Introduction

The study of language goes far back in recorded history. Almost two-and-a-half millenia ago, the Indian grammarian Panini wrote his formal treatises on Sanskrit, Xun Zi appeared as China's first major philosopher of language, and Plato and Aristotle initiated the Greek philosophy of language. Since the renaissance, there has been an increasing focus on the description of individual languages, the exploration of familial relationships between languages, and the formulation of increasingly general theories of language structure. Now, almost every university or college has a language department or even a specialized linguistics department, which means that an immense number of researchers are working in the field and have published an enormous body of primary literature.

Given this wealth of published data, it is not surprising to meet beginning graduate students of linguistics who already identify themselves as 'syntacticians' or 'phoneticians'. This early specialization reflects genuine interest, but is also in part a mechanism by which students block out a large number of possible inputs to be able to concentrate on a more manageable few. In their subsequent research, most researchers narrow down their field of interest even more; they become immersed in the highly conceptual and terminological world of their specialty, and they often write articles comprehensible only to their small group of peers. In other words, linguistics is a mature science and, as in other scientific fields, there can be a communications gap both within the field and, even more so, between the active researchers and the general public.

The *Encyclopedia of Linguistics* provides an accessible overview of and introduction to the multiple facets of the study of language. To bridge this gap between professional linguists and the general public, my editorial colleagues and I made this encyclopedia very readable by eliminating technical terminology as far as possible and by making each essay self-contained.

How to Use This Book

The *Encyclopedia of Linguistics* is organized into a series of 508 free-standing essays, between 1000 and 3000 words in length. They range from factual narrative entries to thematic and analytical discussions, and combinations of all these. Where debates and controversies occur, these are indicated and discussed. As far as possible, this book takes the field of linguistics up to the present, at least to the opening years of the twenty-first century.

Perhaps the most significant feature of the encyclopedia is the easily accessible **A to Z format**. Cross-referencing in the form of **See Also**s at the end of each entry refers the reader to other related essays. A thorough, analytical **Index** complements the accessibility of the entries, easing the reader's entry into the wealth of information provided. **References** at the end of each entry refer the reader to seminal writings as well as some of the most recent work on the subject. Other special features include **12 language-distribution maps** and a **thematic Table of Contents** in addition to an **alphabetical Table of Contents.** In addition, **more than 100 illustrations** are dispersed throughout. A total of **288 scholars** from **34 countries** have contributed their expertise to this encyclopedia.

Contents

These essays have been written by scholars who provide a general introduction to the material without presupposing knowledge about the subject and without going into a

theoretical depth that would raise questions that cannot be answered in the space given. The entries fall into the following thematic categories: linguistic topics (for example, code switching) (50%), languages (for example, Sumerian) (30%), persons (for example, Noam Chomsky) (15%), and regions of the world (for example, Algeria) (5%).

Linguistic Topics

Among these essays are general introductions to major fields of inquiry, such as semantics, historical linguistics, and neurolinguistics. Other articles concentrate on issues within those fields, introducing concepts that are important in linguistics regardless of theoretical perspective, such as 'affix', or 'reference', or which are so commonly used that the concept becomes unquestioned, such as 'phoneme' or 'deep structure'. Other articles describe crucial phenomena that any theory of language has to explain, such as 'acquisition', 'tone', or 'aphasia'.

Languages

These essays cover the major language families of the world and discuss how individual languages are related to each other. Articles concentrating on specific languages from Ainu to Zuni explain where these languages are spoken, by whom, and under what sociopolitical circumstances. They provide a glimpse of the language's structure and highlight particularly interesting characteristics with examples.

Persons

These essays highlight the major theoretical contributions of noted linguists, discuss the influences that led up to their work, and put the contributions into historical perspective, in addition to providing basic biographical sketches.

Regions

These essays map out the linguistic landscape of a particular region. They show which languages are spoken, explain how this particular situation came about historically, and discuss language-political issues relevant in this region.

We have made a concerted effort to cover languages around the globe. Should you note any imbalance in favor of 'western' regions, languages, persons, or topics, this simply reflects that the European languages are the best-studied languages in the world.

Acoustic Phonetics

Acoustic phonetics is the study of the acoustic characteristics of speech. Speech consists of variations in air pressure that result from physical disturbances of air molecules caused by the flow of air out of the lungs. This airflow makes the air molecules alternately crowd together and move apart (oscillate), creating increases and decreases, respectively, in air pressure. The resulting sound wave transmits these changes in pressure from speaker to hearer. Sound waves can be described in terms of physical properties such as cycle, period, frequency, and amplitude. These concepts are most easily illustrated when considering a simple wave corresponding to a pure tone. A cycle is a sequence of one increase and one decrease in air pressure. A period is the amount of time (expressed in seconds or milliseconds) that one cycle takes. Frequency is the number of cycles in one second, expressed in hertz (Hz). An increase in frequency usually results in an increase in perceived pitch. Amplitude refers to the magnitude of vibrations, with larger vibrations resulting in greater peaks of pressure (greater amplitude), which usually result in an increase in perceived loudness.

Unlike pure tones, which rarely occur in the environment, speech sounds are complex waves with combinations of different frequencies and amplitudes. However, as first stated by the French mathematician Fourier (1768–1830), any complex wave can be described as a combination of simple waves. A complex wave has a regular rate of repetition, known as the fundamental frequency ($F0$). Changes in $F0$ give rise to differences in perceived pitch, whereas changes in the number of constituent simple waves and their amplitude relations result in perceived differences in timbre or quality.

Fourier's theorem enables us to describe speech sounds in terms of the frequency and amplitude of each of its constituent simple waves. Such a description is known as the spectrum of a sound. A spectrum is visually displayed as a plot of frequency vs. amplitude, with frequency represented from low to high along the horizontal axis and amplitude from low to high along the vertical axis.

The usual energy source for speech is the airstream generated by the lungs. This steady flow of air is converted into brief puffs of air by the vibrating vocal folds, two muscular folds housed in the larynx. The dominant way of conceptualizing the process of speech production is in terms of the source-filter theory, according to which the acoustic characteristics of speech can be understood as a result of a source component and a filter component. The source component is determined by the rate of vocal fold vibration, which in turn is affected by a number of factors, including the rate of airflow and the mass and stiffness of the vocal folds. The rate of vocal fold vibration directly determines the $F0$ of the waveform. The mean $F0$ for adult women is approximately 220 Hz, and approximately 130 Hz for adult men. In addition to their role as properties of individual speech sounds, $F0$ and amplitude also signal emphasis, stress, and intonation.

For speech, the source component itself has a complex waveform, and its spectrum will typically show the highest energy at the lowest frequencies and a number of higher frequency components that systematically decrease in amplitude. This source component is subsequently modified by the vocal tract above the larynx, which acts as the filter. This filter

enhances energy in certain frequency regions and suppresses energy in others, resulting in a spectrum with peaks and valleys, respectively. The peaks in the spectrum (local energy maxima) are known as formant frequencies. The lowest-frequency peak is known as the first formant, or $F1$, the next lowest is $F2$, and so on. The vocal tract filter is determined by the size and shape of the vocal tract and is therefore directly affected by the position and movement of the articulators such as the tongue, jaw, and lips.

Vowels are typically characterized in terms of the location of the first two formants, as illustrated in Figure 1 for the vowels of American English. For a given speaker, each vowel typically has a unique formant pattern. However, variation in vocal tract size among speakers often leads to a degree of formant overlap for different vowels.

Consonants can also be described in terms of their spectral properties. These sounds are produced with a complete or narrow constriction in the vocal tract, essentially creating a vocal tract with two sections: one behind and the other in front of the constriction. The length of the section in front of the constriction is one of the primary determinants of the spectra of these sounds. The longer this section (i.e. the farther back the constriction), the lower the frequency at which a concentration of energy occurs. For example, consonants like *k* and *g,* which are produced at the back of the mouth, are typically characterized by a concentration of energy between approximately 1,500 and 2,500 Hz, whereas more anterior consonants like *t* and *d* typically have a concentration of energy above 3,000 Hz. Similarly, the sibilants [ʃ, ʒ] produced in the middle of the mouth have major energy around 2,500 to 3,500 Hz, whereas the more anterior ones [s, z] have major energy well above 4,000 to 5,000 Hz. However, in the

case of consonants with a constriction toward the very front of the vocal tract, the extremely short section in front of the constriction does not result in clearly defined spectra. As a result, bilabial [b, p] and labiodental [f, v] consonants are described as having diffuse spectra, without any clear concentration of energy.

From a linguistic point of view, a detailed description of speech sounds in terms of their frequency, in addition to amplitude and duration, can elucidate the factors that shape sound categories and determine phonological processes both within and across languages. In addition, acoustic phonetic analysis may serve to quantify atypical speech patterns produced by nonnative speakers or speakers with specific speech disorders.

Acquisition

Language acquisition is the study of the development of a person's language. It generally refers to the way people learn their native, first, second, or other languages. More specifically, it may refer to the time a language feature has been acquired. This may vary from the first emergence or onset of a language item to the time of its accurate use. As a field of study, it is the subject of linguistics, psychology, and applied linguistics. Its object is to study (1) how languages are learned, (2) what are the developmental stages in this process, and (3) what is the nature of language. To find answers to these questions, researchers apply longitudinal and cross-sectional methods. In the first of these, they study specific developments in the language of individuals or groups over a period of time. In the second, they research a particular feature in the language of a group at a given point in time.

First Language Acquisition

First language acquisition is the child's learning of his or her first or native language. Traditionally, and especially in monolingual societies, 'first' and 'native' language were used synonymously. With the expansion of cross-cultural communication, the two terms become more distinct. For example, children may acquire some knowledge of another language from a nurse or a relative before they acquire their native language, e.g. the language of the country they live in. Thus, a Chinese child born in the United States may first learn Chinese from her parents, and learn English later from English-speaking children and adults. To avoid the confusion arising from the use of 'first' and 'native', another term, 'primary', is sometimes used to indicate a child's first language chronologically.

First Language Acquisition and the Language Acquisition Device
Noam Chomsky's work aroused interest in the way children learn their native language. He believes that children are born with the ability to learn a language, i.e. they are born with a 'language acquisi-tion device'. The latter is species-specific or only for humans, language-specific or only for their first/native language, and innate or only inborn. He also claims that this ability is unconscious and children learn their native language by exposure to it and by using it, and not by being taught or corrected. He argues that as children acquire their native language, they are able to produce sentences that they have not heard before.

While early work on children's language acquisition focused on the development of children's ability to produce novel sentences, more recently, researchers have emphasized children's acquisition of word meanings and their linguistic and cognitive development, their acquisition of the phonology of their native language, and their language development in relation to their interaction with parents and peers. Some researchers also see a parallel between the stages of children's language development regardless of the specific language they are learning.

First Language Acquisition and Cognitive Development
A child's language development is closely related to his or her cognitive development. Here, the ability to identify and form categories and concepts is of crucial importance. 'Categorization' involves the treatment of distinct linguistic phenomena, such as 'worked', 'studied', 'saw', and 'went', as if they were part of the same phenomenon, or the same grammatical category, i.e. past tense. Young children do not have fully developed abilities in categorization. Many childhood first language errors, for example, '*I eated it', point to the gaps in their ability to form categories. Furthermore, even seemingly correct utterances do not imply that the child has achieved an adult stage in the mastery of the corresponding language category.

3

Closely related to the ability to categorize is the ability to differentiate a category, for example, tense, from the mental structure, which it represents, in this case, time. These mental structures are known as 'concepts'. To learn a language, a child must acquire the concepts that underlie linguistic structures. It is not possible to master grammatical categories, such as tense, in any language without mastering concepts such as time, space, modality, causality, and number. Young children's errors in tense indicate that they do not grasp the concept of time.

First Language Acquisition and Social Development

Children's social adjustment is as important as their cognitive growth to their language development. As they acquire various language categories and the concepts they represent, children also learn about the cultural, moral, religious, and other conventions of the society they live in. They learn how to express their thoughts, feelings, and wishes in a socially acceptable manner. For example, children learn that it is not always advisable to speak their minds. As they come to realize that words can serve to make friends as well as enemies, they learn that it is not always possible to tell the truth. In this way, while acquiring their first language, children also develop a social identity. How-ever, their progress is slow and not devoid of some rather amusing or even embarrassing errors. Children learning their first language, therefore, have a long way to go, even after they have acquired the basic concepts and their corresponding language categories. By comparison, adult foreign language learners, who are knowledgeable about the sociocultural aspects of their native language, are a step ahead of child learners, even though they may also be prone to similar social blunders because of sociocultural differences.

First Language Acquisition and the Critical Period

The 'critical period hypothesis' claims that there is a period in child development during which language can be acquired with native-like proficiency. Some, like the biologist Lenneberg, believe that this period lasts until puberty, after which the brain loses some of its ability to adapt due to its laterization, i.e. the establishment of specific language functions in particular parts of the brain. After that, the decreased plasticity of the brain makes the acquisition of another language a psychologically different and more difficult process. While there is compelling evidence that supports those claims, there are also important facts that undermine their veracity. First, the strictly biological evidence is by no means conclusive. Second, other factors, such as lack of motivation, may explain nonnative pronunciation.

First Language Acquisition and Bilingualism

Cognitive and social development, as well as the language acquisition device and the critical period affect the language development of the bilingual as well as the monolingual child.

Bilingual first language acquisition is defined as the parallel acquisition of two languages, which is, supposedly, an evenly paced process. However, such a perfect balance can rarely be achieved. Commonly, the child would use one language in one environment, and another in a different setting. Thus, inevitably, one language gains dominance over the other. This dominance may extend to some or all areas of communication. As a result, the child's other language may become secondary in both development and use. Furthermore, there may be some interference from the dominant language that causes errors in the child's secondary language. However, there is no evidence that this results in massive confusion in one or both languages. Furthermore, there is no evidence that bilingual children differ from other children in their cognitive, social, or language development.

Second Language Acquisition

Second language acquisition (SLA) is defined as the process of becoming competent or proficient in a second or foreign language, from the first use of a language item to its advanced applications at a later stage. As a field of research, SLA is a fairly new interdisciplinary subject with most of its empirical research done since the 1960s. It is largely based on theories and research methods developed in the fields of education, psychology, linguistics, anthropology, foreign languages, English as a second language, and linguistics. In the United States, researchers study the way nonnative speakers acquire English phonology, syntax, and pragmatics. The purpose of SLA studies is to describe and explain the way second languages are learned in terms of both linguistic and communicative competence. To do this, researchers study learners' performance and their intuitions about correct and incorrect use of language. The object of second language acquisition is to find more effective ways of teaching and learning foreign languages, and assumes that such research can affect the way foreign languages are learned.

The Meaning of 'Second Language' in Second Language Acquisition

There are different interpretations and uses of both 'second' and 'acquisition' in SLA. 'Second' may be used to distinguish it from 'foreign' or 'third' language acquisition. Traditionally, the terms 'second' and 'foreign' have been used alternatively to refer to any language other

than the first. More recently, with the emergence of English as a global language and the establishment of Teachers of English to Speakers of other Languages (TESOL) as a worldwide professional organization, a distinction is made between the two. 'Second' language acquisition refers to the study of English by foreigners in countries where English is the native or the official language, whereas 'foreign' language acquisition refers to the study of English everywhere else. Furthermore, this distinction extends to differences in what is learned and how it is learned. Learners of English as a foreign language (EFL) prefer standard varieties of English, whereas learners of English as a second language (ESL) try to blend with their sociolinguistic environment. All of these differences are reflected in the goals and methods of EFL and ESL. A further distinction is made between 'second' and 'third' language acquisition, which marks the learner's relative proficiency rather than the order in which he or she acquired these languages. Sometimes, the term 'alternative' is used to refer to any nonnative language.

The Meaning of 'Acquisition' in Second Language Acquisition

Acquisition is often used to refer to different aspects of the process and results of learning a second language. While trying to find out about the process, i.e. how second languages are learned, researchers often compare different learning experiences that lead to SLA, such as learning a language through organized instruction or in an immersion situation. From a sociolinguistic perspective, acquisition through organized instruction occurs in classrooms with the help of teachers and instructional materials. Acquisition through immersion occurs in social situations using contextual clues. Yet another distinction is made from the psycholinguistic perspective. Klein identifies 'spontaneous' and 'guided' acquisition. The first focuses on everyday communication, whereas the second targets the mastery of the language system. Similarly, from a psychological point of view, Krashen distinguishes between 'acquisition' and 'learning'. In his analysis of the process of mastering a second language, he reserves 'acquisition' for the subconscious process of learning a language by being exposed to it. 'Learning', according to him, is the conscious process of mastering a language by studying it. Ellis finds this distinction problematic and considers its demonstration difficult. Furthermore, he states that researchers disagree about what kinds of performance constitute evidence of 'acquisition'. For some, such evidence can be found in the ways learners speak and write. For others, it is the learner's intuitions about the second language that matter. Yet another group of scholars seek evidence of acquisition by assessing the learner's introspections.

Other researchers analyze what it means to know a second language. From a linguistic perspective, Chomsky focuses on the results of SLA, which he defines as 'competence' and 'performance'. According to him, 'competence' in a second language is the mastery of the internalized grammar that the ideal speaker or hearer, not a real one, has of the whole language. Such mastery enables him/her to produce grammatically correct sentences as well as recognize existing and nonexisting sentences. For example, knowing the rule, which makes 'I speak English' possible, a person can produce 'I speak French' even though he or she may not have seen this before. Furthermore, he or she would know that the form '*I speaking English' is nonexistent. 'Performance' in Chomsky's *Generative Transformational Grammar*, on the other hand, refers to a person's actual use of a language in the understanding and production of sentences. Unlike communicative competence, which is internal and invisible, performance is external and observable. Furthermore, performance does not mirror competence, since people may know how to produce a sentence but may err when they try to do so. Thus, performance can also be defined as the grammar that a person uses to understand and produce language, which is both correct and appropriate. Performance could be used to investigate competence through the analyses of samples of spoken or written discourse. Within performance, Widdowson distinguishes 'usage', which refers to the learner's ability to apply grammar rules accurately in the production of grammatically correct sentences. 'Use', on the other hand, signifies their ability to apply linguistic and sociolinguistic knowledge appropriately and communicate effectively in diverse contexts.

Second Language Acquisition Research

A large part of SLA research is learner based. It describes and analyzes the nature of learner language and learner differences, learning processes, and pedagogical input and output. It does so to provide answers to important second language research questions, which may offer effective solutions to crucial second language classroom problems.

Learner Language in Second Language Acquisition Research

Researchers study learner language by examining samples of oral and written texts. Their goal is to identify errors, establish developmental patterns and sequences, trace variability, and explore use. Errors were first believed to be the result of native language 'transfer' or 'interference'. This view was promoted by numerous contrastive analyses conducted from the 1940s to the 1960s. Such studies compared two languages to find out what similarities and differences

existed between the two. Lado thought that similar elements would be easy to learn, while dissimilar ones would be difficult to master. The belief that linguistic difference could be a predictor of difficulty gave rise to the 'contrastive analysis hypothesis'. That and the behaviorist approach to learning, which claimed that learning is a process of habit formation, led to the belief that SLA should be a process of overcoming habits from the native language and consolidating correct habits in the target language.

In 1967, Pitt Corder proposed a new definition of errors. He thought they were systematic deviations from the norm, which reflect the learner's current stage of second language development. Errors, he claimed, are different from mistakes, which can easily be self-corrected. 'Error analysis' treated errors as a sign of the learner's hypothesis testing, which would ultimately lead to the formation of the correct form and its underlying rule. Thus, errors were seen as part of the learner's language at every stage of its development. To emphasize its unique features, Corder referred to learner language as 'idiosyncratic dialect'. Nemser called it an 'approximative system' and Selinker coined the term 'interlanguage'. Thus, the notion of learner language evolved from a faulty, deviant product of the target language to a continuous, approximative progress towards its mastery. Both contrastive and error analysis were criticized for their exclusive reliance on the analysis of a linguistic product, i.e. errors, to yield insights into a psycholinguistic process, i.e. second language acquisition.

Another feature of learner language is its passage through a sequence of developmental stages, which are universal. Thus, many of the initial utterances that learners produce may be simple formulae, for example, 'What's this'. These are followed by structures of greater morphological and syntactic complexity, for example, 'I wonder what this might be'. The existence of developmental stages in SLA, which are similar to those in first language acquisition, along with some variations in the specific order in which particular features occur, have renewed interest in grammar instruction. In its systematic development, learner language also exhibits certain variability. For example, learners may use the third person singular 's' correctly sometimes and omit it at other times. In addition to lexical and syntactic variability, they often have problems on the pragmatic level, i.e. they may use language or act in a socially inappropriate manner.

Factors in Second Language Acquisition

SLA is also influenced by the environment in which it occurs. Social factors, language input, and interaction affect the way learners acquire a second language. Ellis contends that social factors shape learners' attitudes, which, in turn, may affect motivation and learning outcomes. Social factors include natural and educational settings. For example, natural settings, where English is the native or the official language, offer opportunities different from educational settings, such as the foreign language classroom where the native language is the medium of instruction.

While social factors influence second language acquisition indirectly, input, output, and interaction seem to have a direct impact. 'Input' is the learner's access and exposure to the second language, both written and oral. Exposure to the foreign language may engage learners in 'interactions' with native or nonnative speakers, or it may involve them in listening to tapes, films, radio, and TV programs. Researchers vary in their assessment of the importance of input and interaction. Behaviorist theories emphasize the importance of input. Chomsky, on the other hand, claims that there is no necessary correlation between language input and learner output. Krashen believes that learners acquire language in a natural order as a result of being exposed to 'comprehensible input' addressed to them. In contrast to Krashen, Swain proposes the 'comprehensible output hypothesis', which claims that comprehending input alone will not prepare students to produce language. According to him, it is correct production resulting from challenging practice in speaking and writing that facilitates acquisition. Both the comprehensible input and comprehensible output hypotheses have been criticized on the grounds that the processes of comprehensible input and output and the process of SLA are not the same.

General factors, such as social setting, input, output, and interaction, result in a variety of individual differences in SLA. Furthermore, individual factors, such as age, language aptitude, motivation, cognitive style, and learning strategies can have similar effects. These factors affect second language learning in ways that are mostly independent of the learner. For example, a learner can do nothing about his or her age, or language aptitude. Few learners may have the opportunity to switch from one educational setting to another. Given the appropriate guidance, however, some learners may be able to improve their motivation and learning strategies over time. For example, 'extrinsic motivation', which derives from external rewards, may evolve into 'intrinsic motivation', which derives from personal interests. Learner strategies, which contribute to the learner's conscious efforts to learn, may also change. For example, learners may expand their 'cognitive strategies' by learning new concepts. They may also perfect their 'metacognitive strategies' by

developing their study skills, or enhance their 'social strategies' by practicing their knowledge in authentic social settings.

Acquisition Theories

The goal of acquisition theories is to explain how it is that any normal child, born into any linguistic community, learns the language (or languages) of that community. For many theorists, the challenge is also to explain what appears to be the relatively short time period in which acquisition is achieved, the fact that it appears to be done without either overt teaching or sufficient information from the input (what the child hears [or sees, in the case of sign language]), and to follow a path that seems remarkably similar in all children, despite variation in early childhood experiences and in the types of languages they are exposed to. There is also a consensus that language acquisition is largely independent of cognitive development, despite the fact that some deficits in cognitive development can have an effect on certain aspects of language development. Whether the language is a spoken language or a sign language, whether the language is highly inflected like Finnish or uninflected like Mandarin, whether the child is raised in poverty or luxury, by highly educated or illiterate adults, or even other children, it seems that normally developing children pass through roughly the same stages in the same sequence, and achieve the steady state of acquired language by about the same age.

We know from unfortunate natural experiments in which children are raised in isolation (or near isolation) from language-using older members of our species (i.e. they are severely neglected, or are raised by other animals) that language does not emerge without at least some linguistic exposure—input—during the first few years of life. This strongly suggests that there is a critical or sensitive period during which the mechanism or mechanisms responsible for language development is/are primed to receive input. However, the resilience of language development to quite wide variations in input within any given language community, as well as the similarities among children learning quite different languages, suggest that these mechanisms, whatever they are, must either be quite tolerant of such variation, or be primed in such a way that the crucial input for language acquisition is always made available.

There are important roles for both 'experience-dependent' (nurture) and 'experience-expectant' (nature) learning in language development, and theories are distinguishable in terms of the relative contributions they see for these two types. On the one hand, there are those researchers who see a large didactic role for input (experience-dependent learning), and on the other, there are those who see a much smaller role for input and a much larger role for genetic predispositions that are triggered by linguistic experience (experience-expectant learning). Theories are also distinguishable

in terms of whether they are trying to explain how language emerges on a day-by-day basis in any given child or whether they are trying to explain how what is perceived as a gulf between experience as a child and adult knowledge of language could be bridged in principle. The latter are engaged in trying to solve the 'logical problem of language acquisition'.

Another dimension of difference between theories concerns the nature of the experience-expectant (innate) aspects of language acquisition. There are those researchers, most notably the generative linguists in a broadly Chomskyan paradigm, who argue for a dedicated language acquisition device (LAD), that has evolved to serve the precise purpose of language acquisition. This device is primed specifically to receive linguistic input, and requires a minimal amount of it to set to work building mental representations for language in the mind of the child. The fact that the required triggering input is so minimal provides an explanation for the consistency of language acquisition paths across otherwise fairly widely varying life experiences.

The most elaborated version of the LAD account—the Principles and Parameters approach—suggests that children are born with a Universal Grammar (UG), which means they are (unconsciously) anticipating those features that are common to all languages (the principles), as well as limited options for those things that differ among languages (the parameters). Upon exposure to actual input from a given language, children are able to 'decide' which sort of language they have encountered. So, for example, some languages have basic subject–verb–object organization in which complements are attached to the right of the heads of phrases (thus objects follow verbs, relative clauses follow noun heads, and noun phrases follow prepositions), while other languages are subject–object–verb where the reverse order of complements is found. A child exposed to a language of the first type need only process a simple structure (say one with a verb followed by an object) and it will trigger the expectation that all the other head-complement structures will be in the same order. When all the open parameters have been set, the child possesses the 'core' grammar of the specific language he or she is exposed to. At the same time, however, the child has also been acquiring those aspects of the language that are not anticipated by UG, using experience-dependent learning. These aspects are often together referred to as 'peripheral' grammar. Some researchers in this paradigm have assumed that all principles and parameters are operational or sensitive to the input from the beginning of life. Others have suggested that some may at least emerge with maturation.

In the course of acquisition, generalization (and overgeneralization) allows new knowledge to permeate across-the-board, and 'bootstrapping' allows learning in one area of language to trigger new learning in another. Semantic bootstrapping involves understanding an utterance in context and using it in conjunction with innate expectations of language principles to crack the code of the syntax. (For example, a child who does not yet know the required complements of the verb 'put', can work these out from understanding utterances such as 'Put the cup on the table' in context.) Syntactic bootstrapping involves working from an already understood structure to fill in meanings, semantic information, by deduction. (For example, if you hear 'John glopped his friend on the head and he fell down', you may not know exactly what 'glopped' means, but you can work out a lot of what it must mean.)

The Principles and Parameters (P&P) model has been a highly influential linguistic approach in language acquisition research, even while researchers in psychology and anthropology have been pursuing significantly different lines of investigation. In linguistics, the P&P model lies at the intersection of generative (specifically Chomksyan) linguistic theorizing about the nature of adult mental representations for language and accounts of how children acquire language. It has evolved as an account of how language could actually develop across time, even while its roots are in the 'logical problem of language acquisition' because it assumes that what cannot be learned from the input must be genetically prespecified. It advances various arguments in support of the thesis that the input is in fact incapable of providing sufficient information for language to be learned entirely through experience-dependent mechanisms, and thus that there is an essential problem of the 'poverty of the stimulus'. The account is also strongly modular in the sense that it sees language as being acquired by a specially dedicated mechanism (the LAD), independent of other types of mental representations or mental functioning.

Despite its power within linguistics, accounts predicated on some version of the UG story actually attract only a minority of adherents within the broad field of child language research. Most researchers are convinced that language in its entirety can be worked out by the child on the basis of the input, coupled with innate (nonspecific) predispositions for analyzing their environment. As a result of their analysis, children possess the capacity to produce and comprehend language. They may also have stored mental representations for how language works, but, unlike the P&P account, most of the accounts that rely on processing of the input as the way in which acquisition occurs also regard the endpoint as processes for production

and comprehension, without independent mental representations. Ann Peters and Dan Slobin, for example, have argued that children possess strategies, operating principles, for carving up the speech stream into repeating bits, storing those bits, recognizing the commonalities across them, and thereby building up a performance grammar for comprehension and production called Basic Child Grammar, which subsequently becomes elaborated into an adult grammar.

Another of the processing theories of language acquisition is Elizabeth Bates' and Brian Mac Whinney's Competition Model. Unlike the operating principles approach, this does not argue for a steady state in the form of a grammar at the end of acquisition, but rather for a permanently dynamic response to input throughout life. The impression that language has been definitively learned comes simply from the fact that new input changes the child's system very little if a child remains in the same speech community (although it will usually change with exposure to a new dialect or to a new language). Acquisition takes place as children respond to the distribution of various cues to meaning (word order, inflectional information, intonation and stress, etc.) and respond probabalistically to conflict among them. Since each child processes the input independently, individual differences between children are expected, and advocates of this approach argue that the differences found among children support the model. As they learn more of their language, they pay attention to more and more of the cues and let the stronger ones win out over the weaker ones for their language. So, at an early stage, a child learning English may assume that nouns at the beginning of sentences are agents, but when they begin to pay attention to passive morphology, they will have to adjust their assumptions accordingly. As should be clear from this example, the ability to derive meanings for language from context, in advance of actually understanding how language is structured is crucial (as it is in semantic bootstrapping). Active application of this and other distributional models, aimed at demonstrating that the input is sufficient to account for language acquisition, is seen in the computer-modeled connectionist networks. Attracted by the architectural similarity between computer networks and neurons, these researchers argue that experience with language teaches the network so effectively and so quickly that it gives the impression of prior knowledge.

As already indicated, children frequently seem to rely on pragmatic expectations of what language ought to mean in a given situation as a basis for learning how it is structured. Some theories of language acquisition place an even greater emphasis on the role of the sociopragmatic environment. Jerome Bruner,

for example, argues that the behavior of a child's caretaker provides all the cues that the inherently social child needs to acquire language. The way in which language is used in the here and now, in conjunction with actions that match what is being said, 'scaffolds' the child's understanding of the language. Others see difficulties with this approach, not only because not all successful language learners receive the kind of careful scaffolding it seems to require but also because the parental complexity of language seems to follow rather than lead increasing complexity in the child's language. In these and other ways, the account seems too simple to account for the complexity of the task. A similar approach was advocated by Jean Piaget, who saw language development as the logical extension not of social behavior, but of cognitive development. In Piaget's initial proposal, embedding of sentences was seen as analogous to nesting boxes, and the former dependent on the latter. Although most of his specific predictions have not been supported by subsequent research, it is clear that at least certain aspects of language are intimately related to cognitive development, although the direction of influence is not clear. One area of current research concerns the emergence of the capacity to make informed guesses about what other people know ('theory of mind'), and its relationship to language development. There is considerable discussion about whether the capacity to embed clauses under main verbs such as 'think' and 'know' drives or is driven by the capacity to understand that others may not share the same assumptions as oneself.

Finally, it is worth noting that significant debate surrounds the issue of whether, when an individual learns a second language, they go about it in the same way as a first language learner, or whether it is a fundamentally different process. Evidence suggests that there is some kind of critical period for second language development, as children seem to be able to do it so much better than adolescents and adults. However, it is not yet known when bilingual first language development should be seen as having given way to second language development. Nor is it clear that adults, when given the kind of input and motivation of children, are always incapable of the same level of success. It is also unclear whether second language learners are able to reaccess the learning capacities they had as children learning their first language, or whether these are permanently overridden and made unavailable by the presence of the first language.

Aerodynamics of the Vocal Tract

Speech production may be viewed as a means of converting slow pressure variations in the vocal tract into the rapid pressure variations that constitute sound. When there is a difference in air pressure across a valve and it opens, sound is created by the rapid movement of air. A stop burst is created by the sudden release of air under pressure, the continuous noise of a fricative is created by a similar but slower release, and repetitive release of air through the glottis by the vibrating vocal cords creates voicing. Speech aerodynamics studies in detail as to how these sounds are created, how the air pressures and airflows are generated, and their phonological consequences.

From an aerodynamic point of view, the vocal tract is a system of chambers connected to each other by valves, with some of them having access to the air outside. Most of the chambers are equipped with piston-like structures that can change the volume of their chamber.

There are a few general physical principles that govern the generation of pressures and flows in the vocal tract:

1. For a given mass of air, pressure varies inversely with the volume of the chamber containing it (Boyle–Mariotte's Law).
2. For a given volume of a chamber, pressure varies directly with the mass of air in it.
3. The quantity of airflow (the 'volume velocity') through an aperture varies as a function of the size of the aperture and the pressure difference across it.
4. The velocity of airflow (the so-called 'particle velocity') varies directly with the volume velocity and inversely with the size of the channel it is flowing through. (This principle is important because turbulence, the source of acoustic noise, is a function of air velocity.)
5. When air is flowing through a channel, the pressure it exerts on the walls of a channel at 90° with respect to the direction of airflow varies inversely with the velocity of the airflow (this is the Bernoulli effect).

Four 'air stream mechanisms' for generating the pressures needed in speech are used in languages of the world. They are named for the principal piston-like structure creating the volume change, plus 'egressive' or 'ingressive' to denote whether air moves out of the cavity or into it when the pressure is released to the atmosphere:

Pulmonic egressives: The air in the lungs is compressed by the expiratory muscles acting to decrease the volume of the rib cage; the pressure increases (by principle 1). Sound is created when this air is released at the glottis and/or at any supraglottal constriction, e.g. [p], [l], [m], [o]. All languages use pulmonic egressive sounds and the vast majority like English, Japanese, Finnish, and Hawai'ian use them exclusively.

Glottalic egressive ('ejectives'): With air trapped in the oral cavity between a closed glottis and a supraglottal constriction (and, of course, velic closure), the air is compressed by the elevation of the larynx (the glottis acting like a piston) and some pharyngeal constriction. Such sounds may include stops, affricates, and fricatives, e.g. [p'], [ts'], [f']. Ejectives are found in approximately 18% of the world's languages, e.g. Amharic, Quechua, and Navaho.

Glottalic ingressive ('implosives'): The oral cavity is enlarged (by lowering the larynx and possibly also the jaw) so that the pressure in the oral cavity decreases. Most implosives are voiced, the lowering larynx thus acting like a leaky piston, but voiceless implosives, although quite rare, do exist. Voiced implosives occur in about 10% of the world's languages, e.g. Kalabari, Sindhi, and Xhosa.

Velaric ingressive ('clicks'): Air is trapped between the tongue and the palate (or the lips) and the small cavity is enlarged by the tongue moving down and/or backwards. The air pressure is greatly lowered and when released by the tongue or lips, producing a 'pop' or fricative sound. The sound that comic strips try to convey with 'tsk'! or 'tut-tut' (a sound expressing disapproval or regret) is the alveolar click [!]. The sound of a 'kiss' is the bilabial click [ʘ]. Clicks are found widely in different cultures, but usually as interjections or calls to animals. As speech sounds, they are quite rare and are found only in certain Southern African languages such as Zulu, Xhosa, Ndebele, and !Xóõ. Given that clicks' sound-making structures are so localized in one part of the vocal tract, clicks can be combined simultaneously with sounds made by the other air stream mechanisms, e.g. they can be accompanied by voicing or voicelessness, nasalization, etc.

Voicing and trills: Trills and voicing constitute aerodynamically driven, self-sustaining oscillations. The cycle of vocal cord vibration could start with the vocal cords lightly adducted in the presence of airflow. This causes the subglottal pressure to build up behind the glottal closure, the increased pressure forces the cords apart, and the resulting high rate of airflow through the cords creates a negative pressure between them (by principle 5, above), which 'sucks' the cords together again (along with an elastic recoil force of the vocal cord tissue); the cords close again, and the cycle repeats itself. Trills are created in a similar way.

Obstruent and voicing: Obstruents inherently favor voicelessness for the following reason: voicing requires that there be air flowing between the vocal cords. Obstruents partially or completely block the airflow exiting the oral cavity. But if glottal airflow continues, then the pressure in the oral cavity will rise (by principle 2, above). Then, the difference in the pressure across the glottis will be reduced and may fall below the value needed to maintain the airflow required for vocal cord vibration (by principles 3 and 5, above). Passive yielding of the vocal tract walls to the impinging pressure permits voicing to persist for around 65 msec (more for labial stops, which have more surface area behind the constriction and less for velars). For voicing to be maintained beyond this, some active expansion of the oral cavity is required, e.g. by lowering the larynx and/or the jaw. This leads to many phonological consequences, among them the greater incidence of 'missing [●]' in the stop inventories of languages utilizing a voicing contrast on stops, e.g. as in Dutch, Czech, and Thai, the greater tendency for geminate stops to be voiceless or to undergo devoicing morphophonemically.

Many other common sound patterns in language, e.g. the development of affricates from stops, as well as the way specific speech sounds are modified in certain cases of speech disorders, e.g. cleft palate, laryngectomy, can be explained by reference to speech aerodynamics.

Affixation

Affixation is a morphological process that adds phonological material to a word in order to change its meaning, syntactic properties, or both. Some examples of affixation in English are given in (1).

(1) a. fond   fondness

    b. start   restart

    c. car   cars

In this article, an overview of different types of affixation processes is given, followed by a discussion of how to distinguish affixation from other processes. Then, a number of theoretical problems related to affixation are presented.

Types of Affixation

The phonological material added in affixation is called the *affix*. The affix is attached to the *base*. Different types of affixation can be distinguished on the basis of the position of the affix with respect to the base or on the basis of how affixation affects the meaning of the base. In this section, the emphasis is on the former. The latter is discussed in the section on delimitation issues.

Suffixation is the most common type of affixation. In suffixation, the affix is added to the end of the base. Examples are (1a) and (1c) above. In (1a), the suffix-*ness* is added to the adjective *fond* to produce the noun *fondness*. In (1c), the suffix -*s* is added to the noun *car* to produce the plural of the noun. In most languages, suffixation is the most widespread form of affixation. In languages such as Turkish and Finnish, it is the only type of affixation.

In many respects, *prefixation* is the mirror image of suffixation. In prefixation, the affix is attached to the beginning of the base. An example is (1b) above, where the prefix *re-* is added to the base *start*. Prefixation is less widespread than suffixation, but some languages, e.g. Khmer, only have prefixation. In languages that have both suffixation and prefixation, the former usually has a larger range of functions. Thus, in English, all inflection is expressed by suffixation. In word formation, we find both, but prefixation only rarely changes the syntactic category of the base, as when the verb *enrich* is formed from the adjective *rich*.

In most languages, affixation only involves suffixes and prefixes. *Infixation*, in which the affix is attached inside the base, is much rarer. An example is the infix -*um*- in Tagalog, illustrated in (2).

| (2) | a. bilih ('buy') | bumilih ('bought') |
| | b. gradwet ('graduate') | grumadwet ('graduated') |

The infix in (2) is used to express the past tense of the verb. It attaches itself after the first consonant or cluster of consonants of the base. This is its *anchor point*. In general, the anchor point of an infix is at most one syllable removed from the left or right boundary of the base.

Whether other types of affixation exist depends on the theoretical framework adopted. Thus, *circumfixation* is the simultaneous addition of a prefix and a suffix. The mere observation of a form such as *enrich-*

ment is not sufficient evidence for the existence of a circumfix in English, because the form can be analyzed transparently as a result of suffixation of -*ment* to the verbal base *enrich*, which is in turn the result of prefixation of *en-* to the adjective *rich*. A better candidate for a circumfix is Dutch *ge…te,* exemplified in (3).

| (3) | steen ('stone, rock') | gesteente ('type of stone/rock') |

The change in meaning in (3) can be expressed as a generalization to a type. It can be argued that *ge…te* is a circumfix, because neither *gesteen nor *steente are possible Dutch words. A theory that excludes circumfixes would have to postulate one of these nonexisting forms as an intermediate form in the derivation.

Delimitation Issues

As affixation is the most salient morphological process, it is no surprise that many of the foundational discussions in morphology are directly related to affixation.

A first set of issues concerns the function of affixation. Traditionally, inflection and derivation are distinguished. Inflection adapts a word to its syntactic environment. A prototypical example is the agreement of a verb with its subject in person and number, as illustrated for *sleep* in (4).

| (4) | a. The child sleeps. |
| | b. The children sleep. |

Derivation is a type of word formation that involves affixation. It forms new lexemes, marked by a different syntactic category and/or a different lexical meaning, as illustrated in (1a-b). Another contrast is the one between inflection and stem formation. An example of the latter can be observed in Dutch *kinderstoel* ('highchair'), a compound of *kind* ('child') and *stoel* ('chair'). The form *kinder* is different from the singular (*kind*) and the plural (*kinderen*). The suffix -*er* can be said to produce a secondary stem used in compounds.

Another set of delimitation issues concerns the nature of the affix as a phonologically dependent, morphological unit. Affixes contrast on the one hand with clitics, and on the other with stems used in compounding. Clitics are phonologically dependent particles, i.e. particles that must attach to a host word much like an affix, whose distribution is, however, determined by syntactic rules rather than morphological rules. An example is the Italian clitic pronoun -*ti* ('you') in *incontrarti* ('to meet you'). While these clitics are generally not considered as affixes, Turkish

case and number endings as in (5) are more of a borderline case.

> (5) Ankara ve İzmire gideceğim
> 'Ankara and Izmir I go',
> i.e. I go to Ankara and Izmir

In (5), *Ankara* does not have any case ending, whereas *İzmir* is followed by the dative ending *-e*. Nevertheless, the dative ending applies to the coordinated noun phrase *Ankara ve İzmir*. Therefore, it can be argued that the dative marker is not an inflectional affix but a clitic. Similar observations can be made about the genitive marker in *the queen of England's hat*.

Compounding usually combines items that occur as independent words, e.g. *bookshelf*. Words such as *philanthropic* and *anthropomorphic* share many properties with compounds, but their constituent parts do not occur as independent words (in English). They are often called *neoclassical compounds*. In fact, *anthropo* is the Ancient Greek word for human being, a sense it also has in English words. Although it is not a word in English, it does not behave like an affix either. It has a stem-like meaning and can appear in different positions in a compound. Other elements of the same general type, e.g. *pseudo*, occur almost exclusively as a prefix, often with a reduced meaning more typical of an affix than of a stem, e.g. *pseudocultured*. It is very difficult to draw a clear borderline between stems and affixes among such neoclassical elements. The term *affixoid* is sometimes used to refer to items for which it is difficult to determine whether they are stems or affixes. An example from outside neoclassical word formation is German *reich* ('rich') in *ertragreich* ('productive, profitable'). In English, *-ful* in *successful* is similar.

Affix or Process?

One of the central questions in morphology is whether affixation should be seen as a rule applying to two elements, a base and an affix, or as a process applying to a base. Charles Hockett (1954) calls the first position Item & Arrangement, and the second Item & Process. Although all morphological processes can be described in either framework, some descriptions are more natural than others.

In a strict Item & Arrangement position, such as defended by Rochelle Lieber (1992), stems and affixes have separate entries in the mental lexicon. The suffix *-ness* is described as a noun that requires an adjective to its left. Given an appropriate concept of headedness (cf. below), this explains why *fondness* is a noun. The Item & Arrangement approach works particularly well as long as the form of the resulting word is the concatenation of the forms of the stem and the affix, as in *fondness*. Special provisions have to be made for cases where phonological processes interact with the concatenation, as in (6–8).

> (6) a. active   activity
> b. intend   intention
> (7) a. a house   to house asylum seekers
> b. to read   a good read
> (8) a. live   life
> b. extend   extent

In (6), suffixation triggers a phonological change of the base, stress shift in (6a), and a change of the final consonant in (6b). In an Item & Arrangement account, one might say that these phonological changes are triggered by the affix. In (7), there is no affix, but the relationship between the nouns and verbs is very similar to what we find in cases of genuine affixation such as *encase* and *entertainment*. In an Item & Arrangement account, one might either say that (7) is not affixation but something else (e.g. conversion), or that (7) involves zero affixes, i.e. affixes that do not have a phonological realization. The examples in (8) show that phonological changes can occur without an affix. This can be interpreted as phonological rules triggered by a zero affix or by conversion. The general approach in Item & Arrangement is that concatenation of base and affix is taken as central. Cases such as (6–8) are treated as exceptions to be fitted in.

In an Item & Process approach, as argued for by Stephen Anderson (1992), the process of affixation takes priority over the affix. In (7), the word formation process changes the syntactic properties of the input without affecting its form. In (8), the process modifies the form of the input by changing the quality of the final consonant and, in (8a), of the vowel. In (6), the process affects the form of the input by changing the stress position or the voicedness of the final consonant and appending some further phonological material, the suffix. Affixation of the type illustrated by *fondness*, the prototypical case in Item & Arrangement, is a special case in Item & Process where there is a perfect match between the input and a part of the output of the affixation process.

It is difficult to find conclusive arguments for either Item & Arrangement or Item & Process approaches to affixation. Proponents of Item & Arrangement usually claim that their approach is theoretically more restrictive than Item & Process. Proponents of Item & Process typically argue that processes such as infixation, reduplication, vowel change, consonant change, and conversion are too frequent, especially in non-European languages, to treat them as exceptional compared to 'pure' affixation. Linguistic data alone cannot determine as to which of the two approaches is correct, because every Item & Arrangement account can be reformulated into Item & Process and vice versa.

Headedness

The concept of *head of a word* only makes sense in an Item & Arrangement-based account of morphology. The head determines the syntactic category of the resulting word as well as other properties such as gender in languages that distinguish them. Thus, *fondness* is a noun because *-ness* is the head, and French *activité* ('activity') is a feminine noun because *-ité* is the head.

Different methods have been proposed to determine the head. Anna Maria Di Sciullo and Edwin Williams (1987) propose that the head is always the rightmost element. This concurs with the observation that suffixes often change the syntactic category of their base, but prefixes, as in (1b), usually do not. Exceptions include cases such as *enrich* and *debug*, where the prefixes make verbs out of an adjective and a noun. An alternative proposed by Lieber (1990) is that the last affix to attach is the head. This generalization makes *re-* the head in (1b) and accounts correctly for *enrich* and *debug*, but has problems with prefixes such as *counter-* in (9).

(9)   a. intuitive   counterintuitive
      b. example   counterexample
      c. sign   countersign

In (9), *counter-* is the only (hence last) affix attached, but the syntactic category depends on the word it attaches to. The Spanish diminutive, illustrated in (10), is problematic for both.

(10) a. el pintor   'the painter'
         el pintorsito   'the little painter'
      b. la cancyón   'the song'
         la cancyonsita   'the little song'

The final *-o* and *-a* in (10) are not a part of the affix, but so-called *word markers*, whose form is determined in this case by the grammatical gender of the word (*-o* for masculine, *-a* for feminine). Although the suffix *-sit* is the rightmost element and the only affix, it is the base that determines the gender as indicated by the article. In an Item & Process approach, there is no need for a head, because its function is subsumed in the affixation process.

African American Vernacular English

African American Vernacular English (AAVE) has been known by various names in linguistics, including Negro Nonstandard English, Black English Vernacular, and more recently Ebonics. Except for the last, each name corresponds to a particular time in American history when it was more fashionable to refer to African Americans as Negroes or Blacks, among other names.

The terms have been used to designate nonstandard English varieties spoken by less educated African Americans other than those in coastal Georgia and South Carolina, who speak Gullah, a creole. The average speakers of both vernaculars do not have specific names other than English for the ways they speak; scholars have coined the names to distinguish their

ethnolects (ethnic dialects) from standard English and from European-American vernaculars.

Ebonics, which was first used in print in the work of Robert Williams (1975), is probably the most confusing of the terms. It subsumes Gullah and thus corresponds to what may be identified broadly as *African American English*. However, in the way Williams defines it, it also refers to other language varieties of the black diaspora, including English and non-English creoles of the Atlantic (e.g. Jamaican and Haitian creoles and Nigerian Pidgin English). The name becomes quite useless when it is also extended to cover Niger-Congo languages. The average AAVE speaker might be puzzled as to why their English is lumped with a multitude of other languages they hardly understand, if at all, and why the fact that it is first of all an American linguistic phenomenon is virtually overlooked.

On the basis of literary sources, the predecessors of AAVE must have become distinct from other American English vernaculars already in the early eighteenth century (Brasch 1981). Literary representations of the time are similar to those about the Caribbean, where larger plantations with African majority populations were already booming. It is not clear whether the literary representations (mostly by British, rather than American, authors) reflect the speech of African Americans of the time or, instead, generalized stereotypes that were based on what was developing in the Caribbean. Newspaper advertisements about runaway slaves reveal that slaves born in the colonies (a large proportion by the early eighteenth century) or who had lived there for a long time did not speak differently from the European indentured servants with whom they interacted on a regular basis, before the institutionalization of segregation in tobacco and cotton plantation ex-colonies in the late nineteenth century. This history suggests that, unlike Gullah, AAVE could not have developed as a distinct variety before the late nineteenth century. Aside from letter-writing evidence, more reliable literary representations of AAVE probably also date from the nineteenth century, when most of the authors were also American born.

AAVE has become central to research in American quantitative sociolinguistics and historical dialectology since the 1960s. William Labov, William Stewart, and J.L. Dillard, together with Walt Wolfram and Ralph Fasold, focused on subsets of the following questions: (1) Is AAVE a rule-governed vernacular, and is it a full-fledged language? (2) Is it an American English dialect or is it, instead, an erstwhile creole (similar to those of the Caribbean), and therefore a separate language, which has acquired English-like features by 'decreolization'? (Putatively, this evolution would be caused by approximations by African Americans of standard English structural features, supposedly because of the mass media, mass education, and socioeconomic mobility since the abolition of slavery.) (3) How different is AAVE's system from those of standard English and European American vernaculars such as Appalachian and Ozark English? (4) How does variation work in its system and what is its significance from an evolutionary point of view?

Overall, a very large proportion of the research has been devoted to a small subset of structural features that makes AAVE peculiar, at least by its statistical distribution. This includes the following:

1. AAVE allows the loss of consonant clusters at the end of words, and this means that the final consonant is often dropped in words such as *desk, passed*, and *old* (pronounced *des', pass',* and *ol'*).
2. Diphthongs (double vowel sounds) such as [aw] and [ai], as in *south side,* become long monophthongs (simple vowels): [a:].
3. The 'r' is dropped in front of consonants and at the word end, as in *Lord* and *car* (pronounced *Lo'd, ca'*); the 'r' is pronounced before vowels, as in the words *arrive* and *road.*
4. The copula 'be' is often absent in sentences such as *She cute* and *He gon come.*
5. *Be* is used to denote invariant or repeated states of affairs, as in *He be tired/reading every time I visit him.*
6. AAVE uses multiple negation, as in *He ain go nowhere (nohow).*
7. The negative auxiliary (e.g. *didn't*) is moved to the front of the sentence, as in *Didn't nobody tell me 'hush yoh mouth',* 'Nobody told me, 'hush your mouth'.'
8. AAVE differs from standard English in various aspects of time reference, as in *I been there,* 'I have been there', and *They BEEN married* (with emphasis on *been*), 'They have been married for a long time and still are', and *He done lef when I come,* 'He had already left when I came'.
9. Plural is expressed with *dem* (in alternation with the presence or absence of the standard English plural marker *-s*), as in *dem boys*, and *an dem* signals an 'associative plural', as in *Yolanda an dem,* 'Yolanda and her friends/relatives'.
10. Many words and word meanings are peculiar to African American speech, as in *You are bad* (with *bad* pronounced emphatically and with an extra-long vowel), 'you are impressive/something else', and *you look clean,* 'you look sharp(ly dressed)'.

Interest is now growing in describing not only isolated features but also integrated subsystems of the

vernacular, highlighting, on the one hand, similarities with and differences from other American English varieties and, on the other, how subsystems such as time reference or the noun phrase are internally organized. This is a corollary of the fact that today, studies of AAVE's structure are no longer almost exclusively in the quantitative sociolinguistics paradigm, but also in theoretical linguistics.

There has also been research in African American discourse differences, especially on discourse genres, the structure and contents of some narratives, the form of language used in them, and whether or not the meanings of particular utterances are transparent. Particularly outstanding in this subarea are *playing the dozens*, in which male participants exchange witty, fictional insults directed especially at female relatives and *tall tales* or *toasts*, rhyming epics in which street culture and its heroes are celebrated in a street verbal style.

Afroasiatic

The Afroasiatic (formerly called Hamito-Semitic, also Semito-Hamitic, more recently Afrasian) phylum unites five or six language families that are clearly related, but the relations among the families are far from clear. The confusion—and the profusion of names—result from the history of the study of these languages. Known from antiquity, of course, were three of the principal Semitic languages: Hebrew, Arabic, and Aramaic in its Christian (Syriac) and Jewish literary forms. The Ethiopic literary language Ge'ez became known to European scholars during the Renaissance and was immediately recognized as a close relative of the other three. Beginning in the mid-eighteenth century, a number of ancient languages that survived only in inscriptions were deciphered, starting with Palmyrene, a close relative of Syriac, and Phoenician, which is close to Hebrew. In 1781, the name 'Semitic' was suggested for these languages as a family, on the basis of the 'Table of Nations' in Genesis 10:21–4, where Asshur, Aram, and Eber are among the descendants of Shem.

The nineteenth century brought two supremely important decipherments, those of Egyptian (in the early 1820s) and Akkadian (in its two main varieties, Assyrian and Babylonian, in the late 1840s). Certain peculiarities of the Semitic language structure, when noticed at an early stage in the decipherment of Akkadian by Edward Hincks, proved to be very helpful in making further progress, and there was soon no doubt that another major Semitic language had been discovered. With Egyptian, although Jean-François Champollion already suggested a Hebrew comparison in his initial announcement of the decipherment, and Hincks used Egyptian loanwords in the Hebrew Bible in his analyses of Egyptian, the resemblances were less obvious, and the actual kinship was suggested by the pioneering Egyptologist and linguist Richard Lepsius by 1880.

Also during the mid-nineteenth century, explorers, notably Lepsius, traveling through Abyssinia (modern Ethiopia, biblical Cush) gathered information on the languages they encountered there. Some (notably Amharic, the language of the ruling dynasty) proved to be Semitic languages, others (notably Oromo, which was then called by the insulting name Galla, and

Somali) resembled each other fairly closely and Semitic only remotely; this group was soon dubbed Cushitic. Only in the past generation has it been suggested that 'West Cushitic' is actually a separate branch of Afroasiatic (renamed Omotic), perhaps very distant from Cushitic; this was widely accepted for some time, but opinion may be shifting back to the earlier view. (The principal Omotic language is Wolaytta of Ethiopia, with some 2 million speakers, but very little is known about most of its relatives.) As Africa was partitioned among various colonial powers, naturally the investigation of Africa's indigenous languages was carried out largely by scholars from the respective metropolitan nations. Thus, much of the initial work on Cushitic was done by German and Italian linguists, while French investigators provided most of the descriptions of Berber tongues from North Africa (Morocco to Libya).

The last of the five main branches of Afroasiatic to receive attention is called Chadic, from its location near Lake Chad; the principal language of Nigeria, Hausa, is its main representative, and what little investigation was done was largely carried out by British linguists. The large number of Chadic-speaking communities, their small populations, and their remote locations, mostly in northern Nigeria, are factors that have made Chadic the least known of these groups overall.

Returning to the 'Table of Nations', we find that Ham is listed as the father of Cush and Egypt, so not unreasonably these languages that were clearly, although distantly, related to Semitic came to be called 'Hamitic'. But this proved to be a suboptimal choice for two reasons: linguistically, it implies that all the other families form a unit as against Semitic (implying that the Semitic family was the first to branch off from the others), which is not the case; and ethnographically or anthropologically, it caused the classification of languages to become enmeshed with the spurious notion of a 'Hamitic race' of dark-skinned but European-featured Africans. (In fact, of course, there is no necessary connection between language family relationship and 'race' or ethnic group.) For this reason, the name 'Afroasiatic' is now widely used for the phylum, since it simply names the two continents where it is found. This can be contracted to the convenient 'Afrasian'.

What, then, *are* the relationships among the branches of Afroasiatic? The very nature of the data makes it difficult to achieve consensus. It is as if scholars of Indo-European were faced with only Gothic and the other Germanic languages, Greek, modern Romance and Celtic, Armenian, and the modern Indic languages—analogous, respectively, to Akkadian and the other Semitic languages (an ancient tongue not ances-

tral to any of the modern ones), Egyptian (a single language attested over thousands of years), Cushitic and Omotic (whose common ancestry is disputed), Berber (a close-knit group of dialects with some ancient materials), and Chadic (a vastly differentiated family with a widely used, politically dominant variety). (The Indo-European analogy can also remind us that we have no way of knowing how many languages or entire branches of Afroasiatic have vanished without a trace—what 'Avestan' or 'Umbrian', what 'Tajik' or 'Albanian' there might have been.) Thus, it is no wonder that there are almost as many views of Afroasiatic relationships as there are Afroasiaticists. One view divides the northern groups—Berber, Egyptian, Semitic—from the southern ones—Chadic, Cushitic, Omotic. Another groups Semitic and Cushitic, plus Berber, against Egyptian and Chadic, plus Omotic.

Some characteristics that are widely shared among Afroasiatic languages are as follows. Consonants tend to be fairly numerous and vowels very few. Stops and sibilants appear in three series, voiced (*b d g, z*), voiceless (*p t k, s*), and 'emphatic', customarily marked with a dot (*ṭ, ṣ*). The 'emphasis' appears differently in different languages: in Semitic, it is mostly represented by velarization or pharyngealization (where constriction at the back of the mouth colors the consonant and adjacent vowels), but elsewhere it appears as glottalized or even as implosive varieties of these sounds. There are also a fairly large number of consonants made in the back of the mouth (including the notorious Arabic 'ayn /ʕ/). Another peculiarity is a tendency to laterals (sounds produced with air flowing past the sides of the tongue) and interdentals (with the tongue tip between the front teeth as in English *th* [θ]). Conversely, Afroasiatic languages tend to have the near-minimal vowel set /a i u/ (both long and short).

The best evidence that the Afroasiatic languages are related (rather than reflecting much borrowing of vocabulary and grammatical features) is the shared inflectional paradigms: the personal prefixes and suffixes self-evidently have a common origin throughout. The elements used to derive one verb from another also appear throughout the phylum (Table 1). It is noteworthy that both the earliest and the latest comparative grammars of Semitic, those of Heinrich Zimmern (1898) and Burkhart Kienast (2001), systematically include Afroasiatic comparisons. (Meanwhile, Carl Brockelmann, who compiled the definitive collection of comparative grammatical information on Semitic as then known (1908–1913), apologizes in the preface for excluding 'Hamitic' materials, as the data were inadequate at the time. Other writers on Semitic have followed his lead.) The well-known 'triconsonantal root' structure of the Semitic languages, however, does not appear to be

shared throughout Afroasiatic; elsewhere in the phylum, 'roots' tend to have just two consonants.

The only attempts at description of the grammar of the hypothetical ancestral language 'Proto-Afroasiatic' are the two small volumes by I. M. Diakonoff (1965, 1988), and he changed his mind considerably between the two. A summary, quite close to the earlier version, may be found in his article in the *Encyclopædia Britannica* (1974). Diakonoff must be considered quite brave for even attempting to reconstruct a proto-language, given the nature of the available materials: contrast the situation in Indo-European (the real situation, not the truncated version offered above as a parallel to that in Afroasiatic). Proto-Indo-European can be reconstructed in considerable detail (and with considerable agreement among scholars) because the hypothetical community that would have spoken a language similar to what is reconstructed thrived only a couple of thousand years or so before the earliest available evidence (Hittite, Vedic, Avestan, Mycenean). We can even verify the accuracy of comparative and reconstructive methodology over such a time span because we have the precious case of the Romance languages—reconstructed Proto-Romance is pleasingly similar to Vulgar Latin as it is known

from the first centuries AD. Proto-Semitic may be considered quite reliable for the same reasons—the large amount of data and the small time depth. Contrast the situation in Afroasiatic: one branch (Semitic) well-known, one branch (Egyptian) known in considerable detail over a long time—but with no vowels known, and one branch (Berber) with a scattering of meager inscriptions from Roman times. Thus, four of the six branches are known only or primarily from modern data—and the time depth of Chadic alone is estimated as about the same as that of Indo-European.

It is no wonder, then, that among the three presentations of comparative Afroasiatic vocabulary—those of Marcel Cohen (1947; omitting Chadic, with an occasional Hausa comparison), Christopher Ehret (1995; omitting Berber), and Vladimir Orel and Olga Stolbova (1995)—there is precious little agreement. (Nor has the preliminary requirement of comparative dictionaries of each of the constituent families been accomplished, even for Semitic.) Part of the difficulty is the shortness of words in the languages, with their roots consisting of just two consonants. Thus, it is all the more difficult to proceed to the other main consideration regarding an ancestral language: the homeland of its speakers.

There are three ways of determining where a language family may have originated. One, which is hypothetical, suggests that the area with the greatest concentration of diverse, related languages is likely to be where the family originated. (It is not likely that several related language groups would all happen to move to the same locality!) For Afroasiatic, this points to somewhere in northeast Africa, near where Chadic and Cushitic (and Omotic?) are found, say Ethiopia/Sudan. Further support for this suggestion might be found in the evidence that the Egyptians entered the Nile Valley from the south and settled gradually northward. There is simply nothing but speculation as to why and whence successive populations of Semitic-speakers appeared on the scene in southwest Asia. A second technique is to examine the vocabulary that can be traced back to the protolanguage. A dishearteningly limited number of words appear to have survived from so long ago, but they seem to point to a preagricultural, nonmaritime environment. The third source of information is the accidents of discovery owing to archaeology. Terrain, climate, and politics conspire to make expeditions unlikely; but there is reason to suppose that an Afroasiatic homeland is to be sought in regions that are now the eastern Sahara Desert, but were hospitably temperate over 10,000 years ago. An archaeological horizon in the western Arabian peninsula has been suggested as coordinating with Proto-Semitic speakers, but in the absence of written records, no assignment of languages to archaeological sites can be considered certain.

What of wider connections? From time to time, Afroasiatic is claimed to be part of a still older, vastly extended superstock called 'Nostratic', which is said to incorporate Indo-European, Uralic, Altaic, and various other phyla of Asia. Any perceptible reflection of a Proto-Nostratic must be uninterpretably dim; but a question that seems not to be addressed by Nostraticists is the location of the Proto-Nostratic-speaking community—a location from which all the postulated homelands must be reachable. From this point of view, the suggestion that Afroasiatic is not a member of Nostratic, but is coordinate with the languages that make up 'Eurasiatic', is slightly more tenable. An independent suggestion, made by archaeologists who investigated Indo-European origins, that 'Afroasiatic'—from which they seem to be aware only of Egyptian and Semitic—originated on the southern coast of the Black Sea, is ipso facto untenable.

The careful study of Afroasiatic languages goes back to antiquity. The study of the Afroasiatic phylum is nearly two centuries old. The tasks that remain for researchers are largely the same as those faced by specialists in other languages: intensive fieldwork, especially in Chadic, Cushitic, and Omotic, to record ample information about these languages, and then to bring to bear all the analytic techniques of linguistic theory and comparative method. A difference with Afroasiatic is that it also includes some of the oldest written records on earth, providing a unique cross-section of human linguistic behavior across 5,000 years.

Age and Language

Comprehension and production impose many simultaneous demands on the reader to process information on a number of levels, including syntactic, semantic, and pragmatic. It has been generally assumed that these simultaneous processing demands are handled by a human's working memory and that working

memory capacity declines with age, affecting language processing. Support for this hypothesis is largely correlational. Older adults are typically found to have smaller working memory spans than young adults, and such span measures are found to correlate with language-processing measures. A particular source of difficulty for older adults is the production and comprehension of complex syntactic structures involving multiple levels of sentence embeddings that impose high processing loads on working memory. The spontaneous use of such constructions declines with advancing age, and their use contributes to the breakdown of reading and listening comprehension.

Text processing is particularly vulnerable to the effects of aging; both cross-sectional and longitudinal research shows that older adults' reading comprehension is impaired, as is their listening comprehension. Further, word and name retrieval is disrupted by aging, contributing to an increase in tip-of-the-tongue difficulty in finding words. It is unclear as to whether working memory affects the immediate processing of words and sentences, or whether working memory exerts its affects on the processes involved with the storage, recall, and recognition of linguistic information. The general slowing of cognitive processes with age may also contribute to older adults' processing problems by affecting the speed of lexical access and other component processes. Neural inhibitory mechanisms also appear to weaken with age and permit the intrusion of irrelevant thoughts, personal preoccupations, and idiosyncratic associations during language processing. These irrelevant thoughts compete for processing resources, such as working memory capacity, and impair older adults' comprehension and recall.

A controversial issue in the study of aging and language is 'off-target verbosity'. A minority of older adults have been observed not only to talk a great deal but also to drift from topic to topic, weaving into their conversations many unrelated and irrelevant topics. Off-target verbosity appears to be related to poor performance on tests of the function of particular brain regions, as well as to psychosocial stress, extraversion, limited social support, and decreased social interaction. Whereas off-target verbosity has been cited as providing strong support for inhibitiory deficit theory, others have argued that this speech style is limited to social settings in which older adults construe their task differently than do young adults—as a monolog, responsive to an internal chain of associations.

The debates over working memory capacity limitations and inhibitory deficits are central to the general study of gerontology. These core research issues have been supplemented by two emerging topics: research examining the effects of Alzheimer's disease on language production and comprehension, and research examining how to improve older adults' comprehension of language. Task demands, lapses in attention, response biases, or other cognitive deficits contribute to the syntactic comprehension problems of adults with dementia.

Semantic and lexical processes are particularly disrupted by Alzheimer's dementia. Many researchers have found that tests of implicit word knowledge reveal few differences between dementing adults and normal older adults, and lexical knowledge is commonly found to be preserved. Other researchers have concluded that the structure of semantic knowledge is destroyed by Alzheimer's dementia. As a result, performance on verbal-fluency tasks, such as generating examples of categories or words beginning with a specific letter, is impaired, picture and object naming is hindered, and word associations are destroyed. The semantic network of adults with Alzheimer's dementia may be intact but inaccessible, perhaps due to the general, task-independent slowing of cognitive processes, including lexical access. General slowing may increase progressively with disease severity. A breakdown of inhibitions may also contribute to many of the word retrieval problems experienced by adults with Alzheimer's disease if they are unable to inhibit inappropriate word associations.

A special speech register, sometimes termed 'elderspeak', has been described as an accommodation in communicating with older adults, especially those with dementia. This accommodation is characterized as involving a simplified speech register with exaggerated pitch and intonation, simplified grammar, limited vocabulary, and a slow rate of delivery. Many of the characteristics of elderspeak, such as its slow rate, exaggerated prosody, and simplified syntax and vocabulary, resemble the characteristics of other speech registers such as 'motherese', or the speech used by adults when communicating with small children. Elderspeak may be evoked by the actual communicative needs of the elderly individual as well as by (culturally based) negative stereotypes of older adults, and it is often viewed by older adults as insulting and patronizing. Older adults, especially those in nursing homes, may adapt to situational demands by becoming more accepting of elderspeak. Some form of elderspeak may enhance communication with older adults, especially those with Alzheimer's dementia, but little systematic research has been undertaken to assess intervention and training programs.

In sum, the study of language and aging has focused on the effects of processing limitations on older adults' comprehension and production. Nonetheless, it is important not to lose sight of three general points. First, many aspects of language processing do not change with age, particularly lexical access and semantic

memory, but are vulnerable to the ravages of Alzheimer's disease. Other aspects of language, particularly syntax, may be more resistant to Alzheimer's disease, yet susceptible to age-related decline due to working memory limitations or inhibitory deficits. Second, there has been a gradual shift toward the use of sophisticated methodologies such as the study of self-paced reading times, eye movement patterns, and brain activation patterns to study how aging and dementia affect language processing. Third, the shift toward developing and evaluating practical applications, as seen in the growing body of research on elderspeak, continues. The linkage of basic research on language processing with everyday practicalities has led to the development of consumer standards and guidelines for presenting medical information, and for electronics and telecommunications.

Agreement

Agreement is a means by which languages signal the presence of a grammatical relation—usually the subject of a sentence, but sometimes also the object and/or the indirect object. Typically, it manifests itself as a prefix or a suffix on the verb, as with the English third-person singular marker ***-s*** (e.g. *John **lives** in Maryland*). Some languages have so-called rich agreement—that is, separate forms for nearly every person/number combination. French represents such a case:

(1) *Rich agreement (French)*

1SG	je parl-e	'I speak'
2SG	tu parl-es	'You speak'
3SG	il parl-e	'He speaks'
1PL	nous parl-ons	'We speak'
2PL	vous parl-ez	'You speak'
3PL	ils parl-ent	'They speak'

The features most often associated with agreement are person, number, and gender. Given the logistics of speech, there are at least three persons: those referring to the speaker (first), the hearer (second), and everything else (third). Some languages have a fourth person—obviative—reserved for entities further removed from the speaker/hearer's point of view. Inuktitut (Eskimo) and Algonquian are known for this.

Number usually breaks down into singular and plural, but 'dual' represents another possibility. English recognizes two numbers in its pronominal system, but

as far as agreement is concerned, only third-person subjects are marked: cf. *He understands* but *We understand*.

In addition to person and number, agreement may also involve the gender features of a subject and/or objects. French nouns are divided into two grammatical genders—masculine and feminine. When noun phrases headed by these nouns appear in subject position, agreement can be discerned on predicate adjectives and particles (M = masculine, F = feminine):

(2)   *Gender agreement (French)*

    a. Le soleil est monté   'The sun (M) has risen'

    b. La lune est montée   'The moon (F) has risen'

                   [PARTICIPLE]

    c. Le soleil est brillant   'The sun (M) is bright'

    d. La lune est brillante   'The moon (F) is bright'

                   [ADJECTIVE]

Feminine forms are marked with an extra vowel that—although not pronounced today—were presumably audible at an earlier stage of the language. Of course, grammatical gender is not to be confused with biological gender; the division of nouns into gender classes should be considered as an aid to reference and/or acquisition (German has three genders, for example).

Agreement and Case

As a grammatical category, agreement appears to function like case-markers—special morphemes that attach to noun-phrases (NPs) (rather than verbs) that signal their grammatical function within the sentence (e.g. as subject, object, etc.). In Japanese, for instance, NPs marked with [-ga] are interpreted as subjects, while those marked with [-o] are understood as objects (TOP = topic; COMP = complementizer):

(3)   *Case-marking and grammatical relations (Japanese)*

    Ichiro-wa   Taro-**ga**   hirugohan-**o**
    Ichiro-TOP [Taro-SUBJ   lunch-OBJ

    tabeta-to   iita
    ate]-COMP   said
    'Ichiro said that Taro ate lunch'

In traditional grammar, the case of the subject is called nominative, while that of the direct object is accusative. Since only subjects are associated with agreement in English, this may be taken as a sign of nominative case. Objects are not overtly marked with accusative case, but their grammatical function can be determined by their position following the verb.

Another way in which agreement appears functionally similar to case is through its interaction with transitivity. In languages like Japanese, transitive and intransitive subjects take the same case-marker, and in opposition to objects. This is known as a nominative/accusative case-marking system. English is essentially the same with respect to agreement—that is, it pertains to both types of subject. In some languages, however, intransitive subjects and transitive objects pattern in the same manner, in contrast to transitive subjects. Dyirbal (Australian) has a case-marking system of this type, known as ergative/absolutive (transitive subjects are marked with ergative case). Languages that employ agreement, rather than case to signal grammatical functions can exhibit the same pattern, as in Mam (Mayan) below (ABS = absolutive; ASP = aspect; ERG = ergative):

(4)   *Ergative/absolutive agreement (Mam)*

    a. ma   chiin-x-a
       ASP 1SG/ABS-go
       'I went'
                  [INTRANSITIVE]

    b. ma   chin-ok   t-tzeeq'an-a
       ASP 1SG/ABS   2/ERG-hit
       'You hit me!'
                  [TRANSITIVE]

Why is it important to indicate grammatical functions? Many linguists believe that languages use these devices to identify the participants in the event specified by the verb. In a sentence like 'The President hires young assistants', for example, the verb calls for two participants: someone who initiates the action (the President), and someone/something affected by it (young assistants). The first is sometimes called an Actor, the second (in this sentence) a Patient or Undergoer. Grammatical functions signaled by subject agreement and accusative case (the latter by virtue of its position following the verb) ensure that each participant is interpreted correctly, or that the sentence does not mean 'Young assistants hire the President'. Languages that employ neither case-marking nor agreement must obviously find some other way of interpreting such potentially ambiguous sentences.

Agreement and Inflection

Agreement is often called an inflectional category, as opposed to lexical ones like nouns, verbs, and adjectives. Other inflectional categories include tense, mood, and aspect. Sometimes, agreement is fused with one or more of these to form a single entity. This is the case with the English suffix -s: not only does it signal a third-person singular subject but also present tense and indicative mood. Agreement disappears in the past tense and/or indicative mood: cf. *John **lives** in Maryland now, but last year he **lived** in Maine; Mary wants to stay, but it is necessary that she **leave*** (NOT: ***leaves***). Still, there is some debate as to whether agreement is truly absent from these forms or simply covert—that is, 'present but invisible'. In German, for example, agreement is perfectly compatible with the past tense, and in Palauan (Austronesian) with the irrealis mood (similar to nonindicative):

(5) *Agreement and past tense (German)*

1SG	ich glaub-t-e	'I believed'
2SG	du glaub-t-est	'You believed'
1SG	wir glaub-t-en	'We believed'

(6) *Agreement and irrealis mood (Palauan)*

	REALIS	IRREALIS
1SG	ak-	ku-
2SG	ke-	omo-
3SG	ng-	le-

Object agreement is often associated with the inflectional category aspect. Again, in Palauan, objects of completed events trigger 'perfective' agreement on the verb, whereas objects of ongoing ones do not (IMPF = imperfective; NM = noun-marker; P-preposition; PF = perfective; R = realis):

(7) *Agreement based on aspect (Palauan)*

a. ng-chillebed-ii a bilis
   R3SG-hit-PF3SG NM dog
   'S/he hit the dog'
   [PERFECTIVE]

b. ng-milengelebed er a bilis
   R3SG-hit (IMPF) P NM dog
   'S\he was hitting the dog'
   [IMPERFECTIVE]

The relationship between agreement—which basically pertains to nouns—and tense, mood, and aspect (a property of verbs) is therefore sometimes quite intricate, and poses a major challenge for linguists attempting to explain it.

Nonstandard Cases

While subjects normally trigger agreement in English-tensed clauses, there are a number of cases in which it is suppressed and/or the status of the subject itself is called into question. One case involves 'subjunctive' mood, following verbs like *suggest* and *demand*: cf. *I demanded that he **be** on time; We quickly suggested that she **leave*** (compare: *…that she **should** leave*, which is also acceptable but does not show signs of agreement). Other languages show reduced forms of agreement under negation, or when one grammatical function or another is questioned:

(8) *Reduction of agreement (Chamorro/ Austronesian)*

a. Ha-fa'gasi si Juan i kareta
   3SG-wash Juan car
   'Juan washed the car'
   [NORMAL AGREEMENT]

b. *Hayi ha-fa'gasi i kareta?
   who 3SG-wash car
   'Who washed the car?'
   [WH-QUESTION/NORMAL AGR]

c. Hayi fuma'gasi i kareta?
   who wash+UM car
   'Who washed the car?'
   [WH-QUESTION/SPECIAL AGR]

The existential *there* construction in English arguably has two subjects: one occurring in clause-initial position (filled by *there*), the other post-verbally and signaling agreement: cf. *There's a man standing on the corner* vs. *There **are** three men standing on the corner.* Nevertheless, speakers sometimes take the clause-initial subject as the agreeing one, resulting in sentences like *There's four things that can be said about him.* Other nonstandard (but occurring) breakdowns involve plural complements of singular subjects (*Neither one of you guys **are** going to win*), and coordinate (hence plural) subjects with singular marking on the verb: *The fact that we were bombed, and that the markets reopened so quickly suggests that the foundations of our country are quite strong.*

Exotic Forms of Agreement

Agreement in natural language can deviate significantly from single forms that encode features of person and number. In Potawatomi (Algonquian), each of

these features can be associated with a separate morpheme (OBV = obviative):

(9) *Split agreement (Potawatomi)*

1SG	n-wapm-a	'I see him'
2SG	k-wapm-a	'You see him'
3SG	w-wapm-a-n	'He sees him (OBV)'
1PL	n-wapm-a-mun	'We see them/him (OBV)'
2PL	k-wapm-a-wa	'You see him'
3PL	w-wapm-a-wa-n	'They see them/him (OBV)'

Here, the prefixes [n-], [k-], and [w-] represent first, second-, and third-person subjects, regardless of their number. The suffixes [-wa] and [-mun] indicate plurality (the latter also encodes features of the object, i.e. plurality and/or obviation). Interestingly, the same prefixes and suffixes also appear on nouns to indicate possession and number:

(10) *Nominal agreement*

(Potawatomi; c = alveopalatal affricate)

1SG	n-ciman	'my canoe'
2SG	k-ciman	'your canoe'
3SG	w-ciman	'his/her canoe'
1PL	n-cimanwa-nan	'our canoe'
2PL	k-ciman-wa	'your canoe'
3PL	w-ciman-wa	'their canoe'

In the larger picture then, agreement must be regarded as more than just a property of verbs. 'Subjects' of NPs (possessors) corrolate with sentential subjects: it is no accident that the possessive marker [-s] in English has the shape it does (cf. *John's dog*). In Irish and other Celtic languages, prepositions inflect for the person/number features of their objects; this grammatical relation roughly correlates with sentential objects.

To fully appreciate how complex agreement can be, consider that objects of transitive verbs in Potawatomi can also be associated with separate morphemes of person and number. In (9) above, the suffix [-a] signals that the object is a third person, while [-n] registers its plurality and/or obviation; also notice how the subject plural marker [-wa] intervenes between these two suffixes.

Inuktitut (Eskimo) takes a different tack in the distribution of agreement features, using single forms called portmanteau to encode the person and number of both subject and direct object (ABS = absolutive; AL = allative; CMT = comitative; PRT = participle; REL = relative):

(11) *Portmanteau (Inuktitut)*

a. tuni-jara   nutarar-mut
give-PRT/1SG/3SG child-AL

arna-up   taku-jaa-nut
woman-REL   see-PRT/3SG-AL
'I gave it to the child that the woman saw'

b. arna-up   pilauti-milk
woman-REL knife-CMT

angut   tuni-jaa
man (ABS)   give-PRT/3SG/3SG
'The woman gave the man the knife'

In (11a), the form [-jara] signals a first-person subject and third-person object, while in (11b) [-jaa] indicates two third persons.

Evolution of Agreement

One might well ask why agreement is so pervasive in language, or where it comes from. Many morphemes appear to originate as independent pronouns that slowly undergo a process of phonological reduction and subsequent attachment. A comparison of pronouns and agreement from Udi (Caucasian) demonstrates this most clearly:

(12) *Pronouns and agreement (Udi)*

	AGREEMENT	PRONOUNS
1SG	-zu, -z	zu
2SG	-nu, -n, -ru, -lu	un
3SG	-ne, -le, -re, -n	meno, kano, seno
1PL	-yan	yan
2PL	-nan, -ran, -lan	van, efan
3PL	-q'un	met'ovon, kat'ovon, set'ovon

Although the match-up is far from complete, there is enough similarity of form to allow for a theory of language change. Independent/emphatic pronouns may pass through an intermediate stage of cliticization on their way to becoming agreement morphemes. Pronominal clitics also share the fundamental features of person, number, and gender. French has a series of subject-markers traditionally regarded as pronominal: *je, tu, il,* etc. Nevertheless, these forms cannot be separated from the (auxiliary) verb like their English counterparts; cf. **Il vraiment est retourné* vs. *He really has gone home.* This suggests that *je, tu,* and *il* are clitics, and in the frequent presence of emphatic pronouns may

someday evolve into a new series of agreement morphemes (cf. *Moi, je vais retourné*). Also, note that (except for first- and second-person plurals) the traditional agreement suffixes of modern French are no longer pronounced.

Theory of Agreement

How do linguists analyze agreement? Usually, a local relationship is assumed to hold between the element that triggers it (e.g. the subject NP), and an inflectional head, which may be comprised of tense, mood, or aspect. Agreement is the visible sign of this relationship. This explains why only verbs in tensed clauses show agreement—at least in English. In structural terms, the subject NP is called the specifier of the clause, attached to but outside the immediate domain of inflection: [NP [verb+inflection, etc.]]. This also parallels the internal structure of the NP, where articles like *a, the,* and *some* are attached to but outside the immediate domain of the noun: [the [dog]]. In fact, possessed NPs (e.g. *John's dog*) can be assigned essentially the same structure as a clause if the possessor (*John*) is regarded as a specifier, and the sign of possession ([-*'s*]) as a kind of inflection. It is probably no accident that English uses the same sound to express both specifier–head relationships.

The function of agreement—that is, as a means of highlighting one participant in the event described by the verb—can be explained in the following way. First, a verb's meaning is more closely comprised of its non-Actor participants than its Actor participants. The verb *to kill,* for instance, can involve essential information that is separate from the person who initiates the action (cf. *kill an hour, kill a motion, kill the mood, kill the light*—in addition to the standard meaning 'cause to die'). Languages typically recognize this distinction through the mechanism of case-marking, and non-Actor participants are often made visible through cases selected by the verb. Actors, on the other hand, are less likely to be singled out by case. Instead, they must rely on some other mechanism to be rendered visible, such as agreement. Inflection then—the head of every clause—provides a specifier position that can accommodate one non-case-marked participant for every verb.

Ainu

The Ainu are an indigenous group found mainly on the northern Japanese island of Hokkaido. Physically and linguistically distinct from the neighboring Japanese, at one time the territorial range of the Ainu extended throughout the northern Japanese island of Hokkaido (Yezo), including the Kurile islands to the northeast and southern Sakhalin (Karafuto) to the north. Evidence from place names, however, suggests that at one time the Ainu had also settled in northern Tohoku, on the main Japanese island of Honshu, and on Russia's Kamchatka Peninsula as well. Due to resettlement of the Sakhalin Ainu (1875) and the Kurile Ainu (1884) today, however, the majority of the remaining Ainu are situated on the island of Hokkaido. It should be noted that the Ainu language found in northern Japan is unrelated to the Turkic language bearing the same name that can be found in western China.

The genetic and linguistic history of the Ainu has been the topic of much debate. Physical features such as increased body hair (when compared to the Japanese) and more distinct facial features make the Ainu appear Caucasian to many people and as such the Ainu have sometimes been considered Caucasian (Caucasoid) in ancestry. Other scholars have sought to draw a relationship between the Ainu and native

American groups. Recent studies conducted with DNA testing, however, suggest the possibility that the Ainu are Mongoloid in origin.

Numerous attempts have been made to classify Ainu linguistically, including theories that place Ainu in the Malayo-Polynesian, Paleo-Asiatic, and Ural-Altaic language families. At present, there are several competing theories on the relationship of Ainu with other languages. The first and most widely offered explanation is that Ainu is a language isolate, with at present no apparent relationship with other languages. The second theory rests on the assumption that Ainu is related to the Altaic language family, and languages such as Japanese and Korean. Some studies arguing the latter position suggest that if Ainu is at all connected to other Altaic languages, then the splitting of Ainu from Japanese and other Altaic languages must have occurred at least 10,000 years ago. However, Alexander Vovin (1993), in his work on reconstruction of Proto-Ainu (the hypothesized ancestor language), suggests a connection to the Austro-Asiatic languages of the south. Further complicating matters has been the historical lack of a writing system, and as a consequence, a written record of Ainu over time. The relatively rapid transition from a viable, functioning language with monolingual native speakers to one that is, at present, nearly extinct has further confounded attempts to conclusively place Ainu among the world's languages.

The Ainu have had a continuous presence in Hokkaido for at least the past 1300 years. The first record of the Ainu on Yezo occurs in the Japanese *Kojiki* (A.D. 720) calling them 'Emishi', or those outside of the Japanese law. The Ainu refer to themselves as *Utari* or 'compatriot' in Ainu, and this term is in more frequent use at present because of the sometimes negative connotations that have been leveled on the term 'Ainu' by the Japanese. The word *Ainu* simply means 'human'.

While no written form of Ainu existed until recently (Ainu is now written in Romanized form or with the Japanese *katakana* script), the Ainu culture has developed a rich oral tradition most well known for their epic poems called Yukar. Yukar follow traditional patterns in their subject matter with some of the Yukar told from the perspective of an animal, others based on activities of ancestors, and still others are hero tales. The Yukar differ from the spoken language, tending to exhibit more complex (polysynthetic) word structures and more conservative features than spoken Ainu. These stories have served as a rich source of linguistic material as they maintain archaic forms, providing a rich source of data attesting to earlier forms of the Ainu language. Yukar has come to be a collective term

for all forms of epic story in Ainu but as Masayoshi Shibatani notes,

> In the strict sense of the term yukar refers only to the heroic verse, mythic epics being more specifically referred to as kamuy yukar, mat yukar, or oyna. There are as well prose-style old stories and folktales.

As noted above, Ainu is a polysynthetic language, where words tend to be composed of multiple morphemes. This is particularly the case in classical Ainu. In contrast, colloquially spoken Ainu tends to be more analytical, with more of the morphemes appearing as independent words, suggesting the possibility of a long-term change in progress.

In terms of its grammar, Ainu is a S(ubject)–O(bject)–V(erb) language. But, as seen in the following example, word order is important in determining the grammatical relationship in Ainu.

Kamuy aynu rayke.
bear person kill
'The bear killed the man.'

Aynu kamuy rayke.
person bear kill
'The man killed the bear.'

Phonologically, Ainu has a five-vowel system (/a/, /i/, /e/, /o/, /u/) with syllable-initial vowels preceded by a glottal stop. The consonants of Ainu, 12 in all, include the stops of /p/, /t/, /k/, and the glottal stop, sibilant /s/, glottal fricative /h/, affricate /c/, semi-vowels /w/,/y/, nasals /m/ and /n/, and the liquid /r/. Ainu has a pitch accent system in which syllables are pronounced with high or low pitch. Its syllable structure is C(onsonant)V(owel) or CVC. The exception to this, however, is the Sakhalin dialect, which contained long and short vowel contrasts, also allowing for CVV to occur. Vowel sequences tend to be avoided in other forms of Ainu. Vocalic euphony or vowel harmony, the assimilation of a vowel to another vowel in the word or phrase, is one of the more notable aspects of the sound system of Ainu.

The Ainu vocabulary is rich with references to nature, reflecting the close relationship held between the people and natural phenomena. Most Ainu villages (called *kotan*) were located alongside rivers and coasts and former Ainu settlements are easily recognizable in place names today with endings such as -*nai* or -*pet* (-betsu is the Japanese representation), both meaning 'river', as found in the place names of Wakkanai, Noboribetsu, and Monbetsu. The importance of salmon and bears to Ainu culture is represented by the

abundance of lexical items related to these two animals. Particularly, the role of the bear was an important part of Ainu culture, and they were often kept in villages for ceremonial events and as food.

Within Ainu, three distinct dialect groups are generally recognized, the Kurile, Sakhalin, and Hokkaido dialects, each representing the distinct regions where the Ainu once inhabited. The last speaker of the Sakhalin dialect is believed to have died in 1994. Within these dialect groups, further distinctions can be made, such as that between southern and eastern Hokkaido Ainu. At least 19 dialects of Ainu have been identified, most of which are now extinct.

It is estimated that the number of Ainu descendants (including those of mixed Ainu-Japanese heritage) number around 24,000, with those of solely Ainu descent being very small. Postwar census figures classify the Ainu as Japanese for census purposes; therefore, only estimates of the number of remaining Ainu in Hokkaido are possible. Discrimination aimed at the Ainu by Japanese as well as a Japanese desire to view Japan as a single homogeneous society have further caused many Ainu to conceal their heritage. It is believed that the actual number of Ainu in Hokkaido may be double or triple the figure of the government estimate of 24,000 (1995). The Ainu face regular discrimination in employment and marriage opportunities. Such discrimination and fear of disclosing their Ainu ethnicity have, over time, contributed significantly to the loss of the Ainu language.

The Ainu language and culture have been impacted dramatically by the influx of the Japanese into Hokkaido, which began as early as the 1300s. The peak of the Ainu culture occurred in the thirteenth and fourteenth centuries, prior to the large-scale arrival of the Japanese (wajin), which began in the fifteenth century. From this point onward, battles with the Japanese in 1457, 1669, and 1789, as well as diseases such as smallpox, measles, cholera, and tuberculosis all took their toll on the Ainu.

In 1550, an agreement was reached between the Ainu and the Japanese to allow a Japanese settlement area on Yezo. This would be a turning point in Ainu-Japanese relations. Over the next three centuries, Japanese control of Hokkaido increased and finally in 1869 the official government-sanctioned colonization of Hokkaido began. The Japanese population of Hokkaido quickly grew to over 1 million, placing the Ainu in a minority. From this point onward, the Ainu were systematically stripped of their cultural and linguistic identity, land, and hunting rights through a forced assimilation policy of the Japanese government. Also during this period, disease again struck the Ainu, leading to a decrease in their population.

By 1871, many Ainu customs, including the tattooing of women's mouths and the burning of a familial household upon the death of a family member, were banned. The Ainu language was also banned as the Japanese government set out to assimilate the Ainu into becoming Japanese and officially classifying them as 'former aborigines'. In 1899, the Hokkaido Aborigine Protection Act was created; yet, despite its name, the act did little more than increase the efforts to assimilate the Ainu. The Japanese government encouraged the Ainu to shift from their traditional role as hunter/gatherers to farming. At the same time, Ainu lands were ceased. When land was redistributed to the Ainu, they were given the least fertile lands. In 1901, Ainu children were forced to attend Japanese primary schools and Ainu children began learning Japanese as their first language. The assimilationist policies of the Japanese government resulted in a near elimination of the Ainu language and culture by the mid-twentieth century. Today, there are no monolingual native speakers left.

Today, the Ainu are fluent Japanese speakers. In spite of the past Japanese efforts to eliminate the Ainu language, bilingual speakers of Ainu and Japanese do exist, however, and recently modest efforts have begun to continue the teaching of the Ainu language and traditions to those willing to learn. Ainu language use also continues in ceremonial and ritualistic use and in events performed for tourists. A preserved Ainu village at Shiraoi is maintained for educational and tourism purposes.

In 1946, the Ainu Association of Hokkaido was founded, seeking to bring increased attention to the fight for Ainu rights, the preservation of the language and culture, and a reevaluation of the Hokkaido Aborigine Protection Act.

In 1994, Shigeru Kayano became the first Ainu member of the Japanese Diet (parliament). Subsequently, in 1997, the Japanese government finally and officially recognized the Ainu as the indigenous people of Hokkaido and created the Ainu rights law. This law was designed to replace the Hokkaido Former Aborigine Protection Act. It requires local governments in traditional Ainu areas to support promotion of the Ainu culture, including promotion of the Ainu language. As a result, government-subsidized weekly Ainu language radio broadcasts are offered in Hokkaido with free texts that are widely available. There are also 13 state-supported language classrooms in traditional Ainu villages throughout Hokkaido that seek to provide opportunities for students to learn Ainu. A bi-weekly Ainu language newsletter has also been produced.

The 1997 Ainu rights law provided official recognition to the Ainu and a degree of legimaticy to the

efforts aimed at preservation and revitalization of the language. Whether the Ainu language will undergo a successful revitalization is dependent upon the ability of the Ainu to increase awareness among the Japanese of what might be lost, should the Ainu language and culture disappear.

Akan and Nyo Languages

Nyo, like Left Bank, belongs to the (New) Kwa subfamily of the Niger–Congo group. Nyo has more languages than the Left Bank. There are five daughter languages in Nyo: Agnéby, Attié, Avikam–Alladian, Potou–Tano (which accounts for over half of New Kwa in terms of both the speakers and geographical area), and Ga–Dangme. Potou–Tano is composed up of six language groups: Ega, Potou, Tano (previously called Volta–Comoé), Lelemi (and its related languages), Logba, and Basila–Adele. Westermann classified Avikam–Alladian, Agnéby, Attié, and Potou under the Lagoon subfamily; and Lelemi (and its related languages), Logba, and Basila Adele as Togo–Remnant languages.

Agnéby: The Agnéby languages, a Central Nyo group, are spoken in the Ivory Coast in the Agnéby and Bandama river basins by 230,000 people. Adioukrou, Abiji, and Abbey are the three languages in this group. Adioukrou (Adjukru) is spoken in the north of the Ebrié Lagoon westward of the Agnéby river by about 70,000 people. Abidji is spoken by about 80,000 people in the Abidjan District and in the subdistricts of Sikensi and Dabou. Abidji has two main dialects: Enyembe and Ogbru. Speakers of Abiji tend to be bilingual in Adioukrou, Baoule, and Jula. Important linguistic features include tone and nasalization on syllables. Abbey, spoken by about 80,000 people, is spoken around Agboville and to the north of the Abiji and Krobou areas. Examples of words and their plurals taken from Adioukrou are as follows:

libr 'red'   - ebr 'reds'
lufu 'white' - efu 'whites'
lorɲn 'snake' - morŋn 'snakes'

Attié: Attié is spoken in Côte d'Ivoire by about half a million people living in Abidjan, Anyama, Alep, Adzope, Affery, Agou, Akoupe, and Yakasse–Attobrou. The three main dialects of Attié are Anaindin (Nindin), Ketin, and Bodin (the most prestigious and populous). Most Attié speakers are bilingual in Abbey, Anyin, Baoule, Ebrie, and Jula.

Avikam–Alladian: It is a Western Nyo language spoken in the Western Ivory Coast. It has two languages: Avikam and Alladian. Avikam is spoken in the basin of the Bandama River by 12,000 speakers, whereas Alladian is spoken by about 15,000 people on the east of Avikam.

Potou–Tano: The six language groups identified under Potou–Tano are Ega, Potou, Tano, Lelemi (and its related languages), Logba, and Basila–Adele.

Ega: Ega was originally classified as Kru, but Richards (1982) proved that it is Kwa. It is located inside the Kru area. Like other Kwa languages, Ega has a reflex of the cognate (words maintained by languages of common ancestry) nyɔ /ɲõ/ 'two'.

Potou: It is spoken in the Eastern Ivory Coast Lagoon area by about 75,000 people. Potou has two languages:

Ebiré (spoken by 60,000 people in the north of the Ebiré Lagoon from the Agnéby River to the Potou Lagoon in the east) and Mbatto (spoken by about 15,000 between the Potou Lagoon and the Comoé River).

Tano: Tano, previously called Volta–Comoé, has more speakers than any of the subfamilies of the Potou–Tano group. Tano has four subfamilies: Krobou, Western Tano (Abouré and Eotilé), Central Tano (Bia, Akan), and Guang (Southern and Northern). Krobou has about 6000 speakers and is spoken within the Agnéby language area in the Ivory Coast. Abouré and Eotilé are also spoken in the Ivory Coast. Abouré is spoken by about 40,000 people in the Comoé River basin near the sea, whereas Eotilé is spoken by 3000 people in Vitre #I and Vitre #II on the Ebiré Lagoon to the north of Grand Bassam.

Bia: The Bia languages, sometimes referred to as Nzema–Anyi–Baule, are spoken by nearly two and a half million people in the Bia, Tano, Nzi, Bandama, and Comoé River basins and along the south coast of Ghana and the Ivory Coast. The two main subgroups are: Northern Bia (comprising Anyi, Baule, Chakosi (Anufo)); and Southern Bia (Nzema and Ahanta). Anyi and Nzema are spoken in Ghana and in the Ivory Coast, Baule in the Ivory Coast, Ahanta in Ghana, and Chakosi in Ghana and Togo. Nzema has two dialects: Nzema and Evalue. Anyi also has two dialect groups: Anyi (Aowin) and Sehwi (Sanvi). Anyi has other dialects like Indene, Moronou, Bona, Djoablin, Ano, and Bini (all in the Ivory Coast), and Afema and Brossa in Ghana. Baule, with nearly one and a half million speakers, is the largest language group in the Bia subfamily. Chakosi is found in an enclave in the Gur territory on both sides of the Ghana–Togo border. In Togo, Chakosi is found in Sansanne–Mango and in Ghana, in the Chereponi area. Most speakers of Nzema (about 120,000) are found in Ghana; in the Ivory Coast, there are about 50,000 speakers.

Important linguistic features in the Bia group include consonant mutation (in which consonants change some of their phonetic qualities in certain phonetic or grammatical contexts. For example, in Nzema /k/ changes to /h/ between vowels. /k/ in *kɔ* 'go' becomes /h/ in *jihɔ* 'she's gone') and vowel harmony (cooccurrence restrictions in the distribution of vowels, i.e. the vowels are grouped into two sets and in words of more than one syllable; only vowels from one set occur. For example, in Nzema, words *otosu* mean 'he still cries' and *ɔtɔkʊ* 'he still fights'; all the vowels in *otosu* are produced with an advanced tongue root position, whereas those in *ɔtɔkʊ* are produced with a retracted tongue root). Other linguistic features include double articulated sounds

(single sounds with two different places of articulation, e.g. /kp, tp, gb/ . For example, in Chakosi, the words *kpiɛ* 'old man' and *gblaki* 'to faint' have /kp/ and /gb/, respectively). Bia languages also have tone terracing, where pitch is lowered toward the word end. Plural is formed through affixation. For example, in Baule, the plural marker {-mũ} can be added to any count noun. For example, *wa* 'child' *wamũ* 'children,' ti 'head' *timũ* 'heads.' There are also independent nasalized vowels (phonemic nasalization of vowels). For example, in Baule, *wu* means 'see', whereas *wũ* means 'die'.

Akan

Akan is the largest of the Central Tano group of languages. Until the 1950s, these clusters of mutually intelligible varieties did not have a single name. Some of the dialects (such as Fante, Bono, and Wasa) were viewed as different languages. However, a unified Akan orthography was designed by the Akan Orthography Committee in the 1950s and since then, the name Akan has been adopted as the name of the language.

Akan is spoken by over ten million people in Ghana and in the Ivory Coast. In Ghana, Akan is spoken between the rivers Tano and Volta, stretching from the coast to the inland. Abron (Bono) or Dormaa is spoken in Ghana and in Côte d'Ivoire by about a million people. In Côte d'Ivoire, Akan (Abron) is spoken in the northwest by about 60,000 people. Speakers of Abron speak and understand Asante Twi. Wasa is spoken by nearly 300,000 people in Southwestern Ghana. It has two main dialects called Amenfi and Fianse. Wasa and Abron are mutually intelligible.

In Ghana, Akan is spoken by nearly half of the population as their mother tongue and by two-thirds of the population as a second language. Akan has 11 dialects: Fante (Mfantse), Akuapem, Asante, Agona, Dankyira, Asen, Akyem, Kwawu, Ahafo, Bono (Abron), and Wasa. The Akuapem, Fante, and Asante dialects have different officially recognized orthographies and are used on radio and TV. Quite recently, a unified orthography for all the Akan languages has been adopted.

The Twi (Asante–Akyem–Kwawu) dialects are the largest dialects, with a total population of over seven million. Fante, spoken along the coast, has over two million speakers and four important dialects: Agona, Gomua, Abura, and Anomabu. Akuapem is spoken on the Akwapim Hills between the Akyem and Ga areas.

Important linguistic features include a Subject–Verb–Object word order, example:

S   V   O
Kofi   *nom*   *nkwan* 'Kofi drinks soup'
Ama   *dɔ*   *Kwame* 'Ama loves Kwame'

Akan languages also have two types of vowel harmony: cross-height and rounding. With respect to cross-height harmony, we observe that the vowels are grouped into two sets: advanced /i, e, æ, o, u/ and unadvanced /ɪ, ɛ, a, ɔ, ʊ/. In any word of two or more syllables, only vowels of one harmonic set occur. For example, *obewu,* 'She'll die', has vowels from the advanced set, whereas *ɔbɛwʊ,* 'She'll give birth', has vowels from the unadvanced set of vowels. With respect to rounding harmony, in some of the Akan languages, especially in Fante, vowels of verbal affixes agree with those of a verb root by being advanced or unadvanced, rounded or unrounded. For example, *muruwu,* 'I'm dying', has only rounded advanced vowels, whereas in *miridzi,* 'I'm eating', all the vowels are both advanced and unrounded. Rounding harmony is also found between vowels of nominal roots and affixes in the Asante and Akyem dialects. For example, the vowel of the noun suffix /o/ in *owuo* 'death' agrees in rounding with the vowel /u/ of the noun root, *owu* 'die'. The vowel /e/ suffix of the noun root *esie* 'hill' harmonizes with those of the root /e, i/ by being unrounded.

The Akan languages have uncommon sounds like the alveolo-palatal semivowel /ɥ/, labio palatalized alveolo-palatal affricate /tɕɥ/, occurring in words like we /ɥi/'chew' and Twi /tɕɥi:/ 'name of some Akan dialects'.

Another important feature of the Akan languages is tone terracing (especially downdrifting, where, during the production of long utterances, there is a gradual drop in pitch heights if high tones are interspersed with low tones. The drop in pitch could be such that an utterance final high tone could be lower in pitch than an utterance initial low tone. The final drop in pitch could also reach the bottom of a speaker's pitch range. For example, in: *Pàpá Kòfí dìdí wìé kòtìé* 'Father/Mr. Kofi finishes eating and goes to listen', the initial low tone on /pà/ of *Pàpá* is higher in pitch than the final high tone on /é/ of *kòtìé.*

Guang: The Guang subfamily, which is spoken by about half a million people in Ghana, The Ivory Coast, Togo, and Benin, has more languages than the Central Comoé group. However, the languages in this subfamily are for the most part spoken by small numbers of people. This group of languages subclassify into: North, North-East, Central, and South. North Guang languages include Gonja, Nkonya, Nawuri, and Choroba. Gonja (Ngbanito) is spoken in a large area from Bole to Kamabuie near Salago and between the White Volta, Volta, and Daka rivers in Ghana. In the Ivory Coast, Gonja is spoken in the Bondoukou and in Togo it is spoken at Semere and is called Bazantcé. The Gonja variety spoken in the Republic

of Benin is referred to as Chombulon or Tshummbuli (similar to a Ghanaian Central Guang variety called Nchumburu).

Southern Guang subdivides into Coastal Guang (a dialect cluster—Awutu, Efutu, and Senya). Awutu is spoken in Winneba, Senya Breku, Obutu, and Bawjiase in Ghana, spoken by about 200,000 people, and Hill Guang is spoken by about 150,000 people on the Akwapim Hills and on the left bank of the Volta Lake. Important dialects include Cherepong, Larteh, and Anum (Gwa).

Other Guang subfamilies include Lelemi-Lefana (Buem), Akpafu (Siwu), and Santrokofi spoken in Ghana and Togo by about 45,000 people; Logba spoken by about 4,000 people on the Ghana–Togo border; and Basila–Adele, comprising the Basila and Adele dialects, is spoken by about 10,000 in both Ghana and Togo. Basila has three subdialects: Gokolodjya, Gilempla, and Giseda. Adele has more speakers in Togo (7,000) than in Ghana (3,000).

Like the Akan group of languages, the Guang languages have advanced tongue root vowel harmony. For example, in the following Efutu words, all the vowels are either advanced *oɲi* 'man'or unadvanced *ɔkʊ́ɔ̀* 'again'. The harmony may operate over entire sentences. For example, *muudi nu* 'She is eating (food)'; *mʊ́ǹwɔ́* 'She did not go'.

Negation is formed through affixation and consonant alternation. For example, in Siwu, in negating commands, voiceless stops change into voiced stops and voiced stops become nasals. Also, the morphemic particle daa is preposed to the main verb. Example, *kɛ̀lɛ̀* 'go' dàágɛ́lɛ̀ 'don't go'; *kpɛ̀* 'weed'; dàágbɛ́ 'don't weed'.

Ga–Dangme: Ga–Dangme has two languages: Ga and Dangme. The Ga–Dangme subfamily is spoken in Ghana on the southeastern coast around Accra and inland. Ga is spoken in Ghana along the coast in and around Accra (Ghana's capital), and in the Densu and Kpone basins by about 500,000 speakers. Dangme (Adangme) is spoken along the coast (to the east of Ga) and at the mouth of the Volta and also in the Akwapim Hills. Like Ga, Dangme has over half a million speakers. Dangme has six dialects: Ada, Ningo, Prampram, Shai, Krobo, and Osudoku. Krobo is the largest dialect, with about 300,000 speakers. Structurally, Ga has two tones, High and Low, and a downstepped high tone (a high tone whose pitch has been lowered. Downstep is marked with an exclamation mark placed before the syllable). For example, *ékòmé* 'one', *gbé!kɛ́* 'boy'. Plurals are formed through affixation, (suffixation). For example, *tsò* 'tree', *tsèi* 'trees'; *tʃù* house' *tʃùi* 'houses'. There are three tones, High, Mid, and Low, in Dangme.

Albanian

Albanian is the name English speakers use to refer to the language of Albania (Albanians call the language 'shqipe'), as well as for the branch of the Indo-European family to which it belongs. As a branch of Indo-European, Albanian is a sister to many language groups from Europe to South Asia: Germanic (including English, Swedish, and German, for example), Romance (including French, Spanish, and Italian), Slavic (including Russian, Serbian, and Polish), Indic (including Hindi, Gujarati, and Urdu), Hellenic (Greek), Armenian, and Celtic (including Irish and Scottish Gaelic). Persuasive evidence for the kinship of Albanian with other Indo-European languages was first advanced in the middle of the nineteenth century and continues to be amassed. In addition to regular correspondence of sounds between particular words and parts of words in Albanian with those in several already established Indo-European languages, the evidence lies in features of Albanian verb conjugation and noun declension that reflect a common origin with those languages: for example, the irregular forms of certain verbs (e.g. Albanian *është*=English *is*=Latin *est*=Sanskrit *asti*, while Albanian *jam*=English *am*=Latin *sum*=Sanskrit *asmi*).

Albanian linguists claim that the predecessor of modern Albanian is the ancient Illyrian language, but since little is left of Illyrian, verification for this claim is elusive. The earliest texts clearly identifiable as Albanian are scarce and go back only to the fifteenth century; we have no record of the characteristics of the language during earlier periods, although extensive documentary evidence exists for many other Indo-European languages. To complicate the task of tracing its origins, Albanian, like English, has adopted and adapted a great substance of the vocabulary from other languages throughout its history—in earlier times, basic vocabulary from Latin and Turkish and more recently, technical vocabulary from Italian, Russian, and English.

Today, Albanian is spoken by more than six million people—about three million in Albania itself, another two million in Kosovo, some 300,000 in Macedonia, and at least 700,000 more living mainly in Montenegro, Greece, Turkey, Italy, and the United States. In recent years, both voluntary and forced emigration of Albanians has greatly increased the presence of speakers of the language outside their homelands.

During its known history since the fifteenth century CE, Albanian has been associated with two main dialects: Tosk in the south and Gheg in the north. After World War II, the government made increasingly successful efforts in Albania to adopt a unified written form of the language, called Standard Literary Albanian, and in 1968 this form of Albanian was also adopted for schools and mass media by Albanians in Kosovo. However, for ordinary conversation, few Albanians in Albania and Kosovo completely abandoned their own dialects. In rural areas, 'unified Albanian' may be scarcely used and known only from television and radio, and even well-educated, urban Albanian speakers exhibit regional and social differences in their language, which appear in pronunciation, vocabulary, and grammar. The speech of Albanian speakers living outside Albania reflects their Gheg or Tosk origins.

A modern alphabet was devised for Albanian in 1908. This 36-letter alphabet includes six digraph letters (*th, dh, sh, zh, gj, nj*) and two special characters (*ë and ç*), and was adopted quite readily by speakers. For Gheg words, a carat (^) is used to mark nasalized vowels, but the vowel length so distinctive to Gheg dialects remains unmarked in written Albanian.

In addition to its genetic membership in the Indo-European language family, Albanian shares certain specific features with other Indo-European languages in the Balkan area. For example, like Romanian, Albanian marks 'definiteness' (in English, marked by the word *the*) by endings on nouns: Albanian *gjysh*, 'grandfather' becomes *gjyshi*, 'the grandfather';

similarly, Romanian *bunic*, 'grandfather' becomes *bunicul*, 'the grandfather'.

Particular features of Albanian seem particularly striking to non-Albanians. Already mentioned is the vast number of loan words from the international vocabulary—such as *heroik, burokrat, standardi-zon*—as well as many words from Turkish (during the 400-year occupation of Albania under the Ottoman Empire), such as *penxhere* (window), *fukara* (poor or pauper), and *çoban* (shepherd). Foreign names are generally spelled in Albanian to approximate their sound—to an Albanian ear—in the language from which they derive, so that Heather Lockwood would become Hedhër Lakvud.

As in many other languages, Albanian indicates the grammatical function, or case, of a noun with noun endings. Thus, *gjyshi*, 'the grandfather', is the subject of a verb, but as the direct object of a verb it takes the form *gjyshin*, and as the indirect object of the verb, it takes the form *gjyshit*.

The verb system in Albanian is quite complex. Simple verbs not only have different endings to indicate whether their subject is the person speaking ('first person'), the person spoken to ('second person'), or someone or something else ('third person'), but also whether that subject includes the person speaking ('first person plural'), the person addressed ('second person plural'), or is entirely composed of others ('third person plural'). Those endings also indicate whether the time is present or past; if past, the ending indicates whether the verb applies over time or at a particular moment.

Another set of endings indicate whether the subject is itself the object of the verb. These 'medio-passive' endings are used for a range of functions that are quite different in English. For example, *e rruan* means 'they shave him', but *rruhen* can mean, 'they are shaved' (passive), 'they shave themselves' (reflexive), or 'they shave one another' (reciprocal). Still other sets of verb endings can express the speaker's surprise or dismay, and yet others may express a wish.

Pronouns also take different forms for varying grammatical functions. For example, as subjects of verbs, objects of verbs, and objects of certain prepositions, first- and second-person pronouns have the accented forms shown in Table 1.

Albanian lacks corresponding forms for third-person pronouns, but instead uses a complex system of 'pointing' words that convey the perceived distance of the referent, as well as the referent's number, gender, and case (see Table 2).

Unaccented pronoun forms indicate that the verbs immediately following have an object (direct or indirect) (see Table 3).

These forms appear whether or not an accented object is also present in the sentence, so that 'Agim told me' is *më tha Agimi*, and 'Agim told *me*' is *më tha Agimi mua*; similarly, 'Agim told her' is *i tha Agimi*, and 'Agim told *her*' is *i tha Agimi asaj*. Unaccented third-person direct objects may occur in combination with any unaccented indirect object, yielding the forms shown in Table 4.

The position of the unaccented pronoun (or combination) in Albanian is unique among Indo-European

languages in one particular aspect: in positive commands, it may come directly after the verb, but if the command is addressed to a plural 'you', then it comes before the verb ending.

Finally, Albanian is unusual among languages in its use of a set of 'attributive articles', which indicate that the word after it refers to a noun or pronoun, its 'referent', which may or may not be present in the sentence. The choice of which of the four members of this set (*i, e, të, së*) is to be used is determined by the grammatical form of the referent. Pure adjectives must always be preceded by one of these articles: *këndim i mirë* 'good singing' with the adjective *i mirë* 'good' —contrast the adverb *mirë* 'well' as in *këndon mirë* 'He or she sings well'.

Any noun with a 'genitive' case ending can be preceded by one of these attributive articles, functioning much like English *of* to indicate possession—*djali i Gjonit* (the son of John, or John's son)—but more often to indicate some looser relationship in which the noun after the attributive article narrows the scope of its referent. For example, such a construction may be used to identify:

- the substance of which something is made: *buka e grurit* (the wheat bread, or literally, 'the bread of the wheat')
- a quality that characterizes the referent: *aktet e trimërisë* (acts of bravery)
- the object of an action: *shkelja e rregullit* (the violation of the rule)
- the subject of an action: *ardhja e miqve* (the arrival of friends)
- the whole of which the referent is part: *gjysma e bukës* (half of the loaf)
- the identifying element of the referent: *muaji i korrikut* (the month of July)
- a characterizing quality after the verb 'to be': *është i gojës* (he is articulate, or literally, 'is of the mouth')
- the universe of a superlative: *më i madhi i djemve* (the biggest of the boys)

Among the small national languages of Europe, Albanian can claim a special pride in the consistency of its standard orthography and grammar, and the richness of its vocabulary.

Algeria

Algeria, officially the Democratic and Popular Republic of Algeria, is the second largest country in Africa with 919,595 square miles after Sudan, stretching from the shores of the Mediterranean to the Sahara Desert. It has a population of 31,736,053 (2001 estimate) and is divided into 48 provinces called wilayat and 700 local communes. The population consists of Arabs, Berbers (Kabyles being the largest group followed by Chaouia) and people of mixed Arab and Berber ancestry. Arabs form 80–83%, Berbers 16–20%, and others 1%.

Linguistic independence came rather late to Algeria. During the Muslim expansion of the seventh and eighth centuries, the Arabic language spread from the Arabian Peninsula to North Africa, supplanting the local languages. During the Ottoman Empire, the Arabic language was suppressed, as elsewhere in the Arab World. Later, the French conquest of Algeria in 1830 further complicated the linguistic situation. The authorities introduced French as the sole official language. Their main goal was to replace the Arabic culture by a more 'civilized' culture. The use of Arabic was generally limited to a small minority of religious scholars, and to the rural regions, where Arabic religious schools were set up to teach the *Qur'an.*

After gaining its independence from France in 1962, the Algerian government declared Arabic as the official language, which was a difficult task as very few Algerians were actually literate in Arabic. Teachers were imported from Arab countries such as Egypt and Syria. And in the 1970s, the Arabization policy required that street and shop signs be in Arabic, despite the fact that 60 % of the population could not write or read Arabic. Over the years, Algeria struggled between the pressure to eliminate any legacy from the French colonialism, to meet the demands of the Kabyles to adopt Tamazight as a second official language and to teach in schools, and to bear the costs of rapid Arabization. Arabic is held in high regard because it is the language of the Qur'an. With the spread of Islam, Arabic has become the most used language among the living Semitic languages. It is related to Hebrew, Aramaic, and Amharic. Subgroups of Arabic are Classical Arabic, Eastern Arabic, Western Arabic, and Maltese. The modernized version of Classical Arabic, which is referred to as Modern Standard Arabic, is the language that Arab countries use as their official language.

The linguistic situation in Algeria is complicated, and is a matter of intense discussion within the country itself. Algeria's population diversity is reflected in the large array of languages spoken. Seventeen languages are believed to be spoken in Algeria, Arabic and, most recently, Tamazight, being the official languages. The majority of Algerians speak Arabic, followed by French and Berber. Modern Standard Arabic, a simpler version of Classical Arabic, is taught at schools and is used in formal meetings and in the media, but is not used for ordinary conversation. The Algerian dialect, known as Darja, is used in everyday life. And increasingly, the vernacular is being used in theater and in novels because it is believed to reflect the Algerian culture.

