has recently been made with magnetic resonance imaging (MRI), which provides exceptionally clear cross-sectional images of the vocal

tract, and with ultrasonic techniques, which have been used for recording the movement of the vocal folds and the tongue based on measuring reflections of high-frequency sound waves between tissue and air.

A major issue in speech motor control is understanding a type of phonetic variation known as coarticulation. This comes about because, in contrast to the way in which letters are written on a page, sounds in sequence overlap with, and therefore influence, each other. Consider for example the production of 'pan': the last two phonemes /an/ are oral–nasal meaning that the velum is raised for the /a/ vowel and lowered for /n/. But since the velum can not jump instantaneously between these two states, it already starts to lower during the /a/ making the vowel nasalized well before the tongue tip touches the alveolar ridge for /n/. The production of /a/ is therefore influenced by the following /n/: it is because of this type of coarticulation that the /a/ in 'pan' is phonetically very different from the /a/ in other contexts such as 'pad'. Coarticulation is ubiquitous and, since speech sounds can be communicated at a faster rate if they overlap with each other in time, proponents of the motor theory of speech perception (see next section) have argued that coarticulation is necessary to ensure that speech is produced sufficiently rapidly. Coarticulation may be anticipatory as in the 'pan' example, in which a sound is influenced by a following sound, or perseverative in which the influence is from a preceding sound. Various experiments have shown that it is very difficult to tie coarticulation definitively to any category boundary: coarticulatory influences can spread across phoneme, syllable, and word boundaries; hence, it would be quite possible for the velum to start lowering during the vowel of 'saw' in anticipation of the following /n/ in 'saw another'. Explaining how listeners manage to recover the phonemic and linguistic content of an utterance intended by the listener in the light of these ubiquitous coarticulatory effects is a major research undertaking in speech motor control and its relationship with speech perception.

Another major issue is the extent to which speech motor control is regulated by feedback—that is, information that is relayed back to the higher centers of the brain from hearing oneself speaking (auditory feedback) and detecting the movement of, and contact between the vocal organs (tactile and proprioceptive feedback). Research in this area has been informed both by studying the way in which fine motor control in adults who have become deaf in later life deteriorates, and from so-called immediate compensation experiments, in which investigators seek to determine the extent to which a vocal organ like the jaw can compensate for the lack of movement in the lips, if these are artificially immobilized. Recent research

suggests that feedback may be used to develop an internalized model of feedback: this would allow speech production control to be a good deal more rapid because, instead of having to wait for actual feedback to determine whether speech has been produced as intended, speakers could calculate the feedback they would be expected to get and make any necessary corrections before speech was actually produced.

Speech Acoustics and Speech Perception

This branch of phonetics is concerned with the analysis of acoustic speech signals. Major progress in this area has been possible as a result of at least three major technological developments: the invention of the spectrograph in 1948, allowing an acoustic signal to be represented in terms of its time, frequency, and amplitude components; progress in speech synthesis technology in the 1950s and 1960s, in which utterances could be generated synthetically by machine; and advances in digital speech processing in the 1960s, in which computer algorithms were developed for the rapid calculation of the frequency content of a signal and for representing acoustic speech signals in terms of a small number of parameters.

When a speech sound is produced, an acoustic signal is created whose characteristics are entirely dependent on the actions of the vocal tract that give rise to it. In articulatory-to-acoustic relationships, the aim is to break down the acoustic signal into a number of components that can be related to individual vocal tract actions out of which the speech sounds are formed: we would like to know, for example, how the acoustic signal is changed by opening and closing the velum, protruding the lips for a rounded vowel like [u], opening the mouth for [a], and so on. A major breakthrough in our understanding of such relationships was in the development in the 1950s and 1960s of the acoustic theory of speech production. With such a model, it became possible to reduce the complex shape of the vocal tract to a relatively small number of parameters (for example, vowels can be modeled by the cross-sectional areas and lengths of four interconnecting cylinders) and then to use these parameters to predict the likely acoustic output. This type of model, which was developed primarily by Gunnar Fant in the 1950s and 1960s has been central to a range of research areas in phonetics, including synthesizing speech and predicting the types and distribution of vowels and consonants that are most likely to occur in the world's languages.

When an acoustic signal reaches the listener, it is transformed in various ways as it passes through the ear and is represented by electrical impulses in the

auditory nerve. Auditory phonetics seeks to model these types of transformations in order to obtain a more accurate representation of how listeners actually perceive an acoustic signal. Some researchers hold the view that the auditory transformations reduce the considerable acoustic differences between male and female speech.

Speech perception is concerned with how listeners retrieve phonemes and linguistic units from the acoustic signal. The application of speech synthesis to speech perception—allowing the individual contribution of acoustic cues to the perception of speech to be investigated—was pioneered at the Haskins Laboratories in the United States of America in the early 1950s. Their experiments led to the influential motor theory of speech perception, in which it is proposed that listeners extract or decode phonemes from the acoustic signal by first reconstructing the speech production strategies that could have given rise to them: that is, listeners hear not the acoustic signal but the movements of the vocal tract. In Kenneth Stevens' lexical-access from features model by contrast, which is partly based on the well-known quantal theory of speech perception, it is proposed that there are landmarks of acoustic stability that allow listeners to access the mental lexicon directly without recourse to speech production. In Björn Lindblom's hyper and hypo (H&H) model of speech, the notion that listeners make use of either invariant acoustic or articulatory landmarks is rejected. Instead, speech is said to vary along a continuum from hypo- to hyperarticulation, depending on the speaker's desire to produce speech with a minimum of effort (hypoarticulation) and the need to produce speech clearly (hyperarticulation) at e.g. points of accent and information focus (see above).

Speech perception is further complicated by the way in which decoding linguistic information from the speech signal interacts with 'top-down' processing, that is, with the knowledge of the language that the listener brings to bear in recognizing and understanding speech. It is quite clear that listeners do not recognize speech by first decoding the speech signal into phonemes and subsequently transforming these into words: a listener instead often recognizes a word well before the acoustic signal for that word has occurred in its entirety. Listeners can identify words that may be present only in a substantially impoverished form in the acoustic signal, or perhaps not even physically present at all (see the examples above). A further complicating factor is that, in contrast to the presence of white spaces between printed words on the page, there is no direct information in the acoustic signal about where one word ends and the next begins. Various experiments have suggested that listeners may make

use of prosody (in particular, syllable-structure and word-stress) to divide the stream of speech into separate words. Developing a model of how the available information from the acoustic signal interacts with the listener's knowledge of the language is a major challenge both to understanding how speech is perceived by humans and to developing computers to accomplish an analogous task.

Conclusions

Phoneticians have made considerable progress in understanding how abstract phonemic and prosodic units are related to the physical characteristics of speech sounds in the production and perception of speech in the languages of the world. The acoustic theory of speech production and the synthesis of intelligible speech from text are two examples of significant scientific discoveries in the last 50 years that have very clear practical applications in technology.

The dramatic improvement in the storage and analysis of speech data by computer in the last decade has provided the tools for analyzing a far greater range of speaking styles of naturally occurring spontaneous speech. However, most of the phonetic knowledge is still derived from stylized laboratory speech of English and there is a great lack of comprehensively annotated databases from other languages and in particular from endangered languages. New experimental approaches to measuring the vocal organs have advanced our understanding of speech production control. There is now recorded material spanning several decades, which can be used to provide an experimental basis to sound change. Careful analyses of all these new types of data will lead to more sophisticated models and new discoveries in phonetics in the future.

Phonology

The aim of phonology is to examine the way sounds are organized in languages and to explain the variations that occur. While it is physically possible to produce a wide range of sounds, only a relatively small number of these are used in a language. For example, a nasal preceding a plosive, such as in *mbeke* does not occur in English at the beginning of a word, but it does in several African languages. This is not because English speakers cannot produce the specific sequence of sounds, but because of the way speech sounds in a particular language are organized.

In phonology, the most characteristic properties of different sounds, known as features, are compared to develop rules underlying the use of sounds in groups of languages. Systematic surveys of a representative number of languages are necessary to be able to generalize about sound systems, and to relate the findings to other areas of language (e.g. syntax and morphology). The UPSID database (**U**CLA **P**honological **S**egment **I**nventory **D**atabase), developed by Ian Maddieson and colleagues in the 1980s, contains inventories of over 450 languages of the world. This database, as well as the Stanford Phonology Archive, has become a popular tool in teaching and in phonological and phonetic research. A detailed description of a language is not only of interest for the sake of having a survey of different languages of the world but is also essential to be able to teach foreign learners a language, or to treat children who are not acquiring the sound system of their language properly, or people who have lost the capacity to speak through injury or illness. In addition, speech technology communication systems require knowledge of the structure of a language.

Phonemes and Allophones

A classical approach in phonology is to begin by establishing the phonemic system of a language, i.e. to determine which sounds are phonemes and which are allophones. Substitution of one phoneme for another will result in a word with a different meaning; substitution of one allophone for another one only results in a different pronunciation of the same word. Phonemes are the 'contrastive' sounds of a language: /c/ and /s/ are different phonemes, because 'cat' and 'sat' contrast in meaning. Allophones are the phonetic variations of distinctively used sounds. Sounds that are not distinctive are also known as 'redundant'. In English, aspiration is a redundant feature. However, in Thai, aspiration is distinctive, as the use of aspiration affects the meaning of the utterance. By substituting one sound for the other (the 'commutation test'), it is possible to determine the phonemes of a language. Pairs of words that differ by just one sound, such as 'cat' and 'sat' or 'robe' and 'roam', are called minimal pairs.

Other criteria also help to determine whether speech sounds belong to the same phoneme or not. One is complementary distribution, which refers to the situation where two sounds should not occur in the same environment. For instance, in English, aspirated plosives occur at the beginning of words, but not in consonant clusters. It can be predicted which allophone is pronounced in which context. Where we find the one, we do not find the other: they are mutually exclusive, never occurring in the same phonetic environment. Another criterion is free variation: sounds that occur in the same place in a word can belong to the same phoneme only if they do not change the meaning of the word. For instance, substitution of glottal stop [ʔ] for [t] as in 'butter' does not change the meaning of the word. Therefore, /buʔer/ and /butter/ are not minimal pairs. Also, sounds ought to display a reasonable amount of physical similarity to belong to the same phoneme.

In summary, when two sounds are in complementary distribution or free variation, they are allophones of the same phoneme.

Distinctive Features

A phoneme can be described by several articulatory and acoustical features. One of the main aims of

phonology is to identify the set of distinctive features required to describe the sounds of a language. Distinctive features serve to distinguish one phoneme from another. It is important to describe these detailed aspects of speech sounds, in order to understand how sets of sounds are related.

Tables 1 and 2 list some distinctive features (not exhaustive) of some English vowels and consonants. If a feature is present, it is marked with a (+) sign; if it is not present, it is marked with a minus (−) sign.

The features 'front', 'back', 'high', 'low', and 'round' refer to the position of the tongue in the vocal tract. For front sounds, the body of the tongue is fronted *re* its neutral position (for the /ə/, a schwa), for back sounds it is retracted *re* its neutral position. For high sounds, the body of the tongue is raised *re* the /ə/, while for low sounds it is lowered *re* the /ə/. Rounded sounds are produced with protruding lips.

Voicing refers to the presence or absence of vocal fold vibration. The feature 'continuant' distinguishes between stops (nasal stops included) and other sounds. Anterior sounds are produced with the tongue tip at or before the alveolar ridge in the vocal tract, and coronal sounds are produced with the tongue tip or blade raised (it includes some palatal consonants). Strident sounds are fricatives or affricates (=stop + fricative) with high-frequency noise (a hissing sound). Nasal sounds are produced with the velum lowered, resulting in airflow through the oral and nasal cavities.

The notion of distinctive features is not only relevant for analysis purposes but also for the description of phonological processes. Some phonological processes, such as for instance assimilation, affect certain combinations of features more than others,

and this should be reflected in the phonological representation. This is possible if it is assumed that each distinctive feature is free to act independent of the other features it may be associated with. This approach consisting of 'interconnecting levels' (tiers) is known as autosegmental phonology: each feature can influence a neighboring sound segment, irrespective of whether other associated features do so. In particular, feature geometry describes the (nonlinear) action of one feature on another by representing their relationship as hierarchical (tree) structures.

Rules

Phonological rules make statements about which allophones of a phoneme will occur in a specific context. The change of one item to another item in a certain environment can be stated by a rule. The validity of the rule can then be tested against other examples to determine exceptions between sounds within and across languages. Rules are important for discovering the universal principles governing the use of sounds in languages. It is necessary to specify the item(s) affected, the change(s) that takes place (indicated by '→'), and the environment in which the change occurs (indicated by '/'). In linear rule writing, the original state of affairs is given on the left of the arrow and the structural change and environment on the right of the arrow. For example, in English, vowels are nasalized before a nasal stop. This can be stated as follows:

$$\text{e.g. } /æ/ \rightarrow [\tilde{æ}] / \_\_\_ /n/$$

It is also possible to use brace notation to describe one process in two different environments. The following example states that /t/ can be pronounced as a glottal

TABLE 1 Possible Distinctive Features of Some English Vowels (Not Exhaustive)

	u	ɔ	o	ɑ	ʌ	æ	e	ɛ	i	ɪ	ə
Front	−	−	−	−	−	+	+	+	+	+	−
Back	+	+	+	+	−	−	−	−	−	−	−
High	+	−	−	−	−	−	−	−	+	+	−
Low	−	−	−	+	+	+	−	−	−	−	−
Round	+	+	+	−	−	−	+	−	−	−	−

TABLE 2 Possible Distinctive Features of Some English Consonants (Not Exhaustive)

	p	t	k	b	d	g	m	n	f	s	θ	ʃ	v	z	ð	h	l	r	w	j
Voice	−	−	−	+	+	+	+	+	−	−	−	−	+	+	+	−	+	+	+	+
Continuant	−	−	−	−	−	−	−	−	+	+	+	+	+	+	+	+	+	+	+	+
Strident	−	−	−	−	−	−	−	−	+	+	−	+	+	+	−	−	−	−	−	−
Anterior	+	+	−	+	+	−	+	+	+	+	+	−	+	+	+	−	+	+	−	−
Coronal	−	+	−	−	+	−	−	+	−	+	+	+	−	+	+	−	+	+	−	+
Nasal	−	−	−	−	−	−	+	+	−	−	−	−	−	−	−	−	−	−	−	−

stop before a consonant or the end of a word (such as in 'button').

$$/t/ \rightarrow [\textglotstop]/ \underline{\quad} \begin{Bmatrix} C \\ \# \end{Bmatrix}$$

By using parentheses and braces it is possible to formulate rules of greater complexity. Moreover, the Greek alphabet, or alpha notation, can be used to match features in different places in the rule.

While some rules state how features are affected by the context of other features (feature-changing rules, such as nasalization, glottalization, flapping), other rules can affect the entire segment. For example, in English a schwa is inserted between a final liquid and a nasal, as in [fɪləm] (instead of /fɪlm/). This example of insertion can be described as:

$$\varnothing \rightarrow \text{ə}/ \begin{bmatrix} +\text{cons} \\ +\text{son} \\ -\text{nas} \end{bmatrix} \underline{\quad} \begin{bmatrix} +\text{cons} \\ +\text{nas} \end{bmatrix} \#$$

where 'cons' refers to consonantal sounds, 'son' to sonorant sounds, i.e. sounds that contain considerable energy (such as /m,l,j/), and 'nas' to nasal sounds.

Given the presence of certain features, one can predict the value of other features in that segment. For example, there are no rounded front vowels in English. If a vowel is specified as [-back] it is also [-round]. It is therefore not necessary to specify [-round]. A blank indicates that the feature is predictable by a phonological rule of the language. Similarly, if a phoneme is [+nasal] it is also [+voiced] in English. Sometimes, nasal phonemes are 'devoiced' after an initial /s/ [snʊp]. However, this does not affect the meaning of the word, as is the case in Burmese where /ma/ means 'health' and /mḁ/ means 'order' (therefore, they are different phonemes).

Suprasegmentals

Until now, we have considered the individual phonemes of a sound system. However, several phonological processes affect units that are larger than phonemes, such as syllables, words, phrases, and sentences. In some languages, words contain (with some exceptions) only front or back vowels (e.g. Turkish). The analysis of phonological features in terms of units larger than a phoneme is dealt with by prosodic phonology, and autosegmental phonology. Another branch of phonology, suprasegmental phonology, deals with aspects of pitch, loudness, tempo, rhythm, and tone. A phonological theory concerned with organizing phonemes into groups of relative prominence that emphasizes the relationship between phonemes and rhythm, and intonational stress is known as metrical phonology.

Optimality Theory

Until now, phonological processes have been addressed by means of rules and derivations (derivational Generative Phonology). Application of one rule often affects the subsequent application of some other rule. However, during the last decade, Optimality theory has obtained a dominant role in phonology. This approach has introduced an alternative way of modeling the relationship between words and sounds.

Rather than trying to define how a language's words may be derived by combining given phonemes according to certain rules, Optimality theory approaches the problem from the opposite direction: in principle, any combination of features/sounds is assumed to be possible, but each language imposes certain constraints in a language-specific way on the endless possibilities.

The constraints are assumed to be universal while they may be ranked differently, which allows for language-specific grammars.

While phonology attempts to model knowledge of a language, it should also reflect the fact that languages are learnable. Proponents of Optimality theory argue that apart from dealing with phonological phenomena, it also includes a better learning theory than traditional (derivational) approaches. In addition, Optimality theory has already proven to be a productive new tool in other domains of linguistic analysis, such as morphology, syntax, and even semantics.

Phrase Structure

Sentences are not just linear strings of words. There is ample evidence that words in a sentence can form a unit that excludes other words in the same sentence. Such units are referred to as constituents. Constituents are hierarchically organized, forming larger phrases. For example, a sentence will often consist of a subject and a predicate. The constituent that forms the predicate can in turn consist of several smaller constituents, such as a verb, a direct object, an adverbial, and so on. These constituents, too, may be complex and contain even smaller constituents. The internal structure of sentences and smaller constituents is generally referred to as 'phrase structure'.

Evidence for the assumption that the internal organization of a sentence consists of hierarchically ordered constituents is manifold. One piece of evidence concerns the fact that the words in a sentence can be redistributed in certain ways such that the result is again a grammatical sentence. In such a redistribution process, certain words stay together. This indicates that they form a unit—a constituent. For instance, in the sentence in (1a), the phrase *the films by Pierre Paolo Pasolini* functions as the direct object of the verb *likes*: it is the thing that is liked. It thus forms a semantic unit. That it also forms a syntactic unit is indicated by (1b): the phrase can be placed at the beginning of the sentence as a whole (a process technically known as 'topicalization') and the result is still grammatical. This cannot be done with just any string of words that happen to stand next to each other. This is shown by (1c), where the attempt to topicalize *likes the films*, to the exclusion of the rest of the direct object, results in ungrammaticality. This shows that this string does not form a syntactic unit on which syntactic rules such as topicalization can operate. Thus, *likes the films* is not a constituent of the sentence in (1a). (Ungrammatical examples are marked by an asterisk, following the common convention in the literature).

(1a)   John likes the films by Pierre Paolo Pasolini.
(1b)   The films by Pierre Paolo Pasolini, John likes.
(1c)   *Likes the films, John by Pierre Paolo Pasolini.

Another indication that phrases are structured and consist of constituents is that certain strings of words can be replaced by one word, whereas others cannot. In (1a), *the films by Pierre Paolo Pasolini* can be replaced by the question word *what* (which in English has to be placed at the beginning of the sentence), as

in (2a). Again, this is not possible for *likes the films*, as shown by (2b). Replacement thus gives the same indication of constituency as does redistribution.

(2a)   What does John like? (Answer: The films by P.P. Pasolini).
(2b)   *What does John by Pierre Paolo Pasolini? (Answer: Like the films).

The smallest constituents of a sentence are words, which are further organized into phrases, which in turn are further grouped into larger phrases, and so on.

Phrasal constituents are built around a word that functions as the head of the phrase. The head of a phrase is that word in the phrase which in a sense is its most important part: it cannot be omitted, and it determines most of the syntactic properties of the phrase as a whole. For example, subjects of sentences are very often phrases that are built around a noun. The phrase can consist of just this noun, as in (3a), but more material can be added, as in (3b), where the head *music* is modified by an adjective preceding it, and (3c) where a relative clause following the noun is added. In this way, arbitrarily large phrases can be formed. The head cannot be left out, however, as illustrated in (3d).

(3a)   [Music]$_{NP}$ is his favorite pastime.
(3b)   [Classical music]$_{NP}$ is his favorite pastime.
(3c)   [Classical music written in the twentieth century]$_{NP}$ is his favorite pastime.
(3d)   *[Classical written in the twentieth century]$_{NP}$ is his favorite pastime.

If a phrase is built around a noun, the resulting structure is a *noun phrase*, abbreviated as *NP*. Any phrase headed by a noun has a syntactic distribution that is determined by its head. For instance, phrases headed by a noun may appear in subject, direct object, indirect object positions, etc. In contrast, phrases headed by an adjective (APs) cannot normally function as such.

(4a)   [The girl]$_{NP}$ gave [the boy]$_{NP}$ [a new cd]$_{NP}$.
(4b)   *[Pretty]$_{AP}$ gave the man a new cd.

Adjectival phrases, on the other hand, can act as modifiers to nouns (e.g. the AP *classical* modifies the noun *music* within the NP *classical music* in (3b), whereas NPs do not ordinarily appear in this position (bar exceptional cases like *a London bus*). The distribution of phrases headed by a verb (VPs such as *cook pasta* or *like music*), phrases headed by prepositions

(PPs such as *in the cupboard* and *under the stairs*), and phrases headed by an adverb (AdvPs such as *very quickly* or *yesterday*) is yet different.

Depending on the properties of the head itself, other material within a phrase besides the head can also be obligatory. Certain lexical items require additional elements to be present in a phrase that they are the head of. This can be due, at least in part, to their meaning. For instance, the verb *like* has to combine with an object (5a). Omission of this so-called complement to the verbal head leads to ungrammaticality (5b) in this case. However, not all complements are obligatory. The verb *eat* can combine with an object (5c), but need not necessarily do so (5d). In the latter case, an object is implicitly understood.

(5a) John likes music.
(5b) *John likes.
(5c) John is eating plums.
(5d) John is eating.

Apart from heads and complements, phrases may contain additional, purely optional, material. Such optional elements are referred to as adjuncts. In VPs, they are most often adverbials such as time, place, and manner adverbials; in NPs, modifying relative clauses, for example, can act as adjuncts. Adjuncts differ from heads and complements in not being unique in a phrase. Whereas a phrase can only have one head, and (barring some problematic cases) also only one complement, adjuncts can be freely stacked. This is illustrated in (6).

(6) John often walks his dog in the park, in the spring, on a nice Sunday afternoon, while whistling *The blue Danube*.

An early formalism of expressing the possible constituent structures of sentences made use of so-called rewrite rules (also known as phrase structure rules; see Chomsky 1957, 1965). They have the general form of (7), where XP stands for a phrase of any category, and Y, Z, and W for its constituent parts. The rule in (7) states that the phrase XP consists of Y, Z, and W (in technical parlance, XP is said to be rewritten as Y Z W). Y Z W can be words, but can also be phrases themselves.

(7) XP → Y Z W

Simplifying somewhat, the structure of NPs can be expressed by the rewrite rule (8a). Rule (8a) states that NPs consist of a determiner, optionally an adjective, the head noun, and optionally a PP. The structure of a VP can be given by the rule in (8b), which states that a VP consists of a verb, an NP (functioning as an object), and (optional) adverbs. The structure of a PP can be represented as given by the phrase structure

rule in (8c), which combines a preposition and its complement.

(8a) NP → Det (Adj) N (PP)
(8b) VP → V NP (Adv)
(8c) PP → P NP

It is worth noting that the NP mentioned in (8c) can be rewritten in accordance with (8a), meaning that it can contain a PP. This PP can be rewritten again in accordance with (8c), so that it contains an NP, which can be rewritten yet again in accordance with (8a), and so on, ad infinitum. This results in sequences like in (9). In principle, there is no limit to such sequences, although for practical purposes they will stop at some point. This shows a pervasive property of the phrase structure of natural languages: it is recursive.

(9) I saw the mouse in the hole in the wall of the house next to the river beside the meadow in the county next to …

Sentences are formed by combinations of several phrases, in the simplest of cases an NP that functions as the subject of the sentence and a verb phrase that functions as the predicate (as for instance in [[John]$_{NP}$ [likes Mary]$_{VP}$]$_S$). This is expressed by the rewrite rule in (10).

(10) S → NP VP

Rewrite rules were replaced in favor of a theory of phrase structure, which proved to be very influential. This theory is known as X'-theory (pronounced as X bar theory). It was first proposed in Chomsky (1970), and further elaborated in such works as Jackendoff (1977), Fukui (1986), and Speas (1990). It originated from the idea that all phrases, regardless of the categorial status of their head (i.e. whether they are NPs, VPs, PPs, AdjPs, or AdvPs), are built along the same structural schema, given by the *tree diagram* in Figure 1.

X is a variable standing for a head of any category (N, V, P, A, Adv), YP is the *complement* of the head, while ZP is called its *specifier*. X' and X'' are the *projections* of the head X. When the head X combines with the complement YP, it projects up to the X' (pronounced X bar) level. The X' constituent further combines with a specifier leading to the projection of the X'' (pronounced X double bar) level. In the classical
Figure 1

version of the theory, the X" level is considered to be the highest level up to which the head can project. It is therefore also referred to as the XP level, designating a full phrase.

Examples of how phrases of various types fit into the general scheme in Figure 1 are given in Figure 2.

Like the complement and the head, the specifier is unique. For example, while a noun can take a possessive phrase as specifier, and can take a determiner as specifier, it cannot take both:

(11a) Mary's copy of *Dracula*
(11b) a copy of *Dracula*
(11c) *a Mary's / Mary's a copy of *Dracula*

There are several structural relations that can be defined over the tree diagram in Figure 1. Any two constituents that are immediately dominated by the same node are called sisters. X and YP are sisters, being immediately dominated by the X' node, as are X' and ZP, the latter two being immediately dominated by the XP node. The XP node is said to be the mother of X' and ZP, while the X' node is similarly the mother of the X and YP nodes. The specifier of the head X can therefore be defined as the immediate
daughter of X" and sister of X', and the complement can be defined as the immediate daughter of X' and sister of X.

The schema in Figure 1 cannot accommodate all the possible constituent parts of phrases. In particular, it cannot accommodate the adjuncts in a phrase, of which there can be arbitrarily many (see above). To accommodate adjuncts, it is assumed that bar levels can be reiterated. When an adjunct is added to a phrase, the head does not project to a higher bar level; instead, the bar level is just repeated. In this way, an adjunct that is added at the double-bar level can be formally distinguished from the (unique) specifier of the head: whereas both the adjunct and the specifier are daughters of an X"-node, only the specifier is the sister of an X'-node; the adjunct is the sister of an X"-node (Figure 3).

Because the specifier can also be distinguished from adjuncts by the very fact that adjuncts can be stacked, whereas the specifier is unique, it is not clear that it is essential to distinguish between the two formally as well (see below).

An assumption built into most modern phrase structure theories is that all nodes are maximally binary branching. This means that no node can have more than two daughters. If this assumption is adhered to, 'flat' structures of the type in Figure 4, for a VP that contains both a direct object and an indirect object, are impossible.

The consequence is that there must be a more hierarchical structure inside VP. Evidence for this is said to come from examples like (12a, b). These show that the indirect object can act as antecedent for a reflexive element (for instance, *himself*) inside the direct object,
Figure 2
Figure 3

Figure 4

but not the other way around. Evidence from other types of sentences shows that the antecedent for the reflexive has to be higher in the structure than the reflexive itself. The data in (12a, b) therefore indicate that the indirect object and the direct object are not on the same level in the structure. Instead, the indirect object must be higher than the direct object.

(12a) Mary showed Bill a double of himself.
(12b) *Mary showed a double of himself Bill.

The scheme in Figure 1 is not intended to express a linear order of constituents. The theory of phrase structure in the first instance is about the hierarchical relationship between phrases. Different principles must then determine whether a complement precedes or follows the head, as well as whether the specifier precedes or follows the head.

Syntactic theory distinguishes between two classes of words: lexical and function words. The position of function words in phrase structure theory has always been rather unclear. Recently, such elements have come to be regarded by some as heads of phrases, on par with lexical categories. In line with this development, items like determiners (such as *the* and *a* in English), complementizers (such as *that*, *if*, *whether*), auxiliary verbs and modals (such as *to be*, *can*, *will*), and even inflectional affixes for tense and agreement (such as the English *–ed* suffix in past tense forms) are regarded as the heads of phrases. This view has various consequences for how the internal structure of phrases is supposed to be built up. For instance, a phrase like *the house* is no longer seen as an NP, but rather as a determiner phrase (DP), headed by the determiner D, which takes the NP *house* as its complement, as represented in Figure 5.

Similarly, sentences are now regarded as projections of the inflection we see on the verb, and hence as inflectional phrases or IPs (Figure 6). Subjects are in the specifier position of IP. In the same vein, sentences introduced by a complementizer are regarded as complementizer phrases or CPs. The complementizer head in the CP takes an IP as its complement, which in turn takes a VP as its complement (Figure 7). The specifier position of CP can also host elements in some sentences, such as question words.

The proliferation of functional categories in the theoretical inventory also has consequences for the notion of adjunction. With every additional functional projection, an additional specifier position becomes available. This means that it is at least possible to discard the assumption that bar levels have to be repeated in order to accommodate adjuncts. Instead, every adjunct may be regarded as a specifier of a particular functional projection, as extensively argued in Cinque (1999).
Figure 5
Figure 6
Figure 7

Classical X'-theory not only needs the possibility of repeating bar levels to accommodate all the possible constituents of a phrase, but it suffers from the opposite problem as well: it sometimes forces more syntactic positions to be present in the structure than are actually necessary. For instance, a head can take a specifier while not taking a complement. Whereas (13b) is as well formed as (13a) is, in classical X'-theory there nevertheless is a complement position present in (13b) as well.

(13a) John's collection of mushrooms
(13b) John's collection

It is even possible that a phrase contains just its head, without a specifier or a complement, as for instance in (14b) (vs. (14a), with specifier and complement present). If phrases always have the form of

Figure 1, then in such cases there is both a specifier position and a complement position, neither of them containing any lexical material.

(14a) (I expect) [Mary to win the race]
(14b) (I expect) [to win]

Partly because of this inelegant aspect of X'-theory, a more flexible view of phrase structure has been adopted (see Speas 1986; Chomsky 1994), usually referred to as Bare Phrase Structure theory. Its basic assumption is that a head projects as often as it combines with another phrase, no more and no less. One consequence of this is that it is no longer possible to distinguish between specifiers and adjuncts in structural terms (see also the previous point on functional structure). Instead, the specifier can be distinguished relationally, since it establishes a unique relation with a head.

Pidgins and Creoles

Although until recently creolists were more or less agreed on the definition of 'pidgin' and 'creole', this is no longer so. Also, the adage that 'a creole is a nativized pidgin' (Hall 1966) is no longer universally accepted. It has been observed, for example, that at least some of the French-lexicon creoles do not have a pidgin ancestry (Chaudenson 2001). Further, the more we learn about the transition from pidgin to creole, the less certain we are about where to draw the line between the two (Baker 1995). At the same time, creolists are becoming aware that it may not be justified to group pidgins and creoles together, even though in the past they have often been treated as if they belong to one category. In spite of all these difficulties, some definitions will be presented here, if only to give the reader an idea of the distinctions. A pidgin is a nonprimary language that is the result of language contact. A creole is a primary language that is the result of language contact.

Before explaining these definitions, a brief survey of the pidgins and creoles of the world is useful. According to the most extensive survey that has been made until now (Smith 1995), the total number of pidgins and creoles is around 350, including both the ones that are extinct as well as varieties that are intermediate between a 'true' creole and its related 'lexical donor language' (also called 'lexifier language', 'superstrate language', or simply 'superstrate'). The total number of speakers, including those who only use a creole as a second language (a pidgin is a second language by definition), may be estimated at around 100 million. By far, the largest group, especially among the creoles, is formed by those that have derived the bulk of their lexicon from an Indo-European language such as Portuguese, French, English, Spanish, and Dutch. It is no coincidence, of course, that these are the languages spoken by the European nations that played the leading role in the European expansion. It was the contact between the European languages of the explorers and colonizers, on the one hand, and the non-European languages of the people with whom they came into contact, on the other (referred to as 'substrate language(s)', or simply 'substrate'), that gave rise to the emergence of these pidgins and creoles. Other Indo-European languages, apart from the ones mentioned above, that have played a role in the emergence of pidgins and creoles include German, Russian, Italian, and Hindustani.

Although these European-lexicon pidgins and creoles have attracted the lion's share of the attention of

linguists, there is a significant and linguistically just as important group of pidgins and creoles whose lexicons are based on non-Indo-European languages. The lexifier languages in this group include Arabic, Japanese, Chinese, and a number of Bantu, Austronesian, Australian, Papuan, and Amerindian languages. An important difference with the group of European-lexicon pidgins and creoles is that in many cases no Indo-European language was involved in their formation. Because of this, the study of non-European pidgins and creoles may serve to correct any biases that may have resulted from the focus on European pidgins and creoles that has characterized the field of pidgin and creole linguistics for a long time (see Thomason 1997, 2001). An important question in this regard is whether the features of pidgins and creoles that are sometimes regarded as universal might not be an artifact, resulting from the fact that all the major lexifier languages are structurally similar, belonging as they do to only two branches (Germanic, Romance) within one and the same language family, Indo-European. To get an idea of the variety as well as the geographical distribution of the world's pidgins and creoles, the maps in Holm (2000) are a good starting point. As far as the Pacific is concerned, much more detailed information can be gleaned from the splendid three-volume language atlas edited by Wurm et al. (1996). Unfortunately, a similar work for the Atlantic region is not (yet) available.

As mentioned earlier, the definitions given above require some comments. First of all, what is meant by 'primary' and 'nonprimary' language? If you are multilingual, your primary language is the one with which you feel most at home, the one you use most often, even though it may not be your native language. When we say that a pidgin is a nonprimary language, it means that pidgin-speakers have at least one other language in their repertoire—their primary language— and that the pidgin is used only as an auxiliary language, when communicating with speakers with whom they have no other language in common. Creoles, on the other hand, are primary languages by definition, although, again, this does not mean that they are necessarily native languages. Second, if pidgins are nonprimary languages, is it justified to view them as 'true' languages in the first place? Although this is an interesting question in itself (when is something a language?), it is too complex to be dealt with here. For the purpose of this essay, however, pidgins are referred to as languages. As for creoles, there is no question about it: they are languages just like any other.

The one thing that pidgins and creoles have in common, according to the definitions given above, is that they are a product of language contact. Language contact, therefore, is the key concept in these definitions: it is a necessary, although not sufficient, condition for pidginization and creolization (the process by which a

pidgin or a creole comes into being). This means, first, that there will be no pidginization or creolization without contact, and, second, that contact does not automatically lead to pidginization or creolization. When we look at pidginization and creolization as language contact phenomena, the following questions present themselves:

(1) What other types of language contact are there, apart from pidginization and creolization?
(2) In what ways do pidginization and creolization differ from other types of language contact?
(3) What are the factors that decide whether language contact will lead to pidginization or creolization?

These three questions will guide the remainder of the discussion.

What other types of language contact are there, apart from pidginization and creolization?

The linguistic effects of language contact are dependent on a number of factors, the most important of which is whether or not imperfect language learning plays a role in the contact situation. On the basis of this, two types of language contact can be distinguished (Thomason 2001):

(a) *Shift-induced interference*. When people give up their native language while adopting another one, the new language often displays features from their native language. In this case, the changes in the affected language are a result of imperfect learning.
(b) *Borrowing*. When people maintain their native language, it may still be influenced by another language. This happens when native speakers incorporate features from another language into their native language. In this case, the changes in the affected language are not a result of imperfect learning.

The crucial difference between the two is that in the case of shift-induced interference, speakers introduce changes in a language that is not their native language, while in the case of borrowing they introduce changes in a language that *is* their native language. Although the end-results of these two types of language contact are sometimes hard to distinguish, the processes by which these results come about are very different, for example, in the order in which the different components (lexicon, phonology, etc) of the language system are affected. While borrowing always starts with words and only involves the grammatical system later, it is the other way around in shift-induced interference. The results of the two processes may range from minor changes in the lexicon, such as adoption of a loanword, to major structural changes, such as changes in basic word order.

In what ways do pidginization and creolization differ from other language contact phenomena?

Pidginization and creolization differ from other language contact phenomena (except, perhaps, so-called 'mixed languages'; see relevant lemma) in that neither pidgins nor creoles can be justifiably viewed as changed versions of the languages in contact, while this *is* the case with borrowing and shift-induced interference. In other words, pidgins and creoles are autonomous languages. This entails that they have a grammar of their own, one that is not derivative of or dependent on a pre-existing language. The autonomy of the grammar is the result of a process whereby grammatical 'components' (rules, patterns, processes) that were initially related to one or more of the contributing languages, have become independent. The transition from dependency to independency occurs when these components start interacting with one another to produce a new grammar, rather than forming an incoherent collection of elements derived from other languages.

The idea of pidgins and, especially, creoles as autonomous languages is shared by most creolists, including those who view creolization in terms of either borrowing or shift-induced interference. The view of creolization as a case of (extreme) borrowing is held by Lefebvre (1998), who sees Haitian Creole as the result of a process of relexification, whereby words from the slaves' native language(s) were replaced by similar words from French, while the grammatical structure of the native language(s) was maintained. A very different view is represented by Chaudenson (2001), who believes that—especially the French-lexicon—creoles are the result of a process of language shift (from the slaves' native languages to French), whereby some features may have been introduced as a result of interference. No matter how far apart, both views agree that creoles are autonomous languages, not modified versions of one or more of the contributing languages. The idea of creoles as autonomous languages is also inherent in Thomason's (2001) view of pidginization and creolization as cases of 'abnormal' language transmission. While in 'normal' transmission both the lexicon and the grammatical apparatus are transmitted from one and the same 'parent language' to one or more 'daughter languages,' in cases of 'abnormal' transmission, there are at least two 'parents', one for the lexicon and one for the grammatical system. As a result of this, a pidgin or a creole cannot be a variety of either one of the parent languages; therefore, it is an autonomous system. Finally, in generative approaches to pidginization and creolization (e.g. DeGraff 1999), the question of autonomy hardly arises, as every language—whether pidgin, creole, or something else—is seen as an instantiation of Universal Grammar. Although this brief discussion does not exhaust the list of theories of creole genesis,

it seems fair to say that they all share the concept of autonomicity as a basic feature of pidgins and creoles.

What are the factors that decide whether language contact will lead to pidginization or creolization?

This is one of the fundamental questions regarding pidginization and creolization. Since little attention has been devoted to it, especially from a historical point of view, the discussion here is necessarily tentative. It should also be noted that what follows is restricted to European-lexicon pidgins and creoles (by far the largest group), and that it is not necessarily valid for pidgins and creoles that are lexically based on other languages. It is hoped, however, that insights into the conditions for the genesis of the European-lexicon pidgins and creoles will also shed some light on the other cases.

The European pidgins and creoles both arose in the historical context of the European expansion. This particular phase in history began around 1430 when Prince Henry ('the Navigator') started sending out Portuguese ships to explore the northwestern coast of Africa. Although the exact date when the contacts between Europeans and Africans for the first time led to the emergence of a pidgin or creole language in not known, it is clear that the genesis of the European-lexicon pidgins and creoles took place in the context of the European expansion, whether in Africa, America, Asia, or the Pacific. The age of European expansion was a very special, perhaps even unique, phase in the history of the world, which may be characterized by the following features:

(a) The introduction of trade and production on a truly global scale.
(b) The presence of contact situations characterized by unusually wide social, cultural, and psychological gaps between the parties involved (Europeans on the one hand and Africans, Asians, Native Americans, and Polynesians on the other).
(c) The use of forced labor and forced displacement of large numbers of people (slave trade, indentured labor).
(d) The creation of a new type of society known as 'the plantation complex' (Curtin 1998).

With regard to the last feature, it should be added that, although plantations in the strict sense were not present in every single situation where pidgins and creoles developed, the concept of 'plantation complex' may be interpreted in a sufficiently wide sense to encompass the latter situations as well.

Although the exact relationship between the presence of particular external conditions on the one hand and the emergence of pidgins and creoles on the other is not very clear, a few things may still be said about it. For example, there is the issue of access to the target language. With the increasing disproportion between the

European and non-European segments of the population and the concomitant change from the small-scale 'homestead society' to the large-scale 'plantation society' (Chaudenson 2001), access of the non-Europeans to the European language decreased. However, this cannot be the whole story because there are a number of cases, especially in Spanish colonies, where such disproportion did not lead to pidginization or creolization (McWhorter 2000). Other factors, such as lack of motivation on the part of the enslaved to learn the language of their masters (Baker 1990), may have been involved as well. However, there is another, more elusive, factor that has received little attention until now. If we look at the period of the European expansion from a contemporaneous rather than from a modern perspective, we cannot help but recognize that this unique phase in history confronted all those who were involved in it with an entirely 'new world'. Never before had so many different parts of the world been in contact on such a large and intensive scale. Although the fact that this new contact situation was accompanied by a true 'explosion' of new languages does not necessarily mean that the one was caused by the other, the synchronicity of the two 'events' is striking. It is hoped that future research, especially into the historical dimension of pidginization and creolization, will shed more light on this issue.

Pike, Kenneth Lee

Kenneth Pike, like his predecessors, based his theoretical contribution firmly on linguistic field work. He followed their lead in attempting to explain the ways in which the languages of North America structured words, phrases, and clauses. Unlike his teachers, he added a needed emphasis on meaning and context to earlier analytical methods. Pike's interest in linguistics began when he attended the second session of linguistics training led by William Cameron Townsend in 1935 at a remote Arkansas farm. After this rudimentary training, Pike applied his new knowledge to the study of the complex tone patterns, morphology, and syntax of the Mixtec language in the highlands of Oaxaca, Mexico. The following year (1936), he taught the phonetics component of the Townsend's course, using his personal field experience to explain phonetic concepts. His introduction to the initial writings of Edward Sapir (1921) and Bloomfield (1933) motivated him to attend the 1937 Linguistics Institute of the Linguistics Society of America, where he also met the leading American linguists of the day. He studied under Sapir from 1937 to 1942 at the University of Michigan, focusing on phonetics and descriptive linguistics. Pike was later hired by the university and taught linguistics there from 1948 to 1979.

Pike spent much of his early efforts (1935–1948) on phonetics and phonology (phonemics) and published textbooks in these areas that were used extensively for many years. His personal field studies and his experience as a consultant to other researchers in Latin America led Pike to investigate phonetics and phonology (then called phonemics). His *Phonetics* (1943) was the most complete book of its kind. Pike's phonetic studies provided insights into what he called contrast, variation, and distribution. Contrast refers to the ways in which sounds are different from one another in a particular language. Variation describes the fact that individual sounds are not always pronounced the same way, although native speakers perceive them as the same sound. Distribution deals with the locations in which a sound appears. These three themes continued throughout Pike's writing and formed the basis of his later work on morphology and syntax as well.

Pike pioneered the study of tone languages and helped many other linguists analyze the diverse tone systems of the world. One important contribution was using a constant tone pattern or frame to analyze similar tones. By keeping the frame (such as 'This is a…') constant, linguists could better hear the contrastive tones of the words being studied.

Pike's studies in intonation were likewise an essential tool for many scholars and people involved in teaching English to speakers of other languages. Pike applied intonation studies to poetry as well and published examples of poems (his own included) marked for intonation patterns reflecting how the poem was read by different speakers.

In 1936, Pike developed a 'monolingual demonstration' in which he showed students how to learn a language without relying on English translation. Using a variety of sticks, leaves, and other common objects, Pike would elicit language data from a speaker of a foreign language without using an intermediary language. Within an hour, Pike would be able to explain major features of the sound system, morphology, and syntax of the language. The lecture was very popular, both on campus and in nonacademic settings. It provided a clear illustration of the role of a hypothesis and experimentation in linguistic studies. In 1977, the University of Michigan distributed a video version of one such demonstration of Pike working with a Javanese speaker.

Pike is best known for his work in tagmemics, a theoretical approach to morphology and syntax that integrates language forms and grammatical functions. Based on the concepts of sounds (phonetics) and sound patterns (phonemics), Pike proposed that there were similar features in morphology (morphemes) and syntax (syntagmemes). He defined the tagmeme as a combination of particular grammatical 'slots' or positions with the elements that could 'fill' that position. In English, for example, the subject position (slot) of a sentence can have (be filled by) a Noun Phrase, a pronoun, or proper noun, but not by an adverb or a conjunction. Eventually, Pike would add semantic information to his tagmemic model. In the previous example, Pike noted that the role or function of a Subject in English can be either the person who does the action (an Agent) or the person who is affected by the action (a Patient or Undergoer), as in a passive clause.

Using principles of contrast, variation, and distribution from phonemics (phonology) and phonetics, Pike coined the terms 'emic' and 'etic' in 1954 to discuss word and clause structures. Pike's seminal work *Language in relation to a unified theory of the structure of human behavior* presents his philosophy of language and culture that formed the basis of the emic/etic distinction later used in anthropology and other fields. With his wife and coteacher, Evelyn, Pike developed a unified approach for studies of morphology, syntax, and discourse at a time when other linguists limited syntax to the clause or sentence level. Their *Grammatical analysis* (1982) has been widely used as a textbook in descriptive linguistic methodology.

Pike's early students at the University of Michigan include Alton Becker, Ruth Brend, Charles Fillmore, John Gumperz, Ilse Lehiste, and Velma Pickett. His pioneering work in tagmemics has also been developed by Walter Cook, Soedarjanto, Linda K. Jones, and Robert Longacre, among others. Other linguistic theories overshadowed Pike's work at times, but his teaching and writing influenced hundreds of field linguists and helped them to document indigenous languages around the world. After his retirement from the University of Michigan in 1979, Pike served as an adjunct professor of linguistics at the University of Texas–Arlington.

Pike's contribution to linguistics was overshadowed when tranformational approaches to syntax became popular. Although tagmemics handled a larger portion of the overall linguistic analysis, it did not handle such areas as active vs. passive transformations or the ways in which certain patterns can be derived from other, more basic, patterns.

Pike was one of the first people involved in the Summer Institute of Linguistics (SIL), a Christian organization that sponsors linguistic and cultural research as well as literacy and translation programs in indigenous language communities. When Pike was not teaching at the University of Michigan, he split his time between his long-term research among the Mixtec people and helping his SIL colleagues. In 1951, Pike and his coworkers published a translation of the New Testament in San Miguel Mixtec, the first such translation completed by SIL. From 1936 through 2000, he was regularly involved with SIL schools, first in

Townsend's training program in Arkansas, then at the University of Oklahoma (1941–1987), and later at other locations. As President of the Summer Institute of Linguistics from its incorporation in 1942 until 1978, Pike oversaw the development of SIL's worldwide linguistic research and training in over fifty countries. Pike personally supervised the beginnings of the SIL schools at the University of Oklahoma (1941), in Australia (1950), and in Great Britain (1951). He was also active in the Linguistic Society of America and the Linguistic Association of Canada and the United States.

Pike was the author of more than 20 books and 200 articles, including articles on the interaction of his personal spiritual beliefs and his academic work. He was also a prolific poet and frequently incorporated his poems in his linguistic writing and teaching. He was an outstanding consultant who assisted other linguists to see the patterns in the languages they studied. He frequently coauthored articles with younger colleagues and was coeditor of linguistic volumes in such diverse settings as Indonesia, Nepal, and Papua New Guinea. Pike lectured in 43 countries covering five continents and received eight honorary degrees and numerous other honors including the Presidential Merit Medal from the Philippines (1974). His work with SIL led to his being nominated for the Nobel Peace Prize each year from 1982 to 1996, based on the positive impact of the linguistic, literacy, and translation efforts of SIL in over 1,000 languages.

Biography

Kenneth Lee Pike was born in Woodstock, Connecticut on June 9, 1912. He received his Th.B. (1933) and Ph.D. (1942) for studies in phonetics, mentored by Edward Sapir, University of Michigan. He was a member of the Summer Institute of Linguistics, 1935–2000; President, 1942–1979; and President Emeritus, 1979–2000. He was also Associate Professor of Linguistics, University of Michigan, 1948–1953; Professor of Linguistics, 1954–1979; Chair of Linguistics Department, 1974–1979; and Professor Emeritus 1979–2000. He was Permanent Council Member,

International Phonetic Association, 1945; member, Linguistics Society of America; and President, 1961. Pike was a member of the Linguistics Association of Canada and the United States and its President in 1977. He was also a member, American Academy of Arts and Sciences, 1973 and member of the National Academy of Science, 1985. He was nominated for the Nobel Peace Prize in 1982–1996. He received Fulbright lectureship in the USSR in 1988. Kenneth Lee Pike died in Dallas, Texas on December 31, 2000.

Pintupi and Pama-Nyungan Languages

The Pintupi language is an Australian indigenous language spoken in the Western Desert, eastern Central Australia, which is situated approximately 400 km northwest of Alice Springs in the Northern Territory. It is mainly spoken in and around the Papunya Indigenous Community Settlement. Pintupi belongs to a group of

languages which includes Ngaanyatjarra, Pitjantjatjara/ Yankunytjatjara, Luritja/Pintupi, with the last two language groups being very similar in formation (Simpson 1993:136, 142). These languages form part of the Pama-Nyungan grammar group of Australian languages and exclude other indigenous languages from the north of Western Australia and the north and northwest of the Northern Territory (Yallop, C., p. 16). According to an Inquiry by the Australian Government in 1992, 90 of the original 250 Australian indigenous languages are still living languages and approximately 3,000+ people still speak the eastern Western Desert group of languages. The Western Desert, western Central Australia group of languages include Manjiljarra, Yulparija, Kukatja, Ngaanyatjara, and Ngaatjatjarra languages, with approximately 1,000+ people speaking these languages. This brings the total number of people speaking the Western Desert languages of Central Australia to approximately 5,000, making it the largest group of speakers of traditional indigenous languages in their natural environment in Australia. In 1995, Peter Trudgill wrote in his book *Sociolinguistics*:

> In Australia, for instance, there used to be about 200 aboriginal languages. Of these, 50 are already dead, and another 100 are very close to extinction. Perhaps as few as 30 will make it to the year 2000. (p. 177)

It has therefore become an important task for linguists today to do as much as they can to work toward the preservation of these endangered languages. Australian indigenous people have been either discouraged or forbidden to speak their own languages since colonization, and many Aboriginal languages have been lost to the world. These languages are 'oral' only and have no written form apart from drawings, such as is found in caves, in their natural settings, and it is only in recent times that linguists have been able to do more extensive fieldwork to give written form to the surviving few indigenous languages. Pintupi is one of these languages, and translators, such as Aboriginal Bible translator Ken Hansen, who lived in a Pintupi community for several years, have done significant work in this area.

In his article on 'Translating for the Pintupi', Ken Hansen says that when he first began to learn to speak Pintupi his progress was very slow because the sounds of the indigenous language were more complex than the sounds of English. It was therefore very difficult to transcribe into a written form.

For example, Hansen says the Pintupi language has words such as:

(1)   ngarrinpa   lying
        and ngarinpa   standing
(2)   wangka   talk
        and wanka   alive

While these words seem very similar in structure, just the addition of a longer 'r' sound gives a completely different meaning to the word. The sound 'ng' is also often used at the beginning, or in the middle, of words, making the language difficult to pronounce for English speakers because we are used to using this sound at the end of words, such as in the word 'sing' (Walsh and Yallop 1993:xi).

Hansen also found that it was very important to use the correct words in different social situations, and because of the strange combination of sounds, this was difficult for him to do. His goals were based on the use of the Bible in traditional indigenous language and culture, and he was obviously very committed to his work. He had estimated that it would take him at least 15 years to work out how to write the language by just listening and transcribing the sounds into an alphabet, a dictionary, and a grammar, let alone have enough information about the culture to translate the Bible. There is now a Pintupi/Luritja to English Dictionary available that has been written by him.

Another enormous problem in doing this type of translation is that the Aboriginal people had never heard of things such as a synagogue, and similar concepts such as 'meeting place' had to be used instead. The indigenous word for 'ceremonial offering', 'kunatinpa', could possibly have been used or incorporated here.

Some other examples of Hansen's Pintupi/English translations are (with literal translations and/or explanations):

synagogue	tjuwuku tjaatji
	the Jew's church
king	mayutju pulka
	big boss
angel	nganka ngurrara
	one who belongs in the sky
pharisee	tjuwuku luwuku mikunytju
	a lover of the Jew's law
Holy Spirit	katutjaka kurrunpa
	God's personal spirit
God	katutja
	the one who pertains above
Christ	kirritja
	Christ pronounced in the Pintupi way
Christ	katutjalu tjamatatjunkula wantirriyantja
	the one whom God promised to send long ago

As can be seen from these translations, the effect of British colonization has been that many words that originally come from English origins would not have been in existence in indigenous language prior to this event. They have since been added to the Australian indigenous language and culture. This is particularly

the case with words such as 'big boss', because many indigenous men became stockmen on cattle properties, and the owner was called the 'big boss', 'mayutja pulka', which was then transcribed into Traditional indigenous language. This is a concept that is important to modern social use of indigenous language and has meant the creation of new Aboriginal word usage (Simpson 1993:137–78). One of these words is the Western Desert word for 'spirit', 'kardiya', which is now also used to refer to 'white people'.

As can be seen in modern word usage in indigenous language is the current, and extremely significant, social event taking place in Australia today, the Reconciliation Process, and the use of the word 'sorry'. The Indigenous people are asking the Australian Government and the Australian people as a whole to say 'sorry' for the past injustices that have been done to the Australian Indigenous people (Haebich 2000:569). These injustices include taking the indigenous children from their natural parents and communities and placing them with white families 'for their own good' (Haebich 2000:567–8). Although the present Australian multicultural population was not specifically involved in perpetrating these injustices, it is seen as a token of respect toward the indigenous people, and an acknowledgement of the shame that the people who were responsible for these injustices should feel, for committing these acts. The associated feelings for this can be incorporated into words such as 'kunta', or 'shame', by saying 'sorry' to what is now left of the indigenous community. Part of the meaning of the Pintupi word 'kunta' relates to the English words and concepts for 'shame' and 'respect'. When used to mean 'respect', it is usually symbolic of 'shyness' in not wanting to show disrespect, such as refusing a person to his face without excuses. Someone who is being respectful of others shows embarrassment by saying whatever they have is less significant than the other persons' possessions, and this type of shame is called 'kuntarrinpana tjanampa'. Children are socialized by shaming, and a child is said to be deaf or unheeding, 'patjarru', when young, but needs to be respectful when older and to be aware of 'kunta' as they learn of the need to show respect within the community (Mawr, B:126–157). These emotional concepts have a great significance in the Pintupi understanding of social behavior and it could be further said that this concept is of importance to the indigenous people as a whole. It can then be an integral part of the Reconciliation Process of saying 'sorry', therefore incorporating an important indigenous concept of being sorry for the bad things that someone has done within the indigenous concept of their own culture.

The following are Pintupi concepts with their English meanings relating to feelings:

kunta	shame
rama	mad
ngulu	fear
rarru	anger
pukulpa	happy
ngarru	happy

These concepts have been interpreted by researchers, such as Meyers, as:

(1) 'Mad, crazy persons are said to be "deaf", "rama", because they take no notice of what is being said to them. "Rama", or "not hearing", therefore relates to people who do not take notice of advice and are therefore not thinking.'

(2) 'The English and Pintupi concepts of "fear" or "ngulu" are the same and generally mean to be frightened or afraid of the consequences of one's actions. Men's sacred objects and ritual paraphenalia are often described as "ngulu", or "frightening and dangerous".'

(3) '"Anger" or "rarru" means to "get wild" or "very angry" because he does not feel sorry for his actions. Pintupi descriptions of "rarru" means that their "ears are closed" and they are not thinking of the consequences of their actions.'

(4) 'When a relative comes to visit the Pintupi say one becomes happy, or rejoices, "pukularrinpa". Or men bringing back meat make people happy. It is the opposite of anger, fighting, and sorrow, and is tied to a major Pintupi image of sociality and cooperation, says Meyers. Ceremonies that include song and dance make people happy, and "pukulpa" was traditionally used to stop fighting with an approaching enemy.'

Another way in which indigenous language use is being preserved in Australia today is in bilingual education programs in schools. Pintupi/Luritja is being taught bilingually in Walungurra School, Northern Territory, since 1983, with Luritja language being taught at Papunya (Black 1983:207–20). Another place of bilingual education is of the Diwurruwurru-jarru Community, where the Walpiri language, (also a Pama-Ngungan language) is being taught at Lajamanu, Yuendumu, Nyirripi, and Willowra schools, near Katherine in the north of the Northern Territory (Bavin 1993:85). Kriol is being taught at Barunga School, also in this area (Rhydwen 1993:155–8). In some of these communities, linguist/teachers work alongside indigenous women while the children are taught traditional ways of food gathering. The names

of 'bush tucker' (food), including plant and animal names, and names for 'body parts, are taught in Kriol and Walpiri Language by the Indigenous women in communities near Katherine, and the linguist/teacher teaches the same names in English.

In other bilingual teaching programs, everyday classes are taught in both traditional indigenous language, and English. A significant problem that arises because indigenous language is an oral not written language, is that new words have to be invented to explain how to write things such as commas and full stops, and also in the teaching of mathematics. This is how and where linguists and teachers are working together with indigenous people to preserve Australia's original languages. It is especially important that this work be done as quickly as possible so that indigenous languages are not only lost to their original users, but to the world as a whole as globalization and the common use of English as the predominant language take over.

JOANNE MARIE BAUMGARTNER

Pitcairnese

Pitcairnese is the name of one of two closely related varieties of a language initially formed on Pitcairn island and subsequently transplanted to Norfolk island by descendants of the nine English-speaking sailors who mutinied on HMS *Bounty* in 1789 and their Polynesian companions from Tahiti and Tubuai, one of the Austral Islands of the Tahiti group. Linguists use the name 'Pitcairn-Norfolk' (PN) to refer to both, but speakers call the variety spoken on Pitcairn 'Pitkern' and that on Norfolk Island 'Norfolk.' In 1996, Pitcairn Island Council, prompted by the concern that Pitkern might die out because none of the children were speaking it spontaneously, declared it an official language of the island.

Although there is some disagreement about whether PN is a creole rather than a variety of English, the conditions under which it developed were clearly exceptional because we know the place and time of its formation, as well as details of the origins of the primary individuals involved. PN is one of the few cases in which it is possible to directly trace the survival of some British dialectal features to some of the sailors.

The *Bounty*, sent to Tahiti to transport breadfruit trees to the West Indies as a source of food for slaves, contained no pressganged men and was probably the first British ship to sail with an all-volunteer, hand-picked crew of 45. The cliché 'motley crew' well describes the mutineers, for they covered not only a wide social spectrum ranging from their leader, Fletcher Christian, master's mate, born of an aristocratic family originally from the Isle of Man, to common seaman John Adams, a Cockney and orphaned son of a Thames waterman, brought up in a poor house, but they also covered a wide range of regional varieties of English. Four of the nine mutineers were English, two Scottish, one American (from Philadelphia), one part-West Indian from St. Kitts in the Caribbean, a well-educated son of a navy captain (Edward 'Ned' Young), and one, John Williams, assistant armorer, was a native of Guernsey and spoke French, as Captain William Bligh noted in his list of identifying traits of his men. Of Peter Heywood, he remarked that he spoke with the 'Manx, or Isle of Man' accent.

In their search for a place to hide from the British navy, the mutineers initially sailed back to Tahiti and to Tubuai, where they picked up six men and 12 women, one with a daughter, before settling in 1790 on a remote Pitcairn island more than 2,000 kilometers from Tahiti. This small, two- by one-mile, harborless island with its steep cliffs and lack of reefs or anchorage was at the time uninhabited and incorrectly charted on contemporary maps. Pitcairners' first contact with the outside world occurred 18 years after settlement, in 1808, when Captain Folger of the *Topaz* from Boston was greeted in English by Thursday October Christian, Fletcher Christian's son, and was asked whether he knew Captain Bligh.

Apart from this brief encounter, the settlers lived there for the first 33 years in almost complete isolation, thus permitting no outside influences during the formative period of the language. It was not, however, a tranquil time by any means, with nearly 90% of the founding male population murdered by 1800. Disputes over land and the women led to the violent deaths of all the men except four Polynesians and four mutineers, one Englishman (John Adams), a Scot (William McCoy), one Cornishman (Matthew Quintal), and one West Indian from St. Kitts (Edward Young). Young, McCoy, and Quintal died by 1800, leaving only John Adams, then 33 years old, who remained with nine surviving women and the 23 children born on the island. Outsiders did not enter the colony until the 1820s. The first separation in a community that had lived together as a family for more than 60 years occurred in 1856, when the 194 Pitcairners were resettled on Norfolk Island, originally a penal colony. Eighteen months after their arrival, 17 members of the

Young family sailed the 3,700 miles back to Pitcairn. Five years later, a second party returned. Today, fewer than 50 speakers remain on Pitcairn Island. Present-day Norfolk is spoken by about 700 people; the majority of the island's population is not descended from the original Pitcairners. Some 700 other descendants of the original population live in Australia, New Zealand, and elsewhere.

Because the mutineers were outnumbered by two to one, the odds were that Pitcairn would become predominantly Polynesian in language and culture, particularly because all the women were Polynesian (most of them from Tahiti) and would have been the primary caregivers to the children. There are also hints in both boatswain's mate James Morrison's and midshipman Peter Heywood's accounts of the mutiny that the sailors had begun to intersperse Tahitian words in their speech to one another. Midshipman Roger Byam recalls that by the time the *Bounty* sailed with the by now heavily tattooed sailors after a stay of more than five months in Tahiti, all the men knew some Tahitian words. Some were said to be quite fluent and could be heard carrying on conversations with one another in which barely a word of English was spoken. Yet, the language of power on Pitcairn island was clearly English, and many linguists argue that PN was not a fully developed pidgin or creole because there was no point in its history in which English was not the primary language of the community. Stable pidgins rarely develop where contact involves only two languages. Moreover, the descendants seem to identify more strongly with their English rather than Tahitian lineage, and the predominant influence on the vocabulary, pronunciation, and sentence structure of PN is English.

The main influence of Tahitian survives in the form of a large element of Tahitian vocabulary, particularly for flora, fauna, and foodstuffs, e.g. *buhe*, 'sea eel' (Tahitian *puhi*), and *miti*, 'coconut cream sauce' (Tahitian *miti*). Tahitian influence can also be seen in certain semantic (meaning) shifts that have affected English words, such as *hand*, meaning both 'hand' and 'arm' in PN, paralleling Tahitian *rima*. Otherwise, most of the vocabulary is ultimately of English origin, including a number of dialects. Words can sometimes be traced to the dialects of individual mutineers, e.g. the negative imperative ('do not') *dune* from the Scots probably spoken by John Mills, gunner's mate from Aberdeen, or William McCoy of Rosshire, or *moge*, 'thin' (and possibly also the negative form *kaa/kannt*, 'cannot'), from Edward Young's West Indian English. Other Scots forms include *bole*, 'to make a small hole in anything', *devil's needle*, 'dragonfly', *gaggle*, 'to cackle', and possibly *tayte*, 'potato'. There are also archaisms such as *dub*, 'to square and smooth (timber)', *tardy*, 'late', *paunch*, 'stomach', and a few words of American origin, such as *corn*, 'maize',

and *candy*, 'sweets', possibly because of the presence of Isaac Martin, a mutineer from Philadelphia, or because of the influence of American whalers who visited the island. Other dialect forms include *dunnekin*, 'lavatory', and *grub*, 'food'.

A variety of terms with original nautical reference, such as *all hands*, 'everyone', *deck*, 'floor', and *flog*, 'spank', have extended their meanings in PN. Similarly, *heave ho*, a cry of sailors in raising the anchor up, survives in PN *heway me* (*heave me away*) 'to lift up/ throw/take away/ remove', as does *heway* ('heave away'), now obsolete in English. However, this once nautical usage with the meaning 'to fling, throw or cast, to haul up or raise by means of a rope' does exist in dialectal usage in Scots, where *heave away* means 'to throw away', as well as in some English dialects in which *heave* means 'to lift/raise'.

Although PN was formed independently of Pacific Jargon English, an English-based foreigner talk used in encounters between Europeans and Pacific islanders and found on almost all islands in Polynesia and Micronesia by the 1830s because of the whaling industry, it shares some features in common with other Pacific pidgins and creoles descended from it, e.g. bimorphemic (i.e. two-part) question words such as *whatawe*, 'how' (English 'what way'), verbs generally unmarked for tense (past, present) and aspect (whether the action is completed or not), use of *dem* (English 'them') as a plural marker, e.g. *dem ai*, 'the eyes', and absence of the copula 'be', e.g. *whatawe hem*, 'how is he?' The sailors probably knew some rudiments of Pacific Jargon English with adaptations made during their stay at Tahiti. These features could also have been acquired through contact with visiting whalers. Between 1813 and 1852, 400 visits of ships are recorded, three quarters of which were American, mostly whaling ships. For a time, there was a steady market for the islanders' vegetables. Norfolk islanders also had contact with the whaling trade in the late nineteenth and early twentieth centuries. Many worked as crewmen on whaling ships. They were also in contact with the varieties of Melanesian pidgin spoken by Solomon Islanders and New Hebrideans. In 1867, the Melanesian Mission established a training school for Solomon Islanders on Norfolk. From the 1890s until World War II, Norfolk Islanders worked as plantation managers and cadets in the Solomons. Otherwise, however, PN has far more in common with the Caribbean creoles, no doubt attributable to the influence of Edward Young from St. Kitts. The possessive construction makes use of English 'for' as in *dem ai fo yoen*, 'your eyes'.

A few grammatical features, particularly the personal pronouns, reflect Tahitian influence, e.g. the first-person inclusive dual *hemi* ('you and I'), a literal translation of Tahitian *taua*, composed of English 'thou' + 'me', with the initial sound of 'thee' changed to /h/. This pronoun contrasts with *uklun* ('we/us plural'), whose etymology is unclear. PN, like Tahitian, has dual marking in forms such as *yu tu*, 'you two', contrasting with *yoli*, 'you plural', i.e. three or more. This may also reflect archaic English 'all ye' or 'you all'.

The sound system of PN also shows some influence from Tahitian. Lack of a significant distinction between /r/ and /l/, a feature common to many Polynesian languages, including Tahitian, is found in PN forms such as *stolly*, 'lie' (English 'story'), *morla*, 'tomorrow', and *tomolla*, 'day after tomorrow' (both from English '(to)morrow'). This feature (along with variation between /v/ and /w/, also similar to Tahitian) is a feature typical of St. Kitts too, which may suggest additional influence from the speech of Edward Young. Unlike many pidgins and creoles, PN has preserved consonant clusters under some circumstances, whereas Tahitian has none. However, final t/d are often absent in PN, a common feature of colloquial and dialectal English. PN pronunciations such as /flaid/ for 'Floyd' and /kloi/ for 'cry' may reflect a sound shift that probably originated in London and was well under way by the mid-nineteenth century. It is possible that John Adams is the origin of this feature in PN, although it could also have arisen later by independent innovation or contact with other varieties, such as the one spoken by Young. The vowels of words such as *price* and *choice* still rhyme in St. Kitts today in many people's usage. The /ie/ diphthong (double vowel sound) of *gate* could reflect West Indian or English dialectal influence. Despite the presence of two Scots among the founding English speakers, PN has no trace of /r/ after vowels in words such as *cart*, *barn*, etc.

Place of Articulation

Consonants are formed by creating a constriction in the vocal tract; in producing a consonant, the place of articulation is the part of the vocal tract having the greatest constriction. The symbols used for the description of sounds are taken from the IPA chart, which lists the International Phonetic Alphabet.

The major constriction, which may be a complete or partial closure, is made by the articulators coming together, generally by a lower articulator moving toward an upper articulator. The lower articulators are elements of the lower jaw—the lower lip, the lower teeth, and the tongue. The upper articulators are the upper lip, the upper teeth, the palate, the velum, the uvula, and the rear wall of the pharynx. Places of articulation usually have a compound name giving the lower and upper articulators, with the name of the lower articulator first. Thus, apico-dental indicates that

the lower articulator is the apex of the tongue and that the upper articulator is the upper teeth. Occasionally, when the lower articulator is obvious or unimportant, only the upper articulator is named: e.g. *velar*, used alone, is interpreted as meaning dorso-velar. The major places of articulation are shown in Figure 1.

Places of articulation can be divided into four general categories: labial, coronal, dorsal, and guttural. At each place of articulation, sounds with different manner of articulation can be produced: stops have complete closure at the indicated place, whereas fricatives are pronounced with partial closure, which produces a hissing sound.

Labial sounds are made with one or both lips and include bilabials, labio-dentals, and linguo-labials. The lower lip articulates with the upper lip to form a bilabial consonant. The term bilabial is used rather
Figure 1

than labio-labial. Bilabial stops [p, b] and the nasal [m] are extremely common in languages; indeed, a language without them (e.g. some Oto-Manuean languages) is noteworthy. The bilabial fricatives [ɸ, β], however, are rather uncommon; languages tend to have bilabial stops and labio-dental fricatives.

The lower lip articulates against the upper teeth to form labio-dental consonants. Labio-dental fricatives [f, v] are very common. Labio-dental stops do not occur as distinctive sounds in any language. The labio-dental nasal [ɱ] occurs as a variation of [m] in English words such as *symphony* ['sɪɱfəni], in which it takes the place of articulation of the following labio-dental fricative.

Linguo-labial sounds are very rare sounds made with the tip or blade of the tongue articulating with the upper lip. The IPA uses a diacritic [͜] underneath a labial symbol for this place of articulation: [p̼ b̼].

Coronal sounds are made with the apex, or lamina, of the tongue. They include dentals, alveolars, alveolo-palatals, postalveolars, and retroflex sounds.

Dental sounds can be made with either the tip of the tongue (apico-dental) or with the blade (lamino-dental). The dental fricatives are voiceless [θ] and voiced [ð]; these sounds both occur in English as in the words *thin* and *then*, respectively. Other dental sounds are shown by using the alveolar symbol with the diacritic [̪]; e.g. [t̪ d̪ n̪ l̪ r̪]. Lamino-dental fricatives [s̪ z̪] can be made with the blade of the tongue near the back of the upper teeth, in addition to the apico-dental fricatives [θ ð]. Danish has a dental approximant [ð̞]. Interdentals are made by thrusting the tongue slightly forward so that the tip protrudes between the teeth; they can be symbolized as [θ̟ ð̟]. In English, apico-dentals are normal, although some people occasionally use interdentals in emphatic or exceptionally careful speech.

Like the dentals, alveolar sounds may be made with either the tip or blade of the tongue, known accordingly as apico-alveolar or lamino-alveolar. The symbols for either are [t d n s z]; all of these sounds occur in English. Alveolar and dental sounds are both extremely common in languages; it is rare, however, for a language to have both, except for fricatives.

Postalveolar sounds are made with the blade of the tongue articulating with the area at the back of the alveolar ridge. The fricatives [ʃ ʒ] and affricates [tʃ dʒ] are quite common in the languages of the world. English has these sounds in *shin* [ʃ], *leisure* [ʒ], *chin* [tʃ], and *gin* [dʒ].

The alveolar fricatives [s z] and the postalveolar fricatives [ʃ ʒ] involve some difficulty in describing their point of articulation accurately. Different speakers hold their tongues in somewhat different positions. With the alveolars [s z], the airstream hits the back of the upper teeth. This causes a turbulence that gives them a distinctive sound. For [ʃ ʒ], the air stream hits the back of the lower teeth and produces a slightly different sound.

Two fricatives are given in the International Phonetic Alphabet as alveolo-palatal; these are different from the postalveolars. They are produced with the tip of the tongue near the lower teeth and with the blade quite close to the back of upper teeth. The symbols are [ɕ] for the voiceless fricative and [ʑ] for the voiced fricative. These sounds occur in Mandarin Chinese and in Polish.

For retroflex consonants, the tip of the tongue curls back, and the underside of the tip articulates with the area at the back of the alveolar ridge. The body of the tongue is quite concave. Retroflex consonants are symbolized as [ʈ ɖ ɳ ʂ ʐ ɭ]; they use the alveolar symbols modified by a lower hook. These sounds are common in languages of India.

The English *r* sound is usually called retroflex; however, in practice, the place of articulation may vary from alveolar [ɹ] to retroflex [ɻ]. Further, many speakers of English use a bunched r, in which the tip of the tongue is near the lower teeth and the body of the tongue is pulled up and back toward the palate. Although the articulations of the retroflex and bunched r are very different, the acoustic effect is quite similar.

Dorsal sounds include those made with the front or back of the tongue: palatal, velar, and uvular.

With palatal sounds, the front of the tongue articulates with the palate. The tip of the tongue points down, often touching the lower teeth. Italian has a palatal lateral [ʎ], as in *figlio*, and a palatal nasal [ɲ], as in *signore*; German has a voiceless palatal fricative [ç], as in *ich*. The palatal stops [c ɟ] and the voiced fricative [ʝ] are not common.

Dorso-velar sounds are made with the dorsum of the tongue articulating with the velum. The dorso-velar stops are [k g] as in English *could, good*; the dorso-velar nasal is [ŋ] as in English *sing*. The fricatives are [x], as in German *Bach,* and [ɣ], the voiced equivalent. Frequently, these sounds are simply called dorsals.

The uvular consonants are made with the dorsum of the tongue articulating with the uvula. They are like velar sounds made very far back in the mouth. The symbols are [q] and [ɢ] for the stops, [ɴ] for the nasal, and [χ] and [ʁ] for the fricatives. Uvular sounds are found in Arabic and Inuktitut. Some French accents have an approximant [ʁ] or fricative [ʁ] for the *r* sound.

The guttural sounds include the pharyngeal, epiglottal, and laryngeal places of articulation.

Pharyngeal consonants are made by moving the root of the tongue backward toward the pharyngeal wall. The root of the tongue is the vertical part, forming the forward wall of the pharyngeal cavity. Many people cannot make a complete pharyngeal stop. A pharyngeal nasal stop is physiologically impossible

because, if no air flows through the pharynx, then no air can flow through the nasal passage. For the fricatives, the symbols are [ħ] and [ʕ]; these sounds are found in Arabic and other Semitic languages.

Epiglottal sounds are extremely rare, but they occur in some Semitic and Caucasian languages. For them, the epiglottis moves backward to articulate with the pharyngeal wall. The symbols are [ʡ] for the stop and [ʜ ʢ] for the voiceless and voiced fricatives.

Laryngeal sounds involve the vocal folds; they include the *glottal stop* [ʔ] and the fricatives [h] and [ɦ]. From a phonological point of view, these sounds can all be thought of as consonants with a laryngeal place of articulation, with the *glottal stop* as a laryngeal stop and the sounds [h] and [ɦ] as laryngeal fricatives. From a purely phonetic point of view, however, each of these could be categorized differently: [ʔ] as a state of the glottis involving complete closure of the vocal folds, [h] as a voiceless vowel, and [ɦ] as a breathy voiced vowel. Glottal stop and [h] are very common; [ɦ] is somewhat rare, although it occurs between vowels in English, as in *ahead*.

In general, the major categories of place of articulation (labial, coronal, dorsal, and guttural) are independent of each other. Thus, it is possible to make two stops at the same time, e.g. a dorsal [k] and a labial [p]. Such a sound is said to have a double articulation; for example, with [kp], the place of articulation is labial-velar. It is symbolized as [k͡p], with the tie-bar showing that the [k] and the [p] are made simultaneously. English [w] is a doubly articulated labial-velar approximant: the lips are rounded and the dorsum of the tongue is partially raised toward the velum. Many English speakers pronounce a double articulation in *kitten* [ˈkɪʔtn̩]. Swedish has a doubly articulated voiceless postalveolar-velar fricative [ɧ]; this is the same as a simultaneous [ʃ] and [x].

Secondary articulations involve the addition of a lesser, or secondary, articulation to a greater, or primary, articulation. Thus, by adding lip-rounding to a [t], a labialized [tʷ] is produced. The primary place of articulation is alveolar; the secondary articulation is labial. The common secondary articulations are (shown with [t]) labialization [tʷ], palatalization [tʲ], velarization [tˠ], and pharyngealization [tˤ]. The IPA has alternative symbols for either velarization or pharyngealization [ɫ].

Labialized sounds involve lip rounding; they are quite common. Palatalized consonants have the front of the tongue more toward the palatal region than usual. Palatalized consonants are common in some Slavic languages. Velarized consonants have the tongue toward a position that is more velar than usual, i.e. a high back unrounded vocalic position. The English dark [ɫ], occurring at the ends of words such as *ball*, is an example of a velarized lateral; here, the dorsum of the tongue is raised slightly toward the velum. Pharyngealized sounds are found in Arabic; they involve a retraction of the root, thus effecting a narrowing of the pharynx.

Plurality

The majority of languages have singular and plural forms of words to indicate a single object or a set of more than one object. Some languages (Philippine languages, some languages of Southern Asia, Baltic languages) have a dual form of words to indicate a set of two objects. Dual nouns are used in archaic dialects of

Lithuanian, and some relics are still known in Russian, Ukrainian, and some other Slavic languages. For example, in Russian the word *eye* has the form: *глаз* [glaz] (singular), *глаза* [glaza] (plural). The plural form is actually a relic of the dual. The origin of the dual in these languages can be explained by the fact that some things exist only in a pair: like ears, eyes, knees, legs, and sides.

In most of the modern languages, the dual form has disappeared. Only two categories, i.e. the singular and plural (more than one object) are used; for example, the singular word *leg* in English takes the plural form of *legs*; in Russian it would be *нога* [noga]—*ноги* [nogi]; and in Turkish the same word would be *bacak* in singular and *bacaklar* in plural.

There are also languages that do not have a specific form to indicate plural objects. This can be illustrated by examples from Malay, where a noun *mata* (eye) would normally imply a plural meaning (there are usually two eyes on a face). The same principle would apply to *kaki* (legs). When necessary, the plural form in Malay is created by repeating the noun—*kamus-kamus* (dictionaries), *kanak-kanak* (children).

The plurality of nouns and pronouns as objects in the sentence affects subject–verb agreement. For example, the singular English pronoun *I* requires a singular verb—*I have a beautiful vase for these flowers.* While the plural form of *I*—*we* requires a plural verb—*We have a beautiful vase for these flowers.* The singular noun *sister* requires a singular verb—*My sister goes to the movies every Sunday.* The plural *sisters* requires a plural verb—*My sisters go to the movies every Sunday.*

The following English nouns are grouped according to objects they refer to:

(1) *Sister, house, table, book, mother, minister, teacher, doctor;*
(2) *Milk, coal, chocolate, mud, water, gold, information, sugar, cream;*
(3) *Love, hatred, friendship, hope, charity, justice;*
(4) *Family, group, committee, class, parliament.*

The first group refers to concrete, tangible objects, or persons. They are *count nouns.* The second and third groups of nouns indicate substance (2) or abstract (3) nouns that are not discrete, and therefore cannot be counted. They are *mass nouns.* The last group represents entities or bodies that consist of a number of members. These nouns can be counted. They are *collective nouns.*

Count Nouns

Count nouns can be preceded by the word *some* or the articles *a, an*, and *the.* For example: *A tree has fallen during the storm. The tree has fallen during the storm. Some trees have fallen during the storm.* They can have both singular and plural forms. Most of the count nouns form their plurals by adding -(*e*)*s*. However, there are a number of irregular words, and words borrowed from other languages, from Greek and Latin in particular, that create their plurals in specific ways (see examples below). There are also some English words that can only be either singular or plural.

The plural form of count nouns is formed by adding -(*e*)*s* to the noun:

flower	*flowers*
lady	*ladies*
balloon	*balloons*
lunch	*lunches*
bush	*bushes*
fairy	*fairies*
potato	*potatoes*

A number of irregular nouns in English form their plurals differently, i.e. by changing their vowel or by adding *-en*.

man	*men*
woman	*women*
foot	*feet*
goose	*geese*
mouse	*mice*
louse	*lice*
child	*children*
ox	*oxen*

Those count nouns, which end with *-f*, form plurals by changing *-f* to *-ves*, for example,

wolf	*wolves*
wife	*wives*
scarf	*scarves*

Words borrowed from other languages, Latin and Greek in particular, create their plurals according to the foreign (original) rule, for example:

datum	*data*
stratum	*strata*
larva	*larvae*
criterion	*criteria*

Some English nouns are used only in their singular form, such as *music, chemistry, physics, ceramics, mathematics*, etc. At the same time, there are nouns that are only used in the plural: *jeans, trousers, scissors, spectacles, measles*, etc. However, the language allows for the following phrases if there is a need to indicate the number of some of the above-mentioned words. For example—*Tanya knew she desperately needed another pair of jeans. The office assistant has ordered two pairs of scissors for the department.*

There are cases of nouns that do not change for plural, e.g. *sheep, deer, fish, salmon*, etc. Also, there are words that have two different plural forms that convey different meanings, such as:

craft:	*craft (boats)*
	crafts (handicrafts)
index:	*indexes (alphabetical lists of names, subjects, etc.)*
	indices (algebraic exponents)
medium:	*mediums (at spiritual séances)*
	media (newspapers, television)

Collective Nouns

Collective nouns are the nouns that indicate a group, a body, or an organization that consists of a number of members, for example *family, class, parliament, committee*. They form their plurals in the same way the count nouns do by adding (*e*)*s: families, classes, parliaments, committees*. The fact that a collective noun refers to a number of people does not affect the subject–verb agreement in a sentence. Such words in their singular form are used with singular verb, e.g.—*My family enjoys skiing. The Social Club Committee usually plans the recreational activities of the employees.*

Mass Nouns

Mass nouns are not usually used with the definite article; for instance—*Loyalty is his most valuable characteristic. Sugar adds sweetness to any drink.*

However, in the following examples the mass nouns are modified by further information and can be used with the definite articles—*The love John and Matt shared for their mother finally ended the war between the brothers. The chocolate made in this town is delicious.*

Since the mass nouns refer to abstract, not discrete objects, they cannot be counted. Therefore, they usually do not allow for plural morphology. However, they allow for other means of measurement:

A bottle of milk;
Three cups of tea;
Bars of chocolate;
Patches of mud;
A useful piece of information.

The appearance of such words as *sugars* or *lights* is possible only if they refer to concrete, discrete entities; for example: *Switch off the lights please. Can I have two sugars in my coffee please?*

Polish and West Slavic Languages

The present-day West Slavic language area is made up primarily of the national territories of Poland, the Czech Republic and Slovakia, as well as a small part of south-eastern Germany. By the end of the sixth century CE, migrations of Slavic-speaking people had settled in a wide area of northwestern Europe, and these communities extended as far west as the River Elbe. By the ninth century CE, distinctly West Slavic elements had become noticeable within the Common Slavic used by these settlers, and, by the end of the tenth century, features distinctive of the three West Slavic subdivisions of Lechithic, Czecho-Slovak, and Sorbian had emerged. Apart from one or two isolated remaining pockets of Slavic, the more westerly Slavic-speaking areas were gradually resettled by German speakers in the middle ages, resulting in approximately the West Slavic language area as it exists today.

The modern West Slavic languages are Polish, Czech, Slovak, and Upper and Lower Sorbian. To these is also often added a further member, Cassubian, whose status is disputed between its being a separate language or a dialect of Polish. Until the mid-eighteenth century, another West Slavic language, Polabian, also existed. Polish, Cassubian, and Polabian make up the Lechithic subgroup of West Slavic, Czech, and Slovak make up the Czecho-Slovak subgroup, and Upper and Lower Sorbian make up the Sorbian group. Other divisions have been suggested in the past, involving the merging of Sorbian with either Lechithic or Czecho-Slovak, but this three-group model is the most widely accepted.

West Slavic is distinguished from South and East Slavic primarily on the basis of phonetic differences, such as the retention of /tl/ and /dl/ clusters, which have been reduced to /l/ in South and East Slavic languages. West Slavic languages also have fixed word stress, while most other Slavic languages have moveable stress.

All the West Slavic languages use a Roman-based alphabet, with each language having a set of accented and/or special characters. Polish has the largest set of special characters, including 'hooked' vowel characters that represent nasalized vowels.

Two features of the West Slavic languages have been of particular general interest to linguists. Both are shared with other Slavic languages, but one is especially closely associated with work on West Slavic.

The first feature is the category of aspect, which stands alongside tense to indicate whether an action or event is completed or ongoing, as opposed to whether its occurrence is in the past, present, or future. This is evident in the existence of pairs of related verbs, such as the Lower Sorbian *cytaś* and *docytaś*, where *cytaś* focuses on the general act of reading, while *docytaś* is used for a completed reading session (meaning roughly 'read through to the end').

The other feature is word order within the sentence. All the West Slavic languages mark grammatical functions by the use of special word endings, rather than by word order as is the case in English. They thus permit considerable flexibility in word order, and they use this to give prominence to particular pieces of information within the sentence. This phenomenon has sometimes gone by the name of 'functional sentence perspective' and its theoretical status within general linguistics originated with work on Czech by the Prague School in the 1930s.

Polish and Cassubian

Polish has the largest number of speakers of the West Slavic languages. It is the official language of the Republic of Poland and is thus spoken by around 38.5 million people in that country. It has been estimated that there are several million more speakers outside Poland, including immigrant communities in the United States of America and elsewhere.

The earliest evidence that we have for Polish dates from the twelfth century and consists solely of proper names within an otherwise Latin document. The earliest surviving complete sentence in Polish dates from the thirteenth century and the earliest complete text dates from the fourteenth century.

Within present-day Polish, five main dialect areas are usually recognized: Wielkopolska is an area toward the northwest of Poland, centered around Poznan, Mazowsze is in the northeast and includes Warsaw, Małopolska is in the southeast, Śląsk is a small area toward the southwest, and Kaszuby is another small area in the north around the port of Gdansk. In addition to these, there are also mixed dialect areas, both in the extreme northeast and in the west along the border with Germany. These latter areas were part of Germany until the end of World War II and were then settled by Polish speakers of various dialects.

An increasingly standard form of literary Polish, drawing mostly on the dialects associated with the main cultural centers of Poznan and Gniezno (in the Wielkopolska area) and Cracow (in the Małopolska area) can be identified from the sixteenth century, when there was a flourishing 'golden age' of Polish literature. This literary language was also influenced to a certain extent by Czech, as well as by borrowings from Latin. Following a period of decline for written Polish in the early eighteenth century, a revivalist movement emerged in the late eighteenth and early nineteenth centuries, which aimed to codify the standard language. Although members of this movement took note of the earlier literary language of the sixteenth and seventeenth centuries, it was not primarily an archaizing movement (in contrast to the codification of Czech, outlined below) and consequently the differences between the codified written and contemporary spoken languages were not all that great. Throughout this period, and also thereafter, there was a strong opposition to the adoption of distinct regionalisms into standard Polish. A version of Polish based on the standard written language has become adopted as the standard spoken variety. Today, most Polish speakers who speak a dialect are also able to speak this standard language, and they use it in more formal and public settings.

Distinctive features of Polish include the nasalized vowels mentioned earlier, the marking of gender as well as number and person in certain forms of the verb, and the use of third-person ('he' or 'she' or 'it') verb forms instead of second-person ('you') forms in respectful address.

The Kaszuby dialect (Cassubian in English) is, as stated earlier, often recognized as a separate language within the West Slavic group, although within Poland there is a greater tendency to see it as a dialect of Polish. It certainly possesses greater differences from standard Polish than do the other dialects, and Poles from outside the Cassubian region have difficulty in understanding it. Its status as a separate language is strengthened by a strong Cassubian ethnic identity. It also has its own literary tradition and is used regularly in the local media. Despite these outward attributes of a relatively cohesive language, Cassubian has a high degree of internal dialect variation. There have been various attempts to codify the language, but, to date, there is no formally recognized standard. Arguments against the status of Cassubian as a language are its close relation to Polish and the fact that the Cassubian area is politically a part of the Republic of Poland.

References will sometimes be found to a further West Slavic language, Slovincian, which is now extinct. This was located geographically adjacent to Cassubian, to the northwest of the main Cassubian-speaking area. Although the residents of that area referred to their language as Slovincian, it is almost universally recognized by linguists as having been a subdialect of Cassubian. A combination of earlier Germanization and postwar population movements led to the extinction of Slovincian by the 1950s.

Czech

Czech is the official language of the Czech Republic, spoken by between 9 and 10 million inhabitants, as well as by around 60,000 inhabitants of neighboring Slovakia and by immigrant communities elsewhere.

The earliest surviving example of Czech dates from 1057 CE and consists of a set of glosses on a Latin manuscript. From the thirteenth century onward, a prolific Czech literary tradition exists, which flowered especially in the sixteenth century.

Czech is unusual in that there is a larger than average difference between the standard written and spoken languages. The standard spoken language—known as Common Czech—represents the natural evolution of the Czech language over time. In contrast, standard written Czech stems from essentially artificial codification by linguists in the early to mid-nineteenth century, the most influential of whom were Josef Dobrovský and Josef Jungmann. Dobrovský, who was mainly responsible for codifying the grammar of Czech, based his grammar on substantially earlier literary usage from the golden age of the sixteenth and seventeenth centuries. Thus, in comparison with Common Czech and other West Slavic languages, standard written Czech shows a number of archaic features. For instance, the

six sets of noun endings from earlier Slavic are better preserved in Czech than in any of the other West Slavic languages. Jungmann was more concerned with widening the use of Czech, although his attitude was also essentially purist and he was responsible for introducing a number of distinctively Czech new words in preference to borrowing from other languages.

Besides standard spoken Common Czech, Czech divides into three main dialect areas: Bohemian, Hanák (or Central Moravian), and Lach (or Silesian). Additionally, there are two transitional dialect areas: a southeast Moravian area, whose dialects are closely related to Slovak, and a mixed Czech-Polish dialect area. Standard Common Czech is linked most closely to the central Bohemian dialects, and particularly to the dialect of the main urban center, Prague. There is, however, a degree of regional variation even within Common Czech, and some now suggest that these are of sufficient magnitude to argue that two distinct regional versions of Common Czech exist—Bohemian Common Czech and Moravian Common Czech. As with Polish, there are also mixed dialect regions in areas along the border with Germany, which had been German-speaking prior to the end of World War II.

Slovak

Slovak is the official language of Slovakia, spoken by around 4.6 million people there. A further 300,000 or so speakers are resident in the neighboring Czech Republic.

Slovak is closely related to Czech and the two languages are, broadly speaking, mutually intelligible. This is particularly the case with the southeast Moravian dialects of Czech. However, there are also some differences between the two languages in both sound and word structure. This is especially true of the written languages, owing to the different language varieties that were drawn on during the period of their codification.

As with Czech, the earliest surviving evidence for Slovak comes from a set of eleventh-century glosses. However, in contrast, no substantial literary tradition existed for Slovak prior to around 1780: instead, Czech took on the role of the written language, although Slovak writers did introduce some distinctively Slovak features into their written Czech. A further similarity with Czech is in the date that, and the process by which, the eventual standard written language did develop. Written Slovak was not codified until the 1840s, when a standardized form was produced by L'udevít Štúr in association with a group of other Slovak intellectuals. However, unlike Czech, where much earlier written usage exerted a strong influence on the newly codified language, the Slovak written language was based primarily on a synthesis of the contemporary spoken Central Slovak dialects. This

must at least in part have been a necessity, owing to the paucity of a written Slovak tradition, but it also mirrors the codification of Polish, where contemporary usage had more influence than it did with Czech.

Slovak has three main dialect areas—West, Central, and East—with the West Slovak dialects being closest to their Czech neighbours.

Sorbian (Upper and Lower)

The Sorbs are an indigenous Slavic minority who live in the region of eastern Germany known as Lusatia. Until 1990, Lusatia was part of the former German Democratic Republic. It now belongs to the federal states of Saxony and Brandenburg. In earlier times, Sorbian dialects extended eastward beyond the River Neisse into what is present-day Poland, as well as westward and northward into further regions of Germany. However, Sorbian is now wholly contained within the Lusatian region.

Today, there have been estimated to be around 60,000–70,000 speakers of Sorbian, although all Sorbian speakers are now bilingual in Sorbian and German, and a number of these speakers use the German language for most everyday purposes. Sorbian has survived most strongly in small, closely knit rural communities, and has been noted as being especially strong in a group of villages to the north of Bautzen in Saxony. However, although its strongest base is among the rural community, Sorbian is not a low-prestige rural dialect and has a lively literary and scientific culture.

Apart from proper names, the earliest surviving evidence for Sorbian vocabulary consists of glosses in Latin manuscripts dating from the twelfth century. The earliest continuous Sorbian texts date from the sixteenth century. These earlier Sorbian texts were written in local dialects with distinct differences from one another. In the eighteenth century, three standard written varieties emerged: Lower Sorbian, Catholic Upper Sorbian, and Protestant Upper Sorbian, with Upper Sorbian thus being split on denominational lines. (Since the Lower Sorbians were Protestants, the issue did not arise for that variety.) At that time, only religious texts were published in Sorbian. From the mid-nineteenth century onward, alongside an increase in nonreligious writing, the denominational split in Upper Sorbian was gradually diluted, although it was not until after World War II that the present twofold division of Sorbian was firmly established.

There are two present-day standard varieties of Sorbian. Upper Sorbian is the language of the Sorbs in Upper Lusatia (centered around Bautzen in Saxony) and is the larger of the two varieties with roughly 40,000–50,000 speakers. Lower Sorbian is the language of the Sorbs in Lower Lusatia (centered around Cottbus in Brandenburg), spoken by approximately 20,000 speakers. Upper and Lower Sorbian have a number of differences from one another, and these occur at all language levels, including sound structure (e.g. Lower Sorbian has *góra* in place of Upper Sorbian *hora*), vocabulary (e.g. Lower Sorbian has *jo* for 'yes', whereas Upper Sorbian has *haj*), and grammar (e.g. Upper Sorbian makes more use of possessive adjectives than Lower Sorbian).

In contrast to the two standardized varieties, the features that distinguish the several Sorbian dialects show a rather complex distribution, given the small size of the language area. Nevertheless, broadly speaking, it is possible to make a primary distinction between Upper and Lower Sorbian dialect areas, with a transitional area, showing features of both, located in between.

Having coexisted for such a long time alongside German, Sorbian has been affected by a number of Germanic influences, several of which are not shared by the other West Slavic languages. These influences have occurred not only at the vocabulary level but have also affected the grammar of Sorbian. For example, most Slavic languages do not have articles (such as *a*, *an*, and *the* in English). However, under German influence, Sorbian has made use of its demonstrative pronouns and the number 'one' as, respectively, definite (*the*) and indefinite (*a/an*) articles, although this practice is discouraged in the standard written languages, which have been subject to Slavic purist movements. Lower Sorbian probably retains more German influences than Upper Sorbian, which was subject to a more intensive push toward purism. German influence on Lower Sorbian was formerly also evident at the orthographic level, with much Lower Sorbian publishing using the German *Fraktur* type until around the time of World War II.

As a small minority language within a German-speaking context, the number of speakers of Sorbian has declined substantially over the past century. However, there are lively movements to preserve its use and the future is not necessarily bleak. The rights of the Sorbs have been legally guaranteed within a bilingual framework since the end of World War II, firstly by the former German Democratic Republic and subsequently by the federal states of Brandenburg and Saxony. To promote and maintain the language, a number of initiatives exist, including the provision of bilingual schooling from an early age (the WITAJ initiative).

Polabian

Polabian, sometimes known as Dravaeno-Polabian, is an extinct West Slavic language. The last native speaker is reported to have died in 1756, although there are records of someone able to recite the Lord's Prayer in Polabian as late as 1798. Polabian was formerly spoken in a small

part of the Lüneburg area, which is situated in north Germany between Hamburg and Hannover. It was thus surrounded by German-speaking territory from an early point in its history and was geographically isolated from the other Slavic languages. (Contrast Sorbian, which has retained a border with both Polish and Czech.) Not surprisingly, therefore, it shows evidence of a very strong German influence, especially from the regional Low German varieties, both in vocabulary and grammar.

Very little Polabian material has survived, and much of what has is in the form of isolated words and phrases compiled into dictionaries in the last century of the language's existence. Only a small number of complete texts, such as the Lord's Prayer and a folk song, have been preserved. A figure of around 6,000 recorded vocabulary items has been suggested. This has nevertheless provided enough evidence to suggest that at least three dialects existed.

Despite this lack of material, and in view of its unusual isolation from related languages, Polabian has received continued and substantial attention from linguists, including notable figures such as Trubetzkoy.

Politeness

Politeness refers to how a speaker chooses to phrase an utterance in a particular context, a choice that can reflect the speaker's view of the interpersonal context. There are a number of different approaches to politeness. In a social normative view, to be polite is to speak formally and to behave in accordance with situation-specific rules regarding appropriate linguistic behavior. A variant of this approach has been to regard politeness as one component of pragmatic competence (Leech 1983). In this view, there are conversational maxims (e.g. tact and generosity) that stipulate which linguistic form is preferred over another in any particular context.

Currently, the most popular approach to politeness, based on the work of Brown and Levinson (1987), views politeness as the linguistic means by which people manage each other's 'face'. The concept of face (Goffman 1967) refers to the identity that people present during the course of their interactions with others. Face is assumed to be universal and of two types: negative face, or the desire to have autonomy of action, and positive face, or the desire for closeness with others. One's face is fragile and subject to continued threat during social interaction. For example, criticisms threaten the recipient's positive face, and requests threaten the recipient's negative face. Social interaction thus presents a dilemma for interactants; they want to maintain each other's face, but they are also motivated to perform actions that are face-threatening. This conflict is solved by engaging in face-work, or, more precisely, by being polite.

According to Brown and Levinson (1987), politeness is conveyed by deviating from maximally efficient communication; politeness is thus roughly equated with indirectness. There are many ways this can be accomplished, and Brown and Levinson organized politeness into five superstrategies. They provided evidence for these strategies from three different languages and argued that the linguistic strategies for conveying politeness are universal. The least polite strategy is to perform an act without any politeness, or to perform the act directly. The most polite strategy is to perform the act with an off-record form. Off-record forms are deliberately ambiguous and hence perform a face-threatening act indirectly (e.g. *It's warm in here* as a request to have the window opened). Falling between these two extremes are on-record (i.e. relatively unambiguous) acts with redress emphasizing either positive face or negative face. The former, termed 'positive politeness', functions via an exaggerated emphasis on closeness or solidarity with the hearer. Examples

include the use of slang and familiar address terms, jokes, and presumptuous optimism (*You'll loan me your car, won't you?*). The latter, termed 'negative politeness', functions via attention to the recipient's autonomy. This is accomplished by symbolically lessening any imposition on the hearer. A common method is to use conventionally indirect forms (e.g. *Could you shut the door?*). Research has provided partial support for this typology. It appears, however, that politeness strategies are very diverse and may not be completely captured with this scheme. Also, it is unclear whether politeness should be equated with indirectness; very indirect strategies may sometimes backfire and may be perceived as manipulative.

One of the most important features of a face-management view of politeness is the attempt to specify the relationship between politeness and the interpersonal context. Brown and Levinson (1987) proposed that politeness will vary as a function of the weightiness (or degree of face-threat) of the act to be performed. Weightiness is contextually determined and assumed to be an additive weighting of the following three variables: the intrinsic (and culturally bound) degree of imposition of the act itself (e.g. asking for a loan of $5 is less imposing than asking for a loan of $500), the power of the hearer relative to the speaker, and the degree of social distance between the interlocutors. Thus, increased weightiness (hence, in general, greater politeness) occurs as a function of increasing imposition, hearer power, and relationship distance. Note that in this way the politeness of an utterance cannot be determined in isolation, but rather only in a specific interpersonal context. For example, an utterance perceived as polite when used with an underling may not be polite when directed toward a superior.

Research has provided partial support for these ideas. Many studies have demonstrated that greater speaker power is associated with decreased politeness. Fairly consistent support has also been found for the imposition variable, with increasing imposition associated with increasing politeness. The effects of relationship distance have been the most problematic; whether greater politeness is associated with increasing relationship distance is not clear.

One of the most important issues surrounding politeness is its status as a cultural universal. Although few would argue the claim that politeness exists in all cultures, the claim that positive and negative faces are universal desires motivating the form that politeness takes has been questioned. For example, it has been argued that negative face is relevant only in Western cultures, or cultures in which there is an emphasis on individual autonomy. Although Brown and Levinson (1987) marshaled impressive evidence for the cross-cultural validity of their politeness strategies, empirical support for their claim that they are universal has been rare. Clearly, there is great cultural variability in politeness. The crucial question is whether this variability is a result of differing cultural conceptions of face or whether these differences can be explained at a lower level of abstraction. Face wants may be universal, but cultures will vary in terms of what threatens face, who has power over whom, how much distance is typically assumed, and so on.

Recently, there have been some new developments in politeness theory. Some researchers have used it as a framework for explaining how people interpret indirect utterances. Others have begun to examine nonverbal politeness. Finally, many researchers are now using politeness theory in applied contexts as a means of examining and explaining linguistic behavior in specific contexts, such as courtroom trials, classroom interaction, and political campaigns.

THOMAS M. HOLTGRAVES

Possessives

Possessive marking is used to indicate that two nouns or noun phrases stand in a modifying relationship, namely that of possession. One noun (phrase) is the modifier, the possessor, and the other noun (phrase) is the modified, the possessed. According to the position of the modifier, two kinds of possessives are available

in English: one is marked by the genitive case (*my father's books*) and the other by a preposition (*the books of my father*).

According to traditional grammars, the genitive possessive refers to a specific entity or individual. It is more frequent with modifiers referring to animate entities, i.e. living things, but certain inanimate modifiers can also take the genitive, such as geographical names (**Canada's** *farms*), temporal nouns (**yesterday's** *paper*), and the names of institutions (**the university's** *council*). The use of inanimate modifiers also depends on the modified noun and is generally possible with modified nouns referring to places (*the earth's **surface**, the water's **edge**, at the road's **end***) and measures (*arm's **length***). The preposition *of* is used in partitive constructions (*a piece of wood, a kind of letter*) and expressions denoting a place of origin (*Jesus of Nazareth*), quality (*a man of affairs*), and material (*a sword of steel*).

The genitive modifier can function as a determiner and thus excludes the use of other determiners (such as *the* or *a*). For example, it is not possible to say **the** *my father's **book***. To use a determiner, the so-called 'double genitive' construction must be used—that is, *a book of my father's*. The double genitive can be used with the indefinite article *a* and with demonstrative pronouns such as *that* or *this* (**a/that/this** *book of my father's*). The definite article can generally not be used in double genitive constructions: **the** *book of my father's* is not a possible English phrase. However, if there is a modifying relative clause, use of the definite article becomes possible: **the** *book of my father's **that is on the table***.

Genitive and prepositional markings can reflect the subject/object distinction in constructions like *the enemy's destruction of the city*. Here, the nouns *enemy* and *city* receive the same interpretation as in the sentence *the enemy destroys the city*. In both cases, *the enemy* has a subject-like function, while *the city* is the object. This parallelism was an important piece of evidence in a heated linguistic debate concerning nominalization, the process of deriving a noun such as *destruction* from the corresponding verb, here *destroy*. In grammatical theories of the 1960s, it was assumed that a noun phrase like *John's presentation of the project* is derived from the synonymous sentence *John has presented the project*.

This view changed with Noam Chomsky's widely quoted article 'Remarks on nominalization' (1970). Chomsky argued—convincingly to many linguists—that any noun can 'project' structures containing a subject and an object. Thus, for phrases like *the enemy's destruction of the city*, the base structure would be [*enemy destruction city*]. For comparison, the base structure for *The enemy destroyed the city* would be [*enemy destroy city*]. Nouns and verbs thus 'generate' or 'project' very similar structures at an abstract level.

The only difference between noun phrases and verb phrases (or sentences, for that matter) lies in the elements that are used to mark the exact relationships between the individual items. In the case of noun phrases, the possessive is the relevant grammatical marker for the subject. The markers *'s* and *of* thus were considered to be 'semantically null', i.e. they do not contribute any particular meaning to the sentence. Chomsky (1986) assumed that both are simply overt realizations of the genitive (case).

In fact, possessive markers have no semantic content in cases of so-called 'inalienable' possession. For example, the expression *John's picture* may have two 'inalienable' readings: (1) 'John has created the picture' vs. (2) 'John is in the picture'. Both are cases of inalienable possession, because nobody can take away the fact that 'John created the picture', or nobody can take John out of the picture (without destroying the picture). In other words, the entities *John* and *picture* are inseparable and presuppose each other (i.e. an inherent relationship). If *John* is construed as a creator of the picture, this noun is inserted in the subject position [*John picture*], which automatically leads to the genitive expression *John's picture*. If, on the other hand, *John* is the object of *picture*, the base structure would be [*picture John*], and the default phrasing would be *the picture of John*. However, if no creator is specified, i.e. if the subject position is left empty in the base structure, English allows 'promotion' of the object, which again yields the genitive *John's picture*. Hence the potential ambiguity of English genitive expressions.

However, Mona Anderson (1983) argued that the genitive *'s* does contribute independent meaning in cases of 'alienable' or 'true' possession. Thus, the expression *John's picture* can also be interpreted as 'The picture that John owns'. This means that the relation between *John* and *picture* is not inherent but is established by means of the 'word' or 'lexical unit' *'s*. Note that *'s* can be labeled a word, since it fulfills a function similar to 'full' words, namely *possess* or *own*. In other words, in this case the phrase *John's picture* is projected not from the noun *picture* but rather from the possessive *'s*, and the base structure would be [*John 's picture*], similar to [*John possess picture*] or [*John own picture*].

The idea of lexical *'s* has been commonly accepted since the second half of the 1980s, and it has been extended to other structures. For instance, *his book* has been analyzed as deriving from the base structure [*he's book*], where *he* is the subject and *book* is the object of the word *'s*.

In a crosslinguistic perspective, the distinction between genitive and prepositional possessives is not universal. In French, for example, a genitive marker analogous to the English *'s* does not exist. Thus, the

English expression *Robert's friends* is translated in French as *les amis de Robert* (literally *the friends of Robert*). Russian, on the other hand, has no preposition corresponding to the English *of*. For instance, two constructions are available to translate the English expression *Robert's friends*: (1) *Robertovy druzja*, where *-ov-* is a possessive marker, and (2) *druzja Roberta*, where *-a* is a morphological manifestation of genitive case.

Historically, the marker *'s* originates from the genitive case singular marker *-es* used in Old English. For example, in the sentence *Him sceamode þæs mannes* 'He felt ashamed for the man', this ending is observed on the noun stem *mann* 'man' preceded by the genitive form of the demonstrative *se* 'the, that', i.e. the literal translation would be something like 'To-him there-was-shame the-of man-of.' Similarly, *þurh geswicenysse yfeles* 'by cessation from evil' is literally 'through cessation evil-of', and *cyninges botl* 'a king's palace' is 'king-of palace.' Since the genitive ending already sufficiently performed the function of expressing possession, the preposition *of* did not mark possessive phrases in Old English. Prepositional marking becomes much more frequent in Middle English. The latter is characterized by a common use of the so-called 'group genitive' constructions like *the king of France's son* corresponding to *þæs cyninges sune Frances* 'the-of king-of son France-of' in Old English.

This change was caused by the increasing loss of case inflections and the resulting increased importance of function words.

In conclusion, the possessive markings *'s* and *of* are usually realizations of genitive case in English and establish a grammatical relation between two nouns, but English *'s* also has a lexical use. The manifestation of genitive case varies across languages and historically also within a given language.

Pragmatics

Pragmatics is the study of language use. Whereas the study of grammar focuses on the language system, pragmatics offers a complementary perspective on language, providing an insight into the linguistic choices that users make in social situations. Pragmatics is, for instance, interested in how people pay compliments, engage in small talk, or write e-mails. The communicative functions of utterances or texts, and the speakers' or writers' intentions behind them, are of particular interest. Historically, the emphasis was on spoken language.

The term 'pragmatics' was first used in semiotics, the general theory of signs. In this theory, pragmatics pertains to the relationship between signs and their users. In linguistics, pragmatics deals with verbal signs (words, utterances, texts) and how they are used by humans in communication. The term 'pragmatics' is derived from Greek *pragma*, which means 'action'. Action is defined as intentional behavior. Pragmatics studies verbal communication as a complex form of intentional behavior, which is interactive, i.e. partner oriented, and symbolic, i.e. conventionalized and culture specific. In the English-speaking world, pragmatics was originally considered part of sociolinguistics.

Pragmatics is a relatively young field of study. So far, there is no coherent pragmatic theory. Pragmatics developed from linguistic, philosophical, and sociological approaches to language use. The so-called pragmatic turn in linguistics was brought about by the writings of a group of philosophers known as speech act theorists in the late 1960s. Until then, mainstream linguistics had focused on linguistic forms and structures, neglecting meaning and ignoring communicative functions and language users.

Initially, pragmatics was dominated by the speech act theory. The basic insight of this tradition is that speech is action. Whenever we say something, we do not only produce sound waves, utter words, and produce sentences but we also perform an action. If a mayor says, *I declare this bridge open*, then this bridge is open. In this sense, the mayor has performed an action.

Speech act theory aims at establishing how many fundamentally different ways there are of doing things with words. Bridge-opening belongs to 'declarations', a class of speech acts that all require an institutional context. Four further classes have been identified, which are more likely to occur in everyday communication. These are 'directives', 'commissives', 'expressives', and 'assertives'. Typical examples for these classes are requests, promises, apologies, and statements, respectively.

In linguistics, the study of language use focuses on the individual speech acts that belong to these fundamental classes, e.g. requests, promises, and apologies, and on the linguistic resources used to perform them. Empirical pragmatics aims at systematically determining the different strategies that people actually use to realize a particular speech act. A classic case is requesting. For instance, if you want a person to take out the garbage, you may say: *Take out the garbage!*, *You ought to take out the garbage*, *How about taking out the garbage?*, *Can you take out the garbage?*, *Garbage day tomorrow*, etc. These strategies differ in their degree of directness. The most direct strategy is to use an imperative construction, and the least direct strategy is to only hint at the desired action. Directness must not be confused with politeness. The degree of directness is a feature of any strategy independent of context, whereas the politeness value of an utterance depends entirely on the social situation.

Theories of verbal politeness have also contributed to the development of pragmatics. According to one particular politeness theory, any speech act may, at least potentially, interfere with the wants and needs of hearers. This is obvious if a speaker wants a hearer to do something. It is less obvious in the case of social niceties, but a compliment, for example, may also be interpreted as harassment. Given the threatening potential of all speech acts, speakers are thought to calculate the imposition involved in the respective situation and then select from a range of direct and indirect strategies available for realizing the act in question. Also, any of these strategies can be modified in a number of ways. For instance, speakers can say, *Could you perhaps take out the garbage, darling?*, where *perhaps* and *darling* serve to modify the basic strategy, *Could you take out the garbage?* Modifications are motivated by polite considerations and aim at reducing the social risks involved in performing the act in question.

A distinction can be made between pragmalinguistics and sociopragmatics. 'Pragmalinguistics' is concerned with the verbal resources available for realizing any given speech act. By contrast, 'sociopragmatics' focuses on the polite norms governing the selection of resources relative to social situations. For example, pragmalinguistics identifies the word choices, meaning patterns, and sentence constructions that are used to pay a compliment, whereas sociopragmatics determines who may compliment whom on what in which situations. Pragmalinguistics is language specific, and sociopragmatics culture specific.

In empirical pragmatics, five types of inquiry can be distinguished. Studies may focus on speech act realization in one language alone, or they may compare speech acts across languages. The second type is known as contrastive pragmatics. It aims at answering questions such as these: how do speakers of English and speakers of Japanese formulate complaints? By contrast, cross-cultural pragmatics examines differences and similarities in social norms and cultural values governing polite choices. A typical question is this: how do members of US American culture and members of British culture refuse offers? A fourth branch of empirical pragmatics is interlanguage pragmatics, which is the study of language use in a second or foreign language. The fundamental question here is the following: how do language learners perform and interpret speech acts in the target language? Finally, applied pragmatics focuses on problems of communication in practical contexts, such as courtrooms, medical interviews, or international business encounters.

Both natural and elicited data are analyzed in empirical pragmatics. Natural data, which occur in everyday situations, are recorded by using field notes, audiotape, or video. Further sources are large corpora of spoken language, such as the Santa Barbara Corpus of Spoken American English. Alternatively (or additionally), a wide range of research instruments is used to elicit data. Tools include role plays, questionnaires, and interviews. Fictional material is also used, e.g. dialogue in narrative prose or drama.

All approaches to language use discussed so far focus on speakers and their intentions, rather than on hearers and their interpretations. How hearers understand utterances is dealt with in a theory of conversational maxims, which also developed in speech act philosophy. According to this theory, hearers assume that speakers behave cooperatively at all times (cooperative principle). More specifically, hearers expect speakers to observe a set of conversational maxims, involving 'Don't lie' (maxim of quality), 'Say as much as is necessary, no more and no less' (maxim of quantity), 'Be relevant' (maxim of relation), and 'Be brief' (maxim of manner). If an utterance does not, for example, seem to relate to

what was said before, or if maybe more or less is said than is necessary, then the hearer tries to work out an interpretation that makes sense in the given context. This process is called 'inferencing'. A pragmatic theory of communication and cognition that focuses on the process of understanding utterances is relevance theory. It is based on the conversational maxim of relation.

In everyday communication, people do not always observe the maxims of conversation. For example, people lie, talk too much, or make obscure statements. Such behavior can be explained by assuming that a politeness principle may conflict with the cooperative principle. In a particular situation, conversationalists may rate politeness maxims higher than the conversational maxims. For instance, a 'white lie', which violates the maxim of quality, can sometimes be more considerate than telling the truth. Generally speaking, maxims of politeness minimize unfavorable effects for the hearer or increase favorable effects. For example, positive evaluations expressed in compliments are often maximized, whereas impositions involved in requests are usually reduced.

Most theories of language use and most empirical approaches are speech act-based, i.e. they focus on utterances in isolation. Speech act-based pragmatics is referred to as micropragmatics. Its shortcomings are remedied in macropragmatics, which provides a fuller picture of language use by accounting for the dialogical and interactive nature of human communication. Macropragmatic approaches do not focus on the speaker or hearer alone, but rather on participants in communication who alternately adopt the role of speaker or hearer. Also, they challenge the view that the speech act is the central communicative unit and claim that the 'exchange' is more important. An exchange minimally consists of two speech acts. The first act functions as an initiating 'move', and the second act as a responding 'move'. Moves indicate the interactive function of an act relative to the immediate verbal context. Typical exchanges are question–answer, offer–refusal, and greeting–greeting. Between initiation and response, countering moves can occur, as in *Can you take out the garbage?* (initiating move) *Why don't you take it out yourself?* (countering move) *Okay, okay. Calm down, I will* (responding move). An exchange is closed when an outcome has been reached.

In macropragmatics, complete communicative events such as conversations, interviews, debates, etc. are analyzed. Communicative events are considered hierarchical structures. The hierarchy, starting with the smallest unit, involves acts, moves, exchanges, sequences, and phases. At each of these levels, there are obligatory units (heads) and optional units (supportives). Thus, we distinguish head moves and sup-

portive moves, head exchanges and supportive exchanges, and so on. For example, the utterance *Can you lend me ten dollars? I've left my purse at home* consists of a head move, which is the request, and a supportive move, which is an explanation.

The type of macropragmatics sketched here is based on British discourse analysis, which was developed in linguistics. An alternative approach is conversation analysis, which originates in American sociology. In conversation analysis, the term 'adjacency pair' is used for the exchange unit. Another unit identified in conversation analysis is the 'turn'. Conversationalists take turns at talk. A turn is defined as a speaker's contribution at a particular point in a conversation. It is surrounded by speaker switches. Turns may differ considerably in length. Prototypically, a turn consists of a second pair-part to match the previous speaker's first pair-part and a first pair-part that must be matched by the next speaker. In conversation analysis, the mechanisms of turn-taking and turn-allocation for encounters involving two or more speakers have been identified, and simultaneous speech and interruptions have also been investigated. Conversation analysis differs from discourse analysis in using only naturally occurring conversation, whereas discourse analysis also works with other data types, including fictional dialogue.

Most research in pragmatics deals with present-day language. Recently, however, an interest has also developed in earlier periods. Two branches have evolved, namely, historical pragmatics and diachronic pragmatics. Historical pragmatics deals with previous stages of language, e.g. Old English or Middle English. By contrast, diachronic pragmatics studies development across time. In both types, two alternative perspectives can be adopted. On the one hand, the way in which a particular communicative function, e.g. a speech act, was realized at different times may be examined. On the other the researcher may start with a particular expression, e.g. a routine formula, and describe its uses in certain periods or in the course of history. It is not always possible to keep these two perspectives apart. Typical research topics in historical pragmatics include greetings in the fifteenth century and politeness strategies in Shakespeare's plays. Topics for diachronic pragmatics include, for instance, insults in Old, Middle, and Modern English or changes in apologizing through the ages. Although all historical sources are in the written mode, some include a considerable amount of information on spoken language. For example, court reports may incorporate detailed accounts of what defendants or witnesses actually said. Finally, recent and ongoing pragmatic change may be studied in e-mails and chat-room conversations, because netiquette is only just emerging.

Another recent development in pragmatics is the study of synchronic variation in contemporary language use. Sex differences have been examined to some extent, but regional, social, and ethnic variation has not received much attention in pragmatics. Sociolinguistic research suggests that we can expect speech act realizations, politeness markers, discourse strategies, and turn-taking, etc., to vary across regions, urban and rural communities, social classes, and ethnic groups. This is an area for future investigation.

In short, pragmatics is the study of language use. Pragmatics is not a component of the language system, but it offers a different perspective on verbal phenomena. It examines how linguistic resources are used in communication and investigates a speaker's (or writer's) intentions and a hearer's (or reader's) interpretations. Language use is considered a complex form of social action. The general question addressed in pragmatics is how language functions in the lives of human beings. The focus can be on utterances (micropragmatics) or on longer stretches of discourse (macropragmatics). Pragmalinguistics is concerned with the structural resources that a language provides for conveying particular intentions, whereas sociopragmatics considers language use relative to social situations. There is no coherent pragmatic theory to date. Theoretical pragmatics draws on a number of disciplines, including philosophy, sociology, and anthropology. Speech act theory, politeness theory, discourse analysis, and conversation analysis provide major contributions. Empirical pragmatics involves the investigation of speech act realizations, politeness phenomena, and discourse strategies on the basis of natural, elicited, and also fictional data. The comparison of language use across languages and cultures is also an important empirical research component. Applied pragmatics focuses on problems of communication in practical contexts. Most pragmatic research investigates present-day language, but recent developments also include historical and diachronic perspectives.

Predication

Although predication is extremely important in contemporary linguistic research, it is a very old concept tracing back to Aristotelian logic, where it emerged to indicate the semantic relationship existing between the event described in a proposition and the individuals participating in such an event. Due to its origin in the Western philosophic tradition, the linguistic analysis of predication has been approached for a long time from a semantic perspective. From the 1980s onward, however, its study took a different course due to the advent of several transformational theories mostly devoted to examine the syntactic behavior of predication.

Being traditionally accounted for in semantic terms as the connection between a predicate—the event expressed in the clause—and its arguments—the entities involved in the event—the semantic analysis of predication has been mainly interested in how this linking takes place. The most common answer to this question is found in Theta Theory—that is, the lexico-semantic module of the transformational theoretical framework known as Government and Binding. Since it is chiefly concerned with the predicate's assignment of theta roles to its different arguments, it specifies the exact number of arguments a particular predicate requires and their semantic nature; that is, if they take part in the predication as agents, patients, experiencers, themes, etc. It must be noted, however, that, being unlimited in number, there is no agreement as regards

the name and catalogue of these detailed semantic traits alloted by a predicate to its arguments, generally called theta roles. Regardless, the main principles underlying Theta Theory are formulated in the well-known Theta-Criterion, which postulates the following restrictions on the assignment of theta roles: (a) every argument in a predication must receive one theta role from its predicate; (b) the same theta role cannot be assigned to more than one participant in the predication. According to Theta Theory, then, and as illustrated in *Mary gave some money to her little brother*, a predicate like *give* needs three arguments bearing the following theta roles to be completed: an agent (*Mary*), a theme (*some money*), and a recipient (*her little brother*).

From the syntactic viewpoint, predication is defined via saturation: a predicate is a maximal projection—that is, a full phrasal category—and, consequently, an open function, which must be syntactically closed by the appropriate arguments to form a grammatically acceptable chain. Despite being the maximal projection with the strongest predicative capacity, the verbal phrase is not the only one able to function as predicate: *The girl read her cousin a book*. The adjectival (*Bill is fond of Jan*), the nominal (*This ratty piece of leather is a wallet*), the prepositional (*Those sisters are on drugs*), and the adverbial phrases (*She feels a bit down today*) can also perform, as illustrated between brackets, the predicative function. Although different predicates demand a different number of arguments, as the previous examples show, they all share the property of having, at least, one compulsory argument: their subject. This argument (*The girl, Bill, This ratty piece of leather, Those sisters* and *She* in the previous examples) differs from the rest of possible arguments that a predicate may have both semantically and syntactically: semantically, because it constitutes the starting point for the predication; that is, it is the participant the predication is about; and syntactically, because it is the predicate's only external argument. Although the subject and predicate constituents are unanimously said to be in a relation of mutual c-command—that is, they are syntactic sisters dominated by exactly the same maximal projections—the two main transformational approaches to the study of predication explain the subject–predicate syntactic relationship in different ways: the Predication Theory, for instance, considers that subject and predicate are independent structural components, whose syntactic relation has to be marked by indexing at surface structure, and the Clausal Theory defends, in turn, that they both form a single constituent having clausal status either with or without verb. If this is the case, the clause containing the predication relationship is catalogued as small. An example of a small clause is, thus, represented by *Jill a nice person* in *Rachel considers Jill a nice person*.

Although the previous syntactico-semantic characterization applies to predication in general, some refinements must be made because not all instances of predication exhibit the same grammatical behavior. Predication cannot be considered, therefore, a homogeneous linguistic phenomenon, but rather a heterogenous one involving two distinct classes of predication: primary and secondary predication. The former corresponds to the prototypical notion of predication because, being syntactic and semantically independent, it embodies the basic and matrix predicative relationship occurring at the level of the clause: *John painted the house, John eats carrots*. The latter lacks, in turn, such syntactico-semantic autonomy and must always appear, consequently, complementing an instance of primary predication: *John painted the house red, John eats the carrots raw*. The aforementioned contrast is, furthermore, extremely important because it determines the status of the subject of each type of predication: whereas the subject of a primary predication is systematically, like *John* in the previous examples, the predicate's theta-marked external argument, the subject of a secondary predication displays a dual function: it is the secondary predicate's theta-marked external argument at the same time as a theta-marked argument of the primary predication; notice, for instance, that in the examples above, *the house* and *the carrots* are, on the one hand, the subjects of the secondary predicates *red* and *raw*, and on the other, the direct objects of the primary predicates *painted* and *eats*.

Besides these contrasts, two semantic types of secondary predication must be distinguished: resultative and depictive secondary predication. The former, as illustrated by *the house red* in the previous example, signals a potential result of the action denoted by the verb and can only be predicated by the direct object argument of the primary predication; the latter, in turn, does not maintain any semantic relation with the verbal predicate it complements, because, as shown by *raw* in the aforementioned example, depictive secondary predicates denote intrinsic and temporary properties of the subject or direct object arguments of the primary predication, which must exist at the time of the verbal action.

Professions for Linguists

Linguists study aspects of language, languages, and language use. With this diversity of focus, linguists may be found in many different professions. Linguists are used in both private and public sectors, in jobs related directly to linguistics, as well as in professions where a knowledge of language or language use is highly relevant, although not directly required.

The nature of language has interested scholars for over 2,000 years. The earliest works of a linguistic nature date to some of the first writings known to humankind. Such early linguistic writings include discourse on the nature of language and humanity (e.g. Socrates), the reconstruction of the spoken language of the Vedas (e.g. Panini in India), and the translation of texts and codification of languages (e.g. the trilingual Rosetta Stone, Varro's grammar of Latin). The description of child language acquisition has also fascinated scholars through the ages, including scientists (e.g. Charles Darwin), psychologists (e.g. Piaget), philosophers (e.g. Rousseau), and others. In fact, the disciplines within which linguists have worked have included philosopher (e.g. Plato, Locke, Hume), grammarian (e.g. Dionysius Thrax, Cicero), philologist (e.g. Saussure), anthropologist and field linguist (e.g. Boas, Sapir), psychologist (e.g. Skinner, Piaget), scientist (e.g. Bloomfield), and 'linguist' within an independent field of research (e.g. Chomsky).

In their professions, linguists may focus on the sounds of the language (e.g. phonetics, phonology), the words of the language (e.g. semantics), how words combine (e.g. syntax, discourse), how speakers acquire and/or use language (e.g. sociolinguistics, psycholinguistics, applied linguistics, dialectology), how the human brain processes language (e.g. psycholinguistics, neurolinguistics), how to program machines to carry out voice recognition/voice synthesis (e.g. computational linguistics), or even how animal communication systems, or languages, work (e.g. zoosemiotics).

The sounds of language are the focus of phoneticians in the fields of acoustic phonetics (e.g. the study of the physical properties of speech sounds using instrumental techniques of investigation to provide an objective account of speech patterns, which can be related to the way sounds are produced and heard), auditory phonetics (e.g. the study of the way people perceive sound, as mediated by the ear, auditory nerve, and brain), or articulatory phonetics (e.g. the study of the use of the vocal organs (articulators) to produce the sounds of speech).

The sound systems of language are of interest to phonologists, who study the sound systems of languages and the general or universal properties displayed by these systems.

Phonetics and phonology are also relevant to the teaching of pronunciation, speech pathology and speech therapy, accent reduction, voice and drama coaching, elocution and public speaking, forensic linguistics (e.g. voice recognition, voice printing), sound engineering, and the growing area of speech synthesis and voice activation in the computer industry.

Syntacticians study the structure (or grammar) of languages, including the way words are combined to form sentences, relationships between the elements of sentence structure, and the rules governing the arrangement of sentences in sequences. Meaning in language, in terms of relations such as synonymy and antonymy, is the domain of semanticians. Issues such as to what extent semantic concepts are universal is a current area of focus.

In addition to academic research, syntacticians and semanticists work on dictionaries and grammars of different languages, develop and study computer languages and computer translation, preserve endangered and dying languages through field research, provide forensic analysis for the legal system, develop language tests, develop language policy and other educational curriculum, work in language reconstruction

(with archeologists), etc. Linguists also work for intelligence agencies as spies, translators, interpreters, code-breakers, and computer programmers.

Professions for linguists related to the acquisition of first/child language include developmental linguistics and developmental psychology, psycholinguistics, early childhood education, deaf education, teaching, speech therapy, speech pathology, textbook and curriculum development, and software development. Similarly, professions for linguists related to the acquisition of second or additional languages include applied linguistic research, ESL/EFL teaching, foreign and modern language teaching, bilingual/bicultural education, teacher training, translation, proofreading, marketing, textbook writing and publishing, editing, speech therapy, speech pathology, software development, website design and marketing, on-line teaching, recruiting students for language schools (e.g. agents), owning language schools and other related businesses, developing and implementing multicultural policies, facilitating minority language rights, language policy, language planning in business and government services, and as freelance consultants (e.g. providing program development/analysis, giving seminars on gender issues in the workplace, cross-cultural training, etc.).

Some additional areas within linguistics in which linguists are employed include anthropological linguistics (the study of languages in relation to social and cultural patterns and beliefs); areal linguistics (the study of geographical areas that are characterized by shared linguistic properties); audiology (the study of hearing and hearing disorders) biolinguistics (the study of the biological preconditions for language development and use); dialectology (the study of dialects, dialect geography, or linguistic geography); *historical linguistics* (the study of language variation and/or change); *neurolinguistics* (the study of the basis in the human nervous system for language development and use); philology (the study of language history, including historical study of literary texts); *philosophical linguistics* (the study of the role of language in relation to philosophical concepts, as well as the philosophical status of linguistic theories, meth-

ods, and observations); pragmatics (the study of the conditions on language use deriving from the social situation); semiology (the study of signs and their use, focusing on the mechanisms and patterns of human communication and on the nature and acquisition of knowledge); semiotics (the study of language as one type of sign system, along with bodily gestures, clothing, and the arts); sociolinguistics (the study of how language is integrated with human society with reference to race, ethnicity, class, sex, and social institutions); and zoosemiotics (the study of animal communication systems).

In the new millennium, with globalization and the explosion of new communication technologies, the knowledge and expertise of linguists are increasingly in demand in the fields of education, business, technology, health, law, and communications. The field that began with philosophical explorations of language and humanity is now recognized as being in the forefront of human/machine interfaces in the twenty-first century.

Proficiency Testing

The term proficiency *testing* embodies two main viewpoints: an earlier, traditional one referring to tests of ability to use a language for some extralinguistic purpose, and the more recent 'Proficiency Movement'

in foreign language assessment associated with the American Council on the Teaching of Foreign Languages (ACTFL).

Traditionally, proficiency testing has been contrasted mainly with achievement testing in which the test content and method are based on a language teaching syllabus. The purpose of an achievement test is to find out how much students have learned of what has been taught. By contrast, proficiency tests are not linked to any syllabus but rather attempt to measure how well a learner can use the language regardless of the circumstances in which it was acquired. Lado (1961) was the first to make this contrast explicit:

> [Achievement] tests...attempt to measure how much of a language a student knows. When the...tests are thought of independently of the learning experience, they may then be referred to as proficiency tests. Proficiency tests measure how much of a foreign language a person (not necessarily a student) knows. (p. 369)

Note that Lado speaks of the purpose of the proficiency test as measuring how much of the language a person knows, reflecting his 'discrete point' approach to test development wherein specific grammatical points are tested more or less in isolation. At about the same time, other scholars were calling for proficiency tests that required language performance in contexts of use. For example, Carroll (1961 [1972]) argued that

> an ideal English language proficiency test should make it possible to differentiate, to the greatest possible extent, levels of performance in those dimensions of performance which are relevant to the kinds of situations in which the examinees will find themselves after being selected on the basis of the test. (p. 319)

Thus, Carroll explicitly links proficiency testing to performances relevant to future situations, and this has become the standard view of proficiency: ability to use a language for some extralinguistic purpose (Davies et al. 1999).

The extralinguistic purpose that proficiency testing is most often associated with is admission to academic programs. For example, the two best-known proficiency tests, the Test of English as a Foreign Language (TOEFL) and the International English Language Testing System (IELTS), are both used primarily for admission to university programs in the United States, the United Kingdom, and Australia. These tests were developed to answer the question of whether a candidate for admission to an English-speaking academic institution possesses sufficient English ability to cope with academic work.

However, proficiency tests need not be limited to academic situations only. The focus on future uses of the language naturally leads to tests of languages for specific purposes (LSP). For example, the *Occupational English Test* (OET) was developed in Australia to ascertain whether migrant candidates for licensure in the health professions are able to use English with sufficient ability to work with English-speaking patients and clients; the Japanese Language Test for Tour Guides was also developed in Australia; the Test of English for International Communication (TOEIC) is a US test aimed primarily at international business people; and the Proficiency Test in English for Air Traffic Controllers is a European test for trainee air traffic control officers. These and other specific-purpose language tests were developed without reference to any particular course of instruction but rather on the basis of an analysis of a particular target language use situation (Douglas 2000).

The distinction between achievement and proficiency testing is not entirely rigid, either. For example, Bachman (1990) argues as follows:

> Whether or not the specific abilities measured by a given proficiency test actually differ from those measured by a given achievement test will depend, of course, on the extent to which the theory upon which the proficiency test is based differs from that upon which the syllabus is based (p. 71).

Note that Bachman defines proficiency tests as theory-based, and indeed, it is generally the case that proficiency tests are related to some theory of what it means to know and use a language. Since Hymes's (1972) formulation of communicative competence, proficiency test developers have used theories about the components of language knowledge to guide them in deciding what to test. The current, most well-known framework is that proposed by Bachman (1990) and Bachman and Palmer (1996) of communicative language ability, consisting of grammatical, textual, functional, and sociolinguistic language knowledge, plus strategic competence, which directs the use of one's language knowledge in actual communication.

The so-called Proficiency Movement, although more recent than proficiency testing itself, has its origins in the early days of the assessment of the oral language skills of US Government employees, most notably the Foreign Service Institute (FSI), the Peace Corps, the Central Intelligence Agency (CIA), and the military (Lowe 1988). The FSI (now the Interagency Language Roundtable [ILR]) Oral Proficiency Interview became the standard for the testing of spoken language ability, and the American Council on the Teaching of Foreign Languages referred to it in responding to a mandate from the 1979 President's Commission on Foreign Languages and International Studies to establish a series of nationally recognized descriptors that would facilitate assessment of the proficiency of both students and teachers in foreign language programs. The ACTFL Proficiency Guidelines

(1986, 1999) thus 'represent the combined efforts of groups of educators to provide an operational definition for [proficiency], to represent it as phenomena observable and evolving' (Galloway 1987: 26). The Guidelines are directed primarily at assessing the foreign language proficiency of college and university students in the United States, and consist of descriptors of performance in speaking, listening, reading, and writing at Superior, Advanced, Intermediate, and Novice levels, with the latter three levels divided into high, mid, and low categories.

The focus of the Proficiency Movement, as embodied in the ACTFL Guidelines, is the assessment of language production or performance rather than internalized language knowledge or ability for use (Galloway 1987; Lowe 1988), thus distinguishing the Movement from the more traditional understanding of the concept of proficiency described above.

Pro-forms

In linguistics, a pro-form is generally taken as an element used in place of other linguistic element(s). Pronouns are the most common pro-forms used to substitute for a noun or a noun phrase. 'She', for example, is a third-person singular pronoun used in place of a singular human female animate noun such as a woman as in, 'A woman is coming to see you. *She* has called you earlier.'

Although pronouns have often been used as examples of pro-forms, there are other linguistic elements that have comparable properties but do not substitute for a noun or a noun phrase. '*So*', as in 'He thinks it will rain tonight but I don't think *so*,' substitutes for a whole clause, i.e. 'it will rain'.

Here and *there* are pro-forms for locative expressions; bare noun phrases may be substituted with *what* and *one/ones*, and adjectives by *such* and verb phrases by *do*.

The term 'pro-form' was probably first used by Jerrold Katz and Paul Postal (1964) as a mechanism to explain both syntactic and semantic aspects of the substitutions in the above examples. Syntactically, the pro-constituent guarantees the recoverability of a substitution or deletion. Semantically, the pro-form calls for interpretation by retrieving its equivalents.

The term pro-form, since its introduction, has often been used alternately with pronoun, and now it seems to replace pronoun. However, some linguistic elements seem to have comparable properties to pronouns but they are not substitutes for nouns. In fact, there are many other classes of words than nouns that get a different form in the following mention in a text.

Thus, the term pro-form seems appropriate to be used collectively for any kind of substitution.

In the literature of generative grammars, a pro-form is often found as an element that assumes the process of substitution. In these theories, pro-forms can be used as one of the key tests for constituency in syntax: if a string of words can be replaced by a pro-form, these words form a constituent, i.e. a structural unit within the sentence. To illustrate, in the sentence 'The student read a book in the library,' the pronoun *she* can substitute for the noun phrase 'the student', a *there* can stand in for the prepositional phrase 'in the library', and a *did* can substitute for the verb phrase 'read a book in the library'. Consequently, we may conclude that these three types of phrases are constituents.

Moreover, there are some other terms that are loosely used in place of pro-forms. One of these is ellipsis. Andrew Radford (1997) considers ellipsis a process by which redundant information in a sentence is omitted. Pro-forms, however, are not omissions but substitutions. However, some recent work in natural language processing (e.g. by Daniel Hardt 1993) includes pro-form as one category of elliptical forms.

In terms of semantics, a pro-form has no meaning in itself, rather it requires a retrieval of meaning from a previously mentioned element, or antecedent, i.e. the element for which it substitutes. In other words, pro-forms are semantically bound by other elements.

Proper Nouns

Proper nouns (usually known as 'proper names' by philosophers) are basically names of specific people, places, organizations, months, festivals, and so forth. Typical examples are *John*, *London*, *Oxfam*, *January*, and *Christmas*. The investigation of the semantic meaning of proper nouns goes back to the Greeks. In 200 BCE, the Greek grammarian Dionysius Thrax gave one of the most often used definitions: a proper noun signifies an individual being, whereas a common noun signifies a general substance. As time has gone by, philosophers (e.g. John Stuart Mill, Gottlob Frege, Bertrand Russell, and Saul Kripke) and linguists (e.g. Otto Jespersen, Alan Gardiner, and John Algeo) have put forward a number of criteria for the semantic description of proper nouns with reference to the traditional assumption of a proper–common dichotomy.

One of the earliest and most famous criteria was introduced by the English philosopher John Stuart Mill in *A system of logic* (1843). He suggests that a pure proper noun is a denotative sign without connotation. In contrast to a common noun that both denotes and implies attributes, a proper noun is used to denote a specific or unique individual entity regardless of what properties it has. For example, a proper noun like *Victoria* simply denotes the individuals who are called by *Victoria*. It does not indicate any attributes as belonging to these individuals. Sometimes, we do not even know whether it is a woman's name or a place name. With reference to the semantic information about the entities, pure proper nouns are lexically opaque and the entities they designate are normally unpredictable. On the other hand, a common noun is used to subsume similar entities under a generic concept. For example, various books, irrespective of material, size, or purpose, are subsumed under the generic concept *book*. Thus, the use of a common noun for an entity is completely determined by the meaning of the noun. Common nouns such as *chair* are semantically transparent because they have lexical meaning and carry information.

It has been argued that while proper nouns have no meaning in isolation, they carry descriptive meaning when applied in a specific context to a particular person or place. For example, the proper noun *John* is used in English-speaking countries as a name for a male. However, this culturally specific information should not be identified with the meaning carried by a common noun. The information associated with a proper noun is usually changeable, whereas the meaning of a common noun is basically constant.

Within a given context of utterance, proper nouns together with pronouns are two distinct kinds of singular definite referring expressions that enable the hearer to denote the actual referent from the class of potential referents. Unlike pronouns that have some descriptive meaning, proper nouns have reference but not sense. They identify their referents by making use of the unique and arbitrary association that holds between a proper noun and its referent. Moreover, unlike pronouns that are used by different speakers to denote different entities in different contexts, proper nouns are always claimed in any particular context to refer to one and only one entity, although a proper noun may name many individuals. It follows that a proper noun merely serves as an identification mark by singling out an entity from among similar entities. Its function is precisely that of labeling.

In the 1970s, the American philosopher Saul Kripke (1972, 1980) espoused the view that proper nouns are 'rigid designators' that designate the same individual in all possible states of the world whatever their characteristics happen to be. According to Kripke, the proper name *John* is a rigid designator because it picks out particular individuals who happen to be *John* without any defining characteristics in whatever state of affairs we entertain. However, the common noun *chair* refers to the same thing in the world that happens to fit the defining characteristics.

In some languages such as English, it has long been held that the definition for typical proper nouns should also be laid down on the basis of three additional criteria: orthographic, morphological, and syntactic.

Orthographically, it is a graphic convention that English proper nouns are marked with initial capitalization. By the morphological criterion (i.e. the relationships between the parts that make up the proper noun itself when it is more than a single morpheme), a typical English proper noun has no plural suffix in the strictest sense e.g. *Britain—*Britains*. By the syntactic criteria (i.e. the relationships of the proper noun with other items in the same grammatical construction), typical English proper nouns are not preceded by the article or other determiners since the references that proper nouns have is by their very nature self-determining or inherently definite. Unlike common nouns, proper nouns normally lack the contrastive definiteness (e.g. **an America*, **some Americas*; *an orange*, *some oranges*). Another major syntactic criterion is that proper nouns lack modification. When they have the normal unique denotation, they can only accept nonrestrictive modifiers (e.g. *Mary, who is my sister, is studying abroad—*Mary who is my sister is studying abroad.*). Proper nouns require *the* when they are modified by a restrictive clause (e.g. *The Mary I know is my friend's wife*), but not when they are unrestricted.

While numerous philosophers and linguists have considered proper nouns and common nouns as two discrete categories and the boundary between them as unambiguous, Jespersen (1924) holds that no sharp line can be drawn between proper and common nouns, the difference being one of degree rather than of kind. Later, Quirk et al. (1985) explicitly stated that the class of proper nouns has unclear boundaries and the degree of membership involves the notion of gradience. There are some circumstances in which proper nouns (e.g. *the Avon*, *the Crimea*, *the Himalayas*) behave like common nouns by taking the definite article and the plural form. On the other hand, a number of common nouns with unique denotation are sometimes capitalized and thus enjoy a similar semantic function as proper nouns e.g. *Fortune*, *Wealth*, *Fate*.

Prosody

Prosody refers to the (variations in) rhythm, intonation, and stress patterns in speech. Its role is to emphasize words, to segment a sentence into smaller units, to change the meaning of an utterance (not of a speech sound!), and to resolve syntactic disambiguity (e.g. 'They fed her dog biscuits' Who ate the biscuits? She or the dog?). Apart from these language-dependent aspects, prosody is also used in a more universal manner, to provide cues to the state of the speaker and to convey the speaker's mood (happiness, impatience, boredom, etc.). Prosodic patterns are very important during speech development. They appear in the infant's speech long before the first word: babies often speak nonsense with the correct intonation! Moreover, as boundaries between words are not clearly marked in speaking, infants use prosodic information to 'segment out' words in the continuous stream of speech sounds. This process is termed 'prosodic boot-strapping'. And the importance of prosody also becomes clear when listening to foreign speakers: even if they articulate well, they are not easily understood if their use of stress and timing is incorrect. The same can be said of deaf speakers: their speech is often unintelligible because they cannot master the prosody of their language well. In noisy environments prosody helps the listener to understand the speaker. Moreover, spectrally distorted speech with the original prosody is easier to understand than the original speech signal with distorted prosody. Prosody does not only contribute significantly to the intelligibility of speech but also to its naturalness. Although present-day speech synthesis is highly intelligible, it still sounds artificial. More research on speech prosody is needed to make it sound natural or pleasant enough to listen to for long stretches of time.

The most important prosodic features are intonation, stress, and quantity. The acoustic correlates of these features are fundamental frequency (perceived as pitch), intensity, and duration (although there is no one-to-one correspondence).

Intonation

Variations in tone (word level) and intonation (sentence level) are used to change the meaning of words, to change the function of the utterance (declarative vs. interrogative), to signify attitude and emotion, etc. These changes in fundamental frequency are related to the rate of vibration of the vocal folds. An increase in subglottal pressure and an increase in the tension of the laryngeal muscles (thereby increasing the stiffness of the folds and reducing their local mass) result in an increase in the fundamental frequency. Prosody can be used grammatically, by producing a question with a rising pitch, and a statement with a falling/flat pitch. Intonation also helps to group words, especially in syntactically ambiguous phrases (e.g. a light house keeper). However, there is quite a complex interaction between stress, intonation, and duration in the case of syntactic ambiguities. At some word boundaries, such as between 'gray tie' vs. 'great eye', duration is the primary cue, although the ambiguity can also be resolved through differentiation in intonation.

Stress

Stress usually refers to relative prominence and increased intensity due to increased physical effort. Note, however, that stress is not perceived as loudness, and that intensity is not the only acoustic correlate of greater effort. An increase in stress often co-occurs with an increase in fundamental frequency. After all, both stress and intonation are brought about by an increase in respiratory effort and subglottal pressure. The minimum size of the unit of stress placement is the syllable. At the word level, stress on the first or second syllable is used to differentiate meaning (cf: 'DIgest' and 'to diGEST' or RECord and to reCORD). This is termed lexial stress. At the sentence level, stress is used to draw attention to certain words (emphatic stress) or to differentiate between two words (contrastive stress). Languages are spoken with a certain rhythm. English is a stressed-timed language due to the fact that stressed syllables occur at regular intervals. French and Japanese are referred to as syllable-timed languages because the duration of their syllables remains relatively constant. Stressed syllables have a higher intensity and fundamental frequency than their unstressed counterparts. Apart from these voice source factors, the timing of the articulatory movements of the vowels and consonants produces differences in duration, depending on the position of the utterance in a word or phrase. In many languages, stressed syllables are longer than unstressed ones. The acoustical correlates of stress (especially duration) are, however, language dependent: in Czech, there is hardly an increase in duration on stressed syllables.

Quantity

Quantity is the linguistic term for 'constrastive duration'. Each individual speech sound has an 'intrinsic duration' to specify its identity, but the duration of speech segments or larger units can yield contrastive information, depending on context or the phonological system of the language. For example, the duration of vowels in Finnish can be constrastively short and long. In Norwegian, a long vowel is followed by a short consonant and vice versa. In English, the duration of a vowel preceding a voiced consonant is 1.5 times greater than that of the same vowel preceding a voiceless consonant (sight=197 ms, side=297 ms; Peterson and Lehiste 1960). Vowel duration, and consonant duration to a lesser extent, is also affected by the number of syllables in a word, by syllable stress (where it interacts with fundamental frequency), and by the type of word (function words such as 'in' or 'on' are relatively short). Very often, the last syllable of a word or the last word of an utterance is longer than the same syllable or word in other positions. This temporal effect, called prepausal lengthening, results from a slowing down in the speaking rate and it signals phrase and sentence boundaries. At word level, duration can signal the syntactic structure of a sentence, e.g. 'a gray tie' vs. 'a great eye'. At a sentence level, relative duration does not affect the meaning of individual words.

However, significant changes in tempo may convey information about the mood of the speaker or the circumstances under which the utterance is made.

Psycholinguistics

Psycholinguistics is the discipline of psychology that studies the mental mechanisms of language processing—speaking, listening, reading, and writing—in both a native and a second tongue. Psycholinguistics also studies the processes underlying the acquisition of language, how language processes break down in language pathologies such as dyslexia and aphasia, and how these processes relate to brain function.

Psycholinguistics borrows many of its theoretical constructs from linguistics. Levels of processing, distinguished in theories of language comprehension or language production, correspond to linguistic levels, such as semantics (meaning), the lexicon (vocabulary), syntax (sentence structure), morphology (units that make up words), phonology, and phonetics (sound systems). Furthermore, the processing units that these theories assume correspond to linguistic units, such as the phoneme, the syllable, the morpheme, and the clause. Psycholinguistic experiments provide information about the psychological reality of linguistic units and the way linguistic information is represented and processed in the mind of the language user.

A crucial difference between linguistics and psycholinguistics is the latter's focus on the mental *process*. For instance, in natural speech we can easily produce two words per second. How do speakers find these words so quickly in their (vast) mental lexicon, which contains at least 10,000 words? What happens to these processes when we are unable to say a word, but it is on the tip of our tongue? As another example, when listening to sentences, we can sometimes be led up the 'garden path'. A classic example is 'the horse raced past the barn fell'. Here, one builds up a structural representation of the sentence, but upon reading the last word ('fell'), it turns out to be wrong. How do

readers build up a structural representation? What went wrong with this process in the example?

The scientific inquiry into language processing began in the second half of the nineteenth century. Rudolf Meringer (1859–1931) started to collect speech errors. In contrast to his contemporary Sigmund Freud (1856–1939), he studied the linguistic, rather than psychological, properties of such incidents. Wilhelm Wundt (1832–1920) proposed the first theory of language production, and Gustav Aschaffenburg (1866–1944), by using the technique of word association, investigated the representation of word meaning. The Dutch ophthalmologist Fransiscus Donders (1818–1889) introduced the method of mental chronometry (measuring the time mental processes take). Reaction time studies are still the most common methodology in psycholinguistics.

Around the same time, the French neurologist Paul Broca (1824–1880) tested a patient who had lost his ability to speak. Monsieur Tan, as the patient was known, could produce only a single syllable ('tan'). After Mr. Tan's death, Broca examined the brain of this patient and discovered massive damage to an area in the front part of the brain, which is now known as Broca's area. Broca's discovery, and subsequent studies by the German neurologist Carl Wernicke (1848–1905), marked the beginning of the inquiry into the relationship between language and brain.

In the first half of the twentieth century, psychology was dominated by behaviorism. This approach rejected the notion of 'mental representation' and 'mental process' but focused on what is directly observable: behavior. An exponent of behaviorism was Burrhus F. Skinner (1904–1990), who published his *Verbal behavior* in 1957. In Skinner's approach, the language-acquiring child begins without any linguistic knowledge. It learns language by experience only. Sentences would be produced as associative chains, where one word would be the stimulus that triggered the next word.

A few years later, a young linguist from the Massachusetts Institute of Technology, Noam Chomsky (1928–), published an extremely sharp criticism of Skinner's book. Chomsky argued that Skinner's theory could not work—for instance, a child is exposed to far too few examples of sentences to learn the language by experience only. Instead, Chomsky argued that the child is born with a tacit knowledge of 'universal' grammar, and learning means tuning this grammar to its own language.

Around the same time, psychologists were abandoning behaviorism and became interested in linguistics again. In 1951, a conference was organized at which leading psychologists and linguists discussed the possibilities of 'merging' the fields. At this conference, the term 'psycholinguistics' was launched.

Research in the 1960s and 1970s embraced Chomsky's theory of transformational grammar. This theory provided representations of sentences (called deep structure and surface structure), and procedures that transformed these representations. However, little convincing evidence was found for a correspondence between linguistic transformations and psychological processes, and this approach was largely abandoned in the early 1980s. Research in the 1980s and the 1990s was characterized by three major developments. First, Jerry Fodor published his *The modularity of mind* (1983), in which he presented the theory that many cognitive processes are performed by dedicated processing systems (modules) that operate independent of other processing systems. A large number of studies in modern psycholinguistics have been and still are centered on this theory. Second, psycholinguists designed computer models of language processing. Seminal work in this area was done by James McClelland and David Rummelhart (1989), in particular, on the modeling of word perception. Third, technical advances made it possible to measure the activity of the brain while it was engaged in verbal tasks. Although still in its infancy, the use of such techniques can be considered very promising in studying the representation and processing of linguistic information in the brain.

What are the mental processes involved in using language? In the following paragraphs, a brief overview will be presented of theoretical issues in pivotal language processes: comprehending, speaking, and 'control' processes.

The first challenge in comprehending is to identify words. This is no easy task: the speech signal has to be distinguished from noise, which may distort it. The speech signal is also very variable. One way of dealing with this variation is 'categorical perception'. That is, tokens of a speech sound can be acoustically quite different, but they tend to be perceived as the same sound (e.g. as the speech sounds /b/ or /p/, but never something in between).

Another challenge for the listener is that in continuous speech, there are often no pauses between words. How then do listeners know where one word ends and the next one begins? Psycholinguistic research shows that this depends on the language: different languages provide different cues to word onset (e.g. the pattern of stress), and listeners use these cues.

Visual word recognition—reading words—poses its own problems. English is an alphabetic language (as opposed to, e.g. Chinese). However, the correspondence between printed letters or groups of letters and sounds is often irregular (e.g. in the word 'yacht'). This has led psycholinguists to distinguish two routes for reading: a lexical route, in which letters or groups of letters directly access a word, and a sublexical

route, in which letters are transformed into a phonological code that guides word recognition. The lexical route would be used for reading irregular words; the sublexical route would be used for reading 'nonwords' (e.g. 'climp'). Support for this theory comes not only from distinct patterns of reading disorder (dyslexia) but also from experiments in which the speed of reading irregular and regular words is measured.

Once words are identified, we construct a structural representation of the sentence, so that we can infer who did what to whom. This process is called parsing. Many studies of parsing have analyzed structural ambiguities. In a sentence such as 'the man hit the girl with the guitar', the guitar can be in the possession of the man (and used for hitting the girl), or it can be in the possession of the girl being hit. These interpretations correspond to different sentence structures. Studies with ambiguous sentences have revealed some of the processes involved in parsing. A very important debate centers on the question of what kind of information is available to parsing. In some views, only syntactic information is used. According to other views, parsing is influenced by a variety of factors (e.g. plausibility, or the frequency with which a word occurs in a certain structure).

Sentence understanding does not stop with parsing. We have to integrate the word meanings and the sentence structure into a sentence meaning, and we have to relate this meaning to prior discourse. In one study, brain responses were measured to sentences such as 'I spread my bread with socks', and it was discovered that such stimuli evoke distinct patterns in the electroencephalogram signal. This finding has proved useful for studying these integration processes.

Speaking starts with the decision to engage in a communicative act. This is based on the speaker's intentions, background knowledge, and a mental model of previous dialogue. On the basis of these sources of information, the first step in speaking is the generation of a message. This is the interface between thought and language: the message is not yet language, but it is specific to language. In most theories of language production, the message contains concepts for the things and actions the sentence is about, perspective (is 'in front of' relative to you or me?), and focus (which information is given, and which is new?).

The next step consists of formulation of this message: retrieval of the words and construction of a sentence. There is much evidence that word retrieval consists of two steps: a process that is based on meaning and a process that is based on form. This distinction is based on research that analyzed collections of speech errors and research that measured reaction times in word production. In these tasks, so-called distracter words with either a form or a meaning relation to the target word have different effects. A major issue

is whether these data also imply that there are two separate lexical representations.

Another task of formulation is the construction of a sentence structure. A key finding is the observation that sentence structure is 'persistent'. Speakers have a tendency to reuse a structure that has been recently used before, even if the two sentences do not share any meaning, words, or prosody. This finding strongly suggests that structured representations of sentences are psychologically real. It also provides a technique for determining how sentences are mentally represented.

A final task of formulation is to retrieve pronunciations. A major problem here is that words in real speech do not correspond in a one-to-one fashion to words in their citation form: in connected speech, sounds from one word are often 'merged' with those of another (e.g. 'give it' will often be spoken as 'gi-vit'). Another issue is whether certain representations that are distinguished in theoretical phonology are psychologically real.

The earlier discussion focused mainly on content-directed processes in language use. Yet, there is increasing interest in control processes, which determine when the content-directed processes should engage, and in mental resources, such as memory and attention, which are the 'fuel' on which the content-directed processes run.

First, language is predominantly used in interaction with others. There is a growing body of evidence that partners in a dialogue coordinate with each other: that is, they converge on using the same linguistic structures, such as words, syntax, and description schemes, to denote the same things in the external world. How and why we accomplish such coordination is an important item on the agenda for study.

Second, the language processes may contain errors. Fortunately, there are self-monitoring processes dedicated to intercepting errors and 'repairing' them. How these monitoring processes operate—and how it is possible that they do the job as fast as they do—is, at present, a matter of debate.

Third, the language user is constrained by factors such as attention and memory. In recent years, there has been an increasing interest in how limitations in such 'resources' affect processing. Debate here centers on the nature of such resources: whether they are comparable to the same short-term memory in which one briefly stores the digits of a phone number, or whether there are specialized resources for language processing.

Q

Quantification

A sentence such as *John is happy* consists of a subject (*John*) and a predicate (*is happy*). The predicate attributes the property it describes ('being happy') to the individual the subject refers to ('John'). When the subject noun phrase contains a determiner (*a*, *the*, *some*, *every*, etc.), this element plays a crucial role in the predication process. The contrast in meaning between the sentences *A student is happy* and *Every student is happy* is caused by the different nature of the determiner that expresses the number or quantity of individuals to which the relevant property applies. We say, then, that these sentences differ in quantificational force. The first sentence states that there is (at least) one student who is happy in the situation under consideration. The second sentence states that every individual under consideration is happy. This semantic contrast can be expressed as a contrast in logical form, as defended by the philosophers Gottlob Frege and Bertrand Russell. In first-order logic, the determiner *a/some* is treated as an existential quantifier (meaning 'there is at least one individual for which it is true that…'), and the determiner *every* as the universal quantifier (meaning 'it is true for all individuals that…'). Quantifiers are assumed to bind a variable (x) in a logical statement or proposition. Going back to the above sentences, the paraphrases of their respective logical forms would be the following: *There is at least one individual* x *such that* x *is a student and* x *is happy* and *For every individual* x *if* x *is a student then* x *is happy*.

The first-order logic analysis of quantification has been criticized for positing that the constituents of a noun phrase (i.e. the determiner and the noun) contribute independently to the meaning of a sentence: the determiner quantifies over the whole proposition of which the noun is a part. This runs counter to the common linguistic analysis of sentential expressions. Another limitation is that the first-order logic analysis is not designed to capture the content of the extensive variety of natural language determiners. For example, it has been shown that the English determiner *most* is not expressible in first-order logic. The sentence *Most students are happy* does not mean that most individuals under consideration are students and they are happy (first-order logical meaning). Rather, it means that most of those individuals who are students are also happy.

Generalized Quantifier Theory developed during the 1980s, following the initial contribution of the philosopher Richard Montague, as an attempt to improve the shortcomings of traditional logical analyses of quantification in natural language. The functional nature of the subject—predicate relation that we described at the beginning is reversed. A predicate still expresses a property, but it is not treated as a function that applies directly to the subject (argument). Rather, a subject is viewed as a higher-order expression that expresses a property of the predicate or, equivalently, a set of properties. In general, noun phrases express generalized quantifiers (sets of properties). We can represent the sentences in the previous paragraph compositionally as *some student* (*happy*) and *every student* (*happy*), where the generalized quantifiers associated with *some student* and *every student* are respectively

interpreted as the set of properties that some student or every student has, and what the sentence asserts is that happiness is one of those properties. The sentence will be true or false depending on whether this is the case or not.

The meaning of a noun phrase such as *some student* can also be determined in a compositional fashion. The noun *student* expresses or describes, more technically 'denotes', a set of individuals and the determiner *some* relates it with another set of individuals, namely, that denoted by *happy*. This yields the following logical representation: a/*some* (*student*) (*happy*). Given the particular meaning of the determiner *some*, this expression is true if the intersection of the sets denoted by *students* and *happy* is not empty, i.e. if there is at least one individual who is a student and who is happy. Other determiner meanings can be characterized in a similar fashion: *every* (*student*) (*happy*) is true if the set denoted by *student* is a subset of the set denoted by *happy*; *no* (*student*) (*happy*) is true if the intersection of the sets denoted by *students* and *happy* is empty; *more than three* (*students*) (*happy*) is true if the number of individuals in the intersection of the sets denoted by *students* and *happy* is greater than three; *most* (*students*) (*happy*) is true if the number of individuals in the intersection of those two sets is greater than the number of the individuals in the intersection of the sets denoted by *students* and *not happy*, i.e. the number of those students who are happy is greater than the number of those students who are not happy; etc. In sum, a natural language determiner is a function with two arguments. The first argument corresponds to the noun denotation and the second argument to the content of the sentence verb phrase.

Natural language determiners also satisfy a series of constraints that set them apart from their logical counterparts. For example, all natural language determiners are conservative or live on their first argument—motivating the intuition that the determiner has a close bond with the noun. The sentence *Some sailors left* is equivalent to the sentence *Some sailors are sailors who left*. If we substitute any other determiner for *some* in this sentence, the equivalence still holds. The effect of this constraint is to make natural language quantification inherently restricted to the first argument of the determiner. Thus, in checking whether *some* (*sailors*) (*left*) is true, we do not have to consider those individuals who are not sailors. In other words, in processing the sentence *Some sailors left*, we do not first check who left and then determine whether any of these individuals are sailors; rather, we look at relevant sailors and determine whether some of them left.

Determiners are also characterized by the type of inferences that they license, namely, set-to-subset inferences or set-to-superset inferences. For example, the sentence *No students smoked* entails the sentence *No students smoked cigars*. The property denoted by *smoked cigars* is a subset of the property denoted by *smoked*, so the determiner *no* licenses set-to-subset inferences for its second argument. The same is true for its first argument: the sentence *No students smoked* entails the sentence *No female students smoked*, given that the property denoted by *female students* is a subset of the property denoted by *students*. The determiner function *some* has the opposite pattern and licenses set-to-superset inferences for its two arguments. Thus, we predict that the sentence *Some female students smoke cigars* entails both *Some female students smoke* and *Some students smoke cigars*.

Quantifiers can also be classified according to whether they can occur in an existential construction, i.e. a sentence that asserts the existence of something (*There is…*). Consider the structure *There is/are Q student(s) in the garden*. The determiners *some*, *three*, *no*, *fewer than five*, and *many* can be substituted for *Q* and occur in this construction, whereas the occurrence of determiners such as *every*, *most,* and *all but three* would make the sentence ungrammatical. The determiners that can occur in an existential construction are intersective, i.e. they express a relation of intersection of their two arguments. On the other hand, those determiners that cannot occur in an existential construction are characterized by expressing a relation of inclusion, such as *every*, or proportionality, such as *most*. Definite determiners, whether simple (*the*) or complex (*the ten…*), demonstrative (*this*) determiners, and possessive determiners (*my*) do not occur in existential sentences either. These determiners are all inherently context dependent and thus presuppose or do not assert existence.

When more than one quantifier occur in a sentence, a form of semantic interaction called scope arises. Scopal relations are determined by the different order of quantifiers in the semantic representation of a clause. For example, the sentence *Every student read a book* is ambiguous because it contains two generalized quantifiers: *every student* and *a book*. Under one interpretation, every student read a different book. Under the second, there is a unique book such that every student read it. This ambiguity is a genuine scope ambiguity. In the first reading, the scope order of the quantifiers is the one that respects the linear order of the noun phrases; i.e. the subject noun phrase is more dominant or has scope over the object: *every*

student > a book. The universal generalized quantifier *every student* takes scope over the existential generalized quantifier expressed by *a book*. The second reading is an inverse scope reading in that the scopal order of the quantifiers differs from the surface linear order. In this reading, the existential quantifier takes scope over the universal quantifier: *a book > every student*.

So far, we have considered only nominal quantification, i.e. quantification corresponding to the meaning of noun phrases. However, other elements may also contribute to the quantificational force of a sentence. Adverbs such as *always*, *sometimes*, and *often* are not merely temporal adverbs. In the majority of contexts, they behave as adverbs of quantification. For example, the sentence *Peter always drinks coffee* does not mean that Peter drinks coffee at every moment, but rather that whenever Peter drinks, he drinks coffee. Adverbs of quantification can thus be taken to express quantification over situations.

Interrogative generalized quantifiers are *wh*-phrases such as *who*, *what*, *where*, and *which*. Interrogative determiners are also conservative. The interrogative sentence *Which students are rich?* is equivalent to *Which students are students who are rich?* Interrogative determiners are also uniformly intersective, because the meaning of an interrogative determiner depends on the intersection of its two arguments. For example, a complete answer to *which* (*students*) (*rich*) specifies, in a situation, the intersection of the set of students and the set of rich individuals in that situation. Interrogative determiners and existential determiners such as *some* have a majority of their properties in common. From this point of view, it is not surprising that a significant number of the world's languages use the same lexical expression for interrogatives and existential determiners.

Sometimes, the quantificational force of a sentence cannot be associated with any overt element in the clause. The sentence *Lions are fierce* is usually interpreted as stating that most lions are fierce or that lions are normally fierce. To characterize the semantic properties of this sentence, the existence of hidden elements of diverse quantificational force has to be postulated. In the example under consideration, there is a hidden element of generic force, *Gen*, so the logical representation of this sentence would be *Gen* (*lions*) (*fierce*).

Nominal and adverbial quantification interact in apparently unexpected ways. This interaction arises mostly when an indefinite occurs in the scope of an adverb of quantification in relative constructions, conditional sentences, etc. In the sentence *Every farmer who has a donkey beats it*, the indefinite *a* lacks its typical existential force. The sentence does not mean that every farmer beats one donkey or other (at least one) that he has. Rather, the correct interpretation is that for every pair consisting of a farmer and a donkey owned by that farmer, it is also the case that the farmer beats the donkey. The indefinite seems to have universal force here; so we may conclude that the universal quantifier headed by *every* behaves as a binary quantifier here and associates both with the restriction of the universal noun phrase and with the indefinite one. The same pattern can be observed in the sentence *Always, if a farmer owns a donkey, he beats it*, where the indefinite noun phrases *a farmer* and *a donkey* seem to inherit the universal force from the adverb *always*. Some theories have concluded that indefinites lack quantificational force and inherit their apparent force from other surrounding elements in the clause. In general, adverbs of quantification are taken to transmit their quantificational force to all the indefinites that appear in their scope. This phenomenon is known as unselective quantification. Quantification thus covers a wide range of interesting phenomena and has triggered many debates among linguists and philosophers.

Questions

The term 'questions' in everyday usage refers to utterances inviting a response and that, when spoken, may have specific intonation patterns. Questions can be analyzed for their grammatical forms and also for their functions in discourse. Discussion of questions generally involves both these aspects. The analysis of questions can be used to relate linguistic findings to patterns of social behavior.

In English, questions can be identified and categorized on the basis of syntactic and phonological forms. Four types of questions in English can be distinguished:

(1)   Wh-questions

These are forms beginning with an interrogative element (*who, which, what, why, when, how*, and so on): *Where does Antony work*? *What can Antony do*? The subject (*Antony*) and either an auxiliary (*does*) or modal verb (*can*) are inverted in English. Wh- questions generally require more elaborate answers than those elicited by yes/no questions.

(2)   Yes/no questions

This broad category refers to questions to which the hearer is expected to respond either with yes or no. The following forms can be identified:

a. Inversion of the subject and an auxiliary or modal verb
   Does the race start here?
   Can we finish this now?
b. Statements with a question intonation

In these questions, the speaker presents an utterance in the form of a statement, but marks it as question by a rising and falling tone.
You will be sure to bring it back soon?

(3)   Alternative forms

In these forms, the speaker presents two or more alternative answers within the question.
Will the new administrator work here or on the first floor?

(4)   Tag forms

These forms consist of a declarative utterance followed by a question.
The computer is connected to the internet, isn't it?
Yes/no questions are said to either be neutral or biased toward a positive or negative orientation. For example, the use of the nonassertive form 'anyone' in *Has anyone left*? can be argued to render this question neutral in that it leaves open whether the response will be affirmative or not. However, the use of the more assertive form 'someone' in *Has someone left*? is argued to indicate speaker expectation of a positive response, whereas the use of a negative form hasn't in *Hasn't anyone left*? is argued to indicate a bias toward a negative response.

Generally, questions are understood to be based on presuppositions, or underlying assumptions. For example, the question *When does your brother finish college*? is based on the presuppositions that (1) you have a brother and (2) your brother is at college.

Questions can be examined in relation to their pragmatic functions, namely, their functions to request specific types of linguistic responses. A discourse-based analysis of questions involves a consideration of contextual factors, such as the situation, who knows what, and how the discourse unfolds. Identification of the functions is the primary interest, but identification of the forms that typically realize these functions may follow from this.

From a pragmatic viewpoint, a question can be identified as a question if it fulfills certain conditions: the act of questioning must be genuine, and the speaker must believe in the presuppositions of the question and desire to know the response. For example, a speaker (sitting in the driver's seat in a car with some passengers at the back) produces the following utterance: *Are you ready*? Without a response, the speaker then sets forth on the journey. This indicates that the driver does not desire to know the response. Also, the absence of any response from the passengers indicates that the hearers do not interpret the driver's utterance as seeking a response. Thus, despite the question-like form, the utterance would not be termed a question.

In discourse-based analyses, questions are often referred to as 'elicits' or 'requests', and they are categorized in relation to the specific functions they require of the hearer. One such category is elicits of, or requests for, information. In the following example (data taken from Schegloff 1972:107), A requires information about the location of an address from B.

A *I don't know where the—uh—this address is.*
B *Well, where do—-which part of the town do you live in?*

Another category in a discourse-based analysis is that of elicits of, or requests for, confirmation. These function to invite the hearer to verify or disconfirm the speaker's idea or proposition, as the following example taken from Coulthard and Brazil (1981:84) illustrates.

A *So the meeting's on Friday*
B *Thanks*
A *No I'm asking you*

This example also illustrates that identification of the exact function may be ambiguous and can only be resolved as the discourse unfolds. A's first utterance asks B to confirm that the meeting is on Friday. However, the function of this utterance is unclear, and B understands it as information being provided by A. B thus thanks A for the information. In utterance 3, A then makes explicit the function of the first utterance as an elicit of confirmation.

Other discourse functions of questions have been identified. Elicits of commitment require the hearer to promise further action (e.g. *You will come on Wednesday*?). Elicits of agreement require the hearer to verify that the idea proffered by the speaker is self-evidently true. The following example taken from Tsui (1992:107) illustrates:

(On a sunny day)

A *Lovely day, isn't it?*
B *Yes, beautiful!*

The analysis of questions according to function has been applied to the study of language use in specific situations. For example, analysis of teacher talk has been shown to reveal various didactic functions. These didactic functions include higher cognitive level questions requiring the hearer to manipulate bits of previously learned knowledge to create a response, lower cognitive level questions requiring the hearer simply to recall or recognize factual information, display questions functioning to check or test the student on information known to the teacher, and referential questions seeking information unknown to the teachers themselves.

Conversation analysts have analyzed questioning to identify rules underlying interaction. Questions are identified as the first part of a two-part sequence: question (Q) and answer (A). The person who asks a question has the option of speaking again to ask another question. Thus, there is a chaining rule providing for the sequence Q-A-Q-A-Q-A…. This approach to the analysis of questions has been used to relate linguistic findings to power structures in society. For example, the analysis of interaction may reveal one speaker asking more questions, thus directing the discourse and indicating asymmetrical power relationships.

HELEN BASTURKMEN

Quine, Willard van Orman

Quine is one of the most important analytic philosophers of the twentieth century, a fact eloquently attested to by the fact that in 1987 a supplement to the *Oxford English dictionary* recognized his importance as an eponym by including the entry 'Quinean' with the following definition: 'Of, pertaining to, or characteristic of Willard van. Quine or his theories'. At the time of his death in December 2000, Quine was the Edgar Pierce Professor Emeritus at Harvard, where he had pursued an active career spanning over half a century. His early work was heavily influenced by Rudolf Carnap and other logical positivists. But, as an empiricist and (from the 1960s on) an advocate of a naturalistic epistemology, he distrusted all talk of meaning

equivalence, which was a mainstay of Carnap's reductionist program.

A prolific writer, Quine is widely perceived as a philosophical iconoclast. His early essay 'Two dogmas of empiricism' (published in the 1953 collection) had great impact on the philosophical community. In it, Quine challenged the distinction between 'analytic' and 'synthetic' statements, one of the most fundamental and well-entrenched distinctions of modern philosophy—originally introduced by Kant but already foreshadowed in the work of Locke and Leibniz. According to Kant, an analytic statement was one whose predicate was contained in the concept of its subject. In the case of a synthetic statement, there was no such relation of inclusion between the subject and the predicate. Post-Kantian interpretation had resulted in an extension of the distinction to cover cases other than the simple subject–predicate statements originally envisioned by Kant and, with it, the key criterion for analyticity had become the idea of a sentence being true by virtue of its meaning. The idea had been embraced by the logical positivists of the Vienna Circle who had also extended its scope to include, among other things, all propositions of mathematics.

Quine's attack on the 'analytic/synthetic' distinction was based on his rejection of the notion of 'synonymy', which he thought was a philosophical mare's nest. Synonymy was suspect because it rested on the notion of meaning that too was, Quine argued, incapable of surviving critical scrutiny, notwithstanding the widespread use of the term in philosophical circles. Whatever heuristic value there was to the distinction was due to the fact that understanding a sentence was largely a matter of knowing what experiences would make a given sentence true, a claim long made by empiricists—the so-called analytic statements simply being, under this interpretation, those that have been confirmed on all known occasions.

Unlike the early Wittgenstein and the positivists, Quine saw philosophy as a natural ally of science. In his view, a scientific theory was an intricate web of ideas whose borders touched on concrete experience. No part of the web was immune to revisions in the light of new experience. Furthermore, revisions are never strictly localized but rather affect several parts of the web at once. This meant that individual sentences, considered in isolation, have no meaning, strictly speaking. In addition, Quine held that in talking about the world one characteristically moves from talking *in* certain terms to talking *about* them, that is, from so-called material mode to formal mode—a process that he famously referred to as 'semantic ascent'. On Quine's holistic view of meaning and

evidence, an entire network of beliefs and theoretical predilections is involved every time a scientific hypothesis is put to test. This means, he went on to argue, that no scientific hypothesis can be tested in isolation (this claim is often referred to as 'Quine–Duhem thesis'), just as no single sentence can be said to lend itself to an analysis of its putative meaning.

Skepticism concerning meaning and with it a whole array of assorted concepts such as property, proposition, and necessity as well as the very concept of a concept led Quine to unveil one of his most influential and controversial doctrines, namely the thesis of the 'indeterminacy of translation'. Quine argued that there can be no such thing as radical translation, i.e. translating, as it were, from scratch between two languages totally foreign to each other. A radical translator or interpreter will only have access to certain external facts, but these will be of no help when it comes to deciding between alternative candidates for the translation of an expression from one language to a radically different one. The impossibility of radical translation stems from what Quine called the 'inscrutability of reference' (later renamed 'indeterminacy of reference'). The native word 'gavagai' uttered by the informant as he points at a rabbit jumping past does not authorize one to hypothesize that the two words 'gavagai' and 'rabbit' are translation equivalents; a number of alternative hypotheses, such as that the informant might have been referring to specific rabbit parts or determinate rabbit movements, cannot be ruled out as equally plausible in light of the available empirical evidence.

At a broader level of application, Quine's position meant that, when different theories all seem equally adequate in explaining a given set of behavioral patterns, there can be no choosing among them on grounds of greater psychological reality or whatever. In an important paper titled 'Methodological reflections on current linguistic theory', Quine challenged Noam Chomsky's contention that the best theory is the one that is not only observationally and descriptively adequate, but explanatorily so as well. Quine insisted that, given a native speaker who presumably has a consummate command of his or her language and a hypothetical language learner whose linguistic performance is indistinguishable from that of the former, there is no sense in which the former may be claimed to *know* the language in any deeper sense than the latter. Quine's point was that, insofar as they are meant to be explanations for certain verifiable behavioral phenomena, the 'theory' that the language learner presumably brings to bear on the task of speaking the foreign language is just as good as the

one the native speaker is being claimed to have internalized. Accordingly, Quine dismissed Chomsky's celebrated notion of 'linguistic competence' as scientifically untenable. In the final analysis, Quine's objection to such notions had to do with his firm conviction in the irreducibly public nature of language. Toward the end of his career, he became more and more convinced that one can only learn language from experience with the world at large and that, therefore, there is no way linguistics can avoid embracing behaviorism.

Quine will be remembered as one of the most challenging and dynamic philosophers of the second half of the twentieth century. His hobbies included traveling and collecting stamps. He could never bring himself to use a computer, contenting himself instead with a 1927 Remington typewriter whose keyboard had to be modified to suit his special requirements of characters and type faces.

Biography

Quine was born in Akron, Ohio on June 25, 1908. He graduated from Oberlin College (Oberlin, Ohio) in 1930, and in 1932, barely two years later (an all-time Harvard record), received his doctorate from Harvard, with the famous English philosopher and mathematician Alfred North Whitehead as adviser. He traveled to Europe on a Sheldon Traveling Fellowship and spent the next year in Vienna, Prague, and Warsaw, studying, lecturing and meeting various members of the Vienna Circle, among them Philip Frank, Moritz Schlick, Alfred Tarski, A.J. Ayer, and Rudolf Carnap as well as Kurt Gödel. He started his teaching career at Harvard in 1936 as an Instructor in Philosophy and taught there ever since, except for four years in the US Navy during World War II, serving in Washington and working with cryptoanalysts trying to break the German submarine code. He was promoted to Associate Professor (1941), Professor (1948), and Edgar Pierce Professor (1956). He paid two visits to Oxford: in 1953–1954 as Eastman Visiting Professor, and in 1973–1974 as Savile Fellow of Merton College and Wolfson Lecturer. He was awarded 18 honorary degrees by international institutions, including University of Lille, Oxford University, Cambridge University, Uppsala University, University of Bern, and Harvard University. He received innumerable honorary fellowships and awards, including: Society of Fellows, Harvard University (Junior Fellow, 1933–1936; Senior Fellow, 1949–1978), American Academy of Arts and Sciences (fellow 1949 –), Harvard University (Chairman, Philosophy, 1952–1953), Association for Symbolic Logic (President, 1953–1955), Institute for Advanced Studies (Princeton, NJ, 1956–1957), American Philosophical Association (President 1957), American Philosophical Society, member (1957 –), Centre for Advanced Studies in the Behavioral Sciences (Palo Alto, CA, 1958–1959), British Academy corresponding fellow (1959–), Instituto Brasileiro de Filosofia corresponding member (1963–), Centre for Advanced Studies (Wesleyan University, Middletown, CT), Nicholas Murray Butler gold medal (1965), Columbia University (New York, 1970), National Academy of Sciences fellow (Washington, DC, 1977), Institut de France (1978), Norwegian Academy of Sciences (1979), F. Polacky gold medal (Prague, 1991), Charles University gold medal (Prague, 1993), Rolf Schock Prize (Sweden, 1993), and the Kyoto Prize (Japan, 1996). He retired as Edgar Pierce Professor Emeritus in 1978 from a teaching career in which his pupils had included not only influential philosophers like Donald Davidson but also the satirical songwriter Tom Lehrer and Theodore J. Kaczynski, the so-called 'Unabomber'. He died in Boston on December 25, 2000, aged 92.

Reading

Over the past several centuries, reading has gone from being a relatively obscure intellectual endeavor limited to a small elite segment of the population to a relatively common one. You are, in fact, reading at this very moment. Despite the fact that reading has become so common, and is something you probably do every day, picking a useful definition of reading turns out to be surprisingly difficult.

What Is Reading?

Reading a newspaper article surely counts as reading. But does scanning the stock market results to see how a favorite stock fared this week amount to reading? How about 'reading' a map? Is working through a mathematical proof, or a computer program, reading? Is it reading when you decode and pronounce a nonword such as BOPE?

Definitions of reading run the gamut from 'decoding printed symbols' to 'thinking with a book in front of you'. Differences in opinion about what constitutes a useful definition of reading arise from different answers to two fundamental questions. First, for something to be defined as reading, must it be unique to reading or can it be general to oral language comprehension? Reading almost always is done for the purpose of comprehending meaning, but most comprehension appears to be the same regardless of whether the message was initially processed through the eyes or the ears. Should a book on reading be mostly about language comprehension or should it be mostly about what is unique to reading as opposed to listening? The second fundamental question is whether comprehension is necessary for something to be considered reading. Studies of decoding printed letter strings sometimes use nonwords rather than real words to eliminate the effects of individual differences in vocabulary knowledge. If you can read, you will have little trouble working through a list of nonwords such as HEZ, RAF, POTE, and HINKER, and the processing that is done overlaps with that done when reading real words. But without comprehension, is this reading?

A pragmatic answer to the question of what is reading is to define reading as extracting meaning from print, and to acknowledge that it can be useful to study parts of the reading process such as aspects of decoding that are best viewed when people are asked to pronounce nonwords. In addition, it is important to acknowledge that successful reading requires the coordinated execution of decoding processes that are unique to processing print and comprehension processes that may be common to listening as well as reading.

What Is Being Read?

Humans have used spoken language for at least 100,000 years and perhaps quite a bit longer. In contrast, the earliest artifacts of writing, and hence reading, are cave paintings in southern France and northern Spain, that are approximately 20,000 years old. The paintings depict animals and occasional humans, and it is not clear whether they tell a story or are just pictures that serve some religious or magical purposes. A major advance in writing occurred around 5,000 years

ago in Sumeria. When goods were sent to market, they were accompanied by clay balls. Sealed inside the clay balls were small pieces of clay that represented the goods that were being transported. When the shipment reached the market, the clay ball would be broken open and the shipment would be inspected to make sure nothing had been diverted. Eventually, it became apparent that marks could be pressed into wet clay to represent the goods, saving the trouble of forming the balls filled with small pieces. This, of course, marks the birth of a real writing system.

Today, printed languages vary in terms of what they represent, with three major categories of writing. The Chinese writing system is called a logography. Each character represents a morpheme or minimal unit of meaning. *Beijing* means 'north capital", and is represented in writing by two symbols, one for north and one for capital. The Kana system of Japanese is a syllabary. Each symbol represents a spoken syllable. Finally, English, modern Korean, and many other written languages are alphabets, in which a small set of characters are put together to make a much larger number of words. Dividing the world's languages into three categories is an oversimplification. Thus, some sounds as well as meaning are represented in Chinese writing, and English is best described as a morpho-phonemic representation system as English spellings represent both sounds (phonemes) and (units of) meaning (morphemes). Consequently, the printed word HEALTH has a spelling that makes apparent its relation to the morpheme 'heal' as opposed to a strictly phonetic spelling such as HELTH.

How Do Children Learn to Read?

The obvious answer is that children are taught to read by teachers and parents. But a closer investigation of what is involved suggests it is immodest to assert that teachers or parents actually teach children to read.

Reading involves the coordinated orchestration of just about every process ever studied by cognitive psychologists and linguists. At best, teachers put print in front of children, and point out associations between print and sound or meaning, but the real work of learning to read is done by cognitive and linguistic machinery that is not readily accessible to teachers or learners. It is clear that learning to read an alphabetic system of writing is easier for children who have awareness and access to the sound structure of their oral language (i.e. phonological awareness) that is represented in writing. Thus, the spoken words 'cat', 'rat', and 'sat', have different initial sounds and identical medial and final sounds. To a child who is aware of these similarities and differences, the English system of writing will seem sensible in that these relations in sounds are represented in spelling. Cat, rat, and sat have different initial letters and identical medial and final letters. To a child lacking such an awareness, an alphabetic writing system will seem to be arbitrary and complex.

Reading Impairment

Reading impairment, reading disability, and dyslexia all refer to a level of reading that is below expectations. Expectations for reading can be based on normative data from age-matched peers, or based on an individual child's oral language ability or cognitive ability.

Nature of Reading Impairment

Dyslexia is perhaps the most commonly used term to describe reading impairment, and surely the most misunderstood. The common view of dyslexia is that of a

visual perceptual problem that results in seeing mirror images of words or letters. Thus, individuals with dyslexia are reported to read WAS as SAW, or to confuse the letters 'b' and 'd'. The origin of this view is easily established. Children with reading problems typically became obvious to teachers and parents at the second-grade level, and indeed they can be observed reading WAS for SAW and confusing the letters 'b' and 'd'. But it turns out that normal beginning readers also make similar errors. The fact that words in English are to be read from left to right as opposed to right to left is arbitrary and must be learned. In addition, the letters 'b' and 'd' are both visually confusable and similar in sound (i.e. both stop consonants). Careful analysis of reading errors has shown that second-grade readers with dyslexia make no more reversal errors than do younger normal readers who are at the same level of reading. Thus, second-grade teachers observed only poor readers making reversal errors, whereas kindergarten teachers would know that such errors are quite common.

Another mistaken idea about reading impairment is that it results from erratic or inefficient eye movements. Reading requires highly sophisticated and coordinated eye movements characterized by ballistic movements called saccades and pauses called fixations. During the movements or saccades, little information is available to the eyes beyond a blur. Nearly all information is acquired during fixations. As you read the words on this page, your perception is that your eyes are moving smoothly across the page. This is an example of a situation where perception does not reflect reality. If you observe normal readers reading text by having them read directly across from you while holding a book low enough so you can observe their eyes, you will indeed see that the eyes move across the page in a series of small, but observable jerky movements.

Perform the same experiment on individuals with reading impairment and it will be apparent that their eyes move much more erratically, even moving in the wrong direction at times. Observations like these resulted in the belief that faulty eye movements were the origin of reading impairments, and also resulted in interventions based on eye-movement training. It turns out that this view has it backwards. Indeed, the eye movements of individuals with reading impairments are more erratic than those of normal readers, but the erratic eye movements are the by-product, not the cause, of the impaired reading. The eye movements of individuals with reading impairments do not move across the page as smoothly as do those of normal readers because they are having trouble reading the words. This also explains their greater frequency of

backward eye movements or regressions. Conclusive evidence was provided by careful studies in which normal readers were given material that was as difficult for them to read as is grade-level reading material for individuals with reading impairment, and individuals with reading impairment were given very easy reading material that they could read as well as normal readers could read grade-level material. Under these conditions, the eye movements of normal readers deteriorated to match the previously reported erratic eye movements of individuals with reading impairment, and the eye movements of individuals with reading impairment now looked normal. Additional confirmation came from the results of eye-movement training studies. Although eye-movement training did result in gains performance on eye-movement tasks outside the context of reading, reading performance did not improve.

For the vast majority of individuals with reading impairment, the problem appears to be based in language as opposed to the visual system, and is commonly compounded by ineffective instruction. Compared to reading-level matched controls, most individuals with reading impairment perform poorly on measures of phonological awareness and phonological decoding, and have fewer words that can be decoded by sight. Phonological awareness refers to an individual's awareness and access to the sound structure of an oral language. Phonological decoding refers to decoding words by sounding them out, as when one is asked to decode nonwords such as TANE. The underlying language problem for individuals with reading impairment is likely to be a subtle and not well-understood problem in forming accurate phonological representations, which in turn leads to poor phonological awareness and phonological decoding. Once beginning readers fall behind, they are exposed to reading instruction designed for more advanced readers, which provides little assistance, until they are finally identified as having a reading problem and more appropriate instruction is provided.

Distribution of Reading Impairment

Two important facts about the distribution of reading impairment are counterintuitive. First, despite the fact that boys outnumber girls by roughly four to one in classes and clinics that serve individuals with reading impairments, epidemiological studies in which all children are tested reveal that reading impairment rates for boys and girls are roughly comparable. For every boy with a reading impairment, there is likely to be a girl with an equally severe reading impairment. The overrepresentation of boys in classes and clinics appears to

result from a referral bias that arises because boys are more likely to be disruptive than girls, and hence more likely to be referred for evaluation.

Second, reading impairment is not something that one has or does not have. It is not an all or none phenomenon. The distribution of reading performance is continuous, with no obvious breaks or bumps in the tails of the distribution. Where one draws the line is arbitrary.

Reference

The term 'reference' is ambiguously used to designate (a) the relation between a referring expression and that to which it refers, (b) that to which a referring expression refers (also known as the 'referent'), and (c) the act of referring to some extralinguistic entity or state of affairs, etc. by using a referring expression. Sometimes the terms 'denotation' and 'designation' are used interchangeably with reference in its sense (a)—'denotatum' and 'designatum' being the corresponding variants for the word in its sense (b).

Sense (c) introduces, over and above the referring expression and the referent, a third element, namely the speaker, into the picture. This in turn introduces the possibility that a speaker may succeed in referring to an object, although the referring expression she or he uses is, strictly speaking, inaccurate as a description of it—as when someone says 'That horse is agitated', pointing at a certain restless quadruped that, on closer inspection, turns out to be a mule. A speaker may also successfully refer to an individual whose identity is otherwise unknown to everyone including himself or herself as when someone says 'Smith's murderer is insane', meaning by the referring expression 'Smith's murderer' something like 'whosoever murdered Smith' rather than, say, 'that man in the dock over there, about to be cross-examined'. These cases show that speaker reference and denotation may not always coincide, raising the thorny issue as to which of them should be regarded as basic.

It is also important to distinguish among different kinds of referring expressions. 'That man over there', 'Smith', 'The President of the United States' are examples of singular definite expressions whereas 'horse', 'gold', etc. exemplify general expressions. Scholarly discussion about reference has tended to concentrate on singular definite expressions. Broadly speaking, theories of reference may be grouped under two conflicting approaches: descriptive vs. direct reference approaches.

On the descriptive view, a referring expression does its job by describing features or properties of the referent. The descriptive view hinges crucially on a distinction between *Sinn* (sense) and *Bedeutung* (reference) proposed by the German logician and philosopher Gottlob Frege in order to explain the difference in cognitive value between identity statements of the form '$x = y$' and '$x = x$', where x and y stand for referring expressions. Frege argued that two referring expressions may have different senses but nonetheless have the same reference (i.e. referent), thus making the former equation more informative than the latter. He also insisted that a referring expression can only have a referent provided it has a sense, although having a sense was not a sure guarantee that the term will have a referent (as in the case of 'unicorn' or 'square circle').

Bertrand Russell, who went on to spell out the description theory more articulately, took a narrower view of reference, maintaining that only 'logically

proper names' do the referring and they do it infallibly by naming objects known through 'acquaintance' that included sense-data, certain universals, and possibly ourselves. As for descriptions, he argued—contra Frege—that they are 'incomplete symbols', meaningful only in the sentential contexts in which they occur. Ordinary proper names like 'Bucephalus' and 'Mount Everest' are for Russell, as indeed they were for Frege too, disguised descriptions. So a descriptive phrase such as 'The present King of France' in the sentence 'The present King of France is bald' does not qualify as a genuinely referring expression, because a proper analysis of its logical form will show that what the sentence really says is that France currently has a (an only) king and that he is bald. Thus paraphrased, the singular definite description no longer has a referring function and its presence is explicated in terms of the existential quantifier and the variable within its scope as in

$$(\exists x)\ (Kx\ \&\ (\ (\forall y)\ (Ky \rightarrow y = x)\ )\ \&\ Bx)$$

where 'K' and 'B' stand for the predicates 'The present King of France' and 'Bald', respectively.

Russell's 'theory of definite descriptions' came under attack from Peter F. Strawson, who took up a line of reasoning initiated by Frege and, departing from it in significant ways, insisted that anyone who utters the sentence in question in fact presupposes that there is presently a king of France, rather than asserting it, as Russell's analysis implied. For Strawson, whereas referring expressions indeed have their senses, it is the actual *uses* of those expressions that do the referring. What specific horse is being referred to by the expression 'that horse' can only be resolved by examining an actual use (utterance) of the expression as part of, say, the making of a statement (and not merely the issuance of a sentence), along with the attendant set of actual circumstances. In other words, Strawson foregrounded the pragmatics of reference and claimed speaker reference to be paradigmatic, in opposition to Russell who was primarily interested in sense (a) or the semantics of the term 'reference'.

In contrast to the descriptive approach, direct reference approach harks back to a view taken by J.S. Mill in the nineteenth century. Unlike Frege and Russell, who argued that proper names had senses and that these coincided with the sense of corresponding definite descriptions, Mill had contended that they had no 'connotations' but only their 'denotations' (Mill's terms for sense and reference, respectively). In other words, they simply referred, period, by functioning as a label attached, as it were, directly to the object. Just how this direct contact with the referent is secured is an open question. One suggested answer is that there is a causal link between the use of a term and an original 'baptismal' episode of attaching the name to its

bearer. Not all direct theorists, however, subscribe to the thesis of causality.

Among modern defenders of the direct reference approach are Keith Donnellan, Saul Kripke, and Hilary Putnam. Highlighting the pragmatic aspect of reference, Donnellan argued that there are two distinct uses of definite descriptions, namely 'attributive' and 'referential' uses. In its referential use, a referring expression such as 'Smith's murderer' can succeed in picking up the intended referent, namely, say, the man in the dock awaiting the sentence, even though it may eventually turn out that the man in question is innocent of the charges. In other words, in its referential use a referring expression can refer *in spite of* its sense, contrary to what the descriptivist view predicts. In Donnellan's view, the Russell–Strawson debate was on a nonissue, since the former was thinking exclusively of the attributive use of definite descriptions while the latter was interested only in the referential use, but wrongly believing that the accuracy of the description was a necessary condition for the success of a referential use thereof. An interesting counter-argument to Donnellan's thesis was offered by John Searle, who claimed that the two uses, far from being mutually exclusive, can be explicated in terms of the number of 'aspects' under which a speaker is in a position to refer to the referent in question.

Kripke held that proper names are 'rigid designators', meaning that they have the same referents in all possible worlds. So it is wrong to think that a proper name such as 'George W. Bush' has the same sense as 'The President of the United States of America' because, although the two may indeed refer to the same individual in the actual world, they may not do so in some other possible world (say, the one in which the Supreme Court decision had favored Al Gore instead).

In the 1970s, Hilary Putnam developed the thesis of 'semantic externalism' whose central tenet is that, in many cases such as words referring to natural kinds like 'gold' and 'water', the reference of an expression cannot be thought of as a function of descriptions associated with it in the mind of the user. Thus, in Putnam's view, 'water' refers to the chemical compound H_2O in all possible worlds, irrespective of whether or not one is aware of that scientific truism.

Direct reference theories run into difficulties when called upon to explain the behavior of referring expressions in what are known as intensional or referentially opaque contexts as in 'Juan believes that the Malvinas rightfully belong to Argentina', which has—on one interpretation—a different truth value than the sentence 'Juan believes that the Falklands rightfully belong to Argentina' although 'Falklands' and 'Malvinas' designate the same group of islands (a fact that, as it happens,

Juan is not aware of). The usual answer that whatever difference there may be between the two sentences is not of interest to semantics has not satisfied critics. Causal theorists are also hard put to it to explain changes in the reference of a term over the years (as in the case of 'Yugoslavia' whose referent has significantly changed after successive wars) as well as natural kind terms that are posited rather than effectively attested (as in the case of a missing link to account for the development of human beings from apes).

<div align="right">KANAVILLIL RAJAGOPALAN</div>

Register

Broadly defined, 'register' refers to the way people use language in different situations. The term is often used as a full or partial synonym for style, speech variety or variation, field of discourse, and text type. It is the subject of sociolinguistic, linguistic, and applied linguistic analysis.

Most often, register is used to mean style. In that sense, it refers to the 'stylistic variety', or 'stylistic variation' that occurs in a person's speech or writing in different social contexts. Typically, different registers vary according to their degree of formality. For example, expressions like 'sure', 'no problem', and 'let's have a blast' are associated with informal conversational styles or registers. Utterances like 'in spite of our deliberate efforts to condemn fraud…', on the other hand, are used in formal written texts. In her *Grammar book*, D. Larsen-Freeman offers numerous examples of appropriate and inappropriate use of both formal and informal registers. In the case of phrasal verbs, 'put off', 'call off', and 'show up' are common in informal registers, whereas their one-word synonyms 'postpone', 'cancel', and 'arrive', reflect higher levels of formality. The same applies to relative adverbs. For example, '1950 is the year that I was born in' would occur in more formal texts than '1950 is when I was born'. A connector, such as 'moreover', normally occurs in formal written texts. It would be inappropriate in an informal conversational setting like this, 'Let's go to the beach. *Moreover, let's rent a boat'. It appears from these and other examples that there is an abundance of structures that reflect the subtle nuances of formality, both within a separate linguistic category and across different categories.

Linking register solely to levels of formality in speech and writing, however, would be an oversimplification. Along with levels of formality, scholars also study changes in register based on the speaker's awareness of a broader network of differences in situation, topic, addressee(s), or location. John Lyons emphasizes the complex sociolinguistic nature of register. He discusses it in the framework of context, style, and culture, and more specifically as a feature of 'communicative competence'. He relates it to the appropriate choice of language with regard to 'domain', i.e. a cluster of social situations constrained by a common set of behavioral rules. Within domain, Crystal and Davy identify 'province', i.e. occupational or professional activity with no reference to the individuals engaged in it. For example, the language used in advertising, science, law, and sports can be identified as being typical of the corresponding province, hence the use of 'love' in tennis and 'sentence' in law.

Fishman relates domain to 'subject-matter' on the one hand, and to 'locale' and 'role-relations' on the other. Examples of these would be 'family—home' and 'religion—church'. Within these subject-locales, he identifies certain role-relations, such as 'mother-to-son' and 'priest-to-parishioner'. Thus, a mother talks to her son at a different level of formality if the conversation is held at home or not. Similarly, her choice of language will be different if the topic was 'her son's drunk driving' and 'her son's recent award'. She would also choose a different register if she were to discuss these subjects with other people, at other places. Similar to Crystal and Davy's use of 'province', Quirk defines

register in relation to the 'field of discourse', or the activity in which a speaker is engaged. He categorizes speech varieties as dependent and interdependent according to 'field of discourse'. Speakers who retain regional features in their use of Standard English are examples of the former. Interdependent speech varieties, on the other hand, in a slightly broader use of Fishman's 'locale', are exemplified by topics that are associated with specific regions. Thus, discussions of baseball are in American English. Similarly, coaching is handled by speaking rather than by writing.

Linguistically, register could also be examined on the phonetic, morphological, syntactic, and semantic levels. Yet, it can be most fully analyzed on the 'text' level, e.g. it is suprasentential or above and beyond the sentence. In his *An introduction to functional grammar*, M.A.K. Halliday discusses register in relation to 'texture', or 'text structure', which comprises theme and focus, lexical cohesion, reference, ellipsis and substitution, and conjunction, all of which have a semantic, not grammatical structure. He points out some of the differences in 'theme and rheme' in different text types, such as narratives and instructions. In the following example of a narrative, the participant ('he') remains the topical theme: 'He went to many colleges but he didn't complete any. He always fell into some difficulty. He never hit upon the right thing'. In instructions that have stepwide structure, the theme, or given subject of one clause, becomes the rheme, or new object of the clause that follows it, e.g. 'Turn the stove on. Put a pot on the stove. Pour water into it. Add all ingredients to the water'. Thus, it would be inappropriate to use this kind of stepwide-structured register when writing an expository text, e.g. 'I have twin sisters. My parents love them. They buy them many toys. One such toy is a huge stuffed cat. It now occupies the couch'.

Halliday also defines register by different types of 'lexical cohesion and reference'. He notes that they are built through interlocking referential chain complexes that vary from one register to another and produce a certain global effect, e.g. 'A boy called John. . . John . . . he . . . the lad . . . him . . .' The global effect created by such overlapping referential chains is the source of the dynamic flow of discourse in narratives. According

to him, ellipsis and substitution, which are mostly found in dialogue, have a more local effect because of their shorter lexical reach. Typically, their reach extends over no more than a few consecutive moves, 'A: Would you like to come here? B: Could I bring a friend too? A: Sure. Which one? B: I'll know tomorrow. A: Is it still raining outside?' Such texts are related not so much by ideational as by interpersonal meaning. Halliday also defines the features of oral and written texts or registers. Generally characterized by lexical simplicity, oral texts become complex by being grammatically intricate. They use clauses to express relationships and to achieve dynamic complexity. On the other hand, written and technical texts, in particular, are lexically dense and statically complex because they use nominalization, or a lot of noun phrases, to express relationships. While they have simple clausal patterns, they pack ideas in nominal constructions, i.e. 'advances in technology' instead of 'technology is getting better'. Thus, nominalization, which helps to construct technical terms and develop step-by-step arguments, is often considered the most prominent feature of texts or registers of expert knowledge, prestige, and power.

Reichenbach, Hans

The philosopher Hans Reichenbach was a central figure of logical empiricism in the 1920s and 1930s. The starting point of his research were the philosophical dimensions and implications of relativity theory (*Relativitätstheorie und Erkenntnis a priori, 1920; relativity theory and cognition a priori*), but also more general issues in the

philosophy of space and time *(Axiomatik der relativistischen Raum-Zeit-Lehre (1924; Axioms of relativistic space–time), Philosophie der Raum-Zeit-Lehre (1928; Philosophy of space– time))*. In 1930, he founded the journal *Erkenntnis* (*Cognition*, later called *Journal of Unified Science*), together with Rudolf Carnap from the Vienna Circle. Furthermore, he developed a three-dimensional logic for the interpretation of quantum mechanics *(Philosophic foundations of quantum mechanics, 1944)* and worked on probability.

But linguists usually do not appreciate Reichenbach as a philosopher. In linguistics, he became famous for not more than 12 pages of his complete works, namely for §51 'The tenses of verbs' of his book *Elements of symbolic logic*, 1947.

According to Reichenbach, the tenses of verbs display token reflexivity. The tenses determine time with reference to the time point of the act of speech, i.e. of the token uttered. The time point of the token is called the point of speech (S), and the time point at which the event being talked about took place is called the point of the event (E). Using these two points means assuming three tenses, namely $E < S$ (the simple past in English), $E = S$ (the simple present), and $E > S$ (the simple future). But obviously, there are more than these three tenses in English (and in other languages as well). This is the reason why Reichenbach introduced a third parameter, namely the point of reference (R). What this parameter does becomes most easily clear in narratives. Compare the following passage from W. Somerset Maugham's *Of human bondage*:

> But Philip ceased to think of her a moment after he had settled down in his carriage. He thought only of the future. He had written to Mrs. Otter, the *massière* to whom Hayward had given him an introduction, and had in his pocket an invitation to tea on the following day.

The events related in the simple past perfect (*had settled down..., had written to Mrs. Otter..., had given him an introduction...*) are viewed as being completed from the perspective of a specific point of reference, which is constituted by those events that are related in the simple past (*ceased to think of her..., thought only of the future..., had in his pocket an invitation...*). Thus, the point of reference is a kind of perspective point.

With some tenses, two of the three parameters E, R, and S coincide. The simple past is such a case, with E and R being simultaneous, and both E and R being before S. With other tenses, the three parameters denote distinct times, e.g. in the case of the simple past perfect: E and R are both before S, but E is also before R. The different usages of the simple past and the simple past perfect in the quotation above show this quite clearly.

As for the simple tenses, Reichenbach proposes the following tables, in which the direction of time is represented as the direction of the line from left to right:

Past Perfect	*Simple Past*	*Present Perfect*
I had seen John	I saw John	I have seen John
–X–X–X–>	–X–X–X–>	–X–X–X–>
E R S	R,E S	E S,R

Present	*Simple Future*	*Future Perfect*
I see John	I will see John	I shall have seen John
–X–X–X–>	–X–X–X–>	–X–X–X–>
S,R,E	S,R E	S E R

If there is a progressive form, Reichenbach assumes that the event E covers a certain stretch of time. He calls these extended tenses. Here are two examples:

Past Perfect, Extended	*Simple Past, Extended*
I had been seeing John	I was seeing John
–XXXX–X—X–>	–XXXX—X–>
E R S	R,E S

As for adverbial modification, Reichenbach states that in the presence of positional adverbs like *now* or *yesterday*, only modification of R is possible. This can be illustrated with sentences like *I had met him yesterday*, where *yesterday* is the point of reference, but the meeting (E) has occurred at some time before *yesterday*. Here, R is the carrier of the time position. Therefore, Reichenbach speaks of the positional use of the reference point here.

On the whole, there are 13 possibilities of ordering the three time points E, R, and S. But for English, there are only six tenses in the traditional grammars. The following table summarizes the possibilities, Reichenbach's terms for them, and the traditional terms:

Possibility	Reichenbach's Term	Traditional Term
E_R_S	Anterior past	Past perfect
E,R_S	Simple past	Simple past
R_E_S	Posterior past	—
R_S,E	Posterior past	—
R_S_E	Posterior past	—
E_S,R	Anterior present	Present perfect
S,R,E	Simple present	Present
S,R_E	Posterior present	Simple future
S_E_R	Anterior future	Future perfect
S,E_R	Anterior future	Future perfect
E_S_R	Anterior future	Future perfect
S_R,E	Simple future	Simple future
S_R_E	Posterior future	—

With Reichenbach's terms, the position of R relative to S is indicated by past, present, future, and the position of E relative to R is indicated by anterior, simple, posterior.

As for the posterior future, it is used for instance in *I shall be going to see him*. Sentences like *I did not expect that he would win the race* express the posterior past—like posterior future this is commonly not classified as a tense.

Reichenbach has been criticized for assuming the point of reference because this often coincides with the point of the event or with the point of speech. Nevertheless, his work on tense is considered classic. Within the modern theory of tense, there are many reconstructions and adaptations of Reichenbach, e.g. Klein (1994), Ehrich (1992), Musan (2000), Comrie (1985), Thieroff (1992), and Fabricius-Hansen (1986), to mention just a few.

Biography

Hans Reichenbach was born in Hamburg, Germany, on September 26, 1891. He studied civil engineering, mathematics, physics, and philosophy at Technische Hochschule Stuttgart and Universities of Berlin, Göttingen, and Munich; Ph.D. (1915, Erlangen) for mathematical work about probability; and Habilitation (1920, Technische Hochschule Stuttgart) for philosophical work about relativity theory. He was assistant Professor, Technische Hochschule Stuttgart, 1920–1926; and Professor for Philosophy of Nature and Physics, University of Berlin, 1926–1933; he lost his teaching appointment when the Nazis seized power and emigrated to Turkey; he was Professor for Philosophy, University of Istanbul, 1933-1938. He moved to the United States, and was Professor for Theory of Science, University of California at Los Angeles, 1938–1953. He died in Los Angeles on April 9, 1953.

MONIKA RATHERT

Relevance in Discourse

Since discourse analysis is interested in stretches of text longer than a sentence or an utterance, it has to address the question of coherence—how the different parts of texts hang together. One crucial aspect of coherence will be relevance, how the meanings conveyed by one sentence can be related to or interact with information already in the reader's/hearer's mind, especially information already given in the preceding text.

The first philosopher to emphasize the importance of relevance to discoursal pragmatics was Grice (1975 [1967], 1989). His cooperative principle proposes four maxims that govern conversation in particular, namely quantity (give as much information as is required, no more), quality (only say things that are true for which you have evidence), manner (be clear, orderly, concise, and avoid obscure language), and relation (be relevant).

Sperber and Wilson (1995) and Wilson and Sperber (1987) developed Gricean theory by subsuming all these maxims under relevance. For them, communicative utterances carry the presumption of optimal relevance. Utterances are relevant if the information they convey interacts with the hearer's existing assumptions. These interactions, called contextual effects, can be either the strengthening of an existing assumption, the weakening/cancelation of an existing assumption, or the production of a contextual implication. In the

case of contextual implication, the information given by an utterance interacts with an existing assumption by deductive logic, to create a new assumption. One of Sperber and Wilson's examples is as follows:

A: Would you drive a Rolls Royce?
B: I wouldn't drive any expensive car.

B does not obviously answer A's question. However, if A already knows that a Rolls Royce is an expensive car, this assumption interacts with B's reply to produce the contextual implication 'B would not drive a Rolls Royce'. So, B's answer is still relevant to A's question.

The assumption supplied by the hearer 'a Rolls Royce is an expensive car' is called an implicated premise. That different contextual implications arise from different implicated premises is particularly important to the intertextuality of discourse. Intertextuality, put simply, means the way in which one text impinges on others (Kristeva 1974:59–60). One aspect, viewed from a relevance perspective, is that the information derived from one text can provide implicated premises and effect the contextual implications during the processing of a later text. For example, take the following text:

> It is difficult to see how any organism could remain healthy if feedback messages to the decision-making center were systematically stifled for long periods.

It will be processed and interpreted quite differently, more metaphorically, if the preceding intertext is a) a report showing that many politicians are devoting less and less time to their constituency surgeries/feedback sessions with the electorate rather than b) a feature article on the advances in the effectiveness of the pain-killing sprays used by football-players/athletes.

The relevance of utterances can be computed as a fraction:

$$\frac{\text{contextual effects}}{\text{processing effort.}}$$

All other things being equal, the greater the contextual effects the greater the relevance, and the greater the processing effort the less the relevance. We can see that contextual effects correspond to Gricean maxims of quality and relation; and processing effort corresponds to Grice's maxim of manner (and perhaps quantity). According to this formula, B's reply might not be seen as optimally relevant. B could have reduced the processing effort by simply replying 'No'. However, B's actual answer is likely to produce far more contextual effects than the answer 'No'. For example, if A knows that a Cadillac and a Lexus are also expensive cars, then B's actual reply will generate the contextual implications 'B would not drive a Cadillac or a Lexus'.

Like Gricean pragmatics, relevance theory opposes a code-based theory of communication. A successfully decoded message may be intelligible, as B's answer

above is to A, but to function as relevant in discourse it has to be interpretable, which may involve implication or inferencing. So Grice and Sperber/Wilson prefer an inferential account of communication. In this, coding and decoding using conventional signs are never sufficient for communication, and sometimes even unnecessary. If you ask whether I enjoyed my skiing trip, and I raise my broken leg covered in plaster, this might communicate the answer 'no'. But such an action has no conventional coded meaning. In inferential theories, utterances give evidence for a hypothesis about an intended meaning, often an implied one, as in the examples above.

However, relevance theory goes further than Grice, in maintaining that pragmatic inferential processes are important in making explicit the full propositional content of the utterance, even before implications are made. For example, imagine John has cooked dinner, Mary is sitting in the dining room reading the newspaper, and John comes in and puts the two plates of food on the table. He then says

> It'll get cold.

In order to make the prepositional content complete, we have to infer what 'it' refers to (for example, Mary's dinner rather than the newspaper), disambiguate 'cold' (to mean 'low in temperature' rather than 'experiencing low temperatures'), and narrow down the time reference of 'll' (to mean 'will soon'). This process, an example of what is termed explicature, will give us the relatively complete proposition

> Mary's dinner will soon become low in temperature

This is now intelligible as a complete message. But in order for it to be interpretable, it would have to generate a relevant contextual implication. If it interacts with Mary's existing assumption

> John wants Mary to eat her dinner while it is still hot.

the resulting contextual implication would be

> John wants Mary to come and eat her dinner very soon

(cf. Sperber and Wilson 1995:176–93).

Relevance theory was seen by Wilson and Sperber as a complement to Chomskyan linguistic theory, which deals with semantics but fails to account for the pragmatic meanings generated in discourse. Chomsky is famously uninterested in sociolinguistics. But, as early critics of relevance theory pointed out (Clark 1987), without some theory of social purposes the notion of relevance is rather vacuous. Goatly (1994, 1997) argues that in order to develop as a tool for discourse analysis, relevance theory needs developed notions of social contexts such as the Hallidayan

concepts of register and genre. However, Blass (1990) has argued that relevance theory gives a more satisfactory account of cohesion and coherence than the model of Halliday and Hasan (*Cohesion in English* 1976).

Relevance theory has been interestingly applied to different discourse genres, including work by Tanaka (1994) and Forceville (1994) analyzing advertisements, Campbell (1992) and Moeschler (1989) on argumentation, Wilson (1990) on political language, and Mayher (1990) for language in education.

ANDREW GOATLY

Rhetoric and Linguistics

No discussion regarding the interrelationships between these two disciplines can proceed without a thorough understanding of what their content encompasses, the key to the alliance. The roots of rhetoric date back to the work of Aristotle (384–322 BCE) and the fifth-century sophists (460–380 BCE) such as Protagoras and Gorgias, who in their dialogues about the relationship of truth and reality, and the nature and purpose of spoken discourse consistently demonstrated that, inevitably, for these scholars there was a 'philosophical and pedagogical concern with language' (Gillam 1998:15).

Like linguistics, rhetoric has exhibited organic changes in focus, orientation, and scope over time, evident in the meaning of the word rhetoric, which has acquired meanings that are 'irreducibly multivalent' (Fleming 1998:174). Often associated in modern lay thought with the political rhetoric of 'deceit', rhetoric in academia has moved from being a 'pejorative to an honorific term' (Fleming 1998:169), a return to the classical art of persuasion. Modern uses of the term have broadened the scope of rhetoric to include 'virtually all humanly created symbols from which audi-

ences derive meanings' (Foss et al. 1999:6), an influence triggered by the modern rhetorician Kenneth Burke, who envisioned rhetoric to be 'symbolic inducement' (Burke 1966:296) for the purposes of either cooperation or competition. The site of location has shifted from public spheres of debate such as law, politics, and religion to more private constructions of meaning, particularly the manner in which individuals make sense of their world, a shift that has resulted in the synonymous connotation that rhetoric has acquired in modern times with the term 'composition', the private creation of meaning via the most common symbol of persuasion, writing, in modern universities. In this entry, these terms are sometimes used synonymously. Although the focus in classical accounts is with the construction of truth, modern conceptualizations see rhetoric as providing an arena to question the privileging of some truths over others, in short, 'a tool of critique' to demonstrate that 'reality, belief and language are not lined up as unproblematically as people would like' (Fleming 1998:170), a shift prompting an additional return to antiquarian roots espousing the sophist tradition of Isocrates which stresses civic development

or *Arete* (virtue) on the part of the individual. In such a conceptualization, 'rhetoric is a study that in addition to imparting an art and guiding good practice, encourages critical and substantive reflection about the situated relations of discourse to reason, character, and community in human action' (Fleming 1998:184), a definition stressing the link with linguistics, particularly sociolinguistics.

The link between the two fields is often conceptualized as the applications of linguistic theory to rhetoric, an alliance that can be broadly divided into two periods: optimistic applications of linguistic theory to rhetoric from the 1950s to the mid-1980s— a period of 'a good deal of excitement' (Smitherman 1999:351)— to pessimistic speculations as to the actual applicability of linguistic theory in the early 1990s to the present. It is important to stress that even though the literature seems to insist that the influence was unidirectional, linguistic research has also been influenced by studies in rhetoric. This might be attributed to the parallel development of composition-rhetoric and linguistics in the 1950s and 1960s as 'both fields sought to reinvent themselves and stake intellectual claim to distinct identities among the established disciplines of the academy' (Smitherman 1999:351). Consequently, the antiquarian interest in audience-influenced discourse styles saw linguistic applications in the work of Martin Joos (1961), who outlined five major audience-influenced styles of discourse.

Since language has and continues to be an integral part of rhetoric, especially in approaches labeled epistemic rhetoric, whose primary focus is on the private sphere of semantic generation, particularly the extent to which language simultaneously embodies and generates knowledge, linguists have constantly influenced and been influenced by the field. For instance, Kenneth Pike (1970) developed his theory of tagmemics in response to the argument that since the basis of language was the embodiment of knowledge, such a process could only proceed via access to reoccurring, repeatable units, the kind that language already offers. The dual relationship between these disciplines emerges in the unique conceptualization of Rogerian rhetoric, a persuasive technique based on conciliatory rather than adversarial argumentation. Similar links can be made with the work of Kenneth Burke (1966) whose model of language as action, 'an equipment for living' and 'a strategy for coping' (Warnock 1998:11) had linguistic parallels in the performative model of J.L. Austin's speech act theory.

The influence in the 1950s through the 1970s came from theoretical linguistics, particularly in the early phases, structuralism and, later, generative grammar, as well as applied linguistics, particularly the work of sociolinguists. One of the most overt influences in rhetoric-composition was in the form of the 1974 National Council of Teachers of English (NCTE) statement on 'Student's rights to their own language', a document first drafted by the Conference on College Composition and Communication (CCCC). The 1970s split in linguistics between Cartesian/theoretical linguistics and applied linguistics prompted a shift in influence, with most of the influence coming from applied linguistics. Some of the most commonly cited linguists at this time were Charles C. Fries, Kenneth Pike, Paul Roberts, and Noam Chomsky.

These linguistic influences prompted a shift from prescriptive accounts of written discourse to more descriptive orientations to student writing, as well as an overt recognition that the cultural, linguistic, and rhetorical backgrounds of writers shaped their discursive practices. Other areas of interest in this period came from studies in contrastive rhetoric, whose propounder, Robert Kaplan (1966), was heavily influenced by the work in contrastive analysis in applied linguistics. The aim of such early as well as later theorists such as Ulla Connor was to demonstrate first language sociocognitive influences of speakers engaged in second language rhetorical practices, work resonating the cultural determinism inherent in the linguistic theories of Benjamin Lee Whorf. Recognizing the sociocultural basis of writing, linguists such as Muriel Saville-Troike and Donna M. Johnson have synthesized ethnography of communication approaches with such conceptualizations and devised linguistically oriented rhetorical approaches whose basic premise is 'text as praxis' (Cai 1998:123). Applications of contrastive rhetoric in first language writing are manifest in the works of Mina Shaughnessy and David Bartholomae whose research stresses that student errors in writing may be reflections of systematic sociocultural patterns rather than random performance slips, an approach heavily adopted by theorists in basic writing paradigms such as that developed by Patricia Bizell and Bruce Herzberg who urge for the teaching of effective rhetorical strategies that permit both inter- and intracultural communication.

Research in the 1980s saw a deep alliance between the fields and 'scholarship influenced by Pragmatics, Discourse Analysis and Functionalist Linguistics appeared with some frequency in composition journals and monographs' (Kimball 2000:180). Shirley Brice Heath's (1983) *Ways with words*, an ethnography of speaking approach, influenced rhetoricians interested in issues of literacy and written composition then and even today. Other connections to linguistics came in the alliance with stylistics. This marriage of disciplines saw a culmination in the publication of two books, one by Raskin and Weiser (1987) of *Language and writing: applications of linguistics to rhetoric and*

composition, a book demonstrating pragmatic applications of linguistics in the teaching of rhetoric, and the other by Beale (1987) of *A pragmatic theory of rhetoric*, a rhetorical model based on J.L. Austin's Speech Act Theory (1962) since 'classical concepts of rhetoric square nicely with speech act theory, making them mutually illuminating' (Winterowd 1987:282). One can say that this was the last happy alliance.

By the early 1990s, institutional changes that separated English and Linguistics departments at a number of universities triggered pessimistic feelings on the part of rhetoricians concerning the utility of linguistic analysis, a sentiment often voiced in articulations that the scientific method of linguistics, particularly 'the atomistic nature of most linguistic analysis' (Roy 1991:580), was in contradiction to the humanistic method of rhetoric, a difficulty accentuated even further by the metalanguage adopted by linguistics that prompted Alice Roy (1991), in a classic review of four studies on the alliance, to describe the link as 'problematic' (580). Recent rhetoricians have commented that this pessimism is unwarranted, a consequence of a misapplication of linguistic theory, a view based on 'limited and inaccurate views of linguistics' (Kimball 2000:181). Utilizing research from Gary Olson and Lester Faigley, who review Chomskian applications to rhetoric concluding that 'It's very rare that you ever get a free ride from some other field' (34), prompts Kimball (2000) to call for a renewed interest in the applicability of linguistic theories to rhetoric today.

Obvious examples of such renewed interest come in discourse theories in rhetoric propounded by Kinneavy et al. (1990), as well as social constructivist research in the field by theorists such as Susan Jarratt and Lynn Worsham, Lester Faigley, and James Berlin, all of whom view language to be a complex, pluralistic signifying practice that simultaneously constructs realities as it presents it—a rhetorical paradigm rooted in Roland Barthes's (1968) theory of social semiotics, an approach emphasizing the social and ideological underpinnings of symbol use. These conceptualizations show heavy influences from linguistic research in critical discourse analysis, particularly social semiotics.

Renewed interest has occurred in the area of generative rhetoric, a paradigm originally devised by Christensen and Christensen (1976), who, influenced by generative linguistics, argued that texture in discourse proceeded via syntactic elaboration, particularly via modification and addition. There has been a recent pedagogical push for more overt sentence combining instruction in writing. An exponent, Kimball (2000) argues for this approach to be utilized in the revision stage of writing. Other current applications of linguistics are in genre theory, a theoretical paradigm strongly influenced by the works of M.A.K. Halliday's

systemic functional linguistics. Researchers such as Susan Jarratt and Lynn Worsham, Lester Faigley, and James Berlin push for a view of written rhetoric as situated social action, arguing that the only means to empower neophyte writers from being silenced is to educate them about the genres of powered discourse. Recent reapplications of early psycholinguistic and sociolinguistic models have manifested themselves in whole language teaching approaches to rhetoric, which emphasize linguistic socialization within and not apart from reading, writing, listening, and speaking. Other perspectives in genre theory have influenced rhetorical theories such as the literacy-orality theories of Walter Ong, an extension of Whorfian linguistics situating the source of writer difference in oral vs. analytical cultures, and/or individuals, an outcome of which may be a difference in cognitive complexity. Although this approach has been heavily critiqued in rhetorical and linguistic circles, applications of genre differences in spoken and written discourse have been recently cited by Kimball (2000) as an arena for research. Using the linguistic analyses of linguists such as M.A.K. Halliday, Wallace Chafe and Danielwicz, and Douglas Biber, she argues that some of the difficulties that novice rhetoricians face in this era may be an inability to distinguish between the features of this genre, a knowledge of which is presumed by the academy, and oral discourse. Returning to the unity of the disciplines in classical antiquity has caused some researchers in linguistics to recreate an alliance that benefits both pragmatics and rhetoric.

With the renewed interest in applied linguistic theories, the alliance between rhetoric and linguistics looks promising, a possibility accentuated by the fact that more and more students and faculty in composition-rhetoric and linguistics departments have some exposure to each other. What makes the synthesis even more viable is that the area of interest in both rhetoric and linguistics from antiquity to the present has been questions of language. In both fields therefore, we have to continue to see the product of language as a 'subject of study rather than an object of intervention' (Kimball 2000:188). With this said, one can only predict more of an alliance in this century.

ANJALI PANDEY

Romanian

The Romanian language (*Limba română*) is a Romance language that has been continuously spoken in the east-ern part of the Roman Empire, including the Romanized provinces of Dacia, Southern Pannonia, Dardania, and Moesia, from the moment Latin was brought there until the present. The Romanian language has four main dialects: Daco-Romanian (or Romanian proper), Macedo-Romanian or Aromanian, Megleno-Romanian, and Istro-Romanian. The Aromanian dialect is spoken in Albania, Macedonia, Greece, and Bulgaria by scat-tered minorities, and the main area where Megleno-Romanian is spoken is in Greece. The Istro-Romanian dialect was spoken on the Istrian Peninsula of Croatia. The Daco-Romanian dialect ('Romanian') is spoken by more than 25 million people in Romania, Serbia, Croatia, Slovenia, Bosnia and Herzegovina, Bulgaria, Hungary, and Moldova, as well as in Romanian com-munities in the USA, Australia, Italy, Germany, etc. The variety of Romanian spoken in the Republic of Moldova (east of the Prut river) is officially called 'the Moldavian language'.

The earliest known written document in Romanian is a letter dating from 1521. The present spelling system was settled around 1860–1880. The basis of the standard Romanian language is a combination of the two main geographical varieties, the Moldavian (west of the Prut river) and the Wallachian (Muntenian), the latter playing the more important role in setting the standard. Given the language's relative isolation from the other Romance languages and its close contact with Hungarian and the Slavic languages surrounding Romania, the develop-ment of Romanian followed a different path from those of most other Romance languages.

One of the most important foreign influences came from the Slavic languages. As a liturgical language, Old Slav(on)ic (or Old Bulgarian) provided a relatively large number of words to Romanian. This situation, combined with the fact that until the nineteenth century the Cyrillic alphabet was used to write Romanian and with the geopolitical position of Romania, has misled many peo-ple into thinking that Romanian is a Slavic language and that Romania is a successor state of the Soviet Union. Another major influence in the development of the Romanian vocabulary came from Greek, especially dur-ing the Phanariot period (1711–1821). However, very few of the Greek borrowings are still in use today. Other foreign influences came from Turkish, Hungarian, and German. Turkish influence was prominent in Moldavia

and Wallachia during the Phanariot period, and Hungarian influence was prominent in Transylvania while it was part of the Austro-Hungarian Empire. The German elements used by the Romanian minorities of German origin also played a role in the diversification of the Romanian vocabulary. More recent foreign influences came from French in the first part of the twentieth century, while today massive English influence on the Romanian vocabulary can be easily observed.

Within the geographical area of Romania, there are three main varieties of the language: Moldavian, Wallachian (Muntenian), and Transylvanian. Additionally, in the Republic of Moldavia the inhabitants speak the Bessarabian variety of Romanian, which is characterized by the massive influence of Russian. All these varieties, however, are mutually intelligible. The standard pronunciation of Romanian is based on orthographic norms. In this respect, the principle generally promoted is that of identity between writing and pronunciation.

As far as the vocabulary is concerned, Romanian inherited c. 2,000 original Latin words, but Latin elements make up 60% of the Romanian vocabulary. Most of the original Latin words refer to parts of the human body and have several meanings, including metaphorical ones.

In contrast to the vocabulary, Romanian grammatical structure is almost entirely Latin. There are Latin prepositions (e.g. *cu* 'with') and conjunctions (e.g. *și* 'and'), Latin interrogative pronouns (e.g. *cine* 'who'), Latin endings for marking the plural, Latin verbal endings for marking person and tense, Latin pronouns, and Latin numerals from one to ten.

Romanian grammar involves ten parts of speech: six inflected (noun, article, adjective, pronoun, numeral, and verb) and four noninflected (adverb, preposition, conjunction, and interjection). The following grammatical categories all stem from Latin: gender, number, case, person, comparison, voice, mood, and tense. However, the development from Latin to Modern Standard Romanian generated several differences. Thus, for example, Latin had six cases, while Romanian preserves only five—nominative, genitive, dative, accusative, and vocative.

Gender in Romanian distinguishes masculine, feminine, and neuter (masculine and feminine genders are inherited from Latin, while neuter is a creation within Romanian).

The changes from Latin are typically simplifications (as in all Romance languages), which led to a reorganization of the vocabulary by reducing the complicated forms of the noun and adjective, by simplifying and rearranging the verbal system, and by simplifying the case system.

While the Romance languages usually have reduced nominal declensions, Romanian has three forms of noun inflection inherited from Latin. The declension of adjectives is identical to that of nouns, varying according to gender, number, and case. The pronominal declension is the richest and the closest to the complex Latin system of all the Romance languages. The Romanian verbal system is largely based on Latin. The most noticeable differences from the other Romance languages are the analytic future (*voi citi* 'I shall read') and the supine (*de citit* 'for reading'). Romanian is the only Romance language with a free sequence of tenses and a relatively free word order.

Rules vs. Constraints

The question of whether grammar should be modeled using rules or constraints presents a morass of terminological confusion in addition to some legitimate theoretical issues. In some work, e.g. Karttunen (1993), the terms '(declarative) rules' and 'constraints' are used interchangeably. There are even positions

such as Mohanan's (2000:146), who argues that the distinction is incoherent once we recognize that both rules and constraints express propositions. This article proposes a definition of 'rule' vs. 'constraint' that will surely be inconsistent with other usages, but which provides the basis for discussing competing models of grammar, focussing here on phonology.

The use of both rules and constraints requires a representational matching procedure (RMP) to determine whether a given rule or constraint P applies to a given representation q. Part of the statement of P must be a structural description, SDp. The RMP must evaluate q to determine whether it satisfies SDp. The RMP outputs two possible results: YES, q satisfies the structural description of P; or NO, q does not satisfy the structural description of P. In other words, the RMP defines the domain of the function P. In many theories, the RMP relies on subsumption—q is in the domain of P if SDp subsumes q—although there are other possibilities.

If the RMP determines that q is in the domain of P, we can now distinguish between a rule and a constraint. Consider a rule of the form $R(I) = O$, that is, R maps input I to output O. If q is in the domain of R (i.e. if the RMP determines that q matches I), then that part of q that is identical to I is rewritten as O yielding q': $R(q) = q'$. Thus, we define rules as functions from representations to representations, with both input and output built from the same representational primitives.

In a constraint-based system, if the RMP determines that q is in the domain of a constraint C, then an operation of constraint evaluation must determine whether q satisfies the constraint. If q satisfies C, constraint evaluation outputs the value NOVIOLATION; if q does not satisfy C, constraint evaluation outputs the value VIOLATION. These values then serve as input to another component of the grammar. In some models, if there is any constraint that q violates, then q is ungrammatical. In optimality theory (OT), in contrast, the evaluations of q for each constraint are fed to another component of the grammar, which compares q to competing representations. The output of the grammar typically does violate some constraints in OT, but they must be lower ranked than constraints violated by competing representations.

To reiterate: a rule is defined as a function from representations to representations; a constraint is defined as a function from representations to the set {VIOLATION, NOVIOLATION}. Note that a constraint-based system requires two evaluations of a given representation q—one corresponding to the RMP to determine whether a constraint C is relevant to q and one to the evaluation of whether q violates C.

Equipped with this working distinction between rule and constraint, we can now offer arguments to favor rule-based models of grammar, by pointing out a number of conceptual and empirical problems with constraints. Our first criticism of constraint-based models is related to issues of learnability, acquisition, and the nature of universal grammar (UG), i.e. the human language faculty. Many linguists, especially phonologists, have assumed that both UG and particular grammars contain constraints—either positive or negative conditions that, respectively, must or must not be satisfied by grammatical representations. However, such conditions *cannot* be learned by positive evidence. This is because a generative grammar generates an unbounded number of well-formed structures, but only a finite sample can be encountered by any point in acquisition. The learner may find a supposed ill-formed structure in the next sentence. For example, a putative constraint that all syllables must have onsets may be consistent with the data received up to a given point; however, there is no guarantee that the inductive conclusion consistent with the constraint will turn out to be correct. Therefore, such conditions could only be learned via negative evidence. However, it is generally accepted (see Marcus (1993) for convincing arguments) that negative evidence is neither supplied to the child with sufficient regularity, nor attended to by the child when supplied, to play a significant role in language learning. Thus, the constraints cannot be learned via positive evidence (for reasons of logic), nor through negative evidence (according to the empirical data from language acquisition). So they must be innate.

This conclusion follows from the premises, and it has led to implausibly rich versions of UG. In phonology, for example, innate constraints have been posited to account for the vast variety of phonological alternations seen in the languages of the world. The OT literature provides examples of constraints to account for voicing of initial obstruents in the second member of Japanese compounds, flapping in English, and so on, thus trivializing the notion of UG. Fortunately, the conclusion of innate constraints can be rejected: the problem lies with the assumption that UG, and also particular grammars, consist of constraints. By positing a set of representational and computational primitives, such as syllables and feet, precedence relations, identity evaluations, etc., and a learning mechanism that combines these primitives into rules that capture alternations, a learner can build a language-specific grammar based solely on positive evidence. By positing highly specific rules that conform to the data, the learning path is constrained without the use of constraints.

A cluster of arguments against constraint-based models relate to the fact that they typically depend on adopting a notion of (absolute or relative) ill-formedness

of linguistic representations. Ill-formed representations violate constraints, and this result is passed on to other modules of the grammar. An obvious objection to this approach is that there is a much simpler alternative to the idea that grammars generate ill-formed representations and then reject them as possible outputs—why not assume that the grammar just generates those representations that it outputs? The grammar itself does not need the notion of ill-formedness. Of course, a linguist may refer to a representation as ill-formed, in the sense of 'not generatable by a particular grammar *L*', but this description by a linguist should not be interpreted as a description of an actual property of *L*. Instead of accounting for the infinite set of representations that *L* does not generate, normal scientific practice seems to dictate that we account for what *L* does generate. Ill-formedness, or rather non-formedness, is thus a derivative notion.

Various theories of grammar, including OT and some versions of minimalism and its predecessors posit a mechanism that allows unconstrained generation of linguistic representations. In OT, this device is GEN which, given an input, generates the universal candidate set of possible outputs. In various syntactic theories, an analog to GEN is the 'free' concatenation of morphemes, or the 'free' application of operations such as *Move α*. A derivation which is thus generated will either satisfy certain constraints at PF and LF, the grammar's interface levels, and thus converge; or it will not satisfy those conditions and it will crash. Both the OT approach and the free-generation-with-interface-conditions approach in syntax are flawed in the following (related) ways.

First, it is easy to proclaim something like 'GEN generates any possible linguistic representation' or 'The syntactic component allows *Move α* to apply freely'. However, it is not clear what such statements mean. One could argue that the theory of grammar need not be computationally tractable, since grammar models knowledge and does not necessarily provide an algorithm for humans to produce speech output. However, there must be some mechanism that does generate particular linguistic representations, and it is not unreasonable to ask a theory of grammar to characterize the formal properties of this mechanism. It seems that any implementation of GEN or the syntactic component that incorporates *Move α* will have to be explicit about what it does. One way to achieve this is to be explicit about what the abstract grammar generates.

Second, the free generation-cum-filters model stinks somewhat of antimentalism. It basically says 'We don't care how the candidate forms are generated, as long as they are generated. One way is as good as the next, as long as they are extensionally (empirically) equivalent.' In defining I-language, a matter of 'individual psychology' as the domain of inquiry for linguistics, Chomsky (1986) argued convincingly that the fact that knowledge of language is instantiated in individual minds/brains means that there is necessarily a 'correct' characterization of a speaker's grammar.

Rejecting the view that the language faculty consists of constraints has methodological implications. Just as we do not want the language faculty to contain constraints against grammatical structure, models of the language faculty should not be described via constraints. If our current hypothesis concerning UG is stated only in positive terms, as statements of what grammars have access to or consist of, without prohibitions or constraints, we can achieve a more economical model. The positive terms are just those entities and operations (features, syllables, deletions, insertions (in phonology); and *Merge, Move* and feature-checking (in syntax)) which have been observed empirically or inferred in the course of model construction. When faced with a phenomenon that is not immediately amenable to modeling using existing elements of the vocabulary, scientific methodology (basically Occam's Razor) guides us. We must first try to reduce the new phenomenon to a description in terms of the vocabulary we already have. If this can be shown to be impossible, only then can we justify expanding the vocabulary.

Once one accepts that modules or processes of grammar must have a certain set of properties and that these properties ultimately must be describable in terms of a set of positive statements (a vocabulary) and can be incorporated into the structural descriptions of rules, it appears to be the case that a procedural, or rule-based approach to grammar that generates a sequence of representations constituting a derivation is to be preferred to a constraint-based, nonderivational theory. In other words, grammars can be understood as complex functions mapping inputs to outputs. A rule-based model just breaks the complex function into simpler components in order to understand the whole. A theory that incorporates GEN or *Move α* avoids the problem of characterizing the function that is the grammar.

A further objection to the notion of ill-formedness is the fact that the justification for evaluating representations as ill-formed is typically derived from some version of markedness theory. Depending on the formulation of a given constraint, either matching or failing to fulfill the condition specified by the constraint signals VIOLATION. For example, a constraint formulated as 'Don't have a coda' leads to an evaluation of ill-formedness for a syllable that *has* a coda. A constraint formulated as 'Have an onset' leads to an evaluation of ill-formedness for a syllable that *does not have* an onset. Relative and absolute ill-formedness or markedness

evaluations of linguistic representations are ascribed by linguists for grammar-external reasons, such as ease of articulation or perception, avoidance of ambiguity, etc., and thus have no place in a formal model of grammar—humans know about ambiguity, and can try to avoid it, but grammars do not know anything.

Marked or ill-formed structures typically are claimed to have at least one of the following properties:

- Relative rarity in the languages of the world.
- Late 'acquisition' by children (typically referring to the recognizability of a form in child speech).
- Loss in aphasia (typically referring to the recognizability of a form in aphasic speech).
- Relative difficulty of perception (not always experimentally validated).
- Relative difficulty of articulation (based on impressions of what is hard to say).
- Tendency to be lost in language change and to not arise in language change.

All of these criteria have been criticized by Hale and Reiss (2000a,b; see references therein). These works conclude that the best way to gain an understanding of the computational system of phonology is to assume that the phonetic substance (say, the spectral properties of sound waves, or the physiology of articulation) that leads to the construction of phonological entities (say, feature matrices) *never* directly determines how the phonological entities are treated by the computational system. The computational system treats features as arbitrary symbols.

An additional consideration in evaluating markedness and the notion of grammatical ill-formedness, pointed out by John Ohala over the years, is that building into a theory of universal grammar the articulatory or perceptual basis for a recurring sound pattern leads to an unacceptable duplication of explanatory mechanisms. For example, if we can show in a laboratory that consonant place distinctions are less salient in codas than in onsets, we do not need to build into phonological theory innate constraints that lead to place feature neutralization in codas. The facts of perception demonstrated in the laboratory, combined with a theory of language acquisition and change, will account for the attested patterns. Offering an additional cause, within the phonology, is just bad science.

Based on learnability considerations, the weakness of markedness considerations, and various conceptual arguments, we conclude that a rule-based derivational model of grammar is superior, since it can be stated in purely positive terms, without prohibitions. The problem of inductive uncertainty is avoided, by the learner and the linguist, if we adopt a rule-based model of grammar, as defined here.

CHARLES REISS

Russell, Bertrand Arthur William

A leading British philosopher, logician, essayist, pacifist, and political activist, Bertrand Russell was born in 1872 into a liberal and aristocratic family but was sadly orphaned at the age of 4. He grew up as an *enfant terrible* and later a tireless critic of the establishment, only to be invested with the Order of Merit in 1949 and, a year later, awarded the Nobel Prize for Literature. By the time of his death in 1970 at the age of 97, he had authored some 70 books, and around 4,300 articles, book chapters, reviews, pamphlets etc.,

besides more than 61,000 letters and other documents not originally intended for publication. Along with G.E. Moore, he is widely acclaimed as one of the founders of analytic philosophy and, with Kurt Gödel, he shares the reputation of having made the most significant contribution to the study of logic in the twentieth century. An unflinching pacifist, he was imprisoned for involvement in antiwar protests and dismissed from his job at Cambridge University in 1916, and in 1940 from his job at the City College, New York; years later, in 1961, he was again arrested and imprisoned for a week, this time for engaging in antinuclear protests. As an essayist and pamphleteer, Russell addressed a number of issues of contemporary social, political, and moral concern and never shied away from expressing his views boldly and openly as in his book *Why I am not a Christian*.

Russell was a strong advocate of logicism—the view that all of mathematics is ultimately reducible to logic. To him goes the credit for having directed the attention of fellow philosophers and logicians to the utmost importance of detecting and rooting out contradictions in set theory and elsewhere. In 1901, Russell discovered what is famously known in the literature as 'Russell's paradox', later fully elaborated in his work *Principles of mathematics* (1903). The paradox, or antinomy as it is sometimes called, was identified by imagining a set of all sets that were not members of themselves and asking, apropos of that resultant set, if it was a member of itself, the answer being that it can only be a member of itself by not being a member of itself—which is a blatant contradiction. The discovery of this paradox stimulated intense research in set theory and led to several suggested solutions. Russell's own solution was elaborated in his theory of types, which basically consisted in postulating a hierarchy of sentences with strict prohibition on mixing levels and thus preempting the very question that led to the discovery of the paradox in the first place.

Among Russell's most significant contributions to the philosophy of language is his famous 'theory of definite descriptions' put forward in response to the German logician Gottlob Frege's theory of 'sense' (*Sinn*) and 'reference' (*Bedeutung*). Frege had argued that two expressions, say, 'the morning star' and 'the evening star', although clearly different in their senses, can nevertheless have the same referent, namely, in this particular instance, the planet Venus. Despite its intuitive appeal, Russell found the distinction unsatisfactory and was appalled by what Frege had shown to be an important consequence of the distinction for the very enterprise of logic as it had been traditionally conceived. For, in Frege's view, the sentence 'The present king of France is bald', uttered at a time when France was no longer a monarchy (or, equivalently,

when there was no referent to the descriptive phrase 'the present king of France'), was bereft of any definite truth value, because the existence of the referent is a precondition (or, technically, presupposition) for what is asserted by the sentence to be capable of being either true or false. When the presupposition is not true, what is asserted by the sentence will be neither true nor false. This meant that the time-honored principle of logic known as the law of the excluded middle according to which, given a sentence and its (contradictory) negation, one of them has to be necessarily true no matter what the world is like would be, from now on, subject to the additional constraint that stipulated 'provided the sentence's presuppositions are true'. Russell realized that such a consequence was simply devastating for logic's reputation as a 'science of pure reason'.

Russell's alternative analysis began by showing that the logical form of the sentence under discussion was much more complex than Frege had thought: it was, he argued, actually a conjunction of three separate propositions, namely: (1) There is a present King of France. (2) There is only one king of France. (3) Whosoever is the King of France is bald. Now, it is commonplace in logic that the negation of a compound sentence could be shown to be true if any one (or more) of its constituents is known to be false. So, the nonexistence of a King of France was as strong a reason for a sentence affirming his baldness to be false as the fact of the king being hirsute. What Frege took to be a presupposition of the sentence was thus shown to be capable of being treated as one of its straightforward entailments. Whereas the Fregean analysis demanded a thorough revision of one of the fundamental claims on behalf of logic (in addition to the familiar 'true' and 'false', there was the need to admit of 'neither true nor false' as a third possibility), Russell's solution required no new apparatus other than the standard bivalent logic.

From the 1970s onward, many linguists such as Deirdre Wilson (1975) and Ruth Kempson (1975) have followed Russell's lead and urged that many of the phenomena treated by earlier researchers as presuppositions should be better treated as semantic entailments, and any residual problems such as favored readings (including the intuitive feeling that certain presuppositions do hold good in determinate circumstances) should be accounted for by a separate pragmatic component that will have recourse to such theoretical apparatuses as Grice's theory of conversational maxims. The decision to consign part of the problematic to pragmatics may be seen as having as its ultimate inspirational source a key element in P.F. Strawson's objections to Russell's analysis on the grounds that it did not do full justice to ordinary language. (In a protracted polemic with Russell, Strawson

insisted that there was a need to distinguish a sentence or an expression from a use and an utterance thereof.)

Russell's theory of descriptions provided the logical basis for his epistemology centered on a distinction between 'knowledge by acquaintance' and 'knowledge by description'. Among the objects that could be known through acquaintance Russell included what he referred to as 'logically proper names', whose function was to logically refer to certain objects such as sense data and universals. Ordinary names, by contrast, were regarded by Russell as functioning as definite descriptions in disguise. Russell thus pioneered the program known as 'logical atomism', the *locus classicus* of which is Wittgenstein's *Tratactus logico-philosophicus* (translated into English under the same title in 1922), originally prepared under Russell's own supervision. In Russell's view, the world is wholly made up of atomic facts and every meaningful proposition must be composed of constituents with which we are acquainted.

Among Russell's major publications is the monumental work *Principia mathematica* (1910–1913), written in collaboration with his Cambridge tutor Alfred North Whitehead. His 1912 work, *The problems of philosophy*, has long served as one of the popular introductions to the subject for undergraduates.

Biography

Bertrand Russell was born on May 18, 1872 at Ravenscroft, Wales. He was orphaned at the age of 4, with the death of his mother and sister in 1874, and his father in 1876. In 1876, Russell's grandfather, Lord John Russell (a former Prime Minister of Great Britain), and grandmother succeeded in overturning his father's will to win custody of Russell and his brother. With the death of his grandfather in 1878, Russell's grandmother began supervising his upbringing. In 1890, he went to Trinity College, Cambridge, and three years later was awarded a first class B.A. in Mathematics. In 1901, he discovered Russell's para-

dox. From 1907 to 1910 he worked on *Principia mathematica* in collaboration with A.N. Whitehead. He was elected Fellow of the Royal Society in 1908. He was dismissed from Trinity College for antiwar protests (1916), and was imprisoned for six months for involvement in antiwar protests (1918). He was awarded the Order of Merit (1949) and Nobel Prize for Literature (1950). In 1955, he released the Russell–Einstein Manifesto condemning the nuclear arms race. In 1958, he became founding President of the Campaign for Nuclear Disarmament and was imprisoned for one week in 1961 for leading antinuclear protests. He died in Penrhyndeudraeth, Wales, on February 2, 1970.

Russian and East Slavic Languages

The East Slavic languages—Russian (R), Ukrainian (U), Belarusian (Br)—constitute one of the three branches of the Slavic language family. All three East Slavic languages are written in the Cyrillic alphabet, but Belarusian has a parallel Latin orthographical tradition dating from the mid-sixteenth century.

The East Slavic languages developed from the eastern dialects of Late Common Slavic, when speakers migrated northward and eastward from the presumed Slavic homeland north of the Carpathians around 500 CE into territory sparsely populated by Finno-Ugrian and Baltic peoples. By the eighth century, a lively

trade in furs, amber, wax, honey, slaves, and silver across this vast territory attracted Scandinavian warrior-traders, the Rus', who sought to control the routes that linked the markets of Europe and Asia.

The Rus' dominated the East Slavic tribes in the ninth and tenth centuries, consolidating power first in the lands of the north around Lake Il'men' and at Novgorod, and then in the south at Kiev. They gradually assimilated into the larger Slavic population, leaving traces in the form of a few dozen loanwords (e.g. R *jákor*, U *jákir*, Br *jákar* 'anchor'; cf. Old Swedish *ankari*), but most importantly in the very name Rus', ascribed first to the East Slavs around Kiev and deriva- tively to the Kievan lands. The name ultimately came to refer to East Slavic lands collectively and by exten- sion to all the early East Slavs and to their language, which for the early historical period (up to the four- teenth century) can be called Rusian.

Our direct knowledge of Rusian is complicated by the fact that Rusian Church Slavonic, and not Rusian, was the first written language, gradually introduced after the conversion of the East Slavs to Christianity in 988. Rusian Church Slavonic (hereafter Slavonic) was a local variant of Old Church Slavonic, the liturgical language devised by Saints Cyril and Methodius on the basis of their ninth-century South Slavic (Macedonian) dialect for use in spreading Byzantine Christianity among the Slavs.

Slavonic was basically comprehensible to the East Slavs but contained a number of superficially South Slavic features, primarily of a phonological and mor- phological nature. For example, the Common Slavic roots **gard-* 'fortified town, wall' and **berg-* 'bank, shore' were realized as *grad-*, *brêg-* in Slavonic, where- as the vernacular Rusian had the regular East Slavic pleophonic counterparts *gorod-*, *bereg-*, respectively. Similarly, the Slavonic and Rusian reflexes of the Common Slavic sequence **tj* were *šč* (*shch*) and *č* (*ch*), respectively, and thus Slavonic *svêšča* and Rusian *svêča* 'lamp; candle', both derived from the Common Slavic root **svêt-* 'light' plus the suffix *-j-*. Despite such formal differences, the basic grammar and the majority of the most common lexical items in Slavonic and Rusian were identical. Some scholars prefer to treat them as variants or registers of a single language, whereas others view them as two closely related but separate languages. The latter view is adopted here.

In addition to the superficial distinctions noted above, written Slavonic differed from vernacular Rusian in its richer lexicon, and in its potentially more complex syntax, both inspired by elements of the Bulgarian Slavonic, Serbian Slavonic, or Greek texts that served as sources for translation. Although the pri- mary written record of early Rus' appeared in Slavonic rather than Rusian, lapses in the copying and editing of texts provide evidence of the actual speech habits of the Rusian scribe producing them.

Since the 1950s, archeological exploration has revealed direct examples of written Rusian in docu- ments uncovered in predominately northwestern locales, especially Novgorod, Pskov, and Staraja Russa. Unlike their Slavonic counterparts preserved on costly parchment, these legal and financial docu- ments or personal correspondence were scratched onto disposable birchbark. They provide valuable examples of the Rusian vernacular in a geographically circum- scribed area from the eleventh through the fifteenth centuries.

From the very beginning, strictly Rusian features mingled with those of Slavonic, a situation that became more common as new texts, created and borrowed, provided fresh opportunities for linguistic choice. Generic and thematic factors certainly influenced the predilection for Slavonic in religious and other solemn texts and Russian in mundane ones, but they were not overriding. At times, for example, a scribe might pre- fer Slavonic *gradъ* over Rusian *gorodъ* simply to save the space of one letter on the expensive parchment at the end of a line.

Although there was dialectal divergence among the East Slavs by the time of Christianization, virtually no evidence exists to suggest that it caused any difficulty in communication between residents of the Novgorodian north and the Kievan south. For this reason, the vernac- ular language of the early East Slavs is best considered as Rusian alone, with dialectal variants distributed geo- graphically. Nonetheless, linguistic evolution and his- torical circumstance helped to extend and deepen these distinctions to a point that it is more appropriate to speak of separate languages rather than dialects.

The effects of the phonological change known as the 'jer shift' produced dramatic differences north and south, alternative choices that affected consonant and vowel inventory as well as morphophonemic and mor- phological alternation (see below). Historical and political factors also served to create distinct commu- nities of speakers whose speech patterns became increasingly divergent from one another and subject to influence from other languages. For example, the growing importance of such northeastern centers as Rostov, Suzdal', and Vladimir (twelfth century) in the face of older Novgorod and Kiev; the Mongol inva- sions (mid-thirteenth century); the Novgorodian colo- nization of the north (thirteenth to mid-fifteenth centuries); the incorporation of southwestern Rus' into the Grand Duchy of Lithuania (thirteenth to fourteenth centuries) and Poland (fourteenth century); and the ascendancy of Moscow (fourteenth to fifteenth cen- turies) all contributed to the enhancement of regional linguistic difference.

By the fourteenth century, two language areas of Rus' had developed: a northern, Russian one destined to come under the hegemony of Moscow, and a southern, Ruthenian one, at first found largely within the Lithuanian political orbit, and then from 1569, under the rule of the Polish–Lithuanian Commonwealth. In Ruthenian territory, the prominent distinctions between Belarusian and Ukrainian were apparent by the fifteenth to sixteenth centuries, although their beginnings are discernable three to four centuries earlier. From the mid-seventeenth century, parts of the Ukrainian and Belarusian territories gradually fell under the control of Muscovy, then the Russian Empire, and finally the Soviet Union, a process that extended well into the twentieth century.

Consideration of the structure and dialectal distribution of Rusian provides a common basis for comparing and contrasting the development of the East Slavic languages with respect to each other. Rusian had a rich system of vowels (*i,y,u,ê,e,o,ä,a,ь,ъ*), including two high, lax vowels, the jers (symbolized as front *ь* and back *ъ*, respectively), a higher-mid tense front vowel (symbolized as *ê*), and a low tense front vowel (symbolized as *ä*). Over the course of the eleventh and twelfth centuries, the jers were either reidentified as mid-vowels *e* and *o*, or were lost (e.g. Russian *pьnь* 'stump', *sъnъ* 'sleep; dream' > R,Br *p'en'*, *son*, U *pen'*, *son*). The jer shift reduced the number of distinctive vowels by a third and nearly doubled the inventory of consonants by creating sets of distinctively paired plain (hard) labial and dental consonants (*p,b,m,v,t,d,s,z,n,l,r*) and palatalized (soft) counterparts (*p',b',m',v',t',d',s',z',n',l',r'*). Russian has largely preserved this later Rusian phonemic inheritance, whereas Ukrainian, apart from the dispalatalization (hardening) of consonants before Rusian *i* and *e*, preserved most soft dentals, but hardened soft labials. Belarussian preserved soft labials before vowels, hardened *r'* to *r*, and affricated *t'* and *d'* to *c'* (*ts'*) and *ʒ'* (*dz'*), the result of assibilation, so-called *cekan'e* and *dzekan'e*, respectively. After the jer shift, most new sequences of dentals or palatals plus *j* yielded soft geminate (doubled) dentals and palatals (*r'* and *j* are the exceptions) in Ukrainian and Belarusian, a reflex not typical of Russian, e.g. Rusian *žitьje* 'life', U *žyt't'a*, Br *žic'c'o*, R *žit'jo*.

Many Rusian dialects had a seven-vowel system after the jer shift: *i,e,a,o,u* plus the tense vowels *ê* and *ô*. The latter two were distributed differently, north and south, and were ultimately the most unstable. At the present time, standard Russian and Belarusian each have five-vowel systems (*i,e,a,o,u*), whereas standard Ukrainian has a six-vowel system (*i,y,e,a,o,u*). The higher-mid front *y* is a characteristically Ukrainian distinctive vowel, derived from merged Rusian *i* and *y*,

with *ê* (and typically *ô* as well) subsequently raising and fronting to *i* (so-called *ikavism*), e.g. Russian *lêsъ* 'forest', *stolъ* 'table' > U *l'is*, *st'il*.

The oldest layers of dialectal differentiation in Rusian follow a path from southwest to north and northeast, reflecting the early direction of Slavic development from the original Carpathian center to the northern and eastern periphery. Later innovation is stimulated by the rise of new centers of cultural diffusion, as noted above. Thus, among the oldest isoglosses is one that distinguishes dialects that preserve Common Slavic *g as a stop (the more 'peripheral' North Russian) from those that have lost closure, producing a fricative like γ or *h* (the more 'central' South Russian, Belarusian, Ukrainian). Another isogloss distinguishes the development of the tense jers (in the environment before *j*) as mid-vowels *e* and *o* (the more 'peripheral' Russian) or vowels *i* or *y* (the more 'central' Ruthenian), e.g. Rusian *mъju*, R *moju*, U *myju*, Br *miju* [mýju] 'I wash'. A third, involving the hardening of palatalized labial and dental consonants before Rusian *e*, separates the dialects of Russian and Belarusian (presence of palatalization) from those of Ukrainian (absence of palatalization). Some archaic Carpathian dialects of Ukrainian have preserved the Rusian phonemic distinction between *i* and *y*, unlike the rest of East Slavic.

Rusian, like Slavonic, had a rich system of grammatical categories. Nouns, pronouns, and adjectives were inflected by gender (masculine, feminine, neuter), number (singular, dual, plural), case (nominative, accusative, genitive, locative, dative, instrumental), animacy, and a special vocative form. Verbs were capable of distinguishing mood, tense, voice, and aspect. Participles and adjectives were inflected by gender, number, and case according to two declensions, a 'short' nominal declension and a 'long' adjectival declension, the latter providing expression for definiteness or generic status. All three East Slavic languages have retained the dynamic, free stress characteristic of Rusian.

By the fourteenth century, a number of Rusian grammatical categories had been lost, no longer productive in any of the East Slavic languages. These include dual number, the aorist and imperfect tenses, and case in short adjectives and participles. The perfect took over the function of past tense in all of East Slavic. Ukrainian has preserved a separate vocative form. Ukrainian and Belarusian both have a rarely encountered pluperfect tense. The morphophonemic velar ~ dental sibilant alternation found in most Rusian dialects was retained on a more limited basis in Ukrainian and Belarusian, but lost in Russian (e.g. Rusian *ruka/rucê* 'hand, arm' nom.sg./dat.-loc. sg., U *ruka/ruc'i*, Br *ruka/ruce*, but R *ruka/ruk'e*). Of syntactic interest are

the many East Slavic constructions without overt nominative subjects (e.g. R *mn'e ujt'i* 'I have to go' [lit. to me to go], U *cerkvu bulo zbudovano* 'The church was built' [lit. church~acc.~ was~neut.sg.~ built~neut.sg.~], Br *m'an'e n'e bilo* [byló] *doma* 'I wasn't home' [lit. of me not was-~neut.sg.~ at home]).

Russian

Spoken by approximately 275 million people, 165 million of them natively, Russian is by far the largest of the Slavic languages. The vast majority of Russian speakers reside in the Russian Federation or constitute substantial minorities in several of the republics of the former Soviet Union, including Ukraine, Belarus, Latvia, Kyrgyzstan, and Kazakhstan. It is the major language of the Russian Federation and one of the official languages of Belarus and Kazakhstan. There are significant Russian-speaking communities in Western Europe, the United States, and Canada. Russian is one of the five official languages of the United Nations.

The history of written language in Russian territory is one of continuing tension between Slavonic and vernacular Russian from the fourteenth to the eighteenth centuries. The church-supported emergence of Moscow as the center of the evolving Russian state saw the development of Slavonic into an ever more ornamental, complicated medium with intentional archaization from the late fourteenth century onward, a trend that resonated with the late fourteenth-century reforms in Bulgaria. These changes had the effect of distancing Slavonic from the spoken language by eliminating vernacular forms and introducing artificial elements and grammatical patterns. At the same time, during the fifteenth and sixteenth centuries, the language of the growing Muscovite bureaucracy—the formulaic, vernacular-based chancery language—displayed a normative tendency that elevated the speech patterns of Moscow and avoided the dialectal features of other areas of Russia.

The union of Left-Bank Ukraine and Muscovite Rus' in the mid-seventeenth century provided Ukrainian bookmen with the opportunity to bring to Muscovy their better developed grammatical tradition based on Latin and Greek models. They codified and enriched the Slavonic tradition, particularly with foreign vocabulary from the West, including Latin, primarily through Polish and Ukrainian intermediaries. In their turn, Slavonic and the chancery language influenced the development of vernacular Russian. It was only in the mid-eighteenth century, especially through the grammatical and lexical reforms of Adodurov and especially Lomonosov, that there was a reasoned attempt to control the distribution of foreign, Slavonic, and Russian elements in the Russian written language.

Karamzin in the late eighteenth to early nineteenth century and then Pushkin helped to refine the Russian language by example, setting the stage for it to become a vehicle capable of artistic and scientific expression on the highest levels of European culture.

Russian is traditionally divided into three major dialect zones: north, south, and central. South Russian is distinguished by the presence of two innovations: (1) the fricative γ instead of original stop *g* and (2) *akan'e*. Akan'e refers to the pronunciation of unstressed *o* and *a* as [a] initially or after a hard consonant in the first pretonic syllable (the syllable immediately preceding the stressed one) and as central lax schwa elsewhere (symbolized [ə]): compare *molodój* [məladój] 'young' and *nagradnój* [nəgradnój] 'pertaining to reward'. The large transitional zone between North and South Russian is composed of the central dialects (including Moscow), which show their intermediate status in favoring northern consonantism with *g* and southern vocalism with akan'e. It is the Muscovite dialect that ultimately served as the basis of the standard language: compare NoR *mogú* [mogú], SoR *moγú* [maγú], and standard Russian *mogú* [magú]. In addition to akan'e, standard Russian is also characterized by *ikan'e*, the pronunciation of unstressed *o,a,e* as [i] in the first pretonic syllable after a soft consonant, e.g. *n'os'í* [n'is'í] 'carry' (imperative 2sg.), *zan'alá* [zən'ilá] 'occupy' (past fem.sg.), *n'emój* [n'imój] 'dumb' (adjective nom.sg.masc.)

Ukrainian

Ukrainian is spoken by approximately 49 million people, making it the second largest Slavic language. Most of the speakers of Ukrainian reside in Ukraine, but there are substantial communities in Russia, Poland, Slovakia, Canada, and the United States. Ukrainian is the state language of Ukraine. In addition to Ruthenian (*rus'ka mova*) and plain talk (*prosta mova*), it was also called Little Russian from the mid-seventeenth century to the early twentieth, a derivative from Little Russia, itself a calque of a Byzantine Greek administrative term used to distinguish the more proximate Ukrainian territory from the more distant Muscovite (called Great Russia).

From the late fourteenth century, Ruthenian Slavonic in Ukrainian and Belarusian territories underwent archaization analogous to that of Slavonic in Russian territory. By this time, Galicia had been absorbed into the Kingdom of Poland and the rest of the Ukrainian and Belarusian territories into Lithuania. This turn of events had far-reaching linguistic implications for both Ruthenian and Slavonic. In Polish Galicia the vernacular-based Ruthenian chancery language was ultimately replaced by Latin in accordance with a 1433 decree. In

Lithuania, on the contrary, Ruthenian was elevated in status to become the official language of government administration. Based on the East Slavic vernacular spoken around Vilna (Vilnius), the chancery language developed as a kind of koine, which favored specific Belarusian elements over Ukrainian ones, but avoided the more remarkable characteristics of either, such as Belarusian cekan'e/dzekan'e and akan'e, and Ukrainian ikavism, in its various developmental stages. By the middle of the sixteenth century, spoken and written Ruthenian was making its influence felt in Slavonic in the presence of greater numbers of vernacular forms.

The 1569 Union of Lublin resulted in the merger of Poland and Lithuania as the Polish–Lithuanian Commonwealth. With Poland as the dominant partner, Polish and, to a lesser extent, Latin were introduced as the official languages of government administration throughout the land. Without administrative function, Ruthenian became subject to local adaptation. Features from the western and northern Ukrainian dialects began to dislodge their Belarusian counterparts in the Ukrainian territories to the south, whereas more prominent Belarusian features were developed in the Belarusian territories to the north. Both were subject to heavy Polonization and influence from Slavonic as well.

After the 1596 Union of Brest brought together Catholics and Orthodox Uniates, Polish and Latin began to challenge Slavonic as well in the spiritual sphere. A Slavonic revival begun in the western Ukrainian town of Ostrih resulted in the publication of a complete translation of the Bible in 1581. The revival spread later to L'viv and Kyiv and resulted in new Slavonic dictionaries and grammars.

Ukrainian had become the administrative language in Ukrainian territory east of the Dnieper after an uprising in 1648 resulted in the establishment of a Cossack state, the Hetmanate. It retained that role even after the union with Muscovy in 1654. Mazepa's unsuccessful attempt in 1709 to wrest the Hetmanate from Russian control led to the replacement of Ruthenian Slavonic by Russian Slavonic. Late in the century, Russian replaced Ukrainian as the language of administration, both in the territories of the old Hetmanate, and in the Right-Bank Ukrainian territory acquired in the 1793 and 1795 partitions of Poland.

The emergence of the modern Ukrainian standard language begins with Kotljarevs'kyj's translation-reworking of the *Aeneid* (1798, 1809, 1842), in which he showed a preference for southeastern dialect features (Poltava, Kharkiv, Kyiv). He prepared the way for a flowering of literary Ukrainian during the period of Ukrainian Romanticism (1820s–1840s), chiefly found in the writings of Kvitka, Ševčenko, and Kuliš, all of whom sought to realize a synthesis of Ukrainian

and Slavonic, although not to the degree seen in Russian. Harsh restrictions were imposed by the Russian government on the use of Ukrainian in 1863, leading to the ban on its public use in 1876, a prohibition lifted only in 1905. Meanwhile, the Ukrainian literary tradition that had continued in Polish Galicia (ceded to Austria in 1772, 1795) had an impact on the future development of Ukrainian in eastern Ukraine. The two centers of Ukrainian culture were joined only after World War II. The Soviet period was marked by an intense government campaign of Russification.

Modern Ukrainian competes with Russian and a Russianized Ukrainian hybrid called *surzhyk*, especially in the capital of Kyiv and in eastern Ukraine. Since independence (1991), Ukrainian, the sole state language, has gained considerable ground in the official sphere, especially in government, communication, and education.

Ukrainian is traditionally divided into three major dialect zones: northern, southwestern (including the Carpathians, eastern Poland, and eastern Slovakia), and southeastern. A typical feature of the northern dialects is the presence of diphthongs from older *ê* and *ô* under stress that correspond to monophthongal vowels in the standard language in either the southwest or southeastern variant. The southeastern dialects are characterized by ikavism, whereas this process has been only partly realized in many southwest dialects.

Belarusian

Belarusian has approximately 10 million speakers, most of whom reside in Belarus. There are small communities of Belarusian speakers in Poland, the United States, and Canada. One of the official languages of Belarus, Belarusian (also rarely Belarusan) has been called Belorussian or Byelorussian, a name influenced by the incorporation of Belarusian territory into the Russian Empire. The English rendering of Belarusian as 'White Russian' produces an unfortunate ambiguity with the political term referring to the enemies of the Bolshevik Revolution in Russia.

Following the Union of Brest in 1596, Belarusian (plain talk) increasingly yielded to Latin and finally to Polish as the authoritative written language, and in 1697 it was banned from administrative use completely. During the eighteenth century, Belarusian was largely limited to the burlesque interludes for religious school dramas, themselves written in Slavonic, Latin, or Polish. After Belarusian territory was incorporated into Russia during the partitions of Poland in 1772 and 1795, the Russian government banned the use of Belarusian in schools and in publications, a proscription that lasted until 1905. The publication of a

normative grammar by Branislaw Taraškevič (1918 and later editions) was a major step toward the establishment of a standard literary language. Belarusian was subjected to heavy Russification during the Soviet period. Its fate remains precarious in contemporary Belarus: even in the capital of Minsk, one is more likely to hear Russian or a Russianized Belarusian hybrid called *triasanka* than Belarusian itself.

There are three major dialect areas of Belarusian: northeast, southwest, and a broad central one (including Minsk), transitional to both. The northeastern dialects, themselves phonologically and morphologically transitional to Russian, feature dissimilative akan'e and jakan'e. *Jakan'e* refers to the neutralization of *o,a,e* in unstressed environments after soft consonants in which one of the pronounced variants is [a]. The dissimilative principle yields two basic variants of neutralization in the first pretonic syllable: (1) the low vowel [a] and (2) a nonlow vowel, commonly [ə] in akan'e and [i] in jakan'e. The first pretonic vowel in each case dissimilates the stressed (tonic) vowel in height: if the tonic vowel is high, the first pretonic variant is low, and vice versa; thus *vodí* [vadý] 'water' (gen.sg.), but *vodá* [vədá] 'water' (nom.sg.), *n'osú* [n'asú] 'carry' (nonpast, 1st sg.), but *n'os'éš* [n'is'éš] 'carry' (nonpast, 2nd sg.). The southwestern dialects are phonologically and morphologically transitional to Ukrainian. In all but the southernmost regions, which are devoid of akan'e and jakan'e, strong (nondissimilative) akan'e and jakan'e are predominant: the first pretonic neutralized variant of *o,a,e* is always realized as [a], regardless of the nature of the tonic vowel; thus [vadý], [vadá], [n'asú], [n'as'éš]. Standard Belarusian, based on the central dialects (including Minsk), has strong akan'e and jakan'e as well.

S

Sandhi

Sandhi rules are phonological alternations that are triggered at junctures of words or morphemes. The name sandhi comes from Sanskrit and means 'juncture'. It does not designate one particular phonological process. Instead, it is a nonspecific cover term for any kind of sound mutation that occurs at the edges of words and morphemes, and that is triggered in environments created by morphological or syntactic concatenation operations. Sandhi phenomena are very common across the languages of the world. Some of the best-known examples are tone sandhi, which is found in Chinese for example, Welsh and Irish consonant mutations, and a set of Sanskrit sandhi rules.

Two types of sandhi can be distinguished: internal and external sandhi. Internal sandhi rules are triggered word internally, between two morphemes. External sandhi rules operate at word edges, when two words become adjacent as a result of some syntactic process in the language.

An example of internal sandhi can be found in English words such as symbol and symbiosis. Both words are derived by addition of the prefix *syn* to the stem. In its basic form, this prefix can be observed in words like synthesis, synopsis, syntax, synchronicity, synonym, etc. When combined with a stem beginning with /b/, as in the words symbol and symbiosis, the last consonant of the prefix changes to /m/. This internal sandhi rule is an instance of the phonological process known as place assimilation, in which the place of articulation of some consonant becomes dependent on the place of articulation of an adjacent consonant. In the case at hand, the place of articulation of the consonant /n/ becomes identical to the place of

articulation of the consonant that follows it. The latter consonant can therefore be said to act as the trigger for this phonological change.

One of the internal sandhi rules of Sanskrit is a phonological process known as voice assimilation. The phonological process in question leads to a change of voiceless consonants, such as /p/, /t/, and /d/, turning them into their voiced counterparts /b/, /d/, and /g/. The effect of this rule is observable in the compound *sadaha* 'good day' derived from *sat* 'good' and *aha* 'day'. Compound formation leads to a configuration in which the two segments—the devoiced word final /t/ and the voiced, word initial /a/—become adjacent, and thus creates the conditions for the application of voice assimilation.

Interestingly, the same rule that operates word internally in Sanskrit, between two portions of a compound, also applies as external sandhi between two words of a phrase. For instance, the phrase *samyag uktam* 'correctly spoken' consists of the word *samyak* 'correctly' and *uktam* 'spoken'. Again, voice assimilation of the word-final consonant, in this case /k./, can be observed under the influence of the following voiced segment.

In English, external sandhi may occur in phrases such as *miss you, kiss you, caught you,* etc, where the word final consonant of the verb changes to [sh] or [ch] to give *mi[sh] you, ki[sh] you,* and *cough[ch] you.* This phonological process is known as *palatalization.* Another example of external sandhi is known by the name of *intrusive-R.* It exists in some, but not all, dialects of English. It is a feature of the nonrhotic variants (i.e. those in which the word final /r/ as in *bar, star, Zanzibar,* etc. is not pronounced). Intrusive-R is an

insertion of [r] between two words of which the first word ends in a vowel, while the second begins with one, e.g. *vanilla-r-ice-cream, the idea-r-of it, I saw-r-it,* etc.

An external sandhi rule that is present in some dialects of Italian is known as raddoppiamento sintattico. It is triggered only when the two words between which the sandhi operates are contained in the same local domain. The phonological process involved is the lengthening (or doubling) of the word-initial consonant. It is triggered when the word is preceded by another word ending with a stressed vowel, eg. *città **pp**ulita* 'clean city' from *città* 'city' and ***p**ulita* 'clean', or *metà **ll**ibro* 'half book' from *metà* 'half' and *libro* 'book'. However, for consonant doubling to take place, the words have to be contained within the same phonological phrase. When this requirement is met, as in (1a), and the two words are found within the relevant domain (i.e. the phonological phrase here marked by the subscript Φ), raddoppiamento sintattico takes place. On the other hand, if the two words are separated by a phonological boundary (marked as //), raddoppiamento sintattico fails. This is illustrated by (1b), where the word-initial consonant in *molto* 'old' fails to undergo lengthening.

(1a) (Avra **ll**etò)$_{\Phi}$ (il libro)$_{\Phi}$.
       'He will have read the book.'
(1b) (Visita la citt*à*)$_{\Phi}$ // (molto vechie)$_{\Phi}$.
       'He visits very old cities.'

An important feature of external sandhi is that an application of the phonological process in question is determined by the phrasal groupings of the words involved, as shown by the data in (1a) and (1b). Since the phrasal organization of the sentence is determined by syntax, the conditions under which external sandhi rules apply are to some extent influenced by this component of the grammar. However, this influence only goes some way. The constituents into which words are syntactically organized such as syntactic phrases are not isomorphic to the groupings of words into phonological constituents such as phonological phrases, although there are certain connections between the two. The relationship of syntax and phonology (the syntax–phonology interface) and the field of prosodic phonology in general is a large and fertile field of research (Nespor and Vogel 1986; Selkirk 1984).

Sanskrit

Sanskrit belongs to the Indo-Iranian branch of Indo-European, whose subgroupings are Iranian and Indo-Aryan. Indo-Aryan includes Vedic Sanskrit, Classical Sanskrit, and the Prakrits, or 'vulgar' varieties, which have as their offshoots the modern Indo-Aryan languages, such as Hindi-Urdu, Bengali, Gujerati, Marathi, Panjabi, Sinhalese, and Romani.

Sanskrit is one of the most anciently attested Indo-European languages and has played a crucial role in the reconstruction of Proto-Indo-European. Apart from some isolated forms (see below), the most ancient literary sources are the poems collected in the books of *Veda* (hence the name 'Vedic Sanskrit'), which record an oral tradition, going back to the second millennium BCE. Classical Sanskrit is a highly standardized language, as such used without interruption from its first written attestations, and virtually unchanged until the present; however, in the early phases dialectal variation is visible, even between Vedic and Classical Sanskrit. The former is not the direct ancestor of Sanskrit: its peculiarities include both archaisms and innovations with respect to the classical literary language, pointing toward some kind of diatopic variation. Furthermore, the Prakrits of the Middle Indian period (300 BCE–200 CE) do not derive directly from Classical Sanskrit, but display a variety of different features, some directly connectable to Vedic. Among the Prakrits, the most important as a

literary language is Pāli, the language of the Buddhist Canon. The coexistence of Sanskrit with Prakrits is ancient, and is mostly a matter of social variation: in classical drama, socially inferior characters (including women) usually speak Prakrit.

The Aryan populations reached India toward the end of the second millennium BCE, and established themselves in the upper Indus valley. Before that time, the Aryans had already built a linguistic group distinct from the Iranians, as shown by the traces left during their journey through the Middle East. In the first half of the second millennium BCE, an Aryan aristocracy dominated the Hurrian kingdom of Mitanni, located on the upper course of Tigris and Euphrates. Names of Indic deities are mentioned in a treaty with a Hittite king, and some Indic words are found as loanwords in a Hurrian text of the period, among which are some numerals, which attest a pre-Sanskrit variety (e.g. *aika*, 'one', in which the monophthongization /ai/ > /e/ had not yet taken place, cf. Sanskrit *eka*).

Grammatical Sketch

Phonology and Script

Sanskrit is written in *devanāgari* script, still used for the modern Aryan varieties, which derives from an earlier script, called *brāhmī*. The *devanāgari* is a peculiar writing system, halfway between a syllabary and an alphabet, consisting of 13 signs for vowels and 35 for consonants, plus a number of diacritics and several compound signs used for representing consonant clusters. Consonant signs not followed by any diacritic are understood as containing the consonant and the vowel /a/.

The *devanāgari* script is very well suited for the representation of Sanskrit phonemes, each sign corresponding to a single phoneme (except for diphthong signs) and each phoneme being represented by a sign. Thus, Table 1 can also serve as an inventory of Sanskrit phonemes.

An important feature of Sanskrit phonology, especially in comparison with the other ancient Indo-European languages, lies in the phonologization of both voiced and voiceless aspirates, the existence of a series of retroflex (also called 'cerebral') stops, borrowed from the non-Indo-European substrate languages of India, and the retention of vocalic liquids, partly with length opposition. (Length opposition is only relevant for /r̥/ ~ /r̥ː/; besides, /l̥/ is a very rare phoneme.) From a diachronic point of view, the most significant innovations are found in the vowel system. At an early stage in Proto-Indo-Iranian, the three vowels of Proto-Indo-European, /a/, /o/, and /e/, merged in /a/ (this change involved both short and long vowels). Later, after the separation of Iranian and Indo-Aryan,

short diphthongs underwent monophthongization: /ai/ > /eː/, /au/ > /oː/. Hence, already in Vedic there is again a distinction, at least for long vowels, but the /eː/'s and /oː/'s of Sanskrit do not reflect the same vowels of Proto-Indo-European.

Sanskrit belongs to the so-called *satəm* group within Indo-European, i.e. it is one of those languages, along with the remaining Indo-Iranian languages, Slavic, and Armenian, in which velars changed into spirants or affricates, and labiovelars changed into velars.

A major role in Sanskrit phonology is played by *sandhi*, i.e. a set of phonological rules determined by the clustering of vowels or consonants.

Morphology

Sanskrit morphology is extremely rich. Inflectional classes of nouns are based on the Indo-European distinction between thematic and athematic declension, with subclasses of the latter for stems in nasal, liquid, /i/, /u/, and long vowel. Nouns have eight cases (nominative, vocative, accusative, instrumental, dative, ablative, genitive, and locative) and three numbers (singular, dual, and plural); gender distinctions include masculine, feminine, and neuter. Adjectives, which also inflect for degrees of comparison (comparative and superlative), follow the inflection of nouns for number and case, while pronouns follow special patterns of inflection.

Verbs are traditionally divided into ten classes (eight in Vedic), of which the first, fourth, sixth, and tenth follow the thematic conjugation, while the remaining follow the athematic conjugation. In the thematic conjugation, the thematic vowel -*a*- (< PIE *-o-) is inserted between the stem and the ending; note that, contrary to the other Indo-European languages, which have -*ō* as ending of the first person singular of the present indicative, Sanskrit has reintroduced the ending -*mi* of the athematic declension, so that we find a cumulation of both endings: *bharāmi*, 'I bring', first class, thematic, built with the present stem *bhar-*, ending-*ā* plus ending -*mi* (cp. with Latin *fer-ō*, same meaning). Verbs distinguish three persons in the singular, dual, and plural.

Tenses include the present, the imperfect, the aorist, the perfect, and the future; in addition, Vedic also had a compound pluperfect. In origin, the verb system was based on an aspectual opposition between present and perfect. The present denoted actions or processes, while the perfect denoted states. The Indo-European opposition between perfective/imperfective is continued only formally, in the opposition between aorist and present, but not semantically (see below). Verbs have a special stem for the present, the perfect, and the aorist; the differences among stems are usually based on root gradation, which opposes a reduced

Devanāgarī alphabet

Primary vowels

grade (e.g. *kṛ-*, 'make') to full grade, also called *guṇa* (*kar-*), to lengthened grade, also called *vṛddhi* (*kār-*). (Note that there is no one-to-one correspondence between vowel grade and a specific tense.) The perfect is usually made on a reduplicated stem (e.g. *ca-kar-a*, 'I have made').

Already in Vedic Sanskrit, the aspectual value of the aorist was given up: the aorist is used in reference to recent past, and never without past reference in contrast to the present (as was the Ancient Greek aorist). The perfect added to its original stative meaning a more recent resultative meaning, which also had its temporal implication of remote past. Furthermore, the so-called imperfect, derived from the present tense, was used in narration, where it did not display any particular tendency toward expressing the imperfective aspect.

In Classical Sanskrit, moods include the indicative, the optative, and the imperative for the present tense; the aorist has an indicative and a precative, and the future has a conditional. Vedic had a more developed mood system, which included an indicative, a subjunctive, an optative, and an injunctive, all made on all three stems (present, aorist, and perfect). From a typological point of view, the most interesting feature of this mood system is constituted by the injunctive. In a way, it stands outside mood oppositions, and is used for general statements.

Voice includes an active (*parasmaipada*) and a middle (*ātmanepada*); not all verbs have both voices, but for those that do, the middle mostly has reflexive value. Furthermore, the middle can have passive meaning, except for the present stem, which builds a special passive by adding the suffix *-ya-*.

The Sanskrit verb has a variety of nominal forms: active and middle present, future and perfect participles, a past passive participle, from which a past active participle is also made, a future passive participle, also called gerundive, an indeclinable participle, also called gerund, and an infinitive.

A peculiarity of Sanskrit is the large extent to which composition is used for building nouns. Following the Indian classification, types of compound include *dvandva* (copulative compounds, e.g. *siṃhagajāḥ*, 'lions and elephants', from *siṃha-*, 'lion', plus *gaja-*, 'elephant'), *tatpuruṣa* (determinative: *tat-puruṣa* 'that - man'= 'the man of that one', 'his man'), and *bahuvrīhi* (possessive, or exocentric: *bahu-vrīhi* 'much - rice' = 'having much rice').

Syntax

Sanskrit has free word order, but in unmarked statements displays a tendency toward SOV order; unaccented pronouns and other clitics are consistently placed after the first accented word in the sentence in which they occur (Wackernagel's position), modifying adjectives, genitives, and restrictive relative clauses precede their head, and adpositions mostly follow the noun. OV features are all present in Vedic, too, but Classical Sanskrit is more consistent with respect to them.

Subordination includes relative clauses and a variety of adverbial clauses, with conjunctions derived from the stem of the relative pronoun. Besides, participles and gerunds also contribute to the building of hypotaxis. Participles (especially the past passive participle in *-ta*) and gerunds are often used without the verb 'be', as if they were finite verb forms.

Sanskrit displays a peculiar preference for passive, rather than active construction. The would-be-subject of the active is thus expressed through an agent phrase in the instrumental: *tenedam uktam*, 'he said this', lit.: 'this (was) said by him' (*tena*, 'by him' + *idam*, 'this', *uktam*, past passive participle of *vac-*, 'say'). Impersonal passives with instrumental agent phrases are also found in intransitive verbs; the past participle, however, occurs more frequently with an agent–subject phrase in the nominative, in which case it has active meaning (so *saḥ grāmam gataḥ*, 'he went to town', *sah*, 'he', *grāmam*, 'to-town', *gataḥ*, past participle of *gam-*, 'go', rather than *tena grāmam gatam*, lit.: 'by him (*tena*, instr.) (it was) gone to town').

Sanskrit and Indo-European

The importance of Sanskrit for Indo-European linguistics cannot be overstated: it was only after European scholars learned about it that they realized that their own European languages presented striking similarities among each other, and set out to reconstruct a proto-language. Actually, for some time Sanskrit was even thought to be the proto-language: but also later, after it lost this status, Sanskrit was regarded as the most conservative Indo-European language, especially with respect to its numerous inflectional categories, fully developed in rich and complex paradigms.

The discovery of Anatolian, at the beginning of the twentieth century, gave a serious stroke to the primacy of Sanskrit. Some scholars started to reconstruct a Proto-Indo-European with a smaller case system, with less verbal moods, and in which some basic Greek–Sanskrit isoglosses (augmented past tenses, aorist, dual number, etc.) played a less relevant role. Another challenge to the possible archaic character of Sanskrit has come from the so-called 'ejective model', according to which the stops of Proto-Indo-European include voiceless/glottalized/aspirate, rather than voiceless/voiced/voiced aspirate of the traditional reconstruction (see Hopper 1973). A full discussion of new reconstruction trends can be found in Gamkrelidze and Ivanov (1995).

SILVIA LURAGHI

Sapir, Edward

As a senior in the undergraduate program in German language and literature at Columbia University in 1903–1904, Edward Sapir enrolled in a graduate seminar in American languages taught by the distinguished anthropologist Franz Boas. Sapir had already studied Latin, Greek, French, Spanish, and his major subject German, and now he was exposed to the diversity of the native languages of North America. The effect was not immediate, for Sapir continued on to the master of arts degree, still concentrating on Germanic philology and literature. But his 1905 master's thesis, on traditional German linguistics, did include data from several American languages to demonstrate the grammatical complexity of all languages, those without writing systems as well as those with long established literary traditions. Soon Sapir was engaged in fieldwork, traveling to the West Coast of the United States to study Wishram in Washington in the summer of 1905, and Takelma in Oregon in 1906. Although his Germanic studies had been largely philological and historical, his grammar of Takelma was entirely a synchronic analysis, describing the language without recourse to historical information, a characteristic of most of the linguistic work done under the direction of his mentor, Franz Boas.

Sapir published his master's thesis, in the journal *Modern Philology,* but virtually all of his other early publications were on native American languages. His doctorate was awarded in 1909, with the Takelma grammar serving as his dissertation, and by the end of that year he had published nine articles, reviews, and monographs on the Kwakiutl, Upper Chinook, Yana, Yuchi, and Wishram languages, as well as Takelma. His reputation as a specialist in native American languages was established early, and continued to grow throughout his lifetime, reaching nearly mythic proportions as some admirers attributed to him extensive knowledge, and even fluent command, of languages which he had investigated for just a few days in consultation with a single speaker.

After receiving the doctorate, he took up the post as chief of the Division of Anthropology in the Geological Survey of the Canadian National Museum. This was both a hindrance and an asset to his career as a linguist. On the one hand, the position isolated him from his colleagues in the United States and at times directed his energies toward administration. But the advantages were many, not least of which was control of a research staff and a budget, always too small, with the authority to determine and direct fieldwork. It was Sapir's intent to create a systematic survey of the languages and cultures of all of Canada. Since he was nearly always the only staff member with formal training in linguistics, it was he who did most of the linguistic work, concentrating his attention on the languages of Western Canada. He made many field trips in the years 1910–1915, and thereafter worked frequently with speakers at his office in Ottawa.

The use of trained native assistants for the recording of text was a common practice with Boas and his students, but Sapir was exceptional in recognizing that native speakers' insights were relevant to the development of linguistic theory, especially in the area of phonology. In the early years of Sapir's career, linguists were struggling with the new concept of the phoneme, which Sapir later came to define as

'a functionally significant unit in the rigidly defined pattern or configuration of sounds peculiar to a language . . ., as distinct from . . .the 'sound' or 'phonetic element' as such (an objectively definable entity in the articulated and perceived totality of speech)'. (Sapir, 'The psychological reality of phonemes' 1985[1933]: 46)

One of Sapir's most important and long-lasting contributions to the development of the phoneme concept was his view that the phonemic structure of a language was part of the unconscious knowledge that speakers of a language possessed, part of their 'phonological intuitions.' Drawing on his years of work with native interpreters of American Indian languages, he argued that ordinary speakers hear phonemes, not phonetic details, and he offered evidence in the way that interpreters would transcribe their language, always recording distinctive contrasts in sounds while not noting phonetic differences that were irrelevant to their phonological system. The paper in which these concepts were most clearly expressed was written in French and published in Paris, France in 1933. At that time, it was little noted by American linguists, but when it appeared in an English version in 1949, ten years after Sapir's death, it sparked something of a revival of interest in Sapir's work. His notions of the psychological reality of the phoneme, of native speaker intuition, and of unconscious linguistic knowledge were all to find their way into the development of generative phonology in the late 1950s and 1960s, as did his description of phonological systems as 'sound patterns', explicated in his widely read 1925 article 'Sound patterns in language' published in the first issue of *Language*, journal of the Linguistic Society of America.

Also growing out of Sapir's work in Canada was his genetic classification system for American Indian languages. Drawing on his background in Germanic historical linguistics, Sapir began to apply the techniques of the Indo-European comparative method to the original languages of America. Beginning with the 1891 classification system developed by John Wesley Powell and the Bureau of American Ethnology, Sapir took Powell's 55 'stocks' (or language families) and eventually reduced them to six groups: Eskimo-Aleut, Algonquian-Ritwan, Na-Dene, Penutian, Hokan-Siouan, and Aztec-Tanoan. There was a good deal of controversy at the time over this plan, in part because Sapir provided little evidence to support it. Sapir himself considered the scheme to be probable but not at all proven, given that 'scientific comparative work on these difficult languages is still in its infancy' ('Central and North American languages', 1985[1929]: 169), but his system remains the fundamental reference point for those working on the genetic classification of American Indian languages.

Sapir's most widely read work is the small book *Language*, published in 1921 while he was still in Canada. Aimed at both students of linguistics and the public, the volume predated his work on phonology. Its chapters focus on words and grammar, with a particular emphasis on what is today called linguistic typology, the classification of languages and of features of languages into types based on the structural properties of their units (as opposed to genetic classification based on shared history). Sapir's classification system drew heavily on his background in Germanic linguistics and can be viewed as the twentieth-century apex of nineteenth-century European typology. The system provides categories for the morphology (the processes of word formation) of languages along two dimensions: the extent to which words employ affixes and the ease with which the root and affixes of a word can be segmented. For example, an isolating language would be one in which most words consist solely of roots, with little affixing. Sapir gives Chinese as an example. A language with many affixes intertwined and difficult to segment would be labeled fusional; Sapir cites Salinan, a language of southwest California. This part of Sapir's typology, based as it was on the well–known categories of earlier linguists, has been modified somewhat in terminology, but it remains useful in the classification of morphological types. Sapir, however, also attempted to overlay this system with another, a conceptual classification that distinguished concrete concepts and relational concepts, with further bifurcation into simple and complex. This aspect of his typological classification has not been pursued, but Sapir himself recognized the preliminary nature of his system and the need to explore a greater number of more diverse languages than he was able to consider at the time. This is exactly what modern typologists have done.

Sapir's interest in conceptual categories was manifested in another area of research in which he engaged in the later 1920s and early 1930s—the issue of an international auxiliary language. Beginning in 1925, at about the time he accepted a position at the University of Chicago, Sapir became involved with the International Auxiliary Language Association, Inc. (IALA), headquartered in New York City. Working in cooperation with the co-founder and honorary secretary of the association, Alice Vanderbilt Morris, Sapir wrote a number of scholarly and popular pieces supporting research on and development of an international auxiliary language. He was not alone among linguists in this interest, which was shared most enthusiastically by the Danish linguist Otto Jespersen, a number of other European linguists, as well as by many of Sapir's American colleagues. Sapir served briefly as IALA's linguistic research director and under IALA sponsorship produced three studies of conceptual structure, which comprise Sapir's total output on semantics. He made a number of programmatic statements but did no further work in this area and has had no lasting influence. Linguists' interest in an international auxiliary language dissipated during the 1930s, a period of professionalization within the discipline and of increasing American isolationism on the national scene.

In 1931, Sapir moved from the University of Chicago to Yale University. He never again conducted fieldwork, and he largely withdrew from linguistic study to concentrate on culture and personality. But he did supervise dissertations and postdoctoral work on American languages by a number of Yale students who went on to distinguished careers in linguistics, including Mary R. Haas, Stanley Newman, Morris Swadesh, and Charles F. Voegelin. At Yale, Sapir also came to know Benjamin Lee Whorf, a largely self-educated man interested primarily in philosophical issues and the study of meaning, who associated himself with Sapir and his circle of graduate students. Whorf's linguistic relativity hypothesis (that grammatical structure of a language influences its users' perceptions of the world) became well known beyond the field of linguistics. It is sometimes referred to, incorrectly, as 'the Sapir–Whorf hypothesis', but it was developed fully only after Sapir's death in 1939. Most contemporary linguists found it too speculative, and the hypothesis never became part of mainstream linguistics.

Edward Sapir was a key figure of American linguistics in the first half of the twentieth century, equaled in stature for that period only by his contemporary Leonard Bloomfield. Sapir's students protected and promoted his work and ideas and he remains 'a symbol of scope and insight in the study of language' (Dell Hymes 1985: 598).

Biography

Edward sapir was born on January 26, 1884 in Lauenberg, Germany, now part of Poland, the son of Lithuanian parents who soon moved to England and then on to the United States. He spent his childhood in Richmond, Virginia up to the age of ten, and then in New York City. He began the study of German, French, Spanish, Latin, and Greek at Peter Stuyvesant High School, matriculating with a German major at Columbia University in 1901. He received his B.A. in 1904; M.A. (1905) in Germanic philology and literature; and Ph.D. (1909) in anthropology, specializing in linguistics with a dissertation on the Takelma language of Oregon supervised by Franz Boas. He was Research Associate, Department of Anthropology, University of California, Berkeley, 1907–1908, and Fellow and then instructor at the University of Pennsylvania, 1908–1910. He was Chief, Division of Anthropology, Geological Survey of the Canadian National Museum, Ottawa, 1910–1925. He went to the University of Chicago in 1925, and was promoted to Professor of Anthropology and General Linguistics in 1927. Concurrently, he was also Director of Linguistic Research, International Auxiliary Language Association, New York City, from October 1930 to July 1, 1931. He went to Yale University as Sterling Professor of Anthropology and Linguistics in 1931. He was President, Linguistic Society of America (LSA) in 1933; he also taught Introduction to Linguistic Science and Field Methods at the 1937 summer LSA Linguistic Institute at University of Michigan. Sapir died in New Haven, Connecticut on February 4, 1939.

Sapir–Whorf Hypothesis

The idea that one's native language 'colors' his *Weltanschauung* has been around at least since the days of Johann Gottfried Herder (1744–1803) and Wilhelm von Humboldt (1762–1835). Charles Sanders Peirce (1839–1914) postulates that man's symbolic universe could only make sense via language. Ferdinand de Saussure (1857–1913) *(Cours de linguistique générale* [1916:155]) states that: 'No ideas are established in advance, and nothing is distinct, before the introduction of linguistic structure.' However, the principle of linguistic relativity has largely become associated with Benjamin Lee Whorf (1897–1941), who along with Edward Sapir (1884–1939), his linguistic mentor at Yale University, used linguistics to advocate their position that language influences the way in which a speech community perceives and conceives of its reality.

Part of the groundwork for the Sapir–Whorf hypothesis was laid by Whorf's work as a fire insurance investigator. During his career, he had the opportunity to analyze many reports as to why fires broke out. He found that workers would use extreme caution when around 'full' drums of gasoline. Just as one might expect, workers were careful not to smoke around 'full' drums. Yet, these same workers, when around 'empty' drums of gasoline, would sometimes toss lit cigarettes nearby. This caused a violent explosion because an empty drum still contained volatile gasoline vapor. Thus, an 'empty' drum was really much more of a threat than a 'full' one. Using these data, Whorf concluded that the meanings of certain words had an effect on a person's behavior.

It was the extensive research of both Sapir and Whorf into the grammatical systems of American Indian languages, however, that proved to have the greatest impact on the hypothesis. By predicating their insights into the interrelationships of language and culture on what they had learned from the structures of these languages, the basic idea of language shaping the perceptions of its speakers and providing for them a vehicle so that their experiences and emotions could be placed into significant cognitive categories was given its scientific underpinnings. Generally, Sapir is credited as giving the problem of establishing the link between language and culture its initial formulation, while Whorf is honored as the one who took this idea and developed it further to include grammar in addition to lexis, thereby making it a bona fide hypothesis. Hence, the resultant supposition is commonly given

the designation the 'Whorfian hypothesis'. Some, pointing to Sapir's preeminent stature as a linguist, prefer the appellation the 'Sapir-Whorf hypothesis'. When viewed in terms of output, however, one could counter that a more appropriate label would be the 'Whorf–Sapir hypothesis'.

A rather interesting development in this debate over giving credit where credit is due has been the attempt to disassociate Sapir from the hypothesis entirely. Desirous of preventing the image of the great maestro Sapir from being tarnished by the taint of controversy, some, most notably Alfred L. Kroeber, have claimed that Sapir's views were not really that (pro)Whorfian. This viewpoint is not borne out by an examination of Sapir's own writings. For example, as one can see in a (1929) passage (from the journal *Language*, p. 209), he equated language and thinking in terms of the speech community's overall culture:

> Language is a guide to 'social reality'…it powerfully conditions all our thinking about social problems and processes. Human beings do not live in the objective world alone, nor alone in the world of social activity as ordinarily understood, but are very much at the mercy of the particular language which has become the medium of expression for their society.

There are actually two different versions of the hypothesis. This is understandable when one considers that Whorf did all of his writing from 1925 to 1941, and his ideas were continuously evolving. The strong version of the hypothesis, which is called linguistic determinism, holds that language determines thinking. This position is most difficult to defend primarily because translation between one language and another is possible, and 'thinking' can take place without language; e.g. an artist or sculptor can and often does think with his fingers.

Mirroring Sapir's thoughts, Whorf notes in his (1940) 'Science and linguistics':

> We dissect nature along lines laid down by our native languages…We cut nature up, organize it into concepts, and ascribe significances as we do, largely because we are parties to an agreement to organize it in this way — an agreement that holds throughout our speech community and is codified in the patterns of our language. (Carroll 1956:213).

The milder version of the hypothesis is labeled linguistic relativity, coined by Whorf, since he always tried

to qualify his assertions. This claims that the native language *influences* one's thoughts and perceptions.

Linguistic relativity can be illustrated using one of Whorf's favorite sources of data, (Uto-Aztecan) Hopi. With the exception of birds, there is, according to Whorf, only one word in Hopi for everything that flies. One also notes that Bedouin Arabic dialects have more than 6,000 different lexemes for various types of camels and camel paraphernalia. Perhaps the most incontrovertible piece of evidence in its favor comes from the realm of numbers. Some languages (e.g. Hottentot [Nama]) only have words for the numerals 'one' and 'two' and a word roughly translatable as 'many' for 'three or more' (and a few languages have no numbers at all). Thus, such concepts as googolplex are beyond everyday verbal expression in these languages. Mathematics (as we know it) is thus not possible, i.e. people are indeed 'at the mercy of' their native tongues.

In 'An American Indian Model of the Universe' (*International Journal of American Linguistics* [1950]), Whorf argues that since there is neither an explicit nor an implicit reference to time in Hopi and thus no tenses for its verbs, time and space cannot be the same concepts for Hopis as they are for English speakers. The Hopi *Weltanschauung* is different from that of an SAE (Standard Average European, a Whorfian term) speaker. Many of his other essays present data for his basic contention that Hopi metaphysics, which underlies its cognition, is different from that of an English speaker; i.e. the Hopis calibrate the world differently because their language defines experience differently for them. As more information has surfaced on Hopi, some of Whorf's specific grammatical points have not held up well. This explains why most linguists today believe the Sapir–Whorf hypothesis to be invalid. However, the truth of the matter is that while no one has proved it wrong, neither has anyone proved it right.

Whichever end of the continuum one considers in the relationship between language and culture, it is important to realize the interpenetration of the two. In areas like bilingualism, is it really possible to learn a foreign language without also simultaneously learning the *Weltanschauung* of its speakers? Not only is language part of culture, it allows for its acquisition.

Sapir maintains that 'the worlds in which different societies live are distinct worlds, not merely the same world with different labels attached' (Mandelbaum 1949:162). Whorf took that one step further, asserting that grammar not only allows for the voicing of ideas but it also 'is the shaper of ideas' (Carroll 1956:221).

Saramaccan

Saramaccan (or Saamáka) is the name of the creole language spoken by the Saramaka people, who live along the Suriname River in central Suriname (in the northeast of South America). The names 'Saramaka' and 'Saamáka' derive from the fact that the first settlements of these people were located along the Saramacca River, also in central Suriname. The c. 50,000 Saramaccans living today are the descendants of African slaves who escaped from the plantations to create their own communities in the Suriname rain forest in the seventeenth and eighteenth centuries. These runaway slaves and their descendants are often referred to as 'Maroons', a word derived from Spanish *cimarron*, meaning 'stray animal'. The creole languages spoken by Maroon communities may be referred to as 'maroon creoles', to distinguish them from (former) 'plantation creoles', such as Sranan. There are two Maroon creoles (or rather: groups of Maroon creoles) in Suriname: Saramaccan (including three different dialects) and Ndyuka (used here as a cover term for four different dialects). Maroon

creoles outside of Suriname that are still spoken today include Palenquero (Colombia) and Angolar (São Tomé, an island off the coast of West Central Africa).

The main reason for distinguishing Maroon creoles as a separate category is the fact that, due to their relative isolation from outside influence, they are assumed to be more 'radical' than (former) plantation creoles, which have remained in contact with the language from which they have derived their lexicon (the 'lexifier language'). The term 'radicality' refers to the typological distance between a creole and its lexifier language. Although until now very little comparative research regarding the degree of radicality of different creoles has been done, it seems clear that the typological distance between, say, Saramaccan and its (main) lexifier, English, is larger than that between, say, Cape Verdean Creole and Portuguese. Therefore, Maroon creoles are assumed to be closer to creoles at the time of their formation (say, 300 years ago) than (former) plantation creoles. Among the Maroon creoles, Saramaccan has acquired a special status, especially in research associated with Bioprogram Theory (see e.g. Bickerton 1984), to the extent that it has come to be considered as the most radical creole. According to this view, Saramaccan provides a rare opportunity to get a closer look at the process of creolization.

While there are still important gaps regarding the history of the Saramaka and their language, the following seems to be clear (Smith 2002). The origins of the Saramaka people and their language go back to escapes from plantations that took place before 1700, at a time when the formation of a plantation creole must have been well on its way. Assuming that most of the runaway slaves had been on the plantations for some time before making their escape, they took at least some knowledge of this evolving plantation creole with them. This explains the structural similarities between Saramaccan and Sranan, both of which are descendants of the earlier plantation creole.

In spite of these similarities, however, there are also a number of differences between the two languages. One of these is the proportion of Portuguese-derived words, which is much larger in Saramaccan than it is in Sranan. In the former, one third of the basic vocabulary (basic words such as 'water', 'go', 'big') is derived from Portuguese, while this is much smaller in Sranan. The remainder of the basic vocabulary is largely derived from English (Suriname was an English colony before it became Dutch), while there are also a few items from West African languages. The presence of these Portuguese-based words is explained by the fact that, as has been established by historical research (e.g. Price 1976, 1983), many of the first Saramaka came from plantations owned by Sephardic Jews, who were Portuguese- (and to some extent Spanish-) speaking. Although the presence of many Portuguese-derived words could lead one to view Saramaccan as a creole with two lexifier languages—English and Portuguese—the fact that most function words are from English suggests that the Portuguese element was added later. For this reason, Saramaccan is generally categorized as an English-lexicon creole, albeit one with a strong Portuguese element.

A second difference between Saramaccan and Sranan is related to the fact that the former has a higher percentage of words derived from African languages. This is probably due to the fact that there was much less contact with other languages in the case of Saramaccan than in the case of Sranan. As to the origins of these words, three African languages (or rather: language clusters) have been especially important: Kikongo (a Bantu language), Gbe, and Akan (both of them Kwa languages; both Bantu and Kwa belong to the family of Niger-Congo languages). Although nothing is known about the specific African origins of the individual runaway slaves who formed the 'founder population' of the Saramaka people, we do have reliable information about the origins of the African slaves in general, who were brought to Suriname in the 1675–1700 period (Arends 1995a:243). In this period, roughly speaking, half of all Suriname slaves came from an area where Bantu languages such as Kikongo, were spoken, while the other half came from an area where Kwa languages, such as Gbe and Akan, were spoken. The connection between the ethnolinguistic origins of the Suriname slaves and the traces that were left in the Suriname creoles by their native languages receives further support from the fact that Saramaccan exhibits some rather marked phonological features, such as lexical tone and nasal and complex stops, which are characteristic of these three languages (Bruyn 2002).

Like its sister language Sranan, Saramaccan is well documented in its early stages. In the case of Saramaccan, however, the early documentation is limited to a very short period, roughly 1780–1820. This has to do with the fact that the Moravian Brethren, to whom we owe these early writings, stopped their missionary activities among the Saramaka around 1820. These early documents, which together number well over 2,000 manuscript pages, consist mainly of religious texts, such as Bible translations, although some linguistic descriptive works, such as dictionaries, are included as well (see Arends (1995b) for further information). Unfortunately, however, up to now only a few of these documents have been made available for linguistic research (Arends and Perl 1995).

As to the major structural features of Saramaccan, many of these are also found in Sranan. Here, we will only mention and illustrate some of the features in which the two languages differ. (This section draws heavily on Bruyn 2002; see also Bakker et al. (1995.)

Lexicon. Some examples of Portuguese-derived basic vocabulary items are *búka* (*<boca*) 'mouth' and *dá* (*<dar*) 'give'. In both cases, the equivalent word in Sranan is derived from English: *mofo* (*<mouth*) 'mouth' and *gi* (*<give*) 'give'. Some examples of African-derived words are *katangá* 'cramp' from Kikongo *nkatangá*, *azɛ* 'magic' from Gbe *àze*, and *gongosá* 'gossip' from Twi *ŋkɔŋkɔnsá*.

Phonology. For a language to have lexical tone, as does Saramaccan, means that some words differ only in their tonal pattern, for example in having a low tone in a syllable where the other word has a high tone, while being completely identical in every other respect. An example is the pair *ná~nà*, with the first having a high tone where the second has a low. Despite this (seemingly) small difference, the meaning of the two words is completely opposite: *ná* means 'be', while *nà* means 'be not'. Examples of nasal stops are /mb/ and /nd/; examples of complex stops are /kp/ and /gb/. Note that /mb/, etc., refer to phonemes, not combinations of phonemes. In other words, a word like *mbéti* 'meat, animal' consists of four phonemes, not five.

Morphology. Apart from other functions, reduplication is used in Saramaccan to derive adjectives from verbs, e.g. *nákináki* 'beaten', derived from *náki* 'beat'. These reduplicated forms are used both attributively, as in *dí nákináki miíi* 'the beaten child', and predicatively, as in *dí miíi dɛ nákináki* 'the child has been beaten (is in a beaten state)'. Saramaccan also differs from Sranan in that the agentive suffix *-ma* (*-man* in Sranan) may follow an entire verb phrase, which may itself even contain a subordinate clause. This may result in quite complex agentive nouns, such as *seti-u-kanda-ma* 'precentor' (lit. 'start-to-sing-suffix').

Syntax. The syntactic differences between Saramaccan and Sranan have not been investigated in sufficient detail to allow them to be discussed here. One feature that has drawn considerable attention, however, is the serial verb construction, which is also found in Sranan. For an elaborate discussion of serial verbs in Saramaccan, the reader is referred to Veenstra (1996).

Verbal arts. In the literature on the 'verbal arts' (story telling, song, etc.), Saramaccan is often discussed together with Sranan (Herskovits and Herskovits 1936; Voorhoeve and Lichtveld 1975). A work that is entirely devoted to storytelling in Saramaccan is *Two evenings in Saramaka* by Richard and Sally Price (1991).

JACQUES ARENDS

Saussure, Ferdinand de

Ferdinand de Saussure is known as one of the founders of contemporary linguistics and as the father of European Structuralism. Throughout his life he retained a major interest in historical linguistics, his student dissertation on the *a* vowels of Indo-European (1879) containing the solution to a problem that was to

be empirically confirmed many years later. Certain concepts for which he was to become known were present in his early works, but would be more fully developed in his Geneva lectures, notes from which were published posthumously in 1916 as the *Cours de linguistique générale (Course in general linguistics (CLG))*. In the first three sections of the *Cours*, Saussure attempts to come to grips with the kind of phenomenon that we are studying when we analyze language. In the face of the many possible approaches (historical, sociological, etc.) to the heterogeneous phenomenon that is 'langage' (translated as 'language' or as 'language faculty'), Saussure tries to focus on its essence through a series of binary divisions. First, it is necessary to distinguish the underlying system *('langue')* from its individual representations *('parole')*. Second, Saussure differentiates between the diachronic (evolution of a language) and the synchronic (a snapshot of a language at a particular time), the latter being the proper object of study in general linguistics. 'Langue' is a system in which the whole is more than the sum of the parts (Saussure himself did not use the term structure). The system is made up of units, each of which is defined by its difference from other units, whether words or phonemes (it should be noted Saussure generally used 'phonology' where today we would use 'phonetics' and vice versa). Each unit functions as a linguistic 'sign' composed of two inseparable faces: the *'signifiant'* (signifier or acoustic image) and the *'signifié'* (signified or mental representation of external reality). It is a characteristic feature of sign systems, of which language is the principal one, that the link between the sign and the reality to which it refers is arbitrary. Linguistic signs are linked together either paradigmatically (one is selected from a series, e.g. grammatical cases) and syntagmatically (in a chain within the utterance).

In talking about 'langue', Saussure refers to a mental reality, and to a collective and therefore social phenomenon. That he considers linguistics proper to be a discipline in its own right and as such separate from psychology and sociology does not, however, mean that he denies the links between language and history or society. He has been criticized for neglecting 'parole', syntactic analysis, and units beyond the sentence. It appears from the *CLG* that he intended a 'linguistique de la parole' to follow the 'linguistique de la langue', and that he considered syntax to fall within the remit of 'parole'. The discipline—then still to be established—of which Saussure considered linguistics to be the most important part is semiology (otherwise known as semiotics).

There has been much debate about influences on Saussure's theories, but it is generally agreed that he provides key insights that interlock to form the basis of a new and coherent theory. There is no doubt about the influence of the *CLG* on European Structuralist Linguistics and on Structuralist thought more generally. Firstly, through his lectures in Paris, Saussure exerted a major influence on future generations of French linguists, through Meillet for historical linguistics and Passy and Grammond for phonetics, to Benveniste and Guillaume; in Switzerland, the Geneva School continued his work, with Bally working on a 'linguistique de la parole'. Through his writing and through the presence of Karcevski, he influenced the Prague Circle including Jakobsen, as he did the Copenhagen Circle. In the English-speaking world, his influence existed, but in a weaker form: Bloomfield published a positive review of the *Cours* in 1924, and it is an important point of reference in Chomsky's *Cartesian Linguistics* (with langue/parole being in some ways a precursor of competence/performance). For the Structuralists of the mid-twentieth century in other disciplines, as for the postmodernists, the *CLG* is the fundamental text. Saussure's work has been continuously promoted by the *Cahiers Ferdinand de Saussure* and there has been a regeneration of interest with the ongoing publication of new manuscript material and the creation of an Institut Ferdinand de Saussure. When reading the *Cours*, it is important to remember that Saussure himself did not write it, and also that the English translations of some of his terms are misleading. Thus, the ideas of a major twentieth-century thinker come down to us in a tantalisingly uncertain form.

Biography

Saussure was born in Geneva in 1857 into a family of distinguished scientists and scholars. In 1876, he went to study in Leipzig, where he encountered the 'neogrammarian' movement. In 1877, he presented his first paper to the Société de Linguistique de Paris, and in 1879 published a dissertation entitled *Mémoire sur le système primitif des voyelles des langues indo-européennes,* which immediately brought him renown. The following year, his doctorate on the genitive in Sanskrit was awarded *summa cum laude* and published in 1881. After a field trip to Lithuania in 1880, Saussure went to Paris to study at the Ecole Pratique des Hautes Etudes under Bréal and from the following year began to teach there. In 1891, Saussure returned to Geneva to take up a Chair in Indo-European linguistics, and later in General Linguistics. In three series of lectures (1907, 1908–1909, and 1910–1911), he covered historical linguistics and started to lay the foundations for the science of linguistics. In contrast to the brillance of his early years, in later life Saussure published relatively little, apparently feeling convinced of the need to forge the basic concepts of linguistic analysis but daunted by this

prospect. He developed related interests, writing about the possible widespread presence of anagrams in Latin poetry and about the German epic *Niebelungenlied*. In addition to this crisis of confidence, Saussure suffered from ill health, and died in 1913.

Scandinavia

Scandinavia usually refers to the mainland Scandinavian countries Denmark, Norway, and Sweden. Denmark includes the Faeroes and Greenland, which are autonomous regions of the Danish kingdom. Finland includes the Swedish-speaking Åland Isles in the Baltic Sea. Finnish and Sami—the other main indigenous languages in the region—neither belong to the Nordic (Swe. *nordiska språk*) nor the Scandinavian languages. The general term for Denmark, Finland, Iceland, Norway, and Sweden is the Nordic countries (Swe. *Norden* or *de nordiska länderna*; Fi. *Pohjoismaat*, lit. 'the North countries'). When discussing Scandinavia and its languages, it is for historical and political reasons necessary to include all Nordic countries and the Samis. The Samis, the aboriginal people of the North, are inhabitants of Finland, Norway, and Sweden (and Russia). They form a supranational Sami homeland, Sapme, with its own linguistic and cultural characteristics. Finnish is also spoken in Finland, Norway, and Sweden, and Swedish is spoken in Finland.

Despite many types of language contacts throughout history, the Nordic countries have all attained a proportion of 90% or more speakers, for their dominant national languages, at the cost of inherent cultural and linguistic pluralism. Most speakers of the indigenous minority and secondary official languages of the Nordic countries are bilingual, and many are dominant in their second language, the majority language of their country.

Sweden (Sverige)

Sweden has a parliamentary and democratic monarchy, a population of nine million, and no official language *de jure*. Until 1809 it included Finland, and from 1814 to 1905 it formed a union with Norway.

Swedish is the first language of about 8.3–8.5 million people, Finnish (Sweden Finnish) has about 230,000 speakers (no official language censuses exist); Meänkieli (closely related to Finnish) has about 50,000 speakers, mainly in the North-Swedish Tornedalen region; a Finnish-speaking population in the central forest regions (Värmland, Dalecarlia) became extinct in the late 1960s, after four centuries. An equal amount of Finland Swedish descendants (migrants from Finland), Norwegian, and Danish speakers live in Sweden: about 50,000 each. For Finland, until recently, Sweden has been a buffer zone for cultural influence from Southern and Western Europe. Similarly, Finland has functioned as a buffer zone for Swedish contacts—peaceful and hostile—with Russia and its historical predecessors. The Samis inhabited the Swedish mainland down to central Sweden, when the Scandinavians arrived. In Sweden, Sami has about 20,000 speakers, divided into several (five or more) languages. Some archaic Swedish varieties are occasionally held to be languages, e.g. Älvdalsmål in the province of Dalecarlia (Swe. *mål*, old form for *dialekt*). Capital Stockholm (metropolitan Stockholm area with 1.6 million inhabitants) is multilingual, with some suburbs almost exclusively inhabited by non-Swedish speakers.

The main migrant languages are Albanian, Arabic, Bosnian/Croatian/Serbian, English, Finnish/Meänkieli, Greek, Kurdish, Persian, Spanish, Turkish, and Polish. About 120 languages are taught in hour-based mother tongue instruction in the Swedish basic compulsory school. Since 2000, Sami, Finnish, Meänkieli, Romani Chib, and Yiddish are official minority languages.

Denmark (Danmark)

Denmark has a parliamentary and democratic monarchy, with a population of 5.3 million. Danish is the official language. It is the first language of about 4.9 million Danes. The capital Copenhagen area (København) has about 1.7 million inhabitants.

German is an official regional language in Southern Denmark (20,000 speakers in Northern Schleswig), and a notable population of speakers of Danish lives in Northern Germany/Schleswig, as a result of border treaties between Denmark and Germany. Denmark's long-term enemy was Sweden, with which Denmark fought about the dominance over the Baltic Sea area. Denmark lost three provinces on the Swedish mainland (Scania, Halland, and Blekinge) and Gotland to Sweden in the mid-seventeenth century. The Norwegian provinces of Härjedalen and Jämtland, then parts of Denmark, were lost to Sweden simultaneously. Danish is a former high variety and a secondary school language, in addition to Greenlandic in Greenland (an Eskimoic/Inuit language; *Kalaalit Nunat*) and to Faeroese in the Faeroes. The Faeroes received autonomy in 1948 and Greenland received autonomy in 1979. Danish was temporarily a high variety in Norway during the era of Danish dominance over Norway (1380–1814).

The main migrant languages are Turkish (50,000), German, English, the Scandinavian languages, Bosnian/Croatian/Serbian, Punjabi, Vietnamese, Persian, and Somali.

Norway (Norge, Noreg)

Norway has a parliamentary and democratic monarchy, autonomous since 1814 and independent since 1905, with a population of 4.6 million. The capital Oslo area has about 750,000 inhabitants. Two official varieties of Norwegian are spoken: Nynorsk and Bokmål (about 95% of all Norwegians speak one of them as their first language; Bokmål is chosen by 80-85%). Bokmål is mainly spoken in the urban and northern parts, and Nynorsk in the western/central rural regions. Of the 440 municipalities, 114 have declared themselves as officially Nynorsk-speaking, 175 have declared Bokmål as their official choice, and the rest, 151, are 'neutral'. The larger cities (Oslo, Bergen, Trondheim) have declared themselves 'neutral', but in practice there is a clear dominance for Bokmål.

The largest Nordic population of Sami speakers is found in Norway (30,000). Most of them belong to the North Sami language group. It is a regional official language in Finnmark and Tromsø provinces, Northern Norway, where some of the municipalities are bilingually administrated. Among the indigenous Kvens (who speak a Finnish-related language/variety), in and east of the town of Tromsø, about 3,000 know the language. Several main migrant groups are 'nonvisible minorities'. The main migrant languages are the Scandinavian languages (100,000), English (70,000), Punjabi (24,000), German, Bosnian/Croatian/Serbian, Vietnamese, Turkish, Persian, and Finnish.

Finland (Suomi)

Finland was a part of the Swedish kingdom for about 700 years, until 1809. It was the Autonomous Grand Duchy of the Russian Empire from 1809 to 1917, and became an independent republic in 1917. It has a population of 5.1 million, officially bilingual in Finnish and Swedish (nationally). Sami is an official regional language since 1991. Romani, Tatar, and sign language have been given minority status since 1994, and Russian is on the verge of becoming acknowledged

as one in 2001. In all, 93% speak Finnish as their first language. Finland Swedish (finlandssvenska) is spoken in the southern and southwestern coastal areas. The Finnish Åland Isles in the Baltic Sea have a specific legal and linguistic position; they are officially monolingual in Swedish (League of Nations and the UN, 1921). Finland Swedish, with 297,000 speakers (5.7%), is a fully protected official language (the Constitution and the Language Act, 1919, 1921 and 2004). Finland Swedish is referred to as the East Swedish dialect. It has an overt (Sweden Swedish) and a covert norm (Finland Swedish standard). It is also seen as an archaic Swedish variety, influenced by Finnish. Of the municipalities, 22 are officially Swedish-speaking (2001), 20 are bilingual in Finnish-Swedish, three are bilingual in Finnish-Sami, and 389 are monolingual in Finnish. The capital of Helsinki (Helsingfors; one million inhabitants in the metropolitan area) is bilingual. The vast majority of the Finland Swedish speakers are bilingual, who function as language and culture mediators from and to the other Scandinavian countries. Most Finns learn another national/'domestic' language in school, by force of the Educational Act. English competes with Swedish for Finnish-speaking pupils today. The main migrant languages are Russian (20,000 speakers), Estonian, Somali, Vietnamese, English, Kurdish, and Karelian.

Iceland (Island)

Iceland is a republic, which became independent in 1944, with a population of about 280,000. The capital area of Reykjavík has 150,000 inhabitants. Iceland was under Norwegian rule from 1380 to 1550, and under Danish rule from 1550 to 1848. Icelanders retained Icelandic as their *lingua sacra* during the Reformation. Icelandic is the official language. Iceland is one of the few practically monolingual nation-states of today. In school, Danish and English are secondary languages. An American airbase, Keflavik, is the only additional major language representation of Iceland, but it lives a separate life. Icelandic pupils learn an adapted variety of "Scandinavian" based on modifications of pronunciation and a common Scandinavian vocabulary, for their contacts with Scandinavians, since Icelandic differs considerably from the mainland Scandinavian languages.

Language and corpus planning play an active role in the everyday lives of Icelanders. Language contact effects are, however, inevitable, since quite a few Icelandic students temporarily study abroad (North America, Scandinavia). Today, modern media and communication technology also bring English into the everyday life of Icelanders.

Language Contact Types in Scandinavian/Nordic Past and Present

Several main types of language contacts have existed in Scandinavia. The oldest known one is that of the Sami and Scandinavian (in Sweden and Norway), and Sami and Finnish settlers (in Finland; 2500–200 BC). In older place names and special vocabulary, the Sami impact is still obvious. The impact of the majority languages is more apparent in Sami, however. High proportions of Sami speakers live in the three capitals: Stockholm, Oslo, and Helsinki.

The second type consists of Scandinavian expansionism, which includes the Viking era (800–1100). During this period, the Faeroes, Iceland, and Greenland received their Scandinavian settlers and later, dominance. The Scandinavian/Swedish settlement of southern and western Finland, a third type, is both older and simultaneous with this. These two types of migration formed the basis for Scandinavian "semicommunication" and later pan-Nordism (Swe. *nordism;* see below). Such receptive bilingual communication also developed due to the Danish dominance over Norway and Iceland. The changing borders between Sweden and Denmark–Norway reinforced this; when the former dialect areas of Denmark – Norway were Swedicized from the mid-1600s, new overlapping linguistic continua developed.