After gaining independence, Algeria proceeded to 'arabize' education in order to rid the country of French influence. However, the fact that the country was trying to rediscover its roots while forcing its population into 'modernity' has pushed it to maintain French as a language of science and technology. Thus French became associated with high social and educational status. Arabization on the other hand was pursued for ideological reasons related to nationalism and religion.

Despite the efforts to introduce Arabization to rid the country of the cultural traces left by the long French colonialism, Algerians continue to use French for formal and informal conversations. In fact, French is considered by many the 'unofficial' official language, as it is used in most formal administrative meetings, gatherings, and various other functions. Modern Standard Arabic is used only in formal education, by the media, and for written purposes.

The policy that the Algerian government has adopted toward minority language groups has resulted in tension among the different language users. Arabization, the language policy aimed at expanding the role of Modern Standard Arabic to the detriment of French and local dialects and languages, led to dissatisfaction and resentment among the Berber ethnic minority and the French educated population. Opponents of this policy argued against making Arabic the exclusive language of instruction in public schools when French remains the language of science instruction at the universities.

Most Algerians speak Algerian Arabic, with educated and clerical masses speaking Modern Standard Arabic in formal situations. Arabs usually do not

speak Berber because it is not taught in schools. However, most Berbers speak Arabic and French, especially the younger generation. Currently, there is an active movement to regain the Berber language and teach it in schools. As of recently, Tamazight is being taught in the Kabyle major cities, but not in the non-Berber areas, although there are pockets of Berbers in every major city.

Even though the Algerian census does not gather information about household languages, the number of Berber speakers has been estimated to be as high as 6,000,000 speakers. The Berbers are considered to be the original inhabitants of North Africa. They have lived in Algeria since 3000 BC, or, according to some historians, as early as 8000 BC. The word Berber comes from the Greeks, who used this term to refer to the people of North Africa. Although Berber uses an ancient script called *tifhagh*, it is primarily a spoken language. Currently, Roman script is used to write the Berber language. Most Berbers, especially the Kabyles, maintain their own language and a sense of ethnic identity. The Chaouia, however, tend to be more assimilated to Arab culture than the Kabyles. The Kabyles refer to themselves as *Imazighen*, and to their language as *Tamazight*. The linguistic division between Arabic speakers and *Tamazight* speakers stems mainly from the government policies that favor the Arabic language over the other local languages such as Tamazight. For years, the Algerian government suppressed the Berber languages, depriving those who did not speak, write, or read Arabic from basic human rights such as reading the newspaper and watching television.

The Berbers, also known as *Amazigh* in North Africa, are the original inhabitants of North Africa. Because the Berbers have mingled with other ethnic groups over the centuries, especially the Arabs, their identification is purely linguistic and not racial. The Berber language (*Tamazight*) is primarily oral. Its written form is little known and rarely used. Like Arabic, the Berber language is a branch of the Afro-Asiatic language family. Many languages derive from the Berber language family. Some of the Berber languages, the number of speakers, and the geographical areas where they are mostly spoken are given in table.

As of 2003, 41 years after independence, French is still taught as a second language and is introduced at the second-grade level. French also remains the language of science instruction in all universities after a semi-unsuccessful attempt to arabize the educational system, including higher education. Attempts to substitute English for French as the second national language in the mid-to-late 1990s also failed. However, since 2003, English is being taught at the seventh-grade level, a year earlier than in previous years.

Berber Language	Number of Speakers	Geographical Areas
Kabyle	Up to 6,000,000 (1998)	In the Djudjura mountain range, and along the northern central and eastern coastal region, east of Algiers Main cities: Tizi-Ouzou, Dellys, Bejaia
Chaouia	1,400,000 (1993)	South and southeast of the Grand Kabylie region and south of Constantine, in the Aurès Mountains Main cities: Batna, Ain el Baidha, Ain Mlila
Chenoua	15,000–75,000 (1996)	Small towns east of Algiers
Tachelhit	Unknown	Southern Algeria near the Moroccan border
Tahaggart	25,000 (1987)	Southern Algeria in the Hoggar region Major cities: Djanet and Tamanrasset
Taznatit	40,000 (1995)	Around the city of Timimoun
Tumzabit	70,000 (1995)	Mzab region, 330 miles south of Algiers Main city: Ghardaia

Because the spoken Algerian Arabic is a simplification of Modern Standard Arabic, there is less distinction regarding number and gender. For example, the dual form and the feminine plural do not exist in the Algerian dialect. The Modern Standard Arabic masculine plural form is used in Algerian Arabic for dual, feminine and masculine, and for the feminine plural. Algerian Arabic consists of three major dialects spoken in three major cities: Algiers (center), Constantine (east), and Oran (west). These major dialects differ considerably from the dialects spoken by nomadic people in the Sahara.

Algerian Arabic vs. Modern Standard Arabic

Phonological Differences

Modern Standard Arabic is written from right to left and uses a root system, usually consisting of three consonants. For example, the English word 'merge' would be made up of the root 'm-r-g'. In Arabic, the word 'islam' is made up of the root 's-l-m'. The Arabic script uses symbols for only consonants and

long vowels. The short vowels are not written and are represented by diacritics. However, although morphological and grammatical meaning is indicated by vowels, the vowel diacritics are usually omitted. The reader has to infer its particular meaning and pronunciation from the context.

Even though the Algerian dialect is a variant of Arabic, its vocabulary differs considerably from Modern Standard Arabic. Many words originate from sources other than Modern Standard Arabic, such as Turkish, Spanish, Italian, and most of all *Tamazight* (Berber) and French. However, most of the vocabulary comes from Modern Standard Arabic with phonetic, phonological, and semantic changes. The examples below show Modern Standard Arabic words with Algerian Arabic correspondences. The elements in which the Algerian Arabic words differ from the Algerian Arabic ones are indicated in bold.

The French Influence

The Algerian dialect contains a good number of borrowed French words. However, the borrowed vocabulary is subject to Arabic rules of grammar and pronunciation. For example, French has nasal vowels, but Arabic does not. Therefore, the nasal vowels in borrowed French words are denasalized (1). Also, French sounds that do not exist in Arabic are substituted by Arabic sounds (2). As the Algerian dialect relies heavily on emphatism, loan words are no exception (3). Arabic has three short vowels, *a*, *i*, and *u,* and three corresponding long vowels, *a:*, *i:*, and *u:*. As a result, French vowels that do not exist in Arabic are replaced by one of the three vowels (short or long) (4). French influence extends to syntax as well (5).

French	Algerian Arabic
(1) *bouchon*	*bushu:n* (cork)
(2) *il roule*	*yru:li* (he wanders) The French *r* is replaced by the Arabic *r*.
une serviette	*serbita* (towel) The sound *v* is replaced by b.
une savate	*Sabba:t* (a shoe)
(3) *il sonne*	*ySu:ni* (he rings) The French s is replaced by the emphatic S.
une place	*bla:Sa* (a place)
(4) *un bureau*	*bi:ru* (a desk, an office) The French *ü* is replaced by *i:*.
(5) *une table*	*Tabla* (a table) The Arabic feminine indicator *a* is added.

The linguistic situation in Algeria depends on the future political situation. The Algerian people believe that if the Muslim fundamentalists come to power, the trend will be toward arabization of all sectors of life; on the other hand, if democratization is successful, bilingualism will be stressed with the French language used for the technical and hard sciences, and Arabic for social sciences and civil services. After years of political unrest, the political and cultural situations are far from being resolved. While a solution is being sought for the linguistic conflict, Modern Standard Arabic remains a foreign language for some of the older Algerians, especially the Berbers. However, recent attempts to make Tamazight a second national language have been somewhat successful. In 2002, President Bouteflika announced that the Tamazight language would become an official language in Algeria alongside Arabic.

Altaic

Altaic, in its broadest conception, is a family of languages composed of four subfamilies (Japanese-Okinawan, Mongolic, Tungusic, and Turkic) and two language isolates (Ainu and Korean). However, the status of this family remains a matter of controversy. On the one hand, some scholars who accept the genetic association of Mongolic, Tungusic, and Turkic (hereafter, Altaic proper) do not agree that there is a demonstrable relationship between Altaic proper and Japanese-Okinawan, Korean, or Ainu. On the other hand, some scholars question even the notion of Altaic proper. The skepticism often rests on purely methodological grounds; that is, although they accept the likelihood that Mongolic, Tungusic, and Turkic languages all stem from a common ancestor, some linguists doubt that enough evidence exists to prove this connection conclusively. In other instances, linguists reject even the likelihood of Altaic proper; they argue that the similarities among these language families are better explained by borrowing and contact-induced changes than by a genetic association.

Ainu is spoken on Hokkaido, the northernmost island of Japan, and on Sakhalin Island, which is part of the Russian Federation. Ainu is spoken only as a second language, primarily by older people. Only about 1% of the 18,000 to 25,000 ethnic Ainus claim an ability to speak the language, and the number of fluent speakers is probably a fraction of this small number.

Ainu, as is typical of Altaic languages, has a basic word order of subject–object–verb, but the connection with other Altaic languages is tenuous at best. Such a connection was proposed by John Street (1962) and was argued more forcefully by James Patrie (1982), but few accept Ainu as being part of the Altaic family.

Japanese-Okinawan, a subfamily of Altaic, consists of two branches. The first branch consists solely of Japanese, which is spoken by approximately 130 million people worldwide. The second branch, called Okinawan or Ryukyuan, consists of a set of ten languages, most of which are mutually intelligible to some degree. There are roughly 900,000 speakers of Okinawan languages, although very few of the languages are being transmitted to children at this point. Japanese and the Okinawan languages share roughly 70% of their vocabulary; they are not mutually intelligible.

The earliest written records of Japanese date back to the early eighth century and are composed in Chinese characters. Since then, two different syllabic writing systems derived from Chinese characters have been developed for Japanese: Hiragana and Katakana. Both are syllabic; i.e. each symbol stands for a syllable. Additionally, there is now a phonetic writing system, Romaji, which uses the Roman alphabet. Here, the symbols stand for individual sounds.

Japanese is unlike other Altaic languages in that it possesses a very simple syllable structure; most syllables consist of just a vowel or a consonant followed by a vowel. Also, somewhat unusually among the Altaic languages, Japanese has only five vowels and a small number of consonants. As in other Altaic languages, the basic word order is subject–object–verb, and it uses suffixes to indicate the grammatical function of a noun, i.e. whether the noun is the subject (*-ga*) or an object (*-o, -ni*).

Perhaps the most careful attempt to link Japanese to Altaic proper and to Korean was that presented by Roy Andrew Miller (1971). Despite his efforts, few scholars readily accept the Japanese connection with Altaic, although the affiliation between Japanese and Korean has gained a wider consensus.

Korean is spoken by 65 million people worldwide, the vast majority of them living in North and South Korea. The earliest examples of written Korean used Chinese characters, a practice that continued into the

twentieth century. However, a Korean alphabet, called Hangul, was invented in the fifteenth century. Hangul is now the primary means by which Korean is written.

Chinese has had an obvious effect on Korean. In fact, more than half the Korean words have been borrowed from Chinese. Even so, the structure of Korean remains quite distinct from Chinese, and superficially at least, it shares many properties with Altaic proper. For example, the basic constituent order is subject–object–verb, it has no definite articles, and it exhibits 'vowel harmony'; i.e. vowels within a word tend to assimilate to one another.

A family relationship between Korean and Altaic proper was advanced by two leading Altaicists in the twentieth century: G.J. Ramstedt (1952–1957) and Nicolas Poppe (1965). The connection between Korean and Japanese has received more attention in the intervening years, sometimes being examined within the context of Altaic (for example, by Roy Andrew Miller [1972]) and sometimes independently of Altaic (for example, by Samuel Martin [1966, 1991]).

Mongolic languages are spoken in the central Asian regions of the People's Republic of China, the Russian Federation, and the Republic of Mongolia. Although there has been much debate regarding the internal structure of the family, it is perhaps most often depicted as having two primary branches. Western Mongolic consists of a single language called Moghul. The language, which is mutually unintelligible with all other Mongolic languages, is spoken by fewer than 200 people found in two villages in Afghanistan. Eastern Mongolic is broken down further into three sub-branches: Dagur (which consists solely of the Dagur language, spoken by around 60,000 people in China), Monghuor (a set of closely related languages spoken in China, all of which have been deeply influenced by Chinese and, in some cases, Tibetan languages), and Oirat-Khalka (the subbranch containing most Mongolic languages).

Within the Oirat-Khalka branch, the three most widely spoken languages are Oirat, spoken by approximately 300,000 people in the Kalmyk Autonomous Region in Russia; Buriat, spoken by 350,000 people in the Buriat-Mongol Autonomous Region in Russia; and Khalka, the official language of the Mongolian Republic, with more than 2.3 million speakers. It is this last language that most people refer to when they talk about Mongolian.

The oldest written records of Mongolian date back to the early thirteenth century and take the form of inscriptions, but the literary text known as *The Secret History of the Mongols* had appeared already in 1240. The script used for this early writing was borrowed from the Uighurs, a neighboring Turkic group that had been using the script for many centuries.

Like the other Altaic proper families, Mongolic languages typically use vowel harmony. The basic word order tends to be subject–object–verb, the grammatical function of nouns is signaled by suffixes, and there are no definite articles ("the").

Tungusic languages are spoken over a geographic expanse that goes all the way from the Arctic regions of the Russian Federation to China's Xinjiang Province. Most of these languages were traditionally spoken by small nomadic groups. As nomadism has come to an end in China and Russia, Tungusic speakers have Russified and Sinicized rather rapidly, and most Tungusic languages will probably start to die out in the near future.

Tungusic has traditionally been divided into two branches: Northern Tungusic and Southern Tungusic. The best-known member of the Southern branch is Manchu, which was the official language of China's last dynastic empire. Although the language was used for official purposes well into the twentieth century, very few fluent speakers remain. Sibe, another Southern Tungusic language, which, in fact, might be better labeled a dialect of Manchu, has 27,000 speakers in Xinjiang Province, making it the largest Tungusic language. The Northern branch of Tungusic consists of Even and a cluster of very closely related languages—Evenki, Negidal, Solon, and Orochen. Many scholars suggest that some of the Southern languages should be set off into a third branch of the family, Central Tungusic. The Central Tungusic languages, for example, Nanai, tend to be similar to Southern Tungusic in their pronunciation but similar to Northern Tungusic in the ways in which words are formed.

Only two Tungusic languages have written records that extend back before the twentieth century: Manchu and Jurchen. The Jurchen data date to the twelfth century, but its writing system mixes logographic symbols, which stand for concepts, with symbols for pronunciation, and it is still not completely deciphered. The Manchu script was derived from Mongolic script at the end of the sixteenth century. Today, we have a huge body of Manchu literature spanning the seventeenth to the twentieth centuries.

Tungusic languages are characteristically Altaic in having vowel harmony, case suffixes, and possessive suffixes. Also in line with other Altaic languages, they lack definite articles and have a weak distinction between nouns and adjectives.

The Turkic language family covers a large area from the Balkans and Asia Minor in the southeast to the Central Asian regions of both the Russian Federation and the People's Republic of China and up into the Arctic region of Russia. Turkic is split into two main branches: Bulgar and Common Turkic. The main language in the Bulgar branch is Chuvash, which is

spoken by about 1.5 million people in the Chuvash Autonomous Region of Russia. Chuvash, although grammatically similar to the rest of the Turkic languages, is marked by a series of historical changes in pronunciation that are hard to interpret in the context of Turkic and Altaic. Therefore, some scholars have suggested that Chuvash is actually a sister to proto-Turkic rather than a daughter. That is, instead of a branch of the Turkic family per se, Chuvash and the Turkic family may both be branches of a larger family unit.

Common Turkic is generally divided into four or five subbranches, most of which have languages spoken by more than a million people. The Eastern subbranch includes, among other languages, Uzbek (the national language of Uzbekistan, 15 million speakers) and Uighur (6.7 million speakers, mostly in China). The Southern subbranch includes Turkish (50 million speakers), Azeri (14 million speakers, half in Iran and half in Azerbaijan), and Turkmen (3 million speakers). The Northern subbranch includes Tuvan (200,000 speakers, mostly in Russian but also in Mongolia) and Yakut (300,000 speakers). The Western subbranch constitutes Bashkir (1 million speakers) and Tatar (5.5 million speakers). Many scholars separate out of Western Turkic a fifth subbranch called Central Turkic. Within Central Turkic, one finds the national languages of Kazakhstan, Kazakh (7.6 million speakers), and Kirghiz (2 million speakers).

The earliest written record of a Turkic language was found in a set of inscriptions in Mongolia dating to the early eighth century. These inscriptions were written in Orkhon Turkic and use what is called a runiform script. Some scholars have argued that the script is an invention of Orkhon Turkic speakers, although there is growing consensus that the script is actually of Semitic origin.

Turkic languages are characterized by vowel harmony. Typically, Turkic languages manifest a subject–object–verb word order and heavy use of suffixes. Nouns and adjectives are only weakly distinguished.

Speculation about some kind of genetic relationship among Mongolic, Tungusic, and Turkic stems back to the eighteenth century, and suggestions about the link between these languages and Korean and Japanese arose in the early nineteenth century. Despite a steady stream of scholarship with respect to the classification of these languages over the past 200 years, there is still widespread disagreement about the merits of an Altaic language family and, even granting its existence, which subfamilies should be contained therein.

With respect to Altaic, no one denies that there are a host of putative cognates, i.e. words that are quite obviously related. The issue is whether these cognates reflect shared ancestry or whether they have arisen through extensive borrowing among the languages.

Certainly, there is plenty of evidence that Altaic languages have been in contact for many centuries, and everyone involved in the Altaic debate agrees that much borrowing has taken place. The point of contention is whether these cognates should be dismissed en masse as borrowings or whether a subset of the cognates does in fact reflect a family association.

Adding fuel to the notion that putative Altaic cognates are not good indicators of a family relationship is the fact that among the basic vocabulary in the languages, for example, the lower numerals, body parts, and natural phenomena, the cognate evidence is not compelling. Typically, one expects better cognate evidence in these vocabulary realms.

One of the strongest pieces of evidence in favor of Altaic, or at least Altaic proper, is the first-person singular pronoun ('I'). In Tungusic languages, the nominative form of the pronoun is *bi,* but for all other cases, the stem is *min-*; e.g. Oroqen *min-ŋi,* 'my', is the genitive (possessive) first-person singular. Precisely the same contrast in stems is found widely in Mongolic. Hence, Buriat has *bi,* 'I', for the nominative first-person singular and *min-ni,* 'my', for the genitive. Although the correspondences in Turkic are not perfect, one does find similar patterns in some modern Turkic languages (e.g. Chuvash), and Old Turkic allowed variability in the pronominal stems; this, if not fully corresponding to the Tungusic and Mongolic patterns, shows enough similarity to suggest a connection among all three families.

Ambiguity

'Ambiguity' is the term for the existence of at least two separate, incompatible interpretations of a stretch of speech. Two kinds of ambiguity are recognized: if it is due to words, it is called 'lexical' ambiguity; if it is due to sentence structure, it is called 'structural' ambiguity.

Lexical ambiguity can be either 'polysemy' or 'homonymy'. Homonyms are distinct units in the vocabulary with identical pronunciation ('homophones') and/or spelling ('homographs'). Each of the homonyms in a set has its own meaning, for example, *bank* 'financial institution' vs. *bank* 'slope'. In this example, homophony and homography co-occur. But this need not always be the case; compare *peak* [pi:k] 'summit' and *peek* [pi:k] 'glance', which are homophones but not homographs. From a historical point of view, homonyms cannot be traced back to a common etymological origin, as with *bat:* the word for the flying mammal has a Swedish origin, the word for the implement is related to *battle*. From the contemporary viewpoint, homonyms have no shared meaning either. These two viewpoints are not watertight, however. A very competent speaker knows more about the meaning of a given pair of homonyms than a less competent speaker—but whose competence should be taken as the yardstick? Nor is it clear at which point etymological reconstruction should come to an end.

Multiple meanings distributed over several words with the same pronunciation is called 'homonymy'; multiple meanings within a single word is called 'polysemy'. The different meanings of a polysemous expression have a base meaning in common. Furthermore, the meanings of a polysemous term are often related by metaphor or metonymy, as in *point:* 'punctuation mark', 'sharp end', 'detail, argument', etc. Here, we observe several meanings associated with one word, the shared base meaning of which could be something like 'smallest unit'—either a concrete one ('punctuation mark', 'sharp end') or a metaphorical one ('detail, argument'). There are cases of idiosyncratic polysemy, such as *green* 'a certain color' and 'inexperienced', but there are also cases of systematic polysemy, as in the actual/dispositional distinction (as with *fast* in *this is a fast car*) or the distinction between a building and the institution housed in it (as with *school*).

Structural ambiguity has two subcases as well: 'attachment' ambiguity and 'scope' ambiguity. Attachment ambiguity refers to the possibility that the same sequence of words may be assigned different structures. In *The policeman observes the lady with the telescope*, the prepositional phrase *with the telescope* modifies either *the lady* (thus, the lady is a lady with a telescope) or *observes* (thus, the policeman observes by means of a telescope). The ambiguity of the sentence is an attachment ambiguity—the prepositional phrase may be 'attached' to or associated with different elements in the sentence.

Scope ambiguity refers to the possibility of assuming different logical forms of a sentence. An example is the sentence *Every man loves a woman,* which has two distinct readings: *for each man there is 'his' woman, and he loves her;* or alternatively *there is a specific woman who is loved by all the men.* With the first reading, *every man* 'has scope over' *a woman,* i.e. the sentence is primarily about 'every man'. With the second reading, it is the other way round, i.e. the sentence is primarily about 'a woman'.

Ambiguity, whether lexical or structural, must be distinguished from vagueness. A vague expression is imprecise, whereas an ambiguous expression has several precise meanings. An example of a vague expression is the predicate *red* in *Mary owns a red skirt.* A dark pink or a dark orange skirt would be borderline cases for this sentence, due to the intrinsic vagueness of *red*. Vagueness is 'intrinsic' in the sense that it has nothing to do with lack of knowledge (we know what the color *red* looks like). There is a close connection between vagueness and context dependence. The existence of borderline cases is not necessarily a bad thing, as different usages may be salient in different situations; cf. *Mary owns an expensive skirt*. Depending on the financial situations of Mary and the listeners, the vague predicate *expensive* will have quite different readings. In sum, vagueness may be defined as follows: a sentence is vague if—despite the knowledge of all the circumstances in a given situation—one cannot determine with certainty whether it is true or false. An expression is vague if it occurs in a sentence in such a way that it is responsible for the sentence's vagueness.

Vague sentences violate the principle of classical logic demanding that a sentence be either true or false. Thus, either there is a third truth value (or many) besides 'true' and 'false'—this is assumed in the many-valued logic approach (three-valued logics and fuzzy logics). Or there are gaps in truth-value assignment—this is the thesis of supervaluation semantics.

In sum, vagueness and ambiguity have different communicative statuses. Vagueness is part of the common understanding of the speaker and hearer, accepted

by both. With ambiguity, the situation is different. Usually, the speaker has a certain meaning in mind—there is no vague reading of an ambiguous sentence. Instead, any vague reading of an ambiguous sentence is a communicative breakdown, as ambiguous sentences are always in need of disambiguation.

American Sign Language

American Sign Language (ASL) is a naturally occurring language with a syntax and culture distinct from spoken English. Geopolitically, ASL covers a large territory, serving between 100,000 and 500,000 signers in both Canada and the United States. ASL is not a 'universal sign language', nor does it have close etymological ties with British Sign Language, another distinct signed language. Instead, French Sign Language, or langue des signes française (LSF), has historically given ASL its closest linguistic ties.

Throughout early history deaf people lived isolated lives, possibly communicating with their hearing parents and siblings through the use of idiosyncratically created home signs. As world populations grew, larger metropolitan groups began to provide the contact for visual gestural dialects to emerge. In the late 1760s, the French priest Charles-Michel de l'Epée, concerned for the religious salvation of deaf Parisians, gathered a small group of deaf children together and began teaching them through the use of an invented manual French that he created as an educational counterpart to spoken French. This gathering in Paris is now recognized to be the first public school for the deaf in the world. The home signs and various Parisian dialects that the deaf children brought to their school merged with de l'Epée's 'methodological' signs and subsequently evolved into the language now known as LSF.

The reputation of the school and the emerging language flourished. In the early nineteenth century, a Protestant minister Thomas Hopkins Gallaudet was sent by wealthy American philanthropists to Europe to investigate a school for the deaf in London. Unable to obtain any assistance from England, Gallaudet visited France and eventually persuaded Laurent Clerc, one of the young deaf teachers from de l'Epée's school, to travel back to America with him. Together, they established the first American School for the Deaf in Hartford, Connecticut. The French language taught by Clerc mingled with the indigenous dialects brought in by his young American students from across the developing country. Mingling with a couple of fledging signed languages found in several small established deaf communities such as Martha's Vineyard in Massachusetts (descendants of British immigrants), and Henniker, New Hampshire, a new national signed language began to evolve.

In 1864, a liberal arts college now known as Gallaudet University was established in Washington, DC through the efforts of Abraham Lincoln and Edward Miner Gallaudet, Thomas Hopkins's son. Graduating deaf students, many of whom had previously attended Clerc's Connecticut school, returned to their native homes and frequently established or became responsible for establishing schools for deaf children in their respective states. The unique language mixture of Clerc's LSF signs and indigenous signs brought in or naturally created by Gallaudet students gradually evolved into modern ASL.

Spoken languages can usually trace their history back through many centuries. Even including its historical French ties, ASL has only 250 years of documented language use. Yet, ASL is already following a process of grammatical evolution that spoken languages follow. Cross-linguistic studies of the historical relationships between LSF and ASL reveal paths of lexical and grammatical change taking place in this young signed language.

One example can be found in the semantic changes that have occurred between the LSF nominal sign for 'coin' and a modern ASL discourse marker used to stop arguments or to change the subject (Wilcox 2000). The old LSF classifier noun for money, ARGENT (sign words are conventionally capitalized), semantically evolved into the sign for GIVE (donner), a verb in LSF that can also be found in modern ASL. The verb stem phonology of both 'give' signs has a common etymology, but diverge functionally. Following a path of lexicalization, one GIVE sign became an inflected verb of both literal and metaphorical nature; the other GIVE sign grammaticalized and extended into the word GIVE-IN-ARGUMENT. This verb is used metaphorically only and functions solely as a discourse marker.

Typical paths of grammaticalization in spoken languages reveal that language evolves from the mapping of literal objects onto nouns (nominalization) to semantic shifts of abstraction. The original concrete reference of a French money sign became increasingly abstract as it evolved into the metaphorical discourse marker in ASL. This example, plus the documented grammaticalization of modals such as WILL and MUST, demonstrate that ASL is following a linguistic path of subjectivity taken by many spoken languages.

ASL has an underlying s(ubject)–v(erb)–o(bject) sentence structure. In addition, it is strongly characterized by topic-comment structure. Topics act as discourse pivots to link previous information with the following and also indicates a shift in the point of view that the signer takes of the discourse events (Janzen et al. 1999). Topic marking in ASL is generally a marker with explicit discourse function. The following example also demonstrates the flexible word order of ASL:

[KIP BUY NEW COMPUTER]-topic, CURIOUS
'I wonder if Kip bought a new computer.'

Signed words consist of parts and can be broken down into components called parameters: the handshape, the location, the movement, and the orientation of the palm. These components exhibit both sequentiality and simultaneity when the signed words are put together, differing from spoken languages that are highly sequential. The iconic nature of ASL, with its strong link between form and meaning, is pervasive and is documented throughout its phonological and morphological analysis.

The morphology of ASL verbs is especially complex, more so than spoken English. The verb root is often expressed in the handshape and grammatical information is expressed in the movement, as Ronnie Wilbur describes:

> …in a multimorphemic verb sign, the movement can carry the information regarding the transfer of a theme-object (e.g. GIVE), the starting location can carry the source-agent-subject, the ending location can carry the goal-recipient-indirect-object, the handshape can carry the physical characteristics of the object itself (size and shape indicated by 'handle' classifier), and each piece of information is phonologically distinct from the others. (2000:216)

ASL has a large set of signs called classifiers that can be used to specify something without actually naming the specific referent. Classifiers can represent pronouns and describe in detail the size, shape, depth, or texture of an object, and they can function as a noun and indicate the location of that noun and its actions (Baker-Shenk and Cokely 1999). Classifiers are abundant in ASL and most signed languages.

Another critical component of ASL is the use of nonmanual signs. Grammar can be produced and distributed across the face, the head, and the shoulders. Adverbial and adjectival information can be produced on the mouth, tongue, and cheeks. For example, one visual gesture, 'th', is made with a slack jaw and a protruding tongue pushing through slightly separated lips, and indicates carelessness or incorrectness. Other nonmanual markers such as the eyebrows, the nose, head movements, and eyegaze can coarticulate with signed words or be produced in isolation. These nonmanuals mark wh-questions, yes/no questions, rhetorical questions, conditionals, negations, topics, and relative clauses. Rhetorical questions, uncommonly used in spoken English, are found quite frequently in ASL conversations. A rhetorical question is accompanied by a brow raise and a tilting of the head and often involves the use of the signs WHY, WHAT, WHO, HOW, and REASON. Nonmanual facial expressions can also indicate mood and affect.

Fingerspelling makes use of 26 handshape configurations that correspond to the English alphabet. Fingerspelling is more prevalent in ASL than in other signed languages of the world. It is primarily used to indicate proper nouns and technical terms. Fingerspelling is more than a sequence of canonical handshape-alphabet letter correspondence, however, since the articulatory movements of segments within the fingerspelled word influence each other. Forward (carry-over) and anticipatory assimilation affects the actual shaping of fingerspelled words, creating a fluid transition between letters that is prosodic and complex (Wilcox 1992).

Language borrowing involving fingerspelling takes place through the physical proximity of English and

ASL. Fingerspelled English words are often modified so that they fit better the structure of a sign (Battison 1978). For example, the word A-L-L can be fingerspelled letter by letter, or it can serve as a borrowed loan sign and will be restricted semantically in several ways. Instead of fingerspelling the three letters in the conical signing space in front of the body, a signer can hold up an imagined list with one hand while using the other hand to fingerspell the letters, literally running down the entire length of the arm to show 'all' of the items on the list. Or a two-handed loan sign can fingerspell an abbreviated A-L while sweeping the letters in front of the signer to designate everyone in the room including the signer. This particular lexicalized loan sign is highly productive and limits the semantic meaning according to specific modifications that are applied to the three letters.

The culture of deaf people endures not through artifacts such as food or clothing, but through the powerful use of the language of ASL. Historically, the hearing world has not condoned the language choice of deaf people. A defining event in 1880 still exerts influence on deaf people and their use of signed languages. The representatives of the World Conference for the Deaf in Milan, Italy, voted unanimously (except the American delegates) to ban signed languages from all the schools in Europe and replace it with an 'oral' method of instruction (Lane 1984). Even in America, this edict had a profound effect on the educational systems. Deaf teachers were fired or prevented from educating younger deaf children, teachers who signed were not promoted or respected, older students who might 'contaminate' the younger children were hidden in separate quarters, and curricula were changed to speech-based activities.

The most influential leader of the oral method of educating deaf children was Alexander Graham Bell, the inventor of the telephone. His great influence and wealth had a lasting impact upon the movement. Organizations that were founded by his proponents still work to oppress the use of ASL in the United States today. In the early 1900s, with schools no longer administered by deaf adults, the language was kept alive by the use of deaf children born of deaf people, a heritage unlike that found in spoken languages. Only 8–10% of deaf children are born to deaf parents who sign, which means that around 90% of the ASL-using deaf children learn it from their 'native' peers. The proponents of the oral method were relatively successful in keeping signed language out of the educational arena until the early 1960s when William C. Stokoe's (1965) seminal work on linguistic analysis of ASL appeared. His pioneering work ignited an explosion of research on ASL that now permeates linguistic inquiry. Because of the tenacity of ASL users, along with the backing of research that provides linguistic legitimacy, ASL is now finding rewarding acceptance in schools, universities, courtrooms, and social and business settings across America.

The past 200 years have witnessed a strong expansion of ASL throughout the world due to religious or educational agendas. Also, thousands of deaf students from around the world have attended Gallaudet University (the world's only liberal arts university for deaf people); thus, the signed language can be found throughout Asia, South America, Africa, and Europe — almost every country has deaf alumni who use ASL in addition to their own native signed language. Many deaf people have a working knowledge of ASL and the language is used freely at most of the international deaf conferences and workshops. However, its pervasive use of fingerspelling and marked initialization of English words has thus far prevented it from being accepted as an official signed lingua franca. Nevertheless, ASL users provide incentive to the world's remaining deaf populations to maintain their cultural and linguistic identities as their respective signed languages advance and evolve.

Amharic and Ethiopian Semitic Languages

There are perhaps 11 Ethiopian and Eritrean Semitic (EES) languages now spoken, although the presence of dialect continua and lack of information on intelligibility between varieties makes a fully confident count difficult. Two other languages are known, but are now extinct. These 13 languages are (spelling of names of lesser known varieties varies in the literature):

1. Tigre, of western Eritrea, with dialects on the Red Sea coast and Dahlak islands;
2. Tigrinya, spoken in Eritrea and northern Ethiopia, but especially in Ethiopia's Tigray region;
3. Ge'ez, the ancient language known in epigraphy since about 500 BC, the language of the ancient kingdom of Axum centered on the modern Tigrayan city of the same name, unused as a mother tongue for many centuries, but continuing in regular use as the liturgical language of the Ethiopian Orthodox Christian Church;
4. Gafat, of the Gojjam region of central Ethiopia, extinct now for some 50 years;
5. Amharic, the world's most populous Semitic language after Arabic, with over 16 million speakers in Ethiopia, and long that nation's official language;
6. Argobba, near mutually intelligible neighbor to Amharic, in the northwestern Shewa region;
7. Soddo (also known as Kestane 'Christian'), spoken just west of Addis Ababa, with a dialect Dobbi (or Gogot);
8. Mesqan, south of Soddo, whose linguistic separateness from neighboring varieties is least confident;
9. Chaha and mutually intelligible varieties including Ezha, Gomara, Gura, and Muher, spoken south of Mesqan territory;
10. Inor and mutually intelligible varieties including Endegenya, Enner, Gyeta, Magar, and Mesmes (the latter probably now extinct), southern neighbors of the Chaha group;
11. Silte and mutually intelligible varieties including Enneqor, Ulbareg, and Walane, southeastern neighbors of the Inor group;
12. Zay, about Lake Zway some 70 km south of Addis Ababa; and
13. Harari (Adare), spoken in and about the ancient eastern Ethiopian city of Harar.

Some 76 languages are spoken in Ethiopia and Eritrea, in addition to the 11 Semitic languages, some 21 Cushitic languages, 23 Omotic languages, 20 Nilo-Saharan languages, and one as yet unclassified, Ongata. The presence of so many Semitic, Cushitic, and Omotic languages, three of the six subgroups of the Afroasiatic family (the other three Egyptian, Berber, and Chadic), suggests that the region is one of very early Afroasiatic settlement.

Amharic, with over 16 million mother tongue speakers and, according to the 1994 Ethiopian census, over five million second-language speakers, is by far the most important Ethiopian language, and the second most populous Semitic language after Arabic. Amharic is spoken throughout Ethiopia but particularly in urban areas, and is taught in all public schools. Regional varieties or dialects of Amharic are recognized in regions of Begemder, Gojjam, Wello, and Shewa. The Ethiopian capital city of Addis Ababa (in Shewa) is nowadays the focus of Ethiopian economic and cultural life, and Addis Ababa Amharic has naturally become the prestige dialect.

The numbers of speakers of most Ethiopian languages may be estimated from counts of the 1994 Census of Ethiopia. The Census, however, like much of the linguistic literature, grouped as 'Gurage' the six languages numbered 7–12 in the list, and provided separate figures for only the Soddo and Silte varieties. Amharic has three times more speakers than Tigrinya, with perhaps five and a half million including two million in Eritrea. Tigre may have a million speakers, all in Eritrea, followed by Ethiopian Silte (800,000), Soddo (200,000), and Chaha (perhaps 100,000). Speakers of the others are much fewer in number. The census reported Harari to have 22,000 speakers, and Argobba only 10,000.

The region is naturally characterized by bilingualism and multilingualism, often involving Amharic or Oromo, a Cushitic language (known in the old literature as 'Galla') perhaps as populous as Amharic, and more populous when Oromo speakers of Kenya are added. Research in the late 1960s showed, for example, that in Jimma town of western Ethiopia some 90% of speakers of languages other than Amharic knew Amharic, and 42% of Amharic speakers knew Oromo. Today, perhaps the majority of town and city-dwelling Ethiopians, except in largely Tigrinya-speaking Tigre province, are at least second-language speakers of

Amharic, and knowledge of the language certainly continues to spread throughout the region.

After a largely Tigrayan army overthrew the 1991 *derg* ('committee') communist government in Addis Ababa, whose predecessors had deposed the Amhara emperor Haile Sellassie in 1974, Ethiopian political power lay in the hands of Tigrinya speakers, who have encouraged considerable linguistic freedom of expression and identity including, rather controversially, the use of local-majority languages in public education. Oromo, backed by a nationalist movement, became a growing rival to Amharic-language dominance. With its many second-language speakers and long literary development, however, Amharic has largely continued its dominance in literary culture, education, and public life.

Written in Ge'ez, royal chronicles and religious writings are known from the fourteenth century, and shortly after this time writings in Amharic also began to appear, but especially in the seventeenth century. Publication in Amharic has increased steadily, and Ethiopian publications in Amharic today include writings of all kinds: newspapers, literary and news magazines, drama, novels, history, textbooks, and poetry. Amharic-language magazines are published in Europe and the United States to serve the Ethiopian expatriate populations there. Publication in Tigrinya as well as in Eritrea and Ethiopia's Tigray region has flourished.

Amharic and Tigrinya, and often nowadays other EES languages, are written in the Ge'ez or 'Ethiopic' writing system, an adaptation of the ancient South Arabian writing system, itself the southern adaptation of evolved Egyptian writing sometimes termed 'Sinaitic', whose northern adaptations include Aramaic, Arabic, and Hebrew writing (and Phoenician, perhaps that transformed by the Greeks into their alphabet). The epigraphic record suggests that during the fifth century reign of the Axumite king *Ezana,* Ethiopic writing was significantly modified to include representation of vowels, as regular extensions or shapings of its consonantal characters, approximately as early as in Indic *Kharosthi* writing.

Probably since ancient times, Amharic has spread in territory earlier populated by speakers of other, especially Cushitic, languages, and as a result Amharic has come to share a number of features with these other languages. Amharic has long borrowed from Ge'ez, a favored practice for the modern satisfaction of needs for philosophical, technical, and other new vocabulary. Borrowings from Italian entered the language in the Italian Colonial era, but today the principal source of new words is English, the language of Ethiopian and Eritrean secondary and higher education.

The obvious Semiticness of Amharic may be suggested by a comparison of a selection of five basic words of Hebrew, Classical Arabic, and Amharic.

	'all'	'die'	'eye'	'house'	'name'
Hebrew	*kōl*	*māt*	*ayin*	*bayit*	*šēm*
Arabic	*kull*	*māta*	*ayn*	*bayt*	*ism*
Amharic	*hullu*	*motə*	*ayn*	*bet*	*sɨm*

While a different selection of words might show no similarities, and many similarities that exist are far from obvious, the systematic prevalence of such comparisons as these confirms that Hebrew, Arabic, and Amharic are all descendant languages of that spoken by the first Semitic peoples.

Beyond lexical comparisons, Semitic languages, including EES, are particularly characterized by three-consonant roots filled out by vowels and affixes in word derivation (so-called 'root-and-pattern' morphology), and other characteristics including the presence of a set of subject-agreeing verb prefixes including *y-* for third-person masculine 'he', and *t-* for both second-person 'you' and third-person ('she') feminine:

	3m.sg.	3f.sg.	2m.sg.
Hebrew	*yi-kbad*	*ti-kbad*	*ti-kbad*
Arabic	*ya-kbud*	*ta-kbud*	*ta-kbud*
Amharic	*yɨ-kbəd*	*tɨ-kbəd*	*tɨ-kbəd*

The root (*kbd* heavy') and the prefixes are cognate; a difference is that the Amharic verbs are subjunctives, vs. the present tense of the Hebrew and Arabic.

Within the Semitic family of languages, Amharic and its kin in Eritrea and Ethiopia are typically grouped as 'South Semitic' with the ancient and modern Semitic languages of South Arabia, such as epigraphic Sabaen of Yemen and modern Soqotri of Soqotra island. The unity of EES is suggested by several features which they tend to share, including a non-finite verb conjugation for all but the last of verbs in sequence (Amh. *səbro* 'he having broken'), verbs expressed as compounds of particle + 'say' (*zɨmm alə* 'he was quiet'), and a special verb of presence (Amh. *alləhu* 'I am present').

EES languages are divided into two groups, North (Tigre, Tigrinya, and Ge'ez) and South (Amharic and the rest), which differ in a number of characteristic features, of which two are the presence of so-called 'broken' noun plurals in the North (for example, Tigrinya *sor* 'ox', pl. *'aswar*), formed by modification of root structure instead of affixation, and present-tense doubling of the second root consonant of triconsonantal verbs (compare Tigrinya *yɨsəbbɨr* 'he breaks' vs. Amh. *yɨsəbɨr*). The South EES languages are bifurcated as an eastern group of Amharic and Argobba plus the Silte-group, Zay, and Harari, against a western group of the Chaha-and Inor-group languages plus Mesqan and Soddo. The eastern group typically augments present-tense main verbs with a suffixed auxiliary verb, as in

Amharic main verb *yɨsəbr-al* 'he breaks' vs. subordinate *yɨsəbr.*

Argobba differs from Amharic in small but numerous ways, probably resulting in at least slight mutual nonintelligibility. The divergence of Amharic and Argobba may reasonably have resulted from the separation of these peoples upon the adoption of Islam by the Argobbas in about the sixteenth century. The typical divergence between pairs of EES languages is much greater, on the order suggested by 50% or so of cognates in a hundred words of core vocabulary between North and South EES languages, and about 60% between South EES languages.

Ge'ez, because it is the only anciently known EES language, has sometimes been considered the ancestor language from which all the others descend, as Latin is ancestor to the Romance or Italic languages, but this does not seem to be the case, because there are old linguistic features of the other languages unreasonably absent in Ge'ez, pervasive Ge'ez features unreasonably absent in the others, and because the diversity of the other languages seems too great to date only from the early Axumite times of likely Ge'ez dispersal.

Amharic, like other EES languages, constructs typical transitive sentences with the main constituent order subject–object–verb (SOV), in contrast to the VSO typicality of Semitic Arabic and Hebrew. An Amharic topicalized object can precede a subject, but the verb is rigidly final. Amharic, however, has a number of word-order characteristics inconsistent with the basic SOV type, including prepositions instead of postpositions (*bə-bet* 'in house', *bə-* 'in') and verb prefixal clause subordinators (*sɨ-tsəbr* 'when you break', *sɨ-* 'when'). Typical SOV characteristics of Amharic and EES languages are the linear precedence of adjectives, genitives, and relative clauses before their modified nouns. The syntactic peculiarities of EES are typically attributed to the influence of Cushitic-language neighbors, which are mainly of the consistent SOV type, with postpositions and case suffixing absent in EES. Amharic and most other EES languages usually case-mark only definite objects, Amharic with *-n*: *wɨša-w lɨǰ-u-n nəkkəsə* 'the dog bit the boy'.

Amharic and other EES languages have the phonological characteristic of a series of glottalized ejective consonants, as in Amharic *k'utt'a* 'anger' (with ejectives *k'* and *t'*). These differ from the so-called 'emphatic' velarized/pharyngealized cognate consonants of e.g. Arabic. Some EES languages preserve the Semitic pharyngeals *ħ* and *ʕ*. As in the other Semitic languages, the voiceless labial stops *p* and *p'* are marginal, or limited to loan words such as *ityopp'ya* 'Ethiopia', from Greek. Like most of the EES languages, Amharic has the seven-vowel system *i, e, a, ɨ, ə, u, o;* others have a five-vowel system with length.

Analogical Change

In a general sense, analogy is the correspondence of two or more entities with respect to certain properties. In linguistics, the term 'analogy' is most often used to describe processes in which a new linguistic object is created by aligning an existing linguistic object A with another existing linguistic object B, which serves as a model. A and B usually have some properties in common. For instance, Early Modern English *pigs* and *kine* are both plural nouns but differ in the way the plural is formed: *-s* vs. *-n* + vowel change. The form *pigs*—respectively *horses, stones,* and the like—is considered the model here and the plural of *cow* is aligned with the plural of *pig* and thus, by analogy, *kine* becomes *cows.*

Sound change and analogical change have already been considered by Neogrammarians as the fundamental processes of language change. The two important

types of analogical change are analogical leveling and proportional analogy. Analogical leveling results in the reduction of allomorphy within paradigms. The paradigms of the Old English and Old High German verb meaning 'to choose' contain forms with a fricative [z] or [s], where other forms have an [r]. In both languages, the paradigms were leveled out by adopting the same consonant throughout the whole paradigm. While Modern English chose [z], Modern High German dropped the fricative in favor of [r].

Old Engl.		Mod. Engl.		Old High Germ.		Mod.H.G.
cēo[z]*an*	>	*choo*[z]*e*	PRES	*kiu*[s]*an*	>	*kü*[r]*en*
cēa[s]	>	*cho*[z]*e*	PAST-(SG)	*ko*[s]	>	*ko*[r]
cu[r]*on*	>	*cho*[z]*e*	PAST-(PL)	*ku*[r]*un*	>	*ko*[r]*en*
(*ge-*)*co*[r]*en*	>	*cho*[z]*en*	PAST-PART	(*gi-*)*ko*[r]*an*	>	*geko*[r]*en*

The above example also illustrates the interaction of sound change and analogical change. The alternation of [s] and [z] results from a sound change referred to as 'Verner's Law' and [r] is the result of a subsequent change from [z] to [r] in certain positions ('rhotacism'). Sound change is conditioned by phonetic factors and is not sensitive to the needs of grammatical and semantic functioning. It often obliviates the principle 'one form—one meaning' ('Humboldt's universal'). Analogical leveling is always conditioned by nonphonetic factors and often 'fixes the damage' caused by sound change.

In contrast to sound change, analogy has been considered to be an unsystematic process. This has given rise to the formulation of 'Sturtevant's Paradox': sound change is regular but creates irregularity, whereas analogy is irregular but creates regularity. However, in some cases analogy is fairly systematic. For instance, [z]–[r] alternations of the above type have been leveled out in English quite systematically, as within the paradigms of *loose, freeze, and rise*. There are only very few cases where the [r] has been retained (e.g. *was* vs. *were*).

By proportional analogy—also called 'analogical extension' or 'four-part analogy'—an already existing morpheme or relation becomes generalized to other linguistic forms. In most cases, proportional analogy creates or assimilates derived forms on the basis of another morphological pattern. Proportional analogy proceeds like the solution of an equation of the form:

A : B = C : X solve for X
stone : *stones* = *cow* : X   X = *cows* (< *kine*)

The solution of this equation with respect to the phenomenon mentioned above yields the replacement of *kine* by *cows* as the plural form of *cow*. As with analogical leveling, proportional analogy is not fully systematic: the analogy did not carry over to words like *foot*: *feet* / **foots*.

Other less productive forms of proportional analogy are backformation and hypercorrection. With backformation, it is the morphologically less complex item that is created. In Early Modern English, *pease* was a mass noun, which ended in a sequence that resembled a plural morpheme. Its reanalysis led to the creation of a singular form *pea* by dropping the final fricative. Backformation also occurs as a word-formation process.

bean   : *beans* [-z] = X   : *pease* [-z]
                                                   (X = *pea*)
depression : *depress*   = *aggression* : X
                                                   (X = *aggress*)

Hypercorrection consists in imposing a pattern that relates a colloquial low-prestige variant and a standard higher-prestige variant onto another word presumed to be low prestige. Thereby, an allegedly high-prestige variant of the word is created:

fella' : *fellow*   = *umbrella* : X   (X = *umbrellow*)

Other phenomena that have been discussed under the heading of 'analogy' are blending, contamination, reanalysis, and folk etymology. Blending or 'portmanteau formation' consists in combining parts of existing words where these parts are usually not morphemes. Examples are *brunch* from *breakfast* and *lunch* or *infotainment* from *information* and *entertainment*.

In the case of contamination, a similar fusion of two words occurs but the resulting expression retains the meaning of one of the source words. For example, the [t] of Proto-Indo-European *pətēr* should have turned up as [d] by Verner's Law and a subsequent sound change, yielding *fader*. Instead, contaminated by the regularly derived *brother,* we get *father*.

In reanalysis, a deviant structure is assigned to an expression. The words *napkin* and *apron* both derive from French *nape* 'cloth'. In the second case, the Middle English sequence that results from the combination of the word with an indefinite article *anapron* was reanalyzed as *an apron*, interpreting *n* as part of the article. A related phenomenon is folk etymology. Sometimes, words change on the basis of what a speaker assumes is the etymological origin of the word. For instance, French *crévisse* should occur in English as something like *crevisse*, but appears as

crayfish because the second part got misinterpreted as referring to some kind of fish or aquatic creature.

Theoretical approaches to analogical change manifest themselves in attempts to construct a theory of analogical processes, which is explicit and restrictive and unifies the different forms of analogy (e.g. within generative phonology; cf. Kiparsky 1982). Some researchers formulated a number of principles (sometimes called 'laws') in order to explain why and how analogical changes occur (e.g. Kuryłowicz 1949, Mańczak 1980). These principles are usually subject to counterexamples and should therefore rather be understood as tendencies (cf. McMahon 1994). Among these principles were the following: (i) Analogy proceeds from a basic to a derived form or from a shorter to a longer form. Counterexample: backformations. (ii) More overt and complex markers are favored by analogy. For example, the Old High German plural forms of *Gast* 'guest' and *Topf* 'pan / pot' are *Gästi* and *Topfa*. By analogy *Topfa* adapted to the form *Gästi,* which has the more complex plural marking (umlaut and suffix) yielding *Gäste* and *Töpfe* in Modern High German. Counterexample: Old English *lang* : *leng-ra* turned into *long* : *long-er* analogous to *warm* : *warm-er*, not into *long* : **leng-er*. (iii) In processes of proportional analogy, it is usually the more productive pattern that serves as a model. Counterexample: extension of strong verb forms to weak ones as in the change from *dived* to *dove* as past tense of *dive* analogous to *ride* : *rode*. (iv) Allomorphy gets reduced by analogy (in particular by analogical leveling). Counterexample: the change of the stem *Topf-* to *Töpf-* in German mentioned above. (v) When a new analogical formation becomes accepted (e.g. *brother*) and the older form also survives (*brethren*), the analogical form takes over the basic meaning. Counterexample: blendings.

Analogy has also been considered an important tool in other branches of linguistics like theories on language acquisition, syntax, and orthography: (i) Analogy is assumed to be at work when children overregularize morphological forms, like *goed* instead of *went*. (ii) An example of syntactic analogy is the change of impersonal constructions like *me hungreth*, *me thinks* to the more widespread personal constructions, i.e. to *I hunger*, *I think*. (iii) Modern High German *lieb* 'kind / nice' orthographically reflects a Middle High German diphthong, which has been monophthongized to [i:] in Modern High German. Words like *Wiese* 'lawn' adopted this spelling by proportional analogy, although the Middle High German spelling and pronounciation *wise* showed a monophthong.

Anaphora

Linguistic expressions may have their semantic interpretation determined solely by their lexical content (and the way these lexical items are syntactically arranged), or they may have all or part of their interpretation fixed by a relation to another linguistic expression. Examples of the first type in the following examples include phrases like *the tall woman, bought a car,* and *no tall man.* Examples of the second type include *herself (*see (1)*)*, *she/her* (on the construal whereby *she/her* refers to the same person as *the tall woman*—see (2) and (3)), *his* (on the construal whereby its meaning is determined by

no tall man—see (4)), and the unpronounced verb phrase in (5).

(1) The tall woman hurt herself.
(2) The tall woman realized that she was tired.
(3) The tall woman ran the risk of bumping her head on the low lintel.
(4) No short man runs the risk of bumping his head on a high lintel.
(5) Mary bought a car, and Stanley did ... too.

The study of the syntactic configurations in which the antecedent–dependent pair may occur, and of the types of semantic relation they may bear to each other, is called *anaphora*.

The most widely studied cases of anaphora in generative grammar are those involving nominal expressions like the reflexive in (1) and the pronouns in (2)–(4).

Semantically, anaphoric dependencies between nominals divide into at least two types. When the antecedent refers to an entity in the world (as in (1)–(3)), the relation is that of *coreference*—the dependent refers to whatever the antecedent does, and so they *corefer*. When the antecedent is quantificational, as in (4), the relation is that of *bound-variable anaphora*. *No short man* does not, strictly speaking, refer directly to an entity. Rather, it quantifies over the things that are men, and *his* acts as a bound variable. The sentence essentially means 'no thing x which is a man is such that x runs the risk of bumping x's head… .'

Nominals divide into three types with respect to the syntax of anaphora. *Anaphors* are nominals that must have an antecedent; these include both reflexives (see (1)) and reciprocals, e.g. *each other, one another* in English. *Pronominals*, like *she, her,* and *his,* may have antecedents (as on the most salient interpretations of (2)–(4)), but they need not. Each of (2)–(4) may be interpreted with the pronoun referring to some unmentioned person. Such interpretations typically involve either some kind of ostension (e.g. pointing at the intended referent), or prominence of the referent (e.g. the speaker at a conference). The third type of nominal is those that do not have antecedents at all, like *the tall woman, a low lintel, a car,* and *no tall man*. These are termed *R-expressions* (from 'referring expression').

Each of these three types of nominal has a distinct syntactic distribution with respect to other nominals with which it has an anaphoric relation. These syntactic conditions form the center of Noam Chomsky's Binding Theory (1980s). Each is critically dependent on a structural relationship between two elements called *c-command*. Without going into technical details, one can roughly say that one element c-commands another if it is (a) in a structurally more prominent position and (b) not contained within the same structural unit as the other.

Chomsky's Binding Theory is based on three constraints:

Condition A: an anaphor must be c-commanded by an antecedent within its binding domain.

Condition B: a pronoun must *not* be c-commanded by an antecedent within its binding domain.

Condition C: an R-expression must *not* be c-commanded by any nominal of which it is the antecedent.

In (the majority dialect of) English, the binding domain for an anaphor is the smallest argument phrase containing it and another c-commanding N(oun) P(hrase)—usually the clause. The binding domain for a pronominal is the smallest argument phrase containing it. Grammaticality judgments below (with ungrammaticality indicated by an asterisk) are given for the coreference reading of the antecedent–dependent pair; thus (10) is ungrammatical if *her* and *Mary* corefer).

(9) Mary hurt herself.
(10) * Mary hurt her.
(11) * Mary said that Dan admires herself.
(12) Mary said that Dan admired her.

In (9), *herself* is a reflexive, i.e. a syntactic anaphor. Its antecedent *Mary* is the c-commanding subject of the clause; hence, Condition A is satisfied. In (10), the pronoun *her* is contained in the same clause as the c-commanding antecedent *Mary*, which violates Condition B and makes the sentence ungrammatical. In (11), the reflexive *herself* does not have an antecedent within the binding domain (the embedded clause introduced by *that*), violating Condition A. (12) is grammatical, because the antecedent *Mary* of the pronoun *her* is not located within the same clause. Thus, Conditions A and B are basically *locality* constraints on anaphors and pronominals: anaphors must be close to their antecedents (the antecedent must be local), and pronominals cannot be (the antecedent must not be local).

No locality effects are obtained for Condition C. Coreference is blocked both in the local case (15) and in the long-distance case (16), where the pronoun and R-expression are separated by several clause boundaries:

(15) * She admires Mary.
(16) *She thinks that I said that Dan admires Mary.

In both cases, the main clause subject *she* c-commands *Mary*. If *Mary* is interpreted as the antecedent for *she*, Condition C is violated—the sentence is ungrammatical.

Since c-command plays a critical role, it appears that Chomsky's binding constraints, although they govern a semantic relation, are crucially syntactic in nature. Thus, the binding conditions are a prototypical example of the tight interplay between syntax and semantics. Examination of the parallel conditions in

other languages reveals that the definition of binding domain varies substantially across languages. The study of such a variation has led to detailed examination of dozens of languages, and has also been the subject of a number of studies in the first- and second-language acquisition literature.

Returning to bound-variable anaphora, this has a more restricted syntactic occurrence than coreference.

(17) John/every man said that he was elegant.
(18) [The woman who danced with John/*every man] said that he was elegant.

Coreference may occur where the antecedent c-commands the pronoun, as in (17), where *Every man* is itself the subject of the sentence. When there is no c-command relation as in (18), where *every man* is deeply embedded in the subject phrase, the pronoun cannot have an anaphoric relation to *every man*. An anaphoric interpretation of the pronoun would thus be ungrammatical. Notice that both sentences are grammatical when *every man* is replaced by *John,* because *he* and *John* would simply corefer, i.e. *he* would not be a bound variable.

Anatomy of the Articulatory System

Speech sounds are produced by moving air in and out of the body. To accomplish this, a number of organs in the chest, neck, and head are used. An understanding of these anatomical organs and their functions is a prerequisite for phonetics, the study of speech sounds.

The air pathway (Figure 1) consists of the lungs, larynx, pharynx (throat), oral cavity (mouth), and nasal cavity. The lungs start the process of speech production by pushing air upward. The vocal folds, which are located in the larynx behind the Adam's apple, may vibrate, causing the air that flows through them to vibrate as well. The airstream is then modified by the vocal tract (Figure 4)—the pharynx and the oral and nasal cavities. By altering the shape of the vocal tract, a large variety of sounds can be produced.

The lungs sit inside the rib cage. Expanding the rib cage causes the lungs to expand, and air is drawn in; when the rib cage and lungs are compressed, air is expelled. The lungs are elastic, like a sponge; if their size is changed, this elastic property tends to return the lungs to their resting size. The two lungs are independent. If one is injured, the other one still functions.

Tiny tubes within the lungs, called *alveoli,* combine repeatedly to form larger tubes, ultimately resulting in a single tube for each lung, called a *bronchus.* The two bronchi in turn join to form the *trachea* (windpipe). The top of the trachea is just behind the notch at the top of the breastbone. Lying behind the trachea, the *esophagus* is a tube that carries food to the stomach.

Various muscles of the chest expand and contract the ribcage. The *external intercostal* muscles lift the ribcage, inflating the lungs, and the *internal intercostals* pull the ribcage down, deflating the lungs. The *abdominal muscles* also help to deflate the lungs. The *diaphragm* is a large dome-shaped muscle lying just below the lungs; by contracting, the diaphragm moves downward, increasing the capacity of the lungs. The elasticity of the lungs resists expansion and contraction, attempting to return the lungs to their resting size.

The *larynx* (Figures 2 and 3) is a complex structure, cylindrical in shape, composed of several cartilages. It is found above the trachea. Within the larynx, the ring-shaped *cricoid cartilage* sits immediately atop the trachea. Above the cricoid cartilage is the plough-shaped *thyroid cartilage.* The forward external point of the thyroid cartilage is easily identified as the *Adam's apple.* The back of the thyroid cartilage has two horns pointing down and two pointing up. The two lower horns attach to the cricoid cartilage. The thyroid cartilage provides a shield for the vocal folds, which are attached behind the Adam's apple. The two *arytenoid cartilages* are small pyramid-shaped cartilages sitting

on top of the cricoid cartilage at the back on either side (see Figure 3).

Crucial to speech are the *vocal folds.* These are two horizontal shelves of muscle and ligament. The front part of both vocal folds is attached to the thyroid cartilage. Each vocal fold is attached at the back to one of the two arytenoid cartilages. The vocal folds have a triangular space between them called the *glottis,* through which the air passes upward from the trachea. The vocal folds assume a variety of positions to affect the airstream coming from the lungs. The different positions create the glottal stop as well as different vocal qualities—voiced, voiceless, creaky, breathy, falsetto. In the past, the vocal folds were often called vocal cords; they are, however, solid structures and not cord shaped. The attachment of the horns of the thyroid cartilage to the cricoid cartilage allows the thyroid cartilage to rock backward and forward, changing the tension of the vocal folds; this is the basic mechanism for varying the pitch of the voice (see Figure 3).

The *epiglottis* (Figure 2) is a spoon-shaped cartilage in the pharynx that forms something of a hood over the main part of the larynx. The horseshoe-shaped *hyoid bone* (Figure 2) resides behind the chin; it supports the muscles of the tongue above it, and it also stabilizes the muscles of the larynx from above (see Figure 2).

The *pharynx* is the name for the throat. It is a vertical tube connecting the larynx with the oral and nasal cavities. The rear wall of the pharynx is the *pharyngeal*

wall. The root of the tongue forms the forward wall of the pharynx.

The *oral cavity*, or mouth, is extremely important in the production of speech sounds. The rear of the oral cavity connects to the pharynx. The *upper articulators* are the upper lip, the upper teeth, the upper surface of the mouth, and the back pharyngeal wall (see Figure 4). The *lower articulators* are the lower lip, lower teeth, and tongue. Sounds are formed by moving a lower articulator toward an upper articulator to form a complete or partial obstruction to the airflow.

The lips and teeth are familiar. A bumpy area known as the *alveolar ridge* lies just behind the upper teeth. The hard palate is a smooth bony structure behind the alveolar ridge. In phonetics, the hard palate is normally referred to simply as the *palate*. Behind the palate lies the *velum,* or soft palate. The back of the velum narrows at the back to a thin structure called the *uvula*. The *pharyngeal wall* is considered to be an upper articulator (see Figure 4).

The *lower articulators* are the lower lip, the lower teeth, and the tongue. The *tongue* is the most important of the lower articulators; it is a large, complex organ. Although the surface of the tongue is continu-

ous, without clear landmarks, phoneticians divide it into five parts (see Figure 5).

The *tip*, or *apex*, of the tongue is its foremost part. Just behind the tip of the tongue is a small surface called the *blade*, or *lamina*. The middle portion of the tongue is known as the *front*. It is not literally the front of the tongue, but the surface behind the blade. The rear portion of the horizontal surface of the tongue is called the *back* or *dorsum*. The *root* of the tongue is the rear vertical surface facing the pharyngeal wall (see Figure 5).

The top of the pharynx opens into the *nasal cavity.* The upper surface of the velum is known as the *velic*

surface. The velum can move up or down to close off the passageway to the nasal cavity.

Anatomy of the Auditory System

The auditory system consists of three main sections: the outer ear, the middle ear, and the inner ear. The structure and function of each of these systems will be discussed briefly in the next sections.

Outer Ear

The purpose of the outer ear is to gather sounds from the environment and to funnel them into the auditory system. The outer ear begins at the auricle (also *pinna*) and ends at the eardrum (also *tympanic* membrane). The auricle is mainly composed of elastic cartilage (except for the earlobe) and aids front-to-back localization. It leads to the opening of the ear canal (or external auditory canal). This canal is, approximately, 9 mm high, 6.5 mm wide, and 2.5 cm long, and provides some protection of the eardrum against foreign bodies. The eardrum is a smooth, nearly transparent, membrane of about 80 mm^2 in area. Although it is extremely thin (about 0.07 mm), it is constructed of three layers. It is attached to the handle of the hammer (malleus), the first of three tiny bones (ossicles) in the middle ear.

Middle Ear

The middle ear is an air-filled cavity that is connected to the nose cavity via the eustachian tube. The eustachian tube provides for the aeration and drainage of the middle ear system and makes it possible for air pressure to be the same on both sides of the eardrum (also while yawning or swallowing). While we are awake, the eustachian tube opens approximately once per minute; during sleep it opens, on average, once every 5 min. The eardrum is coupled to the oval window, an entrance to the inner ear, through a chain of three tiny bones, the hammer (malleus), anvil (incus), and stirrup (stapes). Sound waves traveling in the external auditory canal cause the eardrum to vibrate. This vibration is passed on to the middle ear, where a pressure increase is needed because of the mismatch in density and compressibility between air at the eardrum and fluid at the oval window. As the effective surface area of the eardrum is 55 mm^2 and that of the stapes footplate connecting to the oval window is about 3.2 mm^2, the vibratory pressure at the eardrum is funneled and increased by a factor of 17 (55/3.2) at the oval window. Pressure at the oval window is furthermore increased by the three bones acting as a lever system and by the conical shape of the eardrum.

Inner Ear

Although the inner ear is as tiny as a bean, it contains thousands of moving parts and is responsible for sending information to the brain regarding hearing and

balance. The primary auditory organ of the inner ear is the cochlea (latin for *snail*). It is about 1 cm wide, and 5 mm from base to apex in man, makes about two and a half coils, and is filled with fluid. The cochlear coil is divided into three channels: the scala vestibuli, scala media, and scala tympani. The scala vestibuli and scala tympani are filled with perilymph and communicate via an opening at the apex known as the helicotrema. The central duct, the scala media is filled with endolymph and bounded by two membranes, Reissner's membrane (top) and the basilar membrane (bottom), that form a wedge-shaped partition. On the basilar membrane (about 35 mm long), along the full length of the scala media, lies the organ of Corti, which contains the actual receptor cells that are responsible for hearing. On the inner side of the tunnel of Corti, a single row of inner hair cells, approximately 3,400 in total, are lined up side by side along the entire length of the organ of Corti (35 mm). On the outer side of the tunnel of Corti are three rows of outer hair cells, approximately 13,400 in total in humans. Each hair cell has 'hairlike' projections, called stereocilia, projecting from their apical surface. About 90–95% of the fiber of the auditory nerve connect to the inner hair cells. Many outer hair cells converge to a single auditory nerve fiber, while each inner hair cell may excite up to 20 auditory nerve fibers. The outer hair cells act to enhance the selectivity by changing the mechanical properties of the basilar membrane. If the outer hair cells are selectively damaged, there is a loss of sensitivity. The hair cells and nerve fibers are held in place by supporting cells.

The motion of the footplate of the stapes in the oval window moves the fluid of the inner ear. This air vibration, magnified by the middle ear, creates a pressure wave in the fluid, which distorts the basilar membrane in the scala media. Since the fluids of the cochlea are incompressible, the displaced fluid, in turn, causes an outward displacement of the round window. This produces a progressive traveling wave on the membrane from base to apex. Traveling waves produced by high-frequency sounds (shorter wavelength) show maximum displacement near the base of the cochlea, while those produced by a low-frequency sound (longer wavelength) come to a peak near the apex. Arching over the hair cells is the tectorial membrane. The differential motion of the basilar and tectorial membranes results in a shearing motion of the stereocilia of the hair cells. This bending of the hair cells produces an electrical discharge in the cochlear portion of the VIIIth nerve. A chemical is released at the base of the hair cell when the stereocilia are sheared. Although the mechanics of the organ of Corti are very complex as a result of different motions of the basilar membrane (up and down, side to side, etc.), the aforementioned briefly describes how mechanical motion is converted into neural activity in the organ of Corti. The size of the electrical response of the cochlea is directly related to the extent to which the hair cells are sheared.

Ancient Egyptian

Ancient Egyptian is a branch of the Afroasiatic family (also called Hamito-Semitic in traditional comparative linguistics) attested in Egypt from 3000 BCE to 1300 CE. Within its family, it shows the closest relationships to Cushitic, Semitic and Berber. There are two main stages in the development of the Egyptian language (cf. Loprieno 1995):

(1) Earlier Egyptian (3000–1300 BCE), further subdivided into:

(a) Old Egyptian (3000–2000 BCE: Old Kingdom/First Intermediate Period);

(b) Middle or Classical Egyptian (2000–1300 BCE: Middle Kingdom/XVIII Dynasty; used in religious texts until the Greco-Roman period);

(2) Later Egyptian (1300 BCE–1300 CE), further subdivided into:

(a) Late Egyptian (1300–700 BCE: Dynasty XIX/Third Intermediate Period);

(b) Demotic (seventh century BCE to fifth century CE: originally the language of administration during the Late Period, used also in literary texts);

(c) Coptic (fourth to fourteenth century CE: the language of Christian Egypt);

Earlier and Later Egyptian differ from one another in the following respect: the former displays a preference for synthetic grammatical structures (suffixes for gender, number, etc.), whereas the latter shows a tendency towards analytic grammatical devices (prefixation, verbal periphrases). Moreover, Demotic and Coptic differ from previous stages with respect to the graphic system.

Alphabet

Egyptian hyeroglyphs are a complex set of graphemes, variable in number according to the period considered. They are pictographic signs representing any kind of persons, animals and objects. The two components of an Egyptian word are:

(1) A sequence of *phonograms* that may be mono-, bi- or triconsonantal (according to the number of consonantal phonemes represented). The vocalic phonemes are never graphically expressed. Bi- or triconsonantal signs are usually accompanied by the so-called 'phonetic complements', i.e. monoconsonantal phonograms which specify one or more phonemes of the bi- and triconsonantal sign, thus allowing for a more simplified reading of the intended word.

(2) A *semagram,* named *determinative* in Egyptological tradition, usually accompanies the sequence of phonograms spelling out the semantic domain of the word.

Some words are written phonologically, combining (mainly mono-)consonantal signs, many others are written with logograms (referred to as ideograms in the Egyptological literature), i.e. signs either representing the object or another entity phonologically similar in structure to the intended word (as in a *rebus),* or even an object metonymically or metaphorically connected to the intended object. There are 24 monoconsonantal signs.

Hieratic and Demotic writing systems derive from the hieroglyphic one: Hieratic is an italicization of the latter, whereas Demotic stems from the late Hieratic writing. The Coptic writing uses Greek alphabet (with seven additional signs derived from Demotic and representing sounds absent from the Greek alphabet).

Phonology and Pronunciation

The study of Egyptian phonology is made difficult by the writing system used. As noticed above, vowels are never represented in the hieroglyphic alphabet, semivocalic phonemes only seldom. Things are complicated by the fact that the phonological reality of Coptic (vocalic) characters, often invoked as a comparison for the purpose of phonetic reconstruction, is far from being clear, and the Coptic is chronologically far away from the earliest stages of Egyptian language. Therefore, the pronunciation of Egyptian words is often a matter of convention. Other heuristic criteria resorted to by egyptologists in order to reconstruct the phonological reality of Ancient Egyptian are mainly the contemporary transcriptions and renderings of Egyptian words in Akkadian (archive of el-'Amarna, fifteenth to fourteenth century BCE) and in Greek texts (starting from the fourth century BCE). Also, the Egyptian rendering of foreign words may be taken as a reconstructing criterion.

The consonantal inventory of Ancient Egyptian is given in Table 1 (adapted from Loprieno 1995;

TABLE 1   The Consonantal Phonemes of Ancient Egyptian

Consonants	Bilabial	Dental	Alveo-palatal	Palatal	Velar	Uvular	Pharyngeal	Glottal

phonemes are given both in the common transcription system of Egyptian texts and in their supposed phonetic value).

Historically, the opposition between voiceless and voiced phonemes tends to be neutralized into the voiceless variant. The vowel inventory is fairly limited (as usual in Semitic languages), including /i/, /a/ and /u/ and their long counterparts. The phonemes /e/ and /o/ are attested in Later Egyptian.

Morphosyntax

Ancient Egyptian has inherited the preference of languages of its family for bi/triconsonantal roots. The number of consonants in a root may range from one to four, but the vast majority of roots is biconsonantal *(sn* 'brother') or triconsonantal (*ḫpr* 'become'). Entire lexical families may be formed from a given root, either by varying the internal vowels or by means of suffixation. In the transcription system, suffixes are indicated by periods preceding them. As for nominal morphology, there are suffixes marking gender (masculine and feminine) and number (singular, plural, dual [attested only in Early and Middle Egyptian]). In Table 2, the morphemes for gender and number are illustrated for the noun *sn* 'brother'.

TABLE 2 Gender and Number Markers for *sn* 'brother'

	singular	plural	dual
masculine	*sn.Ø*	*sn.w*	*sn.wj*
feminine	*sn.t*	*sn.wt*	*sn.tj*

Early Egyptian has no articles: the form *sn* may refer both to 'a brother' and to 'the brother'. Later, articles arose from the deictic *pꜣ/tꜣ/nꜣ* 'the said'.

When used attributively, adjectives usually follow the noun and agree with it in gender and number (*sn=j nfr* [brother-my beautiful] 'my beautiful brother'/ *sn.t=j nfr.t* [sister-my beautiful] 'my beautiful sister'/, etc.). When used predicatively, they precede the noun and do not agree with it (the so-called adjective verbs: *nfr sn=j* [beautiful brother-my] 'my brother is beautiful'/ *nfr sn.t=j* [beautiful sister-my] 'my sister is beautiful'/ etc.).

Personal pronouns are either independent or affixal; affixal pronouns are further divided into **dependent** and **suffixed** pronouns (see Table 3, adapted from Loprieno 1995): the former are used mainly as objects of transitive verbs, and as subject of adjectival and adverbial phrases, the latter are used to indicate: (i) the possessor in nominal construct state *(sn=j* [brother-I] 'my brother'), (ii) the subject of verbal phrases *(sḏm=j* [hear-I] 'I hear'), (iii) the prepositional complement *(n=j* 'to me (DAT)'). *Independent* pronouns, on the other hand, are used as subjects in nominal phrases *(jnk sn=k* [I brother-you] 'I'm your brother') and in verbal phrases. In both these cases, the pronoun is in focus and conveys contrastive information (as in cleft sentences).

Possessive pronouns ('mine', 'yours', etc.) are formed by a demonstrative pronoun (*pꜣj/tꜣj/nꜣj* 'this (masc./fem./plur.)' agreeing with the possessee) and a suffix pronoun agreeing with the possessor. Possessive pronouns are often used as possessive adjectives in nonofficial texts instead of the suffix pronouns (*pꜣj=j sn* [the-my [mine] brother] 'my brother' instead of *sn=j* [brother-I] 'my brother'). This strategy is the most widespread in Demotic.

2nd person	*.tj*	*.twnj*	*.twnj*
3rd person masculine	*.j > .w*	*.wj*	*.w*
3rd person feminine	*.tj*	*.tj*	*.tj*

Relative pronouns are 'positive' and 'negative' (see Table 4).

The possession relation between two nouns is expressed either (i) with the so-called nominal 'construct state' (i.e. the nouns are juxtaposed with no overt marking of either the possessor or the possessee; the word order of this construction is possessee–possessor: *s3 R^c* [son Ø Ra] 'son of Ra') or (ii) with the determinative pronoun *n(j)*[masc.sg.]/ *nw*[masc.plur.] */nt*[femin. sg. and plur.] 'that of, belonging to', agreeing with the possessee: *s3.t nt R^c* [daughter DET$_{+AGR}$ Ra] 'daughter of Ra'. In the development of the Egyptian language, this determinative pronoun grammaticalized into an invariable genitive marker *n: s3.t nR^c* [daughter DET$_{-AGR}$ Ra] 'daughter of Ra'.

The verbal system of Classical Egyptian is synthetic: T-A-M morphemes *(n* past tense; *t* perfective; *w* prospective aspect and passive voice; *tw* passive voice) and suffix pronouns are attached directly to the verbal root. T-A-M morphemes, if present, precede the suffix pronouns. Some verbal roots ('weak verbs') show a reduplication of the last radical phoneme in non-finite verb forms. The imperative corresponds to the basic form of the root (with no suffix pronouns or reduplication); some verbs, however, display irregular forms of imperative (*rdi* 'to give', imp.: *im*; *ij* 'to go', imp.: *mi*). A form usually called pseudo-participle, old perfective, or stative (cf. Table 5, adapted from Loprieno 1995) is characterized by a series of suffix pronouns different from that sketched in Table 3. This form conveys perfective meaning.

Infinitives bear a Ø-morpheme in the regular verbs and a *.t* feminine ending in the class of 'weak verbs'.

Sentences are classified according to the kind of predicate; compare the following nominal (1), adjectival (2), adverbial (3) and verbal (4) sentences:

(1) *ink sn=k* ('I'm your brother')
(2) *nfr pr=k* ('your house [*pr=k*] is beautiful [*nfr*]')
(3) *s3.t=k m pr=k* ('your daughter [*s3.t=k*] is in [*m*] your house [*pr=k*]')
(4) *sdm=j it=f* ('I hear [*sdm=j*] his father [*it=f*]')

Demotic

The stage of development termed Demotic is characterized by the evolution from a synthetic to an analytic morphology. In the field of nominal morphology, for instance, the development of a definite and indefinite article from the deictic adjective *p3/t3/n3*, 'the said', pairs the progressive loss of the nominal endings (see Table 2).

	Singular definite	Plural definite	Singular indefinite	Plural indefinite
Masculine	*p3 sn*	*n3 sn(.w)*	*w^c sn*	*hjn sn(.w)*
Feminine	*t3 sn(.t)*	*n3 sn(.wt)*	*w^c.t sn(.t)*	*hjn sn(.wt)*

Ancient Greek

Overview

A(ncient) G(reek) belongs to the Indo-European family, of which it constitutes a separate branch. Its primary relevance to Indo-European studies and studies on language change owes to several factors. In the first place, AG is the second earliest attested Indo-European language after Hittite. It is considered to be pretty conservative under different respects (phonology, inventory and realization of inflectional categories, word order, among others). Besides, its development continued after antiquity into the Middle Ages (Byzantine and Medieval Greek) up to the present (Modern Greek), which makes Greek the language with a longest recorded history together with Chinese. Unfortunately, this long time span is not evenly documented: there are breaks, one of which concerns the present discussion, covering the period that goes from the first written attestations (13th century BCE) to the redaction of the Homeric poems (eighth century BCE).

Speakers of some AG varieties are thought to have entered mainland Greece in the second half of the third millennium BCE, then spreading to the Aegean islands, Crete and Cyprus, and slightly later to the Aegean coast of Anatolia, and to Southern Italy and Sicily. The first written sources date back to the second millennium BCE, and were found in Pylos (in the Peloponnesus) and on the island of Crete. The language of these early records is usually referred to as Mycenean Greek.

Although they are several centuries older than the main bulk of AG written sources, the Mycenean tablets do not preserve a sort of "Proto-Greek": in spite of displaying a number of archaic features, including phonemes that later merged with others in all Greek varieties, Mycenean is already characterized as belonging to a specific dialectal group. Dialectal variation is another noteworthy peculiarity of AG: contrary to most ancient languages, AG had various local literary traditions, based on different varieties; furthermore, inscriptions preserve local vernaculars, still different from the standardized literary variety chosen for each dialect. Although variation within the literary language is mostly limited to Pre-Classic time (before the fifth century BCE), specific literary genres remained connected with the dialect in which they had their earliest development, so that classical authors used to give a specific dialectal color to certain types of texts (for example, in Attic tragedy it was customary to introduce a number of Doric features in the choruses, because the invention of choral poetry attributed to the Dorians).

The two most important literary dialects were Ionic and later Attic. Since these two varieties are closely related to each other, and literary Attic gave up a number of vernacular features under the influence of the more prestigious Ionic, the literary dialect is commonly known as "Attic-Ionic". The preservation of dialectal variation was favored by political fragmentation. After the unification of Greece under the Macedonian kings in the fourth century BCE, linguistic unification also started, resulting in the development of a common variety, the *koiné,* which was spoken during the centuries of the Roman (later Byzantine) Empire, and served as the basis for further developments.

Mycenean Greek

M(ycenean) G(reek) is known since the 1950s, when its decipherment was accomplished by Ventries and Chadwick. The Mycenean script, commonly known as Linear B, is a syllabary consisting of around 90 signs for CV syllables, which makes it unsuitable for writing consonant clusters and word final consonants. The clay tablets that document MG were not meant for long term preservation, as shown by the fact that they were not baked: some of them reached us because they were accidentally baked in the fires that destroyed the archives. The tablets mostly contain lists of various items, lists of workers, and some descriptions of land properties. In spite of the limitations connected with the text types and of poor spelling, a number of interesting features can be singled out, including the preservation of the Indo-European labiovelars, changed into bilabial or dental stops in later dialects, and of velar glides, dropped in the later literary varieties, a richer case system, which included at least an independent instrumental case, and systematic omission of the verbal augment. Other peculiarities of MG show its dialectal connections with the Arcado-Cypriot and the Aeolic groups.

The Greek dialects

The Greeks, who lacked political cohesion, identified themselves as opposed to all other peoples on the basis of what they felt as a common language. They divided themselves into three dialectal groups, Ionic (also comprising Attic), Aeolic, and Doric, all connected

with prestigious literary traditions. Modern research has shown that a fourth dialectal group also existed, commonly called Arcado-Cypriot, possibly not recognized by the Greeks because its speakers did not produce any noteworthy literary achievement; furthermore, Doric is now considered a member of a wider group, called Western Greek. Until the decipherment of MG, Greek dialects were classified as belonging to two main groups, Eastern Greek, further divided into Attic-Ionic, Aeolic, and Arcado-Cypriot, and Western Greek, comprising Doric and North Western Greek. The similarities of MG to both the Arcado-Cypriot and the Aeolic groups have led certain scholars to set up a three-way classification, including Attic-Ionic, Achaean (Aeolic, Arcado-Cypriot, and Mycenean), and Western Greek (see Figure 1).

(NB: Southern Italy and Sicily were occupied by speakers of Doric).

Numerous dialectal variants were simply phonetic, although some phonological differences also existed; besides there were morphological and lexical features peculiar of each dialectal group, but all varieties were by and large mutually intelligible.

Written sources

Apart from the Mycenean tablets, the oldest written source is constituted by the Homeric poems. The poems were first written in the eight century BCE (the oldest epigraphic inscriptions also date back to the same century), but their oral composition dates back to several centuries before. Writing had disappeared from Greece after the fall of the Mycenean civilization; early historians trying to reconstruct Greek history describe a sort of "Dark Age" with rather turbulent social habits; they had no memory of the refined civilization that preceded them, and did not know that earlier Greeks had used another writing system centuries past. The Homeric poems were composed during this illiterate time; their language, basically an Ionic variety, preserves a number of archaic features, which makes the poems one of the most important documents for Indo-European studies.

Other early literary texts include Aeolic and Doric poetry from the seventh and sixth centuries; prose was apparently an Ionic invention, the most significant early Ionian prose writer being Herodotus, who composed his *Histories* in the sixth century BCE. The bulk of what is commonly considered classical Greek literature, from the fifth and early fourth centuries BCE, comes from the city of Athens. It is written in literary Attic, and includes the tragedies of Aeschilus, Sophocles, and Euripides, Aristophane's comedies, as well as works by philosophers as Plato, historians as Thucidides, and numerous political orations.

The language of later writers increasingly displays typical features of the *koiné*. One of the most important sources for the knowledge of the latter is constituted by the *New Testament,* written in the first century CE. From the same period we also have a number of non-literary papyri, which help us understand the real extent of changes undergone by the spoken language. For during the first centuries CE literary Greek started to move more and more away from the spoken language, first with a puristic reaction to the intrusion of "vulgar" features (Atticism), and later with the development of a peculiar diglossic situation, which was still characteristic of Modern Greek until the 1960s.

AG was written in alphabetic script, with a wide number of local variants. Table 1 contains the standard Greek alphabet, as used in modern editions of ancient authors; it basically corresponds to the Modern Greek script, although phonetic values are no longer the same.

Morphology

AG has a big number of inflectional categories, both for nouns and for verbs. Its morphology is highly fusional, with a fairly high degree of allomorphy, partly due to simplification of consonantal clusters or monophthongization of diphthongs (vowel contraction).

Nouns are inflected for case (nominative, accusative, genitive, dative, and vocative) and number (singular, plural, and dual); they belong to three genders (masculine, feminine, and neuter). Nominal inflection only employs suffixes. There are three inflectional classes, called first (/a:/ stems), second (/o/ stems), and third declension (consonant and /i/ and /u/ stems); assignment of a noun to a declensional class is determined by its phonological shape. Already in MG /a:/ stems, which were mostly feminine, developed a subclass for masculine nouns, with special endings for the nominative and the genitive singular. The third declension, which displayed the highest degree of allomorphy, lost its productivity rather early, and nouns of the third declension moved to other inflectional classes (some doublets with a consonant and a -o- variant are already found in Homeric Greek; in the *koiné* consonant stems switched massively to -*ā*- stems).

Adjectives, demonstrative, and the definite article (created after Homer) share the inflectional categories of nouns; when modifying nouns they agree with their heads in all inflectional categories. Adjectives are divided into two classes, according to whether they have three different forms for the three genders, or only two (with masculine and feminine undifferentiated). They also inflect for degrees of comparison (comparative and superlative).

Verbs are divided into two classes, thematic and athematic. They are inflected for mood (indicative, optative, imperative, and subjunctive), tense/aspect (present, imperfect, aorist, perfect, future, pluperfect, and future perfect), diathesis (active, middle, and passive), person, and number (singular, plural, and dual). A separate passive is only found in the aorist, perfect, and future; in the other tenses, the middle can have both middle and passive meaning; the imperfect, the perfect and the pluperfect are found in the indicative only, the future and the future perfect only in the indicative and in the subjunctive. Nominal forms of the verb include an array of infinitives and participles and two verbal nouns. Verbal morphology is more varied than nominal morphology: besides suffixes, one also finds prefixes (so-called "augment" for past tenses in the indicative, and reduplication in the perfect and some presents), and alternation of the root vowel (apophony). Below some typical verb forms are analyzed for convenience:

1. *leíp-ō,* first sg. pres. indic., "I leave"
   present stem+inflectional ending

2. *leíp-oi-mi,* first sg. pres. opt., "may I leave"
   present stem+suffix+inflectional ending
3. *é-leip-on,* first sg. imperfect, "I was leaving"
   augment+present stem+inflectional ending
4. *é-leip-s-a,* first sg. aorist indicative, "I left"
   augment+present stem+suffix+inflectional
   ending
5. *é-lip-on,* first sg. aorist indicative, "I left"
   augment+aorist stem+inflectional ending
6. *le-loíp-a,* first sg. perfect, "I left"
   reduplication+perfect stem+inflectional ending

(this verb has two possible aorists, sigmatic, as in (4), with the suffix -*s*- and the same stem as the present, and thematic, as in (5), with apophonic variation of the root vowel).

AG also has a big variety of derivational affixes. Most category changing affixes are suffixes: *díkē,* "right (noun)", *dík-aio-s,* "just (adjective)", *dik-aio-súnē,* "justice (noun)", *dik-áz-ō,* "I judge (verb)". Prefixed derivates normally maintain the same word class of the base: *a-díkaios,* "unjust (adjective)", *sun-dikázō,* "I have a share in judging (verb)". Besides derivation, compounding was also very productive.

Syntax

AG has nominative-accusative alignment. The subject of both transitive and intransitive verbs is inflected in the nominative; note, however, that neuter nouns have nominative=accusative. A further peculiarity of neuter subjects is constituted by incomplete verbal agreement: neuter plural take the verb in the singular: *tà zôia trékhei,* "the animals (pl.) run (3rd sg.)". The subject need not be overtly expressed when it is recoverable from the context; to a lesser extent, the direct object, too, may be omitted if recoverable. Transitive verbs can have passive form, in which case subject function is assigned to the direct object of the corresponding active; the agent may or may not be added as an adjunct (prepositional phrase).

The accusative is basically the case of the direct object of transitive verbs; it also has a limited use as allative (mostly in poetry), and a rather peculiar adverbial use, the "accusative of respect": *pódas* (accusative) *ōkùs* (nominative) *Akhilleús* (nominative), "Achilles swift-footed".

The genitive is used for nouns functioning as modifiers of other nouns. It also has an adverbal use: certain verbs only take the genitive (*árkheín tinos,* "to rule over sbd. (genitive)"), others allow variation of the accusative and the genitive, which in such cases has partitive meaning: *píen tòn oînon / toû oínou,* "to drink (all the) wine (accusative)/ some wine (genitive)". At a pre-literary time the genitive merged with the ablative, and took over its functions; consequently, we find the genitive with verbs that indicate some sort of separation and with the prepositions that take the ablative in the other Indo-European languages (e.g. *ek,* "out of", *apó,* "from", cf. Latin *ex, ab,* both with the ablative).

The dative is the case of the third argument of verbs of exchange and communication; when occurring outside the verbal valency, it can indicate the participant for whose sake an action is performed (benefactive); often it occurs in the "external possessor construction": *epeidḕ dé moi* (dative) *hē mḗtēr eteleútēse,* "after my mother died", "after the mother died on me". The dative merged with two other cases: the locative (possibly already before the Mycenean age), and the instrumental (after MG, where the instrumental case is still preserved). While the locatival function of the plain dative is mostly limited to poetry, its instrumental function was very productive: only around the first century CE prepositional phrases start to be found in place of the plain dative to express instrumental.

Verbal tenses partly have aspectual value, especially outside the indicative mood. The basic aspectual opposition is between the present (imperfective) and the aorist (perfective). The perfect originally had a resultative function, inherited from PIE: pres. *baínō,* "I go", perfect *bébēka:* "I am (in a certain place)". Modality is expressed partly by verbal moods, partly by the modal particle *an,* used in some conditional sentences, and partly by verbal tenses (the imperfect may be used for contrary-to-fact modality). Besides, the optative also has a purely syntactic use when it occurs in subordinate clauses that depend on other subordinate clauses ("oblique optative").

AG has a complex system of hypotaxis, including: (a) complement clauses, which can have the verb in the infinitive and the subject in the accusative or in the nominative, or the conjunction *hóti,* "that", and the same moods/tenses of independent clauses; (b) relative clauses, with the relative pronoun *hḗ, hós, hó;* (c) various types of adverbial clauses. A peculiarity of AG subordination is the extremely widespread and elaborated use of participles. The wide use of participles can at least in part be explained through the need to make up for the lack of adverbial verb forms ("converbs", corresponding to the English gerund); still, the existence of participles for most aspect/tenses and for all diatheses constitutes a rather infrequent typological feature of AG.

AG word order is governed by pragmatic factors. In particular, the finite verb can stand in any position in the sentence, and, if transitive, precede or follow the direct object, both in poetry and in prose. The subject, if expressed, can be placed before or after the verb, but preverbal position is more frequent. Modifiers (both adjectival and nominal) can precede or follow their heads; adpositions mostly precede their complements,

although Homer has some occurrences where they are postposed, and relative clauses follow their head, with few exceptions. The definite article precedes the noun or noun group it determines; if a head noun is followed by an attribute, the article is repeated (*ho anèr ho agathós,* "the good man", lit. "the man the good"). A noteworthy group of words with respect to word order is constituted by so-called "postpositives". Postpositives are various types of conjunctive particles, modal particles, and enclitic pronouns; they all share the peculiarity that they cannot be placed in sentence initial position (this opposes them to prepositives, as the negation *ou,* that can never be sentence final). Most frequently, postpositives are placed after the first word or first constituent in the sentence (Wackernagel's position), thus separating parts of the same constituents, sometimes even the definite article from the noun it determines.

Greek and Indo-European

AG is generally considered a rather conservative Indo-European language. Features that make AG particularly valuable for the reconstruction of PIE include the vowel system, diphthongs, the three series of stops (voiceless, voiced, and aspirated), the retention of numerous inflectional categories, which AG shares with Indo-Iranian, and many of the inflectional affixes, along with the different morphological processes (reduplication, root and suffix apophony, pre- and suffixation) and a highly fusional morphological technique. In spite of case syncretism, AG still preserves the basic uses of cases which can be reconstructed for PIE. Word order variation connected with pragmatic factors is common to many ancient Indo-European languages, although AG appears to have moved in the direction of bigger freedom: in this connection, the retention of Wackernagel's Law for the placement of clitics and other postpositives is a remarkable archaic feature. The field in which AG has innovated most is certainly hypotaxis, whose development is a consequence of the creation of a highly elaborated literary standard.

Animals and Human Language 1: Overview

How is human language related to animal communication systems? While humans are animals with a common chimpanzee–human ancestor living as recently as five million years ago, neither chimpanzees nor any other species naturally use a communication system with anything similar to the complexity of human language. Is human language an enormously elaborated development of an original communication system used by the chimpanzee–human ancestor? Or is it a purely human innovation, unrelated historically to any animal 'language'? There is no consensus on these questions. These two views, 'continuist' and 'discontinuist', respectively, have vigorous champions. Both camps agree, however, that human language and animal communication systems differ significantly. It is these differences, as well as similarities, that provide linguists an opportunity for analysis of the relationship, if any, between human and animal 'language'.

It is tempting to think of language primarily as a tool for objective communication. However, humans also use language to think and to create a mental representation of their experience. Even a hermit who has never spoken for decades will use language for this purpose. Some 'discontinuist' scholars have argued

that the use of language for communication is historically secondary, and that its original function was cognitive. This would render the differences between human language and animal communication less surprising. On the other hand, it is hard to show conclusively that no animal 'language' has cognitive as well as communicative functions. This alleged peculiarity of human language is therefore controversial.

While one commonality among animal communications and human languages is the concern with biological, objective, or factual information, much human discourse is not primarily factual in content. Many animals vocalize to advertise territorial control, or for sexual display. Here, it is not 'what is said' that matters, but merely the fact that the vocalization occurs, and perhaps also its vigor and elaborateness. Similar in function to human singing, factual communication is the primary purpose of animal communication. Human language, however, can also concern abstract thought.

Every normal human adult human has a vocabulary of thousands of items. Among animal communication systems, the total does not exceed a few dozen. This may ensure that the domains of experience within which communication is possible among animals are severely limited, extending scarcely beyond food, danger, sex, and dominance.

The size of human vocabularies is one of the factors that allow us to talk about things outside our immediate environment. The fact that a person lives in New Zealand in the twenty-first century does not prevent her from talking about the surface of the planet Mars, or about the civilization of Egypt in the second millennium BCE. This characteristic of language has been called 'displacement'. In principle, displacement does not presuppose a large vocabulary. A chimpanzee, for example, could conceivably use its danger calls to talk about not immediate danger but a possible danger tomorrow. However, no chimpanzee does this. The only animal communication system that resembles language in respect of displacement is the dance 'language' of bees, which encodes information about the direction, distance, and quality of food sources. Until the 1980s, it was widely thought that animal calls were all subjective or attitudinal, concerned with the animal's state of body or mind ('I'm afraid!', 'I'm hungry!', 'I want sex!') rather than with identifiable external characteristics of their environment. It has now been demonstrated, however, that vervet monkeys use distinct alarm calls for distinct predators (eagles, leopards, and snakes). Furthermore, on hearing such a call a vervet reacts to the call itself, not to the predator whose presence is signaled. These calls lack displacement, but in other respects they have much of the objective semantic character of words in a human language.

A vocabulary of 10,000 items would be hard to manage if each item were an unanalyzable whole. However, the words of human languages can be divided into individual contrasting speech sounds. Approximately 45 (depending on dialect) of such sounds are used in spoken English, while other languages may differ in the number of discrete sounds. All languages share the characteristic of being structured, or patterned, on two levels: a level of meaningful units (words, phrases, sentences) and of meaningless units (sounds, syllables). For example, in the word *pot,* no one sound, *p, t,* or *o,* carries meaning. Of the word *top,* containing the same sounds, the same is true. Rather, it is the relationship of the sounds that imparts meaning to the words. Animal communication systems lack this so-called 'duality of patterning'. Individually meaningful calls are not constructed entirely out of meaningless parts recurring in other calls.

In human language, words are not merely strung together, but are combined into larger units (phrases and sentences) that are systematically interpretable. Thus, for example, all speakers of English will agree on the interpretation of *John will kill the crocodile*, and will agree in interpreting it differently from *The crocodile will kill John.* Here, it is the relationships among words that imparts meaning. This characteristic of language is called syntax. The syntax of human language is open-ended in that phrases and sentences can be embedded within larger phrases and sentences, as in *Mary thinks her father denied that John will kill the crocodile*. No naturally occurring animal communication system has a systematic syntax, even of the most rudimentary kind. In particular, no such system has the open-endedness that human language derives from embedding.

Some apes (mainly chimpanzees) that have been exposed to American Sign Language (ASL) have acquired vocabularies of a hundred or more signs, and have used them to communicate with humans and with each other. However, claims that these apes have mastered elements of ASL syntax are highly controversial. Controversial, too, is the claim that a bonobo, or pigmy chimpanzee, called Kanzi had at the age of eight acquired a systematic mastery of elements of English syntax. What apes can achieve in situations of exposure to human language is remarkable, but their achievements still differ considerably from those of humans. Perhaps, then, it is not in having language that humans are unique, but in having syntax.

While sharing some features, animal communication differs from human language in terms of size of vocabulary, contextual dependence on the environment for communication, and syntax. Examining these aspects of both types of communication systems, and the overlap between them, enables a fuller

understanding of language structure and utility. This more complete analysis could aid research in speech and language disorders and cognitive psychology.

Animals and Human Language 2: Dolphins

Can a dolphin master language? Scientists cannot begin to answer this question until human language has been fully mapped and its defining features agreed upon. In the meantime, those interested in comparative cognition and in the evolution of human language can make great strides by asking smaller and more specific questions. Can a dolphin master an artificial signal system; that is, using signals that are not innate? Can it master a discrete–combinatorial system—here, one in which these artificial signals, each of fixed form, can be combined with each other into strings? Can it further master sequential rules, in which (functionally paralleling grammatical rules) the order of signals affects interpretation?

Since the 1950s, three groups of researchers have worked with bottle-nosed dolphins on the production or comprehension of such artificial, discrete–combinatorial systems, or ADCs. However, virtually all of what is currently known and accepted about dolphins' ADC abilities comes from the work of the last and current group, led by Louis Herman, and most of these data come from two wild-caught female dolphins, Phoenix and Ake. (As is usual in animal language research, individual animals are reported by name.) This work has shown that dolphins can comprehend a small discrete–combinatorial system involving a few sequence-based rules. Dolphin abilities appear to include the following:

(1) Both auditory and visual modality signals. Phoenix obeys computer-generated whistles, while Ake obeys gestures. Many nonhuman animals can only learn easily in one modality; dolphins, like apes and humans, are cognitively flexible enough to master more.

(2) Symbol comprehension. The dolphins' signal set, though small, is open, since the dolphins have mastered signals for objects they could never have encountered in their evolutionary history, (such as frisbees and surfboards). They extend established signals to new examples, and they can comprehend such signals even when they are given for the first time as part of a new function (e.g. a question rather than a command). They can also master displacement, the use of a signal for an object that is not present, indicating that for the dolphin, a signal 'calls to mind' the referent of that signal. All this suggests that dolphins to this extent genuinely comprehend symbols, and are not just responding instrumentally.

(3) The use of signal order. Each of the dolphins has been given a different 'grammar'. (For example, to ask Phoenix to put the small ball into the white hoop, the signal string is SMALL BALL IN WHITE HOOP, while for Ake the same command is WHITE HOOP SMALL BALL IN). Thus, Ake, at least, cannot be memorizing a signal sequence and executing it mindlessly, one signal at a time, in the same order as it is presented. Furthermore, their equal success with two different orders is additional evidence that they are indeed operating from sequence-based rules.

The use of order to assign roles is robust; the dolphins are far less prone than small children to use only the meaning of signals to make sense of strings that violate established sequential rules (e.g. TOSS LEFT FRISBEE rather than the correct LEFT FRISBEE TOSS). Furthermore, if given a 'grammatically' peculiar signal sequence, the dolphins will extract any correct subsequence and act on it, whether it is at the beginning, middle, or end of the whole string.

(4) Categorization of signals into classes (such as things, qualities, and actions). Diverse evidence suggests that, as in human language, it is these categories rather than the actual signals that are ordered in the dolphins' inner rules.

(5) The use of the sign strings in diverse functional contexts.

Most of Herman et al.'s research postdates the ape language controversies of the late 1970s, and has profited extensively from them. Partly by concentrating almost entirely on comprehension rather than production, the program seems to have eliminated most of the errors in method that discredited the early ape work, exceeds even current ape research in its methodological rigor, and is highly replicable.

However, Herman's group has been criticized, first, for not pursuing production skills. Transferring symbol use between comprehension and production can be difficult for common chimpanzees, and one small study with Phoenix suggests that it may prove difficult for dolphins. Perhaps, this is because Herman's program uses food rewards rather than communicative training to shape the dolphins' behavior, and this is a second point of criticism. In apes, giving the same response—food—to every correct signal use has been shown to inhibit development of maximally human-like symbol use.

Third, exactly how many mental rules the dolphins use to interpret their ADC strings is unknown, but (depending on how elaborate each rule is) it may be as few as two. This uncertainty is significant only if it is assumed that the goal is to produce an animal with extensive or full human-like language skills. More realistically, it gives a direction for future research; how many, and how diverse, are the sequential rules that this species can master?

Fourth, early claims that dolphins could master displacement were justly disputed on the grounds that the tests involved were of memory, rather than of ability to use a symbol to access a concept. Subsequent tests have since given better proof of displacement.

Fifth, early and theoretically significant claims of mastery of recursion were also justly disputed. The evidence in question was the ability of the dolphins to respond correctly, on the first trial, to a sequence of two command strings (such as FRISBEE TOSS, BALL TOUCH). Initially offered as evidence for underlying mental recursive rules, these strings appear to require merely iteration, a much simpler rule structure. The early claims of recursion have not been repeated, and to date no other exploration of recursion has been reported.

Sixth, Schusterman and Gisiner have challenged the Herman group's calculations of probability for commands involving goal objects. However, it appears that regardless of which calculation is used, the dolphins do reliably 'pass the test', albeit with more mediocre scores.

Finally, Herman et al. have been criticized for applying linguistic terms such as 'sentence', 'modifier', or indeed 'language' to the dolphins' use of the ADC. What may even be called ownership of linguistic terms is a perennial argument within animal language research. Herman overtly uses linguistic terms as hueristic devices, to provoke reassessment of definitions: others insist that such terms can be used only as defined within one or another established linguistic approach. The issue seems unlikely to be soon resolved.

Animals and Human Language 3: Parrots

In an attempt to determine the relationship between human language and animal communication, researchers have often studied the potential for communication between humans and animals. Beginning in the early 1960s, most studies on animal–human communication focused on great apes and a few cetacean species such as dolphins, as these animals were assumed to possess the potential for complex cognitive abilities considered as prerequisites for language development. Birds, with a few exceptions, were rarely subjects of such studies as they were presumed to be merely talented mimics. For example, experiments on pigeons using standard laboratory paradigms demonstrated capacities far inferior to those of mammals. These results were thought to represent the abilities of all birds, despite evidence suggesting that species such as jays, crows, and parrots might be capable of more impressive cognitive and communicative feats. In particular, parrots, like primates and cetaceans, have large brains, long lives, and highly social natures; couldn't parrots also have evolved complex cognitive capacities? Could proper training enable them to demonstrate language-like abilities comparable to those of nonhuman primates and cetaceans?

Research spanning more than 20 years has provided positive answers to these questions. After being trained with a technique called the model/rival (M/R) procedure, Gray parrots (*Psittacus erithacus*) learned to use aspects of English speech. In the standard M/R protocols, two humans demonstrate the labeling ability that a bird is to acquire. One human trains the second (the model/rival), i.e. presents and asks questions about the item (e.g. 'What's here?'). The trainer rewards correct identification with the item, demonstrating referential and functional use of labels, respectively, by providing a 1:1 correspondence between label and object, and modeling label use as a means to obtain the item. The second human not only is a model for a bird's responses and its rival for the trainer's attention, but also illustrates aversive consequences of errors: trainers respond to errors by scolding, and temporarily hide the object. Birds quickly acquire referential label use with such training.

This two-way communication code was then used to test the parrots' cognitive abilities. The oldest bird in the study, Alex, labels more than 50 objects, seven colors, five shapes, up to 6 quantities, and three categories (color, shape, material). He also appropriately uses 'no', 'come here', 'wanna go X', and 'want Y' (where X and Y are appropriate location or item labels). He correctly responds to questions asking him to judge category, relative size, quantity, similarity or difference in attributes, and to demonstrate label comprehension. When shown a colored wooden block, he can respond to questions of 'What color?', 'What shape?', 'What matter?', and 'What toy?' Given two objects, he can respond vocally to 'What toy?', 'How many?', 'What's same/different?', 'What color bigger/smaller?', 'What matter bigger/smaller?' If given a tray with different numbers of, for example, red and blue balls and blocks, he can respond to 'How many blue blocks?' with the appropriate quantity label. He thus not only produces labels in response to simple queries but also comprehends questions that involve multiple labels and recursion. He combines labels to identify, request, comment upon, or refuse more than 100 items, and to alter his environment. He uses a very limited form of syntax, involving sentence frames (e.g. 'I want X') and consistent application of the adjective–noun order construction. He requests objects in their absence and refuses substitutes, showing that he reacts to the dissonance between the concept encoded in his request and the proffered item. Such data suggest that his labels are representational. He semantically separates labeling from requesting. He practices on his own and builds upon previous knowledge to learn new sounds. After learning 'gray', he spontaneously produced 'grape', 'grate', 'grain', 'cane', and 'chain'. When these words were reinforced with the corresponding object, Alex quickly associated the two.

Particularly noteworthy are additional data demonstrating that Alex's labeling goes well beyond simple association of object and word. His labeling is equally accurate when he is presented with items that are related but not identical to training objects. He also transfers use of utterances learned in one context to another. Thus, after learning to state 'none' when asked 'What's different?' about two identical items, he could, without training, give the same response when asked 'What color bigger?' to two identically sized, differently colored blocks. Although Alex lacks all but a very few verbs, he nevertheless exhibits communicative capacities once presumed limited to humans or nonhuman primates. Similar studies with younger parrots indicate comparable results, demonstrating that Alex is not an exceptional Gray parrot.

Studies on Gray parrots also show that birds given training that lacks some aspect of input present in M/R protocols (reference, functionality, social interaction) fail to acquire referential English speech. If input fails to include, for example, joint attention of the trainer and parrot to the object being labeled, Gray parrots, like young children, do not learn the label. For similar reasons, Gray parrots fail to learn referential use of labels presented only through video or audiotapes. Depending upon the organization of M/R input, these parrots may exhibit a form of mutual exclusivity similar to that of young children: they replicate the stage in which a child believes not only that every object has a label, but also that each object can have only one label. For example, what is called 'dog' cannot be called 'animal'. Such research on acquisition patterns may aid our understanding of other forms of exceptional learning: learning unlikely in the normal course of development but that can occur under certain conditions. These results have implications both for teaching psychology and linguistics students to 'think outside the box' and for designing intervention programs for children who fail to acquire normal communication skills.

Although exceptionally rich, the behavior of the parrots described here is fully equivalent neither to human language nor to the vocal behavior exhibited even by young humans. Some behavior patterns of these birds, however, are comparable to those observed in humans, nonhuman primates, and cetaceans. The parrots' behavior thus demonstrates that certain levels of communication and cognitive development, and the responsible underlying neural structures, are present in birds and not limited to primates or mammals.

Animals and Human Language 4: Primates

Apes (here, orangutans, gorillas and chimpanzee species) are our closest animal relatives. Can they too master language? The earliest researchers to tackle this question, in the 1930s and 1950s, were the Hayes and the Kelloggs. Each team tried to raise an infant chimpanzee to understand and produce speech. Although both chimpanzees reportedly learnt to understand some spoken English, only one produced words — a mere four, and these with much difficulty and apparently with little understanding of their meaning.

The studies were useful, however, in showing that speech is physically impossible for apes. Instead, in the second chapter of ape language research (ALR), apes were taught to use manual signs, to arrange individual plastic symbols into symbol strings, or to point to or press symbols on keyboards.

In 1969, the Gardners reported the first great success with a chimpanzee named Washoe. (As is usual in animal language research, individual animals are reported by name.) They were followed through the 1970s and 1980s with many more chimpanzee projects, led by researchers such as Premack, Rumbaugh, Fouts, and Matsuzawa, and one each with a gorilla, Koko, trained by Francine Patterson, and an orangutan, Lyn Miles' Chantek.

In these programs, many apes soon learnt to produce well over a hundred signs or symbols. They also seemed to use their signs consciously, as true symbols. Many birds and mammals can learn to press certain buttons or produce certain behaviors 'instrumentally' merely for rewards, rather like pushing buttons on a food dispenser. However, the ALR apes extended old

signs to new examples of a referent, applying a sign for 'dog', for example, to a particular dog they had never seen before. Some apes could explicitly distinguish referents (e.g. the actual dog) from the signs for referents (here, the word *dog*), while many appeared to spontaneously invent new signs. Evidence like this suggested that these apes were using their signs as true symbols in a human-like way, rather than just instrumentally.

The researchers of the 1970s also believed that they had found evidence for rudimentary syntax in apes, at the same level, and with the same patterns, as children in the two-word stage of language acquisition. Some apes, such as the Rumbaugh team's Lana, could arrange much longer strings of signs into regular orders. Others, such as the Premack team's Sarah, could react appropriately to sequences that differed in sign order alone, such as RED ON GREEN vs. GREEN ON RED.

From these circumscribed achievements, many researchers of the 1970s argued broadly that apes could master language.

Criticism of the ALR accumulated, however, and towards the end of the 1970s it reached overwhelming proportions. To varying degrees, different ALR programs up to 1980 suffered from the following:

(1) *Redundancy and formulae*: Some apes could produce and respond correctly to long strings of signs, but these strings commonly took on a few formulaic patterns. Rather than manipulating grammatical rules, the apes could have been simply learning a few arbitrary sign sequences in which one or two elements could be varied depending on the context. The apes, it was argued, were merely pressing rote sequences of buttons on a machine, without seeing the buttons as symbols or the sequences as grammar-governed: it was the researchers who were assigning words to buttons and thus translating, for example, the button strings 21593 versus 21598 into 'Please machine give me M&M' versus 'Please machine give me milk'.

(2) *Contextual cues*: Training and testing of signs and strings often took place in sets of many, virtually identical repetitions. How much of the apes' success was due to grasping the signs themselves, and how much was due to their picking up the general pattern of the exercise?

(3) *Paralinguistic cues*: It was often argued that the apes could have been reacting to cues in the body language and gaze of the researchers, rather than to the signs themselves.

(4) *Overgenerous interpretation*: Researchers, it was claimed, were like doting parents, interpreting the random or the natural gestures of the apes as meaningful learnt signs. Secondly, even where clear signs were produced in appropriate contexts and with the same two-word grammar as young children, critics said that the apes' strings should not be assigned a grammar as, unlike children, the apes did not later develop a fuller grammar to justify such 'rich interpretation'.

(5) *Statistical inadequacy*: Those researchers who did undertake careful comprehension tests often gave such restricted answer choices that a high percentage of correct responses could have arisen from chance alone.

(6) *Lack of first trial data*: When tested with new sentences, apes were shown to respond quickly, However, there is a crucial difference between 'quickly' and 'on the first trial'. Only the latter can be used as evidence that the apes have access to grammatical rules, by which to decode the novel sentence: as they are known to quickly master new variations on old routines, it is possible that quick (but not instant) comprehension of novel sentences is merely quick mastery of a new variation on a rote task. The research of the 1970s typically did not identify this crucial first trial data.

(7) Indeed, methodology and testing in general were underreported in the work of this time.

The turning point, however, was the work of a single research group, led by Terrace and working with one chimpanzee, Nim. Careful analysis of certain videos of Nim's signing revealed the following:

(8) His 'grammatical' regularities could be ascribed to imitation. Nim certainly tended to order signs as his teachers did, but the videos showed that his sign strings were commonly repetitions or minor variations on those his teachers had just produced. His 'grammar' could therefore have been the result of simply parroting the true grammar of his human companions.

(9) His 'sentences' could be unusually long, but these long strings consisted of empty repetition. After entering the 'two-word stage', Nim's sign strings never increased in grammatical or semantic complexity. Children, conversely, only produce longer sentences on demonstrably acquiring further grammatical structures.

Terrace then analyzed shorter video segments of apes in other programs, and asserted that the same pattern of imitation could be seen in them.

Further, symbol use came under scrutiny once more. Were the apes consciously using symbols to refer, or were they just 'button-pushing' — behaving

instrumentally? Savage-Rumbaugh and colleagues then demonstrated that:

> (10) Their apes, which used signs appropriately in familiar contexts, were often unable to use the same signs in new tasks. If the apes were genuinely processing the signs as symbols, this failure is unexpected. It suggested that these apes were indeed simply producing signs instrumentally.

Finally, apart from all these methodological flaws, critics could always point to the enormous gap between the small vocabulary, two-word combinations and food-focused conversations of the apes, and the massive vocabulary, complex grammar, and wide-ranging topics of an adult human. For many critics, these differences alone were enough to justify the broad conclusion: 'no ape has shown any abilities relevant to language'.

Thus, in the late 1970s/early 1980s, the second chapter of ALR closed in great acrimony. Critics accused the ALR researchers of naivity and anthropomorphic bias; researchers in turn accused their critics of hysterical denial of ape–human continuity, and of constantly 'shifting the goal-posts' by hastily redefining language each time an ape passed a test of language.

Throughout the 1980s, the third chapter of ALR began. Firstly, the Nim project itself came under fire. The video segments Terrace analyzed were argued to be atypical of Nim's signing. These video segments, although long, were all taken from a single, socially and physically restrictive test situation (and one that the ape apparently found aversive). The tasks were limited to those in which the chances of instrumental signing were arguably maximized. Others who worked with this ape claimed that under better conditions, Nim signed differently.

Nim's signing was also argued to be unrepresentative of the species. The infant Nim had a chaotic social environment; in less than four years, he had a turnover of nearly 60 trainers, almost none with any prior experience of apes or signing. So stressful was this that the chimpanzee became intractable at an unusually young age. If Nim was behaving abnormally in the social context, it is possible that his 'linguistic' behavior was also abnormal.

Most importantly though, Nim, like many other ALR apes of that time, was taught signs through drills and food rewards. Thus, 'symbol' learning and use was in fact taught to these apes as an instrumental task. The natural consequence of this is that their sign use should indeed and predictably be instrumental. If so, such programs cannot reliably tell us much about an ape's ability to acquire symbols.

Savage-Rumbaugh and colleagues developed new methodologies to address this problem, finding that a more human-like social context was a key to human-like symbol use. Their two chimpanzees, Austin and Sherman, repeatedly failed to transfer sign use to new contexts. These failures were repeatedly overcome, not by yet more training for more rewards, but by adjusting the *social* interaction of the two apes from being ape-like to more human-like. Fuller, more human-like symbol use then flowed spontaneously from this.

The Savage-Rumbaugh group also opened a new chapter in ALR research with another chimpanzee, species, the bonobo. In the wild, this species exhibits, some more human-like social features than the common chimpanzee. This may be why captive bonobos appear capable of spontaneously acquiring human-like symbol use. Furthermore, they were found to acquire symbols (including comprehension of spoken words) in the same way as is natural for humans — simply by exposure as an infant to meaningful symbol use. (The latter discovery also showed that chimpanzees, like humans, have an early critical period for effortless 'language' acquisition.)

In many of Savage-Rumbaugh's critical tests, the methodological problems identified in the 1970s were eliminated. The weight of evidence is now in favor of the idea that, under appropriate conditions, bonobos and common chimpanzees can indeed acquire symbols, rather than just instrumentally manipulate signs.