The fourth type is that of continuous migration and settlements of Finns in Sweden and Norway, from about the fifteenth century CE. Vast areas were settled and farmed by Finnish speakers. These so-called forest Finns in central Sweden and southeastern Norway have recently experienced language death. A separate migration was that of Finns to Stockholm, which has been continuous for about 800 years. Migration to Sweden was internal until 1809; later, it reemerged as emigration from Finland to Sweden. Fewer Finns have left for Norway and even less for Denmark. Migration in the other direction has been rare.

Fifth, Latin was the scholarly language for the mainland Scandinavian countries and Finland for several centuries, until the early nineteenth century. The former countries shifted to their national languages earlier than did Finland to Finnish, for cultural, public and educational purposes.

All of the countries faced extensive migration to North America, especially to the regions close to the Great Lakes, during the latter half of the nineteenth century. Scandinavians on an average moved earlier than Finns.

More recently, there have been sporadic migration waves to all of the Scandinavian countries, during and after World War II. Both labor migration and refugee waves have normally been punctual in kind, compared

to the continuous migration between the Nordic countries. Due to the booming post-World War II economy of the Nordic countries, first in Sweden and later in Norway, Denmark, and Finland, all countries have received notable numbers of migrants from first, the neighboring countries, then from Southern Europe, and more recently globally. The most significant of these migration waves was that of Finns to Sweden from the late 1950s to the late 1980s. The free Nordic labor market was one important contributing factor. Today, there are groups of equal size of speakers of Swedish in Finland, as there are speakers of Finnish in Sweden.

A last type of language contact is a matter of cultural and linguistic transfer, rather than the transfer of people. Earlier, Latin, German, and French played such roles. The increasing presence of English in Scandinavia has been seen as an asset since the 1950s, especially in Sweden, but has recently become a matter of concern. English is diminishing the language use domains of the national languages. English is by far the most popular foreign language in school, and it is compulsory. Its impact differs from earlier foreign languages, which were transplanted for specific purposes or by socially defined groups. English is now used as a language of wider communication, and English expressions occur in all types of domains and in all social groups.

The common linguistic and cultural roots, in combination with the later separate historical and political developments in the three countries, make the problems of the concept of language evident. If languages are defined as language forms characterized by mutual intelligibility, Swedish and Norwegian or Norwegian and Danish could be defined as dialects rather than separate languages. On the other hand, speakers of some of the Swedish dialects, such as Scanian (skånska) in the south of Sweden, which until 1645 belonged to Denmark, the northernmost Swedish dialects, which bear evidence of language contacts with Sami and Finnish, or the archaic Gutnish dialects of Gotland, do not share full intelligibility with all other dialects.

Scandinavian Expansionism and Retreat

A division into West vs. East Scandinavian started in Old Scandinavian in the sixth or seventh century, when Norse farmers started sailing westward and inhabited the Faeroes and Iceland. The process was completed in the ninth and tenth centuries CE. This contiguous migration also reached Greenland. From Greenland, Leif Eriksson sailed westward and "discovered" North America in the eleventh century CE. New varieties of Old Norse developed. The daughter languages Icelandic and Faeroese developed, in addition to two extinct languages, Orkney and Shetland

Norn. Initially, speakers of Insular Nordic languages presumably had contacts with Celtic speakers, who had inhabited the same areas temporarily.

Scandinavian raids and trade created external language islands in vast areas of Northern and Western Europe. The Viking age (c. 800–1100 CE) started with tribal chieftains' small-scale raiding. Later, this turned into a large-scale warfare led by powerful Viking dynasties. The improved shipbuilding techniques contributed to this. The Viking period thus changed the language history of e.g. the British Isles. A landmark was the Danish conquest of Britain in the eleventh century CE. The Danes later continued their expansion in more peaceful ways. The Norwegians concentrated their raids to the islands north and west of Scotland and England, including Ireland, Isle of Man, and Scotland itself. Dublin was founded by a Norwegian chieftain in 841 CE. In Normandy, a Danish Duchy was founded in the tenth century by King Rollon. The Swedes established their rule in Kiev, Ukraine, before the Viking age and later in the Baltic countries. Russia was a target for early Swedish Viking trade and raids. Later, it became the target of the unified Swedish kingdom's attempts both to expand and protect itself. Finland was Christianized by the Swedes and thus came under its religious and cultural impact from the twelfth century, even if Scandinavians had lived in the coastal areas for centuries by then.

When the dominance of Denmark weakened, the Viking rule in the Baltic Sea was soon replaced by that of others. The commercial union of the Hanseatic League, especially under the leadership of Lübeck in the fourteenth and fifteenth centuries, was particularly successful. For some time, the League ruled the whole Baltic Sea and the North Sea. The establishment of Low German merchant layers in the main cities, Stockholm, Kalmar and Visby in Sweden, Copenhagen in Denmark, and Bergen in Norway, paved the way for an extensive linguistic influence on the local languages. In Sweden, this created a new prestige language; Low German became the language of the merchants, and the townspeople became highly influenced by its cultural impact. About one-third of modern Swedish consists of Low German vocabulary, for example, *släkt* 'family, relatives', *handel* 'trade', *krig* 'war', *möjlig* 'possible', *bliva* 'be, become', *smaka* 'taste', *skriva* 'write', and *men* 'but'. This indicates a high degree of bilingualism among important sections of Swedish speakers. Another central contribution from Low German was the borrowing of derivational prefixes, like *an-, be-, för-: använda* 'use', *behöva* 'need', *förstå* 'understand', and suffices like *-era, -het, -inna: studera* 'study', *svaghet* 'weakness', *lärarinna* 'female teacher'.

Scandinavian 'semicommunication' refers to the possibility to use one's own language, and to understand

and be understood by speakers of other Scandinavian languages. It functions thanks to the common background of the Scandinavian languages. Finns have in addition learned some Swedish in school or needed it for their civil careers, for several centuries. Icelanders have learned both Danish and, more recently, adapted 'Scandinavian'. With some minor phonological modifications, the use of common vocabulary, and avoidance of 'difficult' language-specific features, most Nordic citizens knowing a Scandinavian language may communicate among themselves. The demand to modify speech is the highest for Danes and Icelanders, who are the furthest away from modern, common Scandinavian. The common historical basis of Danish, Norwegian, Icelandic, and Swedish is one prerequisite of this type of communication. Another is the idea and philosophy of a shared political agenda, which to a high degree was created in the latter half of the 1800s. This pan-Nordic idea means that the countries do not only share historical and cultural features, but they have also attempted to teach each other's languages and about each other's countries in school. Even today, Nordic people may present a common face to other countries and in international cooperation, based on shared values. During the last decades, this linguistic understanding and communicative potential have weakened, and so has the striving for a common political agenda. Denmark, Finland, and Sweden are members of the European Union (EU); Norway and Iceland are not. Nevertheless, in practical administrative, political life and in the attitudes of people from the Nordic countries, there is a sense of togetherness and regional identity, which goes beyond ordinary neighborhood feelings. The Samis were more or less excluded from such cooperation earlier, but they have now created their own Nordic networks, both between Samis in different countries, and between different Sami groups in the same country.

The original Nordism of the 1860s has later been extended in many formalized ways. The exchange of ideas, culture, and ordinary people between the countries has continued and enabled the historically based Scandinavian communication to be prolonged in the form of mutual understanding of each other's languages. Today, Nordism is getting competition from EU- level cooperation. To some extent, it is also challenged by the attempts to integrate the three Baltic countries, Estonia, Latvia, and Lithuania, into the Nordic sphere, in which cooperation in English is preferred.

Searle, John R.

John Searle, the contemporary analytic philosopher, rose to fame with the publication in 1969 of *Speech acts: An essay in the philosophy of language* (SA). In this book, Searle systematized a number of ideas that were originally developed by J.L. Austin whom he knew as a graduate student at Oxford in the 1950s.

Searle's reputation as Austin's main intellectual heir, while no doubt right as far as it goes, must nonetheless be properly qualified. On the one hand, it should not be allowed to eclipse his own important contribution to not only the theory of speech acts in particular and philosophy of language in general but also to the philosophy of mind, a branch of philosophy in which he has established himself as a key, although contentious, figure. On the other hand, it is not entirely true either that his chief merit consisted in simply systematizing and bringing to fruition what his teacher Austin would have done all by himself, had an untimely death not prevented him from doing it. Unfortunately, many writers have helped create the widespread misperception that Searle simply took over from where Austin left off or, equivalently, that, except for some minor differences here and there, the work of the two philosophers constitutes a smooth continuum.

Searle's originality as a philosopher was announced on the very first pages of SA, where he insisted that his work was, as the subtitle proudly proclaimed, an exercise in the philosophy of language rather than Austin's own narrower 'linguistic philosophy'. In fact, Searle has ever since shown little interest in some of the major tenets of linguistic philosophy, notably the idea that a careful analysis of the ordinary, everyday use of language can help solve a great number of philosophical puzzles. Searle's central concern was announced in SA in the form of two aphorisms: (a) Speaking a language is engaging in a form of rule-governed behavior.(b) The basic unit of linguistic communication is the speech act. Searle also made his differences with Austin very clear in his early essay 'Locutionary and illocutionary acts', wherein he argued that Austin's concept of a 'locutinary act' should be replaced by his own notion of a 'propositional act'. For Austin, locutionary acts were the acts of producing utterances with a certain sense and meaning and these were opposed to illocutionary acts (performing certain acts such as promising *in* saying certain words) and perlocutionary acts (doing certain things such as threatening *by* saying certain words). By introducing the concept of proposition into speech act theory, Searle put Austin's philosophical reflections back on the beaten track of analytic philosophy. He also prepared the grounds for locating certain universals in speech acts across the multitude of world's languages, a quest that Austin would in all likelihood have dismissed as premature at best and a wild goose chase at worst. For Searle, illocutionary acts had the form 'F (p)' as their canonical structure—where 'F' denoted an Illocutionary Force Indicating Device (IFID) and the 'p' represented the 'propositional content' of the act in question. As many scholars have pointed out, Searle gave a distinctive Platonic twist to ideas he had origi-

nally picked up from his Oxford mentor who was self-declaredly an Aristotelian.

There can be little doubt that the theory of speech acts, in the form in which it is known to scholars outside the disciplinary bounds of analytic philosophy, is largely due to Searle's decisive intervention. This is especially the case in areas such as linguistics, psychology, sociology, and anthropology where speech act theory has had a tremendous impact. In the early 1970s, for instance, there was a very strong dissident movement called Generative Semantics within the Generative paradigm in linguistics that, spurred on by Searle's innovative idea of prepositional acts, sought to incorporate the concept of speech acts into the semantic component of grammar by stipulating that every sentence had an underlying form with a highest clause that specified its speech act status.

With the publication of *Expression and meaning* (EM) in 1979, Searle marked the consolidation of a theory that, after two decades of rapid expansion and intensive research, had important things to say about a range of interesting phenomena that included metaphor, fiction, and the so-called indirect speech acts (such as, say, the performance of an act of request by asking one's interlocutor a question—as in saying 'Can you please pass the salt' to someone sitting next to you at a dinner table). Searle also indicated that his own future work in the philosophy of language was going to be strongly influenced by the concept of intentionality. In fact, along with his interest in bringing the speech act theory in line with the thesis of intentionality, Searle also announced (in the preface to EM) yet another task for the years ahead: that of providing an adequate formalization of the theory using the resources of modern logic.

In 1983, Searle published *Intentionality* and two years later *Foundations of illocutionary logic* (FIL), in collaboration with the Canadian logician Daniel Vanderveken. Subtitled *An essay in the philosophy of mind*, *Intentionality* marked a decisive turn in Searle's philosophical enterprise and prepared the ground for his later distinctive and often polemical interventions in the then burgeoning new discipline called 'cognitive science'. As regards the second research direction announced in EM, FIL did fulfill the promise. But the scholarly community has been rather critical of the line of inquiry announced in FIL and, to judge from Searle's own lack of enthusiasm in pursuing it, the program no longer seems to enjoy the support of the Berkeley philosopher (although his erstwhile collaborator Vanderveken has single-handedly carried the torch since then).

Scholars are also divided in their full support for the turn marked by *Intentionality*, especially insofar as it is meant to be a complement to his earlier work on speech

acts. Many resent what they see as an exaggerated mentalist swing in conceptualizing speech acts, accompanied by Searle's interest in looking for a universal base to what many see as acts tethered to specific cultures. Some, notably certain scholars with an ethnomethodological orientation, regard Searle's mentalism as a step in the wrong direction away from Austin's more culturally sensitive approach to language.

From the early 1980s onward, Searle has been very active in the philosophy of mind. He has been a tireless critic of those cognitive scientists who have equated the working of a human brain with that of a digital computer. In the philosophy of mind, Searle is also known for his work on the problem of consciousness. His famous Chinese Room Argument, put forward in 1980, according to which a mere computer model of associating symbols is no guarantee of true knowledge of the language in question (say, Chinese), has been discussed over and over again in the literature and has influenced discussion in the area ever since.

Besides his intensive work in academic philosophy, Searle has been an active contributor to periodicals such as the *New York Review of Books,* where he has published scores of reviews and write-ups sharply critical of such contemporary trends as poststructuralism, pragmatism, and deconstruction. He has also taken highly polemical positions on student politics, and politicization of life on campuses.

Biography

John R. Searle has been Mills Professor of the Philosophy of Mind and Language at the University of California at Berkeley since 1959. He was born in Denver, Colorado (USA) in 1932. His father was an AT&T executive and his mother a medical doctor. As a child, he moved to New York, then to New Jersey, and finally to Wisconsin, where he graduated from high school. He began his university work at the University of Wisconsin in 1947, where he stayed till 1952. At 19, as a Rhodes Scholar, he went to England and studied under P.F. Strawson and J.L. Austin at Oxford University (1952–1959), where he took his B.A. First Class Honours (1955), M.A. (1959) and D.Phil. (1959). He was a Lecturer in Philosophy at Christ Church (Oxford) (1957–1959). In 1969, he published *Speech acts: An essay in the philosophy of language*. The same year, he took up a teaching position at UC Berkeley. Searle was elected for Distinguished Teaching Award by UC Berkeley (1999) and was awarded Honorary Degrees by the Universities of Wisconsin (1994) and Adelphi (1993), among others. He has also been a visiting professor at many universities across the five continents.

Second Language: Acquisition

It has been said that multilingual human brains are more common than monolingual ones; most of the people on this planet know more than one language. A major insight from the field of second-language acquisition (SLA) has been that the grammars of second-language learners are systematic and rule-governed.

These so-called 'interlanguage' grammars contain elements from the first language (L1)—e.g. German final devoicing or French verb raising—and elements from the second language (L2)—e.g. Canadian vowel raising or Spanish null subjects. A learner's production (even if it includes errors) is the product of the mental representation of the grammar. There has been debate as to whether interlanguage grammars are subject to the same constraints as the grammars of primary languages—the 'Access to UG' debate. Related to this is the question of whether L2 learners can acquire a linguistic structure (e.g. gender, tone, [strident]) if that structure is completely absent from the L1.

A basic insight from cognitive theory that helps us to understand SLA involves knowledge vs. skill. The knowledge that we store in our heads is a relatively stable trait. You either know the word 'cat' or you do not. You either know that the sentence, 'They is inable to speaked French' is ungrammatical or you do not. Clearly, you have to acquire knowledge of your L2, but you also have to acquire skills. You have to be able to comprehend fast speech, or carry on a conversation. Proficiency in a second language is a complex construct that includes a range of knowledge (from grapheme to phoneme to sentence to text) and a range of abilities (from politeness routines to appropriate register). Can adults attain nativelike proficiency in a second language? Often, this question is investigated under the rubric of the critical period hypothesis. There are undeniably age-related effects in L2 learning; people who start acquiring their L2 early are less likely to have an accent. However, as we have seen, accent is a small part of L2 proficiency. Is there some point after which nativelike proficiency is impossible? The answer to this question depends on which elements of proficiency one is looking at. White and Genesee (1996) have argued that nonnative speakers who started their L2 learning later in their lives can evidence grammatical knowledge and performance that is statistically indistinguishable from native speakers. Bongaerts (1999) has shown this for nonnative accents as well.

One of the most recognizable characteristics of adult SLA is that a great many of the people who attempt it do not sound like native speakers of the language; they may have an accent. This has led some to argue that SLA is fundamentally different from first-language acquisition in that the end point (or ultimate attainment) is so divergent. At the sound level, L2 learners can sound nonnativelike for two reasons. Let us take an example from stress. Many languages mark certain syllables as prominent by stressing them. The second syllable in 'banána' is more prominent than the first or third syllables. Languages vary in where they put the stress, so it is something that has to be learned.

Therefore, this is one possible source of error, and hence one way in which people can sound nonnative-like; they can get the stress placement wrong. This would be a phonological problem. They could, however, put the stress on the right syllable but still not sound like a native speaker, Maybe in their L1, they indicate stress by loudness or vowel length, whereas in English the main means of indicating stress is by a pitch change. This would be an example of a phonetic marker of their accent. The question of why some sounds are harder to learn than others has been addressed from typological (Eckman), phonological (Brown), and phonetic perspectives (Flege).

Languages also vary in terms of their syntactic structures. In English, you need to have a subject for your sentences. You can say 'She speaks French', but not '*Speaks French'. In languages like Spanish, though, you can drop your pronominal subject and say either 'Yo hablo español' or 'Hablo español'. Hence, Spanish speakers of English are going to have to learn that they cannot drop their subjects in English. L2 learners will also have to acquire the grammatical structures necessary for making questions, forming passives, or embedding clauses (just to name a few). They will have to learn to interpret quantifier scope and other subtle semantic properties. These particular structures can be used to identify two main approaches to explanation in SLA.

There are some who argue that structures that are common (or natural) in the world's languages will be easy to learn (regardless of your L1). For example, every language in the world that has null subjects also allows sentences with pronominal subjects. The presence of null subjects implies the presence of subjects. There are no languages that allow *only* null subjects. In this framework, then, it is assumed that null subjects are more marked than pronominal subjects. Furthermore, it is assumed that structures that are more marked will be more difficult to acquire (Eckman 1991).

Generative linguists have also been interested in explaining L2 acquisition. Consider the above examples. Linguists might invoke learnability issues to explain these facts. An English speaker trying to learn Spanish will hear Spanish sentences that have null subjects; there will be positive evidence in the linguistic environment that the learner's current grammar (or hypothesis) is wrong, and they must change it. The Spanish speaker trying to learn English, on the other hand, will begin the process with a grammar that allows both null and overt subjects. When listening to the English sentences of the linguistic environment, they will never hear any sentences that are inconsistent with their grammar. There is no reason for them to change. It has been argued that this may explain some Directionality of Difficulty effects observed in SLA.

939

English speakers have little difficulty in learning to drop their pronouns in Spanish, while Spanish speakers can have trouble learning to always provide a pronominal subject in English.

Second Language: Learning

The ability to learn another communication system, subsequent to a first, acquired during infancy and early childhood, is unique to the human species. In their use of second languages, humans easily outperform even those species endowed with highly elaborate communication systems, among them apes trained to mimic human language. Yet, the question of whether it is possible to learn a second language just like the first, i.e. to proceed through similar developmental phases and attain the same type of knowledge and skills, is controversial. Answers to this and related questions promise to shed light on the nature of the human language capacity, which may explain why much of the research on second-language learning addresses problems that involve comparisons between first- and second-language acquisition.

First languages (L1) are generally understood to be the end products of developments guided by the human language faculty. The core properties of its grammatical components are captured in terms of principles of Universal Grammar (UG). Some of these principles apply invariantly to all languages, whereas others are 'parameterized', i.e. they offer two (or more) options ('parameter values') in which languages may differ. An invariant principle specifies, for example, that sentences need to contain a subject position; a parameterized option allows for this position to be lexically empty (e.g. Spanish—*trabajo en casa*) or it needs to be lexically filled (e.g. its English equivalent *I work at home*). According to this view, UG is a theory about the initial state of language development in that it specifies the kind of implicit, innate knowledge the child brings to the task of acquiring a first language, preceding experience. Moreover, UG constrains the developing grammatical systems so that at every point of development, children's immature grammars UG-conform and are thus 'possible human grammars'. Consequently, L1 acquisition consists of both learning from experience (e.g. lexical learning, learning of language-specific properties) and the activation ('triggering') of principles of UG. When languages vary, children are said to set parameters on one of the given options ('values'), based on their experience with target input. Children growing up with two or more languages can set a parameter on different options, if required by the target systems. Bilingual acquisition during childhood is thus an instance of simultaneous acquisition of two 'first' languages.

Second languages (L2), on the other hand, result from learning processes initiated once a first language has already been acquired, either fully, in the case of adult L2, or partially, in the case of child L2 acquisition. Distinguishing between various acquisitional types implies that substantive differences exist between L1 and L2, and less important ones between child and adult L2. Although much research supports this view, the issue is far from settled. Particularly, the critical age range separating L1 from L2 is a matter of much

controversy; it is clearly not the same for phonological, syntactic, and morphological properties of the target language, with the ability to acquire a native phonology fading out first, possibly at around age 6. A conservative hypothesis consists in classifying as instances of 'L1' those cases in which the child has been exposed to one or more languages before age 3, as 'child L2' cases in which the onset of learning of one or more additional languages lies between the age range 5 and 8 years of age, and as 'adult L2' those cases in which the onset of learning lies after 10. Further research is needed in order to fill the gaps in the given age ranges and to decide whether the critical distinction is indeed the one between L1 and child L2 acquisition.

Descriptively, L1 and L2 acquisition differ in important aspects, namely in the course of acquisition as well as in the final state attained by learners. As for explanation, the question is whether L2 acquisition is guided by the human language faculty and, consequently, whether it eventually leads to a kind of knowledge of the target language that is identical to or at least resembles that of native speakers of the language. This amounts to asking to what extent L2 acquisition is determined by principles of UG. If the approximative systems underlying L2 learners' language use should turn out not to be constrained by UG principles, it would be questionable to refer to them as to 'grammars', in the sense defined for L1. Second languages might then possibly be defined not as 'natural languages', contrary to our initial assumption.

In at least one regard, L2 acquisition does indeed resemble L1 development: one finds strictly ordered developmental sequences. Many, although not all, grammatical characteristics of a language emerge in a fixed order across learners, independently of varying learning contexts, individual properties of the learners, or structural features of their first languages. In the 1970s, the 'morpheme order' studies showed that certain grammatical elements like verb endings (-s, -ed, -ing, etc) tend to appear in the same order in the speech of different child and adult L2 learners of English. Subsequent research analyzing a larger variety of grammatical phenomena (particularly word order) in a number of languages revealed that structural properties of the target languages emerge crossindividually in an invariant order, although the later ones do not depend, in principle, on the earlier ones. Moreover, the order of acquisition and use found in naturalistic L2 acquisition proved to be difficult to manipulate by means of foreign language instruction. It seems, thus, that there exists a hidden logic by which learners of a given target language are guided. A major goal of L2 research is, therefore, to uncover the underlying logic, for this should be crucial in deciding if second languages are indeed natural languages. In view of the fact that L2

acquisition proceeds through an ordered sequence of stages, it is tempting to conclude that both L1 and L2 are guided by the same underlying principles. However, differences also manifest themselves with respect to the developmental sequences. The morpheme order studies showed that the sequences are not exactly the same in L1 and in L2 acquisition, a finding confirmed by subsequent research for a broad range of grammatical phenomena. In sum, although both types of acquisition exhibit a course of development that is uniform across individuals, these invariant aspects are not the same in L1 and L2 acquisition, thus raising the question of whether the underlying principles and mechanisms are identical.

In L1 acquisition, developmental sequences are commonly explained through UG, i.e. the succession of L1 developmental phases can be understood as a reflection of the fact that children increasingly gain more complete access to, or become able to use, the principles of UG and set parameters for the values required by the target grammar. Prerequisites for this development are, most importantly, a growing lexicon and the ability to deal with longer and more complex constructions, as a result of a more powerful working memory and increasing processing capacities.

This kind of explanation cannot simply be carried over to L2 acquisition; older learners can rely on fully developed working memories and on mature language processing systems. While explaining L1–L2 differences, it also suggests that adult L2 learners should outperform child L2 and L1 learners—hardly a satisfying result in view of the fact that L1 development in nonpathological cases leads to remarkably uniform results (despite considerable differences in learning environments), whereas this is only true, at best, for a small group of L2 learners. A possible solution for this problem is that mechanisms of language use play different roles in L1 and L2 acquisition. Whereas in all types of acquisition, they influence the choice of constructions, resulting in preferences of use for particular forms, in L2, they might determine the internal order of acquisitional sequences. This proposal is based on the insight that processing of linguistic forms and constructions requires a certain cognitive capacity. Given that the total amount is limited, learners need to keep low the cognitive costs required by formal aspects of language in order to deal with problems of content and with communicative tasks. Consequently, they first acquire those constructions requiring the least amount of processing capacity. If correct, processability helps to determine the underlying logic of L2 acquisitional sequences. In L1, they follow essentially a grammatical agenda.

Assuming that the explanation of L2 sequences in terms of processability of linguistic forms is correct

does not entail that the human language faculty has no role to play in L2 acquisition. A plausible scenario predicts that the various cognitive resources compete, and that it is due to the fact that some of them, e.g. memory and processing, are more developed that they interfere with the grammatical module in a way that is not possible during early childhood in L1 development. The well-foundedness of this competition hypothesis is difficult to assess, however, since not much empirical work has been dedicated to its scrutiny. Instead, much research since the mid-1980s has tried to find empirical evidence to show that UG is still accessible in L2 acquisition. Further possible sources of knowledge for L2 learners are their respective first and other previously learned languages. To the extent that this type of knowledge interferes with what is offered by UG, this might contribute to an explanation of L1–L2 differences.

The contribution of principles of UG, on the one hand, and transfer of previously acquired knowledge, on the other, can be illustrated by considering the initial state of the learning process. In L1, the initial state is determined by the human language faculty and thus by UG. As for L2, there is broad consensus that learners, at the onset of acquisition, make use of knowledge sources not available to the L1 child, for example, grammatical knowledge or mechanisms of language use previously acquired. The exact nature and amount of transfer, however, is a particularly controversial issue. In the vast amount of publications dedicated to this topic over the last 50 years of research, radically different hypotheses have been defended, from 'full transfer' to attributing a marginal role to syntactic and morphological transfer. It is accepted that previous linguistic experience does influence L2 acquisition, resulting in a different approach to the learning task by L2 as compared to L1 learners. A frequently postulated, although contested, hypothesis claims that parameter settings are transferred from the L1 grammar to the L2 competence. Consequently, learners need to make appropriate changes in order to attain target-conforming knowledge of their L2 system, if source and target grammars differ with respect to particular parameter settings. In principle, this can be achieved either by inductive learning or by 'resetting' the parameters in question. Parameter 'resetting', however, presupposes that learners continue to have access to the various parameter values provided by UG, and this issue therefore represents the core problem in the debate about continuous access to UG. Whereas some researchers claim that L2 learners have 'full access' to UG principles and parameters, others argue that direct access is ruled out for principled reasons and that UG shapes the L2 system merely via the L1 grammar. An intermediate position is defended by those who favor the idea of partial access to UG, meaning that only nonparameterized

principles of UG are operative in L2 acquisition, whereas parameter values not instantiated in the L1 grammar are not available any more, and the respective properties of the target grammars need to be learned empirically. Although some evidence supports the latter hypothesis, the controversy is far from settled and this issue is likely to occupy L2 research in the future.

A further important source of knowledge, in addition to UG and transfer, is the learners' linguistic environment, i.e. input and feedback offered by their interlocutors. Their fully developed cognitive capacities and communicative skills may be expected to enable them to make better use of this source than L1 children. Numerous studies indeed confirm that native interlocutors tend to modify their language use when addressing L2 learners who, themselves, can actively engage in negotiations to provide them with a possibly more comprehensible input, corrections, etc. All this happens in naturalistic acquisition, which has been the object of the preceding remarks since there is no evidence that acquisitional processes differ significantly in tutored learning. But addressee-adapted speech, especially rejection and correction (negative feedback) of target-deviant learner utterances, is of special importance in classroom learning. The question, however, of whether these and other types of input modifications have substantial and long-term effects for the course and the result of learning processes is difficult to answer. From all we know, developmental sequences are not altered, but the rate of acquisition can be speeded up; moreover, certain acquisitional tasks (phonological and lexical learning) seem to be easier to influence in this way than others (grammatical morphology and syntax).

A characteristic feature of L2 learning is its interindividual variability. In spite of the fact that one finds invariable developmental sequences, individuals and groups of learners differ considerably. This refers not only to acquisition rates, use of transfer, etc. but, most significantly, also to ultimate success. Undoubtedly, some learners acquire the knowledge and skills enabling them to perform in a manner that makes their language production indistinguishable from that of native speakers. But we have no satisfying answer, as yet, to the question of why only a few learners achieve nativelike grammatical knowledge. A possible solution is that differences across learners are due to sociopsychological factors, most notably their attitudes and motivation toward the learning task, the target language, etc. But although this is certainly a plausible hypothesis, evidence demonstrating a cause-and-effect relationship between such factors and particular types of learning is scarce.

In conclusion, second-language learning, whether in a naturalistic or in a classroom setting, proceeds

through acquisitional sequences, largely independent of individual factors or contextual influences. These sequences are not identical, however, to those found in L1 development. Moreover, L2 learners vary considerably in the kind of use they make of their linguistic knowledge and in their ultimate attainment. For the time being, only partial and temporary answers are possible to the questions of whether L2 acquisition is guided by UG principles and whether second languages are 'natural languages'. It is not even clear whether 'perfect learners' have acquired a competence of the same nature as the grammatical knowledge of native speakers. Overall, the observable L1–L2 differences suggest that the underlying systems exhibit qualitative differences. This is supported by neurolinguistic evidence, which indicates that grammatical information from second languages is, at least partially, processed differently and in different areas of the brain, when compared to first languages. One may thus speculate that L2 knowledge should be characterized as a hybrid system, combining grammatical principles and mechanisms constrained by the human language faculty with others learned by means of general problem-solving capacities of the cognitive system.

Second Language: Teaching

Second-language teaching (SLT) involves teaching one language to speakers of another language. A distinction is often made between SLT and foreign-language teaching (FLT). The latter refers to teaching a language not widely used in the community in which the language is being learned. For example, teaching English to students in Italy or Japan is often termed FLT, whereas teaching English to learners in the United States and in countries such as Nigeria or India, where English is an official language, is usually referred to as SLT.

For both SLT and FLT, several issues have to be addressed. These include the purpose for which the target language is taught (aim), what is taught (syllabus), how the content is taught (methodology), and how learning is assessed (evaluation).

Consideration of the learners' background is very important when considering the aim of the program. Key factors include the learners' age and proficiency in the target language; their linguistic, cultural, and educational experience; the time and money available for instruction and self-study and associated learning resources; and their reasons for learning the language. Some of these purposes may be quite general. Others may be very specific: for example, airline pilots need English for occupational purposes, British students wishing to attend university in Paris may study French for academic purposes, or Japanese engineers may need to read scientific and technological reports written in English. The analysis of backgrounds, needs, and resources facilitates decisions about the composition of classes, the length and frequency of instruction, the type of teacher deemed most suitable, and the syllabus.

Most SLT syllabuses in Britain and the United States 40 years ago were structural in orientation—that

is, they were based on the formal elements of phonology, syntax, and morphology in the language. Learners were guided to master the formal content of the syllabus at one level of difficulty before moving on to the next. Many SLT programs are still designed in this way. Since the 1970s, however, a wider view of the authentic use of language and increasing attention to the needs of learners have led to the adoption of alternative approaches to syllabus design—especially regarding the teaching of English. Predominant among these is communicative language teaching (CLT), which sees the communication of information and ideas as the primary goal of second-language learning. The emphasis is less on what learners know about the target language at the sentence level (linguistic competence) and more on what they can do with the language in longer stretches of spoken or written discourse (communicative competence). Instead of a linear progression of items presented in order of structural difficulty, language points are sequenced in terms of their perceived usefulness, and they are integrated with other elements and constantly revisited. In the 1980s, there were 'strong' and 'weak' CLT syllabuses; proponents of the strongest versions argued that the explicit teaching of grammatical structures hinders the acquisition and communication of meaning. Weaker versions of CLT incorporated structural elements within a broader framework of communicative functions, language skill development, and interactional learning strategies. More recently, there has been a tendency to reconsider how to focus on form in communicative syllabuses.

The emergence of alternative approaches to syllabus design led to a review of how second languages should be taught. The methodology most often associated with structural syllabuses—the audiolingual method—is underpinned by a behaviorist view of learning. Typically, this involves the presentation of paradigm grammatical structures, followed by repetition and drill with a view to the production of error-free sentences: practice makes perfect. The written language is used largely to reinforce or consolidate language learned orally. In CLT, by contrast, the emphasis is on learning by doing—on communicating fluently rather than accurately, and appropriately in terms of the social context in which the language is used. The four language skills of speaking, listening, reading, and writing are interwoven in meaningful classroom activities. The topics, contexts, and interactional patterns adopted in CLT classrooms reflect the learners' backgrounds and learning needs. The roles of learner and teacher are correspondingly different. In audiolingualism, learners are reactive: they listen to the input and respond by repeating, manipulating, transforming, and memorizing the linguistic data under the direction of the teacher. They are not encouraged to initiate interactions, because this

may lead to error. By contrast, learners in a typical CLT classroom are expected to be mentally proactive in forming and testing their own hypotheses about language and socially active in using the language with fellow learners. The audiolingual teacher models the language input, controls the direction and pace of practice, judges the accuracy of the learners' language behavior, and corrects errors as they occur. The CLT teacher is expected to participate in, rather than dominate, the process of learning—and to exemplify a model communicator, to determine and respond to the culture and needs of the learners, to facilitate group learning (for example, by identifying and enhancing the students' learning styles and strategies), and to organize a variety of resources, among which interactive computer-assisted language learning is becoming increasingly salient.

The emphasis on communication has led to a shift in how to evaluate second-language learning. Knowledge of the discrete phonological, syntactical, and lexical contents of a structural syllabus may be reliably measured by test formats such as multiple-choice questions, gap-filling tasks, sentence completion, and structural transformation exercises. However, the validity of such formats to assess communicative ability is questioned. Rather than measuring knowledge in terms of pass/fail marks, the focus is now on providing descriptive profiles on the basis of criteria-referenced performance in authentic oral and written interaction. Also, based on the assumption that candidates may operate at differential levels of productive or receptive competence, there is now a tendency to evaluate language skills separately, sometimes by portfolios of work and computer-adaptive assessment rather than pencil-and-paper tests. The contexts, materials, and tasks used to evaluate oral or written communication are increasingly designed to reflect the specific purposes of the learners.

Semantic and Discourse Typology

Semantic typology deals with the different types of semantic categories that can be found in natural languages, whereas discourse typology deals with different types of discourse. A very appealing approach to the classification of semantic categories that can be found in the lexicon is Anna Wierzbicka's proposal, which is based on the assumption of the existence of a closed set of semantic primitives that can be used for defining any concept in any language. According to this proposal, the meaning of a word does not depend on the meaning of other words, but rather on a configuration of the semantic primitives. The list she proposes is the following:

Substantives: *I, you, someone/person, something/thing, body*
Determiners: *this, the same, other*
Quantifiers: *one, two, some, all, many/much*
Evaluators: *good, bad*
Descriptors: *big, small*
Mental predicates: *think, know, want, feel, see, hear*
Speech: *say, word, true*
Actions, events, motion: *do, happen, move, touch*
Existence and possession: *there is, have*
Life and death: *live, die*
Time: *when/time, now, before, after, a long time, a short time, for some time, moment*
Space: *where/place, here, above, below, far, near, side, inside*
Logical concepts: *not, maybe, can, because, if*
Intensifier, augmentor: *very, more*
Taxonomy, partonomy: *kind of, part of*
Similarity: *like*

Other classifications are based not on the existence of semantic primitives that can be combined to form definitions, but rather on the existence of semantic fields that group the different concepts that can be expressed through the vocabulary of a language.

The *Longman lexicon of contemporary English* uses the following semantic fields, which are further subdivided:

Life and living things
The body: its functions and welfare
People and the family
Buildings, houses, the home, clothes, belongings, and personal care
Food, drink, and farming
Feelings, emotions, attitudes, and sensations
Thought and communication, language and grammar
Substances, materials, objects, and equipment
Arts and crafts, science and technology, industry and education
Numbers, measurement, money, and commerce
Entertainment, sports, and games
Space and time
Movement, location, travel, and transport
General and abstract terms

These and other groupings can be proposed for content vocabulary, in contrast to grammar words, which are used only for expressing grammatical relations within the sentence. Another approach to a semantic classification takes into account the semantics of the different elements that make up the sentence. It is assumed that in any sentence, there is a predicate (the verb) and several arguments that take up semantic roles. These semantic roles are verb specific (giver, thinker, hearer, etc.), but they can be grouped into more general relations like Agent (entity that performs an action), Experiencer (entity that experiences something, as a 'cognizer', 'perceiver', or 'emoter'), Recipient (entity that receives something), Stimulus (entity that is the object of experience), Theme (entity that is located or that undergoes a change of location), and Patient (entity that undergoes a process or an action initiated by another entity). These semantic

roles can be reduced to only two: Actor and Undergoer. Sentential semantic roles can be found in any language; they only differ in the way in which they are expressed in the grammar of every particular language. There exist many classifications of semantic roles, and each grammatical theory has its own list, so that we may find other role names, like Source, Path, Goal, Location, Object, etc.

In contrast to semantic typologies, discourse typologies are more concerned with broader units, related to discourse. 'Discourse' is a term that covers many kinds of communication. According to the possibilities available, we can establish different general types. A first distinction can be made between oral and written discourse. Oral discourse is characterized by the direct contact made by the participants in the interaction and its immediacy. Oral communication takes place 'in real time', that is, the message is decoded by the receiver as soon as it is encoded into the oral message by the speaker. In such a communicative situation, the message is also conveyed with the help of means other than language, such as hand gestures, intonation, posture, etc. In contrast, written discourse is not so immediate and there is no simultaneous participation of the writer and the reader in the communicative situation. It may take a very long time since the writer writes the message until the reader reads it. Everything should be encoded into the text and may be subject to a much closer scrutiny than the oral message, which means that it requires a more careful production. Another distinction that should be taken into account is the one between everyday and literary language. It is obvious that literary language involves a more careful discourse, which affects organization and the use of vocabulary and discourse markers. However, this is still a basic kind of grouping, which would be previous to a more detailed classification.

Closer to the semantic typologies presented are some classifications that have been proposed for analyzing the internal structure of discourse, such as a classification of different semantic relations within discourse. Discourse fragments can be related according to temporal relations (chronological sequence and temporal overlap), matching relations (contrast and comparison), cause–effect relations, truth-and-validity relations (statement-affirmation, statement-denial, denial-correction, concession-contraexpectation, etc.), alternation relations (contrastive and supplementary), bonding relations (coupling, exemplification, exception), paraphrase, amplification (specification, exemplification), setting relations, etc.

As for the external characterization of discourse, there have been many different attempts to establish an exhaustive classification of discourse types, but all of them accomplish this task partially. A good starting point for a discourse classification would be to take into account the different functions that any discourse may have, which depend on the objectives. The objective of discourse may be information (which is the basis of informative discourse), expression (the basis of narrative discourse), and persuasion (the basis of argumentative discourse). All three types normally appear in combination, but they serve to give some foundation to a more sophisticated classification of discourse types. One of those classifications is Werlich's, in which there are five basic forms underlying all discourse types: descriptive, narrative, explanatory, argumentative, and instructive. These basic forms are related to innate categorization possibilities that human beings have, and they are characteristically expressed by different types of sentences.

These five basic forms have two different methods of presentation: subjective, which shows the writer's perspective, and objective, which is subject to verification by the readers. This gives the following discourse types with subjective presentation: impressionistic description (descriptive), report (narrative), essay (explanatory), comment (argumentative), and instructions (instructive). If the method of presentation is objective, then we have the following types: technical description (descriptive), news story (narrative), explication (explanatory), argumentation (argumentative), and directions, rules, regulations, and statutes (instructive). All of these types have characteristic sentence structures. A further subdivision of discourse types can be carried out according to the 'channel' involved (oral channel vs. written channel).

Another type of classification is based on the discourse situation. Steger et al. distinguish six discourse types according to six types of discourse situation: presentation, message, report, public debate, conversation, and interview. These types are characterized by certain features present in the discourse situation. For some of them (presentation, message, report) there is only one speaker, whereas for others (public debate, conversation, interview) there are multiple speakers. The rank of the actors involved can be equal (in public debate and conversation) or unequal (in the rest). The theme can be predetermined (in all except conversation) or not predetermined (in conversation). Finally, the method of theme treatment can be descriptive (in message and report), argumentative (in presentation, public debate, and interview), or associative (in conversation).

CARLOS INCHAURRALDE

Semantics

Semantics is the study of the meaning of signs and representations, both mental and linguistic. The ultimate target of semantics is the construction of a general theory of meaning.

Following a traditional taxonomy, we can distinguish three different kinds of signs depending on the nature of the relationship between the sign form and its meaning: indexical, iconic, and symbolic signs. Indexical signs are those in which the sign or representation is causally connected to its meaning. The redness of a face, for instance, is an indexical sign of anger or irritation. Certain skin spots are indexical signs of an illness such as measles. This connection is sometimes labeled, following Grice (1957), the natural meaning of a sign. In the case of icons, the relationship between the sign and its meaning is based on a perceptual similarity. The map of a geographical area is thus an iconic sign of the territory it represents. Symbols, finally, are signs whose relationship with their meaning is established through a conventional rule. A red light symbolically, i.e. conventionally, represents the obligation to stop. Individual expressions and sentences of natural languages are paradigmatic examples of this semantic category. Thus, the sentence 'snow is white' is the symbol we use in English to represent the fact that snow is white.

The appeal to this taxonomy implicitly involves the idea that the different relationships that connect the meaning of a sign to its form should be explained following different theoretical principles. Thus, the semantics of indexical signs would depend crucially on a theory of causal relationships; the semantics of icons would depend on the similarity principles that determine perceptual structures; and the semantics of symbols would be characterized in terms of the principles that regulate and constrain the conventional rules that help individuate the symbols' meaning. However, these demarcations are not as clear as they seem. This is especially the case in contemporary semantic theories, which often invoke causal (e.g. Fodor 1990) and perceptual factors in order to explain the meaning of symbols —and not just indexical and iconic signs.

From a philosophical point of view, symbols constitute the fundamental category within a semantic theory. This is the case, at least, within the so-called contemporary analytic tradition in philosophy. If we specify the range of phenomena that a semantic theory addresses following the scheme 'A interprets B as representing C', where 'A' is the interpreter, 'B' is an object, event, symbol or representation, and 'C' is the meaning of B, we can establish some important theoretical demarcations. The formal structure of B is studied by syntax. The relationship between B and its interpreter(s) is the domain of pragmatics. A semantic analysis would shed light on the nature and structure of C as well as on the nature and structure of the relationship between B and C.

Despite these basic differences, there are multiple and complex relationships between these three different disciplines. Thus, the array of meanings that C can represent is constrained by the syntax of B within a particular linguistic or representational system. In order to represent an event, for instance, the type of symbol should be a sentence, not a name. In this sense, logic, an essentially syntactic discipline, is sometimes considered a part of semantics because it aims at explaining the structural properties of the expressions of a language.

If the boundary between syntax and semantics can be fuzzy, the demarcation between semantics and pragmatics is even more problematic. The most radical conception in this sense, namely a conception according to which the notion of meaning of a symbol can be reduced to the conditions of its use (Wittgenstein 1953), denies that there is a distinction at all.

These difficulties notwithstanding, there are indeed certain questions that are the proper domain of semantics. Among these questions, the most prominent is perhaps that of clarifying and determining the very nature of the notion of meaning. In principle, the meaning of an expression could be thought as just what the expression stands for, i.e. its reference. This is a technical sense of reference understood as a function that assigns, to the symbols of a language, different extralinguistic entities taken from a particular domain of interpretation. This definition coincides with the characterization of reference as a semantic value. Its only peculiarity consists in including—as an additional layer of complexity—the idea of a domain of interpretation. In the case of natural languages—i.e. languages such as English or Spanish—this interpretation is already given and the task of a semantic theory is to specify the interpretation already imposed by the way in which the language is used. However, in the case of nonnatural or artificial languages (e.g. the language of logic or mathematics), we have to fix a nonempty domain of objects, if we want the symbols of those languages to mean anything at all, i.e. if we want to interpret those languages or—as is sometimes said when talking about formal languages—if we want to have a model of those languages. Thus, this characterization of the notion of reference responds to the basic requirements of what is known, in mathematics, as model theory (see e.g. Hodges 1993). Although this, in itself, is no more than a branch of mathematics that studies the relationships between different types of languages and different types of mathematical structures, it has strong implications and applications in the territories of semantics, linguistics, and the philosophy of language.

The notion of reference, however, does not completely exhaust the meaning of a symbol. Frege (1892) introduces an additional and even more fundamental semantic concept to complement that of reference: the concept of sense. The need to invoke this new semantic dimension when trying to determine the meaning of a symbol becomes clear whenever we address the issue of explaining why true identity statements involving different proper names (e.g. 'Hesperus is Phosphorus') which refer to the same object (Venus) differ from identity statements that involve the same name (e.g. 'Hesperus is Hesperus'). If the meaning of a proper name (e.g. 'Hesperus') were just its reference (i.e. the planet Venus), the two kinds of identity statements should have the same cognitive value. Since this is not the case—since we might learn something we did not know when we learn that Hesperus is Phosphorus—we have to admit that the meaning of a proper name cannot be just its reference.

The same two concepts—sense and reference— have been used to analyze not just proper names but also other kinds of expressions, such as declarative sentences. In this case, the meaning (sense) of a sentence is characterized as its truth conditions, i.e. as what the world would be like if the sentence were true. The reference of the sentence is its truth value. There are only two truth values in classical semantics: truth and falsity, and establishing the truth value of a sentence, unlike determining its meaning, is an empirical matter. The idea of the meaning of a sentence being its truth conditions has to be amended to cover nondeclarative sentences such as imperatives or questions, but it has been a central notion in all contemporary semantic theories. Thus, Donald Davidson's primary insight, and his major contribution to semantic theory, was to adapt a theory of truth developed by the mathematician Alfred Tarski (1944) to the problem of developing a theory of meaning for natural languages. Tarski assumed the idea of meaning—the idea that a sentence could be the translation of another sentence—to get at the notion of truth. Davidson inverts Tarski's scheme and uses the idea of truth as basic in order to develop a characterization of meaning in terms of truth conditions (Davidson 1984).

Such a characterization of meaning also helps establish what inferences can be legitimately drawn from each sentence, since a valid inference or argument is one in which the truth of the conclusion follows from the truth of the premises. The notion of truth—the core notion in logic—and the notion of meaning—the core notion in semantics—are thus intimately related. In fact, mathematical logic has provided the basic theoretical tools for the development of some of the most interesting semantic theories of this century. In particular, the development of first-order predicate logic by Gottlob Frege opened the door for many applications of semantics within areas such as computer science and artificial intelligence.

Despite this initial success, contemporary semantic theorists tend to question the plausibility of applying the model of first-order logic to natural languages. Natural languages have a much more complicated syntax than the language of first-order logic: expressions are often ambiguous, and there are many kinds of sentences other than declarative sentences. A first attempt at providing an alternative account was developed by Montague (1974), who advocated the use of a more powerful logic (intensional logic) as a way of solving some of the problems encountered within the original Fregean treatment. Montague's proposal allows us to characterize the meaning of sentences involving the idea of necessity or possibility and also of those sentences that express propositional attitudes such as belief or desire. However, even Montague's treatment remains heavily embedded in the formalist approach set up by the mathematical view of semantics and it too has been called into question by more recent semantic theories.

The characterization of the notion of sense, especially when applied to common names, i.e. expressions such as gold, tiger, etc., has also been harshly criticized over the last few decades. This notion was traditionally characterized in terms of a set of necessary and sufficient conditions that determine the reference of an expression. The basic idea of the recent critics is that we can ascribe to the average speaker of a language knowledge of the meaning of an expression without assuming thereby that the speaker knows the set of necessary and sufficient conditions that determine the reference of such an expression. The alternative proposal is to substitute the notion of stereotype for the idea of sufficient and necessary conditions. A stereotype is a mental representation of a paradigmatic instance of an object or property with which the subject has had some kind of experience (Putnam 1975).

In contemporary semantics and philosophy of language, the notions of narrow and wide content have come to substitute those of sense and reference. Although intimately related to the original ones, the new notions have a psychological slant which was not present in earlier versions of the same idea, and are basically used in the context of specifying the meaning of a subject's mental representations.

On the one hand, the narrow content (or meaning) of a mental state is constituted by the intrinsic (i.e. context-independent) properties of the individual who is in that mental state. Internalism is the point of view characterized by the thesis that such contents are individuated without essential reference to the subject's physical and social environment. On the other hand, the externalist claims that contents are individuated 'widely', i.e. by reference to the subject's environmental or social context.

To begin with, we said that the aim of semantics is the development of a theory of meaning. It is important to stress now that one of the most important topics in this discipline is the study of the empirical evidence that verifies—or falsifies—such a theory. This empirical dimension brings semantics into the domain of naturalism, i.e. the domain of empirical science. Dominant naturalistic theories depict semantic properties as properties of some other (more primitive, less problematic) kind since semantic properties are not commonly held to be part of the basic ontological furniture of the world. Most theorists engaged in naturalization projects for semantics thus assume that the program of naturalization demands a higher-to-lower, top-to-bottom, kind of explanatory strategy. They believe, in other words, that the nonsemantic properties on which semantic properties depend, belong to what are intuitively lower levels of description than the semantic level itself (contenders include biological properties; see Millikan 1984). The reductionist flavor is unmistakable here. Achieving a clear understanding of 'naturalism' as applied to semantics and deciding whether a naturalistic semantics is possible are probably two of the most important issues for contemporary philosophy of language and philosophy of mind.

Semiotics

Semiotics is the science of signs. Even though the study of signs has been a constant in the history of thought, we owe the rise of semiotics as a discipline in the modern world to the ideas of the Swiss linguist Ferdinand de Saussure and the American philosophers Charles S. Peirce and Charles W. Morris.

In the tradition of Saussure, a sign is composed of the signifier, i.e. the form that the sign takes, and the signified, i.e. the concept or object it represents. The signifier is characterized as the physical form of the sign. It is important to keep in mind the distinction between the sign *vehicle*, which is just the form in which the sign appears (spoken or written form, for instance), and the sign itself, which includes both the signifier and the signified. The signified has, within this tradition, not a physical but a psychological status. It is interpreted as some kind of mental construct, the psychological impression that the signifier makes on the interpreter of the sign. Given this characterization of how signs represent, the idea of signs referring to objects in the world is excluded from this particular view of semiotics. Signs do refer, but only to mental concepts and psychological entities constructed by the interpreter.

This mentalist understanding of the notion of reference of a sign (the signified) seems to support an idealist philosophical interpretation of reality, i.e. an interpretation according to which there are no ultimate real objects and events in the world regardless of how we construct them throughout the use of signs. It is important to notice, though, that this rather psychologized view of the referent or signified of a sign is not shared by all semioticians. Charles Peirce's proposal, for instance, views the referent of a sign as something with its own ontological status, something external to the sign's interpreter. Peirce's model, by characterizing the referents of signs as something external to the interpreter, as something with an independent ontological weight, seems to suggest a more realist philosophical interpretation of the world according to which reality is composed of objects and properties which stand on their own and independently of our means of describing them or of knowing them via a system of signs.

Saussure calls the relationship between the signifier and the signified the signification. For Saussure, the relationships between signifiers and their signifieds are ontologically arbitrary, but once these relationships have been established by the use of a community throughout history, such arbitrary connections cannot be changed. But regarding this issue of arbitrariness, not all semioticians agree. Most would nonetheless allow that there are degrees of arbitrariness in how the signifier and the signified relate to each other. Thus, following Charles Peirce's model, we can establish three different kinds of signs depending on how the signs vehicles relate to their referents. From the most to the least conventionally based relationships, we find symbols, icons, and indexes. Symbols are purely conventional, i.e. there is no perceptual or naturally recognizable relationship between the signifier and the

signified. An iconic sign is one in which the signifier physically or perceptually resembles the signified (e.g. a portrait or a sculpture). Indexical signs are those in which the signifier is physically or causally connected to the signified, such as smoke to fire, facial spots to measles, etc.

When we talk about signs in this context, we are thus referring not just to linguistic symbols. A sign is anything that stands for something else. Thus, semiotics can be characterized as a theoretical approach to such diverse phenomena as images, sounds, paintings, rituals, gestures, etc., as well as languages. The presence of the theoretical apparatus of linguistics is, however, quite significant since linguistic symbols are still considered paradigmatic within this discipline. In this sense, Claude Lévi-Strauss, a contemporary anthropologist who sees anthropology as a branch of semiotics, claims that 'language is the semiotic system par excellence; it cannot but signify, and exists only through signification' (Lévi-Strauss 1972: 48). Semiotics enjoyed its golden era within the philosophical movement known as Logical Positivism in the 1930s. C.W. Morris' *Foundations of the theory of signs* probably provides the most complete characterization of this theory, presenting it as a science whose main aim is to provide the foundations for any other particular science about signs.

Having such a wide range of phenomena as its subject makes it hard to establish a precise demarcation between semiotics and the other disciplines with which it shares some of the same objects of study, e.g. disciplines such as linguistics, logic, mathematics, esthetics, and anthropology—all of which address, in one way or another, the general phenomenon of signs. Nor is it obvious that the proper theoretical status of semiotics is that of a science, i.e. that we should consider semiotics as having the same theoretical status as other empirical sciences, such as biology or chemistry. Semiotics sometimes appears as a style of philosophical investigation, sometimes as a theory, and some other times as a methodology. In order to gain a better understanding of this discipline, we shall focus here on two issues: the domain of semiotics and its theoretical status.

Semiotic processes or events involve, according to Charles S. Peirce, three factors: a sign, an object, and an interpreter. Depending on which factor gets isolated for study, semiotics splits into three different branches: pure grammar (the study of signs themselves), logic (the study of the object of the sign), and rhetoric (the study of the sign's interpreter). But what characterizes semiotics and makes it different from the other disciplines is that the interrelation between these three factors is absolutely essential for the individuation of semiotic phenomena. Charles W. Morris (1938, 1946)

likewise stresses the dynamic interrelation between sign, denotation, and interpreter. From Morris' point of view, no object, event, or particular action can be considered, in itself, a sign, a denotation, or an interpreter. The properties that characterize each of these entities are relational properties. Such properties are acquired only through a semiotic process, i.e. a process through which something becomes a sign for someone (cf. Morris 1946: 353). Morris establishes four components in this process: the sign (vehicle), the denotation of the sign, the organism for which something is a sign (the interpreter), and the effect the sign produces in the interpreter. Among the multiple examples that Morris provides to illustrate the role played by each of those factors, perhaps the clearest is that of a traveler who, ready to go to a specific geographical area, receives the letter of a friend describing that region. The traveler then packs his luggage in accordance with the information provided by his friend in the letter. In that example, the letter is the sign, the geographic conditions are the denotation of the sign, the traveler's preparations regarding what to pack are the effect that the sign produces in the interpreter, and the traveler, of course, is the interpreter. The most important idea is that none of those factors would belong to these categories were it not for the interrelationships among them (cf. Morris 1938: 3–4).

Despite this theoretical interdependence, Morris, as well as Peirce, concedes that we can isolate the relationships between such categories and define different branches within semiotics. Thus, if we are mainly interested in the relationships between the signs themselves, we focus upon the syntactic dimension of semiotics. We focus on the semantic dimension if we are mainly interested in the relationships between the signs and their denotations and upon the pragmatic dimension if our focus is upon the relationships between signs and their interpreters (Morris 1938: 6–7). These partitions can, in principle, help establish clearer theoretical connections between semiotics and other disciplines. Thus, linguistics and logic are about the syntactic semiotic dimension. The object of semantics is the relationship between signs and their objects—the semantic dimension of semiotics. Pragmatics, finally, is the most problematic discipline whenever we try to assign to it a specific semiotic dimension. The reason for this is that the study of the relationships between signs and their interpreter(s) covers a complex field, which includes psychological, biological, and sociological aspects of sign manipulation. Psychoanalysis, the sociology of knowledge, and even some approaches within esthetics or anthropology all touch upon this pragmatic dimension of semiotics. Furthermore, the problem with this taxonomy is that it seems to suggest that whenever we are doing syntax or semantics, we can ignore the role of the interpreter. However, such a suggestion is highly controversial, especially if we realize that the complex notion of the meaning of a symbol seems to include a variety of aspects related to the interpreter's use of those symbols, thereby blurring the boundaries between semantics and pragmatics. Morris himself downplayed this taxonomy in his later work *Signs, language and behavior*, where he introduces it just as a general suggestion and only in the last chapter. The problem of distinguishing pragmatics and semantics has been and still is one of the central problems in linguistics and the philosophy of language.

So far, we have been talking about the object of semiotics. But what can we say about its theoretical status? For some authors, semiotics ought to be placed at the same level of philosophy of language (where 'language' includes nonverbal languages). Umberto Eco (1984) is perhaps the most fervent advocate of this view. For him, the philosophical character of semiotics turns it into a discipline without any predictive power, and in which the object of study is also always mediated by the general presuppositions of the theory itself (Eco 1984: 10–3). However, this is not a widely shared view. Especially when we talk about specific semiotics (e.g. narrative semiotics, folk semiotics, animal behavior, and human institution semiotics, etc.), the descriptive slant of the discipline is stressed and, with it, its empirical character. Finally—and without considering these distinctions exhaustive—semiotics is sometimes considered more as a general methodology or as the sum of different semiotic methods. From this point of view, the notion of sign is applied not only to linguistic objects but also to objects such as buildings, rituals, landscapes, and star formations. Among the semiotic methods, we can distinguish at least three: formalization, linguistic analysis, and method of interpretation.

The method of interpretation—especially the formalization of natural languages—stresses the syntactic properties of signs and what is sometimes called 'operational meaning': 'operational' because it is normally characterized in terms of rules that specify the admissible forms for manipulating signs. Once signs are stripped of their semantic and pragmatic properties, they constitute a purely syntactic skeleton, ready to be dressed with different interpretations.

The method of linguistic analysis consists in the reconstruction of the deep structure of the analyzed expression and in the enumeration of all their semantic and pragmatic properties. The use of this method is thus complementary to the method of formalization and it allows us to find out what an expression or a particular piece of text really means and what information can be derived from its meaning. The use of this method lies at the heart of so-called 'structural

linguistics' (Saussure 1916). It has also been widely applied to the sciences, paying special attention to the process of elaboration of particular scientific languages and to the creation of new terms.

The method of interpretation consists fundamentally in the symbolic treatment of objects, events, or phenomena that are not themselves signs (e.g. food, rituals, human faces, etc.). When we interpret them in this way, we direct our attention beyond the object or event itself. In so doing, objects, events, and phenomena that are not in principle symbolic at all become an instrumental part of our system of communication. This is probably the most familiar version of what is often understood by 'semiotics', namely, a treatment that can be considered an extension of hermeneutics in the sense of being applied to phenomena that are not intrinsically symbolic. This method is highly relevant for disciplines such as psychology or sociology since one characteristic type of explanation within these sciences consists in bringing to light intentions and motives that are only indirectly expressed in human behavior and human intellectual creations.

Semitic Languages

Four of the five literary Semitic languages that underlie great civilizations of Asia, Africa, and Europe—Arabic, Aramaic, Geʻez or Ethiopic, and Hebrew—are covered elsewhere, so here we concentrate on the fifth, Akkadian; on the less well-known Semitic languages of antiquity; and on what they have in common and how they relate to each other. Semitic itself is one of five or six branches of the Afroasiatic phylum, the only one spoken principally in (southwest) Asia.

General Characteristics

For a thousand years or more, linguists (beginning with the Arab grammarians) have taught that words in Semitic languages are formed from 'roots' consisting of three consonants and no vowels at all, and only 'modifications' of the 'root meaning' are indicated by vowel 'patterns'. But this seems to be an artifact of the writing systems used by the Arab (and Hebrew and Syriac) grammarians, which notated only the consonants, with the short vowels included only optionally and with incidental-looking marks. Moreover, it relates only to verbs, and not to 'primary nouns'. In 1934, an Indo-Europeanist, Louis H. Gray, essayed a description of Semitic that eschewed the root-and-pattern model and observed verb roots of the form CCVC—like many other languages—rather than the unique CCC. (See Table 1. This view has recently been adopted independently by several scholars.)

Typical of the Semitic languages is their way of expressing a relationship between two nouns. Rather than marking the possessor, as in *the king's peace*, Semitic puts the possessed into the CONSTRUCT STATE, as in Akkadian *šulum šarri*, literally 'peace-of king'; cf. *šulmu* 'peace', *šarru* 'king'. These words also illustrate two of the three noun cases: nominative ending in *-u*, genitive (possessive or adnominal) ending in *-i*, and accusative (objective or adverbial) *-a*. Nouns in Semitic have two genders: masculine or feminine.

The morphological typology of Semitic is inflecting; the syntactic typology is basically Verb–Subject–Object, even in those languages where the verb usually comes at the end of a clause: Ethiopic, presumably under the influence of Cushitic languages, and Akkadian, under the influence of Sumerian.

TABLE 1 Consonant Correspondences, Prefix Conjugation, and Verb Stems[1]

Translation	Akkadian	Hebrew	Syriac	Geʿez	Arabic	Proto-Semitic
I guard	*aṣṣuru*	*ʾeṣṣor*	*ettur*	**ʾinṣir*	*ʾanzuru*	*ʾa-nθur*
We grind	*niṭên*	*niṭhan*	*neṭhan*	*niṭhan*	*naṭhanu*	*na-ṭhan*

To be twisted (N)	*naptulu*	*hippātēl*	*— (√ptl)*	*— (√ftl)*	*infitālun*	*ptil*
To be sought for (Gt)	*pitqudu*	*— (√pqd)*	*metpqādū*	*tafaqɨdō*	*iftiqādun*	*pqid*
To find one's match (Dt)	*mutaššulu*	*hitmaššēl*	*metmattālū*	*tamassɨlō*	*tamaθθulun*	*mθul*

[1]The correspondences yielding the 29 reconstructed Proto-Semitic consonants can be read in the rows, as can the prefixes. The last five rows show the most important derived stems: G(round) or Basic stem (in the top 10 rows), D(ouble)=Intensive, Š=Causative, N=Passive, t=Passive/Reciprocal. * marks roots not attested in this language or this stem. — (√…) marks stems not used in this language, with the consonant correspondences for the language.

Classification

The sole representative of East Semitic is Akkadian, which includes the dialects Assyrian, Babylonian, and the recently discovered Eblaite. West Semitic was understood to comprise Northwest (divided into Canaanite and Aramaic) and Southwest (the languages of South Arabia, both Ancient and Modern, and Ethiopia); Arabic used to be included with the Southwest group, but in recent years arguments were advanced that it belonged better with the Northwest group. The criteria for the classification are presented below, following Faber in Hetzron (1997).

Recently, however, *Stammbaum* or 'family tree' diagrams of language family relationships have fallen out of favor, as linguists have recognized the importance of social interaction in the shaping of languages, and a new model for the development of the Semitic languages has been offered (Kienast 2001). It suggests that the successive appearances of the languages in the historical, i.e. written, record represent successive attestations from a single, continually developing speech community (and after they make their entries, of course, each language

would develop independently). This approach helps explain how some characteristics (like noun case endings) can be found in the earliest (Akkadian) and latest (Arabic) forms of Semitic, but not in the intermediate forms (taken to be Ethiopic/South Arabian, Canaanite, and Aramaic in order).

Although Akkadian was deciphered in the late 1840s, its grammar was not well understood before the insights of the Czech-born Leipzig/Ankara/Chicago Assyriologist Benno Landsberger, which were codified first in a chapter by Gotthelf Bergsträsser (1928/1995) and then by Landsberger's student Wolfram von Soden (1952/1995); the earliest form of Akkadian received due attention only with the work of I.J. Gelb in the 1950s. Consequently, Akkadian was not well assimilated into the early comparative sketches and collections of data such as those by William Wright (1890), Theodor Nöldeke (1889/1911), and Carl Brockelmann (1908, 1908–1913) and even that by Landsberger's own teacher Heinrich Zimmern (1898). In these works—and in subsequent manuals, notably the widely used Moscati et al. (1964)—the reconstructed Proto-Semitic bears a very close relationship to Classical

Arabic. (Lipiński (1997) is not suitable for the beginner because, although detailed and up to date, it does not distinguish between the generally accepted opinion and the author's own; but its bibliography is extensive.) Only with the work of Gelb himself (1969) and of fellow Assyriologist Burkhart Kienast (2001) does a Proto-Semitic emerge that offers a more credible abstraction that might foreshadow East Semitic as well as West Semitic.

Even before the decipherment of Mesopotamian cuneiform had progressed very far, the language written with that script could be identified as Semitic (which in turn proved very useful in the decipherment). The clue was the identification of sets of words exhibiting perhaps the most distinctive trait of Semitic morphology: alternations of the type *iprus–iparras–paris*. The precise meanings of these verb paradigms turned out not to be exactly those familiar from Hebrew, Arabic, and Ge'ez, but the forms were identical.

In fact, the divergence in meaning of the verb forms is taken as the most salient characteristic for distinguishing West Semitic as a whole from Akkadian. All Semitic languages have just two basic verb forms: in Akkadian *iprus*, the 'preterite' or past, and *iparras*, the 'present' (persons are identified by prefixes; Table 1); *paris*, the 'stative', stands somewhat outside the system (persons are identified by suffixes; Table 2). But West Semitic has turned the equivalent of *paris*, e.g. Arabic *qatala*, into the 'perfect', denoting completed action (forms of *qatala* 'kill' are traditionally used to illustrate verb forms; this word is not found in Akkadian, and *parāsu* 'divide' serves instead). The forms with a lengthened middle consonant, e.g. *qattala*, are reserved for a quite different function, but one that (with a different selection of vowels) it already had in Akkadian.

This different function is another signal characteristic of Semitic: rich derivational morphology of the verb. English, for example, has pairs of semantically related words like *learn* and *teach*. But in Semitic, 'teach' is literally 'cause to learn': Akk. *lamādu*, *šulmudu*. Besides this CAUSATIVE, Semitic languages have an INTENSIVE—the derivation marked by the lengthened middle consonant—and one or two kinds of PASSIVE (and additional derivations appear in individual languages). Some examples are shown in Table 1.

The forms in Table 1 also exemplify the sound correspondences that both demonstrate the unity of the Semitic family and characterize its different branches. In East Semitic, the five gutturals merge into ' [ʔ], but the three most highly marked ones, *ǵḥ'* [ɣ ħ ʕ], color an adjacent *a* to *e*, while *h* and ' do not.

In Central Semitic, the EMPHATIC series (transcribed with the underdot) is realized with pharyngealization, rather than glottalization as in South and (probably) East Semitic. The nonpast *yaqattal* is replaced by *yaqtulu*. Within Central Semitic, Northwest Semitic is distinguished from Arabic by the change of almost every initial *w* to *y*. Within Northwest Semitic, Canaanite shows several common morphological innovations, and the change of *ā* to *o*. Aramaic displays a simplification and 'neatening' of the derived verb stem system, but its typical phonological change, the interdentals [θ ð] becoming stops [t d], is not found in the earliest attested texts. In Canaanite, the interdentals become sibilants [ʃ ʒ]. (Arabic preserves all the ancient distinctions except one of the sibilants. Semitists usually write *š ś ǵ ḥ* for [ʃ ɬ ɣ x].)

South Semitic's diagnostic morphological innovation is seen in Table 2. The *k* of the old first-person singular has spread to the second person (while in Northwest Semitic, the *t* of the second person has spread to the first). Southeast Semitic (Modern South Arabian) is not the direct descendant of Old (or Epigraphic) South Arabian; the latter is closer to Ethiopic Semitic than the former is to either of them.

TABLE 2 Person, Gender, and Number Suffixes on *paris/qatala* Forms

Specific Languages

Akkadian was spoken in Mesopotamia from before 2500 BCE until the early to mid–first millennium BCE and survived as a literary and then scholarly language into the early centuries CE (Geller 1997). (The latest known dated Akkadian text is from 75 CE.) Akkadian was written by impressing groups of wedges in soft clay shaped into 'tablets', which when they dried (or got baked when a building burned down) were quite permanent, and thousands were recovered when explorers began poking into the remains of ancient cities. Its decipherment in the late 1840s revealed the existence of an unsuspected Mesopotamian civilization of which bare hints were found in the Bible; early on, it was found to have a literature, a religion, and a mythology (including a Flood story) that illuminated not only the Bible but its own society. Even more, though, emerges from the tens of thousands of non-literary tablets recording ordinary transactions of the most varied kind. There are two scholarly dictionaries: Gelb et al. (1956–) and von Soden (1958–1981); Black et al. (2000) is a condensation of the latter.

The second half of the nineteenth century witnessed the discovery of a wide variety of inscriptions in Hebrew and other, closely related Canaanite languages, the first and foremost, and for a long time the earliest (c. 850 BCE), being the stela of King Mesha, in Moabite. Its script is very similar to that of Phoenician, which had been deciphered in the 1760s; unfortunately, the large number of inscriptions in Phoenician (c. 1000 BCE–500 CE), found scattered all round the Mediterranean, including its late variety, the Punic of Carthage and environs, are almost entirely brief and uninformative, so that little can be reconstructed of Phoenician political history. The sole monument in Moabite, however, is a historical inscription resembling contemporary accounts in Aramaic, Akkadian, and Hebrew. In recent decades, it has been joined by similar but less extensive materials in Ammonite and Edomite. All three languages are from east of the Jordan River. Akkadian tablets preserve references to thousands of people whose names are in Amorite, the West Semitic language of the famed King Hammurapi and his dynasty.

An epochal discovery in 1929 at Ras Shamra on the coast of Syria was clay tablets in what soon proved to be a Northwest Semitic language, Ugaritic. Its script is consonantal like Phoenician's, and not derived from Mesopotamian cuneiform despite the use of wedge-made letters. Dating from the fourteenth–thirteenth centuries BCE, Ugaritic is too early to display specifically Canaanite features, but again it preserved texts illuminating the religious background of the Bible. In 1975, farther east in Syria, a large number of clay tablets were found at Tell Mardikh, ancient Ebla. At first their Eblaite language, written in the familiar cuneiform of c. 2500 BCE, was interpreted as also representing a very early relative of Hebrew, but it was soon recognized as a form of Akkadian or as a separate East Semitic language used far to the west.

The South Arabian languages, Modern (Mehri, Ḥarsusi, Baṭhari, Hobyot, Jibbali, and Soqoṭri) and Old (Sabean, Qatabanian, Hadramauti, and Minean), were the first languages (after Phoenician) to be 'discovered' in modern times, in the 1830s. They occupy the southern fringes of the Arabian peninsula and nearby islands. All the proto-Semitic consonants are preserved, and the Old South Arabian script records the 29, and no vowels at all. The modern languages are not written; Mehri and Soqoṭri may have enough speakers not to be immediately endangered.

Semitic Writing

The scriptures of the three Western monotheistic religions are written in Semitic languages (Hebrew, Aramaic, and Arabic). But the Semitic languages hosted the development of the writing systems themselves that serve virtually every language outside East Asia. Mesopotamian cuneiform, after being adapted from its Sumerian original, was used for many languages throughout the ancient Near East (with the exception of Egyptian) over at least 2,000 years, first of all.

Cuneiform was cumbersome, though, requiring the memorization of several hundred characters during years of study. It was when the basic principle of Egyptian hieroglyphics—write only consonants—was applied in a highly simplified manner to an early West Semitic language that the sequence leading to the alphabets of the modern world got going. Little material survives from the earliest stages; by the time of Ugaritic, we see an adaptation of the letters to writing on clay. One variety is found to the south, used in Old North Arabic graffiti and Old South Arabian monumental inscriptions, and then in Ethiopic inscriptions and manuscripts.

The other variety emerges in Phoenician and Aramaic versions; Phoenician survives almost exclusively in its offshoot, the Greek alphabet, and its descendants including the Roman and Cyrillic. Scions of the Aramaic version serve Hebrew, Arabic, and Aramaic—and spread all across South, Southeast, and Inner Asia. The variety of ways in which vowel notation came to the originally consonantal scripts is a saga in itself.

Serbo-Croatian and South Slavic Languages

The South Slavic languages, Serbo-Croatian, Slovene, Bulgarian, and Macedonian, descend from Slavic dialects that were brought to the sub-Alpine and Balkan regions of southwestern Europe c. 500 CE by waves of westward migration along and across the Danube, Drava, and Sava river systems. In their new territory, the South Slavs encountered and undoubtedly mixed with Latin-speaking peoples, probably descendants of older Indo-European-speaking peoples, for example, Illyrian and Thracian.

The exact relationships among the dialects at the time of settlement are uncertain, but it is not the case that there were already nascent Slovene, Serbo-Croatian, Macedonian, and Bulgarian dialects. Rather, these formed over the subsequent millennium. The South Slavic group may now be defined by its geographical discontinuity to the remainder of the Slavic-speaking world. To the north, Slovene is bounded by Friulian and Italian in Italy, by German in Austria, and by Hungarian in Hungary. Croatian and Serbian are also bounded by Hungarian and Romanian (Romania). Bulgarian is bounded by Romanian,

which, together with the Black Sea, separates South Slavic from Ukrainian. Within the South Slavic branch, two subgroups are distinguished: Western South Slavic, constituted by Slovene and Serbo-Croatian, and Eastern South Slavic, constituted by Macedonian and Bulgarian. The languages are also divided along cultural and religious lines: Slovene and Croatian are spoken predominantly by Catholics, whereas Serbian, Macedonian, and Bulgarian are spoken by Eastern Orthodox Christians.

These divisions have determined the choice of alphabet, Latin being chosen in Catholic areas, and Cyrillic (a modified variety of the Greek alphabet) in Eastern Orthodox areas. Bosnia, which has been religiously and ethnically mixed and also includes a significant Muslim population, had vacillated among different alphabets. Since the disintegration of Yugoslavia, the standard Bosnian of Muslims is written in the Latin alphabet, whereas the Bosnian Serbs use Cyrillic. As with most Indo-European languages, the South Slavic group is characterized by many grammatical endings, with nouns and verbs changing form

depending on their position in the sentence or on their function as subjects or objects, singulars or plurals. Slovene and Serbo-Croatian go with the rest of the Slavic-speaking world in having preserved most of these endings in nouns, but verbs have become somewhat simplified. Macedonian and Bulgarian have the opposite: simplified nouns but more complicated verbs.

Serbo-Croatian is spoken by approximately 16 million people. It is the state language of the Republic of Croatia (where it is called Croatian), Bosnia and Herzegovina (where it is called Bosnian), and Serbia and Montenegro (where it is called Serbian); minority speakers are also found in Italy, Hungary, Austria, Romania, Bulgaria, and Macedonia.

The Serbo-Croatian standard was formed in the nineteenth century as a compromise between Serbs and Croats, whose major dialect divisions and corresponding divergent literary traditions, particularly in the Croatian case, had fostered disunity. The Čakavian and Kajkavian dialects, both spoken in Croatian ethnic territory, and which had developed into sophisticated literary vehicles during the Renaissance and Reformation, respectively, were abandoned as models for the standard language in favor of the Štokavian dialect, spoken in Croatia and all of Serbia, as well as in Bosnia and Herzegovina and Montenegro. In Serbia, the new Štokavian-based standard replaced the artificial Slaveno-Serbian literary language, which was based largely on Old Church Slavic. The compromise, which was engineered by intellectuals around the Croat Ljudevit Gaj and the Serb Vuk Karadžić, was codified in the Literary Agreement of 1850. The standard had two varieties, the Croatian (or Western), written in a modified Latin alphabet, and the Serbian (or Eastern), written in a modified Cyrillic. This standard persisted officially as the language of the Croats, Serbs, and (Bosnian and Sandžakian) Muslims, as well as the de facto lingua franca of Yugoslavia, until the disintegration of the state in 1991. Since then, separate Croatian, Serbian, and Bosnian state languages (the latter using the same alphabet as Croatian and having a relatively higher number of Turkish and other Islamic cultural borrowings) have been cultivated, each continuing from their inherited Štokavian-based precursor; all three standard languages remain almost completely mutually intelligible. (For this reason, 'Serbo-Croatian' persists as a linguistically valid term, referring to the speech territory and the common base of the separate language collectively. However, it is no longer considered an acceptable term to most lay speakers or the governments of the successor states.) Other regional movements, including notably a Montenegrin one, suggest the possibility of forming further standard languages in the future.

The Serbo-Croatian speech territory is characterized by three distinct dialect areas, each labeled by both professionals and the laity by the word meaning 'what'. A transitional zone called the Torlak group displays features of both Štokavian and neighboring Macedonian and is thus arguably within the scope of the Balkan *Sprachbund*, an area of linguistic convergence among distantly related or even unrelated languages caused by long-term contact, which also includes Albanian, Aromanian, Greek, Romanian, Romany, and, to some extent, Turkish.

Generally speaking, linguists' attention has been drawn to Serbo-Croatian (as well as Slovene), especially for its phonological (sound pattern) features, high degree of dialect variation, and preservation of key archaisms that aid in the reconstruction of Proto-Slavic, the prehistoric language thought to have been spoken by all Slavs before 500 CE. Standard Slovene and Serbo-Croatian, as reflected in many of their dialects, contrast long and short vowels, and, along with stress, have rising and falling tones (similar to Chinese), e.g. Slovene *brá:t(i)* 'to read' (long low pitch), *brà:t* 'to go read' (long high pitch), and *bràt* 'brother' (short high pitch). Other features are of interest, particularly word and sentence structure, e.g. Serbo-Croatian has begun to simplify its nouns, as has occurred more radically in Macedonian and Bulgarian, by reducing the number of grammatical endings ('cases'), especially in the plural.

Structurally, Slovene is closest to Serbo-Croatian and is spoken by approximately two million people, largely in the Republic of Slovenia, where it is the primary official language (alongside regionally official Italian and Hungarian). It is also spoken by significant minorities in neighboring Italy, Austria, and Hungary.

Modern standard Slovene, which began its development with the religious translations of the Protestant Primus Truber (Primož Trubar in Slovene) in the mid-sixteenth century, was established in largely its current form toward the end of the nineteenth century. It is based on the urban speech of the capital, Ljubljana, and the surrounding central dialects, although it also has features selected from its highly variegated dialects. It is written in a modified variety of the Latin alphabet, similar to Croatian.

With its relatively small speech territory, Slovene has seven dialect bases and greater internal differentiation than any of the South Slavic languages. Speakers from the most extreme dialects (e.g. Rezija, Prekmurje) generally cannot be understood by standard speakers. Slovene preserves archaic features that have been lost in Serbo-Croatian. For example, it distinguishes not just singular and plural but also dual

number (*pogovarjava se* 'we two are conversing'); it makes the future tense with an auxiliary verb and a participle (*bom sedela* 'I shall sit'); and it preserves a special 'supine' form of the verb that signals intention (*kupovat bom šel* 'I shall go to shop'). In contrast to Serbo-Croatian, Slovene has a relatively significant number of borrowings from German (e.g. *farba* 'color' from *Farbe*), Italian (*fant* 'boy' from *fante*), and Friulian (*križ* 'cross' from a seventh-century Friulian form *krože*).

Bulgarian is spoken by approximately nine million people, predominantly in the Republic of Bulgaria, where it is the primary state language, as well as by minority speakers in Serbia and Macedonia. Structurally, Bulgarian is closest in type to Macedonian.

Modern Bulgarian dates to the seventeenth century and developed substantially into its current form in the middle of the nineteenth century. It is based on the Tărnovo dialect of northeastern Bulgaria, but with elements from various dialect areas. Medieval varieties of Bulgarian served as the primary examples of Slavic writing, with prominent writing centers located in Preslav and Tărnovo. Modern Bulgarian is written in a modified variety of Cyrillic.

Macedonian is spoken by approximately two million people, primarily in the Republic of Macedonia. Significant groups of Macedonian speakers are also found in northern Greece, western Bulgaria, Serbia, and in some villages in Albania.

Macedonian was codified as a standard language in 1944, although the beginnings of the contemporary language may be traced to the middle of the nineteenth century. Macedonian is written in a modified variety of the Cyrillic alphabet. The language of the Macedonian speech territory can be traced back organically to the speech that gave rise to the first Slavic written language in the ninth century CE, known today as Old Church Slavic.

Linguists have tended to concentrate on the structure of Macedonian and Bulgarian words and their relationship to syntax and meaning, as well as the interaction of the languages with others in the Balkan linguistic convergence area (or *Sprachbund*). For the period from the tenth to the twelfth centuries, the textual evidence of Proto-Macedonian and Bulgarian is important for the earliest body of attestations of Slavic in general, known as the canonical period of Old Church Slavic. For this reason, Indo-Europeanists have made substantial use of older Macedo-Bulgarian material.

Because of their participation in the convergence area, Macedonian and Bulgarian display features not found elsewhere in the Slavic-speaking world. For example, the category of definiteness is marked by the presence (vs. absence) of an article after the first member of a noun phrase, e.g. Macedonian *Ja vidov zhenata* 'I saw the [a certain] woman' vs. *Vidov zhena* 'I saw a woman'; Serbo-Croatian makes no such distinction, having only *Vidjela sam ženu* 'I saw the/a woman.' A distinction expressed by choices among alternative verb forms is made between witnessed and nonwitnessed events, e.g. Bulgarian *Toj napisa pismoto* 'he wrote the letter [I know so because I saw him do it]' vs. *Toj napisal pismoto* 'he wrote the letter [so it is said—I did not see him do it]'; Serbo-Croatian makes no such distinction, having only *Napisao je pismo* 'He wrote the/a letter.' The inherited infinitive has been lost and replaced by a subordinate clause, e.g. Bulgarian *Iskam da otida na mač* 'I want to go [literally 'that I go'] to a game' vs. Serbo-Croatian *Hoću ići na utakmicu* 'I want to go to a game.' The origin of such convergence features is much debated: they may be a continuation of structures from languages that have disappeared (substratum languages)—Illyrian and Thracian—or a result of language contact itself and diffusion of linguistic features, although the working of both explanations together is not excluded.

The South Slavic languages represent a picture of great diversity among the Slavic languages, and, because they are located at a crossroads of European languages and cultures, they have been affected by contacts with numerous languages. The volatile political fortunes of the region promise to push the development of the languages, especially the newly differentiated Bosnian, Croatian, and Serbian, toward ever greater diversity.

Serial Verb Constructions

Some languages—especially those of West Africa, Southeast Asia, and New Guinea—allow several verbs to appear within a clause to express a single meaning, as illustrated from Kalam (Papua New Guinea), where 'massage' is expressed by the following string of verbs:

pk	*wyk*	*d*	*ap*	*tan*
'strike	rub	hold	come	ascend

d	*ap*	*yap*	*g-*
hold	come	descend	do'

Serial verbs are so prevalent in Kalam that most verbal meanings can be expressed by combining fewer than 100 verb roots.

In other languages, just two or three verbs are serialized. In Paamese (Vanuatu), *vul-* means 'break', but this verb is seldom used, the strong preference being to serialize it with another verb indicating the precise activity that caused the breakage, for example:

Ni-matil	*vul*	*a:i.*
1SING.FUTURE-sleep	break	plank

'I will sleep on the plank, thereby breaking it.'

These constructions represent single clauses, in contrast to both subordinate and coordinate multi-clause constructions. However, it is difficult to clearly and consistently define the term 'serial verb', and there is also the related problem of the wide variation in terminology used to refer to structurally similar or historically related phenomena in different languages. Different writers have referred to 'verbids', 'locative verbs', 'post verbs', 'postverbal prepositions', 'locative copulas', and 'coverbs' to refer to essentially the same patterns in West African languages. Many are not explicit about what they mean by serial verbs, some treating any verb–verb sequences as serial verbs as long as the second verb is not marked as an infinitive, e.g. *Go get the book*. Sebba (1987) provides a more explicit set of criteria for recognizing serial verbs:

(1) Both verbs must be able to function independently within a clause as verbs in their own right.
(2) Both must be interpreted as having the same categories of tense–aspect–mood.
(3) There must be no marking of a clause boundary.
(4) There should be no conjunction appearing between the two.

Some insist that serial verbs must be distinguished from verbal compounding. However, the literature on nominal compounding is replete with statements of difficulties in distinguishing between phrases such as *wood turner* and words such as *woodlice*. Verbal compounding is no less problematic, and any attempt to categorize verbal compounds in many languages typically runs up against the problem of deciding where the boundary between compounding and serialization lies.

However, this has the potential to divert attention away from the real issues. The relevant structures could simply be regarded as complex verbs composed of more than one grammatical element, avoiding a distinction between verbal compounding and verb serialization. The two, in fact, exhibit a variety of similarities crosslinguistically, with the only real difference being that we are dealing with either words or phrases.

Verb serialization can be distinguished from subordination and coordination in that there should be no sentence-level connectives between the various verbal elements. If there is any evidence of subordinators (such as *that* or *which*) or coordinators (such as *and* or *or*)—even if only as an optional variant, as we find with English *Go (and/to) get the book*—then we are dealing with a complex sentence rather than a single clause.

There is considerable diversity within the category of serial verbs among different languages and even within individual languages, with some kinds of serial verb constructions behaving in ways that more closely resemble verbal compounds, and others sharing features with subordinate or coordinate constructions.

Many verb-final languages have clause chains that are structurally midway between serial verbs and complex sentences. There may be extensive juxtaposition of verb phrases without any subordinating or coordinating markers, but with considerable contextual ellipsis of shared arguments. This means that we are dealing with a structural continuum as follows: verbal compounds > serial verbs > clause chains > subordinate clauses > coordinate clauses. It is probably wishful thinking to assume that we can produce a universally applicable definition of verb serialization: rather than a separate universal category, serialization is more accurately characterized as a syndrome of features and phenomena.

Sign Relationships

A signifier, or 'sign' for short, is any *x* that stands for or represents some *y*, that calls some *y* to mind (or is thought of as capable of so doing). For example, a south-pointing weathervane can be a 'sign' that the local wind is a southerly, if so interpreted by a well-disposed observer (Watt 1993:432). By the same token, the word 'unicorn' is a sign of, or signifies, a mythical equine creature with a single helical horn peculiarly susceptible to the importunities of virgins. In the latter case, 'signifies' can be replaced by 'means', but this is not always so. For instance, it would be odd to say that the letter 'A', which signifies the set of sounds comprising the phoneme /a/, 'means' those sounds. And whereas it is safe to say that the word 'thwirk', which has never existed till now, has no meaning at all in the ordinary way, it still signifies something (e.g. that its creator knows how to observe the rules of English phonology). Hence, 'signifies' is the more general term, since 'means' will sometimes seem misused when neither *y* ('a mythical equine. . .') nor *x* ('unicorn') is a linguistic expression.

All living things, from microbes to elephants, and including plants and humans, process signs of one sort or another, whether they be words and sentences or, for plants, the signals of chemicals and light (Sebeok 1989:12–24). Restricting our purview to humans, however, it is safe to say that every signification, every tying of some signified *y* to some signifier *x*, must at a minimum happen in the mind of a human recipient who perceives the *x* and ties a *y* to it. Some other human may have sent the *x* in the hope of its being properly interpreted; but many *x*'s are interpreted in such a way as to defeat any such hope. And many *x*'s are not sent at all, by anybody anywhere. Should a sender use the word 'livid', he or she is likely to find it misinterpreted as meaning 'furious'; when an earthquake is interpreted as signifying God's wrath, this is not owing to its having aimed at that result (or at any other). In sum, all that is necessary for an act of signification to take place is one mind's perceiving some *x*, whatever its source, and tying it to some *y*, however legitimately.

Language is the supreme signifier. Its morphemes, words, phrases, clauses, sentences, paragraphs, and whole discourses are almost entirely emitted in the hope of signifying, whether to ourselves or to others; and we listen and read in the wan hope of being informed. *Homo sapiens* is, above all, *homo signifex* (*homo* the sign-maker).

Signs of whatever sort are often bound into a set, a system, characterized by its members' widespread sharing of attributes. Many such attributes are unconsciously known to the signs' users, since often they can reliably judge whether or not a proposed new member of the set is sufficiently like the old ones (i.e. shares enough of their attributes) to win entry. Some such judgments are quite subtle. For instance, a speaker of English will accept 'thwill' as a possible (or unknown) English word, while rejecting 'thpill' (despite the currency of 'thpill' in the speech of lispers); users of the Romani English alphabet are more likely to accept '0' as a possible new letter than '0' (Jameson 1994). Besides being related to others within their set, signs are also related to what they signify. Thus, a sign may be physically associated with what it signifies, as the weathervane is to the wind that actuates it; or it may be perceived as being physically similar to what it signifies, as the word 'whinny' is to the sound made by a horse; or it may have neither of those ties, being purely arbitrary or conventional, as the word 'horse' is. Thus, in Charles S. Peirce's well-known terms, a sign can be, respectively, 'indexical', 'iconic', or 'symbolic' (Peirce 1935–1966:2.275). Many signs in their

actual occurrence, including words or morphemes, partake of two or even three of these qualities: the stick figure representing 'MAN', for instance, conveys 'Here's a men's room' only when it is on or near an expectably placed door, thus being indexical; it looks a little like a man, thus being also iconic; but it is still highly abstracted or conventional, thus being symbolic as well. And, turning now to words, since 'whinny' is but a poor imitation, it is also partly arbitrary, i.e. symbolic. Even the structure and superficial word order of sentences, although in large part arbitrary (which is why different languages can order things differently), can even then be said to be also somewhat iconic, as when, in English, the order of cardinal sentential elements seems to mirror a feeling that one is better understood when new or indefinite information is withheld till after a given or definite context has been established (Halliday 1967; Clark and Haviland 1977). (Thus, although ordinarily an active sentence is more felicitous than a passive one, this preference is reversed when the underlying subject is indefinite and the object is definite: the passive 'The General's been hit by an arrow' is likely to strike most speakers as more natural than the active 'An arrow's hit the General'.)

The signs habitually used by humans are also, naturally enough, related to their human users. The sounds of a natural language are those the human vocal tract can easily make and the human ear can distinguish, and the letters of the Romani English alphabet are those the human hand + pen (the 'scribal tract') can easily draw and the human eye can discriminate—an obvious point, but one not noted enough.

The signs of language differ but little, at the lower levels (phonemes; morphemes), from the signs of some other systems, either in complexity or even in sheer numbers. Morphemes and the cattle brands of the American West, for instance, have comparable morphologies. On the other hand, the signs of language at the higher levels (phrases, clauses, sentences, discourses) differ in kind from those of any other sign system known, both in their formal complexity and, of course, in their number, which is unbounded. However, despite their differences, all signs, of whatsoever kind, lend themselves to description in terms of how they are related to what they signify, to each other, and to those who send and receive their physical manifestations and interpret them.

WILLIAM C. WATT

Signed Languages

Signed languages are a class of languages in which speech is replaced by manual and facial gesture and auditory reception is replaced by vision. Natural signed languages have evolved within the boundaries of subcultures of deaf communities throughout the world. The term 'signed language' is often used more generally to include alternate sign languages, manual sign systems developed in certain hearing communities as alternatives to spoken language that serve social, religious, or occupational functions. The term is also used to describe manual language codes, sign systems invented by educators to represent spoken languages in manual gestures. The use of the term here will be restricted to those natural signed languages that evolved within deaf communities. A natural sign language is learned as a first language by children in the community, is not related to the spoken language of the broader culture, and possesses the complexity and types of structural features found in spoken languages.

The use of manual signs dates back at least to the early Greeks; Plato mentioned the use of signs by deaf individuals in the *Cratylus*. Signed languages are, however, a recent addition to the study of language and language structure. Serious study of signed

languages began only in the last half of the twentieth century. Prior to that time, signs used in deaf communities were believed to be rooted in a biological gestural system that was universal and, to a great extent, iconic; and signed communication was thought to lack the complexity of spoken languages. Two events occurred in the mid-1900s that changed the status of signed languages. The first systematic analysis of a signed language became available in 1960. In that year, William Stokoe published a monograph on American Sign Language (ASL). Stokoe demonstrated that the signs of ASL possessed an abstract sublexical structure analogous to the phonological structure of words in spoken languages. Five years later, he and two colleagues (Dorothy Casterline and Carl Croneberg) published the first dictionary of a signed language (ASL) based on linguistic principles. In this same time period, rapidly developing video and film technology provided an economical way to capture and preserve dynamic properties of signed languages for analysis. These two developments, video techniques to record basic language data and Stokoe's demonstration that signed languages were subject to the same analytical techniques as spoken languages, provided the basis for the linguistic study of signed languages throughout the world.

Distribution

Currently, at least preliminary descriptions exist for well over 100 signed languages, spanning the major geographical regions of Africa, Asia, Australasia, Europe, and North and South America. The names of these languages typically reflect the geographical area(s) where they are used (e.g. Kenyan Sign Language, Japanese Sign Language, Australian Sign Language or Auslan, Italian Sign Language, ASL, and Brazilian Sign Language, respectively). Many signed languages developed independently within the deaf communities of somewhat isolated regions. Providence Island Sign Language, for example, is the primary language of fewer than two dozen deaf people and a second language for some hearing people on Providence Island, Columbia, a small island off the coast of Nicaragua. Providence Island Sign Language developed independently of the spoken language (English and English Creole) of the island, although deaf residents had no exposure to other signed languages. Signed languages have also developed through processes of migration and cultural contact. With time, historical change produces distinctly different signed languages. For example, three distinct signed languages have been identified in Vietnam: Ho Chi Minh City Sign Language, Hanoi Sign Language, and Haiphong Sign Language. Available evidence of

partial intelligibility indicates that these three languages belong to the same language family.

In many cases, historical and social forces have influenced deaf communities differently from hearing communities in the same regions. Geographical boundaries sometimes follow those for spoken languages, but they often do not. ASL and British Sign Language are not mutually intelligible, for example, although English is the spoken language of both geographic regions. Instead, there are some similarities between ASL and French Sign Language (FSL) because modern ASL is derived from contact between one or more indigenous sign languages in the United States and FSL, brought to the United States in the early 1800s.

Circumstances promoting the emergence of a new signed language have recently provided linguists with the opportunity to examine first hand the forces driving the creation of a new language. The birth of Nicaraguan Sign Language has been extensively documented over the past 25 years. When the Sandinistas came into power in Nicaragua in 1979, formerly isolated deaf children from all parts of the country were brought together in a new residential school for deaf children. The children who arrived possessed only rudimentary idiosyncratic home sign systems. Home sign systems are created by deaf children who live in isolation and have little or no conventional language input. Upon arriving at the school, the Nicaraguan school children immediately began to use signs from their home sign systems with each other. The result was the development of a pidgin language between home sign systems. Exposure of the next generation of school children to the pidgin resulted in the development of a more complex signed language through a gradual process of creolization. The resulting language is the language now called Nicaraguan Sign Language.

Language Structure: Universals and Modality Effects

Abstractness is a defining quality of human language. The addition of signed languages to the inventory of world languages has raised the level of abstractness. Languages are no longer restricted to the vocal–auditory channel. Elimination of this one-time universal appears to have no effect on other proposed universals. Signed languages satisfy most proposed universals, and, where some do not, spoken language counterexamples have also been discovered. Signed languages allow complexity of expression equivalent to that of spoken languages with complexity of grammar that is equivalent to grammars of spoken languages. ASL, for example, shares features with spoken Navajo and Japanese. The form and complexity of grammatical properties in signed languages do not differ from those

of spoken languages, but the means by which those grammatical properties are implemented differ by modality.

Stokoe's analysis of the sublexical structure of ASL signs provided the first example of how a universal grammatical property can be implemented in the manual modality. Stokoe demonstrated that ASL signs could be described by three phonological categories of arbitrary components: 19 handshapes, 12 locations, and 24 movement patterns. Minimal pairs of signs are identical except for a change of one component from one phonological category. Orientation of the hand is also needed in some cases to discriminate certain minimal pairs of ASL signs. Components from the phonological categories were originally thought to occur simultaneously in sign formation. Later analyses, however, have demonstrated that signs, like spoken words, have linear segmental structure. Analyses indicate that sign languages throughout the world use similar components at the phonological level, but the specific inventory of handshapes, locations, and movements differs from language to language.

The use of the gestural–visual channel provides both advantages and constraints for the development of grammatical mechanisms in signed languages. The use of manual articulators results in gross motor movements that take more time to produce than the fine motor movements involved in speech. Time constraints on linear sequencing are complemented, however, by the availability of two articulators, the greater simultaneity of components in word formation in signed languages, the use of three-dimensional space, and the coordinated use of nonmanual and manual components. Some language processes based in the gestural–visual channel appear to be universal to signed languages, whereas others are language specific or are found in a subset of signed languages.

All signed languages analyzed to date possess complex systems for the creation of multimorphemic signs. In spoken languages, complex words are typically created by processes of concatenation. Complex word formation processes differ for signed languages in that simultaneous morphological components take the place of linear strings of affixes. Temporal aspect inflection is carried out through changes in the movement characteristics of sign stems in many signed languages, including ASL, British Sign Language, and Swedish Sign Language. Derivational processes creating nouns from verbs in ASL also involve changes in the movement patterns of the verb forms. In general, the linear affixation processes prominent in spoken languages are rare or nonexistent in signed languages. Instead, these examples of inflectional and derivational morphology involve the simultaneous occurrence of a base sign and morphological markings.

Classifier constructions are ubiquitous in signed languages. Classifier systems take advantage of the spatial medium to express types of motion through space and position in space, as well as stative-descriptive and handling information. Complex predicate classifier constructions are universal to all signed languages analyzed to date. They also exist in evolving languages like Nicaraguan Sign Language and in idiosyncratic home sign systems. In classifier predicates, handshapes that function as classifier morphemes combine with different types of movement morphemes to form complex predicates. Categories of handshape and movement morphemes found in both ASL and Danish Sign Language (taken from Emmorey 2002) illustrate the properties of signed language classifier systems.

Categories of handshape and movement morphemes for ASL and Danish Sign Language include the following:

Handshape Morphemes

Whole entity classifiers: refer to an object as a whole
Handling/instrument classifiers: represent a whole entity, but imply an agent handling the entity
Limb classifiers: represent limbs of animals and humans
Extension and surface classifiers: represent depth and width of an object or width of a surface

Movement Morphemes

Position morphemes: indicate 'to be located', posture, or a change in object orientation
Motion morphemes: indicate movement along a path
Manner morphemes: indicate manner (e.g. speed) of motion without specifying a path
Extension morphemes: depict the outline or configuration of an entity or mass

Each language imposes certain constraints on possible morpheme combinations. Whole entity classifiers combine with extension movement morphemes to indicate spatial arrangement of multiple objects. For example, the ASL handshape classifier for vehicles combined with the linear extension movement morpheme indicates 'cars in a row'. The instrument handshape classifier used to represent 'knife' could not, however, be substituted for the whole entity 'vehicle' classifier to indicate 'a row of knives'.

Signed languages, but not spoken languages, allow for certain types of simultaneous constructions. These constructions involve the use of the two hands to express two different predicates at the same time. In ASL, for example, a simultaneous construction can be used to express, 'The cat jumps on a shelf'. In this construction, the nondominant hand predicate indicates the background element, 'the shelf'. The handshape classifier for narrow surfaces (a flat hand) is combined with the 'hold' morpheme, a static movement morpheme

that indicates static motion or holds the motion of an entity in place for purposes of the construction. The dominant hand predicate combines a classifier handshape used for small animals with an 'arc' motion morpheme. The end of the arc motion makes contact with the nondominate hand, which is located above the level of the starting point of the arc motion.

Manual signs are normally expressed in a signing space that extends vertically from just below the waist to the top of the head and horizontally from just over the signer's shoulder outward a little more than a foot. Lines defined in this space are used to express different forms of temporal reference. The abstract concept of time is overlaid on these time lines. The use of time lines to convey temporal information is found in languages as diverse as ASL, Argentine Sign Language, Australian Sign Language, British Sign Language, Jordanian Sign Language, and the Sign Language of the Netherlands. At least two of these time lines may be universal to signed langauges. One of these time lines is related to immediate context. This time line extends from the top of the dominant shoulder outward, perpendicular to the body. The signer's body provides the reference point for 'the present', with the past behind the signer and the future in front. Temporal adverbs make use of this time line. For example, the sign for YESTERDAY moves backward from the side of the cheek, and TOMORROW moves forward. Adverbial modification of other signs is used to express the past or future. In ASL, for example, the signs for days of the week are made near the body. These signs can be modified to indicate the next occurrence of that day by changing the location of the sign to a point forward on the time line (e.g. MONDAY modified to represent NEXT-MONDAY). A second time line represents succession or duration of time. This time line extends horizontally, parallel to the front of the signer's body. Sign movement from left to right along this time line establishes temporal reference in discourse from early to late in many signed languages. The British Sign Language sign CONTINUE uses this kind of movement to express the persistence of an event or state over a long period of time. Jordanian Sign Language also makes use of the sequential time line, but time from early to late is expressed in right to left movement.

Another common, probably universal, mechanism found in signed languages is the use of spatial location to refer back to something that was previously mentioned and to indicate which nouns in the sentence are subject and object, respectively (agreement). In signed languages, personal pronouns take the form of pointing gestures. Pointing has been co-opted from the gestural realm to form the basis for linguistic pronominal systems in signed languages. Points in signed languages are categorized into handshape, location, and movement components that are individually used to convey different grammatical distinctions that may include person, number, and case. Pointing is used to refer to entities, whether present or not. When the referent is present, the signer points to the actual position of the referent. When the referent is absent, the signer establishes a spatial location for the referent and points toward that spatial location. Signed languages have conventionalized ways of assigning spatial locations for different types of referents.

All signed languages examined to date use modifications of the verb to mark grammatical agreement with subject and object for some classes of verbs. Agreement is marked through modification of the sign's hand orientation and location and direction of the movement. The movement of these verbs is directed from the spatial location marking the subject toward the spatial location marking the object. In Italian Sign Language, for example, the sign for TEACH is composed of an initial handshape that is closed such that the fingertips touch the tip of the thumb. The hand opens to a flat handshape with the fingers spreading as the movement of the sign is produced. In the sentence 'I teach you,' the movement of the sign begins near the signer's dominant shoulder and moves outward toward the spatial location of the addressee. The front/palm of the hand faces the addressee throughout the production of the sign. The location, movement, and hand orientation of the sign TEACH are modified to mark subject and object agreement in the sentence, 'Elena teaches Louis.' If the spatial position marking Elena is to the signer's right and the spatial position marking Louis is to the left, the movement of the verb TEACH is from right to left, beginning at the spatial location marking the subject, Elena, and moving toward the spatial position marking the object, Louis. The hand is oriented toward the spatial location marking Louis as the handshape changes from closed to open.

In addition to the manual channel, signed languages make use of a second, nonmanual, channel to convey grammatical information. Facial expression and changes in head and body position are used to provide distinct linguistic contrasts simultaneously with the production of manual signs. Nonmanual markers are used grammatically to distinguish similar structures across signed languages. These structures include negation, Wh- questions, Yes–No questions, conditionals, relative clauses, and rhetorical questions. In general, the duration of the nonmanual marker indicates to which part of the sentence it applies. The nonmanual component used to mark negation, for example, typically includes a specific facial expression with accompanying head movement. The grammatical facial expression is maintained for the entire duration that it takes to produce the phrase being

negated. Nonmanual components appear to be similar in both form and function across signed languages.

Neural Systems for Language

In the same way that the form of language is not dependent on language modality, the neural systems underlying language processing are not dependent on language modality. Brain-damaged signers display similar types of error patterns as brain-damaged speakers. Language is typically processed in the left hemisphere for both signed and spoken language and specific types of language disorders are localized in the same neuroanatomical structures of the left hemisphere. Classic patterns of Broca's and Wernicke's aphasia have been described for deaf signers. Prosodic disturbances and reduced, 'telegraphic' syntactic constructions are associated with damage to Broca's area of the left hemisphere for both spoken and signed language. Errors in word or phoneme choice and the production of jargon (grammatically correct but unintelligible sentences) are associated with left hemisphere damage in Wernicke's area for both spoken and signed language. Wernicke's area is also involved in language reception. Specific sites in Wernicke's area have been associated with the processing of phonetic–syllabic units, independent of language modality. The left hemisphere appears to be specialized for language, independent of modality. The abstract, modality-independent nature of language, both in language form and in functional neuroanatomy, has rekindled debate about the origin of language.

PATRICIA SIPLE

Sindhi

Sindhi is a language that originated in the Lower Indus Valley region of the Indian subcontinent, spoken by over 40 million people in present-day Pakistan and India and by a large diaspora community around the world. Sindhi belongs to the Indo-Aryan language family within Indo-European, and is classed with Kashmiri in the Northwestern subgroup. Sindhi is the primary language of the province of Sindh in Pakistan, and is spoken along the Indus River Valley stretching into the Thar Desert to the east, and bounded by the Sukkur Dam to the north, the Kirthar Mountain Range to the west, and the Arabian Sea to the southwest. To the south, the Sindhi region extends into the Rann of Kacch in India. While Sindhi is used exclusively or as the primary language in most rural areas within this region, it exists alongside Urdu and English in the urban centers of Sindh Province, including Karachi and Hyderabad, and alongside Hindi, Gujarati, and other regional languages in India. Sindhi is closely related to Siraiki, spoken in the north of Sindh Province, and to Kachhi, spoken to the south in the Kacch region of Gujarat in India.

Background

Sindhi shares many features in common with related Indo-Aryan languages. The sound inventory includes the distinctive voiced and voiceless aspirated obstruents at five places of articulation (labial, dental-alveolar, postalveolar, palato-alveolar, and velar), and a full set of paired long and short vowels, all of which can occur with nasalization. Common features in the morphology include number, gender, and case marking for nouns, a rich system of verb inflection, and a productive

process of compound verb formation. The basic syntactic structures of Sindhi are also common to Indo-Aryan, including a canonical Subject–Object–Verb (SOV) word order that is subject to permutation (i.e. so-called free word order), question formation with no preposing of question words (i.e. question words in situ), and dependent clauses involving the parallel relative–corelative construction.

Sindhi also has several features that differentiate it from other Indo-Aryan languages. Its consonant inventory includes four implosive stops, unique to Sindhi (and its close relatives such as Kacchi and Siraiki) among all Indo-European languages. Sindhi has retained from Sanskrit the full set of five phonemic nasal stops, but reduces all historical geminate consonants -CC- in the word-medial position to a singleton consonant -C-. Although the vowel inventory in Sindhi is common to Indo-Aryan, the status of the word-final short vowels is remarkable. Final short /i,u,a/ express grammatical information such as number, gender, and case on nouns, and yet they are produced with extremely short phonetic duration. These final vowels are typically not recognized by nonnative speakers, despite their important morpho-syntactic function, and are not retained in Sindhi words (e.g. proper names) that are adopted into Urdu, Hindi, or English. Although syllable structure in Sindhi is similar to other Indo-Aryan languages, Sindhi does not allow word-final consonants. Indeed, many Sindhi words that end in a final super-short vowel have cognate forms in related languages that end in a consonant. With respect to morphology, Sindhi differs from most Indo-Aryan languages in its use of pronominal clitics that attach to nouns, postpositions, and verbs. These clitics take the place of full noun phrases to express e.g. the possessor of a noun (*hatʰa-mi* 'my hands'), the complement of a postposition (*vəʈi-mi* 'belonging to me'), and with different clitic sets, the subject, object, or other complement of a verb (*ɓudʰaːrjãː-va* 'I shall tell you').

Linguistic studies of Sindhi are few in number, but include instrumental phonetic studies (Nihalani 1986, 1995), sociolinguistic and dialect studies (Rohra 1971, Bhugio 2001), and contemporary grammatical analysis (Khubchandani 1961). Published Sindhi grammars include Trumpp (1872), Grierson (1919), and Yegorova (1971).

Key Structural Features

Sound Inventory
The Sindhi sound inventory is shown below, and is notable for its inclusion of four implosive stops, which derive from Middle Indo-Aryan geminate voiced stops in medial position, and from singleton voiced stops in the initial position. Phonetic studies show that these

sounds are genuine glottalic ingressives (Nihalani 1986). The postalveolar consonants are apical and the palato-alveolar consonants are laminal; these are termed retroflex and palatal in traditional nomenclature. Sounds that are shown in parentheses in the chart below are either restricted to borrowings (/z, ʃ, x, ɣ/) or occur only as allophonic variants. For instance, the postalveolar rhotic tap [ɽ] is in complementary distribution with the homorganic stop [ɖ]. The aspirated sonorants /mʰ, nʰ, ŋʰ, lʰ ɽʰ,ʋʰ/ occur only in intervocalic position and are never distinguished from a sequence of sonorant + /h/, although speakers will describe them as single sounds, even though they are written as sequences in the Arabic orthography. The vowel inventory consists of the standard symmetrical Indo-Aryan system, comprising five pairs of long and short vowels. Phonetic values shown below are as identified by Nihalani (1995). In addition, all the vowels can occur with nasalization; the long nasal vowels have phonemic status, but nasalization on short vowels can be ascribed to the context of a following tautosyllabic nasal stop (see Table 1).

Morphophonology
Sindhi has a complex system of morphophonological vowel alternations that affect stem-final vowels in certain morphological constructions. These changes are highly idiosyncratic to the specific construction. For example, nouns are marked for plural number by modification of the stem-final thematic vowel alone or in combination with a plural suffix, resulting in plural endings marked variously by /-a, -aː, -ũː, -iũː/, or unmarked, depending on the gender class of the noun and on its lexically determined stem-final thematic vowel: *gʰar-a* 'houses', *pʰiːt-aː* 'wheels', *kʰaʈ-ũː* 'cots', *ɓili- ũ ː* 'cats', *raːti* 'nights'.

There are also very many verb stems that undergo irregular allomorphy in the formation of the Unspecified Perfective (i.e. simple past) tense. A comprehensive discussion of these alternations is provided in Trumpp (1872) and Grierson (1919).

Morphology

Nouns, Adjectives, and Pronouns
Nouns are classed by grammatical gender, and this classification determines the declension pattern for the marking of number and case, expressed primarily through stem vowel alternations. The noun stem ends in a thematic vowel, which for most nouns serves to mark the gender class, although there are numerous exceptional stems whose gender is not predictable on the basis of the final vowel. All nouns are marked for number and case through noun stem modification,

TABLE 1 Sindhi Consonant Inventory

	Labial	Dental	Alveolar	Post alveolar	Palatoalveolar	Velar	Glottal
Stop	p b	t d		ʈ ɖ		k g	
	pʰ bʰ	tʰ dʰ		ʈʰ ɖʰ		kʰ gʰ	
Implosive	ɓ		ɗ		ʄ	ɠ	
Affricate					tʃ tʃʰ		
					dʒ dʒʰ		
Nasal	m		n	ɳ	ɲ	ŋ	
	(mʰ)		(nʰ)	(ɳʰ)			
Fricative	f		s (z)		(ʃ)	(x ɣ)	h
Rhotic			r	(ɽ)			
				ɽʰ

	(ʋʰ)						

Sindhi Vowel Inventory

iː	[i]	eː	[e]	aː	[ɑ]	oː	[o]	uː	[u]
i	[ɪ]	e	[ɛ]	a	[ə]	o	[ɔ]	u	[ʊ]

involving a change in the thematic vowel, sometimes accompanied by suffixation. Patterns of noun stem modification that mark the plural and the nominative, oblique, ablative and vocative cases are illustrated in the example noun paradigms as shown in Table 2 for distinct thematic vowels, grouped by gender class.

The dative, ablative, comitative, and locative cases are marked through the use of a postposition following the noun in the oblique singular form. The genitive postposition has eight variants (of which only two are shown below); it is declined like an adjective and agrees in number and gender with the possessed noun, but bears the case specification of the possessor. There is no accusative postposition, and instead the nominative or dative form is used (depending on the animacy of subject and object). Also, the oblique case forms are used to mark ergative subjects (see Syntax section below).

Case/number marking with postpositions in example phrases with *gʰar-* 'house'

Dative	gʰara kʰeː	*'the house (direct object)'*
Ablative	gʰara kʰã̄ː	*'from (the direction of) the house'*
	gʰara mã̄ː	*'from in the house'*
	gʰara tã̄ː	*'from on the house'*
Comitative	gʰara sã̄ː	*'with the house'*
Locative	gʰara mẽ̄ː	*'in the house'*
	gʰara teː	*'at/on the house'*
	gʰara maɲdʒʰi	*'within the house'*

Genitive		
(masc.)	gʰara joː (daru)	*'(door) of the house'*
	house-masc.,sg.,Obl.|Gen-masc.,sg.,Nom.|door-masc.,sg.,Nom.	
(fem.)	gʰara jiː (dariː)	*'(window) of the house'*
	house-masc.,sg.,Obl.|Gen-fem.,sg.,Nom.|window-fem.,sg.,Nom.	

Adjectives agree with the noun they modify in gender, number, and case, marked through the same kind of alternation of the thematic (final) vowel: *nanɖʰoː gʰaru* 'small house, Nom.' *nanɖʰaː gʰara* 'small houses, Nom.', *nandʰiː meza* 'small table, Nom.', *nandʰiyũː mezĩ̃* 'small tables, Nom.'. Pronouns are marked for number, but case is marked only for nominative and oblique (no ablative or vocative pronoun forms). Gender is distinguished only in the nominative, third-person singular forms. The third-person pronouns are also used for demonstratives, for which there are distinct proximal and distal forms: *hiːu* 'this, masc.', *hu* 'that, masc.', *hiːa* 'this, fem.', *hua* 'that, fem.' The personal pronouns shown in Table 3, including dialectal variants, and similar patterns of declension occur with the distinct relative and correlative pronouns (*joː* relative 'who/that-masc.,sg.,Nom.'; *soː* co-relative 'who/that-masc., sg., Nom.'), and the indefinite pronouns (*koː* indefinite 'anyone/someone-masc.,sg.,Nom.'). Of the interrogative pronouns, only 'who' is marked for number and case (e.g. *keru* 'masc.,sg.,Nom.', *kã̄hĩ* 'masc./fem.,sg.Obl.').

Verbs

The verb complex in Sindhi consists of a primary verb, alone or followed by an auxiliary verb. An operator or modal verb element may also occur, placed in between the primary verb (in participle form) and the auxiliary verb. These parts combine in various ways to produce 17 distinct finite verb forms that encode aspect (perfective, imperfective, unspecified), tense (past, present, future), mood (subjunctive, imperative, presumptive, counterfactual), and concordance (gender and number). Aspect is expressed in the choice of the primary verb form, and is marked by suffixation to the verb stem. In most finite verb forms, tense, mood, and concordance features are expressed on the auxiliary verb, through suffixation or auxiliary verb stem allomorphy. There are also six nonfinite verb forms that function as nominal, adjectival, and adverbial participles. Examples of finite and nonfinite verb forms are shown in Table 4. Each finite and nonfinite verb form can undergo further modification, not shown here, to express voice (active/passive) and valence (transitive/causative) distinctions through the use of suffixes that attach directly to the verb stem.

Syntax

The neutral word order in Sindhi is Subject–Object–Verb, although these elements can be permuted in any order, in which case the first element is typically the Topic. Within phrases, word order is fixed, with the head element always at the end. Thus, the determiner and adjective precede the head noun in a noun phrase: *hi:a suhiɳi: tʃo:kiri:* this|beautiful|girl 'this beautiful girl', *asã:ja: ɓa ɓakra:* our|two|goats 'our two goats'. Similarly, the verb appears at the end of the verb phrase, following any (nonsentential) arguments: *ama:-kʰe tʃiʈʰi: likʰi:* mother-to|letter|wrote 'wrote a letter to mother'.

The subject of the sentence appears in the nominative case with two exceptions: "experiencer" subjects of verbs expressing physical sensation, psychological state or kinship are in the dative case, and the ergative subject of a transitive verb in the perfective aspect is in the oblique case. The verb agrees with the subject if it is nominative, and otherwise agrees with a nominative (inanimate) object if present. If there is no nominative subject or object, the verb takes as default the third person, masculine, singular agreement. An indirect object appears with the dative postposition. There is

TABLE 4 Examples of Finite Verb Forms with the Verb Stem *hal-* 'to go'

Contingent future	hale:	'if he goes'
Present unspecified	hale: tʰo:	'he goes'
Contrafactual unspecified	hale: ha:	'had he gone'
Definite future	halando:	'he will go'
Present habitual	halando: a:he:	'he goes'
Past habitual	halando: huyo:	'he used to go'
Presumptive imperfective	halando: hundo:	'he is probably going'
Subjunctive imperfective	halando: huje:	'(perhaps) he goes'
Present continuous	hali: rahyo: a:he:	'he is going'
Past continuous	hali: rahyo: huyo:	'he was going'
Unspecified perfective	halyo:	'he went'
Present perfective	halyo: a:he:	'he has gone'
Past perfective	halyo: huyo:	'he had gone'
Presumptive perfective	halyo: hundo:	'he must have gone'
Subjunctive perfective	halyo: huje:	'he may have gone'
Past iterative	halyo: the:	'he would go', 'he often went', 'he used to go'
Imperative	halu	'Go!' (informal)
	halo:, halije:	'Go!' (polite)

Examples of Nonfinite Verb Forms with Various Stems

Infinitive	halaɳu	'to go'
	ɖa:iɳu	'to sing'
Adjectival unspecified (masc.,sg.)	ma:riɳo:	'about to be struck'
	waʈʰiɳo:	'about to be taken'
Adjectival imperfective (masc.,sg.)	halando:	'going'
	ma:ri:ndo:	'striking'
Adjectival perfective (masc.,sg.)	halyalu, halyo:	'went'
	ma:ryalu, ma:ryo	'struck'
Adverbial imperfective	halande:	'(as he was) going'
	ma:ri:nde:	'(as he was) striking'
Adverbial perfective	hali:, hali: kare:	'(as he) went'
	ma:re:, ma:re: kare:	'(as he) struck'

no distinct accusative case; a direct object appears with the dative postposition for animate objects, and is in the nominative case for inanimate objects.

Examples of verb agreement with nominative case subjects

hu:a hale: tʰi:

'They (masc.) have read the letter (fem.).'

tavahã: kʰe: hunani sã: ʋaɲaɳo pavando
you,pl.masc.,Obl.| Dat.| them,pl.,Obl.| with| go,Inf.,Obl.| must,**3sg,masc**.
'You (pl.) must go with them.'

Historical Development and Sociopolitical Factors

Sindh is home to the ancient Indus Valley civilization of Mohen-jo-daro, but a historical link between Sindhi and the language of Mohen-jo-daro has not yet been firmly established. Sindh has been subject to foreign rule at many times in its history, and there is evidence of language contact in numerous borrowings from Persian, Arabic, and English. The formation of Pakistan in 1947 had a tremendous impact on Sindhi, as millions of mostly Urdu-speaking immigrants came to Sindh from India. The immigrants were under no pressure to learn Sindhi, and enjoyed the advantage of speaking Urdu, the language chosen as the national language of Pakistan. On the other hand, Sindhi speakers, especially those in urban areas, were compelled to learn Urdu and, in recent years, English. Bughio's (2001) sociolinguistic study reports census data that paint a bleak picture of the diminishing status of Sindhi. Census data from 1941 show that 82% of the Sindh population claimed Sindhi as their mother tongue, while in 1981 this number fell to 52%. Sindh has a large rural population, with 57% of the total population, and in rural areas Sindhi is the mother tongue for 78% of the population, compared to only 18% in

urban areas. The rural and urban populations of Sindh also differ in literacy, with 51% literacy rates in urban areas compared to only 16% in rural areas of which females constitute only 5%. The decline in Sindhi literacy has implications for the survival of the rich body of Sindhi literature, dating from the sixteenth century (Ajwani 1970).

Sino-Tibetan Languages

The Sino-Tibetan languages are spoken by (a) approximately 1.2 billion speakers of Chinese and (b) over 30 million speakers of Tibeto-Burman. The language family extends over a vast linguistic area stretching some 3,500 miles across much of eastern Asia, the Tibetan plateau, and southeast Asia — north- and eastward from the northeastern corner of China along the eastern coasts, southward along the Irrawaddy and Salween Rivers to the Bay of Bengal, and westward along the Himalayas, extending further down to Nepal and India. Besides, Chinese is spoken by several million overseas Chinese in communities across the world. Sino-Tibetan languages comprise the world's second largest language family after Indo-European. As the preceding figures show, Chinese (Sinitic) accounts for most of the family's total speakers.

Despite recent progress, opinions are still sharply divided as to the membership of Sino-Tibetan. Many Chinese scholars hold that Hmong-Mien (previously called Miao-Yao) and Tai-Kadai families should be included, a quarto-partite scheme proposed by Fang-Kuei Li (1973 [1937]). This hypothesis is generally out of favor with other Sino-Tibetanists, who, influenced by Paul Benedict, believe that the large-scale resemblances of structure and vocabulary among the languages in question are due to diffusion rather than genetic inheritance. Some linguists connect Sino-Tibetan with Austronesian, e.g. August Conrady (1916), Laurent Sagart (1993). Others link Sino-Tibetan with Yeniseian and North Caucasus languages in Northern Siberia, e.g. Sergei Starostin (1984). These speculations seem to be based on incomplete or inappropriate evidence, which cannot be substantiated at the present state of knowledge.

The internal composition of Sino-Tibetan, as narrowly defined, appears to be less problematic, despite lack of general consensus. The two major divisions of Sino-Tibetan — Chinese and Tibeto-Burman — can be divided into seven subgroups each. Figure 1 illustrates the genetic schema.

The exact number of Tibeto-Burman languages or dialects is not known, partly because access to some of them by scholars from outside is difficult, and partly because the names and designations of a number of languages are quite confusing. Thus, some languages listed under different names may turn out to be the same language, while others that are lumped together under one name may in fact be different languages altogether. Besides, a number of languages share the same name with non-Tibeto-Burman languages. For example, the Nung language of Tibeto-Burman must be distinguished from the Nung language of the Tai-Kadai family in Guangxi and North Vietnam. Similarly, the Kiao/Kiu language of Tibeto-Burman in China is not the same as that of the Dravidian language in India. Ethnologue lists some 300 languages, a significant number of which are found across national boundaries. Many still await description. A list of Tibeto-Burman languages and dialects with subgroup affiliation is given in James Matisoff (2003:695–704).
Figure 1. Proposed Sino-Tibetan family tree.

In terms of diversity, India has the largest number of languages listed (137), followed by Myanmar (around 80) and China (around 60). Of these, several languages number over a million (Burmese, some 25,000,000; Tibetan, Yi [previously called Lolo], Kham, Tujia, each with over a million). A small number of languages have probably less than a hundred speakers or semispeakers (Xiandao or Samtao, Lui, Samei).

Sinitic languages appear to be more homogeneous in mutual intelligibility than their Tibeto-Burman counterparts. This is partly because they use a common writing system as a lingua franca. Also, it is customary to talk about Chinese as having seven main dialect groups (q.v.), each with several subdialects, but the actual number of languages or dialects could be much higher. One might even count them in the hundreds, as mutual intelligibility can be low (e.g. Mandarin vs. Cantonese; Wu vs. Kejia) and they are quite diversified. Indeed, dialect differences can be so drastic that, in some cases, varieties could reasonably be considered distantly related languages. This diversity probably speaks for dual (Altaic and Austronesian) or even multiple origin of the Chinese language, as suggested by a number of scholars in the field.

Several writing systems are used for Sino-Tibetan languages. Separate traditions characterize Chinese, Tibetan, and Burmese. The Chinese writing system goes back at least 3,000 years. It contains pictographic elements that are preserved in the oracle and animal bone inscriptions and in bronze inscriptions. The Tibetan writing system was derived from the seventh-century Gupta script in a form representing the northwestern variety of the ancient Nam and Zhang-zhung languages. The Burmese writing system dates back to at least the eleventh century. It was based on Old Mon and Pyu, an extinct Sino-Tibetan language found to have existed in Burma since AD 500. The Tomba script of Naxi (Moso) was developed around the twelfth–thirteenth century; this pictographic script was used mainly for religious purposes. Xixia (His-Hsia or Tangut), a Tibeto-Burman language developed in the eleventh to thirteenth century in northwestern China, now extinct, was based on the Chinese model.

The assumed ancestral language Proto-Sino-Tibetan is thought to have split some 6,000 – 7,000 years ago, with the homeland being somewhere on the Himalayan plateau. Proto-Tibeto-Burman is estimated to have a time depth of around 6,000 years (Matisoff 1991). After their split with Tibeto-Burman, Han Chinese at first flourished in the Middle Kingdom (roughly present Shaanxi, Henan, Hebei, Shandong and vicinities) before they established a strong presence south of the Yangtze River around the beginning of the current era (221 BC) (Chang 1999). In the course of intermingling with the coterritorial non-Chinese populations, Chinese speakers have absorbed elements of material cultures and vocabulary from their neighbors. An example is the Yue and Min dialects in south China which possess features that are found to have been borrowed from Kam-Tai, indicating intense contact with the latter. In religion and philosophy, the influence of Indian culture is prevalent, particularly in Tibeto-Burman.

The Sino-Tibetan languages share a set of typological features. The vast majority of lexical roots in Sino-Tibetan languages are monosyllabic. Most Sino-Tibetan languages use intonational pitch (tone) to distinguish word meanings, with the exception of the Bodo-Garo languages of Assam in India and a few Tibetan dialects such as Purik and Ambo, which lack tones. The overwhelming majority of Sino-Tibetan languages possess noun classifiers. Derivational and morphological affixes can be shown to have existed at one time in Sino-Tibetan, for which reconstructions have been proposed at the Proto-Sino-Tibetan level: *s-* (causative), *-s* (nominalizing), *-t* (transitivizing). Morphological processes are characteristically represented in initial consonant alternation and vowel alternation to produce 'word families', that is, variant forms that are partially related to each other phonologically and semantically, comparable to 'doublets' in Indo-European.

However, the Sino-Tibetan languages are quite different in word order. Sinitic languages have the S(ubject)–V(erb)–O(bject) and modifier–modified word order, Tibeto-Burman are basically SOV and

modified–modifier, except for the Karenic languages of Burma and Thailand, the Bai language of Yunnan and Tujia of Hunan and Hubei, which have the SVO order like Chinese.

The idea of Sino-Tibetan as a language family is based on the assumption that Sino-Tibetan languages are all related and are derived from a common source. Since the late nineteenth century, particularly the early twentieth century, scholars have made various attempts to verify the Sino-Tibetan hypothesis. This typically involves searching for cognates (words derived from the same historical source) by comparing reconstructed forms between Chinese and Written Tibetan. Among the important successes were Robert Shafer's multivolume *Introduction to Sino-Tibetan* (1966–1974), as well as Benedict's (1972) *Sino-Tibetan: A conspectus*, where a sizeable number of basic words are shown to be related, such as the following:

English	Chinese	Tibetan
sun	*njit*	*nyi-ma*
moon	*nguat*	*s-ng^w(y)at*
eye	*myak*	*mig*
fire	*h^{w}ər*	*me*
fish	*ngjag*	*nya*
I	*ngag*	*nga*

Subsequent efforts include Coblin (1986), where some 500 cognate sets are proposed. Austin Hale (1982) offers a critique of the research situation up to the early 1980s. A state-of-the-art survey is provided in Thurgood and LaPolla (2003).

On the Chinese front, the great Swedish sinologist Bernhard Karlgren conducted systematic studies of Chinese dialects and the phonetic series from historical and philological sources. He also considered Chinese loanwords in neighboring languages such as Japanese. On the basis of this combined evidence, he was able to propose several thousand reconstructed forms for Old Chinese. These serve as the basis for subsequent enquiries. Further work along these lines has helped to refine the reconstructions (William Baxter 1992). Although much remains to be done, a basic phonological system of Proto Chinese can be established on the basis of the available materials.

Similar achievements characterize Tibeto-Burman studies. The 1980s and the early 1990s witnessed an influx of new data, with detailed descriptions of a significant number of individual languages. Particularly worth noting are two major comparative dictionaries by Chinese researchers (Sun et al [eds.] 1991; Dai, Huang et al. [eds.] 1992), which contain valuable information on some 50 Tibeto-Burman languages in China. Bradley (1997) reports on research in Tibeto-Burman languages of the Himalaya region. In America, a large

research collaboration, the Sino-Tibetan Etymological Dictionary and Thesaurus (STEDT) Project, was initiated in Berkeley in 1987 under the directorship of James Matisoff, culminating in an 800-page monograph, *Handbook of Proto Tibeto-Burman* (Matisoff 2003). This impressive volume contains several hundred cognate sets for Tibeto-Burman. It offers many insightful observations and discussions of morphological and derivational processes, which firmly establish Tibeto-Burman as a major branch of Sino-Tibetan in its own right. However, due to insufficient data, the handbook is able to provide only partial reconstructions of Proto-Tibeto-Burman forms. Problems involving reconstructed tones for Tibeto-Burman have yet to be resolved. A number of proposed protoforms still cannot be verified due to incomplete data. Several etyma are set up provisionally without having established step-by-step sound correspondences in advance. These inefficiencies can only be overcome when solid work on the reconstructions of individual subgroups is carried out. In addition, the issue of loan contact is becoming more acute as it is often exceedingly difficult to separate early loans from inherited cognates. The position of Tujia and Bai within Tibeto-Burman needs to be further examined.

Sino-Tibetan represents one of the oldest and most diverse civilizations and cultures in the world. Although remarkable progress has been made, the field is still in its infancy. Thus, most proposals for external affiliations and internal subgroupings must be considered working hypotheses rather than firm conclusions. Deeper investigations, in collaboration with allied fields of archeology, history, anthropology, and human genetics, will allow verification of these hypotheses, and will enhance our understanding of the complexities of cultural history in this region.

YONGXIAN LUO

Slobin, Dan Isaac

Dan Isaac Slobin is a prolific data-gatherer and avid investigator of child language acquisition. Growing up in the polyglot, immigrant world of Russian Jewish immigrants in the US Midwest, and hearing English, Yiddish, Russian, and Hebrew around him, Dan learned the languages, music, and literature of these cultures. With a father who was a high school teacher of history who loved to travel, Dan and his family lived in Europe and traveled all over the United States and Mexico. As a result, Dan Slobin became hooked on language, languages, and cultures. Philosophically, he was fascinated by the question of how a child becomes a member of a culture, focusing especially on problems of unconscious learning, underlying structure, and mental organization. When he was entering academia in the early 1960s, language was the most obvious and accessible domain in which to look for underlying patterns and their development from a psychological point of view.

Being at the right place and in the right time to take part in the emergence of cognitive science from the world of behaviorism, Dan Slobin's research career has attempted to synthesize the perspectives and insights of the diverse teachers and colleagues from whom he learnt at Harvard and MIT: George Miller, Jerome Bruner, Roger Brown, Eric Lenneberg, Noam Chomsky, and Roman Jakobson.

Dan Slobin was a graduate student at Harvard (1960–1963) when the cognitive revolution was in its infancy. Under the influence of the first phase of Chomsky's transformational grammar, Dan's dissertation, *Grammatical transformations in childhood and adulthood* (Harvard University, 1963), used reaction time to study syntactic processing in both adults and children. His dissertation, in which he found an interaction between semantics and syntax, was one of the first counterthrusts to purely syntactic processing. The dissertation was also significant as it incorporated the diverse interests of his three mentors: George Miller (experimental psychology), Jerome Bruner (cognitive psychology), and Roger Brown (child language development). Under George Miller, Dan Slobin looked for influences of grammatical transformations of reaction time. From Jerome Bruner, Dan considered whether people would pay attention to meaning, as well as form. Additionally, under the influence of Roger Brown, he added a developmental dimension to his dissertation project by including children as well as adults. This early interdisciplinary perspective would set the tone for his research career.

After leaving Harvard with a Ph.D. in Social Relations, Dan Slobin took his first job in the Psychology Department at the University of California at Berkeley, where he has remained throughout his illustrious career. At Berkeley, he was influenced by a group of colleagues who added social, interpersonal, and cultural dimensions to his work, which has grown to include crosslinguistic, cognitive, sociolinguistic, and psycholinguistic perspectives. In California, he worked with Susan Ervin-Tripp, John Gumperz, John Searle, Irving Goffman, Dell Hymes, and Charles Ferguson.

Dan Slobin is credited with focusing the field on the importance of addressing crosslinguistic data when exploring universals in child language acquisition by proposing that different types of languages pose different types of acquisition problems. His research over the past 35 years has been especially concerned with processes of language acquisition and their relations to cognition and thinking on the one hand, and to culture and communication on the other. Throughout his career, Dan has used a crosslinguistic research design in an attempt to identify universal developmental patterns, and has formulated a general model of 'operating principles' for the development of grammar. His multivolume *Crosslinguistic study of language acquisition* summarizes this work and provides a comprehensive contribution to the field of child language acquisition.

Since the late1990s, Dan Slobin has focused on the effect of different languages on psycholinguistic processes, including development and adult behavior, in order to account for specific semantic notions that are encoded in the morphology and syntax of the world's languages (e.g. the origins of grammar). Slobin's most recent work is on early child language development — in the age range from one and a half to five — in a crosslinguistic framework. His interest is in developing relations between language and thought, looking for universal and language-specific patterns. The current focus in the Child Language Research Laboratory is deaf children's acquisition of sign language as a first language, observing a American Sign Language and Sign Language of the Netherlands (SLN), comparing families in which parents are deaf and use a native sign language with the children, and families in which parents are hearing, and are acquiring sign language as a second language.

Thus, in his most recent work, Dan Slobin is again attempting to synthesize research from historical language change and grammaticization, linguistic typology, and universals, pidgin and creole linguistics, sign language, and the study of various discourse forms, especially narrative (both oral and written). This research incorporates experimental and naturalistic methods, as well as computer-aided text analysis.

Biography

Dan Isaac Slobin was born in Detroit, Michigan on May 7, 1939. He received his B.A. in psychology (1960) from the University of Michigan, Phi Beta Kappa, M.A. (1962), and Ph.D. (1964) (Harvard University) for his dissertation on grammatical transformations in childhood and adulthood. He was mentored by George Miller, Jerome Bruner, and Roger Brown. He has held positions in the Department of Psychology at the University of California (Berkeley) since 1964 (Professor since 1972), and also Research Psychologist, Institute of Cognitive Studies and Institute of Human Development. His other positions include: Visiting Professor, Stanford University (1998–1999); Visiting Professor, Summer Linguistics Institute, University of Goettingen, Germany (1992); Visiting Professor, University of Santiago de Compostela, Spain (1989); and Visiting Professor, Summer Linguistics Institute of the Linguistic Society of America, University of New Mexico, Albuquerque (1980, 1995). His research positions include: Institute of Human Development, University of California at Berkeley (1988); Institute of Cognitive Studies, University of California at Berkeley (1964): Visiting Scholar, Laboratoire de Psychologie, CNRS, Paris, France 1964–1985; Visiting Scholar, Max-Planck-Institute for Psycholinguistics, Nijmegen, The Netherlands (1981, 1984–1985, 1992–1999); Visiting Scholar, Department of Linguistics, Tel-Aviv University, Israel (1983–1985); and Visiting Scholar, Department of Psychology, Bogazici University, Istanbul, Turkey (1969–1970, 1972–1973). He has held numerous administrative and editorial positions, and has received awards and grants including the Harvard Foundation for Advanced Study Prize Fellowship (1960–1961); Guggenheim Fellow (1984–1985); and The New York Academy of Sciences Award in the Behavioral Sciences. He has also been a recipient of grants from The Ford Foundation, The W.T. Grant Foundation, National Science Foundation, National Institutes of Mental Health, American Council of Learned Societies, Social Science Research Council, The Sloan Foundation, Israel–United States Binational Science Foundation, Institute of Turkish Studies, American Psychological Association, International Research and Exchange Board (IREX), and the Mellon Foundation.

Sociolect

Sociolinguistics deals with linguistic behavior in society and is especially concerned with the language situation in such social institutions as political parties, governmental administration, and other nationwide institutions. Sociolinguistics is also interested in language situations in small groups, families, and all other types of social organizations, addressing the distribution of language varieties in such institutions. It is the scientific study of language as it varies with social differentiation.

The distribution of languages (and dialects) in a society is normally described in terms of the age, sex, education, occupations, and ethnic membership of the speakers who make up the society. Links among various aspects of the sociolinguistic situation derive from sociological constructs that underlie the social group or social institution and serve as the context for the stable arrangement of the various factors in language environments. They are thought to provide an individual with the orientation needed for acceptable social behavior in any particular context.

Language use can be studied in the home, the school, the church, the government, and so on. Its behavioral characteristics are then described and analyzed. Forms of linguistic behavior that depend on social factors are called 'sociolects'. A sociolect is thus a form of language depending on age differentiation, occupational distribution, sex differentiation, regional differentiation, etc.

For example, in parts of Germany (e.g. Swabia), a local dialect is used at home, in contact with a peer group, and in other private conversation, but it is necessary to switch to the standard language in more formal circumstances and in contact with strangers. This constitutes a particular problem for schools, which must cope with the various linguistic forms and must provide opportunities for different parts of the population to use the various linguistic forms in appropriate situations. Such 'diglossic' situations occur in many societies and may be interpreted as a form of social stratification.

Diglossia

'Diglossia' may be defined as the complementary use of two different languages (or varieties) in different situations of language use (contact) in a society. Each language is appropriate in particular situations. The labels 'High' and 'Low' for the varieties is probably more an idealization than a characteristic of any real social environment, but it is reasonable to use them to suggest social relations: that is, the use of certain High and Low forms serves to provide an orientation for speakers, a mechanism for them to confirm their expectations.

Diglossia is related to prestige factors in society: that is, high social prestige may accord with relative competence (or lack of competence) in a High variety, and vice versa. This is a function of the standardization of the High variety. Consequently, mastering the High variety can also serve as a vehicle for social mobility.

Diglossic differentiation, therefore, constitutes a sociological model that parallels other types of social stratification in a society: that is, it reflects general differentiation in a society. A number of sociolinguistic studies show that this diglossic language distribution exists, and examine its effects on the direction and rate of development of the society. However,

while such studies describe the stratification in society, they do not explain it; this may require a purer sociological study.

Stratification

Social stratification in a society is reflected in its linguistic stratification, and sociolinguistics tends to describe the social structure as the consequence of the linguistic stratification (i.e. the existence of sociolects) and its effects on the behavior of individuals. Thus, linguistic behavior becomes a measure of the structure of social institutions such as governmental administration, education, political parties, etc. Furthermore, there appears to be a tendency to measure differences among ethnic, religious, and cultural institutions exclusively along linguistic grounds. The underlying hypothesis, then, seems to be that differences in language behavior are the most important differences in social behavior. However, there is growing evidence that complex social relationships cannot be described solely in terms of their correlation with linguistic behavior; rather, they must be described through models of social function, i.e. sociological models. This is reflected in sociolinguistic surveys concerning maintaining a language within a society vs. shifting from one language variety to another. There is also a notion that a particular language may constitute a hindrance to modernization or development, but this notion must be questioned in light of the revitalization of a language (e.g. Hebrew in Israel) or of the extinction of a functioning language (e.g. Gaelic in Ireland). The fate of any particular language or dialect in a given society is the result of the needs of that society to organize social behavior. There is evidence for such a view both in stable multilingual situations (e.g. Switzerland, where there are four official languages) and in situations where multilingualism gives way to a stable monolingual situation and/or standardization (e.g. Malaysia, where Malay replaces local languages, and in many other developing countries around the world). Thus, the language situation is a result of a variety of social efforts involved in planning a stable society, and language change is the result of the need to change society and to provide what is necessary for the functional organization of that society. And such changes may be results of changes in the rural–urban population distribution, in industrial environments, or in the integration of immigrants into society.

Minority/Majority Group Relations

Another aspect of research into sociolects is the description of the relationship between minority and majority groups in society. Majorities tend to domi-

nate minorities with respect to social, cultural, and linguistic phenomena, as, for example, can be seen with respect to the Bretons, the people of Alsace-Lorraine, and the people of Provence in France, all of whom are rapidly losing their own languages in favor of French. Planning and stabilizing the minority/majority situation cannot subordinate the minority group to majority interests. Language is a very important indicator of interethnic relationships within a social group. Language marks both the social identity of the individual and social status in society. Ethnic groups, like other social groups (e.g. age, sex, and religious groups), rely heavily on language to mark their separation from other groups — their distinctness. The language factor not only involves the recognition of other groups as different and the accompanying development of cultural stereotypes; it also takes in the organization of all of society: thus, language is not to be interpreted as merely the medium of communication; it is in fact the 'symbol of ethnicity' par excellence.

Intergroup relationships become more complex and more important as ethnic groups experience a greater need to assert their distinctiveness within the larger society. This phenomenon is observable in Great Britain with respect to the Welsh and Scots or in Spain with respect to the Catalans and Basques. The notion that equates culture, society, and language is belied in many instances by the efforts of various (minority) language groups to achieve self-representation and distinctness. The best way to achieve a stable situation, in most instances, would simply be to adopt greater tolerance, because pressure on the minority to accept majority linguistic and social norms tends to create resistance on the part of the minority. Therefore, the majority must tolerate the language of the minority as a sociolect within society. It is apparent that the argument for linguistic unity within a society is an ideological argument and that societies are in fact structured organisms accommodating various language groups and sociolects.

Education

A further area of investigation concerns the interconnection between education and sociolinguistics. Research like Basil Bernstein's (1971) generated interest in the systematic investigation of the educational problems of individuals and groups identified as somehow 'disadvantaged'; outside Britain, more general questions are asked. Although Bernstein's 'code' model provided an insight into the relationship between language and social situation, and thus could be interpreted as a model for the sociolectal organization of society, further research has questioned both the theoretical model and the adequacy of the empirical

data. Sociolinguists are increasingly interested in the overall awareness of language function in education, not only in foreign language teaching but also in mother-tongue teaching. Sociolinguistics can help to answer relevant questions regarding language use in other societies, and mother-tongue education can profit from the sociolinguistic differentiation of components of the teaching process including both teaching materials and techniques. Foreign language teaching must be highly aware of the sociolectal system of a society as well as changes in it. Foreign language teaching was long dominated by psychological models of learning, particularly the behaviorist model, but there has been growing interest in the function of social rules in foreign language learning and use. Such areas as code-switching and the study of the forms and functions of culturally dependent language use (e.g. types of address and the differentiation of varieties with respect to politeness) are also receiving greater attention. In turn, these concerns have led to greater interest in contrastive analysis (across language systems, within language systems, and across cultures). It is increasingly evident that success in foreign language teaching is in part a function of the ability to use the target language socio-functionally: mere accurate manipulation of the vocabulary and grammar of the target language is insufficient; it is also necessary to know the sociolectal system of the foreign society.

Sociolinguistics

Contemporary sociolinguistics is a diverse and thriving field of linguistic inquiry. Its major branches (variationist sociolinguistics, the sociology of language, and the ethnography of communication/interactional sociolinguistics) share an interest in the ways in which human societies organize their social lives in and through language. In recent years, the theoretical models have shifted from static ones, which assumed that the language use of a person was a straightforward expression of their social identity (social class, sex, age, ethnicity, nationality, professional status, and so on), to social constructionist ones, which view language use as a practice that creates social identity. Furthermore, the ways in which power relationships in society constrain the linguistic expression of its members and the interpretation of their utterances have become a central concern.

Linguistics emerged as an academic discipline in the nineteenth century. Some of the founders of the discipline were dialectologists, such as Jules Gilliéron in France or Georg Wenker in Germany. These men were interested in describing regional variation in language in terms of pronunciation, word structure, syntax, and vocabulary, and they produced elaborate dialect atlases for the areas they studied. Their concern with the ways the identities of speakers influence the ways they speak foreshadows the central interest of sociolinguistics. However, sociolinguistics in its modern sense is usually dated from the 1950s. Although work in dialectology continued, mainstream linguistics had marginalized interest in social questions of language use by that time. Language as a system and the rules that govern that system had developed as the central research focus of linguistics, and interest in the

speakers had largely fallen by the wayside. Increasing frustration with this view of language, which seemed very remote from real life, led to at least three new developments, which today make up the three main branches of the diverse field of sociolinguistics.

Dialectology had set out to describe speech differences between speakers of different regional backgrounds. It was a central assumption of that work that such differences could best be observed in rural areas and that NORMs (nonmobile, older, rural males) would speak a dialect in its purest form. Speakers who did not fit this bill, such as city dwellers, were thought to vary their speech haphazardly. New Yorkers, for instance, were known to sometimes pronounce the [r] in words such as *card*, and sometimes not. The general assumption was that there was no pattern to this whatsoever, and the phenomenon was termed 'free variation' until William Labov's work showed otherwise. In the 1960s, William Labov got sales clerks in three New York department stores (one up-market, one medium, and one down-market) to pronounce 'fourth floor' for him by asking where certain products were sold. By pretending to be hard of hearing, he then got them to repeat it. In this way, he got a sample of the [r] use of upper-class, middle-class, and working-class-oriented speakers, in two different styles (casual and careful). He found that the variation was not haphazard at all, but that the working class speakers used [r] in relevant words with the lowest frequency and upper-class-oriented speakers with the highest. Furthermore, all groups used more [r]s in careful pronunciation than in casual pronunciation. These findings of patterned social variation have since been confirmed and elaborated in a number of studies of urban speech variation, mainly in the English-speaking world. All these studies collected speech samples, often through interviews, from a random selection of speakers, representative of social class, ethnic group, sex, age, style (formal vs. casual speech), and so on. Whatever the variable that was studied in a specific community, this research showed that certain variables are indicative of the social background of a speaker. Many of these studies, such as Labov's (1972) work in New York or Horvath's (1985) research in Sydney, have become sociolinguistic classics. However, variationist sociolinguistics has also been heavily criticized for lacking a sophisticated social theory and for reifying social identity by saying, for instance, that working-class women speak in such and such a way. Particularly, language and gender researchers have been concerned with the static picture of female vs. male speech that work tended to paint. The early variationist model did not allow for individual agency, contestation, or change. Consequently, the most exciting work in variationist sociolinguistics is currently inspired by work in language and gender.

Eckert (2000) represents a significant step forward by viewing linguistic variation as social practice. In this view, speakers draw on linguistic resources to project certain identities while rejecting others. Linguistic variation is no longer predetermined by a speaker's place in the social hierarchy, but has become a resource they use to stake their claims to a particular place in their communities.

Another strand of sociolinguistics has been inspired by widespread bi- and multilingualism. For a long time, mainstream linguistics took monolingualism as its paradigm case, despite the fact that the majority of the world's population is bi- or multilingual. In the 1950s, Einar Haugen was one of the first to study language choice by bilinguals in any detail. His central questions continue to be central to the sociology of language: why and how do bilinguals choose one language over the other in a particular situation? Why and how do they sometimes abandon one of their languages and shift to another? Why and how do others maintain their languages? It is usually the use of minority languages that is threatened by languages of wider communication. Minority status may be the result of internal colonization (e.g. Welsh in the United Kingdom), external colonization (e.g. Aboriginal languages in Australia), or migration (e.g. Italian in the United States). State policies have a crucial influence on language maintenance or shift. Such policies may range from genocide and violent repression (e.g. the Aboriginal language of Tasmania in colonial Australia; Kurdish in Turkey) to active promotion of bilingualism (e.g. Singapore or contemporary Australia). Many nations have negative attitudes toward bilingualism, and public discourses about the deficiency of bilinguals negatively affect bilingual usage (e.g. discourses about Spanish in the United States).

Paralleling developments in variationist sociolinguistics, in the 1960s and 1970s, sociologists of language sought to develop taxonomies of social situations that would result in specific language choices. The concept of 'domain' was introduced by Joshua Fishman, who showed that Puerto Ricans in New York consistently chose English or Spanish, depending on whether their linguistic activities occurred in the domain of family, friendship, religion, employment, or education. Since then, code-switching, or the mixing of two or more languages, as often occurs in bilingual speech, has been acknowledged more widely. Furthermore, with the effect of social constructionism on sociolinguistics as a whole, bilingualism researchers have also become wary of seeing language choice as the result of a particular social situation that speakers find themselves in. Rather, they have begun to view language choice as a resource to construct speakers' social identities (similar to the ways in

which monolinguals use different styles to project a particular social identity). Youths in contemporary multiethnic cities around the world have been found to develop their emerging hybrid identities through elaborate language choices. The choices speakers have at their disposal are crucially influenced by power relations in society, and many researchers have found it useful to integrate social constructionist approaches with views that conceptualize languages as cultural currencies—symbolic capital. In this view, language choice is governed by the laws of a market economy: an international language such as English is a hard-currency language, and access to this language is highly desirable but also restricted by its symbolic owners (education boards, television networks, and so on) to safeguard the strength of their currency.

An unresolved (and irresolvable) question for the sociology of language is what a language actually is. Most people think that sociolinguists should at least be able to identify a language unambiguously—that they should be able to draw clear boundaries between languages and be able to say how many languages there are in the world today. They cannot. Even a seemingly unambiguous test such as mutual intelligibility fails: speakers of Danish, Norwegian, and Swedish can understand one another, yet they are said to speak three different languages. By contrast, speakers of Mandarin Chinese and Cantonese Chinese cannot understand one another, despite the fact that they supposedly speak a single language: Chinese. Thus, languages are defined politically rather than linguistically. Max Weinreich is often quoted as having said: 'A language is a dialect with an army and a navy'. Indeed, the development of pidgin and creole languages is another good example of this. Sociolinguists have come to recognize pidgin and creole languages as fascinating instances of language birth. However, outsiders and even speakers themselves often deride these languages as 'not really a language at all' or 'broken English' (in the case of an English-based creole). Only when such languages, which typically evolved in the extreme contact situations of colonialism and slavery, become the official language of a state, such as Tok Pisin in Papua New Guinea, do they get linguistic recognition.

The third major branch of contemporary sociolinguistics is closely connected to anthropological linguistics and also overlaps with conversation and discourse analysis. It is the aim of the ethnography of communication to uncover, describe, and compare the speaking practices of specific communities. Speakers' communicative competence is of central importance in this endeavor. In general linguistics, the concept of competence is used to capture speakers' subconscious knowledge of linguistic rules. Dell Hymes observed that grammatical rules are only half the story. In addi-

tion to the ability to produce grammatically acceptable utterances, speakers also need to know when to speak and when to stay silent, or what is appropriate to say in a particular situation. Dell Hymes was the first to introduce the term 'communicative competence' for these culture-specific speaking rules. Parents spend much more time to socialize their children into socially appropriate speaking rules than teaching them explicit grammatical rules (e.g. *Don't speak with your mouth full!*). Similarly, sharing a common grammatical system does not necessarily guarantee smooth communication, as countless anecdotes about American–British misunderstandings demonstrate.

Ethnographic research is carried out through participant-observation (i.e. researchers become participants in the community they wish to observe). The central goal of this data collection method is the collection of speech that occurs naturally in a social context, rather than being elicited for research purposes. The work of Dell Hymes also provides a framework for the comparison of speaking practices across communities: the so-called SPEAKING grid. SPEAKING stands for setting, participants, ends, act sequence, key, instrumentalities, norms, and genres.

Interactional sociolinguistics developed from the ethnography of communication and is closely associated with the pioneering work of John Gumperz. A central idea is the one of 'contextualization', which posits that certain linguistic cues (e.g. prosody) are used to create a social context and a framework for interpretation. Many such cues are taken for granted, and speakers assume them to be linguistic universals, which in fact they are not. If speakers do not share such presuppositions for the framing and interpretation of communicative interactions, misunderstandings and even communication breakdown may result. Consequently, cross-cultural communication has been of central interest to interactional sociolinguists. Communication in institutional settings has been a further central site of inquiry. Such work, whether on communication in the classroom, in the courtroom, in medical settings, or in the workplace, often has practical applications. It seeks to uncover communication patterns that may give some interactants an advantage over others in such encounters.

From its inception, sociolinguistics has been concerned with power relationships and the differential access to material and symbolic resources that these relationships result in. Many applications result from this fundamental concern. In the field of education, dialect and minority speakers have consistently been found to be less successful than their standard-speaking peers. A number of court cases in the United States have established that such a disadvantage constitutes a form of discrimination. An early one of

these, in Ann Arbor, Michigan, had William Labov testify to the structural equality of African-American vernacular English to other languages. Outside education, sociolinguistic expertise finds applications in cross-cultural and workplace communication, forensic contexts, doctor–patient interactions, and language policy and planning.

Soundwave Analysis

Sound is a form of energy. It is generated by disturbance of particles, and it travels in waves at a certain speed, depending on the compressibility and the resistance of the medium (e.g. 344 m/s in air, 1,500 m/s in water). Most sounds are complex by nature, i.e. they consist of more than one tone, each tone with its own frequency, amplitude, and phase. Over the years, several tools have been developed to analyze speech sounds. The first tools were based on analog techniques, but since the 1950s digital techniques have advanced greatly, and today software packages exist that can be used at home. Digital techniques are more accurate, and are repeatable. One of the most important approaches regarding the analysis of complex sounds (like speech) was proposed by Joseph Fourier, a French mathematician in the second half of the nineteenth century. He showed that a complex speech signal like speech can be considered as consisting of a combination of sine waves (also called sinusoids or pure tones). The sine wave is the simplest of all sounds, and it seems appropriate to discuss its properties first.

Sine Waves

Figure 1 illustrates the three main properties of a sine wave: frequency, amplitude, and phase. The frequency of a wave refers to the repetition of a cycle per unit time (a). The period of a wave is the duration of one cycle, and the frequency is the reciprocal of the period, expressed in Hertz (Hz). The lower the repetition rate, the lower the perceived pitch. Amplitude represents the extent of vibration (b) and is correlated with loudness: the lesser the amplitude, the softer the signal. The phase of the signal is the point in time at which the waveform starts (c). Most sound analysis tools do not take phase differences into account, as they hardly affect the identity of the different sounds.

A complex sound consists of different sine waves, each with its own frequency, amplitude, and phase. In speech, there are two kinds of complex signals: periodic and aperiodic ones. In periodic signals, the vibration repeats itself; in aperiodic signals, the vibration has no repeatable pattern. Vowels usually have a periodic structure due to the continuous vibration of the vocal folds during speech production, while consonants exhibit an aperiodic, noise-like, structure.

Oscillogram

One of the oldest sound analysis tools is the oscillograph (±1930). It displays sound as pressure variations over time and allows the determination of relative amplitude, duration, and fundamental frequency. An example of a digital oscillogram of the word 'soldier'
Figure 1

is given in Figure 2A. Note that the vibration of the /s/ is aperiodic, while that of the vowel nucleus of the /o/ is highly periodic. By selecting a portion of the vowel, preferably somewhere in the middle, it is possible to determine its periodicity and hence its fundamental frequency by taking the reciprocal of the period ($f = 1/T$). The fundamental frequency is the lowest frequency and is the physical measure of vocal fold vibration. This physical property is perceived as the pitch of a signal. It is the primary acoustic cue to intonation and stress in speech and is crucial to phoneme identification in tone languages. The determination of $F0$ is usually done for several numbers of periods to minimize measuring artifacts as much as possible. The main drawback of this method is that the measurements, especially determination of duration, strongly depend on the placing of the cursors. For many speech sounds, it is very difficult to determine exactly where a speech segment begins and where it ends. This is illustrated in Figure 2B for the /o/ of /soldier/. The end of the /s/ is easily determined (a), but the end of the /o/ and beginning of /l/ are not marked clearly (b), so that the duration of /o/ cannot be determined reliably. In addition to this, oscillographic analysis does not suffice to describe some of the important differences among vowels. Observation of these differences requires the generation of spectral representations, that is, plots of signal energy vs. frequency (see further).

Root-Mean-Square Amplitude

In order to determine the amplitude of the (speech) signal, both the negative and positive parts of the waveform must be taken into account. This is done by calculating the root-mean-square (RMS) amplitude of a certain number of samples. First, the samples in a waveform window are squared, so that the portions above and below the line are positive. The squared values in the window are then averaged and squared again (to compensate for the initial squaring), after which another set of samples is selected. RMS amplitude

measurements are useful quantities because they relate directly to the power in the signal.

Spectral Analysis

In order to examine the characteristics of speech sounds in more detail, (parts of) the waveform can be submitted to a spectral analysis, also called Fourier analysis. Recall that Fourier showed that periodic waveforms, no matter how complex, can be analyzed as the sum of sine waves varying in frequency, amplitude, and phase. The resulting power spectrum shows the amplitude of each different component (sine wave) as a function of its frequency. These components are also called harmonics in periodic sounds, because the frequencies of the components are multiples of the fundamental frequency or the first harmonic ($F0$). An example of a spectrum of the vowel /i/ is given in Figure 3. The shape of the spectrum is given by the (imaginary) line connecting the amplitudes of the harmonics. Different (speech) sounds have different spectral envelopes, because different vocal tract configurations result in different resonant frequencies. The first component corresponds to the fundamental frequency (and hence to vocal fold vibration). Components yielding the highest amplitude correspond to the resonant frequencies of the sound, here at approximately 300, 2,000, and 3,100 Hz. Spectral analysis has proved to be a very valuable tool in distinguishing the characteristics of the different vowels and consonants (e.g. different frequency regions of /s/ and /f/) (see Figure 3).

Linear Prediction

A different method for estimating formant frequencies is linear predictive coding (LPC). Like the Fourier transform, it relates a representation in time to one in frequency. However, it is not based on spectral analysis. The hypothesis behind LPC is that a sample is partly predictable from its immediate predecessors.

(a)
Figure 2

Figure 3
This is true under the assumption that speech does not vary too rapidly from sample to sample (which is not always the case). LPC was originally developed as a method of compressing the signal (e.g. for speech synthesis). The algorithm calculates 'predictor' coefficients that correspond to the vocal tract filter function in a linear way. It does not transmit the individual samples, but determines weights and errors that are updated every 10 or 20 ms, depending on the chosen window size. This is an immense saving compared to the original speech signal. Of course, the prediction is not completely accurate, so the transmitted speech is not perfect. Both the Fourier spectrum and LPC have proved to be good methods for estimating formant frequencies. Note, however, that the two methods yield different types of information. The Fourier spectrum shows the harmonics of the fundamental frequency. Formant frequencies are estimated from the harmonics with the highest amplitude. The LPC spectrum does not show harmonics, but (automatically) yields the formant frequencies and bandwidths from the filter functions. In general, both methods compare well.