Savage-Rumbaugh's team have also presented evidence that bonobos can master grammatical cues such as sign order, and even clause structure. Thus, Kanzi, their first successful bonobo, could respond appropriately and differentially to commands such as 'Put the tomato *in the microwave*' versus 'take the tomato that's *in the microwave* outdoors'; an achievement that, in children, is held to indicate a grasp of clause structure.

Nevertheless, as ALR moves into this new territory, new issues arise. Does Kanzi also exploit clause structure and symbol order to decide, for example, what tomato to take, or is his grasp of semantics so good that he is able to deduce much 'grammatical' information just from the meaning of the symbols?

Finally, brain imaging is beginning to enter ALR. At the time of writing, published reports are limited to only one common chimpanzee, from the Rumbaugh program, showing bilateral brain activity, rather than the typical left-hemisphere cortical activity of modern humans. Little can be built as yet from this solitary result, but the chapter that opens here is likely to be an exciting one.

'Can an ape learn a language?' The weight of evidence now indicates that under certain conditions some species can master symbol use. Beyond this, rather than many firm conclusions, ALR has

developed more appropriate methodologies and focused more specific and answerable research questions; 'Which aspects of human language can an ape master? Under what social and training conditions? How, within the brain, does it process its language-like behavior?' This is not surprising and should not be disappointing. In any rapidly developing field, most past research, from the perspective of the present, consists of demonstrations of what does not work and what is not true. ALR is in its infancy, it is to be hoped that the field has decades, perhaps centuries, of research ahead.

Aphasia

Aphasia is an acquired language disorder that occurs after language skills have been completely developed, due to focal brain damage in the hemisphere that is dominant for language (usually the left hemisphere). In this definition, several other language and speech disorders are excluded. The term 'acquired' indicates that aphasia cannot be congenital. Of course, perinatal brain damage may cause speech and language problems, but these are not referred to by the term 'aphasia'. 'Language disorder' distinguishes aphasia from pure articulatory and fluency disorders, which may or may not be the result of brain damage, but are not central to the *language* faculty. The fact that aphasia is a language disorder implies that (usually) the entire language faculty is affected, that is, speaking, comprehension of spoken language, reading, and writing, because the same language system serves these four modalities. Aphasia is by definition due to brain damage. In some psychiatric diseases (e.g. schizophrenia), the production deficits may appear similar, but as there is no focal brain damage, this is not aphasia. The term

'focal' means that the cerebral damage is restricted to rather clearly circumscribed brain lesions, as opposed to *diffuse* brain damage, that is, damage spread over the entire hemisphere. This diffuse cerebral damage may cause language problems (for example, in dementia), but these are quite different, and hence distinguishable from aphasia.

Aphasia is the result of damage to the hemisphere that is dominant for language, most often the left hemisphere. The right hemisphere is involved in communication, however. Although damage in this hemisphere does not affect grammatical or semantic processing, communication may be impaired, because of problems at the discourse level, often referred to as 'pragmatic' problems. In some left-handers, damage to the right hemisphere may result in aphasia.

Typology

The symptoms of aphasia are rather diverse and vary, depending on the site and extension of the lesion. In

general, large lesions cause more severe deficits than small lesions and anterior lesions (in the frontal parts of the left hemisphere) cause an impairment in the ability to construct sentences, whereas lesions to the more posterior parts (the temporal (and parietal) lobes) cause problems in word finding. These relatively selective impairments to the different language levels can best be explained by the so-called 'classic aphasia syndromes'. These are more or less accepted in the aphasiological world, although pure syndromes do not occur regularly (estimated proportions in the entire aphasic population are between 15 and 100%). The main types are the following.

(1) Broca's Aphasia

This aphasia type has been named after Paul Broca (1824–1880), a French neurologist who was the first to mention that impairments to the faculty of speech were caused by a lesion in the left frontal lobe, more specifically to the foot of the third frontal gyrus, now known as *Broca's area* (see Figure 1). (N.B. he did *not* describe what is now called Broca's aphasia). This aphasia type is characterized by slow, elaborated speech in which mainly content words (nouns, verbs, and adjectives) are produced; function words (determiners, prepositions, pronouns) are often omitted. This speech style is called *telegraphic speech*.

In most of the speakers with Broca's aphasia, articulation is affected as well, because the brain site responsible for articulation is so close to the area that, if damaged, it causes Broca's aphasia. Comprehension of spoken language is relatively good: in conversations, speakers with Broca's aphasia understand what is said. When tested for the comprehension of complex syntactic structures, the performance drops dramatically. It is therefore assumed that in Broca's aphasia the grammatical component of language is affected.
Figure 1. Left hemisphere of the human brain.

Reading and writing are also impaired, comparable to oral comprehension and production (see Figure 1).

(2) Wernicke's Aphasia

This aphasia type has been named after Carl Wernicke (1848–1905), a German neurologist who was the first to describe this syndrome. He located the lesion which causes this aphasia type in the posterior parts of the left temporal lobe (see Figure 1). Speech production is fluent and well-articulated, but the aphasic speaker produces sound and word substitutions, so-called 'paraphasias', for example 'spool' for 'spoon' or 'mother' for 'wife'. Distortions of words may be further away from the target words than in these examples, and as a consequence the listener may not recognize existing words; these sound strings are called 'neologisms', for example, 'stroofel'. When many of these words are produced, the text will no longer be understandable, which is referred to as 'jargon' or 'word salad'.

Comprehension of language is moderately to severely impaired. The combination of a severe comprehension and production disorder results in poor communication abilities. Writing and reading are parallelly affected.

(3) Anomic Aphasia

There is no clear lesion site in the brain that is responsible for this aphasia type, but the lesions are usually found in the temporal and/or parietal lobe. Anomic aphasia is characterized by word-finding problems. The oral output of a speaker with anomic aphasia is basically fluent, but due to the pauses that arise from the word-finding problems, speech rate may be low. The word-finding problems are not only recognizable by pauses, but also by the use of less specific words, such as 'thing', 'do', 'here', 'there'. The latter is called 'empty speech'. Comprehension of spoken language is relatively good, although complex commands are difficult to understand. Reading is usually spared as well, but in writing the word-finding problems show up again.

(4) Conduction Aphasia

Conduction aphasia was first described by, again, Carl Wernicke. The name of the syndrome derives from the fact that it is caused by a lesion in the tract that connects Wernicke's and Broca's area. It is characterized by the production of sound errors, for example, 'scrample' for 'scrabble'. The patient is well aware of his errors and this results in many self-corrections, for example, 'scramble, no strapple, no stample …'. The errors are particularly prominent when the patient is asked to repeat longer words and sentences. Comprehension of spoken and written language is relatively good, but

impaired for complex and long sentences. In writing, a similar error pattern is shown as in speaking.

(5) Global Aphasia

The lesion responsible for global aphasia is often large and extends to both the frontal, temporal, and parietal lobes. All language modalities are severely impaired. Spoken output is often restricted to one- or two-word utterances, sometimes only 'yes' and 'no', not always used correctly. Comprehension is severely impaired and reading and writing are hardly possible. This, of course, results in very poor communication abilities.

Again, it should be stressed that although this classification has contributed considerably to the understanding of aphasia, most patients suffer from a 'mixed' form of aphasia, which cannot be labeled with any of the types mentioned above.

Prognosis

Aphasia is caused by brain damage and this is normally irreversible. This does not mean that no improvement is possible. During the first few months and especially the first few weeks following brain damage, spontaneous improvement, if not recovery, is certainly possible. If, however, the symptoms are persistent and are still present after 3–6 months, improvement is questionable. In most countries, aphasic patients are treated by speech therapists. The goal of speech therapy is to teach the patient to deal with his language problems, through improvement of communicative strategies as well as language competence.

Psychosocial Consequences

Above, the linguistic aspects of aphasia were emphasized, since aphasia is a language disorder. One should realize, however, that a language problem has severe consequences for communicative abilities and therefore has a severe impact on the daily life of the patient and his surroundings. Nowadays, part of the speech therapy is focused on this psychosocial aspect of aphasia.

Applied Linguistics: Overview

Applied Linguistics, in its present form, is an emerging multidiscipline, or trans-discipline, developed on a multidisciplinary basis of inquiry into language in use, more specifically, into verbal communication within a given social and/or institutional context. Theoretical and methodological problem-oriented

approaches fundamentally define applied research objects and require the development of multidisciplinary models and methods to fit the process-oriented (rather than product-oriented) and multifaceted contextualized uses of language that researchers in this field of study are facing.

Such a multidisciplinary basis of inquiry involves a combination of approaches from linguistics and several other disciplines within the domain of human sciences, such as psychology, sociology, pedagogy, anthropology, ethnography, philosophy, politics, and psychoanalysis, as well as newer areas of investigation such as, for instance, computer sciences and cybernetics. This inquiry leads to a number of new insights and issues that are extremely relevant in response to the challenge of penetrating deeper into epistemological and ethical questions imposed by the complexity of the real world of human interactions, as well as by the dynamism of language in use, i.e. of language as *parole*, in Saussurean terms, or *performance*, in Chomskyan terms.

Thus, in applied research, real human interactions are seen as a complex object of inquiry with a crucial social and institutional, as well as a psycholinguistic dimension, and not simply as an individual or speaker/hearer subject matter. According to this view, there are also a number of political and ideological aspects of language and discourse to be accounted for, since they shape and are shaped by everyday current linguistic interactions. Similarly, in applied research, language in use is viewed as a complex processual object composed of observed units compiled into a system, which is characterized not simply by a static range of appropriate rules to constrain the shape of words, sentences and texts, but by continuous change and variability.

Although this growing research perspective began to emerge in the 1980s and covers a wide range of issues that go beyond traditional linguistic concerns, it has not rendered irrelevant the significant and ongoing role of the theoretical and methodological contributions of linguistics in applied studies. Nevertheless, by adopting a view of language as a complex and dynamic object, applied studies have challenged various aspects of linguistic tradition and have attempted to offer alternative approaches and issues. A classic example of such a result of applied inquiry is the relevant theoretical and methodological discussions and findings that led to and emerged from the sociolinguistic notion of 'communicative competence' as the ability to use language appropriately in varying social contexts, i.e. in communicative practices that are culturally and historically situated.

As many different authors have pointed out over the last two decades, through multidisciplinary research efforts, Applied Linguistics is also arguing for and responding to critical accounts of the received theories of knowledge that served as the basis of much of the work done in the field since its beginnings, in the 1950s, as a branch of linguistics. In fact, as an emerging scientific area in its own right, Applied Linguistics is increasingly interested in research questions that differ qualitatively from the language-related research carried out in linguistics, as well as from the traditional nontheoretical practical applications of mainstream linguistic findings, which developed when the term 'applied linguistics' was used to designate a subfield of inquiry within the mainstream field of Linguistics. The primary concern of early applied linguists was to develop empirical material for foreign language teaching, which was inspired and oriented by theories, methods and purposes, and, based on linguistic studies, mainly structural linguistics.

Despite the fact that this traditional role assigned to applied linguists is still emphasized by several scholars working on language learning methods and models, the fundamental reevaluation of traditional linguistic conceptions of language, subject, and context by different areas of the social sciences has begun to change the understanding of these ideas and seriously challenges the predominant modes and forms of knowledge of applied research tradition. Over the past two decades, much of the relevant discussions about epistemological and ethical issues within the subfields of bilingualism, language planning, language teaching and learning, and second and foreign language acquisition, for example, involve critical rethinking of traditional approaches.

A good example of this increasingly changing process in action in the applied research tradition is the well-established subfield of second and foreign language teaching and learning. A large body of recent work seeks to understand the role of teachers' and learners' reasons and accounts in the teaching and learning process, as well as the role of the historical, social, and politicoideological aspects of the macrosocial context of society as a whole in the microinteractional context of the school as an institution, which also shapes teacher/learner exchanges in the classroom. Another relevant contribution to this subfield has to do with language and discourse as important sites of subjectivity construction on the one hand, and as important moves in the reproduction of power relationships on the other. Indeed, the purpose of much of the contemporary research on teacher training and instructional materials and methods focuses on exploring these new concerns. Research that explores ethnographic insights and methodologies has been crucial for most of the work involving classroom linguistic interactions, as well as that of collaborative researcher/teacher work in teacher training projects.

In general terms, a great deal of recent rethinking about traditional modes and forms of knowledge in

applied research has drawn on a critical view of positivist epistemologies inherited from mainstream scientific tradition in order to face the new challenges outlined above. In response to the deficiencies of positivist models of understanding language, subject, and context, exploratory analyses of the complementary roles ascribed by other epistemologies to inductive and abductive thinking and to qualitative and quantitative data and methods, for instance, ought to be essential. The attempts to model the dynamism and variations of language as an open and changeable system have, likewise, been of fundamental importance.

Arabic

Arabic is spoken natively by approximately 170 million people (Arabs) living in dozens of countries, most in what is known as 'the Arab world', which stretches from Iraq in Southwest Asia to Morocco in Northwest Africa. It is the language of prayer and scripture for approximately one billion Muslims. Originally the language of some tribes of the Arabian Peninsula, it came to be a major world language as a result of the Islamic conquests that began in the seventh century CE. In 1974, Arabic became one of the six official languages of the United Nations.

Arabic is a Semitic language, one branch of the Afroasiatic language family. Scholars long considered Arabic as a relatively pure and unchanged ancient Semitic language, practically identical to a proposed Proto-Semitic, but this position is now widely viewed as a romantic notion that saw the deserts of Arabia as the guardian of a relatively untouched language. Arabic is conservative in many respects, but also innovative. It alone preserves the full ancient Semitic case-marking system found in Old Akkadian. It participated in or was considerably influenced by some developments found only in South Semitic languages such as South Arabian and Ethiopic, as well as some found only in the Northwest Semitic language complex, which includes Aramaic and Hebrew. Arabic also exhibits innovations not found in other Semitic languages, such as a definite article with *l*.

The origins of the term "Arab" are unknown. Assyrian, Babylonian, and Hebrew use of the word refers to nomads coming from the desert. The earliest clearly attested use of Arabic (written in the Nabataean script) dates to a 328 CE tomb inscription in the Syrian desert. The oldest samples of writing (graffiti and inscriptions) in a script that can be seen as Arabic are also found in Syria and date to the fourth and sixth centuries.

The Arabic alphabet developed from that of the Nabataeans. Unlike Nabataean, Arabic is a cursive script. It consists of 28 letters and is written from right to left. As is typical of Semitic alphabets, the Arabic alphabet contains no letters to indicate short vowels. For example, a word written as *qbl* could be read in a number of ways, including *qabila* 'he accepted' or *qabla* 'before'. Like Nabataean, early forms of the Arabic alphabet failed to distinguish between some phonemes. Typically, a letter could be read in one of two ways, for example, /z/ or /r/. Given the absence of short vowels and the consonantal ambiguity, deciphering the meaning of a given text could pose problems. With the need for more precision, a system that did away with this ambiguity became standard. For example, /z/ is marked

with a dot above the letter in order to distinguish it from /r/. A method for marking short vowels and other phonological details was also devised, but these markings are used mostly in scripture and in materials for beginners, such as children's stories. In practice, the absence of short vowels in most texts is not a problem; context almost always indicates the correct reading (and where this is not the case, a marker is sometimes supplied to assist the reader). That the Arabic alphabet is relatively easy to learn comes as a surprise to foreigners accustomed to seeing the ornate and often complicated calligraphic styles of Arabic that are used in decorating mosques or book covers. Calligraphy plays a central role in Islamic art due to the general avoidance of human and animal figures in art and due to the prominent role of scripture in Islam.

The domination of consonants in Arabic orthography is indicative of a defining characteristic of Semitic languages known as the root and pattern system. Most words are based on a root consisting of three consonants. Arabic, more than any other Semitic language, excels in exploiting this morphological resource. Each root is associated with a core meaning. The systematic manipulation of these roots is the basis of Semitic derivational morphology. For example, the root *d-r-s* is associated with studying. The verb *darasa* 'he studied' is based on the template or pattern $C_1aC_2aC_3a$, the final vowel being the third-person masculine singular perfect conjugation marker; the corresponding $yaC_1C_2uC_3u$ yields *yadrusu* 'he studies' (the prefix *ya* marks it as third-person masculine imperfect and the -*u* suffix indicates indicative mood). Doubling the middle consonant (gemination) of the root—one method for forming causative verbs—produces the verb pattern $C_1aC_2C_2aC_3a$ and results in *darrasa* 'he taught'. The corresponding imperfect, based on the pattern $yuC_1aC_2C_2iC_3u$, is *yudarrisu* 'he teaches'. The corresponding active participle, based on the imperfect verb stem, is *mudarris* 'teacher/teaching' ($muC_1aC_2C_2iC_3$). The 'noun of place' pattern $maC_1C_2aC_3a(t)$—the *t* is not pronounced in some contexts—yields *madrasa(t)* 'school'.

'Arabic' is in fact a cover term for a number of language varieties that could easily be designated distinct languages, given the right social and political circumstances. The Arab world is united by a standardized variety of Arabic used mainly for writing but also for some formal oral communication. Regional differences exist but this is mostly restricted to usage and pronunciation. Linguists often refer to this officially sanctioned variety as Modern Standard Arabic (MSA). MSA is typically learned at school and most Arabs, even those who obtain advanced degrees in an Arab educational system, lack confidence (and typically experience) in using it. In contrast, Arabs grow up speaking a local variety of Arabic that differs considerably from MSA and that is officially denounced but nevertheless thrives. For example, it is the vehicle of most popular music and television programs.

MSA is the modern realization of at least the formal register of Arabic used in parts of the Arabian Peninsula in the sixth and seventh centuries. This variety of Old Arabic was apparently the language of an extensive pre-Islamic oral poetry and it is the language of the Qur'an ('reading, recitation'), the book of scripture that Muslims believe the Prophet Muhammad received over a 23-year period, beginning in 610 CE. Due to a power vacuum, within a hundred years of Muhammad's death, a relatively small number of Arabs and their allies came to control a vast empire stretching from present-day Spain and North Africa to the borders of India. In time, the religion of Islam (and, therefore, Arabic for religious purposes) spread to such far-flung places as China and what is now Indonesia (the latter being the most populous Muslim country).

The language of the Qur'an is commonly held by Muslims to be that of God. Its sound and content are felt to be so interwoven that translation is considered impossible. As a result, there are no official translations; however, translations that attempt to impart its meaning are available. All Muslims are expected to recite scripture and pray in Arabic even if they do not understand what they are saying or reading.

The nature of spoken Arabic before the Islamic conquests is debated. Early sources mention dialectal variation in the Arabian Peninsula but give only glimpses of it. Personal letters and other documents dating to the early Islamic centuries provide much more insight into the nature of early spoken Arabic. From these, it is clear that the essential characteristics of the modern Arabic dialects (collectively called New Arabic), such as the absence of case marking in nouns and adjectives, go back to at least the first centuries of the Islamic era. In other words, the language situation of the modern Arab world—where a variety of Old Arabic is used for formal purposes and a variety of New Arabic (or something akin to it) is the common language—is over a thousand years old. There is no evidence that New Arabic developed later than Old Arabic. On the other hand, there is some evidence that points to Old Arabic containing innovations not known in New Arabic or other Semitic languages.

New Arabic was possibly formed or at the very least significantly affected by the language contact situation that arose from the Islamic conquests. Arabic speakers mixed and intermarried with non-Arabic speakers and Arabic began to gain hold in places far from the Arabian Peninsula. In a gradual process that took centuries, various populations came to adopt Arabic and Islam. Subsequent migrations from the

Arabian Peninsula aided in the spread of Arabic. In the case of places like Persia (modern Iran) and Turkey, the populations embraced Islam but the relatively few Arabs who settled there eventually assimilated the language of the local inhabitants. Nevertheless, both Persian and Turkish borrowed a great deal from Arabic, including its alphabet. This is true of other Asian and African languages.

Although the pre-Islamic Arabs had a highly developed poetic tradition, they did not have a prose or academic literary tradition. This changed soon after the advent of Islam. Classical Arabic developed in response to the new demands placed on Old Arabic. It is theoretically based on the language of the Qur'an. In fact, there are distinct differences (orthographic, grammatical, stylistic…). The vocabulary of Classical Arabic expanded considerably to meet the needs of the empire by deriving new terms from Arabic roots. Classical Arabic soon became the vehicle of an impressive corpus of literary and scientific works, spurred on by the Arabs' contacts with the advanced cultures that they had conquered. For example, the Abbasid dynasty in Baghdad aggressively pursued the translation of Greek philosophical and scientific texts into Arabic. Scholars writing mostly in Arabic proceeded to considerably build on these works. These scholarly works, in turn, were passed on to Western Europe mostly via Spain and Sicily and significantly contributed to European cultural and scientific development. Particularly in the 12th century, and for some time after, learning Arabic was popular in Europe in order to read the scientific works of the Greeks (many of which were preserved only in Arabic) as well as to read the contributions of the Arabs themselves. Through such contact, European languages came to borrow numerous words of Arabic origin, such as *alcohol, asthma,* and *zenith.*

MSA is the modern manifestation of Classical Arabic. However, Classical Arabic's ornate styles and some of its complex grammatical constructions are rarely used. Again, a major difference is found in MSA's new vocabulary and phrasing. Like Classical Arabic, MSA arose in response to a language contact situation—with modern Western Europe, which is usually dated to the French invasion of Egypt in 1798. The importation of Western institutions, like newspapers, has had a profound impact on Arabic. Whereas documents composed before the modern era in Classical Arabic typically targeted a limited and elite audience, the spread of education—particularly in the second half of the twentieth century—has resulted in MSA, a version of Old Arabic streamlined for mass consumption.

The spread of education (among other factors) has also resulted in a blurring of the lines between New and Old Arabic. While mixing has long been a feature of Arabic speech communities, it is now taking place on a far wider scale. There are few 'pure dialect' speakers. MSA elements (mostly lexical) are common even in informal speech. The importation of more informal rhetorical styles (perhaps connected with Western-style democratic values or populist rhetorical approaches) may have contributed to New Arabic spreading to domains and functions formerly associated with Old Arabic. Whatever the causes, new Arabic is commonly used—with a substantial admixture of Old Arabic lexical material in particular—in contexts where it would not have been expected in the past, such as in sermons and university lectures.

A distinctive characteristic of the phonology of nearly all varieties of Arabic is the presence of emphatic consonants paired with nonemphatic counterparts, for example: /t/ and /ṭ/, /d/ and /ḍ/, /s/ and /ṣ/. Emphatic consonants are formed by raising the back of the tongue, which simultaneously results in the tip of the tongue being drawn back somewhat from the point of articulation of the corresponding nonemphatic consonant. Old Arabic has only three vowels, /a/, /i/, and /u/—as in the case of consonants, these may be lengthened with a corresponding difference in meaning. There is considerable allophonic variation in the vowels, which is conditioned by the consonants in a word. Pronunciation and word stress in MSA are typically influenced to a great degree by one's native dialect. New Arabic realizations of the phoneme corresponding to Old Arabic /q/ have become a special regional and social marker. The extreme case is Jordan, where in some rural dialects it is realized as [k], but for Bedouins it is [g]. Its urban distribution is complicated: men not of Palestinian extraction typically use [g], perhaps for its association with Bedouin toughness, whereas men from Palestinian urban families might use [ʔ], unless they want to downplay their Palestinian origins. Urban and increasingly nonurban women favor [ʔ], which is seen as sophisticated.

Much of the morphology of Arabic is a model of logic and order. This is not true, however, of the relationship between singular and plural forms of nouns and adjectives. There are two types of plurals, 'sound' and 'broken' (which designate whether the stem is left intact or is modified to form the plural). Sound plurals are formed by suffixation, for example: *mudarris/ mudarrisuuna* 'teacher/teachers'. The plural of most nouns is of the broken type and numerous patterns are used, for example: *safiir/sufaraaʔ* 'ambassador/s', *madiina(t)/mudun* 'cities', *jariida(t)/jaraaʔid* 'newspaper/s'. Some plural patterns are predictable from the pattern of the singular, most are not. Some nouns have two or more plurals.

The basic word order of Old Arabic is considered to be Verb–Subject–Object, whereas New Arabic is

classified as being of the Subject–Verb–Object type. Both, however, exhibit a good deal of flexibility. The head noun of a noun phrase precedes adjectival modifiers, which agree with the head in number, gender, and definiteness (as well as grammatical case in Old Arabic). Old and New Arabic exhibit intricate patterns of agreement variation. Numeral constructions and the negation of verbs are particulary complex in Old Arabic.

Arabic has played an important role in Western linguistics on a number of fronts. The root-and-pattern system has led to new approaches to morphology. Arabic has played a particularly prominent role in sociolinguistics. Charles Ferguson, a founding figure in the field, was profoundly influenced by his contact with Arabic. Some mark the publication of his paper 'Diglossia' in 1959 as the beginning of sociolinguistics, in which he undertook to describe the particular language situation typical of Arabic speech communities in which two closely related but substantially different varieties of a language (a 'High' and a 'Low' variety) exist side by side in a single speech community in a stable and functionally complementary relationship. This article has resulted in some 3,000 studies of the topic.

The dynamics of Arabic speech communities have also played an important role in language attitude studies, and in challenging theories of language and gender. The fact that some modern spoken varieties of Arabic are mutually unintelligible underscores the difficulty of defining precisely what a language is (as opposed to a dialect). For example, Maltese, the official language of the island nation of Malta located near Sicily, is considered by scholars to be a dialect of Arabic, whereas its speakers typically deny this relationship, prefering to see it as a Semitic language whose roots go back to ancient Phoenician. Maltese is the only variety of New Arabic to become a national language. It is written with Latin characters, with some modifications.

Arabic provides a fascinating case study in language standardization and adaptation. Few languages provide 1,400 years of documented continuous use. In many ways, it has changed remarkably little over the centuries. This applies to both Old and New Arabic, which share far more in common than is genuinely admitted. The modern dialects are so conservative that in at least some ways they are more like Pre-Islamic Arabic and the language of the Qur'an than is the standardized MSA.

The differences between MSA and an Arab's day-to-day speech are real and do present challenges. Some have called for teaching Arab children basic literacy skills in their native dialect, but there is little chance of this idea taking hold in the Arab world in the near future. Old Arabic holds tremendous symbolic value. It binds Arabs to their golden age, when they were cul-turally and scientifically superior to the West. It is a symbol of Muslim unity, as well as the cornerstone of Arab nationalism. As such, it is jealously guarded.

The realities of the modern world undercut this linguistic idealism. In their professional lives, many educated Arabs are more adept or at least more comfortable in expressing themselves in English or French than in MSA. Some influential members of Arab society criticize the Arabic abilities of recent high school graduates while simultaneously sending their own children to English or French private schools. Economic forces similar to those that resulted in their ancestors' learning and eventually adopting Arabic are now drawing young Arabs to write French email messages to Arab friends or to study medicine in English at Arab universities. In short, bilingualism is widespread and growing.

The Arab world is, nevertheless, far from being on the verge of abandoning MSA. In many ways, the modernization of Arabic (its adaptation to the needs of a changing world) over the past two centuries has been quite successful. Moreover, a far greater percentage of Arabs are literate in Arabic than at any time in history. Nevertheless, one wonders what the future holds. Arabic changed a great deal as a result of the contact situation that arose with the Islamic conquests. The present is also a time of intensive language contact. In addition to contact with the West, the very process of educating the masses has resulted in a new contact situation. Millions of Arabs with limited proficiency in MSA are using it on a day-to-day basis. While it is not likely that they will wrench the language from the hands of the traditional gatekeepers, it nevertheless seems unlikely that it could acquire so many users without their leaving their mark on it.

Arabic Traditional Grammar

The essential quality of Arabic linguistics is its pragmatism, that is to say, its concern with what can be done with words in terms of the speaker's intentions, the listener's expectations, and the context of the utterance. The Arabic word for grammar itself is *naḥw*, lit. 'way, manner', i.e. way of speaking, using the same metaphor as other key Islamic terms for kinds of behavior, such as *sunna* 'way [of orthodoxy]', *šarī'a* 'path [of the law]', *ṭarīqa* 'way [of the mystic]', *maḏhab* 'way [of thinking]', i.e. 'school of thought', and it is consequently not surprising that Arabic grammatical analysis should deal primarily with the external features of language, nowadays generally called the surface structure, rather than the implicit or hidden features, viz. the underlying or deep structure. 'Meaning', therefore, is literally' what you have in mind' (*ma'nā*) or 'what you intend' (*murād*), as manifested in and only accessible through what you actually say (*kalām* 'speech').

Accordingly, the criteria for correct speech are the same as those for ethically correct behavior. A wholly successful utterance must be both 'good' (*ḥasan*, lit. 'beautiful'), i.e. well-formed, consisting of the proper words in the proper order, and semantically 'right' (*mustaqīm*, lit. 'morally straight'), i.e. conveying to the listener exactly the meaning intended by the speaker. Ill-formed utterances (*qabīḥ*, lit. 'ugly,' hence 'ethically bad') may still be 'right' if they succeed in conveying the speaker's intended meaning, just as a well-formed utterance may fail to do so, and will thus be termed *ġayr mustaqīm* 'not right'. Finally, some utterances convey no meaning at all, because of inner structural and semantic contradictions: these are labeled *muḥāl* ('wrong', lit. 'perverted, twisted'), i.e. incoherent. Significantly, in the earliest grammar at least, before the influence of Greek logic appeared, the truth or falsehood of an utterance were linguistically irrelevant.

For convenience, Arabic linguistic theory will be dealt with in three terminological groups: (1) systematic, (2) categorical, and (3) functional.

(1) The systematic terminology includes the criteria of correctness mentioned above, to which two further terms of similar ethical origin can be added: each item in an utterance has a given 'status' (*manzila*) and a corresponding 'place' (*mawḍi'*). The formal correctness of an utterance depends on using words in the place

(we would now say 'function') appropriate to their status, just as the moral value of an action is determined by the place and time of its occurrence.

It is a principle of Arabic grammatical analysis that every element operates (or not, according to its status) on the following element, this operation being termed *'amal*, lit. 'effect.' Although this very much resembles the western notion of 'government,' there is no historical or technical connection; 'government' is hierarchical, based on a vertical (paradigmatic) relationship between words, while the Arabic *'amal* is purely linear (syntagmatic), denoting the immediate effect of an 'operator' (*'āmil*) on another element 'operated on' (*ma'mūl fīhi*) sequentially.

Arabic linguistics also recognizes analogy (*qiyās*), both as the inductive device for extracting general principles from the data and as the means by which speakers create new utterances by extrapolating from speech patterns already known.

(2) Morphological categories are very few, being effectively limited to three classes of words: Noun, Verb, and Particle. This division is based on a combination of formal and semantic properties: the Noun (*ism*, lit. 'name') and Verb (*fī'l*, lit. 'act, action') are distinguished by their meaning and by certain unique features (only Nouns have Definite Articles, only Verbs have Tense, for example), while the Particle (*ḥarf*, lit. 'bit, piece') is classified negatively by the absence of a generic meaning and lack of the formal markers of Nouns or Verbs. The full definition of the 'Particle' usually includes the qualification 'which occurs for some [syntactic] meaning' (*jā'a li-ma'nā*) to separate it from other linguistic units also called *ḥarf,* which would nowadays be labeled 'phoneme', 'grapheme', 'lexeme', and other nonsyntactic units.

(3) The functional categories reveal the ultimate preoccupation of Arabic linguistics with speech as behavior. There are more than 70 terms for the various ways in which words can be used, ranging from the decisions of the speaker at the highest level (e.g. *ibtidā'* 'starting an utterance' [specifically a statement of the form 'x is y', where Arabic has no verb for 'is'], *istifhām*

'asking a question') to the specific events occurring within the utterance as a result of grammatical rules (e.g. *naṣb* 'making dependent' [scil. 'accusative' or 'subjunctive'], *taṯniya* 'making dual'). The precise boundary between the speaker's autonomy and submission to grammatical rules is never very clear, but this is intentional, as both the speaker and speech elements can be 'operators' (*'āmil*, see above), i.e. affect the form of words. It is noteworthy that the 70 or more names of speech acts are all expressed in Arabic by Verbal Nouns ('inflecting', 'making diminutive', 'describing [adjectivally]', 'eliding', 'doubling [a sound]' etc.), so that Arabic grammar, like an Islamic legal treatise, is nothing but a list of actions and conditions for their permissibility.

The many functions enable words of the same form class to be subcategorized: thus, Adjectives and Adverbs are simply Nouns used in a certain 'way' (*naḥw*) or 'place' (*mawḍi'*), and conversely Demonstrative and Relative Pronouns, which do not have the form of Nouns, nevertheless have the 'status' (*manzila*) of Nouns and are thus labeled 'noun of pointing' (*ism 'išāra*) and 'noun of the attached [clause]' (*ism al-mawṣūl*), respectively. The western Prepositions, Interjections, Conjunctions, and Articles are all considered Particles (*ḥarf*), and are categorized by the function they express; hence, a Vocative Particle is called a *ḥarf nidā*', 'a bit for calling', a Negative Particle is a *ḥarf nafy*, 'a bit for negating', a [coordinating] Conjunction is a *ḥarf 'aṭf*, 'a bit for joining', and so on. In this way, every speech element, from sound to sentence, is identified and its behavior is accounted for.

The above sketch is based on the description of Arabic by the first grammarian, Sībawayhi (who died in late eighth century AD), which remains unsurpassed for its completeness and scientific adequacy. Later grammar added almost nothing to the data but made substantial changes to the theory as Islamic culture absorbed the methods of Greek science, leading in one direction to a marked pedagogical and scholastic character and in another to increased abstraction and growing interest in underlying features. What might be called the metaphysical aspects of linguistics, such as the origins of language itself, the nature of meaning, and the question of grammatical causality, were enthusiastically and revealingly explored but, as might be expected, they had to be dealt with in a manner that did not conflict with Islamic doctrines.

Aramaic

Aramaic is a northwest Semitic language, related to Hebrew and more distantly to the now extinct Akkadian, which it replaced around the third century BCE as the lingua franca of the middle East, and to Arabic, South Arabian, and Ethiopic.

The nomenclature of Aramaic is quite confusing. Aramaic is sometimes called Chaldee, Chaldaic, or Assyrian. The latter appellation is also used for one of the dialects of Akkadian, and it should not be confused with that different language. In Israel, Aramaic is

sometimes called Kurdish, because Aramaic speakers living there hail from Kurdistan, but the term Kurdish is properly applied to a quite different western Iranian language. An important eastern dialect of Aramaic is usually called Syriac. Syriac has three native scripts that have a one-to-one relationship with the standard Hebrew alphabet, which was itself originally used for Aramaic and pushed out the native Hebrew alphabet during the Babylonian exile. Jewish dialects of Aramaic are normally written in Hebrew characters. Aramaic is indigenous to Syria and is known from the tenth century BCE, but it has been in use at different times from Egypt to India. It has remained a living language in a few areas up to now. Thus, in 1930, in the town of Zakho in Iraqi Kurdistan, there were approximately 1,500 Aramaic-speaking Jews. All of these people and their descendants have moved to Israel, where their language lives on tenuously. There are other small pockets, particularly in Maalula, near Damascus, Syria, where the language is spoken mostly by Greek Catholics. Other related dialects are spoken by Christians in the Tur Abdin area of southern Turkey. Aramaic must nevertheless be considered an endangered language, constantly pressed by Arabic, Hebrew, Turkish, and other languages, and it seems unlikely that there are any monolingual speakers now. In the year 2000 election in the United States, the city of Chicago published instructions for voter registration in various languages, including Aramaic, and offered a telephone hotline where Aramaic speakers could call for information in their own language. There is a section in that city where the shops have Aramaic signs and advertisements. Aramaic is also quite widely used as a liturgical language by ancient Christian churches, including the Chaldean Catholic church, and that of four groups of Malabar Christians in India, known as the Christians of St. Thomas. The latter group has been replacing its Aramaic liturgy with its vernacular Malayalam language. The Samaritans, a Jewish sect that has existed from biblical time until the present day, seem to have spoken Aramaic until about the tenth century CE and possessed texts in the language, but now they speak Arabic. A number of important prayers in the Jewish liturgy are still recited in Aramaic, particularly the *Kaddish* (Doxology) and the *Kol nidre* (annulment of vows).

Aramaic is of crucial importance for religious studies. The biblical books of Daniel and Ezra have substantial portions written in Aramaic, and there is one verse in Jeremiah [10:11], as well as two words in the book of Genesis [31:47.] The last item displays the disparity in the lexicon between Hebrew and Aramaic: Jacob calls a monument Gal-Ed ['heap of witness': the story explains the name of the area east of Jordan called Gilead], whereas Laban calls it Jegar-Sahadutha, which is a literal translation into Aramaic. Additionally, two of the four so-called Ancient Versions of scripture are in Aramaic: the Targum ('translation'), which is a Jewish translation of the Hebrew Scriptures into Aramaic, and the Peshitta ('simple version'), a Christian translation of the Bible into the dialect of Aramaic called Syriac. These versions give important evidence of variant readings and show how obscure passages were understood in olden times. The Talmud, originally oral in nature, is written predominantly in Aramaic, with an admixture of Hebrew. The city of Edessa, now called Sanliurfa, in southeastern Turkey, was once a center of Christian religious schools that produced a vast literature in the Syriac dialect, including philosophy, theology, and poetry, much of which exists in unpublished manuscripts in various scholarly libraries. The scriptures of the Mandaean religion, a dualistic faith that still exists in Iraq and Iran, are written in Mandaic, which is an Aramaic dialect, and adds yet another name to the language.

Various Aramaic inscriptions exist on stone, clay, and other writing materials from the period before 700 BCE over a wide area from Asia Minor to northern Arabia. The importance and international character of the language may be gauged from the fact that when the Akkadian-speaking Assyrians besieged Jerusalem at this time, the officials on the wall begged the emissary to say what he had to say in Aramaic, because they understood it, but did not wish the common people to understand. The emissary refused and spoke his threats as to the horrors of the siege in Hebrew, to discourage the defenders (II Kings 18:26). A particularly important discovery from a later period is a collection of documents, all in Aramaic and written on papyrus, found at the ancient city of Yeb in Egypt, whose ruins are on an island called Elephantine opposite the modern city of Aswan. It seems that there was a Jewish temple in Yeb from the seventh century BCE, and there was a community of Aramaic-speaking Jewish mercenaries who left this substantial evidence of their existence. The documents contain official and private letters, legal documents, and some literary works. Of particular historical importance is a copy of a decree by the Achaemenid king Darius II Nothus, who reigned in the second half of the fifth century BCE, instructing the Jews of Elephantine to observe the Passover. This lent credence to the Aramaic decrees found in the book of Ezra, which some had thought to be forgeries. Another celebrated document is a request for permission to rebuild the magnificent Jewish temple of Yeb, which had been destroyed around 410 BCE by the priests as well as various legal documents, that shed a flood of light on the history of the time.

Aramaic has a large number of dialects, but all have the features characteristic of Semitic languages. Words

of the core vocabulary contain a root, usually of two, three, or four consonants, to which brief prefixes and suffixes are added, and they also undergo internal vowel change; many of these roots have equivalents in other Semitic languages. Nouns have two genders, masculine and feminine, and two numbers, singular and plural. The verb is inflected with suffixes in the perfect tense and with prefixes and suffixes in the imperfect tense, like other Semitic languages. Aramaic numerals above two share the common Semitic peculiarity of using the feminine form with masculine nouns, and vice versa.

Literary western Syriac is a clearly defined standard language. The 22 letters of its alphabet represent the consonants of the language. The vowel system distinguishes /a/,/a:/,/e/, /i/ and /u/; /u/ and /o/ were not distinctive in this dialect. For an illustration of word formation, consider the word [ri:ʃ] 'head.' Pronominal suffixes may be added to nouns, of which this is a selection: [ri:ʃe:h] 'his head', [ri:ʃa:n] 'our head', [ri:ʃkun] 'your (plural) head'. Various nouns have irregularities; thus, the plural of [bra:] 'the son' is [bnaya:], the plural of [ħa:ta:] 'the sister' is [ʔaħwa:ta:], and the plural of [ʔatta:] 'woman, wife' is [neʃe:].

The fact that the participle in Aramaic is not used to construct complex sentences with frequent subordinate clauses, as occurs, say, in Germanic, Slavic, or Dravidian, means that Aramaic syntax is very simple compared with that of those languages. The verb usually comes first, followed by the subject and object, and sentences are linked together by conjunctions. The result is a language that is mostly regular and straightforward, with a minimum of verb tenses, no case endings on nouns, and a native script that serves it well.

Arawak

The Arawak language family is the South American language family with the largest number of languages. Geographically, it spans four countries of Central America—Belize, Honduras, Guatemala, Nicaragua—and eight of South America—Bolivia, Guyana, French Guiana, Suriname, Venezuela, Colombia, Peru, and Brazil (and also formerly Argentina and Paraguay).

There are about 40 living Arawak languages. The first Native American peoples encountered by Columbus—in the Bahamas, Hispaniola, and Puerto Rico—were Arawak-speaking Tainos. Their language became extinct within a hundred years of the Columbian invasion. Spanish—and many other languages—inherited a number of loanwords from Arawak languages. These include widely used words such as *hammock, tobacco, potato, guava,* and many other names for flora and fauna.

The creation of a 'mixed' language of Arawak/Carib origin in the Lesser Antilles is one of the most interesting pieces of evidence for the history of languages in pre-Conquest times. Speakers of Iñeri, a dialect of the Arawak language now (misleadingly) called Island Carib, were conquered by Carib speakers. They developed a 'mixed' Carib/Arawak pidgin that survived until the seventeenth century (Hoff 1994). 'Men's speech' and 'women's speech' were distinguished in the following way. Women used words of Arawak origin, while men used words of Carib origin and grammatical elements mostly of Arawak origin. The pidgin coexisted with Carib used by men and Iñeri used by women

and children; it belonged to both parties and served as a bridge between them. This diglossia gradually died out with the spread of Island Carib to both men and women. As a result, Island Carib, an Arawak language, had a strong influence of Carib with respect to both vocabulary and, possibly, grammar.

The languages in areas settled by the European invaders soon became extinct. Those on the north coast of South America perished first, before 1700. When the search for gold and rubber extended up the Amazon and its tributary the Rio Negro, additional languages succumbed, a process continuing from the eighteenth century to the present day. Sometimes, the Indians retaliated, attacking settlements and missions; but the invaders always returned. Indian rebellions often provoked forced migrations that sometimes ended up in the creation of a new dialect or even language. For instance, in 1797 the British authorities removed the rebellious inhabitants of St. Vincent (an island in the Lesser Antilles) to Belize on the mainland. These were racially a mixture of black slaves and Indians, who spoke Island Carib. This resulted in the creation of a new dialect of Island Carib—known as Central American Island Carib, Kariff, Black Carib, or Garifuna—which by the twentieth century had developed into a separate language, now one of the two Arawak languages with the largest number of speakers.

The overwhelming majority of Arawak languages are now endangered. Even in the few communities with over 1,000 speakers, a national language (Portuguese or Spanish) or a local lingua franca (Lingua Geral Amazônica, Quechua, or Tucano) is gradually gaining ground among younger people. The few healthy Arawak languages include Guajiro in Venezuela and Colombia (probably up to 300,000 speakers) and Garifuna in Central America (with up to 190,000 speakers). The Campa languages (total estimate 40–50,000) form one of the largest groups of indigenous population in Peru.

Most of the materials on Arawak languages collected during the second half of the twentieth century are by missionary linguists. Their quality and quantity vary. A full description is available for only three or four languages.

The fact that Arawak languages were related was first recognized by Father Gilij as early as in 1783. The recognition of the family was based on a comparison of pronominal prefixes in Maipure, a now extinct language from the Orinoco Valley, and Moxo, from Bolivia. Gilij named the family Maipure. Later, it was renamed Arawak by Daniel Brinton after one of the most important languages of the family, Arawak (or Lokono), spoken in the Guianas. This name gained wide acceptance during the following decades. The majority of native South American scholars use the

name Arawak (Aruák) to refer to the group of unquestionably related languages easily recognizable by shared pronominal prefixes such as *nu-* or *ta-* '1sg', *pi-* 'you', and prefixes *ka-* meaning 'have' and *ma-* meaning 'not'. A number of scholars, mainly North Americans, prefer to use the term Arawak(-an) to refer to a much more doubtful higher-level grouping and reserve the term Maipuran (or Maipurean) for the group of undoubtedly related languages, which was claimed to be one branch of 'Arawakan'. Here, I follow South American practice and use the name Arawak for the family of definitely related languages.

The limits of the family were established by the early twentieth century. Problems still exist concerning internal relationships within the family and possible relationships with other groups. Internal classification and subgrouping of Arawak languages remains a matter of debate; further detailed work is needed on both the descriptive and comparative fronts.

The putative studies of 'Arawakan' by Ester Matteson, G. Kingsley Noble, and others are deeply flawed. Unfortunately, these have been adopted as the standard reference for the classification of Arawak languages, especially among some anthropologists, archeologists, and geneticists, influencing ideas on a putative homeland and migration routes for proto-Arawakan. The classification found in Campbell (1997) contains a number of factual mistakes and omissions and has to be treated with extreme caution.

Little is known about a homeland for the Arawak family. The linguistic argument in favor of an Arawak homeland located between the Rio Negro and the Orinoco rivers—or on the Upper Amazon—is based on the fact that there is a higher concentration of structurally divergent languages found in this region. This area has also been suggested as one of the places where agriculture developed. This is highly suggestive and corroborated by a few mythical traditions of northern origin found among Arawak-speaking peoples south of the Amazon. The origin myths of the Tariana, in northwest Amazonia, suggest that they could have come from the north coast of South America.

Arawak languages are complicated in many ways. Words can be differentiated by stress in some

languages, such as Baure and Waurá (south of Amazonas), and Tariana, Achagua, and Warekena (north of Amazonas). At least two use tones, i.e. pitch differences, to distinguish words—Terêna in the south, and Resígaro spoken in the far northeast of Peru.

Each Arawak language has a few prefixes and numerous suffixes. Prefixes are typically monosyllabic, while suffixes can consist of one or more syllables. Roots usually contain two syllables. Prefixes are rather uniform across the family, while suffixes are not. What is an independent word in one language can be a grammatical suffix in another language. An Apurinã noun *maka* means 'clothing'—this is where the English word *hammock* comes from. In Tariana, *-maka* is a classifier for clothing, as in *pa:-maka* 'one piece of clothing' (literally 'one-classifier: clothing').

Most grammatical categories in Arawak languages are expressed on the verb. Cases for marking subjects and objects are atypical. Tariana, spoken in northwest Brazil, has developed cases for such basic grammatical relations to match the pattern in nearby East Tucano languages; cases are also reported for Apurinã.

Arawak languages spoken south of the Amazon ('South Arawak') have a more complex verb structure than those north of the Amazon ('North Arawak'). South Arawak languages such as Amuesha or Campa have up to 30 suffix positions. North Arawak languages such as Tariana or Palikur do not have more than a dozen. Suffixes express meanings that are realized by independent words in familiar Indo-European languages, e.g. 'be about to do something', 'want to do something', 'do late at night', 'do early in the morning', 'do all along the way', 'in vain', 'each other'. A typical example from Amuesha, spoken in Peru, shows the complexity of meaning that verbal suffixes can express *ø-omaz-amy-eʔ-amp^y-es-y-e.s-n-e.n-a* (3person.singular-go.downriver-distributive-epenthetic-dative-epenthetic-plural-epenthetic-late-progressive-reflexive) 'They are going downriver by canoe in the late afternoon stopping often along the way'.

Arawak languages spoken north of the Amazon have evidentials, i.e. forms with which speakers specify how they acquired the information. Baniwa and Piapoco have just a 'reported' evidential, which is used for second-hand information. Tariana has four evidentials: visual (if one saw the event happen), nonvisual (if one heard or smelt it), inferred (if one can judge what happened by some indirect evidence), and reported (if one acquired the information from another person).

Verbs are divided into active verbs ('hit' or 'jump') and stative verbs ('be cold'). All Arawak languages share pronominal affixes and personal pronouns. Pronominal suffixes (e.g. *-ni* 'he') are used for subjects of stative verbs and for direct objects. Subjects of active verbs are expressed by prefixes (e.g. *nu-* 'I').

For instance, in Baniwa, one says *nu-kapa* 'I see' and *nu-watsa* 'I jump', but *nu-kapa-ni* 'I see him' and *hape-ni* 'he is cold' (*nu-* refers to 'I' and *-ni* to 'him'). And 'my hand' is *nu-kapi*.

Some languages have lost the pronominal suffixes; these include Yawalapiti (Xingú park, Brazil) and Chamicuro (Peru) to the south of the Amazon, and Bare, Resígaro, Maipure, and Tariana, to the north. The form of the first person pronoun 'I' is *ta-* in the Caribbean (Lokono, Guajiro, Añun, Taino) and *nu-* in other languages. This is the basis for classification of Arawak languages into *Nu*-Arawak and *Ta*-Arawak.

Most Arawak languages distinguish two genders— masculine and feminine, e.g. Palikur *amepi-yo* 'thief (woman)' (literally 'thief-MASCULINE'), *amepi-ye* 'thief (man)' (literally 'thief-FEMININE'), Tariana *nu-phe-ri* 'my elder brother' (literally 'I-sibling-MASCULINE'), and *nu-phe-ru* 'my elder sister' (literally 'I-sibling-FEMININE'). Genders are not distinguished in the plural. Some languages also have complicated systems of classifiers—these characterize the noun in terms of its shape, size, or function. Tariana and Baniwa have over 40 classifiers, e.g. Tariana *pa:-da* (one-classifier: round) 'one round thing', *hanu-da* (big-classifier: round) 'big round thing', i.e. the suffix *-da* is a classifier for 'round things' and can be attached to numerals ('one'), adjectives ('big'), etc.

All Arawak languages distinguish singular and plural. Plural is only obligatory with human nouns. Plural markers are **-na/-ni* 'animate/human plural', **-pe* 'inanimate/animate non-human plural'.

Throughout the Arawak language family, nouns divide into those that must have a possessor (inalienably possessed) and those that do not require a possessor as a must (alienably possessed). Inalienably possessed nouns include body parts, kinship terms, and a few others, e.g. 'house' or 'name'. Inalienably possessed nouns have an 'unpossessed' form marked with a suffix, e.g. Pareci *no-tiho* 'my face' (literally 'I-face'), *tiho-ti* '(someone's) face' (literally 'face-UNPOSSESSED'). Alienably possessed nouns take a suffix when possessed, e.g. Baniwa *nu-činu-ni* 'my dog' (literally 'I-dog-POSSESSED').

The overwhelming majority of Arawak languages have a negative prefix *ma-* and its positive counterpart *ka-*, e.g. Piro *ka-yhi* 'having teeth' (literally 'POSITIVE-tooth'), *ma-yhi* 'toothless' ('NEGATIVE-tooth'); Bare *ka-witi-w* 'a woman with good eyes' ('POSITIVE-eye-FEMININE'), *ma-witi-w* 'a woman with bad eyes, a blind woman' ('NEGATIVE-eye-FEMININE'). Most languages have just the numbers 'one' (*pa-;* also meaning 'someone, another') and 'two' (*(a)pi* or *yama*).

The common Arawak vocabulary consists mostly of nouns, with quite a few body parts, fauna, flora, and artifacts. Only a few verbs are retained in most Arawak

languages, e.g. *ikau* 'arrive', **pɨ(da)* 'sweep', **po* or **da* 'give', **(i)ya* 'cry', **kama* 'be sick, die', **itha* 'drink'.

Archeology and Language

The history of related languages is at the same time a history of societies to which those languages belonged. When we reconstruct prehistoric relationships among a group of languages, we simultaneously postulate the historical existence of the societies that spoke those languages. Since the very beginnings of linguistics as a science in the nineteenth century, the problem of the archeological correlates of language change and dispersal has thus been crucial to the joint efforts of linguists and archeologists.

It was within the field of Indo-European linguistics that archeological evidence has been more and more widely resorted to determine the location of the Indo-European homeland, the area in which a population spoke Proto-Indo-European, a broadly defined group of dialects that later developed into the various Indo-European languages. The homeland problem can be stated as follows: there are several reasons for supposing that the historical distribution of Indo-European languages is not the original one and that the Indo-European language family, at some time in its prehistoric existence, has occupied a territory far more confined than that of its earliest historically attested branches; Indo-European languages are thus supposed to have spread from somewhere to their historical location in prehistory, invading or occupying areas where languages not belonging to the Indo-European family were spoken; some of these relic non-Indo-European languages are attested throughout Eurasia (Basque, Tartessian, Iberian, Etruscan, Dravidian languages), and are surrounded by Indo-European languages. To some extent, the archeological record can suggest the sociohistorical conditions under which the Indo-Europeanization of Eurasia may have occurred. From the great number of archeological solutions to the homeland problem, one can select three scenarios that enjoy wide currency:

(1) *The continuity hypothesis*. Archeologists have found that there is a major cultural border between the steppe cultures and those of

Northern/Central Europe, which was not seriously transgressed at any period from the Neolithic period onward. Thus, a Proto-Indo-European linguistic continuum should already have existed during the Mesolithic (8500–5000 BC) between the Baltic and the Black/Caspian seas. The Neolithic cultures that emerged throughout this region are then to be considered as ancestral to their respective regional Indo-European languages.

(2) *The Anatolian hypothesis*. According to this hypothesis, the dispersal of Indo-Europeans is connected with the spread of agriculture from Anatolia into Europe and Asia: Indo-European farming colonists absorbed non-Indo-European cultures expanding in a wave of advance.

(3) *The Kurgan model*. According to this model, the Indo-European homeland was located among pastoralist tribes of south Ukraine and south Russia that expanded both to the east and west (the *kurgan* or tumulus being a typical marker of this expansion). This model implies a process of progressive acculturation of non-Indo-European peoples across Europe and Asia.

Archeological models of dispersal have also been applied to other areas. In Australia, patterns of linguistic diffusion show considerable similarities to the patterns of diffusion of nonlinguistic traits. For instance, both the use of dug-out canoes and pearl shell ornaments appear to have permeated down from the coastal regions of northern Australia as far as South Australia, a pattern that closely resembles the south-

ward diffusion of some linguistic traits. In Africa, significant steps have been made toward uncovering the early historical developments among the speakers of each of the major language families of the continent: Nilo-Saharan, Niger-Congo, Afro-Asiatic, and Khoisan. The Proto-Nilo-Saharan speech territory most probably lay in the southern fringe of the central Sahara desert. The early periods of Khoisan history have been played out in eastern Africa: Khoisan speakers were makers of the Eastern African Microlithic Tradition; as early as the sixth millennium BC, Khoisan speakers began to spread south across southern Africa. Proto-Afroasiatics are to be identified with the early wild-grass-collecting cultures of northeastern Africa. The overall history of the dispersal of Niger-Congo languages is exceedingly complex, but an initial stage (between 8000 and 6000 BC) can be clearly identified in which Niger-Congo peoples, starting as far east as the Nuba Mountains of Sudan, expanded south across the woodland savannas of West Africa.

Armenian

Armenian is a cover term for a number of distinct languages, the best known of which are the literary forms Standard Eastern and Western Armenian, Middle (/Medieval/Cilician) Armenian, and Classical Armenian. The label 'Armenian' also encompasses the closely related languages Zok, formerly spoken by the Armenian inhabitants of southeastern Nakhichevan; Kistinək, spoken by the Armenian inhabitants of Musaler, Turkey; Kesbənuək, spoken by the Armenian inhabitants of Kesab, Syria; Homshetsma, spoken by the Hemshinli of northeast Turkey and the Hamshen Armenians of the Black Sea coastal regions of

Abkhazia and Russia; and dozens of other mutually unintelligible variants of Armenian originally spoken in Turkey, Armenia, Azerbaijan, Iran, Georgia, Abkhazia, Russia, and Israel. Lomavren, the language of the Bosha gypsies of Turkey and Armenia, draws its phonology, morphology, and syntax from the Erzerum dialect of Armenian but its lexicon is mostly of Indic origin; for this reason, it is not clear whether or not the language should be classified as a member of the Armenian family. All but Homshetsma employ the Armenian alphabet created by Mesrob at the beginning of the fifth century.

Armenian is an Indo-European language, generally believed to be most closely related to the Greek and Indo-Iranian subgroups. (For instance, all three share a particle *me: used in expressing prohibitions (Greek me:, Sanskrit ma:, Armenian mi) and the imperfect third-person singular particle *e- (as in Greek e-pher-e, Sanskrit a-bhar-a-t, Armenian e-ber '(s)he/it carried').) Because of the large number of loan words from various Middle Iranian languages, especially Parthian, Armenian was thought to be an Iranian dialect until Heinrich Hübschmann demonstrated in 1875 that it was a distinct branch of the Indo-European family. Scholars disagree on how the Armenians came to historical Armenia, the eastern half of present-day Turkey centered around Lake Van and Mount Ararat. Some believe they came southward from the Russian steppe, others believe they and the Hittites came eastward from Greece, and others suggest they moved only a short distance from an original Indo-European homeland in the Transcaucasus. It is most likely that this settlement occurred in the second millennium BC. The earliest mentions of the Armenians occur in the inscriptions of the Achaemenid Persian king Darius (sixth century BC) and the Greek historian Herodotus (fifth century BC).

The earliest written records of the Armenian language date from the fifth century AD, shortly after the conversion of the Armenians to Christianity in the fourth century led to the creation of an Armenian alphabet by Mesrob in around 401 and a systematic program of translating the books of the Bible. The language of the earliest translations was Classical Armenian (also called grabar, 'written (language)'), which continued as the preferred literary form of Armenian until the nineteenth century, when it was supplanted by the two modern literary dialects.

In linguistic terms, Armenian is notable for its significant divergences from Proto-Indo-European (the reconstructed ancestral language of the Indo-European family), particularly in terms of pronunciation and vocabulary. Some of the more striking phonological changes are the development of a rich set of affricates (ts, dz, etc.), the loss of final syllable rimes (e.g. Proto-Indo-European *worgʲom 'work' > Classical Armenian gorts), the change of initial *dw to erk- (e.g. Proto-Indo-European *dwo: '2' > Classical Armenian erku), and the change of original *w to g. Most striking in the vocabulary of Armenian is the rarity of words inherited from Indo-European, and the overwhelming predominance of words of unknown origin. Not surprisingly, native Indo-European words survive primarily in the core vocabulary: mayr 'mother' < *ma:ter, hayr 'father' < *pater, kʰoyr 'sister' < *swesor, kov 'cow' < *gʷows, tun 'house' < *domos, em 'I am' < *esmi. The remainder of the lexicon is drawn primarily from Parthian, and to a lesser extent from Greek and Syriac; several hundred and perhaps as many as several thousand words are of unknown origin, most likely having come from Urartian, Hurrian, and other now-extinct autochthonous languages. Armenian also incorporated large numbers of Arabic words following the expansion of the Arabs in the Middle East in the seventh century, and thousands of Turkish words following the arrival of the Seljuks and other Turkic tribes in Anatolia beginning in the eleventh century.

Although there are dozens of mutually unintelligible varieties of Armenian, all share certain features. Proto-Armenian had four verbal conjugations, characterized by theme vowels -e-,-i-,-ɑ-, and -u- (beɾ-e-m 'I carry', χaws-i-m 'I speak', χnd-a-m 'I rejoice', and zgen-u-m 'I wear'); most modern dialects (including the Western and Eastern literary languages) have completely or partially lost the -u- conjugation, and standard Eastern Armenian has merged the -i- conjugation into the -e- conjugation. There were originally three morphologically distinct sets of personal endings for verbs—present, imperfect, and aorist—which were used in combination with additional tense and aspect markers to form the various tenses and moods. The system of nominal morphology in Proto- and Classical Armenian was rich, preserving the Indo-European nominative, accusative, genitive, dative, instrumental, ablative, and locative cases in both singular and plural (but the Indo-European dual was lost); there were at least eight different declensions, distinguished primarily by different theme vowels. This system was significantly reduced by the medieval period; Middle Armenian and the modern varieties now use the singular endings for the plural as well, and have only one productive declension, formed from parts of the original -i- and -o- declensions. With the exception of pronouns, the inventory of cases has significantly reduced as well: the accusative has merged with the nominative, and the genitive with the dative. Proto-Armenian had several participial forms, but only two of these survive into the modern period: the original past participle -eal is now -el in the Eastern dialects, and the original present participle -oʁ is now used as a present participle and for relativizing subjects of subordinate clauses. The Western dialects have replaced -eal with -ats (> -adz in most varieties) for past participles; all modern dialects also use the -ats participle to relativize nonsubjects of subordinate clauses.

Most of the changes between Classical and Modern Armenian first appeared in the medieval period in Middle Armenian documents, associated with the Armenian kingdom of Cilicia, which flourished from the eleventh to fifteenth centuries AD in what is now south-central Turkey. Middle Armenian is generally

Western in character, although it shares many features with Eastern dialects as well. It inverts the pronunciation of the Classical Armenian plain voiced and voiceless stops (e.g. berem 'I carry' > perem, pat 'wall' > bad), a feature that is preserved in the modern Cilician dialects of Zeytun and Hadjin but differs from the Western and Eastern literary varieties (Eastern preserves the Classical system (bɛrɛm); Western devoices and aspirates the original voiced consonants (pʰɛrɛm)). The Cilician kingdom was in close contact with several Crusader kingdoms, as a result of which it borrowed a significant number of words from Crusader French, most famously what comes out as the standard Western form for 'mister,' *baron*.

In the nineteenth century, Armenian nationalists became interested in developing a literary form of the modern language. This was brought about by excising most Turkish forms from the regional dialects and replacing them with new borrowings from the classical language. The intellectual center around which the new Western literary language was organized was Constantinople, although many features of the standard dialect (including the pronunciation of the consonants) do not come from the Armenian dialect originally spoken there. The same holds for Eastern Armenian with respect to Erevan. The relationship between the two modern literary dialects is somewhat complicated; there are many grammatical differences (e.g. Western gə sirɛm vs. Eastern sirum ɛm 'I love', Western bidi sirɛm vs. Eastern kəsirɛm 'I will love') and lexical differences (e.g. Western dʒɛrmag vs. Eastern spitak 'white'; Western hɔs vs. Eastern ɛstɛʁ 'here', Western bɛdkʰaran vs. Eastern zukʰaran 'bathroom', Western havgitʰ vs. Eastern dzu 'egg'), and most Western speakers have difficulty in understanding Eastern; however Eastern speakers are relatively comfortable with the Western dialect. This asymmetry in mutual intelligibility most likely results from the fact that large numbers of speakers of Western dialects fled to Eastern Armenia following the Russo-Turkish war in 1828 and the Turkish Genocide in 1915–1920, whereas before the fall of the Soviet Union in 1991 most Western Armenians had little or no exposure to Eastern Armenian. The fact that there is some mutual intelligibility in both directions can also be linked to the fact that the literary dialects tend to borrow the same forms from Classical Armenian, and (at least in recent decades) employ the same newly coined words.

The destruction of the Armenian homeland and more than a million Armenians by the Ottoman government in 1915–1920 rendered most nonstandard varieties of modern Armenian moribund; with few exceptions, the Armenians in the diaspora (primarily Lebanon, France, and the United States) speak only Standard Western Armenian. There were approximately 6.8 million speakers of Armenian in 1996, but all varieties of the language except for Standard Eastern Armenian are in immediate danger of extinction as very few diaspora Armenians under the age of 30 speak the language fluently.

Whereas Classical Armenian was relatively Indo-European in its syntactic and morphological structure, all varieties of Modern Armenian are typologically much closer to Turkish and the Balkan languages. Compare, for instance, the formation of relative clauses, exemplified by 'I saw the bird that was singing in the tree': Classical tesi əz-tʰərtʃʰun-ən or ɛrgɛr i vɛraj tsar-oj-n (I.saw specific-bird-definite that was.singing in on tree-genitive-definite), Western dzar-i-n vəra jɛrkʰɔʁ tʰərtʃʰun-ə dɛsa (tree-genitive-definite on singing bird-definite I.saw). Western Armenian has been additionally influenced by Turkish and Greek (cf. əsdɛpʁin 'carrot', istakʰɔz 'lobster', bantʰɔg 'hotel'), whereas Eastern Armenian has been heavily influenced by Russian (e.g. the standard form for 'potatoes' is kʰartʰɔfli, and the word for 'gay' is galubɔj, from the Russian word originally meaning 'sky blue'; the native word for 'blue,' kapujt, cannot be used in this sense).

Artificial Intelligence

Artificial Intelligence (AI) is the subfield of computer science that aims to enhance computers with capabilities traditionally attributed to human intelligence, such as perception, reasoning, understanding, and learning. However, AI researchers usually give more elaborate definitions for AI, focusing either on the problems that

AI aims to solve or on the methods used for approaching them. Thus, AI can be alternatively defined as the effort to make computers capable of solving problems that currently only humans can solve, or as a set of methods for confronting problems for which exact solution algorithms are not yet known. The latter definitions also explain why topics such as symbolic calculus and neural networks are not considered pure AI topics anymore and why some not-well-defined problems, such as natural language understanding, are traditionally positioned in the domain of AI.

AI has been strongly influenced by the works of Norbert Wiener, Claude Shannon, John von Neumann, Alan Turing, and Alonzo Church. However, the term 'artificial intelligence' is attributed to John McCarthy, who introduced it on August 31, 1955, in a document titled *A Proposal for the Dartmouth Summer Research Project on Artificial Intelligence.* The proposal involved a two-month study 'on the basis of the conjecture that every aspect of learning or any other feature of intelligence can in principle be so precisely described that a machine can be made to simulate it'. It was signed by John McCarthy, Marvin L. Minsky, Nathaniel Rochester, and Claude E. Shannon. The conference that was held at Dartmouth College (in Hanover, New Hampshire) the next summer is considered a milestone in the history of AI because it brought together all the researchers interested in the field and established the birth of AI. After the Dartmouth conference, Minsky and McCarthy founded the AI Laboratory at the Massachusetts Institute of Technology, and two other participants—Herbert Simon and Allen Newell— founded the AI Laboratory at Carnegie Mellon University. McCarthy, Minsky, Simon, and Newell are considered the founders of modern AI.

The feasibility of the ultimate AI goal (i.e. the development of intelligent machines) has been questioned repeatedly. A theorem known as the Church–Turing thesis has provided strong supporting evidence, assuming that intelligent behavior is based on some kind of computation. Turing has also described a process to test whether the intelligence of an AI system is comparable to that of a human being. This process is known as the Turing test: a human observer is allowed to interact via a teletype with another human and a machine that pretends to be a human. The observer does not know which is which and tries to figure it out by conversing with both via the teletype. Turing argued that if the machine could successfully fool a knowledgeable observer, then it should certainly be considered intelligent. However, many philosophers, such as John Searle and Hubert Dreyfus, have argued not only against the correctness of the Turing test but also against the feasibility of ever building a nonbiological intelligent machine. This debate led to the formation of two philosophical directions: strong AI and weak AI. Supporters of strong AI believe that computers, even with current technology, are capable of supporting intelligence, given appropriate programming. Supporters of weak AI believe that although programs able to imitate intelligent behavior can be made, it is impossible to make a machine that understands or develops consciousness in the way that humans do.

The distinction between weak and strong AI is closely related to another distinction: that between symbolic and subsymbolic AI. The key assumption of symbolic AI is that knowledge is represented by structures of semantically meaningful symbols and that a set of such symbols is therefore required to support the reasoning process of an intelligent system. A program for proving logical theorems is an example of a symbolic AI system. However, the key assumption of subsymbolic AI is that intelligent behavior can be attained without the need for semantically meaningful symbols. A neural network is an example of a subsymbolic AI system.

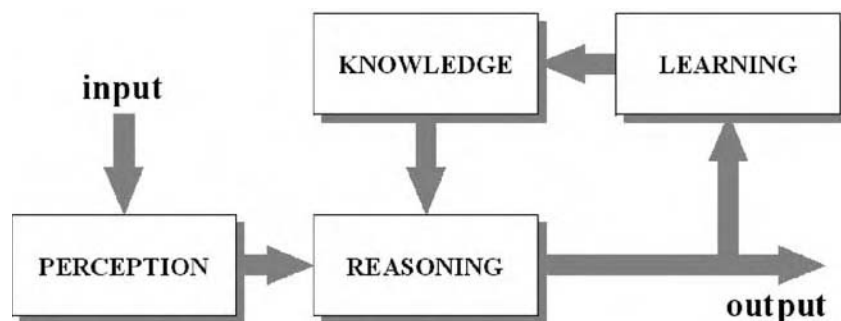
A generic AI system can be described in terms of four main components: perception, reasoning, knowledge, and learning. Figure 1 shows their interconnection. Perception is the task of processing the input to extract structured information needed for the particular task. The reasoning component is responsible for the manipulation of this information, according to the system knowledge contained in the knowledge component. The output of reasoning may be the outcome of the AI system itself, or it may be fed to a learning mechanism


Figure 1. Structure of a Generic Artificial Intelligence System.

whose function is to update the existing knowledge. The structure of Figure 1 should be considered as a descriptive model, not an implementational one, because some systems may lack some components, and others, especially the subsymbolic ones, may have some of the components merged indistinguishably.

However, the majority of the topics addressed by AI concern one or more of the above four components. These topics are discriminated as AI branches, according to the types of problems, the techniques used, and the classes of applications involved. There are many AI branches: search methods, symbolic reasoning, production systems, heuristic techniques, knowledge representation, logic programming, statistical reasoning, fuzzy logic, game playing, planning, vision, natural language processing, machine learning, neural networks, genetic algorithms, common sense reasoning, expert systems, speech understanding, theorem proving, machine translation, robotics, perception, automatic programming, constraint satisfaction, ontology, and intelligent agents, among others. Their outcomes are very diverse. Some of them, such as expert systems and game playing, have produced impressive results, whereas others, such as machine translation and speech understanding, are still far from their goal.

There are several scientific organizations devoted to AI research. Among the best known are the American Association for Artificial Intelligence (AAAI), the European Coordinating Committee for Artificial Intelligence (ECCAI), the Society for Artificial Intelligence and Simulation of Behavior (AISB), and the Special Interest Group on Artificial Intelligence (SIGART) of the Association for Computing Machinery (ACM).

Artificial Languages

The term 'artificial language' can refer to several different kinds of symbolic systems, including programming languages, symbol systems used in various branches of science, 'controlled' languages for unambiguous technical communication, intermediate languages in machine translation, highly regularized ethnic or literary languages, fictional languages created for literary purposes, and planned languages for intercultural communication. In linguistics, the term is most often used to designate this last category, but metaphors and concepts from these neighboring fields are a frequent source of both insight and confusion.

The idea of improving existing languages, by making them more regular, less ambiguous, or more expressive arose in medieval Europe. By the mid-seventeenth century, a number of leading intellectuals, including Jan Amos Komensky (Comenius), René Descartes, Gottfried Leibnitz, and John Wilkins, were investigating the possibility of constructing a linguistic system on the basis of scientific taxonomies and logicomathematical operations. This work inspired many so-called philosophic or a priori language projects throughout the next two centuries, both written (*pasigraphies*) and spoken (*pasilalies*). Despite their influence on the development of mathematics, formal logic, and general linguistic theory, none of these systems acquired a significant body of users.

In the nineteenth century, the rise of historical and evolutionary views of language contributed to a waning of interest in philosophical language projects. At the same time, improvements in transport and communications turned attention toward the practical benefits of a common international language, while the Romantic equation of language with culture and identity led

many to associate the idea of a common language with ideals of peace and brotherhood among nations. Today, all three of these orientations—the philosophical-scientific, the instrumentalist, and the value oriented—can be found among users, researchers, and theorists of international planned languages.

The systematic study of such languages, a field now referred to as *interlinguistics*, was inaugurated in 1903 with the publication of Couturat and Leau's *Histoire de la Langue Universelle* (*History of the Universal Language*), supplemented four years later by *Les Nouvelles Langues Universelles* (*The New Universal Languages*). The authors analyzed a total of 75 language projects and project outlines, most of them originating in the previous half-century. No fewer than 912 projects are listed in the most complete catalogue to date, Aleksandr Duličenko's *Meždunarodnye Vspomogatel'nye Jazyki* (1990: *International Auxiliary Languages*). However, the vast majority of these have seen no practical use, and linguistic research on them is necessarily theoretical. Empirical research requires a community of language users, and the number of projects that has achieved this status is quite small.

The most widely used classificatory scheme in interlinguistics places language projects on a continuum between 'naturalism' (modification of an existing language that leaves most of its features intact) and 'schematism' (implying a high degree of rationalization on a priori lines). All of the more naturalistic projects that have acquired a community of users are Latinate. They include Latino sine flexione (1903), a regularized form of Latin invented by the Italian mathematician Giuseppe Peano; Occidental (1922; later renamed Interlingue), the project of Edgar de Wahl, an Estonian mathematician who had been active in earlier projects; Novial (1928), the creation of Danish linguist Otto Jespersen; and Interlingua (1951), a project published under the auspices of the International Auxiliary Language Association, but primarily designed by its director Alexander Gode. Like the earlier naturalistic projects that it replaced, Interlingua was intended primarily for communication among educated Europeans; Gode's idea was to distill a 'Standard Average European' (a concept inspired by Benjamin Whorf) from lexical and grammatical elements common to English, French, Italian, and Spanish/Portuguese. Interlingua acquired perhaps a few thousand users in the 1950s and 1960s, primarily in the United States and Europe, and retains a small following today.

The remaining language projects to have acquired a body of users display both naturalistic and schematic traits. They are also quite diverse. The earliest of them, Volapük (1879), was developed by Johann Martin Schleyer, a Catholic priest in Baden, southern Germany. The vocabulary of Volapük consisted of arbitrary modifications of Western European words, making new coinages controversial. After its extraordinarily rapid spread in the 1880s, including a certain amount of oral use, Volapük underwent an even more rapid decline in the 1890s in response to internal conflicts over the control and development of the language. It has not been in active use since the 1920s.

Volapük's successor, Esperanto (1887), was published by a Jewish physician in Warsaw, Ludovik Zamenhof. Initially slower to spread than its predecessor, Esperanto experienced explosive growth between 1900 and 1912, the period in which its oral tradition became firmly established. Today, it remains by far the mostly widely used international planned language, and thus it is the most accessible to linguistic study. For much the same reason, it is also the language in which the greatest share—approximately 50%—of the interlinguistic literature has been written. Research on Esperanto is reviewed in greater detail below.

In 1907, Ido, a project derived from Esperanto, was published and quickly attracted some prominent adherents from the Esperanto movement; rivalry between the two languages continued until after World War II. It is now generally accepted that Ido was the creation of Louis Couturat, a prominent French logical philosopher and the principal author of *Histoire de la Langue Universelle* (mentioned previously). Some of Couturat's modifications tended toward greater Latinization. Others introduced greater schematism. Like the Volapük community before it, the Ido movement soon became embroiled in linguistic disputes that alienated many potential users. Today, only a very small community of speakers remains.

The newest language projects to have acquired a small number of users are Glosa, a derivative of Lancelot Hogben's Interglossa (1943), and Lojban, a derivative of James Cooke Brown's Loglan (1955). Glosa combines Greek and Latin words with particles to denote tense, number, and so forth; phrase and sentence construction resemble those of English. Lojban's syntax is based on symbolic logic; it was originally proposed, in the tradition of the philosophic language projects, as a means of exploring the relationship between language and thought, and attempts to use it for oral communication are fairly recent. Neither project has acquired a speech community.

All but the last two projects are discussed in greater detail in Detlev Blanke's seminal work *Internationale Plansprachen* (1985; *International Planned Languages*), the standard reference work on the subject. This work introduced an alternative classificatory scheme, listing 18 stages through which a language project might be expected to pass on its way to full socialization. On this scale, Ido and Interlingua were identified as 'semilanguages', having developed beyond

the project stage to acquire an original and translated literature, oral use at international meetings, and other markers of communicative use. Esperanto, however, was shown to be a qualitatively different phenomenon, being used on a scale and in a range of situations as extensive as, although different from, many ethnic languages.

Zamenhof's original blueprint for Esperanto consisted of 16 short rules on a variety of topics, a glossary of 940 words, some samples of poetry and prose, and a lengthy essay on the key characteristics of his proposal. Like most planned languages, Esperanto uses the Latin alphabet, and pronunciation follows orthography; in words with several syllables, intonational stress falls on the next to last syllable. Chief among its distinguishing features is its system of word-class endings: *-o* marks nouns, *-a* adjectives, and *-e* adverbs; *-i/-is/-as/-os/-us/-u* form verbs in the infinitive, past, present, and future indicative, conditional, and imperative modes, respectively. Apart from certain closed class words (the definite article *la*, prepositions, conjunctions, comparatives, correlatives, and a small number of adverbs ending in *-aŭ*), all lexical items must be combined with one of these endings to function in a sentence. Word roots are borrowed intact or with inflectional endings removed, primarily from Romance (75%), but also from Germanic (20%), Slavic, and other sources. Direct loans from non-European languages remain relatively rare.

A second key characteristic of Esperanto is the invariance and high combinability of all of its elements. Zamenhof introduced more than 20 affixes to express ideas related to the root word, such as 'place of', 'container for', 'opposite of', and so on; these have since been supplemented by a handful of others. Word roots may also be freely combined. Many common compounds have acquired conventional meanings over time, so that *lern-ej-o,* for instance (literally 'learning-site'), usually indicates a school of some kind. Early compound formation was influenced by Germanic and Slavic models (e.g. *el-don-i,* to publish, literally 'to give out'), but modern usage favors greater transparency and what might be called 'indigenous' models, e.g. the direct transformation of adjectives into verbs (*bon-a,* 'good', *bon-i,* 'to be good, to manifest goodness') or the use of affixes and prepositions as independent roots (*ad-e,* 'continually, repeatedly', *per-i,* 'to mediate, broker', *et-a,* 'small').

This introduces a third key characteristic of Esperanto: its evolution through communicative use. Throughout 25 years as the central figure of the movement, Zamenhof consistently emphasized an inductive approach to learning and using the language, with new speakers developing their own tacit linguistic models on the basis of a growing body of literary and scientific texts. This approach is reflected in the exercises of the *Fundamento* (1904; *Foundation of Esperanto*), which Zamenhof persuaded the first international Esperanto congress (1905, Boulogne-sur-Mer) to adopt as an unalterable paradigm of acceptable usage. It also accounts for the effort he invested in translations of such works as Gogol's *The Tax Inspector,* Shakespeare's *Hamlet,* the Old Testament (from Hebrew), and Andersen's *Fables*; these influential texts did much to develop Esperanto literary style and semantics. After World War I, literary and scientific writing in Esperanto flourished and diversified in both book and periodical form; major libraries currently hold 10,000 to 20,000 volumes. Development of the oral language has also been marked, particularly since the 1970s, with the expansion of international telephony and travel. Today, although influential dictionaries, grammars, and textbooks exist, none can be taken as a definitive or complete description of Esperanto as it is actually used.

Valuable research on Esperanto has been carried out both by professional linguists and philologists and by brilliant amateurs such as the Hungarian polymath Kálmán Kalocsay (*Plena Gramatiko de Esperanto,* 1932; *Complete Esperanto Grammar*). Only a small sample of this work is available in English. Particular interest has been focused on the rules governing word and sentence formation; the etymology and semantics of the core vocabulary; the interplay of prescriptive principles (such as the 16 rules), linguistic ideologies, and tacit linguistic models; the relationship between language, culture, and identity; the development of Esperanto literature; and the use of the language in various scientific and technical fields. In the 1980s, a Dutch project examined Esperanto's suitability as an intermediate language for machine translation. The Modern Languages Association of America lists 200 to 300 publications in its annual bibliography.

Several million people have studied Esperanto, on the basis of textbook sales and other data; however, the population of those with an active command of the language is much more difficult to characterize. Taking into account the reported membership of the Universal Esperanto Association (the most representative international organization of Esperanto speakers), annual sales of books and periodicals, and economic barriers to participation, a reasonable current estimate would be something more than 50,000 active speakers, along with a substantially larger number of passively competent, lapsed, or occasional users. Some three quarters of active speakers are located in Europe (including Eastern Europe and Russia), with established communities of users in most East Asian and Latin American countries, in West Africa, and in regionally isolated countries such as Iran and Israel. There are active, self-organizing networks of both young speakers (under 30 years) and Esperanto-speaking families, including a

few hundred first-language speakers. Active specialist organizations exist in many areas, including predominantly oral domains such as popular music and radio broadcasting. Increasingly, the World Wide Web constitutes a valuable tool for research into the language and its domains of use.

MARK FETTES

Aspect

'Aspect' in its proper sense—also called 'grammatical aspect'—is one of the grammatical categories of the verb besides tense, mood, and others. The term 'aspect' is also used as a cover term for grammatical aspect and two other closely related phenomena: 'aktionsart' as a lexical-semantic category of verbs and 'predicational aspect' as a semantic property of verb phrases. Aspect in its broader sense has to do with the internal structure of the event the verb refers to, with the perspective the speaker adopts toward the course and structure of the event, or with both of these.

Because the expression of grammatical aspect is often closely intertwined with the expression of tense, in traditional grammars, aspectual distinctions are often confusingly dealt with under the heading of 'tense'. Among the categorical distinctions in tense-aspect systems that are of an aspectual nature are those between *imparfait* and *passé composé/passé simple* in French, progressive and nonprogressive in English, or imperfect and aorist in Greek. Formally, aspect can be expressed by very different means, e.g. by prefixes and suffixes (Russian), reduplication (Chamorro), inflectional and periphrastic forms within a tense-aspect system (French, English), verb stem formation (Greek), or combinations thereof (Bulgarian).

The main opposition within the grammatical category of aspect is the one between perfective and imperfective aspect. Informally, it is often said that in using the perfective aspect, the speaker looks onto the event from outside as an undivided whole, often focusing on its completion. From the imperfective perspective, the speaker views the event from inside as an ongoing process, a state, or a habitual action without directing attention to the completion of the event. From a textual point of view, verbs in the imperfective aspect contribute to the description of the background of a scene, whereas verbs in the perfective aspect are used to describe the events that take place on this background in their temporal succession. Thus, the Russian equivalent for English *to write* has an imperfective form, *pisat',* and a perfective one, *napisat'*. The imperfective one is used in contexts in which English would use expressions such as *she was writing* or *she used to write*. The perfective form occurs in contexts in which the completion or the result of writing is emphasized (*he wrote/has written the letter*) and in which it occurs in a sequence of events (*he sat down, wrote the letter, and put it in an envelope*). Aspectual semantics is a very intricate matter, and the meaning of the perfective–imperfective opposition involves cross-linguistic differences. Furthermore, some languages do not show a fully developed perfective–imperfective distinction but express aspectual meanings that can roughly be classified as meaning components of the imperfective aspect (progressive vs. nonprogressive aspect, habitual vs. nonhabitual aspect) or the perfective aspect (completive vs. noncompletive aspect).

In contrast to grammatical aspect, the term 'aktionsart'—which translates as 'kind of action' from German—is considered to be a lexical-semantic category. Approaches to aktionsart differ as to whether they consider all verbs to show a certain aktionsart or whether they restrict the term to phenomena in which aktionsart meanings are expressed by certain prefixes or suffixes. Aktionsart distinctions are mainly used to classify verbs according to their reference to parts of events, to events of a certain length, and to repetitions of events (affixes and their translations are underlined): German *loslaufen* 'to start running', Russian *posidet'* 'sit for a while', Russian *kriknut'* 'to scream once', German *austrinken* 'to drink up', Russian *pisyvat'* 'to write repeatedly'. Because both grammatical aspect and aktionsart are mainly expressed by means of word formation in Slavic languages—which have played an important role in research on aspect—the proper distinction between the two categories has always been a subject of debate. The diversity of the phenomena covered by the term 'aktionsart' is reflected in the diverse semantic approaches to aktionsart. It can be observed, though, that formal semantic approaches to aktionsart phenomena often involve notions like 'part of an event' (an event referred to by German *austrinken* 'to drink up' as part of an event referred to by *trinken* 'to drink'), 'recurrence of an event' (*rewrite, rebuild*), and 'event presupposition' (*he ate up* presupposes *he ate*; *she rebuilt the house* presupposes *somebody built the house before*, etc.)

Sometimes, the term 'aktionsart' is also applied to or—better—confused with the phenomenon of 'predicational aspect' (also called 'lexical aspect'). The most influential description of predicational aspect was given by Zeno Vendler (1957), who distinguished four 'time schemata:' (1) statives like *know something, hate somebody*; (2) achievements (roughly, expressions referring to punctual events) like *reach the summit, win a race, recognize somebody*; (3) activities (roughly, expressions referring to events as ongoing or non-culminating) like *push a cart, run,* and *swim*; and (4) accomplishments (roughly, expressions referring to

events as culminating or delimited) like *draw a circle, run a mile, write a letter*. Despite the popularity of these so-called Vendler classes, they are problematic in many respects. In particular, the four classes are distinguished by semantic properties belonging to very different domains (length of event, stativity, completion), and it is often unclear if the domain of the classification is verbs, verb phrases, or sentences.

Formal semantics has been especially interested in the difference between activities (e.g. *she ate, she ate apples, she watched the apples*) and accomplishments (e.g. *she ate the apples*). Expressions describing activities can be modified with phrases like *for ten minutes*, but not phrases like *in ten minutes*. Because *watch the apples* is an activity, *She watched the apples for ten minutes* is acceptable, but *She watched the apples in ten minutes* is not. With accomplishments, such as *eat the apples*, it is the other way around: *She ate the apples in ten minutes* is acceptable, whereas *She ate the apples for ten minutes* only seems to be so if the context forces *eat the apples* to be reinterpreted as an activity.

Assimilation and Coarticulation

Assimilation refers to a change in sound due to the influence of a neighboring sound (aspiration, glottalization, nasal release, etc.). For instance, the /s/ in 'husband' becomes voiced as a result of the voiced phonemes surrounding it. The influence can be either in

anticipation of the next sound (= anticipatory or right-to-left assimilation), or it can be carry-over (left-to-right) assimilation, in which an ongoing feature is continued to the next sound. Assimilation is similar to coarticulation, in that both processes deal with the mod-

ification of sound due to contextual variability. However, the standard generative phonology (Chomsky and Halle, the Sound Pattern of English, 1968) makes a clear-cut distinction between assimilation and coarticulation. Assimilatory processes are part of a grammar and are language specific (although they occur in many languages), and they can be accounted for by phonological rules. Coarticulation results from the inertia of the speech mechanism and is, hence, more universal. Both the distribution (universality vs. language specificity) and the quality of the contextual change (mere articulatory adaptation vs. intentional phonetic modifications) distinguish the two processes. However, there is no simple way of distinguishing between those assimilation effects that are due to the inherent properties or limitations of speech production and those that are not, unless the latter are very obviously language-specific. Assimilation often appears to be motivated by ease of articulation, but what seems easy and natural in one language often turns out to be less so in another.

Assimilation effects are not fully understood: it is not clear to what extent we can explain them by assuming that high-level commands associated with specific segments are confounded by biomechanical 'sloppiness' or to what extent high-level commands are deliberately planned to optimize transitions between targets and to yield the best possible vocal tract performance in running speech.

Assimilation is often mentioned in connection with historical changes. Many of the sound changes in languages can be described as assimilatory. For example, English words such as mission, special, or passion were once pronounced with a medial [sj] but in modern English have [ʃ]: by a process of assimilation, the [s] has been retracted in anticipation of the following [j] or [I]. However, it is important to distinguish between historical processes (which are over and done with) and processes that are still current or operative in the modern language. They are part of the speaker's organization of pronunciation and are relevant to our description of the language (e.g. prefix un-, which is pronounced as [n] in nonvelar contexts (untidy, unsettled) but which are pronounced as [ñ] before a velar (unkind, ungainly).

Place of Articulation

This occurs in English, for example, by 'ratbag' or 'oatmeal' pronounced with [p] instead of [t] in rapid or informal speech, by assimilation of the alveolar stop to a following bilabial.

Manner of Articulation

Here, 'Indian' is pronounced as 'Injun', where the stop [d] and approximant [j] merge to form an affricate (same for soldier).

Voicing

This occurs, for instance, when 'v' in 'have to' is pronounced with an [f] instead of [v] due to assimilation of the voiced fricative to the following voiceless consonant.

Not all speech sounds are equally affected by contextual variability. Bilabial, [b] and [p], tend to be very stable and show no effect of assimilation irrespective of the context. Velars such as [k] and [g] are also stable, although the place of articulation is more fronted in the context of front vowels: the closure of the [k] in 'kick' is more palatal, while that of the [k] in 'cook' is more velar. Of the different plosives, assimilation occurs most in alveolars, i.e. in [t] and [d]. The closure of the [t] or [d] will not be alveolar, but will occur at the place of articulation of the following segment. For instance, the closure of a [t] or [d] before a dental will also sound dental (indicated by a diacritic), e.g. 'ho[t̪ θ]ing 'hot thing', while that before a velar will sound velar, i.e. 'ho[k k]ake', 'hot cake' or 'ba[g g]irl', 'bad girl.' Preceding a bilabial, the [t] or [d] will also be bilabial, i.e. 'hot pie' becomes 'ho[p p]ie' and 'bad boy' becomes 'ba[b b]oy'.

Manner of Assimilation

Alveolar stops are not only influenced by surrounding consonants but also by surrounding vowels. Here, the assimilation involves manner rather than place of articulation. In several North American accents, the [t] and [d] are neutralized, i.e. their characteristic physical properties are replaced by the voiced alveolar flap (transcribed as [ɾ]). This sound contains voicing and a flap (= a very brief contact between the tongue tip and the alveolar ridge). Using this flap, the words 'Adam' and 'atom' may sound identical, both words having the flap for the intervocalic 't' and 'd'. This flapping occurs whenever what would be [t] or [d] in other accents occurs between two vowels, not only within words (see previous example) but also across word boundaries, as in 'ge[ɾ] away' (get away). However, flapping does not occur when the stop precedes a stressed syllable, as in 'attract', where the second syllable carries the stress.

Affricates

There is little assimilation of the affricates in English, although there may be some variation among speakers.

Labiodental fricatives [f] , [v] do not show a great deal of assimilation, although [v] may become a voiceless word, finally preceding a voiceless obstruent (ha[f] to, o[f] course.

In English, in fast speech, dental fricatives [ð] often assimilates entirely to a preceding alveolar sound 'I[n n]epub 'in the pub'.

The alveolar [s] and [z] are often assimilated to the following palatal glide [j] or palatoalveolar fricative as in 'mi[š j]ou' ('miss you'), 'it wa[ʒ j]ellow' ('it was yellow').

Assimilation is quite a general phenomenon in connected speech, but it spreads wider in fast speech than in slow speech. It involves the change of some segment under the influence of another one, and the change makes the two speech sounds more similar. The phrase 'ten books', for example, is pronounced as [tem buks], where /n/ assimilates to the adjacent /b/ by adopting its bilabiality feature. Most forms of assimilation are to be located at the segment spellout level.

Assimilation should be distinguished from coarticulation. Adjacent speech sounds interact because of the physiology and the mechanics of articulation. These interactions become more intense at higher speech rates. They depend on the time allotted to the articulation of syllables (coarticulation).

There is a wide range of assimilation processes that take place across a syllable or word boundary. In Swedish, a syllable final /r/ is integrated with any (phonemically adjacent) apical dental consonant(s) making the latter a retroflex alveolar, and this effect spreads over the word boundary.

Quite often, context-dependent changes involving the same articulatory structures have different acoustic and perceptual manifestations in different languages, so that it is possible to distinguish what can be considered universal phonetic behavior from language particular rules. A classical example is the difference between vowel harmony, an assimilatory process present in a limited number of languages (Hungarian) and the process of vowel to vowel coarticulation, attested in many languages and probably present in all. In other cases, cross-language differences are not easily interpretable and inferences about the nature of the underlying processes can be made only by manipulating some of the speech parameters, for example segmental durations. In a study of vowel nasalization in Spanish and American English, Solé and Ohala (1991) were able to distinguish phonological (language-specific) from phonetic nasalization by manipulating speech rate. They found a quite different distribution of the temporal patterns of nasalization in the two languages, as a function of rate: in American English the extent of nasalization on the vowel preceding the nasal was proportional to the varying vowel duration, while in Spanish it remained constant. They concluded that the spread of nasalization as vowel duration increases in AE must be intentional (phonological), while the short and constant extent of nasalization in Spanish must be an automatic consequence of the speech mechanism, since it reflects the minimum time necessary for the lowering gesture of the velum. However, there is no strict dichotomy between universal and language-specific variations, as coarticulation differs in degree across languages.

Assimilation and Dissimilation

All words have citation forms, or dictionary pronunciations, which occur when they are pronounced in isolation. These dictionary pronunciations may undergo sound changes when the word is used in connected speech. One of the most common processes of sound change is assimilation.

'Assimilation' is a cover term that includes a variety of processes and refers to the change in a language sound that makes it more similar to a neighboring sound. The process by which the Latin word *noctem*, meaning 'night', became *notte* in Italian shows an assimilation of the [k] sound, represented by <c> in the spelling, to the same point of articulation as the following [t].

'Dissimilation' is the opposite process, in which sounds become more unlike neighboring sounds. The German word *Kartoffel* 'potato' comes from an earlier form *Tartuffeln*. In this case, the [t] at the beginning of the word became [k], a sound dissimilar to the following [t]. Compared to assimilation, dissimilation is an uncommon process in the world's languages and can be less obvious to an observer. As an example, in many Bantu languages, prefixes must disagree in voicing with the first consonant of the root. Thus, the consonant of the prefix *tu-/du-* for 'I' changes, depending on whether or not the first consonant of the verb is voiced. Thus, *bona* 'to see' starts with a voiced consonant [b] and 'I see' is consequently *tu-bona,* whereas *soma* 'to read' starts with a voiceless consonant [s], and the prefix shows up with a voiced one: *du-soma* 'I read'.

Assimilation can occur both across word boundaries and within words, with sounds affecting each other in three main ways: regressively, progressively, and bidirectionally.

'Regressive' or 'anticipatory' assimilation refers to the effect of a later sound on an earlier sound. One of the most common types of regressive assimilation in many languages involves nasal consonants, which regularly change place of articulation to match the place of articulation of the following consonant. In English, the <n> in the prefixes *in-* and *un-* is usually pronounced [n] only when the following sound is an alveolar consonant, as in *intention.* In *input,* the following sound is bilabial [p]; hence, the <n> is actually pronounced as bilabial [m].

'Progressive' assimilation refers to the effect of an earlier sound on a later one. The English *-s* morphemes found in plural nouns, third person present tense verbs, and possessives are examples of this type of assimilation, being pronounced [s] after voiceless sounds (e.g. *cats, walks, Pete's,* respectively) and [z] after voiced sounds (e.g. *dogs, reads, Mary's*).

'Bidirectional' or 'coalescent' assimilation occurs when two sounds influence each other, as in the common American English spoken forms for an alveolar consonant followed by an unstressed syllable beginning with a [j]. In the following examples, the [t] and [d] sounds join the [j] to create an affricate: *did you* [dɪd juá] ➔ [dɪdʒ u], *can't you* [kænt juá] ➔ [kæn tʃu], *graduate* [gɹæ dʒueɪt], *ritual* [ɹɪtʃu əɫ].

Assimilation especially affects voicing, manner of articulation, and place of articulation. Voicing assimilation is seen in the case of English *-s,* where the voicing of the first consonant carries over to the voicing of the suffix. The effect of assimilation on place of articulation can be seen in the case of English <n>. The overwhelming pattern for this kind of assimilation is for the first consonant to assimilate to the place of articulation of the second, and not the opposite. In English, this occurs commonly with words like *input*, pronounced usually as *imput,* and *income*, frequently pronounced as *iŋ come*. The same *in-* prefix in Latin before the labial sounds [m], [p], and [b] was written as [m], as in *immemorial, impossible, and imbibe*. Evidence of the manner of articulation assimilation with the *in-* prefix can also be seen historically in Latin in words that were borrowed by French and later English. Before the continuant sounds [l] and [ɹ], *in-* was pronounced and written identically to the following sounds, so that *in+legal* and *in+regular* were written as *illegal* and *irregular*.

The most common explanation for assimilation is that speakers adjust the articulation of sounds because it is easier than keeping each sound distinct in the stream of speech. When speakers are producing hundreds of sounds per minute, it is only natural that the precise articulation of sounds will be affected by other sounds near them. There is also evidence that some types of assimilation may have their roots in listener perceptions rather than speaker articulations.

While assimilation takes place in all languages, the extent of assimilation is sensitive to speech rate and register. All other things being equal, assimilation is more likely to occur in casual styles of speech than in more careful, formal styles. The kinds of assimilation and the extent to which it occurs are also relevant in distinguishing differences in varieties of a language. One clear difference between standard southern British and General American English is in the presence or absence of coalescent assimilation in words such as *gradual* or *issue*. The British pronunciation generally does not assimilate the sounds in the middle of words, i.e. the *du* in *gradual* is pronounced [dju], and the *su* in *issue* is pronounced [sju]. The American pronunciation, however, does assimilate, leading to [dʒ u] and [ʃu], respectively.

Austin, John Langshaw

Austin was a leading member of a school of philosophy variously referred to as 'Oxford philosophy', 'linguistic philosophy', or 'ordinary language philosophy' that developed in Britain in the years between the two World Wars and enjoyed its heyday in the late 1940s through the early 1960s. Each of these descriptive terms is, however, arguably inaccurate to some extent. Not all of the members were, for instance, based at Oxford University; nor is it true that all the philosophers at Oxford were sympathetic to its basic tenets. In fact, it may even be argued that the group did not properly constitute a 'school' but at best a loosely knit gathering of philosophers who shared some common views or at least a certain attitude toward philosophy and who regularly gathered for an informal chat for what were famously known as the 'Saturday morning talks'.

Austin published only seven papers and a book during his lifetime. The book was an English translation of *Grundlagen der Arithmetik* (*Foundations of arithmetic*) by the German mathematician and philosopher Gottlob Frege (1848–1925). Austin's major works *How to do things with words* (HDTW*)* and *Sense and sensibilia* (S&S) were both published posthumously. So too was *Philosophical papers*, a collection of 12 papers, most of which had been originally presented at the annual meetings of the Aristotelian Society and published in the conference proceedings. HDTW and S&S are the written versions (based on Austin's own annotations as well as notes prepared by members of the audience) of two series of talks delivered by Austin at Harvard (1955) and the Berkeley Campus of the University of California (1958), respectively.

HDTW is undoubtedly Austin's major philosophical work and the one responsible for his reputation outside the disciplinary bounds of philosophy, mainly linguistics. In it, Austin develops with great verve a philosophical thesis that, despite its apparent simplicity and unpretentiousness, turned out to be a groundbreaking discovery in philosophical analysis. Austin argued that, contrary to what the weight of philosophical and grammatical tradition would have us believe, not all declarative sentences are used to make statements. While a sentence such as 'The cat is on the mat' may indeed be used to make a statement about a certain state of the world involving a feline creature and its whereabouts at the time of speaking, it is not at all clear that words such as 'I hereby pronounce you man and wife' (as uttered by a priest at a given moment during a marriage ceremony) or 'I name this ship the HMS Queen Elizabeth' (as pronounced by, say, the Prime Minister of Britain at the launching ceremony of the latest addition to his country's naval fleet) are used to make statements. These latter utterances do not describe anything in the world; if anything they help alter the world in significant ways by effectively bringing about certain changes. The priest's words, for instance, literally help 'create' a newly wedded couple. Austin coined the term 'performatives' to refer to the utterances of the latter kind that, despite their declarative form, did not result in statements being made. The former, run-of-the-mill declarative sentences were, by contrast referred to as 'constatives'. Constatives, being straightforward declarations, could be assessed in terms of truth and falsity. The performatives were neither true nor false. They could be considered 'felicitous' or otherwise, depending upon a number of attendant circumstances—in the case of the marriage ceremony, for example, the words had to be pronounced by a priest and nobody else, etc. Furthermore, performatives were not descriptive; to utter them was to perform (whereof the neologism) certain acts—later subsumed under the broader category of 'speech acts'.

Pursuing his line of inquiry, Austin painstakingly sought formal criteria by which to distinguish performatives from constatives. Although a number of candidates emerged, such as the use of the first person, present indicative, active voice, etc., counterexamples

soon convinced Austin that the very attempt was a wild goose chase. Even the hypothesis that peformatives were mostly utterances that were culture-specific (such as marrying in a Christian church) turned out be difficult to sustain. This was confirmed by the discovery that even such ordinary utterances such as 'I promise that *p*' (where *p* is any complement denoting a future course of action to be performed by the speaker) meet all the features that help identify performatives. A promise is neither true nor false; it may be described as infelicitous if it turns out, for instance, that the speaker had no intention whatsoever to carry it out. So a promise is as good a speech act as marrying a couple or launching a ship. And so too are such routine acts as ordering, requesting, etc.

Austin was also struck by the fact that a '*p*' simpliciter can just as well do the job as 'I promise that *p*' provided the circumstances are appropriate. Thus 'Do it' as uttered by an army general to a private is readily understood as an order rather than, say, a request, even in the absence of the 'performative formula' 'I order you to …'. The only difference between them is one of explicitness. Accordingly, Austin distinguished between implicit (or 'primary', as he called them) and 'explicit performatives'.

But then, at this precise stage, the Austin reader is only being prepared for a dramatic turn in Austin's reasoning. The sentence 'The cat is on the mat', he argued, is a primary performative whose explicit counterpart would be 'I state that the cat is on the mat.' This means, Austin went on to argue, that there really are no constatives but only some very 'clever' performatives masquerading as such—so successfully indeed that generations of philosophers were tricked by them. Linguistic activity is fully taken up by the performance of speech acts.

The distinction between constatives and performatives was thus replaced by a three-way distinction: locutionary acts, illocutionary acts, and performative acts. Locutionary acts were acts of producing utterances with certain sense, while illocutionary and perlocutionary acts were acts done *in* saying certain things and *by* saying certain things, respectively. The locutionary acts were further subdivided into 'phonetic acts' (acts of merely uttering certain noises), 'phatic acts' (acts of uttering certain vocables or words), and 'rhetic acts' (acts of using the vocables with a certain more or less definite sense and reference). Unlike the illocutionary acts whose performance depends on the speaker saying the words with a certain intention, etc., perlocutionary acts can be said to be felicitous just in case the hearer reacted to the utterance in the way intended by the speaker. Thus, promising is an illocutionary act whereas threatening is a perlocutionary act. The illocutionary force of an act of promise can be made explicit by the use of the performative verb 'promise' as in 'I promise etc.' Curiously, there are no formulas for making explicit the perlocutionary nature of utterances; utterances such as 'I threaten you that …' and 'I persuade you that …' are bizarre, to say the least. This is but a consequence of the fact that the success of a perlocutionary act depends on the hearer doing his/her (i.e. feeling threatened, persuaded, etc.) part rather than the speaker simply intending to achieve a certain goal.

S&S addresses the familiar problem of sensory perception and argues against the then mainstream view patronized by, among others, A.J. Ayer and H.H. Price, to the effect that what one perceives is a sensory impression which may or may not be an accurate representation of the object perceived. Austin argued that the correct answer to the question 'What exactly is one looking at when one gazes a church camouflaged as a barn or a straight stick placed a glass full of water' should be 'A church-camouflaged-as-a-barn and a stick-made-to-look-bent'. In other words, the epistemic state of the observer is part of the objectual reality that is perceived. Now, this is indeed a bold thesis because it flies in the face of the claim made by naïve realists that truth is nonepistemic.

Austin became a household name in disciplines such as linguistics, psychology, sociology, anthropology, etc., thanks to John Searle who took up the torch after Austin's untimely death in 1960. Searle is widely recognized as Austin's intellectual heir. In fact, many textbook presentations of the speech act theory leave the reader with the impression that there is a smooth continuity between the two. Recently, however, the continuity thesis has been challenged by a growing number of scholars. Austin's philosophy continues to attract attention, and many scholars from fields other than philosophy have come up with fascinating readings of his works.

Biography

John Langshaw Austin was White's Professor of Moral Philosophy at the University of Oxford, England (1952–1960). He was born in Lancaster, England on March 26, 1911, and spent his early years in Scotland. At 13, he obtained a scholarship in classics and went to Shrewsbury school. Five years later, he won another scholarship in classics and moved to Balliol College, Oxford. In 1931, he won the prestigious Gaisford Prize for Greek Prose. He moved to Oxford definitively in 1933, when he was examined and elected to a Fellowship at All Souls College. He moved to Magdalen as a tutor in 1935. In 1939, he published his first paper. The following year, he was commissioned in the Intelligence Corps of the Army

and was posted to the war Office in London. In 1941, he married Jeane Courts. In 1944, he moved to Normandy and from there to Versailles. He left the Army in 1945 with the rank of a lieut.-col. and the title of OBE, and was awarded the Croix de Guerre by the French and appointed Officer of the legion of Merit by the Americans. In 1950, he published an English translation of Gottlob Frege's *Grundlagen der Arithmetik* (*Foundations of Arithmetic)*. He visited Harvard in the spring of 1955 where he delivered the William James lectures (later published as HDTW) and the Berkeley campus of the University of California (where he delivered lectures on perception, later published as S&S). He died of cancer in February 1960.

Australia

Australia with its overseas territories is somewhat smaller than the USA and, despite a population of only 20 million, is linguistically richer than many other countries. Although English is its principal language, Australia is host to some 250 other languages as well. It is an interesting area for studies of languages in contact: (1) Many languages have been imported, and English has undergone independent development. (2) Languages and dialects have influenced each other in many ways, with contact languages emerging. (3) Many communities, especially indigenous ones, are bilingual, although many languages have been lost due to overt pressure or a natural shift to English (rarely to another language); however, a number of languages have been reintroduced in the twentieth century, creating a multilingual environment. (4) Australia has developed language and educational policies that have had important effects on the texture of society.

Much of Australia's pre-European human history—the initial immigration, spread, and growth, social organization, and the relationship of indigenous languages with their neighbors—remains obscure. The population was small; most estimates suggest a figure approximately above 300,000. As for the number of languages, experts agree on about 250 languages with 250–300 dialects, which were tied to social units, i.e. tribes, clans, or moieties. (Today, indigenous Australians tend to speak of 'nations' or 'peoples'.) Each language thus averaged 600 speakers, although there were much smaller and much larger ones. But even the larger languages never exceeded a few thousand speakers. According to indigenous creation stories, languages were implanted onto the land that tribes were granted as caretakers, so that the land, people, and language formed a symbolic unit.

No secure hypothesis regarding genetic affiliation with languages outside the continent can be proposed. Although there is a high level of diversity, especially among non-Pama-Nyungan languages, there is evidence for the assumption that all languages have descended from a 'proto-Australian' language. With respect to their typological affiliation there are competing hypotheses. An older one argues that they form a separate group with two families: the non-Pama-Nyungan languages in the central north and northwest and the Pama-Nyungan languages elsewhere. A more recent one maintains that there are clusters of languages definable in terms of descendency, and others that are more related in terms of areal (or contact) features. But all make use of grammatical inflections, mark semantic roles more than syntactic function, have free word order, and have complicated, subtle distinctions in the semantics of pronouns, kinship relations, and so on.

With 250 languages in use by a small population, multilingualism was common and was maintained through social practices: ceremonies, marriage outside the immediate group, and the association of languages with the land. Intertribal communication was facilitated by the fact that neighboring languages shared linguistic features, by the existence of a shared sign language and translators. There is little indication that languages functioned intertribally, although today some are used as lingua francas.

The continent's isolation meant that European colonization began late. The expansion from early settlements—in the Sydney region, Port Arthur (Tasmania), and Norfolk Island—was slow, and not until the twentieth century had the whole continent been explored. Indigenous cultures and languages were thus better maintained in the remote northwest and center. In areas that were settled early, indigenous languages ceased to be used decades ago. Thanks to language policies and community efforts, over 50,000 people today use an indigenous language in addition to English or a contact language. Efforts are under way to revive or document traditional languages and transmit knowledge about them to children so as to halt the breaking of the chain of transmission and their complete loss.

Contact with English has led to borrowing, restructuring, and code switching. Thus, the word *kangaroo* is used in many languages, although it originated in Queensland. The elaborate kinship terminology is gradually being abandoned and English words like *father* and *brother* acquire indigenous shades of meaning. This example from Warlpiri (around Alice Springs) shows code switching: ***September**-rla-rnalu **meeting** wangka-ja, wali natirli yanurnu **committee member**-patu panu purda-nyanjaku.* 'During September, we attempted to hold an AGM [= annual general meeting], but many committee members were unable to attend.' Although a few languages have the vitality to be used in existing domains of communication, most have peripheral status and have lost the association with the land.

The immigrant population reached the 1 million mark as late as the 1850s. Growth accelerated as the herding, fishing, and manufacturing industries became incentives for immigrants. Although immigration has remained a significant factor, natural growth never fell below the 40% mark per decade from the end of the nineteenth century, which ensured that English could develop reasonably independently from British English. But as most immigrants came from Britain and Ireland, there was a continuous influx of native speakers and an outside model to emulate. Its standing was enhanced by the fact that children of well-off parents were educated in Britain and that higher-level staff in the education system, the churches, and later the Australian Broadcasting Corporation were imported from Britain. Speakers of other languages were assimilated or integrated over time and shifted to English without leaving a linguistic trace.

Immigration of non-English speakers has had peaks and troughs. Nineteenth-century migration was fed mainly by Celtic-speaking Britons, Germans, Chinese, and, from the late nineteenth century, Italians. There were small numbers of Jews, Poles, Afghans, Japanese, Malays, and Indians. Asians and Pacific Islanders were brought in to provide labor, as in households or for camel driving, pearl fishing, or sugar cane growing. Gold fields were multilingual sites, but cities became multilingual as well, while indigenous diversity was suppressed. The 'White Australia' policy from the late 1880s to the mid-1960s put pressure on non-whites to assimilate or emigrate. The education acts (Victoria's was the first in 1872), which made education free and secular, as well as World War I and other developments, sped up the loss of immigrant languages, so that Australia assumed an Anglo-Celtic outlook. English became the only medium of communication in the public domain.

The period from 1945 to the 1980s witnessed renewed waves of immigration. Immigrants in the early post-World War II years were predominantly European and reintroduced their 'Languages-Other-Than-English' (LOTEs). The end of the White Australia policy in the late 1960s triggered an influx of Vietnamese, Chinese, and Middle Eastern immigrants who introduced Vietnamese, Chinese languages, Bahasa Indonesia, Arabic, and other languages. Asian languages are today among the strongest LOTEs and have the youngest speech communities. Most European speech communities are aging; only Greek is holding its ground. Approximately 25% of the population use a LOTE 'at home', according to the 2001 census, which includes the 10% of the 450,000 indigenous Australians who use an indigenous language. There are regional differences among states and cities. Sydney has the largest proportion of LOTE speakers and reflects recent Asian and Middle Eastern immigration, while Melbourne remains more European. Language maintenance and shift depend on well-studied factors, but it is worth pointing out differences between different communities speaking particular LOTEs such as Spanish, Arabic, and Chinese languages regarding maintenance and shift. A very significant effect of recent immigration has been the rise of multiculturalism and, more recently, a concept of pluralism and the persistence of a climate of opinion favorable to language policy and LOTE maintenance.

A significant feature is the existence of contact languages. A pidgin was first attested in Sydney as early as the early 1790s. Its spread followed the paths of the expansion of settlement and exploration. The wider

context of trade in the Pacific ensured that it was influenced by the maritime jargon of the Pacific, which itself had been influenced by that in the Atlantic, by local languages and, later, by South Seas jargon and Melanesian pidgin. It was not merely on the receiving end, but it influenced those pidgins during the nineteenth century as well. Kriol and Torres Strait Creole, two offsprings of Australian pidgins, developed in the Northern Territory and north Queensland, respectively, and are used by more than 10,000 speakers each—more than any traditional language. Depending on their 'broadness', they are more similar either to indigenous languages or to Australian English. Due to decreolization, they now participate in a gradient that connects them with Australian English via Aboriginal English.

Aboriginal English is a dialect of Australian English that straddles the space between pidgin and mainstream English, depending on a speaker's background and region. It has replaced indigenous languages as a source of influence on Australian English. Words like *business, sorry (day),* and *shame* reflect indigenous meanings and relate *business* to traditional practices and *shame* to emotions in the presence of strangers. Aboriginal English is increasingly used in literature.

Independent pidgin formation occurred in Western Australia and, possibly, in Tasmania. Norfolk Island Creole and (British) Pitcairnese are worth noting, both of which go back to the early period of colonization. Immigrant ethnic varieties of English have been reported for Italian, Greek, and Asian communities. English, the typical lingua franca in multilingual settings such as the workplace, has acquired discourse features that reflect the broad cultural background of non-English-speaking immigrants.

No language can be understood without taking into account language contact and the wider situation, and this is especially true of English. Today, Australian English is a distinct center of English, but its historical dependency on British English dialects is well known. Its accent and vocabulary have absorbed features from many dialects, especially Cockney and those of southeastern England, Scotland, and Ireland. Australia's demography ensured that dialects from southeastern England provided the basis for Australian English. Vowels in words like *lead, late,* and *loud* are similar to London's Cockney; those in *lid*, *led* are high, as in traditional accents from southeastern England. The vocabulary has retained dialect words, e.g. *tucker,* and words from late eighteenth-century Anglo-American English, e.g. *township, squatter.* One can find traces of Anglo-American English and the northern type of English in the sentence structure of Australian English, as in the definite article in 'he goes to *the* uni' and the avoidance of *shall* outside very formal con-

texts. Australian English is known for its informality, nonstandard grammar, and slang expressions; note expressions like *bullsh* [= bullshit], *bloody* [as an emotive adjective]*, to have kangas in your paddock* 'to be crazy'. As elsewhere in the English-speaking world, nonstandard grammar contains features like double negation; fairly unique to Australian English is the use of *she* for inanimate objects as in *she'll be alright* 'it'll be alright'. Today, Australian English is fully stratified socially but still lacks well-defined regional patterns. For well over a century, Australian English was considered a low derivation from British English, but the last 40 years have witnessed the rise of a standard variety, which is the target of instruction and use in the public domain. It is now well covered in dictionaries, usage guides, and even grammars. The participation of Australian English in international movements, e.g. nonsexist language, plain English, and the dominance of American English are putting pressure on it to adopt international English, especially American English, terms at the expense of local usages.

A crucial feature of Australian English is the influence of indigenous and, to a lesser extent, immigrant languages. Indigenous loans like *boomerang* and *kangaroo* have become international words. The shift in expressions to denote social units is interesting. The term *Aborigine* is being restricted to a generic use, as regional groups have been adopting indigenous names, e.g. *Koori* (southeast) or *Nyunga* (west), which have become a part of standard Australian English. Most loans are, however, little used. Immigrant languages have had little effect, mainly in the sphere of food, although German has contributed a few additional words. As the title of Australia's informal anthem 'Waltzing Matilda' shows, it is often impossible to ascertain whether a word has come into Australian English directly or by some other route. Both *waltzing* and *matilda* are originally German but are unlikely to have been brought in by immigrants.

With about 250 languages in use, the development and implementation of a comprehensive language policy since the late 1980s is a remarkable fact. Its key features are: (1) English is the de facto national language and should be acquired by all citizens; (2) indigenous languages are to be maintained because they link modern Australia to a distant, indigenous past; and (3) immigrant languages complement English for as long as communities wish to maintain them. Some, such as Chinese, Japanese, German, and Spanish, are seen as beneficial to exports, tourism, and so on, and are offered more widely in education. While multilingualism may not continue on the current level, it has widened the consensus on languages for nationally important functions and has shifted the emphasis from 'high cultural' European languages to the ones

that are closer to Australia's geopolitical region. Although pluralism is still official policy, changes in the political climate and financial constraints have reemphasized the role of English.

Austria

The Republic of Austria is a country situated in Central Europe with an area of 83,853.3 square kilometers and an estimated population of approximately eight million. It is divided politically into nine states (*Bundesländer*) and is bordered by the Czech Republic to the north, Germany to the northwest, Switzerland and Liechtenstein to the west, Italy and Slovenia to the south, and Hungary and Slovakia to the east.

The official language of Austria is German. However, the variety of German spoken in Austria is not identical to that spoken in other areas, such as in the Federal Republic of Germany. Rather, variation is found in the phonological, morphological, syntactical, lexical, and pragmatic levels of language. The most obvious differences between the German in Austria and in Germany are found in the lexicon. Although it is estimated that more than 95% of German vocabulary is common to both these varieties, differences are apparent in everyday vocabulary and also in the vocabulary used in relation to political, social, and economic institutions and structures. Many words specific to Austrian German, so-called Austrianisms, stem from dialects, colloquial speech, or foreign languages. In particular, Austria's proximity to non-German-speaking countries to the south and east is evident in the many borrowed words used in Austria. The Hungarian influence is apparent, for example, in the use of the term *Schinakel* for 'rowing boat', as is the French influence in the use of *Volant* for 'steering wheel'. Differences in the area of syntax include, for instance, the use of the auxiliary *sein* (to be) with the verbs

sitzen (to sit), *stehen* (to stand), *knien* (to kneel), and *hocken* (to squat/ sit) rather than the use of *haben* (to have) as prevalent in Germany. A further example is the use of different genders with particular nouns—while the word for 'salary' is *das Gehalt* in Germany, it is *der Gehalt* in Austria. Variation is also found in the level of language use (pragmatics). It has been established, for instance, that realizations of requests and complaints in Austrian German are longer and include more subjunctives and more modal verbs than in German German. There is no variation in the orthographical level given that the recent spelling reform of the German language was also adopted by Austria.

Up until the early 1980s, the German language was seen from a monocentric point of view. In other words, the German spoken in the Federal Republic of Germany was regarded the standard variety for Austria, as, indeed, it was for other countries in which German is an official language. Any specific features of these subvarieties were consequently viewed as deviations from the main variety. The 1980s witnessed the rejection of such monocentric views and the birth of pluricentricity, whereby German was regarded as a language with a number of national varieties, such as, for example, Austrian German. This view was based on the fact that the German spoken in different countries evidenced linguistic features particular to these areas, and also on the fact that the inhabitants identified with their particular country-specific variety. Current linguistic debate regarding the status of Austrian German concentrates on variants of this

pluricentric thesis. Three particular standpoints are of interest here. Firstly, the pluricentric state-oriented thesis that we have just mentioned suggests that varieties of German should be classified according to the particular nations with which they are associated. This view sees it as irrelevant that features suggested to be specific to Austrian German may also be used in Southern Germany, for example, since such features are not standard in these latter areas—i.e. they are not found in newspapers, for example, while they are in Austria. The pluriareal thesis, on the other hand, suggests that the varieties of German be differentiated according to the areas in which particular features are found, irrespective of national boundaries. Proponents of this view argue that dialects of Southern Germany, such as Bavarian, share many features with Austrian German—consequently, so-called 'Austrianisms' are not Austrian-specific. In addition, they point out that many 'Austrianisms' are not common to Austria as a whole, an east-west divide being identified. The final standpoint is termed pluricentric-neutral and sees Austrian German as the sum of the differences relative to other varieties of German. National or regional factors are irrelevant.

Although the concept of pluricentrism implies that different varieties of a language exist, it does not suggest that all varieties enjoy equal status. The attitudes of the Austrian people to Austrian Standard German vary between viewing it as a soft, melodious language to rejecting it in favor of German Standard German (GSG). Overall, a general, so-called 'linguistic cringe' can be identified among Austrians relative to German Standard German. This stems from the fact that Germany is a vast country, with a much larger population, and much greater economic and political power than Austria. In addition, some semantic confusion exists. Not only does 'German' denote the language but also the people of Germany, leading the 'German' language to be associated with 'the German people'. Also, there is a tendency for Germans to view national varieties of German as regional varieties, given the overlaps that exist between Southern German regional forms and Austrian standard forms. Furthermore, the majority of German language publishing houses are based in Germany, and, thus, commonly demand the use of German Standard German. Finally, the Duden grammar and dictionary, published in Germany, and accepted as a norm in Austria, takes features of German Standard German to be standard and marks Austrianisms in the same way as it does regional variants. Nevertheless, in recent years, an overall increased national awareness has led to a heightened identification with Austrian Standard German. This is reflected, not least, in an increased promotion of the Austrian standard abroad, particularly in the educational context in Eastern Europe.

As far as language planning, i.e. the use of deliberate, often official, measures relating to the status and/or form of a language, is concerned, the codification of Austrian German is yet to be completed. The *Österreichisches Wörterbuch* (ÖWB) (Austrian dictionary), published under the auspices of the Austrian Ministry of Education and the Arts, contains the standard lexicon of Austrian Standard German (ASG) and also includes some grammatical descriptions. However, further detailed descriptions of Austrian Standard German remain to be conducted.

It is not the case that Austrian Standard German is always spoken in Austria. Rather, a complicated continuum between the poles 'dialect' and 'standard' has been identified, with colloquial speech found between the two poles. Regional variation is most pronounced between eastern and western varieties. In addition, due to late industrialization, variation in Austrian German is influenced by social class to a larger extent than is the case in Germany.

Approximately 98% of the population of Austria speak German as their mother tongue. Ethnic minority groups account for the remaining figures. In addition to the ethnic groups of workers and their families from Turkey and the former Yugoslavia who are concentrated in towns and speak Turkish and Serbo-Croatian, respectively, there are four established ethnic minority groups in Austria, namely the Slovenes, the Croats, the Hungarians, and the Czechs, the former two of which are the principal groups. Austrian law ensures the rights of these groups to learn their language in school, to use it in an official capacity, and to mark local signposts bilingually. Speakers are today bilingual, speaking German as well. The coexistence of two or more languages within one state where speakers use these different languages alternately in particular situations (i.e. language contact) has effects both on the development of the languages themselves and also on their status in a particular speech community.

Slovenian is the oldest ethnic minority language of Austria, dating back over a millennium. It is spoken in the southern state of Carinthia (Kärnten) in the Gail, Rosen and Jaun Valley south of Lake Woerth and the capital Klagenfurt, and is divided into several dialects. Language contact has led to changes in the lexical and phonetic levels in both Carinthian Slovenian and Austrian German. *Tscherfl,* borrowed from the Slovenian *črevlje,* is, for example, used in the German Carinthian dialect to mean 'old shoes', and *venahti* from the German *Weihnachten* ('Christmas') is found in Carinthian Slovenian. Despite various efforts by

interested groups to encourage the use of Slovenian, this minority language continues to be used less and less and the majority language, German, is used more and more.

The Croatian minority group has lived in a number of areas in the eastern Austrian state of Burgenland since the fifteenth and sixteenth century at which time whole villages fled the approaching Ottomans and were taken in by feudal lords in need of laborers. These Croatians were speakers of all three Croatian dialects. Today's Burgenland Croatian differs from Croatian proper to such an extent that mutual intelligibility is difficult. This development stems partly from language contact with German and Hungarian, which has led to interference on the level of the lexicon, phonology and syntax, and partly, unlike the case of the Carinthian Slovenians, from efforts of the Austrian Croatian minority to preserve their own identity rather than to nurture links to the homeland—a partial by-product of the fact that whole communities fled together. With the goal of an independent identity in mind, this Croatian minority rejected the adoption of the modern written language of their home country in favor of their own variety of written language, based on Čakaver, the Croatian dialect spoken by the majority of Burgenland Croats. There now also exists a dictionary of Burgenland Croatian. Nonetheless, the trend from monolingualism in Croatian, to bilingualism, and finally to monolingualism in the majority language, German, continues.

Hungarian has been spoken in the state of Burgenland since the tenth and eleventh century when Hungarian guards were sent to the frontier to protect the Hungarian border from the West. This Hungarian-speaking population is concentrated in a number of areas in Burgenland—the most important of which are those in Oberwart (Felsöör) and Oberpullendorf (Felsöpulya). Despite promotion of the language in bilingual schools via the option to learn Hungarian as a noncompulsory subject and the—albeit limited—transmission of Hungarian on television and radio, there is a clear trend toward monolingualism favoring Austrian German.

Finally, Czech is spoken predominantly by former intellectuals of the monarchy in Vienna who, rather than returning to Czechoslovakia upon its new foundation, remained in Austria.

Romany, the language of the gypsies, termed Sinti and Roma by the speakers themselves, originated in India around AD 1000, and is now a language without a particular homeland, not currently spoken in India but rather in Europe and also further afield—in the USA, Australia, and Canada, for example. Corresponding to its wide distribution, there exist approximately two or three dozen dialects of the language, a number of which are currently spoken in Austria. All but exterminated at the hands of the National Socialists in World War II, it is only in recent years that the self-confidence of these speakers has increased, and organizations and interest groups have been established in Austria and elsewhere. In both Burgenland and Vienna, these groups are responsible for the publication of a bilingual newspaper, for example, and once a month a program is also produced and broadcasted by various groups of Romany. Since 1993, the Romany ethnic group has been recognized in Austria. Speakers are usually bilingual, using the minority language predominantly at home and, on occasion, at work also. Dialects of Romany have only been codified to a small extent—the dialect of Romany spoken in the Austrian state of Burgenland being one example of a codified variety.

The principal foreign languages on offer in Austrian secondary schools include English and French, and occasionally Italian or Russian. Latin and Classical Greek are also taught.

Austroasiatic

The Austroasiatic language family contains languages spoken by about 80 million people, primarily in Southeast Asia; however, only two of the languages in the family, Vietnamese and Khmer, have national status. Nowhere do the speakers of major Austroasiatic languages appear to be recent migrants. This is a language family that must have once filled more of the map of Southeast Asia and eastern India, now reduced to scattered islands by encroaching Indo-Aryan, Sino-Tibetan, Tai, and Austronesian languages, including Bengali, Assamese, Burmese, Thai, Lao, and Cham. The Austroasiatic language family is thought to have two major branches, which are typologically very divergent from each other. The division between the Mon-Khmer group and the Munda languages must have taken place many thousands of years ago.

The Munda or Western branch of the Austroasiatic family, spoken entirely in east central India, is distantly related to Mon-Khmer. It shares the South Asian subcontinent with three other language families. Indo-European languages, particularly the Indo-Aryan branch of Indo-European, dominate in the north, while the south is the domain of the Dravidian languages. The subcontinent's northern fringe is occupied by Sino-Tibetan languages, and Austroasiatic languages are scattered from central India eastward into Vietnam. In India itself, the Austroasiatic language with the most speakers is Santali, but the major languages of this family, Vietnamese and Khmer (Cambodian), are spoken in Southeast Asia. The major Sino-Tibetan languages are spoken in East and Southeast Asia (e.g. Chinese, Burmese). In addition to these four families, there is one language isolate, Burushaski, spoken in northern Pakistan, while the genetic affiliations of the Andaman Islands remain unclear.

The Munda branch consists of two groups or sub-branches. The Nahali or Nihali sub-branch has about 5,000 speakers in Madhya Pradesh and Maharashtra, northeastern India, and the genetic affiliation of this language is controversial. The Munda sub-branch is found in northeastern India, in the mountains and plateaus of Madhya Pradesh, Bihar, and Orissa. It is geographically surrounded by Indo-European and Dravidian speakers, whose languages have greater social prestige. It consists of a fairly large number of languages, including Santali (spoken mainly in India, but also in Bangladesh and Nepal), Ho (spoken mainly in Bihar and Orissa, India), Sora (spoken mainly in Orissa, India), Korku

(spoken mainly in Madhya Pradesh, India), Juang (spoken mainly in Orissa, India), Korwa (spoken mainly in Bihar and Madhya Pradesh, India), and Mundari (spoken primarily in Assam and Bihar, India). Mundari are typically hill peoples, while the related Santali is spoken by lowland farmers. Mundari and other Munda languages have been spoken alongside Indo-Aryan languages for two millennia. They show the signs of this long coexistence not only in loan words but also in the structure of typical sentences. Santali is traditionally an unwritten language; speakers who learn to read and write do so in Bengali or Oriya, and on the occasions when Santali is written, Bengali or Oriya scripts are generally used. As with its close relative Mundari, Santali and its speakers have little recorded history before the nineteenth century.

Munda languages appear to have been greatly influenced by their Indo-European and Dravidian neighbors. In contrast to these neighbors, Munda languages have traditionally been unwritten, and their peoples have little recorded history until they came into the sights of British administrators in India's colonial period. Typologically, Munda languages are agglutinative, and very long sequences of affixes may be found, especially in verbs. There is even noun incorporation (e.g. in Sora), which is usually a feature of polysynthetic/incorporating languages. There are two genders for nouns in most of the Munda tongues: animate and inanimate. Munda languages use affixes extensively. Case relations are signaled by word order, postpositions, and pronominal affixes. The basic word order is subject–object–verb. Most Munda languages also have three numbers—singular, dual, and plural. Suffixes and particles placed after the noun are used to express such features as number and possession, which are often indicated in Indo-European tongues by case inflection.

The Mon-Khmer or Eastern are typologically quite different from the Munda languages. The Mon-Khmer languages are mostly prefixing, monosyllabic, usually with a large number of vowel contrasts. The most commonly found word order is subject–verb–object. Vietnamese has borrowed extensively from Chinese, especially during the Tang dynasty, when Vietnam came under the strong cultural and political influence of China, and was even written with Chinese characters until Western Christian missionaries introduced the Roman alphabet. Grammatically, the Mon-Khmer

languages make considerable use of affixes (prefixes, infixes, and suffixes). They are agglutinative in that different linguistic elements, each of which exists separately and has a fixed meaning, are often joined to form one word. Cambodian and Mon have their own scripts, which descended from the alphabets of India. Both are written from left to right.

Scholars have long realized that Khmer and Mon were related, and Mon-Khmer is the well-established group of Austroasiatic languages typified by these two. Mon language is now in decline, as Burmese and Thai expansion supplanted Mon rule. Through Mon, Buddhist culture was transmitted to the early speakers of Burmese. By way of Mon script, Burmese and Shan first became written languages. Mon is now a minority language of southern Burma and central Thailand, and most of its speakers are bilingual in Burmese or Thai. Although Mon is not an official language in Burma, it is now being used again in traditional monastic education, which most boys receive. Mon is not a tonal language but, like Khmer, has a 'clear' and a 'breathy' register, a feature that now forms part of the Burmese sound pattern as well. Modern Mon can be divided into three dialect groups: Pegu, Martaban and Moulmein, and Ye. Mon villages in central Thailand, resulting from settlements in the last three or four hundred years, speak dialects close to those of Martaban and Moulmein.

Khmer language survives, and is now the majority language of Cambodia. Close to Khmer are some minority and hill languages of Southeast Asia, including Sre, Mnong, Stieng, Bahnar, Hre, Sedang, Kuy, Bru, So, and others. Khmer script, like others of South and Southeast Asia, descends from the Brahmi of ancient India.

Mon-Khmer consists of six sub-branches: Nicobarese, Northern Mon-Khmer, Eastern Mon-Khmer, Viet-Muong or Vietic, Monic, and Aslian. Nicobarese consists of six different languages with a total of over 22,000 speakers on Nicobar Islands (under Indian administration) in the Bay of Bengal. These include Car, Nancowry, Great Nicobarese, and others. In these languages, taboo leads to word avoidance on a considerable scale, and thus to a rapid turnover of vocabulary. Thus, despite their dissimilarities among each other, and with other Mon-Khmer languages, the relationships are historically closer than this would suggest.

The Northern Mon-Khmer sub-branch has many languages of very small communities, including Mlabri, spoken by 300 hunter-gatherers. This sub-branch has three sub-branches itself: Khasi or Khasian, Palaungic or Palaung-Wa, and Khmuic. Khmuic consists of several languages spoken in northern Laos and northern Thailand, of which the main one is Khmu.

Khasi or Khasian is spoken mainly in Assam, northern India, and Bangladesh, with over 500,000 speakers. Khasi is the state language of the Indian state of Meghalaya, whose capital is Shillong, and it has many loan words from Bengali, Urdu, and English.

Palaung-Wa, formed by two groups, Wa and Palaung, consists of a large number of minor languages spoken in scattered pockets located in Thailand, Laos, Burma, and Yunnan. Parauk is one of the more prominent languages in this group. Most of the 650,000 speakers live in Burma and China. Wa probably has well over 1,000,000 speakers. The majority of speakers live on the mountainous borderland between Burma and China. The legendary center of the Wa country is Lake Nawngkhio, high in the mountains on the China–Burma frontier. The older history of the language and its speakers is unknown, but Austroasiatic speech may well have a history of several millennia in this region. Apart from their mountain heartland, Wa speakers are found in scattered communities in mountainous parts of Xishuangbanna, the southern Shan State, and northwestern Thailand. Wa languages are largely monosyllabic; they have no tones, but tend to have rich and complicated vowel systems.

The Eastern Mon-Khmer sub-branch is further subdivided into Khmeric, Bahnaric, and Katuic spoken in Vietnam, Malaysia, Thailand, Cambodia, and Laos. Khmeric consists of a single language, Khmer. Most of the over 7 million speakers reside in Cambodia, with others in Vietnam, Malaysia, and Thailand. The Bahnaric sub-branch includes about 35 minor languages spoken in central and southern Vietnam, southern Laos, and eastern Cambodia. Bahnar, with over 85,000 speakers in Vietnam, is one of the major languages. And Katuic sub-branch includes several minor languages scattered in Vietnam, Laos, Thailand, and Cambodia. The Monic sub-branch includes Mon and Nyahkur, spoken in Burma and Thailand. And, the Aslian languages (roughly 40,000 speakers) of inaccessible districts in the Malay Peninsula and southern Thailand include Kensiu, Sengoi, Orang Benuja, Temiar or Northern Sakai, and others with even small numbers.

The Viet-Muong or Vietic sub-branch includes Vietnamese and a number of minor languages spoken in northern Vietnam and northern Laos. Most Vietnamese speakers reside in Vietnam, with the rest in the United States, Cambodia, and China. Muong is spoken in inland northern Vietnam. It has five tones and, like Vietnamese, is a monosyllabic language. It is likely that the speakers of early Muong and of early Vietnamese lived not far apart 2,000 years ago.

The inclusion of Vietnamese and Muong (with some tiny minority languages of Vietnam and Laos) in

the Austroasiatic family continues to be seen as controversial by scholars, since Vietnamese has been under the influence of Chinese for 2,000 years. Whatever its shape at the beginning of this period, Vietnamese is now a tonal language (with six tones that frequently help to distinguish homonyms): its sound pattern rather resembles that of Chinese. Vietnamese is basically monosyllabic, but it has many words of two or more syllables. It uses particles but has no prefixes and suffixes. Word order is very important for showing grammatical relationships since there is no inflection. The vocabulary has many loan words from Chinese; Chinese words now make up as much as 60% of the vocabulary of written Vietnamese. Many of these loans arrived before the tenth century, as is evident when their Vietnamese pronunciation is compared with modern Chinese. An alphabet based on Roman letters and adapted for Vietnamese, as by adding diacriticals, is generally used today in place of the traditional Chinese-type writing of the past.

According to another school of thought, the Mon-Khmer branch is actually two branches. In other words, the Austroasiatic language family is believed to have three branches: the Mon-Khmer languages, the Munda languages, and the Annamese-Muong branches. There is considerable evidence but no definite proof as yet that these groups are derived from a single ancestor language, which is the essential requirement for classification in the same linguistic family. The Annamese-Muong subfamily is composed of Muong and Vietnamese (also called Annamese). The classification of Vietnamese is still disputed; some regard it as a Mon-Khmer tongue, others as a Tai (or Thai) language, and still others as a language unrelated to any other known tongue. It is now generally accepted by nearly all specialists that Vietnamese resembles its Austroasiatic neighbors.

On the basis of some lexical and typological similarities, some linguists speculate that Austroasiatic languages are very distant relatives of Sino-Tibetan. Also, Schmidt (1906) first proposed a relationship between Austroasiatic and Austronesian (the so-called Austric hypothesis) on the basis of certain phonetic, lexical, and grammatical similarities, which was discussed further by Benedict (1973) and Headley (1973). However, most linguists currently maintain that there is very little solid, convincing evidence so far to support either of these hypotheses. The single Austric family grouping has not yet been generally accepted.

Austronesian

The Austronesian language family (formerly Malayo-Polynesian) is the most widespread family in the world and the largest in terms of number of languages, with approximately 1,200 (one fifth of the world's total). The languages are spoken by more than 270 million people in the Malay Peninsula, Madagascar, Indonesia, the Philippines, the island groups of the Central and South Pacific (except for Australia and much of the interior of New Guinea), and New Zealand, as well as in scattered areas of Vietnam, Cambodia, Laos, and Taiwan. Although both the Indo-European and Sino-Tibetan families have considerably more speakers, Austronesian includes some of the world's largest languages in terms of number of speakers, as well as some of the smallest.

Indonesia has 13 Austronesian languages with a million or more speakers, including Indonesian with 17 million, Javanese with 75 million, Madurese with 13 million, Sundanese with 27 million, Balinese and Buginese with 4 million, and Acehnese with 3 million.

Javanese alone accounts for about one quarter of all speakers of Austronesian languages and has more speakers than all of the languages in the Oceanic group.

The other large languages are found in the Philippines, all of whose 160-some languages are Austronesian. Eight have more than a million speakers, such as Tagalog, which is the official language but also one of many regional languages spoken on hundreds of islands with 17 million speakers, Cebuano with 15 million, and Ilocano with 8 million, Hiligaynon with 7 million, Bikol and Waray with 3 million, and Kapampangan and Pangasinan with 2 million.

Outside the Philippines and Indonesia, there are only two Austronesian languages with more than a million speakers: Malay with 17 million and Malagasy on Madagascar, an island off the southeast coast of Africa, with 9 million. Malagasy is the westernmost member, and although it has some influence from mainland African languages, it is classified as Austronesian on the basis of its predominantly Austronesian vocabulary and structure.

Fourteen of the 21 or 22 Austronesian languages spoken by the pre-Chinese aboriginal population on Taiwan are still spoken, although they have been largely submerged by the influence of Chinese immigration from the mainland. The largest language has only 100,000 speakers, and most of the others have only a few thousand or fewer. Some languages, such as Siraya, are already extinct and are documented only in historical texts.

Other Austronesian languages include the Polynesian languages, such as Tongan, Tahitian, and Samoan, all of which have relatively few speakers, particularly Hawaiian, which is severely endangered. In Vanuatu, none of the indigenous Austronesian languages has more than 3,000 speakers, and some there (e.g. Lakona) as well as in New Guinea (e.g. Sirak) have as few as (or fewer than) several hundred speakers. Approximately 600 Austronesian languages are spoken in New Guinea and in scattered coastal areas and on the islands to the east of it, but there are probably fewer than 2 million speakers.

Most of the well-described languages are the larger ones in the Malay and Indonesian archipelagoes and in the Philippines. Politically, the most important language is probably Malay, native to the Malay Peninsula, adjacent portions of southern and central Sumatra, and some smaller neighboring islands. The oldest attestations of the language (in fact, the oldest of any Austronesian language) are found on stone inscriptions in the late seventh century in southern Sumatra. After Islam was introduced at the end of the thirteenth century, Malay-speaking sultanates were established in Malay-speaking regions of the Malay Peninsula, as well as in Brunei on the coast of northwestern Borneo. Malay was spoken on both sides of the strategic Strait of Malacca between Sumatra and the Malay Peninsula. It became an important trade language in the larger region when the India–China trade began around the start of the first century because the preferred route passed through the Strait of Malacca. When the Dutch East India Company arrived in Indonesia at the beginning of the seventeenth century, they found Malay in use as a lingua franca in major ports throughout the archipelago, a role it has retained to some extent today. Malay was chosen as the basis for the national language of Malaysia (Bahasa Malaysia), Brunei (Bahasa Kebangsaan 'national language'), and Indonesia (Bahasa Indonesia), where Malay was felt to be a more neutral alternative to Javanese, the most widely spoken language.

The Austronesian language family is approximately 6,000 years old and can attribute its present wide distribution to the development of open-ocean travel by the ancestors of the present-day speakers. With its multitude of languages on thousands of islands, it has been of key importance in the development of the comparative method in historical linguistics, as well as critical in the study of what clues languages can give us about where the homeland of the language family must have been and what kind of culture the speakers of the ancestral proto-language must have had. Scholars have used the spread of Austronesian to look at issues of importance in human history, such as the spread of agriculture, which Peter Bellwood (1991) argues to be the driving force behind the spread of this language family and others.

Both linguistic and archeological evidence indicate an initial dispersal of Austronesian languages from Taiwan several centuries after Neolithic settlers introduced grain agriculture, pottery making, and domesticated animals to the island from the adjacent mainland of China, approximately 4000–6000 BCE. The linguistic evidence suggests a steady southward and eastward movement, with Austronesian speakers moving around the northern coast of New Guinea into the western Pacific in approximately 2000 BCE. From New Guinea and the Bismarck Archipelago, settlers spread out very rapidly, crossing the ocean in outrigger canoes. There is, however, a puzzling thousand-year gap before the settlement of central and eastern Polynesia, with Hawaii settled only within the past 1,500–1,700 years and New Zealand within roughly the past millennium. Madagascar was settled by immigrants from southeastern Borneo sometime between the seventh and thirteenth centuries CE.

An early split separated the aboriginal Austronesian languages of Taiwan (Formosan) and the rest of the family (Malayo-Polynesian). The designation

'Malayo-Polynesian', formerly applied to the language family as a whole, has been restricted since the mid-1960s to the non-Formosan subgroups of Austronesian. Formosan, however, does not represent a subgroup defined by exclusively shared linguistic innovations. Rather, it is a collective term for a highly diverse group of languages, perhaps as many as six, most of which share broad typological similarities with languages in the Philippines and some other areas, such as Madagascar. Western Malayo-Polynesian is a cover term for the Austronesian languages of the Philippines, western Indonesia (Borneo, Sumatra, Java-Bali-Lombok, Sulawesi), mainland Southeast Asia,

Samoan, and Tahitian, which are remarkable for their wide geographic spread yet close relationship. In addition, some 18 so-called Polynesian Outliers are found in Micronesia and Melanesia. Yapese also seems to be Oceanic, although its place within this group remains uncertain, partly because it shares little vocabulary with more typical languages because of a complex history of borrowing.

The list below shows some very basic items of vocabulary, which reveal the general similarities among some of the languages that have allowed linguists to reconstruct the Austronesian family and to analyze its internal relationships.

Cognates for	'2'	'5' (also 'hand')	'fish'	'fire'	'me/I'

Malagasy	*roa*	*dimy*	*tsondro*	*afo*	*izaho/ahy*
Tagalog	*dalawa*	*lima*	*isda*	*apoy*	*ako*
Fijian	*rua*	*lima*	*ika*	*buka*	*au/noqu*

Madagascar, and at least Chamorro and Palauan in western Micronesia. These languages do not exhibit any of the innovations characteristic of Central-Eastern Malayo-Polynesian. They include some of the largest and best-known Austronesian languages, including Malay, Javanese, Acehnese, Sundanese, Balinese, Buginese, Ilokano, Tagalog, Cebuano, and Malagasy.

The Central Malayo-Polynesian languages are found throughout much of eastern Indonesia, including the Lesser Sunda Islands from Sumbawa through Timor and most of the Moluccas. Many of the changes that define this subgroup apply to most of the languages but do not reach the geographic extremes, leading some scholars to question it. The small group of languages comprising the South Halmahera-West New Guinea subgroup is found in the northern Moluccan island of Halmahera and in the Doberai Peninsula (also called Vogelkop or Bird's Head) of western New Guinea. Most of the languages are known only from short word lists, although preliminary descriptions exist for Buli of Halmahera and Numfor-Biak and Waropen of western New Guinea.

The Oceanic subgroup is the largest and best defined of all major subgroups in Austronesian, including all the languages of Polynesia, all the languages of Micronesia (except Palauan and Chamorro), and all the Austronesian languages of Melanesia east of the Mamberamo River in Irian Jaya. Some of the better-known languages are Motu of southeastern New Guinea, Tolai of New Britain, Mota of the Banks Islands in northern Vanuatu, Chuukese of Chuuk in Micronesia, Fijian, and the many Polynesian languages, including Maori, Hawaiian, Tongan, Niuean,

The Austronesian languages have some of the largest and smallest sound inventories, with these inventories showing areal characteristics. Hyenghène in New Caledonia has 30 consonants, whereas Hawaiian has only eight. Sakao in Vanuatu has 12 vowels, whereas several languages of the Philippines and western Indonesia, such as Cebuano Bisayan and Banjarese, have only three. Rare sounds include pre-nasalized bilabial trills (made by trilling the lips after [m]) of the languages of Manus Island and apico-labial sounds (made by touching the upper lip with the tip of the tongue) of some central Vanuatu languages. Some languages, such as Kiput in Borneo, distinguish short and long vowels as well as short and long consonants. Many Oceanic languages permit no final consonants or consonant clusters. Tonal contrasts are also found in a few Austronesian languages, e.g. in the Chamic languages as well as in two widely separated parts of New Guinea and in southern New Caledonia.

Languages with the word order verb–subject–object (VSO) and verb–object–subject (VOS) are common in Taiwan, the Philippines, and northern Borneo. Other VSO languages are Malagasy and Old Javanese. Although the Polynesian languages are also VSO, they have developed this order through a prior subject–verb–object (SVO) stage, unlike the other languages, which have inherited it from Proto-Austronesian. SVO languages are widely distributed in western and eastern Indonesia, Melanesia, and Micronesia. Subject–object–verb (SOV) languages are restricted to the New Guinea mainland and some nearby islands, where they have been in contact with characteristically SOV Papuan languages.

Most languages of the Philippines and Taiwan, as well as the languages of northern Borneo, northern Sulawesi, and Chamorro and Malagasy, mark verbs with affixes indicating the grammatical role that a specific noun bears in relation to the verb. One of the most fundamental distinctions in the verb systems of Austronesian languages is the division into stative and dynamic verbs. Stative verbs often translate as adjectives in English (e.g. Hawaiian *make* 'die/to be dead'), and in many Austronesian languages it is doubtful whether a category of true adjectives exists.

Most of the languages distinguish between inclusive first-person plural pronouns ('we', listener included) and an exclusive form ('we', listener excluded). Some Oceanic languages distinguish a dual (i.e. 'we/you/they two'). The distinction between alienable and inalienable possession is also characteristic of Oceanic languages. Nouns referring to inalienably possessed entities (e.g. body parts, relatives) are typically a small, closed set, and the nouns referring to alienable possessions can be freely added to. Inalienable and alienable possession are often manifested grammatically in different construction types, and some languages have several subclasses of alienable possession, each with its own marker. Other languages, including many in Micronesia, have developed a complex system of classifiers to mark categories of alienable possession. In Pohnpeian, alienably possessed nouns belong to one of more than 20 different classes, whose members usually have some distinctive semantic feature.

Historical connections are complicated by extensive long-term contacts and movements between Austronesian- and non-Austronesian-speaking peoples, which has also brought about drastic grammatical convergence as well as extensive borrowing of vocabulary. There is still some dispute over the membership of many languages. The Maisin language of southeastern Papua New Guinea is now generally regarded as an Austronesian language with heavy contact influence from Papuan languages. Other controversial or aberrant languages include those of Buka and Bougainville, Arove, Lamogai, and Kaulong of New Britain in Papua New Guinea, Ririo and some other languages of the western Solomons, Asumboa of the Santa Cruz archipelago, Aneityum and some other languages of southern Vanuatu, several languages of New Caledonia, and Nengone and Dehu of the Loyalty Islands in New Caledonia. Most of the Chamic languages distinguish words with different intonations and have also acquired other features characteristic of the Mon-Khmer languages with which they have been in contact in Vietnam and southern China.

Auxiliaries

Auxiliaries are a special type of verb typically expressing the grammatical notions of tense (e.g. past or present), aspect (e.g. finished or continuing), and mood (i.e. commitment to the truth of the utterance). Auxiliaries do not occur by themselves but always 'help' other verbs, hence their name auxiliary, which can be translated as 'helping verb'. Examples of English auxiliaries are *have*, as in *I have eaten*, and *might*, as in *It might rain*. Examples of verbs that are not auxiliaries are *surmise*, *perceive*, *swim*, *understand,* and *eat*. These lexical verbs carry more meaning than auxiliary verbs and are referred to as main verbs. They can occur by themselves, without auxiliaries, as in *they understood that problem*.

The number of auxiliary verbs is limited and they can comprise a relatively short list (about 13 in English). They are often referred to as function words, which are considered a closed class. On the contrary, the number of lexical verbs is vast, and new verbs are invented daily, e.g. *to bookmark a URL*. Hence, they are members of the open class or lexical words.

In addition to lacking meaning, auxiliaries possess a number of unique characteristics of word formation and syntax. For instance, they tend to be unstressed

and therefore can be reduced, or contracted, as in *I'm going there* and *I've seen him*. They are also positioned differently. In English, auxiliaries occur in questions (namely before the subject, as in (1)) and in negative sentences (namely before *not/n't*, as in (2)). If an auxiliary is not present, main verbs need the inclusion of a form of *do*, as in (3) and (4), to question or negate sentences:

(1) Has he eaten yet?
(2) He hasn't eaten yet.
(3) Did he eat yet?
(4) He didn't eat yet.

In other languages, auxiliaries also occupy special positions in the sentence and are marked for negation. In English, auxiliaries are used in tag questions, those tagged onto the end of a statement, such as, *He has eaten, hasn't he*. Again, if a sentence only contains a main verb, the inclusion of a form of *do* is needed, as in *He went, didn't he?*

In English, the auxiliary verbs include (a) *have, be, do, get* and (b) *may, might, can, could, shall, should, will, would,* and *must.* Those listed under (a) can also be used as main verbs, as in *He has a headache*, and the ones listed as (b) are called 'modals', since they help to express mood and modality. A few auxiliaries are marginal since they have characteristics of both main verbs and auxiliaries. For instance, *dare* occurs both with and without *do* in questions, as in (5) and (6), and in negations:

(5) Shall I part my hair behind? Do I dare to eat a peach? (T.S. Eliot in The Love Song of J.A.P. 122)
(6) Dare I eat a peach?

Other marginal auxiliaries (also called semimodals or semiauxiliaries) include *ought (to), need (to), have (got) to, be able to, be going to, be about to, be to,* and *used to*. Modern English is quite unique in being able to 'stack' the auxiliaries, as in (7):

(7) She may have been being seen (while committing that murder).

Historically, auxiliaries have evolved from main verbs. The discovery of these gradual changes inspired many linguistic theories on the nature of linguistic change. Thus, *I have to read a book* is seen as having developed from possessive *I have a book (to read)* to purposive *I have a book to read* to obligation *I have to read a book*. Originally, *have* was a main verb but it developed into a modal. *Have to* is moving toward the reduced form *hafta* in many dialects, but does not yet behave like a modal in terms of its position in negative sentences and questions.

In the late 1970s and early 1980s, auxiliaries cause a very lively debate as to whether the category of AUX, introduced in Chomsky's Syntactic Structures, is universal. Since then, some linguists have argued that all auxiliaries are simply verbs, and others that they are special and that this special category exists universally, hence the similarities between languages as diverse as Japanese, Arabic, and Lummi (a language spoken in the NW of the US). Yet others, working mainly within cognitive linguistics, see auxiliaries in terms of a continuum from auxiliary to main verb, making it possible to think of aspectual verbs, such as *continue, go,* and *got* in *She continued writing, She went fishing,* and *He got going,* as somewhat auxiliary-like and somewhat verb-like. The latter approaches are also interested in what kinds of verbs are the sources of auxiliaries.

Auxiliaries form part of a language's Tense, Mood, Aspect (TMA) system. Even though the core auxiliary is said to express TMA, they may also express passive voice and negation. TMA represents a huge collection of different notions, and not all languages express all. English auxiliaries indicate progressive aspect (as in *I am reading*), present relevance (*I have lived here a long time*), voice (*It was read*), uncertain mood (*It might rain*), polite mood (*Could you please do that*), ability and volition, also considered mood. Other languages indicate how the speaker acquires the knowledge (by direct perception or via hearsay). The similarities of these systems in languages that have developed independently of each other has prompted much debate as to whether this category is biologically innate, i.e. part of Universal Grammar.

In short, auxiliaries are different from main verbs in terms of position, unstressed pronunciation, and uses as TMA markers. This has prompted many linguists to consider them separate from main verbs, and to regard this as a universal property of languages.

Babylonian Traditional Grammar

Ancient Mesopotamia (Iraq) witnessed the first attempts at studying the structure of language. These attempts are preserved in grammatical texts dating from Old Babylonian times (2000–1600 BC), more than a thousand years before Pāṇini's grammar of Sanskrit. As in India and Europe, grammatical study in Mesopotamia emerged following major concerns with the preservation of a classical literature written in a language that was disappearing at the time.

In the Old Babylonian period, two languages were spoken in the area: Akkadian, a group of Semitic dialects (with Babylonian as a principal division), and Sumerian, an isolated language among them. Sumerian, the language of a major part of Ancient Mesopotamian literature, was dying out as a living language and was being replaced by Akkadian. Nevertheless, Sumerian was to remain the literary language used in administrative, legal, scholarly, and religious areas. Texts written in cuneiform script appeared for the first time around 2900 BC. They continued to be written until the beginning of the Christian era.

Since Akkadian coexisted with Sumerian, the awareness of linguistic diversity was alive among their speakers. Sumerian was taught at school and the cuneiform script was the first type of writing that students learned. Copying texts at school was a duty, writing (additional) lines being used as a punishment. Sumerian grammatical texts were subject matters on exams, together with mathematical problems. It is believed that Sumerian grammar was still being taught in southern Mesopotamia under its Persian rulers about a decade before the battle of Marathon (490 BC) (cf. Black 1989:76).

The intricacy of the cuneiform writing system, as well as Sumerian language and culture were taught by means of lists of signs, bilingual vocabularies, and proper grammatical texts. As education in ancient Mesopotamia was orally conducted and it mainly involved memorization, these teaching aids were also used as material for memorizing and copying practice.

The earliest grammatical texts from the Old Babylonian period were studied and developed in the succeeding periods up to the sixth and fifth centuries BC. The earliest grammatical training texts (from c. 3000 BC, cf. Black 1989:76) consisted of lists of words grouped according to their determinatives. They were later complemented (from c. 1900 BC) by lists containing the signs of the cuneiform writing system. They vary from single-column to four-column lists. They include paradigms, lists of morphemes, word lists, as well as other forms of conveying grammatical information, such as dialogues. The texts were written on clay tablets generally forming large collections known as 'series'.

The analytical method characterizing Old Babylonian grammatical texts is the paradigm. The texts contain bilingual lists (Sumerian on the left and Akkadian on the right) of selected forms arranged according to morphologically determined patterns. As there is less variation in the nominal system, much attention is devoted to the Sumerian verbal system. Sumerian is a highly agglutinative ergative language and listing all potential forms of a verb would be almost impossible. Thus, the structure of the paradigm is often governed by Akkadian, showing the appropriate correspondences in forms of the Akkadian verb.

The earliest examples of paradigms date from c. 2500 BC and they include short lists of contrasting verbal forms inserted in word repertoires used in scribal training (cf. the following examples from Civil 1994:77):

Transitive verb:
in-na-sum 'he will give to'
ì-na-sum 'has been given to him'
nu-ì-na-sum 'has not been given to him'
ḫe-na-sum 'let it be given to'

Intransitive verb:
ba-til 'has been finished'
nu-til 'has not finished'
in-til 'he finishes'
ḫe-til 'let him/her/it finish'

The largest and most complex paradigm is that of the Sumerian verb *gen* (Akkadian *alāku*) 'to go', which has 318 entries.

In addition to the verbal paradigms, there are also long paradigms of pronominal forms with different prepositional and conjunctive elements, etc. It is believed that one of these paradigms must have originally had around 1,200 forms (cf. Civil 1994:77).

Besides paradigms, 'grammatical vocabularies' are the second type of Babylonian grammatical texts. Initially, they were probably simple vocabularies of pronominal, adverbial, and prepositional phrases composed in Middle Babylonian times before the twelfth century BC. Larger systematic lists were developed much later (fifth to fourth centuries BC) by the introduction of paradigmatic groups in which one or more elements were systematically varied. Although their organization is less rigorous than that of paradigms, these lists of morphemes are very helpful for present-day linguists, thanks to their tabular form with translations.

Word lists are the largest number of linguistically interesting Sumerian texts. They date from c. 2800 BC, being found among the oldest tablets discovered in Mesopotamia, and are still found until the end of the third millennium. Originally unilingual, lexical compilations turned Sumero-Akkadian bilingual around the eighteenth to seventeenth centuries BC.

Other types of Babylonian grammatical texts include dialogues used in scribal schools for training purposes, often included in parts of the curriculum. They cover various topics related to writing, spelling, and vocabulary. Some were intended for scribal training, and others for instructing administrators and foremen on how to give orders and conduct businesses in Sumerian.

The grammatical tradition of Babylon offers the oldest instance of linguistic analysis and an invaluable source for the reconstruction of Sumerian. It is interesting to observe with Black (1989:96) that, even if it was a closed system, the Babylonian grammatical tradition spread to other territories as well. It reached the Hittite capital Hattusas and the city-state of Ugarit by the thirteenth or twelfth centuries. It also reached Assyria in the eighteenth or seventh centuries.

Balkans

The term 'Balkan' refers to the southeasternmost peninsula of Europe and, collectively, the countries located there. The Balkan Peninsula was named after a mountain range, the Stara Planina in northern Bulgaria whose Turkish name is Balkan (mountain). The relief of the region is shaped by mountain ranges: the Balkan Mountains lie east–west across Bulgaria, the Rhodope Mountains extend along the Greek–Bulgarian border, the Dinaric range extends down the Adriatic coast to the Pindus Mountains in Greece, while in the northwest there are the Julian Alps and the Carpathians. Although there is no sharp separation in the north between the peninsula and Central Europe, the line of the Sava and Danube rivers is commonly considered to be its northern limit. The geographical area covers about 629,000 square kilometers with a population of about 70 million people divided into many countries, including Albania, Bosnia–Herzegovina, Bulgaria,

Macedonia, the mainland of Greece, and the European part of Turkey. Geographically, it also includes parts of Croatia, Slovenia, Serbia and Montenegro (formerly Yugoslavia), and SE Romania, which are often considered Balkan countries as a whole because of their close ties with the region in history and politics.

Linguistic Landscape

In the Balkans, many languages of different genetic affiliation are being spoken belonging to different groups of the Indo-European (IE) family along with some non-IE languages. Most numerous are those of the Slavic family with more than 23 million speakers, including Bulgarian, Macedonian, Bosnian, Croatian, Serbian (the last three were formerly labeled Serbo-Croatian), and Slovenian as national languages, in addition to Slovak, Rusyn, Czech, Polish, Ukrainian, and Russian varieties of the respective ethnic minorities. The languages belonging to the Romance family spoken by about 20 million speakers are (Daco-) Romanian (the official language of modern Romania), Aromanian (also known as Vlach or Macedo-Romanian, the variety of Romanian spoken by minorities in Albania and Greece for at least several centuries), Megleno-Romanian (the variety of Romanian spoken by a minority in Greece), Istro-Romanian, Istro-Romance or Istriot (two archaic languages spoken in Istria on the western part of the Balkans), Italian and Venetian (as minority languages in Croatia and Slovenia), and Judeo-Spanish (in small dispersed communities mainly in Bulgaria, Greece, and Turkey).

Other IE languages spoken on the Balkan are Greek, with about 10 million speakers (in its different dialects and written forms), Albanian, with about 6 million speakers (including its two dialects Tosk Albanian, the official language of Albania, Gheg Albanian spoken in Kosovo as well as Arvanitika—the variety of Tosk Albanian spoken in Greece for some 600 years or more), several idioms of the Indo-Aryan language Romani spoken by about 3 million speakers of dispersed communities in all Balkan countries (Balkan Romani, Vlach Romani, and Sinte Romani), and two Germanic languages—German and Yiddish—spoken by minorities in Romania. There are also non-IE languages that are spoken by minorities on the Balkans—the Uralic, Finno-Ugric language, Hungarian, and a number of Turkic languages belonging to the Altaic family.

This diversity of languages is further reflected in the usage of two alphabets. In the western part of the Balkans, the Slavic languages traditionally have been written in the Latin script (Croatia, Slovenia, and parts of Bosnia and Herzegovina) while the Cyrillic script is used in the eastern parts (Bulgaria, parts of Bosnia and Herzegovina, Montenegro, Macedonia, and Serbia). The use of alphabets is also related to religious influences that have tended to divide the Balkan peoples culturally. The Slovenes and Croats are predominantly Roman Catholic, as are a number of Albanians and Romanians. Islam is adhered to by the Turkish minority, by the majority of Albanians and Gypsies, and by some Bulgarians, while in Bosnia and Herzegovina, and in Macedonia, Montenegro, and Serbia, many indigenous Slavs converted to Islam following the arrival of the Ottoman Turks in the fourteenth century. Elsewhere, the Eastern Orthodox tradition predominates, organized through Bulgarian, Greek, Macedonian, Romanian, Serbian, and Albanian national churches.

Through the long-standing areal contact and extensive exchange of language materials, speakers of typologically distinct languages of the Balkans have adopted features from each other over the centuries, sharing today sets of typological properties termed balkanisms that are not the result of either their common genetic origin or chance. This specific development of the relations between the Balkan languages gave grounds for the term Sprachbund (from German) to be used to denote the particular relations between them in terms of linguistic union. This unity in diversity and similarity without genetic affiliation have remained outstanding features of the linguistic picture of the peninsula, reflecting both the influence of geographical factors and the historical processes of ethnocultural interaction.

Geography

Geographically, the area is composed of two parts: one southern and Mediterranean, and the other northern and continental.

The southern part is open to the easily navigable seas with the Adriatic and Ionian seas on the west, the Sea of Marmora, the Dardanelle and the Aegean Sea on the south, and the Black Sea and the Bosporus on the east. Surrounded on three sides by water, the peninsula has been linked through history with deep and lasting bonds to Anatolia, and Asia beyond, the Italian peninsula to the west, and to the eastern Mediterranean and Egypt to the south. Therefore, it has always been open to various influences and pressures in a permanent exchange of populations to and from all these destinations throughout the whole of its history. This communicative permeability and continuous intimate contacts of its peripheral parts with neighboring non-Balkan areas are contrasted with the central mountainous part characterized by isolation and perpetuation of a most conservative way of life.

Except for the northern plains, which are quite open toward Central Europe, the continental part is

characterized by the mountains that have contributed to the continued fragmentation of human groups in the area. They have been physical obstacles, preventing efforts at regional, economic, and cultural integration dividing the region into small units, in which distinct ethnic groups have tended toward distinct national cultures and languages, local economies, and political autonomy. The mountains have also subdivided the whole area into vertical ecological zones, ranging from lowland farming areas to wooded or rocky uplands acting as places of refuge for ethnic groups expelled from more desirable coast and valley lands throughout history.

Although considerably different, the two parts of the Balkan peninsula are connected by all kinds of historical, cultural, and linguistic links as several rivers crossing the almost continuous mountain barrier provided for continental roads, which, although difficult and dangerous, were always important as lines of communication and channels of exchange of goods and ideas.

History

Since the beginning of its history, the Balkan Peninsula has been very complex from the linguistic point of view, an area of great linguistic diversity in which a variety of different languages have always been in close contact. It has been a crossroads of migration and mixing of peoples for many centuries, so that ethnic diversity has come to be one of its most prominent features. Many different peoples have migrated into the area, absorbing or being absorbed by already existing groups that left traces in the languages spoken there in different layers of language contact.

The whole area shows the same stratification of linguistic elements since early prehistory, which reflects the successive settlement of the region by different populations until today. Archeological and historical data report that the Balkan Peninsula had been an inhabited area even before the immigration of the IE tribes. This pre-IE substratum (or substrata) belonged to an old pre-IE language complex of Mediterranean languages, far related to IE (probably linked with the expansion of agrarian economy along the coast of the Mediterranean around 5000 BC). As they were completely assimilated by later IE expansion, little is known about them, and all opinions about their origin and their relation to the IE family remain purely theoretical. However, there is no doubt that they left traces in all the ancient IE languages of this area. The gradual Indo-Europeanization of the Balkans was a rather long process, which occurred during the second millennium BC. It brought to the region tribal groups speaking several IE languages termed collectively Paleobalkan languages: Illyrian and Venetic to the northwest of the

peninsula, Thracian and Ancient Macedonian to the northeast, Dacian in the north, and Greek to the southeast. With the exception of Greek, very little is known about them from the fragments conserved in ancient Greek manuscripts consisting mainly of toponymic terms, personal names, and some words, aside from the fact that they are all of IE origin. They all seem to be related and have a set of common traits in syntax and morphology with Greek dialects and other languages of the region. The Greeks established colonies outside Greece during the last millennium BC, while during the reign of the Macedonian Alexander the Great in the fourth century BC, much of the Balkan Peninsula came under Greek influence so that the Ancient Macedonian language assimilated entirely by Greek disappeared in the third century BC. This process of Hellenization of the Balkans caused the formation of several common features in all languages that were spoken here later in history.

The Romans first invaded the peninsula in the third century BC, and by the first century AD it was entirely under their control. At the height of Roman power, the Balkan peoples were united under a common legal system, a single ultimate political and military power, and were connected through several important commercial routes. From the third century BC until the time of Slav immigration in the sixth century AD, when the entire region belonged first to the Roman and later to the Byzantine Empire, radical romanization occurred, which is reflected in a number of toponymic traces, while the Latin language of the Roman domination represents a major linguistic substratum of the subsequent Slavic languages.

Venetic was quickly assimilated by Latin under the Roman rule in the first century; Thracian language disappeared in the fifth or sixth century AD, as Thracians were first assimilated by Romans and later by Slavs and Bulgars. The Dacians were assimilated by Romans and are thought to be ancestors to the present Romanians. Some Illyrian tribes were either romanized or assimilated by later Slavic migrations, but others moved south into present-day Albania, where they managed to retain their identity, including the Illyrian language that is said to be the ancestor of the modern Albanian language. Some of the romanized Thracian and Illyrian populations survived by taking refuge in the isolated mountain areas where they lived like shepherds conserving several Balkan Romance varieties.

After the fall of the Roman Empire, this Latin was considerably modified in isolation, developing through absorption of different Paleobalkan substrata in what is today called the Vulgar Latin variants. The mixture of those tongues with later additions of Slavic and other elements created interesting structures and the vocabulary of several Romance varieties still spoken in the

Balkans: Daco-Romanian, Aromanian, Istro-Romanian, and Istro-Romance or Istriot, in addition to Dalmatian, an extinct language spoken along the Adriatic coast until the beginning of the twentieth century.

Later invasions by peoples from the north culminated in the arrival of the South Slavs, who occupied much of the region by the sixth century AD. Consequently, non-Slavic peoples of the Balkans were influenced by Slavic culture, and their languages contain many words of Slavic origin. The Slav invasions were followed by the arrival of other smaller groups. In the seventh century, horsemen called Bulgars settled in the area of present-day Bulgaria, but they became absorbed into the more numerous Slavs and ceased to exist as a separate people. In the ninth century the Hungarians, or Magyars appeared in the Danube Plain, who, unlike most other small groups of invaders, retained their language and culture.

After the fall of the Western Roman Empire in 476, the region of ancient Illyria became part of its eastern portion, the Byzantine Empire, which continued its political, cultural, and linguistic influence through Byzantine Greek on the eastern part of the Balkans for another 1,000 years, until it was defeated by the Turks in 1453. It also introduced Orthodox Christianity to the Romanian and Slavic tribes of this part of the Balkans. For this purpose, in the ninth century, Greek priests Cyril and Methodius translated the Bible from Greek into what is now called Old Church Slavonic, which reflected several Common Slavic features and was at that time widely understood by the Slavs. Translating the Bible, the Byzantine priests introduced plenty of Greek, Latin, and Hebrew words into Slavic.

In the fifteenth century, the Ottoman Empire conquered the peninsula, and a long period of its rule has had a lasting effect on the arrangement and characteristics of the Balkan peoples changing the geographic pattern and cultural characteristics, mainly by forcing migrations throughout the peninsula. For almost 500 years, Albania, Bulgaria, Bosnia and Herzegovina, Montenegro, Serbia, and areas of present-day Romania were under the Turkish control. The area of present-day Croatia and Slovenia in the western part of the peninsula was throughout this period under the political, cultural, and linguistic influence of Italy (Venice) and later German-speaking Austria-Hungary.

The most notable result of these movements of small groups of people and even entire small communities from region to region and small-scale language shifts in certain regions at different times was a radical change in the distribution of various Slavic dialects and linguistic discontinuity in many parts of the Balkans, as well as large-scale multilingualism. During this period, all peoples of the Balkans were strongly influenced by Turkish culture, as reflected in their customs and terminology of dress, food, and music. A large number of Turkish loan words can be referred to as Balkan Turkisms because of their existence in all Balkan languages, Bosnian, Macedonian, Bulgarian, Serbian, Albanian and, to a lesser extent, Romanian and Greek.

The breakup of the Turkish empire in the nineteenth and twentieth centuries led to the establishment of new states that had to find a way of including many nationalities. The recent history of the area reflects a similar fundamental contrast between convergent and divergent tendencies in the development of Balkan cultural and linguistic identity. During the twentieth century, in the multinational state of Yugoslavia including all South Slavs except Bulgarians, Serbo-Croatian as the official language acted as a converging factor, while the later struggle for political independence has contributed to prevailing divergent cultural and linguistic tendencies of various ethnic groups until the present.

Linguistic Union

This common historical fate of the Balkan peoples, their coexistence within the borders of the same empires (Roman, Byzantine, Ottoman), and exposure to similar cultural influences have contributed considerably to the emergence of a shared cultural identity in all fields of human activity including common linguistic features, both lexical and morpho-syntactic. Although the Balkan linguistic phenomena have attracted the attention of numerous linguists since the third decade of the nineteenth century, in spite of their prolonged efforts no general agreement has been reached as to which particular languages belong to the union, the linguistic traits that characterize the area, and the sources of these areal features. It is true, that not all Balkan languages have an equal share in the Balkan Sprachbund and the common properties are most numerous in those parts of the Balkans where the Byzantine and Turkish influence was strong and long term, and where the greatest number of languages are co-territorial. The epicenter of Balkanisms seems to be in the southern bordering area of Macedonia, where Greek, Albanian, Macedonian, Aromanian, and Balkan Romani intersect. Therefore, due to varying distribution of Sprachbund features, many scholars consider five languages including Bulgarian, Macedonian, Greek, Albanian and Romanian, and some southeast Serbian dialects to be the core Balkan languages, while others displaying only some of the features are regarded as less typical and peripheral.

A considerable contribution to the study of these phenomena was offered by Kristian Sandfeld in his classic comparative study of the Balkan languages Linguistique balkanique (1930), in which he recorded

over one hundred Balkan Sprachbund properties, making a distinction between general concordances and concordances between individual Balkan languages. Since then, however, a number of different analyses pointed out different combinations of Balkan Sprachbund properties, although most of them agree along with a number of similarities in vocabulary on one phonological property—the presence of the schwa phoneme, a high or mid central vowel, and six grammatical properties: (1) substitution of case inflections by uninflected function words; (2) grammaticalization of the category of definiteness through definite articles; (3) pronominal doubling of objects; (4) expression of future tense using the verb want; (5) perfect tense with an auxiliary verb corresponding to have; and (6) partial or total loss of the infinitive and its substitution by subjunctive clauses.

In spite of various proposals for source languages of these common features, the exact nature of the contact that led to the Balkan linguistic phenomena remains a matter of some controversy. Several early scholars tried to explain their origin through the substratum hypothesis, suggesting that they developed under the influence of an ancient substrate—that of the Paleobalkan languages Thracian, Dacian, or Illyrian. Other scholars attributed the decisive influence to either Greek or vulgar Balkan Latin. All these hypotheses have been considered to be unrealistic as the Balkan Sprachbund properties developed in the post-Byzantine period and were not present either in classical Greek or Latin, while the Paleobalkan linguistic material is too limited to allow any conclusions of this type. More recent theories suggest multiple causation including the reciprocal influence of the Balkan languages and Slavic influence through massive bi- or multilingualism, sociolinguistic accommodation, or some combination of these factors, which has led to the convergence of different languages.

These contact-induced linguistic changes, however, have not led to a significant, massive restructuring either in syntactic structure or in lexicon, even in the most affected Balkan languages. The Balkan Sprachbund, therefore, has been increasingly seen as a complex of shared features in the respective systems of languages involved, resulting from an interplay of several factors including inheritance, innovation, and contact in a multilingual environment, in which, among the random changes in each language, those were more easily spread that contributed most to direct intertranslatability between them.

The current linguistic tendencies of the Balkans at the beginning of the twenty-first century are closely related to the issues of ethnic identity and are shaped by recent interethnic conflicts resulting in puristic and divergent developmental tendencies in all languages spoken in the region.

Baltic Languages

The Baltic languages, a branch of the Indo-European family of languages, are spoken in the area bordering the Baltic Sea. The principal Baltic languages are Latvian, Lithuanian, spoken on the eastern shores of the Baltic Sea, and Old Prussian (extinct since the seventeenth century). Other extinct Baltic languages are associated

with historical regions of northern Europe, such as Yotvingian, Curonian, Selonian, and Semigallian.

Linguists consider that the Baltic languages are more closely related to Slavic, Germanic, and Indo-Iranian (in that order) than to the other branches of the family. For this reason, some linguists regard Baltic and Slavic as branches of a single Balto-Slavic division of the Indo-European family.

The early common ancestor of the Baltic languages is traditionally referred to as Proto-Baltic and it is believed that it broke off from the other Indo-European languages before 1000 BC. A further division into East Baltic (Latvian and Lithuanian) and West Baltic (Old Prussian) is believed to have taken place before 300 BC.

In terms of phonology and grammar, the Baltic languages are said to be the Indo-European languages closest to Proto-Indo-European. They display a high degree of inflection in both the nominal and verbal systems. Beside Sanskrit, the Baltic languages are sought to be the closest to the origins of the Indo-European languages. The reason is that the Baltic languages, Lithuanian in particular, remained relatively unchanged in time, while other Indo-European languages suffered several alterations. From all Indo-European languages spoken nowadays, Lithuanian has best preserved the ancient sound systems, many morphological and lexical characteristics. Therefore, a basic knowledge of Lithuanian is indispensable in the study of Indo-European languages.

Old Prussian is the most important of the extinct Baltic languages and the most archaic of the recorded Baltic languages. The speakers of Old Prussian were completely assimilated to German territories by the seventeenth century.

The earliest Old Prussian written document is a German–Prussian vocabulary, the so-called Elbing vocabulary, compiled in 1300 AD and consisting of 802 Old Prussian words written in a South Prussian dialect. The most important Old Prussian written records are three catechisms translated from German in the sixteenth century. Every written record in Old Prussian has its own specific orthography.

The Old Prussian nominal system had seven noun types and five cases: nominative, genitive, dative, accusative, and vocative. It did not have the dual number, but only the singular and plural. However, it displayed a neuter gender, lost by Lithuanian and Latvian.

Old Prussian verbs had three separate forms in the plural, but not in the singular. The third person was the same in both the singular and the plural. There were three tenses: present, preterite, and future.

Old Prussian vocabulary was quite similar to Lithuanian and Latvian (closer to Lithuanian than Latvian). The orthography was almost wholly based on the German orthography of that time and was quite inconsistent.

Latvian and Lithuanian are the only Baltic languages still alive. However, Lithuanian is far more archaic than Latvian.

A frequent false impression about the Baltic countries (Estonia, Latvia, and Lithuania) is that they all speak similar languages. In fact, there are three Baltic countries and only two Baltic languages. Latvian and Lithuanian belong to the Baltic subgroup of the Indo-European language family, while Estonian belongs to the Finno-Ugric language family.

Lithuanian

The Lithuanian language, the oldest of the two surviving Baltic languages, is spoken by approximately 3 million people in Lithuania, where it has been the official language since 1918, and by an additional half million elsewhere in the world, in Poland and Belorussia and in such countries as the United States, Canada, and Australia. It is estimated that more than 85% of the population of Lithuania are native Lithuanians.

Lithuanian occupies an important place in linguistics as it is considered to be the most ancient of the living Indo-European languages. It is also the closest language to Proto-Indo-European, the parent language from which all the Indo-European languages emerged. It has inherited many Proto-Indo-European characteristics, such as a pitch-accent system, a rich inflectional case system, and many little-changed Proto-Indo-European word stems. It is believed that Modern Lithuanian is the oldest living Indo-European language; nevertheless, it has one of the most recently established standard literary traditions.

Lithuanian has two main dialect groups, Low (or Western) Lithuanian (along the Baltic coast), with three subdialects, and High (or Eastern) Lithuanian, with four subdialects. Although the country is rather small, it is still rich in dialectal variation. The Low dialect is spoken by the Lowlanders, who live in the west and along the Baltic Sea; High Lithuanian is spoken by the Highlanders, who live in the Eastern (and greater) part of Lithuania.

Even if a literary language had been in use since the sixteenth century, three literary dialects fought for supremacy in the nineteenth century. The most prominent person in the formation of the rules of the standard language was Jonas Jablonskis (1861–1930). Modern Standard Lithuanian is based on the southern branch of the West High Lithuanian dialect and completed its development after the first period of Lithuanian political independence (1918–1940), when it became the country's official language. Lithuanian

experienced a major Russian influence especially after World War II.

Old Lithuanian is known from written documents dating from the sixteenth century, more precisely from 1547 when the first book in Lithuanian was published. Phonetically, Lithuanian went rather far from Indo-European. Baltic languages, as well as Slavic languages, did not preserve aspirated and labiovelar consonants, syllabic sounds, and some vowels including schwa. However, Baltic languages were not influenced by any other non-Indo-European sound system, and basically no new phonemes appeared in Lithuanian.

The most complicated feature of Lithuanian phonetics is stress: there is a system of three tones that is very important in pronunciation. Acute, circumflex, and gravis intonations act for long and short vowels of Lithuanian, and furthermore the stress is absolutely free. The Lithuanian has a free stress in contrast to Latvian fixed stress, which occurs on the first syllable. Lithuanian is rich in the use of diphthongs and, like Latvian, in rising and falling intonations.

Lithuanian is written in the Latin alphabet (33 letters), with additional diacritical marks.

Lithuanian is a highly inflected language. In standard Lithuanian, nouns have seven cases (some dialects have eight or more), three numbers (in classical Lithuanian, while in modern colloquial language the dual number is seldom used), and two genders, masculine and feminine, as neuter disappeared earlier in Baltic languages and was preserved just in some adjective forms. There are twelve inflectional types and five nominal declensions, each of them representing Indo-European nominal stems. The article is not used. Lithuanian adjectives have three declensions.

The Lithuanian pronominal system is a very rich one, with several classes of pronouns: personal, demonstrative, interrogative, attributive, negative, definite, and indefinite. There is also a reflexive pronoun, similar to the one in Romance and Slavic languages.

The Lithuanian verbal system, although less complex than its Proto-Indo-European ancestor, has quite a number of inflected forms. Four simple verb tenses (present, preterite, frequentative past, and future) and several compounds exist in the indicative mood; imperative, subjunctive, reflexive, infinitive, and participial forms are also clearly defined. The frequentative past tense does not exist in Latvian. There are three verbal conjugations. The dual number is also preserved. The third person in Lithuanian, as well as in all other Baltic languages, does not vary in number.

Lithuanian, as well as Latvian, has many compound tense forms, based on the forms of the verb *buti* 'to be' and participles. Lithuanian and Latvian word order is quite free, and, in general, the syntax of both languages is quite similar.

Latvian

Latvian, or Lettish, one of the two surviving Baltic languages, has been the official language of Latvia since 1918, when Latvian independence was won. It is the mother tongue of some 3 million persons living on the eastern shore of the Baltic Sea.

Historically, Latvian has three groups of dialects: Central Latvian, the language of literature; Livonian Latvian, greatly influenced by Livonian and Curonian; and High Latvian (or Latgalian), which underwent considerable Slavic influence. Nowadays, there are two other major dialects: West Latvian (also called Livonian or Tahmian) and East Latvian (High Latvian).

The earliest printed writings in Latvian are translations of religious works: a Roman Catholic catechism, *Catechismus Catholicorum* (1585), a Lutheran version (1586), and a translation of the Bible (1685). In 1638, the first Latvian (–German) dictionary, by Georgius Mancelius, appeared; the first grammar of the Latvian language was published in 1644 by Johann Georg Rehehausen. The works of the Latvians Juris Alunans (1832–1864) and Atis Kronvalds (1837–1875) had a great influence on the development of a standard Latvian language, which was finally established at the end of the nineteenth and the beginning of the twentieth century, based on the Central Latvian dialect.

Latvian is closely related to Lithuanian, but it is less conservative, displaying many sound changes in its historical development. Phonetically, the main difference is that Latvian has its stress always on the first syllable, due to the neighboring Finnish influence. Besides, Latvian has short vowels and monophthongs in the final syllables, while Lithuanian has long vowels and diphthongs. Latvian is more archaic than Lithuanian in the intonations inherited from Proto-Baltic.

Based on the fact that Latvian has undergone a number of linguistic changes that Lithuanian has not, historical linguists generally consider that Latvian is the younger of the two Baltic languages. One of the most important changes is the retraction of main word stress almost always onto the first syllable of a word (an influence from Livonian). Because of the change in the stress pattern of the language, many inflectional endings in Latvian have either shortened or been lost altogether.

Grammatically, Latvian, like Lithuanian, has a rich inflectional morphology, having seven noun cases and six verb declensions. The nominal system lost the dual number and the neuter gender; the instrumental case has the same form as the accusative in the singular and as the dative in the plural. Latvian has six nominal declensions with eight inflectional types.

The verbal system is generally the same as in Lithuanian. It has three conjugations (genetically different). There are three persons, the third of which is the

same (apparently from the time of Proto-Indo-European) in both the singular and the plural (as well as the dual).

The verb in Latvian has three tenses (present, preterite, and future). Distinct characteristics are the descriptive and the obligatory moods. Latvian also has a relatively free word order.

The basic vocabulary is originally Baltic, but there are numerous loan words, mainly from Finnish, German, and Russian. Latvian also had close contacts with Swedish and Polish.

First written in Gothic script, the Latvian language has used the Roman alphabet with diacritical marks to indicate the distinctive quality of some vowels and consonants since 1922. The Latvian alphabet has 33 letters, 11 with diacritical marks. The orthography has undergone numerous changes and improvements, and is now quite closely related to pronunciation.

Bambara, Mandenkan and the Mande languages

Some 35–40 million people in 15 West African states make use of Mande languages as mother tongues or linguae franca (trade languages). These languages are spoken from Senegal to Nigeria and from Mauritania to the Ivory Coast. The name Mande derives from a phonological variant of the name held by the former kingdom of Mali. The official languages of large kingdoms in West Africa were often Mande, such as Soninke in Gana (seventh to eleventh century), Malinke in Mali (thirteenth to fifteenth century), and Bambara in the kingdom of Segou (seventeenth to nineteenth century).

Going back to Joseph Greenberg's classification, the Mande languages, some 100 in total, have been considered to represent one of the main subgroups of Niger-Congo, the largest African language family. The affiliation of the Mande languages to the Niger-Congo group of languages remains tentative. Unlike other Niger-Congo language groups, Mande shows no signs of noun class or concordance systems. Some authors have demonstrated interesting links to Songhai, a language belonging to the Nilo-Saharan group of languages. They showed similarities in the areas of even basic vocabulary (e.g. a similar word root for 'heart'), of word structure and derivation, as well as in word order. Some authors even identified links to such non-African languages as Basque or Canarian in syntax or vocabulary.

Early classifications subdivided the Mande languages into a Mande-Tan and a Mande-Fu group, based on differences in the word for '10' in the individual languages. The current view basically distinguishes between Western and Eastern languages.

Western Mande is dominated by two-tone languages, i.e. languages that use intonational patterns with two pitch levels to express lexical or grammatical meaning. Languages with three pitch levels are rare and found specifically in the Southwestern group. Mani-Bandama languages (Eastern Mande) usually show very reduced and short word forms. They compensate this loss of information by 3–5 different pitch levels, as seen in the Dan language of the Ivory Coast with 5 levels. While other languages often use the syllable as the tone-bearing unit, Mande languages — and specifically Western Mande — assign tonal patterns to the word. Regardless of the number of syllables, words in the Bambara language will always be limited to one of two tonal structures covering the entire word.

Most Mande languages show a very distinct consonant–vowel (CV) syllable structure, and word stems of 2–3 syllables prevail. Specifically in the Mani-Bandama languages, reduction processes are responsible for many monosyllabic word forms and altered syllable structures. In Gban, numerous words display a ClV syllable structure, such as *klɛ̃* 'Moskito'.

The Western Mande languages show 5–7 oral vowels and, at times, as many nasal vowels (7 oral and 7 nasal vowels in Bambara). Many Mani-Bandama and Volta-Niger (Eastern Mande) languages are particularly complex and make fine distinctions between different vowel sounds. Languages with many different vowels often use vowel harmony, which means that all vowels in a given word must share certain characteristics. For example, the Volta-Niger language Northern Samo of Bangasoko only uses either open (long) or closed (short) vowels within the same word stem. The only difference of words like *zɔ́rɓ* 'remove' and *zùró* 'throw' is vowel aperture. These words could just as simply be transcribed as *zùró^O* and *zùró^C*.

Long vowels in Mande languages are historically most often the result of compensating for the loss of a consonant between two vowels. The Mauka language in the Ivory Coast lost most of its intervocalic consonants, a process resulting in increased vowel length, e.g. sìi 'to sit' (Bambara *sìgi*), sì 'spend the night'. Mani-Bandama developed many very short words, so vowel length became an important distinguishing (phonemic) factor between different words. In dialects of Northern Samo, a Volta-Niger language, there are five different vowel lengths, two of which are phonemic.

Some special consonants occur only in specific geographic areas. Doubly articulated stops such as *gb* or *kp*, or ɓ, ɗ and other implosives, are only found in southern regions, not in the Sahel belt. Dialects of the same language may contain these sounds if they are spread further to the south.

Some Niger-Volta and Mani-Bandama languages seem to lack phonemic nasal consonants altogether. If nasal consonants occur in these languages, they are always followed by nasal vowels, i.e. the nasal characteristic is clearly a quality of the vowel. For example, Northern Samo words (Bangasoko dialect), such as *bèré* 'crust, scab' or *mɛ̀nɛ́* 'snake', differ merely in vowel nasalization, which means that 'snake' should be analyzed as *bèré* and *bɛ̀nɛ́*. In several Mani-Bandama and Volta-Niger languages — e.g. Northern Samo or Dan in the Ivory Coast — nasalization appears to be a characteristic of words as a whole: words are either completely oral or completely nasalized.

In Southwestern Mande languages, the initial consonant of certain word classes changes in specific grammatical constructions. In Mende, the initial consonant of nouns changes in possessive constructions: *ndɛndɛí mia*: 'That is the canoe', but *Mɛndɛ lɛ́ndɛí mia* 'That is the Mende canoe'.

Unlike other Niger-Congo language groups, there are absolutely no signs of noun class systems in Mande. With the exception of a feminine pronoun in Jo (Northwestern Mande), gender is nonexistent in Mande. In comparison to other groups of languages, words undergo very little change due to grammatical influences. Typically, the position of a word in the sentence fully determines its function. Compare *cɛ̀ mùso* 'the man's wife' with *mùso cɛ̀* 'the woman's husband'. In most cases, singular and plural nouns have the same form, provided other logical indications of plurality are present. See Mauka *mɔ́ɔ à shyá* 'The persons are numerou's, literally' '*person is numerous*'.

Nouns and verbs are indistinguishable in form in the predominant majority of the Mande languages. Position alone determines the function of such noun–verbs or neutrals. A noun–verb in a nominal position functions as a noun, and as a verb in a verbal position. Compare Bambara *à bɛ́ kúma* 'He talks' with *kúma dòn* 'It's a speech'. These functions are distinct in a purely tonal respect in several languages. In Northern Samo, each nominalized verb receives a high tone on the last syllable. In Kelinga-Bozo, a Western Mande language, the tonal pattern is inverted in the case of a change from a nominal to a verbal function. Compare ʃyâ, 'laugh' with ʃyǎ 'laughter'.

Western Mande often uses affixes to express meanings equivalent to sentential structures in Eastern Mande. For example, the Northern Samo phrase 'to put somebody into the action of ….', *à ba gònì dà táágó mà* 'he made the man march', literally 'he has put the man in the action of marching' is expressed as *à ye cɛ̀ lá-taama* 'He made the man march.' in Bambara, where the prefix la- expresses causation.

Mande languages have *portemanteau* morphemes that express two grammatical meanings simultaneously. For example, the element *mu* in Susu (Western Mande) in *a mu fa* 'He has not arrived' details the negation of action as well as the perfect tense.

In Guro, Northern Samo, and some other languages, final negated sentence markers do appear in addition to the (already negating) portemanteau morphemes. See Northern Samo *à ǹ dàa kɔ́* 'He has not come.' Both *kɔ́* and *ǹ* (portemanteau morpheme) indicate sentence negation. The final negated sentence markers are therefore highly redundant and easily prone to loss. Borrowings of such sentence markers can frequently be seen, particularly from neighboring Gur languages.

Mande languages place the possessor in front of the possessed. In nearly all these languages, two forms of possession are formally distinguished. The possessor may dominate the relation ('active relation') or be unable to determine the nature of the relation with the possessum ('passive relation'). Compare Bambara *n ká só* 'my house which I bought and which I may sell at any moment' with *n ká bolo* 'my hand (given to me at the moment of birth)'. In some languages, e.g. Northern Samo, there is a three-fold distinction of

associations: mutual social relations (e.g. kinship), passive nonsocial relations and active relations.

All Mande languages have subject–object–verb word order. In most Mande languages, a sentence is interpreted as passive if a normally present direct object is missing. Compare Western Mande Jeli *Lamina-a sibeo kunɛ* 'Lamini eats the meat' with *sibeo-a kunɛ Lamini munu* 'The meat is eaten by Lamini'.

The Mande languages often use nouns such as words for body parts as postpositions, i.e. words with grammatical functions. For example, Western Mande Jeli *kɔŋ* 'belly' can double as the postposition 'inside, in'. Thus, Jeli *bɔgɔ kɔŋ* may both be analyzed as 'in the bush' or 'the belly of the bush'.

Mande languages often use nonverbal structures where other languages may prefer a verbal one: Mani-Bandama Guro *e à da-na* 'He comes' is literally 'He is at the place of coming.'

Several Mande peoples in Liberia and Sierra Leone developed writing systems where each letter stands for a syllable. Only the writing system of the Vai in Liberia attracted broad public acceptance. The N'ko script developed in 1949 by the Guinean Souleymane Kanté has become quite popular in Upper Guinea.

Bambara and Mandenkan (Manding)

The so-called Mandenkan (literally: the language of Mali) or Manding is a denomination for some 40 closely related language variants within Central-Southwestern Mande. Formerly regarded as different languages, these variants are now generally considered to be part of a language continuum. There are no clear language boundaries, although communication between the extremes is rather difficult. Paradoxically, such 'dialects' often show more differences than other clearly distinct 'languages'. A Bambara speaker in Bamako has a much better understanding of Ivory Coast Jula than of the Bambara of Beledougou 30 km away from Bamako. Compare 'first name' in Bambara of Bamako *tɔ́gɔ*, in Dioula of Ivory Coast *tɔ́gɔ*, in Mauka (variant of Malinke) of the Ivory Coast *tɔ́ɔ* and in Bambara of the Beledougou *cwáa*.

Mandekan is subdivided into a western and an eastern branch. Eastern Mandenkan comprises all important lingua francae within the Mande language group: Bambara, Malinke, and Jula. Speakers of one of these variants can communicate with 30–35 millions mother tongue and lingua-franca speakers in West Africa. The majority of the population in Mali, Guinea, Ivory Coast, and Gambia speaks Mandenkan as first or second language; important parts of the population of Senegal, Burkina Faso, Guinea-Bissau use Mandenkan as means of communication. The reasons for the ascent of Mandenkan to the dominant language in that part of Africa can be found in (a) the dynamic Mande traders who, over hundreds of years, spread their language along with their products in multiethnic areas; (b) the enormous prestige of Mandenkan as a successor language of the kingdom of Mali, one of the most important African civilizations; (c) the use of Bambara by the French as a means of communication for their West African troops during World War II; (d) the important role of Mandekan variants in traditional and modern entertainment (griots, music, cinema, etc.); and (e) the accelerated intra-African migration over the past 40 years that has increased the necessity of intraethnic means of communication. More than 2 million people from Burkina Faso have migrated to the Ivory Coast — while only 11% speak Mandenkan as mother tongue in the Ivory Coast, 61% use it as lingua franca.

All Mandenkan variants seem to have two different levels of tone, allowing for up to four meaningful tonal patterns, e.g. Mauka in the Ivory Coast *sá:* 'fontanelle', *sá꞉* 'kind of groundnut', *sà:* 'sheep' and *sà꞉* 'salary, pay'. Odiennekan shows inverted tones compared to the other variants of Mandenkan: *á mà dèn yè* 'He has not seen the child'. (Odiennekan), *à má dén yé* (Bambara). The tones of all known Mandekan variants are based on words rather than syllables.

The sound inventory of language variants depends mainly on the language region. Malinke of Kankan in Guinea shows a doubly articulated stop *gb,* unlike the closely related Malinke of Kita further to the North. 'Heavy' is thus *gbílị* in the Malinke of Kankan, but *gílị* in Kita Malinke. Doubly articulated stops and implosives (ɗ, ɓ) only appear in the southern regions of Mandenkan (e.g. in Mauka). Western Mandenkan has five different oral vowels, while Eastern Mandenkan usually has seven. Western Mandenkan quite often shows older elements, such as intervocalic *t,* which has nearly disappeared in Eastern Mandenkan. Compare 'lion' in Mandinka *jàta* and in Bambara *jàra.*

Mandenkan variants are very much alike in word structure and syntax.

Bambara, which is mainly spoken in Mali and adjacent regions, is the most popular Mande language. Used at different levels in Mali by approx. 90% of the population, it offers excellent communication opportunities in the adjacent Ivory Coast and Burkina Faso, both marked by the lingua franca Jula. Jula is actually a Mandekan word for 'dealer'. Jula therefore denotes not the member of an ethnic group, but rather people who speak Mandenkan traders' languages as mother tongues. As the language of (e.g. cola nut) traders was very often Bambara or Malinke, Bambara and Jula are closely related. The Bambara language is used in all parts of society: in tradition and modernity, in movies like those of one of the leading African movie makers,

Souleymane Cissé. Salif Keita and other worldwide acclaimed musicians prefer to sing in Bambara. The dominant use of Bambara on television, including all aspects of publicity, and in the radio of Mali also decisively contributes to its dissemination.

Today, Bambara (Mandenkan) is one of the most dynamic African languages with rapid expansion tendencies to cover the next few decades.

Bar-Hillel, Yehoshua

Yehoshua Bar-Hillel (1915–1975) was an Israeli logician and philosopher of language who made significant contributions in a number of linguistic fields: formal and algebraic linguistics, logical aspects of natural language, and computational linguistics, in particular, machine translation (MT) and information retrieval. His principal essays are included in two collections *Language and Information* and *Aspects of Language*.

In most of his writings, Bar-Hillel's aim was to bridge the 'disastrous' gap between logic and linguistics, believing that linguists (particularly semanticists) had ignored logic to their detriment, and that logicians had ignored linguistics by creating a formal system devoid of any relevance to natural language in actual use. He sought to extend the logical syntax of his mentor Rudolf Carnap, which he believed could serve as 'a methodological and terminological basis for structural linguistics', by describing a formalism for relating lexical items to the specific entities (objects, persons, etc.) they refer to in particular contexts, both in natural and in artificial languages; in this, he anticipated the logical and natural language semantics of Richard Montague. With Carnap he explored the possibilities of a theory of 'semantic information', an extension of inductive and probabilistic logic to the semantics of communication. He also saw logic as a kind of 'universal semantics', providing the framework for expressing relationships among linguistic entities whatever the language (including artificial languages)—in contrast to a linguistics-based 'general semantics'.

Much of his work in the early 1950s was influenced by Norbert Wiener's cybernetics and by the possibilities of the newly invented digital computers to test speculations and theories about logic and language. In May 1951, he was appointed to a position in the MIT Research Laboratory of Electronics, with the task of investigating the application of computers to linguistic work, and specifically MT and information retrieval. He visited all the US groups, wrote the first survey (1951), and convened the first conference (June 1952). The conference was a major factor in launching substantial MT research in the following years. There, Bar-Hillel often expressed 'naïve optimism', which he later regretted; however, he was never a believer in the full automation of translation. For practical reasons, he advocated the collaboration of man and machine, the use of editors to revise MT output, the use of restricted (unambiguous) forms of natural language, and the use of subject-specific dictionaries.

His major contribution to algebraic linguistics was categorial grammar, a 'decision procedure' for identifying constituents in grammatically well-formed sentences, based on the logic of Kazimierz Ajdukiewicz—a further example of bringing logic and linguistics closer. His 1953 essay is recognized as a pioneer article in the field, and he made a number of

important contributions to the theory of formal grammar, much under the influence of Noam Chomsky—a close friend from the 1950s until his death. His theory of categorial grammar was first presented at the MT conference in 1952 as a way of dealing with the syntax of natural language—a topic neglected by most linguists at the time. Later, Bar-Hillel demonstrated that categorial grammar was formally equivalent to context-free grammars, and as such (following Chomsky) inadequate for the description of natural language; he had long recognized its weakness in dealing with discontinuous elements. Consequently (1962), he argued forcefully that MT researchers and computational linguists should base parsers and grammars on Chomsky's type of 'transformational grammar' (i.e. with rules for transforming active sentences into passive, or for showing that *look* and *up* in, e.g. *He looked the word up in the dictionary,* form a single unit 'look up'). However, after his death, renewed interest in nontransformational grammars has shown that categorial grammars can be extended to overcome the deficiencies (cf. Wood 1993), and Bar-Hillel's pioneer work remains influential.

Although a firm supporter of Chomsky's formal grammar theory, he was not uncritical. He disliked the confusing and overworked use of 'theory' for different conceptions and philosophies in linguistics, and he argued for the development of grammars of linguistic performance (language in use) — i.e. parallel to his extension of logic to deal with actual communication. And he was a trenchant critic of the semantic theories of Jerrold Katz and Jerry Fodor, dismissing as simply false their thesis that meaning rules could be exhaustively presented in the form of dictionary entries plus rules of combination, since they had ignored the need for inference rules and for mechanisms to relate words and their external referents.

By the late 1950s, Bar-Hillel's confidence in computational linguistics was waning. He wrote a report for the sponsors of MT research (published 1960), which was highly critical of nearly all current projects. He was particularly critical of those groups adopting statistics-based analyses to 'discover' grammars for computer programs, of those investigating interlinguas (i.e. intermediary language-neutral representations), indeed of any that did not keep to modest and realistic objectives. He was opposed to interlinguas not just in practice (they did not lead to economies of programming) but even more in theory: only a logical semantics could form a sound basis in his view.

His main criticism, however, was directed to the assumption that the goal of MT should be fully automatic high-quality translation, and he included a 'proof' that such a goal was nonfeasible, not just in practice but in principle — arguing that no amount of data (linguistic, encyclopedic, inferential, referential) could ever be sufficient to resolve all ambiguities in texts and to choose the best translations in context. This article was perhaps the single most influential publication in the early history of MT, convincing many outside the field that MT was a misguided activity, and it continues today to be cited as 'evidence' of the impossibility of MT.

Later (1962), he lost his belief that even the man–machine partnership in MT could be cost effective, and the last vestiges of his earlier enthusiasm for cybernetics waned with the realization that the idea of a 'learning machine' was a delusion, since 'all attempts at formalising… inference have completely failed'. On the other hand, later still (1971), he withdrew his harsh judgment about the future of practical MT, conceding that quality in MT could not be an absolute and that, in practice, it varied according to recipients and uses.

Bar-Hillel accepted that he often 'trod on … toes', and he did not, in fact, like the role of devil's advocate, which he often found himself taking. In truth, his criticisms were often expressed forcefully (even bluntly) but they were always pertinent, well-argued, and enlightening.

Biography

Yehoshua Bar-Hillel was born in Vienna on September 8, 1915. He moved to Palestine in 1933, and attended Hebrew University from 1935. He received his M.A. in 'The antinomies of logic' in 1938, and a Ph.D. on 'Theory of syntactic categories' in 1939–1945 (interrupted by four years in Jewish Brigade Group, British Army). He worked as a teacher in high school in 1945–1947, and fought in the Israeli War of Independence in 1947–1949. He was a research fellow at Hebrew University in 1949–1953, and received a visiting fellowship to USA in 1950–1951. Bar-Hillel was appointed research associate in the Research Laboratory of Electronics (RLE), Massachusetts Institute of Technology (MIT) in 1951–1952, and convened the first MT conference (at MIT) in June 1952. He was a senior lecturer in Philosophy at Hebrew University in 1953–1958, and held further appointment at RLE, MIT, 1955–1956. He returned to Hebrew University in 1956 and conducted a study tour of the United States (funded by the US Office of Naval Research) in 1957–1960. He was Associate Professor of Philosophy at Hebrew University in 1958–1961, and visiting professor at the University of California at Berkeley in 1960–1961, and then again at RLE, MIT in 1961. He was Professor of Logic and Philosophy of Science, Hebrew University, in 1961–1975; a member of the Israel Academy of Sciences and Humanities in

1963–1975; secretary and organizer of the third International Congress for Logic, Methodology and Philosophy of Science, Jerusalem, in 1964; visiting professor, University of Michigan, in 1965; visiting professor, University of Southern California, La Jolla, in 1966–1967; president, Division of Logic, Methodology and Philosophy of Science of the International Union of History and Philosophy of Science, in 1966–1968; president, International Union of History and Philosophy of Science, in 1967; visiting professor, University of Konstanz, in 1971; and visiting professor, University of Berlin, in 1972. He died in Jerusalem on September 25, 1975.

Basque

Basque is the oldest continuously spoken language in western Europe. It was already an ancient language, possibly a remnant from the Stone Age, when the Romans first identified it over two millennia ago. Crucial to its survival has been the historically remote habitat of its speakers in the rocky fastness of the western Pyrenees Mountains between Spain and France. The Basque language is related to no language family now extant. Its ancient, remote, and singular nature has intrigued generations of scholars, producing as much speculation as fact.

In Basque itself, the word for the language is *euskara*. Speakers of *euskara*, according to the most recent census data, number over a million people. However, only about two thirds use it as their daily primary language. North central Spain is the home of the overwhelming majority of these speakers. Along a bordering area in southwest France is a smaller group of about a hundred thousand speakers.

The term Basque describes not only a language but also a distinct people and cultural region. This region is called 'Basque Country' (*Euskal Herria*); however, it is not a sovereign country. The effort of some to establish such an independent state has dominated both recent and past Basque history. The struggle has been as futile as it has been violent.

The Basque Country has traditionally lain along the French and Spanish sides of the farthest western edge of the Pyrenees, descending to the Bay of Biscay. The size of the area occupied by the Basques has grown

smaller over the millennia. Basque Country today extends east from around the area of the Spanish city of Bilbao, past San Sebastian, and then veers north at the terminus of the Pyrenees. In France, it extends up past Biarritz, ending around Bayonne. In length, therefore, Basque Country is no more than a hundred miles, with its extent inland being only several dozen miles.

Its total area is a narrow, curvilinear band of less than 4,000 square miles, smaller than the state of Connecticut. In antiquity Basque speakers extended much farther north into France and farther east into the Pyrenees. The Romans identified them as '*vascones*'. The Spanish termed them '*vascos*', and the French, hearing the 'v' as a 'b', as '*basques*'. With the influence of Norman French in England, they were termed Basques in English.

Spain has the largest number of Basque speakers. The urban industrial complex of Bilbao is the largest Basque city, and is the fourth largest city in Spain. Spanish Basque Country comprises three north central provinces, Bizkaiko, Gipuzkoako, and Araba. While not independent, this Spanish Basque Country holds the status of an Autonomous Region, under the constitution of Spain. It is allowed limited local governing authority and elects its own 'president', still recognizing nonetheless the central authority of the Spanish monarchy. *Euskadi* is the name for the Basque political state. There are also some Basque speakers in the mountainous upper parts of the eastern province of Navarra, and in the wine-growing area southward of Riojo. In France, Basque speakers are only in the far southwest province of Pyrénées-Atlantiques and have no autonomous status. Essentially, therefore, Basque Country consists of four provinces in Spain and one in France. The total population is three million people, but much less than a third of these use Basque for daily communication. *Euskal Herria* describes not only the cultural but also the geographic extent of the Basques.

Basques emigrated to the New World in the last century. Leaving their mountain pastures as noted shepherds, a considerable number settled in Nevada. This state holds one of the major communities of Basques outside Spain.

In traveling through Basque Country, one is more likely to hear the language in the rural interior rather than the urban, coastal area. The latter has given Basques a modern prosperity through the steel industry of Bilbao and tourist beach resorts. However, it is in the farms and pasturelands of the interior that Basque has maintained its long-term economic and social survival. Centuries-old stone residences stand as proud homesteads (*baserri* and *borda*) that have been inhabited by the same families for many generations. Here lie the vigor and longevity of Basque.

Surviving from before the invasion of Europe by the Indo-European family of languages that dominate the continent today, Basque falls on the ear as a somewhat hard, guttural language. In looking at a Basque text, one is struck by how often the letter 'k' appears.

Its morphology, in the marking of nouns and verbs for person, number, or time, occurs predominantly by adding a suffix, rarely a prefix. Gender is not normally distinguished. Verbs are primarily transitive, although there are also intransitive verbs and some that are both. The language includes adjectives and pronouns. Moreover, in terms of number there is a distinction between singular and plural, and there is agreement between subject and verb.

Basque syntax uses a standard sentence pattern of subject in the first position, an object in succession, and a verb following: S–O–V. The sentence 'Ann hit John' becomes 'Ana Jonek jo zuen.' Clauses also end in verbs. There are, however, no relative pronouns.

The Basque vocabulary preserves the most ancient pre-Indo-European origin of the language. There are an exceptional number of words for or related to stone. Nevertheless, it has successively accumulated words over the millenia from, for example, Celtic, Latin, and Spanish. The word for 'hello' in Basque is 'augur', derived from the Latin, 'ave'. The initial nucleus of the language was probably in southwestern France, in the province of Acquataine. With the Roman invasions of Hispania and Gaul, Basques retreated south, moving higher and more deeply into the safety of Pyrenees, the strategy whereby the language survived.

There are two major centers for the study and research on Basque culture, history, and language. The first is the University of the Basque Country (in Spanish: *Universidad del Pais Vasco*; in Basque: *EuskalHerriko Unibertsitatea*), with branches in the three Spanish Basque provinces. The other is the Center for Basque Studies at the University of Nevada in Reno.

EDWARD A. RIEDINGER

Baudouin de Courtenay, Jan Ignacy Niecisław

Jan Ignacy Niecisław Baudouin de Courtenay was a pioneer of modern linguistics. He anticipated most of the basic concepts of structuralist theories. In particular, his formative influence on modern phonology is generally acknowledged. However, his contribution to linguistic science is sometimes undervalued since he was not able to fully exploit his own discoveries and never published a major synthetic work.

Baudouin de Courtenay is usually credited with having introduced the linguistic term 'phoneme' to denote a speech sound that distinguishes meaning. He initiated the discussion of what makes sounds distinctive in 1870, in his inaugural lecture at the University of St. Petersburg. In his hands, phonetics became more abstract. He pointed out that the sounds of language are structural entities, rather than mere phonatory and auditory phenomena. Baudouin de Courtenay attempted to relate the study of phonemes to the linguistic intuition of speakers. He noted that the way we perceive different sounds is not always a matter of their physical and physiological properties. The motor-acoustic properties are important elements of linguistic structure as long as they contribute to the function of sounds.

Around the turn of the century, international linguistic thought was strongly influenced by the neogrammarian school, centered on Leipzig. Many of Baudouin de Courtenay's ideas were inspired by opposition to the nineteenth-century philology, concerned exclusively with the history of languages. In particular, he stressed the importance of synchronic analysis and suggested a distinction between language and speech (similar to Ferdinand de Saussure's *langue/parole* dichotomy). Still, Baudouin de Courtenay's views of psychology remained within the dominant framework. He considered association psychology a fundamental achievement of modern science. Therefore, Baudouin de Courtenay tried to build a bridge between his functional definition of the phoneme and psychologism. It resulted in a conception of the phoneme as the psychological equivalent of a speech sound. This mentalistic approach to phonology might be considered parallel to the basic ideas put forward by generativism many years later.

Baudouin de Courtenay proposed a new linguistic discipline, 'psychophonetic phonetics' (corresponding to modern phonology). It would have to occupy itself with the relation between sound and the psychological aspects of audition (as opposed to 'anthropophonic phonetics', studying the production and the audition of sounds). In 1895, Baudouin de Courtenay published his chief work, *Versuch einer Theorie phonetischer Alternationen* (1895; *Essay on a Theory of Phonetic Alternation*). Despite its occasional ambiguity, the views expressed in this book have become part of phonology as we know it today. At the beginning of the twentieth century, the idea of the phoneme started to infiltrate into international linguistics. It was later advanced by such linguists as Ferdinand de Saussure, Nikolai Sergeevič Trubetzkoy, Leonard Bloomfield, and Edward Sapir. Taking the lead from Baudouin de Courtenay, they cleared his theory of its psychological overtones. The distinction between the phoneme and the sound proposed by the Polish linguist may be said to have laid the foundations of structural linguistics.

It is worth noting that Baudouin de Courtenay's interest in what we might call psycholinguistics resulted in many analyses of his own children's speech (over 12,000 pages of manuscripts—most of them still unpublished).

Baudouin de Courtenay advocated a bold and individual theory of the nature of language mixing and change. It was put forward in his article 'O smešannom xaraktere vsex jazykov' (1901; On the Mixed Character of All Languages) and might be said to be a reaction to Schleicher's tree image of Indo-European languages. Baudouin de Courtenay rejected the idea of a pure language and attempted to analyze the mechanism of linguistic convergence. He claimed that languages mix both in space and in time (all languages mix with their earlier stages). When languages of different types mix, they can influence each other. Under such influence, a language may undergo many grammatical changes—it may lose inflection, level paradigms, regularize stress, etc. Therefore, in Baudouin de Courtenay's opinion, it is language contact that causes language change.

Although he occupied himself mainly with general problems—questions of theoretical phonetics, language mixture, relations between linguistics and psychology, etc.—Baudouin de Courtenay was also a specialist in comparative and historical linguistics. He pioneered the issues of Old Polish in his Ph.D. dissertation. Since then, the history of the Polish language was among his permanent interests. He was also an outstanding Slavist. One of the three major palatalizations of velar

consonants that took place in Proto-Slavic is named after Baudouin de Courtenay since it was first described by him.

Baudouin de Courtenay was a very charismatic teacher. He exerted a huge influence on several generations of students. His lectures were usually very informal and thought-provoking. They represented the most advanced linguistics to be found in eastern Europe at that time. Baudouin de Courtenay's long teaching career included professorships at several universities of eastern Europe. It began in 1874 when he was appointed to the faculty of the University of Kazan and lasted until his death. Many of de Courtenay's students became prominent linguists. A number of them were active in OPOJAZ (the most important Russian circle devoted to literary theory and modern linguistics), e.g. Evgenij Dmitrevič Polivanov (1891–1938), one of the pioneers in historical phonology. Also, Kazimierz Nitsch (1874–1958), an outstanding Polish dialectologist, was among the pupils of Baudouin de Courtenay. Most importantly, Baudouin de Courtenay's theories were strongly influenced by his favorite student, Mikołaj Kruszewski (1851–1887). It is very difficult to separate the ideas of the two linguists. Therefore, they are often referred to as the theories of 'the Kazan School'. The time spent in Kazan was the most prolific period in Baudouin de Courtenay's life. However, partly due to Kruszewski's untimely death, Baudouin de Courtenay did not have any direct successors.

Baudouin de Courtenay's absorbing interest in linguistics did not deter him from becoming a political activist. He supported emancipatory and democratic movements. After 1918, when Poland regained independence, he emphasized the importance of securing the civil rights of national minorities (the minorities nominated him as their candidate for the presidency of Poland). It was also reflected in his linguistic research—he collected data on many minority languages (e.g. Kashubian dialects in Poland, Slovene dialects in Italy, local dialects in Slovakia, and Yiddish in eastern Europe).

Biography

Jan Ignacy Niecislaw Baudouin de Courtenay was born in Radzymin, near Warsaw, Poland (then a province of the Russian Empire) on March 13, 1845. He obtained his M.A. (1866), Warsaw (at the Department of Philology and History). He received a scholarship of the Ministry of Education for outstanding achievements and continued his studies in Prague (Bohemia), Jena, and Berlin (Germany), tutored by August Schleicher; he obtained his Ph.D. for work on analogy in Polish declination, University of Leipzig, Germany,

1870, and then worked in St. Petersburg, Russia, on Old Polish and Indo-European, in 1870–1874. He was Professor of Comparative Grammar of the Indo-European languages, University of Kazan, Russia, in 1875-1883 (there tutored Mikołaj Kruszewski). He moved to Dorpat (now Tartu, Estonia), where he was Professor of Comparative Grammar of the Slavic languages, in 1883–1893; he was also Professor of Comparative Linguistics and Sanskrit, Jagiellonian University, Cracow (then the capital of the Austrian partition of Poland), in 1893–1899. He lost his teaching appointment because of his radical articles concerning social policy in the Austrian partition of Poland. He moved again to St. Petersburg, where he worked as Professor, University of St. Petersburg, in 1900–1918. He was imprisoned for three months for publishing a pamphlet on autonomy of nations in 1914. He returned to Poland after World WarI in 1918. and worked as Professor of Comparative Linguistics, Warsaw University, in 1920–1929. He stood as a candidate in a presidential election in 1922. He died in Warsaw on November 3, 1929.

Belgium

Belgium is a small parliamentary and constitutional monarchy in northwest Europe; it shares borders with the Netherlands (north and northeast), France (south and southwest), Germany (east), and Luxembourg (southeast), with the North Sea forming a natural boundary on the northwest. It stretches over 32,547 square kilometers and is divided into ten provinces: five French-speaking provinces in the south (Walloon Brabant, Hainaut, Namur, Liège, and Luxembourg), and five Flemish-speaking provinces in the north (Antwerpen, Flemish Brabant, Limburg, Oost-Vlaanderen, and West-Vlaanderen). The Belgian population numbers 10,213,752 (1999). From a linguistic perspective, Belgium has a dual identity, straddling the divide between Romance and Germanic languages. Three national languages are officially recognized: Dutch, French, and German.

Belgium became independent from the Netherlands in 1830 and it was accepted internationally as a neutral state on the 20th of January the following year. French became the language of the government, although Germanic vernaculars (Flemish dialects) were spoken in the north and east of the fledgling state. (German dialectal varieties were used in what is known as 'Alt-Belgien', an area north of Liège around Vielsalm and Arlon, along the Luxembourg border.) At the time, the higher bourgeoisie and the nobility throughout Europe used French as the language of culture. Moreover, part of the population spoke Romance vernaculars (Walloon, Picardy dialect, and Gaumais) and no other major language appeared to be a reasonable alternative: the Flemish dialects showed no unity, and the closest language, Dutch, was rejected as the Belgian Revolution broke out against Holland.

In the 1830s, the prominent position of the French language in Belgium was hardly challenged as linguistic and political factions were all united in a desire to firmly establish the new country as an internationally recognized power, despite attempts made by William of Orange, the Dutch king, to re-annex Belgium. However, this exemplary Belgian unity did not last very long: Flemish intellectuals started to voice claims for cultural freedom in the late 1830s. They were motivated mainly by a desire to protect the Flemish cultural heritage. The movement took on a more social slant in later years. In the 1870s and 1880s, three important linguistic laws were promulgated. First, in 1873, Flemish citizens were allowed to stand trial in their mother tongue if they wished. This came as a result of unfair trials in the 1860s where the accused were condemned in French, a language they did not understand. Then the administration in Flanders became bilingual (1878), which disqualified Francophone civil servants from taking positions in the north of the country. Finally, part of the teaching in secondary schools of Flanders (1883) was to be undertaken in Flemish. With the growing influence of Flemings in the government of the country, a Walloon movement started to emerge, born of the worries of the Romance population who feared the loss of their privileged position within the nation.

In 1898, Flemish claims were crowned by the so-called *loi d'égalité* (the Equality Law) that established the equivalent of the Flemish and French versions of laws. The weight of Flanders in the national political life was further increased when universal suffrage was granted to all men after World War I. Given that the Flemish population was more numerous, Flemings started to occupy strategic functions in the government. Also, the linguistic composition of the country was further complicated by annexation of new German-speaking territories as a result of the Treaty of Versailles (June 28, 1919). This territory, 'Neubelgien', comprises a southern and a northern part separated by the Walloon cantons of Eupen, Malmédy, and St. Vith. The Flemish- and French-speaking populations steadily grew apart during the twentieth century. In 1912, the 'Lettre au roi' (Letter to

the King) by Jules Destrée, a Walloon socialist, illustrates the growing estrangement between the two parts of the Belgian population: it states that there are no Belgians, but only Flemings and Walloons. In 1932, a new law drew a linguistic border between the two main linguistic regions. This boundary could still be modified according to the results of the census. However, the linguistic questions of the census were suppressed after World War II following their boycott by Flemish mayors. Flemings were concerned about losing Brussels—historically a Flemish city but with an increasing Francophone population—and seeing the Francophone 'oil slick' further expanding in surrounding areas. The Gilson laws painfully established the definitive linguistic border in 1962–1963: they included facilities (the possibility of getting state services in the other language in regions where there was a linguistic minority of at least 30%) for Francophones in Brussels (Drogenbos, Kraainem, Linkebeek, Rhode-St.-Genèse, Wemmel, Wezembeek-Oppem), for Francophones in Flanders (Messines, Espierres, Helchin, Renaix, Biévène, Herstappe, and the well-known Fourons), Flemish in Wallonia (Comines, Dottignies, Enghien, Flobecq, Herseaux, Marcq, Petit-Enghien, and Warneton), and German in Wallonia (the six 'Malmedian communes': Belleveaux-Ligneville, Bevercé, Faymonville, Malmédy, Robertville, and Waimes). The cohesion of the country was thus weakening and it was necessary to reorganize the state. In 1993, Belgium became a federal state after a series of reforms: creation of communities (cultural attributions) in 1970, reinforcement of communities and creation of regions (territorial responsibilities) in 1980, and creation of a third bilingual region, the Brussels Metropolitan Region (Bruxelles Capitale), in 1988–1989.

Present-day Belgium is therefore a federal state that consists of three regions— Flanders, Wallonia, and Brussels— and three communities—Flemish, French, and German. Regions and communities do not correspond, which greatly complicates politics in Belgium. From a linguistic point of view, there are four areas: Flanders speaks Flemish only, Wallonia is Francophone—except for the German region—and Brussels is bilingual, although now mainly Francophone and very cosmopolitan, given the presence of bodies such as NATO and the European Union. Lately, the *Communes à facilités* have been a bone of contention. The Peeters' Circular (1997) tried to suppress facilities for French speakers around Brussels: Flemings do see facilities as a temporary solution to allow integration in the other community, while Francophones understand them as a permanent state that could possibly be extended to other regions (especially around Brussels). This has led to ongoing tensions

between the two parts of the country, and in May 1998, the European Commission had to send a Swiss representative, Domino Columberg, to evaluate the situation in Brussels and write a report on the whole linguistic conflict in Belgium and its possible solution.

By the decree of December 10, 1973, Dutch is the official language of the Flemish Community (5,912,000 inhabitants in Flanders and between 13 [Francophone sources] and 25% [Neerlandophone sources] of Brussels' 953,000 inhabitants). Although a Language Union Treaty was signed between Flanders, Belgium, and the Netherlands on September 9, 1980, Flemish Dutch and Netherlandic Dutch are not identical. The main differences are found in pronunciation, but this does not hamper communication. Lexical differences also appear between the two variants, and Flemish Dutch possesses a more Frenchified vocabulary. There are also minor differences in sentence structure. Flemish dialects are still very vivid, although Dutch is the cultural vector. Standard French in Belgium is nowadays the mother tongue of Wallonia (3,327,000 inhabitants) and of most Belgians and immigrants in Brussels. Romance vernaculars are still used in informal situations among older people and working classes; they can also be used by educated people for sentimental, cultural, or amusement purposes. In any case, they are not the exclusive communication means of any Belgian of the twenty-first century.

French in Belgium presents a series of features that distinguish it from Standard French (which is identified as the Parisian variety). Belgian French—as well as regional varieties in France—possesses specific words influenced by the dialects spoken in the area. However, French in Belgium presents more specific features that are linked with the institutions of the country. This is the case, for example, in *bourgmestre* 'mayor' (*maire* in France) or *candidatures* 'first two years of a degree' (*DEUG* in France). In addition to these, Belgian varieties of French contain more words with foreign origins: Germanic in words such as *kermesse* 'kind of seasonal fairground' (*fête foraine* in France) or *couque* 'bread roll' (*petit pain* in France), Spanish as, for example, in *bodega* (bar found in a cellar) or *escavèche* (a fish dish). Because of the numerous powers that have held sway over the territory of contemporary Belgium, French in Belgium also seems more open to English than the Parisian variety.

Popular varieties of French in Belgium have features of sentence structure that seem to be influenced by Flemish: the position of the adjective before the noun (*une propre chemise* 'one's own shirt' instead of *une chemise propre*); interrogation in *qu'est -ce que c'est pour* (based on the Flemish *wat is het voor* 'what is that for'), or replacement of *pouvoir* 'to be able to'

by *savoir* 'to know'. Finally, some words exist both in France and Belgium but have different meanings in the two countries. For example, *torchon* refers in France to a tea towel but in Belgium to a cloth used for cleaning the floor; *un rideau* is a curtain in France and a net in Belgium.

In spite of some differences, Belgian and French citizens understand each other without problems. Nowadays, specificities tend to fade away because of the development of mass media, but there has always been a great interest in language correction in Francophone Belgium. A feeling of linguistic insecurity (the conviction of not speaking the valued variety of a language) has resulted in the development of a strong grammatical tradition in Belgium, of which Maurice Grevisse's grammar, *Le bon Usage*, is the best-known example. There was a general tendency to imitate French usage until recently; but now, Francophone Belgium appears more autonomous, as shown in the law on the feminization of job descriptions passed in 1993, without waiting for French legislation.

German is spoken only by about 1% of the population. A separate German variety has not developed in Belgium, although there are some specificities. These come first from national institutions; for example, *Permanent-deputation* is used instead of *Länder-regierung*. The differences from Standard German also come from interferences with other vernaculars: Germanic dialect, Walloon, and especially French. These 'gallicisms' appear in borrowed words (e.g. *renovieren*, based on French *rénover* instead of German *erneuern*) and in literal transpositions of phrases (e.g. the French *téléphoner à* has changed the Standard German *telephonieren mit* 'telephone with' into *telephonieren an* 'telephone to').

Languages have thus played a key role in the short history of Belgium. Linguistic tensions have shaped the institutional evolution of the country in making a national state into a federal state. Although the country is nowadays divided between the two main linguistic groups with increasing autonomy, linguistic questions (mainly concerning the future of Brussels) still constitute a major driving force in Belgian politics and are likely to remain so in the twenty-first century.

Benveniste, Emile

Benveniste is best remembered today for his writings on general linguistics and on semiology (following Saussure's usage, this term has been used in Europe more than 'semiotics'). However, the bulk of his publications, of which we can only mention the most important, focus on comparative Indo-European philology. After the death at the front of fellow-student Gauthiot, Benveniste completed his grammar of Sogdian (published in 1929) and then Meillet's grammar of Old Persian (1931). In his thesis *Origines de la formation des noms en indo-européen* (1935), which deals with Indo-European root morphemes, Benveniste broadens out from Iranian languages to the wider Indo-European field. Notes for the sequel to this research, dealing with suffixal modals, were lost when Benveniste's apartment was ransacked during World War II, but were painstakingly reconstructed and published in 1948. Probably the best known of his works

in this area, both because of its less technical nature and because of the fascinating link between language and culture, is his *Le vocabulaire des institutions indo-européennes* (1969; English translation 1973), in which six sections deal with topics such as the vocabulary of kinship or of religion.

In his work on general linguistics, Benveniste elucidated and further developed the foundations laid by Saussure. He is a proponent of the structuralist notion of a system founded on a series of differences; he promotes the new discipline of semiology, and he extends the remit of French linguistics to cover *discours* (discourse) and *parole* (speech). Benveniste participated in the interwar debate on the arbitrary nature of the linguistic sign, maintaining that the link between the sign and external reality is arbitrary, although the link between signified and signifier is a necessary one. Many of Benveniste's most important articles are collected in his *Problèmes de linguistique générale I & II* (1966, 1974; English translation of Vol. 1, 1971). The articles of the first volume were selected by the author himself, but the selection for the second volume, compiled with Benveniste's help when he was in very poor health, has sometimes been questioned. It is particularly for the pioneering work on *énonciation* that the *Problems in General Linguistics* is read today. The French tradition in *énonciation,* aspects of which are dealt with under pragmatics and speech-act theory in English-speaking circles, treats language not as a static product, but as an interlocutionary and intersubjective phenomenon. Thus, Benveniste, in analyzing the personal pronoun system, points to the difference between the I–you pronouns, which are discoursal units, and the third-person pronouns. The first- and second-person pronouns, moreover, are linked to a deictic system of demonstratives, and spatial and temporal adverbs, as well as to the verbal system. French tenses are analyzed by Benveniste according to a distinction between *histoire* (story/history) and *discours* (discourse), adverbs such as 'here' and 'today', for example, relating to a first-person pronoun and being anchored in the discoursal tense system (whereas in a narrative we would hear that X was in such a place on such a date). This work on pronouns and on tense has been influential in both linguistics and literary criticism. In the former, it feeds into various French traditions, from the linguistics of Antoine Culioli to French discourse analysis. The *histoire/discours* distinction was used to great effect (as *récit/discours*) by literary critic Genette among others. It has been pointed out that Benveniste's work should not be seen as fragmented, because even in his work on historical linguistics he shows the same concern to link language and society and to account for the subjective nature of language, as in his writings on general linguistics.

Biography

Benveniste was born in 1902 in Aleppo, but when he was a baby the family moved to Paris. He attended French and rabbinical schools and then went on to study Indo-European philology, and classical, Indian, and Celtic languages at the Sorbonne. Like his master, Meillet, and Saussure before that, he taught at the Ecole Pratique des Hautes Etudes, taking up a post in Comparative Grammar and Iranian in 1927. Ten years later, he succeeded Meillet in the chair of Comparative Grammar at the Collège de France, having defended his thesis on the origin of Indo-European noun formation in 1935. During World War II, he put his scholarly knowledge to practical use, fleeing to Switzerland with the aid of a priest who communicated with him in Sogdian. He became secretary of the Société de Linguistique de Paris, and editor of the society's bulletin. Most of his time was devoted to writing and teaching, although he went on a number of field trips, including visits to Iran, Afghanistan, and the American North West, the results of which fed into his seminars and into articles. Although a reclusive figure, Benveniste was in touch with many of the well-known linguists of his time. His correspondence with Hjelmslev shows a common approach to a structuralist methodology; in 1947, Benveniste became one of the few foreign members of the Copenhagen Linguistic Circle. During the intellectual ferment of the late 1960s in France, Benveniste became a slightly more public figure, giving interviews on linguistic structuralism, and being championed by such thinkers as Kristéva and Barthes. On the founding of the International Association for Semiotic Studies in Paris in January 1969, he became its first president. Benveniste had already suffered a debilitating coronary thrombosis in 1956, and he had an incapacitating stroke in 1969, having seen his book on the vocabulary of Indo-European institutions through to completion only months before. In his last difficult years of failing health, he was nursed with dedication by his sister, and his cause was promoted by contemporaries such as Barthes and Jakobsen. He died in October 1976.

Bever, Thomas

Within linguistics, Thomas Bever can be considered a renaissance scholar. His work impacts the fields of theoretical linguistics, psycholinguistics, cognitive neuroscience, reading, esthetics, and language development. He is probably best known for his work that distinguishes independent systems of language processing (production and perception) from the system that represents grammatical knowledge. He argues that the universal properties of language can come from a variety of sources, including what can be said, understood, remembered, and learned, and are not necessarily the result of grammatical knowledge.

Originally interested in music and theater, Bever reports that he decided to take a major in linguistics primarily because it was the course of study with the fewest requirements that involved language courses. While an undergraduate, he worked in the psycholinguistics lab of Margaret Bulowa (assisting in an early study of language acquisition using a camera system he designed). His undergraduate thesis was on the stages of the acquisition of phoneme perception in infants. He was one of the first students in the linguistics doctoral program at MIT, where he studied both linguistics (mostly phonological theory under Morris Halle) and psychology.

In 1964, Bever was elected to the Harvard Society of Fellows, where he worked in the laboratory of George A. Miller. He continued working with Miller when they both moved to Rockefeller University in 1967. It was in Miller's lab that he first explored the question of the relationship between formal grammatical models and psychological reality. Here, he collaborated extensively with Jerry Fodor, Merrill Garrett, and Jacques Mehler. Bever's earliest work was partly a response to behaviorist claims that speakers and language learners do not have access to 'abstract' or 'deep' levels of language. Using perceptual experiments, Bever and his colleagues showed that speakers do indeed have access to abstract grammatical information. The experiments involved placing a click in a neutral place in the stream of sounds. People tend to perceive these clicks not in the place where they actually occur, but at some phrasal boundary. Bever extended these tests to even more abstract structures. The following two sentences, although apparently similar on the surface, differ in the deep semantic relations underlying them. In (2a), the noun phrase *the troops* is the patient of the main clause. In (2b), the troops is the agent of the embedded clause:

(2) (a) The general defied the t/roops$_i$ [to fight]
         #

     (b) The general desired [the t/roops to fight]
         #

(*from Bever 1998:128*)

Syntactic constituency is marked with square brackets; the placement of the click is marked with a slash. People perceive the click in different places (marked with a #) in the two sentences, corresponding to the structure of the sentence. The click experiment showed that speakers were aware of the deep semantic difference in the structure of these clauses: the click was perceived at a clausal constituent boundary reflecting the deep positioning of the noun phrase.

These click experiments led Bever to another major area of research, that of cerebral dominance (the idea that one half of the brain is more powerful) in language and other cognitive skills, both in humans and in animals.