There is no 'best' method, and errors occur frequently at high fundamental frequencies. The higher the fundamental frequency, the wider apart the harmonics in the spectrum, and the more difficult it becomes to estimate the resonant frequencies. Moreover, most LPC models only account for the resonances (they are all-pole models), not the anti-resonances (zeroes) in speech sounds. This means that LPC is not suitable for determining formant frequencies in speech sounds that contain antiresonances, such as the nasals and laterals (e.g. /m, n, l/), and some fricatives. Another disadvantage of LPC is that the number of formant frequencies has to be specified before the analysis. For every two coefficients, the algorithm has to find a peak in the spectrum. If the number of anticipated peaks is larger than the actual number of peaks, the algorithm will yield values that do not correspond to true peaks in the spectrum. Similarly, if very few peaks are specified, some of the true peaks will not be indicated either. All in all, it is best to use both methods on the same speech sounds, and to compare results. In this way, errors, such as, for instance, confusing a harmonic with a formant frequency, can be avoided.

Filtering

Filters are commonly used in sound analysis. Filters pass energy at certain frequencies but not at others and therefore allow a selective look at the energy in a certain frequency region. A low-pass filter removes all frequencies above a given cut-off frequency; a high-pass filter removes all frequencies below a given cut-off frequency. A band-pass filter allows frequencies between two cut-off frequencies to pass (our telephone network between 300 and 3,400 Hz !), while a band-stop filter removes the information between two given frequencies. In speech, a preemphasis filter is often applied to boost the high-frequency components in amplitude relative to the low-frequency components. It is actually a high-pass filter with a response that usually increases at 6 dB per octave. A preemphasis filter is necessary, because most of the energy in speech is in the lower frequency range. This energy will tend to dominate the analysis if there is no equalization of energy across frequency. Also, before sampling, the input signal must be low-pass filtered at the value of the maximum frequency of interest (usually 10 kHz when the sampling rate is 20 kHz). This antialiasing filter sharply attenuates frequencies above half the sampling rate to avoid aliasing effects.

Spectrographic Analyses

Spectrographic analysis, an important method for visualizing and examining (speech) sounds, is based on band-pass filtering. This method determines the energy of each frequency component as a function of time and, by doing so, clearly illustrates the variation in the acoustical properties over time. While the Fourier spectrum yields information of the frequency components of a certain speech sound in a rather static way, the spectrogram displays the dynamical nature of a stretch of speech. In the analog spectrograph, which was developed in the 1940s, the speech signal is analyzed by a set of band-pass filters, each of which only responds to the energy within its frequency band. In the digital version, the spectral amplitude results from a series of different Fourier analyses. The number of samples in the analysis window determines the width of the analysis. A short analysis window corresponds to a wide bandwidth, and a long analysis window to a narrow bandwidth. Figures 4A and B illustrate a wideband and narrowband analysis of 'The soldier saluted the flag.' In both plots, time is given on the horizontal axis, frequency on the vertical axis, and intensity by the blackness of the pattern. However, as a result of the different filter settings, there is a trade-off between temporal and spectral information. Wideband spectrograms (Figure 4A) yield high temporal resolution. They display the individual voicing pulses (vertical striations) as well as the resonant frequencies (broad bands of energy) of the speech sounds. Spectral changes over relatively brief intervals of time are clearly visible. Note the high-frequency turbulence of the /s/, the dynamic formant patterns, the silence preceding unvoiced plosives, etc. In a wideband analysis frequency resolution is low, and the fundamental frequency is difficult to determine, especially when it is smeared together with the lowest formant frequency. It is possible to determine the average fundamental frequency by calculating the number of glottal pulses per second (vertically), but this is a time-consuming and not very reliable method. The fundamental frequency can be better determined from a narrowband spectrogram (Figure 4B), where the fundamental frequency and its harmonics are displayed as equally-spaced horizontal lines within the broader formants. A narrowband spectrogram has a high-frequency resolution, more fine-grained information, but low temporal resolution. Usually, the average fundamental frequency is determined by counting the first ten harmonics (see arrow in Figure 4B), and by dividing the corresponding frequency on the y-axis by ten (see Figure 4).

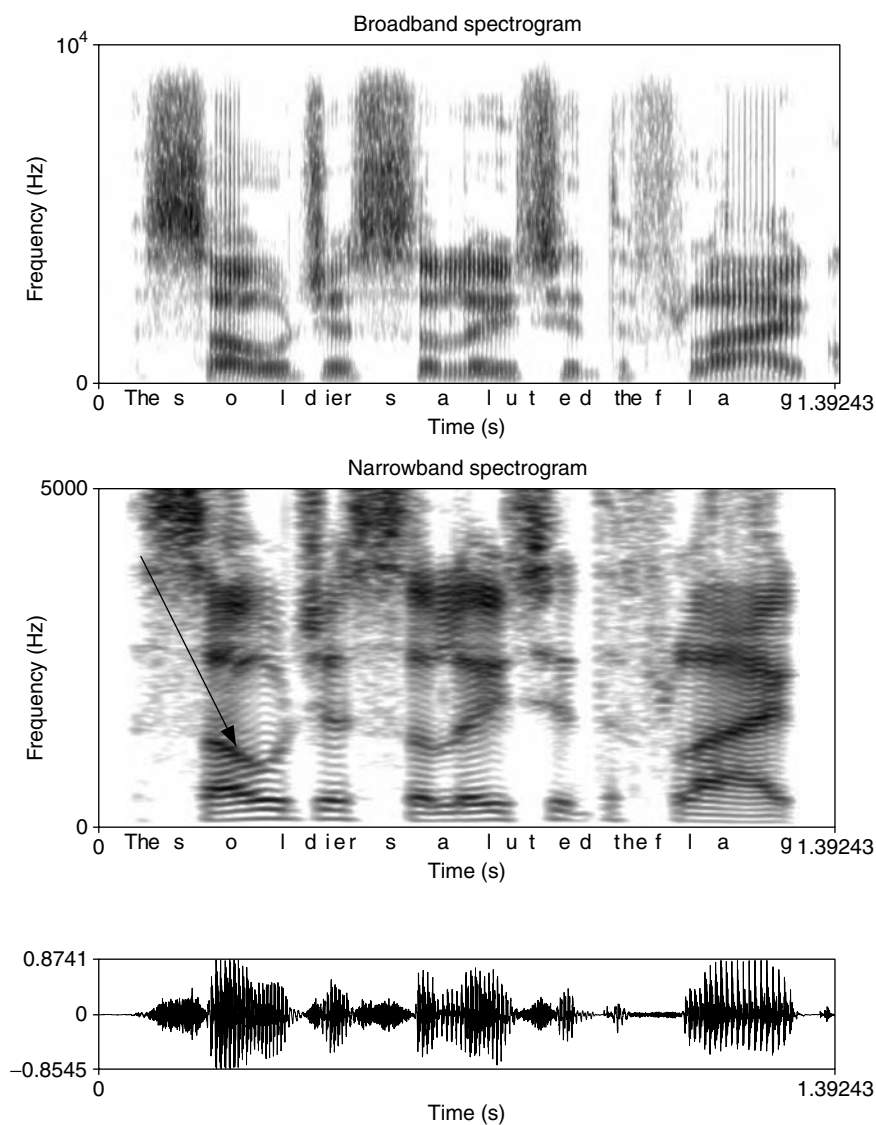
Instead of spectrographic analysis, it is also possible to make use of special algorithms to track the fundamental frequency in the speech signal. However, these programs also make characteristic errors, such as confusing the first formant (resonant) frequency with the fundamental frequency, doubling the fundamental frequency,


Figure 4

finding a fundamental frequency in unvoiced parts of the signal, or failing to find it in voiced sections.

Digitalization, Sampling, and Quantization

Once (personal) computers became popular, many software programs became readily available for digital (speech) sound analyses. Digital techniques can do what the analog systems did, only more precisely and faster. Moreover, digital signals can be stored forever without quality degradation and the stored signal can be reanalyzed, edited, and displayed as often as necessary. Before analysis, however, the speech signal must be transformed to a discrete representation. This means that the speech signal must be sampled at certain, regular, intervals of time. But what should the sampling rate be? If the rate is too low, much of the information of the original signal will be lost or errors can occur in the analysis. The higher the sampling frequency the better the sound quality, but also the larger the required storage capacity and computer memory. For instance, compact disks are sampled at a rate of 44.1 kHz, meaning that the signal is sampled 44,100 times per second. It is not necessary to sample speech at such a high rate, because the main acoustical properties range between 0 and 10,000 Hz. The Nyquist theorem states that the sampling rate should at least be twice the maximum frequency of interest; hence, a sampling rate of 20,000 Hz is appropriate. Together with sampling (discretization as a function of time) the signal must also be quantized (discretization as a function of level). Quantization is expressed in bits: an 8-bit signal has 256 different levels (2^8), and a 15-bit one has 32,768 different levels (2^{15}). Although the increase in the number of quantization levels results

in a better sound quality (due to the fact that there is a more accurate resemblance between the discretized and original signal) it also implies more memory to store the data. For the analysis of speech sound, 12-bit quantization suffices. However, for the analysis of music, finer gradations of amplitude are required, since the dynamic range, i.e. the difference between the quietest and loudest sound of interest, is greater.

Autocorrelation

Instead of determining the fundamental frequency ($F0$) from the time signal (Figure 2) or from a (narrowband) spectrogram (Figure 4B), it can also be detected automatically by a computer algorithm. Over the years, many computer algorithms have been developed, none of which yield a 100% accurate result (one should always check!). This is because of the nonstationary nature of speech, irregularities in vocal cord vibration, the wide range of possible $F0$ values, and degraded speech in noisy environments. In general, the autocorrelation algorithm yields a higher accuracy than the time-domain techniques, but also requires a higher computation load. In the autocorrelation method, the average correlation of part of the speech signal is computed, usually a Hanning window of a constant length, and a delayed copy of itself (= auto). The 'lag' with the highest correlation is then taken as the pitch of the period. The correlation is highest when the delay is close to one pitch period. Pitch extraction with the autocorrelation algorithm works well, because the spectro-temporal changes in voiced segments are usually relatively slow compared to those in the more dynamic speech segments (e.g. voiceless plosives). However, the algorithm also has its drawbacks. A common error produced by the autocorrelation method is pitch doubling, i.e. when a subcomponent of the pitch period is mistakenly identified as the pitch period. Moreover, formant frequency information can affect pitch extraction, to the extent that the output is not the glottal period, but the glottal period plus the period of the first or second formant. Autocorrelation is one of the more reliable methods of determining $F0$.

Cepstral Analysis

Another fairly accurate pitch extraction method is cepstral analysis. This method makes use of the periodic structure of the harmonics in a Fourier spectrum. To determine the interval between subsequent harmonics, a Fourier transform of the log power Fourier spectrum of the original speech signal is taken. The result is a spike at a component that corresponds to the fundamental frequency. Because of the Fourier transformation on a Fourier transformation, the frequency axis of the spectrum is transformed back to a time axis. Note that 'cepstrum' is actually 'spectrum' with the first syllable reversed. Similarly, the 'quefrency' peak (= 'inverse of' frequency) represents the fundamental period.

ASTRID VAN WIERINGEN

South Africa

South Africa, nestled in the southern tip of the African continent, covers 1,211,037 square kilometers. The population of 45.98 million (mid-2000 estimate) includes approximately 26.98 million Africans, 5.99 million Whites, 3.49 million 'Coloreds', and 1.03 million Asians. The African population is made up of Zulu (18.8%), Xhosa (18.3%), Tswana (7.2%), Southern Sotho (6.9%), Northern Sotho (9.8%), Shangaan (Tsonga) (4.2%), Swazi (2.6%), Ndebele (1.5%), and Venda (1.7%). The white population is two-thirds Afrikaans-speaking (a form of Dutch) and one-third English-speaking. The 'Coloreds' are of mixed race, and the Asians are chiefly Indians. The linguistic diversity and complex

history of South Africa poses interesting issues for language students.

South Africa contains two of the four language families (phyla) in Africa: Khoisan and Niger-Kordofanian languages. The Bantu (or Sintu) languages are spoken in South Africa, which are the most widespread and best-known subgroup of Niger-Congo, a subfamily of Niger-Kordofanian family. Sintu reflects the Nguni prefix isi-, denoting language and culture. Sintu languages in South Africa include Nguni languages (Ndebele, Swazi, Xhosa, and Zulu), Sotho languages (North Sotho, South Sotho, and Tswana), Tsonga, and Venda. The Nguni, whose descendants now comprise most of the country's black majority, were established in South Africa by the third century AD. The Nguni languages in South Africa now comprise Xhosa, Zulu, Swazi, Ndebele, Ponso, and Tembu. They are closely related and spoken by most African people in South Africa.

Greenberg (1950, 1963) further developed and popularized the concept of Khoisan as a language phylum. The most prominent feature of the Khoisan languages is the sound system. It contains a large number of ingressive sounds known as clicks, which usually occur word-initially, and are often believed to be remnants of the most ancient sound inventory of human language (Vossen 2000). Also, most Khoisan languages make use of various levels of tone, both lexically and grammatically, and tone-bearing units are syllabic segments such as vowels and nasal consonants. Vowels can occur as oral, nasal, pharyngealized, glottalized, breathy vowels, or combinations thereof.

Several millennia ago, the Khoisan languages predominated all across southern Africa (including most of modern-day South Africa), from the Cape of Good Hope to Somalia and Kenya (Guldemann and Vossen 2000). The Khoisan peoples—Bushmen, Cape Khoikhoi (the so-called Hottentots), and Bergdamara—were the original inhabitants of South Africa, primarily hunters and gatherers, but few now remain. In the seventeenth century, there were still perhaps 200,000 speakers of the Cape Khoikhoi dialects between the Cape and the Transkei, but disease and expropriation of grazing land by European settlers destroyed the Cape Khoikhoi's economic base and language. Now, a large number of Khoisan languages with usually a few hundred speakers each are scattered across the Kalahari region of southern Africa, including northern South Africa. At present, the total population may be estimated to be around 200,000 (Vossen 2000:131).

While the San (Bushmen) and the Khoi (Hottentots) lived in southern Africa possibly as far back as the Stone Age, the Nguni, whose descendants now comprise most of the country's black majority, arrived in South Africa by the third century AD. Up to

the fifteenth century, the Nguni occupied predominantly the northern, eastern, and south-eastern areas of South Africa, while the San and the Khoi occupied the southwestern regions from the Cape to the Orange River. By the nineteenth century, the Nguni and European settlers in South Africa pushed the Khoisan speakers into the Khalahari Desert. Members of the isinguni (the Nguni language group) include the Ndebele, Ngoni, Swazi, Xhosa, Zulu, and some smaller peoples, and speak closely related languages.

Currently, there are 31 main languages in South Africa, of which 27 are living. The extinct languages, all Khoisan languages, are Korana, Seroa, Xam, and Xegwi. The nearly extinct languages are Ng'huki and Xiri; both these are Khoisan languages. Fanagolo is a second language without mother-tongue speakers. The living languages include Afrikaans, Birwa, Chinese (Mandarin), English, Fly Taal, Gujarati, Hindi, Nama, Ndebele, Oorlans, Ronga, Northern Sotho, Southern Sotho (Sesotho), South African Sign Language, Swahili, Swati, Tamil, Tsonga, Tswa, Tswana, Urdu, Venda, Xhosa, and Zulu. Other minor languages include Dutch, German, Greek, Italian, Portuguese, French, and others. Few people in South Africa are monolingual, most are bilingual, and many are multilingual to varying degrees. Several languages are partially intelligible with other languages. For example, Tswa is partially intelligible with Ronga and Tsonga.

Population distribution is extremely uneven—more than two thirds live in the eastern third of the republic and in the southern Cape. Europeans have a widespread geographical distribution, but more than 80% reside in towns. Relatively few Africans are resident in the western Cape, and more than 60% continue to reside in those rural areas that comprised the formal tribal reserves. These extend in a great horseshoe along the southeastern coast and up to the Northern Province and then southwestward to the northeastern Cape. The 'Colored' population are mainly resident in the Cape, and the Asian population is concentrated largely in KwaZulu/Natal and the Witwatersrand.

African languages are unevenly distributed through the population (see, for example, ANC Constitutional Committee 1992). Ndebele is spoken mostly in northern and southern Transvaal. Setswana is the language of the Tswana people, spoken in parts of the Western Transvaal and Northern Cape, as well as a small area within the Orange Free State. Shangaan is spoken in Northern and Eastern Transvaal. Northern Sotho is the group of Sotho dialects spoken in the northern parts of South Africa. South(ern) Sotho is the group of Sotho dialects spoken in Lesotho and Orange Free State, as well as western Transvaal. Siswazi is the language of the Swazi people, spoken mostly in the Kingdom of Swaziland and in the Eastern Transvaal. Tshivenda or

Chivenda is the language of the Venda people, spoken mainly in the Soutpansberg region of the Northern Transvaal. Isixhosa is the language of the Xhosa people traditionally living in what is now the Eastern Cape Province. IsiZulu is the Zulu language; Zulus live mainly in KwaZulu-Natal, but isiZulu is spoken in the Orange Free State and the Eastern Transvaal, as well as Natal.

English was declared the sole official language of the Cape Colony in 1822 (replacing Dutch). Then, on the formation of the Union of South Africa in 1910, English was made the official language together with Dutch (which was replaced by Afrikaans in 1925). Afrikaans is a variant of Dutch spoken by the seventeenth-century colonists, with some lexical and syntactic borrowings from Malay, Bantu languages, Khoisan languages, Portuguese, and other European languages. After the establishment of the republic of South Africa in 1961, this policy of two official languages (English and Afrikaans) continued. The first democratic elections were held in 1994. The Interim Constitution of the new South Africa was adopted in 1994, establishing a federal, democratic, multiparty system, and identifying several aspects of education and language issues. In section 3, subsection 9c and 10d, the Interim Constitution made special mention of the 11 official languages. Eleven languages were accorded official status. The official languages in the 'new South Africa' are Afrikaans, English, isiNdebele (Ndebele), Sesotho sa Leboa, Sesotho (southern Sotho), seSwati, Xitsonga (Tsonga), Setswana (Tswana), Tshivenda (Venda), isiXhosa (Xhosa), and isiZulu (Zulu).

The new constitution of May 8, 1996 guarantees that the government will promote and protect African languages. It stated that the Pan South African Language Board be established to promote the 11 official languages as well as minority languages such as German, Portuguese, and the Indian languages. President Thabo Mbedi notes the progress in the establishment of the Commission for the Protection and Promotion of Language, Cultural, and Religious Rights as enshrined in South Africa's constitution (Mbeki 1999). Several researchers (e.g. Crawhall 1999) criticize the current government language policies for not sufficiently promoting and protecting the indigenous languages of the San, Nama, and the Khoe. The few surviving San and Khoi languages are all at risk of dying out in the next generation; land and natural resource access are essential for maintaining the languages of hunter–gatherers and traditional pastoralists (Crawhall 1999).

While linguistic pluralism is a national objective in democratic South Africa, many people engage in the monolingual practice of English only (Webb 1999). Prabhakaran (1998), for example, describes the complex process of an intergenerational language shift from Telugu, an Indian language, to English. He argues that the main causes of this shift are the dominant official status of the English language, the government language policy, the assimilation between the Andhras and the Tamils, and political factors such as the uprooting of the well-settled Andhra community by the Group Areas Act. English remains the main means of communication in South Africa's urban areas.

Estimates based on the 1991 census (Schuring 1993) indicate that approximately 45% of the South African population have a speaking knowledge of English. The majority of the population speak an African language as home language. Only about 10% of the population cite English as a home language. Of this figure, about one in three English speakers come from ethnic groups other than the white one (in proportionally descending order, from the South African Indian, Colored, and Black ethnic groups) (Lanham 1996). There is presently considerable (and overlapping) variation in the manifestation of English in South Africa. The variety of accents is a consequence of both the varied regional origins of groups of native English speakers who came to Africa at different times, and the variety of the mother tongues of the different ethnic groups. For example, one can distinguish between 'ethnic varieties' such as 'Colored', Black, South African Indian, Afrikaans English, and White South African English (Lanham 1996). And among white English speakers, there has been a traditional threefold distinction between 'conservative', 'respectable', and 'extreme' South African English (Lanham 1982).

Language planning, and particularly the role of the English language in South Africa's linguistic future, receives much debate. Discussions continue on the practicality of the language policy, the multiple vs. single language debate, 'tribalism', and the meaning of language and its role in identity (Finchilescu and Nyawose 1998). For example, Titlestad (1996) argues that the English language will inevitably play a powerful, leading role as an important *lingua franca* because of its role internationally. Since English is the international and intranational language of communication and many South Africans already speak English, he argues, market forces will play a role in ensuring the growth of English in South Africa. However, Webb (1996) maintains that in the interests of serving the needs of speakers of all languages in terms of the constitutional principle of multilingualism, language planning should be conducted from an Afrocentric view where all languages have equal rights.

CAMILLA M. COCKERTON

South America: Argentina

Argentina, at the southern end of South America, has an area of 3,761,274 square kilometers and a population of 36,260,130 (2001 census). It is estimated that at least 35 different languages were spoken in this territory at the time of the first European contact in the early 1500s. In addition to Spanish, the official language, approximately 12 indigenous languages and a number of immigrant languages are also spoken at present.

Indigenous Languages

The indigenous languages of Argentina are classified into eight linguistic groups: Quechua, Tupi-Guarani, Guaycuruan, Matacoan, Lule-Vilela, Araucanian, Chon, and the unclassified language Yahgan. (The numbers of speakers of these languages are estimates, since no official record for the number of speakers for any of the languages exists.)

Quechua

Two varieties of Quechua are spoken in Argentina. One is the variety spoken mostly by migrants from Bolivia, with an estimated 500,000–850,000 speakers. The second is the Quechua spoken in Santiago del Estero, a province in the center of Argentina, known there as Quichua Santiagueño. Santiago del Estero Quechua was brought to this area by Quechua speakers who accompanied Spanish expeditions in the early years of conquest and who settled in the area. There are currently an estimated 60,000–100,000 speakers.

Tupi-Guarani

There are three Tupi-Guarani languages currently spoken in Argentina: Chiriguano, Tapiete, and Guaraní. Chiriguano is spoken by 15,000–21,000 people in the province of Salta, in northern Argentina. (There are approximately 50,000 speakers of Chiriguano in Bolivia.) This language is also spoken by a group called Chané, who at present speak a variety called Chiriguano-Chané. It is claimed that the Chané originally spoke Chané, a language believed by some to be of the Arawakan family. They were enslaved by the Chiriguano people, and eventually shifted to Chiriguano. The variety spoken by the Chané shows traces of the original Chané language, although their language has not been well studied yet. Tapiete (or Ñandeva) is spoken by approximately 400 people in the province of Salta. (There are approximately 3,200 speakers of Tapiete in Paraguay.) It is sometimes described as a variety of Chiriguano with a considerable amount of borrowings from other languages. Guarani is mostly spoken in Paraguay and Eastern Bolivia, but there are at least three varieties of Guarani spoken in Argentina mostly in the provinces of Formosa, Corrientes, and Misiones. Guaraní Correntino or Corrientes Guaraní is spoken mostly in the northeastern part of the country, with a considerable number of migrants in larger urban areas such as Rosario, Córdoba, and Buenos Aires. A second variety is known as Mbya, and is spoken in the province of Misiones mostly by people in rural areas. The third variety is

Paraguayan Guaraní, spoken by Paraguayan immigrants in northeastern Argentina, particularly in provinces closer to the Paraguayan border, and in large urban centers. The estimated number of speakers of the three varieties of Guarani ranges from 100,000 to 1,000,000. This is due partly to the lack of data on the Argentinian varieties, and in part due to the constant, undocumented influx of illegal immigrants from Paraguay.

Guaycuruan

There are four languages that belong to the Guaycuruan language family in Argentina: Mocoví, Pilagá, Toba, and the now extinct Abipón, in the Chaco region. (There is also one other Guaycuruan language, Kadiwéu, spoken in Matto Grosso do Sul, Brazil.) Mocoví is spoken by approximately 5,000 people in the provinces of Santa Fé and Chaco. Pilagá has an estimated 4,000 speakers in Formosa, mostly along the Pilcomayo River. Toba is the Guaycuruan language with the greatest numbers of speakers, 25,000, mostly in the provinces of Chaco and Formosa, but also as migrant groups in Santa Fé, Buenos Aires, and Salta. The Abipón were the first Guaycuruan Indians to settle in missions, known as reducciones, mostly in Santa Fe province; their language became extinct in the early twentieth century. Two other languages mentioned in several colonial sources are also believed to belong in the Guaycuruan family: Payaguá and Charrúa. However, the only extant records of these languages are brief word lists, and the evidence for their classification as Guaycuruan languages is very weak.

Matacoan

The Matacoan family (also known as *Mataguayo* or *Mataco-Mataguayo*) has three languages, spoken in northern Argentina: Wichí, Chorote, and Chulupí. (The fourth Matacoan language is Maká, spoken in Paraguay.) Wichí is commonly known as Mataco, but this is a pejorative term rejected by speakers of the language. It has between 40,000 and 60,000 speakers in Chaco, Salta, and Formosa provinces. Chorote is spoken in Salta by approximately 2,000 people (and an estimated 500 others in Paraguay). Chulupí (also known as Nivaclé and Ahluhlay or Ashlushlay) is spoken by anywhere from 200 to 1,200 people in Salta — estimates vary widely (and perhaps as many as 18,000 in Paraguay). In Argentina, they mostly live in communities mixed with Chorote and Wichí speakers.

Lule-Vilela

This is a small proposed language family, with only two languages: Lule and Vilela. Lule, believed to be a dialect of the Tonocoté language referred to in early documents, was spoken mostly in Tucumán, western Salta, and northwestern Santiago del Estero. It became extinct in the nineteenth century. It is believed to be related to Vilela, a language spoken in the provinces of

Salta and Chaco by a small number of speakers until the mid-1960s, now believed to be extinct.

Araucanian

One language belongs to the Araucanian family, Mapudungun (also known as Mapudungu, Mapuzungun, Araucano, or Mapuche, although the last term refers to the speakers, from *mapu* 'earth' and *che* 'people'). It is spoken by approximately 40,000 people in Argentina in the provinces of Neuquén, Río Negro, La Pampa and Chubut, and various communities in Buenos Aires province. It is also spoken in Chile. Mapudungun spread to Argentina from Chile through the southern Andes before European arrival. There was sporadic contact between the earlier groups in Patagonia and the Mapuche, mostly for commercial purposes, but in the early seventeenth century, large numbers of Mapudungun speakers crossed the Andes spreading into Patagonia and the central plains, known as the Pampas, forcefully occupying Tehuelche territory, imposing their language and culture. This 'Araucanization of the Pampas' lasted until the late nineteenth century, with the violent imposition by the Argentinian government of the authority on the indigenous groups of the area.

Chon

The languages of the Chon family were spoken in Patagonia in southern Argentina and the southern islands. They can be divided into two groups: Island Chon and Tehuelche, reflecting more a geographic grouping than a linguistic one. Two languages belong in the Island Chon group: Haush and Selk'nam, which were spoken in the island of Tierra del Fuego. Haush, or Manek'enk, was spoken in the southeastern tip of the island, and became extinct in the early twentieth century. Only brief vocabularies of Haush remain, dating from the late nineteenth century. Selk'nam, or Ona was spoken in the central and northwestern parts of the island. Although the language was not extensively studied, it is better documented than Haush. By 1973 there were only three speakers of Selk'nam, and the language is now extinct. Some believe Haush to be but a variety of Selk´nam, and not a distinct language. The second group, Tehuelche, was spoken by groups in Patagonia and the Pampas. Four varieties of Tehuelche are reported: Northern Tehuelche, also known as Gününa-küne, was spoken from the Colorado River to the Chubut River. It became extinct in the 1960s. A second variety of Tehuelche is believed to have been spoken in the southern Pampas, from Eastern Neuquen to the Colorado River, but very little documentation exists for the language (mainly toponyms and a few phrases from travelers). Southern Tehuelche was spoken from the Chubut River to the Magellan Strait. Two varieties are reported: Teushen,

now extinct and of which very little is known (briefly reported in vocabularies dating from 1780 to 1900), was spoken between the Chubut and Santa Cruz Rivers. The second variety, known as Tehuelche or Aonek', was spoken from the Santa Cruz River to the Straits of Magellan. Only two speakers of Tehuelche are alive today, but they do not use the language regularly and only remember it partially.

Yahgan

Yahgan, also known as Yámana, was spoken in the southern coast of Tierra del Fuego and the southern islands of the area. The language is not part of the Chon family, and its genetic affiliation is still unclear. The language became extinct in Argentina in the early twentieth century. Today, there is now only one speaker of Yahgan left in Chile, an elderly woman. The only documentation of the language was provided by the first missionary to settle in the area, the Englishman Thomas Bridges.

Other languages

Argentina was first settled by Spanish colonizers in the early 1500s, and while the population grew slowly in the first two centuries, the late nineteenth and twentieth centuries witnessed a surge in immigration, mostly from Europe. Although the Argentinean government provided incentives for the immigrants to settle in the interior of the country, the majority settled in Buenos Aires and surrounding areas. Most first-language speakers of these immigrant languages are first-generation immigrants, and by the second or third generation speakers shift to Spanish, learning the immigrant language (if at all) only as a second language. Two particularly interesting cases are those of Welsh and Korean. A large group of Welsh immigrants settled in the Patagonia, on the Chubut River in 1865 as a result of an agreement between the Argentinean government and English representatives. They were able to maintain their language well into the twentieth century,

gradually shifting to Spanish, after decades of pressure from the Argentinean authorities, so that by the 1940s Welsh was no longer spoken among members of the Welsh community. Korean speakers represent the latest 'wave' of immigration, mostly as a result of a diplomatic agreement between the Argentinean and Korean governments. The largest number of Korean speakers came to Argentina between 1965 and 1989, with most between 1984 and 1989. Patterns of language maintenance among Korean speakers reflect the same trends as other immigrant languages, with second- and third-generation speakers already shifting to Spanish. The immigrant languages with a considerable number of speakers include Italian, German, English, Welsh, Ukrainian, Polish, Lithuanian, Vlach Romani, Arabic, Japanese, and Korean.

South America: Brazil

Occupying nearly half the continent of South America, Brazil is one of the largest and most populous countries in the world, and its inclusion of a major portion of the Amazon Basin adds to its enigmatic and diverse character. Brazil is home to a large number of little-known indigenous languages from a variety of language

families, as well as to several genetic isolates—languages that do not seem to be related to any other known languages. The status of Brazil is also unique in South America as the only country recognizing Portuguese rather than Spanish as its official language. Finally, the importation of African slaves into the region, as well as continued immigration by a variety of ethnic groups, has created an interesting and complex linguistic situation in Brazil.

Indigenous Languages

With no written records documenting precolonial Brazil, estimates of the indigenous population at the time of the Portuguese arrival in 1500 have ranged between one and six million. As a consequence of war and the introduction of such European diseases as smallpox and influenza, the indigenous population was drastically reduced. Today, there are about 200,000 Indians in Brazil.

Despite the loss of languages that certainly occurred due to the loss of human life, about 170 different Amerindian languages remain in the region today. Because little is known about many of these languages, and because contact among the various languages has been great, a great number of classifications have been proposed for the languages of Brazil. One of the most commonly accepted proposes five major families—Arawak, Carib, Tupi, Macro-Je, and Pano—as well as several smaller families and some genetic isolates. The highest density of indigenous languages and indigenous speakers in South America is in the Amazon basin in the northern region of Brazil. Tupi and Arawak are two of the most important of these languages today, and Tupi has contributed greatly to the word stock of Brazilian Portuguese. Sharing a number of similarities with Tupi, Carib is spoken primarily in the northern region of Brazil as well as in the northern South American countries of Colombia, Venezuela, Guyana, Belize, and Guatemala. The two language families are not only thought to have so many similarities due to genetic affiliation, but also because of a great deal of contact among some of the languages of the two families. Although some of the indigenous languages of South America build sentences from very simple words, most tend to favor highly complex word structures and most tend to prefer suffixation over prefixation. In addition to interest in how language families relate to one another genetically, there is also great interest in how languages within families are related to one another geographically, especially those associated with the Amazon Basin, as many families are distributed disparately throughout the area. Additionally, due to a history of slavery among the tribes of the region, multilingualism has been very common among the Indian tribes of the Amazon basin.

Despite some effort to maintain indigenous languages, many languages have been lost due to assimilation into mainstream society. Languages continue to be lost in Brazil as indigenous peoples are assimilated into the mainstream culture and younger generations become monolingual speakers of Portuguese. While the linguistic diversity of Brazil, as with South America as a whole, is widely recognized, description of these languages has been insufficient for a number of reasons such as the bureaucratic difficulties of working with indigenous peoples, inadequate funding, and limited linguistic training.

Portuguese

The Portuguese were the first Europeans in Brazil, arriving in 1500, several years after Christopher Columbus' first voyage to the Caribbean. Although the Spanish, led by Columbus, were the first Europeans to arrive in the New World, the Portuguese had always dominated the seas in terms of long-distance travel. By the end of the fifteenth century, the Portuguese had already succeeded in sailing around Africa to reach India, establishing an important trade route. The discovery of the Americas by the Spanish no doubt threatened Portugal's dominance of the seas, and the Portuguese soon sought to establish their own colonies in the New World.

The status of Brazil as the only Portuguese-speaking country in South America has to do with the ways in which the Portuguese and the Spanish made use of their colonized land. A treaty between Portugal and Spain in 1494 divided South America into two parts, giving Spain control of the western side and Portugal control of the eastern side. In Brazil, the main source of wealth became the production of sugar cane, while in the Spanish colonies, the main source of wealth was the extraction of precious metals, most notably gold and silver. Sugar cane production required a highly organized society in Brazil, with large pieces of land and numerous slave workers imported from Africa. The search for gold and silver, on the other hand, could be done by smaller groups of people, and its success often relied on chance. Thus, while the Portuguese colonization of Brazil was fairly organized, the Spanish colonization of the rest of South America was more fragmented and lacked a single centralized government.

There was never any question that Portuguese would be the official language of Brazil; what was under debate was which Portuguese would be used. The popular Portuguese of Brazil has always been markedly different from European Portuguese. The Brazilian people do not consider themselves direct descendants

of the Portuguese colonists but rather as a mixture of Portuguese, Indian, and African people, and the language of Brazil has always reflected this mixture of cultures. By the nineteenth century, people began to debate the existence of a 'Brazilian language', and writers such as José de Alencar reacted by using words and expressions they felt reflected Brazilian rather than Portuguese culture. This trend continued into the twentieth century, especially in the modernist movement of the 1920s. Nevertheless, Standard Brazilian Portuguese tends to follow norms inherited from European Portuguese, even while allowing for some differences in vocabulary and spelling. For instance, in European Portuguese, the subject (pronoun) of the sentence is frequently dropped, and phrases generally avoid beginning with an object pronoun. Rather, the object pronoun is placed after the verb, as in *esperou-me* 'he or she waited for me' (lit. 'awaited-me'). In colloquial Brazilian Portuguese, however, it is more common to use subject pronouns, and object pronouns are almost always placed before the verb (or not used at all in the case of the third person); thus, *ele/ela me esperou* 'he or she waited for me'. (lit. 'he or she me awaited') However, forms such as *esperou-me* are frequently encountered in texts, and such forms are the ones taught in schools. Although phrases beginning with an object pronoun, such as *me esperou*, are not uncommon in speech, grammarians consider them incorrect usage.

Differences in vocabulary and pronunciation between European and Brazilian Portuguese tend to be less stigmatized than grammatical differences. Many lexical items are different in the two varieties, such as Brazilian *meia* and European *peúga* 'sock'; others have different spellings and/or pronunciations, such as Brazilian *fato* and European *facto* 'fact'. It is pronunciation that most clearly marks speech as either Brazilian or European, regardless of the level of formality. Some highly noticeable differences include the pronunciation of final -e in words like *nove* 'nine' as [i] in Brazilian Portuguese and as either schwa or silent in European Portuguese and the palatalization of /t/ and /d/ before /i/ in most regions of Brazil (i.e. *ti* is pronounced as [tʃi], *di* as [dʒi]).

There are also many varieties of Portuguese in Brazil with every major city noted for having its own accent. Rio de Janeiro, for example, is characterized by its use of alveopalatal s and z in the syllable-final position. A word such as *nós* 'we', then, is normally [nɔʃ] in Rio and surrounding areas, while in most other cities in Brazil, it is typically [nɔs].

African Languages

The ancestors of African Brazilians arrived as slaves beginning in the middle of the sixteenth century and ending with the end of the slave trade in 1850. More than two million slaves were imported into Brazil to provide labor on the sugar plantations and in the gold mines, with the greatest numbers being brought in during the first part of the nineteenth century. This population greatly increased that of Brazil during this period. The varieties of African languages that existed in Brazil were influential in the formation of various Brazilian creoles and had some effect on Brazilian Portuguese; however, these languages have generally been lost in Brazil over the years. Yoruba and other African languages, however, continue to be used in the religious ceremonies of the Candomblé societies.

Creole Languages

The great variety of indigenous languages in Brazil and language contact between them and the early Portuguese, as well as the importation of African slaves, resulted in the development of a variety of pidgins and creoles in Brazil. Lingua Geral, a trade language created by Tupi Indian nations along the coast, for instance, was popular until the end of the seventeenth century and was still used in some isolated areas, particularly in the Amazon Basin, until the late nineteenth century. Brazilian Creole Portuguese is still spoken to some extent, mostly by rural Brazilians of African descent in the north. Although these various contact languages were tolerated and even viewed as useful during the early colonization of Brazil, the rise of Portuguese as the official language of the country, and as the lingua franca in contact situations, has done a great deal to reduce the creole-speaking population.

Other European Languages

Immigration into Brazil by non-Portuguese Europeans began around 1850, primarily involving Italians and Germans settling in the subtropical regions near the Atlantic coast, especially in the states of São Paulo, Paraná, Santa Catarina, and Rio Grande do Sul; immigration by these groups generally ended by the time of World War II. These languages are still used in some of the more homogeneous of these communities to some extent, particularly in religious ceremonies. The Japanese began arriving and settling in approximately the same region around the turn of the twentieth century, and their language is still used to a great extent in Brazil. English and French, and to a lesser extent German and Italian, are taught as second languages in schools.

Illiteracy

In addition to the loss of indigenous languages in Brazil, another significant problem of note is the high

illiteracy rate, estimated in 2002 as 16.7% of the population. Although there are numerous literacy programs available in Brazil, especially in churches, and literacy has become much more widespread since the early 1900s, illiteracy is in reality only a small part of a larger problem. People in the lowest classes are not always encouraged or even expected to go to school, and the drug trade and other crimes often provide a much faster way to make money than getting an education.

Southeast Asia

A region comprising both the Indochinese and Malay peninsulas, as well as several island groups in the area, Southeast Asia is home to a great number of people and cultures. Bordered on the north by the Yangtze River in China, on the east by the South Pacific Ocean, on the south by the Indian Ocean, and on the west by the Indian Ocean, the Bay of Bengal, and the subcontinent of India, Southeast Asia includes the countries of Brunei, Myanmar (formerly Burma), Cambodia (Kampuchea), Indonesia, Laos, Malaysia, Singapore, Thailand, Vietnam, and the Philippine Islands, as well as the southernmost region of China. Owing in part to the diverse geographical makeup of the area and the lengthy and intricate historical relationships of its inhabitants, Southeast Asia is a region of great linguistic variety and complexity.

Although more than a thousand languages are spoken in Southeast Asia, five language families are particularly well represented in the region: Sino-Tibetan, Mon-Khmer, Tai, Miao-Yao (also known as the Hmong-Mien), and Austronesian. While such major languages of the Sino-Tibetan family as Chinese and Tibetan are spoken primarily in China and the Himalayas, speakers of these languages can also be found in great numbers throughout Southeast Asia, particularly in those countries sharing a border with China. In addition to being widely spoken in Southeast Asia, Chinese has also had a great influence on many

languages in the region, particularly with respect to vocabulary. Due to China's long domination of Vietnam from 111 BC to AD 939, Chinese has probably had the greatest influence on Vietnamese, most notably in its legal and medical terminology. A number of other Sino-Tibetan languages are spoken almost exclusively in countries of Southeast Asia, including Burmese, the official language of Myanmar, a country of over 35 million people.

The Mon-Khmer language family is another important family in Southeast Asia and includes Khmer, which is the official language of Cambodia and has approximately seven million speakers, and Mon, which was an important language in earlier times, but has been reduced to about one million speakers. Just as Chinese has had a great influence on the languages of Southeast Asia, so too has Khmer, particularly during the Angkor period, which lasted from approximately the ninth to the fifteenth centuries AD. As a result of Khmer dominance during this period, Khmer vocabulary is well attested in the lexicons of many languages of Southeast Asia, including Thai and Lao. Vietnamese, which is the official language of Vietnam and is spoken by about 80 million, is also classified by most scholars as a member of the Mon-Khmer family; however, this classification has been somewhat controversial, mostly due to the phonemic status of tone in Vietnamese, a trait not shared by other Mon-Khmer languages. This

difference led earlier scholars to classify Vietnamese as a Tai language; however, Haudricourt (1954) accounts for the use of tones in Vietnamese as the result of an evolutionary process in which Vietnamese acquired tones from other languages in Southeast Asia, notably Chinese, via language contact. Linguists often classify the Mon-Khmer family as a member of the Austro-Asiatic family of languages together with the Munda family of India.

Another language family of great importance in Southeast Asia is the Tai family, a group of tonal languages spoken primarily in Thailand, Laos, and southern China. The two major languages of the Tai family are Thai, which is spoken by about 50 million people and is the official language of Thailand, and Lao, which is spoken by about 10 million and is the official language of Laos. Other languages in the Tai family include Shan, a language spoken by over two million in Myanmar, and Chuang, which, with over 15 million speakers, is the language of the largest ethnic minority in China.

Languages in the Miao-Yao family are spoken in isolated areas of southern China and in the northern regions of Laos, Thailand, and Vietnam. The main languages of the group are Miao, which is spoken by about two and a half million people, and Yao, spoken by about one million. Many scholars consider the Miao-Yao family a branch of the Sino-Tibetan family, although it has also been proposed that the family is a branch of either the Tai or the Mon-Khmer family.

The Austronesian languages, formerly called Malayo-Polynesian, are spoken on the Malay Peninsula and on most of the islands to the southeast of mainland Asia. Distribution of the family's languages actually extends far beyond the region of Southeast Asia with member languages spoken from Madagascar to Easter Island and from Taiwan to Hawaii, as well as in and around New Zealand. The family comprises approximately 200 million speakers of at least 500 languages. In Southeast Asia, the principal Austronesian languages are Indonesian, which is the official language of Indonesia and is spoken by about 20 million, and Malay, spoken by about 10 million and the official language of Malay. Some linguists have claimed that Indonesian and Malay are essentially the same language, differing only in orthography and political identity. Another important language of the Austronesian group is Tagalog, which has been the national language of the Philippine Islands since 1962 and has about 15 million speakers.

Despite the great number of differences between the various languages spoken in Southeast Asia, some scholars have pointed out a number of commonalities, suggesting that the languages share a genetic relationship as well as an areal one (see e.g. Matisoff 1978). These shared characteristics include similar patterns of nominalization, compounding, and the use of classifiers rather than morphemes to mark gender. Additional support for this position is that discourse patterns tend to be similar in various Southeast Asian languages. However, the often intense and diverse contact in the region makes it as difficult for linguists to determine whether characteristics have been borrowed by languages as it is to identify with precision the classification of the various languages. In addition to the problem created by contact among neighboring languages for hundreds of years, the great influence over the entire region by such historical powers as Chinese and Khmer, as well as the influence of languages and cultures from outside Southeast Asia, tends to blur the distinction between languages. Numerous words, for instance, have been borrowed into many Southeast Asian languages from Sanskrit, while others have been borrowed from Pali due to the adoption of Buddhism by some Southeast Asian cultures.

Languages well outside Southeast Asia, especially a number of European languages, have also had an impact on the languages of the region. French has been an extremely influential language, particularly in Vietnam and Cambodia, countries that were under the rule of the French from the mid-nineteenth to the mid-twentieth century. During this time, French was recognized as the official language of both countries, serving primarily as the language of government and education. Although both Vietnam and Cambodia became independent of French rule shortly after World War II, the bonds between France and Southeast Asia have not been completely severed as evidenced in the continuing migration of natives of Southeast Asia to France. The influence of the French on various Southeast Asian languages is most readily apparent in their lexicons, especially with respect to words relating to the government and the military. Spanish is also of some significance in Southeast Asia due to its long domination of the Philippines from the mid-sixteenth century until the end of the nineteenth century; the best evidence of Spanish is found in the lexicon of Tagalog, which includes hundreds of Spanish words. English is yet another European language that has had some influence on the region, primarily due to the American presence in the Philippines during the first half of the twentieth century, American involvement in the Vietnam War, and the role of English in international trade and diplomacy.

Contact between Southeast Asians and others has resulted in the formation of a great number of pidgin and creole languages in the area. As in other parts of the world, Portuguese played a crucial and early role in the creation of pidgins and creoles in Southeast Asia, particularly in Indonesia, which hosted a number of Portuguese-based creoles that are now all considered extinct. The Portuguese presence in the region, which

dates back to the fifteenth century, also led to the development of a number of other Portuguese-based creoles, including Burma-Siam Creole Portuguese, of which a small number of speakers can be found in Penang, and Papia Kristang, which is spoken in Malaysia and Singapore. Perhaps an even greater number of pidgins and creoles in Southeast Asia developed due to contact between speakers of Spanish and speakers of various languages on the Philippine Islands, where the number of Creole Spanish speakers stands at around 280,000. These contact languages include Bamboo Spanish and Kitchen Spanish, which are used primarily by Chinese shopkeepers in the Philippine Islands. Another contact language that developed in Southeast Asia, this time as a result of contact between speakers of French and Vietnamese, was Tay Boy, a Vietnamese-French pidgin spoken during the French domination of Vietnam from approximately 1860 to 1960. Contact between speakers of English and Vietnamese during the Vietnam War resulted in Vietnam Pidgin, which is now largely extinct; in Singapore, contact between English speakers and native inhabitants resulted in the formation of Singlish. There is also a mixed language in Southeast Asia called Davaoeno, which is a fusion of Tagalog and Visayan and is spoken by approximately 125,000 speakers in Davao.

One linguistic issue of great importance in Southeast Asia, as it is in Asia in general, concerns the various writing systems that have been implemented to represent the languages of the region. Many Southeast Asian languages, including Burmese, Cambodian, Lao, and Thai, are written in a Brahmi script that was imported from South India in the fourth or fifth century AD and has undergone some modification. Several languages, including Vietnamese and Indonesian, are now written in the Roman alphabet, which was introduced by missionaries in the region in the seventeenth and eighteenth centuries, and, in the case of Vietnamese, replaced an earlier system based on Chinese orthography. Still other languages, such as Malay, have incorporated some Arabic characters into their writing systems. Each of these writing systems presents a number of problems. Although the

Southeast Asian languages that use the Brahmi script have modified it to some degree to reflect the sounds of their own languages, the Indian language that it was borrowed from differed significantly from the Asian languages it is now used to represent. The result has been the extensive use of subscript and superscript symbols to represent vowels. Although some have pointed to it as an example of successful writing reform, Vietnamese shares in this problem and makes such wide use of diacritics that some scholars have remarked that it hardly constitutes true reform (see Hannas 1997). The problem that these systems share is the difficulty they create for printing processes, both because of the amount of paper required for printing the great number of diacritics as well as the extra time required to keyboard the extra symbols. These problems have typically been at the core of the debate over writing reform for Southeast Asian languages in modern times. Another has been that there are many minority languages in Southeast Asia, often spoken in the mountains of the region as opposed to the plains and valleys, for which there are no writing systems at all.

LAMONT ANTIEAU

Soviet Union

From its inception in 1917 to its ultimate breakup in 1991, the Soviet Union was a multilingual and multiethnic state. At its point of greatest expansion, it encompassed some 8,649,490 square miles with a total population of just under 286,000,000. The population is unevenly distributed among the ethnic groups and

languages, with some very large and some quite small in number. Russians comprise the largest single ethnic group, constituting just over 50% of the total population (or slightly more than 145,000,000) in the 1989 census. Russian was one of several Slavic languages spoken in the USSR, although by far the most widely used and it alone had the status of a national lingua franca. The Russian language has by far the largest number of speakers, with 81% of the population seeing itself as fluent in Russian, either as a first or second language.

Language and Ethnicity

The 1989 Soviet census cites approximately 130 ethnic groups (including indigenous and immigrant populations) speaking a total of 150 languages. (Linguists, however, estimate that there were actually closer to 200 languages spoken in the former USSR.) There is not, however, any one-to-one correspondence between language and ethnicity, as these figures show. In the USSR, all citizens aged 16 years and higher were required by law to declare their 'ethnicity' (*natsional'nost'*), which was officially recorded in each individual's (internal) passport. The census regularly asked questions about language use and ethnicity as well, but because language/dialect boundaries were often determined by social and political factors rather than linguistic ones, and the number of official languages and ethnic groups changed in accordance with changing political goals. For example, three Tungusic languages—Even, Evenki, and Negidal—were long considered to be dialects of a single language, although all are linguistically distinct, so that when they each acquired official recognition, there was a net increase in the number of ethnic groups. Accordingly, official Soviet statistics should be taken as providing only partial information about the linguistic map. Speaker population size and density vary significantly: some languages have millions of speakers, while others have only thousands or even hundreds of speakers. Some are in dense speaker communities in urban areas, while others are traditionally nomadic and have dispersed populations.

Linguistic Diversity

The many languages of the USSR can be classified into five large language families: Indo-European, Caucasian, Altaic, Uralic, and Paleo-Siberian. In addition, there are a number of language isolates (e.g. Ket, Nivkh, Yukagir). A number of Indo-European languages are native to territories of the USSR: the East Slavic languages (Russian, Belorussian, and Ukrainian); the Baltic languages (Latvian and Lithuanian); Armenian; a Romance language (Moldovan, which is minimally dis-

tinct from Romanian); Iranian (Tadzhik) as well as Germanic (German and Yiddish), and a few others. Of these genetic groups, Indo-European is the most well defined. The genetic relations of the Uralic languages (e.g. Finno-Ugric languages such as Estonian, Permic, Samoyedic, and Volgaic) are also clear. The Caucasian languages are divided into three or four subgroups, whose relations to one another are disputed. The Altaic languages are commonly divided into three language families (Mongolian, Tungusic, and Turkic), and although these three families constitute clear genetic groups, their relations to one another are the matter of much debate. Paleo-Siberian is an even more loosely defined category, as it groups together the languages of Siberia that do not belong to any of the other genetic groups (e.g. Altaic, Uralic, etc.). Two relatively small language families (Chukotko-Kamchatkan and Eskimo-Aleut) are usually placed in the Paleo-Siberian group.

The Soviet Union was organized into 15 union republics (or SSR, for Soviet Socialist Republic), which can be grouped into categories according to geography: the Baltics (Estonian SSR, Latvian SSR, and Lithuanian SSR); the Caucasus (Armenian SSR, Azerbajdan SSR, and Georgian SSR); Central Asia (Kazakh SSR, Kirgiz SSR, Tadzhik SSR, Turkmen SSR, Uzbek SSR); Slavic territory and Moldova (Belorussian SSR, Moldavian SSR, Russian SFSR, Ukrainian SSR); and the Russian Far East (RSFSR, primarily Siberia). Each Republic bears the name of its majority ethnic group, but it should be stressed that these are political, not ethnolinguistic divisions. Ethnic Russians lived in all republics in varying numbers. The Russian Republic was the largest in terms of territory and also had the highest percentage of ethnic Russians. Moreover, varying numbers of other ethnic groups lived in each of the republics, and some were dispersed over several. The Tatars, for example, with a total population count of 5.5 million in 1989, live scattered in 80 different regions of the former Soviet Union, with only 26.6% of their total numbers living in Tatarstan (Russian SFSR), another 17% in other regions of Russia, 7% in Uzbekistan, and so on.

Soviet Language Policy

The newly formed Soviet state faced illiteracy rates of nearly 100% in some areas, with an overall average literacy rate of only 28.4% for the entire country. In order to achieve their goal of rapid industrialization, the Bolshevik leaders required a fairly educated work force, which made a rapid increase in literacy one of their priorities. The sincerity of early Soviet language policy has been the subject of much debate, but Lenin's basic principle was unambiguous: no one language should be given the status of a state language

but rather, national equality and self-determinism must be promoted. The Declaration of Rights of the People of Russia (November 2, 1917) proclaimed equality for all people, with 'the free development' of the national minorities and ethnic groups inhabiting the USSR. All Soviet citizens were guaranteed education in their native language.

The literacy campaign was a fundamental part of the larger nativization or, literally, 'rooting' (*korenizacija*) policy, a policy intended to educate the indigenous peoples and move them into the workforce, especially into the Soviet administrative workforce. A major obstacle to achieving this goal was the overall low educational levels nationwide. Thus, the success of the nativization policy depended upon the ability of the government to educate its people. At the time of the formation of the Soviet Union, the majority of languages needed linguistic description and codification, and creation of a written form. Some linguistic regions (such as Georgia and Armenia in the Caucasus, and the Turkic-speaking Central Asia) had long-standing literary traditions, as did the Georgian and Armenian languages in the Caucasus and the Turkic languages in Central Asia. At the same time, many of the languages of the newly formed empire lacked written forms. It is estimated that at the time of the Bolshevik Revolution, only 13 languages on Russian territory had a literary norm, and only 19 had any kind of written form at all.

The Roman alphabet was initially chosen as the basis for all new writing systems and was also used for those languages not using Cyrillic, such as those using an Arabic or Mongolic script, although Georgian and Armenian were allowed to maintain their own alphabets. The use of Romanized script was short-lived, being phased out in favor of Cyrillic in the mid- to late 1930s and completed in the early 1940s. This transition to Cyrillic-based alphabets was part of a shift in language policy, which began after Lenin's death in 1924. A key date is 1934, when Stalin effectively ended the nativization campaign in an address to the XVII Party Congress. In March 1938, an official decree made the study of Russian compulsory.

Alphabet creation was just one step in the literacy campaign. Equally important was the creation of a standardized literary form for each of the targeted languages. Originally, emphasis was placed on phonetic spelling, which created problems due to vast dialectical differences for some languages, and due to the large influx of Russian borrowings as a result of the sociopolitical and economic changes. The creation of a new lexical inventory was an equally vital component of this larger campaign. Initially, it was argued that each of the national languages should have a complete inventory of all technical terms, created using language-internal resources wherever possible.

Ultimately, this did not occur, as the spheres of usage of many of the national languages were quite limited, making this native technical terminology superfluous. Where loans were concerned, the early policy was to maintain the pronunciation of the lending language. This policy was changed by the 1950s, when all loanwords were written in the original Russian form.

Despite the many controversial aspects of the Soviet literacy campaign, it did achieve rapid results. The literacy rate climbed dramatically from 44.1% in 1920 to 87.0% in 1939 to an official rate of 99.7% in 1979.

The mid-1950s witnessed yet another major change in language policy. Prior to this period, the national languages were the focus of Soviet language planning. From this time onward, the goal of Soviet language policy was to establish Russian as the language of the Soviet Union. The Khrushchev era (1953–1964) introduced the vision of a new Soviet people, united not only politically but also through the use of one language. Khrushchev declared Russian to be 'the second national language'. Although bilingualism was openly promoted, the very need for national languages (any language other than Russian) was questioned. The Khrushchev introduced the notion of the 'relative' importance of languages, and it became officially acceptable to view some languages as less viable than others: some languages were deemed unsuitable for development. Yet, Lenin's policies of language equality were not officially repudiated, and the Communist Party could invoke them to justify its own policies at any time.

This occurred along with a major change in education policy. Clause 19 of the Education Reforms of 1958–1959 stated that education in the mother tongue was no longer compulsory. By this time, instruction in the native language was offered for most languages with a written form at an elementary level, and at a secondary level for some. One impact of the Education Reforms was pressure to begin instruction in Russian from the earliest grades, and the native language was replaced by Russian in many schools. Even where native-tongue education continued, Russian was a compulsory subject.

The results of the Education Reforms varied throughout the country. Despite the shift in emphasis on Russian, languages spoken by larger populations may have actually gained some ground, in part due to the lessening of cultural restrictions under Khrushchev. This was the case in Central Asia, for example. In contrast, minority languages became seriously threatened as they were no longer used in schools, and publications in these languages were seriously cut back. Regardless of the local-level particulars, the major change of this period is that Russian became the official language of the USSR and occupied a central position in education and government.

This process continued under Brezhnev (1964–1982), in a greater move toward total Russification, with increasing pressure to make Russian the 'second mother tongue'. Official statistics show Russians to be largely monolingual (97%), while over 40% of the non-Russian population claimed itself to be bilingual, and by 1979 a total of 82% of the population claimed some knowledge of Russian. Translation work was primarily unidirectional, from Russian into the native language. The Brezhnev period is characterized by a steady increase in both the sheer volume of instruction in Russian, which was progressively replacing the national languages in non-Russian schools, and a continuous growth in the number of institutions where Russian was the sole operative language. Party rhetoric proclaiming the importance of Russian increased. The official view of a single Soviet ethnic group, the result of 'the convergence and fusion of peoples' (*sblizhenie i slijanie narodov*), was becoming a reality. The sphere of Russian usage spread beyond education to many administrative levels, including local-level administration. It had become the lingua franca of the USSR.

Mikhail Gorbachev came to power in 1985, and his restructuring program, *perestroika*, focused governmental attention on economic and political problems. Until 1989, both language and nationality policies remained essentially unchanged from previous years; in fact, they received little attention from the central government in Moscow. In many regions, the linguistic situation was essentially stable throughout this period; yet, a number of Republics began to change language policies within their own territories. By the end of the Soviet era, most of the territories that remained in the Russian Federation had adapted legislation to place the titular language, the language of the ethnic majority of their region, on an equal level with Russian.

LENORE A. GRENOBLE

Soviet Union: Successor States

Geographically, the former Soviet Union occupied one sixth of the Earth's land surface stretched from the Baltic Sea in the West to the Pacific Ocean in the East, from the Arctic Ocean in the North to the Black Sea and Tian Shan mountains in the South. It accommodated a number of ethnic groups with more than 100 languages, which can be combined into six major language families. There were 15 Union Republics with a total population of more than 240 million people, who shared common Soviet political experience for about 70 years.

The Soviet multilingual state originated from the state of Kievan Rus (ninth–twelfth centuries CE). By the fourteenth century, Moscow accumulated enough power to become a new political center of Slavic-speaking people. The expansion of Russia to the east, north, and south to the areas populated with non-Slavic people started in the sixteenth century. Russia annexed the lands of Kazan and Astrakhan Khaganats (Turkic-speaking people), defeating the Mongol Horde. They also conquered Finns in the northwest (Finno-Ugric language family), and proceeded further to the east, adding Siberia, the Far East, and Alaska to the Empire.

Russian Empire. By the end of the nineteenth century, the Russian Empire celebrated its last acquisition, the territory of Caucasus and Turkistan (present Central Asia). To run such a huge multiethnic state would have been impossible without promoting the use of a single language in all spheres of life including administration, legislation, education, etc.; hence, the Tsarist government began implementing its policy of russification. The policy implied a ban or restrictions on the use of languages other than Russian in government, education, the press, and books. In order to enforce this policy, the government encouraged the migration of ethnic

Russian population into other parts of the Empire and elevated the literacy rate through the study of Russian. The policy of russification was implemented by the Tsarist government in all of the provinces of the Russian Empire since the 1860s. However, in different parts of the Empire, the implementation of this policy was not uniform. On the one hand, in Ukraine any publications in Ukrainian language were prohibited, and the only language of instruction in Ukrainian schools and universities was Russian. Moreover, the Ukrainian and Belarusian languages were considered to be variations of the Russian language. On the other hand, people in Turkistan were not restricted in the use of their languages. Also, the Tsarist government did not attempt to change the Arabic-based alphabet of the Turkistanese into Cyrillic script. Turkistan enjoyed this freedom as a result of the Tsarist government's policy of avoiding unrest in newly acquired territory populated by people of different faith. However, the government encouraged Russians to move to Turkistan, thus providing a base for cultural and linguistic changes. By 1917, most of the major languages of the former Russian Empire had their own alphabets: for example, Central Asians and Azeri people used Arabic script, Baltic peoples used the Latin alphabet, and Armenians and Georgians had alphabets of their own.

Soviet Union. During the time of the Union of Soviet Socialist Republics or USSR (1922–1991), the language policy was a complex issue, revised with every change of the Soviet leadership. The Russian language preserved its dominating role and continued to serve as the lingua franca, enabling communication across the country's numerous ethnic groups. However, the Soviet government imposed several changes in language policy. In the mid-1920s, the Soviet government began a campaign to develop alphabets based on Latin script for most non-Slavic groups of the country. The Arabic script of the Muslim population was changed into Latin script. However, the strong and established traditions of written language in Georgia and Armenia withstood the government's campaign, and the ancient alphabets were preserved. The underlying rationale in the change of alphabets was the attempt of the Soviet government to cut off all the ethnic groups from their cultural, ethnic, religious, and ideological roots, and to begin implementation of the totally new culture and ideology of the Soviet state. Also, alphabets were created for those small ethnic groups who had never had a written language before.

In the late 1930s, there was yet another sudden change in the Soviet language policy, which was only possible due to tough political measures used by the Soviet government. The change, initiated under the rule of Stalin, was aimed at achieving the huge task of

unifying the scripts into Cyrillic, in order to strengthen the Soviet identity and begin the creation of the Soviet nation. The Latin script created for different ethnic groups in the 1920s and 1930s was replaced with a modified Cyrillic. Extra letters were added to the alphabet to reflect those sounds in non-Slavic languages that were not present in Russian.

At the same time, the Soviet government encouraged development of the literary language of each ethnic group, and each ethnic group could proudly name national writers who wrote in their language. Each Union or autonomous republic had radio and later TV channels broadcasting in their national language. Books, newspapers, and magazines were published in national languages as well. Nevertheless, the aim of the Soviet government to strengthen the role of the Russian language was never abandoned. Official propaganda put the Russian language as the language of Lenin, Stalin and the revolution, the language of the largest and greatest nationality, and the language of great Russian writers.

At primary and secondary education levels, people generally had a choice of the language of instruction since there were classes taught in Russian or in the language of the eponymous nationality, Kyrgyz in the Kirgiz SSR, for example, or Moldovan in the Moldavian SSR. At tertiary institutions, Russian was the major language of instruction, with some exceptions. For example, Ukrainian was used as the language of instruction in social sciences, art, and literature in Kiev, or Tajik was used in social sciences, art, and literature in Tajikistan. Similar arrangements existed in each of the 15 Union Republics. All official government business was conducted in Russian, with the exception of local governments in the Union Republics that used local languages as well as Russian. However, military officers gave their orders in Russian. The policy of russification that was continued by the Soviet government created a single literary language, that was used by most of the people in the USSR.

The government encouraged ethnic Russians to move to other parts of the country in order to promote cultural convergence. However, the first wave of Russian migrants did not go willingly. During the collectivization campaign of the 1920s and 1930s, millions of wealthy peasants had their property confiscated and were banished to Siberia, the Far East, or Central Asia, thus diluting the local population. Another wave of migration took place during and after World War II, when plants and factories were moved, together with their workers, from potential war zones in the European part of the USSR to Siberia and Central Asia. The last major wave of migration occurred in the 1950s during the virgin land campaign, when young people from all over the country came to

the Kazakh SSR with the aim of growing wheat in its vast wild steppe. After the completion of the campaign and establishment of kolkhozy (collective farms) in Kazakhstan, some of these people remained in Kazakhstan or moved to the neighboring republics.

During World War II, there was also a relocation of whole ethnic groups away from the war zones. Germans, Crimean Tatars, and Koreans were forcibly relocated to Central Asian Republics, as the Soviet authorities feared their collaboration with the occupation army.

This reshuffling of nations within the country led to a multinational composition of each republic of the Soviet Union. Often, children of at least five different ethnic groups could be sitting in one class. By 1991, the year of dissolution of the USSR, around 25 million of Russians lived outside Russia.

Post-Soviet Era. After the dissolution of the Soviet Union in 1991, 15 new countries appeared on the world map. This event was indicative of many dramatic changes in the lives of the peoples. Along with major economic, political, and social transformations, there were changes in the language policies in each of the new countries.

One of the prominent changes was that the status of the Russian language in all of the new countries, with the exception of the Russian Federation, was reversed. From its dominating position, it now became the language of Russian-speaking minorities. The languages of the titular nations of each new post-Soviet country were declared the state languages, and they are increasingly replacing Russian in all spheres of life, including education, mass media, and administration. Under the Soviet policy of russification, the Russians did not have to learn languages of titular nations of other Soviet republics. In Estonia, for example, according to the 1989 census, around 80% of ethnic Russians did not speak Estonian at all. Dramatic changes in the language policies in the newly independent republics forced a sizeable proportion of the Russian-speaking population (i.e. representatives of nontitular ethnic groups) to leave the places they were born in or lived in for decades and move to Russia, although a considerable number of Russians still live outside the Russian Federation. Here are some figures for 1998: 34.7% of the total population of Kazakhstan were Russians; 30.4% in Latvia; 28.1% in Estonia; 22% in Ukraine, 18% in Kyrgyzstan, 13.2% in Belarus; 13% in Moldova; 8.7% in Lithuania; 6.7% in Turkmenistan, 6.3% in Georgia; 5.5% in Uzbekistan; 3.5% (this number is declining due to emigration) in Tajikistan, 3% in Armenia, and 2.5% in Azerbaijan.

An outstanding example is that of the Baltic countries, Estonia, Latvia, and Lithuania. The Russians who arrived or were born in those countries after the 1940s were not legally considered citizens unless they passed a language examination. The Laws on Citizenship, adopted in the Baltic countries after independence, made most of the representatives of the Russian-speaking minority (Belarusians, Russians, and Ukrainians) 'noncitizens'. This policy created ethnic tensions between the titular nations and Russian-speaking minorities. For example, in Estonia the population of Russian-dominated Narva demanded secession or at least regional autonomy.

A unique language policy is observed in Kyrgyzstan. Although the Kyrgyz language was declared the state language, the Russian language was given official status in 1996 and became the state language along with Kyrgyz in 2000. The reasons were continuing ties with Russia, financial considerations, and the disappearance of the threat of russification, since the majority of the Russian-speaking population had left the republic.

Another change in language policy was demonstrated in the attempts of some of the newly independent countries to change the Cyrillic alphabet to either Latin or Arabic. The changes of the scripts were aimed at highlighting the idea of independence from Russia, of national state-building, and as a symbol of the revival of the nation's culture, traditions, and language. Financial considerations and the enormous complexity of this task prolonged the change of the script in some of the republics. Other republics postponed it indefinitely. In Turkmenistan, a Latin-based Turkish alphabet replaced Cyrillic. Moldova switched to a Latin-based script. Tajikistan is gradually implementing a change to Arabic. In Uzbekistan, the script has been changed to Latin. In Azerbaijan, the alphabet reform of 2001 implies transition to the Latin alphabet. Kyrgyzstan retains the Cyrillic script.

In the Russian Federation, the language situation also changed after 1991. The Russian language is still the lingua franca of this large multinational state. However, the uncontrollable inflow of the foreign, mainly English-based, words in mass media and colloquial language since the cultural isolation of Russia from the West ended together with the Soviet Union. This trend changed the Russian language dramatically. The literary language created during the Soviet time is deteriorating, and new language standards are being created.

Language Families

The 15 former Soviet Union republics bring together six language families: Indo-European, Altaic, Uralic, North-Western, North-Eastern, and South-Caucasian. There are also some limited language groups and separate languages in the far eastern Siberia, which can

FAMILY	Group	Main Languages
Indo-European		
	East-Slavic	Russian, Belarusian, Ukrainian
	Baltic	languages Latvian, Lithuanian
	Romance	languages Moldavian/Romanian
	Iranian	language Tajik, Kurd, Osetin
		languages Armenian language
Altaic		
	Turkic	Azeri, Kazakh, Kyrgyz, Turkmen, Tajik,
		Tatar, Uzbek and other languages
	Manchu-Tungus	Evenk, Even languages
	Mongolian	Buryat, Kalmyk languages
Uralic		
	Finno-Ugric	Estonian, Finnish, Khanty, Mansi, Mari,
		Mordvin, Karelian, Udmurt,
		Komi, Komi-Permyak, Veps languages
	Samoyedic	Nenets, Selkap languages
North-Western Caucasian		Adyghey, Kabardyn, Abkhaz, Circassian languages
South-Eestern Caucasian		Chechen, Lezginian languages
South Caucasian		Georgian language
Paleoasiatic		Chukcha, Koryak, Kamchadal languages and others

Figure 1. Language Families and Groups.

be grouped as a Paleoasiatic group. The languages of this group are not related and are placed together only geographically.

The Indo-European Family

East Slavic Languages: The Russian Federation, The Ukraine, Belarus

Russian. The largest successor to the Soviet Union is the Russian Federation. Its total population in 1998 was 146,001,176, which was represented ethnically as follows: 81.5% of Russians, 3.8% of Tatars, 3% of Ukrainians, 1.2% of Chuvashs, 0.9% of Bashkirs, 0.8% of Belarusians, 0.7% of Mordvins, and 8.1% of others. The Russian Federation is home to more than 70 distinct ethnic groups, some of which are extremely small and the six mentioned above are more than a million of people in each. There are 21 autonomous republics in the Russian Federation as well as ten autonomous districts and one autonomous region.

In spite of enormous ethnic diversity, the official language of the Russian Federation is Russian. The language is also spoken as a secondary language in other republics of the former Soviet Union as well as in some countries of Eastern Europe (former socialist block). Three dialects of Russian, i.e. northern, southern, and central, are only distinct from each other by minor variations in the pronunciation of some consonants and vowels, unlike the significant differences in dialects of European languages. Literary Russian is based on the Moscow (central) dialect and is written in Cyrillic.

Ukrainian. The second largest Slavic state of the former Soviet Union is the Ukraine. In 1998, its population was 49,153,027 with the following ethnic composition: 73% Ukrainians, 22% Russians, 1% Jewish, and 4% other ethnic groups. The Ukrainian language is the state language; Russian and Polish are also spoken. The Ukrainian language is also spoken in Ukrainian communities in Belarus, Russia, Poland, and Slovakia.

Ukrainian is the direct descendant of the language spoken in Kievan Rus and is written in the Cyrillic alphabet. Distinct differences between Russian, Belarusian, and Ukrainian languages emerged somewhere between the twelfth and thirteenth centuries; however, development of the standard Ukrainian

language was postponed due to long political subordination to Russia and Imperial Russia's policy of restrictions in usage of the Ukrainian language. Modern literary Ukrainian language began its development only at the end of the eighteenth century.

Belarusian. The third branch of east Slavic languages is spoken in Belarus (or White Russia). In 1998, there were 10,366,719 people and 77.9% of them were Belarusians. There were also 13.2% Russians, 4.1% Polish, 2.9% Ukrainians, and 1.9% others. The Belarusian language used to be the official language of Lithuania in the thirteenth–sixteenth centuries when Belarus was a part of Lithuania. After the merging of Poland and Lithuania in the sixteenth century, Belarus found itself under Polish jurisdiction until the eighteenth century. There are a large number of borrowings from the Polish language. Belarusian became the official language of Belarus from 1990. Russian language became the second official language of Belarus in 1996. Belarusian is written in the Cyrillic alphabet.

Baltic Languages: Latvia, Lithuania

Latvian. Is the official language of Latvia. Out of the total population of Latvia in 1998 (2,404,926), there were 56.5% Latvians, 30.4% Russians, 4.3% Belarusians, 2.8% Ukrainians, 2.6% Polish, and 3.4% others. In 1989, Latvian language replaced Russian in administration, education, media, etc., although Russian and some other languages are still used in everyday life. Latvian is written in the Latin alphabet.

Lithuanian. Is the official language of Lithuania. In 1998, there were 80.6% Lithuanians out of the total population of the country of 3,620,756 people, 8.7% Russians, 7% Polish, 1.6% Belarusians, and 2.1% others. Along with the official language, Polish and Russian are spoken as well. The first written documents in Lithuanian are recorded back to the sixteenth century. The Lithuanian language is written in the Latin alphabet.

Romance Languages: Moldova

Moldavian/Romanian. The only country of the former Soviet Union where people speak one of the Romance languages is Moldova. The population of Moldova consisted of 4,430,654 people in 1989 and constituted 64.5% Moldovans, 13.8% Ukrainians, 13% Russians, 3.5% Gagauz, 2% Bulgarians, 1.5% Jewish, and 1.7% others. In 1989, the Moldavian language (virtually the same as Romanian) was declared the official language; however, in 1994 the enforcement of the Law on Languages was relaxed due to the

rise of separatist tendencies from Slav-populated areas of Dnestr basin. The Cyrillic alphabet was replaced with Latin.

Armenian: Armenia

Armenian is spoken by a wide Armenian population worldwide. It is the language of Armenians in Armenia, Turkey, and other parts of the former Soviet Union, Middle East, America, Romania, Poland, France, and others. In 1989, in Armenia itself, there were 3,344,336 people and 93% of them were Armenians, 3% were Azeri (nearly all Azeri emigrated in 1993), 2% were Russians, and 2% were others. It is traditionally believed that the Armenian alphabet was created by the scholar and bishop St. Mesrop on the basis of Greek and Aramaic scripts sometime around 405–406 CE. In the twelfth century, there were two more letters added to the alphabet. Armenian literature appeared by the fifth century CE and the modern literary Armenian started developing in the nineteenth century.

Iranian Languages: Tajikistan, The Russian Federation, Georgia, Armenia, and Azerbaijan

Tajik. Is spoken mainly in Tajikistan. There were 6,440,732 people in Tajikistan in 1998 with the following ethnic composition: 64.9% Tajiks, 25% Uzbeks, 3.5% Russians (the number is declining due to emigration), and 6.6% others. Tajik language has been the official language of the country since 1989, although Russian is used in government and business. There are a large number of borrowings from Arab, Uzbek, and Russian languages. Before 1930, it was written in Arabic, when the script was changed to Latin; in 1940, it was changed to Cyrillic. The postindependence government is gradually implementing a change to Arabic.

Osetin and Kurd. There are also other small groups of Iranian-speaking people. Osetins are dispersed throughout Caucasus (Georgia, the Russian Federation). The first written document in the Osetin language is dated back to 941 CE on the basis of the Greek alphabet. In 1844, Shegren created the alphabet on a Cyrillic base, which was changed to Latin in the 1920s. In 1938, the Northern Osetian alphabet was changed to Cyrillic and the South Osetian alphabet was changed to Georgian. The latter was changed to Cyrillic in 1954.

Kurds populate areas in Turkmenistan, Armenia, Georgia, and Azerbaijan, Turkey, Afghanistan, and Lebanon. The Kurds of the Russian Empire used the Arabic alphabet; however, in 1921, it the Soviet government changed it to Armenian, in 1929 to Latin, and in 1946 to Cyrillic.

Altaic Group

Turkic Languages: Azerbaijan, Kazakhstan, Kyrgyzstan, Moldova, Turkmenistan, The Russian Federation, Uzbekistan

Turkic-speaking peoples live mainly in the Central Asian Republics, although there are some Turkic groups in the middle Volga region of Russia (Bashkirs, Tatars, Chuvash) and in the Caucasus (Azeri, Balkars, Karachays, Kumyks, and Nogays). In Siberia, there are numerous groups of Turkic-speaking population who live between the Ural and Lake Baikal (Altais, Khakass, Tofalars, Shors, Tuvans) and also Yakuts who mainly live in the middle Lena basin and Dolgans in the Arctic.

Azeri. Azeri is the state language of Azerbaijan. The total population of the country in 1998 was 7,748,163 people, 90% of whom were Azeri, 3.2% Dagestani, 2.5% Russians, 2% Armenians, and 2.3% were represented by other ethnic groups. The Russian language is still used in the country.

The literary Azeri language began its development from the eleventh century. Modern Azeri is based on Baku and Shemakhan dialects. The original Arabic script used by Azerbaijani people was replaced by Latin in 1929 and by Cyrillic in 1939. After 1991, the government introduced a language reform, part of which was the change to Latin script.

Kazakh. Is mainly spoken in Kazakhstan, which has the second largest population, after Uzbekistan, of the former Soviet Central Asia (16,733,227 people (1996)). The Kazakh language is also spoken in Sinkiang Uygur autonomous region in China and in Uzbekistan, Mongolia, and Afghanistan. In 1996 there were 46% Kazakhs, 34.7% Russians, 4.9% Ukrainians, 3.1% Germans, 2.3% Uzbeks, 1.9% Tatars, and 7.1% others in Kazakhstan. Kazakh people used the Arabic alphabet, which was changed into Latin and later to Cyrillic. The Kazakh language is the state language of Kazakhstan.

Uzbek. Uzbek is spoken primarily in Uzbekistan and in some parts of Kazakhstan, Tajikistan, Turkmenistan, Afghanistan, and China. In 1996, there were 49,153,027 people in the country; 80% of them were Uzbeks, 5.5% Russians, 5% Tajiks, 3% Kazakhs, 2.5% Karakalpaks, 1.5% Tatars, and 2.5% others. The Uzbek language is the official language of the country; however, Russian and Tajik are used as well. Although the Arabic script was used for written language before the Bolshevik Revolution, it was changed first to Latin in 1927 and to Cyrillic in 1940. The postindependence tendency was to change Cyrillic into Latin.

Kyrgyz. Is the state language of Kyrgyzstan with a population of 4,685,230 in 1996. A little more than half the population were Kyrgyzs (52.4%), 18% Russians, 12.9% Uzbeks, 2.5% Ukrainians, 2.4% Germans, and 11.8% other ethnic groups. The Kyrgyz and Russian languages are the state languages. Kyrgyz language used Arabic alphabet up to 1926 when it was changed to Latin; it was changed to Cyrillic in 1940.

Turkmen. Turkmenistan is a country of 4,518,268 (July 2000 est.) people. In 1995, there were 77% Turkmens, 9.2% Uzbeks, 6.7% Russians, 2% Kazakhs, and 5.1% others. The languages spoken are Turkmen, Russian, and Uzbek. The Turkmen language became the official language of Turkmenistan in 1990. A Latin-based Turkish alphabet was introduced in 1993, replacing Cyrillic.

Manchu-Tungus Languages: The Russian Federation

Another branch of Altaic languages, Manchu-Tungus languages, is spoken by the Evenks, Evens, and other small groups dispersed throughout eastern Siberia. These languages had never been written before the Russian revolution; presently, they are written in Cyrillic.

Mongolian Languages: The Russian Federation

The Mongolian languages are spoken in the Lake Baikal region (Buryats) and to the west of the lower Volga (Kalmyks). These languages got their first alphabet, Cyrillic, after the Russian revolution.

The Uralic Group

Finno-Ugric Languages: Estonia, The Russian Federation

The Finno-Ugric languages are spoken in Estonia and the European part of the Russian Federation from northwest (Karelians, Finns, and Veps) to the upper Volga river and the Ural mountains (the Mari, Mordvins, Udmurt, Komi, and Komi-Permyak) to lower Ob' river basin in Siberia (the Mansi and Khanty). The areas of Finno-Ugric-speaking population are intertwined with areas of other language families such as Slavic, Turkic, Baltic, and others. Close contacts with other people led to a large number of borrowings from Russian, Turkic, Romance, Iranian, German, and Baltic languages. Practically all of the Finno-Ugric languages, except Estonian, use the Cyrillic script.

Estonian. The total population of Estonia was 1,431,471 people in 1998. Out of them, Estonians constituted 65.1%, Russians 28.1%, Ukrainians 2.5%,

Belarusians 1.5%, Finns 1%, and others 1.8%. Estonians are the largest group of Finno-Ugric people in the former Soviet Union. Out of two main dialects, northern and southern, the former (or Tallinn) dialect served as a base for the Estonian literary language. The language is most closely related to Finnish, Livonian, Ingrian, Karelian, and Veps languages. It is written in Latin.

The Samoyedic Languages: The Russian Federation

The Samoyedic group is also quite dispersed in the Siberian tundra and taiga from Kola Peninsula to the Yenisey river (spoken by Nenets), around the middle Ob' river (spoken by Selkup) and in Taymyr Peninsula (spoken by Nhanasan). Samoyedic languages are agglutinative in structure and are spoken by a small number of people.

The Caucasian Family

This group is made up of more than 40 languages, that are spoken by about six million people. There are three main branches: North-Western (Abkhazo-Adyghian), North-Eastern (Nakho-Dagestanian), and South (Kartvelian).

North-Western: The Russian Federation, Georgia (Abkhazia)

Adyghey, Kabardyn, Abkhaz. It is characteristic of these languages that they obtained alphabets after the Russian revolution. Adyghey language was first written in Arabic script, which was later changed to Latin (1927) and then to Cyrillic (in 1938). The Abkhazian language was written in Latin since 1928; the script was changed to Georgian in 1938, and then to Cyrillic in 1954. Kabardin language was also first written in Latin (from the mid-1920s), and from 1936 in Cyrillic.

North-Eastern Languages: The Russian Federation, Dagestan, Azerbaijan

Chechen is spoken in Chechnya and Dagestan (the autonomous republics in the Russian Federation). The original Arabic script was changed to Latin in 1927 and to Cyrillic in 1938.

Lezginian language is spoken in Dagestan and Azerbaijan. The Arabic script was used for writing before the Russian revolution; in 1928, it was changed into Latin and in 1938 to Cyrillic.

South Caucasian Languages: Georgia

Georgian. Georgia's population in 1998 reached 5,019,538 people. There were 70.1% Georgians, 8.1% Armenians, 6.3% Russians, 5.7% Azeri, 3% Osetians, 1.8% Abkhaz, and 5% others. Georgian is the official language, although Russian, Armenian, and Azeri are used as well.

Georgian is written in its own alphabet, which is believed to have been derived by King Parnavaz in the third century BCE on the basis of the Aramaic script. The script was subjected to revision under the influence of Greek alphabet when Georgians embraced Christianity in the fourth century CE. In 1926, the Soviet government attempted to replace the alphabet with Latin with no success. Georgian is the only south Caucasian language with old literary traditions. Other south Caucasian languages, such as Mingrelian, Swan, and Laz, acquired written scripts and developed their literary languages mainly after the Russian Revolution.

Paleoasiatic Languages

At the outer edge of far eastern Siberia, there are numerous ethnic groups that speak different languages. One group is the Chukcha (Luorawetlan), Koryak (Nymylan), and Kamchadal (Itelmen), which are spoken from Chukotka to Kamchatka. Another group is the Eskimo-Aleut group. There are also completely isolated languages of people inhabiting Sakhalin Island, lower Amur river, Kolyma lowland, and middle Yenisey river. Some of these languages were influenced by neighboring Yakuts, who speak a Turkic language, and all of them borrowed considerably from Russian. The written scripts of paleoasiatic languages were developed after the Russian revolution.

ALFIA ABAZOVA

Spain

Spain, a country on the Iberian Peninsula in Western Europe, occupies 504,782 square kilometers (194,897 square miles) and has a population of about 40 million people. It is home to Castilian Spanish, a language that has left its linguistic mark in former colonies throughout Latin America and the Philippines, as well as large Spanish-speaking communities in a number of other countries. There are, however, many other languages that also claim Spain as their home; these include historical languages (Iberian, Celtiberian, and Mozarabic), other Romance languages (Catalan, Galician, Aranese, Aragonese, and Asturian), and one language isolate (Basque).

Historical (Extinct) Languages

Several inscriptions dating from the fifth to the first centuries BCE have been found in eastern Spain in a language known as Iberian. Most of these inscriptions are written in the Iberian script, but a small number were written in the Greek script. Scholars have unsuccessfully attempted to find a relationship between this unknown non-Indo-European language and Basque, a language isolate spoken in northern Spain.

Celtiberian is an extinct continental Celtic language (as opposed to the more familiar insular Celtic languages such as Gaelic, Irish, Welsh, etc.) that was spoken in northeastern Spain. The Celtiberians may have inhabited Spain as early as eight BCE. Celtiberian inscriptions and texts date between early two BCE to around one CE. There was no Celtiberian script; earlier inscriptions are written in the Iberian script, and some of the later texts are written in the Latin alphabet. These texts and inscriptions provide important grammatical information but little by way of vocabulary as they tend to be short.

Introduction of Latin

At the beginning of the second century BCE, the Romans entered the Iberian Peninsula and brought with them their language, Latin. This new language gradually absorbed all of the languages, with the exception of Basque, spoken on the peninsula. As a result, all languages currently spoken on the Iberian Peninsula, except Basque, are Romance languages. It is assumed that the original languages of Spain (Iberian, Celtiberian, and Basque) influenced the Latin spoken on the peninsula, contributing to the characteristics of the various vernaculars. A dialect continuum developed on the peninsula; over time, the Latin of the various parts began to differ more and more from one another. By the eighth century CE, five distinct language groups appeared: Galician-Portuguese, Asturian-Leonese, Castilian, Aragonese, and Catalan. Three particular areas in the north gradually gained certain social prestige, thus establishing their eventual domination: Galician-Portuguese, based around Santiago de Compostela in the northwest; Castilian, around Burgos in the north; and Catalan, around Barcelona in the northeast.

A now-extinct Arabic-influenced Ibero-Romance language, Mozarabic, developed in the south during the Middle Ages and was spoken by Mozarabs (Christians under Moorish rule), Muslims, and Jews. No standard language developed because Mozarabic was rarely written; when it was written, it was written in either the Arabic or Hebrew script. Information on this language comes down to us in the following forms: poems written in the Arabic or Hebrew script that form part of longer compositions in Arabic or Hebrew; words and word lists written in the Arabic script; place names; some medieval and early modern Arabic-Latin and Arabic-Spanish dictionaries; and certain post-Reconquest legal documents. Slowly, Portuguese, Castilian, and Catalan speakers reconquered the territories where Mozarabic was spoken. Mozarabic was probably mutually comprehensible with these varieties of Romance but was gradually absorbed by the new dominant language until its disappearance as a separately identifiable language by 13 CE. Some have argued that Mozarabic influenced the

other languages as it was being absorbed, but this is only apparent in vocabulary.

Modern Languages

Because of its instrumental position during the Reconquest, Castile became a dominant force on the peninsula. Castile became politically superior to the other regions, and Castilian, the language of the court, government, and the expanding empire, gained prestige as a result; by the fifteenth century CE, its use as the language of culture and administration spread to non-Castilian areas. In some areas like Galicia, Castilian became the language of the elite, giving rise to diglossia—a situation wherein a speech community uses two languages (or two very distinct varieties of one language) for different social contexts or for performing different functions.

Attempts to use language policies to strengthen Spanish national identity began to be considered in the seventeenth century CE. In addition, three important institutions furthered the position of Castilian throughout Spain: the Catholic Church, the education system, and the military. Charles III declared in 1768 that Castilian was to be used as the language of administration and education throughout Spain. The Castilianization of Spain continued until the latter half of the nineteenth century when a resurgence of cultural activities, including codification and elaboration, in non-Castilian languages occurred; the Romantic Movement motivated these 'renaissances'. In 1932, the king abdicated, and the four-year Second Republic was proclaimed. Greater powers in the form of statutes of local autonomy were given to Catalonia, Galicia, and the Basque Country during this time, although the Civil War meant that, with the exception of Catalonia, they were not able to experience this autonomy properly.

With the end of the Civil War came a dictatorship (Franco's regime), which repressed regional languages to centralize the country. Speaking non-Castilian languages was viewed as antipatriotic and was considered rebellious; punishments included fines and imprisonment. In 1966, the Freedom of Expression Law was passed, which removed strict censorship and allowed instruction in non-Castilian mother-tongue languages and publishing in these languages.

Franco died in 1975, and three years later, the 1978 Constitution was passed. This turned Spain into a Western-style democracy and resulted in the legal recognition of the other languages. Castilian was still the official language of the country, but each of the autonomous communities could declare their own official language alongside Castilian.

Catalan (*català*) (called Valencian (*valencià*) in Valencia) is spoken by approximately 6.5 million people in the autonomous communities of Catalonia, Valencia, the Balearic Islands, and Aragon. From the eleventh to the fourteenth centuries, Catalan was considered a prestigious language comparable to French, Italian, Castilian, and Portuguese. Literature and philosophical works thrived as Catalan replaced Latin and Provençal as the language of cultural and literary production. From the sixteenth century, however, Catalan declined in prominence as Castile's power and control increased. Catalan lost its prestige during this time and largely became a spoken language. This persecution and Castilianization continued until the *Renaixença* 'Renaissance' of the second half of the nineteenth century. Catalan has perhaps had the most successful revival of any of the other minority languages; this may be due to the fact that Catalan had an extensive literary heritage that was written, in contrast to Galician which had more of an oral literary heritage and Basque which did not have much of a literary heritage. In 1914, the *Institut d'Estudis Catalans* 'Institute of Catalan Studies' was set up by the *Mancomunitat*, the predecessor of the current *Generalitat*, the governing body of Catalonia.

Galician (*galego*) is spoken by approximately 2.3 million people in northwestern Spain in the autonomous region of Galicia, where it is one of the official languages. Galician was an important literary language during the Middle Ages and gained prestige as a result, especially in lyric poetry; speakers of Castilian and Leonese frequently composed poetry in Galician because of this prestige. Over the course of the fourteenth century, however, Galician lost ground to Castilian due to the large influx of Castilian nobles and Castilian-speaking priests. This relegated Galician to the low position of a popular spoken form used by peasants. Galician was maintained by the large number of Galician speakers who immigrated to other parts of the Spanish empire, particularly the Americas. Galician did not revive until its *Rexordimento* of the second half of the nineteenth century; the Academy of the Galician Language was founded in 1906.

Basque (*euskara*) is currently spoken by about 565,000 people in the Autonomous Basque Community and the Autonomous Community of Navarre. Not only is it the oldest language still spoken on the Iberian Peninsula but it is also the only non-Indo-European language; it is a language isolate—its relationship with other languages has not yet been (nor, perhaps, will ever be) established. Basque speakers accepted Castilian dominance more readily than the Catalan speakers because, in exchange, they were able to retain their rights. Unlike Catalan and Galician speakers, Basque speakers did not have a large body of written literature to unite their language. The Basque language divided into several dialects, some of which are no longer mutually intelligible.

Aranese (*aranès*) is spoken by approximately 6,000 people in the Val d'Aran, a Pyrenean valley on the French–Spanish border forming a part of the Catalonia Autonomous Community. It is a dialect of Gascon, a variant of Occitan, spoken in southwestern France and is, along with Catalan and Castilian, an official language in the Val d'Aran. In April 1983, Catalonia enacted the Linguistic Normalization Law, as a result of which five steps were taken in support of maintaining Aranese: Aranese was declared an official language of the Val d'Aran, and the right to know and use this language in relations and in public ceremonies within the territory was recognized; the *Generalitat* of Catalonia (the governing body of Catalonia), along with institutions in the Val d'Aran, became obligated to do what was necessary to guarantee the knowledge and normal use of Aranese and to encourage its normalization; the Aranese form of place names in the Val d'Aran was declared the official form; the *Generalitat* became obligated to supply the means necessary to guarantee the teaching and use of Aranese in the schools of the Val d'Aran; and the *Generalitat* was required to take the necessary steps to ensure that Aranese is used in the mass media of the Val d'Aran. The immediate consequences of this law include the creation of a commission to standardize Aranese, the publication of textbooks in Aranese for their use in schools, and a sociolinguistic survey to provide a basis for possible future actions. One of the most important steps, however, was the introduction of Aranese into schools. Aranese is the language of instruction during the first few years of education, although Castilian and Catalan take leading roles later. The Parliament of Catalonia reintroduced the General Council (*Conselh Generau*) into the Val d'Aran, which regularly uses Aranese, and certain government powers were attributed thereto. In addition, there is one program a week on the Catalan television service in the Aranese language and a short daily program in the radio schedule; one Catalan newspaper has a weekly Aranese supplement.

Aragonese is spoken in a few Pyrenean valleys by about 30,000 people in the Aragon Autonomous Community, where it is, along with Castilian and Catalan, an official language. Aragonese appears in some schools as an optional extracurricular subject. It is not used in television; however, it can be heard on the radio, and some infrequent magazines are published in Aragonese. There is a newspaper in North Aragon that includes a weekly Aragonese supplement.

Asturian is spoken in the Asturian Autonomous Community and the north and west parts of Castile-León, and although it is not recognized as an official language, its protection and promotion is stated in the *Statute of Autonomy of Asturias*. Asturian is present in some preprimary and primary schools as the language of instruction and is offered as an elective subject in primary and secondary schools. At the University of Oviedo and in teacher-training college, Asturian is offered as an option. Asturian television programs practically do not exist, although the parliament has approved the procedural stage for a project to create a public television and radio broadcasting institution in Asturias. There is also one weekly newspaper, *Les Noticies*, extracts in other newspapers, and a few magazines published in Asturian. However, the presence of Asturian in government is minimal; only a few departments accept documents written in Asturian, and it is rarely used in courts, legislative texts, or public signs.

Spanish and Iberoromance Languages

Spanish and the Iberoromance languages derive from Latin, which was brought into the Iberic peninsula in the third century BCE, and superseded most of the previously spoken Celtic and non-Indo-European languages. At the time of the Germanic invasion, in the fifth century CE, the Iberic peninsula was not yet

fully romanized, as shown by the survival of the Basque language in the northern region, near the gulf of Guascogne, a language presumably spoken by a much larger part of the population in pre-Roman times. The Germanic people who poured into the area of the Roman empire left deep linguistic traces in the Iberic languages, much in the same way as in the other Romance languages. Peculiar of the Iberic area is the influence of Arabic, following the period of domination from the eighth century BCE to the 'Reconquista', fully accomplished only in 1492.

Drawing the linguistic limits of the Iberoromance area is not without problems. Castilian Spanish and related vernaculars, Portuguese, and Galician certainly belong to the Iberic branch of Romance, but the position of Catalan remains more controversial: both geographically and linguistically, Catalan was closer in origin to the Galloromance branch, especially to Occitan; only later cultural and historical developments created more solid links with the languages of the Iberic peninsula.

The Iberoromance languages share with the rest of Western Romance the palatalization of Latin /kt/, which became /it/, and the retention of -s plural. Other features of Iberoromance include the use of verbs derived from Latin *tenere* (in Portuguese) and *stare* as auxiliaries (the latter also found in the Southern Italian varieties excluding Sicilian) and the prepositional accusative, with the extension of the preposition *a* to animate definite direct objects, which, however, is nowadays fully standardized only in Spanish (note that the prepositional accusative is also found in most Southern Italian varieties, in Sardinian and in Rhetoromance; a similar development in Rumanian involves the preposition *pe*, from Latin *per*).

Spanish (Castilian)

With its more than 330 million speakers, Spanish is one of the most spoken languages in the world, second only to Chinese (data from the 1996 edn. of *Ethnologue*). It is the official language of Spain as well as of Argentina, Bolivia, Columbia, Costa Rica, Cuba, Chile, Ecuador, El Salvador, Guatemala, Honduras, Mexico, Nicaragua, Panamá, Paraguay, Peru, Puerto Rico, Dominican Republic, Uruguay, and Venezuela, and it is spoken as mother tongue by more than 20 million speakers in the United States.

Given its diffusion, Spanish has different standards. Usually, a distinction is made between the peninsular standard, based on Castilian, and the American standard, whose prestige center is Mexico City; the most relevant deviations from this standard in Latin America are found in Argentina.

Special features of Spanish as a Romance language include diphthongization of Latin short /e/ and /o/ under stress in both closed and open syllables, the change /f/ > /h/ in word-initial position (/f/ is retained as such before /ue/), further palatalization of /kt/ (> /it/ in all Western Romance and > /tʃ/ only in Spanish), and lenition of voiced stops in the internal position. The vowel system includes five phonemes, /a/, /e/, /o/, /i/, and /u/, with no distinction between long and short vowels, and there are no cases of vowel reduction. The most important phonological feature that builds an inner isogloss within Spanish varieties is the existence of a distinction between /s/ and /θ/, typical of peninsular standard, but not found in Andalusian and American varieties (see below). Morphologically, vernacular varieties still spoken today are Leonés, in the province of Leon, which shares a number of features of Gallego and Portuguese, Argonés, in the province of Huesca, and Andalusian, much closer to Castilian, in Andalucia. This last variety has among one of its features the so-called *seseo*, that is, convergence of /θ/ and /s/ in /s/ (the opposite phenomenon, called *ceceo*, i.e. convergence of both phonemes in /θ/, is also sporadically attested). Since *seseo* is also found in all Latin American varieties, it was formerly assumed that the latter were based on Andalusian; however, there is evidence for the existence of two spirants in early Mexican Spanish. Most likely, the two spirants were articulatorily closer to each other than /s/ and /θ/, and eventually merged in both Latin America and Andalucia, but became more distinct in Castilian. So /θ/ is a Castilian innovation, which dates after the conquest of Mexico.

In the field of morphology, the largest dialectal variation is found in the pronominal system and the use of verb forms for second person plural. Standard peninsular Spanish has the following set of (accented) personal pronouns:

	Singular	Plural
1.	yo	nosotros/nosotras
2.	tú	vosotros/vosotras
3.	él/ella	ellos/ellas
Polite form	usted	ustedes

The polite form *usted/usetedes*, which, in the standard, agrees with third-person singular/plural verb forms, was created in the course of the Middle Ages; as in some other Romance varieties, most notably Italian, there has been a long oscillation between third-person forms and second-person plural. The form *vos* (an earlier second person plural) is still found in literary peninsular Spanish of the nineteenth century and lies at the basis of *voseo*, i.e. the substitution of second-person singular *tú* with *vos* (see below). The form *vosotros/vosotras* for familiar second-person plural only occurs in Castilian; the other varieties have *ustedes*, either followed by second-person plural verb forms (Andalusian,

Canarian) or by third-person plural verb forms (Latin America). In Argentina, where *voseo* is accepted at the level of the written standard, *vos* is used for familiar second-person singular, followed by verb forms derived from second-person plural, which no longer correspond to the forms used in the peninsular standard (*vos hablás*, 'you (sg.) speak'; the second-person plural of *hablar* in peninsular standard Spanish is *habláis*), and *ustedes* is used for second-person plural, both familiar and polite, followed by third-person verb forms. At the substandard level, *voseo* is found in all Latin America, with the exception of Mexico and Peru, the countries that maintained closer links with Spain after the conquest, due to the existence of the Viceroyalties.

Another peculiarity of Castilian in the field of pronouns is so-called *leísmo*. In the literary standard, *leísmo* is confined to the use of the clitic *le* instead of *lo* for masculine animate definite objects, thus matching (but only for the masculine singular) the distribution of prepositional accusative in the case of noun phrases (or accented pronouns), as in *Maria vi a Juan/Maria le vi* vs. *Maria vi el libro/Maria lo vi* (some speakers, especially in the Madrid and Valladolid areas, also use *le* for inanimate objects).

A variety of Spanish is Judeo-Spanish, or Sefardí, which derived from the language spoken in Spain at the time of the expulsion of Sephardic Jews, in 1492. The expelled Jews moved to different countries, mainly on the shores of the Mediterranean, where small communities thrived until the seventeenth century. Their language, which retains a number of archaic features (for example, retention of initial /f/), is still spoken today by small groups, mostly in Israel.

The first written attestations of Spanish date to the tenth century CE. Early poetic compositions in the Iberic peninsula were written in a southern vernacular, Mozarabic, the language spoken during the Arabic domination. The first literary text in Medieval Castilian is the epic *Cantar del mio Cid*, written around 1140, which narrates the deeds of the hero of the Reconquista.

Portuguese

Portuguese is the official language of Portugal, where it is spoken by about 10 million speakers, and of Brazil; according to the 1995 edition of the *World almanac*, the total speakers of Portuguese were 170 million. European and Brazilian Portuguese differ considerably from each other in various respects.

Portuguese vocalism is rather complicated, if compared with the system of neighboring Spanish, and more similar to the French system, on account of the existence of a phonemic opposition between oral and nasal vowels, and of extensive vowel reduction in unstressed syllables. Two different vowel systems can be set up for stressed and unstressed syllables. In stressed syllables, eight oral vowels and five nasal vowels are distinguished: /i/, /e/, /ɛ/, /ə/, /a/, /ɔ/, /o/, /u/ and /ĩ/, /ẽ/, /ã/, /õ/, /ũ/. In unstressed syllables, the number of distinctions is considerably reduced: in particular, final unstressed vowels are reduced to /ə/, /ɐ/, /u/ and non-final vowels to /i/, /u/, /ə/, /ɐ/. In Brazilian Portuguese, unstressed vowels are reduced to a lesser extent: final unaccented vowels are /i/, /u/, /a/ (realized as [ɐ]) and nonfinal unaccented vowels are /i/, /e/, /a/, /o/, /u/; furthermore, there is no phonemic accented /ə/.

Peculiar to Portuguese are the inflected infinitive and constraints on clitic placement. The inflected infinitive is the outcome of the Latin imperfect subjunctive. Since by regular sound change its forms became identical to the forms of the bare infinitive in the first- and third-person singular, the whole paradigm was reanalyzed as an infinitive with personal endings. Nowadays, it displays the following forms:

Singular	Plural
1. eu falar	falarmos
2. falares	falarem
3. ele/ela falar	falarem

(from the verb *falar*, 'to speak').

European Portuguese has retained a trace of the once pan-Romance Tobler – Mussafia Law, according to which no pronominal clitics could precede the verb when the latter was placed in sentence-initial position. Hence, we find in European Portuguese groups like *disse-mo*, 'he told me', to be compared with Spanish *me dijo*, or Italian *mi disse* (in Brazilian Portuguese this constraint does not hold; in general, clitics are preposed to a much larger extent than in European Portuguese; for example, they are preposed with infinitives: European Portuguese *buscar-me*, 'to look for me', Brazilian Portuguese *me buscar*).

The first attestations of Portuguese and Galician (which in ancient times were not yet distinct) date back to the twelfth century CE; Galician-Portuguese lyrics flourished especially at the court of King Denis (1279–1323).

Galician (Gallego)

Galician is spoken by about four million people, most of them living in the region of Galicia, in Spain, where it has the status of official language together with Spanish. It is intimately related to Portuguese, and the reasons why it is considered a separate language, rather than a vernacular variety, are ultimately political. In the archaic period, until the sixteenth century CE, there was only one literary variety, referred to as Galician-Portuguese; only in the course of the

sixteenth century did Galician separate from Portuguese, although some distinctions emerged, as a consequence of political developments, in the period from 1350 to 1500. The standardization of Galician was a slow and uncertain process, with conflicting tendencies either toward adherence to the Portuguese standard, or to a deeper distinction; only after the death of Franco, with the new Spanish constitution that recognized official status to minority languages, has Galician achieved full recognition.

Catalan (Catalá)

Catalan is spoken by about five million people, for the most part living in Catalunya, in the province of Valencia and in the Balearics, where Catalan is the official language together with Spanish; small Catalan-speaking communities are located in the South of France and in Northern Sardinia. Catalan is also the official language for about 31,000 speakers in the Republic of Andorra.

As already remarked, Catalan was in origin closer to Galloromance, and in particular to Occitan; also geographically, Catalan was closer to the area of the Provence: Catalan-speaking communities in the early Middle Ages were located in the South of France and in present-day Catalunya, and expanded to Valencia during the Reconquista; Mallorca and the Balearics were conquered by Catalan speakers in 1229. As a result of historical developments, Catalan nowadays builds a linguistic bridge between the Iberic and the Galloromance areas.

Features peculiar to Catalan are the vowel system, consisting of eight vowels— /i/, /e/, /ɛ/, /ə/, /a/, /ɔ/, /o/, and /u/— and the loss of diphthongization of Latin short /e/ and /o/ (but in there is evidence for early diphthongization in Medieval Catalan). Palatalization of initial /l/ is a feature of modern Catalan, having started in the sixteenth century (in e.g. *lleit*, 'milk', [ʎeit], cf. Spanish *leche*, French *lait*).

Catalan shares with standard Spanish the distinction between the auxiliaries *ser* and *estar*, although the extent to which *estar* is not as wide as in Spanish (*ser* can also occur when it means 'to be in a certain place', where Spanish has *estar*). An innovation of Catalan is the auxiliary use of *anar*, 'to go', with the infinitive, which yields a periphrastic preterit: *va cantar*, 'he sang', equivalent to Spanish *cantó*. The prepositional accusative did not, in origin, belong to Catalan; today, it has spread from Spanish to some extent, and has become the standard in the case when the object is a strong personal pronoun, or the indefinite *tots*, 'all', 'everybody', or in cases where word order could cause confusion between the subject and the object.

The first attestations of Catalan are somewhat later than those of Spanish and Portuguese, because for a long period Catalan poets used Provençal, which had a higher prestige. The first written document is a liturgical book dating to the beginning of the thirteenth century. In the course of the same century, the Catalan kings extended their reign to the Balearics, Valencia, and Murcia; consequently, Catalan acquired official status. Catalan was also the official language of the kingdom of Aragona, until unification with Castilla in 1479. Spanish then superseded Catalan as the official language; only in the nineteenth century did separatist movements give an important contribution to the maintenance and the standardization of the language.

Spectral Analysis

Speech production and speech acoustics are two main areas of study in experimental phonetics. Speech production is concerned with how the vocal organs move in relation to the linguistic message the speaker intends to deliver. Speech acoustics is concerned with the relationship between the moving vocal organs and the

acoustic signal that they create and also with the way in which the listener is able to recover the linguistic message from the acoustic signal. 'Spectral analysis' refers to any technique that transforms an acoustic signal into its 'frequency components'. Spectral analysis is an indispensable part of speech acoustics, and it has applications in areas such as clinical speech pathology and the development of systems for automatically synthesizing and recognizing speech.

Nature of an Acoustic Signal

An acoustic signal is created whenever an object moves, causing disturbances to the air pressure in its vicinity. These air pressure changes are propagated outward in all directions from the object and, if they are sufficiently large, a sound is heard when they reach a listener's ears. The loudness of the sound is related to the amount or 'amplitude' of air pressure change relative to the atmospheric pressure. Different speech sounds are heard because the moving vocal organs can be configured in a variety of ways and create different patterns of disturbance to the air pressure.

A 'speech pressure waveform' or simply 'waveform' is a record of the amplitude of air pressure changes as a function of time that result from speech production. A waveform provides much information about the differences between broad groups of speech sounds: in Figure 1, the pattern of air pressure variations is very different for the oral stop /t/ compared with the fricative /s/ or the vowel /æ/. But it is generally much less useful for showing the acoustic differences *within* any of these classes (i.e. stop, fricative, vowel), e.g. acoustic differences stemming from the different positions where the airstream is blocked or

constricted in the speaker's mouth (place of articulation). These phonetic distinctions generally only emerge acoustically by transforming a waveform into another kind of display, known as a 'spectrum', which displays the amplitude of air pressure variation as a function of frequency. It is this transformation that is at the core of spectral analysis.

What follows is the description of a type of signal known as a 'sinusoid', which is the building block of spectral analysis, and then a brief introduction to Fourier's theorem, which shows that *any* signal can be represented by the sum of sinusoids—thereby allowing the spectrum to be obtained for any waveform.

Sinusoids

Imagine a wheel with a number of scoops fixed to a water mill that is turned at a constant speed by a flowing river. Suppose a footpath runs alongside it so that half the wheel is below the footpath and the other half is above it (Figure 2), and that the radius of the wheel is one meter and exactly one revolution is completed every second. If at several points in time during the wheel's cycle, measurements are made of the height of one of the scoops above or below the path, the resulting plot is a sinusoid. Since (in this example) the wheel completes one revolution of the cycle every second, the 'frequency' of the sinusoid is said to be one cycle per second or 1 Hertz (abbreviated to 1 Hz). The sinusoid has an axis of amplitude (of height in the case) and an axis of time, but it is possible to represent the same information in a spectrum that has axes of amplitude and frequency. For this example, the spectrum of the sinusoid is a single vertical line, of amplitude 1 (meter), at a frequency of 1 Hz (Figure 3a)
Figure 1. Waveform of the word 'stamp' produced by an adult male speaker of Australian English. The horizontal line corresponds to atmospheric pressure. The vertical lines show the approximate location of the boundaries between the speech sounds.
Figure 2. The circle represents a revolving wheel and the dots are one of the scoops at different time points on the wheel as it revolves. The horizontal dotted line is the path. The values around the circle are the times at which the scoop reaches that point in the wheel's cycle. A plot of the height of the scoop above or below the path as a function of time results in the sinusoid on the right.
Figure 3. Waveform and spectrum of a sinusoid of amplitude 1 and frequency 1 Hz (a); amplitude 2 and frequency 1 Hz (b); amplitude 1 and frequency 2 Hz (c); and amplitude 1 and frequency 1 Hz and phase-shifted $\frac{1}{4}$ cycle earlier (d).

corresponding to the wheel of radius 1 unit that completes one revolution every second.

Now consider the effect on the resulting sinusoid of changing the configuration of the wheel, path, river, and scoop in three different ways. First, there might be a wheel of twice the size (in a different river) that happens to revolve at exactly the same speed as the one that has been considered so far. The resulting sinusoid and spectrum in Figure 3b show that the amplitude has doubled but the frequency is the same—therefore, the spectrum shows a vertical line of 2 units at a frequency of 1 Hz. Second, there might be yet another wheel that

has the same size as the one that was originally considered but that revolves at twice the speed. In this case, the amplitude is still 1 unit, but 2 cycles are completed every second—hence, the resulting frequency is 2 Hz (Figure 3c). The third type of change is one of 'phase', which refers to where in the cycle the measurements are first taken. For example, if the first measurement in Figure 2 is taken a quarter of a cycle earlier, when the scoop is level with the path and rising, the sinusoid is itself shifted a quarter of a cycle back in time (Figure 3d). Notice that the spectrum is unchanged, because neither the amplitude nor the frequency is affected by a change in phase. It turns out that as far as distinguishing acoustically between speech sounds is concerned, phase changes are more or less irrelevant; hence, they are considered no further in this discussion.

Periodic Waveforms and Fourier Analysis

The waveform at the top of Figure 4 is said to be 'periodic' because it has a basic pattern, or 'cycle', that repeats itself in time. The rate at which the pattern in a periodic waveform is repeated is known as its 'fundamental frequency'. This waveform repeats itself 2.5 times a second, and hence its fundamental frequency (which is abbreviated $F0$ or $f0$ and pronounced 'F-zero') is 2.5 Hz.

A listener hears a periodic waveform as having 'pitch'. The pitch is perceived to increase in approximately equal steps on the frequency scale up to about 1,000 Hz, and thereafter it increases approximately logarithmically. A note played on a musical instrument has a periodic waveform and an identifiable pitch, as do most vowels that are produced in speech. On the other hand, the sound produced from rustling leaves or the slamming of a door has an 'aperiodic' waveform with no discernible repeating pattern.

Accordingly, listeners do not hear them as having pitch in the same sense.

Fourier analysis, named after the French mathematician Joseph Fourier (1768–1830), is a technique that allows a waveform to be decomposed into a set of sinusoids. The meaning of 'decomposed' is that if the sinusoids that result from Fourier analysis are summed (i.e. played back at the same time), then the original waveform is exactly reconstructed. In Figure 4, the sum of the simple sinusoids *b*, *c*, *d* yields the complex waveform in *a*.

There is a second important property of Fourier analysis: the sinusoids that result from the decomposition of the type of periodic waveform shown in Figure 4a have frequencies at multiples of the periodic waveform's fundamental frequency. This is why the lowest frequency sinusoid that is produced from Fourier analysis in Figure 4, namely sinusoid *b* (known as the 'fundamental'), also has a frequency of 2.5 Hz, while the next two sinusoids higher in frequency (known as the '2nd and 3rd harmonics') have frequencies of 5

and 7.5 Hz for sinusoids *c* and *d*, respectively. The spectrum of a periodic waveform always consists of a set of discrete lines on the frequency axis and is known as a 'line spectrum'.

The examples so far have been of mathematically pure waveforms. As far as speech production is concerned, most vowels and many voiced consonants are produced with the vocal folds (vocal cords) opening and closing at a rapid rate (typically around 100 times per second or 100 Hz in adult male speakers and just below 200 Hz in adult female speakers), and this periodic vocal fold vibration results acoustically in a waveform that is sufficiently periodic that the harmonics are generally detectable in the spectrum. In Figure 5, there are peaks in the spectrum at intervals of about 90 Hz that are the result of the harmonics, giving rise to a sawtooth effect in the spectrum. This 90 Hz interval is predictable from the waveform in Figure 5 in the following way. The waveform shows that there are 4 cycles in 0.043 seconds. The fundamental frequency is given by the number of cycles per second, which in this case is 4/0.043 Hz or just over 90 Hz.

Voiceless sounds are produced without vocal fold vibration, and the airstream becomes turbulent as it is channeled at high speed through a narrow gap at the consonant's place of articulation. This turbulent airstream, which is audible as the hissing sound in the [s] of 'see' or the [ʃ] of 'she', results in an 'aperiodic' signal that has no cycle or repetitive pattern. In contrast

Figure 4. A periodic waveform and the three sinusoids that are the result of its Fourier analysis. *a*, *b*, *c*, *d* denote amplitude values on the waveforms at the same time point and their relationship is $a = b + c + d$.
Figure 5. Top: Waveform of four pitch periods of the [æ] of 'stamp' from Figure 1 and their durations. Bottom: The spectrum of this waveform showing the first three harmonics (vertical dotted lines) and the frequency location of the first three formants (*F*1, *F*2, *F*3).

to a periodic signal, the spectrum of an aperiodic signal does not have equally spaced harmonic components but is 'continuous': that is, there are spectral components at *all* frequencies (Figure 6).

Formants

Consider the effect of tapping two glass jars, one long and quite wide and the other short and thin. These taps result in two quite different sounds (one sounds much lower in pitch than the other). The reason for these differences is that each jar has its own set of 'resonance frequencies' —these are the frequencies at which the air inside the jar is likely to vibrate at highest amplitude, once the air is set in motion by the tap against its side. The frequencies at which the jar resonates with highest amplitude depend predominantly on the jar's shape. So too in speech production. If you set yourself to produce an [æ] vowel (analogous to one of the jars) and flick a finger against your throat, you will hear a muted sound that decays quickly. If you do it again but set yourself to produce an [i] vowel, you will hear a quite different sound. Since [æ] and [i] are produced with very differently shaped vocal tracts, the set of resonance frequencies, which in the case of the acoustic analysis of voiced sounds are known as 'formant frequencies,' are also quite different.

In the spectrum of a speech sound, the formant or resonance frequencies show up as amplitude peaks and are labeled $F1$ (the first formant frequency), $F2$, $F3$, …, Fn (Figures 5 and 6). The first two formant frequencies provide listeners with the most important information for distinguishing between phonetically different vowels. They are proportional, respectively, to how widely open the lips are and the position between the lips and vocal folds of greatest narrowing in the vocal tract.
Figure 6. Waveform of the section of [s] from 'stamp' in Figure 1 and its spectrum (right). A trend line is superimposed on the spectrum. Three of the resonance frequencies for [s] between 3,000 and 7,000 Hz are marked as R above the spectrum.

Source–Filter Theory of Speech Production

Speech production is often characterized as the composition of a 'source' and a 'filter'. The source causes the air in the vocal tract to vibrate: for voiced sounds, the source is the vibrating vocal folds, and for voiceless sounds it is a turbulent airstream. In speech production, the shape of the vocal tract acts as a filter because it modifies the effects of the source. The different contributions to the spectrum of the source and filter can be seen in Figures 5 and 6: the source results in short-term variation that rides up and down on a longer-term trend line (whose peaks are the formants), which is the acoustic effect of the filter.

In speech production, the source and filter are largely independent of each other because they arise from processes that can themselves be independently varied. In voiced speech, for example, a speaker can produce the same vowel but can vary the pitch (as when singing an [æ] vowel on a rising pitch). The acoustic consequence of this independence of the source and filter is that the formant frequencies are negligibly affected by changes in the harmonic structure. If the same [æ] vowel as in Figure 5 were produced at twice the pitch, the frequency interval between the harmonics (short-term variation) would double, but the shape of the long-term trend line due to the filter (vocal tract shape) would be largely unaffected.

Spectrograms

A spectrogram is a three-dimensional representation that shows how spectral information changes in time. It is calculated by dividing the waveform into equal time sections or 'windows' and applying a Fourier analysis to the waveform within each window. Each analysis produces a spectrum of exactly the kind that has been considered so far but in which the amplitude is represented by a gray scale (white is zero amplitude; black is maximum amplitude). In Figure 7, which is a spectrogram of the waveform in Figure 1, the first three formants in the vowel are clearly visible at about 700, 1,600, and 2,300 Hz.

Figure 7 is an example of what is often known as a 'wideband spectrogram', and it has a 'bandwidth' of 300 Hz. Any two components whose frequency difference is less than the bandwidth are indistinguishable on the frequency axis. Since for this speaker the fundamental frequency for the [æ] vowel was estimated at 90 Hz (Figure 5), the separate harmonics, which occur at 90 Hz intervals, are indistinguishable on this wideband spectrogram, because their frequency separation is less than the 300 Hz bandwidth. The 'temporal resolution' of a spectrogram, which can be used to determine whether two events are separately visible on the time axis, can be estimated from the reciprocal of the band-
Figure 7. Wideband spectrogram and waveform of 'stamp' in Figure 1. The vertical dotted lines mark the approximate location of boundaries between the speech sounds. The white lines on the spectrogram are the first three formant frequencies.

width. For this wideband spectrogram, the temporal resolution is 1/300 second or just over 3 milliseconds. Accordingly, the individual vocal fold closures for the [æ] vowel are separately visible as vertical lines or 'striations' (Figure 7), since the interval between them, which is approximately 1/90 second or 11 milliseconds, is greater than the spectrogram's temporal resolution.

Figure 8 is a 'narrowband spectrogram' that was calculated with a 45 Hz bandwidth. In this case, the vertical striations for [æ] are no longer visible in the vowel, because the temporal resolution, which is given by 1/45 second (just over 22 milliseconds) is greater than the interval between vocal fold closures. But the harmonics *are* visible because the frequency difference between them (90 Hz) is greater than the 45 Hz bandwidth. This type of spectrogram has often been used for measuring the extent and direction of changes in pitch. From Figure 8, it is immediately clear that the word was produced on a falling pitch.

Cepstrally and LPC Smoothed Spectra

Speech scientists often need to be able to estimate the separate contributions to a speech signal of the source and the filter. Two techniques for doing this, which can only be applied to signals that have been digitized on a computer, are 'cepstral analysis' and 'linear predictive coding' (LPC).

The starting point for cepstral analysis is the observation that was made earlier: the spectrum of a speech sound is made up of a rapidly changing part that is due to the source and a slowly varying trend line that is the result of the filter. Consider in the light of this the problem of separating two sinusoids that are merged together in a waveform, one of which varies rapidly and the other slowly (at frequencies of 100 and 5 Hz,
Figure 8. Narrowband spectrogram of 'stamp' in Figure 1. The white lines are the first three formant frequencies.

for example). This separation could be achieved by applying Fourier analysis, resulting in a spectrum with two separate lines at these frequencies. Therefore, if Fourier analysis were applied to a spectrum of speech, then the result, known as a cepstrum, should be a separation of the rapidly and slowly varying components, i.e. of the source from the filter. Since they appear in different parts of the cepstrum, the source can be quite easily removed, leaving only the contribution from the filter.

If Fourier analysis is applied once more, but this time to the cepstrum with the source removed, the result is another spectrum: it very much resembles the original spectrum of the speech signal, but it is considerably less bumpy, precisely because the contribution from the source component has been mostly removed. One of the main advantages of this spectrum, which is known as a 'cepstrally smoothed spectrum', is that it is much easier to see the formant frequencies, since they are not confounded with the short-term effects of the source (Figure 9). The part of the cepstrum that includes information about the filter, known as 'cepstral coefficients', provides considerable information about the acoustic differences between phonetically distinct sounds. For this reason, cepstral coefficients are often used in systems for automatic speech recognition.
Figure 9. Cepstrally smoothed spectrum of the waveform in Figure 5 showing the frequencies of the first four formants.

The basis for the LPC analysis of speech, which in other fields is sometimes known as 'autoregressive analysis', is as follows. If a speech signal is the result of passing a source (vibrating vocal folds or a turbulent airstream) through a filter (representing the shape of the vocal tract), then it can be shown that the same signal is equal to the sum of several 'scaled' and 'delayed' versions of itself added to the source. 'Scaled' means that the speech signal's amplitude is linearly changed: the amplitude of the entire signal might be halved, for example. 'Delayed' means that the entire speech signal is shifted back in time: if the signal is delayed by a fraction of time, then all its values start a fraction of a time earlier. The factor by which each delayed signal is scaled is dependent on the characteristics of the filter and therefore on the shape of the vocal tract. Hence, a model of the vocal tract shape (filter) that could have

given rise to an acoustic speech signal can be reconstructed by estimating the different scale factors on successively delayed versions of that signal. This is what LPC tries to do. The scale factors are known as 'LPC coefficients'.

The Fourier analysis of the LPC coefficients results in an 'LPC-smoothed spectrum'. As with cepstral analysis, the spectrum is smooth because the contribution from the source is minimal. LPC analysis also allows the formant frequencies to be estimated, because there is a direct correspondence between them and the LPC coefficients. The formant frequencies in the spectrograms in Figures 7 and 8 were automatically tracked using LPC analysis.

Speech Acts

In distinguishing between constative and performative language, the twentieth-century English philosopher J.L. Austin initiated 'speech act theory', which has influenced linguistics and literary criticism. Constative language refers to things; performative language does things—it is speech in action.

Constative language reports on reality. We evaluate constative language as true or false. 'The snow is white' is an example, as is the following: 'All men are mortal; Socrates is a man, so Socrates is mortal'. The first example describes a visual phenomenon. The second details a logical relation's

reality and describes Socrates as a man and all men as mortal.

Both examples are statements with a determinable sense and reference, usually called 'meaning'. In addition to simply conveying their meaning, statements may be uttered to bring about effects in listeners or readers. The statement 'There is a hungry lion in the room' produces fear in the room's human occupants, in addition to informing them about the lion. Although clearly a constative sentence, this sentence accomplishes a nonlinguistic speech act: it frightens.

Sentences may be uttered simply to say meaningful words, but in saying these words, a certain effect may be achieved. Both cases are speech acts, but whereas the first aims to achieve a linguistic effect—namely, that the listener understands what is said—the second may aim at nonlinguistic effects—for example, evoking a certain emotional response. Austin refers to constative sentences as 'locutions' and to utterances intended to achieve a different effect as 'illocutions', and the particular intent of illocutions is labeled 'illocutionary force'. A sentence that mentions a person allows us to understand to which person the sentence refers. If, in addition, the sentence commands that we despise or admire that person, the sentence is an illocution. An illocution that not only aims to achieve an effect but is also successful at achieving it is called a 'perlocution'. All commands are thus illocutions, but only commands resulting in obedience are perlocutions.

Illocutionary force is distinct from locutionary sense, reference, and meaning, even though illocutions necessarily involve locutions. Consider the following illocution: 'Impeach George W. Bush, President of the United States: he lied about Iraq's weapons of mass destruction!' This example has illocutionary force whether the words 'he lied about Iraq's weapons of mass destruction' are or are not legally meaningful (is Bush's lying an impeachable offense?) or do or do not have a referent (did Bush lie?). If the example's illocutionary force results in Bush's impeachment, it has achieved a perlocutionary act.

What Austin calls 'performatives' constitute a particular class of illocutions. The typical performative includes a singular first-person pronoun as the subject ('I') and an active verb in the present tense indicative. 'I promise to pay' and 'I declare the meeting over' are examples. 'I declared the meeting over', a constative locution, reports, but does not perform, a past act and can be judged true or false.

Performatives are 'felicitous' or 'infelicitous' rather than true or false. Felicitous performatives conform to particular conditions, which are often institutional conventions, whereas infelicitous performatives do not. A classic example comes from the marriage ceremony. 'I pronounce you husband and wife' does not describe two people as being husband and wife: it makes them husband and wife, but only in the context of certain felicity conditions. If the person uttering the performative lacks authority to perform marriages, the man and the woman are not made husband and wife.

Austin lists general felicity conditions for performatives: that recognized conventions specify who should pronounce the performative, by what procedures, and to what effect; that the participants enact these conventions correctly and completely; and that the person uttering the performative intends it seriously. If, after the jury has returned a 'not guilty' verdict, the judge says to the accused, 'I sentence you to death,' we would have an infelicitous performative because of conventions being violated. If John Doe says, 'I promise to pay' without intending to keep the promise, the performative is infelicitous. Austin does not consider promises or death sentences uttered by an actor playing a character on stage to be performatives because they are not intended seriously: they are fictions.

Speech acts' relations to intention are matters of ongoing debate. In *Limited Inc* (1988), the philosopher Jacques Derrida claims that Austin privileges intention as the anchoring center of the context that grants a performative felicity. Linguistic signs, i.e. words, sentences, and so on, must be able to function in their speakers' or writers' absence. Listeners can understand a voice echoing in a canyon even if the speaker died during enunciation. The voice repeats its message despite the speaker's absence. Signs can be iterated, or repeated, beyond the context of their production. This inherent repeatability, argues Derrida, guarantees that speech acts cannot be fully explained by any given context and cannot wholly depend on intention. A speech act always has a context, but iteration prevents that context from ever completely determining the speech act's meaning. As written or verbal signs, performatives function in the radical absence of their writers or speakers and, thus, their intentions.

Michelle Rosaldo's essay in *Language in society* (1982), 'The things we do with words: Ilongot speech acts and speech act theory in philosophy', argues that a focus on intention, especially in relation to promises, biases speech act theory toward modern individualist ideology by emphasizing autonomous psychological states. Miller's *Speech acts in literature* (2001) extends Derrida's arguments to claim that Austin's lectures at once display and subvert sexist and imperialist ideologies. Miller details how Austin's examples tie intention to a white male speaker's sovereignty. However, Miller argues, Austin unintentionally dismantles the constative/performative opposition, opens the possibility of performatives preceding and establishing their own felicity conditions, and discloses

other features of speech acts that militate against the very ideologies that Austin's arguments harbor.

Countering arguments such as Derrida's, the philosopher John Searle maintains that intentionality is a legitimate foundation of speech act theory. Searle differentiates between intentionality as a prelinguistic feature of human and animal life and intentionality in language, which is ultimately derivative of intentionality as a biological endowment. Language and speech acts are to be explained in terms of intentionality, rather than intentionality being explained in terms of language. Reasserting context as a controlling factor, Searle extends Austin to define types of illocutions (to request, to congratulate, and so on) and their conditions of felicity.

Speech Perception

The speech stream is a continuously varying signal that, contrary to the listener's impression of silence between words, does not contain any pauses. The primary goal of research in speech perception is to illuminate the way in which the listener converts this continuous signal into a sequence of discrete, meaningful units. This process draws on perceptual, linguistic, and cognitive factors.

At least three major issues need to be taken into account when considering the mapping between acoustic parameters and linguistic units. The first concerns the segmentation of the speech stream. Speech is a highly efficient means of communication in which multiple layers of information are transmitted in parallel. Compare, for example, the words 'sea' and 'Sue'. The former consists of an [s] consonant followed by a vowel [i], which is pronounced with unrounded lips, whereas the latter consists of the same initial consonant followed by a rounded vowel [u]. During production of the initial consonant in 'Sue', lip rounding will start in anticipation of the upcoming rounded vowel, a process known as anticipatory coarticulation. As a result, the acoustic properties of [s] preceding [u] will be different from those of [s] preceding [i]. Thus, the pronunciation of the initial sound in the above words provides acoustic cues about the initial sound itself and about the immediately following sound at the same time. This parallel transmission of information can lead to a segmentation problem in that it is difficult or impossible to chop up the speech signal in chunks that correspond to only a single speech sound. In other words, it is difficult—if not impossible—to tell exactly where the consonant ends and the vowel begins.

A second related issue concerns the lack of linearity. Although the listener perceives the speech signal as a linear sequence of units (the size of which is still under debate), the acoustic cues to these units do not necessarily occur in a corresponding left-to-right order in the speech stream. Consequently, acoustic properties appearing later in the speech stream may carry information that is crucial for the identification of an earlier occurring speech sound.

The third issue concerns variability or the lack of invariance. The properties of the acoustic signal that are thought to elicit perception of speech sounds (the acoustic 'cues') are never exactly the same. Sources of variability are, for example, differences in vocal tract size, speaking rate, phonetic context, emphasis, and intonation; these can significantly affect acoustic parameters of the speech signal. For example, the most salient frequencies ('formants') of the vowel in the word *heed* are approximately 300 and 2,300 Hz for an adult male and 500 and 3,100 Hz for a child. However, despite these very different formant frequencies caused by differences in vocal tract size, listeners perceive both utterances as containing the vowel [i]. This illustrates what is known as the invariance problem: acoustic cues to a particular speech sound may not be constant but may instead vary according to the circumstances under which they occur. Thus, listeners have to compensate for such differences, or 'normalize the input'. One of the primary issues in speech perception, then, is how the listener achieves an invariant percept despite great variability in the acoustic input.

Speech perception experiments usually involve manipulated natural speech or synthetic computer-generated speech. Systematic manipulation of individual attributes of speech enables researchers to determine which acoustic properties are necessary and sufficient cues for a particular percept. In applying this methodology to consonants, early research in the 1950s revealed that English listeners use two primary acoustic cues for determining where in the mouth exactly a consonant is articulated: the frequency of the release burst and the formant transitions from the consonant into the following vowel. When the researchers exposed listeners to consonant–vowel sequences, keeping the burst frequency constant, the listeners perceived a [p] when an [i] was following, but a [k] when an [ɑ] was following. Thus, the exact same cue can participate in different perceptions. In highlighting that individual acoustic attributes are highly context dependent, these experiments also exposed the invariance problem.

Debate continues concerning the extent to which the perception of speech involves the use of biological mechanisms evolved especially for speech. Evidence that speech sounds are perceived differently from their nonspeech analogs was first presented in the early 1960s. These studies specifically examined the way in which these two types of sounds are identified and discriminated. Most types of stimuli (e.g. musical tones, colors) are much better discriminated than they are identified. The greater the physical difference between two stimuli, the better their discrimination. This was shown for nonspeech sounds as well. However, this was not true of certain speech sounds, most notably

stop consonants such as [b] or [d]. Discrimination of these sounds was not any better than their identification. For example, in a typical experiment with synthetic speech, an important formant frequency of the consonant was manipulated. Typically, [b] has a formant at 1100 Hz, whereas the equivalent formant of [d] lies at 1,800 Hz. With the help of a speech synthesizer, researchers were able to produce sounds with formants that lie somewhere in between. When listeners were asked to identify such intermediate consonants, it turned out that listeners seem to use a particular frequency as the break-off point: all consonants whose formant exceeded this threshold frequency were identified as [d], and all others were identified as [b]. In another experiment, listeners were presented with a pair of consonant stimuli and asked to tell whether the stimuli were same or different. When the formants of consonants both exceeded or both undercut the threshold frequency, the listeners seemed to answer at random. If one consonant fell into the [d] range and the other into the [b] range, however, listeners were consistently able to categorize them properly, even if the formant frequencies were close together. This pattern of results is known as categorical perception.

It was originally thought that categorical perception occurred only with speech sounds and not with nonspeech sounds, and this would suggest that the perception of speech engaged specialized mechanisms. However, later experiments with carefully controlled nonspeech materials have shown patterns of categorical perception as well. In addition, animals including the chinchilla, macaque, and Japanese quail have also been shown to have human-like categorical perception. These data concerning categorical perception do not readily support postulation of perceptual mechanisms that were specially evolved or adapted for speech. Instead, they seem to favor an interpretation based on general auditory mechanisms and psychoacoustic sensitivity.

The finding of categorical perception suggested that listeners did not perceive any differences between stimuli belonging to the same category. This, however, may have been based on the particular response categories that were typically used in identification and discrimination experiments (e.g. /b/ or /d/, 'same' or 'different', respectively). The use of more sensitive response measures reveals that even though listeners do assign the same label or fail to distinguish between stimuli of the same category, they are in fact aware of subtle differences. These findings indicate that although categories play an important role in the perception of speech, they are not monolithic but have an internal structure to which listeners are sensitive.

The importance of speech categories leads to the question of how they are established. This debate

centers around the issue of whether speech categories are innate or result from exposure to the ambient language. Crucial evidence in this debate is typically drawn from perception experiments with infants. Findings from discrimination experiments with infants as young as one month old suggest that they divide a speech continuum in a way very similar to adults, with two clearly defined categories and a sharp boundary at the adult location. Additional research has shown that infants up to approximately six months of age can not only discriminate speech categories from their native language but also from just about any other language, as well. However, in the second half of the first year of life, infants seem to lose their sensitivity to nonnative distinctions. Presumably, the decrease in sensitivity to contrasts that do not play a role in the native language allows for an increase in attention to other aspects of the speech signal that play a role in word learning, such as sentence structure and intonation. Acquisition of speech categories can thus be understood as the result of the interaction between initial psychoacoustically based sensitivities and an increasing awareness of the structure of the language to be learned.

Because the perception of speech draws on many sources of knowledge, theories of speech perception often account for only a few of its components. Three general classes of models may be distinguished. The motor theory of speech perception deals with acoustic variability by claiming that the listener has specialized neural mechanisms to convert the speech signal into invariant representations of articulatory gestures. These articulatory gestures are the object of speech perception; i.e. this theory assumes that the listener attempts to faithfully reconstruct how the perceived speech sounds were articulated by the speaker. The theory of acoustic invariance claims that invariant acoustic properties do reside in the speech signal. By using specialized neural mechanisms, the listener directly extracts these invariants from the speech signal and maps them onto phonetic features. Finally, pattern recognition models claim that speech perception is much like statistical pattern classification. No specialized mechanisms are required. Instead, the unit of recognition and the structure of categories (e.g. based on prototypes or exemplars) are determined by the nature of the speech signal and general properties of the mammalian auditory system.

There is a growing recognition that a detailed analysis of the speech signal alone will not be sufficient to obtain a genuine understanding of the way in which speech is perceived. Consequently, researchers have started to incorporate findings from additional areas. One such area concerns the way in which the speech signal is transformed by the auditory system. Although the measurements used in phonetic analysis typically represent frequency along a linear scale, it is known that the auditory system warps the signal such that its ultimate representation is more nearly logarithmic in nature. A thorough understanding of these transformations at the auditory periphery and higher levels along the auditory pathway may well have significant implications for the current view of acoustic cues and their variability.

A second area concerns the relation between the speech signal and higher levels of organization of the grammar. The first few decades of research on speech perception emphasized the cataloguing of acoustic cues, that is, the acoustic information that listeners need to extract from the speech signal to recognize individual speech sounds. Since the 1980s, however, increased interest in the way words are recognized has led to research on what is often referred to as spoken or auditory word recognition. A central issue for this research area is if and to what extent 'higher-level' linguistic and cognitive information that is not present in the speech signal contributes to word recognition. Research has shown that when presented with a sequence of speech sounds containing an ambiguous initial consonant, listeners will classify that consonant such that the entire string will result in an existing word instead of a nonword. For example, listeners will report hearing 'beef' rather than 'peef' when presented with the string 'eef' preceded by a sound that is ambiguous between /b/ and /p/. Conversely, listeners will classify the same ambiguous initial consonant as /p/ rather than /b/ when it is followed by 'eace'. Findings such as these are often considered as evidence that lexical information (knowledge about what constitutes a word) affects the listener's interpretation of acoustic–phonetic information. The extent to which there is feedback from higher levels of linguistic representation, such as the lexicon, is still very much under debate.

ALLARD JONGMAN

Speech Processing

Speech processing (SP) is used to facilitate the communication between humans and computers. A system that can converse with a human in a natural and unrestricted way has long been seen as the quintessential challenge in computing.

As a field, SP encompasses a wide variety of disciplines and technologies. From a scientific perspective, it draws on research from Signal Processing, Acoustics, Linguistics (Phonology, Syntax, Pragmatics, etc.), and other areas.

To present the main concepts of SP, we will be introducing a hypothetical computer information system, Sprach (the reader may think of an automated air travel reservation agent or a museum information system). The architecture of Sprach is shown in Figure 1.

We will describe how a user can engage in a conversation with the information system. The sample transcript of the dialogue is shown in Figure 2.

Speech Recognition

Jill, the user of the computer system, can communicate with Sprach using either a microphone or a telephone interface. In both cases, a speech recognizer is needed to convert the acoustic signal into a sequence of words. Given that a telephone samples its input signal at a lower frequency, the quality of speech recognition is lower than with a microphone.

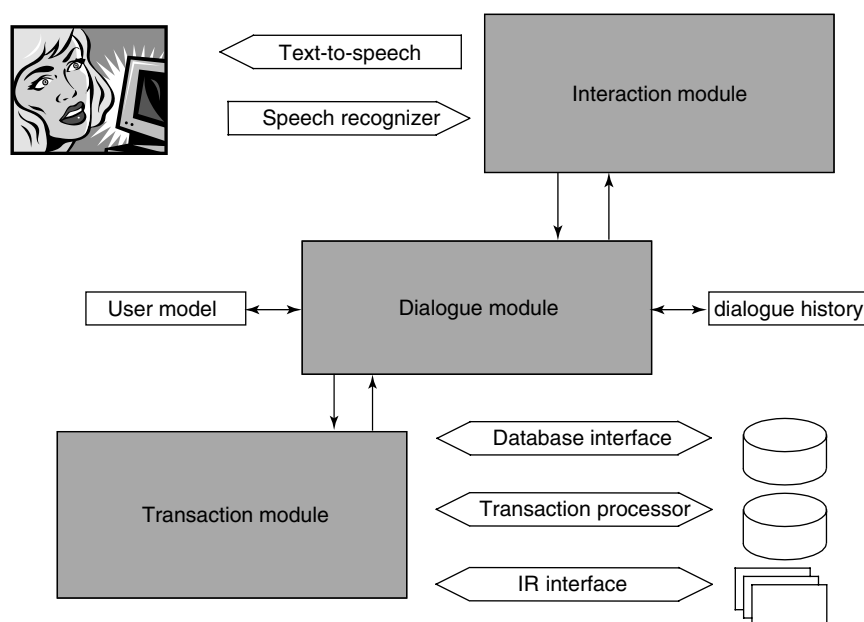
Speech recognizers are typically designed to solve two distinct problems: isolated word recognition and continuous speech recognition. Recognizing continuous speech is more difficult than isolated speech recognition due to the presence of disfluencies (e.g. false starts or interjections such as 'uh' or 'hmm') and prosody effects (e.g. intonation and rhythm). The accuracy of speech recognition also depends on the size of the vocabulary used. It is much easier to tell


Figure 1. Sprach: a generic speech-based information system.

Jill: I would like to fly to Seattle on Friday.
Sprach: I am looking for flights from Detroit to Seattle on Friday,
          March 2. What time of the day do you want to leave?
Jill: I would rather fly early in the morning.
Sprach: American flight 143 leaves Detroit at 7:05 AM and arrives in
          Seattle at 9:28 AM. A ticket costs $590.00. Should I book
          one first-class ticket using your Discover card?
Jill: Yes, please.

Figure 2. A sample dialogue between Jill and Sprach.

apart individual digits from 0 to 9 than to recognize the names of all employees in a given company. Given the variability in speech characteristics among speakers, most practical speech recognizers also need to be trained for a particular user.

One mathematical formalism underlying speech recognition is the noisy channel model. It is used to guess the most likely utterance, given an acoustic signal. The most likely utterance $\hat{W}$ among the space Λ of all utterances $W \in \Lambda$ is identified according to the formula:

$$\hat{W} = \arg \max_{W \in \Lambda} P(W|A) = \arg \max_{W \in \Lambda} P(A|W)P(W)$$

In the formula, $P(A|W)$ is called the acoustic model and is used to estimate the most likely mappings between the acoustic signal A and the input utterance. The term $P(W)$ is known as the language model and is used as a measure of the grammaticality of a given candidate utterance W. Other techniques used in speech processing are Hidden Markov Models, Dynamic Time Warping, and Gaussian Mixture Models. For additional reading, consult the book by Huang et al.

Dialogue Management

Sprach's dialogue module shown in Figure 1 requires two locations to store the history of the interaction with the user. One of them is long-term memory (or user model) in which user preferences and information extracted from past dialogues is stored. For example, long-term memory may contain the city where Jill lives or her favorite airline. On the other hand, the short-term memory is used to represent choices that can be derived from the current dialogue, e.g. the day and time of the desired flight.

In practical speech-based dialogue systems, dialogue interactions between users and the system are often preprogrammed. Recently, VoiceXML has emerged as a standard for encoding information for such applications. VoiceXML is used to annotate computer–human dialogues. Some sample tags are: <MENU> : a list of options, <FORM> : a mechanism for user input, and <EMP> : for emphasized speech. VoiceXML and equivalent markup language facilitate the development of practical speech-based systems.

Back End

The back end of the system is where transactions are processed. Our sample system contains three back ends — an information retrieval (IR) interface, a database system interface, and an interface to a transaction processing component. The IR interface is used to retrieve documents (e.g. e-mail messages) from a server. The transaction processing and database interfaces can be used for a large variety of applications such as hotel or air travel reservation systems.

Text-to-Speech Generation

When Sprach has decided *what* to say, it still has to figure out *how* exactly to utter it. A text-to-speech (TTS) component is used for that purpose. The input to TTS is most often a grammatical sentence, either retrieved from a sentence dictionary or produced by text generation from a logical form. The input sentence is decomposed graphemes (textual units) which are then converted into phonemes (phonetic units). The process of grapheme-to-phoneme translation is often ambiguous, especially in languages with inconsistent pronunciation such as English. In English, the same phoneme /f/ can be generated from multiple graphemes (f, ph, gh, and ff), while the same grapheme can be translated to more than one phoneme (e.g. gh can be /g/, /f/, or silent, among other pronunciations). The two main approaches used in grapheme-to-phoneme translation are rule-based (using linguistically tested translation pairs) and corpus-based (derived from large corpora).

To make the output sound natural, TTS systems make use of intonational (prosody) information. Prosody features are expressed by controlling input parameters of the speech synthesizer. Some prosody features such as pauses can be inferred within a certain margin of error from the syntactic structure of the sentence (e.g. the presence of semicolons, commas, and other punctuation). Features such as timber, dialect, and speech rate are also often included in the generation process, mostly to produce voices that seem to be of different characters.

Evaluation

The speech recognition research community has adopted a set of evaluation metrics that are used to gauge progress over the years. One of these metrics is the error rate, which is simply the percentage of word insertions, deletions, or substitutions that are needed to convert the output of the speech recognizer to the correct text. State-of-the-art recognition systems achieve around 10% word error rates on unconstrained spontaneous speech with a vocabulary of more than 10,000 words. In other words, in a given sentence, one in ten words is incorrectly identified. However, when the text

is constrained, word error rate declines dramatically to approximately 4% for continuous speech with a 1,000-word vocabulary and less than 1% for isolated word recognition.

Evaluating speech generation is significantly more difficult and remains a research challenge.

Speech Processing (Neurobiology)

From a physics point of view, the speech signal is based on a change in pressure propagated through the elastic medium 'air', which leads to a specific particle movement. The speech sound is encoded as a complex particle movement in the frequency and intensity domain and is superimposed on nonspeech-related particle movement (noise). Listening to speech-embedded background noise means (1) detecting the particle movement with a sensory system, (2) filtering out nonspeech-related particle movement, and (3) analyzing the remaining speech-related part of the signal and decoding the meaning. Therefore, hearing sounds, especially listening and comprehending language, is a very complex ability, the neurophysiological basis of which is not yet completely understood. This is even more important when the speech signal being focused upon is disturbed by the noise of other speakers, e.g. in the case of listening to a single speech signal during a noisy party. The ability to extract only the relevant parts of the air particle movement related to the speech signal of a certain speaker (so-called 'cocktail party effect') is an enormous achievement of the neuronal structures involved. However, this powerful discrimination of an acoustic signal is not limited to human language processing. For example, seabirds returning to their colony are able to find their straying offspring by differentiating their specific call ('identificators') among the calls of up to some 10,000 other chicks. Although the physiological basis of analyzing complex sounds is phylogenetically old and quite common in animals, this does not diminish the enormous achievement of the human brain to comprehend spoken language.

The speech signal (encoded as the complex movement of air particles) is gathered, filtered, and ampli-fied by the ear, which is divided into three parts: (1) The external ear, which comprises the cartilaginous pinna and a canal (external auditory meatus) leading to a vibratory motion-sensitive membrane (tympanum). As a consequence of the resonance properties of the ear canal, the pinna, and the head, the frequency range of 1,500 to 7,000 Hz (the main speech range) is preferred while other frequencies are reduced (passive filtered). (2) The middle ear, which comprises the very small bones of the ossicle chain (malleus, incus, stapes), transmits the vibratory motions of the tympanic membrane to the much smaller membrane of the 'oval window' of the inner ear. This part amplifies the signal mechanically by increasing the pressure (gain) due to the ratio of the effective areas of the tympanum to the small oval window and by exerting a lever effect of the oscillating ossicles. (3) The inner ear or cochlea, where the motion of the ossicle chain is coupled to the fluids of the cochlear canals, where the sensory cells (hair cells) are located in the organ of Corti of the scala media. Here, transduction from a vibratory motion to an electrical signal takes place. The following stations of the so-called auditory pathway are shown in Figure 2 of **Brain Organization and Auditory Pathways.**

The process of language analysis takes place at an incredible speed. A trained listener can repeat sentences ('shadowing') with a latency of only 220 ms. This is evidence for the assumption of parallel analysis processes during language comprehension. Experiments show that words are almost comprehended after only 100 ms, a time period that comprises only one to two phonemes. The sound signals are mostly discriminated by phylogenetically old neuronal feature detectors. This is why most mammals (e.g. tested in

chinchillas) are able to discriminate different plosives in a choice reaction experiment. After words have been detected and recognized, the cognitive part of language comprehension sets in: analyzing the meaning of the word, analyzing the meaning of phrases and sentences, and analyzing connotative meaning delivered by contextual information, the speaker's prosody, or nonverbal communication signals. More than milliseconds are required to understand language in that sense; it may take up to several seconds before a listener 'gets the point' of a certain utterance (see time scale in Figure 2 of **Brain Organization and Auditory Pathways**). In addition, such complex analyses and judgments of complex utterances are performed by integrative processes of many different brain areas. During language processing, participating brain processes can be investigated with electrophysiological or brain-imaging techniques. At the moment, the minority of experiments are conducted with invasive electrical recording of single or few neurons. Most electrophysiological results are based on noninvasive observation of the synchronous activity of huge groups of neurons (from some 100,000 up to a few million cells).

Modern electrophysiological and brain-imaging techniques such as electroencephalography (EEG), functional magnetic resonance imaging (fMRI), or positron emission tomography (PET) have led to a new empirical basis for the investigation of cognition (*see* **Neurolinguistics**). While event-related fMRI was introduced only a few years ago, other techniques had already provided a substantial number of results. For example, for more than two decades the use of event-related potential (ERP) techniques has yielded new insights into the physiological processes underlying language. The language-related wave form of the scalp EEG first described by Marta Kutas and Steven A. Hillyard in 1980 was the so-called N400, a large negative ERP component related to semantic analysis of sentence processing. For example, the final word in '*The pizza was too hot to cry*' elicits a huge bilateral negativity at posterior electrode positions between 250 and 600 ms after word onset, with a peak latency of about 400 ms, whereas the final word in the sentence '*The pizza was too hot to eat*' does not. However, a sentence with an intermediate semantic anomaly such as '*The pizza was too hot to drink*' would elicit an N400 with a smaller amplitude, since the peak amplitude corresponds to the extent of the semantic anomaly. In contrast, a sentence with a syntactic anomaly like '*Turtles will spit out things they does not like to eat*' would elicit a positive component (P600), peaking about 600 ms after the onset of the word '*does*'. In recent years, the N400 has been shown for many languages, including American Sign Language (ASL). An additional language-related ERP component is the N280, which can be seen as an indicator for processing closed-class words (function words such as articles, conjunctions, or prepositions) in contrast to open-class words (content words such as verbs, nouns, and adjectives).

Speech Production

Research on speech production studies the processes and representations that are involved in producing an utterance, from generating the concept to be expressed, to the motor movements of the articulatory organs. Although language production has historically been the subject of less research than comprehension, recent

years have seen increased interest in the question of how speakers are able to produce complex and well-formed speech in real time. This increased interest has been accompanied by important methodological developments. Until relatively recently, language production was mainly studied through observational methods, by which researchers collected corpora of naturally occurring spontaneous speech, particularly speech errors, and used these to develop theories of the processes that underlie speech production. Observational methods obviously present methodological difficulties, such as observer bias, infrequency of some phenomena, and the extent to which any corpus is representative of the language as a whole. Some of these problems have been solved with the advent of powerful computers that can collect and process large quantities of natural language. However, methodological developments have also made it possible to study the production of both well- and ill-formed utterances under rigorously controlled laboratory conditions. Experimental manipulations now allow such diverse possibilities as inducing the production of particular syntactic structures or speech errors of interest, as well as investigating the link between how we visually perceive the world and how we describe it.

There is perhaps surprising consensus concerning the overall architecture of the language production system. The model has been articulated in more detail by psycholinguists such as Willem Levelt on the basis of recent experimental research; but in essential respects the currently accepted architecture of the language production system remains largely unchanged from that proposed by Merrill Garrett in the 1970s on the basis of speech error data. According to Willem Levelt's account, production comprises three main stages: conceptualization (generating the prelinguistic message), formulation (translating the message into linguistic form), and articulation (executing the motor programs that realize the linguistic representation). Each has its own characteristic input and output representations. Another component, the self-monitor, is assumed to check for errors or other problems at each level of processing.

During conceptualization, the speaker conceives an intention to express, and selects relevant information. The representations implicated here are assumed to be propositional structures, i.e. prelinguistic representations that involve expressions (or constituent parts of those expressions) that can have truth values. They are also assumed to specify the speaker's perspective, the information structure of the sentence, and any features that are encoded by the grammar (e.g. tense information) of that language. Because languages differ in terms of which semantic features are grammatically

expressed, the features expressed in the pre-linguistic message that is the output of conceptualization vary across languages.

During the next stage, formulation, the speaker converts the prelinguistic message into linguistic form. Formulation is subdivided into stages of grammatical encoding and morpho-phonological encoding. Each stage involves building abstract structure, and retrieving content to fill that structure. Grammatical encoding is concerned with developing syntactic structure. The speaker must select a syntactic structure that can express the intended meaning, and congruent lexical content. Research suggests that grammatical encoding is a two-step process of functional processing followed by positional processing. In functional processing, the speaker retrieves lexical concepts (the semantic content of a lexical entry) and assigns functional relations (subject, direct object, indirect object, etc.) to them. This is the stage at which at least some agreement relations are computed. Functional level representations are unspecified for linear order. Next, in positional processing, the speaker generates a syntactic frame and associates it with the lemma, or syntactic content, of each relevant lexical entry. This syntactic frame specifies in which linear order the individual elements are to appear, i.e. each phrase appears in the position that it will occupy in the final utterance.

The output of grammatical encoding forms the input to morpho-phonological encoding, where the speaker translates the syntactic frame and its content into appropriate articulatory gestures. This involves a number of intermediate stages. First, each word's morphological makeup (involving the relevant word forms) must be retrieved. Next, the individual sounds, syllables, and intonational properties of these morphemes must be specified. Finally, a process of phonetic encoding maps from phonological words to gestural scores, i.e. a pronunciation plan is generated.

The last stage in speech production is articulation, where the speaker executes the abstract gestural scores. This involves the storage of phonetic plans in an articulatory buffer, their retrieval as needed, unpacking the hierarchy of motor programs, and issuing instructions to the neuromotor circuits that control the various articulatory muscles.

This overall architecture is widely accepted, but uncertainty remains concerning the details of the production processes. One question of particular interest is how activation passes between different elements of the production system. Some researchers believe that activation can only flow forward, with later levels of processing (e.g. morpho-phonological processing) being unable to affect earlier levels (e.g. functional

processing). Others believe that activation can flow backward as well as forward. Similarly, it is not clear whether processing is discrete, so that processing must be completed at each level before processing can begin at the next level, or cascaded, so that processing of later levels can begin while processing is still under way at an earlier level. It is also unknown as to how far the incrementality of speech production extends: elements appear to be processed as they become available, but the minimal unit of processing at each level remains unclear. More glaring gaps in our understanding of speech production concern the nature of conceptualization, and the coordination of syntactic structure-building, on the one hand, and lexical retrieval on the other.

HOLLY BRANIGAN AND ROBERT J. HARTSUIKER

Speech Production: Neurobiology

It takes only about two seconds for speakers to compute the correct meaning, grammatical, and sound structures to encode their ideas into speech. How does the brain accomplish this encoding so fast? Which parts of the brain participate in each level of linguistic processing? Neurolinguists have attempted to answer these questions by studying the speech of stroke and cerebral trauma victims who have language impairments called 'aphasias.' These researchers tried to localize, or identify, the regions of the brain responsible for different linguistic processes, such as grammatical encoding and word comprehension. However, continuing research has shown that even if a part of the brain is necessary for a certain aspect of linguistic processing, it is unlikely that this is the only part of the brain involved in that particular linguistic function. Furthermore, studies have shown that brain damage in different parts of the brain can lead to similar language impairments, whereas the inverse is also true: the same locus of brain damage may lead to different language impairments in different people. Knowledge about the contribution of various brain regions to language use is increasing daily because of the development of noninvasive technology such as event-related potentials and neuroimaging techniques such as positron emission tomography, single-photon emission computed tomography, and functional magnetic resonance imaging. These techniques confirm that many parts of the brain contribute to language processing in all linguistic tasks. Nevertheless, various aspects of speech production have proved to be more vulnerable to damage in and around the Sylvian fissure of the left hemisphere, in the regions indicated in Figure 1.

Articulation suffers when there is damage to Broca's area. Damage in this part of the brain, located just forward of the oral motor cortex, impairs the ability to sequence the movements of articulators to produce the sounds of the language. In Broca's aphasia, speech becomes nonfluent and effortful, as if the speaker must consciously control the movements of the articulators to produce spoken words. In fact, the utterances of speakers with Broca's aphasia frequently consist of only one word at a time, with longer utterances being very rare with little grammatical complexity.

Although all aphasics make some errors in pronunciation, the use of sound-related information is most impaired in conduction aphasia, which is caused by damage near the auditory association area in the temporo-parietal cortex. These aphasics produce words that are off-target by one or two sounds, then repeatedly correct themselves as they attempt to produce the target form, e.g. 'I bought a bus, but, boot, book'. Thus, they are aware that they have produced an incorrect word form, but are not sure, until they hear themselves say it, what the correct sound combination is. Importantly, subjects do not consistently make errors on the same word across trials, indicating that the impairment affects the pronunciation of word forms but that the underlying knowledge of the sound structure of words is preserved. Conduction aphasics also
Figure 1. Speech areas in the left hemisphere.

have impaired auditory short-term memory, which interacts with their deficit in pronunciation and results in severe impairments of oral repetition.

Linguistic impairments found in agrammatic aphasia primarily affect words or word parts carrying grammatical information, such as grammatical inflections of verbs and nouns and function words, such as articles and prepositions. Most people with Broca's aphasia are agrammatic, but not all agrammatics have damage in Broca's area. However, all people with agrammatism have damage in or near the Slyvian fissure. In agrammatism, speakers often omit free-standing grammatical words, such as prepositions and articles, but they substitute incorrect inflected forms for correct ones, for example, 'Yesterday dog bark me'. Note that in English it is not clear whether the word form 'bark' has been substituted for 'barked' or whether the past tense inflection (-*ed*) has been omitted. In other words, it is hard to determine from English data whether grammatical inflection is completely unavailable to the aphasic or whether a simpler, uninflected form of a word has been chosen. However, research on aphasic speakers of highly-inflected languages like Russian has shown that the process involves the substitution of one inflected form for another. This means that grammatical information is, in principle, still available to the aphasic, even though the wrong form may be selected.

The connections between the sound form of a word and its meaning are impaired by damage in or near Wernicke's area. This impairment affects both comprehension and production: single-word comprehension is impaired, unrelated words are substituted for appropriate ones (e.g. 'My boss is an envelope'), and patients have no awareness of their own errors. Some

Wernicke's aphasics also produce nonwords, called 'neologisms', as substitutions for real words. Their speech is fluent but full of pronouns and 'empty' words such as *thing, stuff, do, make,* and *get.* Because of unrelated word substitutions, neologisms, and empty speech, it is frequently difficult to understand the speech of Wernicke's aphasics. Consequently, although they produce complex sentences, it is usually impossible to determine whether sentence structures are being used correctly.

The meaning level of language is selectively impaired in Alzheimer's disease and semantic dementia. In these syndromes, word finding is moderately to severely impaired, leading to the production of related words from the same meaning category or more general terms (e.g. saying 'horse' or 'animal' in response to a picture of a deer). These patients score poorly on tasks requiring full knowledge of word meaning, and their spontaneous speech is often empty of content, as in Wernicke's aphasia. These syndromes are characterized by diffuse loss of neurons in the temporal lobe and often throughout the cerebral cortex. Because all aphasics, regardless of the location of cortical damage, produce these same types of semantic errors, it is unlikely that semantic processing is localized to a specific area of the brain.

It is interesting that researchers have not found a particular type of damage that is associated with errors affecting word order or sentence structure, although many researchers see agrammatism as a syntactic impairment. In contrast, all aphasics show varying degrees of impairments of pronunciation, word finding, and understanding of complex sentences. These findings, in conjunction with those of neuroimaging studies, support the assertion that many areas of cerebral cortex contribute to each level of linguistic

processing, although the areas immediately adjacent to the Sylvian fissure seem to hold particular importance for language use.

LORI J.P. ALTMANN

Speech Synthesis

Speech synthesis is the creation of speech sound by means of a machine or a computer. The development of speech synthesis dates back to the end of the eighteenth century when Wolfgang von Kempelen built a speaking machine in Vienna. His apparatus was based on a model of the human vocal tract, with bellows for lungs, a conical resonator that could produce vowel sounds, and constricted portions to create consonantal sounds. Another pioneer was Alexander Graham Bell who, together with his brother, built a talking head with the pharynx, tongue, velum, lips, and teeth made from wood, rubber, and cotton. In the twentieth century, with the invention of electronic circuitry, the vocal tract transfer functions were simulated by (combinations of) sound sources and filters.

Stored Speech

The task of the synthesizer is to create and produce sounds that are recognized as speech. One way to accomplish this is to make use of stored utterances. In general, the quality of prerecorded speech is high, but the vocabulary is fixed and restricted, and is only useful for reproduction (e.g. in cars and aeroplanes). Moreover, despite coding techniques, this synthesis method requires considerable memory capacity for storage. More flexible systems require the conversion of words to a string of phonemes, make use of pronunciation rules (between phonemes and sounds) stored in dictionaries, and add durational and prosodic information. Several text-to-speech synthesis techniques exist, none of which generate speech that sounds completely natural. At present, the two most common (computer) techniques are parametric coding (also called formant synthesis by rule) and concatenative synthesis.

Parametric Coding

This type of synthesizer makes use of the source–filter theory of speech production and strings together several acoustical properties of speech sounds (by means of a set of rules). The sound source is characterized by voiced pulses or noise. Subsequently, filters are used to modify the source, i.e. to produce different resonances or formants of vowel sounds or to pass high-or low-frequency information of consonants. In some systems, several parameters can be altered to convey gender and age. For example, the word 'seek' is generated by first passing noise through a high-pass filter (at about 5,000 Hz), followed by a low first formant (350 Hz) together with a high second formant (2,200 Hz) and high third formant (3,000 Hz) for the vowel /i/, a short silence to simulate pressure buildup before unvoiced plosives and a sharp cutoff sound for /k/. Rules are used to simulate natural timing, stress, and prosody and to create natural connections between the speech sounds.

The advantage of formant-based synthesis is that it requires neither a large storage capacity nor high computational demands. As the acoustic differences between speech sounds can be varied very precisely, this type of synthesis is commonly used for research purposes, for instance, to examine which acoustic properties of speech sounds determine the identity of the speech sound. The disadvantage of this type of synthesis is that it proves to be very difficult to connect the different parameter tracks between adjacent sounds in a natural way. The same speech sound produced in a different context sounds different (e.g. aspirated, unaspirated). Ideally, each different realization of the same speech sound (phoneme) should be represented by the synthesizer. Moreover, speech sounds do not

occur neatly one after the other during production due to coarticulation. Another problem involves the assignment of the correct timing and intonation (cf. 'unit' and 'undo'), and stress differences (cf. 'project' and 'to project'). Although different sets of rules exist to distinguish pronunciations, and to assign syntactic structure (to specify the pronunciation of sound sequences), it remains very difficult to determine the right settings at the right time.

Concatenative Synthesis

Some of the above-mentioned problems can be solved by concatenating pieces of natural recorded speech. For this purpose, diphones and demisyllables are usually used. A diphone is a piece of speech that stretches from the middle of one speech sound to the middle of the following one. They are cut from several recorded utterances, stored, and recombined during synthesis of an utterance. A demisyllable is half a syllable, with the cut in the middle of the vowel. Synthesis of unrestricted English requires approximately 1,000 diphones or demisyllables. Concatenative synthesis is usually highly intelligible and sounds very natural, because the articulatory effects from one phoneme to the next are included. Although the advantage of this type of synthesis is clear, discontinuities can still arise at the boundaries of the diphones or the demisyllables. Moreover, it is not possible to record all existing words spoken with all possible pronunciations. As this type of synthesis also requires considerable storage capacity, voice coding techniques are used to compress the speech sounds.

Application

The best synthesis technique depends on the requirement of the intended application. There is always a trade-off between maximizing speech quality, minimizing memory capacity, and computation time. Speech synthesis is used, among other things, for information retrieval (e.g. banking), for warnings (e.g. in cockpits), in reading machines for the blind, for speech-impaired people, for foreign language learning, in toys, and in speech research. The improvement of speech synthesis lies primarily in a more natural generation of the prosody of speech. Although synthetic speech is highly intelligible, it usually takes half a sentence to know that it is not human. This is often because the listener is distracted by small details, such as timing, voice quality, overarticulation, or unnatural intonation. Whatever the use of synthesized speech, the issues of intelligibility and naturalness will remain challenging in the forthcoming years.

ASTRID VAN WIERINGEN

Sprachbund

The notion of *Sprachbund* (or linguistic area) has been introduced in linguistic theory by Nikolaj Trubetzkoj in 1928. In his famous proposition XVI, put forward on the occasion of the First International Congress of Linguists at The Hague, Trubetzkoj defines *Sprachbünde* as made up of languages displaying a high degree of similarity in syntactic form, some similarity in the principles that govern morphology, and a great number of common culture words—sometimes also an exterior similarity in the inventory of sounds. In modern linguistic theory, *Sprachbund* usually designates an area characterized by a number of linguistic

features shared by a number of languages either unrelated or from different subgroups of the same family. The following linguistic areas have been identified so far: (i) The Balkans (Greek, Albanian, Serbo-Croatian, Bulgarian, Macedonian, and Rumenian); (ii) South Asia (Indian subcontinent); (iii) Meso-America; (iv) Amazonia; (v) Ethiopia; and (vi) Europe.

Each of the aforementioned linguistic areas displays a number of distinctive features. For instance, the Balkan linguistic area, which is by and large the most famous linguistic area identified so far, is characterized by the following features: (a) formation of future and perfect tense using an auxiliary; (b) replacement of infinitives by finite verb forms; (c) postponed articles; and (d) merging of dative and genitive case forms.

Areal linguistics (i.e. the subfield of linguistics which aims at uncovering linguistic areas) has been facing the problem of the number of features necessary to distinguish between proper *Sprachbünde* and simple contact phenomena among a group of languages. According to a widely held view, there should be genealogical diversity of the languages belonging to a linguistic area, although it cannot be excluded that shared features may be due to language contact even in the case of genetically related languages. Moreover, the similarities that characterize a linguistic area should not be trivial, i.e. they should not be the result of typological developments that take place, under the same circumstances, in all or most of the world's languages. Language typology, being traditionally concerned with the classification of languages based on grammatical features independent of genetic relationship, may provide areal linguistics with some evaluation criteria. Similarly, historical linguistics may help areal linguists to exclude that some postulated areal features are due to genetic inheritance.

In some recent developments of areal linguistics, the notions of areality are considered to be of interest irrespective of whether the phenomena examined can be described in terms of linguistic areas in the traditional sense. This change in scientific perspective has led to a rather composite approach to linguistic diversity that could be labeled as 'areal typology' (Östen Dahl 2001): to the extent that typologically interesting features are not evenly spread geographically but tend to cluster in certain areas, areal typology can be considered as the study of the geographical distribution of linguistic features, rather than the characteristics of individual areas. In this vein, Johanna Nichols' important monograph (1992) has provided a complex model of linguistic diversity, which involves two main areal patterns, namely spread and residual zones, the former being areas in which languages tend to spread and mix quickly and repeatedly and the latter being zones where languages tend to remain undisturbed over long periods.

This perspective has been recently applied to the study of Circum-Baltic languages (Koptjevskaja-Tamm and Wälchli 2002) and Mediterranean languages (Ramat and Stolz 2002). In both the Circum-Baltic and the Mediterranean area, there are several convergence/contact phenomena on the microlevel, that interact with phenomena on the macrolevel. This distinction between microlevel and macrolevel phenomena nicely accounts for the internal heterogeneity of linguistic areas. The claim underlying such studies is that the notion of *Sprachbund* tends to overemphasize the overall macrocontact, which is of course justified in certain areas (as the well-established Balkan linguistic area). In other areas, however, intensive microcontacts superimposed on one another may create the impression of an overall macrocontact among the languages, which has not necessarily being there. The obvious consequence of this assumption is that areal phenomena are worth looking at in their own right, even if we are not faced with linguistic areas.

Sranan

Sranan (or Sranan Tongo, lit. 'language of Suriname') is the name of the English-lexicon creole language that has been used in Suriname (in the northeast of South America) since the late seventeenth century. In the past, it has also been referred to as Negro-English, Nengre, or, in a rather derogatory manner, Taki-Taki. It is spoken by some 350,000 people in Suriname, French Guyana, and the Netherlands, either as a first or as a second language. It is the native language of most Surinamese people of African descent, while it serves as an interethnic lingua franca between the other ethnic groups, which include Amerindians, Indians, Javanese, and Chinese. Although it does not have any official status—the only official language in Suriname is Dutch—it is being used more and more in formal contexts, such as education, the media, politics, and public information. Apart from this, there is also a flowering literature in Sranan, especially poetry.

The reason why an English-lexicon creole is spoken in a country that was a Dutch colony throughout most of its existence is purely historical. Before it became a Dutch possession in 1667, Suriname had been an English colony for 17 years, and it is generally assumed that the basis of the Sranan lexicon stems from that period. However, although most of the English had left the colony by 1680, this did not put a definitive stop to the presence of the English in Suriname. Apart from the fact that some of the 'old' English planters returned to Suriname later, new English planters settled there as well. This means that the window of opportunity for Sranan to acquire an English-based lexicon remained open for a longer time than the 30-year period between 1651 and 1680.

Apart from the English element, the Sranan lexicon contains several other layers as well. First, due to the fact that many of the planters in the early period were Portuguese-speaking Jews, a number of Portuguese-derived words have been incorporated into the language. Second, many items from local domains, such as flora and fauna, have Amerindian names, mainly from Arawak and Carib. Third, a fair number of words have been adopted from some of the African languages spoken by the slaves, especially Gbe (a Kwa language, spoken in Ghana, Togo, and Benin), Akan (another Kwa language, spoken in Ghana), and Kikongo (a Bantu language, spoken in Congo-Brazaville and Congo-Kinshasa). Finally, ever since the beginning of Dutch rule, a large number of Dutch-derived words have been borrowed, a process that continues to the present day.

Sranan is somewhat unusual among creoles in general in that it is relatively well documented in its early stages of development. Many written documents—either in printed or manuscript form—are available from the early eighteenth century onward. This is largely due to the work of the Moravian Brethren, a German missionary organization that was very active in Suriname and that produced a large number of religious texts in Sranan as well as a number of invaluable descriptive works such as dictionaries and grammars. Apart from this, there are several printed language primers and dictionaries that were authored by members of the colonial elite. The availability of these early documents has enabled linguists to carry out detailed diachronic research on Sranan, especially on the development of its phonology and syntax (Arends 2002).

As a creole language, Sranan is the product of a process of language contact involving a number of different languages from different language families. Historical research has shown that while the African population consisted of many different ethnolinguistic groups, the majority among them belonged to one of the three larger groups, who spoke either Gbe, Kikongo, or Akan (Arends 1995). This means that the major linguistic input into the creolization process, as far as the African side is concerned, came from these languages. The predominant role of Gbe, Kikongo, and Akan is confirmed by the fact that the African element of the Sranan lexicon is overwhelmingly derived from these three languages. This is further supported by research into other domains such as phonology, lexical semantics, and morphosyntax.

As far as the European population is concerned, it is important to realize that although Suriname was a Dutch colony from 1667 onwards the Dutch were never a majority among the European population. From the late seventeenth to the early nineteenth century, it was the Portuguese Jews who were the numerically most important group among the European population, which, apart from the Dutch, included Germans, French, Scandinavians, and others. As a result, Dutch did not become a majority language among Suriname's Europeans until well into the nineteenth century. This may explain why Sranan was widely used by the Europeans among themselves, even though 'officially' they held it in low esteem.

Below, the major features of each of the linguistic subsystems will be briefly discussed (largely based on Bruyn 2002; see also Adamson and Smith 1995). It

will be followed by a few remarks on the 'verbal arts', an important activity in traditionally oral languages such as Sranan.

Lexicon. About three quarters of the basic vocabulary items are derived from English, while most of the remainder is from Dutch. As for nonbasic vocabulary, this consists mainly of words derived from Dutch, although some items have been taken from other sources, such as Portuguese, Amerindian languages (Arawak, Carib), and African languages. Some examples are *katibo* 'slave' (< Portuguese), *kruyara* 'dug out canoe' (< Arawak), *awara* 'palm species' (< Carib), *agama* 'lizard species' (< Gbe), *pinda* 'peanut' (< Kikongo), *gongosa* 'gossip' (< Akan), and *nyan* 'eat' (< Wolof). Although most English function words were not retained in Sranan, many functional elements are still expressed by English-derived words. This is a result of the fact that English-derived content words from the Sranan lexicon were recruited to fulfill that role. Such a process of grammaticalization results in a content word becoming more grammatical, often being reduced both in its semantic content as well as its phonetic substance. For example, while the English article 'the' was not adopted in Sranan, two definite articles *a* (singular) and *den* (plural) developed out of the demonstrative *dati* 'that' (< English 'that') and the personal pronoun *den* 'they' (< English 'them')respectively. Similarly, while the English indefinite article 'a' was not retained in Sranan, a new indefinite article *wan* 'a' developed, based on the numeral *wan* 'one.' As for the words that were retained from English, their meaning is not necessarily the same as that of its English etymon. This appears, for example, from *anu* (< 'hand'), which means both 'hand' and 'arm,' and *futu* (< 'foot'), which means both 'foot' and 'leg.' Semantic shifts such as these often have their origin in one or more of the African languages spoken by the slaves, many of which have only one word for 'hand+arm' and for 'foot+leg,' respectively. African origins are also responsible for the existence of a word class known as ideophones, words whose only function is to intensify or specify the meaning of another word with which they occur in a fixed combination. For example, the ideophone *fáán*, used to intensify the meaning of the adjective *weti* 'white,' is probably from Gbe. An example is *a weti so fáán* 'he is so very white' (lit. he white so IDEOPHONE).

Phonology. In phonology, there is a clear tendency toward an open syllable structure, which becomes clear from the tendency to add an extra vowel to English-derived words ending in a consonant, such as *udu* 'wood' (< 'wood') and *waka* 'walk' (< 'walk'), or to insert a vowel into some consonant clusters.

Word-final nasals are velarized, something that is reflected in the spelling, as in <Sranan>, which is pronounced [Sranang].

Morphology. The four morphological processes operative in Sranan are conversion, compounding, suffixation, and reduplication. Conversion (also known as multifunctionality or zero derivation) refers to the derivation of a word, e.g. a verb, from another word, e.g. a noun, without any overt change in form. For example, from the adjective *ebi* 'heavy', both a noun *ebi* 'weight' and a verb *ebi* 'to weigh' have been derived in this way. Compounding is a rather common process in Sranan, especially when both elements are nouns, as in *man-pikin* 'son' (lit. 'man child') and *uman-piki* 'daughter' (lit. 'woman child'). One of the few cases of inflection is the use of the noun *man* 'man' as an agentive suffix as in *siki-man* 'sick person' (lit. 'sick man') and *bere-man* 'pregnant woman' (lit. 'belly man'). Finally, reduplication, the creation of a new word by (partially) doubling an already existing word, is quite common. It can be used to create new words belonging to a category different from the base word, as appears from *sisibi* 'broom' (< *sibi* 'to sweep').

Syntax. Sranan is a strict S(ubject)-V(erb)-O(bject) language with a strong tendency toward an isolating morphology. The latter appears from the fact that tense (T), mood (M), and aspect (A) are expressed through independent particles, which are preposed to the verb, rather than through inflection. The TMA system being far too complex to be discussed in any detail, suffice it to say that the distinction between stative verbs ('love') and nonstative verbs ('eat') is of paramount importance for the functioning of the system. For example, while the bare form of a nonstative verb indicates past tense, a bare stative verb indicates present; to indicate present tense, a nonstative verb has to be preceded by the particle *e*. Compare the following examples: *mi nyan fisi* 'I ate fish'; *mi lobi fisi* 'I love fish'; and *mi e nyan fisi* 'I'm eating fish'. While the distinction between stative and nonstative verbs also plays a role in the use of the particle *ben*, other factors, such as discourse structure, come into play here as well, rendering this area of Sranan syntax too complex to be treated any further here. Like many other creoles, Sranan has two copula forms, one (*de*) for location, possession, and existence, and the other (*a*) for nominal predication (although *de* is sometimes used here as well). Adjectival predicates are treated on par with verbal predicates, i.e. they normally follow the subject without an overt copula being inserted in between, as in *yu futu bigi* 'your feet are big' (lit. 'your feet big'). To express intensity or contrast, both verbal and adjectival predicates may be clefted, with a copy of the

predicate left behind, as in *na bigi yu futu bigi* 'Your feet are really big' (lit. 'is big your feet big'). Finally, a syntactic phenomenon known in many creoles is the serial verb construction, where one subject is connected with two or more main verbs, which together form one semantic unit, as in *Rudy ben tyari den buku kon na ini a oso* 'Rudy has brought the books into the house' (lit. 'Rudy has carried the books come at in the house'). In this sentence, the meaning of what is expressed by the preposition 'to' in English is expressed by the verb *kon* 'come,' which forms a series with the verb *tyari* 'carry'. Sranan has a wide variety of different types of serial verb constructions, for the expression of direction, location, instrumental, dative, benefactive, causative, comparative, completion, and complementation. Since both predicate clefting and serial verbs are common features of many West African languages, it seems justified to interpret the occurrence of these constructions in Sranan as retentions from the African languages spoken by the slaves.

Verbal arts. The domain of language use known as the 'verbal arts' includes such activities as story telling and the performance of song and drama. Probably the best known genre is the so-called *Anansi tori*, a type of story named after the trickster-spider Anansi, but including other types of folk tales as well. Although the canonical context for telling *Anansi tori* is at funeral wakes, they may be told on other occasions as well. Both the content and the performative structure of these tales have their roots in West Africa. The basic pattern is the call-and-response structure known from many African-American oral genres, with the story-teller being interrupted by members of the audience punctu-

ating the story with remarks, songs, or even entire 'sub-stories' of their own. The importance of songs, e.g. as an emotional outlet for the slaves, is already apparent from early sources, where reference is made to a social activity known as *pree* 'play' in which dance played an important role. A similar role was played by various kinds of drama, whose origin similarly lies in the plantation period and which continue to be performed to the present day (for splendid collections of Sranan oral literature, see Herskovits and Herskovits (1936) and Voorhoeve and Lichtveld (1975)).

Sri Lanka Portuguese

On May 18, 1498, the Portuguese explorer Vasco da Gama, having discovered a sea route around the Cape of Good Hope, arrived off the coast of Calicut in southwestern India. This event marked the beginning of the first large-scale European presence in South Asia since the expedition of Alexander the Great. As a result of Portuguese contacts, creole languages with Portuguese-based lexicons developed in various coastal communities on the subcontinent, such as Daman, Chaul, Nagapatnam, and Cochin. Collectively known as Indo-Portuguese, these languages all adapted the majority of

their word stock from Portuguese, but developed innovative grammars that combined structural features from Portuguese and local languages with new elements. One of the most important of these creoles is the one still spoken in Sri Lanka (formerly Ceylon). Sri Lanka Portuguese had a longer reign as a lingua franca (language of intergroup communication) than its sister creoles in India and possessed a more copious literature. In addition, it is rivaled for current vitality only by the northern dialects spoken in Korlai, near Bombay (see Clements 1996) and Daman. Sri Lanka Portuguese

is also the most fully described variety of Indo-Portuguese, thanks to the work of Wesleyan missionaries in the early 1800s and to the description published in 1900 by a Goan jesuit priest, Sebastião Rodolfo Dalgado (see Further Reading below). Because of its longevity and voluminous literature, the language is important not only for the study of Indo-Portuguese but also for investigation into the general processes involved in language contact.

Generally, only one language other than Portuguese was spoken in the settings in which the various varieties of Indo-Portuguese developed. This fact sets Indo-Portuguese apart from many other creoles (particularly those labeled 'plantation creoles'), which developed in multilingual settings. In Sri Lanka, two major indigenous languages are spoken: Sinhala, an Indo-Aryan language, and Tamil, a language of the Dravidian family. The initial development of Sri Lanka Portuguese took place among Sinhala speakers along the southwestern coast of the island.

Contacts between Portugal and Sri Lanka began in the early sixteenth century, and these eventually led to the launch of an expedition from Goa in 1517 to establish a fortified trading post at Colombo. Over the following 100 years, the Portuguese extended their control around the entire coast, leaving the independent Kingdom of Kandy in the central highlands. Throughout the area under Portuguese dominion, communities that used Sri Lanka Portuguese as their first language arose as a result of unions between Portuguese soldiers and local women.

Beginning with the union of the Spanish and Portuguese crowns in 1580, events in Europe weakened Portugal's ability to control its vast overseas possessions, which then began to fall prey to the rising power of Holland. The Dutch began cultivating relations with Kandy in 1602, and in 1632 the newly enthroned Raja Sinha II asked for their assistance in expelling the Portuguese. After a long period of conflict, the last Portuguese strongholds capitulated in 1658. From this point on, Sri Lanka Portuguese was isolated from Standard Portuguese. Thus, unlike many creoles, it was not later influenced by the standard language from which it derived its word stock.

Interestingly, because Sri Lanka Portuguese was already established as a lingua franca for communicating with local people, the Dutch continued to use it throughout their rule, and it even became the home language of the families that the Dutch started locally. Dutch and Sri Lanka Portuguese thus came to stand in a relationship known as diglossia, with the former being used as a 'high' (i.e. socially prestigious) language in administration, the courts, and the Dutch Reformed Church, and the latter as a 'low' language for informal face-to-face communication.

The Dutch in their turn were supplanted in 1898 by the British, who, with their victory over Kandy in 1815, completed their dominion over the entire island and held it until Sri Lanka regained its independence in 1948. The British did not copy the Dutch in establishing local families and thus never adopted the creole themselves, but continued to use it as an expedient lingua franca until its functions could be taken over by English. This replacement appears to have occurred around the middle of the nineteenth century. Certainly by 1875, Sri Lanka Portuguese is reported by the Portuguese creolist, Adolpho Coelho, to be 'almost exclusively the language of the descendants of the Portuguese and Dutch'.

Following Dalgado's description of Sri Lanka Portuguese, published in 1900, we heard little further until it was 'rediscovered' in the 1960s by the late Dr. D.E. Hettiaratchi of the University of Sri Lanka, Peradeniya, and editor of the Sinhala Encyclopedia. Currently, the creole is known to be spoken only by 'Portuguese Burghers' in the east-coast towns of Trincomalee and Batticaloa in the predominantly Tamil-speaking area of the island. Due to the modern civil strife in Sri Lanka, recent figures on the number of speakers are not available, but clearly the language is moribund. All Sri Lanka Portuguese speakers are bilingual in Tamil, with some also speaking Sinhala and/or English. In many families, Tamil has supplanted the creole as a home language. This is partly due to marriage with non-creole speakers and partly due to the fact that men must often seek work elsewhere on the island, where they are in a purely Tamil or Sinhala-speaking milieu.

The sounds of sixteenth-century Middle Portuguese are generally found in Sri Lanka Portuguese, although their pronunciation has taken on a local flavor. For example, Sri Lanka Portuguese /v/ is pronounced [ʋ], a sound found in languages throughout the region, and that can be heard in the typical South Asian pronunciation of *vine* or *wine*. On the other hand, Sri Lanka Portuguese sometimes preserves a Middle Portuguese pronunciation now lost in standard varieties of Portuguese; thus, the first consonants of *cegaa* ('arrive;' Standard Portuguese *chegar*) and *juustu* ('correct;' Standard Portuguese *justo*) are pronounced [tʃ] and [dʒ], while in both Portugal and Brazil they have changed to [ʃ] and [ʒ]. Some Middle Portuguese sounds have also disappeared; for example, *x* (pronounced [ʃ]) has been replaced by /s/, as seen in *basu* ('below;' Standard Portuguese *baixo*). More importantly, the entire set of nasalized vowels has disappeared, although an *m* usually appears as evidence of former nasalization. This can be seen in examples such as *paam* ('bread'; Standard Portuguese *pão*) and *amiyaam* ('tomorrow'; Standard Portuguese *amanhã*). Finally, Sri Lanka Portuguese has developed some new sounds.

For example, as in both Sinhala and Tamil, the creole now has a contrast between long and short vowels, which can be seen in pairs such as: *ooy* ('eye'; Standard Portuguese *olho*) vs. *oy* ('today'; Standard Portuguese *hoje*), and *triisti* ('sad'; Standard Portuguese *triste*) vs. *isti* ('this'; Standard Portuguese *este*).

In its grammar, even more than in its phonology, Sri Lanka Portuguese has a predominantly South Asian rather than European character. This can be seen in such features as word order, noun and verb categories, and complex sentence structures involving relative clauses and the quotative construction (explained below). Moreover, Standard Portuguese characteristics such as noun gender and subject–verb agreement are absent from the creole.

The order of the main elements in a Sri Lanka Portuguese sentence is subject–object–verb; for example, *eev eli-pa diñeeru jaa-daa* ('I him money gave' or 'I gave him the money'; Standard Portuguese *Dei o dinheiro para/a ele* or *Lhe dei o dinheiro*). Adjectives and other noun modifiers precede their nouns: *nosa noov ravkiiña* ('our new violin'; Standard Portuguese *nossa rauquinha nova*). Postpositions rather than prepositions are found: *ælmææra ñiva* ('wardrobe on' or 'on top of the wardrobe'; Standard Portuguese *acima do armário*). In all these word-order characteristics, Sri Lanka Portuguese follows the model of Sinhala and Tamil rather than that of Standard Portuguese.

The role that nouns play within a sentence structure is indicated by case suffixes and postpositions, again, as in Sinhala and Tamil. The dialect spoken in Batticaloa has four case suffixes; for example, *ɔɔmi* 'man' has the following forms: *ɔɔmi-pa* (object of verb, recipient, 'to the man'), *ɔɔmi-su* (possessor, 'man's'), *ɔɔmi-ntu* (location, 'in the man'), and *ɔɔmi-ntaa* (person spoken to, person holding something, 'with the man').

The verbal system is interesting because, unlike Sinhala and Tamil, Sri Lanka Portuguese uses prefixes to indicate tense; thus, for the verb *kuziñaa* 'cook', the following forms are found: *ta-kuziñaa* (present), *jaa-kuziñaa* (past), and *lo-kuziñaa* (future). These structures are also quite unlike Standard Portuguese: compare *cosinha* '(he or she) cooks', *cosinhou* '(he or she) cooked', *cosinhará* '(he or she) will cook'. Other prefixes indicate completion, obligation, negation, and conditionality, as in *mes-kuziñaa* 'must cook', and *naa-kuziñaa* 'won't cook'. These prefixes were developed from a variety of Standard Portuguese sources: auxiliary verbs (*ta-* from *está* 'be'), adverbs (*jaa* from *ja* 'already', *lo-* from *logo* 'soon'), adjectives (*mes-* from *mister* 'necessary'), etc. Some auxiliary verbs appear before the main verb, as in Standard Portuguese; others appear after the verb, as in Sinhala and Tamil; some can appear in both positions. Examples are: *kera vii* ('intends to come; Standard

Portuguese *quer vir*); *falaa tiña* ('had told;' Standard Portuguese. *tinha falado*); *naa-pooy botaa* or *pa-botaa naa-poy* ('can't put;' Standard Portuguese *não pode botar*). The categories that these verbal structures represent are generally those of Tamil and Sinhala rather than Standard Portuguese; the completion category is one example, but many others arise. Moreover, Standard Portuguese verbal categories that are not found in Sinhala and Tamil, such as the subjunctive, are also not found in the creole.

Complex sentence structures are also generally modeled on those of Sinhala and Tamil. Relative clauses, for example, always come before the noun they modify and do not use relative pronouns. An example is shown below with Sinhala and Tamil equivalents:

SLP	*botus*	*diñeeru*	*ja-daa*	*pesaam*
Sinhala	*mahattea*	*salli*	*diy-e*	*miniha*
Tamil	*niinka*	*calli-ya*	*kuʈu-tt-a*	*aaḷ*
Gloss	you	money	gave	person

('The person to whom you gave the money'; Standard Portuguese *a pessoa a quem o Senhor dou o dinheiro*).

Another construction typical of Dravidian languages and shared by Sinhala is the so-called 'quotative construction', which marks the object of an overt or implied verb of thinking, naming, speaking, etc. The quoted material is followed by the quotative particle *falaa* or *falaatu* in Sri Lanka Portuguese, *kiyələ* in Sinhala, *enʈu* in Tamil. The quotative particle derives in all three languages from a verb meaning 'say'. In the example below, both the verb 'say' and the quotative particle appear:

SLP	*eli*	*jaa-falaa*	*eev*	*ja-kaa-falaa*	*falaatu*
Sinhala	*eyaa*	*kiwwe*	*mamə*	*kiww-e*	*kiyələ*
Tamil	*avan*	*connaan*	*naan*	*coll-i-ṯ-ṯ-an*	*enʈu*
gloss	he	said	I	have told	QUOTE

('He said "I have told [him]"' or 'He said he had told [you]'; Standard Portuguese *Ele disse que 'eu [lhe] falei'.* or *Ele disse que [lhe] tinha falado.*)

The vast majority of Sri Lanka Portuguese words are Portuguese in origin, but many other items are borrowed from Dutch, English, Sinhala, and Tamil, such as *gɔrgal* 'throat' (Du. gorgel), *ḍɔkʈa* 'doctor' (Eng.), *suura* 'toddy, a drink made from fermented palm sap' (Si. *surə*), *neeli* 'paddy, unhusked rice' (Ta. *nellu*). Occasionally, Sri Lanka Portuguese preserves a Middle Portuguese word no longer current in Standard Portuguese, such as *izmaleeru* ('beggar'; Standard Portuguese *esmoleiro*, archaic).

Literary Sri Lanka Portuguese is largely a nineteenth-century phenomenon. Kenneth David Jackson's book *Sing without shame* demonstrates that an oral tradition existed, which, because of its ties with the

traditions of other Portuguese-speaking communities, probably originated during Portuguese rule on the island. The earliest extant printed records of the creole are the work of Wesleyan missionaries, who made extensive use of Indo-Portuguese in both India and Sri Lanka (see Fox 1819.) Either through ignorance or because of a desire to dignify the low-prestige creole, the missionaries dressed Sri Lanka Portuguese in the trappings of the more prestigious standard language to which it is related, producing a hybrid variety combining Standard Portuguese spelling and generally Standard Portuguese and English grammar with some aspects of creole word structure, particularly in the use of verb prefixes.

The fact that we have reason to be skeptical of nineteenth-century Sri Lanka Portuguese texts should make us equally skeptical of nineteenth-century creole texts in general, and of those purporting to represent other varieties of Indo-Portuguese in particular.

Standard Language

A standard language presupposes diglossia. Diglossia is a situation where dialectal varieties of a language in a polity function differently. The dialect adopted as the official medium of communication in formal settings becomes the standard language. Consequently, a standard language rises from a contention of several dialects. A standard language is the medium of instruction in national education, official correspondence in written communication, and mass communication in mass media like newspapers, television, films, books, and magazines.

Standard Malay in Malaysia went through interlanguage and intralanguage contentions. At the brink of independence in 1957, Malay became the national language of Malaysia and English would be phased out gradually in ten years. To equip Malay with the role of a modern language, a semigovernment body called *Dewan Bahasa dan Pustaka* was set up in 1956 to standardize the Malay spelling, and to coin Malay scientific terminology. At this interlanguage stage, Malay rose above English, Mandarin, and Tamil, among others, as the standard language in all formal settings.

Lingua franca is the common language of social or commercial communication among polyglot societies. *Johor Malay* was the lingua franca in the Malayan world. During the colonial years, *Johor Malay* was the language of publication when the press came to Malaya (preindependent Malaysia) from Singapore via Johor, a southern Malay state, to Kuala Lumpur (see Asmah). In the contention of standard language, the victory normally goes to the dialect with historical advantage. The present modern Standard Malay, however, defies the historical norm. *Johor Malay*, originating from the southern part of the Malay Peninsula, was the Standard Malay until *Kedah Malay* replaced it. Since 1988, *Kedah Malay* was decreed as Standard Malay because the writing system of this northern Malay dialect is phonemic, i.e. its spelling directly corresponds with the pronunciation. The [a] sound in an open syllable in the word-final position is pronounced as /a/ as in /baca/ (read) and /cerita/ (story) in this dialect. In comparison, /baca/ and /cerita/ are uttered as /bace/ and /cerite/ in *Johor Malay*. Due to these user- and education-friendly reasons, students and teachers were instructed to

adopt the standard [a] pronunciation in oral examinations, school lessons, and public speeches. In short, current Standard Malay in Malaysia is a result of both interlanguage and intralanguage competitions.

At the end of 1993, however, the Prime Minister of Malaysia announced that English would be the language of instruction for science and technology at the varsity level. There was an outcry over the threat of English on Standard Malay, which has been the medium of instruction from primary to tertiary education. *Internationalism* was used to describe the new era of change dawning on young polities like Malaysia, which once preoccupied itself with nationalism. Although Malay remains as Malaysia's standard language, its linguistic path transformed from the interlanguage stage to the intralanguage phase and another modern interlanguage attrition in the face of prosperity. In fact, as early as the 1980s, English-educated Malay elites were speaking *Malayish*, a mixture of Malay and English.

To give another language situation, four languages, namely English, Malay, Mandarin, and Tamil, are designated as the official languages in Singapore following a 1956 official report. Through the 1991 *Improving primary school education* report, English has eclipsed the other three official languages as the medium of instruction in Singapore. While the three official languages are taught as mother tongues in school, English dictates the academic future of the students because failing to master the English language is a disadvantage in an education system that offers English as the first language.

Interestingly, there are two varieties of English in Singapore, namely Singapore English or Singlish and Standard Singapore English. Regarded as closely connected to Chinese in terms of ethnicity and language, Singapore English lacks complicated grammatical rules and displays a fair deal of loanwords from Hokkien, a Chinese dialect, and Malay. Typical phrases of Singapore English are, '*Don't play-play*' (Do not fool around), '*Catch no ball*' (Do not understand), and the suffixation of the particle *-lah* as in '*go-lah, eat-lah, please-lah*'. In addition to providing emphasis and a sense of persuasion to the three words, the particle-*lah* can incur a negating sense of disagreement to *please*. Despite the vibrant pragmatics, i.e. situational meaning of words when in use, this variety of local English is considered better than not knowing English at all and is also thought to be associated with the lower classes and low-paid occupations. Students are required to adopt Standard Singapore English as the medium of communication and examination. Lately, as China becomes the new world economy that offers plenty of business opportunities, the go-north investment strategy gathers more momentum among Singapore entrepreneurs. Mandarin in Singapore, although has not made a significant comeback, seems to have a promising linguistic future. There is little research on the relation between Singapore and China Mandarin. Singapore exemplifies another complex inter- and intralanguage situation in the linguistic life span of standard language.

Based on the language of mass media in the United States, especially the English used in Hollywood movies and American sitcoms on television, Standard American English is the standard language that rises above African American English, Cajun English, Latino English, and Chicano English. American English is different from British English as in these contrasts: *windshield–windscreen, hood–bonnet, truck–lorry, expressway–motorway, elevator–lift, mail–post, diaper–nappy, lawyer–barrister, mean– nasty*, and *dumb–stupid*. Mistaken as American English, the word *talented* along with other American English words like *dutiable, presidential, lengthy, finalize, normalcy*, and *irregardless* were once abhorred as nonstandard English. The term Americanism, first used by John Witherspoon in 1781, refers to the use and construction of English vocabulary and sentences in the United States that are different from those in Great Britain. Americanism implies a new English dialect. When do two dialects become two different languages? By the rule of thumb, a situation of two languages arises when two dialects become mutually unintelligible. Languages like Urdu and Hindi spoken in Pakistan and India, however, are mutually intelligible; so are Danish, Norwegian, and Swedish spoken by Danes, Norwegians, and Swedes, respectively.

Story Grammar

The rediscovery of early structuralist work—for example, of Propp's research on the structure of Russian folk tales—and the development of transformational-generative grammar led to the emergence of story grammars in the 1970s. Linguists such as Morton Prince, George Lakoff, and Teun van Dijk and cognitive psychologists such as Jean Mandler and Nancy Stein contributed to this effort.

The story grammar approach holds that (1) simple stories exhibit a typical structure and (2) there is general agreement among listeners whether a given text represents a story. For example, the following set of phrases is considered a story, however trivial: 'A man was very happy, then he married a vain and domineering woman, then, as a result, he was very unhappy,' but the following phrase is not: 'Electrons are constituents of atoms.'

Among psycholinguists and cognitive psychologists, story grammar was viewed as an instance of a schema, an idealized model of the constituents of a story, and the relationship among the constituents. The story schema has been expressed in terms of rewrite rules analogous to those of transformational grammar. Representative of other story grammars, the Mandler grammar includes the following rules:

- Story → Setting and Episode(s)
- Episode → Beginning cause Complex Reaction cause Goal Path cause Ending
- Complex Reaction → Reaction cause Goal
- Goal Path → Attempt cause Outcome

This set of rules, as well as additional rules, generates a hierarchy, whose terminal elements are the surface sentences of a story.

The setting (S) describes the background that enables the events in the story. Usually, the principal characters of the story are introduced in the setting. An episode gives a story its narrative component. An episode is defined from the perspective of a protagonist who is faced with a problem and tries to solve it. The problem is triggered by events described in the beginning (B) of the episode. Then, the protagonist exhibits a reaction (R) to the problem, and he or she sets a goal (G) and makes an attempt (A) to achieve the goal. The result of the attempt is narrated in the outcome (O). The episode concludes with an ending (E), which may report the protagonists' reaction to the outcome, state a general moral, or simply emphasize

the outcome. A canonical episode includes these six constituents, where G, A, and O are obligatory in a well-formed story.

Mandler used the following dog fable to illustrate these story constituents:

- (S) It happened that a dog had got a piece of meat and was carrying it home in his mouth. Now on his way home he had to cross a plank lying across a stream.
- (B) As he crossed he looked down and saw his own shadow reflected in the water beneath.
- (R) Thinking it was another dog with another piece of meat,
- (G) he made up his mind to have that also.
- (A) So he made a snap at the shadow,
- (O) but as he opened his mouth the piece of meat fell out, dropped into the water,
- (E) and was never seen again.

The rules reflect the property of a story that the sentences do not simply represent a sequence of unrelated events. Rather, the events are causally linked as specified by the rules. A story may include multiple episodes that may be sequenced, recursively nested, or exhibit some other relation. For example, an episode may be interrupted because of an obstacle that the protagonist must overcome.

Story grammars have been criticized for various reasons. Computational linguists in the tradition of Roger Schank and Robert Abelson took the story grammar approach to task for abstracting the structure of stories from their content. Similar criticisms have also been raised vis-à-vis the syntactic approach to sentences. In each case, the principal criticism is that grammatical categories cannot be defined independent of the semantic relations of the constituents to one another. As a result, the grammars provide no source for the inferences that readers routinely make. In addition, the story schema, like other schemas, is either too general or too simple to do justice to the wide variety of narratives. Other critics argued that story grammars are technically not grammars at all because they do not specify terminal elements in the manner of transformational-generative grammar.

In defense of story grammars, it should be noted that they are not mutually exclusive from other knowledge sources at different levels of complexity, whether they are scripts, schemas, etc. And it is important to

note that the story grammar approach has produced an impressive body of empirical research validating critical assumptions about the narrative structures specified by story grammar. Consider evidence from three different paradigms: structural judgments, recall patterns, and reading times.

- Judgments of stories: Researchers had people read stories of diverse contents and divide the passages into parts. The structures produced by participants correlated well with the a priori structure of stories provided by story grammar theory.
- Recall patterns: Research revealed that people remember stories better if the stories are well formed. For other stories, people tend to generate 'improved' structures, much in the manner of subjects who 'corrected' a passage with an unfamiliar sentence structure to fit with their expectations. Further empirical studies have shown that people's recall protocols were predicted by the importance of constituents in the story hierarchy, with beginning, attempt, and outcome being best recalled.
- Reading times of story sentences in self-paced reading experiments were found to be sensitive to the episodic structure of simple two-episode

stories. Reading times adjusted for sentence length and other factors were longer at the beginning of episodes than for the remaining constituents. This pattern has been interpreted in terms of readers' effort at calling up the episode schema into memory.

The story grammar approach continues to survive in successor approaches, including causal chain theory and other theories of narrative, as described in Goldman et al.'s (1999) volume cited below.

Structural Interference

As the name signifies, structural interference denotes the intrusion of various linguistic structures of one language in the use of another. These intrusions can be at the level of phonology, morphology, syntax, discourse, pragmatics, and semantics. Some examples of structural interference in terms of transfer are given below:

1. Linguistic Transfer
1.1. Morphological: Doctor**ji**, Master**babu**, [transfer of honorific like 'ji', 'babu', from Indian languages (L1) into English (L2)]
1.2. Lexical: **/computer** eta kinib lagib /
Computer one buy should first person
I should buy a computer
[transfer of L2 lexical item, 'computer' into L1, in this case Assamese)
1.3. Word order: concerned authorities (transfer of L1 i.e. Hindi word order, i.e. adjective + noun into L2, i.e. English)

1.4. Syntactic: I am reading this book since morning (transfer of L1, i.e. Hindi syntactic feature—the use of present continuous tense for present perfect continuous—into L2, i.e. English)
1.5. Semantic: In India, use of 'auntie' for all elderly women
1.6. Discoursal: I respectfully submit the following few lines for your kind consideration (transfer of politeness rules).

2. Cultural Transfer
2.1. Lexical: What is your **good name**? (transfer of the Indian expression 'shubh-naam')
2.2. Discoursal: My nose has been cut; I can no longer show my face to anyone. (transfer of a Hindi idiomatic expression from L1 to L2).

3. Psycholinguistic Transfer

A psycholinguistic transfer is one that is determined by the learner's perception of the relationship between L1 and L2 and certain characteristics of L1 rules and items. Thus, when a German speaker is termed impolite by an English speaker, she or he perceives the two languages to be similar at the level of syntactic, discoursal, and pragmatic features. For example, when a German speaker says, 'You should close the window', in a situation where a native speaker of English will prefer using 'Can/could you close the window?', she or he is not being impolite but is transferring the politeness strategy from her or his L1 to L2 (cf. House and Kasper 1981). Again, when a Hindi speaker says, 'You are lucky, **isn't it**?', she or he uses her or his knowledge of the Hindi question tag *hein na* and transfers the rule of the application of *hein na* to English.

Structural interference is closely context bound. Increasing research evidence shows that learners can produce a significantly more fluent, grammatical, and transfer-free interlanguage (i.e. the separate linguistic system evinced when adult L2 learners attempt to express meaning in a language that they are in the process of learning) in some social contexts rather than in others.

Structural interference can also be strategic: for example, Ervin-Tripp (1969) pointed out that L2 learners might protect themselves from the consequences of sociolinguistic errors by maintaining non-native features in their speech, i.e. they might maintain structural interference to protect themselves from being assessed on the basis of native-speaker norms and expectations. Similarly, there can be deliberate structural interference to exhibit solidarity, or to serve business purposes. Researchers have noted that salespersons use different dialects and intonations depending upon their judgment of the customers' economic, linguistic, and ethnic background. In social research, some specialists suggest the use of the subjects' dialect by the researchers to make the population sample under observation feel at home. Moreover, there are different transferability criteria. The learner's assessment of the interlocutor's receptive knowledge of different language codes as well as processing constraints such as the degree of automatization are relevant factors in transfer as well as in production.

There are various theories about what, how much, why, and how a structural interference occurs. The notion of structural interference was primarily advanced by linguists interested in teaching English to learners of other languages during the 1950s. Under the influence of the structural approach in linguistics and the behaviouristic theory in psychology,

the contrastive analysts (linguists comparing the structures of two/more languages) hypothesized that language learning is habit formation and an old habit affects the formation of a new habit. Therefore, they claimed that by carrying out an explicit analysis of similar and dissimilar features of different languages, we could arrive at a foolproof theory of structural interference. When this theory was found to have loopholes, other theories emerged, stressing the processes of language acquisition. For example, the creative constructionists assume that L1 (first language/mother tongue) and L2 (second/foreign language) acquisition proceed in a similar manner. Hence, L2 acquisition is largely unaffected by L1 transfer, which in turn means structural interference is not related to language acquisition. The interlanguage hypothesis proposed by Selinker (1972), on the other hand, recognizes the major influence of the native language in the learning and use of a second language, but it also mentions some four other processes like overgeneralization of target language rules, strategies of communication, strategies of second language learning, and transfer of training. Interlanguage differs both from the native (NL/L1) and the target language (TL/L2), with fossilization (a stage where L2/TL learning stops due to pressure of communication/use) being the most significant feature. This theory of adult L2 learning is now extended to child language acquisition as well.

Research on the various aspects of structural interference has contributed significantly toward effective learning and teaching of second languages, particularly, teaching of English as a foreign language.

Structuralism

Structuralism is a mode of inquiry that consists in interpreting the phenomena it looks at as made up of relations among the various entities rather than as those entities per se. The particular units are thus defined solely by virtue of the network of relations into which they enter. They are, in other words, defined in negative terms rather than in terms of positive contents, so that any change in any one of the relationships will automatically affect the entire set of relationships within the given structure. Another way of putting this is to say that all structures constitute fully integrated systems, in which the elements are fully dependent on one another and are sensitive to the most minute of alterations taking place in any part of any given system. Because each structure is fully and exhaustively defined by the relations among the elements, it makes little sense to speak of universal structures; each structure is, as it were, a law unto itself. Yet another feature of structures in general is that they provide us with a snapshot of the phenomena rather than the evolutionary stages through which those phenomena pass; they are static and synchronic par excellence. Furthermore, many structuralists have been at pains to point out that the structures they describe are posited as such and not inherent in or latent to the phenomena themselves.

It is important to stress that structuralism did not initially emerge as a school of thought or a philosophical tendency. Yet, toward the end of the nineteenth century and in the early decades of the twentieth century, structuralism had established itself as a major force to reckon with, reaching its pinnacle of glory by the 1930s. Structuralism swept across almost all fields of inquiry, making significant contributions to the humanities and the social sciences. Among the most important names associated with the movement are Ferdinand de Saussure, Claude Lévi-Strauss, Roland Barthes, and Louis Althusser. Ferdinand de Saussure, hailed as the Father of Modern Linguistics and author of *Cours de Linguistique Générale* (1916; *A course in general linguistics*), which was published posthumously, inaugurated the structuralist revolution in linguistics. (It has, however, been argued that some of the key principles of structuralism may actually date back to thinkers such as Leibniz, Marx and Engels, Humboldt, Herder, and so on.)

It is important to point out that the term 'structuralism' came to acquire markedly different characteristics in the United States, where it is used to refer to the set of methodological principles brought to bear on linguistic analysis by the followers of Leonard Bloomfield, whose 1933 book *Language* has been referred to as the Bible of American structuralism. Among the distinguishing traits of Bloomfieldian structuralism are its stubborn aversion to questions of meaning and its close ties with behaviorist psychology. Bloomfield was also keen on making linguistics a genuinely scientific discipline, which, under the terms of the philosophy of science then in vogue, meant rigorously restricting evidence to empirically available data.

But, apart from these crucial differences, Bloomfield's structuralism was at one with its European counterpart in insisting that language be viewed as a self-contained whole and that the entities be identified relationally rather than in terms of any positive content. The key relations were those of contrast and equivalence. The sound system, or phonology, of a given language, for instance, was seen as being made up of units called 'phonemes', whose existence was predicated on the identification in the language in question of a set of contrasts with other phonemic units, each of which was to be likewise posited on the strength of the same principle. The litmus test of a contrast was a 'minimal pair', which is a pair of words identical in every respect except for the particular contrast as in *cat* and *mat*, in which the only difference is marked by the contrast between the phonemes /k/ and /m/, or in the pair *mat* and *mate*, in which the only difference consists in the change of vowels. Where two phonetically distinct items did not enter into a relationship of contrast but instead manifested what is technically known as 'complementary distribution' (that is, where one occurs, the other can never occur), the two variants were to be regarded as systematic variants of the same phoneme called 'allophones'. The same procedures were then applied to other levels of analysis, notably word structure, where the analysis yielded analogous entities such as 'morphemes' and 'allomorphs'. At the sentence level, the structuralist method yielded what is referred to as 'immediate constituent analysis'. Thus, a sentence such as *The dog barked all night* was analyzed as con-

taining the immediate constituents 'the dog' and 'barked all night'. The resulting constituents were further analyzed into the immediate constituents 'the' and 'dog' and 'barked' and 'all night', respectively, and the constituent 'all night' further on into 'all' and 'night', with the process ending once the ultimate constituents had all been identified. Finally, as what would have come as an unpleasant surprise to Bloomfield himself had he lived long enough to witness the development, the techniques of structural analysis were carried over to the analysis of meanings, paving the way for a structurally oriented theory of semantics.

Unlike its European counterpart, Bloomfieldean structuralism invested a considerable amount of effort in identifying what came to be known as 'discovery procedures', that is, a set of methodological principles with guaranteed results that would automatically and infallibly generate the right analysis from a given set of empirical data. These discovery procedures came under heavy attack from Noam Chomsky and the followers of the new paradigm of transformational-generative linguistics that he inaugurated in the 1950s. Chomsky dismissed the whole idea of discovery procedures and claimed that a linguistic theory should instead aim at attaining explanatory, rather than merely observational or descriptive, adequacy.

Despite the major differences between Bloomfieldean linguistics and generative grammar, it is nevertheless true to say that Chomsky's approach is structuralist in an extended sense of this term—although it is also the case that, thanks to the tireless criticism of the early Bloomfieldean practices by the early transformational-generative grammarians, the term 'structuralism' itself fell into disrepute and acquired pejorative connotations that survive now. Chomsky retained the basic idea of language being structured but opted for an atomistic approach to the notion of structure instead of the holistic vision that underwrote the European (mainly French) approach. The elementary building blocks of the structure were no longer negatively defined but were invested with positive attributes. Generative phonology adopted as its basic building blocks 'distinctive features' that were universal and not language specific. The so-called phonemes were from now on seen as merely contingent and language-specific combinations of these features. This important theoretical intervention permitted Chomsky and his followers to posit a universal base for all languages, shifting the focus of attention to language as an innate species-specific attribute of man and redefining linguistics itself as a branch of cognitive psychology.

It should not be concluded from the foregoing remarks that structuralism in its classic sense is by now a spent force. Quite on the contrary, Saussure's teachings continue to inspire generations of scholars and is still a point of reference for so-called post-structuralism, whose advocates, far from rejecting *tout court* the legacy of Saussure's teachings, use them as a springboard for further advancing his insights, albeit to logical consequences unimagined by the Swiss savant. As for Bloomfield's legacy, it too arose from the ashes and gained a further lease on life in the form of what is referred to as neo-Bloomfieldeanism, notably in the work of Bernard Bloch (1907–1965).

Stylistics

Stylistics is the description and analysis of the variability of linguistic forms in actual language use. The concepts of 'style' and 'stylistic variation' in language rest on the general assumption that within the language system, the same content can be encoded in more than one linguistic form. Operating at all linguistic levels (e.g. lexicology, syntax, text linguistics, and intonation), stylisticians analyze both the style of specific texts and stylistic variation across texts. These texts can be literary or nonliterary in nature. Generally speaking, style may be regarded as a choice of linguistic means; as deviation from a norm; as recurrence of linguistic forms; and as comparison.

Considering style as choice, there are a multitude of stylistic factors that lead the language user to prefer certain linguistic forms to others. These factors can be grouped into two categories: user-bound factors and factors referring to the situation where the language is being used. User-bound factors include, among others, the speaker's or writer's age; gender; idiosyncratic preferences; and regional and social background. Situation-bound stylistic factors depend on the given communication situation, such as medium (spoken vs. written); participation in discourse (monologue vs. dialogue); attitude (level of formality); and field of discourse (e.g. technical vs. nontechnical fields). With the caveat that such stylistic factors work simultaneously and influence each other, the effect of one, and only one, stylistic factor on language use provides a hypothetical one-dimensional variety. Drawing on this methodological abstraction, stylistic research has identified many correlations between specific stylistic factors and language use. For example, noun phrases tend to be more complex in written than in spoken language in many speech communities, and passive voice occurs much more frequently in technical fields of discourse than in nontechnical ones.

Style, as deviation from a norm, is a concept that is used traditionally in literary stylistics, regarding literary language as more deviant than nonliterary language use. This not only pertains to formal structures such as metrics and rhyme in poems but to unusual linguistic preferences in general, which an author's poetic license allows. Dylan Thomas's poetry, for example, is characterized by word combinations that are semantically incompatible at first sight and, thus, clearly deviate from what is perceived as normal (e.g. *a grief ago, once below a time*). What actually constitutes the 'norm' is not always explicit in literary stylistics, since this would presuppose the analysis of a large collection of nonliterary texts. However, in the case of authorship identification, statistical approaches were pursued at a relatively early stage. For example, by counting specific lexical features in the political letters written by an anonymous Junius in the 1770s and comparing them with a large collection of texts from the same period, and with samples taken from other possible contemporary authors, the Swedish linguist Ellegård could identify, in the 1960s, the most likely author of those letters.

The concept of style as recurrence of linguistic forms is closely related to a probabilistic and statistical understanding of style, which implicitly underlies the deviation-from-a-norm perspective. It had already been suggested in the 1960s that by focusing on actual language use, stylisticians cannot help describing only characteristic tendencies that are based on implicit norms and undefined statistical experience in, say, given situations and genres. In the last resort, stylistic features remain flexible and do not follow rigid rules, since style is not a matter of grammaticality, but rather of appropriateness. What is appropriate in a given context can be deduced from the frequency of linguistic devices in this specific context. As for the analysis of frequencies, corpus linguistic methods are becoming increasingly important. With the advent of personal computers, huge storage capacities, and relevant software, it is now possible to compile very large collections of texts (corpus (singular), corpora (plural)), which represent a sample of language use in general, and thus enable exhaustive searches for all kinds of linguistic patterns within seconds. This methodology is based on the general approach of style as probability, by allowing for large-scale statistical analyses of text. For example, by using corpora, the notion of text-type—defined by co-occurrences of specific linguistic features—has been introduced to complement the extralinguistic concept of 'genre'. The linguistically defined text types contradict traditionally and nonempirically established genre distinctions to a considerable extent. In particular, many spoken and written genres resemble each other linguistically to a far greater extent in terms of text-types than previously assumed.

Style as comparison puts into perspective a central aspect of the previous approaches. That is, stylistic

analysis always requires an implicit or explicit comparison of linguistic features between specific texts, or between a collection of texts and a given norm. In principle, stylistically relevant features such as style markers may convey either a local stylistic effect (e.g. an isolated technical term in everyday communication) or, in the case of recurrence or co-occurrence, a global stylistic pattern (e.g. specialized vocabulary and passive voice in scientific texts).

From the multitude of linguistic approaches to style, two linguistic schools of the twentieth century have exerted the most decisive influence on the development, terminology, and the state of the art of stylistics: the Prague School and British Contextualism.

The central dictum of Prague School linguistics, going back to the Bauhaus School of architecture, is 'form follows function'. Firmly established since the 1920s, some of this dictum's most important proponents are Lubomír Doležel, Bohuslav Havránek, Roman Jakobson, and Jan Mukařovský. These linguists have paid particular attention to situation-bound stylistic variation. A standard language is supposed to have a communicative and an esthetic function that result in two different 'functional dialects': prosaic language and poetic language. More specific functional dialects may, of course, be identified; for example, the scientific dialect as a subclass of prosaic language, which is characterized by what is called the 'intellectualization of language'—lexicon, syntax, and reference conform to the overall communicative function that requires exact and abstract statements.

A very important notion is the distinction between 'automatization' and 'foregrounding' in language. Automatization refers to the common use of linguistic devices which does not attract particular attention by the language decoder, for example, the use of discourse markers (e.g. *well*, *you know*, *sort of*, *kind of*) in spontaneous spoken conversations. Automatization thus correlates with the usual background pattern, or the norm, in language use—it encompasses those forms and structures that competent language users expect to be used in a given context of situation. Foregrounded linguistic devices, on the other hand, are usually not expected to be used in a specific context and are thus considered conspicuous—they catch the language decoder's attention (e.g. the use of old-fashioned and/or very formal words such as *epicure*, *improvident*, and *whither* in spontaneous spoken conversations). Foregrounding thus captures deviations from the norm. It is obvious that what is considered as automatized and foregrounded language use depends on the communication situation at hand. In technical fields of discourse, for instance, specialized vocabulary items tend to be automatized (e.g. *lambda marker* in molecular biology), but in everyday communication become foregrounded devices.

A different, although conceptually similar, tradition of linguistic stylistics was established by British linguists in the 1930s and came to be called British Contextualism. The most important proponents of British Contextualism include John Rupert Firth, M.A.K. Halliday, and John Sinclair. Their work is characterized by a clear focus, firstly, on the social context in which language is used and, secondly, on the indepth observation of natural language use. From the point of view of British Contextualists, linguists need to describe authentic language use in context and should not confine themselves to invented and isolated sentences. Additionally, linguistics is not considered as an intuition-based study of abstract systems of form as, for example, in the merely formal description of autonomous syntactic rules (as in Chomsky's approach to language), but as the observation-based and empirical analysis of meaning encoded by form. This approach allows for insights into the immense variation within language. It is a fact that depending on the context of situation, all speakers use different 'registers' (i.e. different styles of language, depending on the topic, the addressee, and the medium in a given context of use). Note that there is, of course, a clear correspondence between the concept of register and the Prague School's notion of functional dialect. Although largely abandoned by mainstream linguists in the 1960s and 1970s due to the prevailing Chomskyan school of thought, it had already been suggested by Firth in the 1950s that large collections of text were a prerequisite for an empirical approach to stylistic variation. Thus, it does not come as a tremendous surprise that, among others, Sinclair set out to develop computerized corpora that could be used as empirical databases.

With corpus linguistics now a standard methodology, stylistic analyses have reached an unprecedented degree of explanatory adequacy and empirical accuracy. For example, stylistic features that are beyond most linguists' scope of intuition, such as the nonstandard use of question tags in English-speaking teenagers' talk, are now feasible in quantitative terms. More importantly, there is no longer a bias toward foregrounded phenomena that tend to catch the linguist's attention. A computer, in contrast, does not distinguish between conspicuous and common phenomena and provides an exhaustive array of all kinds of patterns, depending solely on the search query. Thus, the fuzzy concept of 'norm' is about to be put on an empirical footing since the accessible corpus norm represents the norm of a language as a whole.

Stylistics is a linguistic branch that is immediately relevant to foreign language teaching. This applies to both linguistic and literary stylistics. Language learners must know which linguistic devices are preferred by native speakers in specific contexts. Without such a

linguostylistic competence, communication errors may be made in interacting with native speakers, such as using highly formal words in informal settings. Also, learners must have command of text-typological knowledge, which is important, for example, in writing essays. As for literary texts, language learners should acquire a firm understanding of those levels of description where stylistic variation may occur (e.g. by analyzing Hemingway's syntactic simplicity and, moreover, its function).

It should be noted that a specific style is sometimes ascribed to a language in its entirety. Although the underlying norms remain largely unspecified, general tendencies of stylistic preference differ across languages. This is particularly important for translators, but also for language learners. It is, for instance, common for German students of English to transfer the German style of academic writing, which is characterized by heavy noun phrases, to their English essays.

As with any other linguistic branch, stylistics is very much a work in progress. This is because the object of inquiry constantly grows, evolving new and specialized fields of discourse (e.g. genetic engineering, computer sciences). Furthermore, new aspects of stylistic variation come into existence, such as e-mails, a now widely used genre that seems to blur the traditional distinction between spoken and written language. As for empirical approaches to style, new corpora make it possible to address questions of style not possible before. Also, recent theoretical developments will no doubt widen the scope of stylistics. Drawing on British contextualists' distinction between language substance (that is, sound waves in the phonic medium and printed paper in the graphic medium) and language form (that is, anything that can be transferred from one medium into the other), it has been suggested that stylistic analyses should clearly distinguish between medium-dependent and medium-independent stylistic variation. Intonation, for example, is bound to the phonic medium and shows stylistic variation that cannot be mapped onto punctuation in a straightforward and monocausal way. With regard to the graphic substance, English orthography, albeit highly standardized, is also affected by stylistic variation, as deliberate misspellings in the language of advertising and popular culture (e.g. *2* for *to/two/too*, *lynx* for *links*) reveal. On the other hand, words and syntax are linguistic devices that, in principle, are subject to transfer between media, although there are clear medium-dependent preferences of lexical and syntactic choice that need to be investigated further.

The objective and unbiased approach to stylistic variation in authentic language use is a cornerstone of modern descriptive linguistics. Unlike traditional grammar, it clearly rejects the normative prescription of one specific style.

Sumerian

Sumerian was a language spoken in the south of Ancient Mesopotamia (modern Iraq) and is most likely first attested in the archaic texts from Uruk and Jemdet Nasr (from the end of the fourth millennium to the middle of the third). By the end of the third millennium, Sumerian had died out for the most part as a spoken

language. However, it was still used in a wide variety of literary, scholarly, and religious genres, and was preserved in writing until the practical disappearance of the Mesopotamian civilization. Sumerian is an ISOLATE, i.e. it is not related to any other language or language family. Thus, our knowledge of Sumerian grammar and lexicon is mostly based on a large number of bilingual texts (in Sumerian and Akkadian), as well as a stream of scribal and scholastic traditions materialized in a corpus of lexical lists and grammatical texts.

Phonology and the Writing Interface

Mesopotamian CUNEIFORM is the logosyllabic script used for Sumerian. For instance, the sign AN (originally a star) could write the word **an** 'sky, heaven', as well as **dingir** 'god'. As a consequence of this and other processes, cuneiform signs are polyphonic, i.e. they have several readings (e.g. the sign NE can be read {ne}, {de$_3$}, {bi$_2$}, etc.). On the other hand, the writing interface shows HOMOPHONY, because different signs can have the same reading, such as {e}, {e$_2$}, {e$_3$}, {e$_4$}..., {e$_{11}$} (numerical indexes are used to distinguish between homophonous signs). Furthermore, scribes used determinatives preceding or following some nouns and names, simply as reading aids: KI 'place' in **lagaš^{ki}**; DINGIR 'deity' in **^{d}nanna**, etc.

Our knowledge of Sumerian PHONOLOGY is limited by the nature of the writing interface. The vocalic system is quite simple: /a/, /i/, /e/, /u/. The possible existence of an /o/ vowel remains unsubstantiated. Vocalic length does not seem to be phonological. The consonantal system includes three series of stops (/b/ and /p/; /d/ and /t/; and /g/ and /k/), three sibilants (/s/, /z/, and /š/ = IPA ʃ), two laterals (/l/ and /r/), three nasals (/m/, /n/, and /g̃/ or /ŋ/), and a uvular or pharyngeal of undefinable nature (/h/ or /ḫ/). Furthermore, the existence of different 'extra phonemes' (segments that would not be immediately obvious in the writing interface) has been proposed. Among these, the velar nasal /g̃/ or /ŋ/ is now commonly accepted by all Sumerologists—for instance, both {mu} and {gu$_{10}$} are written with the same sign, MU—as well as /d^r/ (most likely /ř/). To further complicate things, some final consonants (*Auslaut*) seem to drop (**kala** 'mighty' < /kalag/), but the same signs have readings with and without *Auslaut*: **kala** = **kalag**; **dug$_4$** = **du$_{11}$** 'to speak'.

Our knowledge of Sumerian PHONOTACTICS is limited. Although the cuneiform system, as most syllabaries, precludes the writing of initial and final consonantal clusters, it is quite likely that Sumerian did have them. In compounds, medial consonantal clusters were also sometimes difficult to indicate: **ki-**

sikil /kiskil/ ('girl'), **gir$_5$-gir$_5$-(r)e** /gigre/ ('to sink, to dive'), etc. Some have suggested that Sumerian may have had lexical tones as a suprasegmental feature, which allegedly would explain the sometimes high number of homophonic terms. However, other factors can explain this: different *Auslaut* consonants, consonantal clusters, etc.

VOWEL HARMONY occurs with several verbal prefixes, and traces of it can be found in some nouns. The explicit writing of vowel harmony developed through time in diverse ways. For instance, in the case of the verbal modal prefix /he-/ or /ha-/ (see below), the orthographic evolution went from one allomorph (**he$_2$-**), to two (**he$_2$-** and **ha-**), and eventually to three (**he$_2$-**, **ha-**, and **hu-**).

Nominal Morphology

Sumerian is an AGGLUTINATIVE language. The grammatical gender is based on an opposition between animate and inanimate nouns, but has no specific morphological marker and only surfaces in morphosyntactical relations between pronouns and their antecedents. Grammatical number (plural vs. singular) does not need to be marked in writing (**lugal** 'king' or 'kings'), but can be made explicit through suffixation (**lugal-e-ne** /lugal-ene/ 'kings') or reduplication (**lugal-lugal** 'kings'). The absence of marker and lexematic reduplication are probably simple orthographic conventions to write the plural, as may be indicated by the construction of plurals with reduplication of the adjective (**dingir gal-gal** = *god-great-great* 'great gods') or with reduplication and an additional suffix (**dingir gal-gal-e-ne** = *god-great-great*-PLURAL 'great gods').

In the nominal system, there are ten cases, which are marked by attaching suffixes to Noun Phrases (NPs). Moreover, cases can also be indicated by inserting prefixes in verbal forms (all elements preceding the stem are called prefixes):

	Nominal suffixes	*Prefixes in verbal chain*
ERGATIVE	/-e/	
ABSOLUTIVE	/-∅/	
GENITIVE	/-ak/	
DATIVE	/-ra/	/-na-/
LOCATIVE	/-a/	/-ni-/
COMITATIVE	/-da/	/-da-/
TERMINATIVE	/-eše/ ({-še$_3$})	/-ši-/
ABLATIVE–INSTRUMENTAL	/-ta/	/-ta-/ or /-ra-/
LOCATIVE–TERMINATIVE	/-e/	/-e-/ (or /-i-/)
EQUATIVE	/-gin/ ({-gin$_7$} = GIM)	

NPs are usually called 'nominal chains' by Sumerologists, because all the suffixes are heaped at the very end of the last syntagm:

dumu lugal kalam-ma-ka-ke₄-ne-ra
/dumu lugal kalam-ak-ak-ene-ra/
son-king-nation-GEN-GEN-PL-DAT
'for the son of the kings of the nation (=Sumer)'

Nonetheless, the syntagmatic structure is not so much that of a chain as it resembles a series of Chinese boxes (Zólyomi 1996):

ᵦ[dumu ₐ[lugal kalam-ak]ₐ-ak-ene]ᵦ-ra

Sumerian is an ERGATIVE language: the subject of an intransitive verb presents the same marker as the object of a transitive verb (the absolutive case), while the subject of a transitive verb presents a marker (the ergative case) that is different from that of the intransitive verb. Thus, Sumerian has /-e/ as the ergative suffix, and /-∅/ as the marker of absolutive case:

lugal-e e₂ mu-un-du₃	'the king built the temple'
lugal i₃-tuš	'the king sat down'
nin-e in-tud-en	'the queen bore me'
nin i₃-tuš	'the queen sat down'

In fact, Sumerian exhibits split ergativity in its morphology. The ergative alignment is strictly followed only in the nominal system. Independent personal pronouns, imperatives, cohortative verbal forms, and a few nonfinite verbal constructions exhibit an accusative alignment. The system of verbal agreement shows a similar split: the *ḫamṭu* forms (perfective) are ergative, whereas the *marû* forms (imperfective) show an accusative pattern.

The Verbal System

Verbal stems are usually divided into two major categories: *ḫamṭu* ('quick, sudden' → perfective) and *marû* ('slow, fat' → imperfective). However, these two labels, rather than native Sumerian grammatical categories, reflect the understanding of the Sumerian verb by Akkadian-speaking scribes. In an early grammatical text, **lugud** ('short') occurs instead of *ḫamṭu*, and **gid₂** ('long') instead of *marû* (Civil 2002)—the same two terms were used by ancient scribes in naming signs according to their shapes. Thus, the same labels, when used to designate verbal stems, refer to the shape of the stems, which would be regarded as long because of reduplication and other possible changes. These two stems marked tense and aspect, perfective and imperfective, as well as mood (deontic versus epistemic) when occurring with certain modal prefixes (see below).

The problem of the marking of the so-called *marû* stem is still widely discussed. It is likely that all verbs had two stems. Affixation verbs perhaps marked the *marû* stem with an affix /-e/; reduplication verbs (like **gar** 'to place') marked it with partial reduplication (**ga₂-ga₂**), as opposed to complete reduplication in *ḫamṭu* forms (**gar-gar**); alternating verbs (such as **e₃** 'to go out') with their 'expanded form' (/e₃-d/); and suppletive or complementary verbs (such as **dug₄**) with completely different lexemes (**e**) (see Yoshikawa 1993: 1–56, 95–104, 114–26). However, it is also possible that many verbs did not have two different stems, and that the only way to distinguish *ḫamṭu* from *marû* in those verbs was through concord (i.e. through pronominal affixes). According to this, /-e/ would not mark *marû* but agreement for the 3rd sg. subjects of transitive *marû* forms (intransitive *marû* forms have /-∅/ in the 3rd sg.).

Verbal forms can present both prefixes and suffixes. Although almost no actual verbal form exhibits all the possible affixes, an ideal table of slots would be as in Table 1.

Whereas some MODAL PREFIXES always indicate the same mood (**ga-** → cohortative; **nu-** →negative; **ša-** → affirmative), others can mark either deontic or epistemic modality, depending on their interaction with the other elements within the TAM system (Civil 2000):

/ha-/ + *ḫamṭu*	→ affirmative	**ha-na-sum** 'I have indeed given'
/ha-/ + *marû*	→ precative	**hu-mu-hul₂-e** 'may you rejoice'
/na-/ + *ḫamṭu*	→ affirmative	**nam-mi-gub** 'he set indeed'
/na-/ + *marû*	→ prohibitive	**na-ab-pad₃-de₃** 'do not tell'
/bara-/ + *ḫamṭu*	→ negative affirmative	**ba-ra-ra-dug₄** 'I have never said to you'
/bara-/ + *marû*	→ vetitive	**ba-ra-pad-re₆** 'he shall not destroy'

Other prefixes in this slot do not really indicate modality: **u₃-** marks anteriority and /inga-/ is actually a proclitic connective particle.

The number, function, rank, compatibility, and morphophonemic shape of the so-called CONJUGATION PREFIXES are still a matter of discussion. For instance, /-m-/ is probably the noninitial allomorph of /mu-/, which explains why both prefixes cannot occur together. It is possible to argue for a rather simple system of conjugation prefixes with only four morphemes: /ba-/;

TABLE 1 Structure of the Sumerian Verbal Chain

1	2	3	4	5	6	7	8	9	10
modal prefixes	connective prefix	"conjugation" prefixes	dative	dimensional infixes	pronominal prefixes	STEM		pronominal suffixes	nominalizer
∅-		i- (V-)							
he₂-		mu- (m-)	-a- (1 sg)	-ši- TERMINATIVE	-∅-/-e- (2 sg)			-en / -en	
ga-	inga-	ba- (b-)	-ra- (2 sg)	-ni- LOCATIVE	-n- (3 sg an)			-en / -en	
bara-		im-ma-	-na- (3 sg)	-da- COMITATIVE	-b- (3 sg in)		-ed	-∅ / -e	-a
na-		a-	-me- (1 pl)	-ta- ABLAT.-INST.				-enden / -enden	
ša-			[*-re- (2 pl)]	-e- / -i- LOCAT.-TERM.				-enzen / -enzen	
u₃-			-ne- (3 pl)					-eš / -ene	
nu-									
al-									

/imma-/; /i-/ or /V-/; and /mu-/. The prefix /bi-/ would be a combination of the prefix /ba-/ followed by the locative-terminative infix, and /imma-/ would be a reduplication of /mu-/ (Karahashi 2000).

All verbal forms seem to start with an obligatory conjugation prefix (/mu-/, /ba-/, or /i-/). The choice of prefix seems governed by FOCUS (Vanstiphout 1985). The prefixes /mu-/ and /ba-/ are mutually exclusive and complementary: /mu-/ is focused for a person but not for a locus, while /ba-/ is focused for a locus but not for a person; and /i-/ is not focused; and hence it is indifferent to this opposition. In discourse, the /i-/ prefix is preferred for supportive, nonsubstantial material (background), but the foreground of regular narrative

a verbal prefix. Moreover, in order to agree with plurals, the pronominal prefixes can occur together with plural pronominal suffixes.

The PRONOMINAL SUFFIXES are identical for all verbal forms with the exception of the 3rd person singular and plural. A 3rd person in the absolutive case shows concord with /-∅/ in the singular and with /-eš/ in the plural. An ergative with a *marû* form shows concord with /-e/ in the singular and /-ene/ in the plural. The absolutive case of a transitive *marû* construction (i.e. the accusative case with *marû*) does not agree with the pronominal suffixes but with the pronominal prefixes (/-b-/ and /-n-/). The distribution of pronominal elements in verbal forms is as follows:

	transitive ḫamṭu	intransitive ḫamṭu	transitive marû	intransitive marû
subject	prefix (+ suffix in pl.)	suffix (3rd -∅/-eš)	suffix (3rd -e/-ene)	suffix (3rd -∅/-eš)
object	suffix (3rd -∅/-eš)		prefix	

discourse is marked by /mu-/ or /ba-/ according to focus:

+ FOCUS			- FOCUS
/mu-/	+ PERSON	- LOCUS	/i-/
/ba-/	- PERSON	+ LOCUS	

The conjugation prefix /a-/ seemingly occurs in nonagentive passive constructions (**an-na-sum** 'it was given to him'). This prefix defocalizes the agent of the sentence, shifting the focus to any other argument (dative, comitative, ablative, and so forth); see Yoshikawa (1995). The occurrence of /a-/, however, may also correspond to local or diachronic dialects (or even to scribal idiolects), since in some texts it is extremely rare or completely unattested, while in others it is quite frequent.

The DIMENSIONAL INFIXES mark case functional relations between the verb and NPs that may be explicit or merely implicit in the sentence. The PRONOMINAL PREFIXES normally agree with the subject of transitive ḫamṭu forms (ergative) and the subject of both transitive and intransitive *marû* forms—the latter showing an accusative alignment. Furthermore, they can also specify that a dimensional prefix (terminative, comitative, etc.) refers to a 2nd or 3rd person, as well as the gender (/-n-/ for animate and /-b-/ for inanimate) of the verbal object or any syntactical argument marked with

With regard to the choice of prefixes vs. suffixes, the ḫamṭu forms follow an ergative pattern, whereas the *marû* ones show accusativity. Nonetheless, the pronominal suffixes used with the *marû* forms do point to an opposition between ergative subject and absolutive subject for the 3rd singular and plural (i.e. they ultimately have an ergative alignment).

The SUFFIX /-ED/ can immediately follow the verbal stem and precede the pronominal suffix. Some consider the /-e-/ in /-ed/ the marker of *marû* (see above). This suffix is much more frequent in nonfinite than in finite verbal constructions (in which it indicates future in diverse modalities): **e₂-mu lu₂ i₃-bur₃-de₃** 'someone could break (/i-bur-(e)d-e/) into my house'; **e₂ du₃-de₃ igi-zu u₃ dug₃-ga nu-ši-ku₄-ku₄** 'in order to build (/du₃-(e)d-e/) the house you will not let sweet sleep enter your eyes'; and **ur-sag e₂-a-na ku₄-ku₄-da-ni ud me₃-še₃ gu₃ ga₂-gar-am₃** 'at entering (/ku₄-ku₄-(e)d-a-ani/ = *enter-enter*-ED-NOMINALIZER-*his*) his house, the warrior was a storm roaring towards battle'. The suffix /-ed/ is never written as such: /-e-/ is written almost exclusively after a consonant, and /d/ is written only when followed by a vowel.

The IMPERATIVE exhibits a reverse order of verbal constituents: it begins with the stem, which is followed by all the prefixes; e.g. **sum-ma-ab** /sum-mu-a-b/ 'give (sg.) it to me', **sum-ma-ab-ze₂-en** /sum-mu-a-b-enzen/ 'give (pl.) it to me'. This phenomenon is similar to the switch from proclisis to enclisis in the imperative in other languages; e.g. Spanish *me lo das* ('you give it to me') vs. *dámelo* ('give it to me').

Morphosyntax

The NOMINALIZER suffix /-a/ can be attached to both nonfinite and finite verbal forms, and can be followed by case endings and pronouns. When the nominalized verbal form agrees with an explicit (such as **lu₂** 'man'→ who/that) or implicit noun that has an antecedent in another sentence, it constitutes the equivalent to an English relative clause: **ensi₂ lu₂ e₂-ninnu in-du₃-a e₂-uru-gir₂-su^ki-ka-ni mu-na-du₃** 'the *ensi*-ruler that built the Eninnu (**lu₂... in-du₃-a** ← /i-du₃-a/), built her temple of the city of Girsu'. Due to the high number of grammatical functions explicitly marked, there is no obvious syntactical opposition between parataxis and hypotaxis (the latter would correspond entirely to nominalized verbal forms). For instance, the word order tends to be almost always Subject–Object–Verb in all sentences.

The verb TO BE (**me**) has a basic essential meaning and does not indicate existence, for which **gal₂** ('to be there, to exist') is used: **pi-lu₅-da ud-bi-ta e-me-a** 'these were (/i-me-a(m)/) the conventions of old times'. It occurs more frequently in the form of an enclitic copula, with the following suffixes:

1st sg.	**-me-en**	1st pl.	**-me-enden**
2nd sg.	**-me-en**	2nd pl.	**-me-enzen**
3rd sg.	**-(a)-m**	3rd pl.	**-me-eš**

E.g., **digir-ra-ni ^dšul-utul₁₂-am₆** 'his god is Šulutul', **ama-mu ze₂-me** 'you are (/ze₂-me-e(n)/) my mother.'

The PRONOMINAL SYSTEM follows an accusative alignment. The pronominal subjects of both transitive and intransitive verbs present the same marker, /-e/:

	1st sg.	2nd sg.	3rd sg.	3rd pl.
SUBJECT	**ga₂-e (me-e)**	**za-e (ze)**	**e-ne**	**e-ne-ne**
DATIVE	**ga₂-a-ra (ma-a-ra)**	**za-a-ra**	**e-ne-ra**	**e-ne-ne-ra**
TERMINATIVE	**ga₂(-a/e)-še₃**	**za(-a/e)-še₃**	**e-ne-še₃**	**e-ne-ne-še₃**
COMITATIVE	**ga₂(-a/e)-da**	**za(-a/e)-da**	**e-ne-da**	**e-ne-ne-da**
EQUATIVE	**ga₂(-a/e)-gin₇**	**za(-a/e)-gin₇**	**e-ne-gin₇**	**e-ne-ne-gin₇**

The POSSESSIVE SUFFIXES can be attached to NPs as well as to nominalized verbal forms:

1st sg.	**-mu (-gu₁₀)** 'my'	1st pl.	**-me** 'our'
2nd sg.	**-zu** 'your'	2nd pl.	**-zu-ne-ne**, **-zu-e-ne-ne**, **-zu-ne** 'your'
3rd sg. an.	**-a-ni** 'his, her'	3rd pl.	**-a-ne-ne** 'their'
3rd sg. in.	**-bi** 'its'		**-bi** 'their' (probably collective)

Sumerian has a number of COMPOUND VERBS, i.e. combinations of a verb and a direct object that become a syntactic and semantic unit: : **igi — bar** ('to look at' ← **bar** 'to open' + **igi** 'eye'), **ki — ag₂** ('to love' ← **ag₂** 'to measure' + **ki** 'place'), etc. The second object of a compound verb is very frequently in the locative–terminative case: **nig₂-dug₃-ge al na-an-ga-am₃-mi-in-dug₄** 'sweet things (/nig₂-dug₃-e/) she has indeed also wished (/na-inga-bi-n-dug₄/, **al — dug₄** 'to desire, wish')'. There are some double compound verbs, in which a whole compound verb becomes the nominal part of a compound verb, whose verbal member is an 'auxiliary' verb, such as **ak** ('to do') and **dug₄** ('to say'): **šu tag — dug₄** ← **šu — tag** 'to cover, decorate' (← **šu** 'hand' + **tag** 'to touch').

A Sumerian Genderlect or Genrelect?

Sumerian is called **eme-gir₁₅** (perhaps 'native tongue') in native Sumerian sources. In some Mesopotamian scholarly texts, a few lexical items and grammatical forms are identified as **eme-sal** (perhaps 'fine language'). It has been argued that **eme-sal** was a women's language (*Frauensprache*) or genderlect, especially because the sign SAL can also be read **munus** 'woman'. The fact is that **eme-sal** is attested in compositions of very specific genres: cultic songs performed by **gala**-priests; diverse texts containing Inanna's speech; some laments over the destruction of cities; a lullaby; about 30 proverbs or short sayings from rhetorical collections; an unpublished composition ('The song of the millstone'); and the 'Dialogues between two women'. No text is entirely written in **eme-sal**, and there is no true consistency in its use; hence, an otherwise 'main-dialect' text may present some scattered **eme-sal** words. In most cases, the occurrence of **eme-sal** forms seems determined mostly by the genre of the text.

GONZALO RUBIO

Swadesh, Morris

Like his teacher Edward Sapir, Morris Swadesh was a prolific data-gatherer and an avid student of languages. He learned Yiddish from his Russian parents. As an undergraduate at the University of Chicago, he studied German and French, and as a graduate and postgraduate at Yale University he concentrated on Nootka, a Canadian indigenous language. On his regular field trips through Canada, the United States, and Mexico, he collected data on more than 20 native languages. In Mexico, he developed programs for indigenous people to attain literacy in their own languages. Later, during World War II, he worked for the war department, editing dictionaries, providing linguistic analyses of foreign languages, and developing teaching materials for Spanish, Russian, Burmese, and Chinese.

Swadesh did his first theoretical work on phonemic analysis, i.e. the analysis of the sound structure or phonology of languages. Sapir, Leonard Bloomfield, Nikolai Trubetzkoy, and others had already advanced the concept of the 'phoneme', an abstract representation of sound types. Swadesh's contribution was to develop a set of principles to help the phonologist discover phonemes on the basis of the distribution of sounds in a given language. If, for example, one sound always occurs at the beginning of words, while another always occurs at the end, Swadesh suggested that these particular sounds are in 'complementary distribution' and thus could potentially be instances of the same sound type or phoneme. These principles were later applied to word and sentence elements by Zellig Harris. Distributional analysis thus became a general 'discovery procedure' for the basic elements of linguistic structure and has remained an integral part of linguistic methodology to this day.

In his extensive investigations of numerous languages, Swadesh gained an increasing appreciation of apparent lexical and structural similarities in different languages, and his interest in comparative historical linguistics grew. Since his study of nearly extinct languages was conducted with limited resources, he felt the need for a standardized procedure for quickly collecting crucial data yielding clues about language relationships.

To determine whether two given languages are related, historical linguists usually use the 'comparative method'. This means that they attempt to reconstruct an ancestor language on the basis of cognates, i.e. arguably related words from different languages (English *hound* is a cognate of German *Hund* 'dog'). Since cultural development is always accompanied by lexical innovations, Swadesh—and many linguists before him—felt that presumably more stable 'basic vocabulary' would be the best place to start looking for cognates. The basic vocabulary of a language describes body parts and functions, such as *skin, blood, drink*, natural phenomena like *water, sky, bird, smoke*, immediate sense experiences, and physical dimensions, such as *long, red, cold*. While the concept of basic vocabulary had been informally used before, Swadesh made it explicit by drafting a list of 100 word meanings that a fieldworker investigating any language could use for identifying the basic vocabulary of that language. The use of this list, now generally known as the 'Swadesh list', has drawn criticism from its inception. Many linguists believe that it is impossible to enumerate universal meanings, and that the identification of semantically equivalent words in different languages is often highly problematic. Nevertheless, the list has become a widely used tool in comparative linguistics.

Even though the notion of basic vocabulary was already contentious, Swadesh pressed forward and used his list for lexicostatistics, a quantitative method

1051

for measuring the similarity of languages. If the basic vocabulary of one language matches that of another by over 90%, Swadesh argued, these languages must be closely related. Most linguists believe that the reconstruction of ancestor languages provides more reliable evidence for the relatedness of languages than statistical analyses; hence, lexicostatistics continues to be viewed with suspicion. Yet, moderate linguists today concede that the Swadesh list and lexicostatistics may be useful for rough initial investigations or for situations where complete data are simply unavailable—which is, in fact, close to what Swadesh had in mind.

Even more controversially, Swadesh claimed that the 'decay' of basic vocabulary could be used for 'glottochronology', the dating of ancestor languages analogous to determining the age of fossils on the basis of radioactive decay. Swadesh came to believe that basic vocabulary decays at a rate of 14% over 1,000 years; hence, languages would retain on average about 86% of their basic vocabulary over this time span. Thus, if the basic vocabularies of the two related languages are found to match by 70%, they can be assumed to have developed from a single language that existed approximately 12 centuries ago. The assumption that basic vocabulary decay is generally uniform has been seriously challenged. If one allows that languages, just like societies, may develop at different rates at different times, the assumption of steady vocabulary decay in particular, and the glottochronological method in general, is seriously undermined.

Swadesh's name has remained symbolic for lexicostatistics and glottochronology, but his central place in the continuing and highly ideological debate about these and related issues seems to rest on misunderstandings and/or polemically slanted readings. He is, for example, accused of introducing lexicostatistics as a shortcut for investigation, attempting to avoid the hard work of reconstruction. However, Swadesh stated repeatedly that a detailed knowledge of the languages under investigation is crucial, and that other data must be considered. Likewise, Swadesh is misleadingly cited as a supporter of the theory that all languages have developed from a single ancestor (the 'monogenesis' theory). He certainly conceded that the instinctive vocalizations of early humanoids may be called a species-specific 'language', but he also surmised that as soon as arbitrary signs—i.e. true words and complex linguistic structures—entered the human repertoire, diversification was the instant result.

These ideas were the focus of his major book, *The origin and diversification of language*, but he died of a heart attack before he was able to complete it. His arguments thus remained somewhat sketchy, which may explain why Swadesh's even-handed and careful deliberations tend to be overshadowed by the bolder aspects of his thought.

Biography

Morris Swadesh was born in Holyoke, Massachusetts on January 22, 1909. He received his B.A. (1930) and M.A. (1931) for his dissertation on Nootka aspect, tutored by Edward Sapir, University of Chicago. He followed Sapir to Yale University, New Haven, Connecticut, for Ph.D. work on Nootka semantics, 1933, and then worked at Yale on synchronic phonological theory and on American English grammar in 1933–1937. He was Assistant Professor, University of Wisconsin, Madison in 1937–1939. He moved to Mexico City, where he became Director, Consejo de Lenguas Indígenas, and Director of Linguistics, Departamento de Asuntos Indígenas, in 1939; he was Professor, Instituto Politécnico Nacional de México, Escuela de Antropología, and Departamento de Asuntos Indigenas, in 1939–1941. Swadesh was a linguist for the War Department in New York City during World War II; he was Associate Professor, City University of New York in 1948, but lost his teaching appointment and had his passport revoked because of 'leftist' views and activities. He worked as a librarian at the Boas Collection, Library of the American Philosophical Society, Philadelphia, PA, 1949–1953, and carried out independent fieldwork in 1953–1956. He moved again to Mexico City, where he became Professor at the Instituto de Historia, Universidad Nacional Autónoma de México, and the Escuela Nacional de Antropología e Historia, 1956–1967. He was a member of the Linguistic Society of America (LSA) in 1931, Life Member in 1937; member of two special interest groups of the LSA in 1939; President of the Linguistic Section of the 29th International Congress of Americanists, 1939; and editor of *Word,* 1946–1949. Swadesh died in Mexico City on July 20, 1967.

Swedish and Scandinavian Languages

Scandinavian languages belong to the Indo-European North-Germanic languages. North-Germanic languages are spoken in the Nordic countries (Denmark (including The Faroes and Greenland), Finland, Iceland, Norway, and Sweden). The concept of Nordic languages (Swe. *nordiska språk*) covers all North-Germanic languages, and Scandinavian languages comprise the three languages Swedish, Danish, and Norwegian. The prehistoric period in Scandinavia is not well known, but by the second century CE, Ancient Scandinavian language(s) were spoken in Denmark, Southern and Central Sweden, and in southern Norway.

Based on older language history the North-Germanic languages have been divided into West-Nordic (Norwegian, Icelandic, and Faroese) and East-Nordic (Danish and Swedish). A more recent division separates North Scandinavian (Norwegian and Swedish) and South Scandinavian (Danish) from Insular Nordic (Icelandic and Faroese; cf. Torp 1982; Vikør 1993). The latter view is central here. The division into West and East Scandinavian was based on isoglosses, for example, the deletion of initial /j/ in West Scandinavian (=Old Norse): Nynorsk *ek*, and Faroese *eg*, Swedish *jag* and Danish *jeg*, 'I'. Changes during the Middle ages in Norwegian/Swedish vs. Danish are considered more significant than the West – East split (in the sixth – seventh centuries CE). For example, the four-case system in Icelandic (with Nominative, Genitive, Dative, and Accusative) developed into a two-case system in the Scandinavian languages (Nom. and Gen.). Another change was the loss of the synthetic verb conjugation, which in the Old Norse system expressed person, number, and mood. Suffixed definite articles developed from the demonstratives, and the passive voice, which evolved from the reflexive pronoun *sik* 'self', for example, Swe. *kalla* 'call' vs. *kalla-s* 'be called', are characteristic of mainland Scandinavian.

Within phonology, the syncope (deletion between consonants) of short, unstressed vowels in plurisyllabic words simplified the Ancient Scandinavian syllable structure. For example, the inscription in the fifth century golden horn from Danish Gallehus, *ek hlewagastiR holtijaR horna tawido*, 'I, HlewagastiR from Holt, made the horn', results in the reconstructed forms: **ek hlégestr hyltir horn táða*, in Old Norse. Plurisyllabic words like *Hlégestr* 'dropped' syllables. Deletion of Ancient Scandinavian final –n caused a changed infinitive form: *fullian* > Swe. *fylla* 'fill', *lausian* > Da. *løysa* 'loosen'. The Umlaut (common Germanic vowel shift) complicated the morphology structure from Ancient Scandinavian to Old Norse. Particularly, /i/ in suffices influenced /a/, /o/, and /u/ in word roots: *ansiR* > *æsir* 'pagan gods', *fōtiR* > *fØtr*, 'feet'. In words like *mann ~ menn* 'man ~ men' and *mús ~ mýss* 'mouse ~ mice', the vowel shift received phonemic weight: Swe. singular *man* vs. plural *män*. The three Scandinavian languages (and German) share the development of /æ/, /Ø/, and /y/, which are represented in writing (Swe. *ä* and No./Da. *æ* for /æ/, Swe. *ö* and No./Da. *ø* for /Ø/ and y for /y/). Swedish also has *å*, for /o/, which was recently adopted by Norwegian and Danish for the digraph *aa*. Diphthongs changed to monophthongs: *lausian* > Swe. *lösa* 'loosen'. The change of diphthongs to monophthongs did not affect Old Norse or some Norwegian dialects: Nynorsk has *stein*, 'stone', *laus* 'loose', and *Øy* 'island', compared to Swedish/Danish *sten*, *lös/løs*, and *ö/ø*.

Danish vs. North Scandinavian Languages

Three changes initiated a unique development for Danish. The neutralization of unstressed vowels in inflectional endings in Danish developed a central vowel/schwaa, which is still spelled with an –e: Da. *holde*, Swe. *hålla* 'to hold'. This initiated a reduction of inflectional morphology and its functions.

Danish unvoiced stops after long vowels became weaker pronounced (lenition). The older forms *rep*

'rope', *bita* 'bite', *høk* 'hawk', and *leka* 'play' developed into *reb*, *bide*, *høg*, and *lege.* This has not been consequently reflected in later spelling conventions in Danish. In Danish, the voiced stops shifted to fricatives. The adjacent dialect areas in Southern Sweden and Norway partly followed suit, but they did not introduce the full set of fricatives.

Danish developed a glottal stop, which was paralleled by the development of a tonal system in Norwegian and Swedish, with two tonemes. The tones make a difference between words such as Swe. ´*anden* 'the duck' (Swe. akut accent) and ˣ*anden* 'the spirit' (grav accent). The glottal stop is not reflected in Danish spelling; it is understood as a prosodic, not a segmental feature. Insular Nordic has neither the glottal stop nor the toneme system. These three phonetical changes added to the differences between Danish and Swedish/Norwegian; Danes and Swedes today have difficulties understanding each other.

Swedish

The separate Swedish development can be divided into five periods: Runic Swedish 800–1225 CE, Classical Old Swedish 1225–1375, Late Old Swedish 1375–1526, Early Modern Swedish 1526–1732, and Modern Swedish from 1732–. These periods are based on features of the written language. The Runic inscriptions (Germanic by origin) were possibly used as early as the second century CE in Denmark. Runes were used in carvings in hard material such as wood, bone, and stone; they have been well retained in runic stones. Runes were used for almost a millennium, even for everyday purposes in the late Middle Ages.

The Scandinavian languages were stabilized by the translations of the New Testament (in 1526 to Swedish) and the Bible (in 1541, Gustav Vasa's Bible). Printing had been introduced in 1483. Some of the major typological changes of Swedish from a synthetic to a more analytic language were completed by the end of the fifteenth century. In 1732, the newpaper *Then Swenska Argus* started appearing (similar to the English *The Spectator*), which had a modernizing impact on the writing of Swedish.

The administration of the Swedish kingdom was centralized early and efficiently by the Vasa dynasty (1523–1654). It used a Stockholm-based chancery style, which facilitated the standardization of Swedish and the evolution of a spoken standard Swedish. The cultivation of Swedish was supported by the foundation of the Swedish Academy in 1786 by King Gustav III. During this period, French also had a great influence on the court and its language.

The Swedish dialects are divided into six major groups: South Swedish (Scania and adjoining provinces), Guthnic dialects (Northwest of Scania;

Western Sweden), Central Swedish, North Swedish, Gutnish (Gotland), and East Swedish dialects (in Finland, influenced by Finnish phonology). The differences between the peripheral dialects are considerable.

Personal pronouns are compulsory to indicate subject person (only tense is expressed in the verbs): *jag talar* 'I speak', *du talar* 'you speak' (second-person singular), *han talar* 'he speaks', *vi talar* 'we speak'. Regular (*titta–tittade–tittat* 'look, looked, looked') and irregular forms (*springa–sprang–sprungit* 'run, ran, run') of verbs exist. The definite–indefinite article system is complex, since congruence of definiteness, gender, and number is expressed. Swedish (and Danish) only has Neuter (de**t**-genus) and Uter (de**n**-genus) gender. For example, *det stora huset* 'the big house', *ett stort hus* 'a big house', and, *den gamla staden* 'the old town', *en gammal stad* 'an old town'.

Word order (basically SVO) has syntactic functions, for example, indicating the type of clause (main–subordinate; declarative–question): *Han <u>kommer inte</u>* (main clause) 'He will not come', vs. *Han säger, att han <u>inte kommer</u>* 'He says, that he will not come'; *<u>Han kommer</u> snart* 'he will come soon', vs. *<u>Kommer han</u> snart?* 'Does he come soon?'.

Swedish is the de facto official language of Sweden. About 8.2–8.3 million speakers of the nine million inhabitants speak it as a first language; the remainder speak it as a second language. In Finland, Swedish is an official national language, with about 300,000 speakers. Emigration to North America started already in the seventeenth century, but had its peak in the late 1800s. The Swedish targets were mainly the farming areas around the Great Lakes. About one million people left Sweden for North America; about 70,000 speak Swedish today (the United States of America). Modern trans-Atlantic migration has targeted the West and East coasts.

Danish

Danish and Swedish have experienced similar developments for their written languages. Old Danish is set to 800–1100 CE, Early Middle Danish 1100–1350, Late Middle Danish 1350–1525, Early Modern Danish 1525–1700, and Modern Danish 1700–. Christianity had a clear impact on this process, both during the eleventh century, and with the Lutheran Reformation in the sixteenth century. Low German language contact effects were extensive during the Late Middle Danish period.

Danish Vikings created a strong position for Danish in Northern Europe. It has retained a dominant position vis-á-vis Norwegian, Icelandic, and Faroese (and Greenlandic). Danish was an urban high-status variety in Norway for seven to eight centuries. This has brought the Norwegian vocabulary close to Danish.

Danish has itself been under continuous pressure from German and Latin.

Similar to Swedish, the oldest written sources, in addition to runic inscriptions, are regional law texts from the thirteenth century. Beginning in the fourteenth century, legends, chronicles, and religious literature were written in and translated into Danish. The influential Bible of King Christian III in 1550 was to a large extent based on Danish dialects. From that period onward, the Zealand dialects, including Roskilde and Copenhagen, have been important. The standardization process was largely adapted to Copenhagen upper-class people's style. The German Oldenburg monarchy, which ruled the country for four centuries up to the mid-nineteenth century, preferred German. Also, Latin and later French were prestigious languages, whereas Danish remained the 'people's' language until the eighteenth century. With the writer Ludvig Holberg (1684–1754), a stable literary development started, which pointed out the route to present-day standard Danish.

Three main Danish dialect areas are recognized: Jutish in Jutland, Insular Danish in Funen and Zealand, and 'East-Danish', in Bornholm and the lost provinces in Southern Sweden. Similar to Swedish, an extensive dialect leveling has taken place recently.

Danish is the first language of about 4.8 million of the 5.1 million inhabitants of Denmark. It is the official language of Denmark, and has a secondary official status in the Faroes and Greenland. About 45,000 speak Danish in North Schleswig, where it can be studied at all levels in school. Danish emigration to North America was extensive in the nineteenth and twentieth centuries. Today, 35,000 descendants speak the language (United States of America), many of whom live on the West Coast.

Norwegian

Norwegian stems from Old Norse (West Scandinavian), 700–1350 CE. The Middle Norwegian period is set to 1350–1525, and Modern Norwegian 1525–. Old Norse represents a more synthetic and Modern Norwegian represents an analytic stage of the language. Written forms of Old Norse include the Icelandic Sagas. The historian Snorri Sturlasson (1179–1241) termed the Old Norse of his day Danish. The idea of different languages (Danish, Icelandic, Norwegian) has thus been promoted later.

Middle Norwegian was under heavy pressure from Danish. Written Norwegian was practically replaced by Danish writing by 1525. Further, the Danish Bible of Christian III was used in Norway. This made the attempt to create a stable, written Norwegian unsuccessful. A Danish-based high variety developed in the towns.

After the Danish secession (1814) of Norway, Danish dominance was challenged. It remained a highly central issue during the whole period of the Norwegian–Swedish Union, 1814–1905. One language political direction was headed by the self-taught linguist Ivar Aasen (1813–1896), who undertook a study of south and west-Norwegian dialects. He founded modern Norwegian dialectology, and through his grammar (1864) and dictionary (1873) based on these dialects, he created a standard written Norwegian, *Nynorsk*. This was in line with the ideas of the nationalistic Romantic era. Nynorsk was given official recognition in Parliament in 1885. The support for Nynorsk has decreased steadily since the 1940s.

Another approach was more pragmatic. The teacher Knud Knudsen (1812–1895) Norwegianized the established, written, Danish-based language according to the middle-class townspeople's speech habits. These were influenced by southeastern dialects and Danish. This created the second Norwegian standard, *Bokmål* (or Dano-Norwegian). Through two spelling reforms (1907 and 1917), Bokmål became more adapted to Norwegian. After the first translation from Danish to Bokmål in 1919, Bokmål has been considered a separate language from Danish. About 1880, the two forms of Norwegian were connected to the political struggle between on the one hand a more radical, parliamentary wing—supporting Nynorsk—and a more urban, Oslo-based conservative wing—supporting Bokmål.

Since the linguistic differences were small it was suggested already in the 1880s, that the two standards be amalgamated to a common Norwegian (*Samnorsk*). The idea slowly gained ground, but after fierce opposition during the 1960s, the official support for this view has been downgraded. A natural leveling has partially closed the linguistic gap, but attitudinal resistance is still strong on both sides. Bokmål is used by more than eight out of ten Norwegians as their school language and written code.

Compared to Danish and Swedish language policies, Norwegian official policy has been both more liberal in relation to dialects, and more puristic regarding language contact effects (from English). Norwegian purism is less protective than the Icelandic attempts to fully replace the influx of international loanwords.

Norwegian dialects are divided into five groups: Western, Central (covering the inland valleys), Eastern, Trønder, and Northern dialects. Nynorsk and its base dialects (Western and Central), have greater similarities with the Insular Nordic languages.

About 95% of the Norwegians speak the official Nynorsk or Bokmål as their mother tongues. About 800,000 Norwegians emigrated to North America. Today, 80,000 know Norwegian in the United States. Many of them migrated to the shores of the Great Lakes, as did the Swedes.

Linguistic Examples of Swedish, Danish, and Norwegian

	Swedish	Danish	Norwegian	
			Bokmål	*Nynorsk*
'one'	ett	et	et	eit
'eye'	öga	øje	øye	auga
'weak'	svag	blød	bløt	blaut
'week'	vecka	uge	uke	veke
'I'	jag	jeg	jeg	eg
'she'	hon	hun	hun	ho
'we'	vi	vi	vi	vi, me
'who'	vem	hvem	hvem	kven
'behind'	bakom	bagved	bakom	attom
'not'	inte	ikke	ikke	ikkje
'fifty'	femtio	halvtres	femti	femti
'swear'	svära	bande	banne	banne
'count'	räkna	tælle	telle	telje
'window'	fönster	vindue	vindu	vindu, vindauge

Sweet, Henry

There were three significant phonetician-linguists in Britain in the nineteenth century: Alexander Melville Bell (1819–1905), Alexander John Ellis (1814–1890), and Henry Sweet (1845–1912). Bell is remembered primarily for his 'Visible Speech' alphabet and the theory of general phonetics that underlies it; Ellis for his studies of English pronunciation, both synchronic and diachronic; and Sweet for his erudite presentation, in a consistently structured and intelligible manner, of material on phonetics and various forms of medieval English. Of the three, it is Sweet who has exerted the strongest influence over the direction that the subjects have taken over the past 130 or so years.

Sweet's interests in the older Germanic languages began relatively early. One of his schoolteachers (and an Anglo-Saxonist), Thomas Oswald Cockayne (1807–1873), may have been instrumental in introducing him to the two languages. On leaving school, he undertook a year's study of Comparative and Germanic Philology at Heidelberg University. A consequence was that he began to collect materials during his teenage years for what was later to become his *Student's dictionary of Anglo-Saxon* (1897). While he was still an undergraduate at Oxford, his edition of King Alfred's *Pastoral Care* was published.

He read Classics ('Greats') at Oxford, but he was hardly assiduous, spending most of his time working, virtually alone, in the field of Germanic languages. At the time of his graduation, he had published not only the *Pastoral Care*, but had critically reviewed a number of scholarly works in the academic press, and had read three papers to the Philological Society. Within a year of graduating, he published his *History of English sounds* (1874).

Throughout his life, he maintained a wide spectrum of academic interests, including phonetics, spelling reform, shorthand, grammar, the teaching and learning of languages, general linguistics, the history of English and other Germanic languages, and literature. Since he had to fulfill two roles, that of the scholar and, secondly, the private teacher whose books for undergraduates and other learners would generate a certain amount of income, he adopted the general strategy of publishing advanced material first, then simplifying some of it in works written intentionally for the student learner.

Meetings of the Philological Society in London were the locus for the exposition of many of his views on language and languages, and he read papers there on a variety of subjects, especially the contemporary forms of a number of languages, including Danish, German, Icelandic, Irish Gaelic, and Swedish. In his

later years, his field of interest widened to take account of aspects of the linguistic structure of Arabic, Chinese, Norwegian, Portuguese, Sanskrit, and Welsh.

His *Handbook of phonetics* (1877) inspired a whole tradition of phonetic studies, especially in Britain and Europe. It expounds a general phonetic theory, illustrated by phonetic transcriptions of various languages, and concludes with an excursus on the nature of phonetic notational systems, including a pivotal discussion of Broad and Narrow Romic notations—equivalent in most respects to phonemic and allophonic notations. Two works on phonetics for the student learner, the *Primer of spoken English* (1890) and the *Primer of phonetics* (1890), present a less detailed account of phonetic theory. The text of the *Primer of spoken English* is essentially a translation of another of Sweet's influential works, his *Elementarbuch des gesprochenen Englisch* (1885), written for German learners of English at a time when radical changes were under way in European schools and universities in the teaching and learning of modern languages. A further work on English phonetics, the *Sounds of English*, appeared in 1908. *The practical study of languages* (1899) discusses in detail the theories and practices of teaching and learning languages.

Sweet's ideas about grammar and grammatical analysis developed relatively slowly. His *New English grammar* (1892, 1898) deals with the contemporary and historical forms of the language. Two simplified accounts, based on the work, are his *Short historical English grammar* (1892) and the *Primer of historical grammar* (1902).

The edition of the *Epinal glossary* (1883), together with a companion volume, *The oldest English texts* (1886) and *King Alfred's Orosius* (1883), provided scholars with the necessary tools for advancing the critical study of the earliest periods of Old English.

The series of works on earlier forms of English, written expressly for the novice learner rather than the scholar, began with the *Anglo-Saxon reader* of 1876, followed by a less demanding account, the *Anglo-Saxon primer* in 1882. Three further intermediate textbooks for students of Old English were Ælfric's *Homilies* (1885), *Extracts from Alfred's Orosius* (1885), and the *Second Anglo-Saxon reader* (1887). For students embarking on the study of Middle English, there were two *Middle English primers* (1884, 1886).

His Icelandic *Primer* (1886) is a classic example of his ability to present the essential facts of a medieval language in a form that is immediately attractive to the learner. The essential linguistic information is described synchronically, with no diachronic or cognate Germanic materials to distract the learner. Sweet's *History of language* (1900), written for the general reader, is an exposition of the principles that underlie comparative philology, with particular reference to the Neo-Grammarian thesis on language change.

Biography

Henry Sweet was born in London on September 15, 1845. He was educated at private schools, but primarily at King's College School, London. He received his B.A. in 1873 from Oxford University, Ph.D. (Hon Causa) from Heidelberg University in 1875; and LL.D. (Hon Causa) from Glasgow University in 1890. He studied Comparative and Germanic Philology at Heidelberg University, 1863–1864. He was an undergraduate student at Balliol College, Oxford, 1869–1873. He obtained his only full-time teaching post, Reader in Phonetics, at Oxford University in 1901. He was President of the International Phonetic Association from 1887 until his death. He was Corresponding Member of the Munich Academy of Sciences, and of the Royal Prussian Academy of Sciences, and an Ordinary Member of the Royal Danish Academy. Sweet died in Oxford on April 30, 1912. The character of Henry Higgins in George Bernard Shaw's (1856–1950) *Pygmalion* is based to some extent on that of Sweet.

Switch-Reference

Switch-reference (first described by William Jacobsen in 'Switch-reference in Hokan-Coahuiltecan', 1967) is one of several subject-linked reference tracking mechanisms that apply outside the domain of a single clause. Switch-reference markers indicate whether the referent of an argument (typically the subject) of one clause is the same as or different from the referent of an argument (typically the subject) of another clause. Switch-reference systems are found in a wide range of languages in North America, Australia, Papua New Guinea, North Asia, and Africa.

Typical Switch-Reference Systems

In a typical switch-reference system, the verb of one clause, the marking clause, is marked to indicate whether or not its subject has the same referent as the subject of another clause, the reference clause. The marking clause can be subordinate to the reference clause, as in the Maricopa examples (1ab) or coordinate with the reference clause as in the Chickasaw examples (2ab). Languages limit what syntactic relationships hold between marking and reference clauses: in some languages, switch-reference is used across a wide range of coordination and subordination relationships, while in others it is used in more limited structures. Switch-reference applies only between clauses that combine to form a single syntactic sentence.

(1a) paan nya-m-chew-<u>k</u>   m-maa-uum
       bread when-you-make-ss you-eat-INCOMPLETE
       'When you make the bread, you'll eat it'
(1b) paan nya-m-chew-<u>m</u>   '-maa-uum
       bread when-you-make-ds I-eat-INCOMPLETE
       'When you make the bread, I'll eat it'
(2a) hi'lha-<u>cha</u> talowa
       dance-COORDINATE = ss sing
       'He danced and sang'
(2b) hi'lha-<u>na</u> talowa
       dance-COORDINATE = DS sing
       'He danced and he (someone else) sang'

(Chickasaw data are from Munro, P. 'When 'Same' is not 'Not Different', 1983: 223)

In (1a) and (2a), the underlined morphemes labeled 'ss' show that the subject of the marking clause has the same referent as the subject of the reference clause; in (1b) and (2b), the morphemes labeled 'DS' show that the subjects of the marking clause and the reference clause have different referents.

Switch-reference marking obligatorily tracks the reference of subjects across clauses within a sentence, even when other morphology makes the switch-reference marking redundant. For example, the agreement prefixes on the verbs in (1b) show that the marking clause has a second-person subject while the reference clause has a first-person subject; but a different-subject suffix is still required on the verb of the marking clause. Similarly, the agreement prefixes on the verbs in (1a) show that both clauses have first-person subjects, but the same-subject suffix is still required.

More complex examples show that the switch-reference marking is sensitive to the syntactic subject, rather than to a logical or underlying subject or agent.

When one clause is subordinate to the other, the marking clause is always the subordinate one, regardless of linear order. For example, in Maricopa, a subordinate marking clause can be initial, final, or embedded in the middle of its reference clause.

Typical Variation in Switch-Reference Systems

Individual languages deal differently with a number of predictable structures, including (1) the assignment of switch-reference marking when the referents of the subjects of the relevant clauses are overlapping, rather than entirely different or completely identical; (2) the assignment of switch-reference marking when the subject of one or both of the clauses does not have a referent; (3) the combination of switch-reference markers with other functional markers (for example,

in Chickasaw (2a), *-cha* marks both coordinate and same subject); and (4) the use of switch-reference-marked verbs that appear to have a primarily discourse function as transitions between sentences or paragraphs.

Uncommon Variants in Switch-Reference Systems

In some languages (e.g. Pima), switch-reference markers are not verbal affixes, but independent particles. In other languages, the system is extended from subjects to include other arguments. For example, Peter Austin (in 'Switch-reference in Australia' in *Language* 57 (1981):325) describes Warlpiri as having a three-way contrast: if the subordinate clause subject is coreferential with the subject of the main clause, the subordinate clause verb is marked with *-karra*; if it is coreferential with the object or dative of the main clause, the marker is *-kurra*; otherwise the marker is *-ngkarni/-rlarni.* In still other languages, the switch-reference system is restricted to a subset of persons, or interacts with a person hierarchy as in Quechua.

Other Reference Tracking Systems

Switch-reference must be distinguished from a number of other systems used by languages to indicate identity or lack of identity of reference of arguments across clauses. For example, a number of African languages have a 'logophoric' pronoun or verbal affix, which appears in clauses that report someone's ideas, words, or feelings. The use of the logophoric pronoun in the reported clause indicates that its referent is the same as the individual whose ideas, words, or feelings are being reported. The logophoric form and the argument it refers back to are not necessarily limited to the subject position and it is limited to reported contexts. Switch-reference, in contrast, seems to be much more strictly linked to syntactic structure and much less linked to particular semantic or discourse contexts; unlike logophoric forms, switch-reference markers are never pronouns and typically are not part of the ordinary verb-agreement system.

Analyses

There are two basic approaches to switch-reference: syntactic/semantic and discourse/pragmatic.

Syntactic/semantic approaches, like Daniel Finer's 1985 *The formal grammar of switch-reference* and George Broadwell's 1997 article in *Atomism and binding,* analyze the assignment or interpretation of switch-reference markers as being controlled by the syntactic structure of the sentence. These accounts take the assignment or interpretation of reference of subjects as basic to the structure, with other functions derivative from this primary use.

Discourse/pragmatic approaches, like David Rising's 1992 *Switch reference in Koasati discourse* and Yan Huang's 2000 *Anaphora: A cross-linguistic study*, assume that the primary use of switch-reference markers is to mark topic or other discourse continuity and the marking of subject identity or lack of identity is derivative.

LYNN GORDON

Switzerland

The Swiss Confederation consists of 26 cantons (states, provinces) within an area of only 41,284 square kilometers. According to the 1990 census, this small country has a population of 6,873,867 speaking four languages: German, French, and Italian, which are shared with its neighbouring countries, and

Romansh, a distinct Romance language, that is, one descended from Latin and related to French, Italian, Spanish, and others. This linguistic mix is the result of the historical processes leading to the composition of modern Switzerland. The original confederation was an oath of eternal allegiance taken between four German-speaking cantons in the mountainous centre of the country, occurring in 1291. The German language had been brought to this area by the Alemannic invaders, part of the expansion of Germanic peoples into the old domains of the Roman Empire from the fifth century onward. After 1291, the confederation expanded, adding more cantons, reaching its present composition only at the beginning of the nineteenth century. While some of these cantons were, like the original four, German speaking, those in the west spoke French, while the incorporation of the southern areas brought in Italian and Romansh. The linguistic boundaries shown on the map below are in fact older than the state boundary of Switzerland. Even the increasing Germanisation of the Romansh area is a process that began well before the area's incorporation into the Swiss Confederation.

All four of these languages are defined as 'national languages' in the federal constitution, and since 1996, when Romansh was added to the other three—as 'official languages' of the confederation. Multiple national languages are unusual, especially for Europe, and Switzerland has been cited as a possible model for the European Union with respect to the accommodation of several official languages. Although Switzerland is at a national level quadrilingual, it is not the case that the four languages are evenly distributed through the population, or that all areas of Switzerland are multilingual. In practice, despite much internal migration and the large foreign population in Switzerland, most areas of the country are essentially monolingual. Each of the three major languages has its territory in which it functions as the single language of public life. The Swiss school system aims to provide all Swiss with some knowledge of a second national language; however, this goal is by no means fully achieved. The following statistics and map show the numerical and geographic distribution of the country's four languages.

Numbers and percentages of Swiss population who nominated one of the national languages as their main language in the 1990 census:

German:	4,374,694	63.6%
French:	1,321,695	19.2%
Italian:	524,116	7.6%
Romansh:	39,632	0.57%

Territories of the four languages of Switzerland (1: French; 2: German; 3. Italian; and 4: Romansh):
The patterns of language use in communication among the language communities of Switzerland vary widely, with the Italian and Romansh speakers far more likely to adapt to their compatriots from the larger communities. Indeed, English—a popular choice as the third school language—is now widely used as a lingua franca. The situation is exacerbated by the perceived dominant position of the German-speaking community, and by the existence of diglossia in the German-speaking area.

Diglossia, as originally defined, is the existence of two distinct forms of the same language within the same community, each with its own functions. Ferguson's (1959) original article on this phenomenon uses German-speaking Switzerland as one of the canonical examples. In this area, Swiss Standard German, which is very similar but not identical to Standard German, is used for most written functions and such highly formal spoken genres as university lectures, while local dialects, known collectively as *Schwyzertüütsch,* are used for most spoken purposes. These dialects are so different from Standard German as to be practically mutually unintelligible with it. The differences are primarily due to varied histories of their sound and grammar systems, but there are also lexical items unique to the Swiss dialects. The table below presents a few examples of these characteristic phonological and lexical distinctions:

English	Zurich German	Standard German
newspaper	*Zytig*	*Zeitung*
house	*Huus*	*Haus*
to take out	*uusenee*	*herausnehmen*
let's go home	*Gömer häi*	*Gehen wir nach Hause*
listen	*lose*	*zuhören*
one, two, three, four, five	*äis, zwoo, drüü, vier, föif*	*eins, zwei, drei, vier, fünf*
I was there	*I bi dëet gsy*	*ich war dort*

There is widespread reluctance among German-speaking Swiss, and in many cases inability, to use Standard German easily for spoken purposes, especially for informal ones; yet, Standard German is what other Swiss learn at school.

Historically, the French and Italian areas of Switzerland had local dialects, but the situation in both these areas differs from that found in German-speaking Switzerland. The local dialects of French belong to the Franco-Provençal group, a family of dialects sharing language attributes with both northern French (to which Standard French belongs historically) and the Occitan languages of the south of France. However, to all intents and purposes, these dialects are now lost in Switzerland. With the exception of a few very old people, everyone in the French-speaking parts of Switzerland speaks Standard French. Standard French is not identical to Parisian French; rather, it incorporates a few older features that have been replaced in Parisian French, as demonstrated in the table below:

English	Swiss Standard French	Parisian French
he must be helped	*il faut **lui** aider*	*il faut **l'**aider*
seventy	*septante*	*soixante-dix* (sixty plus ten)
eighty	*huitante*	*quatre-vingts* (four twenties)
ninety	*nonante*	*quatre-vingt-dix* (four twenties plus ten)

The local dialects of Italian are still spoken, but until recently had low status. Standard Italian was regarded as the language of prestige. In recent decades, however, the Swiss dialects of Italian have gained in usage and prominence as a mark of local identity.

Romansh has been spoken continuously in the southeast portions of Switzerland since Roman times. Linguistically, it shares features with both northern Italian dialects and French. Like other languages of Switzerland, particularly German, it exists as a chain of dialects that have been standardised in various forms since the time of the Reformation in the sixteenth century. Of these five written forms, those of the upper Rhine valley and the lower Engadine (the left- and right-hand ends of area number 4 on the map) have enjoyed particular support. However, despite its long history and its official status at both federal and cantonal levels, Romansh is endangered. A steadily decreasing proportion of Swiss report Romansh as their first language in the

census, held every ten years, and Romansh's territory has been shrinking under pressure from German for many centuries. Virtually all speakers of Romansh are fluent in German, often in addition to other languages as well. There have been and continue to be, however, strenuous efforts to ensure the survival of Romansh.

The precarious state of the language is not helped by the existence of the five written versions. In 1982, a unified written form of the language was introduced greatly facilitating the publication of official materials in Romansh. Even works of literature are now being written in this standard. Founded in 1919 as an umbrella organization for the growing number of societies and groups founded in the previous century to promote and protect Romansh, the Lia Rumantscha, with its seat in Chur, is the main organisation coordinating and driving the work of language maintenance and language planning for Romansh. Although not a statutory body, the Lia Rumantscha is financed by very generous grants from both federal and cantonal governments. Its activities include translation services, terminology creation and definition, publication, and language promotion. In those municipalities with a majority of Romansh speakers, Romansh is used as the language of instruction at junior levels of school, and is available as a subject at secondary and even tertiary levels of education.

The linguistic situation in Switzerland is complicated, and is a matter of intense discussion within the country itself, not least because of the perception that the linguistic communities of Switzerland do not so much live together as past one another. Pride in this 'diversity in unity', however, is an important feature of Swiss identity.

RAY HARLOW

Syllable: Structure

The syllable is defined as a unit of cognitive organization, comprised of a 'sonority peak'. Sonority is traditionally defined as *intrinsic loudness* (Chomsky and Halle 1968). It is rather unclear as to what sonority might translate into in verifiable phonetic terms, but it is generally accepted that the major phonological classes can be ranked from high to low sonority as follows: vowels, glides, liquids, nasals, and obstruents. Following researchers such as Itô, (1989), the segments of a word are exhaustively parsed into syllables. This is termed 'syllabic licensing'. For example, marking syllable boundaries with parentheses, a word like *system* is syllabified as follows: [(sɪs)(təm)].

It is a question of some interest whether syllables are further divided into smaller constituents above the segment level. Many researchers assume that a syllable is subdivided into *onset* and *rhyme* constituents, where the rhyme constituent is perhaps further subdivided into a *nucleus* and *coda*. The onset is composed of all the segments that precede the peak of the syllable. The nucleus is composed of all the vocalic material of the peak; all the material to the right of the nucleus is in the coda. An English syllable like *trounce* [trawns] would have the following structure:
The subsyllabic constituents presented are abbreviated in the obvious fashion and a Greek sigma 'σ' is used for a syllable.

Evidence for the onset-rhyme division comes from two main sources: phonotactics and stress. First, in many languages, while there are a number of restrictions on what consonants can occur together in an onset, there are very few restrictions on what segments can co-occur together across the onset-rhyme division. In English, for example, the only known restriction that plausibly spans the onset-rhyme divide holds that (in many dialects) coronal consonants cannot be followed by the diphthong [ju], e.g. *beauty* [bjuɾi] vs. *duty* [duɾi], *[djuɾi], etc. (see, for example, Hammond 1999).

A second traditional argument for this division comes from stress. It is generally thought that only material from the rhyme of a syllable contributes to the weight of a syllable (see, for example, Hayes 1980). Thus, if stress is attracted to 'heavy' syllables in a language only material from the rhyme can contribute to this weight. An example of such a language is Creek (Haas 1977). Accent falls on the final syllable or the second syllable from the right, whichever is an even number of syllables from the left, except that a heavy syllable restarts the count.

Os'ana 'otter'
hitot'iː 'snow'
'icki 'mother'

Evidence for the nucleus–coda division is a little harder to come by, but has also been adduced from stress systems. There are a number of languages where stress is attracted to syllables where only the nucleus contributes to syllable weight. For example, in Khalkha Mongolian (Street 1963), the leftmost long vowel is stressed. If there is no long vowel, the first syllable is stressed.

bosg'uul 'fugitive'
bari'aad 'after holding'
'ali 'which'
xoyərduɡ'aar 'second'
x'ötəlbərə 'leadership'
ɡar'aasaa 'from one's own hand'

Closed syllables are irrelevant to the computation of stress in Khalkha.

While terms like onset, rhyme, nucleus, and coda are still quite widely used, the world of subsyllabic constituency was thrown into question with the publication of Hayes (1989). Hayes argued against these notions and for a *moraic* characterization of the syllable. The basic idea—according to Hayes—is that there are no subsyllabic constituents. Instead, there is only the *mora*. The mora is a unit of syllabic quantity. Light syllables have one mora; heavy syllables have two (or more) moras. If we assume that English syllables have a maximum of two moras, we might represent the English word *trounce* as follows:
Onset consonants are direct dependents of the syllable node. Elements that we would have formerly put in the

rhyme or nucleus are now docked to mora nodes (abbreviated as Greek mu 'μ'). The number of moras is a function of how weight is assigned in the language in question. The peak of the syllable is generally thought to be always moraic. Long vowels are always bimoraic. Coda consonants may or may not generate their own mora. (There are controversial aspects of the proposal. For example, onset consonants always attach to the σ, or can they dock to the first mora? Can there be moraless syllables? Do moraless coda consonants attach to the final mora or directly to the σ?)

The moraic theory of the syllable accounts directly for quantity–sensitivity in stress systems. If stress is attracted to closed syllables, it is because coda consonants are moraic in the language in question. If stress is attracted to long vowels, but not closed syllables, it is because coda consonants are *not* moraic in the language in question.

Where the moraic theory makes new predictions is its rejection of any sort of onset constituent. Hayes argues that this is required to account for *compensatory lengthening,* the phenomenon whereby a vowel lengthens when a neighboring consonant is deleted. For example, Hayes cites Latin, where an [s] is deleted before a coronal sonorant, triggering lengthening just in case the [s] was a coda. Thus *[kasnus] 'gray' is realized as [kaːnus] while *[snurus] 'daughter-in-law' is realized as [nurus].

Under moraic theory, this has a straightforward analysis. The [s] of *[kasnus] is syllabified as a moraic coda of the first syllable. It is then deleted, leaving the mora behind. The vowel then spreads to the second mora, resulting in a long vowel.
Contrast this with the case of *[snurus], where deletion of the [s] leaves no stranded mora.
The key generalization about Latin is that only a coda consonant can trigger compensatory lengthening. If an onset consonant deletes, there is no compensatory lengthening. If we had an onset constituent, this would make the *wrong* prediction. A deleted onset might leave some sort of slot for a neighboring vowel to lengthen with. This characterization of syllabic weight accounts for several things. First, it directly describes what can contribute to stress attraction. Second, it accounts for why compensatory lengthening never results from loss of an onset consonant.

With the advent of 'Optimality Theory', subsyllabic constituency has come back into vogue. In their presentation of an optimality–theoretic theory of the syllable, Prince and Smolensky (1983) used the terms onset, peak, and coda. This has led a number of researchers to reintroduce subsyllabic constituency into syllabification theory, although Prince and Smolensky acknowledge that they use those terms only as a convenience. It is an unresolved empirical question as to whether Optimality Theory can be directly reformalized without these subsyllabic constituents.

MICHAEL HAMMOND

Syntactic Categories

The words and phrases that make up utterances can be classified as belonging to certain syntactic categories. The criteria for this classification are their function within the clause or phrase, their form, and their distribution, i.e. what other elements they occur with. The term is also used with reference to classes of words and word roots as part of the vocabulary. These two senses are often not distinguished.

A more traditional term that is often used synonymously is 'part of speech'. In traditional grammar, the

following parts of speech were distinguished: verbs, nouns, pronouns, adjectives, adverbs, determiners (articles), prepositions, and conjunctions. This classification goes back to the ancient Greek and Latin grammarians and has been a cornerstone of grammatical description for 2,000 years. It also plays an important role in most modern theories of grammatical structure, although there have been many modifications on the status, the number, and the definition of these categories.

In traditional grammar, the existence of the abovementioned categories was taken for granted. They were axioms in the model of description and served as the background for the definition of other categories and for the analysis of sentences. It was assumed that all languages could be described by using the same set of categories, although the actual forms and functions of nouns, verbs, adjectives, etc., could be different. A similar view is taken within the framework of generative grammar, in which syntactic categories are used to define phrasal categories and remain undefined themselves. It is often assumed that the distinction between nouns and verbs is universal. Furthermore, it is used to characterize other categories; i.e. the four major categories are distinguished with respect to how much they function like a typical noun or verb. In this view, verbs are characterized as verbal and nonnominal, and nouns are nominal and nonverbal. Adjectives are described as having both verbal and nominal properties and prepositions as having neither. This approach allows general statements about categories that include several parts of speech. For example, in some languages, verbs and prepositions, the nonnominal categories, share characteristics that other categories do not have.

A different view was held by the early American structuralists, who challenged traditional grammar in the second quarter of the twentieth century. Instead of assuming universally valid axiomatic categories, they maintained that syntactic categories, or form-classes, should be established on language-particular grounds, that is, on the basis of the formal properties and the distribution of elements of a particular language. A tool for classifying linguistic elements was substitution frames, e.g. 'the ___ is good' for nouns in English. All elements that could fill the slot in such a frame belong to the same distribution class. A careful analysis of the possible substitution frames of words leads to their classification into form-classes. A grammatical description that strictly follows this view comes up with far more classes than the traditional eight parts of speech. Also, these classes were language particular and could not be used for language comparison. For example, English count nouns could be described as a form-class of elements that may appear together with an article and combine with a plural marker. Obviously, another language, which lacks articles or has other means of marking plurality, could

not possess this kind of form-class. If the term noun were used in the description of this language, it would mean something different from what it means in English. For this reason, among others, the traditional part of speech classification was never completely abandoned, and it was revived in generative grammar, which otherwise strove for formal rigor like its predecessor, the structuralistic approach.

Both the traditional parts of speech and the form-classes of structuralist descriptions are primarily concerned with the classification of words. They differ in what aspect of the words they were most interested in.

The object of structuralist form-classes are words as they appear in sentences, units that can be obtained by segmenting utterances into parts and classifying these parts. With this approach, the forms *goes, gone*, and *going* belong to different form-classes because they have different distributions and occupy different slots within an utterance. Traditional grammar, on the other hand, mainly dealt with lexemes, or abstract units of the lexicon that can be realized by one or several word-forms. Here, the lexeme GO, which is realized by the word-forms *go, goes, went, gone*, and *going* is classified only once, namely, as a verb.

The difference between classes of lexemes with their potential forms and functions, and classes of word forms fulfilling a given function in a sentence, has long been ignored. It was obscured by the habit of using the same label for both kinds of categories. For example, the label 'verb' is used both for classes of lexemes like GO and for word-forms used as predicates; in the clause *don't madam me!* (meaning 'don't call me madam'), the word *madam* is a verb in the latter sense, but not in the former.

There are, of course, very obvious links between the two kinds of classes, and these links were particularly strong in the Indo-European languages that had been the model languages for linguistic description for a long time. However, the more linguists explored languages of very different structure, the more it became clear that lexical classes (classes of lexemes) and syntactic word classes have to be established independently of each other. How the two are connected in various languages has been an important topic in the field of language typology in the 1990s. The distinction between the category, or type, of a lexeme and the syntactic category of a word-form has also been integrated into some recent formal theories of syntax.

In a system with a limited number of classes (such as the traditional part-of-speech system), there will always be items that display features of more than one class or that do not fit clearly into one of the classes. This problem can be solved by assuming that classes are not homogeneous but have an internal structure, such that there is a center containing the elements

that meet all criteria typical for the category and a periphery with elements that share only some of these features. This conception of categorization became popular in linguistics in the 1980s, when the concept of prototype was taken over from psychology. Within this view, categories are also allowed to overlap; i.e. words may belong to more than one class.

Another solution lies in categorizing lexemes more than once. Because lexemes have several characteristics that distinguish them and make them similar to other lexemes, several parallel classifications can be established, just as we classify languages according to their historical origin as well as their structural characteristics or their sociolinguistic status. The idea of multiple classification of words has entered linguistic theory only recently and will probably be further elaborated in the future.

The concept of prototype has also been used to solve the old dilemma of universal vs. language-particular categorization. For example, many linguists have been concerned with the question of whether all languages can be said to distinguish nouns and verbs. To tackle this question, a general definition of these categories is needed to ensure that the classes labeled 'noun' and 'verb' are indeed categories of the same kind in different languages. One option is to define the center, or prototype, of the major lexical categories (nouns, verbs, and adjectives) on the grounds of criteria related to meaning and usage. Hence, prototypical nouns are words that designate objects, or time-stable entities, and are used for reference to discourse participants, i.e. what or who is talked about. Prototypical verbs are words that designate actions and are used for the act of predication, and prototypical adjectives designate properties and are used for modification. Within a particular language, one of these categories can be identified if words meeting the general definition are somehow distinguished from other words, i.e. are reasonably considered a lexical class by language-internal criteria such as grammatical inflections and syntactic function. Although the center of each category is determined by the general definition, it is a matter of individual languages as to what further elements the class contains and how classes are delimited. For example, although predicative action words (such as *run*, *push*, *eat*, *sell*) will be verbs in any language that distinguishes such a lexical class, lexemes denoting states or emotions (like *love*, *fear*, *be happy*, *be hungry*) may be verbs in one language and adjectives or nouns in another.

The distinction may be complete, so that e.g. words that are identified as nouns cannot be used in the same syntactic functions and environments as verbs or adjectives. However, we often find that lexemes are not that strictly specified but are used in several functions. In this case, they may be distinguished by the particular word-forms that are possible and necessary in each function. Hence, in many languages, nouns cannot make e.g. tense distinctions, as verbs can, and to have a noun as predicate one often has to use a special device, such as the copula verb in English (*Jane was a girl*, not *Jane girl-ed*).

A language can be said to lack a lexical distinction of parts of speech if any content word can be used in any of the major syntactic constructions and may be combined with the whole range of grammatical markers. Whether such languages exist is still a matter of debate. Certainly, languages differ in how sharp the distinction between lexical classes is drawn, i.e. how important it is for the grammar of the language and whether the elements of a class are more or less specialized for syntactic functions. Latin is an example of a language with clear-cut lexical classes. In English, in contrast, there are many pairs like *to look/a look* or *to move/a move*. Some linguists regard these pairs as two separate lexemes belonging to different classes, whereas others treat them as single multifunctional lexemes.

Whereas the link between a lexical class and a syntactic function is only indirect and often rather weak, matters are different for syntactically determined classes of word-forms. Syntactic theories therefore have been more concerned with the latter, and the term syntactic category is nowadays used in a sense that is only remotely connected to the traditional parts of speech. It covers phrases besides words and also more abstract units that may lack a form, so-called empty categories.

A syntactic category in this sense can be described by a set of features with values specifying the slot in which items belonging to this category can occur. For example, in the clause *she is a linguist*, the category of the word-form *is* will be described by the features 'third person', 'singular', and 'present tense'. As mentioned above, the features 'nominal' and 'verbal' had been derived from the categories noun and verb. Developing this idea further, it becomes possible to characterize a syntactic category entirely by features. In the above example, the syntactic category of *linguist* would thus be the set of the following features: {nominal, nonverbal, singular}. Most contemporary syntactic theories make use of such features but differ in the role attributed to them and their relation to syntactic categories.

Another issue of current debate is the relationship between syntactic categories and sentence structures. In short, the question is which one comes first and should be used to derive the other. This again is connected to the distinction between categories of the lexicon and categories of sentences and how these are related. When sentence structures are derived from word categories, it is supposed that lexemes or word roots are preclassified in the lexicon. For example, the lexicon of English will contain an item *kiss* (noun) and an item *kiss* (verb), the

former defining a noun phrase as in *she gave him <u>a big kiss</u>*, and the latter a verb phrase as in *you may <u>kiss the bride</u>*. According to another position, it is the respective construction that makes *kiss* a noun in the first example and a verb in the latter, whereas in the lexicon, the item *kiss* is not categorized.

Syntactic Typology

Syntactic typology is one of the major branches of linguistic typology, aiming to classify human languages into different types on the basis of their shared syntactic properties, which are not necessarily the result of common origin or geographical contact. Like other branches of linguistic typology, the ultimate goal of such studies is centered on the provision of (syntactic) universals: those qualities that tend to be common in most, if not all, languages, and enable linguists to make hypotheses in their further studies of languages.

The development of syntactic typology owes a lot to the American linguist Joseph Greenberg, whose interest in typology and language universals led him to propose the theory of 'implicational' universals based on syntactic properties (see below).

There are some criteria based on which languages can be typologized syntactically; some of the most important ones are:

(1) Word order. This criterion is the widest known and the oldest way of classifying the languages syntactically. It was so common in the 1960s that one could easily claim that syntactic typology is mainly known to be represented through word-order studies, i.e. how different lexical items are arranged in various languages, to produce syntactic universals.

Studies have shown that, in a transitive clause which mainly has the elements S, V, and O (which stand for Subject, Verb, and Object, respectively), there are logically six possible combinations: SVO, as in English, French, Hausa, Vietnamese, and Thai; SOV, as in Persian, Japanese, Korean, Amharic, Tibetan, Turkish, and Georgian; VSO, as in Welsh, Tongan, Classical Hebrew, Classical Arabic, and Tagalog; VOS, as in Malagasy, Tzotzil (Mexico), and Cakchiquel (Guatemala); OVS, as in Hixkaryana (Brazil) and Barasano (Colombia); and OSV, as in Xavante (Brazil) and Apurina (Brazil).

These orders are, of course, the 'unmarked' order of elements in languages, an order sometimes being called 'canonical order'. Obviously, in languages with rich inflectional systems and therefore 'free word-order' patterns, the canonical order may be altered and changed.

However, these possible compositions are not equal with respect to their frequency. It has been proved that over 95% of the world's languages use one of the patterns SOV, SVO, and VSO as their basic word order, and object-initial languages are extremely rare and uncommon.

Since not all languages express overt subjects, the relative order of verb and object is often considered to be the most important from the point of view of typology. The main interest in classifying languages in this way lies in the 'implicational' relationships, in that we believe certain word orders make it likely for other constructions to occur (more technically speaking: if

X, then Y). For example, an SVO language, such as English, is likely to have prepositions rather than postpositions (such as *up the tree* rather than **the tree up*), and auxiliaries before main verbs (such as *John may come* rather than **John come may*). Such a language is also likely to have relative clauses (beginning with who/which, etc.) after the noun they refer to, such as *The boy who broke the glass escaped* rather than **The who broke the glass boy escaped*. Similar implications may also be provided for other word orders; for example in a VSO language, we have prepositions rather than postpositions, while in an SOV, postpositions are more likely to appear than prepositions.

The general principle behind these observations appears to be a preference for consistency in the position of the main word (or 'head') in any construction with regard to the items attached to it (or the 'modifiers'). Hence, an SVO language such as English is a 'head first' language and an SOV language such as Persian is a 'head last' language. In this case, the linguist is interested in knowing if, for example, genitives appear before or after the noun heads, or whether articles, adjectives, and numerals come before or after the noun heads in a language with a particular word-order.

Although being a very informative source for linguists, word-order typology has its own flaws because (1) it is only relevant to languages with Subjects and Objects, (2) it only deals with languages with a basic word order, while many languages have mixed word orders, and (3) it is only relevant to basic sentences within a language (declarative, nonpronominal, etc.).

The recent developments in syntactic typology have provided use with some other criteria as well (see Nos. 2–9), but basic word order is always standing out as the most fundamental feature of syntactic typology.

(2) Agreement. Agreement refers to a formal relationship between elements in which a form of one word requires a corresponding form of another. This correspondence usually takes place with respect to case, person, number, and gender. For example, in Arabic, noun and their adjectives must correspond to one another in number , gender, and case. Generally, we can assume three important domains in grammatical agreement: (I) The agreement between subject and verb phrase in terms of person and number, as in *I go* and *she goes*. Some languages, however, represent object–verb agreement, like Swahili, Basque, and Caucasian languages (see *Ergativity* below). (II) Nominal agreement with elements related to noun, such as determiners, adjectives, and appositions. Like the German sentence *Sie sucht einen Jungen, ihren kleinsten Sohn* (she is looking for a boy, her youngest son), where the words *Jungen* (boy) and *Sohn* (son) are both accusative and masculine. (III)

Agreement between subject and predicate, in terms of gender, number, or case; as in *He is a waiter/She is a waitress*. This may also show itself in structures where a word refers back to something mentioned previously, as in *I know Jane quite well, **she** was my secretary for long*.

In this case, a syntactic typologist tries to find out if different verb affixes mark person, number, and gender of subject, object, or other noun phrases, and if such agreement is obligatory.

(3) Universals of negative position. Negation is a syntactic (or more technically, "morphosyntactic") process in which a lexical item denies or inverts the meaning of another lexical item or construction. The lexical item that expresses negation is called negator. The position of a negator as a syntactic element is therefore a criterion for syntactic typology; that is, if the negator comes before or after the verbs, or in prefixing verbs, if it is attached to the whole verb, or is placed before the verbal part.

(4) Case-marking patterns. Case is a way of showing grammatical relationship between certain kinds of words by variations in word structure. Languages make use of different means for marking their cases. In some languages, case may be reflected by the use of affixes. In these languages, we either have prepositions (like English and Arabic) or postpositions (like Turkish) or both (like Estonian). There are, of course, some languages that do not make use of adpositions at all, and make use of variations in word endings, like Latin, Estonian, Russian, and Finnish.

On the other hand, in noninflectional languages (like French and English), where sentence structure or word order encode the syntactic functions of the words, we may associate cases with specific syntactic positions.

(5) Wh-movement. Syntactic typologists are also interested in the position of the question words in sentence, and see if it is initial, final, or other.

(6) Relative clause structures. As an implicational result of word-order studies, the questions concerning the use of relatives before or after noun heads is an issue within the domain of syntactic typology.

(7) Causative constructions. A causative is a grammatical or lexical indication of the causal role of a referent in relation to an event or state expressed by a verb. A causative may be indicated by a verbal affix (*black-black**en**, able-**en**able*), or a component of meaning in the verb, or a special construction, like

George had John killed, in comparison with *The sun solidified the mixture.*

(8) Ergativity. In some languages, the form of the object in a transitive clause is the same as that of the subject of an intransitive clause. Such languages are called 'Ergative' languages, as opposed to languages like English, which are typologically entitled 'nominative-accusative' languages. In studying the ergative languages, the linguist has to check if the subject of a transitive clause has a different form; i.e. in some languages, in intransitive clauses some subjects are treated like transitive subjects, and others like transitive objects. A remarkable number of Caucasian (Georgian, Ubykh, Avar), Austronesian (Tongan), Australian (Dyirbal), and Mayan (Tzeltal) languages are ergative.

(9) Pro-drop languages. Some languages can optionally drop pronouns at the beginning of sentences, as in Persian *man Irâni hastam/Irâni hastam* (I am Iranian/Am Iranian) and one that does not usually do so, such as English. Pro-drop languages seem to behave somewhat differently over a range of constructions from languages that do not drop their pronouns.

BEHROOZ MAHMOODI-BAKHTIARI

Syntax

Human languages are productive systems for relating sound (or more generally gesture, as in signed languages) and meaning. The systematic properties on the sound side are the realm of phonology while those on the meaning side belong to semantics. What is in between is syntax. One of the two most fundamental aspects of syntax is that utterances in a human language are structured. Specifically, a sentence is not merely a string of sounds. Minimally, the sounds must be grouped together into words. But a sentence is not just a string of words either. The words are grouped together into units, called 'constituents'. Consider a simple sentence such as:

(1) The man left.

This is not simply a sequence of three autonomous words. *The* and *man* are closely associated in a way in which *man* and *left* are not. The former pair of words constitute a unit based on the noun *man*, as the following two tests indicate. First, a 'pro-form' (in this case, a pronoun) can substitute for *the man*:

(2) He left

No comparable substitution is possible for the sequence *man left* in (1). Second, an adverb modifying the sentence can easily be inserted between *man* and *left*, as in (3), but not between *the* and *man*, as in (4):

(3) The man obviously left

(4) *The obviously man left [* indicates an ungrammatical sentence, a sequence of words that is not a sentence of the language under investigation]

This pattern of data indicates that the sequence *The man* constitutes a unit while the sequence *man left* does not. There is a division of sentence (1) into two constituents. The first part, the subject, is based on a noun (so is often called a noun phrase (NP)), and the second part, the predicate, on a verb; hence a verb phrase (VP). A common notation for representing this division into units, and the 'names' of the units, is displayed in (5).

(5) [$_S$ [$_{NP}$ The man] [$_{VP}$ left]]

The interpretation of (5) is that the sequence *The man* is a unit of structure, and this constituent is called an

NP; *left* is a unit of structure labeled VP; and the entire sequence of words is a unit of structure called S (Sentence). A more complete structural representation of (1) would also indicate the categories of the individual lexical items *The*, a determiner, *man*, a noun, and *left*, a verb. At this point, the labeled bracketing notation becomes rather cumbersome. A standard alternative more graphically represents the structure in the form of a phrase structure 'tree' as in (6).

(6)

```
            S
          /   \
        NP     VP
       /  \     |
     Det   N    V
      |    |    |
     The  man  left
```
The second fundamental syntactic property of human languages is their infinitude. In every human language, ever longer sentences can be created by embedding one clause inside another, a process called recursion. For example, the sentence in (1) can become the 'direct object' of another verb, as in (7), with tree representation (8).

(7) The woman said the man left

(8)

```
              S
           /     \
         NP       VP
        /  \      /  \
      Det   N    V    S
       |    |    |   /  \
      The woman said NP  VP
                    /  \  |
                  Det  N  V
                   |   |  |
                  the man left
```
And (7) can, in turn, be inserted into a still larger sentence:

(9) The child believes the woman said the man left

And so on, with no limit. As a consequence of this recursion, there is no longest sentence, and, thus, there are an infinite number of sentences.

The kind of recursion just seen involves 'subordination', placing one unit of structure inside another. Just as general in the languages of the world is coordination — putting constituents together in parallel with a coordinating conjunction like *and:*

(10)

```
               S
            /     \
          NP       VP
        /  |  \     |
      NP  and  NP   V
     /  \     /  \   |
   Det   N  Det   N left
    |    |   |    |
   The  man the woman
```
This process too can go on without limit:

(11) The man and the woman and the child left
(12) The man and the woman and the child and the dog left

Another phenomenon that falls in the domain of syntax is a particular kind of ambiguity, 'structural ambiguity'. Human languages are filled with ambiguity. Some instances of ambiguity are *lexical*, involving two different words that happen to be pronounced and/or spelled alike. An example is

(13) Meet me at the bank

where I could intend that we gather after depositing our paychecks or that we get together to go fishing. But many other instances of ambiguity do not depend on homonymous words. Each of the following examples feels like it is two different sentences in one, even though the words of each have constant meaning.

(14) Sue interviewed a singer on the stage
[Was the interview on the stage, or just the singer?]

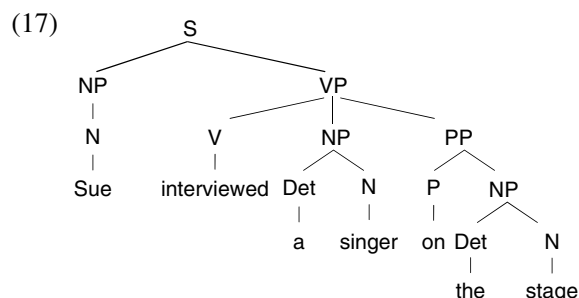
(15) Susan said John resigned in order to protect his reputation
[Was the resignation or the statement to protect John's reputation?]

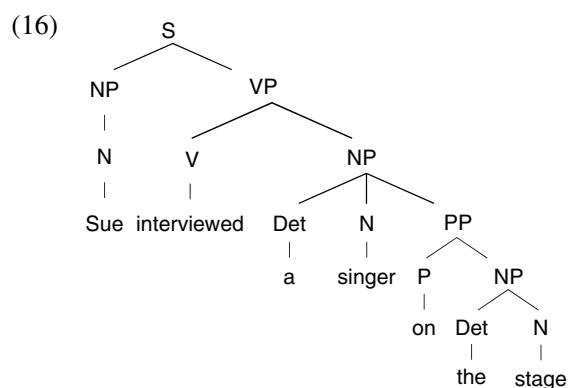
These ambiguities can be captured by positing two different syntactic structures for each two-way ambiguous sentence. For (14), the prepositional phrase (PP) *on the stage* can be inside the direct object NP (where it will modify *singer*) or outside that NP, but still inside the VP (where it will modify *interview*). The two structures are in (16) and (17), respectively.

(16)

```
         S
       /   \
     NP     VP
      |    /  \
      N   V    NP
      |   |   /  |  \
     Sue interviewed Det  N   PP
                      |   |    /  \
                      a singer P   NP
                              |   /  \
                             on Det   N
                                 |    |
                                the  stage
```

(17)

```
           S
         /   \
       NP     VP
        |    / | \
        N   V  NP   PP
        |   |  / \   / \
       Sue interviewed Det N P  NP
                        |  |  | / \
                        a singer on Det N
                                     |   |
                                    the stage
```




A further striking syntactic property of many human languages is the existence of dependency relations between an overtly realized constituent (a 'filler') and a 'gap' (marked by __), as in interrogative sentences like (18).

(18) Who will Mary hire __

Who, the filler, is pronounced at the beginning of the sentence, but is nonetheless interpreted as the direct object, i.e. in the gap position following the verb *hire*, parallel to (19).

(19) Mary will hire someone

One common way, although not the only way, to represent this kind of dependency is through a 'movement transformation' whereby the interrogative word originates in its understood position, then 'moves' to its superficial position at the beginning of the sentence, leaving a gap in its original position.

Such filler-gap dependencies can span a great distance, as shown in (20), where the edges of each embedded clause are marked with brackets, and __ marks the 'understood' position of the interrogative word.

(20) Who did Mary think [that John said [that Susan visited __]]

Compare:

(21) Mary thinks that John said that Susan visited someone

The properties of long-distance relations of this type ('WH-dependencies', so-called because in English, most interrogative words begin with <u>wh</u>) have been a major concern of syntacticians.

While WH-dependencies can occur across unlimited distances, under some circumstances they are heavily bounded. Constraints on these dependencies (sometimes called 3'island constraints') have been another major topic of investigation. One island constraint involves structures built with coordinating conjunctions. Consider the hypothetical question form of (22) in (23):

(22) Mary will blame [Sue and someone else]
(23) *Who will Mary blame [Sue and __]

This is a perfectly coherent thought, but it cannot be expressed with a WH-dependency. A coordinate structure is an island for such dependencies.

Two other types of dependencies involve an overt item in the subject position and a gap in a 'lower' position. At first glance, the examples in (24) and (25) seem identical to each other, but they turn out to have significantly different properties.

(24) Mary is eager [__ to solve the problem]
(25) Mary is likely [__ to solve the problem]

In both (24) and (25), *Mary* is the understood subject of *solve the problem*. In (24), additionally, the property of 'eagerness' is attributed to Mary, while in (25), 'likeliness' is not. This contrast is made particularly clear in sentences with pleonastic (meaningless) subjects:

(26) *There is eager [__ to be a thunderstorm]
(27) There is likely [__ to be a thunderstorm]

The kind of dependency in (24), where the overt subject is understood in both sentences, is often called 'Control'. The contrasting kind in (25) is sometimes called 'Raising' (a term coming from a movement analysis: *Mary* originates in the lower sentence, where its semantic role is determined, and moves into the higher sentence). Passive sentences display a similar dependency, this time between object position and subject position:

(28) John was chosen __

John is the semantic object of the verb, but is phonologically realized in subject position. A particularly interesting dependency of roughly this sort is illustrated in (29).

(29) Mary is easy [__ to please __]

Here, *Mary* is understood as the object of the embedded sentence. (The subject of the embedded sentence is understood as free in reference.) Syntacticians have long been fascinated by contrasts like these, where, item by item, a set of sentences seem identical, but have very different interpretive properties, as in the following three examples, based on the ones just discussed.

(30) Mary is eager to please [*Mary* is understood subject of both sentences]
(31) Mary is likely to please [*Mary* is understood subject of embedded sentence only]
(32) Mary is easy to please [*Mary* is understood object of embedded sentence only]

In addition to filler-gap dependencies, languages also display dependencies between pairs of overtly realized items. One such dependency involves reflexive expressions, as in (33).

(33) John criticized himself

Typically, a reflexive requires an 'antecedent', and the antecedent must be 'higher' in the tree than the reflexive:

(34) *Himself laughed
(35) *Himself criticized John

Reflexive dependencies, like many other dependencies, have locality restrictions. In English, the antecedent must generally be in the same clause as the

reflexive (although many other languages have long-distance reflexives):

(36) *John said that [Mary criticized himself]
(37) *John said that [himself would do the job]

This is a stricter requirement than we saw for interrogative filler-gap dependencies (as in (20)). On the other hand, in contrast to (23), coordinate structures are not islands for reflexives:

(38) John criticized Mary and himself

One major area of syntactic investigation centers on the characterization of divergent locality constraints for the various kinds of dependencies.

Syntacticians have long been concerned with systematic ways that languages differ in their syntactic patterns. For example, while many languages are like English in having filler-gap WH-dependencies, many others, such as Japanese, realize their interrogative words in their 'understood' positions. In terms of movement analyses, interrogative words in these languages do not move. Another systematic difference among languages involves basic word order. English, along with many other languages, has the verb preceding its direct object, and, parallel to this, English has prepositions (i.e. prepositions precede their objects):

(39) Naomi hired Ken

(40)
```
        . . . . VP
             /     \
           V        NP
           |         |
         hired       N
                     |
                    Ken
```
(41) A package arrived from Tokyo

(42)
```
        . . . . PP
             /     \
           V        NP
           |         |
         from        N
                     |
                   Tokyo
```
In Japanese, along with many other languages, the structures are exactly the reverse. Verbs follow their direct objects, and the language has *post*positions instead of *pre*positions:

(43)
```
            VP
          /    \
        NP       V
        |        |
        N        N
        |        |
      Ken-o    yatot-ta
```

(44)
```
            PP
          /    \
        NP       P
        |        |
        N       kara
        |
      Tokyo
```
The lexical item that a phrase is based on (V for VP, P for PP, etc.) is commonly called the 'head' of the phrase. The constituent that serves as 'direct object' of the head is the 'complement'. In these terms, the two language types are characterized as head-complement and complement-head.

In sum, syntax is concerned with the structural properties of sentences in languages. Of equal interest are the general, universal properties, such as phrase structure, recursion, dependencies; and the systematically diverging properties, such as relative order of heads and their complements and how dependency relations are realized.

Taboo

Discussions of 'taboo' words must begin with an understanding of the relationship between language and culture. The term originally comes from Polynesian cultures, in which certain objects, actions, and words were considered to exert harmful power on people. Some words were thought to be dangerous. If someone mentioned the name of an ancestor, for instance, negative consequences could result. Thus, speakers of a language had to avoid using certain names or words, just as they had to avoid offending cultural norms and religious beliefs. Which words were considered 'taboo' and to what degree any words were harmful depended on cultural norms.

Societies that recognize supernatural powers and are concerned about offending nonhuman powers consider words to be very powerful. Cultural norms discourage people from using certain words because the very utterance will cause harm either to the speaker or to other members of the society. Melanesian cultures often have a prohibition on mentioning the name of ancestors to avoid any negative repercussions from the spirit world. Since personal names are related to common words, the vocabulary of some languages has undergone a remarkably rapid change. Speakers of such languages find alternative ways of referring to ancestors and find other ways of talking about the objects that are included in the ancestor's name. These avoidance practices may also extend to how a person can talk about or address in-laws.

The discussion of taboo words in the Western world is also related to cultural norms, but not typically to the supernatural world. Certain words may be avoided because they are considered to be a violation of norms of etiquette. The use of these words is unacceptable to certain people in certain situations. As a society shapes the individual, it passes on a form of moral judgment about particular words. In such a society, there is no supernatural judgment or appeal to spiritual powers, it is rather a societal pressure against the use of these words and phrases.

Linguists have taken a neutral and descriptive stance on taboo words. The role of linguistic studies has been to document which words are avoided in what situations. Linguistics makes no moral or religious judgment on the use of taboo forms. Thus, for example, the journal *Maledicta: The International Journal of Verbal Aggression* includes articles listing taboo forms used by various groups and subgroups of a culture.

In English, words related to certain bodily functions (death, defecation, urination, sexual intercourse) and religious beliefs (hell, damnation, curse, swear) are sometimes considered to be 'taboo', at least in particular segments of the population. Those who consider the words to be offensive will often use a synonymous euphemism in place of the taboo word: 'go number two' instead of 'defecate', 'pass on' instead of 'die'. On the other side of the politeness scale are words that are less neutral and more likely to be limited in public settings: 'take a shit' for 'defecate', 'croak' for 'die'.

Words themselves are not 'taboo', 'dirty', or 'profane'. Many of the words currently considered inappropriate in public settings were the neutral, normal term for an object or action in earlier forms of English.

The term 'shit' was not always deemed inappropriate or impolite. In a similar way, many languages of the world still treat bodily functions in a less euphemistic manner.

Since the use of particular words are determined by the social setting, people use or avoid these forms based on their desire to follow or violate the social norms of the particular situation. Violating social norms may be considered appropriate when those norms are thought to be outmoded or prudish. American humorists such as Lennie Bruce, for example, used taboo words in their routines. Young people might use taboo words to show their disregard for the norms of their elders.

The topic of taboo words has been extended to 'cursing' and 'swearing'. The word 'cursing' is tied to a worldview in which bad or evil can be caused by using words. Likewise, 'swearing' has changed from 'taking an oath'. Both words are now used to refer to offensive language. The terms are used as synonyms for 'profanity', which has its roots in the religious notion of the 'profane' vs. the 'sacred'. Such words are also deemed to be 'dirty' as in 'dirty language', 'filthy words', etc. Newspapers and other public media sources typically restrict the use of particular words, even in direct quotations. Likewise, government regulations of broadcast media require certain words to be censored ('bleeped out').

Racial epithets are also considered to be within the topic of language taboo. The use of racial epithets can be seen as a form of aggression against others. The use of names and words that denigrate a racial group is subject to societal norms. In the United States, there are even laws restricting and condemning such language.

Even though portions of society and even government regulations seek to limit the use of taboo forms, it is the individual speaker who determines his or her own use of these forms. In informal settings among co-workers or in dangerous situations (war, natural catastrophe, etc.), people may use taboo forms as a means of expressing their emotions. In more formal situations, in settings that are less homogeneous or in less stressful situations, the use of taboo language is often more limited.

Tagalog and Philippine Languages

Philippine Languages

Over 150 languages are spoken by the more than 76,500,000 Filipinos who live in an archipelago of around 7,000 islands that stretches over 1,500 kilometers from north to south, and about 800 kilometers from the most western point of Palawan to the most easterly point of Mindanao. Most of the languages are dialectally diverse, with a number constituting extensive dialect chains.

All Philippine languages belong to the Western Malayo-Polynesian group of the Austronesian language family. The archeological record suggests that the earliest Austronesian speakers arrived in the northern Philippines, probably from what is now called Taiwan about 4,500 years ago, at the beginning of the migrations that later took them to the Indo-Malaysian archipelago, and ultimately into the Pacific. Since the time of the first Austronesian habitation of the Philippines, the original language has diversified into a number of fairly clearly defined subgroups (Blust 1991).

Of the 167 Philippine ethnolinguistic groups cited in Grimes (2000), at least ten are presently spoken by more than a million population, and constitute what have been referred to as the 'major' languages of the Philippines. These are Tagalog, Sebuano, Ilokano, Hiligaynon, Bikol, Samar-Leyte, Kapampangan, Pangasinan, Maranao, and Magindanao. The first four of these languages have considerable importance in the Philippines. Tagalog, with some 15,000,000 native speakers, is the native language of Manila and a number of surrounding provinces. It is also the basis of the national language, now known as Filipino. Furthermore, it has become the main language of

movies and comics, and much of the Philippine mass media. It is required to be taught in all the schools in the Philippines, and is rapidly becoming the main second language that people speak throughout the country. Sebuano, Ilokano, and Hiligaynon are widely spoken as regional trade languages. Ilokano is the main language of trade and wider communication spoken throughout northern Luzon. It is also spoken in some areas of southern Mindanao and is the main Philippine language spoken in the United States and other countries to which Filipinos have migrated. Sebuano is used not only in the Visayan area of the Central Philippines, but also in much of southern Mindanao. Hiligaynon is also spoken in some parts of southern Mindanao.

At the other end of the scale, there are scores of languages spoken by relatively small groups of peoples. Many of these languages are spoken in highly isolated areas, such as the remote, mountainous areas of Mindanao, Palawan, and Luzon, as well as on small, isolated islands. Some of the smallest languages, and the ones most in danger of dying out in the very near future are those spoken by some of the approximately 30 surviving Negrito groups, descendants of the original non-Austronesian inhabitants of the Philippines, whose original languages were ultimately replaced by those of the culturally more dominant Austronesians. These include Arta, the language of fewer than a dozen remaining members of a group in Quirino Province, the Atta and Agta groups of Kalinga-Apayao and Cagayan Provinces, some of the Dumagat and Alta groups of Isabela and Quezon Provinces, the Sierra Madre mountain range, and the islands off the eastern coast of Luzon, as well as the many Ayta groups of Bataan and Zambales Provinces. Many of these languages are spoken by fewer than 1,000 people. On a slightly larger scale are the languages spoken in the Cordillera Central, the massive mountain range in the center of northern Luzon. These include closely related varieties of Ifugao, Bontok, Balangaw, Kankanay, and Kalinga, some of which have fewer than 50,000 speakers each. Similarly, the number of speakers of several of the Manobo languages of Mindanao is estimated to be no more than 10,000 to 15,000.