Perhaps Bever's most important contribution to linguistics showed that there is no single system that contributes to our production and processing of language. In Generative Grammar, there are a set of rules

for generating the structure of sentences. These rules constitute our knowledge or 'competence' in language. Linguists tap this knowledge using acceptability judgments. In early work, George Miller hypothesized that the set of generative rules were essentially identical to the set of processes we use to produce and decode sentences. One consequence of this idea is that the more rules involved in generating a sentence, the harder it should be to produce or understand; this hypothesis is often known as the 'Derivational Theory of Complexity'. While initial experimental results testing this were promising, several studies by Bever and his colleagues showed that it was based on some faulty assumptions about how the rules were organized. Bever (in work that continues up to the present time) suggests that perhaps more than one system is at work when processing or producing a sentence. For example, when hearing a sentence, one uses a set of perceptual strategies to provide an initial structure to the sentence. One example of such a strategy is the idea that noun–verb–noun (NVN) sequences map onto agent–action–patient semantics; another is that the first noun–verb sequence heard constitutes the subject and predicate of the main clause. These perceptual strategies are not the same as the generative rules that give us acceptability judgments. Instead, these strategies form a separate cognitive system. Evidence for this proposal comes from the fact that at the stage when children seem to rigidly use perceptual strategies in other domains (such as in estimating numerosity)—at approximately 3 years of age—they rigidly apply linguistic perceptual strategies to sentences they hear, often doing much worse than younger children. For example, in tests where they are asked to identify which picture is best associated with a particular sentence (3), 2-and 4-year-olds both correctly identify *Big Bird* as the agent and *Cookie Monster* as the theme. However, 3-year-olds reverse the roles, consistent with the NVN strategy, which treats the first noun as an agent.

(3) Cookie Monster was hit by Big Bird

Since there is a stage at which children seem to exclusively use these perceptual strategies, it seems reasonable to conclude that they exist.

Obviously, these perceptual strategies must relate in some way to grammatical rules. Bever claims that we use both systems in a kind of 'analysis by synthesis': we use perceptual strategies to provide an initial hypothesis about the structure of the sentence and the semantic relations that underlie it, then we go back with our generative rules and check the structure. One piece of experimental evidence that he presents is that tone and click perception at the end of clauses is poor, suggesting that this is the stage at which synthesis is occurring.

Bever's wide-ranging interests reflect the complexity of the phenomena he studies. His work has raised ques-

tions about the intersections among language acquisition, sentence processing, formal grammar, and neuroscience (among other areas) and has shown that one cannot thoroughly theorize about any one of these without considering the interactions with other domains.

Biography

Thomas Bever was born in Boston, Massachusetts, on December 9, 1939. He completed his B.A. (1961) magna cum laude with highest honors in psychology and linguistics from Harvard, tutored by Roman Jakobson, and his undergraduate thesis was on the stages of the acquisition of phoneme perception in infants. His Ph.D. (1967), Massachusetts Institute of Technology, dissertation on Menomini phonology was supervised by Morris Halle. He was Lecturer, MIT Psychology department, 1964–1966; Assistant Professor, 1967–1969, and Associate Professor, 1969–1970, Rockefeller University; Professor of Psychology, Columbia University, 1970–1986; Chairman, Columbia University Interdisciplinary Ph.D. Program in Psychology and Linguistics, 1973–1986; Pulse Professor of Psychology and Professor of Linguistics, University of Rochester, 1985–1995; Head, Language and Cognition Program 1986–1989 and 1992–1994, Director, Cognitive Science Program 1991–1992, Directory, Center for the Sciences of Language 1988–1995 at the University of Rochester; Research Professor of Cognitive Science, Linguistics and Psychology, University of Arizona, 1995–present; Head, Department of Linguistics, University of Arizona 1998–2003; Phi Beta Kappa 1961, National Institutes of Health Predoctoral Fellowship 1962–1964, Harvard Society of Fellows 1964–1967; National Science Foundation Faculty Fellowship, summers 1974–1977, Guggenheim Fellowship 1976–1977, Fellow, Center for Advanced Study in the Behavioral Sciences 1984–1985; Vice-President, the Rockefeller University Chapter of the American Association of University Professors, 1969–1970; and Co-founder and Associate Editor, *Cognition*, 1973–present.

Bilingual Acquisition

Children growing up exposed to two or more languages acquire each of them in much the same way as monolinguals (speakers of just one language). Bilingual acquisition during childhood can thus be regarded as an instance of simultaneous acquisition of two 'first' languages. In fact, if children are exposed to more than two languages simultaneously, they are able to acquire full competence of each that does not substantially differ from the speaking ability of monolinguals; bilingualism is therefore a special case of multilingualism.

Comparison with monolinguals is one of the main issues in research on bilingual acquisition. It can be extended to all types of acquisition where more than one language is learned, independently of age of onset and proficiency attained in each language. The present discussion, however, is limited to child bilingualism. Whether types of bilingual acquisition should, in fact, be distinguished according to the age of onset of learning ('bilingualism' vs. 'foreign language learning') depends ultimately on the results obtained in these comparisons. Given our current state of knowledge, it is plausible to assume that age of onset is a crucial factor causing fundamental differences between child and adult language acquisition. Consequently, it is necessary to distinguish between simultaneous and successive acquisition of bilingualism. 'Simultaneous' acquisition does not necessarily imply that the child has been exposed to both languages from birth, although this interpretation has

occasionally been suggested. The controversial issue here is the age range during which changes occur, which result in qualitative differences between first and second language acquisition. Although sufficient evidence is not yet available, the period around three years of age appears to be of particular significance. The most widely accepted view is that one may qualify as 'simultaneous' those instances of bilingual acquisition where the child is exposed to two languages before the age of three. In this case, each language of the bilingual is predicted to share crucial similarities with that of the respective monolingual speakers but to exhibit differences in comparison with languages learned at a later age.

The insight that bilingual acquisition proceeds in the same way and leads to the same type of linguistic knowledge as monolingual acquisition is largely due to a number of case studies carried out in the late 1970s and 1980s, although the first monograph documenting the linguistic development of a bilingual child (Ronjat 1913) arrived at a similar conclusion. Until the 1970s, it was frequently assumed that bilinguals face serious difficulties in separating language systems and that they run the risk of ending up with mixed languages. Such views were often the result of inadequate research methodologies. Large-scale studies, frequently focusing on disfavored minority groups, failed to perform in-depth analyses of bilingual language use. Early case studies, carried out by amateurs without the appropriate training, analyzed the language use of

their own children. Some more satisfactory scholarly studies, however, arrived at similar conclusions, mainly because they adopted a monolingual perspective in their investigation of bilingualism. The resulting shortcomings were amended by later research when, beginning in the 1980s, interest in bilingual acquisition increased dramatically.

Other issues that have attracted the attention of both researchers and the interested public involve alleged problems in separating the two languages. Bilinguals tend to mix languages within a conversation or even an utterance; from a monolingual perspective, this appears to indicate an inability to keep the languages apart. It has also been suggested that bilingual children initially go through a phase during which they develop one 'hybrid' system before they are able to differentiate the lexical and grammatical systems they are acquiring. As early as the 1970s, researchers agreed almost unanimously that these children eventually succeed in separating their languages, without much effort or specific pedagogical measures, but parents and educators tended to regard the alleged single linguistic system phase as a potentially serious problem, fearing the possibility of a lasting state of incomplete competence in both languages. More sophisticated analyses of children's language mixing eventually revealed no initial single-system stage. Children have been shown to differentiate linguistic systems from very early on. Grammatical differentiation, for example, is evidenced as soon as multiword utterances are used. Thus, the available empirical evidence does not support the idea of a temporary fusion of grammatical systems, and mixing can for the most part be explained as a particular type of bilingual language use. Early grammatical differentiation, however, does not exclude the possibility of crosslinguistic influence during later developmental phases, resulting either in vocabulary or grammatical transfer or in acceleration or delay of development. The question of whether such influence actually plays a major role in bilingual acquisition continues to be controversial.

Language mixing by adult bilinguals is normally the result of code-switching, a form of language use determined by a complex network of sociolinguistic factors. Code-switching within a single clause is subject to grammatical constraints depending on the structural properties of both languages. Consequently, in order to be able to code-switch, children have to acquire the required social skills and grammatical knowledge. It has therefore been suggested that mixing during initial phases of linguistic development may not yet be adult-like code-switching. However, before the age of 2, children choose the language according to the addressee and begin to comply with

other sociolinguistic requirements. No later than during the first half of the third year, mixes within a single clause conform to grammatical constraints. Since earlier examples consist almost exclusively of single-word mixes, the role of structural constraints is difficult to assess. The frequency of mixing does not generally decrease with grammatical development, contrary to attempts to explain early mixing as resulting from deficient ability. Although not knowing a word in one language may initially lead to mixing, it is also triggered by social context. Most importantly, the language children are exposed to appears to influence their mixing behavior. Not only do children mix more frequently if the persons they interact with mix freely, but also the nature of parent's reaction to child mixing has been argued to be of crucial importance, i.e. parents signal overtly or implicitly whether they encourage or discourage language mixing.

Quantitative and qualitative characteristics of language exposure are also relevant for the question if bilinguals can attain balanced, i.e. equally developed, knowledge of both languages. One language might tend to be dominant (preferred choice, faster recall of words, etc.), but dominance can shift over the lifespan, and it does not seem to affect competence—no convincing evidence supports the idea of 'semicompetence'. Similarly, although it has been suggested that bilingual acquisition is delayed in comparison to monolingual acquisition, onset as well as development are clearly within the limits of monolingual norms, faster bilinguals outperforming slower monolinguals. In both cases, differences concern details of speaking, not qualitative differences in underlying knowledge. This confirms the hypothesis that the human language faculty predisposes the individual to become bilingual.

Bilingual Mixed Languages

It is generally believed that a language's basic vocabulary and grammatical inflections are relatively impervious to foreign influence, and that they are therefore safe diagnostic tools for determining whether given languages are related. It is also said that 'no language is so mixed that it cannot fit unambiguously into a family tree: it will always be possible to show that the bulk of a language's lexicon and grammatical structures come from the same source.' According to these claims, therefore, structurally mixed languages should not exist.

Nevertheless, mixed languages—languages that cannot be classified unequivocally—do in fact exist and are relatively common. The best-known examples are languages that arise as a direct result of language contact and that comprise linguistic material that cannot be traced back to a single source language. Such languages therefore do not belong to any language family and their genesis is not a matter of descent with modification from a single parent language. It is generally accepted that mixed languages are of three types: pidgins, creoles, and bilingual mixtures (also known as 'intertwined languages'). In pidgins and creoles, the vocabulary is usually traceable to a single language, always the language of the dominant group involved in the contact, while the grammatical structure (and often the sound system) generally cannot be traced to any single language. In bilingual mixed languages, the basic vocabulary can always be traced to a single source language and the grammatical structure (including the sound system) to another single source language. Furthermore, the linguistic material from each source language is adopted wholesale without the kind of distortion that occurs in pidgins or creoles. Also bilingual mixtures share a characteristic social feature: all of them are in-group languages used within the community as a sign of community solidarity and are not understood by outsiders, which explains why they have often remained undetected. Any type of language can be involved in bilingual mixed languages, and there are no structural constraints that prevent the 'intertwining' of any two languages, although the result may differ according to the typological properties of the languages involved.

Media Lengua, spoken in Ecuador, is an example of a bilingual mixed language. The vocabulary is of Spanish origin and the grammar stems from Quechua, a Native American language, as the following diagram for the sentence 'I come to ask a favor' shows:

Media Lengua (Ecuador): Spanish lexicon—Quechua grammar; Spanish items are in italics. Source: Muysken (1997).

ML	*Unu fabur* - ta	*pidi* - nga - bu
	ONE FAVOR - ACC	ASK - NOM - BEN

	shamu - xu - ni	
	COME - PROG - 1P	
S	Vengo para pedir un favor	
	COME 1SG FOR ASK-INF A FAVOR

Thus, Media Lengua uses the Quechua grammar as a structural grid into which the Spanish vocabulary items are inserted.

Michif, spoken in Western Canada and in North Dakota, represents a similar case. Here Cree, a Native American language, provides the structural basis for the insertion of French vocabulary.

Over a dozen Romani mixed languages are spoken by Gypsies in Europe and the Middle East. In all cases, the vocabulary is Romani and the grammar comes from the language of the host country (Basque Romani, Spanish Romani, Swedish Romani, Armenian Romani, Turkish Romani, etc.).

The process responsible for such bilingual mixtures has been called 'relexification', where the entire vocabulary or 'lexicon' is borrowed into another language. Conversely, 'regrammaticalization', the intrusion of an entire grammar onto a native lexicon, is equally possible. This seems to be true for the Romani mixed languages, since it is most likely that the language of the host country was learned while maintaining the original Romani vocabulary. This is why it is important to distinguish the linguistic process from the historical or social process of bilingual language mixtures. Linguistically speaking, it is generally the intrusion of a lexicon into a grammatical system (relexification), whereas the sociohistorical process may go either way.

Two specific circumstances for the creation of bilingual mixtures have been proposed. First, the birth of a new ethnic group comes about after a first generation with mothers who speak one language and fathers who speak another. The mixed language will have the grammatical system of the mothers' language and the vocabulary of the fathers' language. Second, a group of nomadic people settle and eventually feel the need for a secret trade language. They will tend to use the grammatical system of the host society and the lexicon of the inherited language. In each case, the language known best provides the grammar. The group creating the mixed language must be highly bilingual when the language mixing starts. Also, the resulting language is always intended as an in-group language and therefore is not intended to bridge a communication gap between speakers of different languages, in contrast to pidgins and creoles.

Bilingualism

Broadly defined, bilingualism denotes the ability to use two languages. This can involve the ability to read, write, comprehend, or speak to varying levels of fluency in each language. There is a wide degree of variation across bilingual speakers in terms of their language skills. This variation stems from the manner in which the languages were acquired, the means by which they were learned, and the frequency of their use. The age of acquisition and degree of exposure to languages will also determine the degree of bilingualism.

In most cases, bilingual speakers have one dominant language, that is, they are more proficient in one or more linguistic levels of language processing in one language than in the other. In some cases, the dominant language is also the native or first language spoken. The second language is often termed 'nondominant' or 'subordinate'. Individuals can be equally proficient in two languages and are then called 'balanced bilinguals'. When individuals learn both languages simultaneously, typically from birth, they are said to be 'compound bilinguals'. In other cases, individuals learn one language first, and a second language in a different context, such as in a different country or with a different parent. The latter bilinguals are often referred to as 'coordinate bilinguals'. When individuals learn a language in this way and the first language remains relatively intact, the term 'additive bilingualism' is used. Interestingly, an individual's second language can sometimes develop into the more dominant language and actually replace the first language learned. For example, an individual born in France who is fluent in French may travel to the United States at a very young age and remain there for many years. This individual may come to know and use English with greater fluency than their native language, French. This type of bilingualism has often been referred to as 'subtractive' and may actually involve the attrition of skills in the earlier language.

Language ability can be tied to specific topics or domains of knowledge that a bilingual possesses. For example, an individual might use Spanish at home and in conversation with friends, but English at work or for technical discussion of a specific topic. Some individuals may be native speakers of a language such as Chinese and have a strong or native-like proficiency in another language, such as English, yet perform all mathematical functions in their native language only. These speakers claim that they have more automatic processing of mathematical concepts in the language

in which they originally learned them. In this way, language use may be context-specific despite a high level of fluency in more than one language. In summary, different sociolinguistic situations may determine the language that is primarily used and the manner in which it is used.

Code-switching, or the alternating use of more than one language, is common among bilingual speakers. Individuals may either mix languages within a statement or switch at defined points such as breaks between topics. While the specific reasons for switching are not yet clearly understood, it is known that bilingual speakers often switch languages in order to facilitate communication or to express concepts that can be language-specific. In this way, code-switching serves a pragmatic or strategic function. Code-switching is a complex, rule-governed phenomenon that is guided by the particular topic, context, or circumstance regarding the communication at hand. The term 'Spanglish' has been accorded to the intermixing of the Spanish and English languages in certain areas within the United States where both languages are often spoken (e.g. Southwestern states, New York, New Jersey, Florida). Researchers view code-switching as advantageous in some situations as it helps to preserve and maintain both languages simultaneously. Others argue that the constant mixing of languages may make it difficult for individuals to know any single language with a high degree of proficiency. Nevertheless, the use of languages in an interrelated way is common among individuals who share a diverse but common language background.

It is agreed that bilingualism is much more the norm around the world than monolingualism. In Indonesia, for example, several hundred languages are in constant use. In Central Europe, the ability to speak more than one language is often typical. Moreover, it has been documented that bilingual speakers possess a certain cognitive or mental flexibility that serves as an asset in cognitive processing in general. For example, bilingual children outperform their monolingual counterparts in tasks that involve role-playing, classifying objects, creativity, concept formation, memory, metalinguistic awareness, perceptual disembedding, problem-solving, role-taking, social sensitivity, and understanding complex instructions. High-performing five- and six-year-old bilingual speakers exhibit a greater degree of divergent

thinking, imagination, grammatical awareness, and perceptual organization. Clearly, bilingual children have more than one way of labeling their environment and have an early awareness of the multiple ways in which concepts can be described and named across languages. Bilingual children simply have more examples for words and grammar to choose from than do monolinguals. Therefore, language competence often influences the range of interactive skills and capabilities that a bilingual can use.

A distinction can also be drawn between 'individual bilingualism' (the bilingual competence of a single individual) and 'societal bilingualism' (the degree to which two languages are used within a society). In some cultures and language groups, bilingualism is widely accepted and languages are almost interchangeable across contexts. In other societies, multiple languages may be used, but they may be directly linked to specific contexts or uses. Diglossia is the term used to describe two functionally different varieties of the same language that are used for specific purposes. For example, some documents may be written in a more formal or Classical Arabic that is distinct from a colloquial Arabic that is more commonly used in conversation.

Other terms that are often used to refer to bilingualism include 'polyglottism' (although 'polyglot' often refers to people who allegedly command an improbably large number of languages) and 'multilingualism'.

Biosemiotics

Biosemiotics deals with all kinds of sign-based processes in living systems. In other words, it is a theory of semiosis in living systems, or biology that interprets living systems as sign systems; or the study of biological codes; or the study of prelinguistic sign processes and signs. These definitions can be taken as (almost) synonymous. The appearance of human language does not mean the primary appearance of signs, because there are signs preceding human language. Accordingly, human language comprises a special type among the sign systems. There exists the *semiotic threshold* between living and nonliving, a natural border between the semiotic and nonsemiotic world, which means that there are no sign processes *per se* in the nonliving world, whereas life is perfused with signs, if it is not composed exclusively of signs. According to a biosemiotic view, life science and sign science are coextensive.

Altogether, there exist five distinctively different levels of sign systems.

(1) *Cellular sign systems*. This is the sign system of any bacterial (and eukaryotic) cell. Its characteristic processes are enzymatic recognition and transmembrane signaling. Its inheritance system combines the epigenetic and genetic, the latter being dominant. It is characterized by microsemiosis. According to Yates (1997:458), microsemiosis 'does not address communication between cells or among cell complexes'. In a cell, true *codes* appear. The codes, as different from other relationships, are the relationships that are not deducible from universal physical laws because they connect independent domains and are fixed due to a unique historical process (Barbieri 2001). Codes as part of any single semiosis turn the web-like set of cellular processes into a meaning-generating interpretation-like process—this is biointerpretation, or biosemiosis.

(2) *Vegetative sign systems*. This includes the communication between the tissues in a multicellular organism. Because the cells of an organism are genetically identical, the differences between the cell types of an organism are based on another inheritance system—the epigenetic one. Vegetative sign systems are responsible for the genesis of a multicellular biological form, the whole morphology of the body as a result of communication between cells (Kull 2000). Morphogenesis and cell differentiation are its typical representatives. In this sense, vegetative sign systems are not confined to plants—they occur in all multicellular organisms. Due to them, organic forms are communicative structures. Vegetative sign systems provide categorization without representation.

(3) *Animal sign systems*. This is the senso-neuro-muscular system, the one that is responsible for the behavior of a motile animal organism. The basic inheritance system here is neuro-humoral (or behavioral). Its characteristic feature is the existence of representations, and thus—Umwelt, the model of the organism's world. Animal sign systems represent the primary modeling systems (according to Sebeok 1994) and are studied by zoosemiotics.

(4) *Linguistic sign systems*. This corresponds to the secondary modeling system (natural language), according to Sebeok (1994) (or primary modeling systems, by Lotman). Different from the animal sign system, it has syntactic signs (Bickerton 1990), i.e. the signs that are used to refer to a type of relation between signs (e.g., a human 'and'—a sign which other animals lack), and is principally symbolic (Deacon 1997). Its characteristic feature is the existence of sentences and thus symbolic language.

(5) *Cultural sign systems*. This corresponds to the tertiary modeling systems, according to Sebeok (or secondary modeling systems, according to Lotman). Their characteristic features include the existence of artistic, ideological, ethical, and similar structures.

When characterizing the semiotic aspects of behavior and communication of different groups of animals (e.g., insects, birds, mammals), it is important to pay attention to (1) the general features of the body plan and sensory apparatus of the animals, and the functional place of the animal group in ecosystems, (2) the main ways and means of active communication, and (3) the main trends in the evolution of communication in the group.

Because nonhuman communication does not use sentences, that is, it is nonpropositional, the entire emphasis of the study in biosemiotics appears to be very different from the one in linguistic sciences. However, biosemiotic knowledge is important for linguistics due to its results in the analysis of more fundamental and general communication phenomena. For instance, the general mechanism of categorization, as known in phonemics, has been shown to be analogous to the mechanisms of speciation in biparental organisms.

A pioneering approach to biosemiotics has been established by the studies of a biologist and philosopher Jakov von Uexküll (1928, 1982, 1992). In the framework of semiotics, biosemiotics has been developed basically together with a turn from a Saussurean dyadic to Peircean triadic concept of sign (Deely 2001) and with a development of concept of semiosphere as a web of all kind of (including interspecific) communication processes. A key concept in it is an analog-digital duality of all organic meaning-generating processes (Hoffmeyer, Emmeche 1991). Since 1990s, biosemiotics has established as a university discipline (Sebeok, Umiker-Sebeok 1992, Kull 2000, Sebeok 2001, Schult 2004).

Bloomfield, Leonard

Leonard Bloomfield may be considered the father of modern American linguistics. His masterwork on general linguistics, *Language* (1933), determined the direction the scientific study of language in the United States would take for the next three decades. A prolific scholar, Leonard Bloomfield's publications cover an impressive spectrum: general linguistics, Indo-European and Germanic philology, dialect geography, linguistic descriptions of the Algonquian American-Indian languages Menomini, Cree, Fox, and Ojibwa, and the Austronesian languages Tagalog and Illocano. Bloomfield's work spawned a generation of American scholars, the neo-Bloomfieldians, who dominated the field of linguistics before Noam Chomsky's theory of transformational grammar became widely accepted in the early 1960s: Bernard Bloch, Robert A. Hall Jr., Zellig Harris, Einar Haugen, Charles F. Hockett, Martin Joos, William Moulton, Eugene Nida, and W. Freeman Twadell, to name but a few.

An adherent of positivism and behaviorist psychology, Bloomfield rejected mentalism, which takes into account nonphysical and hence nonobservable thought processes, insisting that only observable manifestations of language could be the subject of linguistic investigation. He defined the meaning of a linguistic form as the situation in which the speaker utters it and the response that it calls forth in the hearer. The strong rejection of the mentalist approach to the study of meaning became a defining characteristic of Bloomfieldian linguistics and its weakest point, as Noam Chomsky would point out several decades later. A strong believer in the scientific method, Bloomfield argued that language should be studied like a natural science. In *A Set of Postulates for the Science of Language* (1925), he outlined the assumptions underlying structural linguistics in a concise and compressed form.

As a historian of language, Bloomfield studied his subject from the diachronic perspective; as a descriptive structural linguist, he concentrated on the synchronic perspective. A diachronic approach traces the changes a language undergoes from a given point in time to a later date; a synchronic approach describes a language at one particular time. This distinction had not been made by earlier generations of scholars, and Bloomfield, like the French structuralist Ferdinand the Saussure, insisted that both perspectives be kept strictly separate. The classic diachronic approach to linguistic analysis, the comparative method, was pioneered by the *neogrammarians*, a group of nineteenth-century German scholars who established the genetic relationship among Indo-European languages. Cognates (shared vocabulary) are compared to establish the sound changes marking the transition from a common hypothetical ancestor to one or more daughter languages. A comparison of the median consonants in Old English */brothor/,* Old Saxon */brothar/,* and Old High German */bruoder/,* for example, would have led scholars to the conclusion that */th/* was present in proto-Germanic, the shared ancestral language, but changed to */d/* in Old High German. The comparative method rests on the assumption that sound change affects a language without exception and is therefore regular, never occurring sporadically in just a few words. Using the neo-grammarian principle as a working hypothesis, Bloomfield applied the comparative method to Cree, Fox, Menomini, and Ojibwa, languages some European scholars of the time might have considered primitive compared to Sanskrit, Gothic, Latin, or Greek, and proved that they were descended from a common ancestor, proto-Algonquian. In spite of criticism, especially from abroad, Bloomfield remained a confirmed neo-grammarian throughout his career.

Bloomfield's masterwork *Language* introduced innovative methods for descriptive synchronic linguistics and a new terminology soon to be adopted by his American colleagues. The first half of the book is a state-of-the-art presentation of the methods and principles of American structuralism; the second presents the findings of European historical linguists and dialectologists supplemented with Bloomfield's own research materials. He introduces the American reader to the phonemic principle established by the Prague School of Linguistics. Phonemics is the study of the distinctive sounds of a language, those that are recognized by the native speaker as signaling differences in meaning. The initial consonants of *pin, kin, sin, tin* are phonemes of English since their substitution results in a change of meaning. The different articulations of the phoneme */p/* in *pit* (aspirated), *spit* (unaspirated), and *tip* (unreleased), on the other hand, are phonetic variants of the same phoneme, which can never serve to distinguish meaning since their phonetic shape depends on their position in the word. The phonemic principle was the basis for all work in descriptive synchronic linguistics by Bloomfield and his disciples. In *Language,* the synchronic phonemic principle is, for the first time, equated with the diachronic neo-grammarian principle of the

regularity of sound change. American reviewers of *Language* were generally enthusiastic, whereas European scholars tended to be more critical citing the lack of abstract theory, rejection of mentalism, new terminology (sememe, taxeme, glosseme, etc.), and Bloomfield's defense of the neo-grammarian principle. One reviewer considered the work to be typically American: data-oriented, dryly factual, but carefully and systematically executed. In the United States, *Language* became the preferred textbook in introductory linguistics courses for the next quarter of a century following publication. It should be recommended reading for graduate students in linguistics interested in the history of their discipline.

Bloomfield began working with non-European languages early in his career. *Tagalog Texts with Grammatic Analysis* (1917) filled a void in a much neglected field. Based on the data provided by a single informant who dictated texts, it is still considered to be one of the best sources of information on any Austronesian language. While the Algonquian languages had been studied systematically for three centuries, Bloomfield's contribution was the systematic synchronic description of four languages, Cree, Fox, Menomini, and Ojibwa, and the application of the diachronic comparative method to the reconstruction of the hypothetical ancestor, proto-Algonquian. Bloomfield provided a grammatical outline of each of the four living languages as well as of proto-Algonquian, and traced the historic development of each language, thus demonstrating the validity of the comparative method in the process. He also produced the first systematic description of the Algonquian morphology (the study of inflection and word formation), and thereby established the framework for all later studies on the subject. Bloomfield's field methods and methods of linguistic analysis have stood the test of time, and are still used by modern scholars recording unwritten languages or dialects. The bulk of his Algonquian material was published posthumously by Charles F. Hockett, his literary executor.

During World WarII, Bloomfield, like many of his colleagues and students, devoted much of his time to the development of a new foreign language teaching methodology for the War Department. The audiolingual method focused on the spoken, colloquial form of the language rather than the literary standard and introduced practice sessions where the material was transmitted to the learner on the basis of inductive, behaviorist learning principles (oral repetition and memorization). By the 1960s, it had become the almost universally accepted foreign language teaching methodology in the United States and to some extent in Europe. Bloomfield authored and coauthored text books for elementary Dutch and Russian (1944/1945).

Bloomfieldian structuralism with its focus on phonemics and morphology remained the dominant approach to linguistic analysis until the publication of Noam Chomsky's treatises on transformational generative grammar in the late 1950s and early 1960s. After several decades of relative obscurity, Bloomfield's contribution to the field of linguistics is once again appreciated. Leonard Bloomfield suffered a debilitating stroke in 1946, which abruptly terminated his brilliant career and led to his death three years later.

Biography

Leonard Bloomfield was born on April 1, 1887 in Chicago, IL. The son of Austrian immigrants and the nephew of Maurice Bloomfield, a noted scholar of Indo-European philology and Indic studies, Leonard Bloomfield grew up in Chicago and rural Wisconsin.

Fluent in both English and German, he quite naturally gravitated toward the study of Germanic and Indo-European philology. After completing his undergraduate degree at Harvard in 1906, he began graduate studies in German at the University of Wisconsin (1906–1908) and then transferred to the University of Chicago where he received his Ph.D. degree in 1909 with a thesis in historical Germanic linguistics ('A semasiological differentiation in Germanic secondary Ablaut'). After several years of working as an instructor of German at the Universities of Cincinnati (1909) and Illinois Champaign-Urbana (1910–1913), he spent a year, between 1913 and 1914, of advanced study in Indo-European and Germanic philology at the German Universities of Leipzig and Göttingen, where he worked with Karl Brugner, August Leskien, and Jakob Wackernagel, some of the most highly regarded historical linguists of the time. By 1914, he was Assistant Professor of comparative philology and German at the University of Illinois. For the rest of his career, Bloomfield remained an adherent of their particular view of language change. One of the founding members of the *Linguistic Society of America* (1924) with George M. Bolling and Edgar H. Sturtevant, Bloomfield held the chair of Germanic Philology at the University of Chicago from 1927 until 1940 when he accepted a Sterling professorship in Germanic Languages at Yale University. He became president of the *Linguistic Society of America* in 1936. Bloomfield suffered a debilitating stroke in May 1946, which ended his career. He died on April 18, 1949.

RENATE BORN

Boas, Franz

Central to Franz Boas' anthropology, with its subfields of prehistoric archeology, physical anthropology, ethnology, and linguistics, was the idea of culture as a symbolic system or construct of the mind. Accordingly, Boas focused on ethnology and linguistics while he paid less attention to prehistoric archeology and physical anthropology. Language had a special place in Boas' work because it represented the prime example of a human symbolic system and was the best means for classifying the indigenous cultures of North America. Boas was primarily interested in the Native languages of the American Northwest. While he was concerned with the genetic classification of native languages, the main thrust of his work was directed toward investigating categorization in languages and establishing a typology of the inner forms or systems of unconscious grammatical categories of Native American languages.

His early fieldwork for the British Association for the Advancement of Science under the supervision of Horatio Hale (1817–1896) led to grammatical sketches, vocabularies, and linguistic maps of the languages of British Columbia. Boas' lexical and grammatical data of Nootka and Kwakiutl allowed him to unite the two languages as the Wakashan family (1890, 1891a, b). Based on grammatical evidence only, he also made the controversial proposal that Tlingit and Haida were related (1894). Boas' lifelong preoccupation with the languages of this region resulted in grammars of Tsimshian, Chinook (1911a), Tlingit (1917a), and Kwakiutl (1911a, 1947), and collections of native language texts. Boas further noted that some linguistic characteristics were distributed geographically among these languages, an observation that would eventually lead to the establishment of areal-typological studies.

Boas' ideas on linguistic categorization were rooted in nineteenth century German acoustics, psychophysics, and psychology. His exposure to so-called 'alternating sounds', speech sounds that were seemingly vague, during his fieldwork in British Columbia was the reason for a seminal paper, arguing that the vagueness of these sounds was a result of different categorizations of speech sounds in distinct languages and of their varying apperception by speakers of other languages (1889). Eventually, Boas was to argue that linguistic categorization, in general, was the outcome of grouping experiences into classes according to their similarity; however, the criteria underlying the similarity and class membership of experiences were not the same in all languages. In English, for example, the existence of the words *to grip*, *to kick*, *to pound*, and *to bite* indicated that the different activities they designated were classified as separate concepts. By contrast, in Dakota the form *xtaka* 'to grip', which was present in the terms *naxta'ka* 'to kick', *boxta'ka* 'to pound', and *yaxta'ka* 'to bite' suggested that the same activities

were classed under one concept only (1911a). Because linguistic categories did not rise to the level of consciousness, they provided a unique view on the mental processes of abstraction and association.

Influenced by the work of Heyman Steinthal (1823–1899), Boas suggested that the inner forms of languages molded their speakers' thoughts. The unconscious nature of these obligatory categories resulted in their projection onto reality and their objectification. Late in life Boas conceded, however, that although thought was 'directed in various channels' by grammatical categories, their influence was not to be overrated (1942:183). His linguistic relativism was further counterbalanced by the observation that all languages possessed the pronouns *I*, *thou*, and *he* and by his recognition of universal functional relations, such as subject–predicate, noun–attribute, and verb–adverb (1901, 1838). Boas' views suggest that he considered the universal occurrence of these pronouns and functional relations as examples of what Adolf Bastian (1826–1905) had termed *Elementargedanken*, elementary ideas that necessarily occurred everywhere because of the constitution of the human mind. Nevertheless, these ideas were not identical in different contexts but were shaped by different psychological factors and environmental circumstances. One important task of anthropology was the identification of these ideas.

Like Steinthal, Boas therefore objected to the use of grammatical categories derived from Indo-European languages in describing Native American languages. Such a practice distorted the nature of these languages and covered up their 'characteristic psychological categories' (1917b:5–6). Only analytical grammars, which treated languages on their own terms, were acceptable; only they would provide access to the inner form and 'psychological groupings' of a language (1911a:81). These grammars formed the basis for tracing the 'the history of the mental development of various branches of mankind' and for identifying grammatical concepts shared by the languages of the world, albeit in modified form (1911a:71).

The *Handbook of American Indian Languages* (1911–1941) was a monument to Boas' ideas and scholarship. He not only edited the four volumes comprising the *Handbook* but also contributed extensively to the first volume (1911a). Boas wrote the introduction and the grammars of Tsimshian, Kwakiutl, and Chinook and coauthored the grammar of Siouan (Boas and Swanton 1911). His introduction outlined his ideas on language and discussed its place within his anthropological framework. He showed that there was no necessary correlation between culture, language, and race, but that the three were independent of each other. Boas highlighted at length the process of cate-

gorization responsible for producing distinct phonetic, grammatical, and lexical systems characterizing different languages. The *Handbook* grammars were to illustrate the 'psychological principles' underlying Native American languages and to form the basis for establishing a typology of inner forms (1911:v). Boas provided an overview of the grammatical characteristics of Native American Languages and the principles of language classification and reduced John W. Powell's (1834–1902) 58 Native American language families to 55.

Early in his career, Boas (1894) had given more weight to grammatical similarities in determining relationships between languages. When he wrote his introduction to the *Handbook* (1911a), he had moved to a more balanced position that equally stressed phonetic, lexical, and grammatical similarities in classifying languages into families. Simultaneously, Boas increasingly emphasized an alternative to the common origin of seemingly related languages: multiple origins resulting from borrowing of linguistic elements and language mixture (1911a, 1917, 1920, 1929). Boas' late papers on the influence of Spanish on Nahuatl (1930) and of English on Kwakiutl (1932) documented instances of lexical and morphological intermixture between languages.

Biography

Franz Boas was born in Minden, Westfalia, Germany on July 9, 1858. He received a doctorate (1881) from the University of Kiel, Germany for his dissertation on the perception of the color of water. He undertook an expedition to Baffin Island in 1883–1884; habilitation (1886): Berlin University, Germany with a thesis on the geographical results of his Baffin Island trip. He moved to the United States in 1886, and became a US citizen in 1891. He was geographical editor of *Science* in 1887–1888. He carried out intermittent fieldwork for the British Association for the Advancement of Science (BAAS) in British Columbia in 1888–1894. He held a docentship in physical anthropology, Clark University in 1889–1892. He was assistant to F. W. Putnam, Head of the Department of Ethnology and Archaeology at the World Columbian Expedition in 1893–1894. He was assistant curator, American Museum of Natural History in 1895–1905. In the field, he was a member of the Jesup Expedition in 1897, and 1900. He began lecturing at Columbia University in 1896, and received full Professorship in 1899–1936. He was a member of the editorial board and publication committee of the *American Anthropologist*, in 1899–1920; editor of the *Publications of the Jesup North Pacific Expedition*, in 1900–1930; editor of *Journal of American Folklore* in

1908–1925; founder and editor of the *International Journal of American Linguistics* in 1917–1939; editor of the *Columbia University Contributions to Anthropology* in 1913–1936; and editor of the *Handbook of American Indian Languages* in 1911–1941. He was Vice-President of Section H. of the American Association for the Advancement of Science (AAAS) in 1894; President of the American Folklore Society in 1900–1901; Honorary Philologist, Bureau of American Ethnology in 1901–1920; President of the American Anthropological Association in 1907 and 1908; Vice-President and Chairman of Section H. of the AAAS in 1909; President of the 23rd International Congress of Americanists in 1928; President of the Linguistic Society of America (LSA) in 1928–1929; Chairman of the Committee of the American Council of Learned Societies on Research in American Indian Languages; Honorary President of the 24th International Congress of Americanists in 1930; and President of the American Association for the Advancement of Science in 1931. Franz Boas died in New York, NY, USA on December 21, 1942.

Bopp, Franz

Franz Bopp was one of the founders of nineteenth-century comparative philology. He is often given credit for establishing historical linguistics as a serious area of scientific study. He was in a group of pioneering German scholars (such as the brothers August Wilhelm and Friedrich von Schlegel and Wilhelm von Humboldt) that started their study of Sanskrit and Indo-European at the University of Paris and, later on, made it a German monopoly.

Bopp's chief activity centered on the study of the languages of the East. His knowledge of the literature written in Sanskrit and the language itself was truly expert. Bopp was keenly interested in the great Indian epics. He published several episodes from the MahâBhârata, both in Sanskrit and in translated form. He also compiled a Sanskrit and Latin glossary. Many European researchers (e.g. William Carey or Henry Thomas Colebrooke) had already proposed their own grammars of Sanskrit, based on the Indian tradition that stretched back to Panini. Such grammars were obscure and unhelpful from the point of view of scholars who were used to the Western model of paradigms. In his very influential Sanskrit grammar, Bopp abandoned much of the original apparatus of the Indian system of grammatical description. Instead, he adopted the European framework that was grounded in the traditional analyses of Greek and Latin.

Bopp's Sanskrit studies were especially important as the requisite stimulus for great developments in the field of comparative grammar. Bopp traced many similarities between Sanskrit and its Western cognate languages, both in terms of lexical items (roots) and on the syntactic level. He denied the importance of surface differences between grammars, claiming that they do not matter as long as it is possible to reconstruct the way languages have developed from the common source. Therefore, one of his prime objectives was to investigate the oldest accessible form of a given language.

Bopp wrote many monographs on individual languages (e.g. Celtic, Old Prussian, and Albanian) and on languages outside the Indo-European family (e.g. a paper on the relationship between Indo-European and Malayo-Polynesian). His investigation and systematic comparison of a number of languages was a tremendous refinement of descriptive techniques used by linguists at that time.

In his most important work, *Vergleichende Grammatik des Sanskrit, Zend, Griechischen, Lateinischen, Litauischen, Altslavischen, Gothischen und Deutschen* (1833–1852 ; *A Comparative Grammar of the Sanskrit, Zend, Greek, Latin, Lithuanian, Gothic, German, and Slavonic Languages*), Bopp discussed and established relationships between the Indo-European languages. In principle, a resemblance between related languages could be explained in two ways: either by claiming that one of them is derived from the other or by assuming that both are derived from another language. Contrary to many of his contemporaries, Bopp did not regard languages such as Greek or Latin as derived from Sanskrit. He describes Indo-European languages as variations of one original language. However, Sanskrit has preserved more features of the common source than other cognate languages.

Since the publication of his first major work *Über das Conjugationssystem der Sanskritsprache in Vergleichung mit jenem der griechischen, lateinischen, persischen und germanischen Sprache* (1816; On the System of Conjugation in Sanskrit, compared with the Greek, Latin, Persian, and German Languages), Bopp's main interest was focused on detecting the common origin of Indo-European inflections. Primarily, he applied his analysis only to the verb. However, while in London, he published a very influential essay in the Annals of

Oriental Literature (entitled *Analytical comparison of the Sanskrit, Greek, Latin and Teutonic languages, shewing the original identity of their grammatical structure*), in which he included analysis of nonverbal inflection. This essay received considerable public attention, which resulted in Bopp's appointment to the newly established chair of Oriental Literature and General Philology at the University of Berlin in 1821 (an additional factor was Bopp's friendship with Wilhelm von Humboldt, who was at that time the Prussian Minister of Worship and Public Instruction).

Rejecting Friedrich Schlegel's ideas, Bopp advocated an agglutinative theory of the origin of morphological structure. He assumed that grammatical modifications can be expressed only by external additions to the root (i.e. by means of agglutination of separate lexical items which become suffixes). According to Bopp, what Schlegel understood as 'internal' inflexion (a change of root vowels or reduplication) is an example of redundancy in Indo-European—it does not indicate any modification of meaning. Phenomena such as apophony cannot be semantically relevant since they are not separate elements. Bopp analyzed roots as the primitive (monosyllabic) elements of words that can be identified through examination of forms that contain them as a common base. There are two types of roots: verbal (predicative) and pronominal (indicative). A root must be considered to be an abstract entity, which means it does not have to be itself equivalent to any existing word.

Bopp distinguished those aspects of languages that can be formally described from those that are arbitrary. The former comprise what he called 'mechanical' (i.e. phonetic) laws and the origin of the forms indicating grammatical relationships (morphology). On the other hand, in his *Vergleichende Grammatik*, Bopp refers to the relationship between form and meaning as the 'secret of roots'—i.e. he notices that it is impossible to say why a given root means what it means, e.g. why the Indo-European root STHA/STA means 'stand' and not 'go'.

Nineteenth century philologists tended to use biological terminology in describing the way that languages work. Being influenced by contemporary developments of comparative anatomy, they viewed languages as changing and organic. It could be said that Bopp was no exception. He also tried to dissect and classify languages like living organisms. However, he examined them as static entities; the historical process of change did not interest him as much as the structure that resulted from it.

Bopp devoted his life to laborious, quiet study in libraries, remaining aloof from any political or social events. He was a zealous researcher, very cautious and careful, constantly maturing and correcting his works (many of them were reissued with important improvements). He wanted his conclusions to be as objective and nonspeculative as possible. Therefore, he was (and is) sometimes called 'the factual Bopp'.

Biography

Franz Bopp was born in Mainz, Germany on September 14, 1791. He attended lectures in law, logic, esthetics, history, and philosophy at the Aschaffenburg Ecole du Droit, Bavaria, Germany. He moved to Paris, France, to study Sanskrit (together with August Wilhelm von Schlegel and Wilhelm von Humboldt, tutored by Antoine Léonard de Chézy) in 1812–1817, resided in London, England in 1817, and continued his studies in Göttingen, Germany in 1818–1821. He was Extraordinary Professor of Oriental Literature and General Philology, University of Berlin, Germany in 1821 and Ordinary Professor of Oriental Literature and General Philology, University of Berlin, Germany in 1825 (he held this post till death). He was also a member of the Royal Prussian Academy in 1822 and honorary member of the Philological Society. Bopp died in Berlin on October 23, 1867.

Brain Organization and Auditory Pathway

Three major functions of the brain are the integration of sensory input, behavior in general, and coordination of body functions. The development of the brain depends upon both the multicellular structure of creatures and the necessity to control complex behavior of highly developed organisms. Before multicellular organisms evolved, a unicellular organism (Protozoa) already represented an omnipotent life form, which performed e.g. movement, ingestion, and orientation with merely one cell. After the evolutionary emergence of multicellular organisms (Metazoa), certain cells of these organisms adapted functionally and became e.g. secretory, supporting, sensory, or muscle cells. As a result, during this developmental stage an increasing number of specialized body cells had to coordinate with each other; hence, a communication network became necessary.

Communication took place by an additional specialized cell type—the nerve cell. Starting from the stage of simple nerve nets (e.g. in jellyfish), the evolution of nervous systems in animals led to small groups of nerve cells (ganglia), peripheral nervous systems, and central nervous systems (brains). The human central nervous system represents the most complex integration/coordination system: it comprises about 100 billion (10^{11}) nerve cells, each connected, on average, to about 1,000 others. During the nine months of pregnancy, the brain of a human fetus has to grow on average by 250,000 new nerve cells per minute in order to reach its final dimension (on average 1,400 gram). However, after birth the brain mainly controls the basic body functions. The adult brain is not only involved in the coordination of organs, body functions, or parts but also in integrating sensory input, learning, adaptive behavior, and cognition. To reach its full functional state, the newborn's brain has to 'mature' for some additional months, during which period the neural networks for higher sensory and basic cognitive processes have to establish themselves. Beginning already in the uterus, where the unborn child learns parts of the mother's phoneme set, the child's brain needs about two additional years to produce language after birth. This shows the spectrum of the different brain capabilities from controlling body functions to cognitive processes. From an evolutionary point of view, the brain consists of three overlaying brain parts: (1) the approximately 250-million-year-old 'reptile brain', performing coordination of body functions and simple sensory integration, (2) the 'older mammalian brain' performing e.g. complex integration of sensory input and emotions, and (3) the 'only' 50-million-year-old 'young mammalian brain' (neocortex), the neuronal substrate for higher cognitive processes. Even though these brain parts form a functional unit and act as a single organ, these three phylogenetic stages can be assigned to different levels of cognitive performance. Language corresponds to the most developed cognitive process and is only developed in humans.

Due to its importance, the human central nervous system, which consists of the brain and the spinal cord, is protected by three membranous coverings (meninges) and by bony capsules (cranium, backbone). Three main parts of the brain are shown in a side view (see Figure 1): the brain stem (B), the cerebellum (C), and the left cerebral hemisphere (H). The two cerebral hemispheres represent 85% of the brain's weight and are surrounded by the 1.3 to 4.5 mm thick cerebral cortex. The cortex
Figure 1. Brain Organization and Auditory Pathway.

consists of specially organized nerve and glial cells and is compactly folded, which causes its surface enlargement, although the volume remains unchanged. The cortex shows an abundant structure of ridges (gyri) and valleys (sulci) and represents the main neuronal structure for higher cognitive processes. Each hemisphere is divided into four lobes: the frontal, the temporal, the parietal, and the occipital lobe. Anatomically, the brain is divided into five parts, which are shown in Figure 1: the myelencephalon (medulla oblongata), the metencephalon (pons, cerebellum), the mesencephalon, the diencephalon, and the telencephalon (cerebral hemispheres). A major structure for transferring information between both hemispheres is the corpus callosum, a broad nerve tract that also belongs to the telencephalon.

One of the brain's major function lies in the integration of sensory information from the auditory channel. For primates, the auditory input can be seen as the most important input from the environment. Like every other audible sound, language is perceived by the ears and transferred to certain cortical regions across the so-called auditory pathway. The auditory pathway lead from the nerve fibers of the cochlear branch of the VIII cranial nerve (vestibulocochlear nerve) via the primary auditory nuclei of the medulla, to several neural centers of the brain stem, up to the primary and the secondary auditory cortex. Most of the structures analyzing the auditory signal are located in the brain stem, which comprises the medulla, the pons, and the mesencephalon. Since the internal ear lies close to the brain stem, the auditory nerve is only about 5 mm away from

the medulla, near the inferior border of the pons, into which the nerve inserts (see Figure 1).

At first, the sound signal is gathered and filtered by the external ear. After mechanical amplification in the middle ear, the signal is transduced into an electrical signal by sensory cells (organ of Corti) in the inner ear. The organ of Corti of each ear contains about 3,500 inner hair cells and about 12,000 outer hair cells, which are innervated by 30–40,000 fibers of the cochlear branch of the VIII cranial nerve (auditory nerve). About 90% of the fibers are connected to inner hair cells, and these mainly contribute to the information on sound signals for subsequent analysis in the brain. The analysis of the sound signal starts already in the cochlea, e.g. by separating the signal into the frequency domain (frequency dispersion), which will not be discussed here in detail. The major part of the analysis (feature detection) is carried out during the next stations of the projection to the auditory cortices. The detailed function of the auditory cortex is still not understood—however, it is the final place of sound recognition, especially for speech analysis (e.g. phoneme detection). Starting at the cochlea, at each level of the auditory pathway, the neurons are arranged in a well-ordered map that reflects the frequencies of the stimuli (tonotopic organization). Consequently, neurons responsive to low and high frequencies are located at a maximum distance from each other.

While each hemisphere receives sensory input and controls motor movement of the opposite (contralateral) side of the body, the information of each ear goes

to both hemispheres, whereby the majority crosses to the contralateral side. First, all afferent fibers of the auditory nerve terminate in the ipsilateral cochlear nucleus, whereas during projection a major part of the afferences change to the contralateral side of the brain (indicated by line thickness in Figure 2). Due to this crossing of fibers at several stations and the presence of decreasing fibers and parallel processing, the audi-

tory system exhibits increased stability against damage to lower neural structures. The next station of the pathway, the superior olivary complex, already receives bilateral input from both cochlear nuclei. The main processing stations in the superior olivary complex are the medial superior olive, the lateral superior olive, and the medial nucleus of the trapezoid body. The next major station of the auditory pathway is the

Figure 2. Brain Organization and Auditory Pathway.

lateral lemniscus, which is divided into a ventral and a dorsal nucleus. The following two major stations are the inferior colliculus and the medial geniculate body. The primary auditory cortex, which is identical to Brodmans area 41, comprises only a small area of the superior surface of the superior temporal gyrus (Heschl's gyrus) and is the principal target of all ascending auditory pathways (see Figure 2).

In most people, the left hemisphere plays a more important role than the right hemisphere with regard to language processing. Due to the multiple crossing of the signals of each ear, damage in the lower auditory nucleus of one hemisphere does not lead to a unilateral, complete loss of acoustic processing, but results in a bilateral decreased hearing ability. However, substantial left hemispheric brain lesions of language-related cortical areas do not reduce the hearing ability, but only lead to language-specific impairments (see chapters 'Lateralization and Handedness' and 'Aphasia').

Bresnan, Joan

Few students enter Joan Bresnan's classes in syntactic theory and leave without being fascinated about the subject matter of syntax. She is one of the most influential teachers and researchers in the field of syntax in the late twentieth and early twenty-first centuries. Joan Bresnan entered graduate school at the time when transformational approaches to syntax, as developed mainly by her teacher at MIT, Noam Chomsky, constituted the dominant paradigm. Transformational approaches to the analysis of syntactic representation often take one level of representation as the basic point of departure and attempts are then made to derive other levels of representation from this basic level through a series of transformational operations, summarized as move alpha. The most classical example is the passive transformation whereby a passive sentence in a language is derived by applying a passive rule on an active sentence. However, confronted with a lot more natural language data from languages with structures very different from those of the known European languages like English and French, it became clear that other approaches to the analysis of syntax were necessary to address the problems of the transformational approach.

It was at this point that Joan Bresnan drew attention to the role of the lexicon in syntactic analysis. The lexicon in early days of transformational grammar played only a derivative role in syntactic analysis as it was regarded as having too many lexical idiosyncracies in a framework that stressed the role of transformational rules. With evidence from various languages, such as Chichewa and other Bantu languages, native Australian languages, and native American languages, Joan Bresnan demonstrated the important role that lexical information ought to play in syntactic theory. This led to her first major revolution in syntatic theory: the development of the idea of Lexical-Functional Grammar (LFG), and then making it one of the most influential linguistic theories/frameworks of our time. Joan Bresnan developed LFG with Ronald Kaplan in the late 1970s and early 1980s. The term 'Lexical-Functional Grammar' first appeared in Bresnan's edited volume in 1982, *The mental representation of*

grammatical relations. It is a nontransformational and nonderivational approach to the representation of grammatical information. It is lexically oriented and assumes the basic idea that different dimensions of grammatical information can be represented as separate but parallel structures. Grammatical information is represented in LFG in three main structures: the Constituent Structure, where precedence and dominance relations are indicated, the Functional Structure, where grammatical functions such as SUBJECT and OBJECT are indicated, and the Argument Structure, where grammatical roles such as AGENT and THEME are expressed. These levels interact through a system of mapping or correspondence rules.

Joan Bresnan's second major revolutionary contribution to syntactic theory came with the rise of Optimality Theory (OT) in the early 1990s. In this theory of grammar, Universal Grammar is characterized as a set of constraint interactions, with the basic hypothesis that there is a set of universal constraints. Languages satisfy these constraints differently and differences in languages will result from this fact. This approach to grammar is potentially compatible with many theories of grammar that assume an input from which a set of candidate outputs are generated. It was at this point that Joan Bresnan came up with the idea of marrying the basic tenets of OT with those of LFG to form the notion of OT-LFG or what she termed 'Optimal Syntax'. In Optimal Syntax, the universal input is assumed to be modeled by an abstract set of functional structures representing morphosyntactic content in a language-independent format. The universal candidate set in Optimal Syntax should consist of pairs of constituent structures and their corresponding functional structures, which are then matched to the input functional structure through a set of correspondence principles and constraints that decide the optimal candidate from the set of candidates. Optimal Syntax or OT-LFG is one of the most exciting approaches to grammatical studies in the early part of the twenty-first century and this is being led by Joan Bresnan.

In addition to these major contributions in syntactic theory, Joan Bresnan, with her students and colleagues, has also made profound contributions to the description and analysis of particular languages and language groups, including Bantu languages such as Chichewa, and Australian aboriginal languages such as Warlpiri.

Biography

Joan Bresnan was born in Chicago, Illinois, on August 22, 1945. She received a B.A. degree in Philosophy at Reed College in 1966. She completed a Ph.D. on the theory of complementation in English under the supervision of Noam Chomsky at MIT in 1972. From 1972 to 1973, she was Assistant Professor of Linguistics and Philosophy at Stanford University. In 1973, she moved to the University of Massachusetts at Amherst and served as Assistant Professor from that time until 1975. Between 1979 and 1983, she was full Professor at MIT. Joan Bresnan moved back to Stanford University in 1983 as Professor of Linguistics and has remained there to date. Professor Bresnan held a Howard H. and Jessie T. Watkins University Professorship between 1992 and 1997, and in 2000 she was named Sadie Dernham Patek Professor in Humanities. Joan Bresnan has received many awards and fellowships, and is a member of many societies and boards. She was a Guggenheim Fellow from 1975 to 1976, a Fellow at the Center for Advanced Study in the Behavioral Sciences, Stanford University from 1982 to 1983, and a principal investigator of many projects financed by National Science Foundation Grants. She is a member of the editorial boards of many journals and publishing houses such as Cambridge University Press, Linguistic Inquiry, and the Journal of Japanese Linguistics. She is a past member of the Executive Committee of the International Lexical-Functional Grammar Association, and Past President of the Linguistic Society of America.

British Sign Language

British Sign Language (BSL) is the language of the British Deaf community, with its associated social and cultural organizations. There are no accurate figures of the number of users of BSL, but estimates range between 30,000 and 60,000 deaf signers. Hearing children of signing deaf parents may also be included. The number of signers who are not members of the community has increased enormously over the past 15 years, through the widespread uptake of further education classes in BSL. In addition to signers in Britain, BSL is also used by some signers in Ireland, and it is taught as a foreign language to deaf school children in Norway and Russia.

Historical Records of BSL

BSL has no written form. Consequently, historical records of the language are rare. Of the few early recorded references to sign language use in Britain, most are in the form of descriptions in English by hearing writers. We do know that deaf people have been using some form of signing in Britain since at least the sixteenth century. A description of the signs used by a deaf man to make his marriage vows in 1575 is recorded in the parish records of St. Martin's in Leicester. From the mid-seventeeth century onwards, books such as those by Bulwer (1644, 1648) were published, which included drawings of signs and lexical and grammatical descriptions of BSL.

Also, in the mid-seventeenth century, the first manual alphabets appeared. These provide a means of reproducing the orthography of the written language using various configurations of the hands and fingers. Fingerspelling serves as a resource for lexical borrowing and new sign formation. Unlike most deaf communities, the BSL community uses a two-handed alphabet, the earliest version of which was published anonymously in 1698.

BSL was exported by signers to other countries, and was the predecessor of Auslan (Australian Sign Language) and New Zealand Sign Language. It has been suggested that these three languages should be considered as dialects of a single language. There is also evidence of the early influence of BSL on signing in South Africa, Hong Kong, and Newfoundland. Perhaps surprisingly, there are few known links between BSL and American Sign Language (ASL) and the languages are not mutually intelligible. BSL is also not genetically related to Irish Sign Language (ISL) despite their close geographical proximity.

Regional Dialects

There is considerable regional lexical variation in BSL, including core semantic areas such as color terms, days of the week, and numerals. Despite this variation, most signers are familiar with different dialects of BSL, and it appears likely that the use of signing on television over the past 20 years is gradually leading to the development of a national standard.

Grammar of BSL

BSL and other sign languages exhibit structural differences from spoken languages, as use of the visual–spatial modality provides a different range of structural possibilities, including visual imagery, movement in space, and multiple articulators.

In common with all sign languages, BSL signs often reflect visual properties of referents, such as their shape, movement, or how they are handled.

Whether or not a sign is visually motivated, all signs exhibit a conventionalized relationship between the form and the referent.

The placement and movement of signs within a linguistically determined area of space around the signer are a central feature of BSL, having considerable

grammatical functions. As in other sign languages, the movement of verbs between points in space can reflect grammatical relations between referents at the conceptual level, differentiating semantic roles and grammatical classes (subjects and agents, patients and objects of actions), without any implication of a spatially constrained relationship.

Signed language can also convey spatial relations more directly: sentences can be constructed topographically, with the spatial relationships between signs corresponding to actual relationships among the referents.

The availability of two hands, a head, and a face provides BSL and other sign languages with the possibility of using simultaneously articulated structures to place referents in space and represent their relative locations and movements. BSL can also directly represent the timing of two events relative to each other, by showing the two events on two different 'channels'. Sign languages differ in the extent to which they exploit such devices. In a comparison of sentences generated from the same picture materials in ISL and BSL, simultaneous signs appeared in 20% of ISL utterances and 80% of BSL utterances. Simultaneity can also be extended for poetic effect. In a BSL poem by Dorothy Miles, 'Trio', the poet represents herself, a dog, and a bird all dozing together after a good lunch. This is signed by using three articulators simultaneously, using one hand to refer to the dog, one hand to refer to the bird, and the head to refer to the poet.

BSL as a Minority Language

Although BSL is fully independent of English, both lexically and grammatically, English has influenced BSL, as might be expected when any powerful majority language surrounds a minority language. English provides loan signs to BSL through fingerspelling and loan translation.

Family terms, calendar vocabulary items, and signs for units of measurement of time and space in BSL are frequently of English origin. BSL also reflects the influence of English in its use of mouth patterns derived from spoken English ('mouthings'). These are used in a wide variety of ways and in conjunction with other mouth patterns unrelated to English ('mouth gestures'). The use of mouthings varies with age, and social and linguistic background, as well as situational variety. Although mouthings feature in all languages and function in similar ways, anecdotal evidence suggests that BSL uses many more mouthings than, for example, ISL or ASL.

While BSL is a minority language with respect to English and borrows from English, it also acts as a donor to other sign languages, for example, ISL.

Social Situation of BSL

The education of deaf children has had a great impact on BSL. The first schools for deaf children in Britain, using BSL as the language of instruction, were established in the mid-eighteenth century. Although BSL enjoyed widespread use in British deaf schools throughout the nineteenth century, there were always educationalists who believed that deaf children should use English rather than BSL. This philosophy gradually gained strength, and by the early twentieth century signing was banned in schools and children were punished for its use. Signing was reintroduced into deaf education from the 1970s onward, with the acceptance of bilingual (BSL and English) education. However, the closure of many deaf schools has reduced opportunities for deaf children to use sign language at an early age, and this has been viewed as a threat to the viability of BSL in the future, with the removal of children's access to the community of signers and the linguistic and cultural role model that the community provides to young deaf children.

Despite the changes in education policy, the past 20 years have witnessed a substantial improvement in the status of BSL. A weekly program in BSL has been broadcast by the BBC since 1981; a comprehensive dictionary of BSL was published in 1992; and the British government appears poised to offer some formal recognition to BSL as a minority language, and public interest in and acceptability of BSL has probably never been higher.

Brugmann, Karl

Best known as the leading member of the so-called 'Junggrammatiker' ('neogrammarians'), Karl Brugmann played a crucial role in laying the foundations of historical linguistics in the modern sense. In one of his most famous publications, the preface to the *Morphologische Untersuchungen auf dem Gebiete der indogermanischen Sprachen*, Brugmann and his co-editor, H. Osthoff, reacted to current ideas about language change, outlining a theory based on the regularity of sound laws, whose apparent irregularities could only be explained as either the outcome of other sound laws, or as the effect of analogy.

The importance of the concept of sound laws for the development of historical linguistics can hardly be overstated. Before the neogrammarians, phonological change was conceived as applicable in most cases, but no theoretical statement was made about its regularity, and the (apparent) exceptions were left unexplained. By giving regularity the status of a basic requisite, the neogrammarians opened the way to much more refined research in the field of sound change and language change in general, based on the idea that a phenomenon was not exhaustively described, until all possible exceptions or counterexamples had been satisfyingly explained.

Although the achievements of the neogrammarians are best described as the result of in-depth collaboration among a group of scholars who shared the same ideas, Brugmann certainly stood out of the group, with his 400 odd publications, covering various areas of linguistics and philology. The most famous remains his *Grundriß der vergleichenden Grammatik der indogermanischen Sprachen*, whose first volume appeared in 1886. The work, completed in 1901 with the addition of the second volume by Karl Brugmann and three volumes about syntax by Berthold Delbrück, is still the most authoritative reference book in the field.

By shifting emphasis from language classification and reconstruction to language change, the Neogrammarians broke with the tradition of Indo-European linguistics in two ways. In the first place, they brought forth a conception of linguistics as a historical science, thus closer to human sciences, as sociology and psychology, than to natural sciences, to which it was closer before. Furthermore, they provided linguistics with a methodology of its own, no longer borrowed from natural sciences, and not directly dependent on the methods of classical philology. This last point is of crucial importance for the emancipation of linguistics, and caused the most profound break with the scholars of the preceding generation. Brugmann's personal vicissitudes are an example of this break: at the inception of his scientific career, he produced two articles, *Nasalis sonans in der indogermanischen Grundsprache* and *Zur Geschichte der stammabstufenden Deklinationen*, which provoked a harsh reaction from his former teacher Georg Curtius, who, feeling criticized as methodologically inadequate, never wanted to acknowledge his pupil's achievements and, still years later, published a thorough, but by then outdated critique of the Neogrammarians.

Although his major interest was in the fields of phonology and morphology, Brugmann also published some pioneering work on syntax. He was deeply convinced of the importance of a global vision of utterances, prior to the study of forms in isolation, as shown by his statement, 'In fact, all speech is brought about in sentences' ('In der Tat geschiet alles Sprechen in Sätzen'), in the introduction to his posthumously published volume *Die Syntax des einfachen Satzes im Indogermanischen*. Besides the history of ancient languages, some more recent changes also attracted his attention, most notably the creation of dummy subjects in the modern Germanic languages and in French, to which he devoted an essay (*Der Ursprung des Scheinsubjekts 'es' in den germanischen und romanischen Sprachen*).

Brugmann's work on syntax also shows that, in spite of his central concern with language change, he could also give insightful synchronic descriptions of linguistic phenomena. This is mostly shown in his analysis of word order in the ancient languages, based on what could be termed a functional view of sentence structure. Here, as well as in his assessment of the motivation of language change, Brugmann stressed the importance of the psychological dimension of language use, thus highlighting the role of the speaker in the process of language structuring.

Biography

Karl Brugman was born in Wiesbaden (Germany), on March 16, 1849 as Karl Friedrich Christian Brugman (his last name was changed to Brugmann in 1882). He studied in Halle and Leipzig, and received his Ph.D. Leipzig (1871) for his thesis on suppletion in Greek. From 1872 to 1877, he worked as a teacher in Wiesbaden and Leipzig, habilitated in Leipzig in 1877, and was immediately appointed extraordinary professor.

From 1874 to 1877, he was ordinary professor in Freiburg i. Br. and in 1887 he worked as ordinary professor in Leipzig, where a new chair of 'indogermanische Sprachwissenschaft' (Indo-European Linguistics) had been created specifically for him. He held this position until his death, in Leipzig, on June 29, 1919. He was the founder and editor of 'Indogermanische Forschungen' (founded in 1891) and the first chairman of the Indogermanische Gesellschaft in 1912.

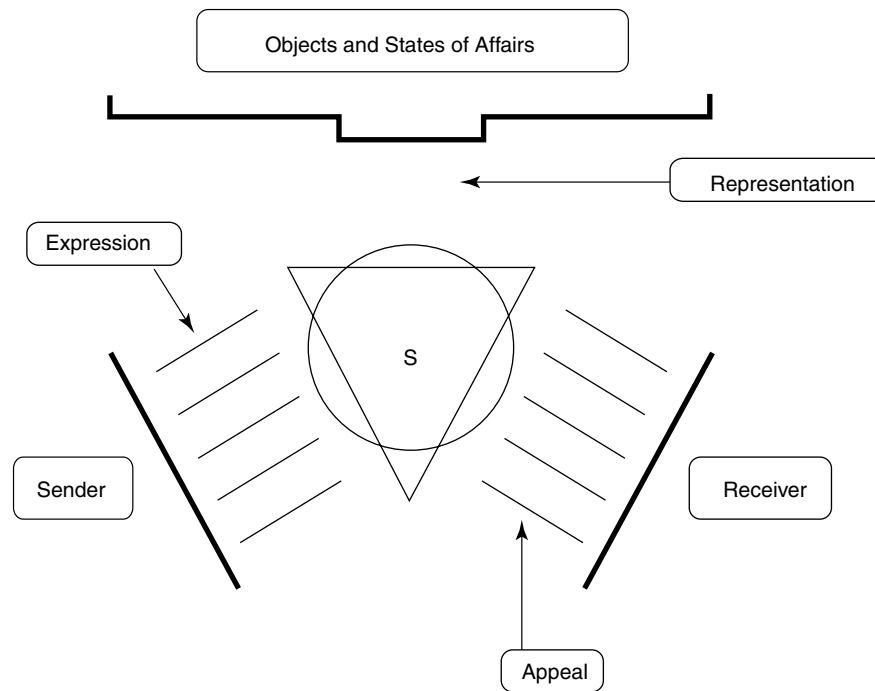
Bühler, Karl

The psychologist and philosopher Karl Bühler started as a member of the Würzburg school of 'Denkpsychologie', where Oswald Külpe was his teacher. Bühler later followed Külpe to Bonn and Munich. In the 1930s, he built up the Psychological Institute of Vienna University, which became one of the most flourishing psychological institutes in Europe. Together with his wife Charlotte, who also worked as a psychologist, he emigrated to Norway and later to the United States when the Nazis had occupied Austria. He spent his last years as a professor of psychiatry in Los Angeles.

Bühler contributed in many ways to the social and cognitive sciences. At the beginning of his career, he worked on the psychology of thinking. Next, he studied human perception and developed a new notion of Gestalt psychology, which he understood as a competitor to the Berlin schools view of Gestalt, as exemplified by Kurt Koffka and Max Wertheimer. Another important part of Bühler's work in collaboration with Charlotte Bühler was developmental psychology. Bühler wrote the most read German textbook on the issue, titled 'Die geistige Entwicklung des Kindes' (1918). Bühler's treatment of the mental development of the child shows a strong concern for the cognitive aspects of language. This research perspective developed into Bühler's 'Sprachtheorie' (1934), which is one of the most important forerunners of semiotics and contemporary cognitive linguistics.

Bühler's most remembered contribution to linguistics is his organon model. See the figure, adapted from 'Sprachtheorie' (1934).

Communication takes place between the speaker (sender) and the listener (receiver), and it is about the objects around us. In Bühler's view, language is an 'organum' or tool for one persons communicating with another about the world. The three main functions of language that Bühler distinguishes in his organon model are *Darstellung* (representation, of states of affairs), *Ausdruck* (expression, of the sender's feelings), and *Appell* (appeal, to the receiver). All functions exist in every single utterance. However, usually one prevails. When the focus is on the feelings of the sender, the expressive function of communication dominates. An object-oriented communication is very neutral or representative. If the focus is on the receiver, we deal with an appeal. The circle in the middle of the illustration above symbolizes the concrete, sensibly given sound. The overlapping triangle symbolizes the meaning of the sound and its *Gestalt*-like features. In


those places where the circle is larger than the triangle, the sound (circle) contains information that lacks meaning (triangle). Where the triangle is larger than the circle, there is a meaning (triangle) lacking an expression in sound (circle). Both phenomena occur all the time in everyday communication. The linguistic sign itself is a symptom, a signal, or a symbol. If it is a symptom, it reveals the interiority or consciousness of the sender. If the sign is a signal, it is directed to the behavior of the receiver. Signs that are mere bearers of information about the states of affairs are symbols, just representing the objects themselves. Roman Jakobson expanded Bühler's model and assumes six functions of language, adding the poetic, phatic, and metalingual function to Bühler's three functions. Karl Popper, who was a student of Bühler's in Vienna, proposes an additional argumentative function.

According to Bühler, the lexicon of a language can be split into the field of symbol words (*Symbolwörter*) and the field of deictic words (*Zeigwörter*). As for deixis, Bühler points out that the listener starts an orientation procedure when the speaker uses a deictic expression.

Bühler shows that the reference is not only based on a sensual perception (when seeing the pointing finger, e.g.). He argues that the pointing finger is the natural instrument of visual demonstration, but it may be replaced by other pointing aids. However, some pointing needs to be done. Bühler's analysis covers the deixis of pronouns ('I', 'you', 'he') and the deixis of time and place expressions ('now', 'here', 'there').

The other field of language, the symbol field, differs radically from deixis. The symbol field is the place for the representational function of language. A symbol bears an invariable content, a content that is independent of the actual situation. The denotation of a deictic (or indexical) expression like 'I' varies from speaker to speaker and from situation to situation. That is the reason why Roman Jakobson calls these expressions 'shifters'. The denotation of a symbolic expression does not vary or shift. Instead, it rigidly denotes always the same thing, like for instance 'Downing Street 10'.

Karl Bühler's *Sprachtheorie* is an important work of twentieth-century linguistics. A historical reevaluation of his work as a whole began in the 1970s. His unpublished works (lectures, manuscripts) are also collected now and edited. It is striking how Bühler's work still stimulates contemporary linguistic research.

Biography

Karl Bühler was born in Meckesheim, Germany on May 27, 1879. He studied human medicine and philosophy at the Universities of Freiburg and Strasbourg. He received a Ph.D. in human medicine (1903, Freiburg) for work related to color perception, a Ph.D. in philosophy (1904, Strasbourg) for work related to Henry Home, and Habilitation (1907, Würzburg) for work on cognitive science. He was assistant professor at the Universities of Würzburg (1906–1909) and Bonn (1909–1913), associate professor at the University of Munich (1913–1918), full professor for philosophy and pedagogy at the Technical University of Dresden (1918–1922), and full professor for psychology at the University of Vienna (1922–1938); he

emigrated to Norway and later to the United States when the Nazis occupied Austria. He was professor at St. Scholastica Duluth College and St. Thomas College at St. Paul, Minnesota (1940–1945), and professor of psychiatry at the University of Southern California, Los Angeles (1945–1955). He died in Los Angeles on October 24, 1963.

Burmese

Burmese is the national language of the country of Burma (also known as Myanmar), located to the southwest of China and to the east of Bangladesh and India. It is estimated that 68% of the population, or between 22 and 31 million people speak Burmese, ranking it 43rd in the world by population. Burmese is directly related to Tibetan and indirectly related to Chinese. It belongs to the Tibeto-Burman language branch of the larger phylum of Sino-Tibetan. Within the Tibeto-Burman grouping of languages, Burmese belongs to the Loloish (Yi) Branch and shares typological characteristics with lesser-known languages of western China, Thailand, Laos, and Vietnam. Some of the better-known minority languages related to Burmese are Lisu, Akha, and Lahu that are found spread across four Southeast Asian countries.

As a result of internal political changes since 1990, an alternate name of *Myanmar* has been used for both the Burmese language and the country of Burma, but most linguists continue to refer to the language as Burmese. Motivation for the name change is unclear, since the name of the language and country has not changed in Burmese itself. There are two speech levels in Burmese. In the more colloquial, common, spoken form of the language, the name for the country and speech is a form of the word *băma*, from which the English form 'Burma' is derived. In the literary, more formal Burmese, the same name is *myanma.*

There are six to ten recognized regional dialects of Burmese, some of which are not mutually intelligible with Standard Burmese. Standard Burmese is spoken in the highly populated, central Irrawaddy River flood plain and delta regions. Other varieties of Burmese, namely Northern Burmese, Arakanese (Yanbye, Chuangtha), Intha, Danu, Taungyo, Yaw, Tavoyan, and Magui, are found in geographically isolated areas blocked by either mountains or larger bodies of water, such as along the long peninsula toward Malaysia or across the Pegu mountains of Central Burma proper, or the more effectively isolating Arakan mountain range in southwestern Burma.

Ancestors of the modern Burmese-speaking people migrated during the second-to-ninth century CE from the Tibetan plateau southward into areas of southwestern China. Following riverine routes along the eastern end of the Himalayan mountains, they eventually descended into the hot, dry regions of the Irrawaddy River flood plain between 800 and 1000 CE. An earlier migration of a Tibeto-Burman speaking population, the Pyu, preceded the Burmese by 400–600 years. When the Burmese migrated to the plains, the Pyu civilization was in decline. Other language contact with Mon-Khmer-speaking populations, principally the Mon, resulted in significant cultural and linguistic changes for the Burmese. The Mon had already successfully developed an advanced Buddhist civilization, which the Burmese eventually emulated, adopting similarly Indic-influenced systems of government, kingship, religion, art, architecture, and a South Indian variety of the Brāhmī alphabet. The first record of writing Burmese was found on a stone inscription dated 1113 CE. The influence of Mon (and Pali) is found lexically in borrowed words for cultural and technological items, as well as common, everyday idioms. Phonologically, Mon's pervasive

influence is marked in the Burmese tonal system, which has adopted voice phonation or register as additional tonal features in addition to simple pitch.

Significance of Burmese

Burmese is one of the two oldest written languages of the Tibeto-Burman language family. The other is Tibetan. These two languages provide an invaluable window on the language and culture of an ancient linguistic world. Without some written forms of ancient languages, the reconstructed genetic relationships proposed between living languages would be far more speculative. Burmese texts also provide an insight into the political and cultural relationships of a Southeast Asian world shortly after the first millenium. Stone inscriptions are the principal media to have survived. The most famous is the Myazedi inscription dated 1113 CE, which records the same text in four languages: Pyu, Burmese, Mon, and Pali.

The Burmese alphabet is adapted from the Mon script and was one of the war trophies resulting from the conquest of the Mon empire in 1044 CE. The distinctive beauty and harmony of the alphabet is displayed in each character shape, variations of a circle. No word space is used; hence, each word is connected to the previous in a continuous right-to-left flow until a semantic juncture is encountered. A brief space is then used, followed by another long string of elegant circles.

Literary Form and Colloquial Language

The term *diglossia* describes a situation where two extremely different forms of the same language are used for different social functions within a society. This situation arose because the ancient written form exerted a conservative force restricting natural language change. Over the centuries, the written form changed little, while the spoken language more freely followed regular sound changes. The extent to which the written form has constrained changes in the colloquial form is unknown.

Literary Burmese, also called Written Burmese, differs from Colloquial Burmese (Spoken) in style, grammar, lexicon, and grammatical particles, which are similar to English prepositions. The most obvious difference between Literary Burmese and Colloquial Burmese is seen in a unique set of postpositional particles, which serve as spatial, temporal, and logical operators orienting nominal units within the sentence. They also serve as case markers indicating sentence relations such as semantic subject, object, and indirect object. Each style has its own unique set of postpositionals.

In some cases, a historical relationship exists between the particle sets, and in other cases a replace-

ment form is used while maintaining the grammatical function. Lexical forms have been recruited over time to serve standard grammatical functions, demonstrating the flexibility of Burmese semantics and the stability of the grammar.

Dictionaries and Grammars

The first English–Burmese dictionary was compiled by Adoniram Judson, a missionary linguist, during the middle of the nineteenth century and is still used today. In 1993, the Myanmar Language Commission produced a highly popular Myanmar–English Dictionary, which includes a history of the Myanmar alphabet. During the 1970s, the Burmese Language Commission released a five-volume, Burmese– Burmese dictionary set.

Numerous grammars of Burmese have been written. The first in English was Adoniram Judson's grammar of 1866. During the British colonial period of 1885–1948, various grammatical studies produced by local and foreign scholars attempted to grapple with Burmese grammatical constructions using Indo-European, or Latinate models. During the 1960s, various revisionist Burmese linguists proposed alternate grammatical categories using only Colloquial Burmese, rather than the higher status, Literary Burmese. This attempt to legitimate modern Colloquial Burmese met with little official acceptance. The School of Oriental and African Studies, University of London, has made a most significant contribution to the study and analysis of colloquial Burmese for English speakers. Okell's Colloquial Burmese grammar volumes and language lessons have made accessible what was once distant and intangible for the language learner. Unpublished doctoral dissertations since the 1980s have further examined the beauty of the Burmese language.

Phonology

Burmese has four lexical tones, which are characterized by both pitch and voice phonation (plain, breathy, and creaky). The syllable consists of two types: a minor and major syllable. Minor syllables occur only with a major syllable, have only a schwa vowel, neutral tone, pattern as only consonant and vowel (CV), and have a reduced inventory of initial consonants that may occur. The major syllable need not occur with a minor syllable, bears one of the four lexical tones (T), patterns with the potential canonical structure of initial consonant (C_i), optional medial consonants (C_m), vowel (V), and optional final glottal or nasalization (C_f). The major syllable canonical shape is $C_i(C_m)V(C_f)T$.

There are 32 possible initial consonants, two medial consonants, ten vowels, and two types of final consonants. The syllable rhyme (VC_f) is historically important

in determining vowel quality changes such as off-gliding, nasalization, and one of the four tones (Table 1).

Some of the more unusual features of Burmese are the voiceless nasals, *hnim* [n̥eĩ] 'to press down', but *nim* [neĩ] 'settle'. The final nasals, while written, are pronounced only as nasalization on the preceding vowel. Final stops, while written, are pronounced as a glottal stop with an abrupt closure and low tone. This has traditionally been called the stopped or checked tone. The voiceless lateral and the aspirated voiceless sibilant are somewhat universally rare sounds. Surprisingly, Burmese shares with English the moderately unusual voiceless and voiced dental fricative.

Grammar

Burmese is a verb-final language. Typical sentence word order is subject, object, verb (SOV).

Subject	Object	Verb
su	*thã mmàng*	*cà-sany*
s/he	rice	eat-realis
	'S/he eats rice.'	

Sentential nominal elements, such as the subject, object, location, or manner, typically occur with a postpositional marker indicating the sentential role of the nominal. Overt marking of subject and object roles is not obligatory in Burmese as in European languages. Often a *postpositional* is used to disambiguate or contrastively emphasize the role of the nominal.

*mranma nong-ngam-**sany***	*tá-khyin-**ká***	*bríthísh-tó-ʔí*	*lak-ʔawk-**só***	*kyà-rawk-**khái-bù-sany***
Burma-country-**topic**	one-time-**past**	British-plural-**genitive**	hand-under-**toward**	fell-arrived past-previously-realis

'At one time Burma fell under subjugation of the British.'

Noun phrases are normally structured with the modifier preceding the head noun. Relative clauses function as a modifier of the head noun but with a postpositional particle marking the relationship between the preceding clause and the following noun. Possessive phrases also function in the same way.

Possessor	Possessed (Head)
bríthísh-tó-ʔí	*lak-ʔawk*
*British-plural-**genitive***	*hand-under*
'subjugation of the British'	

Burmese is one of the languages in the world that requires the use of semantic classifiers when nouns are enumerated. In enumerated noun phrases modifiers follow the nominal head, with the resulting order: head noun, numeral, classifier. This contrary ordering is a kind of appositional phrase in juxtaposition with the nominal phrase.

Burmese treats quantification, plurals, and numeral classifiers, uniquely from other types of specification. Plurals are not as common, nor as grammatically required as in English. Rather, plurals and enumerative phrases make a statement about the topic, and give a sense of inclusion, or definiteness, as articles do in English.

The verb phrase as the last element of the sentence carries the bulk of the action and attitude of the speaker. A series of postpositions refer to the attitude of the speaker to the content of the sentence, the attitude to the hearer, the truth value of the sentence content, and intentionality. Other functions marked by postpositions are verbal aspect (punctiliar, process, completed), mood (declarative, two types of interrogative, imperative), and polarity (positive or negative).

O   Verb Phrase

*bà   lup-**yá-sè-sá-lè***
what   do-**must-yet-realis-question**

   'What else must (you) do?'

Preceding the head verb a limited set of modifiers may occur, which serve as intensifiers, comparatives, manner, or directionals that indicate both actual and metaphorical attunement of the action or state of the main verbal proposition. Following the verb head a more open class of verbal auxiliaries may occur. The juxtaposition of such verbs in Burmese seems to have almost an endless creative potential for creating beauty, humor, and powerful description of visual sense and emotional feeling.

O   Verb Phrase

*ʔaphàm   kham-**swà-rá-hra-sany***
capture   undergo-**go-must-pity-realis**

   '(He) was caught, poor fellow.'

Compounding as a process is extremely productive in Burmese, occurring with words, phrases, and clauses. Compounding occurs with both nominal and verbal constructions. The semantics of the compound construct are not necessarily predictable from the lexical parts but form a semantic blending of various selected components of meaning. Burmese has a noted preference for doublets, such that one compound can be elegantly doubled into a compound of two compounds. Then, these double compounds can be further doubled in a more formal, expressive speech style; veritable doubled pleasure of semantic juxtaposition.

Burushaski

Burushaski (also 'Khajuna, Kanjut') is spoken mostly in the Northern Areas of Pakistan. There are two main dialects of Burushaski: Hunza (HB)/Nager (NB) (approximately 45,000 speakers) and Yasin (YB) (also 'Werchikwar') (approximately 15,000 speakers). The Hunza and Nager variants are quite similar to each other, while the Yasin dialect differs from HB and NB in lexicon, phonology, and morphology. Many HB speakers also speak Shina; YB speakers are bilingual in Khowar. Educated Burushaski speakers also speak and read Urdu, the national and link language of Pakistan. With increasing literacy and bilingualism in

Urdu, many features of Burushaski lexicon and syntax are being influenced by Urdu.

Burushaski is still regarded as a linguistic isolate, although its possible relationship with other languages has long been the subject of intense research. Early attempts to link it with other languages include comparisons with Caucasian and with the Yeneseian languages. Most recently, Čašule (1988) argues that Burushaski is Indo-European, most closely related to the pre-Balkanic languages, especially Phrygian. The most comprehensive grammars of HB are Lorimer (1935a, b, 1938) and Berger (1998); Tiffou (1999) deals with both HB and YB. Anderson (1997, to appear) are English-language analytical summaries of Burushaski phonology and morphology.

Burushaski has recently begun to move toward becoming a literary language. Some writers have chosen to sometimes write in a Roman-based script—in 1980, a Roman-based Burushaski primer was published—while others write in a modified Perso-Arabic script, especially when dealing with religious themes. The Burushaski Research Academy, a local organization, is encouraging the development of writing in Burushaski. Collections of riddles and proverbs have been published in Roman Burushaski, while poetry on religious themes has been published in Perso-Arabic script.

Phonology

Consonants

HB has the consonants shown in Table 1 (Tiffou 1999: 118–9).

In HB, *f* and *x* appear in loan words; *y̱* is a retroflex glide, unique to HB and NB. Except for *y̱*, YB has the same consonants as HB; it also has *x*, corresponding to HB *qh*.

Vowels

Both HB/NB and YB have five basic short vowels, i, e, a, o, u, and two sets of corresponding long vowels (consisting of two time units, or moras), one stressed on the first mora, represented as *áa,* and another stressed on the second mora, represented as *aá*. First-mora stress results in a high-falling pitch, while second-mora stress results in a low-rising pitch contour. Vowel length and moraic stress are contrastive, e.g. *bat* 'stone', *baát* 'cooked rice', and *báat* 'after' (Berger 1998). This places Burushaski in the areal grouping of north Pakistani languages, including at least Shina, Khowar, and Burushaski, with pitch accent systems.

Morphology

Nouns

Burushaski nouns fall into a four-valued gender class system. The four classes are human female (hf), human male (hm), x, and y. The x class includes nonhuman animates and most count nouns, while the y class includes inanimates and mass nouns. The class membership of a noun determines verb and sometimes adjective agreement; in some cases, the stem form of a verb also varies according to the class of the subject or the direct object, e.g. *yáaltas* 'to wash (h or x object) vs. *báaltas* 'to wash (y object), and *wálas* 'to fall (x subject) vs. *balás* 'to fall (y subject). There are numerous plural suffixes in Bur., which are correlated with the class of the noun. For example, *-tiŋ* (hm, hf) in *daraɣá-tiŋ* 'canal overseers'; -ŋ (y) in *hála-ŋ* 'goals (polo)' *-muts* (x) in *baṣá-muts* 'turbans'. Bur. has a suffixal singular article *-an* 'a, one' (from *han* 'one'), and a plural article *–ik;* thus, *hayúr-an* 'a horse'; and *harált-iŋ-ik* '(some) rain-showers' (Berger 1998, I:39, 43).

Nouns have an elaborate case-marking system, consisting of several levels. The basic case endings are

illustrated in Table 2 for one noun of each class (Anderson, to appear).

The ergative case is used for the subjects of transitive verbs, such as 'hit', while the nominative/absolutive case is used for the subject of intransitive verbs, such as 'go'. For some speakers, though, the nominative/absolutive can be used in the future and the present of transitive verbs. The genitive indicates possessors; the dative marks indirect objects, some direct objects, and direction toward something. The ablative indicates direction away from something and appears in comparative constructions. Two examples follow.

> *jáa-r*   *madát*   *a -čh -í*
> I(OBLIQUE)-DATIVE   help   I-give
> 'help me'
> (Berger 1998,I:69)

> *uŋ -tsum*   *je kam*   *a- p -a*
> you-ABLATIVE   I   small   not-be-I
> 'I am not smaller/less than you.'   (Anderson, to appear)

In addition, there are several locative cases, and a fairly large set of 'relational nouns'. These words are nominal in origin, but are undergoing the process of grammaticization into postpositions.

Pronouns

Pronominal prefixes are a central element of Burushaski morphology. In general, these prefixes are used to indicate an affected, animate entity. They are obligatory with certain nouns, e.g. names for body parts and kinship terms, indicating inalienable possession. For example, *-me* 'tooth' cannot stand alone; it must include a prefix indicating 'whose tooth', e.g. *gu-me* 'your tooth'. Some adjectives and postpositions, and a few numbers require pronominal prefixes, as do many verbs. For example, *-apat* 'side of body' is a body part term requiring a pronominal prefix, from which the adjective *-pačim* 'being alongside of __', *go-pačim* 'by your side' (Bashir 1985:3). With verbs, pronominal prefixes index the subject of some intransitive verbs, the object of some transitive verbs, or the indirect object or causee of some ditransitive or

causative verbs. There can be more than one pronominal prefix in a sentence. For example, in the following sentence, the first-person singular pronominal prefix *áa* indexes the affected object 'me', and the second-person singular prefix *kóo* indexes the subject 'you'.

> *áa-lji*   *du-kóo -ṣqalč*   *-um*   *-a*
> me-up.to   *d* -you -overtake(DURATIVE)   -PPL-you
> 'You will overtake me.'
> (Bashir 1985:15, from Lorimer 1938:119)

There are four series of these prefixes (Berger 1998:91). See Table 3.

Independent pronouns also exist. They are:

>   Sg.   Pl.
> 1. *je, já* 'I'   *mi* 'we'
> 2. *un* 'you'   *ma* 'you'
> 3. *iné* (h) 'he, she'   *ué* (h) 'they'
>   *isé* (x) 'it'   *itsé* (x) 'they'
>   *ité* (y) 'it'   *iké* (y) 'they'

Adjectives

Some plural adjectives agree in class with nouns, e.g. *burúm* 'white (sg.)', *burúm-išo* 'white-x pl', *burúm-iŋ* 'white-y pl' (Berger 1998:47). Comparative and superlative constructions are formed analytically with the ablative case.

Verbs

Burushaski has a relatively small number of simple verbs; the majority of verbs consist of a noun or adjective combined with one of a small set of basic verbs (sometimes called "light verbs"), which function to change the noun or adjective into a verb. Of these, the most frequently used are *mánas* 'to be', which forms intransitive verbs, and *étas* 'to do, make', which forms transitives. For example, *naṭ étas* 'to dance', *kárpaṭ étas* 'to quarrel', *kárpaṭ mánas* 'to quarrel'.

The Burushaski verb is agglutinative; that is, it is formed of several separate meaningful units (morphemes), each of which corresponds to a specific meaning element. The general structure of a verb form can be schematized as follows (Anderson, to appear).

These positions are ordered from left to right in the verb form (See Table 4).

One example of a fairly complex verb form, in itself a complete sentence, is given here. Position numbers and morpheme names are indicated; note that not all the positions are filled in any one verb.

TABLE 4

Position	Morpheme	Function
–4	**a-, oó-**	Forms a negative verb
–3	**d-, n-**	Prefixes/preverbs. *d-* indicates (abstract) motion in the direction of speaker or terminus (Bashir 1985) but is no longer productive. *n-* marks the conjunctive participial (also 'converb', 'absolutive') form of the verb.
–2	**Pronominal prefixes**	Index the subject, indirect object, or direct object of a sentence, depending on the transitivity of the verb.
–1	**Causative morpheme -s-**	Indicates either a causative verb, or a benefactive meaning.
0	**verb root**	Contains the basic meaning of the verb.
+1	**plurality marker -ya-**	Marks an action as distributed in some way, either by having a plural subject or by being performed on multiple occasions or in multiple places.
+2	**durative, nonpast participle marker: c, š, c̣, j, y;**	Markers of durative (cf. 'present') base. They indicate that an action is durative, i.e. has temporal extent.
+3	**1st person singular subject -(y)a-**	Marks only first-person singular subjects; thus, position 3 and position 5 cannot both be filled.
+4	**(a) m- participle marker; (b) infinitive -as; (c) conjunctive participle suffix -n; (d) optative -?; (e) optative -áa.**	These all mark nonfinite verb forms, or optatives.
+5	**(a) subject suffixes other than 1st sg.; (b) imperative endings; (c) auxiliary verb ba-.**	The auxiliary *ba-* 'be' forms complex verb tenses and itself has personal endings.
+6	**(a) interrogative; (b) case ending**	(a) Marks the sentence as a question. (b) Enables a sentence to be embedded in a more complex sentence.

a	-tú	-ku	-man	-um	-a
NEG	-d	-you(sg).	-be.born	-NON-DURATIVE-	you(sg)
[–4	–3	–2	0	+4	+5]

'You weren't born'
(Berger 1998,I:91)

Tense forms fall into two categories: those formed on the nondurative (sometimes called 'past') stem and those formed on the durative (sometimes called 'present') stem.

Sentence Structure

Basic Word Order

Burushaski has postpositions, and adjectives precede nouns. The basic word order of a simple sentence is SUBJECT – OBJECT – VERB. For example:

híre   gus   mu-yeétsimi
man   woman   saw
'The man saw the woman.'
(Berger 1998,I:177)

Observe that the direct object 'woman' is expressed on the verb by the prefix *mu-*, for human females.

Complex Sentences

In complex sentences, the subordinate clause usually precedes the main clause. The indigenous strategy for forming subordinate clauses involves using one of the nonfinite verb forms. For example, one type of relative clause is formed with the infinitive:

*[buṭ   bulá **dél-as]**   iné   hír-e*
much polo hit-**INFINITIVE** that man
'the man who plays much polo…'
(Berger 1998,I:186)

Another construction uses the -*m* participle (position +4).

*ja baríŋ   **etum**   ne   hir   šua   bái*
I speech **done** that man good   is
'The man with whom I spoke is good.'
(Tiffou 1999:2000)

In addition, some relative clauses are formed with finite verbs and a relative (-like) element. For example, the following YB sentence:

*ámet caγá-ule gambúrimu bién **(te)**   ṣiéli   duá*
that place-in flowers   are (that) beautiful is
'The place where there are flowers is beautiful.'
(Tiffou 1999:201)

The conjunctive participial form, marked by *n/d-*VERB-*n* (Positions: –3, 0, 2) forms many adverbial clauses. For example:

íne hír-e	***d-ítal-in***	*ṣapík*	*ṣími*
that man	*d*-get up(CONJUNCTIVE PARTICIPLE)	bread	ate

'That man got up and ate bread.'
(Berger 1998, I:189)

In many types of adverbial clauses, a case marker follows a nonfinite verb form. For example:

*sén-as-**ar***
say-INFINITIVE-**DATIVE**
'When he said'
(Berger 1998,I:190)

Subordinating constructions augmented by the complementizer *ke* 'that' (probably an influence from Khowar and/or Urdu) are increasingly frequent. For example,

je girámar	***ke***	*in*	*ními*
I village-to	when	came	he-went

'When I came to the village, he left.'
(Berger 1998, I:191)

Canada

Canada, whose name derives from the Iroquois word [ganá:da] 'settlement', is a confederation of ten provinces and three territories in northern North America. Formerly a British colony, Canada was created by the British North America Act (1867), which joined the provinces of Upper Canada (Ontario), Lower Canada (Québec), New Brunswick, and Nova Scotia into a single dominion. Other provinces joined the confederation at later dates: Manitoba (1870), British Columbia (1871), Prince Edward Island (1873), Alberta (1905), Saskatchewan (1905), and Newfoundland and Labrador (1949). In 1875, the Yukon and Northwest Territories were incorporated into the confederation, and the territory of Nunavut was created in 1999. Although Canada is the second-largest country in the world, encompassing an area of 9,922,385 km^2, it has a population of only 30,007,094 (according to the 2001 census), most of which is concentrated along its southern border with the United States.

In light of its vast size, Canada's present multilingual situation should not be surprising. A distinction is normally made between the 'founding languages' (English and French), the aboriginal (or First Nations) languages, and the 'heritage' (or 'international') languages of immigrant groups, which are neither Anglophone (English speaking) nor Francophone (French speaking). As the following figures from the 2001 census demonstrate, English is claimed by the majority of Canadians both as their mother tongue and as the language they use at home on a daily basis, with French as the second-largest language.

	Home language		Mother tongue	
English	20,011,535	67.5%	17,521,880	59.1%
French	6,531,375	22.0%	6,782,320	22.9%
Nonofficial language	3,096,110	10.5%	5,334,770	18.0%

The British North America Act provided for the use of both English and French in Parliament and the Québec legislature, provisions that were later extended to other provinces and territories, but in practice most of the provincial legislatures and much of the federal government were English dominant until the 1970s. Since the adoption of the Official Languages Act (1969), Canada has maintained a policy of official bilingualism in English and French at the federal level, although all provinces except New Brunswick are still officially monolingual in either French (Québec) or English. Unlike the 'melting pot' policy of the United States, the Canadian policy since 1971 has been one of 'bilingualism within a multicultural framework'. This framework attempts to promote conditions for stable bilingualism, develop the prestige of French in Canada, and protect individual and minority language rights. These rights were further enshrined in the Constitution and the Charter of Rights and Freedoms (1982). The effect of federal policy has been to make competence in both official languages a valuable asset in politics, law, culture, and business. French immersion courses have increased official-language bilingualism among Anglophones, especially in Québec, although Francophones are still the most bilingual nationally.

Canada's first inhabitants arrived from Siberia across the Bering land bridge between 7,000 and 12,000 years ago, bringing languages belonging to linguistic families that are now spread throughout the hemisphere. Although there is disagreement about the exact historical affiliation of these families, Canadian aboriginal languages are usually grouped into 11 families and isolates, most of which are also spoken in the United States, Greenland, or Siberia. Varieties of Inuktitut cover a wide area across the north, from the Yukon to Labrador. British Columbia is home to the widest array of languages, including Kutenai and Tlingit, the Haida dialects, and the Tsimshian, Wakashan, and Salish families. The Athabaskan family stretches across the west from British Columbia to Manitoba and north into the Yukon and Northwest Territories. The Algonquian family, which includes Blackfoot, Cree, Ojibwa, Micmac, and possibly Beothuk (an extinct language of Newfoundland), is the most widespread, with languages spoken from Alberta to Labrador, as well as in New Brunswick and Nova Scotia. Michif, a mixed language that arose from intermarriage among speakers of Cree and French, is spoken in Manitoba. The Dakotan languages (a branch of the Siouan family) are spoken in Manitoba, Saskatchewan, and Alberta, and a number of Iroquoian languages are spoken in Ontario and Québec. According to the 2001 census, the aboriginal languages with the largest number of speakers are Cree, Inuktitut, and Ojibwa.

When the Europeans arrived in North America, there were up to 300 languages spoken in what is now Canada, although nowadays there are fewer than 100. This attrition, the result of infectious diseases brought by Europeans, genocide, and government policies, has only recently begun to be addressed. After Confederation, little attention was given to the linguistic rights of aboriginal peoples, most of whom did not have full citizenship. Until the 1960s, the federal government pursued an assimilationist policy, confining aboriginal peoples to reserves and giving educational authority to religious groups, who enforced instruction in the majority language (English or French). More recently, aboriginal groups such as the Assembly of First Nations have called for a greater degree of self-determination, closing down the residential schools and transferring educational responsibility to local authorities. Some aboriginal languages now have official status in the Northwest Territories and Nunavut. Although federal and provincial funding for aboriginal-language instruction has helped slow language loss to some degree, these programs are inconsistent across the country and do not always promote fluency.

The varieties of French spoken in Canada can be traced to two colonies founded in the early seventeenth century: Acadia (1604; now Nova Scotia, New Brunswick, and Prince Edward Island) and New France (1609, now Québec). Although Acadia was ceded to the British in 1716 and many of the Acadians were later deported, Acadian French survived and spread to Newfoundland, the Îles de la Madeleine, and the Gaspé Peninsula (Québec). By 1762, the British had also conquered New France, but in this case they guaranteed the colonists' right to the French language. Québec French is nowadays the mother tongue of most inhabitants of the province and, because of westward migration in the nineteenth and twentieth centuries, served as the basis of the French spoken in Ontario, Manitoba, and the western provinces. Because of their different patterns of settlement and subsequent development, Acadian and Québec French show a number of distinctions from each other in grammar and pronunciation, especially in their vowel systems and verbal inflection. Both differ from European French, most noticeably in vocabulary and pronunciation, especially Acadian French and colloquial Québec French, which is also known as *joual* (from *cheval* 'horse'). Although there is a perception of massive and pervasive influence from English, anglicisms and English borrowings in fact account for a very small percentage of the total vocabulary.

Although French was originally the majority language of Canada, concentrated in Lower Canada and Acadia, the influx of Anglophone settlers to Upper Canada and the Atlantic provinces resulted in a national decline in the Francophone percentage: from 50% to approximately 25% in the nineteenth century. In addition, in all provinces except Québec and New Brunswick, the Francophone population has gradually been shifting to English. These patterns have decreased the presence of French in Canada while simultaneously increasing its territorialization. By the middle of the twentieth century, these factors, plus the declining birthrate among Québec Francophones, led to the perception of a 'doomsday scenario' in which French would eventually disappear from Canada. In 1976, this perception prompted the newly elected nationalist Parti Québécois government of Québec to pass Bill 101, the *Charte de la Langue Française*. Bill 101 ensures the rights of the Francophone majority by making French the sole official language and requiring all non-Anglophone immigrants to attend French-language schools, all public signs to be in French, and all businesses to conduct their affairs in French. This policy is implemented by three boards responsible for codifying and developing French, monitoring its status, and enforcing the language laws. Despite studies

indicating that Québec Francophones still do not feel that the French language in the province is secure, the language laws have increased the status of French in Québec to the point that it is possible to live and work entirely in French, even in the bilingual city of Montréal, and the percentage of Québécois reporting French as their mother tongue has remained stable (81%) from 1986 to 2001. However, the prestige of English as the language of North American business and culture poses a continuing threat to the maintenance of French in Canada.

The English presence in Canada dates from 1497, when Newfoundland was claimed for the British Crown. Newfoundland was settled between the sixteenth and eighteenth centuries almost entirely from Ireland and southwestern England and remained relatively isolated until World War II, making Newfoundland English distinctive in pronunciation, grammar, and vocabulary from varieties of Canadian English spoken elsewhere. Present-day Standard Canadian English is usually traced to the two waves of immigration of United Empire Loyalists (1776–1793), Americans loyal to the British monarch who fled the American Revolution: one wave came from coastal New England (Connecticut, Massachusetts, Maine, and Rhode Island) and settled in Nova Scotia and New Brunswick, whereas another came from the midland (Pennsylvania, New Jersey, New York, and Vermont) and settled in Ontario. The Loyalists thus served as linguistic models for subsequent settlers recruited by the British government in the nineteenth century from England, Scotland, and Ireland to augment the Anglophone population and supply agricultural and construction workers. Because the western provinces were settled largely by migration from the east, Standard Canadian English is nowadays considered extremely uniform across the country, without the marked regional standards characteristic of the United States. Despite this apparent uniformity, several nonstandard regional varieties persist, such as Newfoundland English, the African-Canadian English spoken by the descendants of Black Loyalists in Nova Scotia, Ottawa Valley English, and the noticeably distinctive pronunciation of certain vowels, especially before [r], in the Atlantic provinces. Although the shared origins of Canadian English and U.S. English make them grammatically very similar, there are differences in pronunciation, vocabulary, and spelling practices. Most noticeable in pronunciation is the raising of the first part of the vowel in words such as 'house', which Americans often hear as 'hoose'. There is considerable variation among Canadians between British and American spelling standards in words such as colour/color and cheque/check.

After 1860, immigration was widened to European countries outside of the British Isles, drawing settlers from Germany, Italy, the Scandinavian nations, and Ukraine. Such settlers, who increased the population of the eastern cities and were instrumental in settling the western provinces, tended to give up their ethnic languages in favor of English, further increasing the Anglophone majority. After 1910, immigration widened to settlers from Russia, Iceland, Finland, Poland, Greece, and the Netherlands. Since World War II, immigrants have also arrived from southeastern Europe, eastern Africa, India, Pakistan, Korea, Vietnam, China, Hong Kong, and the Philippines. With the adoption of multiculturalism as a federal policy in 1971, immigration was seen as a response to falling birthrates and a higher average age in the population. The annual rate of immigration has varied considerably, but currently Canada accepts approximately 200,000 immigrants every year.

The short-term effect of immigration has been to increase the number of nonofficial languages spoken: in the 2001 census, almost 100 nonofficial languages were claimed as a mother tongue by 18% of the population. The ten largest groups are (in descending order) Chinese, Italian, German, Punjabi, Spanish, Portuguese, Polish, Ukrainian, Arabic, and Tagalog (Pilipino). Immigrants tend to settle in southern Ontario (especially Toronto), Vancouver, and Montréal, making Canada's urban population increasingly multiethnic. However, because most immigrants can speak at least one official language within a short time of arrival, the long-term effect of immigration is more likely to be social than linguistic. Indeed, although immigration has contributed to social conflict, the ongoing educational and political accommodation of so many different languages within one state reflects favorably on the Canadian linguistic experiment.

Cape Verdean Creole

The Cape Verde islands belong to the northwestern union of archipelagoes in the Atlantic ocean (including the Canary Islands, the Azores, and Madeira) and are situated approximately 450 kilometers from Senegal and Mauritania. The archipelago is composed of two main clusters of islands: the windward islands and the leeward islands, known locally as Barlavento and Sotavento, respectively. The Barlavento islands include Boavista, Sal, São Nicolau, Santa Luzia, São Vicente, and Santo Antão. The Sotavento islands consist of Brava, Fogo, Santiago, and Maio. Some 450,000 Cape Verdeans currently reside in the islands and one million reside abroad (primarily Portugal, the Netherlands, New England, and California).

Although the Portuguese and the Italians officially discovered the islands in approximately 1460, there is cartographic evidence that the Greeks and the Arabs were already aware of their presence as early as in 1413 (Andrade 1996). Furthermore, the Jalofos tribe is reported to have lived on the island of Santiago prior to the arrival of the Portuguese (Brásio 1962).

Strategically located at the crossroads of Europe, Africa, and America, the archipelago played a critical role in the slave trade from the fifteenth to nineteenth centuries. The Portuguese initially brought the slaves to Cape Verde from Guinea, including Senegal and Sierra Leone. However, competition from other western powers reduced the West African source of slaves for Cape Verde to the limits of present-day Guinea-Bissau by the middle of the sixteenth century (Carreira 1982). Historical sources state that most of the slaves in Cape Verde came from the tribes of the Mandingos, Balantes, Bijagos, Feloupes, Beafadas, Pepels, Quissis, Brames, Banhuns, Peuls, Jalofos, Bambaras, Bololas, and Manjakus (Brasio 1962). The white settlers came from Algarve and Alentejo in Portugal, and also included Jews, Spaniards, Italians, and French (Martinus 1996).

A number of morphophonological and syntactic features distinguish the Barlavento varieties from their Sotavento counterparts, which can, to a certain extent, be related to the greater influence of African languages in the Sotavento varieties. This disparity is in part due to the fact that the Barlavento islands were settled a hundred years later than the Sotavento. As a result, the sociolinguistic situation in Cape Verde is fairly complex; it also involves an ideological dimension, as Portuguese (which provided the language with most of its lexicon) is the only official language in the archipelago to date.

In the phonological domain, all dialects of CVC contain the vowels {u, ɛ, a, e, ó, o, i}. The Barlavento group also preserves the Portuguese diphthongs *ei* and *oi*, which have merged with *e* and *o* in Sotavento. (Compare Port. *Manteiga* 'butter' : Sot. *mantega*, Port. *açoitar* 'to whip' : Sot. *sota*.) Sotavento varieties also typically denasalize word-final vowels; compare Port. *tambén* 'too' : Sot. *tanbe*. The Sotavento varieties change *v* into *b*, as in Port. *vestir* 'to dress' : CVC *bisti*. The Portuguese palatal liquid *lh* typically becomes the affricate *dj* in CVC: Port. *velho* 'old' : CVC *bedju.*

In the morphological domain, Sotavento differs from Barlavento in making productive use of reduplication, a morphological process also found in African languages, whereby a reduplicated adjective or adverb expresses emphasis, as in *moku moku* 'very drunk' or *faxi faxi* 'very quickly'. Noun reduplication may yield a distributive interpretation, as in *dia dia* 'every day', or may simply lead to a change in meaning, as in *boka* 'mouth' → *boka boka* 'in secret'. Lexical categories may shift grammatical category when reduplicated, as in *mansu* 'quiet' (adjective) → *mansu mansu* 'secrecy' (noun). Reduplicative processes of this type are relatively scarce in Barlavento.

The lexicon of Cape Verdean Creole comes primarily from Portuguese, with a smattering of African forms, such as *banbu* 'to carry a child on one's back' from Manding and Manjaku *banbu* (same meaning), *fepu* 'entirely' from Wolof *fepp* 'everywhere', *lokoti* 'to get out of a hole' from Wolof *loqoti* (same meaning) (Santos 1979). Many of the words of African origin refer to flora and fauna.

The verbal system is fairly intricate. The bare verb stem assumes various functions, depending on whether the verb is stative or nonstative. The bare stem of the verb *ten* 'have, own, possess' has a present tense reading, as in *N ten dos fidju* 'I have two sons'. In contrast, the bare stem of a nonstative verb yields a past tense interpretation, as in *N papia ku bu pai* 'I spoke with your father'. Creole languages typically have preverbal unbound markers expressing Tense, Mood, or Aspect (TMA). Cape Verdean Creole has two TMA markers, *ta* and *sta*, which occur preverbally, as illustrated in *algen ku si boka ka ta era kaminhu* 'one who asks does not get lost' and *pamodi bu sta txora?* 'why are you crying?' The marker *dja* in contrast precedes subject clitics but must follow full noun phrases; compare *Dja'N atxa bonberu* 'I found the exterminator' vs. *N atxa bonberu dja poi nunbru na porta* 'I found that the exterminator had

already put the number on the door'. In contrast to other creoles, Cape Verdean Creole possesses the inflected anterior marker –*ba*, which expresses simple past with stative verbs and pluperfect with nonstative verbs, as in *Mininu ten*ba *febri* 'The child had fever' and *João kume-*ba *tudu galinha* 'John had eaten the whole chicken'.

While the importance of inflectional morphology in creoles has been minimized by a number of creolists, Cape Verdean Creole and a few others display inflectional morphology not only on verb stems, as seen with the –*ba* verbal inflection above, but also on noun stems. CVC shares this feature with a number of other creoles and pidgins, such as Guinea-Bissau Creole, Casamance Creole, Ghanaian Pidgin English, and Nigerian Pidgin English. Plural suffixation in Cape Verdean is a productive process subject to definiteness and the animacy hierarchy. (The animacy hierarchy entails that animate entities are more likely than inanimate objects to carry agreement markers such as the plural suffix.) From a cognitive perspective, animate and/or definite entities are more salient in the speaker's consciousness and hence are more likely to be pluralized (Lyons 1999). The following examples illustrate this feature: *Bu tra-badja ku nha povus* 'you worked with my people', *Ami nha mininus, es fika tudu la pa fora* 'As for me, my children, they are all over the place'. Although the study of large corpora reveals that plural suffixation in monolingual speech is sensitive to variables such as [+/-animate], [+/-human], and [+/-definite], it is important to keep in mind that monolingual speech is not a monolithic whole and that speakers may have multiple grammars. Variation in general has been a central theme in the study of Cape Verdean Creole (Baptista 2002). In addition, social class and education, higher degrees of which tend to be bound up with diglossia and bilingualism (cf. Duarte 1994), combine with other social factors to make the Cape Verdean language quite heterogeneous, as is expected of any natural language.

Carib and Cariban Languages

Languages belonging to the Cariban language family are spoken in northern South America, the bulk in northern Brazil, Venezuela, Guyana, Surinam, and French Guiana, with outliers to the west in Colombia and to the south in Central Brazil. The historical literature on the Cariban family names over 100 languages; however, linguistic information (e.g. word lists, brief collections of utterances) exists for maybe half. There is no question that many of the languages spoken at the time of first contact with Europeans have become extinct, but we will never know how many. Currently, some 25 Cariban languages remain, with a cumulative total of between 60,000 and 100,000 speakers; well over half of these speak Carib proper or

one of three closely related languages belonging to a single subgroup (the Pemóng Proper Subgroup), with most Cariban languages having only between 100 and 3,000 speakers. Carib proper (its English name, called Galibi, Kaliña, Kari'na, and Cariña in other countries) is spoken by between 10,000 and 25,000 people along a roughly 1,000-mile arc of the coast and inland from the northeasternmost point of Brazil through French Guiana, Surinam, and Guyana, to the easternmost 300 miles of the Venezuelan coast. Several Caribbean languages historically claimed to be Cariban (Black Carib, Island Carib, Garifuna) are linguistically Arawakan, with some Carib features (mostly vocabulary) due to intensive contact with Carib invaders.

Most languages of the Cariban family are still poorly documented, with unreliably transcribed word lists and poor or no grammatical description. The two best documented Cariban languages are Carib (due mostly to work by Berend Hoff) and Hixkaryana (due exclusively to work by Desmond Derbyshire); work by Sergio Meira on Tiriyó is rapidly bringing a third language into this select group. The Carib language boasts of two grammars, two dictionaries, a collection of texts, several articles on selected linguistic topics and work in progress in both French Guiana and Venezuela; Hixkaryana has two grammars, a collection of texts and several articles, all by Derbyshire. Other Cariban languages with grammars (of uneven quality and comprehensiveness) include Apalaí, De'kwana, Ikpéng (Txikao), Makushi, Pemón, and Waiwai. In the domain of the lexicon, Cariban languages have been represented almost exclusively by bilingual word lists (some labeled dictionaries), with true dictionaries existing for only Carib, Panare, and Pemón. Scholars and students are actively working on projects in every country where Cariban languages are spoken. Ongoing research projects that ought to result in solid primary descriptive materials (text collections, grammars, dictionaries) include: in Brazil, Arara, Ikpéng (Txikão), Ingarikó (Kapóng), Katxúyana, Kuikúru, Tiriyó, Waimiri-Atroari, and Wayana; in Colombia, Yukpa; in French Guiana, Wayana and Kali'na; in Guyana, Akawaio (Kapóng); in Surinam, Tiriyó; and in Venezuela, Japrería, Kari'ña, Mapoyo/Yawarana, Panare, Pemón, and Yukpa.

Given the poor documentation of most Cariban languages, current classifications of the Cariban family are all unconvincing, as are reconstructions of ancestral homelands and migration patterns. The most recent classificatory hypothesis (which will certainly evolve as more data become available) is reproduced here in Table 1; it is derived by modifying Terrence Kaufman's (1994) classification (i) adding suggestions from recent work in Venezuela and the Guiana Plateau, (ii) marking as extinct (†) every language that has not been attested in the last 25 years, (iii) using current

local names for each language, and (iv) conservatively isolating several languages/groups that Kaufman had linked into tentative branches.

In the absence of a solid linguistic classification, discussions of prehistory — especially ancestral homelands and migration patterns — are perforce somewhat speculative. One hypothesis suggests that the ancestral homeland of Proto-Carib was in the Guiana plateau, from which the outlying groups moved southward and westward. Another posits a central Brazilian origin with one or more subsequent northward migrations and rapid expansion upon arrival in the Guiana Plateau. In either scenario, Cariban peoples appear to have occupied the Guiana Plateau for at least three millennia.

Characteristics of Carib and Cariban languages

Phonology
The Carib language has a relatively straightforward sound system, with three voiceless stops /p, t, k/, a voiceless fricative /s/, two nasals /m, n/, two glides /w, j/, and a sound that—depending on the neighboring sounds—surfaces strictly in syllable-final position as either a velar fricative /x/ or a glottal stop /ʔ/. All consonants are palatalized (with tongue movement toward the palate) when adjacent to [i]; /p, t, k/ are pronounced as /b, d, g/ between vowels or after nasals and glides; and the pronounciation of nasals depends on the following consonant. Some Cariban languages (and even some Carib dialects) add further consonants to the above inventory.

The six-vowel system of Carib (and most other Cariban languages) includes three high vowels /i, ɨ, u/, two mid-vowels /e, o/ (usually phonetically [ɛ, ɔ]), and one low vowel /a/. Across the family, the most common addition to this inventory is /ə/, with a few languages adding a second set of mid-vowels [ɛ, ɔ]. Independently, nasalized vowels are attested only in Apalaí. The difference between long and short vowels length is a differentiating factor for words in Carib and several other Cariban languages, but vowels may also be lengthened due to speech rhythm: in an iambic foot structure, the vowel of every second light (short, open) syllable is lengthened (excepting the final syllable, which is never lengthened). Across the family, primary intonational stress has been difficult to identify reliably, and sometimes it appears not to fall on the head of a foot (e.g. in Carib, Hixkaryana, Pemón, and Tiriyó).

Morphology
Carib makes heavy use of affixes, i.e. word particles are added to other words to either add to or change the meaning. In some cases, words together with their affixes may express meanings equivalent to phrases or sentences in other languages. Personal prefixes ('I', 'you', 'he'/'she'/'it') and grammatical prefixes or suffixes appear on verbs, nouns, and postpositions. Carib has suffixes that change nouns to verbs, nouns or verbs to adverbs, and adverbs, verbs, or postpositions to nouns. Most Cariban languages match this profile, with changes usually in the direction of simplification. There are two word classes in Cariban languages, particles and sound symbolic words, to which no affixes may be attached; both are rare in elicited speech but ubiquitous in texts.

Syntax
In Carib and most languages across the family, certain two-word combinations—possessor–possessed, object–postposition, and object–verb—are clearly grammatical units, the tight bond between them demonstrated by invariant order, the inability to interpose words between them, and the fact that they seem to be pronounced as a single word. Beyond these two-word sequences, the word order appears to be quite variable, in Carib or in other Cariban languages.

The Carib main clause consists of an inflected verb, with affixes indicating the type of both subject and object. Noun phrases can optionally occur as subject and object. When both subject and object of a transitive verb are third person, the object immediately precedes the verb, forming a tight verb phrase in a subject–object–verb construction. The subject usually precedes the verb phrase, but this is not always required. When either subject or object is not third person, the subject–object–verb ordering (SOV) remains more frequent, yet all other orders of subject, object, and verb are permitted. Carib distinguishes three degrees of past tense, and each tense has both a perfective and an imperfective form. A similar syntax is found in 19 other Cariban languages, belonging to virtually every proposed branch of the family, which indicates that the common ancestral language (Proto-Carib) also had this structure. Several Cariban languages present the rare basic order OVS, documented first — and most extensively — in Hixkaryana. The OVS order is commonly observed also in languages where it is not clearly 'basic'. While SVO is attested in several Cariban languages, the predominance of SVO in a few languages is most likely attributable to contact with languages of colonization.

Ergativity is pervasive in the Cariban family, and indeed throughout much of South America. In ergative constructions, the subject of an intransitive verb and the direct object of a transitive verb (called the absolutive) receive the same grammatical treatment, that is, they receive the same case-marking, verb agreement, word order, etc. In contrast, the subject of a transitive verb (called the ergative) takes different case-marking, verb agreement, word order, etc. Languages across the family do not use relative clauses, i.e. subordinate clauses that are introduced by words like *that, which, who,* etc. Instead, Cariban languages use affixes to turn the subordinate verb into a noun or an adverb.

Early hypotheses about historical evolution of Cariban grammar held that the ergativity seen in subordinate clauses indicates that Proto-Carib had ergative syntax in both main and subordinate clauses, with the nonergative main clause in today's languages being an innovation. Most recent work argues that the few cases of main clause ergativity in the Cariban family are readily explained as innovations, in which ergatively organized subordinate clause morphosyntax is 'elevated' to main clause status. The origins of all main clause types observed so far in the northern Cariban languages fit this latter hypothesis; however, each new description, especially from the less-known southern Cariban languages of the Xingu valley, will provide new challenges to the historical reconstructions in place so far.

Caribbean

The Caribbean islands (collectively called the West Indies) extend over a thousand miles from the tip of the Florida Peninsula to the northern coast of South America. They vary in size and population, ranging from Cuba, with an area of 42,804 square miles and more than ten million inhabitants, to the small, uninhabited, rocky islets of the Grenadines and the Virgin Islands. Most islands are smaller than Barbados (only 166 square miles), with a quarter of a million inhabitants. Although the islands share in common a long history of colonialism beginning in the fifteenth century, slavery, and economies once dominated exclusively by sugar plantations, each island has its distinctive history, culture, and language or languages. Politically, they comprise 23 entities, ranging from those that are still quasicolonies, such as the French Antilles (a French *département*) and Puerto Rico (officially a commonwealth of the United States), to those that are independent, such as Haiti (formerly a French colony), the Dominican Republic (originally a Spanish colony), and Jamaica (formerly a British colony). Some territories, such as Guyana, have passed through a series of colonial regimes before becoming independent.

Divided linguistically and culturally, the West Indies can be categorized into four distinct groups according to their officially recognized languages, usually the language of the former or current colonizer. The largest group is the Anglophone Caribbean, including the majority of islands outside the Greater Antilles (i.e. Anguilla, Antigua and Barbados, the Bahamas, Barbados, British Virgin Islands, Cayman Islands, Dominica, Grenada, Jamaica, Montserrat, St. Kitts-Nevis, St. Lucia, St. Vincent and the Grenadines, Trinidad and Tobago, Turks and Caicos islands, and the United States Virgin Islands), as well as two mainland nations: Belize in Central America and Guyana in South America. The Hispanophone Caribbean includes Puerto Rico, Cuba, and the Dominican Republic. The Francophone Caribbean includes Haiti and the French Antilles (Guadeloupe, Dominica, Martinique, and St. Lucia) in the Lesser Antilles island group. The Netherland Antilles (Aruba, Bonaire, Curaçao, St. Eustatius, Saba, and St. Maarten) are all that remain of the former Dutch empire in the Caribbean.

The native American population was exterminated first by the Spanish in the Greater Antilles (Cuba, Puerto Rico, and the Dominican Republic) and by the British and French in the Lesser Antilles. The indigenous Arawakan languages became extinct as their speakers died as a result of conquest, disease, or forced labor, and their remnants were absorbed in the Hispanicized population. The islands were repopulated through the introduction of African slaves to cultivate sugar and coffee plantations established by European settlers during the seventeenth and eighteenth centuries. After the abolition of slavery in the British, French, and Dutch territories in the nineteenth century, indentured labor was

introduced for plantation work, particularly from northern India.

The historical partition of the West Indies among the various European colonizers (Spanish, French, British, Dutch, and Danish) has had a number of important consequences. Eric Williams, first and long-time Prime Minister of newly independent Trinidad and Tobago (1962–1981) and founder of the People's National Movement, which led the country to independence, believed that the absence of an indigenous Caribbean language was a major obstacle to decolonization. This meant that there was no rallying point for the nationalist movement. Moreover, the absence of a common language was a hindrance to political, economic, and cultural contacts between the islands. The communication gap existing between the elite, who speak metropolitan European languages, and the masses, who speak creoles, also poses serious problems of social and political organization. Interisland connections have remained weak, because each colonizing power tended to dominate relationships with its own colonies. Where interisland linkage has occurred, it has been confined largely to islands belonging to the same European language group (each of these usually being of the same colonial affiliation). The Hispanophone islands also have a link to Latin America, which is lacking in the English-, French-, and Dutch-speaking territories. Although plantations continue to occupy large portions of land, their social significance has declined as people have left the countryside, either moving to the towns or emigrating to other countries.

Major metropolitan languages of European origin that play a role in the Caribbean today are the languages of the former and present colonial administrations: English, Dutch, French, and Spanish. In addition to the standard varieties of these languages, there are a number of colonial varieties of French in St. Barthélemy (St. Barts) and St. Thomas. Standard Dutch is an official language in the Netherlands Antilles, the only remnant of the Dutch empire. The Caribbean basin constitutes a clearly definable dialect area of American Spanish, including the varieties spoken in Cuba, Puerto Rico, the Dominican Republic, a few places in Trinidad, Guyana, the Caribbean coast of Venezuela and Colombia, and some coastal areas of Central America and Mexico.

Languages of Southeast Asian and Asian origin include varieties of Hindi, Urdu, and Chinese brought by indentured laborers. These languages are primarily nonstandard varieties used as home languages with no wider currency or status, and the younger generation are often no longer fluent in their use.

In their everyday lives, the majority of people in the Caribbean speak creole languages, which have developed from contact between the languages of the colonizers and those of the slave laborers. Nevertheless, the majority of children throughout the Caribbean continue to be educated in metropolitan languages rather than in their own native creole languages. The disparity between home and school language has contributed to a high rate of educational failure and low rates of literacy. Compare Haitian Creole French *Mwen grangou* with standard French *J'ai faim* 'I'm hungry'. Public attitudes to the creoles still tend to be largely negative, and the comments made by some speakers of French Creole from the Eastern Caribbean are typical: 'It's broken French, you can't write it down. No, it's not a language'. Speakers often have no special names for their languages other than *patois* (patwa) or broken English/French.

Despite the school's rejection of the children's native language, creoles today are the most powerful vehicles by means of which local Caribbean identities are formed and expressed. The absence of a high culture expressed through an indigenous language has meant that the voice of the masses and popular culture has generally been expressed through creoles, in both spoken and written forms.

In Jamaica, in particular, a strong, black national identity has gone hand in hand with nationalist politics to foster a powerfully vibrant creative arts movement, whose influence has extended far beyond Jamaica and the Caribbean. Rejecting the term *dialect* because it suggested inferiority, Edward Kamau Brathwaite (1984) argued for the use of what he called 'nation language' (Jamaican Creole English) in poetry as a way of capturing the sounds and rhythm of oral traditions of performance. Inspired by hearing a recording of T.S. Eliot reading from *The Waste Land*, Brathwaite urged poets to model their poetry on the African-derived rhythms of calypso to break the pentameter, which other New World poets before him, such as Walt Whitman, had also sought to undermine. Brathwaite was one of the founders of the Caribbean Artists Movement in 1966 in London, who fostered the development of a West Indian literature rooted in the languages and experiences of the islands. Through the commercial success of performers such as Bob Marley, Mikey Smith, Linton Kwesi Johnson, and Benjamin Zepphaniah, or Mutabaruka, whose music and sound poems were on the British reggae music charts in the late 1970s and early 1980s, the once historically devalued Caribbean popular culture has become part of multicultural Britain.

The Anglophone Caribbean has a population of approximately six million. The three largest

English-creole-speaking communities are Jamaica, Trinidad and Tobago, and Guyana. In most of these communities, standard (usually British) English is the official language and is used in most public sectors of communication. Despite the fact that the creoles of the eastern Caribbean are older, they are closer to standard English than the creoles of the western Caribbean. This is because of the presence of fewer Africans in the early settler population, allowing regional forms of English to be established.

In a small number of places, the creoles coexist with a French creole (e.g. in St. Lucia and Dominica) or with other ethnic languages (e.g. Belize, Guyana, United States Virgin Islands, and Trinidad). In most cases, there is a broad spectrum of varieties, which can be arranged along a continuum from those that are 'deepest', i.e. furthest removed from standard English and spoken by the rural uneducated, to those that are closest to standard English. Most people know several varieties and are able to switch between them depending on the context. Compare some of the variants from Guyanese Creole, *mi gii am/mi bin gii am/mi bin gii ii* with *a geev ii/a geev him* 'I gave him'. The deepest form of creole uses the object form *me* instead of standard English *I*; past tense marking is optional by means of *bin*.

The Afro-Caribbean region has been one of the vibrant areas in the world producing literature in English, as evidenced by the fact that Nobel prizes and other prestigious awards have gone to some of its writers, such as Wole Soyinka from Nigeria and Derek Walcott (born 1930) from St. Lucia, some of whose works draw on pidgin and creole English.

French creoles are spoken primarily on the French Antilles islands (Guadeloupe, Dominica, Martinique, and St. Lucia) of the Lesser Antilles and Haiti, as well as in former French Guaiana on the South American mainland between Suriname and Brazil, today a département of France. Although each creole variety spoken in the French Antilles is slightly different, they are sufficiently similar to one another to constitute a group distinct from Haitian and from the varieties spoken in the Commonwealth Antilles (Trinidad and the Windward Islands of Dominica, St. Lucia, and Grenada), which were British from the eighteenth century until their recent independence. In these countries, English is now the official language. Hence, the creoles coexist with English creoles and standard English and have been influenced by English, whereas Haitian and the French Antilles varieties have continued to be influenced by French. Creole French is still the main vernacular on Dominica and St. Lucia, although English and creole English are gaining ground. There is a fairly strong tradition of written literature, particularly poetry, in the French Antilles. Haiti, occupying the western third of the island of Hispaniola, which it shares with the Dominican Republic, has the largest number of creole speakers (more than six million) in the Caribbean. Independent since 1984, 90% of Haitians speak creole as their only language, and are culturally and linguistically isolated from France. A bilingual elite has continued to maintain French, and French continues to dominate in the public and formal sectors, such as government and education. Since 1983, Haitian Creole has been a co-official language with French and has been used in some primary schools as well as in adult literacy campaigns. Haitian Creole has one of the richest literatures of any creole languages, dating back to the nineteenth century. A creole variety of Spanish called Palenquero is spoken by older people in an isolated village called El Palenque de San Basilio, south of the city of Cartagena on the Caribbean coast of Colombia. Papiamentu is a creole based on Portuguese and Spanish spoken on the Leeward Islands of the Netherland Antilles (Aruba, Bonaire, and Curaçao) just north of Venezuela. Papiamentu has the highest status of any of the Caribbean creoles; it is spoken by virtually all social classes across a wide range of contexts and is used in the media.

Only three creole forms of Dutch are known to have resulted from the presence of Dutch traders and settlers in the Caribbean during the seventeenth and eighteenth centuries. A variety called Negerhollands ('Black Dutch') was present until just recently in the Virgin Islands, ruled first by Denmark and then by the United States. There it was replaced by local forms of English. The other two nearly extinct varieties, Berbice Creole Dutch and Skepi Creole Dutch, arose in what were once separate colonies isolated by great rivers and wildernesses, but became subsequently British Guiana (later independent Guyana) in northern South America. They are now spoken only by older people and are not mutually intelligible.

Case

The notion of case was inherited from traditional grammars describing languages such as Latin, Sanskrit, Russian, and German. In these languages, nouns (or noun phrases) differ according to their particular function in the sentence; i.e. a subject noun would be slightly different when used as an object. Languages differ very much with respect to how case is manifested. There are languages, such as Chinese, that do not mark nouns for case at all. There are also languages with a partial manifestation of case. In English, for example, regular noun phrases do not show case marking, but pronouns do: *he* (nominative case, subject) vs. *him* (accusative case, object) vs. *his* (genitive, or possessive, case). Then, there are languages that have a rich case system, such as German, in which regular noun phrases are marked for case: *Der Hund bellt* 'The dog barks' (nominative, subject) vs. *der Kopf des Hundes* 'the dog's head' (genitive) vs. *Ich gebe dem Hund einen Ball* 'I give a ball to the dog' (dative, indirect object) vs. *Ich sehe den Hund* 'I see the dog' (accusative, direct object).

Given such a variation, there was a long debate in linguistics on whether case is universally active in all languages or whether this notion is relevant only in the description of languages that actually mark their nouns accordingly. In the first half of the twentieth century, the most influential theories on case ignored its syntactic nature and aimed to specify the meaning of different case markers (prepositions, inflections, etc.). Charles Fillmore (1968) introduced the notion of case into the framework of generative grammar, arguing that case reflects meaning relationships between e.g. the verb and the subject or object in a sentence. In the late 1970s, however, Jean-Roger Vergnaud shifted perspective and claimed that case is a manifestation of syntactic relations only. In other words, case marking shows only whether or not a given noun is e.g. the subject or an object, independent of the meaning of the words involved. Noam Chomsky's *Lectures on Government and Binding* (1981) gives a first explicit formulation of case theory as a separate module of Universal Grammar.

The Chomskyan theory of case relies crucially on the assumption that case is present in all languages (in Chinese as well as in English or Russian) and that overt case marking is just a manifestation of an abstract case, which is assigned to noun phrases in a particular syntactic environment. Although traditional grammars use a fairly large number of cases, Chomsky eliminated all but three: nominative (assigned to the subject position of a finite clause, e.g. *John/he speaks well*), accusative (assigned to an object position of a transitive construction, e.g. *We see John/him*), and oblique (assigned by prepositions, e.g. *of John/him, to John/him,* etc.).

For case to be functional, the syntactic environment has to fulfill certain conditions, among them the requirement that a 'case assigner' has to be present. In English, verbs, prepositions, and tense can function as case assigners. A sentence such as *I am happy John* is ungrammatical, because there is no word adjacent to *John* that could possibly assign oblique case to it. *I am happy for John*, on the other hand, does contain the case-assigning preposition *for* and is thus grammatical.

Furthermore, a noun phrase must stand in a particular relation with its case assigner. A sentence such as *John believes that him to be happy* is ungrammatical, because the noun *him* is structurally too far from the case-assigning verb *believes* to receive the proper

accusative case. However, the verb is able to exert the proper influence on the noun phrase if the complementizer *that* is absent: *John <u>believes him</u> to be happy.*

Thus, the case assigner and the case-receiving noun phrase have to be directly adjacent. This is also shown by the contrast between the following sentences: *I see rarely him* and *I see him rarely*. The first one is ungrammatical, because the adverb *rarely* intervenes between the noun phrase *him* and the case-assigning verb *see*. The second one shows *rarely* at the sentence-final position, *see* is adjacent to *him*, and accusative case can be assigned. The sentence is thus grammatical.

According to early syntactic theories, case was discussed solely with respect to the form of nouns. However, Chomsky argued in *Knowledge of Language* (1986) that case seems to be crucial for the proper interpretation of the sentence. Thus, case is not only a formal requirement but also plays a role in meaning.

Case is an abstract notion and can be divided into two kinds: 'structural case' and 'inherent case'. Nominative and accusative are considered structural cases, because they refer only to the formal properties of the sentence: they mark whether a given noun is a subject or an object. Dative, genitive, etc., i.e. the oblique cases, are inherent cases because they depend on a meaning relationship between the case assigner and the noun phrase that is assigned the case.

The notion of inherent case implies that nouns, as well as adjectives, can be regarded as case assigners. Thus, in *a gift <u>to</u> my friend* and *a gift <u>of</u> my friend,* the case relationship is one between the two noun phrases *a gift* and *my friend*. Thus, *a gift* is said to be the case assigner, whereas *my friend* receives case. The prepositions *to* and *of* are interpreted as realizations of the dative and genitive cases, respectively.

'Abstract case' remains a very important concept in linguistics. The question about the nature of case and its role in syntax is still open.

Causation

The notion of CAUSATION, whereby an agent causes an event to occur has long been considered to be a fundamental semantic primitive. This can be seen in work in a variety of traditions: Generative Semantics, Functional Linguistics, Cognitive Linguistics, Conceptual/Event Structure, Role and Reference Grammar, and Proto-Roles, to name a few. Many of these approaches assume that there is a fundamental relation between an agent of causation (CAUSER) and the CAUSED EVENT. In some cases, the causation is effect through an intermediary (CAUSEE).

The expression of causation can be intrinsic to certain predicates (LEXICAL CAUSATIVES) or can be part of a productive process by which a language encodes causation (PRODUCTIVE CAUSATIVES). Lexical causatives include predicates that inherently denote a causative relation (1) or can form part of an inchoative/causative alternation (2). Productive causatives involve a separate causative predicate, either a separate word (ANALYTIC CAUSATIVES—3a) or a causative morpheme (SYNTHETIC CAUSATIVES—3b):

Lexical Causatives:

(1) The farmer killed the duckling. *Inherent causative*

(2) a. The window broke. *Inchoative*
    b. The child broke the glass. *Causative*

Productive Causatives:

(3) a. The farmer made the duckling die. *Analytic causative*

    b. Adam çocuğa kaıyı aç-**tür**-dı *Synthetic causative (Turkish)*

    'The man made the child open the door.'

A good deal of interest with respect to the linguistics of causation comes from the manners in which languages tend to productively encode the notion of causation. This article surveys two dimensions of the encoding of causation: CLAUSALITY and CAUSEE ENCODING.

A striking aspect of productive causative constructions is the manner in which they simultaneously exhibit both biclausal and monoclausal characteristics. Because productive analytic causatives have two distinct predicates, a base predicate (e.g. *die* in 3a) and a causative predicate (e.g. *make*), it is not surprising that they behave as two clauses. More surprising are the monoclausal aspects of these constructions. For example, analytic causatives in Spanish appear to be standard biclausal constructions with embedded infinitival clauses:

(4) El maestro les hizo leer ese libro a los estudiantes.

    'The teacher made the students read that book.'

However, on closer inspection, various local dependencies, which are normally restricted to single clauses, can span the two predicates. For example, the placement of object clitics is normally clause-bounded; the clitic occurs with the verb of which it is an object. However, in the case of causative constructions, a clitic may (and sometimes must) occur with the causative predicate (known as CLITIC CLIMBING):

(5) El maestro se **lo** hizo leer a los estudiantes.

    'The teacher made the students read it.'

This is one of several clause-bounded phenomena that are mitigated across causative and base predicates, and a way in which causative constructions, even when expressed analytically, share characteristics with monoclauses (cf. Aissen 1979; Aissen and Perlmutter 1983; Rizzi 1978; Burzio 1986, among others). This has led to analyses in terms of COMPLEX PREDICATE formation. While the mechanics of such analyses have differed, the basic insight is the same: two predicates define a single clausal domain (see Moore (1996) for a survey of approaches).

Because the causative and base predicates form something like a single, complex predicate, the arguments of the two predicates become coarguments. In this way, the argument that would have been the subject of the base predicate (the CAUSEE argument) can no longer be a subject, as that role is taken by the CAUSER argument. While languages vary in how the causee argument is encoded, there is a good deal of cross-linguistic consistency; this is true regardless of whether a productive causative is expressed analytically or synthetically (see Gibson and Raposo 1986). Two basic patterns are widespread—one having to do with the valence of the base predicate, and the other with the semantics of the causative predicate:

(6) *Causee encoding—valence based*:

    (a) If the base predicate is INTRANSITIVE, the causee is encoded as a DIRECT OBJECT.

    (b) If the base predicate is TRANSITIVE, the causee is encoded as an INDIRECT OBJECT or as an OBLIQUE.

(7) *Causee encoding—semantically based:*

    (a) If the causee undergoes DIRECT CAUSATION, it is encoded as a DIRECT OBJECT.

    (b) If the causee undergoes INDIRECT CAUSATION, it is encoded as an INDIRECT OBJECT or as an OBLIQUE.

Spanish causatives exhibit both of these encoding patterns:

(8) *Causee encoding based on valence of base predicate:*

    a. José *los* hizo trabajar. *Intransitive base predicate*

    'Jose made *them*$_{DO}$ work.'

    b José *les* hizo leer el libro.
Transitive base predicate

    'Jose made *them*$_{IO}$ read the book.'

(9) *Causee encoding based on directness of causation:*

    a. *La* hice probarlo a la fuerza.
Direct causation
'I made *her*$_{DO}$ try/taste it by force.'

    b. *Le* hice probarlo diciéndole que era riquísimo.
Indirect causation
'I had *her*$_{IO}$ try/taste it by telling her it was delicious.'

Analyses that deal with the two types of encoding patterns include those of Comrie (1981), Cole (1983), and Ackerman and Moore (1999).

Causation is a pervasive semantic notion that exhibits strikingly consistent patterns of grammaticization cross-linguistically.

Celtic Languages

'*Gallia est omnis divisa in partes tres, quarum unam incolunt Belgae, aliam Aquitani, tertiam qui ipsorum linguae Celtae, nostra Galli appellantur. Hi omnes lingua, institutis, legibus se differunt.*'

'All Gaul is divided into three parts, one of which the Belgae inhabit, the Aquitani another, those who in their own language are called Celts, in our Gauls, the third. All these differ from each other in language, customs and laws.' (Caesar, *De bello gallico* I,1)

Celtic is classified as a separate branch of the Indo-European (IE) language family. Like Greek and Latin, Celtic is a Centum language. It can be further subdivided into Continental and Insular Celtic. The division into Continental and Insular Celtic languages is not merely geographically based, but also genetically based. While the Gaulish and Brittonic languages share some features, excluding Celtiberian and Goidelic, the Insular and Continental division is based on commonalties in sound shifts from IE.

Although scholars agree on the relationship between ancient and modern Celtic languages, it must be stressed that speakers of different Continental Celtic languages did not refer to themselves as mutually related 'Celts'. These languages died out before the end of the Roman Empire, while evidence of the Celtic languages in the British Isles starts in the Early Middle Ages. This makes comparison of ancient modern Celtic languages problematic. The living Celtic languages can be further subdivided into Goidelic (Gaelic) and Brittonic (British). The descendants of Goidelic are Modern Irish and Scottish Gaelic spoken in Ireland and Scotland and the now extinct Manx, whose alleged last native speaker died in 1974. The Brittonic Celtic languages are Welsh in Wales, Breton in Britanny and Cornish, which died out in the eighteenth or nineteenth century.

In pre-Roman times, Continental Celtic languages were spoken all over Europe. Lepontic is attested in northern Italy before the arrival of the Gauls. Gaulish (in today's France) is known through personal names in Latin texts and some inscriptions in Greek script and a considerable amount in Latin; Celtiberian (or Hispano-Celtic) on the Iberian peninsula in Iberian script (Iberian being a non-Indo-European language), Galatian in Asia Minor, today's Turkey. A contested issue is the 'celticity' of Lusitanian, attested in three pre-Roman inscriptions in the west of the Iberian peninsula. Archeologically, the original native place of the Celts must have been in Central Europe, somewhere between Bohemia and Bavaria. The earliest clearly datable sources go back to the sixth century BCE.

Today, the surviving Celtic languages are confined to the westernmost parts of Europe, the *Celtic fringe*: the west, northwest and southwest of Ireland, Scottish Highlands and Western Isles, large parts of Wales and western Britanny. Remnants of Celtic-speaking people are also to be found in the Americas: Welsh-speaking people in Patagonia (Argentina) and some Scottish Gaelic in Nova Scotia (Canada). Exactly when and in how many migration waves the Celts came to Ireland is hard to determine. The oldest Irish coherent manuscript text *Amra Choluim Cille* goes back to 600 CE,

making Irish the oldest attested continental European language after Greek and Latin. Within the written Irish tradition, three main periods can be distinguished: Old Irish, Middle Irish, and Modern Irish. The Great Famine (1845–1948) nearly eradicated the Modern Irish language. More than one million people starved, while another million fled to America. Today, after efforts to revive the endangered language, only three main dialects are distinguished according to the provinces in which they are spoken: *Connacht, Ulster,* and *Munster Irish. A* standard language, mainly based on Munster Irish, also exists. Irish has been the official language of Ireland since the establishment of the Free State in 1922.

In the study of Celtic languages, phonology plays a large role as Old Irish preserves few case or personal endings. As early as Common Celtic times, the sound *p* had disappeared. Therefore, the IE word for *father* appears in Old Irish as *athair.* According to some scholars (see Untermann and Wodtko 1997), the existence of *p* in Lusitan makes it probable that this loss was not a common Celtic phenomenon. Another peculiarity of Celtic languages are the so-called initial mutations. Simply speaking, mutation means that the sound dropped at the end of one word affects the first sound of the following word. One of the most interesting characteristics of Celtic languages is their syntax: the basic word order is Verb–Subject–Object, where the verb stands at the beginning of the sentence. For example, in Irish, *D'oscail mé an doras* (lit. 'Opened I the door'), the verb not the subject is first.

Irish

The sound system of Irish is fairly complicated compared to English. For each consonant, there is a palatal equivalent, making it similar to Russian. Lenition, a sound assimilation, and eclipsis, the omission of symbols, make the orthography look somewhat strange to the native speaker of English. Examples include phrases like *i nGaillimh* and *ó Bhaile Átha Cliath* for 'in Galway' and 'from Dublin' and surnames like *Ní Dhomhnaill* for female 'Mac Donald'. Two verbs for 'to be' exist in Irish, one being the copula *is* and the other the substantive verb *tá.* Their distribution is very similar to Spanish *ser* and *estar.* There is no word for 'to have' in Irish, as for many—in other languages clearly verbal concepts like 'to love', 'to owe', 'to know', etc., are all phrasal verbs containing the verb 'to be' (e.g. Ir. *Tá grá agam duit* lit, 'there is love at me to you'). This gives us a picture of a language that on the one hand has a clearly verb-centered syntax, but on the other very few strictly verbal concepts.

Scottish Gaelic

Before the Middle Ages (approximately tenth century CE), there was no difference between the Gaelic spoken in Scotland and the one in Ireland, since they both developed from the same parent language, Old Irish. The Reformation played a key role in linguistic self-definition. After the Jacobite Rising in 1745, a huge deportation of Scottish Gaelic-speaking population to Overseas initiated the blackest chapter in the history of Scotland: the Clearances. In the first half of the nineteenth century, Gaelic-speaking peasants were systematically driven from their land in order to give way to extensive sheep breeding. Today, Gaelic is a community language only in the Western Isles and on parts of Europe's western seaboard. Many linguistic phenomena encountered in Modern Irish, especially the Ulster Dialect, are found in Scottish Gaelic as well, including sound changes, mutations, and spelling.

Welsh

Written Old Welsh texts are attested from the ninth century. Until 1288, Welsh had status in administration and government. The Bible translations in 1567 (New Testament by William Salesbury and Richard Davies) and 1588 (the whole Bible by William Morgan) played a crucial role in Welsh history. Today, linguists distinguish two main dialects based on lexical variation: Northwalian Welsh and Southwalian Welsh, each comprising a number of more localized dialects, and the Literary or Formal Welsh language, itself comprising a number of written varieties or 'dialects'.

Welsh has a few distinctive consonant sounds, the most unusual being the voiceless lateral fricative *ll* and the voiceless alveolar trill *rh.* The unusual spellings *w* for [u] and *u* for [i] makes it seem as if there are too few vowels in a word. Three initial mutations, soft mutation, aspirate mutation, and nasal mutation, are present, and Welsh shares the VSO syntactic pattern: *Agorodd y dyn y drws* (lit. 'Opened the man the door').

Breton

Brittany was settled by people fleeing from Anglo-Saxons between the fourth and sixth century CE. Breton is therefore a Britannic language, even though Britanny is geographically European mainland. There is no unique standard written language. The main dialects are Cornouaille, Leon and Tregor, and Vannetais. Due to historical circumstances, Britanny has always been bilingual. As a consequence of permanent language contact, Breton has a very

French-sounding accentuation and sound system and also the strongest tendencies of all Celtic languages toward dropping its verb initial sentence structure.

Celtic Scholarship began in 1707 with the Welsh historian Edward Lhuyd (1660–1709) and his unfinished work *Archaeologia Britannica*. In 1853, Johann Kaspar Zeuss (1806–1856) published his *Grammatica Celtica*, which must be regarded as a further milestone in the establishment of Celtic Studies. A few more prominent Celticists were German native speakers: Ernst Windisch (1844–1918), Rudolf Thurneysen (1857–1940), Kuno Meyer (1858–1919), Julius Pokorny (1887–1970), and last but not the least Dane Holger Pedersen (1867–1953). Old Irish is most prominently studied, followed by Middle Welsh. Recent developments in European archeology have led to an increase in often-controversial works on Continental Celtic.

What all Celtic languages spoken nowadays have in common is that they are endangered minority languages, due to the predominance of English or, in Britany, French. Celtic linguistic history must be examined within the context of industrialization, and its negative influence on indigenous languages. Oral tradition is dying out in the wake of modern media, and today nearly all adult Celtic native speakers are bilingual. The British Labour Party has been regarded by some as the 'rescuer' of the Celts in Great Britain since it has engaged in decentralization and the founding of regional parliaments and assemblies. However, the future of the Celts as well as the languages remains to be seen.

Chafe, Wallace

From the very beginning of his linguistic career Wallace Chafe has been involved in studies of American Indian languages, in particular, of the Iroquoian and Caddoan language families. In 1962, he published a general survey of the sociolinguistic state of the native languages of North America, indicating the number of speakers and the age of the youngest speakers, which remains relevant even now, 40 years later.

Among American Indian languages, Chafe has been involved most of all with Seneca, an Iroquoian language spoken in New York state, a polysynthetic language with the agent–patient system of role marking on the verb. Seneca examples cited in Chafe's work often demonstrate vast differences in conceptualization possible across human languages, especially as compared to European languages. Chafe also studied languages of the Caddoan language family, distantly related to Iroquoian.

In 1970, Chafe published a monograph entitled *A semantically based sketch of Onondaga* (Iroquoian) that was revolutionary for its time, being markedly different from both traditional American descriptivism with its emphasis on formal patterns and the growing

generative approach based on axioms of universal syntax. Chafe chose meaning as his starting point and presented the linguistic material as a system of mappings 'meaning => form'. In general, Chafe is unique among the American linguists of his generation in never being tempted to accept the generative Chomskyan approach.

This orientation toward semantics was also the chief element of his well-known book *Meaning and the structure of language* (1970), later translated into five languages. One of the main components of that book is a semantic classification of verbs. Along with Charles Fillmore, Chafe was among the first who realized the importance of semantic roles. The book also clearly demonstrated a typical feature of Chafe's subsequent publications — a very clear and simple style of writing that is of great persuasive force.

In the 1970s, the main focus of Chafe's theoretical research interests shifted to natural discourse. At that time, the trend that later acquired the label 'functionalism' and became a radical alternative to generativism started to take shape in the United States. Although Chafe was never an ideolog, he became one of the leading functionalists.

From the very beginning of his discourse studies, Chafe relied on a cognitive approach and tried to reconstruct the mental processes of a speaking person. In that respect, he was far ahead of the other students of text. In a widely known 1976 article, Chafe approached such familiar phenomena as referential devices, word order, and choice of subject from a cognitive perspective. His studies of the 1970s culminated in the 1980 monograph *The pear stories* in which an unusual method of data collection was used: Chafe and his younger associates (D. Tannen, J. du Bois, P. Clancy, among others) showed a short film of a boy collecting pears to speakers of different languages and ages who later retold what they saw. Thus, the input was controlled, and the different versions of the pear stories were available for comparison. Many innovative conclusions concerning processes of the verbalization of visual experience, the dynamics of human consciousness, cultural differences in emphasizing different layers of information, and the cognitive basis of grammatical choices were drawn in that study.

The following stage of Chafe's work is reflected in his recent (1994) book *Discourse, consciousness, and time.* This work looks into relationships between language and consciousness, the latter understood by Chafe as the mental system crucially responsible for discourse production. According to Chafe, language and consciousness cannot be understood and explored in isolation from each other. Chafe evaluates both disciplines studying those two domains, that is, modern linguistics and psychology, in a very critical vein, in particular, for their reliance upon artificial data and distrust toward introspective methods of research. Chafe emphasizes the use of introspection as a source of insights into language and cognitive processes, as well as the priority of natural data. The latter concern results from Chafe's inherent connection with the American ethnographic tradition that has always emphasized the importance of natural empirical data.

In this 1994 book, Chafe explores two main problems. The first is the explanation of linguistic phenomena on the basis of processes occurring in the speaker's consciousness. Consciousness can be immediate (a reflection of what is here and now) and displaced (memories, imagination). Immediate consciousness is more basic and elementary, while displaced consciousness can only be understood as a modification or complication of immediate consciousness. The second problem is the comparison of spoken and written language. Spoken language is more basic and universal, despite the fact that for decades linguists have directed their attention to written or quasi-written language only. Chafe gives priority to the spoken mode, but has also studied properties that distinguish written language.

The fundamental unit of discourse, according to Chafe, is the intonation unit, which is a quantum of discourse corresponding to one focus of consciousness. Each intonation unit typically contains one element of new information. The opposition 'given vs. accessible vs. new' is responsible for prosodic (stressed vs. unstressed) and lexical (pronoun vs. noun) realizations of referents. The status of syntactic subject, central for English grammar, is explained on the basis of the notion of the starting point for the expression of a focus of consciousness. The important light subject constraint suggests that subjects are normally given or accessible, and can be new only under very special conditions. The intermediate status of accessible information is the base for defining a discourse topic, which, in its turn, underlies a definition of sentence.

Among various modifications related to written language and the displaced mode of consciousness, prose written in the third person and quoted speech are discussed.

At present, Chafe is engaged in producing descriptions of the Seneca and Caddo languages, and he is also investigating the uses of prosody in ordinary speech, particularly for the expression of emotions and humor, and relations between language and music.

Among the main characteristics of Chafe's style of scientific thinking are the ability to look afresh at ordinary phenomena and to integrate a broad range of facts into a coherent picture, as well as independence from the dominant trends of thought. There is no doubt that Chafe is among the leading figures and a classic of modern linguistics, but like Sapir he has not created a circle of immediate followers and his works are not in the mainstream of modern linguistics.

Biography

Wallace Chafe was born in Cambridge, Massachusetts on September 3, 1927. He served in the US Navy, 1945–1946, and Central Intelligence Agency, 1950–1954. He received his B.A. in German from Yale University in 1950 and M.A. in linguistics from Yale University in 1956. He received his Ph.D. in linguistics from Yale University in 1958 for a dissertation on the Seneca language. He was Assistant Professor of Modern Languages at the University of Buffalo, 1958–1959, and linguist in the Bureau of American Ethnology, Smithsonian Institution, 1959–1962. In 1962, he moved to the University of California at Berkeley and worked there in the Department of Linguistics until 1986. From 1986 onward, he worked in the Department of Linguistics at the University of California at Santa Barbara. At present, he is Professor Emeritus at UCSB. He was Fellow of the Center for Advanced Study in the Behavioral Sciences, Palo, 1976–1977. He held a number of additional teaching appointments, including the Linguistic Institute of the Linguistic Society of America, in the summer of 1995, Albuquerque, New Mexico. Chafe was editor of the Mouton Grammar Library, 1984–1991; Topic Editor, Oxford International Encyclopedia of Linguistics; President of the Society for the Study of the Indigenous Languages of the Americas, 1985–1986; Associate Director of the Linguistic Institute of the Linguistic Society of America, Georgetown University, 1985; co-Director of the Center for the Study of Writing, Berkeley, 1985–1986; and member of the Linguistic Society of America Executive Committee, 1987–1989. He was also Member of the advisory and editorial boards of: International Journal of American Linguistics; Anthropological Linguistics; John Benjamins Typological Studies in Language Series; International Pragmatics Association; Humor: International Journal of Humor Research; Text: An Interdisciplinary Journal for the Study of Discourse; and Consciousness and Cognition. In addition, he was a member of the following professional societies: Linguistic Society of America; American Anthropological Association; American Psychological Association; American Psychological Society; Society for Linguistic Anthropology; Society for the Study of the Indigenous Languages of the Americas; International Society for Historical Linguistics; and International Pragmatics Association. He was Skomp Distinguished Lecturer, Indiana University, 1997, and received the medal of the University of Helsinki in 1998.

Chao Yuen Ren

A Chinese–American linguist and one of the leading figures in American Structuralism, Chao Yuen Ren made important contributions in the general theory of language and by introducing the Chinese language(s) as an object of research to a broader linguistic community. His work covers a wide range of issues both in theoretical and in applied linguistics, including fieldwork on Chinese dialects (usually conceived today as separate languages), the grammar of Modern Chinese, Chinese lexicography, practical material for Chinese language teaching, language standardization in China, the general theory of language, and studies in sociolinguistics.

Born into a family belonging to the old scholar and mandarin class, Chao's interest in linguistic variability was aroused during early childhood, when he came into contact with, and learned to speak, a number of different dialects. His family originally came from the town of Changzhou (between Nanjing and Shanghai), where the westernmost variety of the Wu dialect group is spoken. During the first half of his childhood, however, the family lived in various places in Hebei province, Northern China, and frequently moved around between the then provincial capital Baoding and smaller places. In those years, Chao was therefore exposed not only to the Wu dialects spoken by the older generations of his family but also to different varieties of Northern Mandarin, which he heard from his surroundings.

Although he majored in mathematics and physics at Cornell University, he increasingly took an interest in philosophy and was influenced in particular by the writings of Bertrand Russell. However, he kept up his strong interest in languages, further stimulated by a course in phonetics and other linguistic courses. During those years, he also learned German and French, and picked up more Chinese dialects from Chinese fellow students. During his graduate studies in the Department of Philosophy at Harvard, he attended an introductory course in linguistics and took quite a few language courses on the side, among them a course in Sanskrit.

During the winter of 1920/1921, Chao served as an interpreter to Bertrand Russell during his lecture tour in China and made full use of his mastery of the dialects. This experience provided a challenge to Chao in a way physics never had, and it was then that he decided upon linguistics as a major field of study and research. Therefore, while teaching philosophy at Harvard during the next three years, he took linguistic courses at the same time, and subsequently went to Europe to work and study with the phoneticians Daniel Jones and Stephen Jones, the linguists Joseph Vendryes and Antoine Meillet, and the sinologists Bernhard Karlgren, Paul Pelliot, and Henri Maspero.

After his return to China, primarily to teach Chinese phonology, he spent more than ten years making and organizing surveys of the Chinese dialects, which resulted in a number of pioneering studies: the first one was on the Wu dialects of Jiangsu and Zhejiang provinces (1926–1927), published as his ground-breaking *Studies in the modern Wu dialects* (1928), followed by surveys on the Yue dialects of Guangdong and Guangxi provinces (1928–1929), Minnan dialects of Shantou and Chaozhou and the dialects of Anhui (1934), Jiangxi and Hunan (1935), and Hubei provinces (1936). During the late 1920s, he was also active in the Committee on Unification of the National Language and headed a group of Chinese linguists who developed a new system of Latinization for Chinese, National Language Romanization (*Gwoyeu Romatzyh*), which was unique in using spelling variants instead of diacritics to express the tones of Chinese.

Chao had plans for a dialectal survey of the whole country, but his fieldwork was eventually interrupted by the political development in China and the outbreak of war with Japan. Following these events, in 1938 he came to the United States for good and subsequently taught at the University of Hawaii; at Yale, where he met Leonard Bloomfield, Edward Sapir, and Bernard Bloch; at Harvard; and, finally, at the University of California, from where he retired in 1960.

Chao's pioneering fieldwork on the Chinese dialects is clearly one of his main contributions to linguistics. Before him, the European sinologists Henri Maspero (1883–1945) and Bernard Karlgren (1889–1978) had used Chinese dialect data in comparative studies for reconstructing earlier stages of Chinese (in particular, what Karlgren called 'Ancient Chinese'), but they were interested in Chinese dialects only to the degree that they had preserved the phonetic features of those earlier stages. Chao, however, was the first to look at the Chinese dialects from a truly modern perspective, recognizing them as objects worth studying for their own sake. He carried out wide-ranging dialect surveys using the most modern sound recording devices of the times, and he included real dialect words found in nonlearned, colloquial speech. Although Chao's fieldwork was disrupted by the historical events in China and thus remained

fragmentary, it provided a solid foundation for later work, much of which was done by his students.

In the field of Chinese grammar and language teaching, Chao wrote two epoch-making books in which he applied the grammatical approach of American structuralism to the description of Modern Chinese: *Mandarin primer,* published in 1948 as a textbook for American students learning Chinese, contains an introductory grammatical sketch that was translated into Chinese and had a tremendous impact in China, effectively introducing the methodology of structuralism to a wide Chinese audience. The grammatical sketch of the *Primer* provided the best linguistic description of Modern Chinese until 1968, when Chao published *A grammar of spoken Chinese*, a monumental work that was the first comprehensive reference grammar of Chinese written in English, and that is arguably the best description of Modern Chinese to this day.

In Chinese lexicography, Chao and Yang's *Concise dictionary of spoken Chinese* (1947) made a number of important lexicographic innovations, restricting entries to those morphemes that occur in the modern spoken or written language, marking the morphemes as 'free' or 'bound' from the point of view of the modern language, and as 'literary' if they occur in the written language only. Pronunciation of the entries is given in National Language Romanization.

Among Chao's works on theoretical phonology, the most influential one was his classical paper 'The non-uniqueness of phonemic solutions of phonetic systems' (1934/1957), which deals with the definition of the phoneme and tries to show that the principles for establishing a system of phonemes for a given language depend on a number of possible objectives set up by the linguist, some of which are external to the language system itself. Chao also introduced a convenient device of representing tones in phonetic or phonological transcriptions, which became known as 'tone letters' and was later adopted for the International Phonetic Alphabet. Over the years, a number of important articles on the problems of phonetics and transcription followed.

More than anyone else, Chao laid the foundation for studying Chinese within the international perspective of modern linguistics, and played a key role in introducing the ideas of Western linguistics to linguistic scholars inside China. Outside the area of linguistics, Chao is remembered as an outstanding translator (*Alice's adventures in wonderland,* 1922) and as a composer of Chinese and Western music.

Biography

Chao was born in Tianjin, China, on November 3, 1892. From the age of seven, he was given a traditional Chinese education in the family school at home. The family returned to Changzhou in 1901, and after both his parents died in 1904, he spent a year in his aunt's home in Suzhou. After attending a primary school in Changzhou in 1906, he was sent to Nanjing for three years to continue his studies. In 1910, he passed a government examination, which earned him a scholarship for studying in the United States of America, and he went to the Tsing Hua College in Beijing to prepare himself. Chao thus studied mathematics and physics at Cornell University, Ithaca, B.A. (1914), followed by physics and philosophy at Harvard, where he earned his Ph.D. degree in 1918 with *Continuity, a study in methodology*, which was supervised by the philosopher and logician Henry Maurice Sheffer. Chao received the post-doctorate Sheldon Fellowship, 1918–1919 and went on to teach physics at Cornell in 1919–1920. He then went back to China to teach mathematics at Tsing Hua College in Beijing, but was soon asked to interpret for Bertrand Russell on his lecture tour of China, 1920–1921. Afterwards, he returned to Harvard to teach philosophy and Chinese, at the same time taking linguistic courses (1921–1924). He went to Europe to visit the sinologist Bernhard Karlgren in Gothenburg, took courses in phonetics with Daniel Jones and Stephen Jones in London, and attended lectures by Joseph Vendryes, Antoine Meillet, Henri Maspero, and Paul Pelliot in Paris (1924). Returning to China, he taught Chinese phonology and music at Tsing Hua College's newly established Institute of Sinology (1925), and then conducted and organized fieldwork on Chinese dialects between 1926 and 1936. He was an active member of the Committee on Unification of the National Language and the chairman of the Linguistics Section of the Institute of History and Philology, Academia Sinica (1929–1938). He was visiting professor at the Sunyatsen University, Canton (1928—1929) and then temporarily returned to the United States of America as the director of the Chinese Educational Mission in 1932–1933. He obtained his American citizenship in 1938 and then taught literary Chinese as a visiting professor at the University of Hawaii (1938–1939) and Yale (1939–1941) before returning to Harvard once again, as a researcher with the Harvard-Yenching Institute's Chinese–English Dictionary Project. He also taught Chinese and Cantonese, and served as head of Harvard's wartime Chinese language program (1941–1947). He became Professor of Oriental Languages and Linguistics at the University of California, Berkeley in 1947 and was made Agassiz Professor of Oriental Languages and Linguistics in 1952. A guest lecturer at National Taiwan University and Kyoto University, Japan in 1959, he retired the following year, in 1960.

Chao was also President of the Linguistic Society of America, 1945; full member of the Academia Sinica, 1947; Fellow of the American Academy of Arts

and Sciences, 1948; and President of the American Oriental Society, 1960. He earned honorary degrees from Princeton University (1946), the University of California (1962), and Ohio State University (1970) and was named Honorary Professor at Beijing University in 1981. Chao died in Cambridge, Massachusetts, on February 24, 1982.

China

The region of China discussed in this essay covers the entire territory claimed by the People's Republic of China, including Taiwan. It consists of 23 provinces, five autonomous regions, four municipalities, and two special administrative regions in an area of over 9,630,000 square kilometers. With a population of 1,295,330,000 (in the 2000 census), China is the most populous country and one of the most diversified regions in terms of languages and cultures in the world. No accurate number for languages spoken in China is available, but at least 235 languages (including signed languages and ten extinct languages) have existed in this region, cf. Grimes's *Ethnologue* (2000). Barring a few exceptions, they belong to one of the following groups (parenthetical figures indicate number of members and the group's percentage of total living languages): Sinitic (13, 5.78%), Tibeto-Burman (72, 32%), Tai-Kadai (31, 13.78%), Hmong-Mien (32, 14.22%), Altaic (25, 11.11%), Austro-Asiatic (24, 10.67%), Austronesian (18, 8%), and Indo-European (4, 1.78%). Figure 1 outlines their approximate distribution in China.

The map shows that Sinitic sits in the center, but it has spread out to every corner of China. There has been a general migration flow of people from the north to the south throughout much of the history of China. Southward invasion by Altaic speakers sometimes leads to the spreading of Chinese further north, as in the case of Manchu's government. On the other hand, southward expansions and escapes by Sinitic speakers are responsible, in part, for the migration of Hmong-Mien and Tai-Kadai speakers to their present-day habitation.

Scholars in China generally consider the Sino-Tibetan family to consist of four branches: Sinitic, Tibeto-Burman, Tai-Kadai, and Hmong-Mien (Miao-Yao). While the typological profiles of the latter two are rather similar to that of Sinitic, their genetic relationship with the family remains to be proven. Table 1 summarizes three aspects of the major language groups as to whether their members (confined to those in China) are tone languages, whether morphemes (the smallest unit that carries a meaning) in the languages are predominantly monosyllabic, and in what order the Subject (S), Verb (V), and Object (O) appear in canonical sentences.

The boundary between language and dialect is fuzzy in nature, and highly controversial when political factors are taken into consideration. The case of Chinese is a good example of this. The Chinese identify themselves ethnically as *Han*, and *Hanyu* is the

official language of China. From a strictly linguistic point of view (based on mutual intelligibility), however, at least 13 Chinese languages are spoken in modern China (see Figure 2). In the Chinese tradition, these are construed as dialects of *Hanyu* or subdialects therein. Prior to the twentieth century, Classical Chinese had been used in writing for all purposes, serving as the official language of the emperor for many dynasties. At the May 4th movement in 1919, student protesters in Beijing held among their goals a standard written language based on the modern Chinese speech. The then Government of the Republic of China responded by designating *Gwoyu* 'national language', based on Beijing Mandarin, as

the standard language of the new republic. Later in the 1950s, the Government of the People's Republic of China promoted *Putonghua* 'common language' (also based on Beijing Mandarin) as the national language. *Gwoyu* (still in use in Taiwan) and *Putonghua* have little difference in phonology. Their divergence has largely resulted from further language standardization introduced on the mainland, notably the replacement of phonetic characters by *pinyin* in the Roman alphabet and especially the use of simplified characters. The latter has compromised the antediluvian tradition of a unified written form for the Chinese since the unification of the warring states in China in 221 BCE.

Encyclopedia Sinica (1988) estimates the number of speakers of seven major dialect groups of *Hanyu* in the early 1980s as follows: over 700 million for Mandarin, 70 million for Wu, 40 million for Yue, 40 million for Min, 25 million for Xiang, 30 million for Gan, and 37 million for Hakka. Figure 2 shows the relation between 13 identified Sinitic languages. The tentative placement of Wan Nan is geographically motivated.

The Yangtze River is the watershed between Northern Chinese and Southern Chinese. Mandarin stretches from the vast region north of the Yangtze River to southwestern China provinces of Sichuan, Yunnan, Guizhou, western Hunan, and northwestern Guangxi. Following the escape of the Nationalist government from the mainland, a sizable number of Mandarin speakers settled down in Taiwan in the

1950s. More than 870 million people (in the late 1990s) speak Mandarin as a first language, including nearly all Manchu and the entire population of Hui, the second and third largest minority nationalities of China. The figure rises well beyond one billion if the number of fluent speakers of Mandarin as a second language is taken into account. Mandarin has four major dialects: Northern Mandarin, Northwestern Mandarin, Southwestern Mandarin, and Lower Yangtze Mandarin.

Found in coastal provinces, Wu is spoken on the east coast, Yue on the south coast, and Min on the southeast. The Yangtze Delta can be considered as the homeland of Wu. Wu is spoken nowadays in Zhejian province and much of the area south of the Yangtze River in Jiangsu province. It has five dialects: Taihu (which includes Shanghai as one of its six subdialects), Taizhou, Wenzhou, Wuzhou, and Liqu. The homeland of Yue (Cantonese) is in the Pearl Delta; from there, it spreads to a large part of Guangdong province and as far as southeastern Guangxi. Yue dialects include Yuehai (which is spoken in Guangzhou, Hong Kong, and Macau), Siyi, Gaoyang, and Guinan.

Min is regarded as the fourth largest dialect of *Hanyu*, and also the most diversified one with respect to dialectal difference. Indeed, the diversion is so significant that it warrants the treatment of Min as a linguistic group comprising five consanguineous, but distinct, languages. Li's *Dialects of Fujian* (1997) describes the distribution of these languages as follows: excluding a small Wu-spoken area in the northern corner and about one third of the province in western Fujian (where Hakka and Gan are spoken), the rest of Fujian can be divided into six areas: the south-

ern half contains Min Nan and Pu-xian (the latter occupies only a corner in the east), and the northern half contains Min Dong (in the eastern half), Min Bei (about 60% of the remainder in the north), and Min Zhong (the western half of the leftover). A transitional language between Min Nan and Min Dong exists in Youxi county, the very center of the province.

Min Nan is the largest Min language, with 25.7 million speakers (in 1984) in southern Fujian, eastern and western parts of Guangdong, parts of Hainan and Zhejiang, and an additional 15 million speakers (in 1993) in Taiwan. Major Min Nan dialects include Hokkien, Chao-Shan, Leizhou, Hainan, and Zhenan Min. Many can be subdivided, e.g. Hokkien has four subdialects: Amoy, Quanzhou, Zhangzhou, and Longyan. Pu-xian and Min Zhong occupy the smallest areas among the Sinitic, but Pu-xian has around three million speakers, whereas speakers of Min Zhong are less than one million. They each have two dialects, and so do Min Dong and Min Bei.

Xiang is mainly spoken in much of the eastern half of Hunan province. With Mandarin dominant in the north and in the west, Xiang has been under great pressure of assimilation. The influence of Mandarin represents a primary factor for variation between its two dialects: Northern Xiang is subject to more innovation, while Southern Xiang is more conservative. Gan is largely spoken in Jiangxi province, with five major dialects: Chang-Jing, Yi-Liu, Ji-Cha, Fu-Guang, and Ying-Yi. It is the closest relative of Hakka.

The distribution of Hakka is unique among Southern Chinese in that it covers the widest area in China, but often with a low concentration; it does not have a home base in any province. While the border area between northeastern Guangdong, southern

Jiangxi, and southwestern Fujian has a higher concentration of Hakka speakers, small Hakka-speaking communities are scattered in parts of Taiwan, Hunan, Sichuan, Guangxi, and throughout Guangdong. Major Hakka dialects include Min-ke, Yue-Tai, Yuezhong, Yuebei, Yugui, Tonggu, etc. The majority of She nationality also speak Hakka as their first language.

Jinyu and Wan Nan are two of the less-known Chinese languages. Spoken in Shanxi province and adjacent areas in Shaanxi and Henan provinces, Jinyu is generally assumed to be a subdialect of Northwestern Mandarin. Wan Nan is mainly spoken in an area called Huizhou in southern Anhui province. It is usually treated as a subdialect of Lower Yangtze Mandarin.

The Chinese government recognizes only 55 minority nationalities. Their total population is about 106.8 million, or 8.25% of China's population (in the 2000 census). Around 60% of them are native speakers of over 94% of languages in China. Table 2 shows the top 12 minority languages, each with one million or more speakers (in the early 1980s or 1990s).

Spreading across Xizang Tibetan Autonomous Region, southeastern Qinghai, western Sichuan, and much of the Yunnan provinces, Tibeto-Burman accounts for almost one third of identified languages in China. The three largest groups within it are Yi-Burmese (28 languages), Himalayish (17 languages), and Qiangic (15 languages). Speakers of Yi-Burmese in China exceed 6.4 million, including such nationalities as Yi, Hani, Lisu, Lahu, Naxi, Nu, Jino, and Achang. Chinese scholars consider that Yi nationalities speak six rather distinct "dialects" (just as the Chinese themselves do). Yi nationalities use an ideographic system for writing their languages, but characters vary considerably from district to district over southeastern Sichuan, Guizhou, and Yunnan. A set of

standard characters based on Sichuan Yi was introduced in 1975. Tomba is the traditional writing developed by Naxi nationality. The hieroglyphic writing, however, is restricted to religious texts only.

Himalayish languages have about 4.1 million speakers in China. Over 82% of them speak Tibetan, Khams, or Amdo. These three consanguineous languages (regarded as 'dialects' of Tibetan in China) share a common writing script adapted from the Indic syllabic writing system. Besides Tibetan nationality, the other official nationality for speakers of Himalayish is Moinba (whose population was less than 8,000 in the 1990 census). Exclusive to China, Qiangic languages have about 490,000 speakers in total. Approximately one fifth of Qiangic speakers are Qiang or Pumi nationalities; the rest identify themselves officially as being of Tibetan nationality. Historically, their languages have no written form, with the exception of Tangut (an extinct relative), which had a logographic writing modeled after Chinese characters. Bai, Tujia, Jingpo, Drung, and Lhoba are among the 17 official nationalities speaking Tibeto-Burman languages in China.

Spoken in much of Guangxi Zhuang Autonomous Region, Hainan, southern Guizhou, and southwestern Yunnan, Tai-Kadai has the second greatest number of speakers in China. Chinese scholars regard Northern Zhuang and Southern Zhuang as dialects of Zhuang, which was once written in logographic characters akin to Chinese characters, but a new Roman orthography was introduced in the late 1950s. Together with 20 others, the Zhuang languages belong to the Kam-Tai group. Seven nationalities are designated for the 20 million speakers of Kam-Tai, namely Zhuang, Buyi, Dai, Dong, Sui, Mulam, and Maonan. The Dai have adapted Brahmi script (a syllabic Indic script) for writing Lü and Tai Nüa for many centuries. Kadai (81,000

speakers in five languages) and Hlai (747,000 speakers in two languages) are two smaller groups within Tai-Kadai. Gelao and Li are the two official nationalities speaking Kadai and Hlai, respectively.

All 32 Hmong-Mien languages found in the world have speakers in China, scattered in various parts of Guizhou, Hunan, Guangdong, Guangxi, and Yunnan. The three official nationalities—Miao, Yao, and She—correspond to the three language groups within Hmong-Mien. Hmongic is the largest, comprising 26 languages spoken by 4.2 million people who are mostly Miao, but some are Yao. Over 1.1 million Yao speak five Mienic languages, but less than 1,000 She speak the singleton language in the Ho Nte group. Hmong-Mien languages have no traditional writing, but Roman orthographies have been devised for several larger languages since the 1950s.

With 11 Turkic languages, eight Mongolic languages, and five Tungusic languages, all three major branches of the Altaic family are present in China. Spoken along the northern and northwestern border of China—mostly in Heilongjiang province, Inner Mongolian Autonomous Region, and Xinjiang Uygur Autonomous Region—by 18 nationalities, the Altaic languages amount to 25, if Korean is included. Khakas, Nanai, and Manchu each have less than 50 speakers in China. According to estimates of the 1990s, Turkic has over 8.49 million speakers among Uygur, Kazak, Kirgiz, Salar, Bonan, Ozbek, Tatar, and Yugur nationalities; Mongolic has nearly 4.15 million speakers among Mongol, Tu, Daur, Dongxiang, and Yugur nationalities; and Tungusic has about 49,700 speakers among Xibe, Ewinki, Oroqen, Hezhen, and Manchu nationalities. Arabic script is used for writing Uyghur, Kazakh, and Kirghiz, whereas traditional Mongolian script is used for writing Mongolian and Xibe. Koreans write in Hangul, a phonetic-based spelling system created in 1444.

Va, Blang, and De'ang nationalities in western Yunnan, plus Jing nationality on the south coast of Guangxi, are speakers of Austro-Asiatic languages. All 24 Austro-Asiatic languages of China belong to the Mon-Khmer branch, with around 381,000 speakers in total. Only one sixth of them have more than 10,000 speakers. Parauk is the largest, with about 180,000 speakers (in 1990).

The mainland government designates an Austronesian-speaking minority in Taiwan as Gaoshan nationality, but on the island they are further divided into nine ethnic groups, collectively referred to as Aborigines. The total number of Austronesian speakers in China is around 339,800 for 18 Austronesian languages. Those spoken on the Taiwan island belong to the Formosan branch, which comprises three groups: Paiwanic (ten languages), Tsouic (four languages), and Atayalic (two languages). The largest is

Amis (with 130,000 speakers) of the Paiwanic group, which lost seven members during the colonial rule of Japan (from 1895 to 1945). Grimes's *Ethnologue* reports that another four Paiwanic languages and two Tsouic languages are nearly extinct. Unlike mainland China, Taiwan has witnessed language extinction similar to that found in Australia and North America, in the violent way of supplanting an aboriginal language with a colonial one. Under the rule of the Nationalist government in the 1950s, linguistic imperialism was imposed on the Taiwanese people with Mandarin in lieu of Japanese. As the Taiwan government has advocated multiculturalism in recent years, the environment has began to change to one propitious for linguistic diversity. Yet, many educated Chinese parents in Taipei (the capital city) prefer speaking Mandarin to their young children, even though they are native speakers of Min Nan. Mandarin has undoubtedly established its superior status in Taiwan over the half century.

The firmly established status of Mandarin is also unchallengeable in mainland China. While the Chinese government does not adopt any aggressive language policies to wipe out linguistic minorities, policies that would sustain linguistic diversity are equally lacking. It is stated in the Chinese Constitution that minority nationalities have the right to maintain their own languages, but this by no means implies active promotion of minority languages. In spite of the availability of newly devised orthographies for languages of a few larger nationalities, the priority for mastering *Putonghua*, which is often the sole language in education and mass media, cannot be mistaken. Ethnic minorities have been in a plight parallel to that of new immigrants in countries such as the United States. In order to become part of the mainstream society, they have to give up their native languages, sometimes eagerly. Interethnic marriage (not necessarily with *Han*-Chinese) in cities is another factor for prompting children to become monolingual in Mandarin. This kind of language shift is usually completed within several generations, characterized by bilingual speakers during the peaceful transition.

Bilingual speakers of autochthonous languages are legion in China but the bias toward Mandarin is conspicuous. Most of the bilinguals, except for a small fraction of minority nationalities, are literate only in standard Chinese based on Mandarin. Linguistic minorities surrounded by larger communities of different languages are likely to become multilingual in several oral languages, e.g. some Zhuang nationalities speak Yue and Mandarin in addition to their native language and some Pumi nationalities are fluent in Prinmi, Mandarin, and Sichuan Yi. While considerable ethnic minorities (especially those above the age of 50) are fluent in two or more languages, the ratio of

monolingual Mandarin speakers in minority nationalities is steadily rising.

Ethnic minorities are not alone under the pressure of linguistic absorption. All languages other than Mandarin are facing varied degrees of endangerment, as *Putonghua* is upheld as the national language at the expense of the others. For instance, vernacular pronunciation of Chinese characters is no longer taught in school (except in Hong Kong and Macau). In the past, Wu, Yue, Min Nan, and other Sinitic languages were featured in vernacular operas in different parts of the country, but nowadays popular songs are sung exclusively in *Putonghua* in mainland China. These suggest an ever-shrinking room for the survival of other languages in China.

The linguistic landscape in China is byzantine. Many languages are awaiting in-depth studies and proper classification, while some are yet to be discovered. Hopefully, these would be accomplished before language death accelerates under the momentous impact of the on-going economic development and modernization.

Chinese (Mandarin)

The Chinese language is represented by groups of dialects that are approximately as distant from each other as English from German, or French and Spanish. The traditional classification has been into seven major groups: Mandarin, Wu, Xiang, Gan, Min, Yue, and Hakka. Collectively, these dialects are spoken by more speakers than any other language in the world. Of these, Mandarin has the special status of having been the official language of China for most of Chinese history. As such, Mandarin is the first dialect learned by the great majority of people in China, and is acquired to various degrees of proficiency by speakers of all other dialects. Thus, there are well over a billion people who use Mandarin in some way or other in their lives.

Whereas the other dialects are concentrated mostly along the southeastern coast, Mandarin is distributed widely all over China. The Mandarin spoken in Harbin in the northeast is clearly different from the Mandarin spoken in Chengdu in the southwest, a thousand miles away. Because Beijing has been the capital of China for most of the past millennium, its speech has become an official linguistic standard, recognizing of course that the term Mandarin in its wide sense actually covers many varieties of speech.

There are many ways to refer to this language. Traditionally, when there is no need to differentiate it from the other major dialects, Mandarin is simply called 'Chinese'. We will follow this tradition in the present article. The word 'Mandarin' actually means 'official', corresponding to the Chinese word 'guan'. Thus, the Chinese counterpart to 'Mandarin' as a language is 'Guanhua', or 'official speech'. To emphasize its wide usage and enhance its populist intent, the term currently preferred is 'Putonghua', where 'putong' means 'common'. The term 'Guoyu', or 'national language', is used in Taiwan. The term 'Huayu' is used in Singapore, where 'hua' is an auspicious word that has been used to designate ethnic Chinese since the ancient Xia dynasty, some 4,000 years ago. In fact, the two elements 'hua' and 'xia' are often used together as a compound to refer to the long ethnic heritage.

Lastly, the term 'Sinitic' is used in more technical discussions, such as 'the Sinitic language', meaning 'the Chinese language'. The stem 'Sin-' probably derives from the name of the Qin dynasty (221–206

BCE), when China was first unified politically. 'Sino-Tibetan' refers to the family of languages one branch of which is Sinitic; another branch is Tibeto-Burman, which contains several hundred languages spoken in Western China and around the Himalaya mountains. The traditional classification of Sino-Tibetan is that proposed by F.K. Li; it includes a third branch of Zhuang-Dong languages, and a fourth branch of Miao-Yao languages. This four-branch hypothesis has recently become controversial as more data on minority languages became available, although the relation between Chinese and Tibeto-Burman has never been disputed. It has been estimated that the Chinese and Tibet-Burman retained their unity until about 6,000 years ago, when extensive migrations radiated outward from its homeland, presumably in northern China, which ultimately gave rise to the hundreds of languages we see today.

There have been efforts to connect the Sino-Tibetan languages to much more distant origins. In the early part of the twentieth century, the American linguist Edward Sapir remarked on the deep similarities between Tibetan and some of the native languages of North America. More recently, research is being done on the Dene-Caucasian hypothesis, which posits that groups as distant as the Na-Dene languages of North America, the Yeniseian languages in Siberia, Basque in Western Europe, among others, are all related to Sino-Tibetan.

A competing hypothesis links Chinese to the Austronesian languages, thus implying an ancient homeland more to the south. Such hypotheses on distant prehistories are intrinsically fascinating, although naturally they are more difficult to verify, often for lack of adequate data or precise methodology. An encouraging development in recent years is the increase in interdisciplinary collaboration, particularly among linguists, anthropologists, and geneticists, which significantly broadens our perspectives on human evolution, and brings new promise that the controversies surrounding the ancestry of the Chinese language can eventually be resolved.

The earliest specimens of Chinese date back some 3,400 years, in the form of inscriptions on animal bones and on bronze artifacts. These inscriptions were made for the purpose of divination or for various historical or ritual purposes. Although both the inscribed characters and the language they represented have changed over the centuries, their ancestral relations with modern characters and contemporary Chinese can be clearly established. Thus of all the modern languages, Chinese can boast of the longest period of continuous use.

Since the characters often contain a phonetic component, they also gave valuable indirect clues for the reconstruction of the spoken language. Efforts to understand the shape, sound, and semantics of the ancient characters have accumulated over the centuries into an impressive body of philological scholarship in China. This scholarship received a major impetus from abroad some 2000 years ago, when Buddhism first came into China. With the religious teachings came the Sanskrit language and its quasialphabetic spelling system, which in turn stimulated the phonetic analysis of the Chinese language.

Under this influence, Chinese scholars divided into the syllable for the time in terms of the fanqie system. A character X can be spelled by two other characters, A and B, where A indicates the initial consonant of X and B indicates the remainder of the syllable of X. The fanqie system fails to help when the reader does not know either A or B. Around 1,700 years ago, Chinese scholars first began writing about the four tones that their language had, which were named *ping, shang, qu,* and *ru*. Rime dictionaries were compiled around 1,500 years ago, phonetic charts were constructed 1,000 years ago, and by 400 years ago, scholars had achieved a reasonable understanding of the history of the language.

Chinese and western traditions began to come together around the beginning of the twentieth century. In 1898, the first western style grammar of Chinese was published by Ma Jianzhong, who studied several European languages while in Shanghai, and who later received training in Paris. Early in the twentieth century, the Swedish scholar Bernhard Karlgren traveled to China to conduct fieldwork on Chinese dialects, which he published as part of his dissertation, 1915–1926. Karlgren was the first to integrate the philological achievements of the Chinese scholars with the real sounds of modern dialects to arrive at systematic reconstructions. Although many aspects of these reconstructions have been superseded, his work has provided an invaluable stimulus for integrating western ideas into Chinese scholarship.

A very important source of data for reconstructions, investigated by Chinese scholars over many centuries, is the Shijing, a body of some 300 poems and songs that date back to around 3,000 years ago. This work is variously known in English as the Book of Poetry, the Book of Songs, or the Book of Odes. By investigating which sets of characters rimed in the Shijing, and by integrating this knowledge with the phonetic information contained in the individual characters, we can go a long way toward inferring how they were pronounced. The language of the Shijing is referred to as Old Chinese. Thanks to the early rime dictionaries, the best known of which is the Qiejun, we can also reconstruct the language of the seventh century, which is referred to as Middle Chinese.

Mandarin can be traced back to another famous rime dictionary, the Zhongyuan Yinyun, compiled in the early fourteenth century. Another important source of information on the sounds of this period is the

'Phags-pa alphabet, invented by a Tibetan lama in 1260, by order of Kubli Khan. The language revealed by these sources is called Old Mandarin.

Phonology

Some of the distinct aspects of Mandarin can be discussed by reference to the structure of the syllable, as shown in the following chart:

Tone				
Initial	Final			
	Medial	Rime		
		Nucleus		Ending

All the dialects of Chinese can be described according to the above chart, since they all share the same syllable structure. The three basic building blocks are the tone, the initial, and the final. In European languages, a syllable is distinguished from other syllables by its vowels, such as 'me' vs. 'moo', or by its consonants, such as 'me' vs. 'bee'. In a tone language, a syllable is distinguished along an additional dimension, as illustrated in the illustration below. A Chinese syllable is also distinguished by its vowels and consonants.

These are illustrated for Mandarin as spoken in Beijing in Figure 1 by 'ma' vs. 'mi' for vowel distinctions, and by 'ma' vs. 'pa' for consonant distinctions. Additionally, 'ma' can carry any of four distinct tones, yielding four completely unrelated words with the meanings of 'to scold', 'hemp', 'mother', and 'horse'. Tone is produced primarily by shaping the pitch contour of the voice by varying the rate of vibration of the vocal folds. The pitch contours of these four words, as pronounced by the present author, are shown in the computer traces in Figure 1. We can see, for example, that the pitch contour for 'to scold' is primarily falling while for 'hemp' it is rising. For other varieties of Mandarin, both the number of tones and the shapes of their pitch contours will be different.

Going back to the chart of the syllable, the initial represents at most one consonant. Thus, there are no consonant clusters in Chinese, such as in English 'spy' or 'pry'. The medial may be any one of the three onglides: 'i', 'u', or 'ü'. The nucleus in Mandarin is a simple vowel, although it may be a diphthong in other dialects. The ending may be any one of the three consonants 'r', 'n', or 'ng'. Thus, a Chinese syllable 'liàng', which means 'light', contains each of the following elements:

Tone: high falling,
Initial: l,
Medial: i,
Nucleus: a,
Ending: ng.

Morphology

In Chinese, by far the great majority of morphemes are represented by single syllables. Since single syllables are written by single characters, there is good correspondence between the minimal units of the sound system, the writing system, and the grammatical system, i.e. syllable = morpheme = character.

In contrast to European languages, word formation in Chinese does not involve any inflectional morphology to speak of, such as one finds in 'books', 'walked', etc. This poses no problem, of course, since information regarding gender, number, and case in nouns and tense in verbs is usually provided by the context. The speaker is not forced by the grammar, for instance, to choose 'he' or 'she' when referring to a friend, since both of these are *ta* in Chinese. On the other hand, Chinese does make use of derivational morphology, such as:

Prefixes— *di wu* 'the fifth', *tou wu* 'the first five',
Suffixes— *zhuantou* 'brick', *zhitou* 'finger', *haizi* 'child', *maozi* 'hat'.

There is an interesting compounding process, whereby opposites are conjoined to form a word. For example, *da* 'big' and *xiao* 'small' are conjoined to mean 'size; *lai* 'come' and *wang* 'go' combine to mean 'social visitation'. A particularly interesting word formed by this process is from *dong* 'east' and *xi* 'west'; the word *dongxi* now has the very general meaning of 'thing' and is used very productively. While English has similar words like 'flip-flop' and 'zig-zag', the two processes are different in that the two members of the Chinese compounding are not phonetically related.

Another interesting process of derivational morphology is reduplication. The process works in several different ways. One area of reduplication has to do with the formation of kinship terms. Whereas most languages have 'papa' and 'mama', such terms are much more abundant in Chinese, e.g. *didi* 'younger brother', *nainai* 'grandmother', *jiujiu* 'maternal uncle', etc. Another area of reduplication has to do with certain nouns to convey the meaning of 'every', e.g. *tiantian* 'every day', *renren* 'every person', *jiajia* 'every family', etc.

Verbs reduplicate, to convey a range of meanings, such as transitory action, e.g. *kankan* 'to take a look', *changchang* 'to have a taste', *tantan* 'to have a chat', etc. When the verb is disyllabic, the reduplication applies to the two syllables together, e.g *shangliang-shangliang* 'to discuss a little', or *yanjiuyanjiu* 'to investigate a little'. Adjectives also reduplicate to form adverbs by taking the particle *de*. Thus, *kuai* means 'quick' and *kuaikuaide pao* means 'run quickly'; *qing*

means 'light' and *qingqingde fangxia* means 'put down lightly'. However, when the adjective is disyllabic, the pattern of reduplication is different from that of the verb. The reduplication here is syllable by syllable, e.g. *an'anjingjingde* from *anjing* means 'quietly' and *gaogaoxingxingde* from *gaoxing* means 'happily'.

In addition to the compounding and reduplication discussed above, another distinctive aspect of Chinese morphology is the use of classifiers. In English, one uses measure words to quantify mass nouns, in expressions such as 'a grain of sand', 'a head of cattle', or 'a piece of cloth'. Many classifiers in Chinese, however, have very little semantic content to speak of, such as in *yige ren* 'one-classifier person', *yipi ma* 'one-classifier horse', *yijian dayi* 'one-classifier coat', *yiben shu* 'one-classifier book', etc. In learning how to use a noun in Chinese, one needs to learn the appropriate classifier for it.

Syntax

Since the language has very little inflectional morphology, grammatical relations among the words are primarily indicated by word order. The basic syntax in Chinese is subject–verb–object, much as in English. A typical declarative sentence with the perfective aspect marker *le* would be:

[1] *Ta mai-le shu.* 'He sell-aspect book.'

A major feature of Chinese syntax is that modificational structures precede the modified. This means that the head is always at the end of phrases. We have seen above that adverbs precede the verb in the verb phrase *kuaikuaide pao* 'run quickly'. In noun phrases, numerals, possessive, adjectives all precede the noun, such as *tade sanben hong shu* 'his three red books'. This applies to relative clauses as well, with the help of the particle *de*, as in *zuotian zai xianggang kande shu* 'yesterday in Hong Kong read-particle book'.

There are two syntactic variants of a declarative sentence: the disposal form with the particle *ba* shown in [2], and the passive form with the particle *bei* shown in [3]:

[2] *Ta ba shu mai-le.*
[3] *Shu bei ta mai-le.*

In these variants, the object is fronted to precede the verb. The meaning of the passive sentence [3] is comparable to that of passive sentences in English. However, the disposal form has no ready counterpart in the syntax of European languages. Although it is a form that is frequently used, its meaning and range of use are topics for which there is no general agreement as yet among Chinese grammarians.

In forming yes–no questions, the typical process for European languages is the inversion of word order, such as 'can he sell books?' formed from 'he can sell books'. English is unusual in the respect that a periphrastic 'do' is used to carry the tense, such as 'did he sell books?' formed from 'he sold books'. Rather than inversion, the typical process for Chinese is to conjoin an affirmative verb phrase with its negative counterpart. The negative counterpart to [1] is [4]:

[4] *Ta mei-you mai shu.* 'He neg-aspect sell book'

Conjoining [1] and [4], we obtain either the question forms [5] or [6] below, depending on whether we delete repeated materials from the affirmative or negative verb phrase:

[5] *Ta mai-le shu mei-you?* 'He sell-aspect book neg-aspect?'
[6] *Ta you mei-you mai shu?* 'He aspect neg-aspect sell book?'

Corresponding to the WH question words in English, i.e. 'who, what, when', Chinese has *shei, shemme,* and *shemme shihou,* respectively. These have been called SH words. In English, WH words need to be moved to the front of the sentence; in Chinese there is no such movement. Going back to [1], we may form the questions [7] and [8] as follows:

[7] *Shei mai-le shu?* 'Who sell-aspect book?'
[8] *Ta mai-li shemme?* 'He sell-aspect what?'

Because of the required movement, the English translation of [8] would be 'What did he sell?'

Every language has a stock of prefabricated phrases that have a richer cultural content, sometimes by means of their historical allusions. Such phrases are learned as complete units, rather than formed spontaneously for the moment. Thus, in English, we might say 'He is the early bird that caught the worm this time'; or 'Aren't you the hostess with the mostess?' Chinese is extremely rich in this regard, particularly in phrases formed with four syllables. These range from colloquial expressions such as *you tou hua nao* 'oily head slippery brain', used to describe someone devious, to forms that are more literary such as *pao zhuan yin yu* 'throw brick induce jade', used as a gesture of humility to say that what you have to offer is not worthy of what you are about to receive.

Because they can have a wide range of cultural associations, prefabricated phrases are sometimes difficult to understand, especially when they are used as part of language games. A striking case of misunderstanding took place when the American writer Edgar Snow interviewed Mao Zedong. Mao described himself with the expression *heshang da shan*, which literally means

'monk with umbrella'. This led Snow to evoke a poignant image: 'He was, he said, only a lone monk walking in the world with a leaky umbrella' [Life Magazine, April 4, 1971]. In actuality, the second part of this four-syllable expression is *wu fa wu tian*, which could mean 'no hair no sky' or 'no law no heaven.' The concept 'heaven' is especially important in this context because in traditional Chinese culture, the ruler governs by *tianming*, i.e. 'mandate of heaven'. The key to this expression is the fact that *fa* is a homonym that means either 'hair', which a monk lacks, or 'law'. The true message Mao was conveying is one of bravado—defying heaven—which Snow completely missed because of the cultural and linguistic gap.

There are many other interesting aspects of the Chinese language: Boltz (1994) gives a good survey of the Chinese writing system, for example, and Huang et al. (1996) discuss the special challenges that Chinese poses to natural language processing—interfacing the language with the computer.

Chinese and Japanese Traditional Grammar

The Chinese linguistic tradition bequeathed an analysis of tone, foreshadowed twentieth-century views of syllable structure, and contributed a moral and political perspective on the question of discrepancy between word meaning and word usage. In addition, explication of the formation of Chinese graphs made an important contribution to the understanding of writing systems. The Japanese tradition, on the other hand, offers unique perspectives on defining parts of speech, and analyzing the ways in which the parts combine to form larger wholes. Both traditions bear a debt to the linguistic tradition of India, some of which was transmitted through the powerful vehicle of Buddhism, in the intersection of phonetic analysis and sacred sound. Also common to both was the impetus of early poetry, in the desire to know the precise sounds and meanings of the past.

The Chinese debate on 'rectification of names' originates in several passages from the *Analects* of Confucius, wherein the belief that use of words should reflect reality is asserted. When it does not, the people cannot be properly governed. Xun Zi (c. 313–238 BCE), regarded as China's first major philosopher of language, contributed to this debate in a work titled *Zheng Ming* (*Rectification of names*), which addresses the origin of names, in terms similar to those found in Plato's *Cratylus*. Unlike *Cratylus*, however, the main focus does not concern whether language is to be trusted as epistemology. In Xun Zi's view, names are established by convention, and have no inherent correctness. They thus cannot represent absolute standards for human behavior.

Hsü Shen (58–147 CE) compiled the *Shuo wen jie zi* (first century CE, *Explanations of simple graphs and*

analyses of composite graphs), the first major lexicon, and one of the most significant works of the Chinese tradition. The 9,353 graphs contained in the work are organized under 540 radicals. One reason for its landmark status derives from the fact that this is the first surviving account of the six principles of formation of the Chinese graph, including that of semantic radical plus phonetic element, which accounts for more than 90% of modern graphs.

A poet, Shen Yue (441–513), is traditionally credited with the first analysis of Chinese tones, recognizing and naming four types. The tradition of rhyme books is thought to have originated as an aid to composition of poetry, and the technique of *fan qie* (reverse cutting) used therein prefigures twentieth-century notions of the syllable as composed of an internal structure, with onset and rhyme. The purpose of the rhyme books was to indicate the pronunciation of the monosyllabic graphs of Chinese, and did so by first making four major tonal divisions, and then within each tonal section, listing graphs in charts arranged by initial sound, and by the remainder, or rhyme. The so-called 'cutting' involved indicating pronunciation of a given graph by providing two other graphs having the same initial and rhyme portions, respectively. The *Qie yun* (601 CE), compiled by Lu Fayan, is the earliest major example of the genre.

Rhyme tables, the earliest known example of which is the *Yunjing* (twelfth century, *Mirror of rhymes*), provided a more detailed classification of all of the syllables of Chinese. In these works, initials are arranged according to articulatory categories such as 'tongue sounds', or dentals, and characterized in terms of phonation by such terms as 'clear' (voiceless) or 'muddy' (voiced).

In Japan, early linguistic studies were concerned with determining the sound correlates to different sets of phonograms in Old Japanese, which had merged into single sounds in later stages of Japanese. Notable in their efforts in this regard were the poet Fujiwara Teika (1162–1241) and Buddhist monk Keichû (1640–1701).

Analysis of morphology and syntax in traditional Japanese grammar is largely a concern with tactics: the combinatorial properties and functions of various verbal and adjectival suffixes, on the one hand, and postpositions or particles, on the other. Fujitani Nariakira (1738–1779) created the first comprehensive grammatical framework, using the metaphor of clothing: he categorized nouns as 'names', verbs and adjectives as 'clothes', adverbs as 'hairpins', and postpositions and suffixes as 'binding cords'. His best-known works are the *Kazashishô* (1767, *On hairpins*) and the *Ayuishô* (1773, *On binding cords*).

In his *Teniwoha himokagami* (1771, *Survey of particles*), Motoori Norinaga (1730–1801) explicated the ways in which certain emotive particles trigger concord with inflectional endings in the verb, and coined the term *kakari-musubi*, still in use today, to refer to it. In *Mikuni kotoba katsuyôshô* (1782, *On inflections in our language*), Motoori laid the groundwork for understanding the patterns of verbal conjugation.

Suzuki Akira (1764–1837), student of Motoori Norinaga, in his *Gengo shishûron* (1824, *On the four categories in language*), breaks down parts of speech into nouns, verbs (activities), and adjectives (states), on the one hand, and particles and bound suffixes, on the other. Underlying this categorization is a conceptualization of content vs. function words, said to have been drawn under the influence of such a classification for Chinese. These grammatical studies from the early modern period fall under the scholarly domain of *kokugaku* (nativism), while the work of those continuing in the same vein in the twentieth century is termed *kokugogaku* (national language studies), as separate from the western-influenced discipline of linguistics (*gengogaku*).

The most influential twentieth-century figure to continue along nativist lines was Tokieda Motoki (1900–1967), who expanded the framework to encompass all languages, without restriction to Japanese. He added a subjective, performative dimension to the bifurcation of content words, or *shi* (in his view, objectively conceptualized) vs. function words, or *ji*, which express the emotions, attitude, or judgments of the speaker. Under this view, content words are nested within function words in an iconic display, which leaves the subjective elements rightmost at each level of grammatical construction.

Major work on Japanese dialects was carried out by the folklorist Yanagita Kunio (1875–1962) in his *Kagyû-kô* (1927, *Thoughts on 'Snail'*), where he posited the 'circle theory' of linguistic diffusion, and linguist Hattori Shirô (1908–), in his investigations of the geographical distribution of accent patterns. The National Language Research Institute has published two major dialect atlases: the *Linguistic atlas of Japan* (1981–1985) and the *Grammar atlas of Japanese dialects* (1989–).

Chinese Pidgin English

Were Chinese Pidgin English not widely known by that name, it would be preferable to use the alternative, China Coast Pidgin. While having significant influence, English alone did not provide the core of conventions that came to constitute the language. Instead, there was convergence of English and Cantonese features in a process of mutual accommodation. Indeed, the hybrid nature of the structures of Chinese Pidgin English makes it a crucial piece of evidence in debate within creole linguistics, reflecting a shift away from particularist notions of pidgins and creoles to one in which they are considered merely relative, although related, forms of contact languages.

Chinese Pidgin English originated during the first locally regulated phase of trade between Chinese and English in the late seventeenth century (c. 1689–1748). It found a stable form in and around Canton for about another century (1748–1842), and was thereafter disseminated further up the Chinese coast during the remainder of the nineteenth century, and beyond by the Chinese diaspora to the Pacific and even the United States (1842–1890). Finally, Chinese Pidgin English fell into obsolescence during the twentieth century when it was heavily anglicized and lost many of its original structures as numerous speakers came to target English as a lingua franca.

Unfortunately, with the exception of slender second-hand evidence from the first period of genesis, mostly in European travel accounts, almost all the data we have fall between 1836 and 1901, and, heavily anglicized, are not reliable. The early data, however tenuous, nonetheless reflect a process of mutual accommodation in which speakers had to make guesses about what their interlocutors would understand and 'right' guesses would be incorporated into the grammar of the developing contact language. Balanced against the predominance of English etymons in Chinese Pidgin English is the relative importance of Cantonese syntax and phonology, such that to most English speakers, Chinese Pidgin English was hardly more intelligible than Chinese itself. There is convincing documentary evidence that the right guesses that set the parameters of Chinese Pidgin English took place within the trade factories at Canton between 1699 and 1748, where its inchoate forms were the instrument of limited exchange between the 'supercargoes' or British East India Company property agents, and the Cantonese-speaking domestics assigned to them by their authorized 'Hong merchant' interlocutors.

One objection to such a scenario is the undeniable impact of Portuguese on Chinese Pidgin English, one that might lead us to suspect that its origins go back to the arrival of the Portuguese along the south China coast in 1557—English 'Canton' is derived from the Portuguese pronunciation of *Guangzhou*. Some of the earliest fragments of putative Chinese Pidgin English appear to contain more Portuguese than English, which would tend to point toward a Portuguese base, e.g. this phrase from 1748:

(1) Carei grandi hola,   pickenini hola?
    Want   large   whore, small   whore
    Quer   grande [puta], pequena   [puta] (Ptg)
    'Do you prefer a big or a small prostitute?'

There is no doubt that Portuguese or some pidginized form of it was spoken along the China coast up to and throughout the time Chinese Pidgin English was formed. In Macao, there eventually formed *Macaista*, a variety of creolized Portuguese. Maritime and pidginized Portuguese were used from the Indian subcontinent across through Malaysia and Indonesia. As for Canton itself, we know that the first requirement of a supercargo on English ships trading to China was a knowledge of Portuguese. Yet, in the final analysis it is unlikely that a prior Portuguese pidgin served as the base of incipient

Chinese Pidgin English, not so much because the Portuguese contribution was limited to an ever-decreasing percentage of its lexicon but rather because the role of Cantonese is predominant both in pronunciation and word structure, from which fact we can suppose that the majority of early pidgin learners were native Cantonese speakers who adopted the vocabulary of the supercargo masters to whom they were assigned.

The Canton-based pattern of trade that formed Chinese Pidgin English continued until the end of the eighteenth century. In 1796, the Emperor banned the opium trade, at which point the English turned to smuggling. In 1840, a second attempt was made to ban opium, which led to the Opium War and the Nanking Treaty of 1842, opening the doors to China. The focus of contact shifted from Canton to the Treaty cities and to Hong Kong. As the monopoly of the Hong Kong merchants broke down, contacts began to proliferate between aspiring Chinese entrepreneurs and the quickly increasing number of foreigners in south China. The habit of resorting to Chinese Pidgin English was carried into new sites of trade where the status and practice of the language changed. As speakers of standard English began entering the Chinese community from the late nineteenth century onward, Chinese Pidgin English became increasingly associated with the servants of foreigners, and was deprecated. Eventually, Chinese Pidgin English was conveyed first as far north along the coast as Shanghai and Tientsin, British

traders taking their Cantonese servants with them as China was forced open to trade. After economic conditions worsened throughout the nineteenth century, there was a large Cantonese diaspora to California, Hawaii, Australia, and Singapore. At the same time, the core of Chinese Pidgin English, learned and transmitted as an auxiliary second language for several generations, began to dissolve. It was this late period of its history, roughly from 1842 onward, that gave rise to stereotypes and misunderstandings, which have tended not only to mask the originality of this language but also to confuse it with all forms of imperfectly learned English, which it was not.

Chinese Pidgin Russian

Not surprisingly, the Russian expansion across the Ural mountains into Siberia and America led to a number of contact languages to a greater or lesser extent lexically based on Russian. We have documentation of such varieties from four locations—Kyakhta (on the Mongolian border), Manchuria, the Taymyr Peninsula, and in the Ussuri area just north of Machuria. The respective pidgins are hereafter abbreviated as KPR, MPR, TPR, and UPR.

It is also possible that further varieties exist or have existed in Siberia, as well as in areas of (attempted) Russian colonization in Alaska, California, and Hawaii. In addition, mention will be made of Russenorsk (RN), a trade pidgin of the Arctic Ocean based partly on Russian and partly on Norwegian. I will not, however, discuss Mednyj Aleut, spoken in

the Strait of Bering, since, although a contact language, it is not a pidgin (but rather a variety of Aleut with Russian verbal morphology).

MPR emerged in the very beginning of the twentieth century, when Russians managed the Manchurian railway. It began to decline after World War II, when both parties took an increasing interest in learning the other's language, and definitively dropped out of use when the new political climate put an end to Sino-Russian friendship. People who remember the pidgin are still alive, however; thus, research is still possible, but urgent.

KPR emerged as a result of trade between Russians and Chinese in the eighteenth century. The pidgin has been considered extinct, but in 1990 some speakers were found among Chinese merchants in the Mongolian capital of Ulan Bator.

TPR, also called *Govorka*, is used between speakers of Samoyedic, Turkic, and Tungusic languages on the Taymyr Peninsula in northernmost Siberia. It has been declining in favor of Russian since World War II, and is now spoken only by elderly people. Fortunately, research on TPR is currently carried out by German linguist Dieter Stern.

UPR is the least well documented of the Russian pidgins, at it is known virtually exclusively through accounts of Russian expeditions to the area in the late nineteenth and early twentieth centuries.

Russenorsk, finally, was used in the trade between Russians and Norwegians in the border area until the beginning of the twentieth century. There is a relative wealth of material on this pidgin, which has been analyzed primarily by Norwegian linguists.

Although Russenorsk and TPR are no doubt local developments, it should be emphasized that the relationship between the Far Eastern varieties is unclear, and, indeed, many authors treat them all as 'Chinese Pidgin Russian'.

In most of the pidgins, there is a tendency toward syllabic simplification, favoring CV syllables. Other phonological aspects are highly variable, as they display influences from surrounding languages, such as the devoicing of Russian plosives in MPR, the replacement of /f/ with /p/ in KPR, and the merger of /s, z, ʃ, t͡ʃ/ in TPR.

Lexically, some of the varieties are remarkably mixed. This is particularly true for RN, in which only about half of the vocabulary was of Russian origin, and MPR, where approximately one third of the lexicon was non-Russian (mainly from Mandarin). Some lexical influence from local languages is reported for the other varieties as well. In addition to the lexical items themselves, some calquing from substrate languages has also been observed.

As in all pidgins, the small lexicon entails an exceptional degree of polysemy and multifunctionality, the serious semantic underspecification leading to a strong reliance on context for disambiguation.

As for the derivation of the Russian forms, it is noteworthy that the verbs are often developed from imperatives rather than from infinitives, as in pidgins lexically based on Western European languages.

The basic word order is of particular interest, for only MPR was consistently SVO, like both Russian and Mandarin. RN was basically SVO, but used SOV with adverbials. The other varieties are predominantly SOV, presumably due to substrate influences. TPR is also spectacular in having the order REL N. Another un-Indo-European feature is the optional lack of fronting of interrogative pronouns. As would be expected from SOV languages, postverbal auxiliaries are attested.

Tense/Mode/Aspect (TMA) marking is usually rather restricted. TPR encodes tense, but not aspect. If the little data available there are indeed reliable, UPR is remarkable, and possibly unique among pidgin langauges, in having a grammaticalized evidentiality marker. This, however, seems to have been the only TMA category in the language. Russenorsk had no grammaticalized TMA marking at all, whereas the other Far Eastern varieties seem to have made optional use of nonbound morphemes for this purpose.

Negation is Russian style in MPR, but postverbal in the other Asian varieties. Russenorsk had a preverbal negation, or rather two of them, which usually occupied the second position in the sentence. Nominal number is usually left unmarked, although TPR has optional morphemes derived from Russian words meaning 'much' and 'they all'. Grammatical gender has not survived in any of the varieties.

One of the shibboleths of pidginhood is a limited adpositional inventory. Russenorsk had *po* as its only preposition, corresponding for the most part to *za* in the Far East. These items expressed more or less any spatial relationship imaginable. The same job is carried out by *mesto* in TPR, which, however, also has a sociative adposition *meste*. It is noteworthy that adpositions in TPR are post- rather than prenominal.

Reduplication is absent from Russenorsk and MPR, but has been reported for KPR.

As in many other pidgins, juxtaposition is frequently used to indicate possessive relationship, and in a similar manner, clauses are to a great extent joined paratactically without any overt conjunction or subjunction (although such clauses do exist).

Again, as one would expect from pidgins, bound morphology is scarce, although there are a couple of potential candidates for the status of bound morphemes.

The pronominal systems also merit mention. The forms themselves, invariable with regard to syntactic function, are mostly derived from Russian genitives, possibly a carryover from Russian foreigner talk. Exceptions to this are the TPR forms, and the 2sg form elsewhere, which derive from Russian accusatives. They have been subject to some rather far-reaching restructuring, however, in particular in TPR. There, only the singular forms have been taken over, with additional morphemes marking number. Even more conspicuous is the presence of an inclusive/exclusive distinction for nonsingular pronouns.

Chinook Jargon

Chinook Jargon is a pidgin language of the Pacific Northwest that is first attested reliably from the first decade of the nineteenth century, in the journals of Lewis and Clark; the earliest extensive documentation is by Horatio Hale (1846). Its lexifier language—the language from which most of its vocabulary is drawn—was Lower Chinook (Shoalwater), the language of a once-powerful tribe at the mouth of the Columbia River. At its peak, Chinook Jargon was spoken as far north as southern Alaska, as far south as the northern border of California, and as far east as the Idaho panhandle in the United States and interior British Columbia in Canada. It flourished especially between c. 1850 and 1950, when it was a primary medium of communication between Whites, on the one hand, and Native Americans and Native Canadians on the other. Its use declined sharply in the late twentieth century as English replaced it everywhere in the Northwest. As late as 1980, however, monthly sermons were delivered in Chinook Jargon in at least one British Columbian church, and a few elderly fluent speakers on the Grand Ronde Reservation in Oregon contributed to its survival by teaching it to younger tribal members. Efforts are currently under way to revitalize Chinook Jargon, especially at Grand Ronde.

By the late twentieth century, Chinook Jargon was the main or only Native language spoken on the reservation, where members of six Native tribes descended from speakers of three completely different indigenous language families. As Henry Zenk has noted (1984), Chinook Jargon became 'an important factor in the sense of identity and solidarity that many Natives of the reservation period came to feel as "Grand Ronde Indians".' Chinook Jargon thus performed its traditional function as a lingua franca even toward the end of its continuous existence.

Like other classic trade pidgins, Chinook Jargon has a limited vocabulary. Over 600 Chinook Jargon words are reliably attested—that is, they occur in at least two independent sources, and usually in more than two. Of these, perhaps a third come from French or English, reflecting the widespread use of Chinook Jargon as a lingua franca between Whites and Natives in the late nineteenth and early twentieth century. The earliest Chinook Jargon sources, from the first half of the nineteenth century, also list English and French words, but not nearly as many as in the later documentation. A rough count of c. 650 Chinook Jargon words must certainly omit many that were in common use: even the most ambitious dictionaries inevitably omit many of a language's words, and the published Chinook Jargon dictionaries (e.g. Shaw 1909) are not especially ambitious.

Chinook Jargon phonemes are typical for an indigenous language of the Pacific Northwest. More than 30 consonant phonemes are attested, in a few to numerous words, in at least two independent sources each. Many of the consonants are unfamiliar to speakers of English and other European languages: glottalized (specifically, ejective) stops and affricates, uvular as well as velar obstruents, a glottalized lateral affricate, and a lateral fricative. Moreover, Chinook Jargon words often contain consonant clusters that are completely foreign to European languages, e.g. in /tk'up/ 'white, light in color', /ptSix/ 'thin', and /tL'm@n/ 'soft, ground up'. Chinook Jargon thus presents a striking counterexample to the often-repeated claim that pidgin structures are maximally simple, and the consistency of many of its phonological features

across Native speakers from numerous tribes offers a counterexample to the common claim that pidgin structures show more internal variation than nonpidgin languages. To judge by the surviving documentation and the few existing tape recordings from the mid-twentieth century, most White speakers of Chinook Jargon did not learn either the non-European sounds or the non-European consonant clusters of the pidgin (but see Demers et al. (1871) for a notable exception).

Also, like other classic trade pidgins, Chinook Jargon has limited morphosyntactic resources. It entirely lacks the complex morphological (word) structures that characterize Native languages in the region, and its range of syntactic constructions is not large. As with the sound system, its syntactic structures closely resemble those of Native Northwest languages—with one possible major exception, the dominant S(ubject)–V(erb)–O(bject) word order. Most Northwest languages are verb-initial; Chinook Jargon syntax is verb-initial only with adjectival predicates, e.g. _Hayas ulu tsuq nayka_ ‘I am very thirsty’ (lit. ‘much hungry water I’). Besides the SVO word order, the constructions are clearly Native, not based on either English or French. They include, among others, sentence-initial negation, yes/no questions formed with an optional question particle, and an imperative construction (‘it would be good if you would do X’).

The question of the pidgin’s origin remains highly controversial. One hypothesis is that Chinook Jargon predates extensive contact with Whites in the Northwest—that it was used as a means of intertribal communication, perhaps at first between speakers of Lower Chinook and their Native slaves. (‘Slave jargons’ are reported elsewhere in the Northwest, for instance among the Nez Perce.) Based on this theory, Chinook Jargon achieved its later spread when Whites adopted it for use as a lingua franca, shortly after 1806. The second origin hypothesis is that Chinook Jargon arose as a lingua franca only after Whites arrived in large numbers in the Northwest. A common feature of this theory is the proposal that a Nootka trade jargon (or pidgin) arose first on Vancouver Island, at the end of the eighteenth century or early in the nineteenth century, and then spread to the mouth of the Columbia River when Whites ventured there for trade; the Nootka trade jargon/pidgin was then relexified through the replacement of most Nootka words by Chinook words.

Evidence adduced in support of the second theory is primarily lexical. Most of the lexicon of early Chinook Jargon, including the bulk of the basic vocabulary, comes from Lower Chinook, but two or three dozen words (some of them quite basic) are from Nootka, and a smaller number of words come from Salishan and other languages of the region. In addi-tion, quite a few words entered the pidgin from French and then English, especially after about 1850.

The hypothesized contribution of the Nootka Jargon to the initial formation of Chinook Jargon is predicated on the assumption that such basic words would necessarily have been in Chinook Jargon from the beginning, not added later after Chinook Jargon was fully formed. Against this assumption, however, is the undoubted fact that, while the Nootka words in Chinook Jargon show clear signs of transmission from Whites, the Chinookan and Salishan words in Chinook Jargon were clearly transmitted from Natives to other Natives. Words of Chinookan and Salishan origin show all the elaborate features of typical Northwest phonological systems, including glottalized stops, velar vs. uvular dorsal obstruents, and lateral fricatives and affricates. This is not the case with Nootka-origin words: they are significantly distorted in comparison to their Nootka source words, with virtually no sounds that would be foreign to English and French speakers. The transmission of some of the Nootka jargon/pidgin words to Chinook Jargon is therefore much more likely to have occurred after, not before, the crystallization of Chinook Jargon as a pidgin language.

Both origin theories are plausible. The postcontact theory has been popular in part because Chinook Jargon, from the time it was first documented, already had the Nootka words and a fair number of French and English words. Also, of course, all Chinook Jargon documentation is necessarily postcontact, since Natives in the Northwest had no writing before Whites arrived. The precontact origin theory is preferable if one adopts the standard simplicity criterion of historical linguistics: the Native phonology and syntax are easily accounted for if Natives created Chinook Jargon without significant participation by Whites, but if the pidgin arose postcontact, with some French- and/or English-influenced structural features, those features must have been lost before the pidgin was documented. Based on this criterion, the precontact origin is the simpler hypothesis. But not all pidgin/creole specialists accept this criterion; hence, the controversy continues.

The future of Chinook Jargon is in some doubt, because the Grand Ronde elders and others who spoke the language as part of their ordinary daily lives are now gone. Its fate rests with the younger enthusiasts, especially younger tribal members, who are now working to prevent the pidgin from disappearing.

Chomsky, Noam

Noam Chomsky is one of the most profound and influential thinkers of our time, 'arguably the most important intellectual alive' (*New York Times Book Review*, February 25, 1979), an evaluation in accord with the fact that he is the world's most cited living author in several citation indexes.

In his early years, Chomsky read Hebrew literature with his father, a professor of Hebrew and Jewish education at Gratz College in Philadelphia (and president of its faculty for 45 years), considered 'one of the world's foremost Hebrew grammarians' (*New York Times* obituary, July 22, 1977). His immersion in the Jewish cultural tradition was deep. Out of this experience, his budding political interests converged toward what was then mainstream Zionism (now widely considered 'anti-Zionism').

Politics brought Chomsky into linguistics. As a teenager, he was deeply interested in radical politics with an anarchist or left-wing Marxist flavor (strongly anti-Leninist, and more generally anti-Bolshevik). Through these political interests, he met Zellig Harris, whom Chomsky has described as 'a person of unusual brilliance and originality' and very broad interests. Harris was not only an acute left-libertarian thinker and analyst but also a leading figure in linguistics, teaching at the University of Pennsylvania, and the most rigorous practitioner of the reigning structuralist methodology. Harris was surely the linguist best prepared to initiate someone with Chomsky's mind and inclinations into the field of linguistics (as then understood). He also interested him in the study of philosophy, logic, and mathematics, fields that were to open for him the avenue to major discoveries. The first reading Chomsky did in linguistics, before he had taken any courses, was the proofreading of Harris's important *Methods of structural linguistics* (1951), the most exacting exposition of immediately pre-Chomskyan linguistic theory. The Preface (dated January 1947) records that 'N. Chomsky has given much-needed assistance with the manuscript.'

Since the appearance of his first published book, *Syntactic Structures*, in 1957, Chomsky has been recognized as 'an eminent and revolutionary scholar in the field of linguistics', to quote from a representative blurb. Chomsky almost single-handedly assimilated psychology to the natural sciences by formulating 'transformational generative grammar' (a model for the 'cognitive sciences', of which it was the first). This theory takes for granted the now widely (although not unanimously) held view that all human languages operate under the same general principles in spite of their superficial diversity. Particularly important in this context is that the universal foundation for language is taken to be inherent in (and an essential part of) 'human nature', this being the central notion in both of Chomsky's main endeavors. Thus, Chomsky rejected behaviorism, unequivocally so in his renowned 1959 review of B.F. Skinner's 1957 *Verbal behavior*, a review that demonstrated the inability of the behaviorist approach to account for any but the most superficial aspects of human language.

Chomsky redefined the nature and scope of linguistics. As the *Encyclopedia Britannica* (1992) says, '... there is no major theoretical issue in linguistics today that is debated in terms other than those in which he has chosen to define it'. A recent book on the future of science describes him, accurately, as 'the most important linguist who has ever lived'. As John Lyons says in *Chomsky* (1970), he has spoken 'with unrivaled authority in all aspects of grammatical theory' since *Syntactic structures* 'revolutionized the scientific study of language', fundamentally changing the then current understanding of language and the mind/brain.

Chomsky's most fundamental contribution has been to open the way for the cognitive natural sciences. His

specific model for human language (transformational generative grammar) can be regarded as a confluence of traditional (and long-forgotten) concerns of the study of language and the mind (as in the work of Wilhelm von Humboldt or Otto Jespersen) and new understanding provided by the formal sciences in the late 1930s, particularly recursive function theory. The basic idea is that a sentence is the result of a computation producing a 'derivation', beginning with an abstract structural representation sequentially altered by structure-dependent operations ('transformations'). Chomsky's unusual knowledge of philosophy, logic, and mathematics allowed him to make this model precise, and to go on to develop, in the late 1950s, algebraic linguistics, a branch of abstract algebra, which is now part of computer science. (For Israeli logician and mathematician Yehoshua Bar-Hillel, one of its most eminent practitioners, Chomsky was not just the founder of algebraic linguistics but also 'by far the best man in this exciting new field'.)

Chomsky's written output is truly prodigious, encompassing, in linguistics alone, dozens of books and nearly 200 articles (and several times that in political analysis). His first substantial contribution to the development of generative grammar was his B.A. thesis (1949), an examination of certain morphophonemic alternations in Modern Hebrew, revised and expanded in his M.A. thesis (1951), and revised once more that year (that version was eventually published in 1979). Although this work had no impact on the field of linguistics at the time, it did introduce numerous technical devices that would eventually be of major significance, including abstract underlying syntactic and phonological forms and crucially ordered rules deriving surface forms from these underlying forms. Significantly, already in this early work, Chomsky was emphasizing that a grammar is a finite characterization of an infinite set of sentences. This theme continues to be of profound importance in linguistics.

Over the next few years, while a Junior Fellow of the Society of Fellows at Harvard University, Chomsky wrote *The logical structure of linguistic theory* (LSLT), a monumental work (completed in 1955, but published, and only in part, 20 years later) that laid out the formal basis for a complete theory of linguistic structure. The concepts and technical notions that were to become central to theoretical linguistics for the next several decades were developed in this paper, including the crucial idea of abstract underlying structure. Made precise are such concepts as level of representation, phrase structure rule, phrase marker, grammatical transformation, and derived constituent structure. LSLT is also rich in conceptual and empirical arguments, and it provides an extraordinarily detailed account of the syntax of English. Many of the patterns Chomsky explained had never even been noted before. Further, many of the analyses he presented have yet to be surpassed. However, like the M.A. thesis, LSLT had no direct impact on the field at the time. Within two years, though, LSLT had a revolutionary indirect influence, since the material contained in it formed the basis for the lecture notes that were published in 1957 as *Syntactic structures*, a book whose unprecedented influence was noted above.

The year 1965 witnessed the publication of Chomsky's next major book, *Aspects of the theory of syntax*, which made fully explicit the role of linguistics in the investigation of the human mind. Its first chapter, originally written during the year Chomsky spent at the Institute for Advanced Studies at Princeton (1958–1959), remains one of the clearest and most forceful expositions of the major goal of generative theorizing: providing an account of how the child presented with limited evidence develops a computational system making possible the production and comprehension of an unlimited number of brand new sentences ('explanatory adequacy'). The book laid out what came to be called the 'standard theory' of syntax. In this theory, the syntactic derivation of a sentence begins with deep structure (DS), a representation constructed via phrase structure rules and lexical insertion rules. Grammatical relations are fully determined at this level. Transformations then successively, and cyclically ('bottom up'), modify this representation, eventually producing surface structure (SS), the input to the phonological component. This contrasts with the LSLT model, wherein the recursive component is the transformational one: ever larger structures are created not by phrase structure rules but by generalized transformations, which embed one structure inside another. (Interestingly, in Chomsky's 'minimalist program' of the 1990s, there is a return to generalized transformations.) Versions of the standard theory (including the 'extended standard theory' and the 'revised extended standard theory') dominated syntactic theorizing for more than two decades.

While Chomsky is most closely associated with syntactic theory, much of his early work was concerned with phonology, culminating in the groundbreaking book in 1968, *The sound pattern of English* (co-authored by Morris Halle), which was a detailed study of the phonology of English, but, just as importantly, a full-blown theory of the phonological component of linguistic theory and its interaction with the syntactic component. Also noteworthy is the elaborated outline of a theory of markedness, which sought to explain why certain phonological processes are much more common than others.

Chomsky's concern with explanatory adequacy led in due course to the 'Government-Binding' model,

articulated in *Lectures on government and binding* (1981). In this model, the language (and dialect)-specific and construction-specific rules of earlier frameworks are replaced by operations of great generality whose functioning is constrained by universal conditions. The rules and conditions are 'principles', and the limited range of variation available for them constitutes the 'parameters'. (Chomsky came to prefer the name 'Principles and Parameters' for the model, reasoning that government and binding are just two among many technical devices in the theory, and not necessarily the most important ones.) The P&P model—the first one ever to suggest a substantive solution to the fundamental problem of language acquisition—represents a radical break from the rich tradition of thousands of years of linguistic inquiry. It is true, though, that the entire (modern) generative grammar period is in many ways a new era.

The P&P model was in turn further refined in Chomsky's 'minimalist program' of the 1990s and early 2000s (see Chomsky (1995), the second chapter of which was written and circulated in 1988, based on lectures in 1986 and 1987). The P&P model had DS, SS, Logical Form (LF), and Phonetic Form (PF) as significant levels of representation. Given that a human language is a way of relating sound (or, more generally, gesture, as in sign languages) and meaning, minimalism seeks to establish that there are no levels except the 'interface' levels PF and LF. In the most recent developments of the theory, Chomsky suggests, in another partial return to an earlier formulation, that even PF and LF, as specific levels of representation in the technical sense, do not exist. Rather, throughout the derivation, the syntactic structure thus far created is encapsulated and sent off to the interface components for phonetic and semantic interpretation. The minimalist program further maintains that derivations and representations conform to an 'economy' criterion demanding that they be minimal in a sense determined by the language faculty: no extra steps in derivations and no extra symbols in representations. A major technical goal is to reduce all constraints on representation to 'bare output conditions', determined by the properties of the mental systems that the linguistic computational system must interface with that are external to the computational system itself.

A direct consequence of Chomsky's scientific work is that it provides strong evidence in support of epistemological rationalism, as he was quick to point out. Early on, he turned to the serious study of the Cartesian tradition, which he was to revive and update, shortly after he made his initial discoveries. These discoveries made it possible for him to go well beyond the programmatic insights of the Cartesians, and give substance to their central claims, in the process reconstructing the enduring ideas of the first phase of the age of modern philosophy (a not always recognized antecedent of the cognitive revolution of the 1950s), on which Chomsky has shed much light as an intellectual historian. It seems fair to describe him as the scholar who is to the period initiated by the cognitive revolution of the mid-1950s what Descartes was to the first phase of the age of modern philosophy.

Biography

Noam Chomsky was born in Philadelphia, Pennsylvania on December 7, 1928. His father, William Chomsky, was a noted Hebrew scholar who wrote *Hebrew, the eternal language*. While studying at the University of Pennsylvania under the supervision of Zellig Harris, he was also a Junior Fellow of the Harvard Society of Fellows from 1951 to 1955. After receiving a Ph.D. in linguistics from the University of Pennsylvania in 1955, Chomsky joined the faculty at MIT under the sponsorship of Morris Halle and was promoted to full professor of Foreign Languages and Linguistics in 1961, appointed Ferrari Ward Professor of Linguistics in 1966, and Institute Professor in 1976. Since 1967, when the University of London and the University of Chicago awarded him his first two honorary doctorates, he has been the recipient of scores of honorary degrees throughout the world. In 1969, he delivered the John Locke Lectures at Oxford University, and in 1970, the Bertrand Russell Memorial Lecture at Cambridge University. Among the almost countless other honors that he has received is the 1988 Kyoto Prize in basic science, created in 1984 for the purpose of recognizing outstanding achievements in categories not named by the Nobel Prizes. In 1984, he received the Distinguished Scientific Contribution Award of the American Psychological Association 'for enlarging our definition of scientific psychology'.

Clark, Eve V.

Educated in France and the United Kingdom, Eve V. Clark started her linguistics career in the United States at Stanford University. She worked on the Language Universals Project led by Joseph Greenberg and Charles Ferguson and became one of the first faculty members of the Linguistics Department. She has worked extensively in various subfields of linguistics including pragmatics, lexical semantics, and psycholinguistics. Her greatest contribution to linguistics and psychology is her groundbreaking research on meaning acquisition—in particular, her earlier work on the semantic feature hypothesis, her comparative studies of children's word formation, and her current research on adults' offers of and children's uptake of lexical and semantic information.

In the 1970s, Eve Clark's research focused mostly on the semantic feature hypothesis. Simply put, the semantic feature hypothesis states that in learning a new word, children only learn some of its semantic features and then add to this knowledge as they find out more about what the word means. In one of her earliest studies, Clark looked at the acquisition of the meaning of *before* and *after*. The acquisition order of these two words is as follows: (1) children did not understand either word; (2) they understood *before* but not *after*; (3) they interpreted *after* as if it meant *before*; and finally, (4) they understood both words correctly. Notice that the meaning of these two words is made up of two components—namely, Time and Prior, and these components can have either a positive

or negative value. A positive value of Time shows that the word refers to some aspect of time. Similarly, the values of Prior indicate that one event precedes (positive) and follows (negative) the other. In light of the semantic analysis of these two words, one can see that children do not understand the component Time at first. Once they understand that both *before* and *after* contain the component Time, they may still not have acquired the feature Prior. At the third stage, they understand the positive member of Prior (i.e. *before*) but not the negative member (i.e. *after*)—in other words, the positive value of Prior is learned before the negative one. Finally, they understand both. Clark showed that this type of analysis could explain the findings of other studies on the acquisition of other relational terms such as *more–less, high–low,* and *tall–short.*

In the 1980s, Clark's research focused on word formation in acquisition. With colleagues Ruth Berman, Barbara Hecht, and Randa Mulford, she conducted extensive comparative studies of children's word formation in English, French, and Hebrew. She proposed several principles—semantic transparency, productivity, and conventionality—that influence children's acquisition of word-formation devices (e.g. compounding, affixation) in language. For instance, younger English-speaking children (e.g. aged three) often rely on simple compounds (e.g. *plant-man*) to coin new nouns; their use of *-er* for agents (e.g. *wall-builder*) is rather inconsistent.