Prior to European settlement in the Philippines beginning with the Spanish in 1521, Philippine languages had already been strongly influenced by contact with traders from outside the country. The Chinese (primarily speakers of Hokkien) had established enclaves in major port areas (beginning around the twelfth century CE). Similarly, traders speaking a variety of Malay probably used in Brunei, Malaysia had firmly established themselves in the Manila area at least 100 years prior to the arrival of the Spanish. Their influence on Tagalog was considerable. But it was the Spanish occupation of the Philippines for over 400 years that had the most impact on the languages of the country. Probably every Philippine language has a large number of words that are ultimately of Spanish origin. There is at least one language in the Philippines that shows a far greater influence from Spanish than does Tagalog. This language, called Chavacano or Zamboangueño, is a creole language spoken mainly in Zamboanga City and surrounding areas.

The other major influence on Philippine languages has come from English as a result of the 50 years that America colonized the Philippines. English is still spoken widely throughout the Philippines, is one of the languages used in education, and continues to influence Philippine languages.

Most Philippine languages have sound systems that are relatively simple. Most have between three and six vowels. Tagalog originally had three distinctive vowels, *i*, *a*, and *u*, but two more vowels, *e* and *o*, have developed as a result of influence from Spanish borrowings. Many languages still retain the same vowel system that has been reconstructed for Proto-Austronesian, with four vowels, *i*, *a*, *u*, and *ə* (Reid 1973). Similarly, most Philippine languages have fewer than 18 consonants. They are nontonal, but some have lexical stress and distinguish vowel length. A number of the languages of northern Luzon, such as Inialoi, exhibit complex morphophonemic variation.

Most Philippine languages have only two or three different kinds of syllables. Words are commonly built using just two syllable types, CV and CVC, where C stands for any consonant and V for any vowel. The disyllabic Tagalog word *bahay* 'house' is typical of the great majority of common nouns in Tagalog and other Philippine languages. Verbs are commonly morphologically highly complex, with various prefixes, infixes, and suffixes providing both syntactic and semantic information. A wide variety of reduplicative processes is also found.

Tagalog

Tagalog is a nonconfigurational language (Kroeger 1993). Its basic sentences are predicate initial, with nominal complements typically following the predicate. Noun phrase word order is not rigid, except that actors typically precede other actants, and full NPs which carry nominative case tend to occur later in the sentence. Since there is no copula verb, Tagalog sentences may have a noun, an adjectival form, or a prepositional phrase as the predicate of a sentence: e.g. *Doktor ang bisita.* 'The visitor is a doctor.' *Maganda ang babae.* 'The woman is beautiful.' *Nasa kusina ang regalo.* 'The gift is in the kitchen.' NPs are typically introduced by one of a small number of short, unstressed words, often

referred to as determiners, that provide information about the case, plurality, and personhood of the following noun, as in Table 1. Most common nouns are not inflected for plurality, but may have a plural word *mga* (/maŋa/) following the determiner to mark plurality: e.g. *Tumakbo ang mga batà* . 'The children ran.' Nominative forms typically mark an NP as specific or definite. They may also mark topicalized NPs and definite NPs functioning as predicates.

Tagalog distinguishes three case-marked sets of personal pronouns, as shown in Table 2. In addition to pronouns that refer to the speaker (first person), directly address the hearer (second person), or refer to a third person, Tagalog like other Philippine languages has distinct forms for first person plural exclusive ('we, not you'), and first person plural inclusive ('we all'). Pronouns with dual reference ('we, two'), while common in many Philippine languages, are used only in rural areas where Tagalog is spoken. An irregular combined form of Genitive 1s and Nominative 2p, *kita*, occurs, e.g. *Iniibig kita.* 'I love you.' Third person pronouns do not distinguish gender. Nominative pronouns also function as predicates: e.g. *Ikaw ang anak ni Pedro.* 'You are the child of Pedro.' Genitive forms express not only possessors that follow their noun heads, but also actor participants in a clause: e.g. *Ibinigay nila ang libro sa titser nila.* 'They gave the book to their teacher.' Pronominal forms, as well as clitic adverbs such as *na* 'already', *pa* 'yet', and *din* 'also', occur as second position clitics attaching to the first constituent within the clause, such as a negative auxiliary, e.g. *Hindi ko pa rin binili ang libro.* 'I still haven't bought the book yet', or a fronted adverb, e.g. *Bukas na siya papasok.* 'He will enter tomorrow already.'

TABLE 1   Tagalog Determiners

	Nominative	Genitive	Oblique	Locative
Common	*ang*	*ng* /naŋ/	*ng* /naŋ/	*sa*
Personal				
Singular	*si*	*ni*	—	*kay*
Plural	*sina*	*nina*	—	*kina*

TABLE 2   Tagalog Personal Pronouns

	Nominative	Genitive	Locative
Singular			
1st person	*ako*	*ko*	*akin*
1st pers. dual	*kata*	*nita*	*kanita*
2nd person	*ka / ikaw*	*mo*	*iyo*
3rd person	*siya*	*niya*	*kaniya*
Plural			
1st pers. excl.	*kami*	*namin*	*amin*
1st pers. incl.	*tayo*	*natin*	*atin*
2nd person	*kayo*	*ninyo*	*inyo*
3rd person	*sila*	*nila*	*kanila*

Relative clauses follow their head noun and are linked to it by a 'ligature' *na* (following consonants) or *-ng* (following vowels). Their structure follows the so-called gap strategy, with the gap corresponding to the nominative NP of the relative clause, e.g. *ang babaeng pumasok* 'the woman who entered', *ang bahay **na** bibilhin ko* 'the house that I will buy'. A ligature also links a main verb and its complement, e.g. *Huwag kang umiyak.* 'Don't cry.'

Tagalog is typical of other Philippine languages that have traditionally been considered to be typologically different from other languages in that they have been assumed to have a unique type of grammatical system, known as the 'focus system'. This is a system characterized by the use of verbal affixes to indicate the thematic role of the NP bearing the nominative case in a sentence. The term 'focus system' was first introduced to describe the languages of the Philippines. Subsequently, other Austronesian languages exhibiting a similar type of grammatical system (such as many of the languages in Taiwan, Sabah, northern Sarawak, and northern Sulawesi, as well as Malagasy, Palauan, and Chamorro) have been described as having a 'Philippine-type' syntax.

Basic verbal clauses in Tagalog have one of two basic structures. 'Actor focus' verbs carry one of a set of affixes on the verb that indicate that the actor is expressed by the Nominative case. These may be monadic, expecting only one NP, e.g. with infix *-um-*: *Pumasok si Nila.* 'Nila entered.', or dyadic, in which case an additional NP expressing a theme argument occurs, expressed by the oblique case when indefinite, or a partitive, definite NP, e.g. ***Bum**ili sila ng mangga.* 'They bought mangoes'; ***Um**inom noon ang mga batà.* 'The children drank some of that.' Such sentences are syntactically intransitive. 'Nonactor focus' verbs carry one of a different set of affixes on the verb that indicates whether some participant other than the actor carries Nominative case. In these sentences, the actor carries Genitive case. All are syntactically transitive: e.g. Goal focus, with *–in*: *Bibilh**in** nina Juan ang mga mangga bukas.* 'Juan (and companions) will buy the mangoes tomorrow.' Location focus, with *–an*: *Bibilh**an** nila ng mangga ang mga batà.* 'They will buy mangoes from the children.' Beneficiary focus, with *i-*: ***I**bibili nila ng mangga ang batà.* 'They will buy the child a mango.' Instrument focus, with *ipang-*: ***Ipam**bibili nila ng mangga ang pera nila.* 'They will buy mangoes with their money.'

In addition to the affixes that mark focus or voice, verbs also carry a wide range of affixes marking temporal aspect (perfective, imperfective, and contemplated), and mood (volitional vs. nonvolitional). They may also be derived with a causative affix, introducing an additional actant (a causer) into the clause.

The grammatical system of Philippine-type languages has been a topic of considerable controversy in linguistic analysis. Hardly any of the statements made in this article have gone unchallenged in recent times. Various issues discussed in the literature are the following: Do Philippine languages have a 'subject', and if they do, which NP is it? Are Philippine languages accusative, ergative, split-ergative, or some other type? Do Philippine languages have a true passive construction? Do they have an antipassive construction? Do the 'focus affixes' constitute inflectional voice morphology on the verb, or are they derivational 'applicative' affixes?

LAWRENCE A. REID

Tamil

Tamil is a language of the Dravidian family that originated in southern India and spread in prehistoric times to Sri Lanka. In the nineteenth century, the British colonial empire enabled Tamils from India to seek work as laborers in Malaysia, Singapore, Sri Lanka, Burma, southern Africa, Fiji, Reunion, Mauritius, and the West Indies. Many well-educated Sri Lanka Tamils found higher status jobs in Malaysia and Singapore. More recently, Tamils have looked to the Middle East, the United Kingdom, North America, and Australia for employment. In addition, thousands of Sri Lanka Tamils seeking asylum from the troubles in their homeland have fled to India, Western Europe, North America, and Australia. The distribution of the over 63 million native speakers of Tamil in various countries is roughly as follows: India, 58.6 million, primarily in Tamil Nadu and neighboring states; Sri Lanka, 3 million; Malaysia, 1.3 million of 1.5 million ethnic Tamils; South Africa, 250,000; Canada, 160,000; Singapore, 120,000 of 191,000 ethnic Tamils; Reunion, 120,000, a figure that may include second-language speakers; United Kingdom, 100,000; France, 60,000; Germany, 50,000; Switzerland, 40,000; United States, 35,000; Australia, 30,000; Italy, 25,000; Mauritius, 22,000 of a total of 100,000 ethnic Tamils; Netherlands, 20,000; Norway, 8,000; Denmark, 7,000; Fiji 6,600; New Zealand, 3,000; Sweden, 2,000. In all communities outside India and Sri Lanka, younger generations are no longer learning Tamil, so that in some cases these figures exaggerate the number of actual speakers.

Tamil exhibits 'diglossia': a formal or 'High' variety is used in public speaking and most writing, while colloquial or 'Low' varieties are used in face-to-face interactions and in writing intended to convey an informal chatty or 'hip' style. Differences between formal and colloquial varieties are found in pronunciation, grammar, and vocabulary. Colloquial Tamil has much more variation according to region and social class than formal Tamil does: the greatest differences are between Sri Lanka and India, with different subvarieties within

each of these. Differences in the usage of different social groups are also found, as, for example, between Brahmin and non-Brahmin varieties in India. Some examples are given Table 1 comparing formal Tamil with the principal colloquial varieties of India and Sri Lanka.

In vocabulary that is not borrowed from unrelated languages like Sanskrit or English, formal Tamil has the consonants / p t t̪ t̤ c k m n ŋ ɲ r ɻ l ɭ ʋ j / and the vowels / i e a o u /. All consonants except /r/ and /ɻ/ are found single (short) or geminate (long), and all vowels may be short or long. The consonants and vowels are essentially the same as those believed to have been used in Proto-Dravidian, the common ancestral language of the entire Dravidian family. Unlike the other Dravidian languages, Tamil has not augmented the single series of voiceless stops /p t t̪ t̤ c k / with voiced or aspirated ones, although the voiceless stops have variants that include voiced stops such as [b, d] and continuants; and for many Indian speakers, a series of voiced stops occurs in loanwords such as *bassu* 'bus' and *daakam* 'thirst'. Other sounds that occur only in loanwords are / h /, / ʃ /, and / æ /. Colloquial Tamil has generally lost /ɻ/, replacing it with / ɭ / or / j /; Indian varieties have also lost / t̪ /, but Sri Lanka Tamil preserves it as / r / or / t̪ /. Two characteristics of the pronunciation of colloquial Indian Tamil distinguish it from Sri Lankan varieties: the insertion of / j / before / i / or / e / and of / ʋ / before / u / or / o / when these vowels begin a word; and nasalized vowels that result from the loss of / m / or / n / at the end of a word, as in [pɐjjẽ] from *pajjan* 'boy.' Sri Lanka Tamil, for its part, is characterized by the retracted pronunciation of / i / and / e / before certain consonants, as in [kɜɜ kkɾɐn] from *keekkɾan* 'I ask', and the fronted pronunciation of / a / before alveolar consonants, as in [pælli] from *pallu* 'tooth'.

Tamil has been written since the third century BCE. Like many South Asian literary languages, it has its own

script, which descends ultimately from a variant of the Brahmi script used during the reign of Emperor Ashoka (273–232 BCE). The writing system is well adapted to represent the pronunciation of formal Tamil, except that a few symbols are superfluous, such as those that represent the combinations /aj/ and /aʋ/ as though they were diphthongs, and the symbols for [n̪] and [ŋ], which are just variants of /n/. A second script, the Grantha script, was developed in the fifth century CE to write Sanskrit in South India. Grantha symbols for /dʒ/, /ṣ/, /s/, /h/, and /kṣ/ have been adopted into the Tamil script to represent sounds occurring in loanwords.

A Tamil word consists of a root plus a series of suffixes. Word order is strictly 'head-final': that is to say, adjectives and relative clauses precede the nouns they modify; adverbs, direct objects, and indirect objects precede verbs; auxiliaries follow main verbs; and postpositions are used rather than prepositions. Formal Tamil is more conservative and exhibits characteristics of an earlier stage of the spoken language. Thus, some of the suffixes of colloquial Tamil have developed from earlier postpositions, auxiliaries, etc., which still appear as separate words in formal Tamil. Examples can be seen in the last three examples in the table above.

Case suffixes and postpositions are used to indicate the grammatical functions of nouns and pronouns. In head-final languages like Tamil, the distinction between postpositions and case endings is sometimes fuzzy; indeed, as mentioned above, the latter can develop from the former. To illustrate this point further, traditional grammars of formal Tamil recognize eight cases: nominative (subject), accusative (direct object), instrumental (by using …), associative (together with …), dative (to …), ablative (from …), genitive (of …), and locative (at …), but the ablative is not a case in formal Tamil: rather, it is a combination of the locative case and the postposition *iruntu,* as seen in the example 'from the house' above. In colloquial varieties, however, the postposition and locative have fused into a single unit and can be considered a separate case form.

Pronoun categories include the expected first, second, and third person forms ('I/you/he'). In the first-person plural ('we'), there is an additional distinction (lacking in colloquial Sri Lanka Tamil) between 'inclusive' and 'exclusive' (*naam* 'we, including you' vs. *naankaḷ* 'we, not including you'). The second person distinguishes between the familiar singular *nii* and the plural or polite singular form *niinkaḷ;* a singular polite form, *niir,* is also less commonly found. The third-person pronouns are the most numerous and show the greatest variation from one variety of Tamil to another. First, there are three parallel sets of 'deictic' (pointing) pronouns, which are distinguished by their initial

TABLE 1 Comparison of Formal Tamil with Colloquial Forms of India and Sri Lanka

	Common Indian Colloquial	Sri Lanka Colloquial (Jaffna)	Formal Tamil
[I] gave	kuʈutteen	kuʈuttanaan	koʈutteen
[I] gave (perfective)	kuʈuttiʈʈeen	kuʈuttiʈʈan	koʈuttu ʋiʈʈeen
[you] ask	keekkriinka	keekkrijaḷ	keeʈkiʈiirkaḷ
very	rompa	miccam	mikaʋum
boy	pajjan	poɖijan	pajjan
from the house	ʋiiʈʈulerntu	ʋiiʈʈulerntu	ʋiiʈʈil iruntu
must go	pookaɳum	pooka ooɳum / pooka ʋeeɳum	pooka ʋeeɳum
didn't come	ʋarale	ʋareelle	ʋara ʋillai

vowel; for example, *itu* 'it, this one', *atu* 'it, that one', *etu* 'which one'. These three sets can be called 'proximal' (*i-*), 'distal' (*a-*), and 'interrogative' (*e-*). In formal Tamil, each of these sets has six members; illustrating with the distal set, these are: *avar* 'he or she, that (human, respectful) person', *avan* 'he, that (human, nonrespectful, male) person,' *aval* 'she, that (human, non-respectful, female) person', *atu* "it, that (non-human) one", *avarkal* 'they; those (human) people', and *avajkal* 'they, those (non-human) ones'. In addition to these deictic pronouns, two further interrogative pronouns are found: *enna* 'what' and *jaar* 'who'. Many other deictic words also have proximal, distal, and interrogative forms, for example *ippootu* 'now', *appootu* 'then', *eppootu* 'when'; *ittanaj* 'this many', *attanaj* 'that many', *ettanaj* 'how many'; and *ippati* 'thus, like this', *appati* 'thus, like that,' *eppati* 'how'. Finally, the Jaffna dialect of Sri Lanka Tamil has a fourth set of addressee-proximal deictics in *u-*. For example, Jaffna Tamil distinguishes between *itu* 'it, this one near me/us', *utu* 'it, that one near you', *atu* 'it, that one (not near you or me/us)', and *etu* 'which one'.

Verbs do much of the grammatical work in a Tamil sentence, and as a result there is a rich set of verb forms; a selection of these is given in Table 2. For regular verbs, the verbal root serves as the base of the imperative. The infinitive is also closely related to the root form of the verb. Three tenses (present, past, and future) are found, and these take additional suffixes to agree with the subject. The infinitive and tense stems also serve as the base on which other forms are built; finally the infinitive and the past participle combine with a variety of auxiliary verbs. In colloquial Tamil, some of these auxiliaries are reduced to suffixes, as seen in the example '[I] gave (perfective)' above. Colloquial Tamil has also developed new formations not found in formal Tamil; an example is the past formation of Jaffna Tamil seen above in the example '[I] gave'.

It can be seen from the examples that the human vs. nonhuman distinction found in the pronouns has parallels in the verbal system; for example, the human present and future, built on the corresponding tense stems, are structurally different from the nonhuman present and future, built on the infinitive stem. Less apparent is the fact that the positive and negative systems of Tamil are somewhat independent of one another. In most languages, each positive form has a corresponding negative form with a similar structure. But in Tamil, this is not the case: the distinctions of tense (present, past, future) and aspect (progressive, perfect, perfective) found in the positive are replaced in the negative by just the simple negative, the future human negative, and the future nonhuman negative; of these three, only the future nonhuman negative has

TABLE 2   Selected Forms for the Verb koṭu 'give' (Formal Tamil)

Imperative	
koṭu	imperative 'give'
Infinitive	
koṭu-kk-a	infinitive 'to give'
Tense forms	
koṭu-kkiṯ-aan	rational present 'he gives/is giving'
koṭu-tt-aan	past 'he gave'
koṭu-pp-aan	rational future (potential/habitual) 'he will give; he gives; he used to give'
Forms built on infinitive stem	
koṭu-kk-alaam	permissive/speculative 'may/could give'
koṭu-kk-aṭṭum	Optative 'let [him] give'
koṭu-kk-atu	nonrational present 'it gives/is giving'
koṭu-kk-um	nonrational future (potential/habitual) 'it will give; it gives; it used to give'
koṭu-kk-aatu	nonrational future (potential/habitual) negative 'it won't give; it doesn't give; it used not to give'
Forms built on present stem	
koṭu-kkiṯ-a	pres. verbal adjective '[who] gives'
koṭu-kkiṯ-atu	pres. verbal noun 'giving'
Forms built on past stem	
koṭu-tt-a	past verbal adjective '[who] gave'
koṭu-tt-aal	conditional 'if [he] gave/gives'
koṭu-tt-u	past participle 'having given'
Forms built on future stem	
koṭu-pp-atu	future verbal noun 'giving'
Infinitive + auxiliary	
koṭu-kk-a muṭij-um	habilitative 'can give'
koṭu-kk-a ʋeeṇṭ-um	debitive 'should/must give'
koṭu-kk-a ʋillaj	simple negative 'didn't give/isn't giving/won't give'
koṭu-kk-a maaṭṭ-aan	future rational neg. (potential/habitual; volitive) 'he won't give; he doesn't give; he used not to give'
koṭu-kk-a ppaṭ-utu	passive 'it is given'
koṭu-kk-a ʋaj-kkiṯ -aan	Causative 'he makes [someone] give'
Past participle + auxiliary	
koṭu-tt-u kko-ṇṭ- iru-kkiṯ-aan	pres. progressive 'he is giving'
koṭu-tt- iru-kkiṯ-aan	pres. perfect 'he has given'
koṭu-tt-u ʋi□ṭu-kiṯ-aan	pres. perfective 'he (definitely/completely) gives/is giving'

any structural similarity to the positive form it negates. Moreover, the human future positive is not completely equivalent semantically to the human future negative, which carries connotations of intention.

Among the constructions typical of Tamil and other Dravidian languages are the conjunctive participle, the relative clause, and the quotative. In the conjunctive participle construction, found throughout the South Asian linguistic area, all but the final verb in a sequence of verbs are represented as past participles (emphasized in the following examples): *dʒejalalitaaʋiṉ ʋiiṭṭukku **ppooj** aʋaraj cantittaar* 'He

went to Jeyalalitha's house and met her' (literally 'Jeyalalitha's house **having-gone,** her met'); *tankaɭuʈaja paʈaja dʒanapatijaj aluvalaka kaʈʈattukk uɭ iruntu **taɭɭi** taratara-enʈu **iʈuttu ppooj** naʈucaalajil tuukkil pooʈʈaarkaɭ* "They pushed their own former president out from inside his office building, went dragging him along the ground and hanged him in the middle of the road" (literally "their-own former president office building inside from **having-pushed** along-the-ground **having-dragged having-gone** in-the-middle-of-the-road in-a-noose put").

Relative clauses in Tamil and other Dravidian languages are formed without relative pronouns, by using a verbal adjective (emphasized in the following examples); the relative clause precedes the noun it modifies, and the verbal adjective is the last item in the relative clause: *[naan **koʈutta**] pputtakam...* "The book that I gave…" (literally "I **having-given** book"); *inta aarajccijin muʈivil [ve ɭijaana] viʂajam [nammaj ellaam niccajam atirccikk u ɭɭaakkukiʈa] maatiri taan irukkiʈatu* "The information which has been released in the results of this research is of the very sort that will certainly subject us all to shock" (literally "this research's results-in **having-been-released** information us all certainly shock-to **subjecting** type EMPHATIC is").

Finally, the quotative construction marks the complement of an overt or understood verb of saying, thinking, hearing, etc. with a QUOTATIVE complementizer derived from the verb *en* 'say'. As can be seen in the following examples, Tamil makes no distinction between direct and indirect discourse. *'atil enna viceeʂam enʈu' avacarappaʈa veeɳʈaam* 'Don't be in a hurry [to say] "What's special about that?"' (literally "'that-in what special" QUOTATIVE hurry don't'); *'anta maaʈʈaj naan vaanki-kkoɭkiʈeen' enʈu mookan keeʈʈu-kkoɳʈ-um kuuʈa, 'muʈijaatu' enʈu raaman maʈutt-u viʈʈaar* 'Even when Mohan offered to buy the cow, Raman refused [saying] "[you] cannot"' (literally "'that cow I will-buy" QUOTATIVE Mohan having-asked-even, "cannot" QUOTATIVE Raman refused').

Tarascan

Tarascan is the name of a language (and its indigenous speakers) spoken in the mountainous north central region of the state of Michoacan, Mexico. Tarascan speakers call themselves and their language *Purépecha,* variously written as Purhépecha, P'urepecha, P'orepecha, Phurhépecha, and sometimes shortened to P'oré or P'uré simply to denote things Tarascan. Many consider *Purépecha* preferable to *Tarascan,* an anglicized version of the Spanish word *tarasco.* The generally accepted etymology of 'tarasco' derives from stories of the first contact with Europeans, who through various means acquired for themselves

daughters of the Tarascan nobles and princes. *Tarháskua* means 'son-in-law', 'daughter-in-law', or 'father-in-law' in the indigenous language, all relationships which, in effect, the Spaniards acquired with the Tarascans. The repeated, and uninformed, use of the word is said to have spread among the Spaniards as a reference to the Indians. The etymology of the word 'purépecha' has two basic strands. Some have traced its meaning to refer to migration, travel, and alliances while other scholars take the word to mean 'common people' *(plebeyos)*.

The geographic range of spoken Tarascan is today limited to the state of Michoacán. Historically, however, the Tarascan empire (known to the Spaniards as the 'Western Empire') was much larger. Prior to European contact, the Tarascans are thought to have exerted their political and cultural influence as far north as the present-day state of Durango. They maintained a militarized border against the Aztecs, established as far east as Guanajuato and the Valley of Toluca, and to the west their control reached the Pacific Ocean. Tarascan presence is thus estimated to have covered an area nearly equal in size to the empire of the Aztecs, extending over virtually all of present-day Michoacán and with settlements or influence in portions of the states of Guerrero, México, Jalisco, Guanajuato, Querétaro, Colima, Nayarit, Sinaloa, and Durango.

Through the centuries the extent of spoken Tarascan has shrunk significantly, to the point where it is now found in a well-defined area comprising about 3,500 square miles in north central and northwestern Michoacán only. Researchers commonly describe four distinct zones of Tarascan speech: the Zacapu Marsh region, the Lake Pátzcuaro region, including the town bearing that name and the villages surrounding the lake, an area called La Cañada de Chilchota (Los Once Pueblos), once containing 11 towns, now nine, to the north and west of the Lake, and the mountainous region due west of Lake Pátzcuaro called the Tarascan Sierra (also known as *La Meseta Tarasca).* The Sierra hosts the largest percentage of Tarascan speakers (an estimated 60% as opposed to 19% in the next largest zone, the Lake Region). Tarascan speakers are distributed in 95 of Michoacán's 113 *municipios.* Researchers have observed that it is commonly thought throughout the region that 'real' Tarascan is spoken in the Sierra.

The number and location of Tarascan speakers has historically been difficult to assess, given the remote nature of many of the villages where the language is spoken. Through much of the middle part of the twentieth century, the numbers were variously pegged at 50,000 to 80,000 speakers. More recently, some linguistic survey counts have put the numbers as high as 100,000 and 120,000. The Mexican National Indigenous Institute *(*Instituto Nacional Indigenista*, or INI) in its most recent count puts the number at just under 100,000 speakers in the state of Michoacán itself. Linguistic surveys have also revealed differing degrees of Tarascan-Spanish bilingualism throughout the region, the smaller, less hispanicized towns, of course, with higher rates of Tarascan use. Approximately 7,217 (8% of the Tarascan-speaking population of the state) are monolingual. Despite the historical decline in numbers of speakers, Mexican census data since 1970 have revealed an average annual increase of 2.6% in the number of speakers, compared to an average annual growth rate of 2.1% for the state's population as a whole. This increase in the number of speakers is owed in part to the work of the Purhépecha Language Academy (La Academia de la Lengua Purhé) and the Center for Investigations of P'urhépecha Culture (Centro de Investigaciones de la Cultura P'urhépecha) (Argueta 2003). The spoken language is characterized by clear dialect differences, some regional (Sierra, Cañada, Lake, as mentioned above), but others in much closer proximity, from village to village (Friedrich 1975).

Interest in the ethnography and language of the Tarascan people dates to the first half of the sixteenth century, shortly after contact with the Europeans. The Franciscans accompanying the Spanish showed immediate interest in the ethnographic and linguistic characteristics of the Tarascans, documenting their findings in the *Relación de Michoacán,* probably begun in 1539 (finished and presented to the Viceroy in 1541). The first systematic linguistic works on Tarascan were undertaken by the Franciscans around the middle of the sixteenth century, and at least three dictionaries and two grammars of the language were produced in the 1600s. The earliest of these works, titled *Vocabulario en la lengua de Michuacan,* was brought to fruition in 1559 by Fr. Maturino Gilberti and subsequently reedited in 1898 by Nicolás León, in 1901 by Antonio Peñafiel, and yet again in 1962 by Ernesto Ramos Meza.

Despite more than four centuries of linguistic analysis, the origins of both the Tarascan language and its people remain puzzling. It is certain that the Tarascan language bears no linguistic relationship with any of the original languages spoken in Mexico. Scholars generally agree that its genetic relationships are difficult, if not impossible, to define for any other languages as well. Attempts have been made on various fronts to trace the origins of the language and its speakers. Linguistic and material cultural evidence is cited to support the idea of a historic connection between the Tarascan language

and the Pacific Coast of South America, most notably with Quechua of Peru, but observed phonetic similarities with indigenous languages of Peru may be merely coincidental. Recent evidence is interpreted by some to indicate linguistic, material culture, and even physiological links to Central American groups. Other scholars do not believe the evidence points unequivocally to a southern provenance and remain open to a northern or northwestern origin. Swadesh (1969) determined Tarascan to be an autonomous linguistic family, a finding with which others concur.

The phonological characteristics of the Tarascan language are relatively clear-cut.

6 vowels:

i	u	e
a	o	

ï (predictably following the consonants s, ts, and ts')

16 Consonants:

P	t	ts	Ch	k
b	d	g	S	J
ill	n	r	X	

rh (a retroflexed 'r')

Five of the consonants take phonologically distinctive aspiration:

p'	t'	ts'	ch'	k'

Despite its straightforward appearance, this phonological pattern is subject to a complex set of morphophonemic rules, which include vowel lengthening, stop epenthesis, nasal assimilation, stop assimilation, retroflexion, vowel deletion, and final devoicing. Lengthy words comprised of many suffixes and multiple roots are a regular feature of the language. Verbs are inflected for person, number, tense, as well as mode and interrogation. Formality is also marked on the verbs (as well as on pronouns). Ordered suffixation characterizes the verbal structure, such that verbs may develop extensive forms. For example:

Unandontskuarhinsïndiksï *(from* uandontskuarhini 'to converse, to chat')
Syllable patterns follow eight types:

V	VV	VC	CV	CVC
CVV	CCV	CCVV		

Word order is generally Subject–Object–Verb.

A sample of written Tarascan (taken from the popular folk song *Dalia Tsïtsïki*) is as follows:

Ay dalia tsïtsïki emenda anapu, ka shankar t'u sesarhati tsïpajka; ka aimindu tumbiecha ishï jarashtia su sha aru komjarhani erontashïn. Isï sha jaueru iamindu tumbiecha nochkan ji tiempushin isï tsïperan, no *para ji trabajimbo ekarha askia.*

The strength of the Tarascan language (as measured by the language surveys of the Mexican Census data) is encouraging. Only speakers over the age of 5 are counted for the language census. Government efforts in bilingual teacher education, bilingual schools, and language research and training efforts through the INI have together effected a slowing in the numeric decline of Tarascan speakers. Work by scholars in the Instituto Michoacano de Cultura del Gobiemo del Estado and in the Colegio de Michoacán have resulted in growing interest, training, awareness, and standardization (of the alphabet, training materials, and of teaching methodology) for the survival of this linguistic isolate.

Teaching: Curricula

The term 'curriculum' refers to the content and aims of a course, the teaching procedures that will be followed, and the ways in which student learning will be assessed. For some, curriculum is synonymous with 'syllabus', that is, the listing and sequencing of course content. The terms 'syllabus' and 'method' are also sometimes used interchangeably. In its broadest sense, a curriculum includes all of these: syllabus, aims, method, and means of assessment.

A helpful way to summarize key issues in language curriculum design is through Richards and Rodgers' notions of approach, design, and procedure. 'Approach' refers to the theory of language and language learning that underlies the particular approach to course development. 'Design' includes the objectives, organization, and content of the particular syllabus type, kinds of teaching and learning activities, teacher and learner roles, and the role of instructional materials. 'Procedure' describes the classroom techniques and practices that might be employed within the particular approach.

For a long time, the overriding approach to language curriculum design was based on the structural syllabus; that is, the listing of grammatical items to be learned. This was the basis of the grammar-translation method, which dominated language teaching from the 1840s to the 1940s. Structural syllabi are still used today, but primarily with a different approach to methodology and in combination with other approaches to syllabus design.

Situational language teaching, or the oral approach, became the primary avenue toward language teaching in Britain in the 1950s. The aim of this approach was to develop learners' spoken language skills in everyday situations. Hence, lessons might be labeled 'eating out' or 'at the bank'. The view of language in this approach was still structural, however, but with a focus on oral practice and the use of sentence patterns and drills. The audiolingual method, which emerged in the United States at the same time, was similar in its view of language and use of methodology.

A major shift occurred, however, in the late 1960s, when applied linguists began to question the theoretical assumptions underlying situational language teaching and audiolingualism. Drawing on the work of scholars such as M.A.K. Halliday, Dell Hymes, John Langshaw Austin, and John Searle, what came to be known as the 'functional-notional' or the 'communicative' approach to language teaching emerged. This view saw the aim of language learning as involving more than just the acquisition of linguistic structures. The aim was the achievement of communicative proficiency and the ability to convey meaning in a range of communicative situations. This shift in the aim of language learning programs had a dramatic impact on language-learning curricula.

The basis of this new approach comprised the concepts of 'functions' and 'notions', based on the work of Austin and Searle, and of the applied linguist Wilkins, as well as the concept of communicative competence, based on the work of Hymes. Functions are the things that people 'do' with language, such as asking for information, greeting, apologizing, and inviting. Examples of notions are frequency, duration, location, and quantity. Communicative competence includes knowledge about language as well as methods of using language in appropriate ways to achieve particular goals. Language-learning programs were changed to make communicative competence, rather than (just) linguistic competence, the overall goal. As a result, lists of functions and notions and communicative appropriateness were added to the language-learning curriculum.

The communicative approach is still used today, but with a number of subsequent refinements and redevelopments. These include programs that focus on skills development (such as listening for 'gist', deciphering the main idea, and guessing vocabulary from context); programs that focus on tasks (such as exchanging information, solving problems, making decisions, reading a job advertisement, making an appointment, and writing a résumé); and programs organized around a particular content area (such as first year university science and technology) or themes (such as food, families, employment, and pollution). Other syllabus types include the 'lexical' approach, which focuses on the acquisition of particular vocabulary items, and text- or genre-based approaches, which use whole texts as the starting point for language program development and consider what it is that learners need to know and accomplish in order to produce an example of a particular genre. A further development is the 'negotiated syllabus', in which teachers and learners negotiate the

aims of the program, course content, and sometimes methodology. Often, however, language-learning curricula will be 'mixed' or 'multistranded', in that they will combine a number of these program types in order to be most useful and comprehensive for a particular group of learners.

James Dean Brown's *The elements of language curriculum* (1995*)* describes the main components of a language-learning program as needs analysis, goals and objectives, testing, materials, teaching, and evaluation. 'Needs analysis' refers to the identification of the language that students need in order to achieve particular goals, along with the identification of the learners' linguistic competence in relation to these goals. Needs analysis is an especially important component of programs that are designed for specific purpose language use, such as academic English and business English programs. 'Goals and objectives' refer to the overall reason or purpose of the program, as well as what learners are expected to be able to do with language by the end of the program. 'Evaluation' includes the ways in which learners' progress will be assessed in relation to the program's goals and objectives. Once needs have been established and goals and objectives have been set, the curriculum planner is able to go about adopting ready-made materials for the program, adapting materials as required, or developing new materials. Decisions then proceed regarding teaching approaches and program evaluation; that is, how the program might best be taught and how it can best be assessed in terms of its overall effectiveness.

Teaching: Methods

A teaching method, sometimes referred to as a methodology, is a coherent and theory-based characterization of the language-teaching process, usually prescribing one set of classroom practices, procedures, strategies and techniques and often proscribing others.

A method is always informed by a broader approach or underlying philosophy. This would normally include a set of beliefs about language and how it works, about how people learn or acquire language, about curriculum design and general educational approaches, about general learning theories, and about the purposes of language learning.

Since there is general debate and disagreement about all of these broader issues, it is not surprising to find that the search for the 'best' language-teaching method has been fruitless. Studies that have sought to compare different methods to determine their effectiveness have remained inconclusive, partly because there are so many variables involved in the language teaching and learning process, partly because, as a number of empirical studies have discovered, the actual activities in observed classrooms often seem indistinguishable no matter what method is being used, and partly because it is almost impossible to ascribe cause and effect in anything other than trivial or short-lived learning.

The history of language-teaching methods has largely been one of fluctuation between form and function, between learning about the target language and learning through actually trying to use it, and between focus on the written language and focus on the spoken language. While there is little doubt that the vast majority of those people who successfully and fluently use more than one language—and there are many more bilinguals and multilinguals in the world than monolinguals—learned their languages outside the classroom by using them for real purposes in the real world, the issue of formal instruction is more complex. For example, language instruction in formal classroom settings has in many cases not included the purpose of learning to communicate in an everyday sense, but has instead focused on gaining access to the literary canon of the target language or has been for the specific purpose of understanding ancient texts for historical, cultural, or archeological reasons.

In the study of languages that are no longer spoken naturally, focus is necessarily on understanding the mechanics of the written language—the grammar and the meaning of words. The widespread study of Latin and Greek in western schools from the Middle Ages onward had a major influence on the teaching of languages more generally and meant that the grammar-translation method was the dominant—although not unchallenged—paradigm for language teaching until well into the twentieth century.

The major challenge came late in the nineteenth century when thinkers such as Henry Sweet in England and Wilhelm Viëtor in Germany argued strongly for the primacy of speech over writing, the inductive learning of grammar, and the avoidance of translation, using only the target language as far as possible. This ultimately led to the development of the direct method, also influenced by studies of natural language learning, especially in childhood. The direct method was readily adopted by private language schools, where native speakers of the target language were recruited as teachers. It was much less influential in formal education systems, where nonnative speakers often struggled with the fluency needed to implement the method, and where the emphasis on spoken language made formal assessment of students much more difficult.

The audiolingual method, the development of which owed much to the wartime need for fluent and convincing speakers of other languages, was a building-block approach based on a thorough analysis of language grounded in structuralist traditions and on the theories of behaviorist psychology, with its emphasis on stimulus–response conditioning and learning through habit formation. It became the dominant language-teaching method by the 1960s despite the fact that its theoretical foundations were already being severely eroded through the development of transformational grammar and Noam Chomsky's 1959 attack on habit formation as a basis for language learning. Many activities in the language-teaching classroom today still show allegiance to audiolingual and behaviorist principles.

The dominant paradigm over the last 30 years in language-teaching worldwide has been communicative language teaching. The approach foregrounds the use of language as a means of communication, with the assumption that much learning of language takes place through language in use rather than language as an object of study. Communicative language teaching was reinforced by advances in error analysis and second language acquisition studies in the 1970s, which strongly suggested that learners proceed developmentally through a predictable series of stages in which the production of errors plays an important part. It is also closely linked with the notion of language in context and with those sociolinguistic theories, especially M.A.K. Halliday's systemic-functional grammar and Dell Hymes' notion of communicative competence, that take context into account in their investigations of how people use language. The key concept in communicative language teaching is that learners learn through the use of language in meaningful activities. It is not simply a matter of contextualization of the language—it must be use of language that is meaningful for the learners.

The development of language for specific purposes, where language learning occurs while the ostensible focus is on communicating for some other purpose, can be seen as a special case of communicative language teaching. Similarly, Stephen Krashen and Tracy Tyrell's natural approach (1983), originating in studies of English-speaking Canadian students studying in French-medium schools ('immersion'), can be classified as communicative language teaching. Both of these have been very influential at a policy level, and there has been considerable work on language across the curriculum and on bilingual and immersion education.

An allegiance to the principles of communicative language teaching has shown up in national curricula in recent times, for example, in countries such as China, Korea, Japan, and Thailand; however, there are obstacles to implementation in practice, and communicative language teaching has been criticized for conflicting with local cultural values and for its unrealistic expectations of the teacher's own language proficiency.

The very concept of a language-teaching 'method' has also come under attack recently, with several theorists and researchers finding that the concept has little justification in actual classroom practices. Jack Richards (1990) has suggested that teachers would be better advised to focus 'not on the search for the best method, but rather on the circumstances and conditions

under which more effective teaching and learning are accomplished'.

Telugu

Telugu is a Dravidian language, one of the language families found in South Asia. The Dravidian family is divided into three subgroups: South Dravidian, Central Dravidian, and North Dravidian. Telugu belongs to the Central Dravidian subgroup. Some other languages of this subgroup—Gondi, Konda, Pengo, Manda, Kui, Kuvi—have sometimes been treated as a separate group called South-Central Dravidian. Kolami, Naiki, Parji, and Gadaba are the other languages in Central Dravidian.

Telugu is mainly spoken in the State of Andhra Pradesh in the south central part of India. Telugu is also spoken in the neighboring states—Tamil Nadu, Karnataka, Maharashtra, and Orissa. It is spoken by migrants in South Africa, Mauritius, Fiji Islands, Malaysia, Singapore, and the United States of America. The earliest written records of Telugu from the second century BC consist mainly of records of names. Numerous inscriptions written in Telugu are available from the sixth century AD. From the twelfth century onward, literary and grammatical treatises started being composed. On the basis of the available materials, some scholars have divided the history of the Telugu language into six periods:

(1)	Early Old Telugu	AD 200–AD 700
(2)	Late Old Telugu	AD 700–AD 1200
(3)	Early Middle Telugu	AD 1201–AD 1400
(4)	Late Middle Telugu	AD 1401–AD 1600
(5)	Early Modern Telugu	AD 1601–AD 1900
(6)	Modern Telugu	AD 1901–onward

Regional variations give us the following picture of dialects and subdialects:

(1) Coastal Dialect	—	Districts of Andhra Pradesh
(i) North Coastal	—	Vijayanagaram Vishakapatanam Srikakulam
(ii) Central Coastal	—	West Godavari East Godavari Krishna Guntur
(iii) South Coastal	—	Prakasam Nellore
(2) Rayalaseema Dialect		
(i) Southern Rayalaseema	—	Chittoor
(ii) Central Rayalaseema	—	Cuddapah Kurnool
(iii) Western Rayalaseema	—	Anantapur
(3) Telangana Dialect		
(i) Central Telangana	—	Medak Ranga Reddy Hyderabad
(ii) North Telangana	—	Adilabad Karimnagar Nizamabad
(iii) South Telangana	—	Mahaboobnagar
(iv) East Telangana	—	Warangal Nalgonda Khammam

Telugu shares the presence of cerebral consonants (ṭ, ṇ, Ḷ) with the other Dravidian languages. These consonants are not present in any of the Indo-European groups (the tongue position differs slightly from that used to produce English [d, n, l]) excepting in the Indo-Aryan subgroup, which perhaps is due to the influence of Dravidian languages.

Similarly, Telugu has long and short varieties of central vowels (e, ē, o, ō), which again is true in other Dravidian languages, but not in Indo-Aryan languages (e.g. erugu (to know), ērugu (to shit), toḍa (thigh), tōḍa (with)).

Telugu draws a distinction between voiced and voiceless consonants (e.g. /d/ vs. /t/), which is not the case in e.g. Tamil (a South Dravidian language). In Tamil, b, d, g, ḍ, j occur only in postnasal positions—i.e. after *n* or *m*—whereas p, t, k, ṭ, c occur word initially or in clusters. In Telugu, the following word pairs show that the difference between k/g or t/d is crucial: kampa (thorny wood) vs. gampa (basket), āṭa (play) vs. āḍa (feminine), kanta (hole) vs. kanda (an edible root).

Aspiration of consonants is also a contrastive feature that Telugu has acquired from Sanskrit and built into its orthographic system (e.g. d vs. dh); its orthographic system is derived from the Ashok Brahmi script. Speakers of nonstandard varieties of Telugu, however, tend to drop aspiration in their speech.

'Friction' (of voiceless labiodentals) is a feature that Telugu has recently borrowed from English but it is not integrated into its script, e.g. coffee (kāfī), sofa (sōfā). It is represented in the script by bilabial voiceless aspirate, i.e. the sound [f] is written as *ph*.

Sandhi and vowel harmony are reflected in the orthography that is phonemic (letters stand for individual speech sounds) and syllabic (letters stand for syllables). Keeping in mind the behavior of sounds in Sandhi, Telugu consonants can be classified as follows:

(1)	Dorsals	k, kh, g, gh
(2)	Apicals	ṭ, ṭh, ḍ, ḍh, n, ṇ, l, Ḷ, r
(3)	Laminals	t, th, d, dh, č, čh, ǰ, s, ś, ṣ
(4)	Labials	p, ph, b, bh, m

t/d and č/ǰ are regarded as belonging to one category (laminal), as examples of Sandhi (microjuncture) phenomena show: a phonological rule of Telugu states that a short vowel gets deleted between consonants of the same category. This juxtaposes two consonants and causes one of them to assimilate to the other. For example:

cādu   +   cukka   →   c ā c c u k k a
[substance   [dot]
used as dot
on one's forehead]

If we had treated d and c as belonging to two different classes, the deletion of the final /u/ as well as the subsequent assimilatory change from /d/ to /c/ (to match the following /c/) could not be treated as an instance of the broader Sandhi rule.

Vowel harmony in Telugu affects noninitial syllables:

enimidi   +   lu   →   enumudulu
'eight'   pl

All vowels in the first word assimilate (are harmonized) to the vowel in the suffix *-lu*. This kind of harmonization does not cross a geminate (doubled)_ consonant or a consonant cluster:

engili   +   lu   →   engiḶḶu
[partly   [pl]   (remnants of
eaten food]   eaten food)

Telugu, like other Indian languages, is a postpositional language, i.e. particles equivalent to English prepositions (such as *with*) follow the noun or noun phrase:

atanu   →   atani   tō
[that he   his   with (= with him)
nonpolite]

Nouns and pronouns that do not end in 'u' do not have distinct oblique form:

rangaḍu   →   rangaḍi tō
Ranga   Ranga with
āme   →   āme tō
[that she   her with (with her)
polite]
reḍḍi   →   reḍḍitō
Reddy   Reddy with (with
                                 Reddy)

In Telugu, the finiteness is expressed by the GNP (Gender Number Person) marker, which comes at the end of a verbal expression. If the GNP marker is absent, the verbal unit is nonfinite.

āme   ninna   vacci   īrōju   veḶḶindi
She   yesterday   come-perf.   today   go-perf.-she
She came yesterday and went (back) today

Here the marker '-i-' in *vacci* and *veḶḶindi* shows completion of action—hence 'perfective' suffix. 'ninna' and 'īrōju' refer to time. As the action is complete, people consider this also to be past tense.

As in the case of other languages, Telugu kinship terms reflect certain cultural phenomena like the

'marriage' relationship. In English, an 'uncle' could be maternal or paternal. Telugu has different terms for them. The maternal uncle, the father-in-law, and the paternal aunt's husband are all referred to as 'māma'. Similarly, the paternal aunt, the mother-in-law, and the maternal uncle's wife are referred to as 'atta'; both the atta's and the māma's daughter/son can become one's spouse.

In North India, where Indo-Aryan languages like Hindi and Punjabi are spoken, the maternal uncle, the father-in-law, and the paternal aunt's husband are given different terms because the maternal uncle's and the paternal aunt's son/ daughter cannot be taken as one's spouse.

Because Telugu words tend to end in a vowel, the language has been described by Charles Philip Brown, a great lexicographer, as 'the Italian of the East'.

Tense and Aspect Marking

From the point of view of language typology, the most common grammatical means expressing tense and aspect are past, future, perfect (these three expressing tense) and progressive, imperfective, perfective (these three expressing aspect); cf. Dahl (1985), Bybee (1985), and Bybee and Dahl (1989). In the majority of cases, the present is morphologically unmarked, which is the reason why it is usually not regarded as a separate grammatical morpheme. The six tense–aspect expressions mentioned are found alone or in combination: e.g. in the case of the *pluperfect* (*John had seen the woman*, past plus perfect) or past progressive (*John was seeing the woman*, progressive plus past). Tense and aspect may be expressed either by periphrastic or by inflectional (or bound) expressions. Typologically, perfect and progressive have a very strong tendency for periphrastic expressions, while past, imperfective, and perfective prefer the bound variant. Future does not favor either periphrastic or inflectional expressions.

Tense is a grammatical category that specifies a time at which the corresponding tenseless sentence is true. Compare *I was often in Venice,* uttered at a certain time *t:* past expresses that there is a period of time before the speech time *t* at which the tenseless sentence *I often be in Venice* is true. Past indicates that the event at issue precedes speech time; future indicates that it follows speech time. Perfect (also called anterior) is used for events preceding speech time or some other reference time and still being relevant at that reference time.

Aspect is not relational like tense, but focuses the internal temporal structure of events. The progressive (also called continuous) indicates that an event is still in progress, relative to some explicit or implicit reference time, cf. *John was dancing (when Mary came in),* where the reference time is given through Mary's coming in. The perfective is used when the event is viewed as a bounded whole, whereas situations described in the imperfective are not seen as bounded. In Slavic languages, the imperfective/perfective distinction is mostly expressed morphologically, cf. Russian *pisal* 'to write' (imperfective) vs. *napisal* 'to finish writing' (perfective).

Now let us examine some common tense–aspect expressions in detail. As for the perfect, there are at least four different types of periphrastic constructions (cf. Dahl 1985): first, copula plus past participle (e.g. in Hindi, Bulgarian); second, auxiliary 'have' plus past participle (originally possessive constructions, e.g. in most Germanic and Romance languages); third, main verb plus particle 'already' (e.g. in Yoruba, Isekiri); fourth, constructions with auxiliaries historically developed from verbs meaning 'finish' or 'throw away' (e.g. in Sango, Ewe). The present perfect in English has the following uses (cf. McCawley 1971): (a) to indicate that a state of affairs prevailed throughout some interval stretching from the past into the present (universal perfect—*I've known Max since 1960*); (b) to indicate the existence of past events (existential perfect—*I have read Principia Mathematica five times*); (c) to indicate that the direct

effect of a past event still continues (stative/resultative perfect—*I can't come to your party tonight—I've caught the flu*); (d) to report hot news (hot news perfect–*Malcom X has just been assassinated*).

The *progressive* usually combines with the present and the past. Like the perfect, the progressive tends towards periphrasis. The periphrastic expressions are locative, meaning 'to be located in or at an activity'; cf. Bybee and Dahl (1989). Explicit variants (copula plus locative adposition plus nominalized verb) are most frequent, e.g. in Irish *tá sé ag dúnadh an dorais* ('he is at shutting the door'). Locative meaning is part of almost all progressives, even of the English progressive, although not overtly. But the English progressive like in *John is jumping* is historically derived from the construction *John is a-jumping*, where 'a' is actually the locative preposition 'on'. Although the progressive usually describes events that are still in progress at reference time, note that e.g. the English progressive has a wider use. In *John is writing his thesis*, the activity need not be in progress at reference time but rather at a larger time-interval properly including reference time. In addition, examples like *John is working on his thesis everyday* show that the progressive is also possible with habitual activities, at least in English.

The future does not favor either periphrastic or inflectional expressions. Common lexical sources for the future are the following: first, an auxiliary with the former meaning of 'want' (e.g. in Mandarin and Swahili, and also English 'will'); second, a verb meaning 'to owe' (e.g. in the Western Romance languages, Korean, and also English 'shall', derived from 'sceallan'); third, like the English going-to-future, a collocation meaning 'movement toward a goal'. The difference between the English will-future and the going-to-future is easily felt in minimal pairs like *there is going to be a riot here* vs. *there will be a riot here*. Only the going-to-future expresses that the riot is already in its preparation phase and on its way to happening. The will-future, in contrast, just makes a prediction, but the riot can also happen some weeks later, with no preparatory actions of it at the present moment.

The most widespread type of bound or inflectional tense-aspect is what Bybee and Dahl (1989) call the tripartite system. The past/nonpast distinction is added to the perfective/imperfective distinction, with perfective combining only with past, and the past/nonpast distinction only occurring in the imperfective. About every second language seems to have this tripartite system (e.g. Mandarin Chinese, French, Kurdish). Interestingly, the two distinctions are independent, because it is also possible to have the perfective/imperfective distinction but lacking past (e.g. in Arabic), or to have past but lacking the perfective/imperfective distinction, as in English. The tense–aspect systems of many Slavic languages are not simply tripartite, however. Russian, for example, allows present-imperfective, past-imperfective, past-perfective, future-perfective, and future-imperfective. The system of Ukrainian is even richer; in addition to the Russian possibilities, we also find perfect-imperfective, perfect-perfective, pluperfect-imperfective and pluperfect-perfective.

MONIKA RATHERT

Tense: Syntax

Often, theories of tense try to assign a constant meaning to morphological tenses like future, preterite, or present. But a closer look at the data shows that one has to distinguish between morphological tense (small letters in this article) and semantic TENSE (capitals). Russian, for example, expresses a telic semantic FUTURE by a combination of morphological perfective plus morphological present. A German semantic FUTURE may be a morphological present.

While it is more or less known what the morphology of a morphological tense is, the semantics of a semantic TENSE is notoriously unclear. Some regard TENSES as operators (e.g. Ogihara 1996; Dowty 1979); others view them as constraints on variables (e.g. Partee 1973). The nature of the temporal relations is debated, too: most people regard TENSES as two-place operators, but there are also some (Nerbonne 1985; Ehrich 1992) modeling the three Reichenbachian parameters *E*, *R*, and *S* as a three-place relation. For most researchers, TENSES locate the time variable of the verb; others view them as restrictions on the possible denotations of this variable (Dowty 1982; Nerbonne 1985).

An interesting issue of morphological tense vs. semantic TENSE is given by the sequence-of-tense (SOT) phenomena. Now it is widely accepted that tense in attitude-complements may be ignored in the semantics, i.e. that tense in attitude-complements may be no TENSE, that there is TENSE-deletion or empty TENSE.

The interpretation of temporal expressions in embedded contexts is a complex issue; there are contrasts between temporal expressions in the scope of attitude verbs and those in adjunct clauses, and there is significant cross-linguistic variation (Kusumoto 1999; Ogihara 1996).

The semantic treatment of embedded tenses began with Enç (1986, 1987). According to her, tenses are to be considered referential expressions denoting times; they fill temporal argument positions. Tenses are subject to anchoring principles that are sensitive to GB-style binding restrictions. This works fine for matrix clause but, as pointed out by Ogihara (1996), it runs into trouble when applied to multiple embeddings. In these cases, a tense has to meet contradictory anchoring requirements:

(1) John decided a week ago that in ten days at breakfast he would say to his mother that they were having their last meal together

In (1), the time of their last meal is understood as simultaneous to John's speech (thought there is a past tense) and, considering the presence of the adverbial 'in ten days', this time is in the future with respect to speech time.

A semantically more sophisticated analysis is proposed by Ogihara (1996). He developed an analysis in which TENSES are Priorean operators, predicates take a time variable as their argument, and the simultaneous interpretation is accounted for by the application of a TENSE deletion rule. When a PAST TENSE is c-commanded by (embedded in) another PAST TENSE, the former is deleted and the embedded sentence becomes TENSEless:

(2) John said that Mary was pregnant
John PAST say that Mary PAST be pregnant
John PAST say that Mary $\varnothing$ be pregnant

Ogihara's system was also developed in order to account for the crosslinguistic contrast between English and Japanese. In Japanese, we find the semantically right TENSE configuration since simultaneity under a matrix PAST is expressed by the TENSEless 'present' and there is no need for the deletion rule:

(3) Bernhard-wa Junko-ga byookida to it-ta
B.-TOP Junko sick-$\varnothing$ that say-
-SUBJECT PAST
'Bernhard said that Junko was sick'

Moreover, Ogihara can account for the English–Japanese contrast of TENSE interpretation in relative clauses. A PAST TENSE relative clause embedded under a matrix PAST TENSE can have a simultaneous interpretation by the application of the deletion rule:

(4) John saw a girl who was running
John PAST see a girl who PAST be running
John PAST see a girl who $\varnothing$ be running

In Japanese, the simultaneity under a matrix PAST is expressed by the TENSEless 'present' and there is, again, no need for the deletion rule:

(5) Mariko-wa naiteiru otoko- hanasi
noko-ni kaketa
Mariko-TOP cry-teiru $\varnothing$ boy-to talk-PAST
'Mariko talked to the boy who was crying'

Expressions other than 'real' tenses but associated with PAST-TENSE-like interpretations also trigger TENSE deletion in Ogihara's system. TENSE deletion can be triggered by the perfect and by certain noun complements:

(6) John believes Mary to have claimed that she was innocent

(7) John's claim that he was innocent is well known

Ogihara accounts for the phenomena by assuming that a noun like *claim* can be associated with the syntactic features [+PAST], [–PAST], the perfect with the feature [+PAST], the past tense with [+PAST], and the present tense with [+PRES]. Under these assumptions, the SOT rule is simply sensitive to the syntactic features [+PAST] and [+PRES]:

(8) SOT rule: If a tense feature B is the local tense feature of a tense feature A at LF, and A and B are occurrences of the same feature, A and the tense associated with A are optionally deleted.

Ogihara's analysis is problematic for the following example, where the embedded future tense can only have a simultaneous interpretation:

(9) Jen   said that   would   move to
                 Cecilia   Amherst
     Jen PAST-say that   woll-PAST move to
                 Cecilia   Amherst
     Jen PAST-say that   woll-$\varnothing$ move to
                 Cecilia   Amherst

According to Ogihara, *would* has to be analyzed as composed of a TENSEless future operator *woll* and the PAST TENSE. Since the PAST TENSE on *woll* is c-commanded by the matrix PAST TENSE, it can be deleted, giving rise to the correct future-in-past interpretation. But since the TENSE deletion rule is optional, it should be possible to retain the embedded PAST, giving rise to a shifted future-in-past reading: there is a time *t* preceding Jen's speaking, and after this time (potentially before Jen's speaking), Cecilia moves to Amherst. This is clearly not a possible reading. In order to avoid the problem, Ogihara has to say that the SOT rule is obligatory in the case of *would*.

Since it is a syntactic configuration that triggers the application of the deletion rule, Ogihara's system cannot account for non-SOT languages such as Russian or Polish. In these languages, the present tense has different interpretations in complement and relative clauses when embedded under a matrix PAST.

MONIKA RATHERT

Tewa and the Kiowa-Tanoan Languages

The Kiowa-Tanoan language family consists of four branches: Kiowa, Towa, Tiwa, and Tewa. Although they are not so radically divergent that they suggest a long time-depth to account for internal diversity, the speech communities associated with them and their component languages reside in two distinct cultural areas of Native North America. Kiowa has long been associated with the Southern Plains cultural area. This area is often associated with its cultural emphases on the tipi, the horse, the bison, and the sun dance ritual complex. In contrast, Towa, Tiwa, and Tewa—usually grouped together as the Tanoan languages—represent the Pueblo cultural area of the southwest. These cultures were known for their large, sedentary agricultural villages featuring elaborate ceremonial calendars. Anthropologists have located the Kiowas near the head of the Missouri River around 1700. While their earlier history is more difficult to construct, it is likely given both archeological and linguistic evidence that the Kiowas abandoned a more Pueblo-like adaptation in what is today Northern New Mexico well prior to Spanish exploration in the mid-sixteenth century, and began a process of cultural transformation that made them exemplars of the Southern Plains culture area. Part of the linguistic evidence for such an interpretation rests on the well-established fact that speech communities associated with every other branch of the Kiowa-Tanoan language family was associated with sedentary settlements in the Rio Grande River Valley of northern New Mexico at the time of Spanish contact in 1540.

Within the Tanoan group, the Towa branch consists of only one existing Pueblo community, Jemez Pueblo, although the extinct Pueblo of Pecos also spoke this language prior to abandonment.

The Tiwa branch is divided into Northern and Southern Tiwa languages, each having multiple dialects. In Northern Tiwa are the dialects of Taos and Picuris while Southern Tiwa consists of Sandia, Isleta, and Ysleta del Sur. The last of these dialects was formerly spoken in the Rio Grande area but transported by Isletans who migrated with the Spanish to El Paso in 1682 in the wake of the Pueblo Revolt of 1680. The Tewa branch consists of two languages—Rio Grande and Arizona Tewa. Rio Grande Tewa is or was spoken

in the following Pueblos—San Juan, San Ildefonso, Nambe, Santa Clara, Pojoaque, and Tesuque. In the last two of these Pueblos, the Tewa language has not continued except through the in-migration of speakers from other Tewa-speaking pueblos. Of the dialects currently maintained, Santa Clara is usually regarded as the most divergent. Arizona Tewa, which is currently spoken on First Mesa of the Hopi Reservation in northeastern Arizona, was formerly spoken by the Southern Tewa, also known as Tano, who occupied the Galisteo Basin of Northern New Mexico prior to their exodus from New Mexico after the (Second) Pueblo Revolt of 1696. Also known as the Hopi-Tewa or the Hano Tewa, the Arizona Tewa have continued to maintain their language for more than 300 years despite their relocation and accommodation to their more numerous Hopi neighbors.

Some Structural Features of Kiowa-Tanoan Languages

Most Kiowa-Tanoan languages have a large inventory of consonants, which includes a four-way contrast between voiced, voiceless, aspirated, and glottalized stops (e.g. b, p, ph, p'—where the voiceless bilabial is accompanied by a closure of the glottis as in the American English expression 'oh-oh'). The vowel system usually contains six vowel qualities but also adds vowel length and an oral/nasal contrast to expand the inventory. Some of the Kiowa-Tanoan languages have well-attested tonal contrasts. In Arizona Tewa, which has two tones, nouns pronounced identically in terms of consonants and vowels but contrasting in pitch may be different words—'shirt' (low tone) and 'digging stick' (high tone). The languages all have an elaborate verbal morphology. Verbs obligatorily consist of a pronominal prefix that codes the subject (and sometimes the object as well), the verb stem, and one or more tense–aspect suffixes. But verbs can also include prefixes that encode negation and adverbial manner information, incorporated objects (such as things owned or possessed), and suffixes indicating that the verb is part of a dependent clause rather than the main sentence. The intricate pronominal prefixes of these language encode the person (I, you, he/she/it) and number (singular, dual, and plural (>2)) of the subject and inflect for stative and possessive constructions. Other prefix sets supply pronouns for transitive sentences which often distinguish between agentive, reflexive-reciprocal, and inverse constructions. The last of these provides a means of making the recipients of action rather than its agents the subject of the sentence. As such, they resemble passive sentences in English, but unlike English passives, Tewa inverse constructions remain fully transitive. The most

common basic word order in the language appears to be Subject–Object–Verb and all languages accordingly feature postpostional phrases (e.g. house-into) rather than prepositional phrases.

Historical Linguistics—An Overview

The relatively close relationship of the Tanoan languages was first recognized by John Wesley Powell in 1891 on the basis of a lexical comparison of linguistic data that he had collected. J.P. Harrington was the first to link this group to Kiowa in 1910 when he published a list of likely cognate words they shared. Further comparative evidence was amassed until the relationship was definitively established by Kenneth Hale in 1967 when he successfully reconstructed the phonology of Proto-Kiowa-Tanoan—the 'protolanguage' or antecedent ancestral language, which precedes the emergence of the Kiowa, Towa, Tiwa, and Tewa branches.

Although Kiowa is the most recently detected member of the family, it is not necessarily the most divergent. The apparent divergence is greatly magnified by Kiowa's relative removal from recent contact with other related languages and by linguistic adaptation to a rather different cultural area. Although the Tanoan languages clearly share many more vocabulary items, formal resemblances in grammar crosscut the family and make Kiowa appear more like just another related language rather than like one that is marginally related.

Researchers have posited a deeper historical linguistic relationship that would relate the Kiowa-Tanoan language family to the Uto-Aztecan family of North and Meso-America. The linguist Edward Sapir, in his classifications of 1921 and 1929, was the first to posit such a relationship and this largely impressionistic assessment of verbal morphology later led to a more systematic examination of possible cognate lexical items by George Trager and Benjamin Whorf in 1937. Since that time, collective historical linguistic scholarship has undermined anything that might approximate a 'proof' of relationship and suggested that existing research is at best inconclusive. At the present time, this posited relationship must await new research before it can be definitively confirmed or disconfirmed.

Contemporary Speech Communities

Like virtually all indigenous languages that do not enjoy state support, many of the existing Kiowa-Tanoan languages are spoken by relatively small populations in which speakers are not evenly distributed across all generations. For the Kiowa, who now live primarily in southwestern Oklahoma in Caddo, Kiowa, and Comanche counties, there are about 300 adult

speakers exhibiting a wide range of fluency. Towa, spoken at Jemez, is reported as spoken throughout the community of about 2,000. The Northern Tiwa-speaking community of Taos, according to surveys conducted in 1980, has about 800 speakers across all generations and represents, after Jemez, the next most vital of Kiowa-Tanoan speech communities. Picuris has slightly more than 100 speakers. Of the Southern Tiwa dialects, Sandia has about 150 while Isleta has ten times that number. The Ysleta del Sur dialect is not fluently spoken anymore. Some members of the community remember some of the distinctive vocabulary of their ancestral language. As for Tewa, estimates based on surveys of various kinds count 1,200 speakers of Rio Grande Tewa and about 300 for Arizona Tewa. In both communities, there are children still learning the language, although the percentage still learning the language in their homes may be slightly less than 50%. Language renewal programs of various types exist in Southern Tiwa, San Juan Tewa, and some other communities as resources used by these native communities in their ongoing efforts to control and maintain their heritage languages.

Language and Culture

In all Kiowa-Tanoan speech communities, as in Native American communities more generally, speech is highly regarded as a powerful form of action and not reduced, as in some Western folk views, to labeling functions that linguists call 'denotation'. In all the Kiowa-Tanoan-speaking communities, traditional storytelling was viewed as an essential aspect of language socialization. In these stories children would experience the early moral training of learning from the positive and negative models provided by the story characters. In all communities, lively and engaging performances—typically by parents and grandparents—called attention to the dramatic power of language to entertain and instruct. All narrators use 'hearsay' grammatical devices to traditionalize and create a proper sense of authenticity for their narratives. Storytellers in the Kiowa tradition tell their stories collaboratively with their audiences. They expect considerable audience involvement as both narrators and audience members openly comment on the story as it progresses. In the Pueblo cultures of the Tanoan communities, audience involvement is more limited to stylized interjections that encourage the storyteller to continue that the narrative and that demonstrate the involvement of the audience. Kiowa narrators especially value humor and use many puns toward that end, whereas the verbal artistry of Tanoan storytellers is more centered on unfolding their stories through the dialogue of their characters.

While linguistic and speech-making skills were an important resource associated with tribal leadership among the Kiowa, the role of cultural models of speaking provided by the theocratic elite is especially pronounced in Tanoan communities. In many of these communities, the religious language of the kiva—the ceremonial chambers of native religious activity—provided a powerful, ideal model for everyday speech. Since this ceremonial register embodied both religious authority and the political power of the religious elite, it provided a natural symbol of good and effective speech, which accounts for the usual characterization of Pueblo cultures as 'linguistically conservative'. Such a cultural standard provides a model analogous to the standardized languages of state societies, which enjoy a high prestige, in part, because they are the official languages of state-owned and controlled institutions like public education and the broadcast media.

Some of the ideals embodied by kiva speech, which have had a demonstrable effect on speakers of Tanoan languages, are its emphasis on indigenous purism and the valorization of traditional forms. In the ceremonial speech of the kiva, no mixing of language is permitted; such mixing is in fact considered a punishable offense. Given this cultural ideal of linguistic purity, it is not surprising to find well-attested patterns in all the Tanoan languages of rejecting possible loanwords in favor of extending or combining existing terms. For example, the first word for automobiles among the Arizona Tewa was not a loanword from English 'car' or 'auto' but rather the word wa-tege (wind-wagon). For both Rio Grande and Arizona Tewa, patterns of linguistic purism have been well documented by Edward P. Dozier (Santa Clara Tewa) and Paul V. Kroskrity. Although bilingualism in Spanish for the Rio Grande Pueblos is traceable to the colonial occupation of the seventeenth century, less than 5% of the Rio Grande Tewa vocabulary is from Spanish, and for the Arizona Tewa who actively removed themselves from Spanish domination around 1700, less than 20 Spanish loanwords are attested. For the Arizona Tewa, this pattern of resistance to loanwords has also extended to their Hopi neighbors. Despite bilingualism in Hopi, pervasive intermarriage, and other forms of cultural integration, they only have two Hopi loanwords. In a similar fashion, the ceremonial emphasis on reproducing traditional forms as precisely as possible extends to a cultural value on traditionalizing narrative and other speech genres so that speakers lend their voices to the tradition of 'speaking the past'.

Text Linguistics

In the 1960s, widespread dissatisfaction with prevailing models of linguistics, particularly in continental Europe and the United Kingdom, led to the rise of 'text linguistics' as a new linguistic subdiscipline. At that time, phonetics/phonology, morphology, and syntax were considered to be the core fields of linguistic inquiry. Furthermore, most linguists restricted their attention to the structure of the language system (*langue*) at the expense of language in use (*parole*). '*Langue*' is the idealized knowledge of a language that a competent speaker has. '*Parole*' refers to the less than perfect utterances this knowledge results in, characterized, for instance, by errors, repetitions, and hesitations due to processing constraints or not paying attention. The language system was thought to provide a window into the human mind, while 'language in use' was deemed too unsystematic and limited to be of real theoretical interest.

Consequently, the two central concerns of early text linguists were (a) linguistic modeling above the level of the sentence, and (b) a focus on language in use. The relationship between these two concerns has changed over time, however. Initially, most text linguists wanted to show only that structural properties extended beyond the level of the sentence. In the 1960s, Peter Hartmann, a German linguist, felt that the emphasis on phonemes, morphemes, and sentences was misplaced, as none of these elements alone constituted communication. Communication only occurs when these units are joined together in a text and, consequently, he viewed the text as the primary linguistic sign ('*das originäre sprachliche Zeichen*'). The search for a 'text grammar' or 'text syntax', therefore, abounds in this early work. However, it soon became apparent that textual rules do not have the same status as syntactic rules. The flouting of a syntactic rule results in an ungrammatical sentence. For instance, a syntactic rule of English is the categorical subject–verb–object order as in *The baby* (S) *loves* (V) *her new toy* (O). Violating that order by switching the constituents around as in *Loves* (V) *her new toy* (O) *the baby* (S) produces an ungrammatical sentence. However, textual rules may easily be flouted in certain contexts or for stylistic reasons and the text will still remain acceptable. For instance, a textual rule would be that pronouns normally appear after the element they refer to, as in *The baby loves her new toy. It makes such a funny sound*, where 'it' refers back to 'her new toy'. However, it is easy to image a context in which it would be perfectly acceptable to change the order around: *It makes such a funny sound. The baby loves her new toy.*

At that point, text linguistics began to examine the *langue–parole* distinction more critically. This was not a completely novel undertaking, as functional linguists had always been wary of the distinction. Functional linguists of the Prague School (founded as the '*Cercle Linguistique de Prague*' in 1926 by Villem Mathesius, Joseph Vachek, and others), for instance, had always maintained that language can only be described on the basis of authentic speech samples. As a result, they had also dismissed the strict distinction between *langue* and *parole*. In addition to the Prague School of functional linguistics, an important British group of functional linguists centered around John Firth, Michael Halliday, and John Sinclair, a recent offshoot of which is the Sydney School. As a consequence of the developing interest in texts, functional linguistics—a marginalized type of linguistic inquiry—gained in importance. It became increasingly apparent to text linguists that the only way to investigate textual structures was by turning to corpora of naturally occurring language. Text linguists also became increasingly interested in the patterns of

speech (initially, 'texts' had been thought of mainly as written language).

In 1981, Robert de Beaugrande and Wolfgang Dressler developed a set of criteria in an effort to define the characteristics of text as both (a) a unit of language above the sentence level and (b) language in use. These seven criteria are cohesion, coherence, intentionality, acceptability, informativity, situationality, and intertextuality.

First and foremost, texts are characterized by internal links. The word 'text' derives from Latin 'textus', which means '(inter)woven'. Grammatical links are known as 'cohesion' and semantic links as 'coherence'. Cohesion may be achieved through repetition, pronouns, ellipsis, conjunctions, and similar devices. However, textual linkage does not suffice to make a text. In the following example, all the links are present: 'I went to the library. Libraries contain books. Big volumes are heavy'. Despite the fact that 'library' and 'libraries' are linked through repetition, and 'books' and 'volumes' through synonymy, it is difficult to image a context where this would be an appropriate text. The textual characteristics of 'intentionality' and 'acceptability' refer to the fact that it is essential that a sender (the speaker or writer) intends to produce a well-formed text, and that addressees (hearers or readers) are prepared to accept the text as a communication that makes sense to them. Both senders and addressees usually rely on their encyclopedic knowledge (knowledge they have about the world that is not encoded in a particular text), in order to encode and decode texts. 'Informativity' refers to the relationship between old and new information that a text contains. A text containing only old information is dull; a text containing only new information becomes impossible to process. Therefore, senders produce texts that are in line with what they believe their addressees will already know, or not yet know. 'Situationality' refers to the factors that make a text appropriate to a particular situation. Finally, texts are 'intertextual' because they depend upon a knowledge of other texts to be understood. Such intertextual knowledge may refer to text types (we have certain expectations about what a letter looks like, or an encyclopedia entry) or to allusions (the slogan 'Just say know' as used in a students' union campaign alludes to the antidrug campaign 'Just say no', and the intertextuality forms an additional layer of meaning).

As the two understandings of text (as linguistic unit above the level of the sentence, and as language in use) became increasingly integrated, the need for a grammatical model able to incorporate the context has risen in importance. Halliday and other systemic functional linguists suggest that textual variation forms patterns along three dimensions of the context: field, tenor, and mode. 'Field' refers to context as social action. For instance, if a text about text linguistics is written for an encyclopedia entry, the language used will differ significantly from a text about the same topic that is produced as so-called 'cocktail party talk'. 'Tenor' refers to the role structure that pertains between the interactants, i.e. a text that is produced as a student–teacher exchange will differ from one that is produced as a marital communication. Finally, 'mode' refers to the symbolic organization of the text (e.g. written vs. spoken language).

The increasing focus on 'language in use' has blurred the boundaries between text linguistics and other fields of linguistics that share this concern, such as conversation analysis, discourse analysis, the ethnography of communication, interactional sociolinguistics, or pragmatics. Even if it seems likely that discourse analysis will eventually fully absorb text linguistics, text linguistics has to be credited with opening up new horizons for linguistics—by looking beyond the sentence, by trying to theorize context as part of grammar, and by opening the doors for interdisciplinary cooperation with education, literary studies, and other fields.

Text Understanding

Text understanding (Grosz et al. 1989; Scha et al. 1987; Singer 1990) is a cognitive process in which a text, i.e. a written sequence of 'coherent' sentences, is read and the human reader is able to decode all or most of the propositions encoded in that source. (In case the reader is a computer, we refer to this process as automatic text understanding (Schank and Christopher 1981)). Determining these propositions is, first of all, a challenging *semantic/conceptual* recognition problem. Because texts such as newspaper articles, cooking recipes, or business letters contain a large number of propositions, two additional layers help to structure the textual information flow. One is constituted by *structural organization* patterns of texts themselves, which reflect several mechanisms concerning how sets of text propositions are properly 'packaged'. Conditions of textual well-formedness can then be stated in a 'text' grammar much in the same way as a standard sentence grammar reflects sentential and phrasal well-formedness criteria. The second important issue concerns the *pragmatic* factors underlying text understanding, i.e. assumptions both writers and readers rely on (such that certain beliefs are shared or implicit goals can be recognized) in order to discern the *intended* (not only the literal) interpretation of a text. Therefore, we will consider text understanding from these three different angles, viz. the semantic/conceptual, structural, and pragmatic level (Grosz and Candace 1986).

In order to decode the contents encoded in a text, linguistic knowledge from various sources must be combined—knowledge of the morphological structure of the words and their organization in the lexicon, as well as grammatical knowledge in terms of syntax and semantics. Rather than just extending truth-functional semantic sentence analysis up to the text level (Kamp and Uwe 1993), text understanding—and hence the computation of text propositions—is deeply rooted in the knowledge of the textual domain. This background knowledge has to be made explicit in terms of a domain knowledge base, a repository that contains common-sense knowledge, as well as fairly specialized domain knowledge, e.g. from science, sports, or economy.

As far as the organization of that knowledge is concerned, research in text comprehension indicates that it seems beneficial to have structured knowledge representation formats (such as frames, scripts, or semantic networks) available. Such representation structures offer a densely packed interpretation context with taxonomic concept hierarchies, as well as default properties and predictive expectations that guide the recognition and incremental interpretation of objects and events. Text understanding processes operate on facts and basic propositions comprised of this a priori knowledge, either by finding a direct match with given knowledge structures, or by inferring a proper linkage, i.e. by employing reasoning mechanisms in order to link single propositions from a text to that background knowledge (Schank and Christopher 1981). Most of these inferences are merely plausible (e.g. inductive, abductive, uncertain, or default-based) rather than strictly deductive. As a result of incrementally assimilating knowledge from texts, one acquires entirely new propositions, modifies already known propositions, or even retracts propositions completely.

Text propositions are considered to be basic conceptual units such as predicate-argument pairs. For instance, in 'Peter met John on the beach. They spent three hours together.', we distinguish a MEETING-1 event whose actors are PETER and JOHN, whose location is ON-BEACH and whose duration is 3-HOURS. From this, we may construct the following predicate-argument representations as the main propositions:

MEET-ACTORS (MEETING-1, {PETER, JOHN})
MEET-LOCATION (MEETING-1, ON-BEACH)
MEET-DURATION (MEETING-1, 3-HOURS)

Even this small text fragment already features a pattern of text structure that guides our interpretation of both sentences. We may only derive the third proposition (specifying the duration of the meeting) when we interpret the pronoun '*they*' at the beginning of the second sentence as denoting '*Peter and John*' as they meet on the beach. This is an example of a reference due to anaphora: an anaphoric expression ('*they*') referring to some referents previously introduced in the text (the antecedent)—in this example, the ad hoc group of people is composed of '*Peter and John*'. Anaphoric reference is one of the basic *text cohesion* mechanisms that create local connections between adjacent sentences at the semantic/conceptual level.

In order to account for such cohesion phenomena, special representational devices for the history of a discourse (such as focus stacks, focus spaces, or centering lists (Walker et al. 1988)) must be available. They help to keep track of the attentional structure of

a text, e.g. by recording the kinds of specific discourse entities mentioned in the text, the order and syntactic embeddings in which they were introduced, etc. Such a device makes explicit the context created by the various utterances in a text in terms of the salience status of discourse entities and, thus, helps to minimize the number of alternative interpretations (ambiguities) that are likely to otherwise arise.

Text cohesion mechanisms are supplemented by *text coherence* patterns that relate to the global organizational structure of a text. Examples of this are various forms of coherence relations, e.g. causality, contrast, or elaboration (Mann and Sandra, 1988), hierarchically linking simple, as well as more and more complex proposition sets from the text. Moreover, text macroorganization patterns such as genre-specific superstructures or story grammars constrain the overall structure of the entire text (e.g. the composition rules underlying a weather report or a hospital discharge summary) (van Dijk 1977). Discourse structures of this type can be signaled by cue phrases (such as 'but', 'for example', 'however') and are, therefore, easily recognized, but they may also require elaborate inferencing on rich knowledge structures.

At the *pragmatic* level (Cohen et al. 1990), text understanding relies on discourse constraints that hold irrespective of particular utterances in a text and characterize a generally valid framework of human communication. They require the representation and recognition of various presuppositions (knowledge assumed to be mutually shared between the writer and the reader), goals, plans, and intentions of the writer, and adherence to truly general communication principles based on plausibility and rationality (such as several conversation maxims). These underpinnings of text understanding are intended to keep it focused by relying on a set of reasonable, socially accepted conventions for felicitous and compact textual information transfer. The pragmatic level of text understanding implies that utterances in a text contain more than they literally indicate in terms of semantic/conceptual information (a phenomenon called *conversational implicature*). The reader's construal of the implicit intentions, plans, and beliefs that the writer had for producing the text constitutes the key for a successful textual information transfer (Morgan and Georgia 1980).

A problem with defining text understanding in terms of the recognition of text propositions is that it is almost impossible to reach a consensus among different readers as to what exactly constitutes the proper set of propositions of an underlying text. Because this makes it difficult to judge whether a reader has or has not understood a text, several proposals have been made concerning how to assess the depth and accuracy of text understanding in a more or less indirect way. The following tasks have been considered useful in reaching that goal:

- In the *paraphrasing* task, subjects are asked to rewrite the contents of a source text in their own words, while keeping in mind any piece of information they have acquired from that source text. By way of comparing the propositions of the source text with those from the newly generated paraphrase text, the level of detail of text understanding can be made explicit.
- In the *question answering* task, subjects are asked particular questions whose answer is contained only in the source text. The answer to a question may either be explicitly stated in the underlying text, or it may have to be inferentially derived when it is merely implicit in the proposition set. Correctly answering a question is then taken as an indication of profound understanding of the source text.
- In the *summarizing* task, subjects are asked to compress the contents of a source text with respect to the most relevant propositions contained in it. Psycholinguists have a clear understanding of how one moves from a large set of basic propositions (*micro*propositions) to a generalized set of so-called *macro*propositions, which is the equivalent of a summary at the representation level. Transformations operating on micropropositions generate macropropositions by way of generalizing single statements along taxonomic concept hierarchies, in turn eliminating irrelevant details and abstracting single actions in more general event patterns (Kintsch and Teun 1978). Producing a reasonable summary is then considered to be evidence of an adequate understanding of the source text.

Thai and Tai Languages

Thai (Bangkok Thai, Standard Thai, Central Thai, or Siamese) is the national language of Thailand. It is spoken by approximately 60 million speakers, at least half of whom speak other languages and dialects as their mother tongues. The standard language, based on the speech of the elite and the upper middle class in Bangkok, is used as the medium of instruction in schools throughout the country. Regional dialects outside Bangkok and the Central Plains include Northern Thai (Kam Muang or Lanna), Northeastern Thai (Isan or Lao), and Southern Thai (Paktai). Although these varieties are generally considered dialects of Bangkok Thai, they are more closely related to other languages of the same family spoken in neighboring countries. For example, Northern Thai is more similar to Shan or Tai Yai in northern Burma, and Northeastern Thai to Lao. Strong regional identities exist in these regions, particularly among speakers of Southern Thai (most of whom are Muslim Malays) and northeasterners who call themselves and their language Lao. The name Thai-Isan is a newly coined term introduced by the Thai kingdom to promote nationalism among northeastern speakers. Apart from Thai and its dialects, other languages spoken in Thailand include Chinese (mainly in Bangkok and the central region), Malay in the south, and Mon-Khmer languages in the northeast. In addition, there are a number of hill tribe languages such as Karen, Hmong, Yao, Lisu, Lahu, and Akha in Tak, Chiang Mai, Chiang Rai, and Mae Hong Son in the north. Other Tai varieties are also spoken in scattered communities, such as Tai Yai in Mae Hong Son, Tai Ya and Tai Lue in Chiang Rai, and Phu Thai in Nakhon Phanom.

The word Tai (without the *h*) has two major uses: (1) it refers to a group of languages, including Thai and Lao, which are spoken in a vast geographical area of Southeast Asia ranging from southwestern China and northern Vietnam to the Indian state of Assam; (2) it is the name of a language family, the Tai family, a subgroup of Tai-Kadai or Kam-Tai. The term Kadai was coined by Paul K. Benedict to refer to a group of languages closely related to Tai such as Li (Hlai), Lakkia (Lajia), and Gelao, which are spoken mainly in China. The relationships between Tai and Kadai or Tai and Kam (Dong) languages as well as between Tai-Kadai and other language families in Southeast Asia are still controversial. According to Benedict, the Tai family is a branch of Austro-Tai, because it shows strong affinities with Austronesian, another major family in Southeast Asia comprising more than 1,000 languages. Scholars in China, on the other hand, view Tai (so-called Daic) as a branch of Sino-Tibetan, a superfamily that consists of Chinese (Sinitic), Tibeto-Burman, and Hmong-Mien (Miao-Yao). A view generally held by linguists today is that Tai-Kadai or Daic is a separate language family, which has no proved connection with either Austronesian or Sino-Tibetan. Hypotheses about Proto-Tai have been debated since the turn of the twentieth century and have motivated a good number of works on comparative Tai linguistics, particularly in the areas of pronunciation and vocabulary.

Within the Tai family, Fang Kuei-Li distinguished three branches: Southwestern Tai (comprising the well-documented languages of Assam, Burma, Yunnan, Thailand, Laos, and northern Vietnam), Central Tai (the most notable members are Nung and Tho spoken in northern Vietnam and areas of Guangxi adjacent to northeastern Vietnam), and Northern Tai (e.g. Northern Zhuang, Buyi, Yay, Saek, and Li). Zhuang is spoken in the Zhuang Autonomous Prefecture in Guangxi and Wenshan County in Yunnan. The Zhuang constitute the largest of China's 56 official minority nationalities, numbering nearly 20 million speakers. There are two main Zhuang languages: Northern Zhuang (already mentioned) and Southern Zhuang. The latter shows affinity with Central Tai languages and is classified as a member of this group. Spoken in the upper Red River area in Vietnam, Yay (Giy) has been richly described by William J. Gedney. Saek (previously classified as a Mon-Khmer language) is spoken in Laos and Thailand. It has been reported to maintain the archaic final consonant -*l.* Saek has also been investigated by Gedney.

In China, speakers of Tai languages are centered in autonomous prefectures and counties in the southwestern provinces of Yunnan, Guizhou, Guangxi, along the border region of Hunan, and Hainan Island. They are officially recognized as the Dai (China's Latin-script equivalent of *Tai,* referring to speakers of the southwestern branch), Zhuang, Buyi, Dong, Li, and Gelao. The majority of the Dai speak Tai Lue and are concentrated in Xishuangbanna Dai Autonomous Prefecture in Yunnan. Tai Nuea or Tai Luea is spoken in Dehong-Dai-Jinpo Autonomous Prefecture along the Yunnan–Burma border. This language shares several characteristics with Tai varieties in Shan of upper Burma. White Tai (Tai Don), Red Tai (Tai Daeng), and Black Tai (Tai Dam), all belonging to the southwestern branch, are spoken in various places in northern Vietnam. They are mutually intelligible and can be classified as dialects of a single language. Black Tai speakers, numbering approximately 500,000, were originally centered in Muang Thaeng (Dienbienphu) in Vietnam but they have now settled in Laos and several provinces in Thailand.

With a writing system based on Indic-derived scripts, several Tai languages have enjoyed long literary traditions. Although Ahom has become virtually extinct as a spoken language since the nineteenth century, its literary legacy provides an important clue to Tai-Ahom worldviews. The use of Lanna script in northern Thailand is today limited to religious texts. The use of the present-day Thai script for the standard written language in Thailand can be traced back to the reign of King Ramkhamhaeng during the Sukhothai period in the mid thirteenth century. The Sukhothai writing system was borrowed from Khmer

(Cambodian) and subsequently developed to accommodate special characteristics of the Thai language as it was spoken then. On the evidence of the Ramkhamhaeng Inscription (1292 CE), Sukhothai Thai included four kinds of syllables. The first three categories, ending in a vowel or sonorant (so-called *unchecked, live,* or *free* syllables), used contrasting tones (see below), whereas the fourth kind, ending in stops /p t k/ (*checked* or *dead* syllables), exhibited no tonal contrasts. In the Ayutthaya period (fourteenth to eighteenth centuries CE), the language underwent two major changes, which resulted from tonal splitting and from borrowing words from Khmer, Pali, and Sanskrit. The tonal split, which also affected other Tai languages, although at a much earlier date, was conditioned by the nature of the initial consonant and split the system of three tones into a system of five in Modern Thai. Some Tai languages have been reported to have as many as nine tones.

The inventories of sounds in Central and Northern Tai are generally different from those in the Southwestern branch. For example, Nung and Tho have peculiar initials such as *py-* or *phy-* for words that share ancestry with those beginning with *t-* in the Southwestern varieties. Li (Hlai), a Northern Tai variety from Hainan Island, has preglottalized stops and contains the rare voiced stop *g.* Southern Zhuang contains an aspirated stop series but Northern Zhuang has only unaspirated stops.

A syllable in Thai and Tai languages consists of an initial consonant or consonant cluster, a vowel or diphthong, and a tone, and may or may not have a final consonant. When the final consonant is present, it is either a voiceless stop /p t k ʔ/, a nasal /m n/, or a semivowel /y w/. The glottal stop /ʔ/ is an innovation in modern Tai languages; it probably did not exist in the ancestor language Proto-Tai. Words that contrast in tones convey different meanings. For example, the following words in Bangkok Thai mean different things depending on the pitch with which they are pronounced: *naa1* 'field', *naa2* 'sentence-final particle', *naa3* 'face', *naa4* 'mother's younger sibling', *naa5* 'thick'. The numbers 1–5 refer to different qualities of pitches: 1 = mid level, 2 = low level, 3 = falling, 4 = high level, and 5 = rising. Checked syllables have fewer tonal possibilities than unchecked syllables. Black Tai, for example, chooses from six tones on unchecked syllables but only two tones on checked syllables. Weak syllables are also common in Thai and Tai languages. The tone on such syllables is usually neutralized. The Thai *kra-* in *krathaʔ4* 'pan', *krathaŋ5* 'flowerpot', is a clear example of this type.

Most inherited Tai words are monosyllabic. The situation in Thai is more complicated due to words borrowed from other languages. Pali loans and compounds

greatly increase the number of polysyllabic words in the language and distinguish it from the Tai languages of China, which are heavily influenced by Chinese. Contacts with other languages thus result in finer lexical distinctions between dialects of a single language. For example, Tai Ya speakers from Muang Ya in Yunnan have difficulty communicating with their relatives in a transplanted community in Chiang Rai. Another common feature of Thai and Tai as well as non-Tai languages in Southeast Asia is the use of doublets and elaborate expressions. These are two- to four-syllable words which contain repeated or synonymous information. They usually convey idiomatic or figurative meanings and characterize playful speech. For example, the expression in Bangkok Thai *kin1 khaaw3 kin1 plaa1* (eat + rice + eat + fish) simply means 'to eat' but it is composed of two identical words (first and third syllables) and two words with similar meanings (second and fourth syllables).

Grammatical relations in Thai and Tai languages are indicated by word order, not by word inflections. Subject–Verb–Object is the usual pattern, although other patterns occur: Object–Subject–Verb (for object emphasis), Verb–Subject (stating existence), and Subject–Object–Verb (as in Khamti, a Tai variety in Ahom). An important characteristic of spoken and written texts is that virtually everything except verbs or adjectives can be omitted. Pronouns are especially prone to deletion. Nouns do not have plural forms, and verbs express no tense. To indicate whether actions have already taken place or will take place, the speaker counts on the addressee's interpretation and makes use of temporal adverbs, preverbal auxiliaries, as well as serial verb constructions (series of verbs that occur in concatenation without intervening words). It is still controversial as to whether there are true adjectives and prepositions in these languages, as the former generally behave in the same way as verbs and the latter can function as nouns.

Classifiers (category-words used in e.g. counting, somewhat like English *a slice of bread, a slice of pizza*) are found throughout the family, suggesting that this is an inherited trait from Proto-Tai. However, there are variations among the languages and dialects. For example, Bangkok Thai and Tai Lue have the Southeast Asian pattern with the following order: noun + numeral + classifier, whereas Black Tai and White Tai follow the Chinese pattern with the order numeral + classifier + noun. Classifiers can substitute for modified nouns in both Thai and less well-known varieties such as Tai Lue and Tai Nuea. These linguistic forms are generally used to indicate shape, size, flexibility, and animacy. Although classifiers are similar in grammar and meaning in various Tai languages, they differ in number and usage. There is a tendency for some

classifiers in Bangkok Thai to be of limited use and some to be used more extensively. For example, *chɯak3* 'classifier for elephants' is being replaced by *tua1* 'classifier for animals' in young people's speech. In the same way, *ʔan1* 'classifier for things' has been extended to cover other nouns that formerly required special classifiers.

Pronouns in Thai and Tai languages are of special interest to linguists, as there are many ways to express 'I' and 'you' depending on the sex of the speaker, the relationship between the speaker and the addressee, and the formality of the situation. Kinship terms, words expressing occupations, and nicknames can be used in this context. Furthermore, these languages employ a number of sentence-final particles, another areal feature in Southeast Asia. These particles are used to perform different kinds of speech acts and convey the speaker's attitudes toward the utterance. Like pronouns, they are used in accordance with the social status of the speaker with respect to the addressee, degrees of intimacy, and politeness. According to Gedney, pronouns and particles are what distinguish languages of this family which are far apart from one another, rendering them mutually unintelligible.

Thematic Structure

Thematic structure is a list of specifications in the lexicon about the thematic relations that hold between a predicate and its arguments. In some approaches, 'thematic structure' is referred to as 'thematic grid', 'theta grid', or 'argument structure'.

'Argument' and 'thematic relation' are lexical semantic notions. The event or state of affairs a verb denotes entails a fixed number of participants, which mostly have to be expressed in every well-formed sentence in which the verb is contained. These are the arguments of the verb. Although obligatory syntactic realization is not a necessary criterion for the identification of arguments, it is true that an argument is still implicit in the meaning of the verb even if it is not expressed in a sentence. In *Fred eats an apple with great relish*, for example, the expressions *Fred* and *an apple* realize the arguments of the verb *eat*. If *eat* is used intransitively, e.g. *Fred is eating with great relish*, we still understand that Fred is relishing something he eats. The lexical entry of a verb specifies for each argument the way in which it is involved in the denoted event. In the example above, Fred is the instigator of the eating event and the apple is the object that is affected. The roles participants may have in events denoted by verbs are the thematic relations. Other common names in different theories are 'thematic' or 'theta roles' ('Θ roles'), 'semantic roles', 'participant roles' and so on. They are generally subsumed under labels like 'agent', 'patient', 'goal', 'beneficiary', and 'experiencer'. Theories differ with respect to the number of labels they assume and the way in which they define the corresponding thematic relations.

In linguistic theories, thematic relations serve as an interface between lexical semantics and syntax. In different theories, there are various syntactic generalizations that refer to thematic relations, but almost every theory uses them overtly or covertly to predict the syntactic realization of arguments, e.g. as subject, object or indirect object, or with respect to case marking or syntactic alignment of the corresponding noun phrase.

The notion 'thematic relation' was first introduced in Gruber's *Lexical structures in syntax and semantics* (1976) and in Fillmore's *The case for case* (1968), who called them 'deep cases'. Fillmore assumed that each argument is associated with a preposition that corresponds to its deep case. Every argument is inserted with its preposition into a unique syntactic position in deep structure. In the examples in (1), *John* has the deep case 'agentive', *the door* the deep case 'objective', and *the wind* the deep case 'instrumental'. The agentive and the instrumental take the prepositions *by* and *with*, respectively, cf. (1a), (1c), and the preposition of the objective is zero, cf. (1a–d).

(1a) John opened the door with the key.
(1b) The key opened the door.
(1c) The door was opened by John.
(1d) The door opened.

'Agentive' is, in Fillmore's theory, 'the case of the typically animate perceived instigator of the action identified by the verb'; 'instrumental' is 'the case of the inanimate object or force causally involved in the action or state identified by the verb', and 'objective' 'should be limited to things that are affected by the action or state identified by the verb'; cf. Fillmore (1968:24f.).

In the course of the derivation of an active sentence, an agentive moves to subject position, where its preposition is deleted, cf. (1a). If no agentive is present at deep structure, the instrumental will move to subject position where its preposition is deleted. Even objectives can move to subject position, if they are the only argument in active sentences, cf. (1d), or in passive sentences, then the agentive remains with its preposition in its original deep structure position, cf. (1c).

Later approaches in Generative Grammar departed from the postulation that arguments are inserted into deep structure with prepositions according to their thematic relations. They nonetheless continued to adhere to the idea that there is a one-to-one correspondence

between thematic relations and syntactic positions. Chomsky (1981) introduced in his *Lectures on government and binding* (GB) the 'theta criterion', which poses the following twofold restrictions on thematic structure: (1) each argument is assigned one and only one theta role; and (2) each theta role is assigned to one and only one argument. In (1a) and (1b), we have two different variants of the verb *open.* In (1a) the agent role is assigned to the subject, the direct object is assigned the theme role, and the prepositional phrase is an instrument(al). (1b) differs from (1a) in that the subject bears the instrument role. Both sentences meet the theta criterion because there is no argument without a theta role and no theta role is assigned twice in one sentence. The theta criterion correctly rules out sentences like *The key opened the door with the bit,* where the instrument role is assigned to *the key* and *the bit* (unless the subject is interpreted as a character in a fable or cartoon), or *John and the key opened the door,* where the collective subject is assigned the instrument and the agent role at the same time. In GB it was assumed that the verb in (1d) assigns the theme role to the direct object, but that it fails to assign case to this argument. It was postulated that a verb's failure to assign case to the direct object always correlates with its failure to assign a theta role to its subject. In other words, in the underlying structure of (1d) the subject position is empty and the direct object lacks a case feature. In order to receive case, the phrase moves to the subject position and thus yields the surface structure in (1d). Passive sentences like (1d) were also accounted for by movement of the direct object to the subject position, but in this case the theta role of the subject and the case of the direct object was assumed to be absorbed by the passive verb. (The apparent agent *by John* in (1d) does not represent an argument of the passive verb. Instead it is assumed to be an adjunct.)

While in GB for most arguments a thematic and a grammatical relation is specified in the lexical entry of the verb, other theories provide algorithms that predict the grammatical relation or the morphosyntactic realization of arguments from their thematic relations. Such theories are called 'linking theories'. The examples in (1) illustrate the fact that, in English, agents, instruments, and themes or patients can all become subject of active sentences. However, an agent will always be realized as subject while an instrument cannot become subject if the thematic structure contains an agent, and a patient or a theme can only become subject if it is the only argument in the thematic structure. These generalizations seem to hold cross-linguistically for languages that have accusative case systems like English. In some contemporary approaches, the different ranking of thematic relations with respect to

Figure 1

the choice of subject and the application of other syntactic rules is reflected by thematic hierarchies, cf. Van Valin's (1993) Role and Reference Grammar (RRG: 41) (see Figure 1).

On this continuum, thematic relations that are nearer to the left end share more properties with the agent ('the willful, volitional, instigating participant', cf. RRG: 42), while thematic relations that are nearer to the right end are more patient-like ('the nonwillful, noninstigating, maximally affected participant', cf. RRG: 42). 'Effector' is a generic term for instruments and forces, experiencers are, for example, nonwillful instigators of perceiving events, and themes undergo a change of location but not a change of state or condition. Sources, paths, goals, and recipients are grouped together, because they do not compete with each other for subjecthood or other syntactic relations. They do, however, compete with the theme. The mapping of thematic relations to syntactic relations proceeds in the following way: (1) The highest ranking thematic relation in a thematic structure is assigned the macrorole 'actor' and the lowest ranking thematic relation is assigned the macrorole 'undergoer'. If a verb has more than one argument, in accusative languages the actor is mapped to the subject and the undergoer to the direct object. Any remaining arguments are assigned cases or prepositions according to their thematic relations. The choice of the particular case or preposition is language-specific. While in example (1a) the agent *John* outranks the theme *the door*, in (1b) it is the effector *the key*. Thus, *John* and *the key* are actors in (1a) and (1b), respectively, and *the door* is undergoer in both sentences. In (1c) and (1d) *open* has only one argument, the theme *the door*. Since the verb does not express an activity in either case, the argument is an undergoer, but this does not affect the choice of the grammatical relations, since only arguments are always realized as subjects.

One advantage of RRG is that it captures distinctions between thematic relations like agent and effector and at the same time allows for generalizations over a wide range of thematic relations, for example, with respect to linking. Still a disadvantage of RRG is that it operates with role labels. A thematic relation that is covered by a role label is defined by a number of related properties (e.g. Van Valin's definition of the agent above), which may not all apply to every argument for which the role label was intended. Because in every theory there is a residue of arguments that do not

fit in any role label category or that do fit equally in two or more categories and whose assignment to one or another label often seems to be subject to theoretic bias, many critics have rejected the theoretic value of thematic relations altogether. Dowty's (1991) *Thematic proto roles and argument selection* (TPR) offers a solution to this problem: in this model, thematic relations are characterized by already familiar properties like volitionality, etc. that are entailed by the verb of its arguments. These properties come from two finite sets that define the prototypical agent and the prototypical patient, respectively, and combine freely with each other. The proto-agent properties are (1) volitional involvement in the event or state, (2) sentience/perception, (3) causing an event or state in another participant, and (4) movement relative to another participant. The proto-patient properties are (1) undergoes a change of state, (2) incremental theme (a participant that successively undergoes a change of state in an event that does not end before every part of the participant has been affected, e.g. *a pizza* in *Bert ate a pizza*), (3) causally affected by another participant, and (4) stationary relative to movement of another participant (TPR: 572). Dowty's model permits a very fine-grained distinction of thematic relations since arguments can be characterized by a great variety of properties from one or both concepts, or even by the absence of proto-role properties. On the other hand, due to the limited number of proto-role properties and the mutual independence of the properties, it is possible to generalize over very large classes of arguments that share a certain property, regardless of other possible proto-role properties these arguments may have. The linking rules in TPR correctly predict that the only argument or the argument that has the greatest number of proto-agent properties in the thematic structure of a verb is lexicalized as the subject. The argument that bears the greatest number of proto-patient properties becomes direct object. For thematic structures with three arguments, it holds that the argument having less proto-agent properties than the subject and less proto-patient properties than the direct object will be the indirect object.

Because of its obvious advantages, Dowty's model has received wide acknowledgment in the literature. However, his linking rules have been subject to the criticism that they refer to grammatical relations and not to morphosyntactic features. As Primus's (1999) *Cases and thematic roles* exhaustively shows, notions like subject and object only apply consistently to languages with accusative case systems, but not to ergative and split intransitivity languages. As a consequence, Primus modified Dowty's model in order to achieve universal validity, like it was intended by Dowty in the first place.

Tibetan

Tibetan belongs to the Bodish branch of the Tibeto-Burman division of the Sino-Tibetan language family. It is closely related to Newar and Tamang, indigenous languages of Nepal; distantly related to other Tibeto-Burman languages such as Akha, Lahu, Karen, and Burmese; and remotely related to Chinese. It is spoken by approximately five million people in six different nation-states: China, Burma, India, Nepal, Bhutan, and Pakistan. Only in Bhutan is it the national language. Significant groups of Tibetan speakers are also found in exile communities in India, Nepal, Bhutan, and several western countries: at least 100,000 Tibetans fled

Tibet in 1959 when China took it over. Of the five million Tibetans, 2,100,000 speakers are concentrated in the Tibetan Autonomous Region, with Lhasa as the main municipality, and 2,500,000 speakers are found in several Tibetan autonomous prefectures and counties in four western provinces of China: Qinghai, southwest Gansu, western Sichuan, and northwest Yunnan. The remainder are in the Himalayan regions covering the northern tip of Burma, northern Nepal, Bhutan, the Indian states of Arunachal, Sikkim, Himachal Pradesh, and Uttar Pradesh, the states of Jammu and Kashmir (divided between India and Pakistan), and a Pakistani district of Baltistan.

Tibetan-speaking people in the Himalayas are known as *Bhotia* (from the word *bod,* the name of Tibet). A minority group in eastern Nepal numbering approximately 14,000, more commonly known as the Sharpa (Sherpa), speaks the southern variety of Central Tibetan. The Bhutanese call their national language Dzhongkha and do not classify themselves as Tibetans. Ethnic Tibetans in China are officially designated as the Tibetan nationality (*zàngzú* in Chinese or *bod-rig,* a newly coined term in Tibetan). The Jiarong (Rgyarong), Baima, and other ethnic groups of western Sichuan consider themselves Tibetans and are officially included within the Tibetan nationality, although they speak non-Tibetan languages as their mother tongues. The variety of Tibetan spoken in Baltistan is called Balti, but it acquires another name (Purik) when spoken on the Indian side.

With historical evidence dating back to the seventh century, Tibet was an important empire of Central Asia extending its influence to the Tang dynasty of Imperial China and ruling over small kingoms such as the Nan Chao Kingdom (present-day Dali) in southwest China. It was in contact with several nation-states of Asia, including India, from where it borrowed a writing system. The Tibetan script—with 30 consonant and four vowel signs and a few punctuation marks—was modeled after the Brahmi script during the reign of King Srongtsan Gampo (617–650 CE). The language from this period through the ninth century, known as Old Tibetan, was used mainly to record royal documents and historical chronicles. A large number of Old Tibetan manuscripts found in the Dunhuang caves are among the most important materials for the study of the proto-history and proto-language of Tibet. The majority of these materials have been cataloged and preserved in national libraries in France and England.

Classical Tibetan (sometimes called *Chöke* by western scholars) has developed since the eleventh century. It remains in use as the medium for religious texts and other kinds of learned discourse. This literary variety was adopted as the liturgical language by Mongols and other non-Tibetan-speaking groups in Nepal who are influenced by Tibetan Buddhism such as the Tamang, Gurung, Thakali, and Manang. It has served as the standard written language for all learned documents in Bhutan. The written variety from the nineteenth century, which was developed from Classical Tibetan with influence from the Lhasa colloquial, is called Modern Literary Tibetan or Newspaper Tibetan. It is used widely in Tibetan communities in China and elsewhere as the standard medium for newspapers, magazines, and other kinds of modern writings, including radio broadcasts. Other varieties that have developed from Classical Tibetan but are based on regional idioms also emerged, but their use is limited to particular regions. Written Tibetan, specifically Classical Tibetan, still represents the pronunciation of the language as it was in the ninth century, when it underwent a major reform. Hence, there are considerable differences between Written Tibetan and modern spoken dialects. For example, the greeting expression *bkra-shis bde-legs* 'Good luck' is pronounced *trashi tele* in Lhasa speech.

Spoken Tibetan is divided into several dialects and subdialects that are quite different from one another. The number of dialects varies, depending on the geographical areas under investigation. Most authorities agree that there are at least four major dialects: Central Tibetan (Ü-tsang), Northeastern Tibetan (more commonly known as Amdo), Eastern Tibetan (Kham), and Western Tibetan (Töö). Central Tibetan, which includes Lhasa, the standard dialect, Shigatse, and other subdialects, is spoken in the Tibet Autonomous Region (TAR) and along the Tibet–Nepal border. Amdo is spoken in Gansu and Qinghai provinces. Kham is found in Sichuan, Qinghai and Yunnan provinces, and some parts of TAR. Western Tibetan includes Ngari in TAR, Ladakhi in India, and Balti in Pakistan. Chinese linguists pay attention only to the first three groups, as they are the major dialects spoken in China.

Within Kham Tibetan, two groups are distinguished: valley or sedentary dialects (*Rongke*) and nomadic dialects (*Drokke*). Each category is further divided into several subdialects. Amdo too is divided into valley dialects and nomadic dialects, although the difference between these two categories is not so great as in Kham. There is a continuum of mutual intelligibility among the speakers of these dialects. Amdo speakers are reported to have problems understanding Lhasa speakers and vice versa, and thus it is common for the two groups to resort to Chinese as a lingua franca. For each region, one subdialect associated with cultural heritage, education, or political power is generally considered to be more prestigious than the others and serves as a regional lingua franca. Lhasa Tibetan is a subdialect of Central Tibetan, but because it is spoken

in the metropolitan and pilgrimage center and former seat of government, it is generally regarded by Tibetans as the most prestigious form. Lhasa Koiné, with loanwords from Nepali, Hindi, or English, is spoken in exile communities by refugees who came from various linguistic backgrounds. Other regional koinés in Tibetan territories in China include the Labrang dialect of Amdo and the Derge dialect of Kham.

The majority of words in Tibetan are disyllabic. A basic monosyllabic word consists of an initial and a vowel and may or may not have a final consonant, e.g. *bod* 'Tibet' (*phöö* in the Lhasa dialect; *wot* in the Amdo dialect). Consonant clusters are common in written Tibetan and archaic dialects—those containing archaic features and therefore closer to written Tibetan—namely Amdo and western dialects. The number of initial consonants varies from one dialect to another. There are 28 consonants in Lhasa Tibetan. Kham valley dialects have about 40 consonants. Tibetan presents an interesting case for the study of the origin of tones (i.e. intonational differences that distinguish word meanings), as this innovative feature of distinguishing meanings by musical pitch alone is found only in some modern dialects. Central Tibetan and Kham Tibetan exhibit a well-developed system of lexical tones, whereas Amdo and Western Tibetan do not have tones. The number of tones ranges from two to four. Tibetan dialects in Nepal display a two-tone system (high tone vs. low tone). Most Kham dialects contain four tones (high tone, low tone, rising tone, and falling tone). Initial and final consonants are relatively simple in these tonal dialects. In addition to tones, some of these dialects also developed a rich inventory of diphthongs.

Like the majority of Tibeto-Burman languages, Tibetan has the subject–object–verb word order. Grammatical relations are expressed by means of case particles. Five cases are distinguished for most spoken and written varieties: ergative–instrumental, ablative, absolutive, genitive, and dative–locative. The genitive case particle also functions as a relative clause marker. The ergative and the instrumental case markers are homophonous but they are attached to nouns with different semantic roles: the ergative particle marks an actor, which is chiefly animate, whereas the instrumental particle marks an instrument. Likewise, the dative and the locative case particles are identical in form, but they have different functions: the former marks a recipient or a patient (an entity, generally an animate being, affected by the action); the latter is attached to a place or time. Written Tibetan is a prototypical example of an ergative language: subjects of verbs that can occur with objects require ergative case marking, whereas objects of such verbs and subjects of verbs that never take objects behave differently: they are unmarked, which

indicates absolutive case. Lhasa Tibetan is often cited by linguists as a language with a 'split' ergative-marking pattern: ergative subjects are required only when reported actions have already taken place. Therefore, the subject in *khōŋ-ki tà tçí sὲε sōŋ* 'He killed a tiger' requires an ergative case particle because the verb indicates a past event, whereas the subject of *khōŋ tà tçí sὲε-ki rè* ''He will kill a tiger' does not.

Tibetan nouns express neither gender nor number. Plurality is indicated by the plural marker *tsho* as well as *dag* and *rnams* (the latter two are more common in written texts). In modern dialects, these plural particles are generally employed only with pronouns. Adjectives follow nouns. Determiners (words that modify noun phrases) include the number 'one' *gcig,* which functions as an indefinite article, and the spatial demonstratives *di* 'this' and *de* 'that' functioning as definite articles. Negation is indicated by *mi-* or *ma-,* which is prefixed to the main verb. In Lhasa Tibetan, it is more common to use sentence-final negative verbs, i.e. *min* and *me,* when the subject is first person 'I', and the negative prefixes when the subject is second or third person, i.e. 'you' or 'he or she or it'. A sentence may consist of a single clause or a series of clauses chained together with the main clause as the last element. Because of this characteristic, Tibetan is typologically classified as a 'clause-chaining' language.

Verbs in Old Tibetan and Classical Tibetan, most of which are monosyllabic, have variant forms corresponding to tenses (future, present, past) and mood (imperative). In Central Tibetan and Kham Tibetan, this distinction is neutralized: there is only one form for each verb. Instead, sentence-final auxiliary verbs are employed to convey, for example, tense. These auxiliary verbs and verbs equivalent to 'to be' or 'to exist' are used according to person (whether or not the subject is first person) and evidentiality (whether or not the person has witnessed the event described in the utterance). Person marking in Tibetan is different from person agreement, a common feature of languages of the Himalayan branch of the Tibeto-Burman group. The emergence of person and evidential markings in modern spoken dialects of Tibetan has attracted a great deal of attention from linguists. These phenomena are also found in other Bodish languages.

Tibetan has a well-defined and productive system of honorifics (*zhesa*). These are special words (mainly nouns and verbs) used when referring to Buddhas and deities and in everyday conversation when one talks with people of higher social standing, elderly and respectable people including monks, officials, teachers, and one's own parents and elder siblings. Honorific vocabulary, which stands in parallel with ordinary vocabulary (*phal-skad*), is common in Old Tibetan texts and has developed into a complicated

system in Lhasa Tibetan. It is found in most of the dialects but in a relatively less sophisticated manner. Contrary to stereotypes among native speakers, honorifics are used among Kham speakers, but mainly when they engage in conversation with monks, high officials, or the elderly. The following expressions represent two ways of saying 'his hat', with the structure [he-genitive hat]: *khō-ki zhamo* (ordinary speech) and *khōŋ-ki üzha* (honorific speech). The honorific compound *üzha*, which consists of *ü*, the honorific root for 'head,' and *zha*, the ordinary root for 'hat,' is typical of how honorific nouns are formed in Tibetan.

Given that most Tibetan-speaking areas are inaccessible for fieldwork, both a basic description and an investigation of contemporary aspects of Tibetan languages and dialects still await linguists today. With continuing sociocultural and political changes, Tibetan remains one of the most challenging areas of study for the twenty-first century.

KRISADAWAN HONGLADAROM

Time and Tense

The tense of a sentence is a grammatical category that specifies a time at which the situation described by the sentence is the case. In a sentence like *I was often in Venice,* the past tense *was* indicates that the situation was the case before the time at which the sentence was uttered. Thus, tense mostly gives us information about the distance between a certain situation and the utterance time. Besides the grammatical category of tense, there are also lexical means of expressing location in time: temporal adverbs (*last year, yesterday,* etc., cf. *John left home **yesterday**),* prepositions of time *(in, at, on,* etc., cf. *John left home **at** lunch time),* and temporal conjunctions *(when, after, before* etc., cf. *John left home **when** the phone rang).*

Although tense is marked on the verb in many languages, many researchers assume that tenses modify sentences as a whole. Thus, a common analysis of *I was often in Venice* is PRET *(I often be in Venice),* where PRET is the abstract marker for preterite tense (simple past). Sentences in the present are analyzed in the same manner: PRES *(John go to the cinema)* is the analysis of *John goes to the cinema.* However, the treatment of the complex tenses like perfect and pluperfect is not that straightforward. Some analyze a complex tense as a single modifier. Thus, *John has gone to the zoo* would be represented as PERF *(John go to the zoo),* whereas *John had gone to the zoo* would be PLUPERF *(John go to the zoo).* Others assume that the complex tenses are combinations of modifiers, where the perfect combines PRES and PERF, and the pluperfect PRET and PERF. In these combinatorial accounts, *John has gone to the zoo* is analyzed as PRES *(PERF (John go to the zoo)),* whereas *John had gone to the zoo* would be PRET *(PERF (John go to the zoo)).* At first glance, the combinatorial account seems more attractive because it mirrors the actual words being used: present tense (*has*) and past tense (*had*) combine with perfect (*gone*). However, not all semanticists are convinced that tense on an abstract level necessarily keeps these modifiers separate. The theory of tense outlined here was heavily influenced by the work of Hans Reichenbach.

Another very influential source for tense theory was tense logic. The treatment of tenses as sentence modifiers, which was sketched above, goes back to tense logic. Tense logicians assigned indefinite meanings to the tenses. Compare the sentence *I turned off the stove,* represented as PRET *(I turn off the stove)*. This is considered true if and only if there is an indefinite time before the time of the utterance at which 'I' turn off the stove. But this indefinite meaning of the preterite is counterintuitive: anyone uttering the sentence will have a certain (definite) time of turning off in mind (for instance the time after the meal was ready). The point becomes even clearer with negation: *I didn't turn off the stove* does not mean that there is no turning off in the past. Instead, it means that there is a definite time in the past, and at this time 'I' did not turn off the stove. To say that tenses are definite means that a context is required for the listener to determine which exact point or stretch in time is being talked about. Relevant contexts are the immediate situation of utterance (in the case of the present tense) and times mentioned in previous discourse (in the case of the past tense).

Whereas 'classical' tense logic confined itself to single, isolated sentences without context, more recent work on tense has also focused on tense in discourse. Discourse may be 'temporally connected' or 'temporally free'. A sequence of two sentences forms a temporally connected discourse if the second sentence is temporally interpreted by taking elements from the first one. An example is: *Al went to New York. The others were there, too.* In contrast, temporally free discourse lacks a direct temporal connection. Compare: *Al went to New York. The others were there **once,** too.*

The division between sentences in the preterite whose events overlap each other and sentences where the events follow each other is related in a very systematic way to the types of the events being described. If both events are accomplishments or achievements, then the events are understood as happening in succession: *Jameson entered the room. He switched on the light.* If both sentences contain states or activities, then the events overlap each other: *Jameson cleaned the room. It was very cold in there.* However, if one of the two sentences contains a state or an activity, and the other an accomplishment or achievement, both overlap and succession are possible. The following is an example of succession: *He switched off the light. Now it was pitch-dark around him.* The darkness is due to the switching off and thus cannot overlap it. The following is an example of overlap: *He switched off the light. It was very cold in the room.* Interestingly, the progressive tense (marked with *-ing* in English) behaves like states or activities: if one of the two sentences contains a progressive, and the other an accomplishment or achievement, both overlap and succession is possible: *He awoke to the sound of her screeching. She was shaking him* (overlap); *He opened the door again. The man outside was smiling at him* (succession).

Tiv and Tivoid Languages

Tiv (Mitshi, Munshi) is spoken in Eastern Nigeria in an area all along the Katsina Ala and its tributaries, crossing the Benue where the Katsina Ala joins it and north of Makurdi, and in a few isolated villages across the border in Cameroon. Tiv's neighbors to the east are the Jukun; to the north Alago is spoken; to the east Eloyi, Agatu, and Igede; and to the south one finds a number of related languages/dialects, all of which are listed below. In the standard reference works it is classified as Bantoid—Benue-Kwa—Niger-Congo. Still, there is well-justified, long-standing discussion on just how close Tiv is to Bantu itself. Munshi is a derogative name for the Tiv

used by their neighbors. The term is a Hausa corruption of the Jukun term for the Tiv 'Mbitse' or 'Mbiche'.

Within Tiv proper very little dialect variation is known, even though it might be possible, based on differences in the realization of front vowels, to speak of the Iharev, Kparev, Kunav, Shitire, and Utisha dialects. The Shitire 'dialect' is used in most of the vernacular published literature.

To the Tivoid subgroup of Bantoid belong a series of very closely, potentially mutually intelligible languages spoken on either side of the Nigerian (N)–Cameroonian (C) border along the 6th latitude north. Included in this group are the following:

Abon (N), Avande (C), Batomo (C), Batu cluster (N), Bitare (N), Evant (N), Iceve-Maci (N), Iyive (N), Mesaka (C), Ndii (C, N) Oliti (C), Otank (N), Tiv (N), Tivi (C), and Yiive (C).

While there are around 2,500,000 speakers of Tiv, most of the other members of this subgroup are spoken by only a few thousand speakers.

Tiv was first documented by Clarke 1848—some number names and basic nouns—under the name 'Appa' and by Koelle 1854, who gave a lengthy word list. Significant linguistic works include the dictionary and grammar of Abraham and Malherbe, and the sketches of Lukas, Arnott, Sibomana, and Jockers. The language is used in primary schools and there are some readers for adult education. There is a Bible (1964) and a modest amount of liturgical literature. Tiv is used in regional radio broadcasts; newspapers or journals in Tiv existed until the early 1980s, but have since been discontinued.

Bohannan and Bohannan (1953:11) report that some people as far away as Bamenda, Cameroon used Tiv as a trade language. Today this no longer seems to be the case. Tiv does, however, enjoy a rapid expansion to the north, much to the dismay of its neighbors.

While Tiv is relatively well documented, for the other Tivoid languages the documentation is restricted to a few short word lists.

Some Structural Facts

Phonology. There are 26 consonants, six vowels, and three tones, low, mid, and high [ˋ ˉ ˊ] (Table 1). Tones are normally not marked in the official orthography. A number of morphophonemic rules are to be observed. Particularly interesting are the palatalization and labialization of stem-initial consonants under the influence of prefix vowels (see below) and stem alternations, in verbs due to the conjugational type and in nouns due to noun class prefixes.

Morphology, nouns. There are 12 noun classes grouped into 16 genders: 1|2; 1|4; 1|6; 5|4; 5|6; 5|6; 7|6; 7|6.a; 7|8; 9|4; 9|6; 14|8; 15|4; 15|6; 15|6.a; 6.a. Morphological agreement is shown in all categories of modifiers, in the pronominal system, and in the form of subject agreement on the verb. Noun class prefix as well as suffix markings are to be observed on the nouns and the adjectives. In Table 2, samples of each noun class each with one modifier category are given. The numbers to the left (and those given for the genders above) refer to the corresponding numbers of the Benue-Congo noun class system.

While only class (6a) nouns show clear prefixes and suffixes, e.g. ḿ-kúlé-m 'oil', remnants of class prefixes and/or suffixes can be established for all nouns. In some cases, the noun class prefixes have been incorporated into the stem: historical *u- is realized as labialization on the first consonant, e.g. kwāsé 'woman' compare kàsév 'women', while prefix i- causes palatalization of the first consonant, e.g. ínyáhá 'paddles', cf. náhá 'paddle'.

Modifiers always follow the head noun.

TABLE 1 Consonants and Vowels

	Bilabial	Labio-dental	Alveolar	Postalveolar	Palatal	Labio-velar	Velar	Glottal
Nasal	m		n		ny [ɲ]		ng [ŋ]	
Plosive	p, b		t, d			kp, gb	k, g	
Affricative			ts, dz	c [tʃ], j [dʒ]				
Fricative		f, v	s, z	sh [ʃ]			gh [γ]	
Lateral			l~r					
Approximant	w				y			h

	Front		Back
High	i		u
	e		o
			ọ[ɔ]
Low		a	

TABLE 2

	Sample Noun	Meaning	my	this, these	one	two	bad	Pro	subject concord	Rel
1	kwāsé	*woman*	wàmˊ	ngù	mòmˊ		ù bó	únˋ	á	ù
2	kàsév	*women*	ávˉ	mbáˋ		ú hálˉ	mbà bóvˊ	vé	vé	mbà
3	náhá	*paddle*	wámˊ	ngúˋ	mómˉ		ú bō	ú	ú	úū
4	ínyáhá	*paddles*	yámˊ	ngî̀		í hyálˉ	í bō	í	í	ī̀
5	íkyésé	*basket*	yámˊ	ngî̀	í mómˉ		í bō	í	í	ī̀
6	ákésé	*baskets*	ámˊ	ngáˋ		á hálˉ	á bō	á	á	áā
6a	ḿkúlém	*oil*	ámˉ	máˋ		ḿ hálˉ	mà bómˊ	má	má	mà
7	íny'álégh'	*money*	yághˉ	kî̀	í mómˉ		kì bóghˊ	kí	kí	kì
8	íkyáv'	*loads*	yávˉ	mbî̀		í hyálˉ	mbì bóvˊ	mbí	mbí	mbì
9	ìwyá	*dog*	yàmˊ	ngì	ì mòmˊ		ì bó	ì	ì	ì
14	ángév'	*disease*	ávˉ	mbúù	mómˉ		mbù bóvˊ	mbú	mbú	mbù
15	gbógh'	*stick*	ághˉ	kúˋ	mómˉ		kù bóghˊ	kú	kú	kù

Verbs. Verb stems (and also some nouns) may show internal alternations:

tèmà	tùmà	*sit*
nyímè	nyúmè	*refuse*
sèngè	sòngu	*slaughter*

Since not all verbs undergo these alternations, there is no immediate explanation for these changes although they appear to be remnants of an earlier (ATR) vowel harmony system.

There are traces of verb extensional suffixes. Five morphemes have been identified. It is not clear to what extent these processes are productive; they do not seem to play a role in marking participants.

sV	yóò	*announce*	yóò-sò	*talk a great deal*
rˋ	búghˋ	*open*	búghù-rˋ	*burst open*
ghˋ	pérˋ	*cross (a river)*	pérè-ghˋ	*cross over (road)*
mˋ	lèghˋ	*soft*	lèghè-mˋ	*be soft*
nˋ	pùù	*despise*	pùù-nˋ	*find fault with*

The tense–aspect–modality (TAM) system is extremely complex and only superficially described. A selection of the many forms that exist for each verb is given below. It should be noted that TAM is frequently marked with tones as well as TAM markers before the verb and vowel alternations after the stem.

	vèndà	*Refuse*
INFINITIVE	ù-vèndá-ń	*to refuse*
GERUND	vèndà-ń	*'refusing'*
RESTRICTED PAST PERFECT	ḿ-ˋvèndé	*I refused*
PRESENT HABITUAL I	mbá vé ˋvendá	*they usually refuse*
PRESENT HABITUAL II	Dàm ˋ ˋvèndé	*Dam usually refuses*
PRESENT HABITUAL III	mbá ˋvé véndá-ń	*they ususally refuse*
IMPERATIVE	ˋvèndá	*refuse!*
NEGATIVE IMPERATIVE	dé ˋvèndá-ń gá	*don't refuse!*
SUBJUNCTIVE, HORTATIVE	à vénda	*let him refuse!*

| PAST PERFECT | á vénde | *he refused* |
| *etc.* | | |

Syntax. Tiv is a basic SVO language. Sample sentences taken from the Tiv dialect spoken just across the Cameroonian border giving core participants show a strict S V, S V O, S V DAT O order:

Wán	lá	à-kpé		
Child	DEF	it-died		

The child died.

Wán	lá	à-yá	àyàbà	
Child	DEF	it-eat	plantain	

The child ate plantain.

Wán	lá	à-ná	tùɔ TM	àyàbà
Child	DEF	it-give	chief	plantain

The child gave the chief plantain.

Additional participants are expressed by a series of prepositions:

Wán	lá	à-gbé	shìn	ngèr
Child	def	it-fall	into	water

The child fell into the water.

Negation, even in complex sentences, is marked at the very end of a sentence:

m̀.fá	àlù	wán	lá	à-kpé	gá.
I-know	if	child	DEF	it-die	NEG

I don't know whether the child died.

In some cases, as in the following focus construction, negation is additionally marked on the verb:

tùɔ TM	ù	wán	lá	(à)-ne-ná	àyàbà	gá
Chief	REL	child	DEF	(it)-NEG-give	plantain	NEG

It's not a chief the child gave the plantain.

Relativization is marked by a REL ative pronoun indicating gender and number at the beginning and a low tone at the end of the relative sentence. The low tone has the effect of down-stepping the following high-toned syllable. If the relativized noun is marked with the invariable definitizer **lá**, the relative clause appears between the head noun and the **lá**. If, moreover, the relativized noun is definite, a resumptive pronoun appears in the 'original' syntactic position in the relative clause:

Wán	ù	m̀-méngé	`	ndí
Child	REL	i-see	REL	lost

A child I saw is lost.

Wán	ù	m̀-méngé	àná	lá	`	ndí
Child	REL	i-see	PRO	DEF	REL	lost

The child I saw is lost.

In relativized objects of prepositions, a shortened form of the resumptive pronoun appears as well. The preposition maintains its original syntactic position:

(à)-lú	shìn	yò	ì	wán	lá	gbé	shìn	mì	`.
(he) live	in	house	REL	child	DEF	fall	into	pro	REL

He lives in the house the child fell into.

There is no clear evidence of serialization. Complex structures giving the appearance of serialization are instances of simple conjoined sentences:

wán	lá	à-té	àyàbà,	à-dzé	từɔ̀ TM	ámì.
child	DEF	it-take	Plantain	it-go	to chief	with them

The child took the plantain (and) went to the chief with them.

Only in cases where verbs of motion that do not require a goal are involved does one obligatorily find **dze** 'go' as the second verb. The latter then requires the expected preposition:

wán	lá	à-yévísí	dzé	shìn	yò
child	DEF	it-run	go	into	house

The child ran into the house.

Comparatives have the Africa-typical structure: X exceeds Y in Z, or X is Z, exceeds Y:

unòr(-mban)	bàìkɔ́	hèmbà	ùnor-ngèr
elephant	fat	exceed	hippopotamus

An elephant is fatter than a hippo.

unòr(-mban)	hèmbá	bàìkɔ́-n	ùnor-ngèr
elephant	exceeds	being fat	hippopotamus

An elephant is fatter than a hippo.

There are a good number of ideophones; not all of them, however, are semantically 'identical' to the head verb:

gbúká	lá	gbà	pùú
gun	DEF	fire	BANG

The gun went off 'bang'.

In this case pùú is the sound made by the gun and only that. In the following two sentences, however, **pùlùtùtù** and **cìcá** can be used with any color to express intensity:

àvámbè	nìà	pùlùtùtù cìcá
blood	red	INTENSE

blood is absolutely red

àlísì	yìlè	pùlùtùtù cìcá
charcoal	black	INTENSE

charcoal is absolutely black

Tivoid. Aside from a very large number of vocabulary resemblances, all languages belonging to the Tivoid subgroup share a complex nominal system where a noun is marked both by a prefix and a suffix. A single example—the word for *oil*—suffices to show the unity of Tivoid on the one hand and the close, but non-Tivoid character of neighboring Bantoid languages on the other:

Tivoid		other Bantoid	
BATOMO	mákutúm	AMANAVIL	mètí
BELEGETE	mutum	AMASI	òmìlí
ICHEVE	mukurem	AMBELE	mùút
NDII	mkutem	ASAKA	ɔ́múú
OLITI	mùkùlémí	ASUMBO	mɔɔ́t
TIV	ḿkúrém	ESIMBI	mìri
TIVI	íŋkùlŋ	KENYANG	bawet
YIIVE	mǝkùtèm	MESAKA	òmbúl

F. K. ERHARD VOELTZ

Tocharian

Tocharian is the name applied to a small group of extinct Indo-European language varieties attested in fragmentary manuscripts first discovered in the last decade of the nineteenth century CE. The recovery of manuscripts in Tocharian as well as others written in Khotanese Saka, Sanskrit, and various Turkic and Sino-Tibetan languages from the Taklamakan Desert, Tarim Basin, and region south of the Tian Shan range, all located in the modern-day Xinjiang Uygur Autonomous Region of northwestern China, was a consequence of the many exploratory expeditions undertaken around the turn of the century along the ancient Silk Road trade routes. The majority of extant Tocharian texts originate, by most estimates, from the sixth to ninth centuries CE, after which the Tocharian-speaking culture is believed to have assimilated with neighboring (e.g. Turkic) cultures or died out.

The texts, written on palm leaves, paper scrolls, and wooden tablets, represent a diverse array of genres and subject matter, from scientific, legal, and commercial documents (such as caravan passes) to dramas, narratives, poetry, and Buddhist and Manichaean religious works. A modified form of the Brāhmī script of northern India, the writing system employed in the Tocharian texts, consists of a syllabary in which each consonantal letter is paired with an inherent (unwritten) vowel. Vowels other than this inherent vowel are indicated with distinctive letters or diacritics.

The first extensive analysis and decipherment of the hitherto unknown Tocharian language were made by Emil Sieg and Wilhelm Siegling in 1908. The decipherment was facilitated by the knowledge of other languages written in Brāhmī and related syllabaries as well as the existence of bilingual Buddhist religious texts (in the original Sanskrit, accompanied by Tocharian translations). It is still under debate whether the name Tocharian itself is the most proper name for this language (group); this topic alone has yielded much speculation about the origins of Tocharian and its speakers. The name Tocharian is associated with a people called the Tocharoi, who, as suggested in the writings of the ancient Greeks Strabo and Ptolemy, at one time inhabited the area formerly known as Bactria in present-day Afghanistan and Tajikistan. Although the existence of the Tocharoi is not in question, some scholars believe that they were of Iranian stock and bore no relation to the speakers of the non-Iranian language in the Tocharian manuscripts. Still others who may not necessarily share this belief maintain that the name *Tuγri* (*Twγry/Twghry/Twqri*) found in the neighboring Turkish language Uygur would be more appropriate as a name for Tocharian. Despite the conflicting views among scholars on these matters, however, the name Tocharian has prevailed within the general community of linguists.

Apart from their association with the Tocharoi, it has also been suggested that the speakers of Tocharian were one and the same with a culture that the Chinese called the Yuezhi, a confederacy of several (possibly Indo-European-speaking) tribes originally living at the edge of the Gobi Desert in present-day Gansu Province of northern China and not overly distant from the sites of the Tocharian discoveries. Having suffered a major military defeat in the middle of the second century BCE, evidence from Chinese and Greek annals as well as from sites along the migration route exhibiting Yuezhi-particular burial practices corroborates the view that Yuezhi tribes journeyed west out of China, deeper into central Asia. By the early 130s BCE, some of the Yuezhi tribes had arrived in Bactria and neighboring Sogdiana surrounding present-day Samarkand in Uzbekistan. These tribes that had reached Bactria are known as the Greater Yuezhi. At around 50 CE they may have established the Kushan Empire that extended into northern India. Some generally accepted views are that neither the Tocharoi of Greek sources nor the Greater Yuezhi were the speakers behind the Tocharian manuscripts. Others suggest that both peoples were actually one and the same since both ended up in Bactria and appeared to have had otherwise similar histories according to the written records available. These are fair assumptions given the fact that by the early second century BCE the Greater Yuezhi had already migrated well past the sites of the Tocharian manuscripts first produced approximately 650–750 years later.

At least one more possibility for a Yuezhi-Tocharian connection exists, however. The Lesser Yuezhi, who evidently halted their migration out of more easterly districts of China well short of the trek completed by their Greater Yuezhi kinsmen to Bactria, may have settled south of the Tarim Basin and Taklamakan Desert for a time. Between the cities of Niya and Loulan in this area (both buried by sand over the ages), documents in the Indic language Niya Prakrit came to light and have been claimed to demonstrate signs of influence from a Tocharian language, which may have existed in the vicinity at least several centuries prior to the period of the Tocharian manuscripts found further north. It is possible that the (Lesser) Yuezhi, if not of Iranian origin, as commonly believed, were the speakers of this hypothetical southern Tocharian language and eventually migrated north where they gave rise to the speakers of the attested manuscripts. If correct, this theory would serve to link the Greater Yuezhi, as kinsmen of the Lesser Yuezhi, with one or more Tocharian languages. New manuscript discoveries along the migratory paths of the Greater Yuezhi to Bactria would clarify this view.

It has been suggested that Tocharian was employed as a lingua franca along the Silk Road and other trade routes in the region among people who spoke mutually unintelligible languages. However, most of the Tocharian manuscripts—in two distinct Tocharian varieties no less (A and B)—have been concentrated within a single region and little to no evidence of a significant Tocharian presence beyond the confines of the Tarim Basin has appeared to date to confirm this view. Whatever their origins, the speakers of Tocharian appear to have filled many cultural and economic roles in northwestern China for at least three centuries from the mid to late first millennium CE. They played a considerable role, for example, in the spread of Buddhism and Manichaeism (with roots in northern India and Persia, respectively) into western China. Trade and other forms of contact with the Chinese, Persians, Turks, various cultures from India, and others secured for the Tocharian speakers of the Tarim Basin sites a position of great influence, which endured for some time.

From a linguistic standpoint, scholars were at once amazed and perplexed after it was determined that Tocharian was in fact Indo-European. A traditional and previously straightforward way of grouping the Indo-European languages was to refer to the *centum/satem* divide. Languages of the *centum* group (so-called after the Latin word for '100') such as Celtic, Germanic, Greek, and Italic have velar reflexes (or later correspondents) of velar sounds (e.g. /k/ and /x/) of the reconstructed Proto-Indo-European (PIE) language, while languages of the *satem* group (so-called after the Avestan word for '100') such as Armenian, Indo-Iranian, and Slavic have sibilant reflexes (e.g. /s/ and /š/). Since the word for '100' is *känt* in Tocharian A and *kante* in Tocharian B, the once solid west/east grouping seen in the *centum/satem* divide was disturbed.

With regard to geographical and social distinctions among the varieties of Tocharian, which some consider separate languages, others merely dialects of a single language, Tocharian A was found concentrated in the oasis town of Turfan and to a lesser extent further west at the central site of Karashahr, while Tocharian B was mainly concentrated in Kucha, the westernmost of the three primary sites, and found to some extent in both Karashahr and Turfan as well. Based on these geographical differences, Tocharian A has also been called East Tocharian, Turfanian, Karashahrian, and Agnean (after the former state of Agni situated around Karashahr), while Tocharian B has also been referred to as West Tocharian and Kuchean (after the former state of Kuchi and its site around Kucha). Under one proposal, both varieties of Tocharian were living languages, with B having been imported to the two eastern sites by Buddhist missionaries. A second suggests that A was a dead language used primarily for liturgical purposes

while B was the living language used in everyday life since it was common to all three sites.

While the status of Tocharian as a member of Indo-European remains uncontroversial, the exact relationship between the Tocharian languages and other Indo-European branches has long been subject to speculation. Linguists have made attempts to establish genetic ties between Tocharian and each of the Anatolian, Balto-Slavic, Celtic, Germanic, Greek, Indo-Iranian, and Italic branches at one time or another—in other words, between Tocharian and most of the Indo-European subgroupings. This only serves to demonstrate the relatively modest consensus that exists over the complex position occupied by Tocharian within the Indo-European context in historical, linguistic, and social terms.

The phonology (sound structure) of Tocharian is characterized by palatalized variants of almost all consonants, a single series of stop consonants (i.e. voiceless /p/, /t/, /k/ but no voiced /b/, /d/, /g/ or voiced aspirated correspondents—all three series existed in PIE), the loss of final consonants in A and B (e.g. PIE *tod → B te 'this'/'it') and final vowels in A (e.g. klots 'ear' vs. B klautso, lānts 'queen' vs. B lāntsa, wäl 'king' vs. B walo), and some loss of PIE distinctions between short and long vowels. Singular and plural, as well as dual (e.g. B wi rsoñc 'two spans' vs. the plural form rsonta) and further subtleties in number distinction, are also characteristic of Tocharian. A unique feature of Tocharian among the Indo-European languages is its elaborate system of several primary cases (e.g. nominative and genitive) and a host of secondary cases such as the perlative, allative, and comitative, each of which has a specific grammatical function. The secondary cases are formed by the suffixation of various postpositional elements to forms in the oblique, one of the primary cases. Within the verbal system, both active and medio-passive voices are found. The latter is marked in the present tense by an -r ending (e.g. A klyosamtär and B klyausemtär 'we hear') as in some other centum languages and Indo-Iranian from the satem group. Lexical borrowings from Sanskrit and neighboring Iranian languages are common. Tocharian is thought to have been influenced lexically and structurally, to various extents, by the myriad of non-Indo-European languages in northwestern China and its periphery, such as Sino-Tibetan and Turkic, as well as those encountered by the ancestors of the Tocharian speakers along the eastward migratory paths out of the central Indo-European homeland and eventually into China (e.g. Finno-Ugric languages).

The harsh, arid environment around the Taklamakan Desert region, which was ideal for safeguarding the Tocharian manuscripts for up to 1,500 years, was also instrumental in preserving several groups of mummified humans first discovered during the Western expeditions of the late nineteenth and early twentieth centuries CE. These mummies, however, have only been widely known and studied in the last quarter of the twentieth century CE. Due to their blonde and reddish hair and other distinctive bodily features, some scholars claim that these mummies were the ancestors of the Tocharian speakers. Clearly, they are not easily identifiable with most of the cultures from the past or present that are commonly linked to the region, such as the Chinese, Mongols, and Turks, but rather have appearances more typical of Europeans. Additional clues such as wall paintings found in caves around Kucha and Turfan depicting humans with red hair, along with the proximity of the mummy sites to the sites of the Tocharian manuscripts, all serve to fuel the proposed connection of the mummies with the speakers of Tocharian.

The discovery of Tocharian has influenced many Indo-Europeanists to reconsider their views about the history of the Indo-Europeans and the development and interrelations of the languages attributed to them. Various forms of linguistic and archeological evidence may serve to further unlock the secrets presented by the speakers of Tocharian A and B (and perhaps other varieties of Tocharian that have left little to no trace).

Among the major figures whose works are not listed in the References section but who have nonetheless made substantial contributions to the advancement of knowledge about the origins of Tocharian and its speakers are Elizabeth J.W. Barber, Gerd Carling, Walter Couvreur, Viacheslav V. Ivanov, Jay H. Jasanoff, Sylvain Lévi, Victor H. Mair, James P. Mallory, Antoine Meillet, Holger Pedersen, John H.W. Penney, Pavel Poucha, Ernst Schwentner, and Werner Winter.

Tok Pisin

Tok Pisin (or New Guinea Pidgin) is the dialect of Melanesian Pidgin spoken in Papua New Guinea. It serves as the main language of wider communication in a country where more than 800 separate indigenous languages are spoken by a population of nearly five million. The two other dialects of Melanesian Pidgin are Pijin, spoken in the Solomon Islands (with more than 80 indigenous languages and a population of around 480,000), and Bislama, spoken in Vanuatu (more than 100 languages, population 192,000). Torres Strait Creole (also known as Broken or Yumiplatok)—spoken by approximately 10,000 people around the northern tip of eastern Australia—is closely related to Melanesian Pidgin but is usually considered to be a separate language.

Melanesian Pidgin is an example of a contact language—a new language that developed in a situation in which speakers of different languages needed to communicate but did not share a common language. Most of the vocabulary comes from one language, called the 'lexifier' (English, in the case of Melanesian Pidgin), but the words often have different meanings. For example, in Tok Pisin, *spak,* derived from English *spark,* means 'drunk'. Many words are also derived from other languages (see below). Furthermore, the phonology and morphosyntax of a contact language such as Tok Pisin are distinct from those of the lexifier. For example, in phonology, Tok Pisin has a five-vowel system (a, e, i, o, u) and only 15 consonants (represented in writing as b, d, g, h, k, l, m, n, p, r, s, t, v, w, and y). The English phoneme inventory contains about twice as many elements. For sentence structure and meaning, Tok Pisin uses separate words to show number and tense (see examples below) where English generally uses suffixes, e.g. *-s* and *-ed.* However, Tok Pisin has a few suffixes not found in English, such as *-pela* on adjectives, e.g. *bikpela haus* 'big house' and *-im* on transitive verbs (see below).

Such a contact language is called a 'pidgin' when it continues to be used primarily as a second language for intergroup communication, and it is called a 'creole' when it becomes the mother tongue of a particular community of speakers. As will be seen below, there is some controversy about whether Tok Pisin is actually a pidgin or a creole.

Because Melanesian Pidgin is a contact language that came into being fairly recently, we can describe almost its entire history. The first stage of the development of Melanesian Pidgin dates from the early 1800s, when Melanesians began to have frequent contact with Europeans (including Australians and Americans). This was the result of whaling in the region, followed by trading in sandalwood and bêche-de-mer. Because Melanesia is one of the most linguistically diverse areas of the world, it was impossible for Europeans to learn the local languages for trading (as they did in other areas of the Pacific). Thus, to communicate, they used simplified English or existing contact languages, such as South Seas Jargon and various forms of Aboriginal Pidgin English from Australia. As a result of these limited encounters, many Melanesians picked up some English vocabulary and phrases from the existing contact languages.

The second stage came with the beginning of the Pacific labor trade in 1863, when Melanesians started to be recruited (and in some cases kidnapped) to become laborers for plantations in Queensland (Australia) and Samoa. Melanesians from diverse areas found themselves literally in the same boat, and their only common language was what they had acquired from earlier contacts with Europeans. Thus, they used this to communicate with one another on the ships and later on the plantations. With continued use, new features were

added, norms began to emerge, and a stable pidgin language began to develop—early Melanesian Pidgin.

The earliest Queensland laborers were mainly from the New Hebrides (now Vanuatu) and the Solomon Islands. Some laborers from German New Guinea also went to Queensland in 1883 and 1884, but many more went to plantations in German-controlled Samoa, from 1879 to 1912. Laborers from the other countries also started going to Samoa in 1878, and many of these had already worked in Queensland. Thus, early Melanesian Pidgin was transported to Samoa. However, after 1885, laborers from the New Hebrides and Solomon Islands were no longer recruited for Samoa, and early Melanesian Pidgin began to diverge into two slightly different varieties—one spoken in Queensland and one in Samoa.

The third stage of development began when laborers returned to their home islands, after their contracts finished, and brought the developing pidgin with them. Previously, these islands had no language of wider communication; because the pidgin served this function well, it spread rapidly. It was also used by the large-scale internal labor force that worked on the plantations of German New Guinea, the New Hebrides, and the Solomon Islands after the external labor trade had ended at the turn of the century. In each of these countries, early Melanesian Pidgin further stabilized and changed under the influence of the local indigenous languages. Today, the three dialects differ mainly in vocabulary and a few grammatical rules (see below).

After Tok Pisin had stabilized, it began to be used for new functions, such as religion. It was developed into a written language by missionaries in the 1930s and was later used in newspapers and radio broadcasting. As its use was extended into new areas, it changed linguistically to become more complex; i.e. it acquired more vocabulary and more grammatical rules and inflections. (The same process occurred with Bislama and Pijin.) Thus, in both function and structure, Tok Pisin (and Melanesian Pidgin as a whole) became what is called an 'expanded pidgin'.

Finally, in recent years, especially in urban areas of Papua New Guinea, such as Port Moresby and Lae, many people have been marrying outside their traditional language groups. Thus, often the common language of the parents is Tok Pisin, and this is what their children acquire as their first language. Because of this nativization (the process of a pidgin becoming a native language), some linguists apply the term 'creole' to Tok Pisin (and Melanesian Pidgin in general), emphasizing that it has thousands of native speakers and has the functions and grammatical features found in typical creoles. Those who say that it is still a pidgin demonstrate that more than 90% of its speakers have learned it as a second rather than a first language and

that nearly all of the Tok Pisin-speaking population are bi- or multilingual, whereas creole-speaking populations are most often monolingual.

Today Tok Pisin is the lingua franca of the entire country of Papua New Guinea; it is known by an estimated three quarters of the country's nearly five million inhabitants. It is the most widely used language of urban areas and is also widely spoken in rural areas in the northern part of the country.

Tok Pisin is used to some extent in radio and television broadcasting, especially in interviews and news reports. (It is also used in some of Radio Australia's Papua New Guinea Service broadcasts.) The weekly Tok Pisin newspaper *Wantok* has a readership of more than 10,000, and many government publications are also written in Tok Pisin. The language is widely used in religion, and there is a Tok Pisin translation of the New Testament of the Bible.

The constitution of Papua New Guinea recognizes Tok Pisin as one of the national languages. (The constitution of Vanuatu names Bislama as the national language.) Although English is more widely used for government business, much of the debate in Parliament is in Tok Pisin.

Until recently, English was the official language of education in Papua New Guinea, and it was used in all government schools (although Tok Pisin was widely used in community and church-run preschools and vocational schools). However, with the recent education reform, communities can choose the language to be used in the first three years of elementary education, and many have chosen Tok Pisin. Although many people still feel that Tok Pisin is inferior to English, most accept it as a separate language and an important language of Papua New Guinean identity.

Tok Pisin differs from the other two dialects because, as mentioned above, most of the returned laborers had worked in Samoa rather than Queensland. In addition, nearly all of the New Guinea laborers were from New Britain and New Ireland and the neighboring small islands, where the internal German-owned plantations were also located. Thus, Tok Pisin has many words from the languages of these islands (especially Tolai), as well as some from Samoan and German. Some examples are *kiau* 'egg' and *lapun* 'old' from Tolai, *malolo* 'rest' from Samoan, and *gumi* 'rubber', *beten* 'pray', and *raus* 'get out!' from German.

Bislama has many words derived from the languages of central Vanuatu, e.g. *nakamal* 'meeting house' and *nabanga* 'banyan tree'. Bislama also differs from both Tok Pisin and Pijin in having many words derived from French. (Both France and Britain were the former colonial powers in Vanuatu.) Some examples are *bonane* 'New Year's celebration', *pima*

'chilli', and *lafet* 'holiday'. Pijin differs from the other two dialects in having very few words derived from local languages or any language other than English.

An example of a grammatical difference between the three dialects is in the way they indicate progressive aspect (marked with *-ing* in English). Tok Pisin most often uses *wok long* (literally 'work at') before the verb or the locative or existential verb *stap* 'stay, exist' after the verb (with an intervening *i*); Bislama also uses *stap* but before the verb; and Pijin sometimes uses initial consonant–vowel reduplication (but often does not mark progressive aspect). For example, 'I'm drinking' would be the following in the three dialects: *Mi wok long dring* or *Mi dring i stap* (Tok Pisin); *Mi stap dring* (Bislama); and *Mi didring* (Pijin).

Tok Pisin has been the focus of research testing several theoretical questions in creolistics (the study of pidgin and creole languages). The first concerns 'typical' creole features and developmental history. Creole genesis (or 'creolization') in areas such as the Caribbean is believed to have occurred very quickly, with stabilization and expansion occurring along with nativization. However, the creolization of Tok Pisin has been taking place gradually, with stabilization and then expansion occurring before nativization. Nevertheless, it shares many features with other creoles, such as the following:

(1) Tense, aspect, and modality are indicated by separate words occurring before the verb, e.g. *Em i bin wok asde,* 'he worked yesterday' and *Em bai i wok tumora,* 'he will work tomorrow'.
(2) Lack of a copula (a form of the verb 'to be'), e.g. *mi hanggre,* 'I'm hungry'.
(3) Use of the third-person plural pronoun (*ol* in Tok Pisin) as a plural marker, e.g. *mi lukim ol dok,* 'I saw the dogs'.

Second is the theoretical question of discontinuity. It has been claimed that creoles are structurally discontinuous from their pidgin predecessors in having many more complex structures. These are supposedly innovations of children that occurred during nativization and could be attributed to their innate language faculty. Tok Pisin differs from nearly all known creoles in that it is still acquiring native speakers, and therefore it has provided a good opportunity for studying creolization as it occurs. Because it was believed that grammatical expansion in creoles is the result of nativization, researchers expected to find discontinuity between the Tok Pisin spoken as a second language by adults and the creolized Tok Pisin of children who acquired it as a first language. However, no substantive differences have been found.

Last is the question of substrate influence—the degree to which the first languages of the originators of the pidgin or creole (the substrate or substratum languages) have affected its structure. Although many scholars have downplayed the role of substrate influence in pidgins and creoles, many features of Melanesian Pidgin are clearly derived from or reinforced by those of the Oceanic Austronesian substrate languages. These include the following:

(1) The transitive suffix (showing that the verb takes a direct object) (*-im* in Tok Pisin), e.g. *meri i bin boilim wara,* 'the woman boiled the water'.
(2) The subject referencing marker *(i)* in the verb phrase, e.g. *Tom i wok long Mosbi,* 'Tom works in Port Moresby'.
(3) Exclusiveness and dual and trial number marked in the pronoun system, e.g. *yumi* (first-person plural inclusive, i.e. 'we, including you') vs. *mipela* (first-person plural exclusive, i.e. 'we, not including you') and *yu* (second-person singular, i.e. 'you, one person'), *yutupela* (second-person dual, i.e. 'you, two persons'), *yutripela* (second-person trial, i.e. 'you, three persons'), and *yupela* (second-person plural, i.e. 'you, many people').

Tone Languages

In addition to consonants and vowels, languages also use the suprasegmental to convey different meanings. Through stress, English contrasts such pairs of words as /ˈinsult/ vs. /inˈsult/ and /ˈpermit/ vs. /perˈmit/. Many languages employ tone for similar purposes, but they differ from stress languages in some significant ways. First of all, tone languages regard tone as an important means to contrast lexical meanings. Thus, Mandarin distinguishes unrelated words by tone alone (the raised numerals indicate relative pitch levels at which a tone starts and ends, with ^{5} representing the highest and ^{1} the lowest): /aj^{55}/ 'sadness' vs. /aj^{35}/ 'suffer' vs. /aj^{214}/ '(of height) short' vs. /aj^{51}/ 'love'. (cf. the English examples above, where stress contrasts only word categories—nouns vs. verbs). Second, the occurrence of tone in a word is not predictable, whereas the assignment of stress is rule-governed. Therefore, we may define tone language as one that uses distinctive pitch to contrast concrete meanings of simple words, with the assignment of tone unpredictable by phonological rules.

Lexical tone and stress need not be regarded as a pair of dichotomies, however. Indeed, some languages make use of both. While no European language is predominantly tonal, most dialects of Norwegian, Swedish, Slovene, Serbo-Croatian, and Lithuanian have prosodic systems with a combination of tone and stress. In these Scandinavian languages, tone assignment is sensitive to stress, whereas the reverse applies to the South Slavic and Baltic languages—the stress assignment is said to be sensitive to tone.

Based on distinctive organizations of tones, three major types of tone language can be recognized, i.e. syllable-tone, word-tone, and pitch-accent languages. Syllable-tone languages represent the best-known type of tone system, in which the syllable constitutes the basic domain for each tonal category. Cantonese is an excellent example of a syllable-tone language, e.g. /fu^{55}/ 'call aloud', /fu^{35}/ 'tiger', /fu^{33}/ 'rich', /fu^{21}/ 'hold', /fu^{13}/ 'woman', and /fu^{22}/ 'father'. The tone may change, under certain circumstances, from one category to another. However, individual tonal components of a category do not spread freely in syllable-tone languages. Only rarely do we see the copying of an entire tonal category from one syllable onto an adjacent one in such languages.

Taking the simple word as its basic domain, word-tone languages assign tonal categories to the word as a whole, irrespective of the number of syllables available. Core tonal categories can exhaustively be identified in shorter words. Mende (an African language) has a word-tone system. The actual patterns for words carrying the tonal category of LH (a low tone plus a high tone, to be signified with the diacritics ˋ and ´, respectively) thus vary as follows: /mbǎ/ 'rice', /fàndé/ 'cotton', /ndàvúlá/ 'sling'. The LH pattern is observed only in disyllabic words; it becomes a rising tone in monosyllabic words, whereas in trisyllabic words the H tone spreads onto the final syllable. Tone-spreading within the basic domain of tonal categories is common.

Pitch-accent languages such as Japanese generate tonal patterns in an abstract domain, which may be called 'templet'. They do not directly contrast one tone against another. Instead, tonal categories emerge from the orderly placement of a marked tone at the nth position in the templet, where n typically starts from 0 or 1 and continues up to n. Tone-spreading may occur within the templet to increase the repertoire of tonal categories. As the pattern of a tonal category is predetermined in the templet, situational neutralization of two tonal categories is possible in shorter words. For instance, the citation form of Tokyo Japanese /hàná/ is ambiguous between 'nose' and 'flower', while in fact the two carry different tonal categories. The neutralization ceases when the nouns are attached with the topic clitic /wa/: /hàná wá/ 'as for noses' vs. /hàná wà/ 'as for flowers'. The major characteristics of these three types of tonal system are summarized in Table 1.

TABLE 1 A Comparison of Syllable-Tone, Word-Tone, and Pitch-Accent Languages

	Syllable-Tone	Word-Tone	Pitch-Accent
Basic domain of tonal categories	Syllable	Word	Templet
Manifest of all tonal categories in shorter words	Yes	Yes	Not necessary
Neutralization of tonal contrasts in the citation form	Impossible	Not possible	Possible
Spreading of individual tone component	Rare	Common	Common

Tone Languages of Asia

Tone languages are abundant in Asia, stretching from Japan in the east to Nepal in the west, and from China in the north to Thailand and Myanmar (Burma) in the south. Sporadic tone languages are also found in Indonesia and Pakistan. Sino-Tibetan comprises the largest family of tone languages in this region, but some Tibeto-Burman languages have no tones, e.g. Amdo Tibetan and the Kiranti languages of Nepal. All of the Tai-Kadai (including Thai and Lao) and Hmong-Mien (Miao-Yao) languages, spoken in Southeast Asia and southern China, are tonal. Nontonal Southeast Asian languages are mainly those of the Austronesian (including Malay, Indonesian, and Pilipino) and Austroasiatic families, with the notable exception of Vietnamese.

Tone is well developed in all Chinese languages. Classic works describe Middle Chinese as having four tonal categories: Level, Rising, Departing, and Entering. Later linguistic development has brought tonal systems of Chinese to extreme diversity. Among Mandarin dialects, for example, some have more tones than Beijing, while others have fewer. Furthermore, pitch values for the same tonal category may also vary from one dialect to another, as shown in Table 2.

Korean represents an unusual case of dialectal variation in tone. While the Central dialect of Seoul is no longer tonal, tone distinctions in Middle Korean have been retained in Northeastern (Hamkyeng) and Southeastern (Kyengsang) dialects. The latter has such contrast as /mál/ 'horse' vs. /māl/ 'measure' vs. /màl/ 'word'.

The majority of tone languages in China and Southeast Asia are of the type of syllable-tone. Word-tone languages are found mainly in Tibeto-Burman languages of Tibet and Nepal, including Ü (Lhasa Tibetan), Tamang, Thakali, and Gurung. In addition, Shanghainese has also been identified as a type of word-tone language.

The best-known pitch-accent language is Tokyo Japanese. Apart from toneless dialects such as Sendai, all Japanese dialects have pitch-accent systems—some simpler while others more elaborate. Another pitch-accent language is Prinmi (Pumi), a Tibeto-Burman language of southwestern China. A three-way contrast exists in monosyllabic words, e.g. /ʃî/ 'louse' (high-falling) vs. /ʃí/ 'hundred' (high-level) vs. /ʃǐ/ 'new' (rising), but the first two words are nearly neutralized in the citation form. Tonal distinctions in Prinmi are made by specifying the locus of the H tone in the templet and whether it spreads to the next unit. Expressing these two parameters as [n] [±spread], the full patterns of the seven tonal categories of Prinmi are illustrated as in Table 3.

Tone Languages of Africa

The great majority of African languages south of the Sahara have tone. Except for Fulani, Wolof, and Swahili, the rest of the Niger-Congo family are almost all tonal. So are the Nilo-Saharan and Khoisan families. Afroasiatic languages, other than Semitic (e.g. Arabic and Amharic) and Berber, are also tonal. With a wealth of complicated tonal data, African languages have contributed significantly to the advance of autosegmental phonology.

While only a few Asian languages use tone to distinguish word categories, African languages frequently exploit tone to signify grammatical categories such as tense, gender, number, and so forth. Shona (spoken in Zimbabwe) contrasts lexical and/or grammatical meanings of the following set of words by tone alone: (1a) /vá-nò-pàr-à/ 'they offend', (1b) /và-nó-pàr-à/ 'the ones who offend', (2a) /vá-nò-pár-á/ 'they scrape', (2b) /và-nó-pár-á/ 'the ones who scrape'. Similarly, tone in Hausa (spoken in Niger and northern Nigeria) differentiates lexical meanings, e.g. /góoràa/ 'bamboo' vs. /gòoráa/ 'large gourd', and grammatical meanings, e.g. /màatáa/ 'wife' vs. /máatáa/ 'wives', and /kíráa/ 'call' vs. /kíràa/ 'calling'. Indeed, the grammatical tone predominates in most African languages. Another remarkable phenomenon observed in many African tone languages is 'downstep', in which a floating low tone (resulted from deletion of segments) causes the pitch of a high tone to be lowered.

With typological similarity to Southeast Asian languages, some West African languages have developed syllable-tone systems, e.g. Grebo (spoken in Liberia). The language has four primary tonal categories (the lowered numeral₁ indicates the highest pitch): (A)

TABLE 2 Varying Pitch Values of the Tonal Categories in Major Dialects of Mandarin

Tonal Categories	Beijing	Wuhan	Guiyang	Chongqing	Kunming
(1) *Yin-ping* (High-level)	55	55	55	55	44
(2) *Yang-ping* (Low-level)	35	213	21	11	31
(3) *Shangsheng* (Rising)	214	42	53	42	53
(4) *Qusheng* (Departing)	51	35	24	24	212

TABLE 3 Tonal Categories in the Pitch-Accent System of Prinmi (R=Rising)

Category	Parameters	Monosyllable	Disyllable	Trisyllable	Quadrisyllable
A	[1] [−spread]	Falling	**H**-L	**H**-L-L	**H**-L-L-L
B	[1] [+spread]	High	**H**-H	**H**-H-L	**H**-H-L-L
C	[2] [−spread]	Rising	L-**H**	L-**H**-L	L-**H**-L-L
D	[2] [+spread]		L-**H**	L-**H**-H	L-**H**-H-L
E	[3] [−spread]		L-R	L-L-**H**	L-L-**H**-L
F	[3] [+spread]			L-L-**H**	L-L-**H**-H
G	[4] [spread]			L-L-R	L-L-L-**H**

High Rising: /na$_{21}$/ 'drink', (B) High: /na$_{22}$/ 'fire', (C) Mid Rising: /hɛ̃$_{32}$/ 'four', and (D) Low: /tɛ̃$_{44}$/ 'test'.

Mende (spoken in Sierra Leone) has a word-tone system with five major tonal categories: H, L, HL, LH, and LHL. The following words belong to the final category: /mbã/ 'companion', /nyàhâ/ 'woman', and /nìḱinì/ 'groundnut'. Etung (spoken in Nigeria) also appears to be a word-tone language. It has eight tonal categories: H, L, HL, LH, HLH, HHL, LHL, and LLH.

Somali (spoken mainly in Somalia, Ethiopia, and Kenya) is a pitch-accent language. According to Saeed's *Somali* (1999), its tonal system is organized into three major categories: (A) H on the last mora (a short vowel has a mora, whereas a long vowel or diphthong has two), (B) H on the penultimate mora, and (C) H on nowhere, i.e. L throughout. Note that the locus of H in the templet is counted from the right. Furthermore, Somali does not multiple its tonal categories with H-spreading; H always spreads leftward to the vowel in the same syllable. The three tonal categories are exemplified as follows: (A) /wéyl/ 'female calf', /ˋinán/ 'girl'; (B) /wéỳl/ 'male calf', /ˋinàn/ 'boy'; and (C) /àmà/ 'or', /kùlùlàà/ 'hot (past tense)'.

Although representative syllable-tone, word-tone, and pitch-accent languages can be identified, a large number of African languages do not fit into these prototypes; many have been regarded instead as 'restricted tone languages'. Some of them might have pitch-accent systems. Many Bantu languages appear to be intermediate between word-tone and pitch-accent systems. We shall arrive at a better classification of these languages when a thorough understanding of the fundamental organization of their tonal systems is available.

Other Tone Languages

Many indigenous languages of the Americas, especially those of Central America, are tonal. Tone development differs considerably among North American languages, e.g. while Achumawi (of northern California) has tone, no tone contrast exists in Atsugewi, a closely related language. Like African languages, American languages employ tone for both lexical and grammatical contrasts.

The San Juan Copala dialect of Trique (spoken in Mexico) shows a syllable-tone system with eight tonal categories, e.g. /yã$_{21}$/ 'be sitting', /yã$_{32}$/ 'corncob', /yã$_{33}$/ 'he is sitting', /yã$_{34}$/ 'salt', /yã$_{35}$/ 'scar', /yã$_{44}$/ 'unmarried', /yã$_{55}$/ 'one (in certain number phrases)', and /yã$_{53}$/ 'Spanish moss'. Similarly, minimal sets of tonal contrast in Sarcee (spoken in Canada) may distinguish word meanings or grammatical meanings: /míɬ/ 'moth' vs. /mīɬ/ 'snare' vs. /mìɬ/ 'sleep' and /-ló/ 'hurt (continuative)' vs. /-lō/ 'hurt (imperfective)' vs. /-lò/ 'hurt (perfective)'. Stress plays an important role in the tonal system of some Central American languages such as the Chinantec languages.

Donohue reports in *Linguistic typology* (1997) that many languages in New Guinea have tone. Iau (spoken in Irian Jaya, Indonesia) has a syllable-tone system with eight tonal categories: /du^{44}/ 'wild pig', /u^{33}/ 'tree', /da^{45}/ 'dog', /tai^{23}/ 'landed', /tai^{42}/ 'fallen', /tai^{423}/ 'falling', /of^{43}/ 'arm', and /ko^{32}/ 'breadfruit'. Teléfól (spoken in Papua New Guinea) is a simple syllable-tone language with a rising tone against a falling one: /kŭl/ 'hand' vs. /kûl/ 'frog'. Word-tone languages include Enga, Kairi, and Usarufa, etc. Kairi has four tonal categories: H, LH, HL, and LHL. The final one always contains a falling tone, e.g. /pâ/ 'tree species', /tùĥi/ 'lid', and /àràmèrâu/ 'basket type'. Pitch-accent languages are numerous in New Guinea, but tone-spreading is generally absent. Una (spoken in Irian Jaya) generates four tonal categories by placing the marked H on the *n*th syllable, where *n* varies from 0 to 3: (A) /kàl/ 'marsupial species'; (B) /kál/ 'tree species', /kúnkàlyà/ 'joint'; (C) /kùnkályà/ 'pimple'; and (D) /bìlbìlýi/ 'building materials'.

Translation

Translation occurs when a message or text produced in one language (the 'source' language) is converted into a message or text in another language (the 'receptor' or 'target' language). When used in contrast to interpreting (the conversion of spoken text), translation denotes the conversion of written text. Conversion, however, may often be across different modes, as in 'sight translation', in which a written source text is converted into a spoken target text. Here, therefore, we take the wider definition. Messages can also be translated between varieties of one language (e.g. supplying standard-language subtitles for dialect film dialogue).

Translation studies is a long-established discipline that examines both theory and practice. It has three main concerns:

- Prescriptive: To give practical advice to translators. This tradition has existed for millennia: written advice dates back, e.g. to Cicero in ancient Rome, or to Zhi Qian in third century CE China. More recently, it expresses itself in the search for reliable means of assessing translation quality and in an academic interest in translator training issues.
- Philosophical: Scholars and philosophers, from the medieval Jewish cabalists to Jacques Derrida in modern France, have explored how translation, as communication that transcends a single language, might shed light on key issues of human communication, for example, whether there might have been a single ancestor of all the world's languages, whether meaning is tied to language or independent of it, or whether one person's words mean the same when spoken by another.
- (Applied) linguistics: Nowadays, however, translation studies is usually seen as a discipline that explores the nature of cross-language communication. It draws on (and contributes to) a wide range of fields, such as semantics, pragmatics and discourse analysis, psycholinguistics, communication science, and culture and gender studies.

A key concept in translation studies is that of 'equivalence': the degree of similarity between source and target text or text element (section, paragraph, phrase, or word). In size terms, the target may be roughly as long as the source; it may summarize the source (e.g. an English précis of Japanese company documentation); or it may be an exegetic (explanatory) expansion of the source (e.g. when translating holy scriptures). In qualitative terms, the target may

- Parallel the source's exact words and syntax (an 'interlinear' translation), often in order to explain or gloss the source.
- Reproduce the source's semantic content (a literal translation).
- Convey the source's communicative effect (a 'communicative' or 'dynamic-equivalent' translation), e.g. when translating the Chinese *Chi fan le ma?* (literally, 'Have you eaten yet?') as 'How are you?'

Establishing 'correct' equivalence becomes especially problematic when source and target languages are very different in terms of

- Culture (e.g. how can one convey the sense of the Arabic word *jihad* to a reader with no understanding of Islam?).
- Time (e.g. should one translate Shakespeare into modern or Renaissance French?).
- Linguistic explicitness: For instance, classical Chinese poetry's lack of pronouns causes problems for the translator into modern English (should the subject be 'I' or 'she'?).

Recent models of translation see texts within the framework of a wider communicative act, in which the translator—as source-text receiver and target-text producer—is a key actor:

Original writer/speaker → Writes/speaks → Source text → Read/heard by → Translator → Writes/speaks → Target text →Read/heard by → Target reader/listener

An expert translator has reading and writing (or listening and speaking) expertise in one or more specialist genres; moreover, one source text may have several different equivalents, none of which is necessarily the best. Hence, the translator is now seen as less of a reproducer and more of a creator or re-creator, making active choices on the basis of genre knowledge, intuitive feel, and personal preference. At the whole-text level, translators may have to choose between

- Source-oriented translation: Staying faithful to the original writer's or speaker's wording and intentions. This may involve 'foreignizing' (deliberately retaining source-language or source-culture features), 'idiosyncratic' translation (reproducing the original's stylistic individualities), or both.

- Target-oriented translation: Keeping the target text's new purpose and readership uppermost in mind. For example, the great Arab translator Hunayn Ibn Ishaq (809–873 CE) chose to convert the Greek specialist medical manuscripts of Galen into popular-medicine handbooks. This may also involve 'domesticating' (adapting the text to target-culture norms), 'smoothing' (removing the source's stylistic individualities), or both.

In recent years, translation process studies have examined how translators translate. Among the typical features of translating written prose revealed by these studies are the following:

- During translation, the translator reads ahead a sentence or so at a time, analyzing sentences into clauses and clauses into phrases.
- By default, the actual translating tends to occur phrase by phrase.

- Translators regularly backtrack to modify the emerging target text in terms of word choice, discourse, style, and so on.
- First drafts are usually revised, preferably at a later date.

In much technical or commercial translating (as opposed to literature or advertising, for example), there may be no conflict between source- and target-oriented tactics, because many source and target genres (e.g. Dutch and American air-conditioning documentation) follow the same textual rules. At word, phrase, or clause level, however, problems inevitably occur; much of the translator's creativity consists of selecting strategies for solving such problems. Among the translation strategies identified by translation process research are the following:

- Consulting a dictionary or other reference materials.
- Paraphrasing or adding an explanation.
- Compensation (e.g. replacing a pun by an idiom, or by a pun in a different place).

The translator may also have to make ideological decisions. Choosing whom to translate and not to translate in a region of conflicting identities (e.g. 1990s Bosnia and Serbia) inevitably means taking sides. Translating into a world language such as English, especially if domesticating tactics (see above) are used, may risk contributing to a neoimperialist McDonaldization of world culture, although it may equally be a way for 'minor' cultures to make themselves heard on their own terms. Feminist translation theory raises ideological issues that extend beyond gender, such as whether translators should 'improve' offensive (e.g. sexist) texts or the role of the translator in rediscovering forgotten (female) writers.

FRANCIS R. JONES

Trubetzkoy, Nikolai Sergeyevich

Nikolai Sergeyevich Trubetzkoy was an important member of the Linguistic Circle of Prague, a group of linguists interested mainly in the analysis of the sound systems of languages. Following the French linguist Ferdinand de Saussure, these linguists based their work on a distinction between parole, language being used, and langue, language as knowledge. In terms of sound systems, this distinction appears as a clear division between phonetics, the science of speech sounds as actually produced by speakers, and phonology, the science of language sounds as mental representations.

Trubetzkoy published extensively during the 1920s and his writing defines the Prague School views on phonology. The most comprehensive and explicit formulation of his theory can be found in his *Grundzüge der Phonologie*, published posthumously in 1939 (English translation 1939, *Principles of phonology*).

Phonetics, as Trubetzkoy sees it, is the study of speech sounds as they are physically instantiated, i.e. it deals with the production or articulation of speech sounds and their acoustic features that are relevant for perception. Phonology is a level of analysis that is one step removed from the physical dimension: it abstracts away from the variability of actual pronunciations and attempts to filter out the constant characteristics or features of speech sounds that, for example, allow a hearer to perceive equivalent utterances of different speakers as essentially the same. Thus, phonology describes the abstract mental representations of speech sounds that must be more or less the same for all speakers belonging to a given speech community. While the one is more concrete and the other more abstract, phonetics and phonology nevertheless inform on and borrow concepts from each other.

A phonological description starts with the discovery of those phonetic features that differentiate meanings in a given language. Pit and bit mean different things in English and differ only insofar as the first sound bit is produced with vibrating vocal cords ([b] is 'voiced'), while the first sound in pit is not ([p] is 'voiceless'). Thus, the voiced/voiceless distinction is crucial in English (it is not necessarily so in other languages), and voicing is thus referred to as a 'distinctive feature' in the phonology of English. *Principles of phonology* concentrates mainly on such distinctive features.

Building on a concept elaborated by the Russian linguist Jan Baudouin de Courtenay, Trubetzkoy argued that words contain 'phonemes,' basic sound units that distinguish one word from another. Trubetzkoy was a structuralist thinker, i.e. he did not think that phonemes could be defined by themselves, but only in relation to each other. The basic measure of difference is opposition; a sound stands in opposition to another insofar as the presence of one means the absence of the other. If the presence or absence of a given sound unit creates differences in meaning in a given language, it is a phoneme of that language.

This concept of phoneme developed by Trubetzkoy is typical of the so-called functionalist approach of the Linguistic Circle of Prague. For Trubetzkoy, the phoneme can be defined neither by its psychological character nor by its relationship with its phonetic variants, but by its function. This is where Trubetzkoy's thinking differs from that of his contemporaries such as Leonard Bloomfield or Daniel Jones.

Once the phoneme inventory of a language is established, the phonologist must determine the distinctive features that differentiate the phonemes from one another. /p/ and /b/ differ, for example, in voicing, while /p/ and /t/ differ insofar as they are articulated in specific different locations in the mouth. In his work on distinctive features, Trubetzkoy developed two important concepts: 'neutralization' and 'archiphoneme'. Sometimes, different phonemes of a given language are pronounced exactly alike, i.e. their distinctive feature has been suppressed. If this occurs in a systematic fashion, e.g. in a particular position within a word, Trubetzkoy says that the distinctive feature has been neutralized. German, for example, distinguishes the phonemes /t/ and /d/, i.e. voicing is a distinctive feature just as in English. German, however, devoices sounds at the end of words: *Rad* 'wheel' is pronounced exactly like *Rat* 'counsel'. Thus, German neutralizes the voicing distinction in word-final position. Trubetzkoy calls the representation of such neutralized elements 'archiphonemes'. Thus, an archiphoneme is a phonological unit characterized by only those distinctive features that have not been neutralized. Thus, Trubetzkoy's idea of the archiphoneme is related to the concept of phonemic 'underspecification' in modern distinctive feature theories.

Phonemes and distinctive features are the main phonological elements that Trubetzkoy used to describe the phonological system of a given language. These elements are defined through their relationships with the other elements of the phonological system of that language. These ideas are the basis of the structuralist (and

functionalist) phonology for which Trubetzkoy is mostly known.

However, Trubetzkoy is also well known as the first linguist who called for a new discipline, namely 'morphonology' (or 'morphophonology'), to describe the interaction of phonological and word structures (morphemes). In his principal work on morphonology ('Gedanken über Morphonologie'), Trubetzkoy discusses the phonological structure of morphemes and develops a theory of how the phonological shape of morphemes changes under particular conditions.

Biography

Nikalai Sergeyerich trubetzkoy was born in Moscow, Russia on April 4, 1890. He began studying Russian ethnography and folklore at the age of 13 and published on Slavic languages and Finnish folklore before entering university. He studied at the University of Moscow in 1908–1912. He received his doctorate from Moscow in 1913 with a dissertation on the future tense in Indo-European. He became Assistant Professor, University of Moscow in 1915; he fled to Rostov after the 1917 Russian Revolution, where he taught Slavic Philology at the University. He was Professor of Comparative Linguistics at the University of Sofia (Bulgaria), 1920–1922, and Professor of Slavic Philology, University of Vienna, 1922–1938.

He was a member of the Prague Linguistic Circle since 1926 and a member of the Academy of Sciences at Vienna, in 1930. Trubetzkey died on June 25, 1938.

Tuareg and Berber Languages

Berber, which is the mother tongue of the first inhabitants of North Africa, is a Hamito-semitic language. It is spoken chiefly in North Africa, namely: Morocco, Algeria, Tunisia, Libya, and Egypt. Berber is also spoken by the Tuareg populations in Mali, Niger, and Burkina-Faso. The regions where Berber is used are discontinuous in nature; that is, they are surrounded by Arabophone or other populations. These discontinuous groups may range in size from a tribe, a village, or even a greatly populated center.

The Berber population can be divided into four major groups. First, we have Morocco, where the Berberophones are estimated to comprise about 40% of the overall population. Second, there is Algeria, in which approximately 25% of the population is Berber (cf. Grandguillaume 1983; Chaker 1990 and Ennaji 1991). This means that the Berber-speaking population is around 9.5 million in Morocco and 5.5 million in Algeria. Third, we have the Tuareg populations, which represent around 3 million people scattered in the sub-Saharan countries, namely: Niger, Mali, and Libya. The fourth population group totals about 140,000 people; these are generally in small and isolated areas, particularly in Tunisia (less than 100,000) Mauritania (about 10,000 people), and Siwa in Egypt (30,000 people). cf. Chaker (1990) and Mustapha (1993).

Tuareg

Tuareg is a variety of Berber spoken in Mali and Niger in West Africa; it has an alphabet called Tifinagh. Tuareg people used to be called 'hommes bleus' (blue people) because they lived in an immense desert and were brave and respectable people. The Tuareg were colonized by France until 1960 when Mali and Niger obtained independence.

Today, Tuareg people are scattered over Mali and Niger; after four decades of independence, Tuareg people living in these two countries feel excluded and their language and culture marginalized. Many cultural associations in the region militate for the official recognition and revitalizing of Tuareg language and culture. In a letter addressed to the United Nations on August 1, 1997, Abdoulahi Attayoub, president of the association 'Survie Touarègue' asked the UN to protect the Tuareg minorities in Mali and Niger whose rights were violated and whose lives were in danger because of racial discrimination instituted by the regimes in place. Thus, thousands of Tuareg people were killed by the army in both countries between 1980 and 1995. Others fled their country and settled in Algeria, Mauritania, and Burkina-Faso, where they still live in hard conditions (see the journal *Tifinagh* 1998, issue 3).

Since the periods of independence, the different governments that took power in Niger and Mali marginalized the Tuareg people and often attempted to wipe out their language and culture. The Tuareg regions have been deprived of all hope of socioeconomic development, and their cultural space has been denied to them.

The Tuareg people live in Central Sahara and on the borders with the Sahel. They call themselves Imajighen, Imoushagh, or Imouhagh depending on the regions; their language is called Tamajeq, Tamasheq, or Tamaheq. The Tuareg language is generally considered the most well-preserved and the richest of the Berber languages. Tuareg people have retained an original alphabet called Tifinagh, which is derived from an ancient Berber writing system that was used in all North Africa and in the Sahara.

The oral tradition in Ahaggar shows that Tuareg people are the descendants of Tin-Hinan, queen and mythical ancestor of the north. Their political system was based on a confederation, where power belonged to the direct descendants of this queen mother, who is the founder of the linguistic community of the Tuareg language. All Tuareg people have a common history, the same language, and the same lifestyle, which are the bases of a solid feeling of belonging to their land and of a common cultural identity called Temoust.

Traditionally, there were seven Tuareg confederations, which are today distributed as follows: Ahaggar (in Algeria and Niger), Ajjer (in Libya and Algeria), Aïr (in Niger), Azawad (in Niger and Mali), Adghagh (in Mali), Tadamakkat (in Mali), and Oudlan (in Burkina-Faso). Today's political borders are inherited from the days of colonization; they have cut the Tuareg country into many parts that are integrated into the five countries cited above.

Because of the lack of a census where the linguistic factor is taken seriously into account, the population of Tuareg people is estimated to be around three million: 1.5 million in Niger, 1 million in Mali, and 500, 000 in the other countries (Algeria, Libya, and Burkina-Faso). Today, the Tuareg people, who are generally proud of their langue, struggle to freely use their mother tongue and their culture. But because of the pressure put by the authorities in both Niger and Mali on Tuareg people, some young native speakers feel it is degrading to speak *Tamacheq* in public (see Elékou 1998).

Berber Languages

Of all the North African countries, Morocco has the largest Berber-speaking population, followed by Algeria. The above estimates are only tentative, as exact figures are impossible to provide given that the old censuses in Morocco (1982) and in Algeria (1986) did not take into account the linguistic situation. However, the most recent Moroccan census (organized in 1994), which was also concerned with the linguistic factor, reveals that approximately 11 million Moroccans speak Berber today.

Nearly half of the Moroccan population is Berberophone; i.e. they are monolingual Berbers, and the majority of them are bilingual because they also speak Dialectal Arabic. The monolinguals are basically very small children and old people who do not participate in active life, whereas the bilinguals are usually the young and the educated. Berberophones are considered illiterate as long as they do not master Standard Arabic or French.

Berber is a spoken language with virtually no real written history. Unlike the North African populations, the Tuareg populations in the south of Algeria and Mauritania — as mentioned above — have preserved an old writing system called *Tifinagh*, which has been handed down from generation to generation through centuries. However, there is no evidence that *Tifinagh* has ever been utilized to write down history or literature.

Today, the Classical Arabic script is at times used by creative writers, close friends, or members of a family to write personal letters. Resorting to writing Berber in Arabic script is often due to the lack of mastery of the Classical Arabic language. The Moroccan Association of Cultural Exchange publishes a periodical in Berber entitled *Amud*, where Berber is written by means of the Arabic writing system. In Algeria, Berber textbooks and novels are written in Latin script (cf. for example, the works of Mouloud Mammeri, Rachid Aliche, and Ramdane Achab). The Tifinagh script, which has been recently revived and modernized, is widespread in the Berber populated area of Kabylie (see Chaker 1984:37).

In Morocco, there are three main Berber dialects. First, there is Tarifit used in the Rif, north of the country. Second, there is Tamazight, spoken in the Middle Atlas, and east of the High Atlas. Third, there is Tashlhit, spoken in the High Atlas and the Anti-Atlas Mountains, south of Morocco.

The Berber dialects spoken in Morocco are generally mutually intelligible unless the two varieties in question are situated at extreme geographical points. For example, a native speaker of Tarifit in the north can hardly understand or communicate with a speaker of Tashlhit in the south. Additionally, the Berber dialects used in Morocco and Algeria are usually mutually incomprehensible.

In Algeria, there exist four major Berber dialects. First, there is Kabyle, which is spoken in the area of Kabylie, near Algiers and Bougie. Second, there is the Shawia dialect spoken by the populations of Aures, north of Constantine. Third, there is the Tuareg dialect, which is a variety that is largely used in the extreme south of Algeria. Fourth, there is the Mzab dialect in the Ibadhits, notably in Ghardaia.

In Tunisia, the Berber population is less important. Berber is spoken only in the extreme south of the country. There exist a handful Berberophone villages, chiefly situated in Djerba, in the west of Matmata, and in the east of Gafsa (cf. Payne 1983; Chaker 1984).

The traditional segmentation of Berberophone regions into zones does not genuinely reflect the considerable effect of rural exodus that the Maghreb (Morocco, Algeria, Tunisia, and Libya) has witnessed since Independence. As a result, there are nowadays vast Berberophone populations in the urban centers of the Maghreb. Thus, Berber is also spoken in the cities of Algiers, Oran, Tizi-Ouzou, Agadir, Casablanca, Rabat, Fès, Nador, Tangier, and, in fact, in most large cities (see Chaker 1990; Ennaji 1991).

Although there are many Berber dialects, Berber is fundamentally one language (cf. Boukous 1975; Chaker 1984). Although most Berber dialects are generally mutually unintelligible, they share similarities at the phonological, morphological, syntactic, and lexical levels, as will be seen below (cf. Basset 1959; Applegate 1970 for details).

The Linguistic Features of Berber

Historically, Berber has borrowed mainly from Latin, Arabic, and French. The remnants of Latin loanwords are limited to a dozen or so. Nonetheless, the most well-known loans come from Dialectal Arabic and French. Most of these borrowings are nowadays completely adapted to the patterns of Berber. For instance, the Latin words *asinus* (little donkey), *burrhus* (coat), *tussis* (cough) are pronounced *asinus, abernus,* and *tusut* in Tamazight, the Berber dialect of the Moroccan Middle Atlas; The Dialectal Arabic words *sa:'a* (watch) and *Tbib* (doctor) become *tassa't* and *adbib*, respectively, in Berber. The French loans *veste* (vest) and *automobile* (car) become *lfista* and *Tomobil*, respectively, in Berber (see Ennaji 1991).

On the other hand, Berber itself has affected Dialectal Arabic in many ways. A multitude of Berber terms are incorporated in the latter language. If we take the Moroccan context for illustration, we notice that Berber intonation has infiltrated the Moroccan Arabic sound pattern, especially in the cities neighboring Berber villages. Moroccan Arabic is also full of Berber loans; for instance, the following Moroccan Arabic words originate from Berber: *brra* (outside), *berrm* (turn), *atay* (tea), *taRunja* (prayer for rain), and *tiwizi* (collective land ploughing).

Most of these lexical items are fully integrated in the Dialectal Arabic inflectional system and so widespread that few Moroccan Arabic speakers today will recognize them as Berber. However, the more a Berber dialect is geographically distant or isolated from the urban centers, the less affected it is by the Arabic language. This is evidenced by the fact that in towns and cities, Berberophones tend to use more Arabic loans than in the rural Berber areas. Nonetheless, the young generation of Berberophones is much more influenced by Arabic than the old generation. This is mainly due to the importance of urbanization and the expansion of schooling and Arabization in the educational system (see Ennaji 1988; Elbiad 1991).

Linguistically, Berber has the following intrinsic features. First, phonologically, it resembles Dialectal Arabic in that most of the consonants and vowels existing in Dialectal Arabic do exist in Berber. Nevertheless, there is a difference as far as the verb system is concerned. The latter is not much affected by Dialectal Arabic. For example, most of the loan verbs are integrated in Berber verb morphology with no consequence on the verb group pattern. By way of illustration: *xdm* (work) --> *i-xdm* (he worked); *jawb* (answer) ---> *t-jawb* (she answered). This shows that the Berber verb inflection is essential for sentence formation and meaning, which accounts for the verb system's resistance to Arabic influence.

Evolution of Berber

Berber has experienced a gradual regression in Tunisia, Morocco, and Algeria. As we have already mentioned, the number of Berber speakers in Tunisia has dramatically dwindled to about 100,000, while in Morocco and Algeria the number of competent native speakers of Berber is also regressing, especially in urban areas where Dialectal Arabic is more powerful and commonly used.

Four major reasons lie behind the regression of Berber. First, there is the phenomenon of rapid urbanization, which is itself the result of migration from rural areas to urban centers. Thousands of Moroccan Berberophones have quit their homes and villages in the last four decades to settle down in cities

like Casablanca, Agadir, Rabat, Nador, El-Hoceima, Fès, and Marrakesh to better their lives.

Second, there is the expansion of free education since Independence. Thus, the schooling of Berber-speaking children meant their Arabization and their gradual loss of competence in Berber for the latter is excluded from education. This is a factor that can be remedied if Berber is seriously taught as a language in public schools.

Third, there is the fact that most Moroccans are aware that Berber is pragmatically a local language whose use is not widespread, unlike Arabic or French, and hence it is not useful in business, science, technology, and international affairs. Its role is merely confined to the cultural, social, and historical domains (cf. Ennaji 1991).

Finally, the fact that Berber is officially treated as 'a dialect' discourages people from using it in all walks of life. Many Berberophone parents no longer interact with their own children in Berber, simply because they feel that Berber lacks prestige and does not enjoy the status of a language (see Boukous 1997). One way of verifying the regression of Berber is to examine the domains in which it is normally used. Unlike in the 1940s and 1950s when Berber was spoken not only at home but also in the public administration and in political circles, nowadays Berber is virtually limited to home and to conversation among close friends. Dialectal Arabic is rapidly gaining ground to the detriment of Berber even in homes of Berberophones and even in rural areas where Berber was hitherto the predominant language of communication. For instance, Berber is implicitly rejected in administrative offices, in the private sector, and in political spheres (cf. Sadiqi 1997; Boukous 1997). Because of this rapid decline, intellectuals and progressive forces in the region have recently begun a campaign seeking the revitalization of the Berber language and culture. This campaign has resulted in positive changes in officials' and people's attitudes toward Berber, as we will see in the section below.

Tuareg and the other Berber languages are spoken in the Maghreb and the Sahel. They enjoy both historicity and vitality. They are historically among the oldest languages in the world. Tuareg Berber is marginalized although it is spoken by approximately 3 million people scattered around five different countries: Mali, Niger, Burkina-Faso, Algeria, and Libya. It is the Berber cultural influence that gives Morocco and Algeria their history, and that makes them so different from the rest of the Arab world. Berber remains vital because it is still spoken by a great part of the population in North Africa. The recent revival of interest in Berber language and culture is a good indication that its vitality will be strengthened to the extent that it may be raised to the level of a standardized and codified language in the future.

Tungusic

The Tungusic languages are spoken by small, mostly rural populations scattered across East Asia. The northernmost language, Even, is found in the northeastern region of Siberia between the Lena and Anadyr' rivers, although one Even speech community is located farther east on the Kamchatka peninsula. The southern

geographic boundary of the Tungusic languages is defined by Solon and Orochen, which are situated in and around the Hinggan mountains of China. To the west, one finds Evenki speakers along the Yenisey River in Russia and Sibe communities in Xinjiang Province in China. To the east, speakers of Orok and Evenki inhabit Sakhalin Island. Despite the large area over which the Tungusic languages are spread, the highest density of Tungusic languages is within the Amur River basin in southeastern Siberia, where there are speakers of Oroch, Negidal, Evenki, Nanai, Udege, Orok, Kili, and Ulch.

Although scholars agree that the Tungusic languages constitute a distinct language family, some uncertainty surrounds exactly how individual languages are related. The family is commonly divided into three main branches: Southern Tungusic (comprising Manchu, Sibe, and the dead language Jurchen), Central Tungusic (comprising Kili, Nanai, Oroch, Orok, Udege, and Ulch), and Northern Tungusic (comprising Even, Evenki, Negidal, Orochen, and Solon). Two points of contention surround this classification. First, disagreements have persisted about how to classify certain languages and dialects, particularly those listed above as Central Tungusic. Second, some linguists argue that Central Tungusic is sufficiently close to Southern Tungusic to warrant combining these two branches into one. Indeed, this notion also characterized many of the early efforts to classify the Tungusic languages, notably the pioneering work of V.I. Cincius and Johannes Benzing. This two-way classification of Tungusic accounts for why the family is commonly referred to as Manchu-Tungusic, with Manchu representing the Southern/Central branch and Tungusic representing the Northern branch.

Regardless of whether a two-way or a three-way classification of Tungusic languages ultimately proves correct, there are certain criteria that have played, and will continue to play, a crucial role in determining the historical relationships among these languages. For example, most Tungusic experts place great significance on the correspondence of word-initial *f-* in Manchu and Sibe with word-initial *p-* in many (but not all) of the Central Tungusic languages and word-initial *h-*, *x-*, or no consonant in Northern Tungusic (e.g. Manchu *faxun* 'liver', Nanai *pa*, Orok *paka*, Negidal *xaxin*, Evenki *hakin*, Orochen *axin*). Another useful characteristic commonly examined for classification purposes is the presence vs. absence of *-g-* between vowels. Where many (but not all) Northern Tungusic languages use the sound intervocalically, it tends not to appear in Southern and Central Tungusic (cf. Orochen *buga* 'land' vs. Manchu *bua* vs. Ulch *bua*).

Traditionally, speakers of most Tungusic languages were organized into small nomadic groups that engaged in hunting or reindeer herding. Their mode of subsistence made it necessary for individual clans to be small and for the clans to be spatially dispersed so as not to overgraze or overhunt particular regions. Although individual clans would remain in contact with each other, the degree of interaction was limited; yet it was not uncommon for individual or families to switch from one clan to another, particularly for the purpose of marriage. The linguistic consequence of these social characteristics was extensive dialect differentiation. These dialects frequently form a dialect chain: speech varieties that are close to each other along the chain are mutually intelligible and are clearly dialect-like in their differences. Varieties farther apart on the chain, however, cease to be mutually intelligible and are thus different enough to be called separate languages. As a result, it is a matter of some difficulty today to make a clear demarcation between languages and dialects; thus, lists of Tungusic languages can vary in content from as few as six members to as many as 17.

An added complication is that Tungusic groups are commonly referred to by names that have been given to them by political authorities and other outsiders. These names do not always accurately reflect linguistic realities. For example, Ewenki (Chinese *Ewenke*) and Orochen (Chinese *Elunchun*) are the names given to two of China's official minorities. The former suggests a connection to the Evenki, one of the official minorities of the Russian Federation. However, some of the Orochen groups in China have a closer linguistic connection to the Russian Evenki than do the Ewenki. Even more confusing is that what the Chinese have designated as a single unit, the Ewenki, turns out to be three linguistically distinct groups, the Solon, the Khamnigan Evenki, and the Yakut Evenki. The last of these groups is intimately connected to the Evenki of Russia, the first two far less so.

Although some points of uncertainty remain regarding the internal classification of Tungusic, much greater debate has emerged over the relationship of the Tungusic family to other language families. In particular, many scholars argue that Tungusic is a member of a macrofamily called Altaic, along with at least Turkic and Mongolic, and perhaps Japanese, Korean, and Ainu as well. Despite a superficial similarity in the grammars of all these languages and suggestive evidence based on shared vocabulary and sound correspondences, proponents of Altaic have not yet been able to demonstrate their hypothesis to the satisfaction of many linguists. Therefore, the question of the connection between Tungusic and other language families remains an exciting area of current research.

The most familiar Tungusic language is Manchu, which served as the language of the Qing dynasty of China (1644–1911), one of the largest empires in his-

tory. Manchu and Jurchen hold a special place within Tungusic as the only two languages for which we have written records that predate the twentieth century. The system used to write Manchu can be described as either an alphabet or a syllabary, i.e. it contained symbols both for individual sounds and for syllables. It was derived from Mongolic script at the very end of the sixteenth century, and the language was used for all manner of official documents and for the translation of many Chinese classics; consequently, a large corpus of written Manchu exists, which has proved invaluable for the reconstruction of proto-Tungusic, the ancestor language, and for attempts to link Tungusic to other language families.

During the reign of the Qing emperors, the use of Manchu steadily declined as more and more ethnic Manchus employed Chinese for their everyday activities. By the time the Qing empire was overthrown in the early twentieth century, the Manchu people had been so thoroughly assimilated into the Chinese language and culture that a linguistically distinct Manchu people had ceased to exist. Despite nearly 10 million people claiming Manchu ethnicity in China today, the best estimates of fluent speakers of the language place the number between five and 30.

The oldest records of a Tungusic language come from Jurchen, a language spoken by the founders of the Jin dynasty of China (1115–1234). These records take the form of inscriptions found in northeastern China and in Korea. The Jurchen writing system, which appears to combine symbols for words as well as for syllables, has not been fully deciphered. However, enough evidence from Chinese lists of Jurchen words exists to establish that the language is closely related to Manchu, either as a historically earlier variety of Manchu or as a dialect parallel to Manchu.

In terms of the number of speakers, the largest Tungusic language is Sibe (Chinese *Xibe*), which, according to the 1982 Chinese census, had 26,760 speakers. Sibe is a dialect of Manchu but has been designated separately within China, primarily because of the presence of a Sibe group in the Jungaria region of Xinjiang Province. Over time this group, which has its origins in Manchu military units sent to protect the frontiers of the Qing dynasty in the mid-eighteenth century, has developed independently from other ethnic Manchu groups. Moreover, the Sibe have been linguistically and culturally influenced by Mongolic and Turkic groups living in Xinjiang.

The only other Tungusic languages that currently have a critical mass of fluent speakers are Solon (estimated 14,000 speakers), Siberian Evenki (estimated 10,000), Even (estimated 7,400), and Nanai (estimated 6,000). In very few of the communities where these language are spoken, however, do children learn them.

Therefore, it is likely that all the Tungusic languages, with the exception of Sibe, will become moribund within the next generation.

In terms of their structural features, Tungusic languages tend to organize their basic clause structure around the pattern Subject–Object–Verb, although individual languages vary in how rigid this word order is. They have large numbers of suffixes, which are used not only on verbs, nouns, and adjectives, but on closed class items such as numerals. For example, Oroqen builds a number of words from numeral roots: *ilan* 'three', *ila-Nna* 'three animals', *ila-la* 'three days', *ila-na* 'a group consisting of three animals', *ila-tal* 'three each', *ila-ra* 'three times', *ila-kan* 'only three', and *ila-ki* 'third'.

Another common characteristic of Tungusic is vowel harmony. Most significantly, the vowels in certain suffixes must match the properties of vowels that are in the word root. For example, in Sibe many derivational and inflectional suffixes have two forms, one with the vowel [u] and one with the vowel [ɨ]. The choice of suffix form is determined by the last vowel in the root. If this root vowel is pronounced with rounded lips, then the suffix containing [u], also a rounded vowel, is employed. If the last root vowel is not rounded, the suffix containing [I], a non-rounded vowel, is used (e.g. *batur* 'hero' yields *batur-lu* 'to be heroic', while *ɔldʒi* 'a capturing' becomes *ɔldʒi-lɨ* 'to capture someone'). Although all Tungusic languages exhibit some harmonizing processes, there is tremendous variation in the form that the harmony takes and in how productive it is. Sibe possesses only rounding harmony, as just illustrated. Other Tungusic languages also have harmony based on the feature of vowel tenseness (e.g. Nanai, where suffixes with a tense vowel, such as the adjective-forming *-su*, as in *densi-* 'to care for'/*d´nsi-su* 'careful', have an alternative form that contains a lax vowel *-sˑ*, as in *sa-* 'to know'/*sa-sˑ* 'well-informed'). Still other Tungusic languages, such as dialects of Oroqen and Solon, have both types of harmony.

Tungusic languages make frequent use of converbs, which are verb forms used for subordinate structures. Consider the following example from Evenki: *si: ↔m↔-tΣ↔l↔ ⫟-s nuŋartin ŋ↔n↔-dʒ↔ŋ↔ ⫟-tin* 'After you come, they will go.' (literally: 'you come they go'). The converb is *↔m↔tʃ↔l↔ ⫟s*, which has been created by attaching *-tʃ↔l↔* to the verb root *↔m↔-* 'come'. This particular suffix indicates that the event expressed by the converb preceded the event expressed by the main verb. Evenki possesses 12 other converb-forming suffixes. The suffixes allow speakers to express many different meanings including simultaneity, posteriority, condition, and purpose.

Another characteristic property of Tungusic languages is that they employ case suffixes on nouns to

indicate grammatical functions. In this regard, the Northern Tungusic languages tend to have far more case inflections than the Southern Tungusic languages. For example, Even differentiates at least 12 cases (*etiken* 'old man', *etike-m* 'old man' (object), *etiken-du* 'old man' (indirect object), *etiken-n'* 'with the old man', *etike-n'un*, *etiken-duk*, *etiken-dula* 'at the old man', *etiken-duli*, *etiken-taki* 'to the old man', *etike-ŋitʃ*, *etike-kla*, *etike-kli*), whereas written Manchu has only five (*ama* 'father', *ama-i* 'of the father', *ama de* 'father' (indirect object), *ama be* 'father' (direct object), and *ama ci*).

Unlike Southern Tungusic, Northern Tungusic languages also contain a set of nominal suffixes that indicate possession (e.g. Oroqen *murin-iw* 'horse-my', *murin-iy* 'horse-your (sing.)', *murin-in* 'horse-his/her', *muri-mun* 'horse-our/excluding the listener', *murin-tir* 'horse-our/including the listener', *murin-ʃun* 'horse-your (pl.)', *murin-tin* 'horse-their').

LINDSAY WHALEY

Turing, Alan

Alan Turing made foundational contributions to philosophy, mathematics, biology, artificial intelligence, and computer science. He, as much as anyone, invented and showed how to program the digital electronic computer. From September 1939, his work on computation was war-driven and practical. He developed high-speed computing devices needed to decipher German Enigma Machine messages to and from U-boats, countering the most serious threat by far to Britain's survival during World War II.

Because of official secrecy, his war time exploits were unknown until the 1980s. By then some of his inventions no longer seemed connected to a real human being. For example, Turing's 1936 paper, 'On computable numbers', was soon seen as the most important theoretical paper ever written on computation. Hence, mathematicians, engineers, and computer scientists came to write of 'turing machines' and 'universal turing machines' almost forgetting that there was an Alan Turing.

In his 1936 paper, Turing answered the deepest computational question — whether there is a finite mechanical procedure for deciding whether any given mathematical statement is true or false. Turing realized that the key was to specify what a 'mechanical procedure' (or computation) was. Mathematicians tended to assume that it meant 'explicit, step-by-step, requiring-no-creativity' and left it at that. Turing saw that if a procedure were mechanical, it could be automated.

Turing's answer is to imagine a starkly minimal machine. He called it a 'theoretical computing engine', because he had no intention of building one. This is a machine with which to think. It is fed by an indefinitely long tape divided into frames like those on a roll of film. The machine has a 'read head', which can tell whether the frame under it has a '/', a '\', or is blank. The read head is also a 'write head' that can erase, write in a '/', or '\', or do nothing. The machine can also move one frame forward or backward or stay in place. Then there is another move and so on. At the beginning of each move, the machine is in one of a small number of 'internal states' and this may switch to another after the move. The machine is built to enact instructions in its machine table of the form 'if / is read and the internal state is 1, then erase, move one frame forward, and go into state 2'. A turing machine for adding would get, say, the input sequence '// //' and then automatically change it into '////' through a long series of steps and then stop. For us this is the computation '2+2=4'. Because Turing was thinking about a theoretical device, he did not mind that a million

would be represented by a like number of '/'s. Indeed, he insisted that an actual and literal universal turing machine would be much too slow for practical computation.

Turing goes on to show that anything mathematicians call a mechanical problem or computation can be represented by some turing machine. Further, he shows that there is a universal turing machine. Depending on the input tape sequence, this turing machine can turn itself into any particular turing machine, do a computation, and then turn itself into another turing machine and do a computation, and so on. In 1936, Turing thought up the general-purpose digital computer and gave its definitive abstract description. The tape can also store data and programs ('memory', 'skills', 'plans'), represent incoming data ('sensory input'), and issue output instructions ('motor outputs'). Thus, Turing has also given the framework in which to describe any sort of individual thinker. As many scientists have said since the 1960s, each human is, more or less, a universal turing machine and so are our digital electronic computers; for the same reason, we now think of thinking as computing or data-processing. To return to his original question, Turing also showed that no possible computer (digital electric, human, or alien) can decide the truth or falsity of every mathematical formula. Turing broke the species barrier: given his minimalist physical description of computability, anything could be a mind whatever its physical composition.

His 1950 paper, 'Computing machinery and intelligence', set the agenda for cognitive science. From it, scientists and philosophers extracted the goal of writing 'intelligent' computer programs good enough to pass the 'turing test' for simulating human intelligence. Although some computer scientists boasted that they would program a 'passer' within a decade, they have not come close after five decades. Turing also suggested several other ways, aside from programming, that might be used to simulate human intelligence. When he did so, he anticipated approaches that were explored in the 1980s and 1990s — training connectionist nets, sending a 'child machine' to school, perhaps equipping it with eyes, ears, and hands. The centrality of natural language in Turing's test, and in human intelligence, is reinforced by the continuing failure of machine translation from one human language to another. Computers now easily exceed the most talented humans in arithmetic calculation and chess playing, but none come anywhere close to the performance of ordinary human translators (in merely taking dictation, our most sophisticated voice recognition programs do not come close to matching the performance of ordinary human secretaries).

In his 1950 paper that created the field of artificial intelligence, Turing asks you to imagine the following 'imitation game'. We have some judges who communicate by a terminal to A and B terminals. One of these terminals is operated by a woman, one by a man. Under the judges' questioning, the woman tries to convince them that she is the woman, while the man tries to convince them that he is the woman. For example, the judges might ask, 'How do you do your hair?' Turing comments that the best strategy for the woman is to tell the truth. Interrogators look for inconsistencies. Telling the truth is the simplest way to avoid them. The man is going to have a lot to keep track of. If the man manages to win, you might say that he can think like a woman.

Turing then proposes that we substitute a computer for the man. If the computer 'passes', that proves that the computer can think like a human being and that proves that the computer can think period. Turing remarked that the test draws a clear line between the physical and mental. He likened putting the contestants in separate rooms, so the judges cannot see them, to musical contests where the players perform behind a screen, so the judges would not be biased by their physical appearance. This is what we now call the 'Turing test'. Turing did not think it was going to be easy to create a passer. He provided a vivid and testable goal for artificial intelligence research.

On the other hand, some of Turing's work was so far ahead of his time that it earned credit only in retrospect. His last published paper (1952) anticipated the most important new approach—chaotic, structure-spawning reactions—in the last half century of developmental biology. But it was not until the late 1970s that scientists began to refer to 'turing structures'.

Biography

Alan Turing was born on June 23, 1912, in London. He studied in Sherborne School, 1926–1931 and Wrangler, Mathematics Tripos, King's College, Cambridge, 1931. He received his Ph.D. from Princeton University in 1938; he was Fellow, King's College, 1935–1945; Princeton University, 1936–1938; British Foreign Office, Bletchley Park, 1939–1945; National Physical Laboratory, 1945–1948; and University of Manchester, 1948–1954. He received the Smith's Prize from Cambridge University in 1936 and the Order of the British Empire in 1946. He was Fellow, Royal Society in 1951. In 1952, Alan Turing was convicted of 'homosexual acts' and legally forced to take huge hormone doses that rendered a man who nearly represented Britain in the 1948 Olympic marathon impotent, femininely breasted, and obese. He died of self-administered cyanide on June 7, 1954, in Manchester, England.

Turkey

The name Turkey, as historical Anatolia (and a small part of the European mainland) was officially renamed in 1923, incorrectly implies that the land is home to the Turkish language. In fact, Anatolia was the traditional home of a number of Indo-European languages (notably Ionic Greek in the west, Hittite in the center, Pontic Greek in the north, and Armenian in the east) and several autochthonous languages including Hurrian, Hattic, Urartian, and Laz. Turkish and its closest relatives only began to appear in Anatolia in the eleventh century AD, and during the six centuries of Ottoman rule (thirteenth to twentieth centuries) expanded far beyond the borders of present-day Turkey and largely supplanted its linguistic predecessors. Dialects of Turkish are still spoken in small pockets in the Balkans, especially Greece and Bulgaria, as well as in Syria. More recently several other language families have become established in Turkey, notably Kurdish in the southeast and various northwest Caucasian languages in the north and west.

These minority groups and their languages and cultures were tolerated to some extent during most of the Ottoman period, but the Empire in its last days and the Republic that replaced it (1923–present) has implemented a number of military and legal actions designed to minimize their presence, most importantly the elimination of the sizeable Armenian and Greek populations in 1915–1922, the name substitution program, which replaced more than 30,000 traditional place names (primarily Greek and Armenian) with new Turkish names, and Law 2932, passed in 1983, which prohibits publishing in languages other than Turkish. Children, moreover, are generally forbidden to speak a language other than Turkish at school, and with few exceptions, radio and television broadcasts in minority languages (especially Kurdish) are not allowed. Only the officially recognized religious minorities (Greeks, Armenians, and Jews) are permitted to teach in their respective languages at the primary and secondary school levels. As a result of these constraints and increasing urbanization over the last few decades, the many minority languages of Turkey have been severely eroded, and many have disappeared entirely. There are at least 37 languages currently or formerly spoken natively in Turkey, but most of these are in danger of disappearing in the near future.

The largest language at present is Turkish, spoken by more than 60 million residents of Turkey, about 90% of the population. As of 1995, there were some 13 million additional speakers in other countries, primarily Germany, Bulgaria, Greece, Macedonia and Yugoslavia, the Netherlands, France, Romania, and Cyprus. Other Turkic languages are represented in Turkey as well, including (as of 1982) Azeri (530,000 in the Kars province), Gagauz (327,000), Kazakh (600+), Kirghiz (1,137 in the provinces of Van and Kars), Tatar (several thousand, including the Crimean Tatar village of Karakuyu in the province of Ankara), Turkmen (925 in the province of Tokat), Uyghur (500+ in Kayseri and Istanbul), and Uzbek (1,981 in the provinces of Hatay, Gaziantep, and Urfa).

Within the Indo-European family, the largest representatives in Turkey until the early twentieth century were Greek and Armenian, which had about two million speakers each in Turkey in 1900. At the present time, there remain a few tens of thousands of Greek speakers in Turkey (mostly Muslims from the eastern Black Sea area; Orthodox Greeks now number only 3,000 in the entire country), and less than 50,000 speakers of (Western) Armenian, almost all of them in Istanbul.

There are also dozens of villages in Artvin, the northeasternmost province of Turkey, in which varieties of Homshetsma, a western Armenian dialect, are still spoken. The exact number of Hemshinli who still speak their ancestral language is unknown; 20–30,000 would be a rough estimate. All Hemshinli speak Turkish as well, and the western Hemshinli (who live in the Rize province) now speak only Turkish, peppered with remnants of their original Armenian dialect (Bläsing 1992). This change was precipitated by the conversion of the Hemshinli from the Armenian Apostolic church to Islam beginning in the sixteenth century; those Armenians who did not wish to convert fled primarily to the Black Sea coastal regions of Abkhazia and Russia, where they still reside today. Most Hemshinli at present do not consider themselves to be Armenian, and many of those who speak Homshetsma are unaware that it is a form of Armenian, a belief that is facilitated by the large number of Turkish loanwords and the Turkic-like structure of the grammatical system.

The Boshas or Poshas, sometimes referred to as Armenian gypsies (because of their language, not their ethnicity), also reside in Turkey (chiefly Istanbul; there are also communities in Erevan, Armenia, Javaxk, Georgia, along the Black Sea, and in other areas fomerly inhabited by Armenians) and speak a language related to Armenian. This language, Lomavren (containing Lom 'gypsy' + the Armenian language suffix -(e)rēn), is a 'mixed language', wherein the lexicon is largely Indic (as with all gypsy languages) and the grammar and phonology are based on the Armenian dialect of Erzerum in northeast Turkey, where the Boshas once resided. As of 1982, there were also at least two other gypsy languages spoken natively in Turkey: approximately 20,000 speakers of Domari, mainly in western Turkey, and some 40,000 speakers of Balkan Romani (Arlija).

The Indo-European branch that is best represented in Turkey today is Iranian, thanks primarily to the several million speakers of Kurmanji and other dialects of Kurdish, but also Zaza (or Dimli; one million speakers in 1992), Herki, and Shikaki. Bilingualism with Turkish among the Iranian populations in Turkey is not as common as it is with the other minority languages, presumably due to the significantly greater size and viability of the community, geographical obscurity, and the lower literacy rate (28%) than in the population as a whole (about 70%).

Speakers of the northeast Iranian language Ossetic have been reported in Bitlis (Digor dialect) and Sarıkamış and Erzerum (Iron dialect). Speakers of various Ossetic dialects have also been reported in Muğla, Kars, and Antalya.

At least two Balkan Slavic languages are represented in Turkey as well: Bulgarian (270,000 speakers in 1993, scattered in Edirne and other western provinces) and Bosnian (20,000 first language speakers in 1980, out of an estimated 61,000 Bosnian Turks scattered through western Turkey). It is not entirely clear how these populations have been affected by the upheavals in Bosnia and Kossovo in the 1990s, but there was at least a temporary exodus to Turkey during that period; the same holds for the Albanian speakers in Turkey, who numbered about 65,000 in 1993, scattered over western Turkey.

The Anatolian branch of Indo-European was located entirely in what is now called Turkey. The family includes Hittite, Luvian, Lycian, Lydian, Palaic, and Carian, and appears to have completely died out by about the end of the first millennium BC. Extensive collections of cuneiform tablets (in Hittite and Luvian), heiroglyphic inscriptions (in Luvian), and inscriptions in Greek letters (in Lycian, Lydian, Palaic, and Carian) were unearthed and deciphered in the twentieth century. The Indo-European language Phrygian was also spoken in the western half of Turkey, and it too is now long extinct.

Two Caucasian language families are fairly well represented in Turkey, partly due to spillover at the Georgian border in northeastern Turkey, and partly thanks to the massive influx of refugees from the northwest Caucasus following the defeat of the Caucasian confederation by Russia in 1864, as a result of which the Czar deported roughly half of the Northwest Caucasian population to the Ottoman Empire. Some Northwest Caucasian languages survived only in the diaspora, such as Ubykh (now extinct) and the Sadz dialects of Abkhaz. Other Northwest Caucasian languages still to be found in Turkey today include Abaza (10,000 speakers in Turkey as of 1995), Abkhaz (35,000 speakers in Turkey as of 1993, mainly in Artvin in northeast Turkey and villages in the provinces of Bolu and Sakarya), Adyghe (130,000 in 1965, in various provinces in central and western Anatolia), and Kabardian (202,000 speakers in Turkey as of 1993, primarily around Kayseri).

Northeastern Turkey contains the westernmost component of the South Caucasian language family, notably Laz (92,000 speakers in Turkey in 1980 along the Black Sea Coast of the provinces of Rize, Artvin, Sakarya, Kocaeli, and Bolu) and Georgian (some 40,000 first language speakers in 1980 out of 91,000 ethnic Imerxev, a Georgian minority, located primarily in the provinces of Artvin, Ordu, and Sakarya).

Several Semitic languages survive in Turkey, including Arabic (400,000 speakers as of 1996), Turoyo/Suryani (3,000 speakers in 1994, originally in

the Mardin province), and Hertevin (250–300 speakers in 1994, originally in the village of Ekindüzü in the Siirt province). Turoyo is a modern descendant of Syriac, the language of the Syrian church, which was centered in Edessa (modern Şanlıurfa, in southeastern Turkey) and spoken until about the twelfth century AD, although it is still used as a literary secular language by some members of the Syrian church.

One may also classify the language of the Sephardic Jews, Ladino (or Judeo-Spanish, as it is sometimes called) as partially Semitic, although its core is an Iberian Romance language closely related to Spanish. As of 1980, it was estimated to have 8,000 or fewer first language speakers, mainly in Istanbul but also in Izmir. The Dönme, adherents of Shabbetai Zevi who converted to Islam, also speak Ladino; there were 15,000 of them residing in Turkey in 1976. Almost all speakers of Ladino are bilingual in Turkish.

Turkey also possesses at least one distinct signed language, Turkish Sign Language. To the best of my knowledge, no linguistic studies have been carried out on this language.

Typology

At its core, typology is the classification of languages on the basis of shared formal characteristics. In this way, it is distinct from genetic classification, which attempts to determine shared ancestry among languages, and from demographic classification, which categorizes languages based on geography, the numbers of speakers, or other social variables. The ultimate goals of typology are to ascertain the ways in which languages are similar in structure and to determine just how different human languages can be. Concomitant to these goals is the discovery of traits in language that are logically distinct but actually occur together.

It should be stressed that typology is not a theory of language structure. It does not attempt to provide a formal model of sentence structure or sound systems. Rather, typology is an approach that one can take in investigating the composition of human languages, an approach that is driven by a method of crosslinguistic comparison and rests on the assumption that structural similarities between languages disclose fundamental properties of human language more generally.

Universals

One of the core notions of typology is that of the 'language universal', a statement about what is always or nearly always true about language structure. Universals that are without exception, such as 'all languages possess both vowels and consonants', are called 'absolute'. Universals that admit exceptions but hold true to a statistically significant degree are referred to as 'probabilistic' universals. An example of a probabilistic universal is 'Languages nearly always distinguish between nouns and verbs'. While noun–verb polarity is a dominant characteristic in languages, there are a few known languages, such as Tongan, which lack it; hence, the property does not hold as an absolute universal.

The universals noted so far assert the presence of a single structural property, and as such they logically

define two types of languages: those that have the property and those that lack it. The latter is only possible in the case of probabilistic universals. However, many typological universals are stated in the form of 'implications'. That is, the statement of the universal carries a condition. An example of an implicational universal is: 'Languages with dominant Verb Subject Object order are always prepositional' (Greenberg 1966). Here the property of having prepositions (as opposed to postpositions) is said to depend on another property, namely having a certain word order in the sentence. This implication is absolute, but many implicational universals are probabilistic as well.

Both simple and implicational universals reveal something significant about the form language takes, but in different ways. Simple universals bring language structure into relief against ways we might imagine it could be different. We can create a mental construct of a language that lacks consonants, for instance, but such a language simply does not exist. Implicational universals, on the other hand, underscore connections between language properties that are logically distinct. There is no a priori reason that the order of subjects, objects, and verbs should be tied into a language using prepositions, yet there the correlation exists.

Sampling

For many reasons, not all human languages can be simultaneously compared. Many languages have died leaving behind no trace, and many languages have not yet come into being. Detailed descriptions are only available for a fraction of known languages. Therefore, by necessity, typologists must create a sample of languages when they carry out their research.

Since most typological universals are probabilistic, the structure of the sample is of great import. If the languages in the sample are not selected to protect against certain biases, then the information that is gleaned will be unreliable. Two main types of bias must be controlled for when constructing a sample: a genetic bias and an areal bias. Languages that are in the same language branch or language family may be similar because they have retained features from a common ancestor. If a particular family is represented in the sample disproportionately, then a pattern might emerge that reflects the properties of this language family rather than languages in general, and thus the sample would be genetically biased. An areal bias can arise in a language sample when a disproportionate number of languages from one geographical region is used. Since languages that are in close proximity tend to influence each other's structure, certain structural features come to be shared by all languages in a given area. By placing too many languages from one area

into a sample, any shared areal features will be overrepresented in the data.

Word-Order Typology

Although typological studies have probed into many facets of language structure, the most prominent focus of research in the last 50 years has been on word order. Joseph Greenberg's seminal publication in 1966, 'Some universals of grammar with particular reference to the order of meaningful elements', identified 45 universals, 28 of which dealt with the relative order of sentence elements. Greenberg's universals were of the implicational sort; e.g. he proposed, 'If the nominal object always precedes the verb, then verb forms subordinate to the main verb also precede it' (1966:110).

In Greenberg's universals, there is repeated reference to the ordering of subject, object, and verb in the precondition of the universal. This striking fact led other linguists, in particular W.P. Lehmann, to propose that the relative ordering of verbs and objects was in some sense basic to language structure, and the relative ordering of other constituents was largely predictable once the order of verb and object was known. For instance, according to Lehmann, in languages with the most common order Verb–Object, one would more than likely find prepositions before the nouns they governed, nouns before modifying adjectives, negatives before verbs, and comparative adjectives before the standards of comparison. In languages where the most common order is Object–Verb, just the opposite orderings are predicted to occur.

There have been four further developments of note in word-order studies. First, efforts have been made to recast the correlations like those explored by Lehmann in terms of more abstract grammatical concepts such as 'head' and 'modifier' instead of treating verb vis-à-vis object as the dominant organizing principle. Second, there has been much discussion regarding why such correlations between sentence elements exist and regarding the ways individual languages depart from the word-order patterns that normally hold sway. Third, in 1983 the linguist John Hawkins attempted to provide a fuller set of absolute universals of word order that would allow linguists to get a better idea of possible, typical, and impossible language types. In order to formulate his universals in absolute terms, Hawkins used multiple preconditions. For example, one of Hawkins's universals claims that if a language has Subject–Object–Verb order, AND the language puts adjectives before nouns, then the language will also put genitives (possessors) before their governing nouns. Finally, by improving on the sampling methods employed in earlier word-order studies, linguists have provided a much better basis for claims

about correlations. Notable in this area is the work of Matthew Dryer, who has demonstrated, among other things, that earlier claims about the correlation between verb/object ordering and noun/adjective are suspect, as is the correlation between verb/object and negative/verb.

Morphological Typology

Typologists of the nineteenth century wondered whether languages could be categorized on the basis of their word structure (morphology). This early work was revised by the great American linguist Edward Sapir, who proposed that languages could be classified on the basis of two independent parameters: how many word elements are permitted within individual words, and how much the pronunciation changes when word parts are put together. With respect to the first parameter, languages are said to be 'analytic' (or 'isolating'), i.e. words are not divisible into parts; 'synthetic', i.e. manifesting a limited number of word parts per word; or 'polysynthetic', i.e. employing many parts per word. With respect to the second parameter, nonisolating languages are either 'fusional', where the word parts are relatively difficult to isolate from each other and show considerable variation in their sound structure depending on the particular combinations; or 'agglutinative', meaning that they have easily identified word parts.

Because these labels appear to be impressionistic rather than categorical, and because no language is of a pure type (for example, agglutinative languages invariably have some fusional aspect), contemporary typologists have paid relatively little attention to developing Sapir's morphological typology. Even so, the terminology is widely employed to provide broad characterizations of languages in terms of their overall word structure.

In recent years, far more attention has been paid to a different parameter related to word structure, 'head marking' vs. 'dependent marking', a distinction explored most thoroughly in the work of Johanna Nichols. In constructions involving a head element and an element that depends on it, languages vary with respect to how their relationship is indicated. Consider possessive constructions, where the possessor is the dependent and the possessed element is the head. English, for example, is said to use dependent marking to express the dependency, because the possessor appears either with the possessive *-s* (*John's house*) or in the form of a prepositional phrase (*the house of John*). Other languages mark the head in this construction (e.g. Hungarian *az ember ház-a* 'the man's house', literally 'the house man-his'). Still other languages mark both the head and the dependent, or do not mark either of them. Languages can then be placed into types based on the general preference they display for head marking, dependent marking, double marking, or no marking. Once so categorized, links between this parameter and other structural traits can be explored.

Explanations for Universals

Although typology is not a theory of language per se, the discipline has traditionally been aligned with functionalist and historical approaches to language. The link is most clearly revealed in the kinds of explanations that typologists offer for the universals they have discovered. Rather than provide explanations based on the system of language itself, typological explanations are typically external to the language system. That is, the explanations rest on considerations about how language is used, how it is perceived, how it is processed, and how it is shaped by human cognition. Moreover, the explanations tend to be cast in a historical perspective. It is assumed that a language comes to have the shape it does because of the interaction of regular processes of historical change with functional pressures that nudge speakers to maximize the efficiency of their languages for communication.

To better exemplify the nature of typological explanations, consider the phenomenon of 'pro-drop'. In many languages where the verb agrees with the subject, a subject pronoun need not be included. In Spanish, for instance, the sentence *Yo bailo* 'I am dancing' is more commonly rendered *Bailo*, without the subject pronoun *Yo* 'I'. Because information about the subject is included in the verb (the ending *-o* indicates a first person singular subject), the dropping of *Yo* causes no loss of information. In contrast, English verbs show very little agreement with subjects, and the dropping of a subject pronoun is not permitted, presumably because information about the subject cannot be recovered from the verb. This link between subject agreement and the ability to drop subject pronouns is a strong one. Typologists see the link as part of a larger functional pressure on language referred to as 'economy'. Languages tend to be economical, eliminating redundant information where possible. Over time, in a language where information is being expressed redundantly in the grammar, the grammar changes to eliminate the redundancy.

The functional pressures operating on language are often expressed in terms of 'markedness'. The core idea behind markedness is that there are asymmetrical relationships between grammatical elements that are otherwise equal. For example, the sounds [p], [t], and [k] (as well as several other sounds) form a natural class in that they are all voiceless stops. As members of this set, they all have equal status. However, when one examines the set of voiceless stops that occur in the sound systems of languages, it becomes apparent

that there is something special about [t]: If a language only has only one voiceless stop, it is very likely to be [t]. And when one considers [p] and [k], one finds something special about [k]: if a language has [p], then it also has [k]. Therefore, although these sounds are equal in terms of their membership in the natural class of voiceless stops, they are unequal in the way that they are distributed in languages. [t] is then said to be 'unmarked' relative to [k] or [p]. Furthermore, [k] is unmarked relative to [p]. When a series of these markedness pairs occurs within a set of otherwise equal elements, the serial relationships can be expressed in terms of a 'markedness hierarchy'. For the case at hand, the hierarchy is $t<k<p$, with the least marked member furthest to the left on the hierarchy.

Such hierarchies are commonplace in typology. Some of the better known hierarchies include the grammatical relations hierarchy (subject < object < indirect object < other), the number hierarchy (singular<plural<dual<trial/paucal, i.e. 'three/few'), the animacy hierarchy (first and second person pronouns < third person pronouns < proper names < human nouns < animate nouns < inanimate nouns), and the color term hierarchy (white/black < red < green/yellow <blue < brown). While all these hierarchies obviously have quite different implications for what the structure of language is like, they all highlight the sometimes surprising asymmetry that arises between grammatical elements in language.

U

Udmurt

Udmurt, also known as Votyak, is a language with an old written literature, which has long been neglected by scholars, politicians, and even the inhabitants of the Udmurt Republic itself. The alternative name was promulgated via Russian and is now considered old-fashioned; indeed, many ethnic Udmurts also consider it disparaging. The word *Udmurt* is formed by the compounding of *murt* 'human being' and **odo* (the latter is of obscure origin).

The earliest extant literary texts in Udmurt date from the sixteenth century and are typically word lists. The first grammar of Udmurt was published at the end of the eighteenth century, while in the mid-nineteenth century the Gospel texts of the New Testament were translated. Following the Great October Revolution and the inception of the Communist state, many other works of literature have been translated into Udmurt, including the leading texts of Marxism–Leninism.

The Udmurts and their language developed between the Volga-Kama and Vyatka Rivers during the second half of the first millennium of the Christian era and there has been a distinct Udmurt nation since c. 1100. In terms of genealogical classification, the Udmurt language belongs to the Permian branch of the Finno-Ugric languages of the Uralic family, and is most closely related to the Komi languages: Komi-Zuryanskiy and especially Komi-Permyalskiy. The two peoples separated between c. AD 900 and 1100 and today the two languages (Udmurt and Komi) are not mutually comprehensible; however, they occasionally present noticeable similarities in vocabulary. For example, *night* is Udmurt *uj* and Komi *voj*. The oldest Permian language, Old Permian, cannot really be said to be the precursor of any one of the modern Permian languages; however, it is considered to be closer to Komi-Zuryanskiy (also known as Komi, the language of the Komi Republic) than to Udmurt. According to scholars, the relationship between Udmurt and Komi is similar to that which holds between Russian and Polish. The phonetic system and grammatical structures of these languages are almost identical, and they have much common vocabulary. Through the centuries, the Udmurt people have come into contact with many different peoples and their languages and this has affected their language. During the first half of the second millennium of the Christian era, the Tatars were the most significant contacts; however, during recent years, the influence of ethnic Russians has proved more decisive. As a result, loanwords from Russian, or through Russian, are common: for example, *tsement* 'cement', *t'ipovoj* 'typical', or *sborn'ik* 'collection'.

Udmurt is spoken principally in the Udmurt Republic, which lies some 1,325 kilometers east of Moscow in the Pre-Ural region of the Russian Federation. Approximately, two thirds of all Udmurts live in the Republic, where they constitute c. 30% of the population. The remainder of the population of the Udmurt Republic are predominantly ethnic Russians. The final third of Udmurts live chiefly in the Perm, Kirov, and Yekaterinburg provinces of the Russian Federation and also Tatarstan and Bashkorstan. It is difficult to quote a precise figure for the total number of ethnic Udmurts; however, a population of between approximately 600,000 and 750,000 is generally agreed upon and this concurs with the 1989 Russian Federation census statistics, which indicated a poten-

UDMURT

tial population of c. 740,000 Udmurts. Where agreement ends, however, is on the question of the number of Udmurt speakers.

Udmurt had never been an official state language, and by the beginning of the twentieth century it had all but died out. It was not until the 1920s and 1930s that there was any concerted effort to preserve the language, and the culmination of this may be seen in the 1994 constitution. In this document, Udmurt is presented as one of the two official languages of the Udmurt Republic, along with Russian. However, according to some sources, there has been considerable opposition to the state sponsorship of the language, and now those areas of life where Udmurt is used and where it holds prestige are limited. There is considerable debate as to the current number of speakers of Udmurt, with figures ranging from in excess of 500,000 at one extreme to under 50,000 at the other end of the spectrum. Both sets of figures should be viewed with caution until reliable statistical data can be researched. However, UNESCO classifies Udmurt as an 'endangered' language and it would be safe to say that Udmurt is not a language enjoying a renaissance at the present time.

Udmurt is written using a modified version of the Cyrillic alphabet consisting of 38 characters. However, prior to 1930 both the Latin and the Cyrillic alphabets had been used. The language can be divided into four main dialects and these are typically referred to as the Northern, Southern, Central, and Peripheral dialects. The first three of these groups refer to the geographical location, within the Udmurt Republic, of the speakers, while the final group is the term used to refer to those speakers who live outside the Republic, notably in Tatarstan and Bashkorstan. These dialects are mutually comprehensible, although they do differ to some degree from each other in terms of vocabulary and, to a lesser degree, pronunciation.

Udmurt has seven vowels and 26 consonants. Syllables can be formed by combining consonant (C) and vowel (V) sounds in a way that can be presented schematically as follows: (C(C))V(V)(C(C))—segments in parentheses are optional.

V:	*api* (noun)	'elder sister'
CV:	*ju* (noun)	'grain'
CVC:	*tus* (noun)	'appearance'
CCV:	*visjas'kyny* (verb)	'to detach oneself'
VC:	*an* (noun)	'chin'
VCC:	*akt* (noun)	'document' (loanword from Russian)
CVV:	*tue* (adverb)	'this year'
CVCC:	*šal'kketyny* (verb)	'to flap'
CVVC:	*kuat'* (numeral)	'six'

Thus, it can be seen that syllables require a vowel sound, which may be either long or short. The core vowel sound may be preceded, succeeded, or framed by (clusters of) consonant sounds. The one proviso is that consonant clusters may not exceed two consonant sounds. Word stress typically falls on the final syllable of the word; however, in certain circumstances the first syllable carries the main stress. This is usually the case, among others, with imperatives and adverbs and adjectives, which have been created through a process of reduplication: for example, *gordgord* 'bright red'.

Udmurt has six parts of speech: adjective, noun, numeral, particle, pronoun, and verb. These categories may then be subdivided further. Nouns in Udmurt are inflected for case, number (singular and plural), and possession. Udmurt has 15 grammatical cases, which are marked via affixes. Besides indicating whether a noun represents the subject or object of a clause, the cases of Udmurt are furthermore used to encode information such as 'from…', 'to…', 'with…', etc. Possessive inflectional affixes may also be added to adjectives, nouns, numerals, and pronouns to provide information on number (i.e. singular and plural) and person (first, second, or third). Interestingly, there is no case that corresponds to the Indo-European vocative (used to mark the addressee of an utterance). Udmurt verbs fall into two conjugation patterns, depending on the last vowel of the stem. Verbs in Udmurt are inflected for mood, negation, nonfinite categories (gerund, infinitive, and participle), person, and tense.

In affirmative intransitive sentences, the typical word order is: subject–(adverb)–verb, or in short S–(A)–V. Since the copula (i.e. 'to be') is not required to be used in the present tense, this structure may be reduced to S–A. In affirmative transitive sentences, the typical unmarked word order is: subject–(adverb)–object–verb, or S–(A)–O–V.

Negation in Udmurt is typically expressed via a negative auxiliary or negative particle, which is placed before the verb; thus, S–(A)–(O)–Neg–V.

The word order in imperative sentences is usually verb initial, except in those cases where a personal pronoun is present. In the latter case, the personal pronoun is initial: (PersPro)–V. When the imperative is negated, the negative is placed in clause initial position: i.e. Neg–V.

Interrogative sentences in Udmurt appear to have no set word order pattern, since interrogation may be marked in a number of ways: an interrogative particle may be affixed to the word which forms the focus of the question; or this word may be stressed to mark the sentence as a question. However, some tendencies may be discerned. Interrogation sentences with a question word normally follow the pattern Q–S–V (where Q is the question word).

Adverbial phrases in Udmurt may appear at the beginning, middle, or end of a sentence. Adverbial positioning may be to an extent determined by the adverbial category; thus, adverbs of time and place

often occur in sentence-initial position, while certain other adverbs may appear immediately before the object or the verb.

KARL BERNHARDT

United States

The United States is a country of some 250 million people spanning a large portion of the North American continent. Language has been a controversial political subject in the United States since the time of Noah Webster, and the controversy continues in debates about language in the schools and the unofficial status of English today. Although today it is an essentially monolingual English-speaking country, the United States has a rich and varied linguistic heritage which includes indigenous languages, immigrant languages, American Sign Language, and a wide variety of English dialects.

Indigenous Languages

At the time when settlers of European descent arrived in the territory that is now the United States, there were at least 300 languages spoken there. Most of these languages are either extinct or endangered today, with fewer than 50 having more than 1,000 speakers. Those with more than 10,000 speakers (data from 1977–1990) are listed below:

Indigenous Languages with More Than 10,000 Speakers

Language	Number of Speakers	Family
Papago-Pima	12,000	Uto-Aztecan
Western Apache	13,000	Na-Dené
Central Yupik	15,000	Eskimo-Aleut
Dakota	15,000	Siouan
Cherokee	22,500	Iroquoian
Western Cree	35,000	Algonquian
Western Ojibwa	35,000	Algonquian

Language families with the widest geographical distribution in the United States include Algonquian, Aztec-Tanoan, Eskimo-Aleut, Macro-Siouan, Na-Dené, and Penutian. Hawaiian, an Austronesian language, is spoken by fewer than 1,000 people today.

The serious study of aboriginal languages of the Americas, following the lead of Franz Boas, in combination with developments stemming from European philology, formed the basis for modern linguistics. The following statement is from the resolution on Language Rights passed by the Linguistic Society of America.

> Many past and present members of the Society have devoted their professional lives to documenting and analyzing the native languages of the United States. Unfortunately, most of the indigenous languages of the United States are severely threatened. All too often their eradication was deliberate government policy…. The decline of America's indigenous languages has been closely linked to the loss of much of the culture of their speakers. Because of this history, the Society believes that the government and people of the United States have a special obligation to enable indigenous peoples to retain their languages and cultures. The Society strongly supports the federal recognition of this obligation, as expressed in the Native American Languages Act.

This Act of Congress states that 'It is the policy of the United States to… preserve, protect, and promote the rights and freedom of Native Americans to use, practice, and develop Native American languages'. This is a major reversal in policy from the days when Indian children were removed from their tribes and sent to English-only boarding schools where they were

punished for speaking their native languages. These earlier educational policies led to the loss of languages of tribes that had survived the warfare and epidemics that had destroyed so many other tribal languages. There are few monolingual speakers of indigenous languages in the United States today, a fact that suggests their impending replacement by English. Although some Native American languages are now being taught in tribal schools, it remains to be seen whether these languages can survive as a means of everyday communication.

History of American English

At the end of the eighteenth century, in the midst of anti-British sentiment born of revolutionary fervor, Americans declared verbal independence and the language that was formerly just 'English' became British English and American English. This was the first of many such splits into national varieties that were yet to come as a result of the far-reaching colonialism of the British Empire. Despite the fact that the English believed the speech of the American settlers to be corrupt and full of 'barbarisms', Webster defended it in his *Dissertations on the English language* by declaring that 'the people of America… speak the most pure English now known in the world'. His spelling reforms and insistence on middle class rather than aristocratic norms were intended as a contribution to the formation of an American identity.

In colonial times, however, a number of European languages were spoken in North America. English came to predominate, but not without feeling the influence of these, and some of the indigenous languages, upon its vocabulary. Even before the arrival of the Mayflower, words were borrowed into English from the indigenous people of the Americas, especially the Caribbean, via Spanish; other Native American words were introduced into English by French-speaking explorers. The Algonquian languages were the source of most borrowings from Native American languages, as this language family included the speech of the tribes along the Eastern Seaboard that were the first ones encountered by the English settlers. The settlers coexisted fairly peaceably with the Indians for the first few years, and they had need of words to describe native flora and fauna that were not found in the Old World. As hostilities worsened and settlement moved westward, most borrowings were limited to place names.

Early on, words entered English from contact with the Dutch in New York and the Germans in Pennsylvania. More lexical and even grammatical influences were to come from the many immigrant languages that arrived in later years. The impact of these immigrant languages helped to create some of the differences between regional dialects of English,

e.g. Yiddish in New York City, Scandinavian languages in the Upper Midwest, and, of course, Spanish in the Southwest, although the latter predates the founding of the United States and cannot be considered an immigrant language.

Main Sources of Borrowings in American English

Languages/ Language Groups	Predominant Region/Era	Examples
Algonquian	Eastern New England, 17th century	Moose, raccoon, squash, pecan
West African	South, 18th century	Yam, okra, banjo, jazz, tote
Dutch	Hudson Valley, 18th century	Cookie, coleslaw, boss, sleigh
German	Pennsylvania, 19th century	Cluck, dunk, hamburger, pretzel
French	Great Lakes, Louisiana, 18th, 19th centuries	Prairie, portage, armoire, jambalaya
Spanish	Southwest, 19th century	Coyote, marijuana, ranch, cafeteria
Yiddish	New York City, 20th century	Schmuck, kibitzer, phooey, schmooze

When the United States took over, first, the Louisiana Territory from the French and, later, Texas, California, and the Southwest from the Spanish, the nation thereby incorporated the many speakers of languages other than English who were already living in these areas. The US government allowed French and Spanish use to continue for a number of years in the local governments of states like Louisiana and California, although in at least two instances (New Mexico and Hawaii), the preponderance of non-English speakers in annexed territories became an obstacle to acceptance into statehood. During the many debates over the years about the status of languages other than English (and their speakers), critics have often overlooked the fact that many non-English speakers did not come to the United States voluntarily. In addition to the cases of French, Spanish, and Hawaiian and other indigenous languages noted above, many Chinese speakers were brought to the West Coast as forced laborers. The largest group of non-English speakers in US history also came involuntarily, brought as slaves from West Africa.

The debate among linguists over the history of African American Vernacular English (AAVE) has still not been resolved, although it has been one of the most productive areas of linguistic study in the United States for over 30 years, spurring a vast amount of research on Creole languages and on nonstandard varieties of English in the United States. The sides have been characterized as 'Anglicist' vs. 'Creolist'

hypotheses, and the most simplistic description of these points of view is that AAVE originated either from the nonstandard British-based varieties of English learned by the slaves or from a widespread Creole language that once existed in the slave-owning areas of the South. Most linguists today agree that a multiplicity of factors shaped the language of African Americans, including African substrate languages like Wolof and Yoruba, English-based Caribbean Creoles, the British dialects of white indentured servants, and developing American English dialects, both standard and nonstandard, as well as language-learning features that may be attributable to Universal Grammar. It is likely that the first slaves to be brought to the United States, who worked as domestic servants or on small farms where there was ample exposure to native speakers of English, were able to learn English just as other immigrants did. As more and more slaves were brought in, both directly from Africa and via the Caribbean, opportunities to learn from native speakers diminished as the ratio of blacks to whites grew. It is likely that a true Creole only developed along the coast of South Carolina and Georgia, where large, labor-intensive rice plantations produced demographics similar to those on the sugar plantations of the Caribbean. (This now mostly decreolized variety is known as Gullah or Geechee, and it is the source of the Afro-Seminole Creole in Texas.) Elsewhere in the South, a variety developed among African Americans that was very similar to white varieties of English in the region, due to mutual influence, and which had a Creole-like tense and aspect system (see below). This variety was taken northward to cities such as Detroit, Chicago, New York, and Philadelphia when many blacks left the South during the first decades of the twentieth century, fleeing poverty and racially motivated violence.

Features of AAVE

Copula absence
She pretty. They in the house.
Invariant/nonfinite be (habitual aspect)
He be in school every day.
Stressed been (remote tense)
He BEEN ate it. She BEEN gone.
Perfect done (completive aspect)
They done left the house.
Lack of verbal morphology
She always go to that store. The building burn last week.

While AAVE thus spread from south to north, other dialects spread with the population from east to west. Quite a lot of dialect mixing occurred in the early settlement period, as colonists in any one town might have come from various parts of England, Ireland, Wales, Germany, or elsewhere. There was probably a period of 'koineization', when a leveling process

occurred, although some scholars believe that even in colonial times, regional dialect differences existed. It is possible to distinguish four streams of settlement from different parts of the British Isles that may have played a role in the formation of the major dialects of American English. The eastern part of England was the origin of many New England settlers, while Pennsylvania and Delaware were settled by people from northern England, and the South by colonists predominantly from the southwest of England. Inland areas, including Appalachia, were settled slightly later by the people known as the Scots-Irish, or Ulster Scots, who were of Scottish descent but who came to the United States after a sojourn in northern Ireland.

Four major dialect areas of the eastern United States were defined by Hans Kurath based on data collected for the Linguistic Atlas of the United States and Canada, an ambitious undertaking begun in the 1920s that was designed to map the dialect areas of English-speaking North America. Two influential publications based on the atlas data (a 'word geography' and a volume describing the pronunciation of influential citizens in various regions) provided the basic outline of dialect areas in the United States for many years. Kurath proposed two primary boundaries and a secondary boundary as shown in the map (Figure 1), forming the North, North Midland, South Midland, and South dialect areas. Today, many linguists believe the primary and secondary boundaries to be reversed, i.e. that the major division is North vs. South, with two main subregions within each, corresponding to essentially the same areas Kurath identified but now known as Upper and Lower North and Upper and Lower South (Figure 2). The dialect areas remained fairly distinct as settlement proceeded westward as far as the Mississippi River, but west of there, their features were mixed together. Although there are some identifiable dialect regions in the West, as the most recently settled area of the United States, dialect differentiation is not as sharp as in the East. Likewise, dialect differences in the United States in general are more subtle than those in the long-populated countryside of Europe and England.

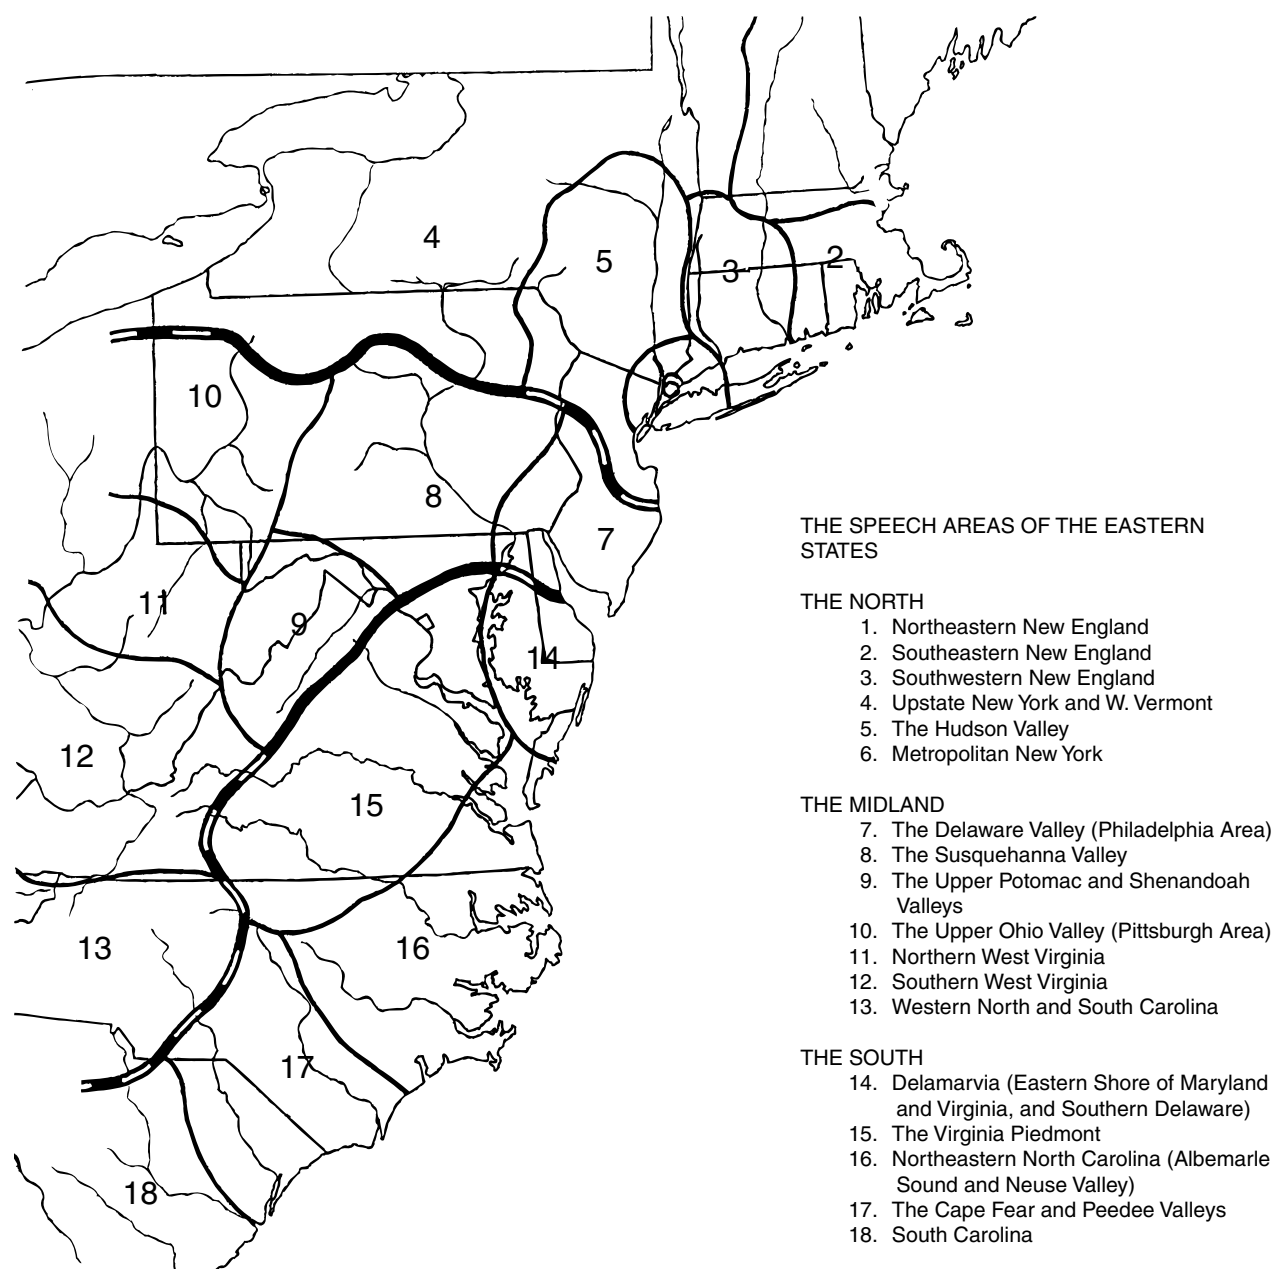
The vocabulary of American English is expanding at a tremendous rate, coinciding with the twentieth century developments of universal public education, improvements in transportation, mass media, and a consumer culture. Words for archaic features of the culture, such as premechanized agriculture, are disappearing, along with the many lexical items that simply drop out of fashion over the years. On the other hand, a great deal of vocabulary has been added through technological change, especially in the field of computers. Cultural changes have also given us brand names that are widely known and used. New words are added from many sources. Slang is spread through youth culture,


Figure 1. Major dialect areas of the US: Kurath (1949).

THE SPEECH AREAS OF THE EASTERN STATES

THE NORTH
1. Northeastern New England
2. Southeastern New England
3. Southwestern New England
4. Upstate New York and W. Vermont
5. The Hudson Valley
6. Metropolitan New York

THE MIDLAND
7. The Delaware Valley (Philadelphia Area)
8. The Susquehanna Valley
9. The Upper Potomac and Shenandoah Valleys
10. The Upper Ohio Valley (Pittsburgh Area)
11. Northern West Virginia
12. Southern West Virginia
13. Western North and South Carolina

THE SOUTH
14. Delamarvia (Eastern Shore of Maryland and Virginia, and Southern Delaware)
15. The Virginia Piedmont
16. Northeastern North Carolina (Albemarle Sound and Neuse Valley)
17. The Cape Fear and Peedee Valleys
18. South Carolina

and through mass-distributed music and other electronic media; some slang words are ephemeral, but others, such as *cool* and *dude*, have persisted for many generations. And borrowings from immigrant languages continue, although these terms may be regionally limited. Despite increasing geographical mobility and exposure to other dialects, regionalisms in the vocabulary do remain, as documented in one of the most significant American dictionary projects, the multivolume *Dictionary of American regional english*. Another

important recent lexicographical work on American English is the *Historical dictionary of American slang*. These two projects expand our resources on American English far beyond the reach of the best current unabridged dictionaries with an American perspective, *Webster's third* and *Random House*.

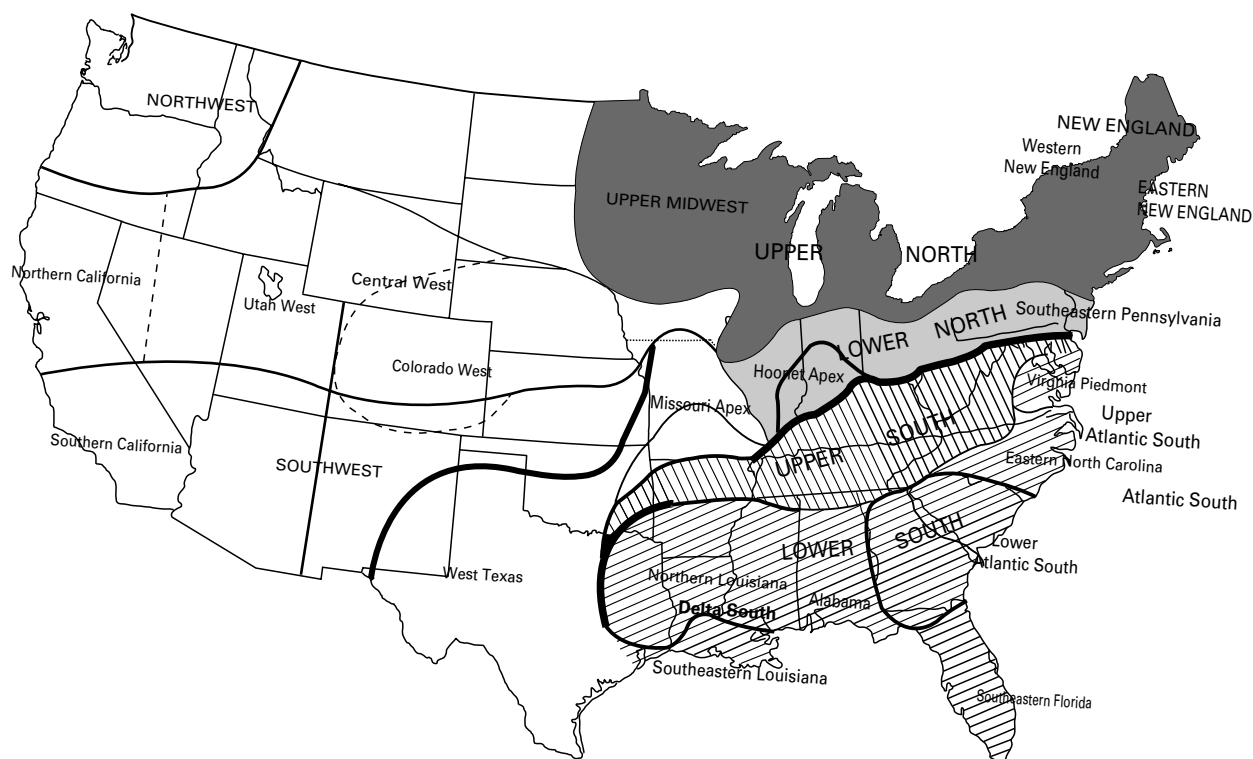
American English grammar has diverged from that of British English in a number of ways, for example, in retaining many uses of the subjunctive and in the use of auxiliary verbs.


Figure 2. Major dialect areas of the US: Carver (1987).

Some Grammatical Differences between US English and English English

US English	English English
The salad has olives in it.	The salad has olives in.
In the future, we will change the plan.	In future, we will change the plan.
John gave it to me.	John gave me it.
Do you have any apples?	Have you any apples?
I won't be able to go.	I shan't be able to go.
If I were you, I wouldn't do it.	If I was you, I wouldn't do it.

Standard English grammar is that which is used by the most educated, upper social classes in all regions and which carries the prestige of being regarded as 'correct' or 'good' English by all. English syntax and morphology vary in nonstandard dialects across the United States, with much of the variation involving verb forms in the past and past participle. Nonstandard speech is usually stigmatized because it is typical of the working class or minority ethnic groups. These nonstandard dialects of English in all parts of the United States exhibit many of the same features, including lack of subject–verb agreement, as in *he don't*, *we wasn't*, and multiple negation (*they don't know nothing*), often including *ain't*.

Pronunciation changes continue to spread across the United States, although dialectologists have moved from a 'wave' model of understanding change as moving outward in an even pattern from a geographic origin (like waves in a pond) to a model where change moves from one large urban area to another before diffusing into suburbs, smaller cities, and finally rural areas. One important survey conducted by William Labov and colleagues, the Phonological Atlas of the United States, has documented several sound changes in the form of vowel shifts and mergers. In most of the United States, the vowels in *lot* and *law* are merging, and other shifts are taking place in some Northern cities (e.g. the raising of the vowel in *bag* toward the vowel of *beg*) and in the South (e.g. the merger of the vowels of *pen* and *pin* before nasal consonants) (Figures 3 and 4).

There is no single standard of pronunciation in the United States, but rather a number of 'regional standards', characterized by the accents of the upper-middle class. This includes people like lawyers, doctors, bankers, and politicians, economically successful and highly visible members of the community who often speak with a regionally identifiable accent that is the local prestige norm. Although people who move from one region to another may drop features of their native dialects that are stigmatized in other regions, and broadcasters are trained to do the same thing, this accentless type of speech is not required for success even at the national level: witness the speech of recent

/i/ (*beet*)   /u/ (*boot*)

  /ɪ/ (*bit*)   /ʊ/ (*put*)
     →

presidents, the strong New England accent of the elder Bush and the Texas sound of the younger one, the Southern accents of Clinton and Carter, and the Boston accent of the Kennedys.

The speech patterns of traditionally economically depressed regions of the United States (e.g. the South), or areas with larger concentrations of working class speakers (e.g. New Jersey, the Appalachians), like the speech patterns of poor people in general, have been stigmatized on a national level. The most prestigious US dialect is one that dialectologists have labeled Inland North, which encompasses upstate New York; the northern parts of Ohio, Indiana, and Illinois; Michigan; and Wisconsin. Studies of language attitudes have shown the speech of the South to be consistently labeled as the 'least correct', although not necessarily the 'least pleasant'. Sociolinguists call this type of positive assessment of speakers of nonstandard dialects, as being more friendly and sincere, 'covert prestige'. The idea that nonstandard speech can be valued as sounding more masculine has led researchers to invoke covert prestige to explain the tendency of men in the United States to use more nonstandard features than women of the same social class. Other factors could explain this finding as well, especially the higher educational levels and Standard English skills expected of women in many low-paying jobs.

Correlational studies of how nonlinguistic variables such as social class, sex, age, region, and race influence speech patterns have taught us much about the complexity of American English. This subfield of linguistics is known as language variation study, and it includes what has traditionally been called dialectology as well as much of the subject matter of sociolinguistics. Sociolinguistics also includes the study of language attitudes, sometimes called perceptual dialectology. In many ways, the attitudes toward low-status varieties of English, especially ethnically-based varieties like AAVE, parallel attitudes toward languages other than English in the United States. These attitudes have led to political controversy over the use of languages and varieties other than Standard English, especially in the schools.

Immigrant Languages and Language in the Schools

Although the United States has no official language, English serves as the de facto national language, with 87% of the adult population speaking *only* English, and 80% of those who speak another language at home also speaking English 'well' or 'very well'. Bilingualism in the United States has mostly been 'subtractive', leading to loss of the language other than English within three generations for immigrants. The rate at which immigrants are learning English has not changed, but public perception today is that Spanish-speaking immigrants are not learning English. This is due to continued high numbers of new immigrants from Mexico and elsewhere in Latin America. Early in the twentieth century, there were complaints that Italian, Jewish, Greek, and Slavic immigrants were not learning English; the ethnic languages spoken by these groups are disappearing quickly less than 100 years later. Demographic projections predicting that Caucasians will comprise less than 50% of the population by the mid-twenty-first century have fueled fears that English speakers will become a minority in the United States. Opposition to the use of languages other than English in the public sphere by anyone besides tourists has often been linked historically to xenophobia and nativism, as when racist, anti-Catholic, and anti-immigrant political groups in the late nineteenth century fought to enact language restrictions.

Germans, who were part of the earliest European settlements in the United States, were probably more successful at maintaining their language than any other non-English-speaking group. (However, the claim that a proposed law making German the official language of the United States failed by just one vote is a myth: rather, the Congress declined, in a close vote, to take up a proposal to print laws in German as well as in English.) Although Benjamin Franklin and others complained about the use of German in Pennsylvania, German communities there and later in the Midwest continued to use German as the language of instruc-

tion in both public and parochial schools up until World War I, when nationalistic sentiment put an end to the teaching of German even as a foreign language. In some places, German textbooks were burned by mobs. Many Americans came to view bilingualism as unpatriotic and deviant, and some states even forbade the teaching of any foreign language for a time. Beliefs that bilingualism is somehow harmful persist, so that the Linguistic Society of America found it necessary to include the following in a press release on language rights: 'There is no convincing evidence that bilingualism by itself impedes cognitive or educational development. On the contrary, there is evidence that it may actually enhance certain types of intelligence.' The only places where a form of German remains viable today are the Amish communities, principally in southeastern Pennsylvania. There are, however, two other European languages that have been spoken in the United States for centuries: French varieties in Louisiana and Maine, and Spanish, which has spread from the Southwest into many urban areas.

Most Spanish speakers in the United States today are Mexican-Americans, or Chicanos. The linguistic competence of Chicanos may include a plethora of languages and varieties, as listed by Anzaldúa:

- Standard English
- Working-class and slang English
- Standard Spanish
- Standard Mexican Spanish
- North Mexican Spanish dialect
- Chicano Spanish (Texas, New Mexico, Arizona, and California have regional variations)
- Tex-Mex [a code-switched variety]
- Pachuco [an argot]

In addition, there are at least as many varieties of Spanish in the United States as there are countries of origin for Hispanics, including the prominent Caribbean dialects of Cuba and the US-governed colony of Puerto Rico. The first European settlements in what is now the United States were the Spanish settlements in Florida and Georgia. Spaniards also established missions in California very early; however, the Spanish variety that has been continued from colonial times is that which was brought into the Southwest, especially Arizona, New Mexico, and Colorado by settlers from 'old' Mexico before those states were part of the United States. Ironically, due to demographic changes and the economic power of Anglo retirees, Arizona has been one of the most active states in pushing for 'English Only' restrictions.

The English Language Amendment is a bill that has been introduced in Congress in several forms but that has never passed. It would make English the official language of the United States. There are many differ-

ent interpretations of what this would mean, but most of them involve curtailing government services or documents in languages other than English. In response to this and similar initiatives that have been passed in a growing number of states, the Linguistic Society of America passed the following resolution, mentioned above and excerpted below:

All residents of the United States should be guaranteed the following linguistic rights:

- To be allowed to express themselves, publicly or privately, in the language of their choice.
- To maintain their native language and, should they so desire, to pass it on to their children.
- When their facility in English is inadequate, to be provided a qualified interpreter in any proceeding in which the government endeavors to deprive them of life, liberty or property. Moreover, where there is a substantial linguistic minority in a community, interpretation ought to be provided by courts and other state agencies in any matter that significantly affects the public.
- To have their children educated in a manner that affirmatively acknowledges their native language abilities as well as ensures their acquisition of English. Children can learn only when they understand their teachers. As a consequence, some use of children's native language in the classroom is often desirable if they are to be educated successfully.
- To conduct business in the language of their choice.
- To use their preferred language for private conversations in the workplace.
- To have the opportunity to learn to speak, read, and write English.

This statement on linguistic rights refers to the benefits of at least some instruction in languages other than English, or bilingual education. Bilingual education is not common in the United States and where it does exist, it is usually 'transitional', meant to help students keep up with their other subjects, which they study in their native language, while they study English intensively in order to join a mainstream classroom as soon as possible. Linguists would like to see bilingual education also used for the purposes of language maintenance in order to foster a plurality of languages and cultures in the United States, especially where endangered languages are spoken, e.g. indigenous languages or Cajun French.

In Louisiana, there is a state-sponsored program, the Council for the Development of French in Louisiana (CODOFIL), which is trying to raise the status of French there and to keep it from dying out. This program sponsors activities ranging from radio

and television broadcasts in Cajun French to recruiting Francophone teachers from around the world to offer second-language classes, including immersion programs, in French. Unfortunately, it has been difficult to bridge the gap between the standard Metropolitan French of these teachers and the vernacular variety spoken by the descendants of the Acadians (who came to the United States after being persecuted and forced out of Canada). About 10% of French speakers in Louisiana speak Creole French rather than Cajun French. The CODOFIL mission statement sums up the political issues surrounding the use of minority languages in the United States:

> While we would be the last to argue that a U.S. citizen or resident does not need to speak English in order to survive and thrive in our society, we should not predicate fluency in English upon the elimination of other languages. We in Louisiana have seen first hand the effects of this linguistic genocide. Although our parents and grandparents were beaten, punished and humiliated for speaking French on the schoolgrounds, we have come to realize that full participation in American democracy does not necessarily mean forgetting our roots.

For many minority groups in the United States, there is a tension between the need to assimilate to the majority culture to attain economic and professional success and the need to maintain their ethnic identity. This is the issue that educators have tried to address by proposing that schools allow both bilingualism and bidialectalism in classrooms (as occurs, for example, in Hawaii, where half of the population speaks Hawaiian Creole; students read and write in English, but the teachers explain things in Creole). For years, schools have taken the subtractive approach to teaching Standard English, both to students whose native language is not English and to students who speak a nonstandard variety of English. This 'replacive' view assumes that Standard English is inherently superior to all other varieties, which are given labels ranging from 'substandard' and 'bad' to 'gibberish'. The stigmatization of other varieties often evokes two types of responses from students: a defensive, resistant stance toward a teacher who is trying to take away the language of their family, neighborhood, and church; or the development of low self-esteem and the internalization of the belief that their native language (and by extension, culture) is inferior. By fostering bidialectalism and bilingualism, encouraging students to be fluent in both Standard English and their vernacular, and teaching them which is appropriate in which situations, schools can lower failure and dropout rates that are tied to language difficulties.

The Native American Language Act states, 'There is convincing evidence that student achievement and performance, community and school pride, and education-al opportunity is clearly and directly tied to respect for, and support of, the first language of the child or student.' This same rationale for an 'additive' approach in the classroom can be applied to any minority language in the United States. African American Vernacular English, in particular, has been at the center of heated debates over the role of languages other than Standard English in the classroom. In 1972, linguists were involved in a court case in Ann Arbor, Michigan, where the judge ruled that AAVE was sufficiently different from Standard English to merit special treatment. Teachers were to give AAVE speakers additional help in acquiring Standard English, partly by learning about the syntactic and phonological rules of AAVE themselves so that they could point out the systematic differences to their students. A similar situation arose in Oakland, California, in 1996, when the school board adopted a policy designed to help speakers of 'Ebonics' (AAVE) learn Standard English by educating teachers about dialect differences. The public interpreted both of these attempts as a requirement to force teachers and non-AAVE-speaking students to use AAVE in the classroom (not the case), and as a plan intended to keep African American students from learning Standard English and thus denying them the social benefits that come with a fluent command of Standard English (also not the case).

Similar issues revolve around the question of the role of American Sign Language (ASL) for Deaf students. ASL was developed by educators Thomas Gallaudet and Laurent Clerc, who in the early nineteenth century introduced signs from a visual–spatial language used in France, combining them with signs already in use in the United States. ASL is not simply a signed form of English. In fact, it is grammatically unrelated to English; British Sign Language and ASL are not mutally intelligible, ASL being more closely related to French Sign Language. Linguists have described ASL in terms of its phonology (handshapes), morphology (location of sign in relation to the body, movement of articulators, and facial expressions), and syntax (sequence of signs). Children in an ASL home environment acquire ASL as their native language in the same way as other children acquire spoken languages, e.g. 'babbling' with their fingers at the appropriate stage of development. These children must become bilingual if they are to learn to read and write in English. Some members of the deaf community feel that it is an unnecesary burden on children if they are also required to learn an oral approach, which involves lip reading and the production of speech sounds. It is difficult for a deaf person to learn to pronounce a spoken language well enough to be understood by people who are not immediate family. The same issues of opportunity, identity, and community

that affect other speakers of minority languages in the United States confront bilingual ASL/English speakers, both negatively in terms of language prejudice and positively in terms of having a wide range of communicative abilities.

Languages with more than 100,000 speakers in the United States, from 1990 Census and Ethnologue.

Spanish	17,339,172	Arabic	355,150
French	1,702,176	Hindi (Urdu)	331,484
German	1,547,099	Russian	241,798
Italian	1,308,648	Yiddish	213,064
Chinese	1,249,213	Thai (Laotian)	206,266
Tagalog	843,251	Persian	201,865
Polish	723,483	French Creole	187,658
Romani	650,000	Armenian	149,694
Hawaiian Creole	600,000	Navaho	148,530
Korean	626,478	Hungarian	147,902
Vietnamese	507,069	Hebrew	144,292
Portuguese	429,860	Dutch	142,684
Japanese	427,657	Mon-Khmer (Cambodian)	127,441
Greek	388,260	Gujarathi	102,418

The economic power and cultural influence of the United States is furthering the rapid spread of English across the globe, with some 700 million fluent speakers around the world, and English functioning as an important language in 75 different countries. Many countries that formerly looked to a British model for the teaching of English as a foreign language are now adopting American English norms. Thus, it is true that the dominant language of the United States has an impact far beyond its borders. The importance of American English is not likely to decline soon, either within or outside the United States.

Universal Grammar

Universal grammar (UG) is a theory both about the essential nature of human language and about how language is acquired by children. The concept of UG was first suggested by Noam Chomsky in his early work on generative grammar, and it continued to evolve throughout his later writings on syntactic theory. A detailed exposition of UG appears in his 1981 work *Lectures on government and binding*. This book serves as the basis

for a particular version of UG envisioned as a system of universal principles interacting with parameters of variation. This version of UG is central to the syntactic theory, known as Principles and Parameters Theory, and has been the basis for much current research in the fields of syntax and language acquisition.

The history of UG is intimately related to conflicting theories about the nature of language acquisition. In response to the behaviorist view of language acquisition as imitation and stimulus–response learning, Chomsky argued that language acquisition did not involve learning, but was instead the result of the activation of a totally innate capacity for language, namely, UG.

Support for UG comes from observations of how children's language acquisition differs from other kinds of learning and how it is not merely imitation. First, all children acquire language at a time in their life when they cannot learn any other skill of similar complexity. Furthermore, all children achieve approximately the same degree of skill (i.e. native speaker fluency) regardless of the infinite variations in their environmental stimuli. The language children produce is not merely an imitation of the adult speech they hear around them: they often use innovative structures that they could not possibly have heard from an adult. Children are not actively taught by adults which language structures are grammatical and which ones are not; they acquire a sense of the difference merely through exposure, and they generally do not respond to corrections when they do receive them. Finally, only humans seem to be able to acquire language. Primates cannot acquire most grammatical features of language, even through intensive behavioral training.

Chomsky concluded from observations such as these that language must in some sense be an inborn ability universally present in humans. At first, he described the innate ability to acquire language by using the metaphor of a 'black box', or device in the brain: the language acquisition device (LAD). Today, the concept of UG has replaced the metaphor of the device and the term LAD. It is UG that is envisioned as a biological 'language organ', and it is the nature of UG itself that allows humans to acquire language quickly and flawlessly.

UG contains the basics that all human languages have in common. Specifically, this includes the modular organization of the language faculty itself, a set of universal principles governing the structures of human language, and a set of parameters defining the possible limits of language-specific variations. This is the picture of UG that has arisen within Principles and Parameters Theory. It provides an account for both the fundamental similarities and the vast amount of observable variation among existing human languages. It also embodies predictions about what constitutes a possible human language.

Language may be structured as a system of interacting modules or subsystems. These modules are specialized in their function, much like bodily organs, and are usually assumed to include systems devoted to vocabulary, grammar, pronunciation, and meaning. UG is not seen as a list of universally valid rules for the correct formation of language structures. As Chomsky points out, lists of individual rules cannot adequately model the nature of language competency in fluent speakers or how this competency is acquired. On the contrary, learners do not need to acquire any organizational principle for the complexities of language: the framework is already provided for them by UG, and it is the same for all languages.

UG is assumed to contain a set of universal principles that are valid for all human languages. These are thought to include principles about the way language is structured into phrases. For example, a basic template governing the shape of syntactic structures and a general rule relating different syntactic structures to each other are both assumed to be principles of UG. The principles are innate and immediately available to the learner, and they are perhaps the most crucial tool in UG in its role as a language acquisition device. Because they radically reduce the number of possible analyses that a learner might assign to any one sentence, the UG principles, in a sense, allow the learner to automatically recognize the correct structure of language input during the acquisition process.

Of course, individual human languages show a great deal of surface variation in terms of the sounds they use, the structure of words, and the order in which words are combined. The language learner's task is to acquire the specific characteristics of the language of his or her community. UG therefore is said to include a set of parameters listing which aspects of language may show variation and defining what the boundaries for such variation may be. For example, one area in which languages exhibit systematic variation is their placement of *wh*- words (*what, who*, and so on) in the sentence. Some languages, such as English, position *wh*- words at the beginning of the sentence, whereas others, such as Chinese, do not. Languages on the whole seem to pattern either like English or like Chinese in this respect. The two options are therefore interpreted as the two possible UG 'settings' for a *wh*-placement parameter. A language learner is said to set the value for such a parameter through direct experience with input from the language being learned. Most parameters are thought to be binary in nature, i.e. they allow only two alternatives, like this one. Parameter setting has been compared with a process of setting electrical switches or filling in the blanks of a form. Thus, parameter setting is the real work of language acquisition. UG provides a structured framework and

all the possible choices, and ensures that the choices will be set correctly.

Utterance-Centered Linguistics

When approaching the study of language, a fundamental issue is to determine the basic unit for analysis. This decision will depend on the features of language and its use, which are of most interest to a particular researcher. In the case of utterance-centered linguistics, utterances rather than, for instance, words or sentences are taken as the unit for analysis.

An utterance is any contextualized sequence of naturally occurring language that may be distinguished from other sequences of language spoken or written by the same person or by other people in the same context. Very brief utterances may take the form of far less than a sentence: perhaps just a sigh or a grunt that conveys meaning without words or grammar. Other utterances may be realized by a single word or a grammatically incomplete sentence: for example, *Okay.* or *Got it!* Or utterances may take the form of a whole sentence— *Could you close the window?*—or even a number of sentences in a row (as in an extended request for assistance, with reasons and expressions of anticipatory gratitude). One or more naturally occurring oral or written utterances constitute a discourse. Utterance-centered linguistics studies discourses: component utterances may be analyzed either according to the linguistic features that mark or create coherence among them, or in terms of their embodiment of speech acts. A speech act is an intended meaning conveyed by a speaker or writer. Arguably, the most influential approach to utterance-centered linguistics has focused on speech acts, particularly in oral language.

Although utterances have no fixed grammatical structure, they do have structural requirements with regard to speech acts. Each will convey at least one speech act, sometimes a number of them simultaneously. Consider the following short discourse:

A: *It's twenty minutes past six.*
B: *Sorry. The boss called an unexpected meeting.*

This discourse may be viewed as consisting of three utterances: (1) the comment uttered by *A* and (2) and (3) the response to it uttered by *B*, with each utterance realizing at least one speech act: viz. (1) reproaching, (2) apologizing, and (3) justifying. In this discourse, also, it is noteworthy that whereas *Sorry.* is an incomplete sentence which therefore might be said to have a defective grammatical structure, this is not the only utterance where the hearer's understanding cannot be determined by the grammatical structure of the message alone. For instance, utterance (1)—although grammatically complete—is not accurately interpretable as a reproach only on the basis of its grammatical structure: grammatically, it is just an assertion. Full understanding depends on taking nonlinguistic contextual factors into account as well: what prior arrangement did the two speakers make? and what grounds might *A* have for feeling disappointed or angry if *B* failed to carry through? Clearly, *A* has framed utterance (1) on the assumption that *B* will readily comprehend the reproach through reliance not only on linguistic features but also on contextual knowledge and inferences. And the same assumption underlies *B's* response.

So utterance-centered linguistics views language as a socially contextualized rather than a strictly form-based phenomenon; this focus makes utterance-centered linguistics particularly effective for the study of natural language, since actual language users plainly conceptualize speaking or writing as a process of using utterances to perform speech acts with real-life consequences, not as a process of producing grammatically correct sentences. A key early figure in this tradition was J.L. Austin, the title of whose influential book, *How to do things with words* (1962), reflects his thesis that language use is a form of social action. Utterances are actions in the sense of being attempts to get others to do certain things, to entertain certain thoughts, or to experience certain emotions. Thus, Austin's work drew

1149

attention to the fact that real-life language users would be perplexed or even annoyed if their interlocutors interpreted their utterances only in terms of grammar, which in itself commonly gives no explicit indication of the intended meaning (speech act). For instance, anyone who asked another person in the street, *Do you know where the nearest bus stop is?* would doubtless feel insulted by the reply, *Yes, I know*. To treat an utterance simply as a more or less well-formed grammatical sentence is willfully to miss the point. In the above example, the lost person's utterance is evidently intended as a request for information, not as a mere yes–no question, and so any appropriate response would necessarily include an effort to provide directions.

Analyzing utterances and the utterance structure of discourses requires linguists to develop principles for disentangling separate but sometimes closely similar speech acts, for example *promising* and *threatening*. John Searle (1969, 1979) made important contributions in that respect. Also, he proposed (1975) a useful distinction between direct and indirect speech acts: this contrast has proven to be valuable because it allows analysts to address the way in which, for instance, the above utterance, *Do you know where the nearest bus stop is?* indirectly realizes the speech act of requesting information by directly performing a quite different speech act, a simple yes–no question. A further significant contribution was made by H. Paul Grice (1975, 1981), who suggested a possible set of maxims (guidelines) which—if shared by all speakers in a speech community—could explain the remarkable degree of confidence and accuracy with which speakers formulate and hearers interpret utterances embodying indirect speech acts.

The social orientation of utterance-centered linguistics has had very fruitful implications. Perhaps most profoundly, its willingness to recognize the multiple and indirect functioning of many utterances allows for thought-provoking links with the concept of deconstruction in semiotics, with all its cultural, political, and aesthetic reverberations. Moreover, utterance-centered linguistics has opened the way to important innovations in language teaching methodology and course design, made possible by structuring activities and curricula around utterances rather than sentences.

V

Variation

What is often known as 'variation theory' in sociolinguistics refers to the research paradigm developed by William Labov in the 1960s for the quantitative study of language variation and change. All variation in speech that cannot be explained on a purely linguistic level was once regarded as random or haphazard. In English, for example, the alternation of *-in'* and *-ing* in words such as *swimmin'* or *swimming* is sometimes called 'free variation', that is, speakers might choose to say *swimmin'* or *swimming* randomly. Variation theory aims to show that this type of variability is by no means random; rather, a statistical and comparative study involving multiple speakers and social contexts can demonstrate that it is correlated with various social and linguistic dimensions. In other words, the goal of variation theory is to explore the systematic nature of variability in language.

To conduct a variation study, investigators first need to select a variable—such as a sound (phonological) segment that tends to vary in pronunciation—and quantify occurrences of variants of this variable in the speech of different individuals in a given community. Take the example of word-final consonant cluster reduction in various English dialects. Words such as *wind, test*, and *pact* are sometimes reduced to *win'*, *tes'*, and *pac'*, respectively. In this case, the two variants of this variable (i.e. word-final consonant cluster such as *-nd, -st*, and *-kt*) are (1) reduced consonant clusters (e.g. *tes'*) and (2) nonreduced consonant clusters (e.g. *test*). Investigators then propose possible factors that might influence word-final consonant cluster reduction. These factors are of two major types. First, there are factors internal to the language system itself.

For instance, the phonological environment that follows the cluster might be an important internal factor—it is possible that word-final consonant clusters are more likely to be reduced when followed by a consonant (e.g. *east coast*) than by a vowel (e.g. *east end*). In addition, there are social or external factors that may favor or disfavor word-final consonant cluster reduction. Age, gender, social class, and contextual style are some of the external factors that are often taken into consideration in variation studies. Investigators might hypothesize that a speaker from a working-class area would be more likely to say *eas'* instead of *east* than speakers from other communities. Similarly, a speaker might say *pac'* for *pact* in casual speech but not in formal speech. Finally, multiple-regression analyses—statistical analyses that determine the significance of multiple factors—are performed. The rule of word-final consonant cluster reduction is not categorical (that is, not all speakers from working-class areas reduce consonant clusters in word-final positions, and no speaker would do so at all times). The goal of the statistical analyses is to determine which factors increase or decrease the likelihood of consonant cluster reduction.

With the use of quantification and statistics, investigators can make accurate statements about fine-grained differences between groups of speakers in a community. When examined at the level of the community, what seems to be random phonetic variation is actually systematically patterned and correlated with various social and language-internal factors. In his study of New Yorkers' speech, for example, Labov (1972) showed that both higher social class and higher

degrees of formality favored conservative (or 'standard') pronunciations. Furthermore, an innovation that occurred in working-class speech was likely to appear in the informal speech of all speakers. In addition to social class and contextual style, Labov showed that variation in New Yorkers' speech was correlated with age as well. In the case of syllable-final *r*, its occurrence was not significant for speakers from all social classes in the two oldest age groups (50–75 and 40–49). In other words, speakers in these age groups did not usually pronounce the *r* in words like *car* and *teacher*. However, the pronunciation was a prestige marker for speakers under 40 years old: speakers from the upper middle class consistently pronounced *r* in syllable-final position more often than those from other social classes, and a regular increase in the use of *r* marked the move from casual to formal speech styles. Examining age as one of the social factors allows investigators to observe language change in 'apparent time' by listening to the speech of different generations in a given community. The use of different variants of a variable shows that language change does not take place abruptly, but rather in small gradations.

Nevertheless, generalizations obtained through statistical techniques are merely descriptive statements. Correlations between variation in language, on the one hand, and linguistic and social dimensions, on the other, need to be explained with solid reasoning. While the relationship between variation in speech and language-internal factors can be accounted for by certain linguistic mechanisms (e.g. word-final consonant cluster reduction can be explained in terms of the simplification process), sociolinguists look to sociology and anthropology for insights into the relationship between language variation and variation in society. Although the notion of social class is still considered a key dimension in sociolinguistic change, John Rickford (1986) and a host of others have argued that social class needs to be modified for non-Western societies. Furthermore, the concept of social network—that is, the sum of relationships that an individual shares with other people—has received increased attention in recent years (see Milroy 1987). Others, most notably Penelope Eckert (2000), advocate an ethnographic approach to the study of language variation and change. Investigators who adopt this approach do not decide a priori which social factors should be examined in relation to language variation; rather, they participate in the everyday lives of the speakers and understand the social dimensions that matter most to members of the community. Instead of relying on ad hoc explanations, they offer more grounded social explanations for linguistic behavior, in that they possess a better understanding of the social meanings associated with linguistic variation in the communities they study.

Vietnamese

Vietnamese is spoken by approximately 65 million of the 80 million inhabitants of the Southeast Asian country of Vietnam. Nearly two million additional speakers of Vietnamese live outside the country, with over a million residing in North and South America, mainly in the United States and Canada, and approximately 400,000 in Europe, particularly in France, Great Britain, Germany, and Switzerland. Speakers of Vietnamese can also be found in Australia, New Zealand, Hong Kong, and Japan. Vietnamese has often played a secondary role to other languages in Vietnam, particularly Chinese, which was the language of Vietnam's ruling class from 111 BC to AD 939, and French, which served as the country's official language from the late nineteenth century until the mid-twentieth century. However, Vietnamese is now recognized as the official language of Vietnam, becoming the medium of instruction in schools in 1945.

Because of the similarities and differences that Vietnamese shares with other Southeast Asian

languages, linguists have had difficulty establishing the genetic affiliation of the language with absolute certainty. Due in part to the great number of Chinese words in the Vietnamese lexicon, Vietnamese was at one time considered to be a member of the Sino-Tibetan family. More recently, linguists have attributed this similarity in word stock to the long domination of Vietnam by the Chinese and have explored similarities between Vietnamese and the members of other language families. French scholar Henri Maspéro (1912) proposed that the genesis of Vietnamese resulted from the fusion of a member of the Mon-Khmer family, such as Khmer (formerly Cambodian), and a Tai language, such as Thai. Ultimately, Maspéro identified Vietnamese as a Tai language because of its use of tone, a characteristic feature of Tai languages that is uncharacteristic of Mon-Khmer languages. A number of other linguists, however, have argued that Vietnamese originated as a Mon-Khmer language that adopted a tonal system through contact with speakers of Thai. French botanist–linguist André Haudricourt (1954) argued that the phenomenon of tonal genesis in Vietnamese was an evolutionary process in which the language acquired three tones by the sixth century through language contact, and doubled this number by the twelfth century to the six tones currently used in the Hanoi dialect of Vietnamese. This account, coupled with the observation of the similarity between Vietnamese and Muong by Pryzluski (see Meillet and Cohen 1924), has convinced many linguists that both Vietnamese and Muong belong to the Mon-Khmer phylum in the Austro-Asiatic family.

Although linguists have repudiated anything more than a distant genetic relationship between Vietnamese and Chinese, the two languages have a number of similarities. The most apparent among these is the great number of Chinese words in the Vietnamese lexicon, many of which were borrowed during the Chinese domination of Vietnam from 111 BC to AD 939. During this period, Chinese was not only used among many of the officials of Vietnam, but also as a medium of education; as a result, the language of law, politics, history, medicine, science, and technology in Vietnamese include a great number of borrowings from Chinese. While some of these words have been modified to such an extent by Vietnamese speakers that they can hardly be recognized as Chinese anymore, others are referred to as 'Sino-Vietnamese' because they are pronounced as they would have been in ancient Chinese. Vietnam's proximity to populations of Malay and Thai speakers has resulted in the Vietnamese lexicon including borrowings from these languages; Vietnamese has also borrowed words from French, English, and Russian as a result of colonization, war, and political alliance.

Vietnamese and Chinese share a number of other characteristics leading to the false impression that the two languages are closely related. One of the most significant of these characteristics is that both languages are considered tonal because they recognize tone as phonemic, i.e. tone makes a difference in meaning. For example, in the Hanoi dialect of Vietnamese, which recognizes six different tones, the word phonetically realized as [ma] has six different meanings depending on which of the six tones (high, low-falling, high-rising, creaking-rising, dipping-rising, and constricted) is used. In addition to the explanation of tonal genesis by Haudricourt, linguists have attributed this commonality to contact between speakers of Vietnamese and Chinese, particularly the Chinese dialects spoken in the southern provinces near the border of Vietnam, which tend to have more tones than other Chinese dialects.

Like other languages spoken in Southeast Asia, Vietnamese is a morphologically isolating language, a typology that Vietnamese also shares with Chinese. Characterized by the absence of bound inflections, isolating languages contrast with synthetic languages, which use affixes on words to indicate such things as number, tense, and agreement. For example, by affixing the bound morpheme /s/ to a noun or /ed/ to a verb, speakers of English respectively show plurality and past tense. In an isolating language like Vietnamese, however, words and morphemes tend to have a one-to-one relationship, so that when Vietnamese speakers want to show plurality, they must use a separate word or grammatical particle elsewhere in the sentence. As in Chinese, there tends to be a one-to-one relationship between syllables and morphemes in Vietnamese, which has led some scholars to deem Vietnamese as monosyllabic. Other scholars, however, have taken issue with this characterization and have pointed out that the Vietnamese lexicon includes many words that are disyllabic, as well as words that have three or four syllables (Hannas 1997:76–77). The perception that Vietnamese is monosyllabic has also been attributed to the Vietnamese orthographic practice of putting a space between every syllable of a word.

Although it lacks inflectional morphology, Vietnamese employs derivational morphology as a means for creating new words. Vietnamese uses prefixing and suffixing, which are two processes of affixation used productively in many of the world's languages, including English; however, in contrast to many other Southeast Asian languages, Vietnamese does not use infixing, a type of affixation in which a morpheme is inserted into the root of a word. Another very productive process of deriving new words in Vietnamese is compounding, not only as a process of creating new nouns but in the derivation of new verbs and adjectives. Reduplication, which is the process of deriving a word

by copying all or part of a word and affixing it to itself, is yet another morphological process that is used often in Vietnamese and other Southeast Asian languages, as well as Chinese. Like many of the world's languages that use reduplication productively, Vietnamese commonly uses reduplication to pluralize and intensify the original semantics of a word, as well as to show reciprocity. Reduplication is also commonly used in onomatopoetic expressions in Vietnamese, as is also the case in other languages of the world.

The basic syntactic structure of Vietnamese is subject–verb–object (SVO). Because it is an isolating language, Vietnamese relies heavily on word order to show the grammatical roles being played by various arguments in a sentence. Vietnamese also uses special markers to indicate such things as the tense of verbs and the number and gender of nouns. In Vietnamese, a tense marker is placed before the verb that it modifies, and negative markers also appear in preverbal position. Adjectives come after the nouns they modify in Vietnamese. Content questions, or questions that demand an answer besides yes or no, are formed by inserting an interrogative word in the position in the sentence in which the unknown material should be, leaving the sentence in its basic SVO order. Although SVO is the basic word order in Vietnamese, object–subject–verb (OSV) order is also commonly used when a speaker moves an object to the beginning of a sentence to give it emphasis over the subject, a process known as topicalization.

The system of personal pronouns in Vietnamese is rather complex due to the use of pronouns not only as substitutes for the name of a person or group of persons, as they are in English, but also as a way of marking the status of participants and referents in conversations. Based largely on factors such as age and familiarity, the use of various pronouns to mark status requires speakers to evaluate whether they are superior or inferior to those with whom they are speaking, and this decision affects which first-person pronouns they use, as well as second-person pronouns. As is the case in other cultures that use languages with similar pronoun systems, there are social consequences for choosing the wrong pronouns in Vietnamese. The pronoun system also has two forms for the first-person plural pronoun: one to be used when speakers wish to include their addressees in the group for which they are using the pronoun (inclusive) and another if the addressees are not included (exclusive).

Like other Asian languages, Vietnamese also has a complex system of kinship terms, or terms that speakers use to address and to refer to members of their own family, which reflects the extended and patrilineal nature of the family structure. In speaking to members of their immediate family, children must use various

first-person pronouns depending on whether they are addressing their parents, elder siblings, or younger siblings. In using the second person, children must use pronouns reflecting the distinction in gender when addressing their parents, a distinction that is preserved when children address elder brothers and sisters. This distinction is not maintained when parents address children or when elder siblings address younger siblings. As in the use of personal pronouns, the choice of an inappropriate kinship term may have consequences. Apparently borrowed from the South Chinese, one custom that is commonly used among the lower classes of Vietnam is the use of *kin numeratives*. A device used for designating grown-up children, a common pattern is to call the eldest child 'Number One', the second child 'Number Two', and so on. An interesting variation of this occurs in southern Vietnam, where 'Number Two' is used to refer to the eldest son or daughter, with speculation that the Vietnamese word for 'Number One' was reserved for the mother because she is considered the father's first child (Dinh-Hoa 1980:32).

Three different orthographic systems have been used during the history of writing in Vietnamese. The first was *chu nho*, which was borrowed directly from the Chinese and was the official written language from as early as the eleventh century until the nineteenth century. The next was *chu nom*, a writing system based on the Chinese system but altered to phonetically represent spoken Vietnamese. The invention of this system is generally attributed to Han Thuyen, a famous Vietnamese poet of the thirteenth century. The modern spelling system is *quoc ngu*, a Roman alphabet devised by Catholic missionaries from Europe to translate scripture into the language in a way that would make sense to the Vietnamese, as well as to the missionaries who read aloud from it. During French domination of the country from the late nineteenth century to the mid-twentieth century, the French used *quoc ngu* to introduce the Vietnamese to French language and literature. Although many have praised the success of the Vietnamese in replacing the Chinese writing system with a more phonetic alphabet, others have pointed out that the extensive use of diacritics to indicate tones in *quoc ngu* creates a system nearly as complicated as the one it was intended to replace (Hannas 1997:75).

Vietnam is characterized by three dialect areas: northern, central, and southern, perhaps reflecting the division of Vietnam into three states by the French during their domination. The northern dialect area includes Hanoi, the capital city of Vietnam. Ho Chi Minh City (formerly Saigon) is the largest city in Vietnam and is in the southern dialect region. The differences between the three dialects are mainly at the levels of pronunciation and vocabulary and are not great enough to cause

1154

much difficulty in communication among speakers of different dialects. Although Vietnam does not have a spoken standard, with each locale maintaining its own dialectal flavor, the dialect spoken in Hanoi is the dialect used most often in the media.

Visual Word Recognition

Visual word recognition refers to the process by which readers identify written words. Recognizing a word enables a reader to use the word's phonology to read aloud or to use the word's semantics to determine its meaning. Skilled reading is marked by the ability to recognize words quickly and with relatively little effort.

There are two major approaches to modeling cognition in general, and word recognition in particular. Cognitive neuropsychologists of the nineteenth century assumed that the language processing system was modular and that component structures and processes could be represented as a box-and-arrow diagram. This approach fell out of favor in the first half of the twentieth century, but remains popular in the twenty-first century. The revival is bracketed by two seminal articles in *Psychological review:* Morton's (1969) logogen model and Coltheart's (2001) dual route cascaded (DRC) model.

That portion of the DRC concerned with reading aloud can be used to provide an example of the modular approach. The model assumes two principal pathways by which a printed word can be read aloud. Both routes are initiated by a common process of orthographic analysis, which leads to the identification of the word's constituent letters. The lexical route uses the letter identities to activate an entry in a mental dictionary called the orthographic input lexicon. In turn, the pathway from the orthographic input lexicon to the phonological output lexicon activates the word's phonology. The other major route processes the letters in left-to-right order and applies a set of grapheme–phoneme rules. For example, the grapheme consisting of the first two letters of SHEEP is translated as the phoneme that sounds like 'sh'. Both of these routes compute a pronunciation that is represented as a sequence of phonemes. The eventual response is based on combining the outputs of both routes in a response buffer.

The lexical route is needed in order to correctly pronounce words that have an irregular spelling–sound correspondence such as PINT because the phonology generated by the rule route favors a pronunciation that would rhyme with the regular words HINT and MINT. The rule route is needed in order to model the ability of humans to easily read aloud nonwords like MAVE. In this case, the lexical route would have no entry for MAVE and could not generate a pronunciation other than by analogy to similar real words. This division of labor allows dual-route models to offer compelling explanations for different types of acquired dyslexias that together form a double dissociation. For example, damage to the lexical route should lead to specific difficulties with irregular words like PINT (surface dyslexia), but preserve the ability to read nonwords and regular words. On the other hand, damage restricted to the rule route should lead to specific difficulties in reading nonwords (phonological dyslexia), but preserve the ability to read both regular and irregular words.

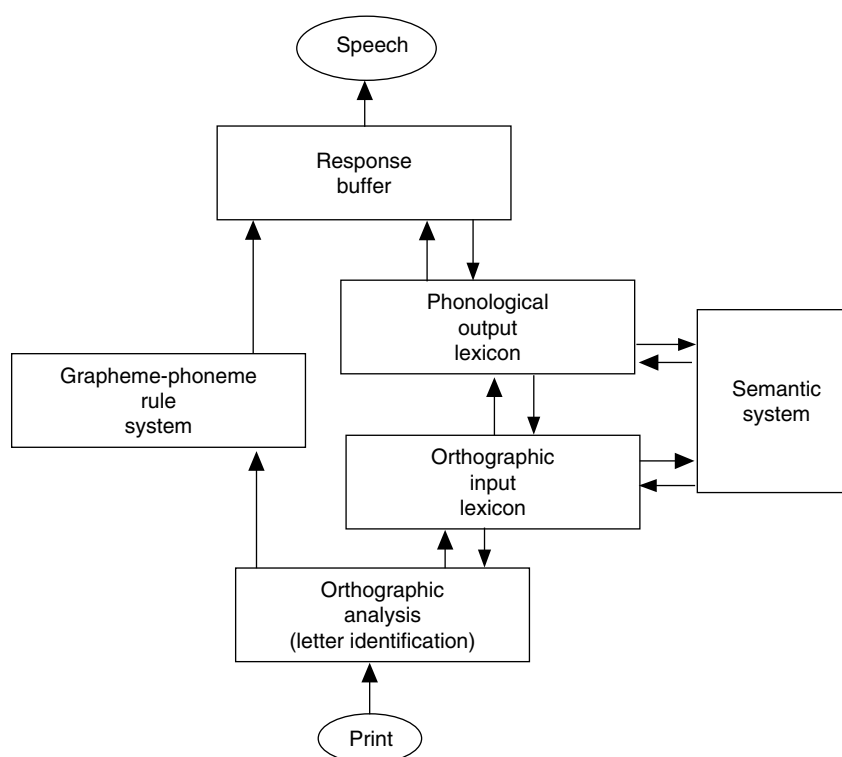
The DRC is also a computational model, meaning that it has been implemented as a computer program that performs reading tasks by using the same structures and processes hypothesized for human readers. The reading tasks studied most often are reading aloud


Figure 1
Figure 2

and the lexical-decision task. In the latter, participants are asked to make speedy responses as to whether a letter string is a word or a nonword. DRC can simulate the speed and accuracy of human readers in response to many different characteristics of words. These include spelling–sound regularity, frequency of occurrence, and the orthographic similarity of a target word to other words.

One heavily researched phenomenon in word recognition that the DRC has not simulated is semantic priming. Semantic priming occurs when the response to a target word like DOCTOR is faster when preceded by a related prime like NURSE. In theory, DRC could account for semantic priming because, in addition to the direct pathway from the orthographic input lexicon to the phonological output lexicon, there

is also a mediated pathway through a semantic system that contains semantic representations of each word. However, the semantic pathway has not been implemented in the computational model because developing realistic semantic representations is more difficult than representing orthography and phonology. However, powerful new tools like latent semantic analysis and other high-dimensional representations based on the co-occurrence of words in very large corpora of text make it likely that computational models will soon be able to address more adequately the very important role of semantics in word recognition.

The second major approach used to model word recognition uses learning algorithms in conjunction with networks that have distributed representations. The seminal model of this type was Seidenberg and McClelland's distributed developmental model (DDM, 1989). Using the DDM as an example and reading aloud as the task of interest, this computational model is based on a network with three layers. The input units represent orthography, but that representation is distributed across a large set of nodes. This means that individual nodes do not symbolize individual letters. Rather, a given node is sensitive to many letter sequences and, conversely, a letter in a specific input location will partially activate many different input nodes. The third, or output, layer codes phonology with a similar type of distributed representation.

The middle hidden layer has no symbolic representations at all. Each node in one layer is connected to every node at the next layer. Each connection has a weight that is initially set at a random value, but during training the back propagation learning algorithm progressively adjusts the weights such that each input (printed word) more and more closely approximates the correct output (pronunciation). In the DDM, both irregular words and nonwords can be read aloud by using a single pathway from input (orthography) through the hidden layer to output (phonology). In contrast to dual-route models, it does so without the explicit representation of grapheme–phoneme rules or the explicit representation of words in a mental lexicon. The DDM and its successors have also enjoyed considerable success in simulating the performance obtained with people in reading tasks.

Voice

'Voice' is a technical term for the description of sentence structure. It encompasses a range of grammatical constructions that differ in the correlation between the semantic and grammatical function of particular sentence elements. The English sentence *John kissed Mary*, for example, has two noun phrases: *John* and *Mary*. The first, the subject, performs the action described by the sentence and is thus interpreted as the 'agent'. The second, the object, undergoes the action and is thus interpreted as the 'patient'. In an English active sentence such as this one, the grammatical function 'subject' thus correlates with the semantic role 'agent', whereas the 'object' fulfills the semantic role of 'patient'. In languages such as English, 'active' is the basic voice, because it appears with all verbs and does not require any specific marking on the words involved (e.g. *was kissed*). These languages typically also have 'passive' and 'middle' constructions, which are discussed below.

There are many languages (so-called ergative languages), however, in which sentences where the patient surfaces as subject are the basic ones. A cross-linguistically valid definition of voice is thus difficult, and any characterization of voice in terms of information sequencing or in terms of cognitive processes raises a number of problems, because the voice systems of different languages differ enormously from one another.

A passive construction or sentence is one in which a somehow marked form of the verb has a nonagent (typically a patient) subject, whereas the agent may or may not appear as an object introduced by a preposition (e.g. *Mary was kissed [by John]*). The passive has traditionally been analyzed as the result of a grammatical operation (passivization); the active sentence used to be regarded as the basic one, which would somehow need to be changed to become a passive sentence. Passive sentences were considered to be synonymous paraphrases of their active counterparts. *John kissed Mary* and *Mary was kissed by John* were regarded as essentially equivalent utterances. Since the 1980s, however, several studies have taken into consideration that the passive may have different connotations in context; i.e. the choice between an active and a passive sentence is more than just a random stylistic one. Rather, it is seen as a matter of relative prominence of agent and patient—passive and active differ in terms of information packaging or sequencing, or in terms of foregrounding of information. Because the subject is usually the topic of the sentence, a passive sentence is thus argued to foreground the patient role. Although supported by psycholinguistic experiments, this view of passive constructions has been widely challenged, and it has been claimed that the main function of passive sentences is not the foregrounding of the patient but rather the defocusing or backgrounding of the agent. This would account for the fact that in a significant number of cases the passive voice does not signal that

the patient is topical, but simply indicates that the agent is not important. A case in point is the so-called impersonal passive (e.g. German *Es wurde hier getanzt,* 'There was dancing here'). Because in impersonal passives there is no patient role, patient topicalization cannot be considered as the function of these passives.

Some verbs, such as English *sink,* appear in pairs such as *The enemy sank the ship* vs. *The ship sank.* The object of the first clause corresponds to the subject of the second. The verb in the second clause would thus be expected to occur with passive marking, which, however, is not the case. These verbs have sometimes been labeled 'middle verbs' because they seem to break out of the active/passive dichotomy. Other constructions typically referred to as 'middle' are reflexive sentences. An example would be the Spanish sentence *Juan se ve,* 'John sees himself'. The primary function of this construction is to encode the identity of agent and patient. The argument that this is somewhat in between active and passive has been extended to other functions or meanings of the reflexive marker, such as the encoding of an action performed on the subject's body, as in the Spanish *Juan se peina el pelo,* 'John combs his hair'; the expression of situations that occur entirely within the subject's sphere, as in sentences with the Spanish verb *sentirse,* 'feel' (literally 'feel-self'); or even the expression of passive meaning, as in Spanish *aquí se habla Español,* 'Spanish is spoken here'. In some languages, the opposition active/middle is actually encoded in alternating verb forms. This can be observed in Sanskrit and Greek (both ancient and modern), both members of the Indo-European family, and in languages such as Tula (a Niger-Congo language) and Tamil (a Dravidian language). In these languages, the middle voice usually denotes actions that are performed on the body or on a part of it, as well as spontaneous actions, i.e. events presupposing no causal agent.

Thus, many languages distinguish between active and passive voice and may also include a middle voice. Ergative languages approach the same issue from the opposite side and seem to focus on the patient rather than the agent. To further complicate the issue, in some languages, the question of whether or not the subject of the sentence is an agent or not becomes altogether secondary. These languages, for instance, Philippine languages or native American Algonquian languages, concentrate instead on 'empathy'. Empathy is an all-encompassing complex system involving features such as animacy, (perceptive) salience, (potential) agency, whether or not something has been mentioned before, etc. 'Inverse voice' contrasts here with 'direct voice'. The inverse voice indicates that the agent ranks lower on the empathy scale than the other role, whereas the direct voice is used when the agent is higher on the empathy scale. In both inverse and direct clauses, the agent usually has subject properties; for example, it agrees with the verb. Talmy Givón (1994) distinguishes between semantic and pragmatic inverse systems. In the latter, the choice between a direct or an inverse clause is a matter of which of the two participants is more salient in the specific discourse. However, in semantic inverse systems, the decision between inverse and direct voice depends on more objective relations, such as animacy: if the subject refers to an animate entity (e.g. an animal), while the object refers to an inanimate one (e.g. a rock), the direct voice would be used, because the animate subject is higher on the empathy scale than the inanimate object.

Vowel Harmony

Vowel harmony is a well-known but not yet well-understood phenomenon found in many languages native to Eurasia, Africa, and, to a lesser extent, other places. Hungarian, Finnish, and Turkish number among the best-known cases of harmony. The Uralic and Altaic language families, spoken across a vast geographic area of Eurasia from Korea to Turkey, exhibit vowel harmony to varying degrees in most of their member languages (Hungarian, Finnish, Turkish, Mongolian, Manchu, and so forth). Harmony is not found in any familiar Indo-European languages (e.g. Greek, French, or English).

Simply stated, harmony is when vowels within a word are required to resemble one other in terms of some property. For example, in the Tuvan word *tooruksug,* meaning 'smelling like a pine cone', all vowels are 'labial' (pronounced with rounded lips). Tuvan has an ample supply of vowels that do not use lip-rounding, yet the vowels here—taking their cue from the first vowel—are all rounded.

There are several basic types of harmony, each named for the speech organs involved. These include palatal/velar (also called 'backness') harmony, labial (also called 'rounding') harmony, and tongue root (also called ATR) harmony. Palatal harmony requires vowels to be alike in terms of whether they are pronounced with the tongue body toward the front of the oral cavity (close to the palate) or toward the back (close to the velum). Labial harmony requires vowels to be alike in having lip rounding. Tongue root harmony requires vowels to be alike in whether the tongue body is pushed toward the front of the mouth or pulled toward the back.

A language may have more than one harmony system. Turkish has palatal and labial harmony, whereas Classical Manchu had tongue root and labial harmony. Two separate harmony systems, when present, may operate in an independent or semi-independent manner.

Not all vowels participate equally in harmony. Typically, some restrictions are placed on which vowels cause harmony and which ones obey it. Such restrictions usually refer to some feature other than the harmonic one. In Tuvan, for example, any labial vowel can trigger labial harmony (forcing adjacent vowels to also be labial), but only high vowels (vowels that are pronounced with more tension in the tongue and mouth, such as in *seek* or *plume*) undergo labial harmony (vowels that obey harmony are underlined herein):

Tuvan

Low vowels (pronounced with less tension, as in *long*) do not obey labial harmony:
  xol-da 'in (the) hand'
  xöl-de 'in (the) lake'
  High vowels must obey labial harmony:
  xol-u̲ 'his hand'
  xöl-ü̲ 'his lake'

Vowel harmony may be thought of as a restriction on which vowels may occur together within the same word. In Turkic languages, all vowels can be divided into two natural classes: those pronounced with the tongue in the back part of the oral cavity, and those pronounced with the tongue toward the front. In a Turkic language with eight vowels, four of them will belong to the front (palatal) class and four to the back (velar) class. For a typical Turkic vowel inventory, see below:

	front (palatal)	*back (velar)*
High	i ü	ɯ u
Low	e ö	a o

(labial vowels are ü, u, ö, o)

Within any single word (including any affixes added to that word), vowels from the front and back classes do not mix:

Tuvan

is	'footprint'
is-te̲r-i̲vi̲s-te̲	'in our footprints'
aas	'mouth'
aas-ta̲r-u̲vu̲s-ta̲	'in our mouths'

Harmony applies only within a word. No harmony system allows harmony to carry across a longer span, such as two distinct words or an entire sentence. At the level of word structure, harmony systems may be divided into two basic types, depending on what element controls harmony. In 'root-controlled' harmony, vowels in a word root determine the quality of vowels appearing in affixes. In 'dominant–recessive' harmony, neither roots nor affixes take precedence. Instead, if any vowel belonging to the dominant class appears anywhere in the root or a suffix, it forces all other vowels in the word to shift over to that class. A word may contain weak (recessive) vowels only if no strong vowels are present.

No harmony system is exceptionless: typically, a language will have some nonharmonic native words or affixes. A language that has been in long-term contact

with a nonharmony language (e.g. Russian or Farsi) may have a large supply of nonharmonic loan-words.

Nonetheless, these disharmonic elements may participate productively in harmony. Usually, the final vowel of a nonharmonic word determines the harmony of the following suffix vowels:

Classical Manchu (disharmonic words)

age	'prince'
age-s<u>e</u>	'princes'
dahema	'uncle'
dahema-s<u>a</u>	'uncles'

How is harmony related to the mechanics of speaking? Vowel harmony makes some sense when viewed in terms of natural movements of the speech organs. For example, when you round your lips to pronounce 'oo', this gesture may carry over onto the next vowel. This tendency might account for common slips of the tongue in English, for example, saying *kangaroo moot* when you meant to say *kangaroo meat.* Physical speech mechanisms provide a natural foundation for harmony. But they do not explain why certain languages (and not others) adopt harmony as a fundamental organizing principle of their sound systems. Harmony likely traces its origins to natural speech mechanics, but it has evolved into a more abstract way of organizing the sounds of particular languages. Thus, harmony can work at cross-purposes with the mechanics of speech— it may impose conditions that do not obviously facilitate either speech production or perception.

For example, in Tofa, if a word contains [j] (the sound written with a 'y' in English), all vowels next to [j] must be pronounced in the front of the mouth, as if they belonged to the palatal class. However, for purposes of harmony, the speaker may ignore the fronting effect that [j] has on some vowels, considering them to be back vowels despite their palatal quality. Any suffix the speaker adds will thus contain a velar vowel:

Tofa

xöjen-d<u>a</u>	'in (the) cliff'

In this case, harmony clearly does not facilitate pronunciation, because Tofa speakers are not accustomed to mixing palatal and velar vowels within a word. But it does serve to maintain the integrity (at an abstract level) of harmony as a system.

Besides ease of pronunciation for the speaker, what other advantage might harmony offer in language design? Some linguists have argued that harmony helps to make clear to the hearer the boundary between one word and the next. But this can be true only if two adjacent words belong to different harmony classes. It has also been suggested that harmony increases the likelihood that the hearer will correctly identify certain vowels. If a speaker notices that the vowel of the first

syllable is palatal, he or she can be fairly certain that each following vowel also belongs to the palatal set. This reduces by one half the range of potential vowels he or she must listen for in succeeding syllables, and it may lessen the cognitive processing required.

Many harmony languages have vowels that fail to participate fully or at all. Instead, they may either obstruct the harmony pattern or remain invisible to it. So-called opaque vowels block the current harmony pattern and start a new pattern. The Turkish suffix *-gen* (corresponding to English *-gon*, as in *octagon*) contains a front (palatal) vowel that never alternates to obey harmony. Vowels following *-gen* must be palatal, even when the prevailing pattern in the word is velar:

Turkish

alt ɯ	'eight'
alt ɯ-gen	'octagon'
alt ɯ-gen-l<u>e</u>r	'octagons'

So-called transparent or neutral vowels allow harmony to pass through them, without being affected and without blocking it. In Karelian (a Uralic language), backness harmony dictates that if the first syllable contains a front vowel, all the following syllables contain front vowels. Likewise, if it contains a back vowel, the following syllables have back vowels. Exceptions are the front vowels [e] and [i], which remain indifferent to harmony and may appear anywhere.

Most harmony languages tolerate some disharmony, which can result from internal processes or from borrowing foreign words. Internally, consonants may interfere with the harmony system, imposing their own conditions that override it. Syllable structures may also impose limitations on harmony: in Turkmen, for example, labial harmony does not affect vowels in word-final syllables containing a vowel. In Turkish, the presence of a velar consonant [g] may force an adjacent vowel to be velar, even though the other vowels in the word are palatal. Modern Turkish also has a high percentage of nonharmonic loan-words in its lexicon: *taksi* 'taxi', *kitap* 'book'. Some harmony languages alter borrowed words to render them more harmonic.

The Turkic languages range from almost perfectly harmonic to hardly harmonic at all. These languages illustrate the possibilities of change and evolution in harmony. The plural suffixes in Old Turkic and two of its daughter languages, Turkish (highly harmonic) and Uzbek (barely harmonic), show two possible paths along which harmony can proceed (see below).

	back suffix	front suffix
Old Turkic (harmonic)	-l<u>a</u>r	-l<u>e</u>r
Turkish (harmonic)	-l<u>a</u>r	-l<u>e</u>r
Uzbek (not harmonic)	-lar	-lar

Harmony as a pattern can best be understood by considering those in which it fails to apply as well as those in which it applies. Many unanswered questions remain in understanding vowel harmony. Dozens of languages known to have harmony remain largely undocumented, and new types will certainly be discovered.

W
Wackernagel, Jacob

Wilhelm Wackernagel, Jacob's father, originally from Berlin, moved to Basle in 1833, where he was appointed professor for German Studies at the local university. The Wackernagel family developed a very close link with the city of Basle: Jacob's brother Rudolf, who worked for the city archives, wrote a history of Basle reaching back to the sixteenth century, and Jacob lived in Basle and taught at the University of Basle until his death, with only one interruption, during which he taught at the University of Göttingen, in the years preceding World War I. Jacob's life was entirely devoted to studying and teaching classical philology and the ancient Indo-European languages. He had his first appointment at the age of 24; his teacher of Greek was Friedrich Nietzsche.

Wackernagel can be considered a member of the second generation of the 'Neogrammarians', a school of linguists interested in studying how languages change over time. Among his contemporaries, he occupies a special position because of his interest in sentence structure, something that had been investigated to a much lesser extent than pronunciation and word structure. A survey of the courses he gave in his years as professor shows that syntax was a recurring topic already in the 1880s; in 1904 Wackernagel was offering a course in historical syntax, a topic which can still sound innovative today.

In his 1892 essay *Über ein Gesetz der indogermanischen Wortstellung (On a law about Indo-European word order)*, Wackernagel pointed out that in the ancient Indo-European languages a number of particles, conjunctions, pronouns, and verbs took a peculiar position in the sentence, nowadays known as the 'Wackernagel position' or

'P2', because it is situated immediately after the first word with intonational emphasis (accent). All words in P2 share the characteristic that they are unaccented (or weakly accented). This tendency is most visible in Sanskrit and Homeric Greek, but Wackernagel found its traces in other Indo-European languages as well, and he surmised that Proto-Indo-European, the hypothesized ancestor language of all Indo-European languages, followed the same pattern. Thus, Wackernagel reconstructed Proto-Indo-European as having essentially a similar word order to Modern High German, having the tensed verb obligatorily in second position in main clauses and in final position in subordinate clauses.

Wackernagel's hypothesis was received with varying degrees of approval by his contemporaries; especially the idea that the position of the tensed verb in Proto-Indo-European was the same as in German did not meet general consent. However, the fact that various types of unaccented item were placed in P2 found a striking confirmation when Hittite was finally deciphered in 1916, for unstressed pronouns and particles follow the pattern described by Wackernagel virtually without exception in this language.

In the second half of the twentieth century, progress in the study of unaccented particles (usually referred to as 'clitics') and knowledge of previously unknown non-Indo-European languages has demonstrated that the Wackernagel position is not a unique feature of Indo-European. Being unstressed, clitics need what is commonly called a phonological host, i.e. an accented word with which they can form a phonological unit. P2 is one of the possible positions for clitics, found in e.g. some Australian and Uto-Aztecan languages.

Wackernagel's other major accomplishment in the field of syntax is constituted by the two volumes of lectures on syntax (*Vorlesungen über Syntax*), 1926–1928, in which the scholar addressed several problems connected with the syntactic behavior of nouns and verbs in the Indo-European languages (mostly based on Latin, Greek, and Germanic). Wackernagel's approach is typical of historical linguistics in the late nineteenth to early twentieth century, insofar as—from today's perspective—the word is still the dominant unit of analysis. In Wackernagel's times, linguists were in the process of developing distinctive theories of word and sentence structure, but word-related issues were still defining and delimiting syntactic problems. Although he announced a further volume on sentence structure, Wackernagel never wrote it. Since the newly individuated field of syntax could not yet rely on a theoretical framework, Wackernagel's syntactic work remains descriptive, his insights mostly deriving from his deep knowledge of languages and texts.

Biography

Jacob Wackernagel was born in Basle in 1853. He studied Classical Philology in Basle, and was then appointed in the same university, where he taught from 1877 to 1902. He was appointed in Göttingen in 1902–1915. Then he returned to Basle and resumed his former position, which he held until 1937. He died in Basle on May 22, 1938.

SILVIA LURAGHI

Warao

Warao is an Amerindian language spoken in the Orinoco Delta and adjoining areas in northeastern Venezuela and Guyana. Its speakers, the Warao, are the aboriginal population of the Delta, who have been present for as long as 9,000 years (W. Wilbert 1995:336). They have an estimated population of about 30,000, which is increasing. Although they form the second largest indigenous group in Venezuela, given that the total indigenous population of the country comprises only 1.5%, they are clearly a minority. The latest reliable official census rates 90% of the Venezuelan Warao as speaking their indigenous language and 48% of them as being bilingual in Warao and Spanish (Venezuela 1993). Especially in the central part of the Delta, missionary boarding schools have had the—albeit unintended—effect of language loss. There are therefore a growing number of monolingual Spanish speakers in this area and in the slums found in Tucupita and Barrancas.

The estimated 1,000 Warao on the Guyanese side are all in close contact with wider Guyanese society so that all of them can be assumed to be English speaking: some being bilingual Warao-English or even trilingual including Spanish. There is however the tendency to give up Warao (Forte 2000).

Social and Political Status of the Language

Up to now, Warao is a language with no genuine writing tradition. Nevertheless, recordings mainly of myths have been written down and published by anthropologists (J. Wilbert 1970; Heinen 1988), missionaries, and linguists (Osborn 1966a, b, 1967; Lavandero 1991, 1992). The diversified oral tradition includes different styles of speech and various genres. It differentiates for instance between '*denobo*' (<*deje nobo*: old stories) mythology on the one hand and '*deje jiro*' (new stories) or '*deje kwamotane abane*,'

which contain recent stories, gossip, and jokes, on the other hand. In addition, there is special language use during ritual as in shamanistic curing sessions and wailing for the dead (Briggs 1993).

The large majority of Warao speakers live in communities that are exclusively Warao. Outside these communities there is no social space for the usage of the indigenous language. In Guyana, there has been no bilingual education so far (Forte 2000). In Venezuela, indigenous languages were authorized for school education by a presidential decree in 1979, and official alphabets for most of them including Warao were released subsequently. Nevertheless, due to lack of political support these regulations were never put to practice on a larger scale (Villalón 1994). Warao language and culture are subject to strong pressure by the Spanish- and English-speaking majority, urging them to assimilate into the national Criollo or Creole culture of the respective countries. The awareness among the Warao concerning their language and culture as being endangered is just starting to rise, but still the future of their whole cultural heritage has to be regarded as most uncertain.

Dialects

There is no reliable information concerning the number of dialects. Some authors claim that there are none (Romero-Figeroa 1997); others have suggested that there are only slight regional variations (Osborn 1966a:108f.). For their part, Warao speakers claim not being able to understand speakers from certain other groups. Due to Delta internal migration, the situation has become regionally complex. Nevertheless, at least four major linguistic and cultural variants have been assumed by most researchers (Weisshar 1982; Wilbert 1957). Certainly, the different Warao groups are for ecological and historical reasons culturally quite heterogenous (Heinen and Garcia-Castro 2000).

Genealogy

Because of a lack of historical information, it is impossible to prove membership in a language family for Warao and it has therefore to be considered an isolate (Weisshar 1982). Certain resemblances with other languages have to be attributed to the phenomenon of a 'linguistic area', where languages of a certain region (in this case the Amazon and neighboring areas) show similarities across the boundaries of different language families.

Typology

Typologically speaking, Warao shows characteristics of an 'agglutinating' language. Languages of this type tend

to have one morpheme (smallest meaningful unit, which can be a word or a part of a word) per grammatical function. Larger words are then composed of a basic word or root and these morphemes. In the case of Warao, most of them—suffixes—occur after the root, although some of them—prefixes—are attached in front of it. For example, the phrase: '*ine najoro-turu-ae*', structurally 'I food+almost-would-have+completed-action', equals the English expression 'I almost ate.' (Please note that in these examples of Warao, the Spanish-based official spelling is used and the letter 'j' therefore corresponds to 'h' for English speakers. Hyphens are intended to clarify the structure of a word.)

Word Classes

The categories of adjective and noun are not clear-cut. A word can function as noun or adjective according to its place in a sentence and the suffixes it combines with. Nouns and adjectives do not have gender. There are furthermore 'noun–verbs' (Osborn 1967). Normally verbs and nouns can be distributionally differentiated according to the suffixes and prefixes (classed together as affixes) that can occur with them. Some roots, however, can combine with verb and noun affixes alike. To give an example, the root '*najoro*' (food) alone is a noun that can combine, for example, with the suffix '-*noko*' (place/instrument) to form '*najoro-noko*' (place of the food/instrument for eating). On the other hand, in the construction '*najoro-ya*' (literally, food+durative aspect), 'is/are eating', the same root functions as part of a verb combining with a verb suffix.

Tense, Mood, and Time

In Warao a wide range of such notions as tense, aspect, and mood are marked on the verb. The above-mentioned morphemes accomplish this task mainly suffixed to the basic verb form. In order to clarify this point, there is a nonexhaustive list of examples given below. However, as there is no consistent labeling in the literature for these forms, I will limit myself to give an approximate translation into English:

najoro-kitane (to eat)
i-najoro-kitane (to cause someone to eat/to feed someone)
najoro-kitia (going to eat immediately)
najoro-te (probably going to eat in the future)
najoro-ya (is/are eating at that moment/will surely be eating in the future)
najoro-ae (ate)
najoro-ya-ja (eating)
najoro-kuna (could eat)
najoro-turu-ae (was/were about to eat)

najoro-mejerei (in order to have him/her eat)
najoro-moana (has/have not yet eaten but should have done so)
najoro-komoni (cannot eat)
najoro! (eat!, singular)
najoro-kotu! (eat!, plural)
najoro-na-ja (is/are not eating)
najoro-na-tan-ae (has/have not eaten)
najoro-naka! (don't eat!, singular)
najoro-naka ja-kotu! (don't eat!, plural)

In this last example, '*jakitane*' (to be/to have) functions as an auxiliary verb taking on the imperative plural ending '*-kotu*' because it is impossible to attach it to the preceding suffix '*-naka*'.