This finding is in accordance with the principle of semantic transparency: while the head noun *-man* is semantically transparent to them (i.e. they know what the noun *man* means), younger children still need to analyze *-er* to obtain the agentive meaning of the suffix. As children get older, they replace words that they have coined through compounding with those conventionally used (e.g. *plant-man* with *gardener*). This provides evidence for the principle of conventionality: 'For certain meanings, a conventional word or word formation device exists that should be used in the language community' (Clark and Berman 1984:549). Another principle is productivity: [T]hose word-formation devices used most often by adults in word innovations are preferred in the language for constructing new word forms' (ibid.: 548). Empirical evidence shows that children rely on this in acquiring word-formation devices. For instance, among the agentive suffixes *-er*, *-ist*, and *-ian* in English, *-er* is the most frequent. According to the principle of productivity, children should acquire *-er* before the others, and this turns out to be the case (see Clark and Cohen 1984). Cross-linguistic studies have shown that regardless of the language being acquired, these principles play a significant role in children's acquisition and use of word formation.

Since the 1990s, Clark's research has centered on the pragmatics of child-directed speech, especially its relation to children's meaning acquisition. In acquiring vocabulary, children need to learn to link specific terms with their conventional meanings. In the last few decades, some researchers have proposed that children observe certain built-in constraints in mapping meanings onto word forms, e.g. the mutual exclusivity constraint where each referent is picked out by just one word. However, studies have shown that the constraint approach underestimates the importance of adult contribution. Children as young as two years old can and do make use of lexical and semantic information offered to them by adults. For example, two-year-olds readily accept and use multiple terms for the same referent (e.g. *dog* and *spaniel*) when adults provide them with this information. An alternative to the constraint approach is to examine the role of adult-directed speech in meaning acquisition and children's uptake of adults' offers of words and relations among words. Clark's current research goals are to (1) establish the range of adults' offers of words and relations and (2) determine how effective different types of offers are for word learning, as measured by children's uptake.

The central themes in much of Clark's research are the emphases on general cognitive principles and on social interaction in language acquisition. While many studies on meaning acquisition focus on specific constraints, the principles that Clark proposed for meaning acquisition apply to other facets of language acquisition and to adult language use as well. For instance, the pragmatic principles of conventionality and contrast (i.e., a difference in meaning is marked by a difference in form) are not only essential to children's acquisition of meaning but also guide adult speakers in their uses of language. The explanatory power of these principles reflects the strength of Clark's research.

Biography

Eve V. Clark was born in Camberley, UK, July 26, 1942. She received her M.A. Hons. (1965) in French Language and Literature, with minors in Spanish and Phonetics, University of Edinburgh; Postgraduate Diploma in General Linguistics (1966), University of Edinburgh; and Ph.D. in Linguistics (1969), University of Edinburgh. She was Assistant Instructor and Instructor in the Department of French at the University of Pittsburgh (1967–1969); Research Associate, Language Universals Project, Stanford University (1969–1970); Lecturer, Assistant Professor, Associate Professor, and Full Professor, Stanford University (1970–present); Visiting Scientist, Max-Planck-Institut für Psycholinguistik Nijmegen, The Netherlands (1981, 1983–1984, 1990–1991, 1997–1998); Fellow, Center for Advanced Study in the Behavioral Sciences, Stanford, California (1979–1980); Guggenheim Fellow, John Simon Guggenheim Memorial Foundation (1983–1984); and Foreign Member, Royal Netherlands Academy of Arts and Sciences (KNAW) (elected 1991).

Clause

Sentences can be of arbitrary length. Every well-formed sentence, however, can be adequately described in terms of its internal structure: the words it contains, the phrases these build and the morphemes they are made up from, and other such relations. Beyond the regular phrase level—noun phrase (NP), verb phrase (VP), etc.—sentences can be divided into clauses. Above all, a sentence is always a clause; but some sentences may consist of more than one clause.

In traditional grammar, the distinction is made between *main* (subordinate) and *subordinate* (dependent) clauses. In a sentence like *John likes Mary*, the whole structure is also one clause, but in the slightly longer sentence *John likes Mary **when she plays football,*** the boldfaced part is a separate clause all by itself. In generative grammar, the term *embedded* is used to indicate that the subordinate clause is embedded under the main clause, but still part of the same sentence. This is more than mere notation: traditional grammar does not consider subordinate clauses to be clauses proper; in the generative approach, however, all well-formed sentences are clauses, and every (grammatical) embedded clause is by definition a well-formed structure on the sentential level, hence a clause.

The sentence–clause distinction in generative terms (as in the Principles-and-Parameters theory) is often one of categorial projection, selection, and complementation. Two main categories are decisive for the type of structure: the Inflectional Phrase (or IP for short, formerly S) and the Complementizer Phrase (CP or S'). IP denotes the traditional concept that a well-formed sentence consists of a subject and a predicate (often the verb phrase VP). In X'-theory, the canonical subject position is the specifier of IP. The sentence *John likes Mary* can adequately be described in terms of an IP (and further internal structure). The CP-level is invoked for additional material, such as the question *Who does John like?*, which is transformationally derived from the former sentence. Here, the subject *John* occupies the same position in a structural description (i.e. the tree or the phrase-marker) of the sentence as the original sentence. But it is assumed that the object *who* has moved from its canonical predicate- or VP-internal position to the beginning of the sentence, the specifier of CP.

We can thus see that IP and CP can be well-formed main clauses. Finiteness plays a role for, but is no essential identifier of, main vs. subordinate clauses. In principle, any clause can be finite or nonfinite. As a rule of thumb, unmarked, declarative sentences—what have sometimes been dubbed *kernel sentences*—are IPs, while more complicated or derived structures (including interrogatives, imperatives, or exclamatives, such as *Does John likes Mary?*, *Play better soccer now!,* or *What a great game she played!*) are usually CPs. Another rule of thumb is that a well-formed clause contains only one subject and one predicate (i.e. one main verb and its potential complements, depending on whether the verb is an intransitive, a transitive, or a ditransitive verb, for example). But virtually every clause can be embedded under or subordinated to a higher clause. This depends on the type of clause and/or on the potential main clause predicate.

Addressing the former first, subordinate or embedded clauses come in various types. We commonly

distinguish between *adverbial*, *complement,* and *relative* clauses. An adverbial clause (also *oblique clause*) relates to the main clause through the semantic meanings expressed by adverbs, such as time, manner, place, instrument, circumstance, concession, purpose, result, cause, or condition. In English, adverbial clauses are typically introduced by a *subordinating conjunction* (or *subordinator*), an element that links the adverbial clause to the higher main clause. An example is *John likes Mary because she plays soccer well*. Other subordinators are *after*, *when*, *whenever*, *while*, *as*, *although*, or *if*. In generative analysis, subordinators invariably head a CP-projection; adverbial clauses are thus CPs.

Complement clauses are characterized as clauses that serve as a complement to a lexical item, i.e. without which that lexical item would not be complete. This addresses the role of the potential main clause predicate mentioned above. Two major classifications of complement clauses exist, namely noun-complement and verb-complement clauses. Just as some physical object must be expressed to form a complete structure of the verb *throw* (as in *The goalkeeper threw **the ball***), as part of the definition or subcategorization frame of that verb, some clause must be expressed to satisfy the subcategorization frame of a verb like *tell*. The boldfaced part in *Mary told John **(that) she played soccer*** is a complement clause, namely complement to the main verb *tell*. (Naturally, *tell* can also take an NP as a complement, as in *Mary told John **a lie***, but we concentrate on clauses here.) In this case, the complementizer *that* is optional; it can be sued or left out. In this instance, other elements could also be used instead, such as *why* or *how*. The important relation is that between the main verb *tell* and the proposition expressed by the following clause. A similar relationship can be found with certain nouns. A noun like *fact* takes a complement clause. For example, we say *John likes the fact **that Mary plays soccer***. It is thus part of the subcategorization frame of a noun like *fact* that it must be followed by a complement clause.

Relative clauses, finally, modify, describe, or further specify a noun, but are structurally part of the entire noun phrase, i.e. the *head noun*, any other modifiers of it, and the relative clause form one constituent. Moreover, relative clauses are optional, not obligatory. Thus, while in a noun-complement clause, the complement clause must be used, relative clauses need not be. Consider, for example, the sentence *John likes the girl **who plays soccer***. The boldfaced part is a relative clause, adding further information about the NP, *the girl*. This type is a *restrictive* relative clause, which is characterized by being essential for identification (otherwise we would not know which girl John likes). A *nonrestrictive* relative clause is not required for identification of the NP, as in *Mary, **who plays soccer**, is a nice girl*.

To sum up, the property of human language that sentences can be of infinite length does not mean that longer sentences cannot be analyzed. Rather, a property of language is that sentences can consist of more than one clause, but each clause can be clearly identified. We distinguish between a (unique) main clause and (any number of) subordinate clauses. The latter come in three types: adverbial, complement, and relative clauses.

Clause-Type Indicators

Communicating by language is a highly structured and goal-directed social activity that serves many purposes: making contact, delivering a speech, telling a joke, expressing surprise, gathering information, giving orders, and so forth. For verbal interaction to be effective, the speaker has to formulate what he or she wants

to say in such a way that its communicative intention is recognizable or identifiable to the other participants in the speech situation. Making a statement will naturally take a different form than posing a question or issuing a command. In language theory, the systematic relation between the grammatical form of sentences and their conventionalized conversational use is called clause type.

The three major clause types that occur most frequently in the world's languages are declaratives, interrogatives, and imperatives, which correlate with statements of facts, inquiries, and directives (a cover term for commands, requests, orders, and the like), respectively. Clause types represent a grammatical system in at least two respects. First, one can easily construct triplets of corresponding declaratives, yes–no questions, and imperatives (e.g. *John left in a hurry; did John leave in a hurry?; leave us alone!*). Second, clause types are mutually exclusive, no sentence belonging simultaneously to two different types.

To distinguish one clause type from another on a formal basis, languages resort to a large variety of grammatical devices, which include changes in the shape of verbs, word-order alternations, different intonation patterns, and special particles and affixes. The concern here is with such dedicated affixes and particles, which are put to use as clause-type indicators. Clause-type indicators constitute a subset of function words with a primarily classificatory function that mark the sentence they modify as a declarative or an interrogative construction. Out of the ordinary as sentence-type indicators may look at first sight, they are also attested in English. Consider, for instance, the subordinating conjunctions *that* and *whether*, which introduce embedded declarative and interrogative sentences, respectively (e.g. *John said **that** there would be enough food at the party* vs. *John wondered **whether** there would be enough food at the party*).

As many linguists have observed, declarative sentences tend to be the most unmarked of these clause types: they typically occur without any clause type indicator or specific ordering and impose the fewest restrictions on what verbal categories can be selected. There are, however, many languages with marked declaratives. For example, Welsh (a Celtic language of the British Isles) has a clause-initial particle *y(r)*, which is placed in declarative constructions with periphrastic verb forms, which are composed of the present and the imperfect forms of *bod* 'to be' (third-person masc. sing. *mae* 'he is') and a verbal noun (e.g. *Y mae Siôn yn gweld draig* [PARTICLE is John PROGRESSIVE.PARTICLE see _{VERBAL-NOUN}] 'John sees (lit. is seeing) a dragon'). The declarative particle *y(r)* contrasts with other sentence-type indicators like the negative particle *ní(d)* and the question particle

a, neither of which can occur together with *y(r)*. Yet, the particle *y(r)* is absent in embedded and verb-initial declarative constructions. In Maale (an Omotic language of Southern Ethiopia), all clause types are marked by a special verbal affix. Thus, the main verb of affirmative declarative clauses contains the affix *–ne* (e.g. *ʔ–atsí ziginó mukk–é–**ne*** [man yesterday come-PERFECTIVE-AFFIRMATIVE. DECLARATIVE] 'The man came yesterday'), while the corresponding interrogatives are characterized by the affix *–iya* when the main verb is marked for Perfective aspect, which indicates the completion of the event that is described (e.g. *ʔ–atsí ziginó mukk–é–**iya***? [man yesterday come-PERFECTIVE-INTERROGATIVE] 'Did the man come yesterday?').

A more complex situation is obtained in languages with so-called evidential systems. Evidential particles (or affixes) indicate the source reliability of the speaker's knowledge and the kind of evidence he or she adduces for what is being communicated. In languages with elaborate evidential marking, such as Tuyuca (a Tucanoan language spoken in Colombia and Brazil), there are no unmarked declaratives, since every sentence must contain an evidential marker qualifying the information on which an assertion is based. A simple declarative like *he played soccer* corresponds to five different verbal constructions, each associated with a specific evidential marker. Compare: *díiga apé–**wi*** [soccer play-VISUAL] 'he played soccer' (I say him play), *díiga apé–**ti*** [soccer play-NON-VISUAL] 'he played soccer' (I heard the game and him, but I didn't see it or him), *díiga apé–**yi*** [soccer play-APPARENT] 'he played soccer' (I have evidence that he played soccer, but I didn't actually see the game), *díiga apé–**yigɨ*** [soccer play-HEARSAY] 'he played soccer' (I obtained the information from someone else), *díiga apé–**hîyi*** [soccer play-DEDUCTIVE] 'he played soccer' (it is reasonable to assume it).

Interrogative sentences come in two varieties: yes–no questions, where the truth of the questioned statement is at issue (e.g. *Was John invited to the party?*) and the constituent question, where the question word or phrase signals the missing piece of information (e.g. ***Who was invited to the Party?***).

In Polish, the question marker *czy* is used to distinguish main and embedded yes-or-no questions from declarative sentences (e.g. *Pan Kowalski był w Austrii* 'Mr. Kowalski has been to Austria' vs. ***czy** Pan Kowalski był w Austrii* 'Has Mr. Kowalski been to Austria?' and *nie pytałem **czy** Pan Kowalski był w Austrii* 'I did not ask <u>whether</u> Mr. Kowalski had been to Austria'). In Mandarin Chinese, question words like *shei* and *shemne* convey not only a question interpretation 'who' and 'what' but may also be interpreted as indefinite pronouns 'someone, anyone' and 'something, anything' (e.g. ***shei** mai–le yi–ben-shu*? [who

buy-ASPECT one-CLASSIFIER -book] '<u>who</u> bought a
book?' vs. *ta bu xiang jian **shei*** [S/he not want see
who] 'She (or he) does not want to see anyone'). If, on
the other hand, the question particle *ne* occurs in sen-
tence-final position, only the interrogative and not the
indefinite interpretation of the question word is avail-
able (e.g. Hufei *mai–le shemne ne*? [Hufei buy-ASPECT
what INTERROGATIVE.PARTICLE] '<u>What</u> did Hufei buy?'
[NOT 'Hufei bought <u>something</u>']). Languages with
dedicated interrogative particles like Chinese leave the
question word in exactly the same syntactic position as
the corresponding declarative sentence, while lan-
guages without such clause-typing devices, like
English, place the question word in front of the clause
and require the inversion of the auxiliary verb and sub-
ject (and insertion of *do* if there is no auxiliary verb).

With evidential particles and affixes being a relative-
ly recent discovery, more research needs to be done to
clarify the functional role of such clause-type indicators.

Clinical Linguistics

Clinical linguistics, a branch of applied linguistics, is
the use of linguistics to describe, analyze, and treat
language disability. The study of linguistic aspects of
communication disorders is of relevance to a broader
understanding of language and linguistic theory.
Practitioners of clinical linguistics range from aca-
demic linguists with research and teaching interests in
language disability to practicing professionals such as
speech and language pathologists/therapists, educa-
tional and clinical psychologists, and neurologists.
Research in the field tends to be multifaceted, drawing
on a wide range of disciplines in addition to linguis-
tics, such as psycholinguistics, cognitive science, neu-
roscience, and biomedical science.

Although systematic phonetic descriptions of speech
disorders have been routine since the 1950s, clinical lin-
guistics did not emerge as a coherent discipline inclu-
sive of phonology, grammar, semantics, and pragmatics
until the late 1970s. This was in part due to the pioneer-
ing work of David Crystal whose book *Clinical linguis-
tics* (1981) has been particularly influential in defining

the area. Other milestones were the establishment of the
journal *Clinical linguistics and phonetics* in 1987 and
the founding of the International Clinical Phonetics and
Linguistics Association (ICPLA) in 1991.

Rather than diagnosing using medical criteria, clini-
cal linguistics focuses on the linguistic manifestations
of the disorder, aiming to provide a comprehensive
typology of language disorders based on their linguistic
characteristics. This approach aids in diagnosing and
treating impairments of unknown underlying causes.
For example, there is as yet no agreed medical explana-
tion for Specific Language Impairment (SLI), a condi-
tion found in children who have problems with spoken
language but no other obvious cognitive or neurological
deficit. In spite of this, it is still possible to describe the
linguistic characteristics of SLI precisely enough for
research purposes and for devising remedial programs.

There appears to be no level of language organiza-
tion that is immune to impairment. Language disor-
ders are equally likely to be found in adults and in
children who are still acquiring language, and in both

213

the production and comprehension of spoken, written, and signed language. Anatomical deficits such as cleft palate may affect a speaker's phonetics and phonology, resulting in an inability to differentiate pairs of words such as 'bat' and 'mat'. Grammar, semantics, and pragmatics may be impaired as a result of developmental disorders in children or a stroke in adults. A child with SLI might repeat 'Has the mouse been chased by the cat?' as 'A mouse chasing cat'. A stroke patient might see nothing wrong with adding a past tense suffix to nouns, resulting in words like 'towned' and 'faithed', due to problems with word formation. People with autism find it difficult to make use of context to infer nonliteral meaning.

Any linguistic theory that purports to throw light on the nature of the human mind should describe both the normal and the pathological. Some have argued that certain syntactic anomalies found in the language of people with Broca's aphasia, a condition resulting from damage to Broca's area of the brain, can be explained using Chomsky's 'Principles and Parameters' theory of syntactic structure. These researchers believe that such anomalies provide evidence that syntactic abilities are separate from other cognitive skills. In addition, data from children with SLI and Williams Syndrome, a genetic condition in which linguistic proficiency develops despite poor cognitive abilities, have been use d to support a similar view of syntax as an autonomous mental 'module'. Others, however, cite evidence from a range of language disorders in support of a nonmodularist, functionalist account of language suggesting a considerable degree of codependency between linguistic and cognitive processes. Clinical linguistic research will continue to play a key role in debates of this kind.

The range of analytical methods used in clinical linguistics is comparable to that found in other areas of linguistics. Both theory-based and data-driven approaches are used, with a wide selection of materials produced for purposes of diagnosis, assessment, and intervention. Nevertheless, clinical linguistics is still a new field and a great deal of exploratory work remains to be done, particularly in the form of case studies and in areas such as semantics. Often, it is only when a complex system goes wrong that we become aware of the contribution—and even the existence—of its component subsystems. One potential growth area for clinical linguistics, therefore, is its role in informing and evaluating linguistic theory and in illuminating our understanding of normal language structure and use.

Code-Switching

Speakers of more than one language (e.g. bilinguals) are known for their ability to code-switch or mix their languages during communication. This phenomenon occurs when bilinguals substitute a word or phrase from one language with a phrase or word from another language. While some linguists suggest that people code-switch as a strategy in order to be better understood and to enhance the listeners' comprehension, code-switching among

bilinguals has traditionally been viewed as a strategy to compensate for diminished language proficiency. The premise behind this theory is that bilinguals code-switch because they do not know either language completely. This argument is also known as semilingualism, meaning bilinguals 'almost' speak both languages correctly. However, language proficiency is not clearly defined, as it is unclear whether reading and writing language skills should take precedence over spoken skills in determining language proficiency. This reliance on reading and writing is problematic because most bilinguals receive their formal education in one language, while a majority of their social interactions take place in the other language. Thus, when their reading and writing abilities are tested in both languages, the language in which bilinguals received more formal education will usually fare better.

Recent psycholinguistic research has focused on how code-switching is a natural product of the interaction of the bilingual's two languages. Early researchers viewed code-switching as evidence that the bilinguals' two languages were organized in separate and distinct mental dictionaries. For example, a general finding throughout the literature is that bilinguals take longer to read and comprehend sentences containing code-switched words as compared to monolingual sentences. Apparently, this time-consuming process is due to a 'mental switch mechanism' that determines which of the bilingual's two mental dictionaries are 'on' or 'off' during the course of language comprehension. This mental switch is responsible for selecting the appropriate mental dictionary to be used during the comprehension of a sentence. Other research shows that bilinguals comprehend code-switched words faster when there is an overlap between the two languages' sound systems. For example, Chinese–English bilinguals, where Chinese is the native language, take longer to recognize English code-switched words in Chinese sentences, but only if the English words begin with consonant–consonant clusters (e.g. block), as opposed to consonant–vowel clusters (e.g. big), because the Chinese language words do not begin with consonant–consonant clusters. Other important factors reported to influence the recognition of code-switched words include context, phonetics, homophonic (e.g. words pronounced the same) and homographic (e.g. words spelled the same) overlap between the two languages.

Another current view suggests that language dominance, which language is used more frequently, plays an important role in code-switching. For example, Spanish–English bilinguals report more linguistic interference (code-switching) when they communicate in Spanish, their first language, and little or no code-switching when they communicate in English, their second language. In other words, these bilinguals code-switch more when they communicate in Spanish than when they use English. Psycholinguistic evidence also suggests that bilinguals retrieve English code-switched words faster when they listen to Spanish sentences, whereas they are slower to retrieve Spanish code-switched words as they listen to English sentences. This evidence suggests that the bilingual relies on the second language as opposed to the first. How are these findings explained? The general premise behind this view is that after a certain level of fluency and frequent use of the second language, a language shift occurs. That is, during early stages of bilingualism, Spanish–English bilinguals rely on their first language when they communicate in their second language. As a result, bilinguals are more likely to code-switch to Spanish, when they communicate in English. However, as the second language becomes the dominant language, bilinguals rely on the second language when they communicate in the first language. In this case, bilinguals code-switch to English when they communicate in Spanish. The second language becomes more readily accessible and bilinguals come to rely on it more. Regardless of which language the bilingual learned first, the more active (dominant) language determines which mental dictionary is going to be accessed faster. This argument is reasonable since most bilinguals in the United States, whose first language is Spanish, obtain their formal education in English. Likewise, many of their everyday interactions involve the second language. As a result, words and concepts in English, the second language, become more accessible than words in Spanish, the first language. Thus, code-switching is not the same for both languages. Rather, it depends on language dominance.

In short, code-switching among bilinguals may be indicative of difficulties in retrieval (access) affected by a combination of closely related factors such as language use (i.e. how often the first language is used) and word frequency (i.e. how much a particular word is used in the language). Examination of code-switching behavior can contribute to a further understanding of second-language acquisition, as well as language acquisition and development, and general linguistic theory.

Coherence in Discourse

Discourse is a communicative event in which language plays a prominent role. It minimally requires a sender (writer, speaker), a receiver (reader, listener), and a message that is being communicated. This message is not just a concatenation of clauses; it forms a unified, coherent whole. Both the sender and receiver normally have the implicit agreement that the message being communicated is coherent.

Coherence in discourse has been studied in a range of disciplines, including linguistics, philology, sociology, philosophy, psychology, and computer science. Linguists identify and analyze inventories of the linguistic markers of coherence that are available in a language. Sociologists explore the production and comprehension of coherent discourse in naturalistic conversations that involve different groups and cultures. Psychologists collect data in experiments that test hypotheses about the effect of coherence on cognitive processing and representations. Computer scientists design and test computer models that attempt to produce and test coherent text.

The term *coherence* has been defined in various ways. Some researchers apply the term *cohesion* to the surface structure of the text and the term *coherence* to the concepts and relations underlying its meaning. *Cohesion* has sometimes been applied to smaller units of language in the text, and *coherence,* to some general overall interrelatedness in the text. Other researchers have defined *cohesion* as continuity in word and sentence structure, and *coherence* as continuity in meaning and context. As in the case of *coherence*, *discourse* has been defined in different ways. Several years ago, the term *discourse* was reserved for dialogue, and *text* was reserved for monologue. In contemporary research, *discourse* covers both monologic and dialogic spoken and written language.

Somewhat more subtle distinctions are sometimes made. One can distinguish between discourse-as-product (the linguistic construct) and discourse-as-process (the communicative event). *Coherence* can be reserved for the conceptual relationships that comprehenders use to construct a coherent mental representation accommodated by what is said in the discourse. *Cohesion* is limited to the linguistic markers that cue the comprehender on how to build such coherent representations. Cohesion emphasizes discourse-as-product, and coherence emphasizes discourse-as-process.

Cohesion alone is not sufficient for the interpretation of the discourse. Comprehenders generate inferences on the basis of background knowledge and discourse constraints. Much of the background knowledge is experiential; hence, it involves common procedures and activities (called *scripts*), social interactions, and spatial settings. For instance, a narrative usually describes a setting, an action sequence with a conflict and plot, and an outcome. A script for eating in a restaurant would furnish inferences and help coherently tie together the explicit content of a narrative about a bad restaurant experience. Although cohesion alone cannot fully account for coherence in discourse, the psycholinguistic literature has shown that cohesion facilitates coherence.

Cohesion and coherence can be divided into local (microstructure) and global (macrostructure). Local cohesion and coherence are related to the interrelatedness between adjacent discourse segments. Global cohesion and coherence are related to the interrelatedness of larger spans of discourse. For instance, scripted action sequences are globally coherent. Also, there are the rhetorical structures of narrative (such as setting + conflict + plot + resolution), expository (such as claim + evidence, problem + solution), and other discourse genres.

Cohesion and coherence can be grammar driven and vocabulary driven. Grammar-driven cohesion refers to sentence structure, word structure, and the intonation of the discourse segments. Vocabulary-driven cohesion

refers to the lexical vocabulary of the discourse segment. These cohesion cues activate vocabulary-driven (pre-grammatical, knowledge-based) and grammar-driven (syntax-based) coherence. Vocabulary-driven and grammar-driven coherence are not necessarily mutually exclusive but often support each other, as illustrated below.

Consider the sentence **The dean** (i) *read* **the New York Times** (ii) *in* **his office** (iii). A paraphrase with grammar-driven cohesion would reduce the discourse elements to the grammatical necessities: **He** (i) *always reads* **it** (ii) **there** (iii). A vocabulary-driven paraphrase, on the other hand, would find meaningful lexical alternatives, as in **The man** (i) *always reads* **the newspaper** (ii) **behind his desk** (iii).

In addition to the distinctions between local and global and between grammar- and vocabulary-driven cohesion, the types of cohesion discussed below have often been recognized.

Conjunctions relate adjacent discourse segments. There have been several classifications of these conjunctions in virtually every field. Most of these classifications include additive (*and*, *but*), temporal (*before*, *until*), and causal (*because*, *although*) conjunctions that are either extensive (*and*, *before*, *because*) or adversative (*but*, *until*, *although*).

Coreference specifies that two expressions refer to the same entity. Often, the coreference is grammar driven by the use of pronouns, both pronominal (*he, she*) and reflexive (*himself, herself*). The interpretation of these pronouns is determined by their antecedents, i.e. previously mentioned words referring to the same person or object. The coreference can be both forward and backward. *Anaphoric* reference is a backward reference to an antecedent noun phrase or clause that was introduced earlier in the discourse (**John** *kissed* **Mary** *because* **he** *loved* **her**). *Cataphoric* reference is a forward reference to a noun phrase or clause that will be mentioned later in the text (*Because* **he** *loved* **her**, **John** *kissed* **Mary**).

With substitution, repeated forms, and ellipsis, a constituent of one expression is replaced by a constituent of another (substitution), is repeated (repeated forms), or is omitted (ellipsis). The intended meanings can be reconstructed from the preceding discourse and from world knowledge.

Will we make it on time?

(1) *I think so* (substitution of *we will make it in time* by *so*).
(2) *Yes, we will make it on time* (repeated forms).
(3) *If we hurry* (ellipsis: *we will make it on time* is omitted).

With lexical relationships, the type of cohesion is vocabulary driven. Two lexical items are related to each other insofar as they mean the same thing (synonyms) or the opposite thing (antonyms), stand in a superset/subset relationship (hypernym vs. hyponym, respectively), or have some other conceptual relationship.

(1) **The tax collector** *sent another letter*.
(2) *I don't like* **this guy**.
(3) **That monster** *never leaves us alone.*
(4) **The sweetheart** *keeps asking for more each year*

With comparison, a constituent in an expression is compared with a constituent in another expression (*I like the oak cabinet. The pine desk is much nicer*).

Discourse psychologists have extensively investigated five cohesion and coherence relations that are related to the previously mentioned seven: referential, spatial, causal, temporal, and additive relationships. They answer the questions of the who, where, why, when, and what of the events described by the discourse. Explicit markers facilitate the comprehension process.

Several classifications of relations have been proposed. Some focus only on the closed set of grammar-driven cohesion, whereas others include vocabulary-driven relations and relations that are reconstructed from world knowledge and the unique situation conveyed in the text. Those classifications that go beyond grammar consider the intentions of the producer of the communicative event. In written monologic discourse, comprehenders can rely on linguistic cues to a great extent (although not completely). However, in oral dialogic discourse, there are conversational cues that go well beyond print, such as intonation, gestures, and the physical environment.

A complete theory of discourse coherence requires a harmonious layering of several levels, including vocabulary, sentence structure, meaning, discourse context, style, and world knowledge. When these levels lack coordination, the coherence is more difficult. To get the message across, the sender will try to coordinate the levels. The receiver assumes that the sender's message is intended to be well formed and will make every attempt to construct a coherent interpretation.

Color Terms

Color terms have been used in anthropological and cognitive linguistics to investigate whether certain aspects of meaning are universally found in all languages. The classic study of color terminology, Berlin and Kay 1969, is often cited as proof against the Sapir–Whorf hypothesis of 'linguistic relativity' or 'linguistic determinism.' This hypothesis argues that language affects or even determines cognition—that is, that the categories present in the language a person speaks will influence the way that person thinks, the way he or she perceives the world. Languages vary as to which 'basic color terms' occur in the vocabulary. Berlin and Kay set out to test whether the presence or absence of a color category in the language affects the way in which speakers see colors. In the course of their research, they found evidence favoring a 'prototype' theory of meaning and evidence for universal tendencies in the structuring of color vocabulary in the world's languages.

Berlin and Kay gave color charts to speakers of 98 different languages and asked them to sort the 329 colored squares into categories that corresponded to the others): white, black, red, yellow, green, blue, brown, purple, pink, orange, and gray.

Interestingly, these terms occurred in predictable patterns, and Berlin and Kay proposed a scheme of 'implicational universals' to explain the evolution of color terminology. Some languages have only two basic color terms, and these are always *black* and *white*. If a third is added, as in the Arawak language of the Caribbean or in Swahili of East Africa, it is always *red*. After red, languages with four color categories contain either *yellow* or a term that encompasses both blue and green (Kay devised the term 'grue'); languages with five colors include both *yellow* and *grue*, with differentiation between *green* and *blue* occurring in the six-color system. *Brown* is added as the seventh, then *purple, pink, orange,* and *gray,* which do not follow a specific ordering. An example of an implicational universal that follows from this discovery would be that languages with a term for blue will always have words for black, white, red, yellow, and green. The sequence can be depicted as shown below:

black and white	>	red	>	"grue" or yellow	>	yellow or "grue"	>	blue and green	>	brown	>	purple pink orange or gray

basic color terms in their language. They put three limits on what could count as a basic color term:

(1) It had to be a simple word; e.g. *reddish-brown* is not a basic color term.
(2) It had to apply generally, not in a specific domain (like *blonde* or *sienna*).
(3) It could not count as a 'kind of ___', in the way that *emerald* and *olive* are kinds of green.

They found that the most basic color terms any language has is 11, as in English (also Tagalog, Zuni, and

The orderly sequence for the development of color terms leads us to the idea that they might reflect cognitive universals, and this is indeed what Berlin and Kay found in their research on the focal meanings of the color terms. When they asked people to choose the best example of each of the basic color terms from the chart, choices were remarkably similar around the world. For example, people whose language contained no term for orange chose the same focus for yellow as those whose language had terms for both yellow and orange; people whose language contained only three

color terms had the same focus for red as those whose language had all 11 terms. This is the finding that refutes the so-called strong version of the Sapir–Whorf hypothesis (a version espoused by neither Edward Sapir nor Benjamin Lee Whorf), that our perception will be determined by the categories of our language. For color, at least, perception seems to follow universal human neural response patterns in a way that is unaffected by our language habits, although there have been dissenting claims suggesting that Berlin and Kay's experimental methods may not accurately reflect the way speakers apply color terms to objects in the real world.

The existence of universals for the core meanings of color terms does not contradict the fact that culture does play a role both in determining the wider meaning of color terms for speakers and in the inventory of non-basic terms for colors in one's speech repertoire. Color terms may be closely associated metaphorically with objects in our experience, for example, the sun with yellow, or fire with red. Color vocabulary may be highly elaborated in some cultures and for some speakers, according to the importance of color in various arenas of daily life. A painter or an interior decorator, for example, will have an extensive lexicon of color terms. In American society, women have larger color vocabularies than men, due to the sexual division of labor in purchasing clothing and household furnishings and the proliferation of color terms as a form of marketing in American consumer culture.

In applying color terms to objects and to parts of the color chart that are farther away from the focal colors, speakers seem to compare the color in question with the focal color and to judge both similarities and differences. The task of drawing boundaries on the color chart around the limits of each color produced more varied answers than determining the best example of a color did. The focal color seems to act as a prototype for that color. Prototype theory views word meaning as the set of referents that can be designated by that word, which is determined by how those referents compare to a prototypical exemplar of the category. This produces 'fuzzy sets', with some uncertainty about whether referents that are marginal really belong to the category or not. Is *turquoise* a kind of blue or a kind of green? Is *burgundy* a kind of red or a kind of purple? Different people will give different answers.

Researchers continue to debate the ways in which meanings of color terms are encoded in our minds. There are still questions about how language and culture relate to cognition, including whether cognitive images or concepts of color are based solely on neurologically determined perceptions that are universal for humans or whether they are molded in part by linguistic and cultural experience that includes using color words in ways quite different from an experimental setting.

Communication Theory

The contents of the terms 'communication' and 'communication theory' are notoriously vague.

A straightforward psychologist's definition is the following: 'communication is the discriminatory response of an organism to a stimulus'. Thus, Pavlovian conditioning would also be an instance of communication. This is strange to the linguist, because it is generally accepted that not even the learning of languages is a simple conditioning process. How could it be possible that after such a complicated process like language acquisition human beings use their languages for communicative purposes that are as simple as Pavlovian conditioning? The stimulus–response theory does not seem to be on the right track.

Another way to define communication is by information. Often, the term 'communication theory' is used in the strict sense of information theory. Information theory originated in problems around telecommunication techniques and was developed by Claude Shannon and Warren Weaver in 1949. This theory of communication suggests the following schema for communicative acts:

Source ——> Transmitter ——> Channel ——>
Receiver ——> Destination

In effect, the source sends some message to the destination. But let us look at the details between source and destination. First, the message is encoded into a signal; this is done by the transmitter. This point is important in telecommunication; however, in ordinary face-to-face talk, source and transmitter coincide. Leaving the receiver, the signal is sent through the channel. In ordinary face-to-face talk, the channel would be the air channel. But in telecommunication, it would be the electric channel. In the channel, signals are usually changed, or, rather, distorted by the noise. In ordinary face-to-face talk, the surrounding sounds that are not part of the conversation would be the noise of the channel. After the channel, the signal reaches the receiver. There, the decoding of the signal takes place, and we end up with a message again. This message is finally stored in the destination. In ordinary face-to-face talk, receiver and destination coincide.

As precise as this schema is, and as useful as it is for telecommunication, it neglects several factors of natural communication. First, the message lacks interpretation. It seems odd to say that the message is finally just 'stored' in the destination. This is not even true for the simplest acts of communication. If my neighbor at the dinner table utters 'could you please pass me the salt', I would not just store this message in my brain. Instead, I would interpret the message as nonliteral, and furthermore as an instruction to pass the salt to my neighbor. This simple example demonstrates that, often, people communicate because they want others to do certain things. This leads to the next factor of communication that is neglected in the Shannon–Weaver model: the dialogic nature of communication. Natural communication is not just one way as in the Shannon/Weaver schema; normally, something goes back to the sender.

Considerable research has been done to capture the necessary dialogism of communication. The most interesting schools are the Bakhtin Circle, the Prague school, and some versions of functionalism.

Let us focus on the Bakhtin Circle. In the pre-Stalin era, a group of three scholars emerged with some common views on communication and cognition: the literary critic Mikhail Bakhtin, the psychologist Lev Vygotsky, and the philosopher Valentin Voloshinov. Due to political reasons, it took some time before their work reached western research. But since the 1960s and 1970s, their ideas have influenced western psychology and text linguistics. The main idea of these scholars is that the language sign is inherently dialogic, and that all manifestations of the signs are inherently dialogic. Language is formed in the process of social interaction. While the ruling stratum tries to posit a single discourse as exemplary, the subaltern classes are inclined to subvert this monologic closure. In the sphere of literature, poetry and the epic represent the centripetal forces within the cultural arena while the novel is the structurally elaborated expression of popular 'ideologiekritik' (ideology criticism). In Bakhtin's now famous study *Problemy tvorchestva Dostoevskogo* ('Problems of Dostoevskii's work'), it is argued that Dostoevskii's work is imbued with a profoundly democratic spirit. Bakhtin argues that Dostoevskii's creative method is not Hegelian. In a Hegelian scheme, two positions struggle for ascendancy but are transformed into a synthesis at the end. According to Bakhtin, Dostoevskii does not merge the voices into one final, authoritative voice as in the Hegelian absolute. Instead, Dostoevskii presents an unmerged dialogue of voices, each given equal rights. Bakhtin calls this type of dialogue 'polyphonic'. The voice of the narrator resides beside the voices of the other characters. Voices intersect and interact, mutually illuminating their ideological structures, potentialities, biases, and limitations. Polyphony is also observed across different texts: for instance, literary texts show 'intertextuality', which means that they refer to other texts, thus yielding a huge larger text together. 'Voicing' is not only a characteristic of literary texts. In ordinary speech, several factors also lead to a multivoiced message: the cultural context, the social relations between the persons involved in the communication, the context of the situation — all these factors have an effect on the message. Linguistics, however, usually concentrates on only some aspects of communication, leaving cultural and social factors aside.

So far, we have concentrated on the two forms of verbal communication: written and oral communication. But human communication may also be nonverbal. There are many different channels of nonverbal communication: facial expressions, hand gestures, body movements ('kinesics'), and touch ('haptics'). All these modes of nonverbal communication make use of signs, movement, or touch. In animal communication, there are — in addition to nonverbal and (partly) verbal communication — other ways of communication, namely by smell and taste. Human beings do not make much use of smell and taste in the communicative

domain. Humans receive information about the world through the channels of smell and taste, for instance, while eating. But they do not use smell and taste for communication. Body smells seem to have a communicative function only in sexuality.

We have seen that communication has many aspects, and as many as communication theory has. If the focus of attention is more on social factors, the dialogism of communication will be important; if information structure plays a greater role, the theory will be more technical. Little attention has been paid to integrate the findings on nonverbal communication into the general frameworks existing for verbal communication. This might be an interesting field of study for the future.

Comparative Method

The comparative method is the most important of the various methods and techniques used to recover linguistic history. It is also of interest in language classification, in linguistic prehistory, and in research on distant genetic relationships, determining whether seemingly interrelated languages descend from a common ancestor after all. It is generally recognized that 6,000 languages are currently spoken all over the world (one quarter with fewer than 1,000 speakers), and they are grouped into more than 30 widely recognized families. It is estimated that half of those languages will die in the next century. The comparative method is therefore of much help in clarifying their status and evolution through time.

The comparative method is a set of principles and a methodology for comparing forms from related languages to reconstruct an earlier (proto-) language or an earlier state of a language. The aim of reconstruction is to recover as much as possible of the proto-language from a comparison of the descendant languages and to determine what changes have taken place in the various languages that developed from the proto-language.

The comparative method was developed in nineteenth-century Germany for the reconstruction of Proto-Indo-European and was afterward applied to the study of other language families. It is considered the most outstanding achievement of linguistic scholarship in the nineteenth century and was originally stimulated by the discovery by an English orientalist, Sir

William Jones, in 1786, that Sanskrit was related to Latin, Greek, and German. His famous speech to the Asiatic Society of Bengal marks the beginning of comparative philology.

Furthermore, the year 1816, when the German scholar Franz Bopp presented the linguistic public with language material from Sanskrit compared with some other Indo-European languages, remains a historical date in linguistics, because Bopp was the first to realize that the question of the mutual relations of Indo-European languages was worth becoming the subject of specialized inquiry. Indo-European was posited as a hypothetical ancestor language, and comparative studies were almost exclusively focused on the Indo-European language family.

Six years later, another German scholar, Jacob Grimm, included a systematic survey of the relationships between Germanic consonants and their correspondents in Greek, Latin, and Sanskrit in the second edition of his comparative grammar of Germanic languages. He established the existence of a circular 'soundshift' (*Lautverschiebung*) governing these relationships in the prehistory of Germanic. Grimm observed that when other Indo-European languages such as Latin and Greek have a voiced unaspirated stop (*b, d*), Gothic has the corresponding voiceless unaspirated stop (*p, t*), and that, when other Indo-European languages have a voiceless unaspirated stop, Gothic has a voiceless fricative (*f, θ*). In other words, the voiced stops inherited from Proto-Indo-European

became voiceless, and the voiceless stops became fricatives. His discovery is known in linguistics under the name of *Grimm's Law* (or the Germanic consonant shift), although Grimm himself did not use the term *law.* Grimm's Law was probably first worked out in detail by the Danish linguist Rasmus Rask (whose studies, being written in Danish, were less accessible to most European scholars).

However, linguists found at least two classes of exceptions to Grimm's Law with respect to Indo-European voiceless stops: there are cases in which Proto-Indo-European voiceless stops remain voiceless stops in Germanic and cases in which Proto-Indo-European voiceless stops become voiced stops in Germanic. Grimm's Law was thus corrected in 1875 by the Danish linguist Karl Adolf Verner, who examined words in Vedic Sanskrit and Attic Greek that are related to Germanic words that reflect Indo-European voiceless stops as voiced stops. He discovered that in all such cases, the Proto-Indo-European word had intonational stress after the voiceless stop. Verner understood that what seems to be an exception to sound laws may be governed by some other regularity and that sound changes may be unconditioned or may depend on the environment in which the sound occurs. This was a very important step in linguistics, and ancestral common forms could be reconstructed by using the principle of regular sound change and postulating a number of different sound laws that operated independently in the different branches of the Indo-European family.

The comparative method was often criticized because it is based on a misleading genealogical metaphor. In the 1850s, the German linguist August Schleicher transferred the Darwinian view of evolution to language and introduced the model of the evolutionary 'family tree' to comparative linguistics. As at that time it was customary to concentrate on the reconstruction of what was supposed to be the source of all Indo-European languages, Schleicher ventured an actual reconstruction of a short text, the 'fable of the sheep and the horses'.

During the second half of the nineteenth century, a group of four young scholars known collectively as the *Junggrammatiker* ('young grammarians' or 'neogrammarians') proclaimed the 'absolute exceptionlessness of sound laws', i.e. all changes in the sound system of a language as it developed through time were subject to the operation of regular sound laws. The assumption that sound laws were in principle absolutely regular in their operation was quite generally accepted and had become the landmark of the comparative method.

Realizing that sound changes occur in defined geographical regions that do not coincide with the spread of an official standard language, the German scholar Johannes Schmidt criticized the family-tree theory as unrealistic and misleading. According to his theory, known in linguistics as 'the wave theory' (1872), each sound law has its own territory, and different linguistic changes will spread, like waves, from a politically, commercially, or culturally important center along the main lines of communication. These innovations will not necessarily cover exactly the same area.

A real achievement of the method of reconstruction was the Laryngeal Hypothesis presented by the famous Swiss linguist Ferdinand de Saussure in his 300-page *Mémoire sur le Système Primitif des Voyelles dans les Langues Indo-Européennes* (1879; Report on the Primitive System of Vowels in Indo-European Languages): there had to be two hypothetical sounds for Proto-Indo-European, not attested in any of the Indo-European languages known at that time, but sufficient to solve several puzzling irregularities in the development of certain vowels in a number of languages. He was fairly conservative about claiming what they must have been, but he called them laryngeals, indicating that these sounds must have been articulated with the larynx (voice box) as the main articulator, and pointed out the precise locations in words where they must have occurred. Fifteen years after Saussure's death, when the ancient Anatolian language Hittite, the oldest attested Indo-European language, was deciphered, linguists found with amazement that Saussure was right: Hittite had the laryngeal sounds, and they were placed exactly where Saussure had predicted just on the basis of careful reconstruction.

The history of comparative philology (this was the name for linguistics at that time) shows that the comparative method addresses directly only material in the related languages that is inherited from the proto-language and has no means of its own for dealing with borrowings. All things considered, there are four basic assumptions on which the comparative method is based: (1) the proto-language was uniform, with no dialect variation; (2) language splits are sudden; (3) after the split up of the proto-language, there is no subsequent contact among the related languages; and (4) sound change is regular.

Nowadays, the work of reconstruction usually begins with phonology, i.e. with an attempt to reconstruct the sound system; this in turn leads to reconstruction of the vocabulary and grammar of the proto-language. In the nineteenth century, comparative studies were entirely word based: it was words or lexical word stems that were reconstructed and followed through history. Only after the knowledge of phonetics

had begun to increase did linguists realize that they should start reconstruction with sounds, not with lexical items. Consequently, historical linguistics has often enjoyed great success in reconstructing ancestral phonological systems and vocabularies. But for grammatical systems, the situation is slightly more complicated: grammatical patterns are often seriously perturbed by independent and cointeracting processes of change, and grammar usually undergoes more dramatic changes than the sound system and even the vocabulary.

Generally, studies in the comparative method start with the assumption that certain languages are related and hence descended from a common ancestor. The first step in the work of reconstruction is to find sets of putatively related words in the languages or dialects being compared, i.e. placing side by side a number of words with similar meanings from the languages under comparison, for example, Sanskrit *pita,* Latin *pater,* Greek *pater,* and Gothic *fadar*, all of them meaning 'father'. Such sets of 'cognate' forms should be examined for what seem to be systematic correspondences in their sound structure. Each correspondence must yield a plausible-looking sound in the ancestral language, one that could reasonably have developed into the sounds that are found in the several daughter languages; phonological change should be taken into account, because any difference in the form of cognates is a consequence of sound change in one or more of the languages. Establishing regular correspondences between languages permits the assumption that the languages in question are genetically related; these correspondences can also be used to formulate likely hypotheses about what changes gave rise to those correspondences, and to reconstruct antecedent unattested forms in the proto-language from those changes.

A set of 'reconstructed' sounds can then be postulated (marked with an asterisk by the standard convention) to which the sounds in the attested languages can be systematically related by means of sound laws. With these results, each word surviving in the various daughters may be put face to face with its form in the ancestral language. The reconstructed Proto-Indo-European word for 'father' is *pəter*. If neither chance nor borrowing can account for observed similarities, shared inheritance (i.e. 'genetic' relatedness) is the only possibility.

Languages replace lexical items over time; the more the time, the fewer the items retained from the ancestral language, and the fewer the potential cognates. This is why linguists agree that it is convenient to start with cognates belonging to the basic vocabulary, because they resist borrowing more than other components of the vocabulary. The final step is to determine what system of sounds the ancestral language apparently had and what the rules were for combining these sounds.

The success of any reconstruction depends on the material at hand and on the ability of the comparative linguist to decipher what happened in the history of the languages under comparison. Generally, the longer in the past the proto-language split up, the more linguistic changes will have occurred and the more difficult the task of reconstruction with full success is going to be.

The choice of languages is also very important. If we simply pick some arbitrary languages and compare them, we cannot expect to see systematic correspondences appear, even if the languages selected are indeed genetically related. The comparative method has to be applied carefully and thoughtfully, and every piece of information must be taken into consideration as possibly relevant. Linguists have to be aware of a number of potential difficulties that might lead the reconstruction into error. Perhaps the most obvious point is that the comparative method cannot recover any feature of the ancestral language that has disappeared without a trace in all the attested daughters. Other problems are loanwords, pure coincidences, nursery words, imitative words, and phonaesthetic words (sound symbolism), because these tend to be somewhat similar even in unrelated languages.

Compositional Semantics

Compositional semantics includes all approaches to the meaning of natural language that subsume, in one formulation or another, the principle of 'compositionality of meaning'. Very generally put, this principle reads: 'The meaning of a complex expression is a function of the meanings of its parts.' This is often called Frege's principle, although it cannot be found in explicit form in his writings. Almost any theory of meaning for natural language is based on this principle. There is a psychological motivation for this, because the principle is able to explain how a speaker can understand sentences never heard before.

A more explicit formulation of the principle is: 'The meaning of an expression is a function of the meanings of its parts and of the way they are syntactically combined.' This formulation makes it explicit that the meanings of the parts are not sufficient for determining the meaning of the whole, and that the way the parts fit together is responsible for differences in meaning (*John hit Mary* vs. *Mary hit John*). In this form, the principle is rather uncontroversial, although when one looks at the way the relation *is a function of* is spelled out in different semantic theories, there is considerable diversity.

This principle is the fundamental one in Montague Grammar, an application of the essential methods of formal logic to the study of natural language semantics: it helps in designing a finite system (with a limited number of words and ways of combining them) with infinite output (meanings for all possible sentences). One of the basic tenets of Montague Grammar is the 'rule-to-rule' correspondence between syntax and semantics: the syntax contains several rules that provide several ways to form a complex expression from parts, each with a specific semantic effect (i.e. for each syntactic rule, there is a corresponding semantic rule). Put informally, the meaning of a complex expression results from the application of a semantic rule to the meanings of the parts of the expression.

Some natural language expressions have been claimed to be difficulties for a compositional approach to semantics. One such difficulty is represented by compound nouns such as *bookworm* (which is not normally a worm but a person) or *ashtray* (which is not a tray). However, most of these challenges have been successfully met by insightful compositional analyses.

Due to its psychological plausibility, the compositionality principle characterizes not only formal approaches to semantics but also one major area of cognitive linguistics. In Adele Goldberg's Construction Grammar, for instance, syntactic constructions are considered to be substantive principles of semantic composition: since the constructions per se are taken to be meaningful, the meaning of linguistic expressions is the result of integrating the meanings of the words into the meanings of constructions.

Compounding

Compounding is the process of creating new words whose elements are smaller words. For example, the relatively new English word *chatline* is created by compounding (a process sometimes termed 'composi-tion') from the two simpler words *chat* and *line*. A word formed in this way is called a 'compound'.

The 'words' that are the constituent parts of compounds may be subject to specific formal requirements,

which depend on the language concerned. In the Latin compound *liquefacio,* 'to dissolve', *facio* means 'I make', but *lique,* although clearly related to *liquidus,* 'liquid', cannot occur by itself, but only in compounds and other derivative word-forms. In the Danish compound *sovesofa,* 'sleep sofa, sofa bed', the verb in the first element of the compound is in the infinitive. In other languages, although it is rare, finite verb-forms can be used, as in Arabana-Wangkangurru *yanhi·rnda· tharka·kura* 'speak-pres-stand-past.continuous = they were standing talking'. In languages like Finnish and Sanskrit, both basic and inflected forms of nouns can be found in the first element of compounds. Compounds usually consist of two parts: a modifying word and a modified one. The modified word is called the 'head' of the compound because it contributes the dominant meaning and determines whether the compound is, e.g. a noun or a verb. Whatever the form of the modifying element of the compound, it is usually fixed in the compound and does not change depending on the environment in which the compound occurs. The head element, however, may be inflected, e.g. for tense (in the case of verbs) or number (in the case of nouns).

Typically, compounds denote hyponyms, or special cases, of their head. A *chatline*, for example, is a type of line, not a type of chat. In English, the head is almost always the right-hand element in the compound. In a language like French, however, the head is frequently on the left: a *leçon-cuisine,* literally 'lesson cookery' (cooking lesson), is a type of *leçon* and not a type of *cuisine*. *Rolls-Royce* is quite correctly translated into French as *Royce-Rolls.* A remarkable number of languages show both patterns of headedness in compounds. In either case, compounds are ideal constructions for creating names for subtypes.

Because compounds are typically hyponyms of their head element, they also take their part of speech from their head element: for example, *chatline* has a noun in its head and is hence a noun, *user-friendly* has an adjective in its head and is thus an adjective, and *stage-dive* has a verb in its head and is consequently a verb.

Compounds in which this is true are called 'endocentric compounds' because their center of meaning lies within the compound itself (Greek *endo,* 'inside'). There are also 'exocentric compounds' (Greek *exo,* 'outside'), which are not hyponyms of their head element (an *egghead* is a kind of person, not a kind of head) or, more radically, whose part of speech is not deducible from that of their elements (for example, *put-down* consists of a verb, *put,* and a preposition, *down,* but it acts as a noun).

Although exocentric compounds are not hyponyms of their own heads, they can still be seen to be headed, in that one element modifies the other. A *redneck* may not be a type of neck, but it is still clear that *red* modifies *neck* and that *redneck* thus has its own right-hand head;

a *bas-bleu* (French) 'bluestocking' (literally, 'stocking blue') may not be a stocking, but not only does *bleu* obviously modify *bas*, the construction as a whole takes its gender from *bas*.

The same is not so obviously true of another type of compound, sometimes called 'coordinative compounds'. Here, two elements are put together, and the compound either denotes the unity of the two elements or is used as the superordinate term for things that include the two named elements. In the first case, we get things such as Marathi *āī-bāp,* 'parents' (literally 'mother–father'); in the latter case, we get things like Kannada *bassu karu,* 'vehicles' (literally 'bus–car'). The borderline between coordinative and endocentric compounds is often blurry, and classifications may vary for different scholars: several distinguishable classes of compounds similar to coordinative compounds are found, but they are not always kept clearly apart.

All the examples that have been considered so far are examples of what are usually called 'root' or 'primary' compounds. One of the typical characteristics of primary compounds is the wide range of possible meaning relations between the elements. For example, a *flour mill* grinds flour, but a *water-mill* is powered by water, whereas a *sawmill* uses a saw as an instrument in its work. There is nothing overt in these words to show that they have different interpretations, and the same form may have different interpretations on different occasions: the *Washington flight* may be the flight to Washington or the flight arriving from Washington.

A contrasting set of compounds, usually called 'synthetic' or 'verbal' compounds (some scholars distinguish between the two labels), has a very restricted interpretation. These are words such as *bus driver*, in which the head element is a derivative of a verb and in which the modifying element must be interpreted as an argument of that verb. The argument concerned is usually the direct object of the verb (as in *bus driver,* 'someone who drives buses') but may on occasions be other arguments, such as instrument in *hand-sewn* and subject in *consumer spending.*

Precisely where compounding stops and sentence formation begins is a matter of some dispute. In particular, it is not clear whether structures like Onondaga *waʔ·ha·hwist·ahtu·ʔt·aʔ,* 'he lost money' (in which the direct object *money* is directly attached to the verb *lost*) should be regarded as a compound or some other construction.

Computational Linguistics

Computational linguistics is a discipline between computer science and linguistics, for which the main concern is the computational aspects of human language. These are aspects that can be put into the form of a sequence of instructions that a computer can understand. For example, if we have a sentence like *John runs*, we can set up some simple grammar rules. These rules state that a sentence is made up of a noun and a verb, a noun is always *John,* and a verb is always *runs*. Of course, this grammar only produces our sentence, but it is a grammar that can be used very easily in a computer program. We only have to put three instructions (Sentence = Noun + Verb, Noun = *John*, and Verb = *runs*), in a format that the machine understands, to produce the sentence. We say then that this grammar is fit for computation. We do not include in our definition those tools that computer science gives us for the study of language. Sometimes these are also presented under the generic label, but they are normally not considered to be part of this field.

Two main practical goals in computational linguistics have been *machine translation* and *natural language interaction* with computers and machines. When we refer to 'natural language', we are doing so in contrast to 'artificial language'. Language can be called 'natural' when it can be used for communicating with people in the same way as a human being would do.

Machine translation, that is, translation carried out by a computer, was the first goal of computational linguistics. When scientists started to work in this field, it looked like an easy task. It was thought to be just a question of making words and expressions in the source language correspond to words and expressions in the target language. Very soon it became clear that it was not so simple, since language has a structure that is more complex than just a lexicon database. There is more to language than just words.

However imperfect the process still is, though, automated translation now gets much better results than in the past. And it has achieved them through a systematic approach to how to perform the task. From the very early years of machine translation studies, we have two main approaches to the problem of automating translation. The first method involves carrying out a direct translation from one language into the other. The second method is the 'transfer' grammar approach, in which everything is translated to a kind of intermediate language. From here, it is easier to make a translation to many other languages. This intermediate grammar may have the form of a real human language (Esperanto or English are examples), or a certain symbolic language. A simple example is the following: we have the French sentence *Marie aime Jean* and then we can make a translation to a simplified English sentence of the form *Marie(S)-love-Jean(O)*, with *S* marking the subject and *O* the object. From this intermediate sentence, we translate again, now into Spanish: *Marie ama a Jean*. The technique is very useful when translating to and from many different languages, since we have an intermediate expression from which we can easily make translations that are faithful to the same extent to the basic structure. Both techniques have their advantages and drawbacks.

In addition, even if there should not be any problem at all with the translation strategy adopted, there are other facts that machine translation has not properly accounted for to date, the most important being the resolution of ambiguity in language. The phrase *The cover of the book which I like* has syntactic ambiguity, since we cannot be sure whether what I like is the cover or the book. Similarly, *The seal is on the rock* has semantic ambiguity, since we do not know whether what is on the rock is an animal (*a seal*) or some kind of stamp (*a seal*). We may also have pragmatic ambiguity, of which a very simple case is the difficulty to translate the English pronoun *you* into languages like Spanish, French, German, or Japanese, where there are several different ways of referring to a second person according to degrees of formality or to the relation between the speaker (or writer) and the

hearer (or reader). Obviously, the computer cannot infer this type of information, which depends on the communicative situation.

Of all these types of ambiguity, the most important for machine translation is the last one, since it cannot be resolved by looking at the immediate linguistic context.

Another main area that computational linguistics has always been interested in is the interaction with machines using natural language. This can be done through the use of the written word or through the use of oral speech. In the latter case, the system needs to incorporate a module for speech recognition, in addition to the other modules used for linguistic processing that we have mentioned. The usefulness of mechanisms that react to ordinary speech in activities where free hands are needed has led to the development of such systems for cars, planes, or control of processes in factories, which are typical examples. In all these cases, in addition to the procedures of language analysis and generation, there are special calculations that take into account the noise that may accompany ordinary language.

In particular, there has been a special concern in trying to produce language in a manner as human-like as possible in *expert systems*. An expert system is a system capable of reasoning in a way similar to a specialist in a certain field, and it is therefore necessary, or at least very convenient, that the queries can be carried out in a language as close as possible to natural human language. This is so because expert systems are intended for use in many kinds of settings, and may have to be operated by persons with different degrees of expertise. It is also important to try to reproduce the typical interactive client–expert exchange.

In natural language interaction there are two main strategies. The oldest and the easiest is to check for certain words and expressions, ignoring the rest of the message. This is the direct, crude approach. According to the expressions the system recognizes, it gives certain answers. This was the approach used in Eliza, a program created by Joseph Weizenbaum in 1964–1966. It was designed to take on the role of a Rogerian psychotherapist, and it produced responses according to the trigger expressions that appeared. Thus, to a sentence with the word *friends*, it could react saying something like *Why are you thinking of your friends now?* so that to the sentence *I have many friends*, or *My wife has many friends*, we would get the question, *Why are you thinking of your friends now?* The rigidity of this approach is obvious, although it is the most economical by far.

On the other hand, we have systems where there is a special module for language recognition, in which sentences are *parsed* (analyzed) and semantic inter-pretations are assigned to them. This is the true computational linguistics approach, which has also found problems similar to the ones mentioned for machine translation. It is this approach that shall be explained below.

In computational linguistics, the structure of sentences needs to be represented in some way. In order to do this, the computer has some internal arrangement of data that corresponds to the semantic structures of the knowledge that we have in our mind, and that helps clarify the way in which the linguistic message organizes the information it conveys. This arrangement is in the form of a *semantic representation*. The computer also knows about the rules of the language for putting words and sounds (or letters) together. These are *syntactic and phonetic (or graphemic) rules*.

The semantic representations used in computational linguistics try to make the most of the resources that the machine offers, but they also try to be faithful to the structure of concepts. Let us take the example of the concept 'bird' to illustrate how these representations can be made. When we think of a bird, we immediately visualize an animal with wings and feathers. In our mind, we have a link between the concept 'bird' and the concepts 'wing' or 'feather'. If we write the words 'bird', 'wing', and 'feather', and draw two lines from the label 'bird', one to the label 'wing' and another to the label 'feather', we will have a representation of the above image by using a labeled diagram. If we now add more words to the diagram, such as, for instance, 'beak', 'egg', 'nest', or 'to fly', the diagram becomes more complex, but now the links start to be of different kinds. A bird normally 'has' a beak, 'lays' eggs, 'builds' nests, or just 'flies'. These different types of relation also need to be labeled. Finally, we now know that not all these features are necessary and sufficient, but rather prototypical. It is difficult to imagine a bird without a beak or wings, but certainly not all of them fly or build nests. This is more difficult to put in our diagram, but we can try to use some numbers that denote to which extent these features can be applicable.

When our diagram becomes larger, it should look like a *net*. In fact, it is a way of depicting a *semantic net*, a kind of representation that is being used in computational linguistics since the late 1960s. Semantic nets are incorporated in the data of computational linguistic applications, so that the semantic structure of sentences is interpreted or generated by building small nets that match the connections that appear in the larger ones. As a formalism, a semantic net consists of a collection of points (the labels 'bird', 'wing', 'feather', etc. in our example) called *nodes*, each representing a concept. A node may be

connected to any other node in the net by means of *relations* that in turn carry labels ('have', 'build', 'fly', etc.). There are some conventions: two very typical relations normally referred to in computational linguistics books are the labels IS-A (x 'is a' y) and H-A-P (x 'has as part' y). But any other that corresponds to common English verbs or adjectives (LIKE, COLOUR, etc.) can also be used.

Let us look at another example. A semantic net for the sentence *Mary likes Peter* could be the following:

GIRL		BOY
IS-A		IS-A
MARY	LIKES	PETER
H-A-P		
EYES		
COLOUR		
BLUE		

This net provides a semantic representation for the message conveyed. However, most of the information is not in the sentence itself, which only carries labels. We retrieve all the additional information from structures of knowledge that are either in our mind or in the computer's data. There is a matching process in order to see which parts of the sentence's semantic structure and the program's data coincide. It is like having two pictures in two transparencies, A and B, of a face and a nose. The nose has more detail in B, but it coincides partially with what is drawn in A; hence, we know that it corresponds to that face. In addition, when we put the two transparencies together, the face receives a better drawing, with the addition of a more detailed nose.

This matching process is currently referred to in computational linguistics as *unification*, and it is considered a very powerful resource for natural language processing. When a computer programmer uses a programming language such as PROLOG, for instance, there is an extensive use of unification.

We can illustrate this by having a close look at how PROLOG works. As has just been stated, PROLOG is a programming language, and all programming languages have a vocabulary and a syntax, exactly in the same way as natural languages do. In the vocabulary, we have strings of symbols that stand for *variables* (with capital letters, e.g. *X, YW, AA*) or for *constants* (without capital letters, e.g. *a, bb, person, mother*). The corresponding items in a natural language for variables would be pronouns (which stand for other terms). For constants, we have proper nouns (which, in ideal cases, refer to unique entities).

Statements in PROLOG normally have a structure in which there is one predicate and several arguments. If A is the predicate and x, y the arguments, the convention is to write A (x, y). The symbol :- is used to assign several statements as conditions for the truth of another one, and the resulting structure is called a *rule*. An example will help to understand this. Below there is PROLOG rule:

```
aunt (X, Y) :-
    female (X),
    brothers (X, Z),
    parent (Z, Y).
```

Let us translate these statements into understandable English (on the right):

aunt (X, Y) :-	'X (a variable) is Y's (another variable) aunt if...'
female (X),	'X is a female'
brothers (X, Z),	'X and Z (a third variable) are brothers/sisters'
parent (Z, Y).	'Z is a parent of Y'

In plain English, this would be something like 'Some entity X is the aunt of some other entity Y if the entity X is a female, the entities X and Z are brothers or sisters, and the entity Z is one of Y's parents.'

The computer programmer writes this rule as part of a larger program, and we can also add some information to the program's database by writing the following statements:

female (mary)	'Mary is a female'
brothers (mary, john)	'Mary and John are sister and brother'
parent (john, jim)	'John is one of Jim's parents'

(Notice that the terms 'female', 'mary', 'john', etc. have no capital letters, because they are constants.)

The computer operator may wish at some stage to know who is Mary's nephew, or to whom she is an aunt. We can then make use of the 'aunt' rule. The operator writes:

?- aunt (mary, Y)   'Mary is Y's aunt'

As this is a plain statement (not a rule), the PROLOG system looks for a suitable term that can change the variable Y into a constant. If you look at the information provided in the statements that have been incorporated into the program so far, this term is *jim*. Accordingly, it answers:

Y = jim

We then say that *jim instantiates* the variable Y.

The PROLOG system has carried out a *unification* process in order to come to the right solution. It has

unified the rule and the statements in the following way:

```
aunt (mary [=X], Y) :-
    female (mary [=X])
    brothers (mary [=X], john [=Z])
    parent (john [=Z], jim [=Y])
```

So that Y = jim.

Unification is a very important procedure in computational linguistics. It simulates on a computer the processes that take place when we compare information from our mental store with the information in the linguistic message.

Another well-known programming language for artificial intelligence is LISP, of which many different versions have been created afterwards (schema, xlisp, etc.). LISP stands for 'List Processing', and it is a complementary approach to PROLOG. Whereas in PROLOG we had a deductive mechanism that unified knowledge structures, in LISP we have a powerful engine for processing lists. This is useful in computational linguistics, where syntactic parsing is an important step in the analysis of sentences. An additional important feature, which is very convenient for many artificial-intelligence approaches is that LISP programs are able to self-modify, making it possible to write code that 'learns', or that adapts itself to changing circumstances.

PATR (Shieber 1986) is a declarative language that has eventually become a standard in computational linguistics. This is so because it is very easily adaptable to many different theories. In fact, many current developments use feature structures and unification in a PATR style. The most prominent characteristics of the other two languages that we have seen here, unification (PROLOG) and string concatenation (LISP), are used in this language.

With respect to semantic nets, computer scientists soon found that representations like the ones shown above fail to give detailed information about the situations that are represented. Location, time, setting, etc., were notions that did not appear in the structures. This led to more complex representations, in which concept nodes were used for events as well as objects, and cases appeared as labels in semantic nets. Parallel to the relation IS-A for objects, there is also now ACT-OF. In the sentence *John throws the ball*, John is linked through an AGENT relation to a node. 'The ball' is also linked to that same node by the relation OBJECT. And the node is linked to 'throw' by means of ACT-OF, which therefore links particular instances of events to the general node for a certain action in the knowledge database.

An example of how the semantic net paradigm can be realized is R.C.'s (1973) theory of conceptual dependency. This author's graphs follow the formal structure of a dependency grammar, and have four different types of nodes. These are symbolized by PP, ACT, PA, and AA, corresponding very roughly to noun, verb, adjective, and adverb, respectively. Schank makes use of a small set of primitive actions (PROPEL, MOVE, INGEST, EXPEL, GRASP, PTRANS, MTRANS, ATRANS, SPEAK, ATTEND, and MBUILD) and the default action DO. With the help of a small number of states, this author claims that the meaning of all verbs can be represented. It is interesting to see how the semantic primitive approach is used here. In addition, we also have rules that must be applied for well-formed conceptualizations.

Sets of semantic primitives have been used in many CL systems. However, it is important to clarify here that there is no claim about their universality or a very strong psychological justification. The use of a limited set has more to do with a question of convenience.

Computer-Assisted Language Learning (CALL)

Computer-assisted language learning (CALL) has been an important aspect of language teaching and learning since the 1960s, and its developments have been influenced and shaped by those occurring more generally in the fields of education and applied linguistics. The first applications of computers in language teaching were

based on large-scale, specialized mainframe computers, and hundreds of person-hours of programming were needed to develop the instructional software. These computer-assisted instruction (CAI) systems were meant to be 'stand-alone', which meant that all aspects of teaching and learning were contained within the hardware and software. It was very difficult (or often impossible) for teachers to tailor the software to their classroom teaching, and some of the earliest complaints about CAI were related to this problem. The teaching approach used in CAI systems was tutorial (drill and practice) and was based on behaviorist learning theories that were popular at the time. Among the early CAI projects, perhaps the two most influential for language teachers, were PLATO (Programmed Logic for Automatic Teaching Operations) and TICCIT (Time-shared, Interactive Computer-Controlled Information Television), developed at the University of Illinois and Brigham Young University, respectively.

In the 1970s and 1980s, the change to more communicative approaches to language teaching and learning coincided with the development of microcomputers and the corresponding proliferation of software. Many programs were still tutorial (drill and practice), but more general learning tools, including, for example, word-processing, database, spreadsheet, and, by the 1980s, communications software, were adopted from the business environment. In addition, authoring software (high-level programming languages) helped teachers write computer programs to complement their other classroom activities. Consistent with new communicative approaches to language teaching, teachers began to group students so that they could work together in teams to write simple software programs. Not only did this new instructional approach help students to become more independent learners, but also team-programming provided them with opportunities to practice language in authentic communicative contexts.

Since the 1990s, with the advent of inexpensive memory and other hardware components, for example, resident CD-ROM or DVD (digital video disk) players, teachers have had access to a range of commercially developed, multimedia language software. Such software is usually created as a hypertext environment in which text, sound, video, and graphics are creatively linked to one another. Students can point and click on different words, ideas, or branches of a program and move through instructional material at their own pace, according to their personal interests. However, multimedia software can be expensive and cannot always be tailored to individual classroom learning needs. Some researchers have also questioned whether reading and writing in hypertext environments, disjointed as it can be, helps or hinders language learning.

Also since the early 1990s, access to global communication networks and the World Wide Web, and the availability of point-and-click Web-browsing software, has become increasingly easy to use and inexpensive. The Internet has made global communication, through electronic mail (e-mail), commonplace and has led to a variety of tandem language-learning projects. For example, English-speaking students studying French in the United States could be paired electronically with French-speaking students studying English in Canada. Both groups write to each other in the target language and then send, read, or reply to messages at their convenience; they do not need to be on-line at the same time (asynchronous communication). Learning is aided as students work at their own pace and help each other to notice problems in grammatical forms or learn how to express ideas in more natural, idiomatic language. In addition, students can provide insights to their e-mail partners about respective cultural practices and norms. Such peer-based sharing of ideas to help learners develop a deeper understanding of language is called 'scaffolding' and has been influenced by learning theories from education and psychology.

In contrast, synchronous communication, in which all people are on-line and writing (typing) at the same time, is also used in CALL classrooms. Synchronous communication, for example, in on-line chatrooms, requires students to log into centralized 'rooms' on the Web, where they can adopt pseudonyms or even assume different on-line identities. The pace of written exchanges is fast, and the style of language is often informal. Many language teachers believe that unless there is a well-developed curriculum structure and educational purpose to synchronous communication, students may not learn appropriate linguistic forms. In fact, some researchers believe that on-line chatroom communication involves a new, hybrid form of language that incorporates features of both speaking and writing.

Although the Internet supports the exchange of written text through e-mail or in chatrooms, it also provides access to a variety of other language-teaching resources. These include, for example, access to Web-based software (much of which can be downloaded) and specialized Web sites containing organized links to language-learning resources around the world. For example, students can read daily newspapers, listen to live radio broadcasts, or watch and listen to television news from a variety of countries. As a result, access to 'authentic' language resources is becoming easier for teachers, but how to evaluate, organize, and integrate on-line materials so that students can learn language in a structured manner have become important issues in teacher training. Certainly, there is a growing acceptance

that the role of the teacher and student in CALL class-rooms is changing, with teachers assuming more facilitative, guiding roles and students becoming more autonomous learners.

The latest technological changes that are affecting CALL include wireless communication, which relies on radio signals, rather than physical wiring, to connect to the Internet, and a variety of new software tools. For example, it is now possible for students to use wireless laptop computers, video cameras, and word-processing and movie-editing software to write, film, and review their own language materials. Such a project-based approach to teaching and learning could effectively integrate current theories of autonomous learning, peer scaffolding of learning, and authentic communication. Regardless of the technology used, however, the overriding issue for teachers will remain how to coordinate learning experiences so that students have meaningful access to language—however sophisticated their computers and whichever software they use.

Comrie, Bernard

Bernard Comrie is one of the leading figures in language typology. As a fieldwork typologist, Comrie has carried out studies on Fula, Tunisian Arabic, Malayalam, Moroccan Arabic, Khmer, Tsez, Sudanese Arabic, Maltese, and Basque, on which he has taught field methods classes. He has also worked in depth in the field on two additional languages: Haruai and Bezhta. Comrie has also taught and researched Historical Linguistics and Diachronic Syntax.

Although typological linguistics is the overall approach that is closest to his own, his work has very close ties with cognitive linguistics. Even if as a formal framework, Relational Grammar is now virtually dead, in terms of formal approaches to grammar, Comrie believes that linguists have learned a lot about the grammars of different languages and about the general properties of language from that framework.

Comrie has been influential in the recent upsurge of interest in linguistic typology, both through his general books on the topic and through individual articles. Within typology, the areas in which he has had most impact are relative clauses, causative constructions, and grammatical relations. In addition, his books on tense and aspect have had an important role in generating interest in these topics, even among linguists who end up disagreeing with his approach.

Some common linguistic terms are actually used for the first time in his papers. The term 'accessibility hierarchy' came with Keenan and Comrie (1977). His book *Aspect* played a major role in getting the distinction widely accepted between 'perfect' and 'perfective'. He is perhaps the first linguist to introduce, among other terms, the 'S, A, P' terminology (as opposed to Dixon's similar 'S, A, O').

One of the main features in his thinking has been the integration of links between language and other phenomena, in particular cognitive and social. He is in search of correlating linguistic and other (genetic, archeological) evidence for human prehistory. He insists that these different disciplines provide us with different windows into human prehistory that must then be reconciled with one another, rather than presupposing, for instance, a close connection between language families and biological populations.

Comrie's ideas have not remained static. In some of his later articles (e.g. 'Rethinking the typology of relative clauses', 1998), he has argued for substantial revisions to the ways in which typologists and other

linguists look at relative clauses, in particular, paying more attention to semantic and pragmatic factors. With regard to aspect, he gives more import to the role of lexical properties of verbs than he did in the mid-1970s.

Comrie's first publications were articles derived from his doctoral dissertation, and thus dealing with generative grammar. However, his first articles in the field of universals and typology include 'Noun phrase accessibility and universal grammar', written jointly with Edward L. Keenan (1977). He has a remarkable number of publications, mostly on the typology of ergativity, aspect, causative constructions, and nominalizations. His major publications include *Aspect* (1976), *Lingua descriptive studies: questionnaire* (with Norval Smith, 1977), *The Russian language since the Revolution* (with Gerald Stone, 1978), *Language universals and linguistic typology: syntax and morphology* (1981), *The languages of the Soviet Union* (with B.G. Hewitt and J.R. Payne 1981), *Tense* (1985), and *The Russian language in the twentieth century* (with Gerald Stone and Maria Polinsky 1996). To this list, we should add his several important edited volumes (like *Classification of grammatical categories* (1978), *Studies in the languages of the USSR* (1981), *The world's major languages* (1987), *The Slavonic languages* (with Greville G. Corbett 1993), and some others, along with dozens of articles on language typology.

Biography

Bernard Comrie was born on May 23, 1947 in Sunderland, England. By 14 years of age, he knew French and had already started learning Latin, German, Ancient Greek, and Russian. Coming across R.H. Robins' textbook on linguistics left a deep impression on him, showing him not only that there is a field called linguistics, but that it is also a systematic, scientific endeavor.

Comrie studied Modern and Medieval Languages (mainly French, German, Russian, Linguistics) at the University of Cambridge, receiving a B.A. (1968) and a Ph.D. in Linguistics (1972). His dissertation 'Aspects of sentence complementation in Russian' was written under the supervision of Pieter A.M. Seuren.

Comrie taught linguistics as a University Lecturer in Linguistics at the University of Cambridge (1974–1978). In 1978, he joined the Department of Linguistics at the University of Southern California, Los Angeles, and worked there as a Professor of Linguistics until 1998. Since 1997, he is director of the Max Planck Institute for Evolutionary Anthropology in Leipzig, Germany, in addition to being a part-time Distinguished Professor of Linguistics at the University of California, Santa Barbara (since 2002). In addition, he holds honorary positions as a Research Professor of Linguistics, University of Southern California (since 1998) and as a Professor of Linguistics, University of Leipzig (since 1999).

Configurationality

English is a configurational language because the grammatical functions subject and object appear compulsorily in particular syntactic positions: nearly every English clause must have an overt preverbal subject and every English transitive clause must have an overt postverbal object. Of the three main constituents of the clause—subject, verb, and object—the syntactic relationship between verb and object is *bounded*, as opposed to the syntactic relationship between subject and verb, which is *unbounded*. The strong syntactic

ties between verb and object, which together constitute a phrasal unit, the verb phrase (hereafter VP), are evidenced by tests like VP deletion *(Mark washed his car and Bill did [wash the car] too),* VP pronominalization *(Mark washed his car and so did Bill),* and VP fronting *(Mark said that he would wash his car and wash his car he did).* What these tests show is that subjects appear outside the verb phrase in *syntactically unmarked English sentences* (that is, less complex and more frequent than their unmarked counterparts), whereas objects are immediately contained in the VP in English. Subjects and objects, therefore, exhibit different properties of coding and behavior (coding properties are morphological properties such as agreement with the verb, while behavior properties are distributional and include, for example, the omissibility of the subject in a coordinate subject construction like *Matthews complained angrily and left the room*): for instance, in English the verb agrees with the subject—not with the object—in number and person (*He **writes** vs. They **write***) and the subject—not the object—of dependent clauses can be raised to—becomes—subject or object of the matrix (main) clause under certain conditions (*They consider that she is bright/I consider her bright/She is considered bright*).

This correspondence between grammatical functions and syntactic positions or *phrase structure configurations* has motivated the configurational definition of subject and object according to which the subject is the noun phrase directly dominated by the node sentence and the object is the noun phrase directly dominated by the node VP (subconstituents are immediately dominated by the constituents where they belong). This configurational definition puts aside functional relations like subject and object to the benefit of structural aspects of constituency, including, at least dependence (constituents have heads on which subconstituents depend), hierarchy (constituents consist of compulsory and optional subconstituents), and linearization (constituents take up a clausal position relative to the verb).

In this approach, case assignment (as in *who–whom–whose–to whom*) and agreement (as in *I eat* vs. *she eats*) crucially depend on the asymmetry between the noun phrases that bear subject and object: the object requires syntactic continuity with respect to the verb; the subject does not. Syntactic continuity is defined as a relation of adjacency between a head and one of its dependents or between two heads: in *Peter sent them **to the Greens,*** the preposition and the noun phrase it governs are adjacent to each other in the linear order of the sentence, whereas in ***Whom** did Peter send them **to?*** the sequence noun phrase-stranded (that is, final) preposition is interrupted by the subject, the verb, and the object, thus constituting an instance of syntactic discontinuity. Syntactic continuity is often referred to in the literature as *local dependency,* as opposed to *nonlocal dependency* or syntactic discontinuity.

Theoretically speaking, the problem arises of how to account for syntactic discontinuity in grammatical phenomena like case assignment and agreement. In general, two solutions have been adopted: *monostratal* theories recognize a single *level of syntactic representation,* or, more clearly, a single linguistic representation, in which the order and form of the elements of the expansion (including grammatical case and phonological properties of accent, rhythm, and intonation) do not necessarily reflect the order and form of the elements of the sentence that the speaker utters, whereas *multistratal* theories recognize more than one level of syntactic representation, or, in other words, more than one linguistic representation, in such a way that every level represents the sentence that the speaker utters in a less abstract way than the preceding level (abstractness is understood as the distance between the linguistic expression and its representation). Multistratal theories justify the necessity of defining multiple levels of representation on the grounds of the existence of *syntactically marked constructions* (that is, more complex and less frequent than their unmarked counterparts) like passives, questions, preposition stranding, etc., which result from the application of a number of structure-changing operation rules or *transformations* between the deep (more abstract) and the surface (less abstract) levels of syntactic representation. Structure-changing operations fall into three types: first, operations of deletion of specified elements, as in *I met a man **who was wearing a yellow coat*** vs. *I met a **man wearing a yellow coat;*** second, operations of substitution of one specified element by another specified element, as *in These are **the shoes** [I bought the which in Paris]* vs. *These are **the shoes which I bought in Paris;*** and third, operations of permutations of specified elements, as in *Jim doesn´t like **bananas*** vs. ***Bananas** Jim doesn´t like.*

The existence of the node VP, which is criterial for configurationality, has been questioned on a cross-linguistic basis. The interlinguistic evidence provided includes: first, the lack of adjacency between the object and the verb in VSO and OSV languages; second, the syntactically unconstrained permutability of the subject and object in languages such as Latin, where the order of the major elements of the clause can be SVO as well as OVS; and, third, the optionality of overt subject and object in languages like Navajo, a language in which some clauses consist simply of the element V. In consequence, a division into configurational (with VP) and nonconfigurational (without a VP) languages is proposed. Although nonconfigurational languages often coincide with relatively free constituent order languages, this is not always

the case: there are languages, like Navajo, with a relatively rigid constituent order that qualify as nonconfigurational. Navajo has a rich system of verbal prefixes, including prefixes of person and number of the subject and object, thus allowing for *null nominals* (*phonologically empty*, or nonexistent) in the function of both subject and object.

Another dimension has been explored in which languages can be configurational or nonconfigurational: the discoursive dimension. A language is discourse configurational if it assigns the discourse functions of topic and focus. The discourse function topic is used for foregrounding a discourse topic about something that is predicated. Such a discourse topic may or may not coincide with the grammatical subject and is usually placed in a particular structural position, typically clause-initial. The discourse function of focus is used to highlight particular aspects of the predication about the topic. The constituent that bears focus either appears in a particular structural position, typically clause-final, or receives special morphosyntactic coding or prominence, or participates in marked syntactic constructions.

Connectionism

In the 1980s, the connectionist view, an alternative to rule-based approaches to language, gained increasing acceptance among cognitive scientists. According to this view, our knowledge of language is the result of our interaction with the universe of linguistic utterances that we encounter.

The principal tool of connectionist research to study the acquisition and use of linguistic knowledge is the neural network. A neural network is a computer simulation inspired by neural processes that govern the brain. Neural networks consist of primitive nerve-like processing units, connected at multiple points. The strength of these connections depends on past experience. Accumulated experiences shape the connections, using weights that represent the knowledge of the network. Environmental events are registered via input units as patterns of activation, where the activation is expressed numerically. Thus, the vector (0, 1) indicates activations of 0 and 1 for two input units.

Networks vary in complexity in the number of layers of units and patterns of connectivity. A unit transforms input signals into an activation function and passes the activation forward to other units; therefore, information in neural networks is represented by patterns of activation spread over many neurons and the links between them. The networks are said to represent knowledge in a distributed manner, as a single network can accommodate multiple pairs of independent input–output patterns.

Learning is a natural property of connectionist networks. Learning involves a change of the connection weights in the network as a result of a specific training regimen. Connectionist networks are applied to a wide variety of linguistic phenomena, including recognition, pronunciation, morphology, and syntax, typically with an eye toward simulating empirical effects observed in psychological research. The interactive nature and sensitivity to multiple inputs of connectionist networks are well suited to simulating the recognition of various linguistic structures. An early interactive model by McClelland and Rumelhart (1986) was capable of simulating the word superiority effect, the finding that letters are recognized better when they occur in the context of words rather than in isolation.

Connectionist researchers have also trained networks to acquire spelling-to-sound correspondences by associating orthographic input signals with corresponding phonological outputs. Networks have been trained to mimic the acquisition of morphological knowledge of speakers, for example, of the regular and irregular past tense of English verbs, indicating that children more easily learn those irregular verbs that use the stem for the past tense, as in *hit*.

At least two classes of models of syntactic parsing, or sentence construction are advanced through connectionist modeling. One interprets sentences via case role assignments, while the other constructs phrase structure trees. In both approaches, multiple constraints change as a listener progresses through a sentence. In the first model, each successive word in a sentence imposes constraints on the interpretation of the current case assignment and the entire sentence. The second approach uses a recurrent network to acquire and to discover the phrase tree structure of sentences.

Although increasingly popular for these and other applications (e.g. the lexicon, language impairment, and language production), neural networks remain controversial. According to Pinker (1999), the models suffer from an inherent design flaw, as they do not take advantage of the computational device of a variable, which can stand for a class of words regardless of the particulars of context. The connectionist models are limited by their contradiction between the averaging mechanism and the value of information about the individual nuances so common in language.

Finally, although networks acquire their knowledge without programmer intervention, the programmer has great latitude in shaping the architecture and the processing details of a network. Frequently, in a manner not apparent to others, a theorist determines all of the features of a model, including the number of input units, hidden units, and output units, as well as the pattern of connections between units. While the networks can simulate many empirical findings, there have been both failures of prediction and very powerful predictions, for example, in the domain of speech recognition.

In spite of these criticisms, the neural network approach has become a part of the landscape in cognitive science and—due to its psychological plausibility—will continue to be a significant player in the field.

Constituency Test

Constituency and Phrase Structure

Constituency has played an important role in grammatical theory, especially regarding the empirical evaluation of different approaches to phrase structure. A constituent corresponds to a unit in the syntactic structure.

Consider the sentence *The janitor read magazines in the morning*. One can account for it as representing a sentence S, containing a noun phrase (NP) *the janitor* and a verb phrase (VP) *read magazines in the morning*.

Both NP and VP are units of S, they are constituents of S. The VP in turn can be analyzed as containing the verb *read*, the NP *magazines* as well as the prepositional phrase (PP) *in the morning*, which are all constituents of the VP. A formal representation in which the major constituents of the sentence are labeled would thus be:

(1) $[_S [_{NP}$ The janitor] $[_{VP}$ read $[_{NP}$ magazines] $[_{PP}$ in the morning]]]

Constituency Tests

Many grammatical operations can only target strings of words that form constituents. This has given rise to a number of widely recognized *Constituency Tests*. The rationale is that a string of words that are taken to form a constituent has to pass one or more constituency tests. The most common tests are summarized below.

Replacement or Substitution Test

A constituent can be replaced by a proform (e.g. a pronominal — *it, he* — or expressions such as *there, then, do so*). The replacing expression can be interpreted in a context so that the meaning of the replaced constituent is completely recovered. For instance, both the underlined subject NP (*a janitor*) and the entire VP in (4) can be replaced by proforms (*he* and *did so*, respectively), showing that they are constituents.

(4) [NP The janitor]$_j$ [VP read magazines in the library]$_k$. [*He*]$_j$ [*did so*]$_k$ everyday.

On the other hand, there is no proform that can substitute for a string of words that spans over parts of different constituents, such as [the janitor read].

Displacement Tests

A constituent can be realized in a position that is different from its canonical position in a sentence, i.e. it appears to be 'displaced'. There are different types of displacement, depending on what additional elements are added to the sentence. In *Clefting*, a structure like (5a) is generated with the addition of *it was…that* supporting dislocation of *in the morning*. However, *magazines in the morning*, which is not a constituent, cannot be clefted, as (5b) shows (the asterisk shows ungrammaticality):

(5) a. *It was* [PP in the morning] *that* the janitor read magazines.
    b. * It was [magazines in the morning] that the janitor read.

In *Preposing,* the material added to the dislocated constituent is usually a form of the copula *be* and a wh-word (e.g. *what, who, where*). The bracketed (embedded) sentence in (6a) is a constituent, and thus it can be displaced, as the preposing structure in (6b) shows:

(6) a. The janitor said [$_S$ that he is on vacation this week].
    b. [$_S$ That he is on vacation this week] *is what* the janitor said.

In *Topicalization,* no material is added to the dislocated constituent. Topicalization is fairly restricted in

English; hence, the embedded clause in (6a) cannot be easily topicalized.

(7) *[That he is on vacation this week] the janitor said.

This restrictive character of topicalization yields an important conclusion. The fact that a given string of words satisfies a constituency test (i.e. any test) is in general sufficient to indicate that this string is a constituent. However, this does not mean that *all* constituency tests can equally felicitously be applied, since each type of sentence structure may be subject to certain constraints (as, e.g. in topicalization).

Coordination Test

The coordination test shows that only constituents can be conjoined (8a), with the additional requirement that they correspond to the same kind of phrase, as shown by the ungrammaticality of (8b):

(8) a. The janitor read magazines [PP in the morning] and [PP in the afternoon].
    b. *Sue drove [NP a car] and [PP to Ottawa].

Relevance of Constituency

Constituency has been a powerful test to evaluate and select among different approaches to phrase structure and grammatical theory. For example, it empirically supported the adoption of X'-Theory in the 1980s, which claimed that the major sentence constituents in turn have internal structure. For instance, *read magazines* in (1) can be shown in (9) to behave as a constituent, excluding *in the morning*.

(9) [Read magazines] *was what* the janitor did in the morning.

This may be taken as evidence for a more fine-grained phrase structure with an additional level between V(erb) and VP, called V' (hence X'-Theory):

(10) [$_{VP}$ [$_{V'}$ read [$_{NP}$ magazines]] [$_{PP}$ in the morning]]]

Context

Contexts are texts' 'nontexts' and thus relational phenomena. They are caused by figure/ground mechanisms where texts are focused figures and their contexts function as their (back)grounds. Contexts are accordingly always changing. Particular academic fields prioritize particular kinds of researched objects, and accordingly particular kinds of contexts. An overall workable definition of context consequently may not be found, since it would be too general to cover the diverse and specific needs of subdisciplines. This tension between specific and general is captured in the aphorism *Meaning is context bound, but context is boundless* (Culler 1981:24).

Nevertheless, contexts as phenomena have become increasingly important within linguistics, and in general. Everyday configurations and common-sense understandings, reflected in different dictionary definitions, are commonly twofold. Contexts are seen as textual elements embedding particular utterances, and as circumstances surrounding particular situational events. Yet, new insights into how language functions challenge these definitions. First, the notion of text is expanding, incorporating even the meanings associated with pictures, films, and bodies. Thus, an extended concept of text destabilizes a seemingly safe ground for a definition of context. Second, contexts are seen as interactive and not just as passive 'embedding' phenomena, a position that triggers new questions.

When is a context? To report observed situations implies both decontextualizing and recontextualizing. Through decontextualization, focused events are separated from their original environment, and hence their original contexts are destroyed. In order to reconstruct meaning for receivers of reports that are separated from the original context, a text needs to be sufficiently (re)contextualized. However, the report now consists of elements of both the 'original' text and elements of its

new context. Hence, texts, traveling through time, space, and culture, will always occur in new contexts. The *when* question thus leads to a *where* question.

A simple answer to *Where is context?* is: internal and/or external. An internal perception implies seeing contexts as general premises for interpreting utterances, while an external perception perceives the material world as constitutive for contexts. However, both views tend to be static. A dynamic view implies that contexts are not just *around* texts as pre-fixed situations, but are dynamically woven *into* utterances while uttering. Hence, there are contextual elements or hints *within* most texts, which assist the interpretation of the intended meaning. The merging of given (G) and new (N) in texts is regulated by such hints: *Once upon a time there was a boy* [boy N]. *The boy* [boy G] *had a nut* [nut N]. *The nut* [nut G] *had a little hole* [little hole N], etc.

However, the opening phrase, *Once upon a time...,* only seems to imply a fairy tale. Rather, it is an *example* of just another context, namely the genre and context of an entry in the genre and context of an encyclopedia. The outcome is an inclusive embeddedness characteristic for contexts as phenomena [encyclopedia [entry [example [fairy tale hint]]]]. Hence, utterances are *doubly contextual,* relying on existing contexts for their production and interpretation and being, in their own right, events that shape new contexts for following actions.

How 'given' and 'new' are combined depends on the kinds of communication, such as discourses, registers, or genres. Concrete texts and utterances focus on the micro level, while discourses, registers, and genres are active as contexts at a macro level. They can create or are presuppositions for contexts of situations.

Some text theories try to specify contextual constituents more systematically, as M.A.K. Halliday and

his followers (e.g. C.M.I.M. Matthiessen and Jim Martin) do in Systemic Functional Grammar. This approach is contextual and sees language principally as meaning-potential for combining text and context and suggests that language has three interactive main functions: textual, ideational, and interpersonal. Similarly, Jürgen Habermas (1984) sees each person's communicative context as a 'lifeworld' consisting of a triad of three basic interactive elements: inner nature (self), outer nature (world), and others (society). Although he is not arguing that lifeworld *is* context, his triad can be linked to Halliday's so that the textual function is respectively related to communicators, the ideational to world, and the interpersonal to society, so that all elements define each other mutually.

Following Halliday and Habermas and others on this matter, a triadic understanding will imply that both language (or utterances and texts) and context (genres and discourses) will be triadic. They are all interrelated and constitute a systemic *contextual* lifeworld. Consequently, contexts are always and simultaneously embodied, world-related, and societal.

Embodied contexts, however, will in turn function as discursive resources for uttering and as such distribute power asymmetrically, even in a context that is seemingly equal for all the participants. Thus, classroom episodes with students and teacher, medical consultations between patients and doctor, command situations between soldiers and officer, will represent not only different embodied communicational resources, but different contextual power relationships.

If contexts are systemic and interrelated, academic fields have to find their place in such a system, by developing awareness of similarities and differences vis-à-vis other fields. Subdisciplines within linguistics are likely to focus on textually established contexts. The nearest contexts for sounds are words, the nearest contexts for words are sentences, etc. Fields such as applied linguistics and anthropological linguistics, for instance, will need to take the larger, more general contextual aspects, such as genres and discourses, into consideration as relevant for the (re)production of meaning.

Context can be seen as a relational concept in transition and hence open to reconceptualization. To rethink something means to recontextualize it. Thus, reconceptualization is recontextualization.

Conversation Analysis

Conversation analysis (CA) involves the study of spoken interactions. In CA, naturally occurring talk is recorded, transcribed, and then analyzed. The term conversation analysis, however, may be misleading, as a range of spoken interactions are studied under the heading 'conversation', from casual conversation to

more formal talk such as courtroom interactions or medical consultations. As a result, CA is increasingly referred to as the study of 'talk-in-interaction', although this term has also been criticized for ignoring nonverbal issues such as pauses, gestures, or gaze.

Traditionally associated with sociologist and others working in the ethnomethodological tradition, CA is used in different ways by different scholars. Scholars from a variety of fields, such as linguists, anthropologists, and communication specialists, also analyze spoken interactions, using a range of methods, and based on varying assumptions.

Conversation analysis began in the 1960s with the work of American sociologists Harvey Sacks, Emanuel Schegloff, Gail Jefferson, and others, influenced by Erving Goffman's focus on everyday interactions and by Harold Garfinkel, the founder of ethnomethodology. Ethnomethodology is concerned with uncovering participants' (as vs. researchers') perspectives on the activities in which they are involved. Ethnomethodologists seek to understand how people produce and understand daily activities, including conversation.

Within this tradition, CA sees talk as social action, and attempts to uncover the structural properties of talk in terms of the sequential development of talk. CA provides a substantive body of evidence indicating that talk is rule-oriented. One area of investigation is turn-taking. CA revealed that speakers tend to obey a rule of one-speaker-at-a-time. Several features of talk are related to this preference, including when speakers chose to begin their turns. Another finding is the adjacency pair, a two-turn sequence of adjacent utterances by successive speakers. The first utterance sets up an expectation for the second. An example is greeting–greeting. When a speaker greets another speaker, there is an expectation that the next utterance will be a return greeting. Other areas of investigation in CA have included the concept of repair, or what happens when a speaker misspeaks or is not understood, laughter, and storytelling.

A number of assumptions underlie this methodology used within CA, the ideas that data should consist of multiple instances of naturally occurring talk, not constructed examples, that talk should be transcribed in such a manner as to attempt to capture the sense of the sequential development of the talk, of how the interaction unfolded, and that no item is too small to be investigated. As a result, transcriptions include such items as overlapping speech of multiple speakers talking at once, pauses, laughter, and changes in volume. In addition, CA tends to dismiss assumed categories of sociocultural context such as status or gender, claiming that the relevance of these categories must be demonstrated within the data analyzed.

The term 'context' is used to refer to the textual environment, rather than the sociopolitical environment. Talk can be both context bound, in that we understand utterances because of their sequential placement within a conversation, and context free. Conversationalists seek to find meaning, interpreting utterances in relation to prior utterances or knowledge, and in this sense, all utterances are context bound. Conversation is context free in that there are rules of conversation that are general and are not constrained by changes in such things as the participants or setting: participants in talk still take turns, repair misunderstandings, and the like.

Context is also both retrospective and prospective. What is said in a given moment emerges in part because of what was said in immediately prior utterances, and it also influences what will be said next. In this manner, participants mutually construct talk. CA within the ethnomethodological tradition has a number of limitations. Much of the work in the field has been carried out in English. Cross-cultural studies have not always concurred with its findings. CA has also been criticized for ignoring the larger influences of sociocultural context, and for not acknowledging the benefits of quantitative analyses of spoken interactions.

Scholars from a variety of fields have undertaken analyses of spoken interactions, often addressing the limitations mentioned above. Dell Hymes's ethnography of speaking, also known as the ethnography of communication, is one such area that explicitly examines larger sociocultural contexts such as participant roles or setting. One goal of this approach is cross-cultural comparisons of interactions. Work on speech acts focuses on talk as performing social actions such as complimenting or apologizing. Analysts in the Gricean tradition also tend to use constructed examples of talk in order to determine the cooperative principles of conversation.

Interactional sociolinguistics provides another avenue into the analysis of spoken interactions, as does variation analysis. Much of this work examines how people vary their talk as a result of changes in sociocultural contexts.

Conversation analysis has contributed to linguistics, in part by making talk itself a focus of serious academic investigation. We now understand a great deal about the structure of talk, and therefore how deviations from our expectations of how talk should proceed lead us to interpret—rightly or wrongly—our speech partners' intentions. Fail to answer a greeting with a greeting, for example, and you may well be judged as rude in certain speech communities. CA is also combined with other linguistic disciplines and approaches, such as second-language acquisition and syntactic analysis, investigating how syntactic choices

are affected by the emerging nature of discourse. As CA is incorporated into wider circles of linguistic research, a more complete understanding of the various components and functions of language is possible.

Coordination

A coordination joins two sentence elements, called conjuncts. In a coordinate structure like *cats and dogs,* the conjunction coordinates the conjunct *cats* with the conjunct *dogs*. In many languages, conjunctions like *and* or *or* can conjoin words or phrases of virtually every category, under the condition that the categories being conjoined are of the same sort. It might appear as if coordination was a relatively simple phenomenon. However, coordination is notoriously difficult for linguistic theory to define.

Although a wide variety of structures can be conjoined, not all coordinations are acceptable. One of the first generalizations regarding coordination is Ross's Coordinate Structure Constraint (1967). This constraint states that coordination does not allow for asymmetrical constructions. For example, the sentence *This is the man whom Kim likes and Sandy hates Pat* is unacceptable, because only the first conjunct is relativized. The sentence *This is the man whom Kim likes and Sandy hates* is acceptable, because both conjuncts are relativized.

The Coordinate Structure Constraint might be explained by the requirement that the conjuncts in a coordinate construction must be of the same 'sort'. This requirement is sometimes referred to as the Law of Coordination of Likes. Linguists are uncertain as to the relationship between 'sort' and syntactic category. The sentence *Pat is stupid and a liar* shows that being of the same syntactic category is too strong a requirement for conjuncts in a coordinate construction, since an adjective phrase (*stupid*) can be conjoined with a noun phrase (*a liar*). It is therefore unclear what it means for two conjuncts to be of the same sort.

Linguists are further concerned with which material is allowed as a conjunct in a coordinate construction. The second example showed conjoined sentences, but coordination is also possible for noun phrases as in *the apples and the pears*, verb phrases like *run fast or jump high* and adjectival phrases such as *rich and very famous,* etc. Both sentences and phrases intuitively form meaningful units within a sentence, called constituents; however, not all sentence elements can be constituents. Subject and verb do not form a constituent in some frameworks of generative grammar. However, they can occur together as a conjunct in the sentence *Kim bought, and Sandy sold, three paintings yesterday*. The possibility of this 'nonconstituent coordination' has led a number of linguists to relax the notion of constituency. In categorial grammar, for example, subject and verb can form a constituent. Coordination phenomena can therefore provide a testing ground for even basic theoretical notions such as constituency.

Another important question concerns the way coordination of phrases is interpreted, as phrasal coordination seems strongly related to sentential coordination. The sentence *Kim ran and jumped*, in which two verb phrases are conjoined, has the same interpretation as the coordination *Kim ran and Kim jumped*, in which two sentences are conjoined. The dominant approach in generative syntactic theories indicates that phrasal coordination can be derived from sentential coordination by means of reduction rules. This approach states that *Kim ran and jumped* is the result of a reduction rule having deleted the subject of the second conjunct, *Kim*. Much syntactic research focuses on formulating appropriate reduction rules. This has turned out to be

quite difficult due to the potential for phrasal constructions such as *Kim and Sandy are similar,* which lack a sentential source.

The work of Richard Montague in the early 1970s ushered in the method of deriving the interpretation of conjoined phrases directly from their surface form. Semantic explanations of phrasal coordination differ from strictly syntactic ones. In semantic analysis, conjuncts are interpreted as functions that require certain semantic arguments to make a sentence. The semantic type of *ran* requires a subject to yield an interpretable sentence. Because *jumped* is of the same semantic type as *ran*, *ran* and *jumped* can be conjoined according to the Law of Coordination of Likes. If this conjoined verb phrase is applied to the subject *Kim*, the resulting interpretation will be that Kim ran and Kim jumped. Under this semantic approach, the interpretation of phrasal coordination is related to, but not derived from, the interpretation of sentential coordination.

Further, a problem particular to syntactic analysis concerns how to formally represent coordination, as the conjunction structure appears to contradict current models of sentence construction. The term 'coordination' implies that the conjuncts are located at the same structural level. However, this view is incompatible with the assumption in generative syntax that syntactic structures are formed by repeatedly unifying two elements at a time. The argument that a conjunction unifies its two conjuncts at the same level entails the conclusion that syntactic structures can unify three elements. Some linguists attempt to remedy this apparent contradiction by suggesting a subordinating structure for coordination, in which the conjunction combines with one conjunct first and the resulting constituent then combines with the other conjunct. Others suggest the hypothesis that both conjuncts basically stand in

exactly the same relationship to the conjunction, and that the two conjuncts essentially introduce a third structural dimension.

Although various solutions have been proposed, there is not yet a satisfactory explanation for all of the problems discussed here. Coordination occurs both in phrase structure and sentence structure, but the relationship between the two remains unclear. The role of coordination in sentence construction is also largely undetermined. Coordination therefore remains a phenomenon that is difficult to explain for any formal linguistic theory.

Coptic Egyptian

In the course of its productive language history, which spans a period of over 4,000 years, Ancient Egyptian went through several developmental stages. Its latest stage is Coptic Egyptian (not to be confused with Egyptian Arabic), which is the vernacular of late-antique and medieval Christian Egypt (fourth to fourteenth centuries AD). The modern term Coptic is derived from Arabic *qubṭī*, itself a corruption of the Greek word (*ai*)*gypt*(*ios*) 'Egyptian'.

The Copto-Greek alphabet

Coptic, like many other ancient languages of literature, has been passed down to us through large corpora of texts. These texts were written in a highly standardized notational system of alphabetic signs representing the different sounds of the Coptic language. The origin of the Coptic writing system lies in occasional Greek transcriptions of native words in Egyptian texts of the Hellenistic and Roman periods. In the first three

centuries AD, the use of such transcriptions became increasingly common and entire corpora of texts with a predominantly magical character were written in a Greek-derived alphabet. The Christianization of the country in the fourth century AD constituted a turning point: the abandonment of the pagan literary tradition and culture manifested itself in the replacement of hieroglyphic writing and Demotic, its cursive variant, by Greek script. In its present form, the Copto-Greek alphabet consists of 32 letters, 24 of which are taken from Greek and eight from Demotic writing. With the exception of the monosyllabic grapheme *ti*, the Demotic-based signs represent phonemes that were absent in Greek, but which are part of the native Coptic Egyptian sound system.

Bilingualism and linguistic borrowing

The emergence of Coptic was the result of intensive language contact in a bilingual (Egyptian–Greek) speech community. Greek was not only the language of the literate elite but also the language of the Holy Scriptures and the new religion, and hence a language of great cultural importance. The impact of this prestigious language on the native vernacular was all-pervasive. Although no clear statistics are available at present, it is estimated that approximately 40% of the Coptic vocabulary consists of Greek loanwords. The transfer of Greek lexical material into the Coptic vocabulary was not only restricted to content words (nouns, verbs, adjectives) with a clear link to Hellenistic and Christian culture (e.g. *te-psikhɛ* 'the soul', *klɛronomei̯* 'to inherit', *hagios* 'holy'), but also involved a variety of Greek function words (i.e. grammatical words with no descriptive-lexical content), such as sentence conjunctions, discourse markers, and some types of adverbs and prepositions (e.g. *hɔste* 'such that', *ɛ* 'or', *oude* 'and not', *alla* 'but'). Despite the massive influx of Greek items, grammatically organized words (pronouns, articles, numbers, and the like) are all drawn from the native stock. To fit into Coptic phrase structure, Greek loanwords underwent minor changes in the course of borrowing.

Dialect variation

Coptic Egyptian is actually a dialect cluster, consisting of at least six regional varieties, two of which gained supraregional importance: Sahidic, the language of the whole Nile valley above the Delta, and Bohairic, the language of the Nile Delta. Sahidic and Bohairic Coptic differ significantly from one another in a number of grammatical features (sound system, verbal morphology, syntax) and the amount of lexical and grammatical borrowing from Greek. Both language varieties also differ with respect to the time depth of their attestation. Prior to the Arabic conquest in AD 641, Sahidic was the predominant literary dialect of Coptic. Its supremacy became challenged by Bohairic Coptic from the ninth century onward. By the eleventh century, Bohairic had replaced Sahidic as the official church language and had become the sole representative of Coptic Egyptian, which survived as the liturgical language of the present-day Coptic Orthodox Church. The language material of the following typological sketch is exclusively drawn from Sahidic Coptic, the main reference dialect.

Phonology

The sound system of Sahidic Coptic consists of 20 consonants (p, t, k, d, g, kʲ, f, s, ʃ, h, β, z, tʃ, m, n, l, r, w, y, ʔ) and eight vowels (i, e, ɛ, u, o, ɔ, a, ə). Its most striking property is the absence of voiced consonants (i.e. consonants produced with a vibration of the vocal cords) in the class of stops (consonants produced by making a closure at the lips), fricatives (consonants where the airflow is constricted to form a turbulence but is not interrupted), and affricatives (sounds produced by an initial closure that is released gradually, making it sound like a fricative), the main exception being the voiced fricative /β/. It is worthwhile pointing out that the voiced stops /d/ and /g/ as well the voiced fricative /z/ have a special status as loan phonemes that are by and large restricted to Greek borrowings. The glottal stop /ʔ/ (a sound produced by a complete but brief contraction of the vocal cords) has no alphabetic sign of its own. Yet, its presence in the Sahidic sound system can be deduced from a sequence of two identical vowel letters that indicates 'broken' vowels, i.e. long vowels that are pronounced with a brief interruption (e.g. *maatʃe* /maʔatʃe/ 'ear', *mɛɛʃe* /mɛʔɛʃe/ 'crowd'). Coptic has pairs of vowels: /e/ vs. /ɛ/ and /o/ vs. /ɔ/. The schwa /ə/ (a colorless, unstressed vowel) is graphically expressed not by a letter, but rather a special diacritic, the so-called supralinear stroke (a vertical line above a letter), e.g. *n̄* /ən/ 'of'. Stress (indicated as ˈ) is lodged only on those syllables that either contain a long vowel (ː) (e.g. *noute* /nuːˈ.te/ 'god') or a vowel–consonant sequence (e.g. *anaʃ* /a.naˈʃ/ 'oath'). Moreover, there is at most one main stress per word, regardless of its length.

Noun morphology

Unlike Pre-Coptic Egyptian, Coptic has only a few word formation processes for the makeup of nouns. Thus, there are only a few lexical items where number (singular vs. plural) and gender (masculine vs. feminine) are marked on the noun itself (e.g. *son* 'brother',

sɔne 'sister', *sneṷ* 'brothers, fellow monks'). In the vast majority of cases, gender and number distinctions are expressed on the definite article, which is placed in front of the noun it modifies (e.g. *p-rɔme* 'the (sing. masc.) man', *te-shime* 'the (sing. fem.) woman', *ne-shime* 'the (pl.) women'). The Sahidic determiner system offers a three-way contrast between a definite, an indefinite, and a zero article (e.g. *p-rɔme* 'the (sing. masc.) man'; *u-rɔme* 'a man', *hen-rɔme* 'men'; *rɔme* 'man'). Besides the indefinite and definite articles, there are demonstratives articles, so-called because they indicate closeness or distance to the location of the speaker: *peḭ-rɔme* 'this (sing. masc.) man' vs. 'that man' (lit. the man who is (over) *there*). Both demonstrative articles have corresponding demonstrative pronouns, which have a word-like status: *paḭ* 'this one' vs. *p-et-əmmaṷ* 'that one'.

Reference to grammatical person (the speaker, the addressee, and a third party) is expressed by two sets of pronouns: independent pronouns and bound pronouns. Independent pronouns have a word-like status, while bound pronouns form an inseparable unit with the sentence element they modify. Different forms exist for pronominal prefixes that precede and pronominal suffixes that follow their host. Table 1 presents the pronominal paradigm of Sahidic Coptic (-∅ indicates a null morpheme, i.e. a grammatical element that is not pronounced). Independent pronouns have an emphatic meaning and place the entity or object they refer to at the center of attention. Pronominal prefixes and suffixes, on the other hand, lack such a highlighting function. While independent pronouns are restricted to peripheral syntactic positions (e.g. *ntos de a-s-onk-s ehraḭ* '(as for) her (ntos), she leaped up herself' (Eudoxia 50:17)), bound pronouns are compatible with all nominal positions of the clause (e.g. *a-f-ent-s* 'he brought it', *nɛ-tən* 'for you').

Verb morphology

The basic principle of Coptic verb formation, which it shares with Semitic languages, is that of 'root-and-pat-tern'. As the terminology suggests, verbal stems are derived from relatively abstract form-meaning representations (roots) by the superimposition of particular consonant–vowel patterns with a basic meaning. For example, a verbal root like /*m-s* / 'BEAR, GENERATE' may surface in at least four word formation patterns that are distinguished from one another by means of vowel change (Ablaut) and syllable structure. These are the absolute state *mise* 'to give birth', the nominal state *mes,* and the corresponding pronominal state *mest* 'to deliver', which combine with a nominal and pronominal object, respectively, and the Stative *mose* 'to be bred'. The absolute state and the construct state (i.e. the nominal and the pronominal states together) describe events that *change* over time, while Statives refer to states or conditions that *last* for some time. The absolute state and the construct states, in turn, differ syntactically in the way they express the direct object relation. In the absolute state, the direct object is encoded as a prepositional phrase (e.g. *mise n-u-ʃeʔere n-shime* 'to give birth to a girl' (Miracles of Apa Mêna 10[b]:33–4)). In the construct state, however, direct objecthood is indicated by the juxtaposition of the verb and the nominal or pronominal object (e.g. *mes p-ʃr-howt* 'to deliver the male child' (Apocalypse 12:13) vs. *mest-f* 'to deliver it' (Miracles of Apa Mêna 10[b]:26)).

Conjugation system

Coptic has more than 20 different verb conjugations (i.e. the pattern in which verb forms can appear) for the expression of tense (i.e. the location of events in time), aspect (i.e. the ongoing state, completion, or multiple occurrence of events), and mood (i.e. the commitment of the speaker toward the truth of the reported events). At the foundation of this richness of meaning distinctions is the subdivision of the four absolute tenses (the Present, the Habitual, the Future, and the Perfect) into two conjugation classes, traditionally known as first and second tenses. The second tenses are morphologically derived from the 'basic' first tenses by adding the relative markers *e-* or *ənt-* in front of the verbal cluster (Table 2).

First and second have exactly the same temporal and aspectual interpretation, but differ from one another with respect to their syntactic distribution. First

Future	f-na-sɔtəm	e-f-na-sɔtəm	'he is going to listen'
Perfect	a-f-sɔtəm	ənt-a-f-sɔtəm	'he listened'

tenses appear in pragmatically neutral declarative clauses (e.g. *eịs hɛʔɛte anon ne.k-həmhal tən-sɔtəm* 'Look, *we*, your servants, *are listening*!' (Eudoxia 62:03)). The derived second tenses are used in the context of relative clauses (e.g. *u-hɔβ* [*ere p-nuːte moste əmmo-f*]'a thing [that God *hates* (it)]' (Acts of Andrew & Paul 202:126–7), constituent questions (e.g. *e-tetən-ʃine ənsa nim*'Whom *are you* (woman) *looking* for?' (John 18:4), as well as a range of declarative focus contexts (e.g. *awo p-woeịn e-f-r woeịn həm pə-kake* 'and (as for) the LIGHT, *it is shining* in the DARKNESS' (John 1:5)).

Apart from absolute tenses, Coptic has several syntactically dependent verbal tenses and moods. Relative tenses locate some event with respect to another event and express three types of temporal relations: precedence, subsequence, or simultaneity. In doing so, relative tenses often indicate a logical or causal connection between two events. In negative tenses, negative meaning (the equivalent of English *not*) and a particular time value are fused together in a single indivisible unit. Take for instance the Negative Future *ənne-f-sɔtəm* 'he shall not hear', where the conjugation *ənne* combines future tense with negative meaning, which are expressed by two separate elements (viz. *shall* and *not*) in the English equivalent. Moreover, Coptic has two different moods for the imperative (e.g. *sɔtəm* 'Listen!'), which expresses commands, and the optative, which expresses wishes (e.g. *mare-f- sɔtəm* 'may he listen'). See Table 3 for further illustration.

The clause-initial or medial position of tense-aspect-mood markers, their morphological independence from the verb, as well as their agreement behavior (variant forms for nominal and pronominal subjects, e.g. (Habitual) *ʃare p-rome sotəm* 'the man listens (usually)' vs. *ʃa-f-sotəm* 'he listens (usually)'

provides *prima facie* evidence for their categorical status as auxiliary verbs. Due to their semantic erosion, these auxiliaries have a fully grammaticalized meaning and function, which is typical of free functional morphemes.