Taken together, '*jakitane*' with '*tikitane*' (to say/to do) and '*takitane*' (to be/to do) form an interesting group. They can not only be used as auxiliaries and as suffixes but also as clause introducers. As in '*ta-kore*' (literally, this being so), then/when.

Analyzing '*najoro-na-ta-n-ae*' (has/have not eaten) from the above list, '*ta-n-ae*' really is the root of the verb '*ta-kitane*', followed by a marker for singularity of action '*-n-*', followed by the suffix expressing completeness of an action: 'food+not+do+singularity of action+completed action'.

Discourse Markers

In addition, there are morphemes that allow the modification of verbs, nouns, and adjectives and sometimes range over the whole sentence: So, for instance, '*-yama*' is a citation marker specifying that something is known from hearsay: *najoro-ae-yama* (it is said/someone told that he ate). It is prevalent in storytelling.

Other morphemes like '*-kore*' or '*-rone*', which mean 'while/if' and 'although', respectively, play the role of conjunctions connecting sentences or phrases: *nojoro-ya-kore dani mi-ae* (while I was eating I saw my mother); *najoro-ya-rone dani mi-ae* (although I was eating I saw my mother). For questioning a sentence, the suffix '*-ra*' is attached to the last word of that sentence.

Sentence Structure

As regards the 'basic' or unmarked word order in Warao, there is no general agreement. Some take a Subject–Object–Verb (SOV) word order to be basic (Osborn 1966b) while others argue in favor of Object–Subject–Verb (OSV) (Romero-Figeroa 1997). All that can be stated safely is that Warao is a 'verb-final' language.

In a number of languages, the copula 'to be' (as in an English sentence of the type: 'I am Warao') is not obligatory. The same holds true for Warao. Thus, '*ine warao*' (literally, I Warao) would be the equivalent of the English sentence.

The direct complements of a verb (subject, object) do not have case marking or gender and are often omitted, especially when they have been mentioned previously or are assumed to be known. Besides, there are stylistic reasons for omission. Nouns can take on suffixes (*-si/-ma/-to*) that specify that they are not the subject of a sentence: *dima-si konaria* (he takes father along) as opposed to *dima konaria* (father takes something/someone along).

A study of the 'pivot' in Warao is yet lacking. In languages with nominative and accusative case marking, the nominative (case of the subject of an intransitive and a transitive sentence) functions as the pivot. Thus, two sentences are connected having a common subject: 'the man ate an apple and smiled'. In ergative languages, however, which show the same case for the subject of an intransitive sentence and for the object of a transitive one, this juncture would be impossible. 'The man ate an apple and smelled good' would hence mean that the apple smelled good, not the man. In Warao storytelling, such connections are frequently made. This gives rise to the question of whether this language is syntactically ergative.

Person, Number, and Plurality of Action

Basically, there is no agreement for person and number on the verb, although interestingly singularity or plurality of the action itself can be marked and thus emphasized. Compare, for example, '*boro-te*' (will be jumping) with '*boro-bu-te*' (will be jumping repeatedly/a lot of people will be jumping). Here the morpheme '*-bu-*' underlines that the action is performed repeatedly either by one person or simultaneously by many.

The case of a morpheme that depicts singularity ('*-n-*') is more complicated as some verbs exist both with and without this morpheme and others only occur in one of these forms. An example of alternating verbs would be *ine oa-e* (I grabbed several things) in opposition to '*ine oa-n-ae*' (I grabbed once/one thing). It is not clear whether or not '*-n-*' is still a productive morpheme.

With respect to number marking on nouns, there is a suffix '*-tuma*' that is often regarded as plurality marker. But it is not obligatory and, especially when used with people, rather expresses the idea of 'the-ones- belonging-to' as in '*Maria-tuma*' (Maria and her friends/family).

Possession and Article

The possessive construction has the form 'possessor possession-marker+possessed-item': *dima a-janoko* (father's house, literally 'father his-house').

There is no definite or indefinite article in Warao. But person markers used in possessive constructions function like a definite article. In the following text recorded by the author, definiteness is assured in this way:

Tau-tuma manamo ja. Ta-kore a-raiba a-rajia tane.

Two womenfolk is/has. Then her older sister her younger sister so (literal translation).

There were two women: an older and a younger sister (free translation).

Future of the Language

Clearly a most interesting language with phenomena awaiting to be investigated, Warao presents a challenge to linguists. Unfortunately, like most amerindian languages the future vitality of Warao is not assured.

Wayampi and Tupi-Guarani Languages

Wayampi is one of the more than 40 closely related languages that comprise the Tupi-Guarani language family. These languages descend from a common ancestor, referred to as Proto-Tupi-Guarani, whose speakers probably lived in or around the state of Rondonia in western Brazil. Long before the arrival of Europeans to the New World, extensive migration of small groups contributed toward the development of a large number of closely related languages, scattered throughout the Amazon region and beyond. As individual groups migrated, many of them through the Amazon rain forest, they eventually lost contact with each other. The language spoken by each group gradually changed in unique ways, until the speech of the individual groups was no longer mutually intelligible. There are no written records for this early history.

The first contacts that Europeans had with Tupi-Guarani languages were with Tupinambá and Guarani, at that time spoken along the eastern coast of South America. As explorers, anthropologists, and linguists came in contact with other indigenous groups whose languages showed a high degree of similarity in vocabulary and word structure to Tupinambá and Guarani, they referred to these languages as Tupi-Guarani languages.

The Tupi-Guarani family is one branch of a larger grouping of Tupi languages. Tupi-Guarani languages have a number of features that define them as a group, separate from the other Tupi languages. For example,

they have a set of free personal pronouns that are obvious cognates (having been derived from a single source); other Tupi languages do not have this set. Tupi-Guarani languages also share a set of verbal prefixes which refer to the subject: *a-* 'I', *oro-* 'we exclusive (he/she and I)', *ja-* 'we inclusive (you and I)', *ere-* 'you (sg)', *pe-* 'you (pl)', and *o-* 'he/she/it/they'. They also share a number of basic vocabulary items that are different from forms in other Tupi languages.

Wayampi

Wayampi (with variant spellings Guayapi, Waiãpi, Wayãpi, Wajapĩ, Oiampi, Oyampi, and Oyampik) is the autodenomination of a language group of approximately 1,800 speakers, living on the two sides of the Brazil–French Guiana border. They are one of the three Tupi-Guarani language groups residing on the north side of the Amazon River.

Originally residing near the mouth of the lower Xingu River, the Wayampi migrated north across the Amazon and up the Jari River in the mid-1700s. During the first half of the twentieth century, there were four dialect groups of Wayampi: one on the Oiapoque and Camopi rivers in French Guiana, another on the Cuc River in the Brazilian state of Amapá, a third group living east of the Cuc River in the area that they call *Kumakary [kumakarɨ]*, and a fourth group living farther south, on small tributaries of the Amapari and Nipuku rivers.

The group on the Cuc River had ongoing contact with the groups in both Oiapoque and Kumakary. Around the middle of the twentieth century, the Amapari group came in contact with the group from Kumakary, and the two groups eventually merged. Through these contacts the people from the Amapari area learned of the group on the Cuc River, with whom they began to develop a trading relationship. However, this relationship was interrupted around 1970 when a dysentery epidemic in the Cuc River area took the lives of a large number of people. After that, most of the survivors moved to French Guiana, where they merged with the Oiapoque group.

In spite of their relative isolation from the outside world, the Wayampi were visited by French explorers in the late nineteenth century, among them Henri Coudreau (1892), who published an impressive word list.

The general phonological pattern for Wayampi is consonants alternating with vowels. The consonant set includes *p,t,k,kʷ,ʔ,m,n,ŋ, ŋʷ,r,s,h*, and, in the Amapari dialect, *β*. There are two semivowels, *w* and *j*. The set of vowels includes *i,e,ɨ,a,u,o.* There is an oral set and a nasalized set of vowels. When nasalization occurs, it affects the entire morpheme and not just a single vowel, such as *apasĩ [ãpãsĩ]* '(to) tie'. In the Amapari

dialect, there is only one back nasalized vowel, and younger speakers are merging the central nasalized vowels as well.

Grammatically, Wayampi has a number of features that are different from Indo-European languages but are quite common to Tupi-Guarani languages and, in fact, to Amazonian languages in general. Like other Tupi-Guarani languages, Wayampi is agglutinative, which means that words can take multiple prefixes and suffixes. This is most visible in verbs. In the following example from the Cuc dialect, the verb stem (*kusu* 'wash') is preceded by an incorporated object (*po* 'hand'), which is in turn preceded by three prefixes. There are also two suffixes following the verb stem:

n-o-i-po-kusu-ɨtɨ-i
not-he-self-hand-wash-never-not
'He never washes his (own) hands.' (literally, 'he never hand-washes himself')

Typologically, one of the areas of greatest interest to linguists studying Wayampi and related languages is the system of person markers which occur on verbs. Transitive verbs, those which express an action on an object, are prefixed by person markers from one of two sets, one referring to the subject and the other referring to the object. For example, there are two prefixes referring to first-person singular: *a-* 'I' (subject) and *e-* 'me' (object), as in the following examples: *a-pota* 'I like (him)' and *e-pota* '(he) likes me'. There are complicated rules governing the choice of sets, but, in general, first person ('I/we'), whether subject or object, is considered the most important and must be referred to on the verb, as in the examples above. Second person ('you') is second in priority, and third person ('he/she/it/they') has the lowest priority. This is one type of 'split-ergative' system. The 'subject' prefix is also used for intransitive verbs, and the 'object' prefix is used for a set of stative verbs: *a-poreŋeta* 'I speak' and *e-karaɨ* 'I have a fever'. This type of system is characteristic of Tupi-Guarani languages. Variations of split ergativity occur in other Amazonian languages as well.

When two verbs are perceived by the speaker to be part of a single action, with the same subject, they occur together in a single phrase as 'serial verbs'. If the second verb is transitive, as in the second sentence below, it must take an object prefix rather than a subject prefix. (In third person, there is no grammatical distinction between masculine, feminine, and neuter.)

o-o   o-jau
he-go he-bathe
'He went to bathe.'

o-nupã   pira i-juka
he(subj)-beat fish it(obj)-kill
'He beat the fish and killed it.'

Unlike other Tupi-Guarani languages, Wayampi does not take a special suffix to mark the second serial verb.

Noun phrases are short and are generally limited to one other constituent besides the noun. They follow one of the following patterns:

Demonstrative-Noun:
aʔe kuimaʔe   'that man'
that man
Number-Noun:
moapɨ kuimaʔe   'three men'
three   man
Noun-Relative Clause:
kuimaʔe i-tekorã maʔẽ   '(the) man that is sick'
man   him-sick RELATIVIZER
Genitive-Noun:
papa po   'father's hand'
father hand
Noun-Postposition:
ɨa   pupe   'in the canoe'
canoe in

Pronominal possessors are indicated by the 'object' prefixes: *e-po* 'my hand', *ne-po* 'your (sg) hand'. The same is true for the pronominal object of a postposition: *e-pupe* 'inside me', *i-pupe* 'inside it'.

Wayampi is what is referred to as a 'flexible word-order' language. Unlike English, which generally puts the subject before the verb and the object after the verb, Wayampi uses other criteria to determine what information goes before the verb and what goes after. For example, new information is introduced before the verb, but when it is referred to again, it occurs after the verb. In the following example, the participants of an all-night festival announce their intentions:

jeʔiwe   ture oro-itɨ-ta,
early.morning flute we(exclusive)-quit-future

eʔi kupa
said plural.subject

''Early in the morning we will quit playing flutes', they said.'

Both the time and the object (flute) are new information and come before the verb (underlined). Once introduced, they are subsequently referred in postverbal position, as in the following example:

o-itɨ   jeʔiwe   ture kupa
they-quit early.morning flute plural.subject
'They quit playing the flutes early in the morning.'

In spite of the flexible word order, there is no grammatical case marking on nouns to distinguish subjects from objects. Often only one noun is actually specified in the sentence and the other is indicated only by the prefixing on the verb or is simply understood from context. In the sentences above, it is obvious that *ture* 'flute' is an object, not a subject, since the verb (*itɨ* 'quit') requires an animate subject.

Very little has been published on the discourse of other Tupi-Guarani languages, so it is not possible to say to what degree Wayampi discourse is characteristic of the family as a whole. However, this type of discourse system is not unusual among American indigenous languages.

Other Tupi-Guarani Languages

The Tupi-Guarani family and member languages have been studied extensively from the perspectives of historical linguistics and syntactic typology. Reconstructions have been done of Proto-Tupi-Guarani grammar and sound system. Using the criteria of a shared history of phonological changes from the reconstructed proto-language, Aryon Rodrigues has divided the Tupi-Guarani languages into eight subgroups.

Languages in subgroup 1 are Guaranian languages, spoken in southern Brazil, Paraguay, Bolivia, and northern Argentina. One form of Guarani, now referred to as Old Guarani, has been known from the time of the Spanish explorers who first came to the area south of São Paulo. This language was documented and described by the Jesuit priest Antonio Ruiz de Montoya (1639). In time, Guarani came to be used extensively among colonists. Gradually, a no indigenous variety of the language developed, which is now spoken by 95% of the population of Paraguay.

Languages in subgroup 2 are spoken in Bolivia: Sirionó and Guarayu. Languages in subgroup 3 were spoken along the Atlantic coast and up the Amazon river. The most well-known language from this group is Tupinambá, which was documented extensively by another Jesuit priest, Joseph de Anchieta (1595). Although now extinct, Tupinambá was used extensively for many years among colonists. Finally, a royal decree in the eighteenth century dictated that Portuguese citizens use Portuguese rather than an indigenous language as their means of communication. Even so, the nonindigenous variety of Tupinambá, now called *Nheengatu*, is still spoken today as the mother tongue of a nonindigenous population of about 3,000, in the upper Amazon region. Brazilian Portuguese has a large number of words borrowed from Tupinambá, especially place names and terms for flora and fauna native to Brazil. Even English has borrowed words from Tupinambá: jaguar, toucan, piranha, tapioca, and manioc.

Speakers of languages of subgroup 4 reside at the eastern edge of the Amazon rain forest and beyond, in

the Brazilian states of Tocantins, Maranhão, and Pará. They include Asuriní of Tocantins, Parakanã, Tapirapé, Guajajára.

Languages of subgroup 5 are west of subgroup 4, in Pará and northern Mato Grosso. They include Asuriní of Xingu and Kayabí.

Still further west, in Amazonas, Rondônia, and Acre, are the speakers of subgroup 6: particularly the Kawahíb dialect cluster. These groups live closest to the area where their Proto-Tupi-Guarani ancestors probably lived.

Subgroup 7 includes just one language: Kamayurá, located in the Xingu Park in Mato Grosso.

Subgroup 8, of which Wayampi is a member, includes the three language groups located on the north side of the Amazon, who live in southern French Guiana or northern Brazil. It also includes several language groups who live on the south side of the Amazon in the states of Pará or Maranhão, among them Guajá and Urubú-Kaapor.

CHERYL JENSEN

Weinreich, Uriel

An authority in a number of disciplines, Uriel Weinreich made significant contributions to several aspects of linguistics and was particularly interested in those facets dealing with the interaction of language and society. His specialties included but were not limited to language change, semantic theory, and the Yiddish language. Born in Lithuania, Weinreich moved to the United States in his early teens, served in the US Army during World War II, was naturalized as an American citizen soon after, and worked for a brief time with the State Department. As a scholar, Weinreich made his home at Columbia University, where he received his undergraduate and graduate degrees and later taught linguistics and Yiddish until his death at the age of 40.

One of Weinreich's major contributions to linguistics was his work on language change and variation. Under the guidance of his advisor Andre Martinet, Weinreich wrote both his master's thesis and his dissertation on the role of language contact in linguistic change, and this work later served as the foundation for his book *Languages in contact* (1953). In his article 'Is a structural dialectology possible?' (1954), Weinreich called for scholars working in the seemingly adverse frameworks of structural linguistics and dialectology to find a common ground on which to work together toward a better understanding of language. Weinreich also worked on a model of language change that would be completed and published posthumously by his students William Labov and Marvin Herzog in an article entitled 'Empirical foundations for a theory of language change' (1967). In this work, Weinreich et al. argue that a model of language that 'accommodates the facts of variable usage and its social and stylistic determinants not only leads to more adequate descriptions of linguistic competence, but also naturally yields a theory of language change that bypasses the fruitless paradoxes with which historical linguistics has been struggling for over a half century' (Weinreich, Labov and Herzog, 'Empirical foundations for a theory of language change', 1967:99).

As part of their proposal, Weinreich et al. downplay the role of the idiolect in linguistic change in favor of an explanation that takes into account the interrelationship of linguistic and social factors. In this respect, Weinreich's ideas had a profound effect on Labov, for whom Weinreich served as thesis and dissertation director, in his pioneering work in the emerging field of sociolinguistics.

Weinreich also made a significant contribution to the study of semantics. Frustrated with a doctrine of

linguistics that chose to ignore the issue of semantics because of the difficulty it created, Weinreich saw promise in the generative grammar espoused by Chomsky (1957, 1965) because he believed that this formal approach could be used to account for meaning, despite Chomsky's avoidance of semantics in his own work. Weinreich was, however, critical of many of the approaches to semantics that were in vogue during his career. For instance, he asserted that 'systematic semantics is doomed to an isolated place within linguistics as a whole so long as paradigmatic relations are the only form of patterning to which attention is given. It is undoubtedly important to understand how the meaning of a word in a vocabulary is determined by other words in the same vocabulary; however, an account must still be given of the way in which the meaning of a sentence is composed out of the meanings of individual words' (Weinreich, *Explorations in semantic theory*, 1972:112).

Weinreich also took exception to the theoretical assumption of many working in semantics that semantics begins where syntax ends; instead, Weinreich believed that syntax and semantics are so intertwined that only a theory taking into account the interrelation between them could adequately represent the complexity of language. He pointed out that although generativists postulated syntax and semantics to be separate domains, they had never succeeded in discovering the boundary between the two. Weinreich was particularly critical of the Katz–Fodor model of generative semantics (see Weinreich 1972) on the grounds that their analysis focused on a limited part of semantic competence and concentrated too much on ambiguity. Weinreich argued that 'grammatical theory is not required to explain how a hearer of such ambiguous expressions guesses which of two deep structures is represented by a given occurrence of a surface structure, nor is the goal of grammatical theory limited to the calculation of such ambiguities' (Weinreich, *Explorations in semantic theory*, 1972:18–19). Weinreich was also critical of the Katz–Fodor model because he said that it ignored semantic deviations, instead of trying to account for them.

Like his father, Yiddish scholar Max Weinreich—a driving force behind the YIVO Institute for Jewish Research and a proponent of the claim that Yiddish was a unique creation of Jews and not simply derived from German—Uriel Weinreich was a scholar of Yiddish and worked hard for the preservation of the language, collecting a great number of Yiddishisms for various books on the subject. His textbook on the subject, *College Yiddish*, was first published in 1949 and has since been published in numerous editions. In 1959, Weinreich and his wife, the folklorist Beatrice Silverman Weinreich, began interviewing Jews living in Israel, France, the United States, and Canada, with a questionnaire comprising more than 3,000 questions and taking some 15 hours to complete. This work served as the foundation for a comparative study of Jewish culture throughout Europe before World War II that culminated in the *Language and cultural atlas of Ashkenazic Jewry*, which Uriel directed until just before his death. Now under the direction of Herzog, the first volume of the project was published in 1991. The *Modern English–Yiddish and Yiddish–English dictionary*, which Weinreich compiled by applying his theory of systematic lexicography, was published posthumously in 1968. To honor the man and his work, the Uriel Weinreich Program in Yiddish Language, Literature, and Culture was established as a summer program in 1968, cosponsored by Columbia University and the YIVO Institute for Jewish Research.

Biography

Uriel Weinreich was born in 1926 in Vilnius (Russian *Vilna*), Lithuania. He moved to the United States with his family in 1940, when his father, Yiddish scholar Max Weinreich, joined the faculty of New York City College. He served as first lieutenant in the US Army from 1944 to 1946 and was naturalized as an American citizen in 1945. After his term of service, Weinreich enrolled in Columbia University and received his BA in 1948, his MA in 1949, and his PhD in 1951, completing a thesis and dissertation under Andre Martinet, work which would eventually culminate in his book *Languages in contact* (1953). He performed fieldwork in Switzerland from 1949 to 1950 under a research fellowship from the American Council of Learned Societies. He worked as an editor and information specialist with the State Department from 1951 to 1952, and was Chair of the Department of Linguistics at Columbia University. Weinreich became the first Atran Professor of Yiddish Language, Literature and Culture at Columbia University in 1952, and was Member, Linguistic Society of America in 1951, serving as vice president in 1964, and co-editor of Word from 1953 to 1960. He began work on the *Language and cultural atlas of Ashkenazic Jewry* in 1959 and served as its director until his demise. Weinreich continued teaching until two days before cancer took his life on March 30, 1967.

Western Caribbean Creole(s)

Western Caribbean Creole (WCC, hereafter) belongs to the western branch of Atlantic, English-based Creoles. It has features common to the broader linguistic designation, West Indian Creole (Winford 1985; Grimes 2001; Roberts 1996). Varieties of WCC developed in predominantly English-speaking western Caribbean nations, including Jamaica, Belize, and Barbados. Believed by some linguists (Hancock 1980; Niles, 1980) to be a dialect of English, Barbados Creole, popularly known as *Bajan* or 'Barbadian nonstandard English' (Fields 1995), 'has the fewest Creole features' (Roberts 1996:87), and its Creole status is somewhat controversial. It differs from other varieties of West Indian Creole primarily phonologically (Grimes 2001). Researchers such as Cassidy (1980) and Fields (1995) maintain that early Bajan was a Creole. Fields (1995) makes a case for its Creole ancestry, arguing that contemporary Bajan is simply a Creole-in-transition. While Hancock (1980) and Niles (1980) agree that early Bajan was probably a Creole, they differ in their accounts of precisely when Barbados Creole existed. Cassidy (1986) contends that Barbados Creole could only have developed after 1650, when conditions were favorable for its genesis.

The largest number of speakers of WCC is found in Jamaica, followed by Belize. In Jamaica, this language is known as Jamaican, Jamaican Creole (English), or Bongo Talk [*Bongo* is an Afro-Caribbean dance]. Linguists tend to use the label West(ern) Caribbean Creole. The variety spoken in Belize—slightly different—is referred to as Creola, Kriol, or Belize Creole (Boland 1986, 1991; Escure 1981, 1997; Greene 1999). So frequent is the use of WCC in these countries that it is the primary language and preferred lingua franca of the majority of residents. In Jamaica, for instance, the official language is English, but the use of WCC is more widespread. It, therefore, functions like the quasi-official language.

Despite its frequent use, WCC continues to be stigmatized, particularly by its educated speakers (Le Page 1966; Nettleford 1966; Allsopp 1996; Spears and Winford 1997), many of whom use this code as well. WCC may have started out as a pidgin or, in Romaine's (1994) opinion, as a *jargon* or a short-lived pidgin. Instances of the earlier form are found in anglophone Caribbean work-songs, and in dancing and folk songs from 1793 to 1907 such as the anonymous 'Freedom a Come Oh!' (Freedom, Here I Come!, where the 'Oh' might very well be a remnant of the Kwa honorific particle 'o(h)' used extensively in Yoruba and Nigerian Pidgin), 'Negro Song at Cornwall', and 'Sangaree Kill de Captain' (Sangaree Killed the Captain) (see Burnett 1986:3–12). Sprinklings of WCC can also be found in veteran Jamaican writer, Roger Mais's (1905–1954) *The hills were joyful together*, and in Vic S. Reid's works. WCC is presently the native or first language of a large percentage of users; hence the descriptive term, *Creole*.

Creolization is the term used to describe the formative process it is believed to have undergone. WCC and its eastern Caribbean and West African equivalents, such as Guyanese (see Bickerton 1973; Rickford 1987), Krio, or Nigerian Pidgin (Faraclas 1996), respectively, exhibit a *Creole continuum*, or a range of varieties. At one end is the *basilect*, a variety with minimal structure and associated functions, and at the other end lies the *acrolect*, a fully expanded variety, used, like any primary language, for all possible language

functions. The *mesolect* constitutes the mid-range. It is more compact than the acrolect, but serves a greater range of functions than the basilect. The different lects tend to be socially stratified (Pandey 1997). Mesolectal WCC is a combination of English and Creole words. The acrolect tends to contain few Creole words. Examples include:

(1) Acrolect: 'Don't lie to yuself', 'Dis is crazy' (Patterson 1964:16, 186).
(2) Mesolect: 'No matter if he is Jesus or him is Jah. Him not gwan like dis one lickle bit' (Cliff 1996:16).

[Translation: It doesn't matter if he is Jesus or Jah (Haile Selassie). He will not like this even a little.]

(3) Basilect: 'God nuh mus' be Hinglish. But me did' 'ear once dat Jesus did' ave bad 'air. Mus' be one joke 'pon we' (Cliff 1996:17–18).

[Translation: It seems God must be English then. But once I heard that Jesus had bad hair (reference to him as African). It must be a joke being played on us.]

The speech of the poor and less educated Barbadian is very similar to the mesolect found in neighboring anglophone nations, leading linguists like Alleyne (1979) and Fields (1995) to contend that it is in the mesolectal stages.

The term creole continuum was first used by creolist Derek Bickerton (1981), and has been applied to a variety of Pacific and Atlantic Creole contexts (colonized coastal territories). It is also termed a post-creole continuum (Rickford 1987), as it mirrors a process of decreolization or progressive assimilation toward a standard language. Bajan might be one such example (Cassidy 1980, 1986; Rickford 1992; Rickford and Handler 1994; Fields 1995). In Cassidy's (1980) view, Bajan decreolized earlier than other Caribbean Creoles. Decreolization is not necessarily chronological. In other words, it is more often the case that the different lects coexist, rather than in isolation, changing over time in lectal designation.

Jamaican Creole is viewed as a paradigm example of WCC (Lalla and D'Costa 1990; Mufwene 1993:142). Many Jamaicans (Bennett 1966, 1981; MacCallum 1999; Donnell and Welsh 1996) refer to it as *Patois*, the French term for a pidgin. The presence of large numbers of French migrants, and the island's proximity to French-colonized Caribbean nations might have something to do with this label. The anglicized Patwa is also used by some. Like all varieties of WCC, Jamaican Creole is English-based, which means that the bulk of its vocabulary is drawn from English, while its grammatical and discourse structure mirror the influence of other (non-European) languages. It contains ingredients from the different colonizing and Diaspora languages

that constitute the sociolinguistic mosaic of this region (Burnett 1986:xxv). In the words of well-known Jamaican poet and storyteller, Louise Bennett:

> The Jamaican patois has obviously Standard English as its roots but has been spiced with the tongues of the Arawak and Carib Indians (the original inhabitants; Africans brought over as slaves; Spaniards, the first conquerors; the migrating French, Chinese and East Indians; the Colonizing British; and in recent times, visitors from North America and the Rastafarian religion (1981:i).

In many ways, then, it is a linguistic chutney of sorts, much like chutney music, a variety of Soka music composed in Trinidad. Bennett draws heavily on WCC in her works. Exemplary poems include, among others, 'Jamaica Patois', 'Jamaica Obeah' (Jamaican Juju Man), 'Weh Dem Deh?' (Where are They?), 'Solja Bwoys' (Soldier Boys), 'White Pickney', 'Show Yuh Foot' (Show Your Foot), 'Him de Yah' (He is Jesus), 'Me Bredda' (My Brother), 'New Govanah', 'Train Leff Miss Hayes', 'Pass fe White', and 'De Royal Commotion'.

One of the most widely studied Caribbean Creoles, the variety used in Jamaica has the longest-standing history of use in Caribbean literature, including folklore (see McKay 1933; Bennett 1966; Burnett 1986; Mordecai and Morris 1980; Senior 1989; Cliff 1996; Donnell and Welsh 1996; Patterson 1998; MacCallum 1999, among others), music, and other artistic media. The international attention and recognition Jamaican music, dub poetry and music (see Allen 1990; Breeze 1991, 1997; Smith 1979), and Rastafarianism have attracted have helped spread WCC to other parts of the Caribbean, and have helped familiarize others outside the region with its unique rhythms, sounds, and structure. Much like rap is to the African American community in the United States, dub poetry and music are signature forms of Black folk-culture in Jamaica and the Caribbean as a whole.

Dub poetry refers to 'Lines meant to be spoken, generally to a two-beat rhythm, and dealing mostly with the life experiences and/or point of view of Black people in or from the Caribbean' (Allsopp 206). Dub music, derived from Reggae, is also a two-beat rhythm created principally by bass and drums. Both art forms employ principally WCC lyrics. When one speaks of Creole, it is no wonder, then, that the layperson generally thinks of Jamaica(n). The increasing use of 'I', a symbol of self-respect and group solidarity, in the Jamaican variety of WCC (see Pollard 1986), as a popular substitute for the Creole 'mi', and in words like 'I-lect' (Rasta dialect or Rasta Talk), 'I-quality' (equality), 'Idren' (brethen), and 'I're' (alright) can be attributed to Rastafarianism, and are a reminder of the Rastas's reverence for Ras Tafari (Emperor Haile Selassie).

Exemplary proverbs in WCC include 'Cockroach no business in fowl-yard' (i.e. Mind your own business), 'De higher monkey clim, de mo im expose' (i.e. promotion has its price—pretentiousness), and 'Yu lay wid dawg, yu get wid flea' (i.e. bad company corrupts). WCC is so important a part of Belizean and Jamaican culture that visitors to these countries are advised to familiarize themselves with the distinctive features of WCC (see Porter and Prince 2000; Brosnahan and Keller 1997). As regards Jamaica, Porter and Prince (2000) offer the following overview and advice:

> The unofficial language is a patois.... This archaic and simplified structure, coupled with African accents and special intonation, can make the language difficult to understand. Some of the most interesting anecdotes and fables are usually told in the patois, so understanding its structure can add to your insight into Jamaican culture.... Proverbs and place-names [e.g. Red Gal Ring] express some of the vitality [of patois].... The patois has been embellished and altered with the growth of Rastafarianism. (196)

In their focus on Belize, Brosnahan and Keller (1997) describe WCC as Belize's 'own colorful Creole dialect' (276). Bolland (1977) describes it as 'a means of expression through which proverbs, sayings, and folktales' convey 'African values and wisdom' (12), and as a code language used to satirize the British.

In Belize, the Kriol Projek, a national organization, continues to play a seminal role in educating citizens about the culture and creativity inherent in Kriol. This organization, and the present Governor General have compiled and printed folktales in Kriol for use in (Belize's) schools. As few Belizeans are used to seeing Kriol in writing, these publications are accompanied by CDs, so that students can hear the Kriol.

The presence of branches of the University of the West Indies in both Barbados and Jamaica helps ensure that WCC continues to be well researched. Some of the earliest studies of WCC include F.G. Cassidy's 1961 text; B.L. Bailey's (1962) *Language guide to Jamaica*, for US Peace Corp volunteers, her (1953) M.A. thesis, a version of which was published in 1966; and Cassidy and Le Page (1967). In the United Kingdom, WCC is the most identifiable and influential of all Caribbean languages owing to the large numbers of Jamaican immigrants. In fact, the evolution of British Black English has been attributed, in large part, to the frequency of use of Jamaican Creole in the United Kingdom (Sutcliffe and Wong 1986). WCC is very similar to West African Pidgin English, leading many creolists (Le Page 1966; Dalphinis 1985; Faraclas 1996; Roberts 1996) to argue in favor of the Afrogenesis hypothesis, which traces its roots to Africa, and highlights the influence of West

African languages. According to one view, for instance, 'Created in West Africa, ... work pidgins were transported across oceans where they took on new roles as lingua francas among the enslaved....' (McWhorter 1997: 240). Dalphinis (1985) observes that '[B]oth in the analysis of the Creole languages of the Caribbean as well as Caribbean culture, it is clear that Europe has affected Africa but equally Africa has affected Europe; the words are European, but the syntax is African' (95).

Representative features of WCC include (see Winford 1985, 1993; Roy 1986; Escure 1978, 1983; Patrick 1993; LaCharité 1999, among others):

(1) The zero copula or 'be' verb before adjectives, as in 'Di pikni sik' (The child is sick) or 'Di chile/chilin sik' and 'im hongry' (She or he's hungry) in Kriol, 'im [Bradda Anancy] always foolin every oda creature' (MacCallum 1999:19), and 'We making history' (Cliff 1996:5).

(2) Nonmarking of the suffix in the third-person singular present, as in 'I laik it' (Kriol for 'She or He likes it'), and the use of nonfinite verbs to convey multiple meanings, e.g. 'Dat sopoz to daan' (Kriol for 'That's supposed to have been done') and 'De chilin jos ron' (Kriol for 'The children just keep running around').

(3) Spelling pronunciations; words are pronounced the way they are spelled, and vice versa, e.g. 'dat' for 'that', 'de' for 'the', 'dis' for 'this', and the use of 'Dem' for many English words, including plural marker, as in (15); and 'they', 'them', and 'their(s)' as in 'Mi a sel dem az mi laik' (Bailey 1966:57), meaning 'I am selling them as I like'.

(4) Nonmarking of possessive case; possession clarified through noun juxtaposition, as in 'so many people life' (MacCallum 1999:20), 'she sister husban get one job up a Mona' (from Louise Bennett's 'Jamaica Patois'), 'mai li breda fren' (i.e. Kriol for 'My little brother's friend'), and 'person business' in (5).

(5) Multiple meanings associated with 'for', pronounced 'fi', as in 'Dem always start wid anancy ... lookin fi smbady... im always wan fi push up imself inna every oda person business' (MacCallum 1999:19). [Gloss: They always start with Anancy looking *for* somebody.... He always tries *to* stick his nose in other people's business.] An example from Bailey (1966:127) is 'Im kom ya fo bada mi', meaning 'He has come here to bother me'.

(6) Multiple meanings for 'no' (i.e. as 'not', 'don't', 'doesn't', and 'didn't'); double negatives

and preverbal negation, e.g. 'Im no know what mek anancy stay so wutless... and no seem fi care' (MacCallum 1996:19) [He didn't know what makes/made anancy so worthless... and not seem to care].

(7) Absence of auxiliary verbs, including 'do' in negations, as in 'I no kom bak' (Escure 1980:34), meaning 'She or he didn't come back', 'Me no 'ave not'in fe hide' (Patterson 1964:62), meaning 'I don't have anything to hide', and 'People talking around you' (V.S. Reid, 'New Day', p. 198), as well as the use of the double negative, as in Black English Vernacular.

(8) Zero tense specifiers or the default use of the present tense to represent all tenses. Tense is clarified through the conjoining of base verbs and/or context, e.g. (7), 'Toder mornin me go ask her wat she tink about de war' (from 'Jamaica Patois'), and 'Licklemos' she draw me in. But me stop because of lickle monies...' (Cliff 1996:19), which translates as 'A little more and she draws/drew me in. But I stopped because I didn't have a lot of money.'

(9) Nonmarking of plurals, as in 'Tu Bwai' (Kriol) or 'Tu bwoy' (Jamaican Creole), and 'Ho moch man?' (Kriol for 'How many men?')

(10) The use of 'vex' to mean 'distraught', 'troubled', 'disturbed', and 'disoriented', as in 'anancy being anancy was vex' (MacCallum 1999:20). Given the pronunciation differences between Kriol and Jamaican Creole, this word is prounced and written as 'bex' in Kriol. This probably has to do with the Spanish influence in Belize; /b/ and /v/ tend to be conflated in Spanish. Hence, 'I bex' would mean 'She or He's mad/frustrated.'

(11) The use of 'tief' as a verb for 'steal', 'stole', and 'stolen', as in 'afta anancy tief away dat magic calabash' (MacCallum 1999:19) and 'Tiefin de cow' (MacCallum 1999:22). An example from Kriol is 'Bra Anansi de plan tu go tiif ya hag' (Escure 1981:34) or 'Brother Anansi is planning to go steal a hog.'

(12) A relatively compact vocabulary (in contrast to Standard English) in which many words mean more than one thing, depending on the context, e.g. 'me' for 'me', 'my', and 'mine;' and *man hag* and *uman hag* versus the distinct English words, *boar* and *sow*.

(13) Related to (12), two or more meanings are assigned to a single verb; for instance, 'get' expresses both 'possession' and 'existence', as in 'Im get wan pikni' (She or He has one child) and 'im get good life.'

(14) Consonant reduction, as in 'im' vs. 'him', 'an' for 'and', 'a' for 'at', 'ow' vs. 'how', 'wha' vs. 'what', 'round' for 'around', 'ac' vs. 'act', and 'lookin' vs. 'looking'. This is sometimes accompanied by the prevocalic insertion of sounds like aspiration or /h/. Examples from Cliff (1996) include: 'Is hokay wid me, wunna know. Dem nuh 'tink like brute—hall a dem?' (10) [Translation: It's okay with me, you (plural) know. Don't they think like brutes—all of them?]

(15) 'Cyaan' or 'Kyaan' has context-dependent, opposite meanings, including 'can' and 'can't', as in 'di biebi-dem kyaan fiid themselves' (Bailey 1966:132), meaning 'The babies can't feed themselves' and 'Lord Jesus, hear me nuh, why dem cyaan behave demselves' (Cliff 1996:18), meaning 'Lord Jesus, please hear me. Why can't they behave themselves?' One of dub poet Michael Smith's poems is 'Mi cyaan believe it.'

(16) Emphatic 'nuh' as in 'God nuh say so?' (Cliff 1996:18), meaning 'Didn't God say so?'; Africanisms like *deh* and *fe*; and other culture-specific terms such as *Myal-man, Obeah-man*, and *Jumby-man*; e.g. 'Hear me, Myal-man. Hear me, Obeah-man. Hear me, Jumby-man.... Suffering nuh mus' be meant for we.... How long mus' we wait to get t'rough?' (Cliff 1996:16–17), which is essentially an invocation that translates as 'Please hear me Myal-man (one who performs good miracles). Please hear me Obeah-man (one who works in the 'dark' arts). Please hear me Jumby-man (one who is like a spirit or ghost). Suffering must be meant for us. How long must we wait to get through?'

Most of these are characteristic of West African Pidgin. WCC is an oral tongue, so it is written in accordance with a writer's perception of how it sounds. It is believed to echo the orality of African folklore and traditions (see Burnett 1986; Bennett 1940, 1966, 1979; Toolan 1992; Brathwaite 1993; Lalla 1996; Warner-Lewis 1997; Balutansky and Sourieau 1998). Those who employ it argue in favor of its legitimacy. Like Jamaican poet Claude McKay, who was the first to employ solely WCC in his first two (1912) books, one of the earliest Caribbean writers to make use of WCC in her writing, despite the criticism she received for doing so (see Brathwaite 1993: 282–3), was Louise Bennett. One of the region's most influential writers—particularly as regards her use of Patois—Bennett has been described as the 'only poet who has really hit the truth about her society

through its own language' (Espinet 1990:346). She is famous for her Anancy poems, many of which can be found in *Jamaican labrish*, which means Jamaican Gossip. Anancy is a legendary trickster (spider) in Jamaican folklore, and references to Anancy tend to be more authentic and culturally flavored in WCC than in (Standard) English. An example of an Anancy poem in which the poet switches between WCC and English is Shara MacCullum's poem 'Jack Mandoora: Me No Choose None'.

After Bennett paved the way for WCC usage, many Caribbean writers began to 'explore ways of working the rich ore of dialect in literary contexts' (Burnett 1986:xxv). As a result of the negative associations of the term 'pidgin', the term 'nation language', coined by Barbadian poet, Kamau Brathwaite—another luminary Caribbean poet—is frequently employed in the region's literary circle. This term is believed to aptly echo the functional dimensions served by WCC (Burnett 1986:xxv). Brathwaite (1993) defines it as 'Creole English... the kind of English spoken by the people who were brought to the Caribbean' (260) and 'not the official English' which 'is an imperial language' (259).

Louise Bennett, and other Caribbean writers who employ WCC in their works have helped both promote and sustain this language. In Burnett's words, 'The hybrid tongues which result [in the literature] have an enormous range of nuance and vigor of expression, with the limitation that only the locals catch every resonance' (xxv–xxvi). Noted artists include Orlando Patterson, Michelle Cliff, Lorna Goodison, Merle Collins, Erna Brodber, Patricia Powell, Honor Ford-Smith, Olive Senior, and Pauline Crawford (all Jamaican), and Zee Edgell, Amy Nicholas, Rutheen Taylor, Ushanda Io Elima, and Ziola M. Ellis from Belize. Edgell's *Beka lamb*, co-recipient of the Fawcett Society Book prize in 1992, contains some WCC and was the first Belizean novel to win international acclaim.

Any discussion of WCC would be incomplete without reference to the historical context that engendered WCC, and its popular acceptance. Caribbean Creole is believed to define and authenticate the Caribbean experience (Lamming 1960; Glissant 1989; Gikanda 1992; Benítez-Rojo 1992; Walcott 1993; Hamner 1997). It is no wonder the term *Creole* has many meanings in this region; it is used to describe the language, the people, and the culture (see Brathwaite 1977, 1993; Edgell 1982). To the Caribbean writer, Creole and creolization have acquired vital sociopolitical associations. Creole is conceptualized as 'a new mode of expression and representation' (Gikanda 1992:2) and creolization as a 'counter-discourse away from outmoded and conventional modes of representation associated with colonial domination' (5). In the collection *Caribbean creolization*, some of the region's foremost artists reflect on creolization and their reasons for employing Creole. The discussion opens with a quote from Edouard Glissant:

> Creolization's most manifest symbol is the Creole language. Its genius rests on its being always open.... Thus, creolization carries in itself the adventure of multilingualism along with the extraordinary explosion of cultures. But this explosion does not mean their scattering nor their mutual dilution. It is the violent manifestation of their assented, free sharing (1).

Part One is titled 'Creolization and the creative imagination', and Part Two, 'Creolization, literature, and the politics of language'. The consensus among the contributors is that Creole (including WCC) is a malleable, poetic-license-engendering and liberating indigenous code, free from colonial associations, and best suited to the themes that Caribbeans can relate to. Creolization is defined as 'a cultural process rooted in long-lasting psychological, spiritual, anthropological, and linguistic experiences' (9). Various historical and metaphorical terms are used to describe WCC and its formation, including: *blendings, cradle-hammock, marronage, rhizomatic transcultural exchanges, hybridity, métissage, mediation (contexts), linguistic crossbreeding* borne of plantations, and 'a language of mixed sounds, tonalities, rhythms, and flavors' (10). Some of these descriptors are constructs associated with prominent Caribbean writers. The metaphor of the shipwreck is utilized by some, including Nobel laureate Derek Walcott (1993:11), to describe creolization.

A prime example of an instructional text aimed at eliciting respect for WCC or 'Patois English' (Bennett 1981:i) is *Jamaica maddah goose*. This bilingual collection of nursery rhymes has a clear message, stated in Bennett's introduction:

> Standard English is the official language of the Jamaican businessman, educator, professional and mass media. But it is the mellifluous patois that is the language of the people.... [T]he pictures and, basically, the words are authored by Jamaican art students. Hopefully they reflect what all Jamaican children behold around them. Our only regret is that you can't hear these nursery rhymes spoken. Because patois is a language of melody and rhythm, a language to be heard. It is a vital language, an everchanging language, a language of the street and the scholar. And a language to be appreciated in its own right (i).

Exemplary nursery rhymes in WCC include 'Lickle Miss Julie' (Little Miss Muffet), 'Ole Maddah Hubad' (Old Mother Hubbard), and 'Mary Had Wan Lickle

Lam'. Bennett's mission—to destigmatize WCC—is clear in her poem 'Bans O' Killing', which begins:

> So yuh a de man, me hear bout!
> Ah yuh dem say dah-teck
> Whole heap 'English oat' sey dat
> Yuh gwine kill dialect!

[Translation: So you're the man I've heard about. Ah! You're the one they say uses piles of words and (that) vows to kill Creole!]

The poem continues with the following message, portending a bright future for WCC:

> Dah language wey yuh proud o'
> Wha yuh honour and respeck
> Po' Mass Charlie: Yuh noh know sey
> Dat it spring from dialect!

[Translation: The language that you are proud of, that you honor and respect, Poor Mr. Charlie; you don't (even) know that it came from the dialect you despise!]

Whorf, Benjamin Lee

Along with his mentor, Edward Sapir (1884–1939), Benjamin Lee Whorf is best known today for the principle of linguistic relativity, also called the Sapir–Whorf hypothesis (see 'Sapir–Whorf hypothesis'). Basically self-educated in linguistics and without a Ph.D. (although he did study for a time with Edward Sapir at Yale University starting in 1931), Whorf published extensively on American Indian languages, especially (Uto-Aztecan) Hopi, and also wrote on many other related linguistic topics for a variety of publications. As a result of his research into the structure of these languages, he came to assert that language and culture were intimately related such that one's native language, i.e. its structure or grammar and vocabulary, influences the way a speech community perceives and conceives of its reality.

Whorf's fascination with ciphers, puzzles, and codes as a child as well as his interest in religion led to his reading a French mystic, theosophist, and quasilinguist, Antoine Fabre d'Olivet (1768–1825), whose *The Hebrew tongue restored*, originally published in French in 1815–1816 (translated by Nayan Redfield, Whorf's neighbor, New York: G.P. Putnam's Sons, 1923), exerted a profound influence on the Methodist Episcopal/Theosophist Whorf, about whom he wrote: '[he] cut loose from dead traditional grammar, anticipated the modern concept of the phoneme…, saw the importance of language for logic and what today would be called psychology' (Rollins 1980: 49). Reading another theosophist–linguist helped develop Whorf's ideas even further—Frederick Max Müller (1823–1900), who maintained in his *The science of thought* (1887:295): 'Language is not outside the mind, but is the outside of the mind. Language is very thought as thought is very language.'

Part of the groundwork for the Sapir–Whorf hypothesis was laid by Whorf's work as a fire insurance investigator. During his career, he had the opportunity to analyze many reports as to why fires broke out. He found that workers would use extreme caution when around 'full' drums of gasoline. Just as one might expect, workers were careful not to smoke around 'full' drums. Yet, these same workers when around 'empty' drums of gasoline would sometimes toss lit cigarettes nearby. This caused a violent explosion because an empty drum still contained volatile gasoline vapor. Thus, an 'empty' drum was really much more of a threat than a 'full' one. Using these data, Whorf concluded that the meanings of certain words had an affect on a person's behavior.

It was the painstaking research of both Sapir and Whorf into the grammatical systems of American Indian languages, however, that proved to have the greatest impact on Whorf's subsequent thinking. By predicating their insights into the interrelationships of language and culture on what they had learned from the structures of these languages, the basic idea of language shaping the perceptions of its speakers and providing for them a vehicle so that their experiences and emotions could be placed into significant cognitive categories was given its scientific underpinnings. Generally, Sapir is credited as giving the problem of establishing the link between language and culture its initial formulation (continuing in the tradition of Johann Gottfried Herder, 1744–1803, and Wilhelm von Humboldt, 1762–1835), while Whorf is honored as the one who took this idea and developed it further to include grammar in addition to lexis, thereby making it into a bona fide hypothesis. However, it must be noted that there are really two different versions of the hypothesis. This is understandable when one considers that Whorf did all of his professional writing in the rather short period from 1925 until his untimely death in 1941, and his ideas, quite naturally, were continuously evolving. The strong version of the hypothesis, which is called linguistic determinism, holds that language determines thinking. This position is most difficult to defend primarily because translation between one language and another is possible, and 'thinking' can take place without language at all; e.g. an artist or sculptor can and often does think with his fingers.

Mirroring Sapir's thoughts, Whorf notes in his (1940) 'Science and linguistics':

> We dissect nature along lines laid down by our native languages… We cut nature up, organize it into concepts, and ascribe significances as we do, largely because we are parties to an agreement to organize it in this way—an agreement that holds throughout our speech community and is codified in the patterns of our language. (Carroll 1956:213)

The milder version of the hypothesis is labeled linguistic relativity. This claims that the native language influences thoughts and perceptions. In fact, it was Whorf who coined the phrase 'linguistic relativity', since he always tried to qualify his assertions. In 'Linguistics as an exact science', Whorf maintains:

> …what I have called the 'linguistic relativity principle' … means, in informal terms, that users of markedly different grammars are pointed by their grammars toward different types of observations and different evaluations of externally similar acts of observation, and hence are not equivalent as observers but must arrive at somewhat different views of the world. (Carroll 1956:221)

One of Whorf's most famous essays, 'A linguistic consideration of thinking in primitive communities', asserts that the problem of 'thinking' by so-called 'primitive' peoples is 'approachable through linguistics' (Carroll 1956:65). Further, as linguists have come to fully appreciate only fairly recently, Whorf believed that 'linguistics is essentially the quest of MEANING' (1956:73). Examples are given of things which are relatively easy to say in Hopi but awkward or clumsy to say in SAE (Standard Average European) languages. Whorf concludes that Hopi reveals a 'higher plane of thinking' (ibid.).

In 'Language, mind, and reality', published in India a year after his death, Whorf explains the 'obviative' in Algonkian languages. It is in essence two third persons (Carroll 1956:265), one of which we traditionally refer to as the fourth person. This aids in compact description of complicated situations, for which we should have to resort to cumbersome phraseology. Let us symbolize their third and fourth persons by attaching the numerals 3 and 4 to our written words. The Algonkians might tell the story of William Tell like this: 'William Tell called his[3] son and told him[4] to bring him[3] his[3] bow and arrow…' He remarked that 'such a device would greatly help in specifying our complex legal situations, getting rid of the 'party of the first part'…, 'the party of the second part', the 'aforementioned' or the 'aforesaid' (ibid.).

For those wishing to go to the fountainhead of the debate over language's influence on thought, Whorf's writings still provide for a satisfying journey.

Biography

Benjamin Lee Whorf was born in Winthrop, Massachusetts on April 24, 1897. He graduated from Winthrop High School in 1914, and did his B.S. (1919) in chemical engineering (MIT). In 1920, he began his career as a trainee in fire prevention engineering for the Hartford Fire Insurance Company. He was appointed as a Special Agent for the company in 1928. Eventually,

he became a recognized expert in industrial fire prevention, writing 'Blazing Icicles', which offered a linguistic interpretation of the cause of some fires. He was promoted as Assistant Secretary of the company in 1940.

During the 1930s he regularly visited a Hopi informant in New York City, and five years later had prepared a grammar and dictionary (Unpublished Papers, Yale University). He published much of his research in the major recognized outlets, such as *Language, International Journal of American Linguistics*, and *American Anthropologist*. Although he was offered academic positions, he decided to remain with the Hartford Fire Insurance Company, since he believed it afforded him greater opportunity to do what he wanted. He died of cancer on July 26, 1941.

Wittgenstein, Ludwig

Ludwig Josef Johann Wittgenstein was a charismatic Austrian philosopher whose philosophical career developed mainly in England. Wittgenstein's life was a search for a special kind of spirituality by means of philosophical activity. This spirituality is evidenced by some idiosyncratic ethical and even metaphysical ideas in his *Notebooks* 1914–1916 and *Secret diaries*. Wittgenstein's work was very influential in twentieth-century philosophy. He also shaped linguistics —especially pragmatics— mainly through his *Philosophical investigations*, published in 1953. His theory of language-games and his idea that 'the meaning of a word lies in its use' became the basis of certain theoretical frameworks in linguistics. His philosophy of language and his scientific epistemology are also reflected in most of the current social sciences.

The end of the nineteenth and the beginning of the twentieth century saw the arrival of the philosophy of language. Analytical philosophers like Gottlob Frege (1848–1925) conceded a central role to language in philosophical theory, and they begun the construction of a general theory of meaning, which greatly influenced Wittgenstein's thinking. Wittgenstein made two prima facie contradictory contributions to this linguistically oriented philosophy: his *Tractatus logico-philosophicus* (1922) represents an exercise in analytical philosophy (which regards everyday language as an impure vehicle of thought), while his *Philosophical*

investigations (1954) influenced the so-called ordinary language philosophy (which relinquishes the search for an ideal logical language). This is the reason why one traditionally speaks of the 'first' and the 'second' Wittgenstein. However, these 'two' Wittgensteins are reconcilable, as shown below.

Wittgenstein wrote the *Tractatus logico-philosophicus* during World War I, while in a prison camp, and sent it to his teacher and colleague Bertrand Russell (1872–1970). The *Tractatus* was published in England in 1922 with the help of Russell, who also wrote the Prologue. The *Tractatus* is a collection of numbered statements elaborating on some philosophical problems discovered by Frege and Russell. The *Tractatus* expounds a philosophy of language and mathematics and is a reflection on the nature of life and philosophy. For Wittgenstein, philosophy is mainly an activity, not a doctrine, and so his philosophy must be understood through his works.

Wittgenstein's philosophy, as presented in the *Tractatus*, relates three elements: reality, thought, and language. Reality exists, thought is the interpretation of reality, and language is the expression of thought. Wittgenstein calls the logical identity between the structure of reality, the structure of thought, and the structure of language 'isomorphism'. For him, logic is the ideal language, but only a tool for description. Language is used to describe facts, although there

remain things that cannot be said. Therefore, the *Tractatus* reaches the now famous conclusion: 'what we cannot speak about we must pass over in silence'. Thus, Wittgenstein studies the limits of language and correspondingly the limits of oneself: 'The limits of my language are the limits of my world' (*Tractatus* 5.6).

The *Tractatus* inspired some meetings of a group of philosophers referred to as the 'Vienna Circle', who developed the so-called *logical positivism* or *neopositivism*. The principles of particular appeal to the Vienna Circle were the analytical characteristics of logic, the claim that sentences need to be verifiable to be true and the idea that philosophy clarifies truth instead of discovering it.

The blue and brown books mark a transition from the *Tractatus* to the *Philosophical investigations*, that is, from the *first* to the *second* Wittgenstein. The *Philosophical investigations* were published posthumously, and are a collection of Wittgenstein's work between 1941 and 1949. The concept of philosophy, the rules of language, and the theory of language games are its main topics. It is precisely the concept of 'language game' that reconciles the *Tractatus* and the *Philosophical investigations* as discussed below.

The *Philosophical investigations* shares with the *Tractatus* that philosophy is seen as an activity, and this activity consists of the analysis of language. However, in the *Tractatus*, Wittgenstein was only interested in the logical truth or falsity of sentences. In the *Investigations*, on the other hand, he was willing to look for the meaning of words as expressed in their everyday use. Wittgenstein thus acknowledged that we are primarily users of language and only secondarily analysts of language.

For Wittgenstein, the meaning of words and propositions is identifiable in their use in language, and this use is shaped in 'language games'. The concept of language games highlights the idea that language use is rule-governed, i.e. the game metaphor is a model of the rule-based aspects of language. Wittgenstein uses the term 'game' broadly:

'23. […] Review the multiplicity of language-games in the following examples, and in others:
Giving orders, and obeying them-
Describing the appearance of an object, or giving its measurements-
Constructing an object from a description (a drawing)-
Reporting an event-
Speculating about an event-
Forming and testing a hypothesis-
Presenting the results of an experiment in tables and diagrams-
Making up a story; and reading it-
Play-acting-
Singing catches-
Guessing riddles-
Making a joke; telling it-
Solving a problem in practical arithmetic-
Translating from one language into another-
Asking, thanking, cursing, greeting, praying.'

Because the game metaphor thus extends to all rule-governed uses of language, formal language or the language of logic can also be viewed as a language game. Hence, the *Tractatus* is also reflected on in the *Philosophical investigations*. Wittgenstein's work is thus a language game itself, which highlights the self-reflexive perspective a Wittgensteinian approach has to take.

Understanding the meaning of a word requires a knowledge of linguistic and extralinguistic facts, and Wittgenstein asserted that the analysis of language use is as important as logical analysis. This represented a 'linguistic turn' in the philosophy of language, and the resulting requirement of critically reflecting on terminology now forms an important part of the scientific epistemology of many social sciences. Since the *Philosophical investigations* with its 'language games' introduced a rule-based view of discourse, it can be viewed as the philosophical basis of pragmatics. Members of the Oxford School such as G. Ryle, P.F. Strawson, and notably J.L. Austin, who developed the theory of 'speech acts', were heavily influenced by Wittgenstein's ideas. Thus, after philosophy turned to language, linguistics turned to philosophy: 'this was the "pragmatic turn", which led to a proliferation of communicative and social studies of speech in action and action in speech' (Nerlich and Clarke 1996:6).

Biography

Born in Vienna, Austria, on April 26, 1889 to a wealthy family, Ludwig Wittgenstein was educated in an artistic and intellectual environment at home until he was 14. From 1903 to 1906 he studied mathematics and natural sciences in Vienna, and from 1906 to 1911 he studied Mechanical Engineering in Berlin and Manchester. He went to Cambridge in 1911 to attend lectures given by Bertrand Russell on mathematical logic, but left Cambridge somewhat disappointed with the knowledge he gained there and went to Skjolden, Norway. He joined the Austrian army from 1914; in 1918 he became prisoner of the Italians. During these war years he wrote the *Tractatus*, which he sent to Russell while he was in a prison camp. Released in 1919, he became primary teacher in 1920 and taught until 1925. After fulfilling various posts, he returned to academic life in 1929: he taught at Trinity College. That year he submitted the *Tractatus* as his doctoral thesis. In 1939 he became Professor of Philosophy, and remained at Cambridge except for the World War

II period. In 1947 he retired to Ireland, and in 1949 came back to Oxford because of his illness. He continued working until he died in Cambridge on April 29, 1951. A large part of his works was published posthumously.

Wolof and Atlantic Languages

Wolof is an Atlantic language of the Niger-Congo phylum, spoken primarily in Senegal and the Gambia on the Atlantic coast of West Africa. Wolof serves as a lingua franca in Senegal, where approximately 40% of the population speak it as a first language and 45% speak it as a second language. Extrapolating from the 1988 census figures, there are currently at least three million native speakers of the language, and at least as many who speak it as a second or third language, making for a total of no less than six million speakers.

The Atlantic languages are spoken almost exclusively along the West African coast from the Senegal river that forms the border between Mauritania and Senegal southward to Sierra Leone and Liberia, generally abutting languages of the Mande family toward the east. Atlantic languages with the greatest numbers of speakers include Fula, which is spoken across the Sahel; Wolof and Seereer, both spoken primarily in Senegal; and Temne, spoken in Sierra Leone. Fula (also *Peul* in French from Wolof *Pël*, and Fulani in various languages, including English, from Hausa *Fùláánìì*) is known by its speakers as Pulaar (or Pular) in the western dialects and Fulfulde in the eastern ones. It is spoken by several million people across a noncontiguous stretch of West Africa. Fula speakers are found from Mauritania and Senegal in the west to Chad and Sudan in the east, including significant populations in Guinea, Mali, Burkina Faso, Nigeria, Niger, and Cameroon. The different dialects of Fula are for the most part mutually intelligible, although influence from neighboring languages has resulted in some significant lexical differences between dialects. Contemporary research confirms Koelle's (1854) hypothesis that places the Fula-speaking heartland in the Fouta Toro region of northern Senegal, with subsequent eastward expansions of Fula-speaking peoples, many of whom were and still are cattle-herding pastoralists. Seereer is spoken by approximately seven hundred thousand people concentrated in the western and central areas of Senegal, centered on the historical region of Siin (Sine), and in parts of the Gambia. Most Seereer speakers speak Wolof as a second language. Temne is one of the major languages of Sierra Leone, spoken in the central part of the country, mostly to the north of Freetown, and current estimates, although possibly low, are that it has approximately one million two hundred thousand speakers.

Atlantic was recognized as a group of related languages as early as Koelle's (1854) *Polyglotta Africana*, where it goes by the name of North-West Atlantic. Westermann (1927) renamed the language group West Atlantic, a name retained by Greenberg in his classification of African languages published in 1963. The name was subsequently shortened to Atlantic by Doneux (1975). Most contemporary classifications of Atlantic consider it to be an early branching of Niger-Congo, concurrent with or subsequent to the Mande branching. Until Greenberg's classification, and largely

as a result of using cultural and ethnic criteria rather than linguistic ones, Fula had been classified apart from the Atlantic languages. Linguistic evidence, however, showed that Fula was clearly an Atlantic language with a strong resemblance to Seereer. Most contemporary classifications of Atlantic, including Wilson (1989), are based on or respond to Sapir's (1971) lexicostatistical study of the languages. Comparing 100 core lexical items across languages, which revealed rather low correspondences, Sapir nevertheless posits a Northern Branch, Southern Branch, and a single isolated language, Bijago (or Bijogo), spoken on the Bijago Islands off the coast of Guinea Bissau. Sapir's Northern Branch of Atlantic is comprised of five subgroups: (A) Senegal languages (Fula and Seereer, Wolof); (B) Cangin languages (Non, Ndut, Lehar, Safen, also sometimes called Seereer-Non, Seereer-Ndut, etc.); (C) Bak languages (Diola cluster, Manjaku and Papel, Balanta); (D) Eastern Senegal — Portuguese Guinea (now Guinea Bissau) languages (Tenda group: Tanda, Basari, Bedik, and Konyagi; Biafada and Pajade; Kobiana and Banhum; and (E) a nameless group (Nala, Mbulungish, and Baga Mboteni). The Southern Branch is comprised of three subgroups: (A) Sua; (B) Mel languages (Temne and Baga Koba, Sherbro, Mmani, Krim and Kisi, Gola); and (C) Limba. Recent unpublished work on the isolate, Bijogo, suggests that it may be the most conservative Atlantic language, especially since its noun class markers most closely resemble those of the Bantu languages. The low scores found by Sapir for cognates between Atlantic languages are corroborated by Bennett and Sterk (1977), who find that the Atlantic languages generally show no more genetic affinity with each other than they do with the rest of the Niger-Congo phylum. Although grammatical and lexical similarities are to be found within various subgroups, to date linguists have not found any evidence of shared innovation common to the Atlantic languages, leaving their coherence as a genetically related family a matter of convention rather than fact.

Salient characteristics of the Atlantic languages include an SVO word order, extensive noun class systems, and verbal extensions, as well as a perfective/imperfective aspectual distinction in the verbal system, a syntactically encoded focus system, and verb serialization. These features are not unique to Atlantic languages but are, in fact, common to the Niger-Congo phylum as a whole. The trait most closely associated with, although not unique to, the Atlantic languages is morphologically conditioned stem-initial consonant mutation, which is found on nouns, adjectives (for those languages that have them), and verbs throughout the language group.

The consonantal inventories of Atlantic languages generally distinguish four places of articulation: labial, alveolar, palatal, and velar. Some languages, including Wolof and Seereer, also have one or more uvular consonants. Prenasalized stops and implosive consonants are common, although Wolof does not have the latter, and word-initial voiceless prenasalized stops have all but disappeared from the language, being retained only in place names (such as *Mpal*) or by older rural Wolof speakers. Seereer is phonetically quite unusual in having a series of both voiced and voiceless implosive stops in three places of articulation: bilabial, alveolar, and palatal. A basic five-vowel system is augmented with [+/−ATR] (advanced tongue root) contrasts for mid-vowels in many Atlantic languages. These are phonemic in Wolof, as evidenced by pairs such as *reer* [−ATR] 'dinner' and *réer* [+ATR] 'to be lost'. Wolof also makes an [ATR] contrast between the low vowel [a], which is [−ATR], and a central schwa-like vowel written as ë. Many Atlantic languages, including Wolof, contrast both consonant and vowel length; Seereer contrasts only the latter. While almost all Niger-Congo languages, including most Atlantic languages, are tonal, the northern Senegal languages, Fula, Seereer, and Wolof, are not, although a high-pitch accent is associated with ideophones.

Morphologically conditioned consonant mutation is found stem initially in verbs and nouns in a great number of Atlantic languages. In noun stems, initial consonants may have up to three homorganic variants conditioned by noun class. The variants are known as grades, following Arnott (1970). In Fula, these take the form of a continuant, a stop, and a prenasalized stop as in the singular (Class 1), plural (Class 2), and diminutive plural (Class 21) words for 'man' (*gorko, worɓe, ⁿgoron*) and 'woman' (*debbo, rewɓe, ⁿdewon*). Seereer exhibits a similar type of consonant mutation, as well as one that shows alternations between a voiced stop, voiceless stop, and prenasalized stop. The word for 'man' in its singular (Class 1), plural (Class 2) and diminutive singular (Class 12) forms (*okoor, goor, oⁿgoor*) illustrates the latter type of mutation, while the same forms for the word for 'woman' (*otew, rew, oⁿdew*) illustrate the former. This type of consonant mutation in the Atlantic languages has been analyzed as the historical result of the erosion of noun class prefixes which had a phonological effect on the stem-initial consonant. Remnants of prefixes are seen in some Atlantic languages like Seereer, providing incontrovertible evidence that Atlantic languages, like other Niger-Congo languages, and particularly Bantu languages, at one time had a complete set of noun class prefixes. Such prefixes eroded phonologically over time only to be renewed in many cases, such as Fula, by suffixes. Wolof exhibits an advanced stage in the erosion of noun class morphology: for the most part, nouns are not marked for class so that their singular

and plural forms are identical. A few lexicalized exceptions to this generalization, including the words for 'eye/s' (*bët/gët*) and 'person/people' (*waa/gaa*), provide evidence of a once robust inflectional system. Consonant mutation is nevertheless quite productive in other areas of the grammar, including diminutive formation, which requires a prenasalized form, and verb to noun derivation.

Wolof has ten noun classes: eight singular and two plural. Of the singular noun classes, one, the s-class, serves a second function as a diminutive class. A noun class marker appears in the form of a single consonant on nominal dependents such as determiners and relative particles. The word for 'person' (*nit*) is in the k-class, and the word for 'bird' (*picc*) is in the m-class, hence the following forms: *nit ki* 'the person'/ *picc mi* 'the bird': *nit kële* 'that person' / *picc mële* 'that bird'; *nit ku baax* 'person who is good'/ *picc mu baax* 'bird that is good'. A problematic aspect of Wolof class assignment, remarked upon by several scholars, is the tendency for the class marker to repeat the initial consonant of certain nouns, in a process akin to consonant harmony or reduplication. Phonologically conditioned agreement poses a substantial problem for linguistic theory in general and the lexicalist hypothesis in particular, since syntax should not have access to the phonology. A second noted trend in the evolution of the Wolof noun class system is a tendency toward assigning nouns to the default b-class. The origins of this tendency are to be found in a combination of morphological and sociolinguistic factors (Irvine 1978; Mc Laughlin 1997).

African languages in general, including Atlantic languages, have had a profound effect on contemporary linguistic theory. Consonant mutation in the Atlantic languages, and particularly in Fula, has substantially informed underspecification theory and, more recently, theories of featural affixation. The interaction of consonant mutation and reduplication in Seereer-Siin has had implications for correspondence theory; and the facts of ATR vowel harmony in Wolof, which has vowels that are both opaque and neutral to the process, have also been instrumental in theoretical advances in that area. The clause structure of Wolof has also provided evidence for the projection of a sigma phrase within the principles and parameters framework.

The sociolinguistics of Wolof are of particular interest. Wolofization, or the spread of Wolof as a lingua franca in Senegal, has been increasing steadily since the colonial period when it was used widely in the coastal cities. Wolofization is an urban phenomenon, and it is the specifically urban variety of Wolof that continues to spread, even to the point where it has replaced Portuguese creole as the predominant language of Ziguinchor, the largest city in the Casamance region of southern Senegal. Urban Wolof is substantially different from dialects spoken in the predominantly rural Wolof heartland. Its main characteristics are extensive lexical borrowing from French, the former colonial language and current official language of the country, and the reduction of the noun class system toward the default b-class. Urban Wolof has an ambiguous status. On the one hand, as the language of the capital it holds a certain prestige, especially among youth, and its mastery implies a certain urban sophistication. On the other hand, it is recognized as being a hybrid language and looked down upon as 'impure', especially by those who are not ethnically Wolof.

In the domain of discourse, elaborate speech in Wolof is associated with griots or verbal artists who are of low social status. Irvine (1978) has documented the avoidance of elaborate speech as an attempt to manipulate social status.

Finally, although there is an official Wolof orthography in the Roman script, it is not widely used. The preferred writing system is an *ajami* version known as *wolofal*, which is a modified Arabic script, made popular through widespread informal Islamic education and attendance at Qur'anic schools.

Word

Although many language users intuitively know what a 'word' is, an unequivocal and clear-cut linguistic definition cannot be given. The concept of 'word' is highly ambiguous and refers to different phenomena. On the one hand, words are language units at the intersection of two linguistic levels of description: morphology (which is the arrangement of meaningful sound sequences, or morphemes, in words) and syntax (which is the arrangement of words in sentences). Accordingly, lexicology is the linguistic branch that deals with words, which thus implies both morphological and syntactic aspects. On the other hand, words are regarded as basic units in the psychological reality of language acquisition, production, and processing: words in the mind. An attempt to produce a system reflecting the versatility of the notion of 'word' would need to describe words as both 'linguistic structures' (although of different kinds) and as parts of the mental lexicon.

The linguistic notion of 'word' captures three fundamentally different, but closely related, concepts that will be indicated in the following as word$_1$, word$_2$, and word$_3$. To begin with, so-called 'word forms' (i.e. word$_1$) refer to the physical substance of words in spoken and written language: phonological word forms in speech, and orthographic word forms in writing. For example, /bɔɪ/ and /bɔɪz/ are two phonological word forms, i.e. specific combinations of sounds in the phonic medium. On the other hand, *boy*, *boy's*, *boys*, and *boys'* represent four corresponding orthographic word forms, or combinations of letters (and apostrophes) in the written medium. The six word forms provide the inventory of possible word-form realizations of one underlying abstract unit, the lexeme *BOY*.

The lexeme (word$_2$), usually given in capitalized letters, is what all the actual word forms have in common at an abstract level. It is this abstract unit of a lexeme that is at the basis of a dictionary since all word forms of one and the same lexeme are subsumed under the same dictionary entry.

While word forms represent merely physical forms in terms of sounds or letters, lexemes—in a first approximation—are examples of linguistic signs. That is to say, a lexeme connects potential forms (i.e. the signifier) to an abstract meaning encoded by these forms (i.e. the signified), such as the phonological word forms /teɪbl/ and /teɪblz/ (i.e. the signifier) to the meaning of 'piece of furniture consisting of a flat top supported on one or more legs' (i.e. the signified). This arbitrary, but fixed, form-meaning relation is inherent to the lexeme as a linguistic sign. However, a lexeme actually forms a set of several linguistic signs: some word forms of a lexeme may be linked to specific (sub-) meanings of the lexeme and vice versa. For example, all orthographic word forms of the verb YIELD, i.e. *yield*, *yields*, *yielded*, *yielding*, are linked to the possible meanings 'give way' and 'lead to'. On the other hand, a third meaning of the verb, 'produce', is strongly associated with the first two aforementioned word forms. To be able to refer to such subsets of word forms with a specific range of meaning, the concept of 'lexical unit' or 'lexical linguistic sign' has been introduced.

Apart from word forms and lexemes (including lexical units), the concept of 'word' can also be approached from a grammatical perspective. A grammatical word (i.e. word$_3$) is immediately relevant to syntax and has specific morphological features. The distinction between word forms and grammatical words is important because one word form may represent different grammatical words (a phenomenon called 'syncretism'). For example, the phonological word form /bɔɪz/ can be regarded as a realization of the plural form, the singular genitive, and the plural genitive. In applying the concept of grammatical words, linguists are particularly interested in the question of how words, as minimal syntactic units, are arranged in grammatical structures. Irrespective of the specific grammatical principles at work, grammatical words have a certain ability to change position in a sentence (i.e. 'positional mobility'). Thus, it is often possible to shift a grammatical word, in its entirety, to a different position in a given sentence without jeopardizing the grammatical integrity of that sentence. It goes without saying that in English, which has a comparatively fixed word order, the overall degree of positional mobility is lower than, for example, in German, which allows for much more word-order variation. In terms of their internal structure, however, grammatical words are stable, in that the sequence of morphemes is, in principle, not subject to variation: for instance, *boy-ish* is a possible adjective in English, but the reversed sequence, i.e. **ish-boy*, is not permitted.

Words also play an important role in the mental processes that underlie language use. It is reasonable to assume that words are stored in the mind in a highly structured way. This orderliness of the complex mental lexicon permits the amazing speed of lexical retrieval in natural speech. It is widely accepted that the mental

lexicon presumably does not list each and every word in a random order. Rather, a list of lexical structures (words, word groups, word components) is supposed to be complemented with a set of rules and principles on how to combine these structures. This concept avoids, for instance, a listing of different words ending in the same suffix as separate entries: for example, *boyish* and *girlish* are derived from applying the same combinatorial rule to the base entries *boy* and *girl*, respectively. Such systematic combinations presuppose a mental capacity for analyzing complex words in speech processing, which is subsumed under the notion of 'morphological parsing'. In the aforementioned example, morphological parsing would refer to speakers' ability to strip the suffix *-ish* and to identify a general rule that makes it possible to derive an adjective from a noun by adding this suffix to the noun.

The importance of words for the linguistic competence in the mind and the highly structured design of the mental lexicon are also corroborated by research into language acquisition. The surprisingly rapid development of child language is to a large extent based on the acquisition of thousands of words in a comparatively short time. At a more or less specific stage of this development, children tend to overgeneralize morphological rules. For instance, they add the regular past tense morpheme (*-ed* in English) to all regular verbs (*learn* becomes *learned*) and irregular verbs (*go* becomes **goed*). This phenomenon reflects the tendency for a child's mental lexicon to comprise both basic elements (*learn*, *go*, *-ed*) and so-called rules of morphological parsing to combine these elements and analyze the combinations (verb_present + *-ed* = verb_past).

Lexical disorders, too, shed light on the structure of the mental lexicon. Aphasia—a condition of speechlessness that stroke patients often display when specific areas of the brain are affected—is a compelling example of such a disorder. Broca's aphasia, for example, leads to 'telegraphic speech', or the omission of function words (e.g. articles like *the*, prepositions like *of*), whereas patients suffering from Wernicke's aphasia show difficulty in lexical selection (i.e. they very often do not produce the words they want but other words with different meanings, which often renders their speech unintelligible).

In the light of their structural and mental significance, it is reasonable to assume that words are the most basic linguistic units. However, the overall importance of words for language to function is largely at odds with the yet unresolved problem of word identification. What is relatively simple in written language, where words are usually separated by spaces from each other (though not the case in all languages), is far more complicated in spoken language. Several

attempts have been made to establish criteria for a reliable identification of words in the continuous stream of speech sounds. For example, words are said to be demarcated by positions at which pausing is, at least, possible. Another suggestion is to look for those stretches of sounds that could stand meaningfully on their own. Although these two approaches and others may be useful for the majority of words, other cases cannot be clarified, such as compounds, which might be considered as one word or as several words.

In all languages, linguists set out to group words into word classes. Generally, one can distinguish between 'open' and 'closed' word classes. Open word classes can always have new words freely added to them; in most languages, these classes include nouns, verbs, adjectives, and adverbs. In contrast, usually no new members can be added to closed word classes. In English, for example, prepositions (e.g. *under*), conjunctions (e.g. *because*), pronouns (e.g. *mine*), determiners (e.g. *the*), and numerals (e.g. *first*) are the primary closed word classes. The basis for the categorization of words into classes is provided by their morphosyntactic behavior. Nouns, for instance, are almost always able to take a plural form (disregarding exceptions). As with word identification, word class categorization is not straightforward in all cases. An important example in English is, perhaps, the word class of adverbs. This class contains members that are extremely dissimilar in structural terms, such as the prototypical adverb *rapidly* and the negative particle *not*.

Words have an internal structure themselves and are at the same time the basic units of larger structures. The former aspect refers to the domain of 'derivational morphology', i.e. the linguistic description of processes and phenomena of word formation. The latter aspect captures the fact that words play a key role in syntactic structures, which they enter in a principle-guided fashion. Moreover, a given word in a specific position tends to predict, to a large extent, the range of words possible both before and after it. If the probability of two words occurring next to each other is significantly high, this phenomenon is called 'collocation' (from *co-location*).

With collocations, corpus linguistics has definitely broken new ground. In searching very large computer collections of text (so-called corpora) for co-occurrences, it is now possible to base the concept of collocation on an empirical foundation. By applying such corpus linguistic methods, it can be statistically determined to what extent a given word predicts another word in its immediate neighborhood. For example, *strong* and *argument* co-occur in significant frequency in authentic English language use. Their combination is thus not of a random nature but constitutes a collocation, i.e. a lexical co-selection. Furthermore, specific

words tend to occur in a restricted range of grammatical patterns (a phenomenon called 'colligation', from *co-ligation*). For example, *naked eye* almost exclusively occurs in the grammatical pattern 'verb/adjective + preposition + definite article + *naked eye*' as in *visible to the naked eye*. Collocations and colligations reveal that lexical choices and grammatical choices are not independent of each other but that lexis and grammar are intricately intertwined. One could argue that the traditionally established distinction between lexis and grammar should eventually be overcome altogether and be replaced with an integrated lexicogrammar (or a 'pattern grammar').

The linguistic level of words, i.e. lexicology, is of particular interest for dictionary makers or lexicographers. They take an inventory of the words of a language but, by definition, are bound to fail to give an exhaustive account of all words in existence at a given time. Although it is impossible to list all words in a given language, the use of dictionaries has led to a high degree of standardization in orthographic and phonological word forms; they are, of course, a helpful tool for language users in general and language learners in particular. Dictionaries should include orthographic, phonological, grammatical, and semantic information about words, thereby strongly resembling the composition of the mental lexicon as hypothesized by psycholinguists. One ought to bear in mind, however, that the mental lexicon is based on a list of entries and rules to combine them, whereas dictionaries usually contain only an alphabetical list of entries. Furthermore, large dictionaries represent enormous and idealized word lists of which no single native speaker has command: they approximate the so-called 'magnavocabulary' of a language in its entirety, but do not correspond to the specific vocabulary that an individual speaker has at his or her disposal.

The object of inquiry for lexicographers and lexicologists is in constant flux. Productivity and imagination in human languages are perhaps most obvious at the level of words.

Word Order

Sentences consist of words that are combined in certain patterned ways to convey meaning. One important dimension of this system of combination is linear order: the order in which words are combined to form phrases and sentences is fundamental to the syntactic structure of any language.

The importance of word order in English, for example, can be seen in the following sentences, in which an asterisk indicates that an order is ungrammatical:

(1) *A dog bit the man.*

(2) *The man bit a dog.*

(3) **Bit a the man dog.*

Only the word order change between (1) and (2) signals a crucial meaning change, and (3) shows that words

cannot be combined haphazardly, but must be ordered by rules. Word order is just as important to the structure of separate phrases as it is to a whole sentence. In English, a long nominal phrase such as *these three new white cotton sheets* is grammatical, but it becomes unintelligible or odd if the ordering of even one word is altered: **new these three white cotton sheets*.

The rules governing word order are specific to each language and may show considerable variation. Nevertheless, research has identified certain universal word order patterns. Typological studies of hundreds of languages show that each one may be classified into one of three basic word order types according to how the three main syntactic constituents—subject (S), verb (V), and object (O)—are ordered within a basic declarative sentence. According to studies by Greenberg (1966) and Tomlin (1986), the most common word order type is SOV, which is found in 37–45% of the languages studied. This order is basic in languages such as Japanese, Turkish, and Chinese. The SVO order of languages such as English, French, and Spanish is nearly as common, occurring in 35–43%. The VSO order found in languages such as Irish, Maori, and Berber is the rarest, with estimates varying from 9% to 20%.

Logically, there are at least three other possible word order types—VOS, OSV, and OVS. However, these orders are virtually nonexistent. Their absence is often interpreted as a universal preference for ordering subjects before objects. One possible functional explanation for this preference may be that it reflects the way in which humans arrange information cognitively and that subjects are often more salient cognitively than objects. The relative rarity of the VSO order suggests that there is a preference for keeping the verb and object together as a unit, as they are in the SVO and SOV orders.

Some researchers, for example Lehmann, instead simplify the three basic word order types into two, making VSO a variation of an underlying SVO structure. In this view, all languages use either a basic VO or OV order. Hawkins and Vennemann have also expressed this as a general head-dependent (i.e. VO) vs. dependent-head (OV) order, which can be seen to govern the ordering of all types of phrases within one language.

Phrase-internal orderings among word categories such as nouns (*house, dog,* etc.), determiners (*the, a,* etc.), adjectives (*green, dark,* etc.), possessives (*my, your,* etc.), and adpositions (*in, for, of,* etc.) show interesting correlations with the three basic sentential word orders. For example, VSO languages tend to use prepositions (*in* in the phrase *in the house*), whereas SOV languages use postpositions (literally translated, *the house in*). Similarly, VSO languages follow noun–adjective order (*house white*), whereas SOV languages follow adjective–noun order (*white house*). Such correlations also support the OV vs. VO typology, although there are languages that contain exceptions.

Languages differ in the degree to which they allow or exploit variations from the basic SVO, SOV, or VSO word order. Variations are typically used to convey a certain style or focus, emphasize a particular word or phrase, or signal that a sentence has a special discourse function, such as a question or command. It is not uncommon to find that one word order is standard in finite (tensed) main clauses and that another is the norm in infinitive (untensed) clauses. Adverbs (such as *luckily*), which are optional elements, are particularly flexible in their possible placements. In terms of language processing, the very first and last positions in each sentence are significantly prominent positions. Often a phrase will be ordered first or last to emphasize and focus attention on it. Very long phrases, such as *the three young men who washed the car for me last Saturday,* are often positioned last or at least moved rightward, possibly because this makes them easier to process. The first and last positions are also the most common ones for special question-marking particles in those languages that use such particles.

The second position in a sentence ('Wackernagel position') also seems to have special significance. One group of languages normally classified as SVO shows a basic word order in which the first position may actually be occupied by any type of phrase (not just the subject), as long as the verb consistently appears in second position. This word order pattern is known as verb-second or V2 order and has been studied extensively in research on the Scandinavian languages, German, Dutch, and Yiddish. Second position also seems to be a preferred position in many languages for the placement of clitics, i.e. elements that cannot stand alone but must attach to an independent 'host' word.

Finally, some languages, such as Polish, may be classified as showing 'free word order' at the sentence level. That is, it is possible to combine phrases in many different ways and still convey essentially the same meaning. Also, some languages allow for discontinuous constituents, in which the words of one phrase may be separated rather than appearing as one continuous string of words. These ordering phenomena present interesting challenges to existing theories of both linear and hierarchical syntactic structure.

In summary, it is most common for languages to identify one basic word order for the subject, object, and verb in each sentence, but to allow for some stylistic variations. In either case, word order is rule governed and shows some universal tendencies that may reflect possible constraints on how humans process language.

Word Sense Disambiguation

A word is semantically ambiguous if it has more than one sense. Word sense disambiguation (WSD) is the process of deciding which sense is correct in a given context. The process of WSD is illustrated by Rayson and Wilson's SEMSTAT (Thomas and Wilson 1996), a semantic tagger that reads in a text and assigns a code number standing for a particular word sense to each word in that text. For each word, a lexicon is first checked to see what senses that word can take. Many words are unambiguous, but if more than one sense is possible for a given word, WSD techniques come into play, making use of the following types of information:

(1) The part of speech (POS) tag assigned by the CLAWS POS tagger (Garside et al. 1987). For example, if 'spring' is a verb, we know it must mean 'jump'. Wilks and Stevenson (1996) have shown that POS tagging greatly assists in the problem of word sense disambiguation.

(2) The general likelihood of a word taking a particular meaning, as found in certain frequency dictionaries. For example, if a corpus has 5,651 occurrences of 'bridge' in the sense of a bridge over a river, and only 194 occurrences of 'bridge' in the sense of a dental bridge, then the simplest technique is to assume that the more common sense of 'bridge over a river' is always the correct one. According to Allen (1995), this simple technique is about 70% accurate over English as a whole.

(3) Idiom lists are kept. If an entire idiomatic phrase is found in the text being analyzed, it is assumed that the idiomatic meaning of each word in the phrase is more likely than individual interpretations of the words.

(4) The domain of discourse can be an indicator. For example, if the topic of discussion is footwear, then 'boot' is unlikely to refer to the boot of a car.

(5) Special rules have been developed for the auxiliary verbs 'be' and 'have'.

(6) Collocations are pairs or groups of words that frequently appear in the same context. Are any collocates of the word, suggesting a particular interpretation, found in its immediate vicinity? We would, for example, prefer the dental sense of 'bridge' if the context contains collocates such as 'dentist' or 'cavity'. This technique is also called proximity disambiguation. The amount of text on either side of a word in which we look for collocates is called the window. One statistical measure of collocation strength is mutual information (Church and Hanks 1990).

SENSEVAL is an open evaluation exercise for WSD programs, first taking place in 1998 with WSD tasks for English, French, and Italian (Kilgarriff and Palmer 2000).

A corpus manually annotated with the correct sense of each word was used as a 'gold standard', against which the output of each of the programs was

concerned. The SENSEVAL systems could make use of the rich HECTOR dictionary rather than a simple lexicon. In HECTOR, for each homograph, there is a separate entry for each sense distinction, including fields for word sense definition, POS information, and examples of usage. This enabled the development of the following techniques:

(1) Collocation filters. These were used by various authors, the main variations being in (a) the window length and (b) whether to measure word–word, word–phrase, or noun–argument collocations. In order to calculate collocation statistics for verbs and the nouns they are associated with, shallow parsing is required beforehand.

(2) Manually created idiom extraction patterns, such as 'shake in \w* (shoes|boots|seat)' would cover any of the (variable form) idioms 'shake in your boots', 'shake in one's seat', etc.

(3) Matching dictionary example sentences with a window of input text. A score is given for the number of identical words occurring in the dictionary example and the text window. The sense with the highest scoring example is chosen. Similarly, one can count matches that involve semantically related words (such as words with the same Roget's thesaurus categories) in the matching score, rather than insisting on exact word matches. Various measures of similarity between test sequences and dictionary examples (glosses) have been suggested.

(4) Conceptual density. All possible senses of all content words in the input sentence are marked in a hierarchy such as Word-Net (Fellbaum 1998). The portion of the hierarchy with the greatest concentration of marked nodes (including one for the word being tested) will reflect the sense of the test word.

(5) Development of decision trees. According to the nature (word classes or individual words) of the neighbors of the test word, decisions are taken in an order designed to yield maximum information at each branch point, and to determine the sense of the test word in as few steps as possible. A similar technique for French grammatical words is described by Hug (2000).

(6) A number of systems use machine learning techniques for finding the combination of features (e.g. collocates, POS of words in the window) most likely to reveal word sense.

(7) Use of a thesaurus to overcome data sparseness. A recurring problem with WSD, compared with POS tagging, is that there are more word senses than syntactic categories, meaning a much larger amount of training data is required. Use of a thesaurus helps overcome this problem, as frequencies of word classes are studied rather than those of individual words.

In the next SENSEVAL evaluation, the WordNet hierarchy will be used rather than the HECTOR dictionary. Other interesting WSD methods described in the literature are as follows:

(1) Gale et al. (1992) used machine-readable texts and their translations, noting, for example, that the sense of 'drugs' which translates into French as 'mediacaments' collocates with 'prescription', 'patent', and 'generic', while the sense which translates as 'drogues' collocates with 'abuse', 'paraphernalia', and 'illicit'.

(2) Biber (1993) used the multivariate statistical technique of factor analysis to discover the four basic senses of the word 'right' in a corpus, according to their various collocates.

Working Memory

The term 'working memory' (WM) refers to the assumption that some form of temporary storage and manipulation of information within the time range of a few seconds is necessary for performing virtually all cognitive operations. Thus, understanding and analyzing a sentence, performing a mental arithmetic problem, or recalling a telephone number requires the activation of the working memory system.

A multicomponent WM system was proposed as an alternative conceptualization of the so-called short-term memory, considering the unitary system and experimental results, which led to its abandonment as a concept. The most commonly accepted WM model was proposed by Alan Baddeley and colleagues during the 1970s and consists of three main components: an attentional-controlling system (central executive) aided by two slave systems responsible for the temporary storage and manipulation of either visual/spatial material (visuospatial sketch pad) or acoustic/speech-based material (phonological loop) (Figure 1).

The central executive, the most important yet least well-understood component of the WM, is a limited-capacity processor that is responsible for providing the link between the slave systems and the so-called long-term memory. It is assumed to be an attentional control system and is responsible for online data storage and the selection, initiation, and termination of processing routines (e.g. encoding, storing, and retrieving). Recent findings point to distinct areas of the prefrontal cortex of the brain as neuronal substrate for the central executive (Figure 2), which controls the activity of the more posterior sensory areas that also contribute to WM. The prefrontal cortex appears to hold relevant information online as well as to perform complex processing functions.

The visuospatial sketch pad (or scratch pad) has a visual component, which is concerned with the analysis of color and shape, and a spatial component, which is concerned with location. Besides the important role of the prefrontal cortex for both components, the visual component has its neuronal correlates in bilateral occipitotemporal brain regions whereas the spatial component has its neuronal substrate in right occipitoparietal regions.

The phonological loop, which also comprises two components, is responsible for the storage and manipulation of sounds. The first component is a phonological store, which is capable of holding traces of acoustic or speech-based material for 1–2 seconds. The phonological store receives directly and unavoidably any information auditorily presented and stores it in terms of a sound-based code. It has its neuronal correlates in the left posterior parietal cortex and is also able to receive visually presented items, but these must first be converted into an articulatory form before gaining access to the store. The second component is an articulatory control process, which refreshes memory traces by subvocal rehearsal of phonological information. The neuronal substrate for subvocal rehearsal lies in left hemispheric speech areas, including Broca's area, the premotor cortex, and the supplementary motor area (SMA). Prevention of subvocal rehearsal results in very rapid forgetting.

Convincing evidence for the existence of such different components included in the WM model comes

Figure 1. Scheme of the multicomponent WM model after Baddeley (1986).
Figure 2. Left-hemispheric scheme of the brain lobes. In the frontal lobe, schematic positions of left-hemispheric brain areas are indicated, which are important concerning WM: Broca's area (1); premotor cortex (2); supplementary motor area (3); dorsolateral prefrontal cortex (4); orbital prefrontal cortex (5); primary auditory cortex (6); primary visual cortex (7).

from studies of brain-damaged patients with specific memory impairments. Some patients show selective deficits of auditory verbal WM, which was attributed either to selective impairment of the phonological store or of rehearsal processes. Other patients have a specific impairment of the visuospatial sketch pad or of the central executive.

WM and Language Processing

Concerning the relationship between WM and language processing, the phonological loop and the central executive are the most important components of the model. In fact, the visuospatial sketch pad might also play a role in some aspects of language processing, for example, in text comprehension in as much as mental imagery might be involved. The functional role of the phonological loop is probably to facilitate long-term phonological learning, as is needed to acquire both native and second language. Indeed, phonological learning is probably a primary determinant for successful first-language acquisition. It is necessary for the acquisition of new vocabulary and language comprehension as a whole. The function of the central executive is the inhibition of irrelevant information as well as activation and maintenance of information relevant during language comprehension. While listening to human speech, WM is used to hold the segments of sentences 'on-line' millisecond by millisecond. WM is necessary to carry forward, in real time, the subject of a sentence and associate it with verbs and objects in order to comprehend the sense and meaning of sentences. Some of the best evidence for WM playing a substantial role in language processing comes from studies that show substantial correlation between the measure of a person's verbal working memory capacity and the person's performance on language-understanding tasks. Therefore, subjects are divided into those with either high or low WM span, with the latter being more likely to be misled by inappropriate context. Generally, persons with a high working memory span seem to be better at language comprehension and syntactic analysis.

To test the influence of WM load on comprehension, some common paradigms in language research are used such as the comparison of simple subject–verb–object constructions (1a) with passive constructions (1b), which are harder to understand. Similarly, right-branching structures (2a) are easier to understand than center-embedded sentences (2b), since the main clause subject has to be kept in mind till the end of the embedded phrase. Furthermore, sentences with embedded relative clauses are used (3a) or constructions such

as in (3b), which are even more difficult to comprehend due to greater demands on WM. Subjects with low WM span have substantially more problems in understanding the more difficult sentences, and furthermore need more processing time.

(1) a. The dog chased the child.
   b. The child was chased by the dog.
(2) a. The child chased the dog that jumped from the table.
   b. The dog that jumped from the table chased the child.
(3) a. The dog that chased the child jumped from the table.
   b. The dog that the child chased jumped from the table.

WM is studied in humans mainly by the use of behavioral paradigms, most recently in conjunction with brain-imaging techniques. It has been shown that WM relies on cooperation among distributed areas of the brain, with the precise regions depending on whether tasks entail remembering objects, locations, or words. The prefrontal cortex is apparently working as the coordinator of the activity of these various regions.

SABINE WEISS

Writing Systems

Writing is distinguished from other forms of pictorial representation in that it relates directly to linguistic expression. Thus, a picture of a man feeding a dog, no matter how eloquent, is not writing. Writing as a means of representing linguistic expression probably first arose in Mesopotamia at the end of the fourth millennium BC, although some recent discoveries suggest that the earliest writing in Egypt might be contemporaneous or even earlier.

From a linguistic point of view, writing systems can be classified in terms of the kinds of linguistic elements that form the basic units of the system, with a basic division into logographic, syllabic, and alphabetic types, although there are also intermediate types (such as alphasyllabic) and writing systems that combine more than one type. The scale logographic–syllabic–alphabetic also corresponds approximately to the historical development of writing systems.

In a logographic system, there is a separate symbol for each morpheme of the language in question. The closest modern writing system to a pure logographic system is that of Chinese. In (Mandarin) Chinese, the words for 'lake' and 'pot' are both pronounced alike, *hú*, but have written forms that are completely different, as in examples (a) and (b), respectively. Although the term logographic might suggest one symbol per word, this is not strictly accurate, since a word consisting of more than one morpheme, such as *wǒ-men* 'we', literally I-PLURAL, is written with two symbols, one for each morpheme, as in (c).

湖　　壺　　我们
(a)　(b)　(c)

In a syllabic system, there is a separate symbol for each syllable. Japanese uses two syllabaries (sets of syllabic symbols), illustrated here with the hiragana syllabary. The symbols in (d), (e), and (f) are, respectively, the syllables [ta], [to], and [no]. Note that there is no similarity between the symbols for [ta] and [to] corresponding to the shared initial [t], and no similarity between the symbols for [to] and [no] corresponding to the shared vowel [o].

た　　と　　の
(d)　(e)　(f)

In an alphabetic system, there is a separate symbol for each phoneme of the language. The Latin, Greek, and Cyrillic alphabets (the last used, for instance, for Russian) are all at least in principle alphabetic writing systems, so that in regularly spelled English words like *ran, run, bun, but,* each orthographic symbol (*a, b, r, n, t, u*) corresponds to a single phoneme. The earliest alphabetic writing systems departed from this pattern in an interesting and systematic way: they wrote only consonants. This consonantal writing system survives, with certain modifications, in the modern Arabic and Hebrew writing systems. The Arabic word as written in (g) represents only the consonants [k], [t], and [b], in that order (although read from right to left in Arabic). The word would most probably be read as *kataba* 'he wrote', although it could in principle also be read as *kutiba* 'it was written'. It is possible to add diacritics to indicate the vowels, as in (h) for *kataba* and (i) for *kutiba*, but it is not usual to do so, since the correct interpretation can usually be derived from the context by someone with native-like fluency in reading the language. The first alphabet to use both consonant and vowel symbols consistently was the Greek alphabet.

كُتِبَ　كَتَبَ　كتب
(g)　　(h)　　(i)

An interesting halfway stage between alphabetic and syllabic writing is found in the so-called alphasyllabic writing system, found in most of the indigenous scripts of South Asia (e.g. Devanagari, Bengali, Tamil), South-East Asia (e.g. Burmese, Thai), and Ethiopia and Eritrea (e.g. Amharic). Here, the basic symbols of the writing system represent consonants, but modifications are added to indicate vowels, thus giving rise to complex symbols that represent syllables. Examples (j), (k), (l), and (m) are from the Devanagari script, used for writing modern Hindi, and represent, respectively, [ke], [pe], [ku], and [pu]. The vowel [e] is represented by a kind of hook above the consonant symbol, and the vowel [u] by a kind of hook below.

के　पे　कु　पु
(j)　(k)　(l)　(m)

Occasionally, one finds orthographic representation of distinctive features, i.e. the individual phonetic parameters that make up a phoneme, although only in particular parts of the system. In Czech, for instance,

which uses the Latin alphabet, palatalization is indicated by means of a so-called hook placed above the nonpalatalized correspondent, so that alongside *s*, *z*, and *c* (the last like the initial consonant of *tsetse*), one has *š* (like the initial consonant of *ship*), *ž* (like the final consonant of *rouge*), and *č* (like the initial consonant of *chip*).

Few writing systems correspond exactly to one or other of the ideal types. The Chinese writing system, although basically logographic, makes some concessions to pronunciation, so that like-sounding words sometimes incorporate an identical element. In Mandarin Chinese, the pronunciation *huáng* corresponds to the three meanings (among others) 'emperor', 'locust', and 'afraid', which use the symbols shown in (n), (o), and (p), respectively. It will be seen that the symbols for 'locust' and 'afraid' include as their right-hand component the symbol for 'emperor'. In addition, symbols can be used in writing foreign words purely for their phonetic value; thus, the Chinese for Berlin is *bólín*, written as in (q), where the two symbols normally represent, respectively, 'cypress' and 'grove'. This is essentially the same as the rebus principle often used in children's picture writing puzzles, where for instance a picture of a bee might represent the like-sounded verb 'be'.

皇　　蝗　　惶　　柏林
(n)　　(o)　　(p)　　(q)

Although vowels are not universally written in Arabic, long vowels nearly always are, a departure away from a purely consonantal writing system, so that the word *kaatib* 'secretary', as in (r), does differ in writing from item (g).

كاتب
(r)

Probably the most complex mixed script in use today is that of Japanese, which uses (simplifying somewhat) logographic symbols of Chinese origin for roots (e.g. *hito* 'man', *mi-* 'see'), syllabic symbols from the hiragana syllabary for particles and suffixes (e.g. nominative *ga*, accusative *o*, past tense *-ta*), and syllabic symbols from the katakana syllabary for loanwords from other languages (e.g. *doa* 'door'), as illustrated in (s).

人	が	ドア	を	見た。
hito	ga	do-a	o	mi-ta.
man	NOMINATIVE	door	ACCUSATIVE	see-PAST

'The man saw the door.'
(s)

English is notorious for its departures from the regular principles of alphabetic writing, so that we find words with the same pronunciation but different spellings (e.g. *bear, bare*), words with the same spelling but different pronunciations (e.g. *lead* as in *I will lead you to the restaurant*; *lead* as in *lead piping*), as well as words whose spelling seems to bear no relation to their pronunciation (e.g. *eye*). As Bernard Shaw once observed, from the spelling of the [f] of *enough*, the [ɪ] of *women*, and the [ʃ] of *nation*, one might deduce that *fish* ought to be spelled *ghoti*! This contrasts with some other languages using the Latin alphabet, where the phonemic principle is strictly observed, as in Finnish, or at least more strictly observed, as in Spanish.

It is interesting to ask why such discrepancies between spelling and pronunciation exist. Occasionally, they simply reflect random decisions by scribes that happen to have gained acceptance into the language, as in the spelling *delight*, where the *gh* has no justification, either synchronically or diachronically. In many instances, however, irregular spellings reflect earlier pronunciations, i.e. the spelling was originally justified in terms of the pronunciation at that time, and in the meantime the pronunciation has changed but the spelling has remained conservative. The *gh* of such words as *light* and *bright* was pronounced like the *ch* sound in *loch* until medieval times in English, and indeed it is still so pronounced in some Scottish dialects; similarly, until medieval times the initial consonants of *knee* and *gnaw* were pronounced. Where another language has or had prestige in a community, loan words may retain, in whole or in part, the spelling of the original language, which accounts for the initial *p* in *psychology* (from Greek, the source of much English scientific terminology).

One recurrent deviation that is found from phonemic writing in many languages of the world is the application of the so-called morphophonemic principle, whereby the same morpheme is written in the same way even when its pronunciation changes. In English, for instance, the regular plural suffix is written *-s* even though it is sometimes pronounced [s] (after voiceless consonants, e.g. *cats*), sometimes [z] (elsewhere, e.g. *dogs*, *zebras*). Likewise, unstressed vowels in English are often reduced in pronunciation to schwa, but the same spelling is retained as when the vowel is stressed; compare the spelling of both stem vowels in *torrent*, stressed on the first syllable, and *torrential*, stressed on the second syllable. Another example of morphophonemic spelling in English is the invariant spelling of the root in the adjective *divine* and the derived noun *divinity*, even though the stressed vowel is pronounced [ai] in the former, but [ɪ] in the latter.

It is often difficult to tell whether certain spellings are really historical or morphophonemic, since morphophonemic alternations often reflect sound changes that have differentially affected an originally identical sound in different environments. Thus, the spelling of the Russian word for 'wave' has an *o* in the first unstressed syllable in the singular, as in (t) (corresponding to *volna* in Latin script), even though this unstressed vowel is pronounced [a]. This can be explained both historically and morphophonemically. Historically, because this was an earlier pronunciation, still preserved in northern dialects, whereas other dialects have merged earlier unstressed [o] and [a]. Morphophonemically, because this vowel is stressed and pronounced [o] in the plural, as in (u) (corresponding to *volny* in Latin script).

волна	волны
(t)	(u)

The development of writing must be seen as one of the greatest achievements of humanity, permitting, even before the advent of audio and video recording, the preservation of texts for future generations and their transmission to distant locations. The decipherment of such ancient writing systems as Egyptian hieroglyphs in the nineteenth century and Mayan glyphs in the twentieth century is not only an intellectual achievement on the part of the decoders, but has also provided us with new insights into societies of the past.

BERNARD COMRIE

Y

Yémba and the Grassfields Bantu Languages

The Grassfields Bantu Languages

The Grassfields languages form the principal subgroup of Southern Bantoid, within the Niger-Congo phylum that dominates sub-Saharan Africa. Some 65 Grassfields languages are spoken in the mountainous plateau of the western and northwestern provinces of Cameroon (see Figure 1), the region that is thought to be the origin of the original Bantu expansion. These languages exhibit predominantly subject–verb–object word order, a noun class system (typically prefixes), noun class agreement between words in the noun phrase, and complex tone systems. Many of these features are illustrated below for Yémba. The segmental inventories of Grassfields languages typically include (prenasalized) stops, fricatives, affricates, liquids, nasals and glides with labial, labiodental, alveolar, palatal, velar and glottal places of articulation. Some languages also exhibit labiovelars and implosives.

Key distinguishing features of Grassfields languages with respect to narrow Bantu are the simplified verbal morphology and the smaller number of noun classes, the loss of final vowels from Proto-Bantu roots, the 'floating' tones that interact in highly complex ways with their surroundings, and the addition of a high central vowel to the five-vowel system of Proto-Bantu.

Within Grassfields, three main subfamilies are distinguished: Mbam-Nkam (34 languages), Ring (16 languages), and Momo (eight languages). Within Mbam-Nkam four subgroups are distinguished, the largest being the Bamiléké languages (the name 'Bamileke' is a corruption of mbə ləkʉɔ, literally *people of the ravine*).

Yémba

Yémba is a Bamiléké language spoken by over 300,000 people in the region around the town of Dschang [tʃaŋ], and the language is most widely known by this latter name. About ten dialects have been identified, the most significant being those of Bafou to the north and Foréké-Dschang to the south. A Roman-based orthography was established in the early 1930s and literacy was promoted first at a school in the paramount chief's compound, and later in mission and government schools. Around the time of independence in 1960, education in local languages was forceably halted because it was viewed as tribalism and an obstacle to nation building. By 1980 the political climate had changed and the development of local languages was linked to the construction of a new noncolonial pan-African identity. A national alphabet based on the International Phonetic Alphabet (IPA) and derived from the Africa script was introduced, and the Yémba orthography was duly modified. The following text illustrates the orthography, where acute accent marks high tone and macron marks mid-tone.

> Kaŋ pɔ́ mbhū̄ é lelá' ŋ́gɔ̄ mésō, ḿbú ńzīŋɛ́ ta' enɔ. Pɔ́ lelá' ńnāŋ tɛ eshū̄' amɔ̄' álī'í, ḿbɛ́ á ápa, ńdɔk ŋgū̄ɔ́ á ŋ́kā' ŋiŋ njʉ́ʉ́ a apumā. Pɔ́ le gē é tō á ḿba, ŋ́gɔ́ɔ mbɔŋ. Pɔ́ le gū̄ɔ́ tɛ ŋkó éwú, kaŋ á le mɛ́ mbhū̄ ŋ́gɛː «Esó, pá' meŋ ŋkʉ́ɔ́k ḿbiŋ nzéŋ ńzāŋné lā, meŋ ɛ̄ kɔ́'á áthū̄, é kāp, o gɔ́ á ésī ńnɔŋ mbétʒ́ ńnéŋ á ńtē á ápa».

Yémba lacks the labiovelars and implosives found in some of the other Grassfields languages, and it has augmented the Proto-Grassfields six-vowel system with a series of mid-vowels. Diachronic processes,

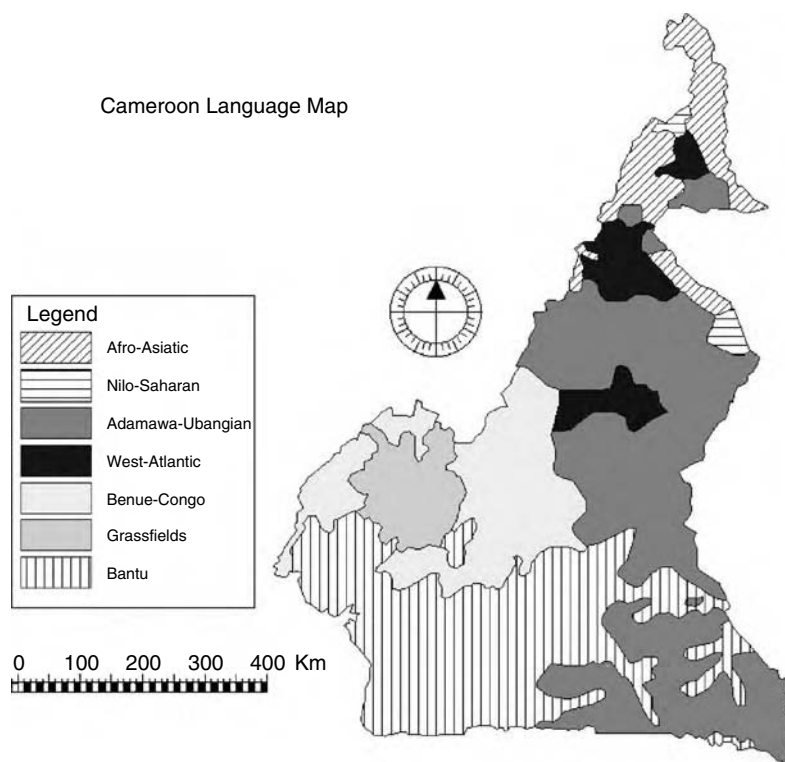
Cameroon Language Map


Figure 1. Cameroon language map showing principal families.

such as the loss of final consonants and the devoicing of high vowels, are still manifested synchronically in some complex morphophonological processes. Notable consequences of these processes are highly complex tonal patterns, and heavily aspirated syllables. This aspiration is most striking after voiced obstruents (e.g. /ghíɛ́ / [ɣiɛ́] *fly!*).

Like the other Grassfields languages, Yémba exhibits lexical and grammatical tone. The following nouns have a lɔ́- class 5 prefix, followed by the tə̌ŋ syllable that carries H, HL, LH, and L tones (from Proto-Bantu HH, HL, LH, and LL): lə̀tɔ̌ŋ [-ʹ] *feather*, lə̀t⁺ɔ́ŋ [-ˉ] *reading*, lə̀tɔ̀ŋ° [--] *navel*, and lə̀tɔ̀ŋ [-ˌ] *finishing*. These examples demonstrate that tone is a lexical property of words. However, tone in Yémba also has a grammatical function. The following examples illustrate how tonal distinctions alone can convey tense distinctions. The words used in the examples are: ə̀-fɔ̀ *CL1-chief*, kə̀mtè *bury*, and mə̀m-bh⁺ú *CL10-dogs* (ə̀- and mə̀m- are class 1 and 10 noun class prefixes). The words ɔ́ and ɔ̀ are known as concord markers, serving no purpose other than to link the subject and verb.

(1) ə̀fɔ̀ ɔ́ ⁺kə̀mtè ⁺mə̀mbhú [-l-ˉl--l-] 'the chief buried dogs (immediate past)'
(2) ə̀fɔ̀ ɔ̀ kə̀mtè mə̀mbh⁺ú [-l--l---l-] 'the chief buries dogs (simple present)'
(3) ə̀fɔ̀ ɔ̀ ⁺kə̀mtè ⁺mə̀mbhú [-l--l--l-] 'the chief will bury dogs (immediate future)'

The investigation of Grassfields tone systems has stimulated important theoretical advances in autosegmental phonology.

STEVEN BIRD

Yiddish

Yiddish is the historical language of the North European 'Ashkenazic' Jews and their descendants worldwide (Ashkenaz denoted an Iranian people in the Bible, which in the Middle Ages was used to refer to Slavic, and then, by about 1100, to Germans and German Jews). Since the 1600s, the language has been called *jidiš* 'Jewish' (earlier native names are unknown), and more recently *mame-lošn* ('mother tongue') and *žargon* ('jargon', often contemptuous in languages other than Slavic).

Yiddish is traditionally regarded as a derivative of High German, which first formed in southern Germany c. 1000 CE. In the thirteenth century, Yiddish speakers began migrating to Poland; dialects spoken there and in Belarus', Ukraine, Russia, the Baltic lands, and Romania are called 'Eastern Yiddish', which is used by most contemporary speakers of the language. Speakers in Holland, Hungary, the German-speaking and Bohemian-Moravian lands, however, use what is known as 'Western Yiddish'. Although the two spoken Yiddishes were always distinct, the Eastern Yiddish literary language was largely based on Western norms until the early nineteenth century. A new view holds that Eastern and eastern Western Yiddish (in the originally bilingual eastern German and Slavic lands) are instead a multilayered Slavic language with a predominantly German lexicon formed between the ninth and twelfth centuries, while western Western Yiddish (best called 'Judeo-German') is Germanic, having been formed by French Jews in the Rhineland between the tenth and late fourteenth centuries (and now extinct). Both Romance and Slavic Jewish settlements in Germany (the latter of local and Balkan stock) date to the ninth to tenth centuries. Hence, Yiddish is the only living Indo-European language whose genetic assignment is still being debated.

The mass migration of speakers to Palestine and the Americas, beginning in the 1880s, resulted in most migrants eventually 'losing' their language; they stopped speaking their first language and switched to the predominant language of their new homeland. Language shift from Yiddish to Russian was also rapid in the Soviet Union, without outward migration. Nevertheless, in 1939, Yiddish speakers probably numbered ten million worldwide. Accelerated by the Nazi German extermination of the European Jews, the number of speakers today, found primarily in Israel and the Americas, has dropped to around one million. Although Yiddish never enjoyed official status except in the 'Jewish Autonomous Region' of Eastern Siberia (Russia) formed after the Revolution, and in Soviet Belarus' and Ukraine (until the early 1930s), it has been the object of organized standardization efforts in Europe and America since 1908.

In addition to being Indo-European, Yiddish is a member of a genetically mixed 'family' of some two dozen languages adapted by Jews from non-Jewish linguistic stock, such as Arabic, Berber, Chinese, Greek, Iranian, Romance, and Slavic, and it therefore owes its *raison d'être* to common processes of formation and (Hebrew) enrichment. Of the Jewish languages, Yiddish has by far the largest number of speakers, and the richest literature. Yiddish was taught in the early 1700s in German universities, and since the twentieth century has stood at the cutting edge of modern linguistic theory, particularly since top theoreticians such as Edward Sapir, Roman Jakobson, Max and Uriel Weinreich, and Edward Stankiewicz made it their occasional or sole area of interest. Yiddish was the first Jewish and Soviet language to be the subject of a linguistic atlas (see Vilenkin 1931, and now Herzog et al. 1992–2000).

Taking Western and Eastern Yiddish as a whole, Yiddish enjoys the broadest expanse of any European language, with the exception of Russian and perhaps Romani (Gypsy); in the sixteenth century Yiddish was spoken from Holland to Ukraine, and from the Baltic Sea to Northern Italy and in Ottoman Palestine. While Yiddish was obsolescent in its German homeland and western Hungary from about 1750 (being displaced by standard German, after passing optionally through a stage of slightly Yiddishized German until the early twentieth century), it reached Russia and America in the late eighteenth to early nineteenth century, and by the late nineteenth century had arrived in the other inhabited continents, including remote Harbin (Manchuria) and Shanghai. In an unusual sociolinguistic development, Yiddish is now obsolescent for the most part except among ultra-orthodox Jews.

Yiddish is largely written phonetically in the Hebrew (Aramaic) alphabet, although Hebraisms and Aramaisms are spelled etymologically (except in Soviet Yiddish, which uses an entirely phonetic spelling). Eastern Yiddish generally comprises approximately 75% Germanisms, 15% Hebraisms, and 10% Slavisms; in German-speaking milieus, Yiddish often acquires a much higher Hebrew component so as not to be easily understood by German speakers (some of

these Hebraisms entered German beginning with the 1400s, then—through German—into other European slang registers). There are also small unique Romance, Greek, Turkic, and Iranian components.

The origin of Yiddish has recently become a key topic in Yiddish linguistic discussion. In the 'traditional' model of Yiddish genesis, proposed by Max Weinreich (1973), the language's unique Romanisms suggest the founders of Yiddish came from France and Italy. Weinreich envisioned Yiddish born in the Rhineland and Regensburg, then largely reshaped in Bavaria-Franconia, prior to spreading into monolingual Slavic lands. Seven hundred years of contact with Slavic, beginning with Sorbian and Polabian in the ninth century and culminating with Russian in the eighteenth century, rendered parts of Western and all of its Eastern Yiddish offspring heavily Slavicized. Examples of Slavic features are the possessive pronouns inflected only for number; the leveling out/addition of morphophonemic alternations in Germanisms; the distribution (and often indeclinability) of the reflexive pronoun *zix*; two degrees of diminutive; the double negative; analytic expression of comparative and superlative adjectives; recalibration of German verbal prefixes; psycho-ostensive expressions; the resumptive pronoun; no verb-final position in subordinate clauses; exclusive use of the present perfect to express past time; initial *s* and *x* (in non-German components); the absence of [ç]; and final voiced consonants (the last feature was probably original, and not restored under Slavic influence). While some of these features are found in German dialects (often spoken in former Slavic areas), Eastern Yiddish almost never has 'German' features unknown to Slavic.

Since the late 1980s, the obvious similarity of Yiddish to Bavarian dialects and the lack of features from southwestern German led linguists to favor a (south)eastern birthplace. The Danube rather than the Rhine venue is further supported by the likelihood that the few unique old Romance elements all derive from Balkan Romance languages, Friulan, Rhaeto-Romance, or Italian and hardly ever from French, except in Germanic Western Yiddish. The origin, language, and fate of the Jews in fourth-century Roman Rhineland are unknown.

Between 1991 and 1993, while accepting an eastern German venue for the birth of Yiddish, Wexler proposed that Sorbian Jews in Eastern Germany—comprising mainly local and Balkan proselytes and some ethnic Jews—'relexified' their West Slavic language to High German by the twelfth century. Relexification means that the Jews retained Sorbian grammar, phonology, and phonotactics while replacing most of the original lexicon with German words—whose meanings were assigned by the original Slavic vocabulary they replaced (see Horvath and Wexler 1997). In the kind of vocabulary replacement known as relexification, the substratal Slavic semantic and derivational parameters are kept, so that one can predict with considerable accuracy which superstratal German components can be accepted—unlike straightforward bilingual interference, which is always unpredictable and usually involves vocabulary exclusively. Parts of the German lexicon incompatible with Sorbian are blocked in Yiddish, to be replaced by genuine and many newly coined Hebraisms, unrelexified Slavisms, or other acceptable Germanisms. For example, German uses a common root for *Gewitter* ('storm') and *Wetter* ('weather'). Wexler expects relexifiers to accept at best one Germanism because Upper Sorbian denotes the two differently; see *hrimanje* and *wjedro*, respectively. Not surprisingly, Yiddish has only *veter* 'weather'. The use of separate words in Slavic makes German *Sturm* 'storm' possible for Yiddish (as *šturem*). Only relexification can account for the mass of Hebraisms as well as the very reduced German lexicon in Yiddish (and almost total impoverishment of German synonyms), compared with Central and Bavarian German dialects that conceivably were the relexifier sources for Yiddish. Following the relexification process that created it, Yiddish came to borrow additional German, Hebrew, and Slavic lexicon wihout reference to Slavic grammar.

Yiddish speakers have an enormous Hebrew-Aramaic lexicon (in all semantic domains) and a morphology used mainly with Semitisms, unmatched by any other Jewish language. This is because the blockage of so much German vocabulary obliged Yiddish speakers to invent many Hebrew forms and/or meanings as replacements, such as Yiddish *nadn* ('dowry') and *xmime* ('extreme heat'—an invention of Yiddish speakers, based on Slavic lexicons which, unlike German, have a word for 'extreme heat' that differs from the usual word for 'hot') vs. Hebrew *nādān* ('sheath') and *ħam* 'hot'. The Yiddish pronunciation of Hebrew predates the emergence of Yiddish, but the origins remain unclear. Yiddish Bibles, first attested in Germany in the 1400s, reveal many atypical Germanisms, and slavishly follow Hebrew syntax and derivational patterns; hence, they are really 'relexifications' of Biblical Hebrew into Yiddish lexicon, i.e. they utilize the original Old Hebrew grammar but replace almost all of the Old Hebrew lexicon by German-origin words. The latter are often used in ways that are unintelligible to German speakers. 'Yiddish' Bible language is best defined as a lexically deviant variant of Old Hebrew.

A Slavic affiliation for Yiddish is supported by its Slavic-type syntax, phonology, and phonotactics, as

well as the role of the derivational morphology; only the lexicon (including the inflectional and most of the derivational morphology) is predominantly German. A specifically Sorbian substratum for Yiddish is supported by the shape and geography of some unrelexified Yiddish Slavisms and the striking parallels in the distribution of Hebraisms in Yiddish vs. Germanisms in Sorbian, which points to a common speech community. Hence, Eastern Yiddish is probably an unusual dialect of Sorbian rather than a Slavicized form of German.

There is agreement that Yiddish speakers reached the Belarusian and Ukrainian lands in the 1400s, where they encountered Slavic-speaking Jews. The 'Yiddish-is-Germanic' school believes that the latter, few in number, shifted to Yiddish. In the 'Yiddish-is-Slavic' model, the local East Slavic Jews allegedly carried out the process of relexification a second time, as is borne out by the existence of uniquely East Slavic grammatical features in Yiddish, such as gender correspondences that differ from those found in German, and the original use of the German plural suffix *-(e)n* as a dual (significantly, the Yiddish dual matches the distribution of the Belarusian-Ukrainian 'pseudo-dual' ending used after 2–3–4; the dual is a category that has never been acquired through language contact). The attraction to Yiddish by East Slavic-speaking Jews attests to their high regard for Ashkenazic culture and desire to differentiate themselves more sharply from the coterritorial non-Jews; their ability to reform imported Sorbian Yiddish attests to their numerical superiority over the Ashkenazic immigrants. Indigenous East Slavic Jews could only be descended largely from the Turko-Iranian converts to Judaism in the Khazar Empire. A Khazar component in Yiddish is also suggested by a few unique Iranian and Turkic elements: e.g. Yiddish *šabaš* 'tip given to musicians at a wedding by guests who join in the dancing'; *šibeš* 'small coin; trifle' stems from Persian *šābāš* (in Slavic and other European slang vocabularies, the word is formally and/or semantically distorted); *nar*, plural *naronim* 'fool', derives from Persian *ner* 'man' rather than from German *Narr* 'fool' ~ Old Ukrainian *nar'-ci*, *nor'ci* 'Ossetian epic heroes' (Yiddish *-on-* from Old Hebrew and Old Ukrainian *-ci* both express an agentive noun); *pejsex* 'Passover' comes from Hebrew, but its use as a male name for children born during the holiday mirrors Turkic practice (the word as a name is first attested in tenth-century Khazar Hebrew); and a periphrastic conjugation that combines Hebrew masculine singular participles, now indeclinable, with a Yiddish auxiliary (e.g. Hebrew *bōdeq* 'inspecting' became Yiddish *bojdek zajn* 'inspect', with *zajn* 'be' from German). A Turko-Iranian origin for this conjugation is suggested by its geography within Yiddish (it is much less productive in Western Yiddish and altogether unknown in German slang), and by its use in Judeo-Belarusian (attested in the seventeenth century) and in the Turkic and Iranian languages spoken by Muslims (for Arabic loans).

Many scholars speak of a Western–Eastern Yiddish dialect continuum, with Western providing the input for Eastern Yiddish (Herzog et al. 2000). Yet it is also commonly assumed that Eastern Yiddish dialects developed in situ, rather than being imported from Western Yiddish 'readymade'. A multilayered West–East Slavic affiliation for Yiddish requires exploring, in future, to what extent Eastern Yiddish dialects match differences among the dialects of coterritorial Slavic languages.

Regardless of its origin, Yiddish holds an abiding interest for students of Jewish linguistics and history, bilingualism, minority ethnolects, creole linguistics, German, Slavic, unspoken Ashkenazic Hebrew, Modern Hebrew, and Esperanto (the last three are demonstrably Slavic Yiddish—the first two relexified to Old Hebrew and the third to Latinoid roots). This is because Yiddish provides clues to Jewish ethnogenesis and migrational patterns that are not recoverable from the notoriously sparse historical and archeological evidence; Yiddish is an ideal laboratory for the study of relexification, since the dual processes of relexification in that language are considerably older than the relexification found in numerous creole languages (e.g. Haitian Creole); finally, repeated exposure over a millennium to the same languages (German, Slavic, Hebrew) makes Yiddish a unique laboratory for students of bilingual interference.

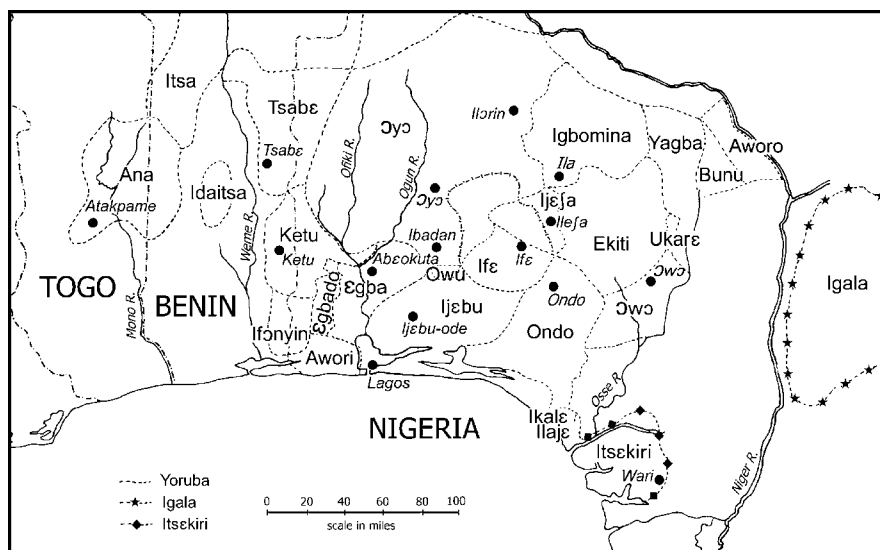
Yoruba and Yoruboid Languages

Yoruboid languages (YRB)—Yoruba, Igala, and Itsɛkiri—are classified as the Defoid group, a branch of Benue-Congo, which is a subgroup of Niger-Congo languages. Yoruba, the most widely spoken of the group, has over 20 million speakers in southwestern Nigeria, southeastern Benin, and central and northern Togo. In Sierra Leone, the influence of Yoruba is evident in Krio loanwords and personal names. Outside West Africa, Yoruba is used in religious contexts in Brazil and Cuba, as well as in cultural revitalization movements such as the ɔyɔtũɟi village, a Black Nationalist community in South Carolina. Yoruba has over 20 distinct dialects. In Nigeria, Standard Yoruba is the literary usage and is taught in schools up to the university level. It is also spoken by younger generations as a second or third language because of the implementation of the 1981 National Policy on Education, which requires high school students to learn a major Nigerian language in addition to their mother tongue. Furthermore, Yoruba is the official language in southwestern Nigeria and is used for government notices, radio, television, and newspapers. Igala is spoken by approximately 800,000 people in central Nigeria and Itsɛkiri is spoken by about 500,000 people in midwestern Nigeria. Igala and Itsɛkiri are taught in primary schools and are used in radio and television broadcasting. The distribution of Yoruboid languages is shown in Map 1.

Phonology (Sound Patterns)

The sound inventory of YRB includes the consonants shown in Table 1. In the Stop series, voiced (sounds produced with the vibration of the vocal cords) and


Map 1. Yoruba and Yoruboid languages.

unvoiced (sounds produced without vocal cord vibration) consonants are attested. However, /b/ and /ɟ/ have no unvoiced counterparts. The velar stops—kʷ and gʷ—are found in Igala, Itsɛkiri, and southeastern dialects of Yoruba such as Ondo and, but they are realized as /k/ and /g/ in Standard Yoruba and northwestern dialects. Fricatives (sounds produced with audible friction) are generally unvoiced. The only voiced fricative, /ɣ/, is attested in Itsɛkiri and southeastern Yoruba dialects, and it is the equivalent of /w/ in Igala and northwestern Yoruba dialects. Yoruba /s/ may correspond to Igala [r], [l], or [h], depending on the context. An /s/ occurring before an oral vowel (vowel pronounced through the mouth) is an [r] in Igala (Yoruba /ɛsɛ̀/ is realized as /ɛ́rɛ̀/ 'foot'); when /s/ precedes a nasal vowel (vowel pronounced by allowing air to pass out through the nose), it is realized as [l] (Yoruba /ɛ̀sɔ̃́/ is Igala /ɛ̀lá/ 'nine'); an /s/ occurring before /i/ is an [h] (Yoruba /ɛ̀sì/ is Igala /òhì/ 'answer').

Besides consonants, there are seven oral vowels: [i e ɛ a ɔ o u]; in addition, [ɪ ʊ] occur in Igala and some Yoruba dialects. Nasal vowels are also attested. As shown in Table 2, dialects of Yoruba have four to six nasal vowels, Itsɛkiri has three nasal vowels, but Igala has no nasal vowels.

Oral vowels exhibit co-occurrence restrictions. For instance, /ɛ/ and /ɔ/ do not co-occur with /e/ and /o/ in nouns: ɔ̀bɛ 'knife', ɛbɔ 'sacrifice', ekpo 'palm-oil', ɔ̀kpó 'pillar'. Consonant–vowel co-occurrence restrictions are also attested. For example, /r/, /ɣ/, /w/, and /h/ are nasalized when nasal vowels occur after them: ɪyɔ̃̀ 'pounded yam', irĩ̀ 'iron', ìwɔ̃̀ 'measurement', ah̃ɔ̃̀ 'tongue'.

There are three tones (pitches): High (´), Low (`), and Mid (unmarked). These tones are crucial for understanding the phonology and syntax (sentence structure) of YRB languages. For example, tone can distinguish words: bí 'give birth', bì 'vomit', bɪ 'ask', arò 'lamentation', aro 'cymbal', aró 'indigo', àró 'a granary'. Tone may also serve a grammatical function. For example, within a statement, a high tone must occur between the subject and the verb: Dajɔ̀ (a name); Dayɔ̀ ɔ́ ra òrombó 'Dayo bought (some) oranges'.

Tone is used in other contexts. For instance, it is used in whistled Yoruba, a language used to communicate over long distances on farms. As speakers talk and whistle simultaneously, the language is transformed: consonants are devoiced (produced without vocal cord vibration) or turned to [h] and all vowels are changed to [u] because whistling involves lip puckering, the articulatory gesture required for the production of [u]. However, all tones are retained without any alteration. The retention of tones enables speakers to understand the meaning of whistled language. For instance, a farmer just arriving on the farm may greet farmers in nearby farms using any of the whistled forms in (2) and (3). As shown below, although the consonants and vowels of these whistled forms are altered, they have the same meaning as the nonwhistled form in (1):

(1) Nonwhistled Yoruba: ara iwájú, ɛ kú iʃɛ́ o 'people who arrived before me, greetings at work'

(2) Whistled form with devoiced consonants: u̥rú u̥w̥ú̥ɟú u kú u̥ʃú u

(3) Whistled form with [h] replacement: uhú uhúhú, u hú uhú u

The Yoruba talking drum, a pressure drum, which accompanies singing during festivals and important ceremonies, also uses tone. This drum 'speaks' by reproducing the tones of vowels. For example, a

TABLE 1 Consonants

	Labial	Alveolar	Palatal	Velar	Labial–Velar	Glottal
Stop						
Voiceless		t		kʷ	k͡p	
Voiced	b	d	ɟ	gʷ	g͡b	
Fricative				.		h
Voiceless	f	s	ʃ			h
Voiced				ɣ		
Nasal	m	n				
Liquid		l r				
Glide			y		w	

TABLE 2 Nasal Vowels

Yoruba	Itsɛkiri	Igala
Iɟeʃa: ĩ ɪ̃ ɛ̃ ɔ̃ ʊ̃ ũ	ĩ ɔ̃ ũ	No nasal vowels
Ilaɟe: ĩ ɛ̃ ã ɔ̃ ũ		
Standard Yoruba: ĩ ɛ̃ ɔ̃ ũ		

notable citizen who has just returned from a trip may be greeted with these words using drums:

(4) Words: a ti ń retí ìrɛ; káábɔ̀, ʃé dáadaa lo dé 'we have been expecting you; welcome, did you arrive well?'

Talking drum: Mid Mid High Mid High Low Mid, High High Low High High Mid High Mid Mid High Because the talking drum produces only tones, its language could be ambiguous. For instance, the signature tune of Radio Nigeria Ibadan, given in (5), could be assigned the interpretations in (6):

(5) Talking drum: High High Low Low High High Mid High High Mid Low

(6) Possible interpretations

a. rédó nàìɟíríá la tí ń fɔhṹ
'we are broadcasting from Radio Nigeria'

b. tólúbàdɔ̃̀ bá kú ta ní ó ɟoyè
'if the king of Ibadan dies, who will succeed him?'

c. nǐnṹ kòkò dúdú la ti ń sebè,
'we cook soup in a black pot'

Syllables may be expressed as Consonant–Vowel (lɔ 'go'), Vowel (ilé 'house'), or N, a syllabic nasal (òntè 'stamp'). Syllables with consonant clusters and those ending in consonants are unattested. Hence, when English words with such unacceptable sequences are borrowed, they are restructured through consonant deletion and vowel insertion, as follows:

(7)

English	YRB
kettle	kɛ́tù
buckle	bɔ́kù
travel	tíráfù
brick	bíríkì

The Consonant–Vowel syllable plays an important role in Yoruba phonology. For instance, ɛnɔ̃̀, a Yoruba secret language game, disguises words by adding a Consonant–Vowel syllable to the end of every syllable. As shown in (8), the consonant of the added syllable is fixed—a/g/; however, the vowel and tone of this syllable vary, based on the vowel and tone of the base form. Another property of this game is that the final Consonant–Vowel tag is always preceded by a syllabic nasal:

(8) Nondisguised form: olú kò lɔsílé
'Olu did not go home' Olu NEG. go to house
Disguised form: ogolúgú kògò lɔgɔ sígíléŋ́gè
'Olu did not go home'

Word-initial high tones are also sensitive to syllable shapes. For example, whereas a word-initial Vowel or Consonant–Vowel syllable may bear a high tone in Igala, only Consonant–Vowel syllables may have a high tone in Yoruba and Its ɛkiri . Hence, vowel-initial words with high tones in Igala surface with mid tones in Yoruba:

(9)

Yoruba	Igala	Gloss
imú	ímɔ	nose
etí	étí	ear
fújɛ́	fújɛ́fújɛ́	to be light
tǐrǐ̃	fíílí	narrow, thin

Morphology (Word Structure)

Prefixation, reduplication, truncation, compounding, and desentencing are the principal word formation devices. Although inflection does not play a role in Yoruba and Igala, Itsɛkiri distinguishes between singular and plural nouns, as shown below:

(10)

Yoruba	Igala	Itsɛkiri	Gloss
obĩrĩ	ónobùlɛ	obirɛ̃̀	woman
obĩrĩ	ónobùlɛ	ebirɛ̃̀	women

Prefixation (the process of attaching an affix to a word to derive a new word) is a device used to derive nouns from existing verbs. For example, a vowel may be prefixed to a verb or verb phrase to form a noun, as follows:

(11) à−lɔ 'going' <à+lɔ 'prefix +go'

ɔ− 'singer' <ɔ+ 'prefix
kɔrĩ kɔrĩ +sing'

Reduplication (process of repetition) is used to form words denoting intensity; it is also used to form distributive nouns, profession-based names, and names denoting endearment:

(12) Base   Reduplicated Form

Intensity:

kíá	'quick'	kíákíá	'quickly'
kpú	'much'	kpúkpɔ́	'very much'
kpɔ́		kpúkpɔ́	

Distributive:

oʃù	'month'	oʃooʃú	'every month'
àg	'elder'	àgbà	'every elder'
bà		àgbà	

Profession agentive:

wolé	'examine house'	woléwolé	'sanitary inspector'
mɔ̃́	'build house'	mɔ̃́lé	'builder'
lé		mɔ̃́lé	

Diminutives:

| adé | 'a name' | ádéadè | 'diminutive form' |
| olú | 'a name' | ólúolù | 'diminutive form' |

Truncation (shortening or abbreviation) is the device adopted in creating shortened names, which are commonly used in informal contexts:

(13)

Full Name	Shortened Form
adéwɔlé	adé or wɔlé
olúkɔ́lá	olú or kɔ́lá
ɔlábɔ̀dé	ɔlá or bɔ̀dé
modúkpɛ́	modú or dúkpɛ́

Compounds (words consisting of two or more words) are formed from two or more nouns, as follows:

(14)

ìdí kɔ̀	'motor park'	<ì dí	'base/ bottom'	+ɔkɔ̀	'vehicle'
ɛrɔ̃̀ ko	'animal'	<ɛrɔ̃̀	'meat'	+oko	'farm'
ɔmɔ̃́ bĩrĩ̀	'girl'	<ɔmɔ̃́	'child'	+obĩrĩ̀	'woman'
ɔmɔ̃́ kas è	'toe'	<ɔmɔ̃́	'child'	+ì ka +ɛsɛ̀	'finger' 'leg'

A rather different but common morphological process in YRB and Benue-Congo languages is desentencing, a process used to form names. Desentencing involves turning a full sentence into a name, as follows:

(15)

Sentence	Name	Gloss
ɔlá wɔ ilé	ɔláwɔlé	honor enters the house
adé yí mi ká	adéyíŋká	crown surrounds me
akĩ̀ dé ilé	akĩ̀déilé	valor arrives in the house
olú dá mi sí	olúdámisí	the Lord kept me alive

Syntax (Sentence Structure)

Nouns, verbs, and prepositions are the major word categories. Some words, which function as adjectives and adverbs in English, are expressed as verbs. For example, the adjective 'red' and the adverb 'again' are used as verbs in the following Yoruba sentences:

(16)

| olú | pukpa | 'Olu is red: Olu is fair-skinned' |
| Olu | red | |

| olú | tũ̀ ń sáré | 'Olu is running again' |
| Olu | repeat is run | |

The basic word order is S(ubject–)V(erb–)O(bject). Within phrases, the head of the phrase occurs in the initial position. Hence, in a noun phrase, the noun occurs first, followed by adjectives and relative clauses. In verb and prepositional phrases, the verb and preposition appear first and their objects occur after them:

(17)

a.	Word order:	olú ra iwé Olu buy book	'Olu bought a book'
b.	Noun phrase:	ɔmɔ̃̀ dúdú child black	'black child'
c.	Verb phrase:	ra iwé buy book	'buy a book'
d.	Prepositional phrase:	sí oko to farm	'to the farm'

The basic SVO word order may be altered to form focus sentences, sentences in which a given word or phrase is fronted for emphatic purposes. In some Yoruba dialects, a focused word or phrase is usually followed by the focus marker *ni*; in other dialects, the focus marker appears at the end of the sentence; in Its Ekiri, only fronting applies, and the focus marker is not used. The following examples illustrate subject fronting, derived from a basic sentence such as (17a):

(18)

| Standard Yoruba Subject Focus: | olú ni Olu focus | ó ra iwé 3SG buy book | 'It is Olu who bought a book' |

(19)

Ukarɛ Yoruba:	olú Olu	ó ra iwéaĩ̃ 3SG	'It is Olu who bought a book'
Subject Focus:		buy book focus	
2	3		4

(20)

| Itsɛkiri Subject Focus: | olú òũ̀ é ra iwé Olu 3SG buy book | | 'It is Olu who bought a book' |

As shown in (18) through (20), a pronoun (3SG) replaces a fronted subject. In contrast, a fronted object does not produce the same effect:

(21) Standard
Yoruba
Object   ìwé ni olú rà   'It is a book
Focus: that Olu
                                  bought'
                                  book focus
                                  Olu buy

Serial-Verb-Construction (SVC) is another principal point of syntactic interest. SVCs have sequences of verbs, which share the same subject and object. They are different from coordinate clauses in that the verbs use one tense and aspect, and allow only one negative:

(22) a. olú   ra àgbàdo ɟɛ   'Olu will buy
     yóó   some corn and
                   eat them'
                   Olu FUT
                   buy corn eat

     b. olú   ra àgbàdo ɟɛ   'Olu did not
        kò   buy and eat
                                       some corn'
                   Olu NEG
                   buy corn eat

As shown below, it is ungrammatical to assign separate tense or negative markers to a serial verb construction:

(23) *olú yóó   'Olu will buy some
     ra àgbàdo yóó ɟɛ   corn and eat them'

     Olu FUT buy corn
     FUT eat

     *olú kò,   'Olu did not buy and eat
     ra àgbàdo   some corn'
     kò ɟɛ
     Olu NEG buy corn
     NEG eat

YRB languages typically divide pronouns into two sets, long and short pronouns:

(24)
Yoruba		Igala		Gloss
Long	Short	Long	Short	
èmi	mo, m	omi	ù, ǹ	I
ìwɔ	o	ùwE,	ɛ̀	You
òũ	ó	òũ	ì	He/she/it

Long pronouns are also called independent pronouns because they behave like nouns in terms of fronting and coordination, as shown by these examples:

(25) Basic   ìwɔ́ ra   'you bought
     Sentence: àgbádá   a flowing
                                  gown'

     Subject   ìwɔ ni o   'it is you
     Focus: ra àgbáda   who bought
                                  a flowing
                                  gown'

     Coordination: ìwɔ àti o   'you and
                   lú ra à   Olu bought
                   gbáda   a flowing
                                   gown'

Unlike long pronouns, short pronouns can neither be fronted nor coordinated with a noun.

Politeness

Finally, politeness is an essential aspect of Yoruba, Itsɛkiri, and Igala culture, and language is used to convey respect, especially for older people and those in authority. Politeness is expressed by the choice of pronouns in reference and address. For instance, the plural forms of the second and third person pronouns (èyĩ 'you pl.,' àwɔ̃ 'they') are considered respectful and appropriate whereas singular forms are considered impolite (ìwɔ 'you sg.,' òũ 'he/she').

ỌLANIKẸ ỌLA ORIE

Z

Zipf, George Kingsley

A philologist who studied and taught German and linguistics at Harvard University for most of his academic career, George Kingsley Zipf was one of the first scholars to use statistics in the study of language. Although he is perhaps best known today for the statistical formula bearing his name, Zipf did not actually create the formula; it was used earlier in the writings of such scholars as J.B. Estoup and Vilfredo Pareto. However, Zipf served as its most ardent proponent, applying the formula to language and a variety of other social phenomena in his argument for a human ecology.

Zipf began his work on the relationship between frequency and language as a graduate student at Harvard, where he successfully defended a dissertation on the effect of relative frequency on phonetic change. In this work, Zipf argued for a Principle of Relative Frequency, which said that

> the accent or degree of conspicuousness of any word, syllable, or sound is inversely proportionate to the relative frequency of that word, syllable, or sound, among its fellow words, syllables, or sounds in the stream of spoken language. As any element's usage becomes more frequent, its form tends to become less accented, or more easily pronounceable, and vice versa. (1932:1)

Using the Chinese, French, and English languages, as well as a number of writings in Latin, Zipf addressed the correlation between the size of a word and its frequency in a language, finding that the size of words in the language is inversely proportional to its frequency in the language, so that short words will occur very often in the language and long words will occur infrequently. He also argued that the use of abbreviations among speakers followed this same trend. Zipf's explanation for the correlation between the two was that 'High frequency is the cause of small magnitude' (1935:29) and he attributed this correlation to a Principle of Least Effort, which he said 'means … that a person … will strive to solve his problems in such a way as to minimize the total work that he must expend in solving both his immediate problems and his probable future problems…' (1949:1).

To explain, Zipf used the analogy of an artisan's workbench. According to this analogy, the tools of an artisan that are used more often will be placed nearer the artisan's chair so that they may be retrieved with the least possible effort on the artisan's part, while the tools that are rarely used will be placed farther away from the artisan.

Following the same line of reasoning, Zipf also worked on the relationship between rank and frequency of words in a language. Zipf found that the frequency of a work in a language is *inversely proportional* to the rank of that word in the language, so that if a word ranks first in the language, it will be used far more frequently than those words ranked lower in the language. Conversely, a word that ranks 100th in the language will be used far more rarely than words that rank closer to one in the language. In the form of an equation, this takes the form of Rank times Frequency equals Constant.

Zipf later applied his formula to the populations and ranks of city with some success. In the introduction to his National Unity and Disunity (1941), Zipf explains that if readers were to look at the US Census in any given year they would find the city with the greatest population to rank first, the second-ranking city would have half the

population of the first, the third-ranking city would have one third the population, and so on. Zipf added that the size and rank of incomes would also follow this simple mathematical formula. Zipf inferred from this that communities—cities as well as nations—worked by the same principles as other organisms, so that we should think of a population as a 'natural biosocial entity'.

From the beginning, Zipf's work has been the subject of much criticism. Perhaps greatest among these concerns is Zipf's attempt to explain his findings with the Principle of Least Effort, due to the significant problem of identifying articulatory features that are universally 'difficult' or 'easy'. Another criticism that many people have made—and one that is supported by Zipf's evidence of the formula working in fields besides linguistics—is that Zipf's Law does not succeed so much at describing how language works as it does at describing how mathematics works. Finally, although Zipf's Law typically works well with respect to objects that are ranked in the middle of lists, it is less dependable with objects ranked very low or very high, a problem that has led some, such as mathematician Benoit Mandelbrot in his work on fractal geometry (1982), to make some modifications when using the formula.

Although there are problems with Zipf's Law, and certainly with the inferences that Zipf made from his formulations, Zipf should be recognized as one of the pioneers of the use of statistical analyses in linguistics in general and the current subfield of corpus linguistics in particular. Zipf's Law is also commonly used in mathematics, physics, library science, and memetic science, which is the quantitative analysis of cultural transfer. Zipf died on September 25, 1950 in Newton, Massachusetts, after a long illness.

Biography

Born in Freeport, Illinois, on January 7, 1902, George Kingsley Zipf received his B.A. (1924) and his Ph.D. (1930) in Comparative Philology from Harvard College, completing a dissertation on relative frequency of use as a cause of phonetic change in language evolution. He was Instructor of German at Harvard until 1936, Assistant Professor of German until 1939, and University Lecturer until 1950. He spent the year after his graduation from Harvard studying at the University of Bonn and the University of Berlin. He was Member of Linguistic Society of America (LSA), 1931, and served on the Committee on Quantitative Linguistics, created by the Sixth International Congress of Linguists, in 1948. He died in Newton, Massachusetts, on September 25, 1950.

Zulu and Southern Bantu Languages

The Sintu (Bantu) languages are the most widespread and best-known subgroup of Niger-Congo (the form Sintu reflects the Nguni prefix isi-, denoting language and culture). According to Greenberg's (1963) classification, the Niger-Congo is a subfamily of the Niger-Kordofanian family, one of the four language families in Africa. The Sintu languages cover most of the vast southern third of Africa, from the equatorial rain forest of Gabon and southern Cameroon to the highlands of Kenya and from the Ubangi River in the Central African Republic nearly to the Cape of Good Hope in South Africa. Some of the well-known Sintu languages include Zulu, Kongo, Lingala, Shona, Bemba, Ganda, and Gikuyu.

Despite their vast extent today, Sintu languages belong to just one subgroup of the Benue-Congo branch of Niger-Congo (Williamson and Blench 2000). Sintu languages spread eastward and southward from West Africa (modern-day eastern Nigeria and Cameroon) in the early centuries of the first millennium AD. They only spread over the regions they now occupy during the last 4,000 years. The ancestral Sintu language, proto-Bantu, was spoken somewhere probably in eastern Nigeria, West Africa. Then, for reasons unknown, early Sintu communities began expanding into new territories, first through the equatorial rain forest belt and along its margins, and then, between about 500 BC and AD 300, eastward and southward into eastern and southern Africa. It remains unknown what languages preceded the Sintu in the equatorial forest and the adjoining savannas, but in southern Africa the earlier languages often belonged to the Khoisan family.

As Sintu languages spread throughout Africa, their features remained remarkably stable over great distances and long periods of time. Their main features are the systems of noun classes and agglutinative verb morphology. Guthrie (1948) divided Bantu (Sintu) languages into six areas: northwest Central Africa, west and southwest Central Africa, east central, northeast central, southeast, and south. Some of the most important representative members of the southeast area include Shona, Tsonga, Ronga, Makua, and Yao; those of the south area include Swazi, Tswana, and Zulu-Xhosa. In Voegelin and Voegelin's (1997) similar classification of the world's languages, 'Bantu proper' is divided into seven major areas: central eastern, central western, Kari, northeastern, northwestern, southeastern, and southwestern areas. Languages of the southeastern area are divided into two groups: Makua, Matumbi, and Yao, with speakers in Tanzania, Mozambique, and Malawi; and Chopi, Nguni, Shona, Sotho-Tswana, Tswa-Ronga, and Venda, with speakers in Zimbabwe, Botswana, South Africa, Swaziland, and Lesotho. The Nguni include isiSwati, isiXhosa, Gaika, Gcaleka, Mpondo, Mpondomse, Ndlambe, and *isiZulu.* The southwestern area contains two subdivisions: Chokwe-Luchazi, Lozi, Luyana, Subiya, with speakers in Botswana, Zambia, Angola, and Zaire; and Herero, Ndonga, Umbundu, and Yeye reside in Angola, Namibia, and Botswana.

The languages that Guthrie (1948) recognized as Bantu are now referred to as 'Narrow Bantu' (Williamson and Blench 2000). All major modern attempts to clarify Narrow Bantu have not produced an agreed overall scheme (Nurse 1996). The most widespread agreement is that there is a northwest Bantu (Sintu); some authors see a division between east and west Bantu (Sintu). The southern Sintu languages include Xhosa, Zulu, Sotho, Tsonga, and Tswana. The

high degree of structural unity among most Sintu languages, the wide area of contact among them, and significant mutual influence among Sintu languages make classification difficult.

The most typical feature of Sintu morphology is the class prefix system (Campbell 1991). Proto-Bantu had 19 noun classes, while Sotho, for example, has only seven. Sintu languages have long been appreciated by scholars for their distinctive morphology, being highly agglutinative, and allowing great structural complexity to nominal and even more so to verbal forms. There are very few root adjectives in Sintu; some examples are –*kulu* (large in *isiZulu*) and –*bi* (bad in *isiZulu*). The conjunctive pronouns, subjective and objective, are remarkably homogeneous over most of the Sintu area. Most primary verb roots are disyllables, and derived stems are formed by suffixation. For example, bonana means 'to see each other' in *isiZulu*. Some Sintu languages have a neutral passive of state ub –V*ka(la);* for example, in *isiZulu inkanyezi ya.bona.ka.la* ('the star was visible'). Moods are generally marked by suffix. Most Sintu languages have seven moods: infinitive, indicative, imperative, subjunctive, perfect, continuative, and relative. In terms of syntax, the typical Sintu verbal complex consists of prefix (subject concord marker)–tense marker–object marker–stem–modal/voice marker.

Current thinking is that the Nguni were one of three large African migrant groups whose tradition of horticulture and cattle breeding combine the major cultural attributes of West, Central and North East Africa, from where they moved along separate routes to southern Africa. The Nguni followed an inland course via the headwaters of the Zambesi, where contact with San hunters produced the 'click' sounds that characterize their languages today. They moved southward to the most northerly bend of the Limpopo River, which marks the boundary between present-day South Africa and Zimbabwe, sometime between the middle of the fifteenth and the third century AD. The Nguni supposedly split into separate migrations, moving in different stages into what is now called KwaZulu-Natal and the Eastern Province (formerly known as the Transkei). They fell broadly into four regional divisions: the Mhlubi, Mtetwa, Ndwandwe, and Ngwane.

Some of those who settled in northern KwaZulu-Natal doubled back into what is now Swaziland, while those who first entered the Transkei were the forebears of the Pondo. The last to leave the Limpopo settled for a while in what is now the southeastern region of the Mpumalanga province; and then they moved on in easy stages into central KwaZulu-Natal. Finding the northeast and northwest already occupied, two smaller groups moved on. One of these, finding the coastal regions of the south settled by the Pondo, kept to the

inland high ground, to become the Xhosa. The other of the two smaller groups found a home as the coastal neighbors of the Pondo to become the Thembu of today. Thus, the Nguni divided into two large segments, North and South. The Xhosa, Pondo, and Thembu of the Eastern Cape (formerly Transkei) and areas further south are major representatives of the South Nguni, while the Zulu, the Swazi of Swaziland, and the Ndbele (in the present provinces of Gauteng and Mpumalanga) are of the Northern Nguni.

The final Nguni migration populated the heart of KwaZulu-Natal where the small and unimportant Zulu clan was later to succeed the Ndwandwe and Mthetwa empires, respectively, in the northwest and northeast. Under their famous chief, Shaka kaSenzangakhona (c. 1787–1828), the first kind of this unified group of Nguni clans and chiefdoms, they became the rulers of the northern half of KwaZulu-Natal from the Tugela River in the south to the border of Mozambique in the north. A long line of descendants link these historic figures with the current royal house headed by King Goodwill Zwelethini.

Prior to the Zulu king Shaka, Zulu referred strictly to a relatively small clan of people living in the middle reaches of the White Mfolozi River. When Shaka founded the Zulu kingdom in the early nineteenth century, he extended the use of Zulu to the many clans he incorporated into the Zulu state. European anthropologists and linguists, who saw the Zulu language as central in defining identity, categorized people of Natal and Zululand as Zulus (Harries 1993).

The Nguni languages are closely related, and now spoken by most people in South Africa. On purely linguistic grounds, there are two main languages in southern Africa that have severally mutually intelligible dialects: Nguni (with varieties like Ndebele, Swazi, Xhosa, Zulu) and Sotho (northern Sotho, southern Sotho, Tswana) (Wolff 2000). In particular, *isiZulu* is closely related to Swazi and Xhosa. However, members of these speech communities, for several reasons, consider themselves to have separate languages, not just dialects, and unique historical, ethnic, and social backgrounds (Campbell et al. 1995). Language is closely linked with ethnic identity in South Africa.

Outside Khoisan, clicks are known to occur only in South African Sintu languages such as Zulu, southern Sotho, Yeyi, and Xhosa, and in the Cushitic language Dahalo. A click is a multiply articulated sound produced by forming one closure in the front of the mouth with the lips of the tongue in front and another in the back of the mouth with the tongue dorsum. The clicks are a result of borrowing from Khoisan by way of long-enduring and intensive contacts, rather than a genuine part of the sound inventories in Sintu languages themselves. For example, the Zulu click sounds consist of a

dental, palatal, and lateral click, each containing four phonemes—a surd, its aspirate, its voiced allophone, and its nasal (Campbell 1991:163).

IsiZulu is now the best-known language in South Africa, besides English. In 1995, there were 9,140,000 Zulu people in southern Africa. They consisted of 8,778,000 Zulu people in South Africa (about 18.8% of the population), 37,480 in Malawi, 76,000 in Swaziland, and 248,000 in Lesotho (Grimes 1996). Now about 22.4% of the South African population use it as their home language, while others speak it as a second language.

IsiZulu was first studied by foreign linguists in the nineteenth century. Natal's first Anglican bishop, John William Colenso, and his assistant, William Ngidi, translated and studied the Zulu language (*isiZulu*) in the 1850s and early 1860s (Guy 1997). *IsiZulu* is a tonal language, closely related to Swazi and Xhosa. Its two dialects are Lala and Qwabe. The standardization of *IsiZulu* is now controlled from Kwa-Zulu.

There are also several slang languages that are variations of *isiZulu*. For example, Tsotsitaal, Iscamtho, and Fanagolo are slang languages that are based on Afrikaans, English, and Zulu. Fanagolo is a second language only, with no mother tongue speakers, widely used in towns and gold, diamond, coal, and copper mining areas, while Tsotsitaal and Iscamtho are spoken in black urban townships in South Africa (Slabbert and Myers Scotton 1997).

Zuni

The Zuni language spoken in the Pueblo region of the southwestern United States is a linguistic isolate as yet unproven to be related to any other known language. According to suggestive archeological records, Zuni land claims, and references to sites in oral tradition, the territory in which Zuni was originally spoken extended over much of what is now the four-corner region of New Mexico, Arizona, Utah, and Colorado. Today, Zuni is spoken at Zuni Pueblo and its associated villages and farming communities (Nutria, Ojo Caliente, Blackrock, Pescado) in northwest New Mexico, approximately 150 miles west of Albuquerque.

The Pueblo region is recognized as an important area of shared culture and history encompassing four other language families native to North America in addition to Zuni (Keresan, Kiowa-Tanoan, Uto-Aztecan, and more recently Athapaskan). Despite several attempts, genetic linguistic affiliation has not successfully been demonstrated between Zuni and any other language. One such attempt proposed a link to the Penutian languages of California. Subsequent investigation of the evidence presented has discredited this proposal, although the mistaken categorization of Zuni as Penutian has persisted.

Zuni differs from its closest geographical linguistic neighbors in many typological respects, for example, in lacking much of the complex verbal morphology typical of languages of this area as well as their associated free word order. Zuni has a basic word order of S(ubject)–O(bject)–V(erb), but special conditions on the position of pronouns or on words containing contrastive focus frequently result in OSV order. Evidence of loanwords in Zuni from Keresan (e.g. Zuni *k'yaššita*, Acoma Keresan *sk'a'šу* 'fish'; Zuni *pu:la*, Acoma Keresan *pú:r'ai'ką* 'butterfly'; Zuni *'uwakya*, 'great-grandson' Acoma Keresan *'úwa'ką* 'baby') suggests a history of contact between Zuni and the Pueblos further to the east along the Rio Grande. The effect of this con-

tact on Zuni grammatical structure, however, is less apparent. Influence on grammatical structure as a result of contact with Uto-Aztecan speakers to the west is more easily detected. For instance, the system of clause linkage indicating continued vs. changed events along with a continued vs. change in sentence subject is constructed in similar fashion to that of Hopi, currently spoken in Arizona several hundred miles away.

While a great deal of archeological and anthropological work has been done at Zuni over the past century, the Zuni language has received less attention than other languages of Native North America, possibly due to its isolate status. Early documentation includes word lists collected by Catholic missionaries. Transcriptions of letters, stories and prayers from the nineteenth century have also been found in archives. Brief grammatical sketches were published in the 1930s and 1960s, as well as a short lexicon of words and grammatical endings. An orthography was constructed in the 1970s that is currently in use at the Pueblo for citation of Zuni words and names; however, Zuni in daily life largely remains an unwritten language. The orthography does not strictly follow standard linguistic practices for transcription; for example, it transcribes the voiceless stops [p, t] as 'b' and 'd', respectively, and it reduces some geminate (doubled) consonants to single consonants.

Among the interesting phonetic properties of Zuni are the glottalized series of consonants and the correlation between word stress and vowel tensing. (Word stress falls on the initial syllable, and the further a vowel occurs from this stress the laxer its pronunciation.) The phonological structure allows only a single consonant at the beginning of a word, only two consonants contiguous in the middle of a word, and only a subset of consonants at the end of a word. The language contains both long vowels and consonants (geminates), and adjacent consonants frequently assimilate to result in a

geminate, both historically as well as in active pronunciation. Similar to English, Zuni has a nominative/accusative case system and inflects only pronouns for case. Unlike pronominal elements of other languages in the geographical area, Zuni pronouns are obligatory independent forms and not inflectional morphology on the verb. Interestingly, while Zuni does not allow for pronouns to be dropped, it has no third person pronouns. Consequently, a verb appearing on its own receives third person anaphoric interpretation for its subject (and object if it takes one), cf. *'awakya,* find-past, 'he/she found him/her/it'. Zuni noun stems are marked with different inflectional endings in the singular and in the plural (*te'le* 'pot' vs. *tewe* 'pots'), and nouns have endings that classify the noun based partly on semantic classes and partly on the number of syllables of the stem (*no'le* 'bean' vs. *no'linne* 'nose').

Syntactic properties of broader typological interest include noun incorporation, which takes the special phonological form of a noun reduced to its initial consonant and vowel and attaches this reduced form as an affix to the verb. Furthermore, Zuni makes abundant use of sentence initial particles to indicate a range of meaning from aspect to modality. Zuni lacks the ability to form finite subordinate clause structures of the kind selected by verbs of attitude evaluation, such as the equivalent of 'I think that I will go' and instead uses this finely detailed system of sentence initial particles to convey attitude.

The population of Zuni Pueblo is currently around 10,000+, and it is estimated that 70–80% of speakers use Zuni as a first language. Many of the oldest generation of speakers are bilingual in Spanish, while English has been increasing as second and first language among younger generations.