Syntax

The basic word order, from which other word-order patterns are derived, is subject–verb–object (SVO). Word-order alternations are, however, extremely common and motivated by pragmatic considerations. The topic status (i.e. the presupposed, familiar or known character) of a noun or pronoun is generally indicated by placing it into the left periphery of the clause, its grammatical function being resumed by a pronoun with identical person, number, and gender specification (e.g. *p-aŋgelos de m-p-tʃoeịs a-f-wonh-f e-p-arkhiepiskopos* 'the angel of the Lord, *he* revealed himself to the archbishop' (Mêna, 4b:6–9)). Verb–subject order has a 'presentative' meaning and is used for the introduction of new discourse participants. Notice that the nominal subject that is removed from its sentence-initial position is supplied with the particle *nkʲi* (e.g. *f-nɛu nkʲi u-aŋgelos nte p-nuːte* '(there) comes *an angel* of God' (Budge, Coptic Martyrdoms 214:22)). To highlight the subject or object, a special construction type is used: the cleft sentence. It is called cleft sentence because it consists of two parts: a sentence-initial noun or pronoun and a relative clause (given in brackets) (e.g. *awo m-pe.u-kʲβoi an pe* [*ənt-a-f-tutʃo-ụ*] 'and (it) is not *their arm* that has saved them'(Psalm 43:4)). More research is needed to clarify the relation between pragmatic prominence and sentence form in Coptic Egyptian.

Corpus Linguistics

During the last three decades of the twentieth century, computer technology has made it possible to conduct extensive and complex research on specific linguistic features — either lexical items or grammatical structures—and their systematic associations with other linguistic and nonlinguistic features. These nonlinguistic features include registers or specific varieties of language (e.g. religious, political, scientific) and dialects, which are regional or social varieties of a language. This new type of research is part of *corpus linguistics*, which is the empirical study of language using computer techniques and software to analyze large, carefully selected and compiled databases of naturally occurring language (Conrad 2000).

Corpus linguistics represents a departure from the dominant mentalist approach to linguistic research, which emphasizes the processes taking place in the human mind (e.g. a Universal Grammar-centered approach to second language acquisition studies). This type of research is characterized by the empirical analyses of actual patterns of language use in large and principled databases or corpora. Corpus linguistics utilizes both quantitative and qualitative analytical techniques and relies on computers to perform complex analyses. (See Biber, Conard & Reppen (1998) and Kennedy (1998) for a detailed account of corpus-based investigations of language structure and use.)

Corpus-Based Investigations of Language Use

Although language structure has traditionally been studied using nonempirical methods and relying on the researcher's intuitions, extensive corpus-based studies describing various aspects of language use were carried out in the 1980s and 1990s (Aarts 1991, Aijmer and Altenberg (eds.) 1991, Biber 1995, Leech 1991, Sinclair 1987, 1991, Stubbs 1995, Svartvik 1990).

As Biber et al. (1996:115) point out, 'it is in the area of language use that corpus-based techniques have had the most impact'. These studies complement descriptive language structure investigations and previously neglected aspects of English grammar (Crystal 1979). Early studies in corpus linguistics focused on the occurrence of linguistic items (e.g. noun, verb, and adjective frequencies), but the development of more powerful techniques has enabled researchers to identify and analyze complex association patterns. Corpus-based research has shown that these linguistic association patterns generally fall into two major categories: lexical associations and grammatical associations. In the first case, the goal is to investigate how a linguistic feature is systematically associated with particular words. In the second case, the researcher investigates how a linguistic feature is systematically associated with grammatical features in the immediate context.

With respect to lexical associations, a concordancer shows which words collocate with each target word in a corpus that is representative of a specific register or dialect. For example, in a corpus of working-class northern New Jersey cyber discourse, we find that the mental verb *know,* which appears 15 times in a small sample thread (7,000 total words)**,** collocates primarily with personal pronouns *I, you, they*, and *we.* This usage reflects the informal nature of cyber exchanges, which characterizes casual face-to-face interaction among peers or friends.

The results of empirical, large-scale corpus-based research projects (data from a 5.7-million-word sample from the Longman—Lancaster Corpus) have

shown that where certain words are nearly synonymous in isolation, careful analysis reveals that they tend to be used with very different kinds of words. For example, Biber et al. (1998, chapter 2) demonstrate that the word *big* commonly co-occurs with *toe,* while *large* commonly co-occurs with *number.*

Linguistic features are also systematically associated with grammatical features in the immediate context as shown by corpus-based research. For example, one of the factors differentiating *that-clauses* and *to-clauses* is their lexical associations. 'The verbs such as *suggest*, *conclude*, *guess*, and **argue** can control a *that-clause* but not a *to-clause*; the verbs *begin*, *start*, and *try* can control a *to-clause* but not a *that-clause*' (Biber et al. 1998, chapter 3).

There are many promising applications of corpus-based research that have to be explored. For example, it is hoped that new grammar teaching materials for English-as-a-Second Language (ESL) learners will incorporate the results of corpus-based research. Conrad (2000) and Granger (2002) explain that corpus research complements innovations in grammar pedagogy by encouraging instructors to design and implement consciousness-raising activities for second and foreign language learners. (See Conrad (2000) for an overview of the applications of Corpus Linguistics in grammar teaching in the twenty-first century, and Granger (1998a; 1998b; 2002) for a discussion of learner corpora compilation processes.)

Corpus Analysis Tools and Corpora Used in Corpus Linguistics

Since corpus linguistics utilizes large and representative collections of natural texts, there are several types of tools that can be used to conduct research: commercially available packages or concordancing programs (e.g. LEXA, MonoConc, MicroConcord, TACT, WordSmith, WordCruncher) and computer programs developed by researchers for specific types of analyses. These latter types of programs are used to investigate complex grammatical constructions or association patterns, such as Biber et al.'s (1998) study involving the omission of *that* from *that-clauses*.

There are at least 31 commercially and publicly available corpora of written and spoken texts. These databases contain millions of words and are divided primarily into three categories: written, spoken, and historical. These corpora are further subdivided into American English, British English, and texts of other varieties of English. Corpora also exist for languages other than English. (See Appendix in Biber et al. 1998: 282–7.)

Potential Limitations of Corpus Linguistics

It is important to understand that meticulous qualitative analyses of single texts (e.g. historical, spoken, written, and learner-centered) are usually undertaken before embarking on corpus-based research. A careful micro-analysis of linguistic features in written or spoken discourse helps us frame new research questions and hypotheses. Thus, corpus-based analysis should be seen as a complementary approach to the more traditional approaches that have often focused on language structure. The strength of corpus linguistics lies in its investigations of language use, which necessitate empirical analysis of large databases of authentic texts.

There are basically four potential limitations of corpus-based research. The first one is the time-consuming nature of compiling a corpus and tagging parts of speech, errors, or other features. The second limitation concerns the nature of the corpus data collected. This type of research often involves collecting and storing large corpora that may need to be continuously updated.

The third limitation is that relying on computers forces linguists to concentrate primarily on written rather than spoken language. Lastly, there is a potential limitation of a philosophical nature, namely that a corpus is a finite sample of an infinite population. This means that researchers are often extrapolating from what is found in a corpus to what is true of the language or language variety it is supposed to represent (Leech 1998). Thus, one needs to be cautious in drawing general inferences from the results of corpus-based analyses.

Despite its potential limitations, almost any aspect of linguistics can be studied from a use perspective. Corpus linguistics provides a variety of tools and methods that make large-scale research on complex linguistic phenomena an extremely productive and challenging undertaking.

Courtroom Discourse

Studies in courtroom discourse often focus on the significance of certain kinds of interactions between specific linguistic features and their pragmatic or sociointeractional functions in the courtroom. Research carried out in North Carolina beginning in the 1970s, for instance, resulted in a series of publications suggesting broadly that lay witnesses are persuasive or not depending upon the extent to which they use "powerful" or "powerless" language. The validity of the study's methodology has been questioned, but the publications generated by the study have clearly served to advance our understanding of the role of language in judicial process, particularly where the questioning of lay witnesses is concerned.

Other research has explored the questioning tactics used by attorneys during direct and cross-examination of witnesses. The use of open-ended wh-questions (who, what, where, when, how, etc.) tends to elicit narrative responses from witnesses, and therefore more information, whereas yes/no questions tend and are usually intended to limit the amount and type of information that can be offered. A number of studies examine such patterns, and it is usual for trial practice courses in law schools to include material on such topics, often recommending that wh-questions be used during direct examination and that yes/no questions be used during cross-examination. For a recent example of such a study, see Sandra Harris' (2001) examination

of the O.J. Simpson, Louise Woodward, and Oklahoma federal building bombing cases.

It is usual for defense attorneys to omit mention of the agent in cases of sexual assault or rape; the tactic is thought to take the focus off the accused rapist. The grammar and prosody of reported speech can be used to impeach or cast doubt on a witness's testimony. Janet Cotterill examined the O.J. Simpson trial and explored how metaphors can be a rich source of indirect messages, noting that several were used in defense attorney Johnny Cochran's closing arguments.

In a more general sense, courtroom discourse includes attention not only to adversarial questioning techniques, particularly as used in direct and cross-examination, but also to all spoken language used during the trial process. In order to look meaningfully at the full range of courtroom discourse, one must recognize that a number of speech genres are used during the trial process. Anglo-American lawyers like to talk about the need for a theory of the case. Once that theory is developed, all portions of trial process are theoretically dedicated to developing that theory and persuading the judge and/or jury that it is the correct one. In the process of moving through trial process, lawyers make use of opening statements, voir dire, direct examination, cross-examination, possible redirect and recross, and then closing statements. They also usually participate in the wording of jury instructions, and they make and respond to objections during testimony. For each of these steps, discourse strategies are developed.

Based on an examination of a single case, Gail Stygall (1994) suggests that analysis of legal language needs to move away from mere descriptive analysis to an examination of how the maintenance of legal language serves institutional power and dominance.

More specifically, John Gibbons (2003) suggests that the very real power and dominance problems in the courtroom arise from the legal genres used in courtroom discourse and the fact that they are addressed to two very different audiences, lay persons, often jurors, on the one hand, and of course judges and lawyers on the other hand. Gibbons calls this the two-audience dilemma and cites jury instructions as a particularly difficult genre, because "[j]urists persist in administering these instructions to jurors because they have survived on appeal to a higher court... The view that jurors remember and understand any instructions given them and that therefore it is more important to focus on an instruction's survivability on legal appeal than on its comprehensibility, is ill-informed" (English and Sales 1997. 383).

Where jury instructions are concerned, it is an established fact that since the early 1970s, findings by many social scientists confirm that lay persons are frequently bewildered by the wording of jury instructions. The exact syntactic and semantic bars to juror comprehension of instructions are now well documented by linguists and psycholinguists. These scholars have demonstrated that instructions can be made more comprehensible by simplifying sentence structure and by giving additional information about the meanings of abstract terms in both civil and criminal cases.

We know a great deal about the problems faced by lay jurors because of the extensive amount of research that has been completed. But lay witnesses face similar problems. They contend with very sophisticated question-and-answer tactics on direct and cross-examination, usually with little or no preparation. And, of course, court interpreters and translators face the same problems, even as they deal with the challenge of working with more than one language.

All phases of pretrial, trial, and posttrial (appeal) procedure involve judicial procedures in which lay persons must deal with legal language and discourse patterns, including legal genres, with which they are quite unfamiliar. Jury instructions have been examined in great detail; research on other patterns and genres remains to be done.

It seems likely that much additional research will be reported over the next few years. Increasing numbers of linguists have been focusing on language and law issues, and there are now at least two academic organizations that regularly focus on the kinds of topics involved in courtroom discourse. Since 1990, the Law and Society Association, an international association that meets outside the United States every third year, has scheduled sessions on Language and Law at its annual meetings. The International Association of Forensic Linguists (IAFL) came into existence as a result of a series of workshops and conferences in the early 1990s; it meets biannually, usually outside the United States The IAFL publishes a journal, until recently titled *Forensic Linguistics: The International Journal of Speech, Language and the Law*. Future issues will drop the original title and use the original subtitle only.

Crioulo, Gulf of Guinea

Gulf of Guinea Crioulo (GGC) is a cover term for four creoles lexically based on Portuguese. They are spoken on the three islands of São Tomé (around 100,000 inhabitants), Príncipe, and Annobón (about 5,000 each), of which the former two constitute an independent republic while the latter belongs to Equatorial Guinea.

In the following, the languages will be referred to as Sãotomense, Principense, Annobonese, and Angolar, although they are also known by other names. Sãotomense and Angolar are both spoken on São Tomé, the latter by descendants of runaway plantation slaves in the south of the island.

Previously uninhabited, toward the end of the fifteenth century the islands were settled by Portuguese and their African slaves, the latter of which were brought partly from what is today the coast of Nigeria, and partly from Bantu-speaking areas around the mouth of the Congo. It is in this early period that GGC is assumed to have emerged.

GGC varieties are interesting for a number of reasons, not least because they probably are among the oldest creoles known. They are also typologically unusually distant from their lexifier.

All four creoles coexist in a diglossic relationship with the official languages of the two countries (Spanish on Annobón, Portuguese in the case of the three others) and are used neither in media nor education.

Although influenced by Spanish, GGC does not seem to be seriously threatened on Annobón, where it is the universal vernacular (although all speakers are proficient in Spanish). Angolar is believed to have about 9,000 speakers, but is giving way to both Sãotomense and Portuguese. It is not entirely clear how many speakers use Sãotomense or Príncipense. According to a mid-1990s source, virtually everybody on São Tomé was capable of speaking Portuguese, while only half of the children were competent in Sãotomense, indicating language shift. For reasons yet to be fully understood, this process started earlier and has proceeded further on the smaller Príncipe, and in the 1987 census, less than 16% of the population were reported to speak the language, including virtually no children.

The four GGCs share a number of features on all levels, suggesting a common origin. These include, among others things, a circumverbal sentence negation that can be reconstructed as /na … fa/, the second part of which appears clause-finally. This and other similarities can presumably be traced back to São Tomé, which was the first of the three islands to be settled. Subsequently, however, the languages have drifted apart to a degree where mutual comprehension is difficult, albeit possible.

Like other creoles, GGCs are heavily analytic, and a participial suffix /-du ~ -ɾu/ seems to be the only attested bound morpheme.

The Tense Mode Aspect system is mostly preverbal, and typically includes a past marker *tava* (< P *estava*), an imperfective element *ka* (< P *ficar, cá* or *capaz*?), indicating habitual aspect in isolation, and progressive when preceded by the copula *sa*), and completive particles *za* and *kaba* (< P *já* and *acabar* respectively).

Features that set GGC apart from Portuguese, but make them similar to other creoles in the Atlantic area, include reflexive constructions involving the word for 'body', the use of 3pl as a nominal pluralizer, and use of verb serialization, for all of which African influence may plausibly be invoked.

249

Although being SVO, the GGC languages display several rather exotic orderings from a European perspective, such as N NUM ɔmã dɔs 'two hands').

Principense includes a coarticulated stop /g͡ɓ/, corresponding to /kw/ elsewhere. It is not clear whether nasal+stop sequences should be regarded as cluster or as single phonemes. In all varieties except Principense, Portuguese /v/ turns up as /ɓ/ in some items. Principense and Angolar have a rhotic phoneme, but otherwise Portuguese rhotics appear as laterals or are deleted.

All have depalatalized etymological /ʃ, ʒ/ into /s, z/, but also sport a productive palatalization rule whereby /t, d, s, z/ are realized as [t͡ʃ, d͡ʒ, ʃ, ʒ] before high front vocoids (exceptions: Principense lacks [d͡ʒ], and Angolar has /θ, ð/ in positions where its sisters have /s, z/).

Another segmental difference within the group is that in Annobonese the velar plosive /k/ is realized as [x] before back vowels (including /a/).

The GCCs have been argued to be either tonal or pitch-accent languages. All varieties have a few words that are etymologically consonant-initial, but that have been equipped with a prothetic vowel, possibly deriving from the Portuguese definite article. These items all belong to the core lexicon, and are, interestingly, far more common in Principense (e.g. *ufógo* 'fire') than elsewhere (*fógo*).

With the exception of Angolar (see below), the African lexical contribution is limited to a couple of hundred items at the most. A third of these are derived from languages of present-day Nigeria, most of the remainder being of Bantu origin. The latter group is better represented in Sãotomense than elsewhere. Noteworthy African contributions include 3pl pronouns, and also a 2pl form in Principense.

Not unexpectedly, the Annobonese lexicon nowadays contains a fair proportion of Spanish loans. Due to labor migration to Fernando Poo, where pidgin/creole English is the lingua franca, Annobonese has also assimilated some lexical items from this language.

Lexically, Angolar is the odd man out in the GGC group. While being structurally very similar to Sãotomense, it contains an unusually high proportion of African lexicon, largely derived from Kimbundu.

Crioulo, Upper Guinea

Upper Guinea Crioulo is a continuum of Portuguese-vocabulary creoles spoken mainly on the Cape Verde Islands and in Guinea-Bissau. A variety of Guinea-Bissau Creole also spills over into Casamance, the southernmost province of Senegal. The total number of native speakers is estimated at 400,000 in Cape Verde, 250,000 in Guinea-Bissau, and 40,000 in Senegal. In addition, there are half a million second-language speakers in Guinea-Bissau and some 20,000 in Casamance. There is also an important diaspora of Cape Verdeans in both Europe and the United States.

Despite not having official status in either of the three countries (although since 1998 the 'national language' of Cape Verde), Portuguese Creole nevertheless has a strong position in Cape Verde by virtue of it being the native language of the entire population, and in Guinea-Bissau through being the only nationwide lingua franca.

Judgments on how similar Cape Verde and Guinea-Bissau Crioulo really are differ. While some Cape Verdeans claim to be unable to understand Guinea-Bissau Crioulo, others treat all Upper Guinea

Portuguese Creoles as dialects of one language. In any case, the differences lie more in pronunciation and vocabulary than in structure. Also, Cape Verde Crioulo is in itself rather heterogeneous, and the varieties of the northern Sotavento islands are in most respects intermediate between those of the southerly Barlavento islands and Guinea-Bissau Portuguese Creole. These three main varieties thus constitute a continuum.

Some authors insist that Cape Verde and Guinea-Bissau Portuguese Creole emerged independently, despite the great similarities. Most, however, seem to agree that they are somehow genetically related. Even so, there are two possibilities—did the ancestral Creole travel from the mainland to the islands or vice versa? Both hypotheses have been suggested, without any conclusive evidence being presented for either.

Regardless of the direction of influences during the birth of the Upper Guinea Portuguese Creoles, it is clear that Cape Verde Crioulo has had some impact on the mainland varieties from at least the eighteenth century. First, the Portuguese often used Cape Verdean employees in Guinea-Bissau. Second, famine led to migration toward the mainland in the late 1800s, and third, islanders were prominent in the independence movement.

Anyone accustomed to the better-known Caribbean creoles will notice the—as yet unexplained—absence of many of their characteristic features in the Upper Guinea Portuguese Creoles.

Broadly speaking, the Sotavento varieties (and even more so Guinea Bissau Portuguese Creole) are typologically more distant from Portuguese, and present more features perceived as typical of creole languages. This is manifested e.g. in the use of (mostly) independent words to mark tense. Although usually referred to as a creole, it may be that Barlavento Cape Verde Crioulo should more properly be designated as a semi-creole.

Although there is little evidence of this, many an observer has suggested that the Cape Verde dialects have in general been significantly more creole-like, and that decreolization has brought them closer to Portuguese with time. Today, Many Cape Verdeans are competent in Portuguese, which remains the official language. An obvious difference between the Cape Verde dialects and the mainland is that the latter creole varieties are still in close contact with African languages. At least some change in the direction of Portuguese has taken place during the twentieth century, and is reflected in variation between e.g. more Portuguese-like Guinea-Bissau /adiviɲa/ vs. basilectal /dibiɲa/ 'to guess' (<*adivinhar*) /aʒudar/ vs. /ɟuda/ 'to help' (<*ajudar*).

Lexically, all Upper Guinea Portuguese Creoles are overwhelmingly Portuguese, and only about 150 African items have been attested in each variety, few of which can be considered part of the core vocabulary. In addition to this, there are a number of idioms of seemingly African origin.

Conspicuous phonological features include the replacement of /z/ by /s/ in some varieties, and the realization of Portuguese /ʎ/ as /ɟ/. Furthermore, Portuguese <x> generally turns out as /s/ in Upper Guinea Portuguese Creoles, while instances of orthographic <ch> (/t͡ʃ/ in older Portuguese) become /c/ or /t͡ʃ/. Portuguese syllable structures have, especially in the mainland varieties, drifted toward a Cape Verde structure.

Affixes are scarce, but less so than in most creoles. In Guinea-Bissau, verbs are morphologically marked for causative and passive, in addition to which there are about eight or nine other productive affixes. Comparatives are basically expressed via independent particles across the board, mostly using /mas ADJ (di) ke/ 'more ... than'.

Tense, mood, and aspect are for the most part marked by means of free adverbial markers, including a progressive seemingly derived from *estar* and a past from *jà*. In addition, there is a suffixed *-ba*, probably derived from the Portuguese imperfect *-va*.

As opposed to Portuguese, sentences in the Upper Guinea Portuguese Creoles may not have a subject that is merely implied, although overt subject pronouns frequently attach to the following verb.

Number is normally not marked on nouns, although usually on determiners. Portuguese definite articles have also been lost, with demonstratives taking over some of their functions. The sentence negator is normally not a reflex of Portuguese *não* 'not', but rather /ka/, probably from Portuguese *nunca* 'never'.

In many respects, it is striking, however, how much like Portuguese Creoles are in their syntax. Cape Verde Crioulo replicates the Ibero-Romance distinction between the copulas *ser* and *estar*, relatively faithfully and many varieties also display (variable) adjectival agreement, as in /kaza bnita(a)/ 'beautiful house'. Passives are also constructed very much like in Portuguese. Within the Cape Verde dialects, creole-like structures vary with more Romance-like constructions, as in /kes fiɟu di ʃefi/ vs. /keʃ fiɟ cɛf/ 'the chief's sons'.

Relatively few structural features can reliably be related to African languages. The distinction in Cape Verde Criolo between the two *habeo* verbs /tẽ)/ 'to have, to own' vs. /teni/ 'to have (at hand)' has been suggested to mirror Wolof, one of the African languages with the greatest influence on Portuguese Creoles. Other possible African features include the replacement of etymological /v/ by /b/ in some varieties, and the use of the word 'head' for 'self'.

Dakota and Siouan Languages

The Siouan languages are referred to in more recent literature as the Siouan-Catawban family, as the older term often really meant only the Western Siouan languages, which consists of most of the languages, whereas Catawban and Woccon comprise the Eastern Siouan group. The Siouan-Catawban languages, of which the Dakota languages are one branch, were spoken, at the time of European contact, as far north as Alberta and Saskatchewan, stretching southward through the middle of the United States into Mississippi and Arkansas. Those languages still spoken today are found mainly on reservations in North and South Dakota, Nebraska, Montana, Minnesota, Manitoba, Saskatchewan, and Alberta. There are 20 known languages in all. According to J.W. Powell (1891), in 1890, there were approximately 43,400 officially recognized Siouan tribe members. According to 2000 US Census Bureau statistics, 153,360 people identified themselves as Siouan tribe members, and in Canada, 3,880 people reported membership in a Siouan/Dakota tribe in 2001.

The term 'Siouan' seems to have originated from the shortened colonial French, *Nadouessioux*, an interpretation of an Ojibwa term meaning 'a small rattle snake' or 'the snake-like ones'. In either case, it was a term for a traditional Ojibwa enemy.

The designation 'Sioux' at the time of first contact by Europeans referred to a rather loose confederation of seven tribes—the Sioux nation. The people of these tribes called themselves the Dakota, the Lakota, or the Nakota, which meant 'allies'. These three groups are usually referred to as 'Dakota' and their dialects make up the Dakota languages, which in turn, are part of the Siouan-Catawban languages. The distinction among these three languages was based on what is called the *d/l/n* correspondences; where Dakota has *d*, Lakota has an *l,* and Nakota has an *n*. However, further study has shown that this distinction is inadequate and not necessarily accurate for these languages. Furthermore, Assiniboine and Stoney have been shown to be related to the Dakota languages despite the relationship not having been recognized initially as these two tribes had already split from the Dakotas prior to contact in 1640.

The Siouan-Catawban languages consist of four main branches: a Mississippi Valley group, also called Siouan Proper or Mississippi River; a Missouri Valley group; an Ohio Valley group or Southeastern group; and an eastern group, Catawban. The only language in dispute over its placement is Mandan, which is listed in the Ethnologue as part of the Mississippi group, but others believe that it may stand alone as a subgroup since similarities to either Mississippi group languages or Missouri Valley languages are probably due to borrowing.

Mississippi Valley Languages

The Mississippi Valley languages are divided into four subcategories: the Dakota languages, the Dhegiha languages, the Chiwere languages, and Hochunk. The Dakotan languages were once thought to consist of three or four languages, Lakota (also called Teton), Dakota (also called Santee or Santee-Sisseton), and Nakota (also called Yankton or Yanktonai), but recent work suggests that there are five dialects, including

Assiniboine and Stoney. Total speakers in both the United States and Canada number about 19,000. Dakota (also *Dakhota)* has approximately 4,000 to 5,000 speakers, including children and about 30 monolinguals. There are 250 speakers of Nakota and about 6,000 to 7,000 speakers of Lakota (also *Lakhota)* out of a population of 20,000 according to the 1990 US Census. Assiniboine (also called Hohe) has about 150 to 300 fluent speakers in Canada and Montana out of a population of 3,500 tribal members. Assiniboine shares nearly 90% lexical similarity to Lakota and Stoney, and 90% to 94% similarity to Dakota. Stoney is spoken by 1,000 to 1,500 people out of a population of 3,200 in Canada. Although Stoney shares approximately 90% lexical similarity with Assiniboine, the two languages are not immediately mutually intelligible.

Most of the Dakota tribes have undertaken some measures to preserve their languages or increase the number of speakers. Some Lakota communities are making an effort to teach their children the language since they estimate that by 2013, less than 10% will be able to speak the language if they cannot find a way to stop the language loss. The tribe is working with Indiana University to establish language revitalization projects. The Stoney tribe has also initiated a Language Project, and Dakota and Lakota are taught in schools in North and South Dakota, Montana, Nebraska, Oregon, and Minnesota.

There are four Dhegiha languages: Quapaw, Osage, Kansa, and Omaha-Ponca. Quapaw (also called Arkansas) became extinct sometime in the 1970s or 1980s although there are still nearly 2,000 tribe members. Kansa is also nearly extinct, with just a couple of elderly speakers left. Both languages were last spoken in northern Oklahoma. Omaha-Ponca is considered one language that has barely perceptible differences to nonspeakers. Estimates of numbers of speakers are consistent for Ponca at about 25 fluent speakers, all over 65, but varies widely for Omaha from 20 or so fluent speakers over 60 years old to 1,500 speakers. Most sources agree with an estimate of a couple of dozen speakers. Only a handful of speakers remain for the last language, Osage. The 2000 US Census asserts that over 15,000 people claim membership in the Osage tribe. Speakers and linguists working on the Dhegiha languages have preserved these languages in grammars, dictionaries, and/or texts and a few classes are taught in some of the languages, but it is doubtful that any of these languages will be able to revitalize.

The third branch of the Mississippi Valley group, Chiwere, is sometimes listed as two languages, Iowa and Oto, or as one, Iowa-Oto. The dialects are nearly indistinguishable and are divided on tribal lines rather than linguistic criteria. The Missouria joined the Oto in the late 1700s, so that their dialect, which is believed to have been another language of the Mississippi Valley group, is no longer distinct. The last fluent speaker of Oto died in 1996 and only half a dozen fluent speakers of Iowa remain.

The last language of the Mississippi Valley group was formally known as Winnebago, now Hochunk, 'people of the sacred language'. Winnebago was the name used by the Algonquin, which meant 'foreigners' and adopted by the Europeans. The Winnebago changed their name officially to the Hochunk Nation due, in part, to the association of the name to the RV brand as well as a desire to name themselves. There are about 250 speakers left in a population of about 6,000, but the tribe has undertaken measures to reverse their language loss, including building a Language and Culture Center in Wisconsin with a mission to teach Hochunk to all tribe members, especially the children, from kindergarten through college.

The Missouri Valley Languages

The Missouri Valley group includes two closely related languages, Crow and Hidatsa. Crow is a growing language through efforts of the tribe, including establishing their own two-year college where approximately 75% of students speak Crow as their first language. While classes are not conducted in Crow, the business functions are. In total, there are about 4,500 Crow speakers. Hidatsa, on the other hand, is spoken by just over 100 speakers, all elderly, who live in western North Dakota. There are no efforts to revitalize this language; hence, it will probably become extinct in the next generation.

The Ohio Valley Languages

The Ohio Valley Languages include the extinct languages Tutelo, Ofo, and Biloxi. Ofo and Biloxi were last spoken during the first half of the twentieth century and the last speaker of Tutelo died in the latter half of the century. Tutelo is also sometimes referred to as Saponi, but only a list of Saponi words has survived. They were probably dialects as it has been reported that Saponi and Tutelo speakers could understand one another.

Catawba and Mandan

The remaining languages of the Siouan-Catawban family are the most distant. The Catawban group is usually not listed as a group but a single language, Catawba. However, it is believed that there once were a number of languages that fit into this branch. Adequate materials exist on Catawba, but only a vocabulary list of 143 words in Woccon, a language

that seems to be related by both morphological and lexical properties to Catawba, but these properties are not found in other Siouan groupings. Catawba became extinct when the last speaker died in 1996.

The last language, Mandan, has been thought to stand alone as a branch of the Siouan-Catawban languages while others feel it belongs with the Mississippi Valley group. The resemblances to Crow and Hidatsa are probably due to borrowing, while properties linking it to Mississippi Valley languages were inherited. Mandan is nearly extinct with only six speakers left, all of whom are also Hidatsa speakers.

Siouan-Catawban Features

The Siouan-Catawban languages are generally characterized by Subject–Object–Verb word order. The sound system of the languages is generally typified by the fact that stops ([p, t, k]) have several distinct manners of articulation—unaspirated, aspirated, as well as ejective. The languages have a full inventory of voiceless fricatives, two nasals, *m* and *n*, and the glides *w* and *y*. Most of the languages have three nasal vowels plus five oral vowels, and the vowel length is distinctive.

Morphologically, the Siouan-Catawban languages make extensive and complex use of affixes. Verbs are the most highly inflected category, taking locative, instrumental, reflexive, and pronominal affixes. Case marking is also a feature. Pronominal prefixes are used to indicate first, second, and inclusive persons, while the third person is generally left unmarked or implied.

These pronominal prefixes occur in two sets: one for semantic agents (the entity performing an action) and the other for patients (the entity affected by an action). Particles on the verb may encode a host of other meanings, including plurality and negation. Some languages have such particles for marking word forms that are exclusively used by males or females in commands, assertions, or in giving permission. In these languages, it is also common for nouns to become an integral part of the verb.

Deep Structure

The distinction of the *deep* ('underlying') and the 'surface' structure of a sentence reflects the fact that the actual structure of the sentence, in which the verb can be understood as a predicate accompanied by one or more arguments (and adjuncts, adverbials), is expressed more or less regularly by the means of endings, function words (especially prepositions and conjunctions), and word order. Thus, e.g. the English prepositions *in, into,* and *from* carry the functions of Locative, Goal, and Origin, respectively; the surface subject (preceding the verb) expresses the deep subject (Actor) with a verb in the active voice (*Jim saw Mary*) and the deep object with a verb in the passive

(*Jim was seen by Mary*). The distinction of deep and surface structure, already discussed by H.B. Curry (1961), was systematically elaborated in the 1960s, in connection with *constituency*-based grammars (especially with the transformational description of language, initiated by N. Chomsky). Later, this distinction became characteristic of some of the linguistic approaches based on *dependency* syntax. We present here first a brief survey of the position of this level in different stages of theories based on constituent structure (and transformations), and then we outline the present-day role of deep structure in descriptions using dependency syntax, with illustrations taken from

the Praguian approach of Functional Generative Description.

Chomsky's (1965) *Standard Theory* of linguistic description was later *extended* to contain not only a division of the sentence into constituents (such as the verb and its arguments) but also the opposition of initial Phrase Markers (as the representations generated by a context-free phrase structure grammar) and enriched *D-structures*. The transformational component, which took the D-structures as its input, then consisted of the single, general rule 'move alpha', and transferred these structures into S-structures. The word order in an S-structure may differ from the underlying order due to the operation of the rule 'move alpha', i.e. to some of the constituents moving (usually to the left). Traces of the source positions of such movements are indicated in the S-structures by the symbol 't'.

Let us illustrate the framework of the Extended Standard Theory by the following examples:

(1) (a) You told me that Bill saw who?
    (b) Who did you tell me that Bill saw t?
(2) The police know who the FBI discovered that Bill shot t.

While in (1)(a) the *wh*-pronoun occupies its primary position as the direct object of the verb form *saw*, in (1)(b) this pronoun has undergone two movements determined by the cyclic application of 'move alpha'. In both cases, it moves to the beginning of the given clause. Also in (2), the pronoun *who* has moved in a similar way, although here it has not been placed at the initial position of the whole sentence.

Substantial contributions to the discussion on the levels of the system of language can be seen in C. Fillmore's account of '*deep cases*' (such as Agentive, Experiencer, Theme, Instrument), as well as in the controversy between N. Chomsky's 'interpretative semantics' and the 'generative semantics' of G. Lakoff, J. McCawley, and others, or in J. Bresnan's distinction between constituent structure and *functional* structure.

In the recent approach, formulated by N. Chomsky in the 1990s and called *Minimalism*, the derivation of a sentence is characterized as starting by the choice of lexical units, which may then undergo the effects of the 'merge and move' rules (combining words in accordance with restrictions defined in the lexicon, see Abraham et al. 1996). To a certain degree, the position occupied in the preceding versions of Chomskyan linguistic description by the deep structure can be compared to the '*spellout*' point of the derivation; at this point, the representation of the sentence reaches the form from which its phonological form is derived. Another counterpart of deep

structure in the minimalist framework is *Logical Form*, which reflects the semantically relevant patterning of the sentence.

The concept of deep structure (partly even with the use of Curry's term 'tectogrammatics') was further elaborated in the context of *Dependency Grammar*, which analyzes the composition of the sentence from word forms, and shows that the sentence is patterned in a highly perspicuous way. The verb can be understood as the center ('head') of the sentence, on which its arguments (such as subject, direct and indirect object, etc.), adjuncts (adverbials of place, time, manner, cause, etc.) depend, since every verb determines a set of such (obligatory and optional) complements. Dependency Grammar emerged in European linguistics in the 1830s (with K. Becker) and penetrated into school teaching in several countries of the Continent. It was systematically elaborated in the 1930s by L. Tesnière from a viewpoint closely related to the Prague School of functional and structural linguistics.

While some of the dependency-based approaches render just a kind of 'surface structure' of the sentence (often found useful in computational linguistics), other such theories work with *deep* structure; cf. especially the frameworks of I. Mel'chuk, J.D. Apresjan, and the Praguian Functional Generative Description (FGD, see Sgall et al. 1986; Hajičová et al. 1998). The sentence is then described as consisting of pairs of lexical *heads* and their *dependents* (modifiers, complements). A typical sentence can be patterned as a dependency tree (a finite graph in which every pair of nodes is connected by a single sequence of edges, and a single node is determined as the root of the tree); every edge connects a head with one of its dependents, cf. Figure 1.

(3) My friend Jim prefers girls who have dark hair. In FGD the tree can be written in a linearized form, with pairs of parentheses used to embrace every dependent:

(3') (((my) friend) Jim) prefers (girls ((who) have ((dark) hair)))

The underlying syntactic functions are rendered by labels of the edges of the tree, or by indices at the

parentheses (at those oriented towards the head), and the values of grammatical categories (tense, aspect, number, etc.) are represented by indices of the labels of nodes. Example (4), whose deep-structure representation (4') displays a small subset of the values, illustrates the handling of the relations of coordination and apposition in FGD:

(4) Mary and Jim, her husband, who live in Boston, have two sons.

(4') $(((Mary\ Jim)_{\text{Conjunction}}\ ((she)_{\text{Appurtenance}}\ husband.\text{Sing})_{\text{Apposition}}\ (_{\text{Descriptive}}\ (who.\text{Plur})_{\text{Actor}}\ live.\text{Present.Indicative}\ (_{\text{Locative}}\ Boston))_{\text{Actor}}\ have.\text{Present.Indicative}\ (_{\text{Objective}}\ (two)_{\text{Restrictive}}\ son.\text{Plur})$

This account reflects the fact that the deep structure requires a descriptive framework of more dimensions than the two that characterize a tree; cf. the groups connected by *and* (conjunction) and by the first comma (apposition) in (4). Such a view differs from that of I. Mel'chuk, who understands coordination as a specific case of dependency.

The syntactic properties of a lexical unit are handled on the basis of its possible dependents, such as Actor (deep subject), Addressee (deep indirect object), Objective (deep direct object), Means, Locative. With nouns, possible dependents are the Restrictive or Nonrestrictive (Descriptive) adjunct, Appurtenance, etc. These kinds of dependencies are expressed by function words, endings, or word order. The syntactic *valency* of a word (its 'valency frame') comprises its obligatory and optional dependents, their properties, restrictions on their combinations, on their movement, etc. Lexical entries thus contain much of the grammatical information.

The distinction between a head and a dependent can be specified on the basis of an operational criterion: the dependent is syntactically omissible, if not in a lexically specified pair of words, then at the level of word classes: e.g. in ((very) slow) *progress,* the syntactic potential of the heads prototypically is identical to that of the whole groups. In *Jim met Sally* nothing can be deleted, but other cases show that the verb is never deletable (without a specific context), whereas object can be absent not only with objectless verbs (*sleep, emerge*) but also with verbs like *read*. Verbs such as *rain* even occur without a lexical subject (*it* as in *it rains* is not a lexical subject, but rather a filler without semantic relevance).

The linearized form of the underlying representations is made possible thanks to their *projectivity* (nonprojective, i.e. discontinuous sentence parts are handled by rules mediating between underlying and morphemic representations). The possibility of linearizing the prototypical structures shows that the

more-dimensional networks can be handled by limited means, similar to those of the propositional calculus. This may be useful for specifying how the core of language can be acquired by children.

A formal definition of deep structure has been formulated by Petkevič (1995) both in the form of a generative procedure and in that of a declarative definition. Other components of a complex description can handle the relationships between underlying syntax, morphemics, and phonology, including the more or less regular expression of grammatical values by morphemes, function words, and specific word order positions, as well as the possibility of a zero expression and other specific phenomena.

The importance of the *interactive* communicative conditioning of language makes it necessary to analyze the sentence with due regard to its position in the context, paying attention to its *topic-focus articulation*. This articulation, which includes the specific syntactic positions of focus-sensitive operators such as negation or *only, even, also* (see Hajičová et al. 1998), reflects the degree to which the structure of natural language has been influenced by the 'given-new' strategy (starting a prototypical utterance by referring to items activated in the hearer's memory).

Definiteness

Primarily a pragmatic, essentially deictic ('pointing at') function, definiteness is expressed cross-linguistically by different devices: phonological, morphological, syntactic, and lexical. The most characteristic such device is the definite article (*the*), i.e. a bound morpheme operating on a noun or noun phrase. When it operates on a nonnominal element, the latter is nominalized—it is turned into a noun. Conversely, all deictics and nominals that function deictically (i.e. all linguistic elements that 'point out' a referent), including proper nouns, are definite intrinsically.

Definiteness is a scalar opposition, i.e. definiteness/indefiniteness are two poles between which there are multiple intermediate points. Nonreferential indefiniteness and denominalization are iconically bound to be marked by zero (indicated below by ø), intermediate degrees are cross-linguistically marked by several devices, e.g. indefinite articles (*a*), a clitic deictic demonstrative (*this-*), etc.

Definiteness is a multidimensional notion that can combine referentiality, specificity, identification, actualization, genericity, individuation, familiarity, and shared knowledge. Some combinations are:

—definite referential, specific, identifying, cf. ***The book*** *I am reading is Tom Sawyer*;
—indefinite referential, specific, nonidentifying, cf. *Tom Sawyer is **a book I** am reading*;
—definite referential, specific, shared knowledge, cf. *I'm looking for **the book** [**I** was reading] #*
—indefinite referential, specific, nonshared knowledge cf. *I'm looking for **a book** [bu:k]… (≈ that was here a minute ago] #*
—indefinite nonreferential, nonspecific, nonshared knowledge cf. *I'm looking for **a book** [buk] # (≈ any book).*

The last two utterances clearly differ by content and context. The first of the two may answer a question of the type *What are you looking for [on the table/in the room/...]?*, or: *Have you lost anything*?, etc. The person answering has a specific book in mind. The second utterance, on the other hand, may represent the first sentence of a client entering a store, who does not necessarily have a specific book in mind. As far as form is concerned, both utterances are likely to differ as well, by means of vowel length, intonation and prosody. In the first one, the accentuated vowel of the indefinite noun is likely to be slightly longer than in the second utterance, where it is non-marked for length. The intonation contour of the first is less clear-cut and the utterance does not end as abruptly as the second, whose intonation contour is the one characteristic of the affirmative sentence, with a clear descent of tone and ending in a clear-cut pause.

In English, if an abstract noun is definite, it is actualized, cf. *ø **Truth** is what we should stand for, but **the truth** is that we don't.* Other nouns whose referents too are seen as nonindividuated, i.e. mass nouns, are incompatible with the indefinite article, cf. ***The / *a sand***. Compatibility is obtained through individuation by numeral classifiers, cf. ***a grain*** *of sand.* When a member of a set is definite but nonreferential, nonspecific, nonindividuated, it is generic, i.e. stands for the whole set and is equivalent to the indefinite nonreferential, nonspecific, nonindividuated plural, cf. ***The bear*** *hibernates* ≈ *ø **Bears** hibernate*. ***A bear*** *hibernates*, in contrast, would be indefinite nonreferential, nonspecific, individuated. Unique elements are definite, e.g. ***the sun***, although they may not be, if they are seen as part of a set, cf. *love under **another sun***. There are languages that devote a special form or syntactic structure to mark the indefinite partially referential, cf. French *Je cherche **du pain** 'I'm looking for **some bread'***.

Negative constructions are hardly compatible with definiteness since most of its dimensions are absent, cf. Fr. *Je veux de **la soupe** 'I want **some soup'*** vs. *Je ne veux pas de ø **soupe** 'I do not want ø **soup'**,* Russian *Ivan kupil **komputer** 'Ivan bought **a computer'*** (accusative) vs. *Ivan ne kupil **komputera** 'Ivan did not buy **a(ny) computer'*** (genitive).This is valid for ergative languages too, cf. Basque *Nik dut baratze bat* 'I have a garden' (absolutive) vs. *nik ez dut baratzerik* 'I do not have a garden' (partitive). If negation is identified contrastively, definiteness is possible, cf. *Je ne veux pas **la soupe,** je veux **la salade** 'I do not want **the soup**, I want **the salad'***.

Nouns that are incorporated into a verb are incompatible with definiteness, cf. *to go hunt **a bear*** vs. *to go ø **bearhunting***, and so are other denominalized nouns, e.g. adverbialized ones, cf. *take ø **fire***.

A particular effect is obtained when definiteness operates on nouns definite by nature, e.g. proper names (of which the definite article is not a permanent constituent)

—referential, specific, cf. *I'm looking for ø **(Mr.) Jones***
—referential, specific, identifying, cf. *I'm looking for **the Mr. Jones** who was here yesterday*

—referential, specific, nonidentifying, cf. *I'm looking for **a Mr. Jones** who is supposed to live here* (when an explicit article is present, prefixed civility classifiers (*Mr...*) or suffixed human classifiers (*...boy/girl*), cf. ***a/the Mr. Jones/Jones boy/guy/Beth girl,*** etc. block the reifying effect of the article).

In English, the definite article allows also to pluralize and actualize proper nouns, e.g. last names: ***The Smiths***. In Córdoba (Argentina) Spanish, in rural French, etc., it is first names that are actualized by the definite article in all functions to convey familiarity. On the other hand, when an indefinite article is used with a proper name, it strips it of its individuality and makes it the representative of a class, cf.: *It would take **a Henry James** to describe that man's psychology*. There are languages in which the definite article operates on proper nouns that are the topic of the utterance. Topicality (old information) and definiteness are narrowly correlated, as are focality (new information) and indefiniteness. In Nêlêmwâ (Melanesian), /-xe/ functions both as a definite article and a topicalizer. Topics tend to be subjectal, agentive, human, deictic, and first actants of transitive verbs; topical nouns with any or some of these properties tend to be definite. Focal (new information) ones tend to be predicative, objectal, patientive, nonhuman, nondeictic, second actants of transitive verbs and indefinite. If definite and/or human, they are discursively marked, and often formally as well, cf. Sp. *Vi **la casa** 'I saw **the house**'* vs. *Vi **a la mujer** 'I saw **the woman**'* Contemporary Hebrew (CH) *[ra?iti ø dira]* vs. *[ra?iti ?et ha-?iʃa]*, Guaraní *[aheʃa oga-ø]* vs. *[aheʃa kuña-me]*. Hence, existential constructions (*There is...*) in which the noun is the focus are cross-linguistically incompatible with definiteness, cf. Spanish **Hay **el libro#** * 'There is **the book#**'* (the asterisk marks ungrammaticality), CH **[yeʃ ha-sefer#]*, Fr. **Il y a **le livre#*** 'id.' One way to override this contraint, viz. to actualize or topicalize an indefinite noun, is to use a deictic demonstrative, cf. *There was **a guy#*** vs. *There was **this guy,** who...* or to focalize the existential, cf. **CH** *[yeʃ ø-sefer#]* vs. *[yeʃ **no ha-sefer#**]*. Conversely, a means to focalize a definite noun is the presentative construction, cf. *Here is **the book,** Fr. Voilà **le livre**,* **CH** *[hine ha-sefer]*, Sp. *He aquí **el libro***. Accordingly, the definiteness gradient correlates with (1) aspect: bounded action ~ definite agent vs. unbounded action ~ indefinite agent; note that genericity blocks the actualizing aspect, cf. *ø **The bear** hibernates /* is hibernating*; (2) dynamicity: active verb ~ definite agent vs. stative verb/adjective/nominal predicate ~ indefinite actant; (3) inherency: operating on a nominal predicate, the indefinite article assigns the subject to a set established by that predicate, cf. German *Die Kirsche ist ø **sauer** 'The cherry is sour'* vs. *Die Kirsche ist **eine***

sauere 'The cherry is of the sour type', Fr. *Il est ø psychologue* 'He understands people' vs. *C'est **un** psychologue* 'He is a psychologist'. The link between (1), (2), and (3) is apparent in Spanish, where *estar* ('be', punctual-dynamic-accidental) is incompatible with the indefinite article, while *ser* ('be', durative-stative-inherent) is compatible with it, cf. respectively **Está / Es una cereza amarga/(un) sicólogo;* (4) noun class, including sex gender. In languages displaying this category, its marks coalesce with those of deixis and often definiteness so that the class prefixes in Bantu; Guaykuru (Amerind); etc., function as definite articles.

Diachronically, a definite article is descended from a deictic demonstrative. Discursively, the definite article is an anaphoric i.e. an intradiscursive deictic device *par excellence*, i.e. it always points to something mentioned, either previously or afterwards, or given/inferable from context (including general truths). This is accomplished either explicitly, cf. *We reached **a river** nearby. **The river** was majestic,* or implicitly, cf. *We reached **a river** nearby. **The other bank** was too distant to be seen.* Deixis is also the first function cast upon the definite article by the child acquiring language. These facts illustrate that definiteness is essentially deictic, and hence of a communicative-pragmatic nature, which is why it is conveyed in all tongues, albeit not necessarily by a specific morpheme. Quintilian's (born AD 35) words: *Noster sermo articulos non desiderat, ideo in alias partes orationis sparguntur* 'Our language does not want articles; hence, thei(r functions) are cast upon other parts of the sentence' apply cross-linguistically; languages not having developed a specific form of a deictic demonstrative to work as a definite article apply to other mechanisms to perform this task. Classical Latin is an example, cross-linguistically current, of definiteness marking in a tongue with no articles: a definite noun is placed in sentence initial position (which often coincides with subject position). There are languages that developed a definite article, then lost it as such either by phonological or by semantic attrition, and then developed a new one. This includes, among others, African languages of various stocks. In Ethiopian-sporadically in Ge'ez and widely in Amharic-a 3rd p. possessive suffix (of deictic origin) is used as a definite article. In Nahuatl, the deictic-nominalizer /in/ functions as definite article when prefixed to the noun; this is corroborated by the fact that when a noun does not bear such a prefix, it is predicative. The suffix /-tl/ marks a vast majority of nouns (except in incorporation, in the plural, when the noun is possessed and in quantifiers, indefinites, and interrogatives); Neo-Aramaic /-a/ behaves similarly. Those are erstwhile deictics that cliticized into definite articles, and then spread to all nouns in all positions and became mere nominalizers.

The numeral 'one' often develops a clitic form to mark an indefinite noun as referential, and the process

starts by marking it as specific: CH [ʔexad/ʔaxat] 'one', respectively, m. and f., evolved a clitic form [-(ʔe)xad/-(ʔa)xat], cf. **[cipor(ʔa)xat *ʔamr-a li*] *'a (certain) bird told me'* vs.[ha-xasida *hi cipor-nod ø*] *'the stork is a migrating bird'*. At present, an anteposed, concording and often stressed form of */ʔejze/* 'which', followed by the relative particle /ʃe/ and a third person deictic is spreading to focalize not the noun itself but its being indefinite referential, specific-, cf. *[jeʃ ʔejzoʃehi hitkadmut]* 'there is some [undoubted] progress]'. Both recent marks are incompatible with each other as well as with the definite article */ha-/* and with a free deictic, which confirms that (in)definiteness is a scalar opposition.

Deixis

Deixis concerns the ways in which languages encode or grammaticalize information regarding the extralinguistic context in which utterances occur, and the ways in which the interpretation of utterances depends on the analysis of that context. For instance, the sentence 'Peter likes me' cannot be properly interpreted unless we know certain details about the context in which it was uttered, namely, the identity of the speaker.

The study of deixis goes back to the work of the ancient Greek grammarians (the term 'deixis' is the Greek word for 'pointing' or 'indicating'). Although deixis has proved itself as a central linguistic concept, during the twentieth century there has been a considerable philosophical interest in deictic phenomena. In fact, the topic was reintroduced into modern linguistics by the German philosopher Karl Bühler in his book *Sprachtheorie* (1934; *Theory of language*). Three main categories of deixis have been traditionally distinguished: person, time, and place. It is generally accepted that deixis is an egocentric system in that the speaker chooses his own perspective when integrating personal, temporal, and spatial information into the message: the central person is the speaker, the central time is the time at which the speaker encodes the message, and the central place is the speaker's location at coding time.

Person deixis involves the identification of the participants in the communicative situation as well as other individuals referred to in the utterance. Among the linguistic expressions that fulfill this identifying function, personal pronouns and inflectional affixes

attached to nouns and verbs are the most usual ones. The basic grammatical distinctions in person deixis are the categories of first, second, and third person: the first person refers to the speaker himself, the second person refers to the addressee, whereas the third person refers to a person or persons who are part of the conversational group but who are neither the speaker nor the addressee. In addition to this contrast, person deictic items typically include information about number and gender. The singular/plural distinction is the primary number opposition in all languages. As regards gender, person deictic items may convey information about the sex (semantic gender) or arbitrary class (grammatical gender) of their referents.

Place deixis deals with the specification of the spatial location of the entities referred to in the utterance. Although locations are most commonly established by reference to that of the speaker, some languages also take the addressee's position as the central place. The basic spatial contrast in most languages, illustrated by the English pair *here* vs. *there*, is that of 'proximal to the speaker' and 'distal to the speaker'. Many languages, however, exhibit a three-fold opposition; Spanish, for example, distinguishes three locative adverbs: *aquí* ('near the speaker'), *allí* ('far from the speaker'), and *ahí* ('a little way from the speaker'). Spatial relations may be expressed linguistically by a wide range of items. The most common perhaps are locative adverbs (*here/there*), demonstrative pronouns (*I will take **that***), and adjectives (***this** house*).

Time deixis involves the identification of the time of the events described in the utterance by reference to the time of the communicative situation itself. Time deixis is commonly treated as a metaphorical extension of place deixis: time is seen as a unidirectional stream in which events are located before (or behind), after (or ahead), or simultaneous with the time at which the utterance is produced. Probably, the most common temporal deictic device is tense, although some languages, like Chinese, lack this verbal category. Languages also rely on temporal adverbs (*now/then*) and demonstratives. Demonstratives are said to be imported from the local domain and used metaphorically in expressions like *this week*, which implies proximity to the utterance time, or *that evening,* which implies remoteness. Finally, most languages have lexical items that specify temporal relations, like the English words *today* or *yesterday.*

In the early 1970s, Fillmore's works brought a renewed interest in the study of deixis and new types were added to the traditional inventory. Among them, the most widely accepted are discourse and social deixis.

Discourse deixis concerns the use of certain expressions within the discourse to refer, not to an extralinguistic entity, but to some portion of the discourse itself. Since discourse develops in time, discourse deixis makes use of terms borrowed from time deixis. For example, the expression *the last paragraph* would be analogous to *last week.* In a similar way, discourse can be thought of as having a spatial extension since any point within it can be located either behind or ahead of a central reference point. Thus, place deictic expressions like the adverbs *above* and *below* or the demonstratives *this* and *that* are commonly used to refer to a preceding or following portion of discourse.

Social deixis involves the encoding of the social status and rank of the participants in the communicative situation and the social and personal relationship between them or between one of them and persons referred to. One of the most obvious manifestations of social deixis is the choice of specific pronominal forms (known as 'honorifics') to refer to the addressee in many European languages: French and German, for example, make a distinction between the familiar terms *tu* and *du* and the polite terms *vous* and *Sie,* respectively. Social status can also be encoded throughout particles and affixes that indicate, as in Japanese, respect or deference. Titles of address (*Mr. President* or *My Lord* in the courtroom) also fulfill this social deictic function. Many languages also make a division between two or more registers in which different vocabulary and syntactic constructions are used depending on whether the communicative situation is seen as formal or informal.

In short, the essential feature of deictic expressions is that their semantic values depend on the real-world context in which they appear. Thus, deixis constitutes a natural link between semantics and pragmatics. However, deixis is also bound to nonlinguistic aspects such as the speaker's attitude or the interaction of grammar and culture and thus it offers itself as a common meeting ground for investigations undertaken from different perspectives such as those of philosophy, cognitive psychology, psycholinguistics, sociolinguistics, or anthropology.

Determiner

A *determiner* is a member of a syntactic category that combines with a noun (e.g. *house, book*) to express information about the reference, quantity, proximity, or gender of the noun. It is a function word that adds grammatical information to the basic meaning of a noun. It may appear in different languages as an independent word (English *a, the*), an affix to a noun (Farsi *kitob-ro,* 'book-the'), a combination of both independent word and affix (Swedish *den vita bilen,* 'the white car-the'), or a whole phrase (as *the dog's* in *the dog's owner*). There are several subtypes of determiners, each with its own particular function.

Basic determiners, or articles (*a, an, the*), give information about the definiteness of a noun. Their use depends on the discourse context. In general, a speaker will use the indefinite articles *a* or *an* to introduce a noun into a conversation or to name one that does not have any specific reference. The definite article *the* introduces a noun that has a unique reference and is familiar or readily identifiable from context. The articles thus play an important role in discourse in signaling the appearance of new referents (with indefinite articles) and maintaining their status as current topics of conversation (with the definite article). Not all languages make use of an overt indefinite article, however. Often there may be only one basic definite article, with bare nouns interpreted as indefinite. In English, the absence of an overt article signals either a mass noun (*rice, butter*) or a generic use of a countable noun, i.e. a noun used to identify a class of objects of a certain type, as *students* in *Students cannot afford to live here.*

The use of the indefinite article *a* in English is complicated by the fact that it is ambiguous with respect to specificity. The sentence *I am looking for a woman with red hair* has two interpretations. The article *a* could signal that the speaker is searching for a type of woman identifiable only by the characteristic of hair color. Or, it could signal that he is in fact searching for a particular woman, whom he already knows. The first interpretation is a nonspecific reading of the article *a*, whereas the second interpretation is a specific reading.

Both interpretations are indefinite. Specificity is thus a different concept from definiteness, although both are encoded in the same determiners in English. In other languages, specificity may be more clearly encoded in determiners that are different from definite and indefinite articles. Or, unlike in English, the concept of specificity, rather than definiteness, may be the key factor in how articles are interpreted.

Demonstratives (this, that, these, those) are determiners whose main function is deictic, or 'pointing out'. They indicate the proximity or closeness of a noun to the speaker. A *proximal demonstrative* identifies a noun as close to the speaker *(this chair)*, whereas a *distal demonstrative* identifies it as distant from the speaker *(that chair)*. The distance can be metaphorical or temporal rather than physical, as in *that situation* or *this week*. Although systems of two degrees of proximity are the most common, some languages may express more. Maori, for instance, identifies three degrees of proximity: close to the speaker, distant from the speaker, and distant from both speaker and hearer.

A secondary use of the proximal demonstratives *this* and *these* is to introduce an indefinite but specific noun that will figure prominently in the conversation that follows—for example, *There was this car blocking the intersection,* or *This guy called for you.* In such constructions, the demonstrative is a stylistic alternative to the indefinite article *a*. As these examples suggest, this is a colloquial use of the demonstrative, and it typically appears in openings to anecdotes and jokes. It is an exceptional indefinite use of the demonstrative, which is otherwise inherently definite when used deictically.

Quantifiers are determiners that express the quantity of a noun, for example, *some, any, most,* and the negative quantifier *no*. Quantifiers interact in complex ways with articles and demonstratives. Some are compatible only with definite interpretations *(all, both, every, most)*, whereas others are inherently indefinite *(some)*. *All* and *both* are the only determiners that can combine with other definite determiners in English, as in *all the students*. None of the quantifiers

may combine with indefinite determiners: *all some students*, *each a student. All* and *both* are sometimes referred to as *predeterminers* and might be better analyzed as a separate category of word.

Possessive determiners include possessive pronouns such as *my* and *your* and entire noun phrases marked with the possessive inflection *-'s,* as in *every man's rights.* Possessive determiners imply definiteness and give specific information about the relationship of one noun with another. Usually, this is a matter of ownership, but it could also be a matter of origin or inclusion. In some languages, possessive determiners can encode a distinction of 'alienable' vs. 'inalienable' possession. In inalienable possession, a noun (typically a body part or kinship term) cannot be separated from the possessor. In alienable possession, a noun can be separated from the possessor, and the relationship of possession can be terminated. This is usually the case with inanimate objects. This very specific information can be encoded in the form of the possessive determiner.

Wh- determiners can take the place of any of the other determiner types if the identity, quantity, or ownership of a noun is unknown and must be questioned: *Which chair? What book? Whose rights? Wh-* determiners thus express unspecific reference in English.

In older grammars, the determiner is not always recognized as a separate syntactic category, or the term may be used only to refer to the basic indefinite and definite articles. Instead, the subtypes of determiners listed above are often treated as completely separate word classes. It is fairly recent that these have been given a unified analysis as members of the more general category of *determiner.* This change is motivated by the fact that they all precede a noun and may substitute for one another but in effect never co-occur in the same phrase. Thus, *the these papers* is ungrammatical. A unified analysis is also supported by the similarities in their meanings and the way in which some imply the definiteness usually encoded by *the.* Given this view, even personal pronouns such as *you* and *we* may be classified as determiners, because they may combine with nouns and signal definite and deictic meanings in phrases such as *you hypocrites* and *we taxpayers.*

The determiner's status as a function word was re-evaluated during the mid-1980s, when syntactic theory began to reinterpret all types of function words as the most important (i.e. 'head') words in a phrase. Before this time, function words were viewed as being dependent on lexical categories such as nouns and verbs. Steven Abney argued in 1987 that the determiner was the head of its own determiner phrase rather than simply a word appearing in a noun phrase headed by a noun. By this analysis, which is known as the DP (Determiner Phrase) Hypothesis and is now widely accepted, a phrase such as *the house* is a DP structure, with the determiner *the* acting as the head of the construction. Most determiners are like *the* in that they must combine with a following nominal category, such as *house.* However, personal pronouns may be analyzed as independent DPs that do not necessarily need to combine with any other category.

The DP analysis is supported by facts about the form, word order, and meaning of determiners in many languages. In particular, the DP analysis is a fruitful means of representing similarities between nominal phrases and full sentences. Noam Chomsky pointed out in the 1970s that a nominal construction such as *the Romans' destruction of Carthage* is in many ways analogous to a corresponding sentence *The Romans destroyed Carthage.* The information carried by the determiner is central to the grammatical interpretation of the noun, in the same way that the information carried by tense and inflectional elements is central to the interpretation of a sentence. Because tense and inflection are assumed to be the head categories of the sentence, it follows that the determiner should be analyzed as the head of the nominal construction. The possessive determiner (*the Romans'*) is the structural parallel of the subject of a full sentence.

In some languages, a determiner may agree syntactically with the noun it accompanies. That is, it may show inflection to indicate that it shares grammatical features such as number (singular or plural) or gender with the noun. Agreement between determiners and nouns is similar to the agreement of the subject and verb in a sentence. Extensions of the DP analysis have therefore suggested that the structure of nominal phrases is very similar to that of sentences.

Developmental Stages

Identifying the stages of language development cannot be done independent of the notions of 'comprehension' vs. 'production' and 'competence' vs. 'performance', because, when we claim that a child has acquired 'the past tense' or 'how to tell a structured story', we need to know whether we mean that the child shows evidence of comprehending, say, the difference between past and present tense, or whether the child accurately codes the distinction between them in his or her speech or writing. Beyond this, it is possible that data from neither comprehension nor production accurately reflects the child's mental representations (competence). Performance, in other words, always risks being an inadequate reflection of competence.

Despite these problems, most child language researchers are confident in crediting a child with having acquired a particular aspect of language when they demonstrate it in their production in around 90% of the required contexts. Hence, if a child is using the regular past tense '-ed' ending in nine out of every ten cases where it is required, then we can say the child has acquired it. Given that comprehension almost always precedes productive capacity, this conservative approach is generally justified. There are, though, situations in which children (some more than others) pick up chunks of language, sometimes quite large ones, without really understanding what they mean or how they are constructed. In these cases, production precedes comprehension, and crediting acquisition needs to wait for the child's internal analysis of the chunks.

Notions of general, across-the-board stages of language development are difficult to maintain, even when variations in individual children's rate of development are taken into account. Although writers often refer to 'the one-word stage', 'the multiword stage', etc. these provide little substantive information, actually only serving to trigger the association that, in the first case, we are probably talking about (normally developing full-term) children in their second year of life, and in the second, slightly older children, but still preschoolers. The problem with identifying across the board stages is, firstly, that the range of normal language development is large and shades imperceptibly into language disorder. Secondly, the stages are not discrete, one-word utterances co-occurring with two-word utterances for some time. Thirdly, while some aspects of language development are relatively independent of others (e.g. the acquisition of adjectives, or of consonant clusters), others reflect highly dependent relationships. For example, a child will not be able to advance in developing negation in English without the development of the copular verb and the auxiliary system, including insertion of 'do', since the negative particle (n't) suffixes to these tensed verbs in most instances. (Thus, an early expression of negation such as 'Not fit' becomes 'It doesn't fit.' or 'It can't fit.') The issue of what is related to what is extremely important in discussions of the modularity of language, both in terms of the relationship of language development with nonlinguistic development, and in terms of the internal connectedness of developments within language. This is an area where linguistic theory and first language acquisition research are vitally connected.

Language in Infancy

Although infants under a year old do not yet produce language, they are building mental representations for language and are beginning to comprehend the language(s) around them. In addition, the ability to communicate desires and beliefs by vocalization (including intonation) and both hand, face, and body gesture combined with appropriate eye gaze, develops rapidly in the prelinguistic phase. For those who see pragmatic development as part of language development (some do, some do not), the emergence of gesture and nonverbal vocalization, along with the ability to get and direct the attention of another person and engage in reciprocal turn-taking, are all important milestones of pragmatic competence that are in place prelinguistically.

Much of the language used to a preverbal child is comprehensible from accompanying nonverbal clues (e.g. 'Get me the ball' accompanied by a pointing gesture), and in most cases it is the context, rather than the words spoken, which allows the child to understand. In their own productions, children begin with cries and coos, which give way to 'babbling' at around six months. Babbling is characterized by increasingly stable vocalizations that, over a six-month period, approximate the word structure of the language(s) they are exposed to. Toward the end of the babbling stage, 'proto-words' emerge. These are relatively stable vocalizations that seem to have a recognizable meaning. By the time first words emerge, around the end of the first year, infants show significantly more advanced responses to language than their own productions would indicate.

Deciding when the prelinguistic phase has given way to the linguistic depends on cultural norms, children's control over their vocal apparatus, and normal individual variation. Whether a proto-word is recognized as a word depends on how like a recognizable adult word it is, and the extent to which the adults around the child are willing to interpret them as such. In some cultures, it is the emergence of a particular word (e.g. the word for 'breast') that is seen as marking the emergence of language. Finally, some children seem to experiment freely with early words, while others hang back until they are capable of clearer, more recognizable speech.

Language in the Preschool Years

Many observers have noted that lexical development starts slowly (about one new word per week), but that somewhere around the 50-word mark, many children (but not all) experience a sudden increase in vocabulary acquisition. They then add words at a rate that translates into an average of nine new words per day for the next ten years or more. In production, children generally begin by acquiring names for people and objects in their environment as well as useful interpersonal expressions such as 'hi!' and 'bye-bye', with some children having a greater proportion of such expressions in their early vocabularies than others. Pronunciations are often simplified through the use of strategies such as regularizing the consonant–vowel syllable structure ('wawa' for 'water'), deleting final consonants ('du' for 'duck'), simplifying consonant clusters ('tain' for 'train'), and avoiding difficult (and typologically rare) sounds such as /r/ and /θ/. Words also start out restricted in their reference (e.g. 'teddy' may start out being applied to only the child's own teddy, or only to teddies when they are in the child's home), only gradually coming to have the usage of the adult language, and not infrequently passing through a stage of being overextended in their use (e.g. 'teddy' applies temporarily to all soft toys). Words overextended in production in this way are not usually overextended in comprehension. In comprehension, during the second year of life, children begin to be able to understand a wide range of words for people, games and routines, familiar objects, animals, body parts, and action words. They pick up some of these words on only one exposure.

In languages such as English where word order is the main indicator of who does what to whom, early development is marked by the absence in the production of inflectional and derivational bound morphemes and of function words such as prepositions, auxiliaries, and articles. However, in more richly inflected languages, such as Spanish and Finnish, there is evidence at even the single-word stage that bound morphemes such as verbal inflections are beginning to emerge, and as the single-word stage gives way to the multiword stage, children acquiring such languages advance faster in morphology than those learning languages like English (even though full mastery of these systems may take the learner of Finnish well into adolescence).

Researchers have noted that there is a relatively predictable order of acquisition of functional morphemes in English, from the progressive '-ing', prepositions 'in' and 'on', and plural 's' through to the contractible copula and auxiliary, as in 'He's happy' and 'He's walking', respectively. This order, first explored by Roger Brown (1973), is often used to estimate a child's stage of development. The mean length of utterance (MLU), a measure of productive capacity proposed by Brown, is also used. An MLU of between 1.50 and 2.0 represents Stage 1 of development and is usually attained during the second year. MLU then rises through four successive stages to Stage 5 when MLU reaches 4.0 or above, normally at around three-and-a-half years of age. However, children may vary individually in terms of both the pace and overall rate of development.

As MLU rises, children's utterances not only include more content words but also come to include both function words such as 'he', 'not', and 'a', and bound morphemes such as '-ing', '-ed', and '-s'. In adding bound morphemes in their productions, children also try to rationalize the system by overgeneralizing endings to produce things such as 'breaked', 'goed', and 'deers'. Gradually, however (and it is a slow process), irregular forms such as 'broke' and 'went', which tend to make a brief appearance early in development and then disappear as the overgeneralizations take over, reappear and shut out the earlier forms. As complexity increases, children's capacity for expressing basic sentence types (affirmative declaratives, negative declaratives, interrogatives, etc.) becomes more sophisticated in ways that are difficult to describe independent of a particular theory of syntax. Whether acquisition is seen as the accumulation of constructions or the genetically powered interplay of abstract features and the lexicon will affect how the increasing complexity of a child's utterances is viewed. Gradually, though, the auxiliary system emerges, adverbs are put in the right places, subjects of sentences are expressed, etc. Then, at around three years of age, complex sentences begin to emerge with the successive appearance of complements of verbs such as 'think' and 'know' ('I think you're funny', 'I know how many legs a dinosaur has'), infinitive complements ('I want to go to school'), relative clauses ('That's the teddy that Mummy bought me'), conditionals ('I can if I want to'), and conjunctions ('I have to go 'cos it's time', 'I went to Grandma's and we had tea'.).

Semantic development is intimately bound up with cognitive/conceptual development and it is not clear whether language acquisition introduces new semantic possibilities, or whether it provides coding opportunities for concepts already developed through observation of the world, including the language of others in context. Researchers have suggested that certain overarching semantic relationships appear early as soon as words are combined. These include 'nonexistence', argued to be characterized by the expressions 'no more' and 'allgone'; 'recurrence' ('more noise' and 'nother raisin'); and 'attribution' ('microphone hot' and 'animal book'). Later, more mature semantic notions, such as existence ('There dog') and negation ('No fish'), develop followed by quantificational notions coded by words such as 'some', 'lots of', 'many', 'few', and 'several'.

The preschool period is when conversations can be reliably started and maintained linguistically, when children begin to adapt their messages to different audiences, when miscommunications can be repaired, and when stories begin to have proper beginnings, middles, and ends. Words such as 'here' and 'there','this' and 'that', together with 'I/me', 'you', and 'us', whose references shift depending on who is talking, also begin to be used more accurately.

Language in the School Years

Although much of language development is complete by age five, some syntactic constructions do not appear for many children until they enter school. The passive construction in English ('The book was written by the teacher') is one such. However, it might be noted that in languages such as Sesotho, where the passive is used extensively in speech, it appears much earlier. Irregular past tense forms such as 'fell' and 'brought' may not win out over 'falled' and 'bringed' or 'brang' until at least the age of eight or nine, if ever. Complex sentences with relative clauses and other types of complement begin development in the preschool years, but are not consolidated until middle childhood. The extent to which children learn advanced literary constructions is driven by individual interests and educational expectations. The capacity to read and write and to engage in abstract thought drives both late syntactic development and unlimited vocabulary development.

Around the age of six or seven, the capacity to reflect on language itself, to be metalinguistically aware, emerges. This capacity culminates in the ability, among other things, to define abstract nouns, explain the meaning of idioms and proverbs, and solve complex verbal analogy problems. It is also reflected in verbal humor and, coupled with developments in the ability to 'read' the minds of others, the capacity to exploit complex social uses of language, for example, in narratives.

Dialectology

Dialectology investigates regionally and socially conditioned linguistic variation, called *regional dialectology* and *social dialectology* (or sociolinguistics). In the history of the discipline of dialectology, the following motivations can be distinguished: normative interests, which prevailed in the sixteenth and seventeenth

centuries (correct standard language vs. incorrect dialect); antiquarian interests, starting in the second half of the seventeenth century, when dialect lexicography began; documentary interests in the nineteenth and twentieth centuries (written records of spoken language, including the collection of fairy tales and phonographic records); linguistic interests, also in the nineteenth and twentieth centuries (language history, local dialect monographs, dialect geography, semantic field theory, and structural and generative dialectology); interests in cultural geography in the twentieth century (extralinguistic interpretations of sound and word geography); and psycholinguistic and sociolinguistic interests, also dating from the twentieth century. Although the psycholinguistic approach tries to discern from the dialect the view of life underlying it, and vice versa—this line of research has not had much of an effect—the sociolinguistic approach deals with broad matters such as language and society, dialect and education, and dialect as a language barrier. Finally, an interest in nonlinguists' views of areal linguistics arose in the last decades of the twentieth century; it is called *perceptual dialectology*.

In the beginning of the nineteenth century, linguists often referred to as *Neogrammarians* tried to prove that the sound system of the languages develops and changes according to rigid and highly regular 'sound laws', the term *law* being understood as in the natural sciences. The perceived regularity of sound changes, they thought, could best be observed in dialects, but as it turned out later, this was not the case.

The comparative method of the nineteenth century had produced two theories with regard to linguistic relationships. One was the naturalistic concept of the family tree theory, advocated by August Schleicher, and—in contrast to this theory—the wave theory of Johannes Schmidt, a student of Schleicher's who maintained that adjacent regions resembled each other most and that differences increased with distance. Research in dialect geography or geolinguistics later revealed that this is largely the picture presented by dialects. In modern terminology, these situations are called *geographical dialect continua*. At their farthest geographical points, dialects may no longer be mutually intelligible, but they will be linked by a chain of mutual intelligibility.

An important aim of dialectology is to delineate dialect areas. Traditionally, this has been done—and still is—by drawing lines on linguistic maps, enclosing one linguistic phenomenon each time and isolating it from its surroundings. These lines are called *isoglosses*. Because isoglosses often do not overlap, Hans Kurath coined the term *heterogloss*, which reflects the conceptual content more accurately. However, more and more modern linguistic atlases no longer show isoglosses or heteroglosses, but rather symbols that reveal transition zones much more clearly and are thus more suited to linguistic reality. In delimiting dialect areas, a qualitative approach must be distinguished from a quantitative one. In the first case, a few features, or often only a single feature, are chosen to differentiate dialects from each other. The more important the chosen feature, the more reliable the dialectal structure obtained. Phonemic features carry more weight than phonetic or lexical ones. Phonemes are the smallest units differentiating the meaning of a language. They are structural linguistic features and thus very stable. In contrast, phonetic features are nonstructural; they show a great deal of variation. The least stable element of a language is its lexicon. A lexical feature is therefore least reliable in differentiating dialects. In a limited quantitative approach, a dozen or more features are selected from any linguistic level—whether it is from the sound, word formation, sentence structure, or vocabulary systems—their borders are calculated, and thicker or thinner lines are drawn according to the number of features they distinguish. Then, the results of the various linguistic levels are compared with one another to see whether they are in substantial agreement or not. In recent years, the use of the computer has made it possible to quantify enormous amounts of data and to present the results on linguistic maps. This branch of linguistic geography, which makes use of highly sophisticated statistical methods, is called *dialectometry* or *dynamic dialectology*. Whereas the procedure involving isoglosses/heteroglosses is a sample of a sample, the dialectometric approach is more objective and exact because it is capable of taking into account all the available linguistic data collected in a certain area. Dialectometry sets off the linear approach of traditional dialectology with an areal one. Its methodological procedure is based on the question of identity or nonidentity of two linguistic forms.

Dialectology has also contributed to linguistic theory. In the field of structural dialectology advocated first by Uriel Weinreich in 1954, mention must be made of the principle of maximum differentiation between two phonemes and the description and comparison of dialectal systems, to which members of the Prague Linguistic Circle have also greatly contributed. By formulating diafeature rules, as attempted by, e.g. Lawrence M. Davis in 1973, taking into account both regional and social variation in language, it has been shown that dialectology added an important dimension to generative phonology, too (see, e.g. Rudolph C. Troike 1971).

Results in dialect geography are normally presented in linguistic atlases. Apart from regional and national linguistic atlases, there are atlases of language groups, such as the Panslavic linguistic atlas. The most comprehensive atlas so far is the *Atlas Linguarum*

Europae, the European linguistic atlas, which covers all six language families and their dialects spoken in the whole of Europe. Also, *Sprachbund* phenomena can be treated in a similar way. A Sprachbund is formed by a group of related or nonrelated languages that show systematic similarities in grammar and lexicon, which cannot be accounted for by direct relationship with a common underlying language. An (not undisputed) example of a Sprachbund comprises the Balkan languages. The production of linguistic atlases today involves the most recent information technology, including speaking linguistic atlases.

Schmidt's wave theory was also applied to social dialects. As early as in 1933, Leonard Bloomfield noted: 'The higher the social position of the nonstandard speaker, the more nearly does he approach the standard language' (*Language*, p. 49). Such situations are called *social dialect continua.*

Diglossia

In his seminal article in *Word* (1959), Charles Ferguson defined diglossia as:

> 'a relatively stable language situation in which, in addition to the primary dialects of the language (which may include a standard or regional standards), there is a very divergent, highly codified (often grammatically more complex) superposed variety, the vehicle of a large and respected body of written literature, either of an earlier period or in another speech community, which is learned largely by formal education and is used for most written and formal spoken purposes but is not used by any section of the community for ordinary conversation.'

Using the examples of Greek, Arabic, Haitian Creole, and Swiss German, Ferguson pointed out several characteristics that are common across all diglossic situations. First of all, in terms of function, there is a strict division of labor between the two language varieties: while the superposed variety or the H(igh) variety is used mostly in prestigious domains such as education and government, the vernacular or the L(ow) variety is restricted to informal domains (e.g. family, neighborhood). Second, although the two varieties are genetically related to each other, the H variety is structurally more complex than the L variety. Third, the H variety is more highly valued than the L variety: although there is a sizeable body of literature written in the H variety, the L variety is rarely used in the written form except in

dialect poetry and advertising. Fourth, given its superior status as the language used in prestigious domains, the H variety also tends to be more standardized than the L variety—grammars and dictionaries are written for the H variety, but not usually for the L variety. Fifth, while the L variety is the language of the home, the H variety is not spoken natively by anyone in the community and has to be learned through schooling. Finally, although the L variety may gradually replace the H variety due to factors such as more widespread literacy and broader communication among different regional and social groups, a diglossic situation is relatively stable—it can persist for centuries or even millennia.

A diglossic situation is likely to come into existence under the following conditions: (1) when literacy in the community is restricted to a small elite; (2) when there is a sizeable body of literature in a language closely related to the vernacular of the community, and this literature embodies some of the fundamental values of the community; and (3) when a considerable period of time elapses following the establishment of these two conditions. Nevertheless, although these social contexts favor the emergence of diglossia, they do not necessarily lead to its development. In fact, it is possible that diglossia may develop from other origins.

Diglossic situations are different from other commonly found language situations in several respects.

In contrast to a diglossic situation, a bilingual situation does not maintain a clear functional compartmentalization of the two varieties. In many Arabic-speaking countries (one of Ferguson's canonical examples), for instance, although colloquial Arabic serves as the basic medium of interaction, Standard Arabic is still the preferred variety for formal purposes. However, in a bilingual community such as Flemish- and French-speaking Belgium, both varieties are used to perform similar functions in formal and informal domains. Furthermore, while a diglossic situation involves two genetically related language varieties (at least according to Ferguson's (1959) definition), two or more unrelated languages often coexist in a bilingual or multilingual community (e.g. English, Chinese, Malay, and Tamil in Singapore).

A diglossic situation is also different from a standard-with-dialects situation. In a community with standard-with-dialects variation, there are those who use the standard language (which is usually the more highly valued variety) in everyday conversation and speak it as their mother tongue. In a diglossic community such as German-speaking Switzerland (another one of Ferguson's examples), the H variety (*Hochdeutsch*) is only learned through formal schooling and is not used as the medium of everyday interaction. On the other hand, in Italy (a standard-with-dialects situation), a considerable number of people speak standard Italian natively and use it in formal as well as informal settings.

Ferguson's article has spurred interest in and stimulated research on this particular type of linguistic phenomenon. In particular, there have been numerous efforts over the years to rework Ferguson's definition of diglossia. In particular, while maintaining the strict functional compartmentalization of the two varieties, Joshua Fishman broadened the definition of diglossia to include genetically unrelated varieties. Thus, according to this broad definition, Spanish- and Guaraní-speaking Paraguay would be classified as a diglossic community, in that the two genetically unrelated varieties function like H and L varieties in diglossic situations. However, some have criticized that this definition dilutes the original meanings of diglossia. Although the Spanish-Guaraní situation in Paraguay resembles, say, the diglossic situation in Arabic-speaking Syria, the two differ from each other in terms of the social history of the code matrix and the social processes that led to their emergence. While the former came into being as a result of colonial contact—in other words, the confluence of two independent sociolinguistic traditions, the latter was derived from the internal functional differentiation within a single sociolinguistic tradition. Furthermore, when language shift occurs in a bilingual community such as Paraguay, it is usually the more prestigious variety or the H variety that replaces the L variety. On the other hand, in the terminal stages of diglossia (in Ferguson's sense), the L variety often displaces the H variety. Synchronically speaking, the two language situations may appear the same. Diachronically speaking, however, they are rather different.

In recent years, scholars have called for a shift in focus in research on diglossia. Some suggest more cross-community studies that examine the origin and the development of various diglossic situations. Another kind of productive research, as Ferguson pointed out in a more recent article, would be studying a given diglossic situation during a period of rapid social and linguistic change.

Discourse Analysis

The term discourse analysis was introduced by Zellig Harris in 1952. In an effort to analyze connected speech and writing, Harris took language description beyond the sentence, examining what language elements might occur next to each other, or in the same linguistic environment.

Originating in the field of sociology in the early 1960s, conversation analysis explores norms and patterns in spoken interactions. Conversation analysis pays particular attention to everyday interactions such as casual conversations, 'chat', and 'ordinary narratives'. Conversation analysts have, however, also examined other interactions such as doctor–patient consultations, legal hearings, news interviews, psychiatric interviews, and interactions in courtrooms and classrooms. One of the aims of the conversation analyst is to avoid prior assumptions or speculations about analytical categories in the analysis of their data. Rather, they look for phenomena that regularly occur and then make that the point of further investigation. Researchers are particularly interested in the sequential structure and coherence of conversations.

The areas of research known as 'contrastive rhetoric' and 'contrastive discourse analysis' compare written and spoken genres in different languages and cultures. Kaplan's work in the mid-1960s is especially important here. Kaplan analyzed the organization of English as a second-language students' essays and found different patterns of organization for students from different cultural backgrounds. While many studies in this are focused on academic writing, studies have also been carried out that examine genres such as economic reports, business letters, and the use of language in everyday interactions from the point of view of discourse structuring, politeness strategies, and reader/writer/speaker orientations.

The Birmingham model of discourse analysis (see Sinclair and Coulthard 1975) proposed a 'rank structure' view of discourse, where discourse is made up of a number of lower level parts, much as a sentence is made up of ranked elements such as the clause, phrase, and word. Researchers recorded a number of British primary school classrooms based on the categories of lesson, and proposed a rank structure for the lesson: transaction, exchange, move, and act. They then drew up rules based on the data to show how the acts combined together to form moves, and the moves formed various kinds of exchange. The Birmingham approach has since been applied to many different interactional settings, such as medical examinations, TV quiz shows, and everyday conversation. The notion of moves has also been used in the area of genre analysis where researchers such as Swales and Dudley-Evans have examined the organizational structure of academic genres such as research articles, theses, and dissertations.

The Australian 'genre school', which originated in Sydney in the 1980s, utilizes the notion of language as a system of choices and views on the social functions of language are important here. Research in this area has examined spoken and written texts such as service encounters, academic essays, casual conversations,

and 'description', 'procedure', and 'exposition'-type texts. In particular, researchers use typical organizational structures and the language that is typically used in the realization of particular genres, to determine the relationship between grammatical and lexical items in texts. More recent research considers how relations of power and ideology shape discourse, and the effects that discourse has upon social identities, relations, knowledge, and beliefs. Critical contrastive rhetoric examines cultural differences in language and communication, viewing these differences as dynamic and situated in relations of power and ideologies.

A number of aspects of language use considered under the heading of discourse analysis are also often discussed under the more general heading of pragmatics. Pragmatics is especially interested in the relationship between language and context. It includes the study of how the interpretation of language depends on knowledge of the world, how speakers use and understand utterances, and how language use is influenced by relationships between speakers and hearers. In a relatively short time, the field of Discourse Analysis has examined issues of structure and coherence, while also placing the discussion within a broader social context. Research provides insights into the organization and interpretation of spoken and written discourse. However, what each of these schools of thought reveals is, in part, a result of the perspective the researchers have taken, and the questions they have asked.

Discourse Strategies

The concept of discourse strategy is based on a view of communication as a purposeful social activity. The success of this activity will depend on the application of a series of tactics involving linguistic resources (e.g. sounds, words, grammatical structures, topics, functions) as well as nonlinguistic resources (e.g. gestures, dress, proximity). According to this view, discourse strategies are all those linguistic moves that competent language users make, from several possible choices, in order to achieve their aim in what they consider to be the most efficient, effective, and appropriate way. The linguistic choices that language users make in adopting a particular communicative move may involve aspects related to form, i.e. how to say something, as well as aspects related to content, i.e. what to say. Formal choices include pronunciation, grammar, wording, and textual organization. Content choices basically involve the introduction of particular topics and functions.

Taking into account the cognitive process involved, discourse strategies may be approached from two points of view: (1) as an individual enterprise or (2) as a result of a social, interactional process involving the active participation of more than one individual. According to the first approach, a discourse strategy is an individual's implementation of a mental plan in response to an internal signal that a communicative problem needs to be solved. The second approach considers that discourse strategies can be studied as a result of the joint effort (represented by specific verbal moves) of two or more discourse participants to reach an agreement on their communicative and social intentions.

Besides being problem-based and intentional, discourse strategies are often defined as conscious. This is not a characteristic on which everybody agrees. Thus, it could well be that although at some point a speaker may have consciously decided to make a particular verbal move (for instance, responding to a greeting like *How do you do?* with the same question), this expression forms part of such a frequent communicative routine that it has become an automatic, and fairly obligatory, move. From this point of view, and given the difficulty in having access to the workings of speakers' minds, it might be better to avoid the issue of consciousness and to consider a discourse strategy as a systematic way of using language, which is generally recognized by the members of the speech community as aiming at a particular communicative goal.

One way of classifying discourse strategies is to take into account the communicative goal of the speaker. Thus, it is possible to conceive that human communication is the result of the speakers' mutual agreement to abide by two types of constraints related to (1) their social self and (2) the mode of communication being used. In this sense, speakers' deployment of a particular discourse strategy should be interpreted as an attempt to achieve their goal and, at the same time, attend to one or more communicative constraints. Thus, an utterance like *Can I have a cup of coffee?* can be interpreted as a means for the speaker to obtain a drink while attending to the social constraint of avoiding the impression that the conversation partner is being imposed on to carry out the action. Likewise, the use of a signal like *yeah* or *uh-huh* can be understood as a discourse strategy aimed at coping with the constraint of reciprocity that characterizes face-to-face conversation. The constraints proposed below should be understood not as precise maxims of communicative behavior but rather as scales along which individuals locate their discourse strategies depending on their cultural values and the situation in which they find themselves.

The constraints related to the social self that have been studied in greater detail are (1) presentation of self, (2) size of imposition, (3) social distance, and (4) power. In order to attend to each of these constraints, language users can adopt a series of discourse strategies that are conventionally accepted as effective moves. Let us look at some examples. To 'present' ourselves, we tend to avoid assertiveness by preceding our statements with parenthetical verbs like *I think...* or *I guess...* . In order to mitigate the 'imposition' of a

271

command like *Give me a cigarette*, we may express it by means of the question *Can I have a cigarette?* To attend to the 'social distance' or 'solidarity' constraint, we can address someone by their first name instead of their surname. Finally, it is possible to interpret a request for permission and its subsequent granting or refusal as a discourse strategy to acknowledge the 'power relationship' between the discourse participants. Depending on the context or their personality, the speakers may decide on the way they want to respond to the constraints and, consequently, on the 'discourse strategies' they will adopt. For instance, given a particular situation, it is not at all impossible to think of a speaker who at some point decides to show himself or herself as assertive, imposing, distant, and equal in power to the other speaker.

As for the constraints imposed by the mode of communication, in the case of face-to-face conversation, we can mention (1) topical coherence, (2) turn-taking, and (3) linear structure. To attend to the first constraint, speakers make use of discourse strategies like *by the way*, *like I said,* or *anyway* to introduce, reintroduce, or change a topic, respectively. The turn-taking constraint requires the speakers' deployment of strategies for taking the turn (e.g. *yeah but ...*, *let me just ...*), holding the turn (e.g. fillers like *um* or *well*, repetitions), and yielding the turn (e.g. questions, appealers like *you know, right?*). Finally, the constraint imposed by the fact that we produce and process language linearly, that is, one word after another, requires speakers to adopt discourse strategies like the use of the passive construction to change the information focus of the utterance or the choice from a wide array of connecting words or phrases to express the meaning relationship between one utterance and the following one. Other systems of communication (e.g. letters, e-mail, telephone, visual signals) may have different constraints and consequently may demand different discourse strategies.

Dravidian

A group of 24 languages spoken primarily in the Indian subcontinent make up the Dravidian family of languages. It is the second largest group of languages spoken in India, Indo-Aryan, a branch of Indo-European, being the largest. The other language groups of the subcontinent are Afro-Asiatic and Sino-Tibetan.

Out of 24 languages of the Dravidian group, four major literary Dravidian languages of the Southern Dravidian group are spoken in the southern Indian provinces of Karnataka, Andhra Pradesh, Tamil Nadu, and Kerala. Kannada is the language of Karnataka (40,000,000 speakers), Telugu, numerically the largest, is spoken in the province of Andhra Pradesh (over 75,000,000 speakers), Tamil, the oldest of all Dravidian languages, is spoken in the province of Tamil Nadu (70,000,000 speakers) and Malayalam is spoken in the province of Kerala (30,000,000 speakers). Irula, Kurumba, Tulu, Badaga, Toda, Kota, Koraga, and Kodagu are minor languages of the southern branch. The other minor languages are spoken in the northern and central parts of the Indian subcontinent.

Northern Dravidian languages, Brahui, Kurukh, and Malto are spoken in the province of Baluchistan in Pakistan, Bengal, and Orissa in India, Nepal, and Bangladesh.

Central Dravidian languages are represented by Gondi, Konda, Kuvi, Pengo, Manda, Parji, Kolami, Naikri, Gadaba and Naiki, and Kui. These are nonliterary languages spoken in the provinces of Andhra Pradesh, Madhya Pradesh, and Orissa in India.

The Dravidian languages form completely a separate group of languages, although Indo-Aryan languages have influenced the development of these languages primarily in the domain of phonology and lexicon. However, there have been attempts made earlier to link Dravidian languages to Finno-Ugric and Altaic group of languages.

Speakers of Dravidian languages have lived in the Indian subcontinent for more than 3,500 years and they have recorded history of more than 2,000 years. It was once thought that Dravidians were native to the Indian subcontinent. But, recent archeological, anthropological, and ethnographic studies dispute this claim. Based on the types of agricultural and navigational instruments used by these people, it is now believed that Dravidians must have come from West Africa and the Mediterranean region, and settled in the Indus river basin in present-day Pakistan around 4000 BC. The Dravidian civilization that flourished in and around Harappa and Mohenjedaro region on the banks of the Indus River came to be known as the 'Indus valley civilization'. The period of this civilization is broadly placed between 2500 and 1700 BC. Excavations done at this site led to the discovery of over 3,000 seals. These seals have logo-syllabic and pictographic writings on them. Attempts have been made to decipher these writings with very little success so far.

Typological Characteristics

Phonologically, the Dravidian consonant system consists of obstruents (p. t. ṭ. č, k); nasals (ṇ, n, ñ, m); laterals (l, ḷ); the flap (r(D)); semivowels (y, w); glottal (h), and voiced retroflex continuant (ṟ). The presence of retroflex series (ṭ, ṇ, ḷ, ṛ) is characteristic of the Dravidian consonant inventory.

Dravidian has five vowels (i, e, o, u, a) and the vowel length is distinctive. Word stress is predictable. If a word has short vowels, the initial syllable receives the primary stress. However, if a word has a syllable with long vowels (VV), then the syllable with long vowels receives the primary stress. The syllable pattern is basically of Consonant–Vowel (open syllable) type except that sonorants can close the syllable in some languages. If a root word/stem ends with an obstruent, a default vowel (u) is added to the end of the word; e.g. Kannada *kaaḍ.* root word for 'forest', is pronounced as *kaaḍu.*

Dravidian words are easily segmented into its constituent morphemes; e.g. Kannada *maaḍisikonḍanu* '(he) made (him) (do) (it)' is composed of *maaḍ* 'to do, make' + *is* 'causative' + *koḷ* 'reflexive' + *ḍ* 'past tense' + *an* 'third-person singular masculine' + *u* 'default vowel'. Dravidian words mostly have only suffixes and no prefixes.

Nouns in Dravidian inflect for case, number, gender, and person. Verbs in Dravidian are either finite or nonfinite. Finite verbs are inflected for both tense and subject–verb agreement while nonfinite verbs are not. Finite verbs are marked either for past or nonpast tense.

The default word order in a simple sentence is Subject–Object–Verb. Word order is free except that the verb has to be in the final position. In a typical complex sentence, the matrix clause follows rather than precedes its complement; e.g. Kannada *meeriyu awanige suḷḷu heeḷidaḷu endu (complement clause) jaananu tiḷididdanu (matrix clause)* 'John thought that Mary lied to him'. Similarly, relative clauses precede the noun they modify.

Dravidian languages use 'Brahmi' script, which has an alpha-syllabic writing style with diacritics used for vowels occurring in postconsonantal position.

Dutch

Dutch is one of the Western Germanic languages, a branch that belongs to the Germanic subgroup of the Indo-European family of languages. It stands about midway between English and German (both geographically and lexically) and is the closest to English of all the major languages of the Germanic family.

Dutch is an official language in the Netherlands and Belgium. It is the mother tongue of more than 21 million people in the Netherlands, in several provinces of Belgium called Flanders (Ghent, Brabant, Antwerpen, and Limburg), in the former Dutch colonies in America (Surinam) and Asia (Indonesia), and in the Netherlands Antilles in the Caribbean Sea.

In Belgium, the language is called Flemish (*Vlaams*), although there is practically no difference compared with Dutch in the Netherlands. Dutch and Flemish are actually the same language, but because of long-lasting cultural and religious reasons, there are two separate terms for one and the same language. The Flemish areas have been subject to French influence, especially from 1830 onward, when the state of Belgium came into being with French as the sole official language. In 1921, Belgium was divided into two linguistic sectors. Flemish became the official language in East Flanders, West Flanders, Antwerp, Limburg, and eastern Brabant, and French became the official language in all the other provinces. This linguistic frontier was adjusted in 1962 and 1963, and the two principal areas were made formally unilingual, but the Brussels region has remained bilingual (the Belgian capital was originally a Dutch-speaking town). However, the requirement for unilingualism applied only to the so-called *buitendienst* 'foreign affairs', i.e. it became compulsory in communications with officials and in official life in general, with a free choice for 'domestic affairs'.

The ancestor of Dutch was the West Low Franconian dialect of Germanic tribes. The history of the Dutch language (whose origin has been set by linguists at approximately 700 CE) may be divided into three main periods—Old, Middle, and Modern Dutch. Old Dutch extends to approximately 1150; there are few direct records of this language, but the only important extant monument of this period is a translation of the Psalter. Middle Dutch extends from 1150 to 1500 and is characterized by a significant influence from Latin and French and by the first Dutch dictionaries. In contrast to Old Dutch, a large number of Middle Dutch texts, both literary and official, have survived. Even from the time before 1300, more than 2,000 texts have been preserved. A large number of these texts are to be found in the *Corpus Gysseling*, which is a standard edition of Middle Dutch texts from the period before 1300.

In the sixteenth and seventeenth centuries, a new linguistic consciousness developed in the Netherlands. During this period, Modern Dutch began to form on the base of the dialect of the Amsterdam region after it had become the capital of an independent nation. In 1584, the first Dutch grammar appeared, written by the rhetorician H.L. Spieghel, the so-called *Twespraack vande Nederduitsche Letterkunst*, 'Dialogue of Dutch Letter Craft', presented in the form of a dialogue (*tweespraak*).

Modern Standard Dutch is the direct heir of the dialects spoken in the provinces of North and South Holland and Utrecht. Starting in the nineteenth century, this standard Dutch increasingly replaced the dialects of other provinces, even in oral use, especially among the more cultivated classes, and it was also adopted in Belgium.

Despite the rather limited geographical distribution of the Dutch language, there are a wide variety of regional dialects whose mutual intelligibility is often low. Traditionally, linguists divided Modern Dutch dialects into six large groups: (1) the central-western dialects, including all those in the provinces of North and South Holland and Utrecht, large parts of Gelderland, and the Zeeland Isles; (2) the northeastern dialects (often called 'Saxon') in Groningen, Drenthe, Overijsel, and the eastern part of Gelderland; (3) the central-southern dialects in the Netherlands province of North Brabant and adjacent parts of Limburg, and in the Belgian provinces of Antwerp, Brabant, and East Flanders; (4) the southwestern dialects in the Belgian province of West Flanders, French-Flanders, Zeeland, and the islands of Goeree and Overflakkee in the province of South Holland; (5) the southeastern dialects (often called 'Eastern Low Franconian') in Belgian and Dutch Limburg and some villages in north Brabant; and (6) the northwestern dialects in North Holland above the IJsselmeer, the non-Frisian Wadden islands, the coastal stretch of Holland province, and the South Holland islands apart from Goeree and Overflakkee.

Dialects that are geographically widely separated from each other sometimes show very significant differences: a speaker of the Groningen dialect will

scarcely be able to communicate with a speaker of West Flemish, unless they both speak standard Dutch. For most Dutch and Flemish speakers, the most evident division is into northern and southern dialects—to the South of the 'great rivers' (the Rhine and the Meuse), people use a 'soft *g*' that is not found in the North. For dialectologists, the contrast between East and West is more important because the western dialects still show a number of Coastal Germanic characteristics.

The Modern Dutch vowel system is the result of a great number of changes, but the Proto-Germanic consonant system has generally survived in Dutch.

The history of the Dutch language witnessed constant simplification in the domain of word structure. The noun system in Middle Dutch displayed three genders: common, neuter, and feminine. Today, Dutch nouns may be either common gender nouns or neuter nouns, with the former taking the definite article *de* and the latter *het*: *de man* 'the man', *de vrouw* 'the woman', *het kind* 'the child', *het huis* 'the house'. The feminine gender has been lost.

In the pronominal system, most pronominal categories make the distinction between two forms according to the nature of the concepts they stand for. Generally, there is a 'neutral' form, used for singular nonhuman referents, and one used for human referents, either plural or singular. Personal pronouns are the only Dutch words that still display a clear opposition between subject and object forms, i.e. Dutch pronouns distinguish between nominative and accusative case. However, there is no difference between 'accusative' (direct object) and 'dative' (indirect object) uses of the object forms.

Dutch word order is generally subject–object–verb; i.e. in basic main clauses, the verb is always in the second position, and it usually follows the subject. The verb appears at the end of the clause in subordinate clauses. It comes at the beginning of the clause in yes/no questions and imperative clauses and in main clauses preceded by a subordinate clause.

The Dutch language has known a long literature tradition, and its lexicon remains quite rich. Moreover, it is quite pure, because Dutch did not borrow many words from other languages. The languages that influenced Dutch over the centuries were French and its northern dialects (especially Picardian), mainly in Belgium, and classical and medieval Latin. Words of Germanic origin form the overwhelming majority of the noncomplex part of the basic vocabulary.

The Dutch spelling system (orthography) is based on the rules devised and published by the Dutch linguists De Vries and Lammert Allard Te Winkel in 1864 and was adopted officially both in Belgium and in the Netherlands in the second half of the nineteenth century. Its authors had used the criterion of 'received

pronunciation'; i.e. generally Dutch orthography closely reflects pronunciation.

Most loanwords come from English, not just as a matter of new technical concepts, but also of loans in varied areas of everyday life. In many cases, the spelling and pronunciation of the English words are adapted to fit Dutch usage. There are also many German loanwords in Dutch. Some of them are already so old and so adapted to Dutch usage that most people do not even realize that the words are of German origin (e.g. *tijdschrift* 'newspaper'). Other German loan-words have managed to retain their original sound and spelling, e.g. *sowieso* 'anyway'. Nowadays, the German influence has weakened because of the strong influence of English. Alongside many French loanwords, there are Dutch equivalents that could not be driven out completely and are now used in parallel. However, the French word is often preferred: *jus d'orange/sinaasappelsap* 'orange juice'.

Dutch had contacts mainly within the Germanic group of Indo-European languages. Contact of Dutch and native languages gave rise to creoles in the Dutch East Indies (as the so-called language of the Sinyos and Nonahs 'gentlemen and ladies'), in the former Danish Antilles (whose colonists were mainly Dutchmen), and in South Africa.

A language that has evolved directly from Dutch is *Afrikaans,* one of the two official languages of the Republic of South Africa, the other being English. It is spoken by more than 4 million people of the various ethnic groups found in the country. Afrikaans is also one of the two official languages of Namibia, a former protectorate of South Africa.

Like Dutch, Afrikaans is also a member of the Western Germanic languages. It developed in the seventeenth century from Dutch brought to South Africa by the first settlers from Holland. Originally, it was a popular dialect composed of Dutch with several borrowings from aboriginal languages of Africa (especially from the Khoisan family and the Niger-Congo family). By 1900, Afrikaans was emerging as an independent language, and in 1925 it was finally recognized as an official language, having been used in the schools and church since 1914 and permitted for use in universities since 1918.

At the level of pronunciation, there is an appreciable difference between Afrikaans and Dutch. Where Dutch uses *oo*, Afrikaans often has *eu,* and Dutch *a* and *aa* were replaced by *e*. Afrikaans is almost the only Germanic language that uses nasal vowels, especially before *s*.

The Afrikaans noun, displaying a pattern similar to the Dutch noun, fully lost the gender distinction.

The Afrikaans verbal system is characterized by the complete loss of person and number. In order to indicate tense, Afrikaans uses auxiliary verbs and adverbs.

During its history, Afrikaans was significantly influenced by the Zulu, Bushmen, and Gottentote languages of Africa, mainly with respect to vocabulary. The drastic simplifications in word structure may also be the result of lengthy contact with African, Portuguese, and Malayan languages as well.

Dyslexia

There are two broad categories of dyslexia: acquired and developmental. 'Acquired dyslexia' is a failure of the ability to read that sometimes follows a stroke or other condition that causes injury to the brain. Lesions of the parietal lobe and occipital regions, in particular, sometimes result in severe reading and/or writing difficulties. Often, there is some recovery, particularly if remedial training is given. The more common use of the term 'dyslexia' refers to developmental reading disability. 'Developmental dyslexia' is the failure to learn to read despite receiving instruction that is normally adequate. 'Dyslexia' has sometimes been applied to people who are nearly incapable of reading the simplest text. However, the term is more often used inclusively, of individuals who may read but do so with difficulty in comparison to their peers. A dyslexic, then, is someone whose level of reading ability, as measured by standardized tests, is substantially below the expected level for his or her age and level of schooling. For example, a child whose spoken language is English and who is of adequate intelligence and education but who reads below the 25th percentile on a standardized reading test may be considered dyslexic.

A precise definition of dyslexia depends on whether it is based only on a reader's performance relative to his or her peers (as in the example above), or on a discrepancy between the individual's reading performance and his or her general intellectual functioning. As an example of the latter, a conservative definition of dyslexia has been suggested for individuals whose reading test scores are more than 1.5 standard errors lower than their IQ scores (about a 75% difference) and who have at least the minimal intelligence needed to benefit from instruction in reading (e.g. an IQ of 80). However, discrepancy definitions are problematic. For example, a reader who has a high IQ but reads only moderately well would deviate from expectations of what should have been achieved, given his or her strong intelligence. Such a person would be classified as dyslexic by this formula in spite of being functionally literate. Further, definitions based on discrepancies between reading achievement and IQ have little theoretical or practical significance. It is adequate to define dyslexia only in terms of the reading performance itself relative to reading performance norms for the reader's age (omitting any reference to an IQ discrepancy).

A persistent myth is that dyslexics see letters and words backward. This belief is without foundation. Although reversals can be observed in many beginning readers, these reversals are caused by faulty learning, not by disordered visual perception. Few of these children become dyslexic. Current understanding of dyslexia is that it is not primarily a visual but a language-based disorder, particularly a disorder of sound perception and production. In order to read print in an alphabetic writing system (such as English, Russian, or Arabic—but not Chinese or Japanese), good readers must be able to read words they have never seen before. In order to do this, they must understand the alphabetic principle: that letters correspond to sound units or segments, the fundamental components of speech. To do this requires, in turn, an ability to understand that spoken words are sequences of those sound

segments. With this understanding, a reader can 'sound out' (or 'decode') a printed word, thereby identifying it. Children who are dyslexic nearly always lack an ability to understand consciously the segmental nature of the spoken word. Tests designed to assess a child's ability may ask questions like, 'Can you say *monkey* without the *mmmm*?' or 'Which word has more sounds in it, *car* or *cart*?' The child who cannot respond appropriately is not able to consciously analyze the spoken form. Such a child is at an obvious disadvantage in learning spelling-to-sound correspondences.

Dyslexia is less prominent when the written language's spelling represents the spoken word in a simple, unambiguous manner. For example, the writing systems for Finnish, Russian, and Spanish (to name only a few so-called 'transparent' alphabetic orthographies) have an unambiguous relationship between each sound unit and each letter of the alphabet. Nearly all children who have adequate intelligence learn to decode in these languages. In contrast, so-called 'opaque' writing systems like English and Hebrew have a great deal of ambiguity in letter-to-sound relationships. In English, for example, there are many letters (in particular the vowels), each of which corresponds to several sounds. For example, the consonant letter *g* has three different pronunciations in the words *giant, get,* and *night*. Moreover, there are many sounds that can be represented by different spellings, e.g. compare the identical vowel sound in the words *chief, beef,* and *leaf*.

However, even if a child is able to sound out printed words, she or he will not necessarily become a skilled reader who can read words fluently (i.e. in a rapid, automatic manner) and comprehend well what is read. Even in writing systems that are not opaque or even alphabetic, nonfluent readers exist. Good comprehension in reading depends critically on being able to recognize printed words rapidly. Slow word recognition requires so much of the reader's attention and short-term memory that there is little left over to devote to the cognitive processing demands of comprehension (which includes understanding both grammatical information and meaning). For alphabetic writing systems, slow decoding is seen as the primary bottleneck that blocks good comprehension.

Current evidence from brain imaging research indicates that dyslexics are deficient in certain brain areas believed to be involved in sound processing, visual processing, and the coordination of the two. In spite of congenital individual differences in neurobiology, initial studies suggest that children who are identified early with neurological deficits in brain areas affecting their reading ability can be helped. Most useful is an intensive program of reading instruction that emphasizes the segmental nature of the spoken word and its correspondences to the writing system. This general approach is popularly called 'phonics', although, within that rubric, there are many different methods that differ in detail and effectiveness.

E

Emeneau, Murray Barnson

Growing up in Lunenberg, a linguistically unique small town in Nova Scotia, studying French, German, Latin, and Greek, it is easy to comprehend how a bright Canadian lad was destined to become a linguist. Combining a background in the classics, general linguistics, and anthropology, Murray Barnson Emeneau became one of the greatest linguistic Indologists of all time. A prolific author, no linguist interested in India can afford not to read him, while every general linguist will profit from his lucid prose, no matter what the field of specialization. Among his most noteworthy contributions are his work on the Indian *Sprachbund* or 'linguistic area', bilingualism and structural borrowing, linguistic prehistory, as well as Dravidian comparative linguistics and etymology.

Emeneau's overall approach to linguistics was influenced by the Boasian and Sapirian traditions, which consider it a major branch of cultural anthropology. His anthropological background was largely self-taught through voluminous reading, auditing courses taught by Edward Sapir while still at Yale, and associating with him from 1931 to 1935, and through three years of fieldwork on nonliterary languages in British India. Since academic positions were hard to secure during the years of the Great Depression and were virtually nonexistent for Indologists, Emeneau went off to India on a fellowship from Yale, the American Council of Learned Societies, and the American Philosophical Society. There, he did fieldwork from 1935 to 1938 in the Nilgiris on three little-known Dravidian languages: Toda, Kota, and Kodagu, as well as in central India, where he studied Kolami.

Thoroughly versed in Greek, Latin, Sanskrit, and comparative Indo-European at Dalhousie University, Halifax, Nova Scotia, Oxford University, and Yale, Emeneau brought with him a superb background for his (1931) Ph.D. dissertation, an edition of a Sanskrit folk tale text. His rigorous training under teachers Franklin Edgerton and Edgar H. Sturtevant, together with his experience in linguistic fieldwork, led to his innovative research of the Indian linguistic area — a topic that was totally neglected. Although the notion of the *Sprachbund* was known from the Caucasus, the Balkans, and the northwest coast of the United States (American Indian languages), Emeneau's pioneering investigation of the Indian scene describes a situation in which 'languages belonging to more than one family show traits in common which do not belong to the other members of (at least) one of the families' (Emeneau 1980:127). Franz Boas and Edward Sapir had discussed the problems of the diffusion of linguistic traits across genetic boundaries, using data from various American Indian phyla, and Emeneau used their methodology to investigate the historical relationships of the three major subcontinent language families coming in contact: Indo-Aryan, Dravidian, and Munda (Austro-Asiatic).

Lexical borrowing has long been recognized, and all the Dravidian languages have loan words from Sanskrit and later Indo-Aryan languages. The Munda languages have been influenced by Indo-Aryan vocabulary, and Indo-Aryan languages have borrowed Dravidian words. The relationship among the three families is a direct reflection of the linguistic history and prehistory of India.

Two phonological features used by Emeneau are illustrative of the linguistic diffusion described above. Most Indian languages have a set of retroflex consonants that contrast with dentals. A situation of pre-Indo-Aryan and pre-Dravidian bilingualism allowed pre-Indo-Aryan allophones to diffuse as redistributed retroflex phonemes. Furthermore, Emeneau demonstrated that the Peshawar dialect of (Iranian) Pashto has been Indianized in the occurrence of the retroflexes as well as in borrowing many words from modern Indo-Aryan. Since the retroflexes are Proto-Dravidian and not Proto-Indo-European, this is a clear case of phonological influence, or as Emeneau put it, 'the Indianization of the Indo-European component' (1980:111).

Another example of phonological influence concerns the palatals. In Marathi, the palatals of Old Indo-Aryan affricated into *č* and *ǰ* before front vowels and *ts* and *dz* before back vowels. As a similar development occurs in Indo-Aryan Oriya, in two Dravidian languages, Telugu and Kannada, and in the Munda language Kurky, one can conclude that all of these languages are in contact and form a continuum across central India.

One of the most interesting phenomena used by Emeneau to illustrate areal diffusion is the case of numeral classifiers. The research demonstrates that Indo-Aryan is closer to Dravidian than to Indo-European. Further, the Magadhan languages of modern Indo-Aryan seem to be the origin of all Indian classifier systems.

Two other areal traits deserve mention. First, Dravidian and Indo-Aryan have similar onomatopoeic systems, each with stems that occur in reduplicated and nonreduplicated forms and verbal derivations therefrom. Since it is doubtful that the Indo-Aryan system derives from that of Proto-Indo-European, Dravidian influence is likely, which would account for the Rigvedic occurrences. Second, the North Indo-Aryan verbal system of intransitive, transitive, and causative is reminiscent of the Dravidian causative system.

As for Emeneau's comparative Dravidian work, the genetic relationship among the members of this closely related family (more like Romance than like Indo-European [1980:74]) was of interest to him from the very beginning, and etymologies were easy to discern. Emeneau correctly theorized that the relationship among Latin, English, and Proto-Indo-European was mirrored by that of Kolami, Telugu, and Proto-Dravidian. Emeneau's research on the Kolami lexicon may serve as illustrative: 720 words had good Dravidian etymologies; however, 166 of these were found to be borrowings from Telugu. Desiring to produce a definitive etymological dictionary of this neglected family, Emeneau traveled to England in 1949 and proposed a comparative Dravidian dictionary to England's leading Indologist, the late Thomas Burrow of Oxford University. In many ways, Emeneau's *magum opus*, the coauthored *Dravidian etymological dictionary* (Oxford: Clarendon Press), first published in 1961, 2nd ed. in 1984, capped a long and as yet unfinished distinguished career.

Biography

Murray Barnson Emeneau was born in Lunenburg, Nova Scotia on February 28, 1904. He received his BA (1923 Dalhousie University and 1926 Oxon.), MA (1935 Oxon.), and Ph.D. (1931) from Yale University. He was a Rhodes Scholar in 1923–1926; Governor-General's Gold Medallist 1923; Guggenheim Fellow in 1949–1950, 1956–1957; Faculty Research Lecturer, UC Berkeley in 1955–1956; and Wilbur Lucius Cross Medallist, Yale Graduate School in 1969. He was an instructor of Latin in Yale in 1926–1931; he carried out anthropological linguistic research in India on Dravidian languages in 1935–1938. He was Assistant Professor of Sanskrit and General Linguistics at UC Berkeley in 1940–1943; Associate Professor, 1943–1946; Professor, 1946–1971; and Founder and Chairman, Dept. of Linguistics, UC Berkeley, 1953. He received honorary degrees (L.H.D.) from the University of Chicago in 1968; LL.D. from Dalhousie University in 1970; D.Litt. Emotion and Language

There is no established definition of emotion. The term is usually used to refer to feelings, such as joy, jealousy, or disappointment, but it is also used to refer to more diffuse types of moods, such as irritability or stress. Furthermore, it is not clear how many emotions exist. Many disciplines have addressed the issue, and results diverge considerably. Some accounts from psychology list more than 500, but other accounts assume a much smaller number.

Expressing emotions is one of the most fundamental functions of language. This function has been termed 'emotive' (or 'expressive'). Although it may not be the dominant function in many cases, the emotive function affects virtually all utterances.

Emotions may be expressed at all linguistic levels. Semilinguistic noises, such as *wow*, *ouch*, or *tut-tut*, are traditionally classified as interjections. Interjections are considered purely emotive signs. They do not have any cognitive meaning. A conventional feature on the phonetic level is the emphatic prolongation of a vowel, as in [bi:g] for *big*, as opposed to neutral [big]. Intonation and other phenomena, such as word stress, also play an important role. On the word level, the emotive function is expressed, for example, by the so-called diminutive suffixes and familiarity markers, as in *doggie*, *weirdo*, *fats*, and *babykins*. Other word-formation devices include reduplication, e.g. *teeny-weeny*, *okey-dokey*. Emotion can also be expressed by stylistically marked word choices, e.g. *bean* for head. Further lexical means include terms of endearment and swear words. On the sentence level, we find intensification and emphatic repetition (e.g. *This is very very ugly*, *He worked and worked*) and exclamations such as *What a sight!* On the discourse level, speech acts such as insults are important means of communicating emotions. Ritualized communicative patterns are used to react to social standard situations concerning illness, death, birth, etc.; i.e. they are expressions of grief, sadness, commiseration, or happiness.

A distinction can be made between words that express emotions and words that evoke emotions. The latter type can be illustrated by examples such as *mother*, *brother*, *friend*, or *hometown*. Furthermore, utterances may evoke an emotion in the addressee; e.g. a derogatory remark may cause an outburst of fury.

Emotions can also be expressed paralinguistically. Relevant paralinguistic features involve higher pitch, increased tempo, a trembling or a creaky voice, groaning, giggling, and laughing. It is worth noting that different ways of laughing may express different emotions, e.g. an embarrassed laugh, a derisive laugh, or relieved laughter.

Problems in verbal planning and delivery can also signal emotion. Examples include hesitation, repetition, stammering, and unfinished sentences. On the level of turn-taking and discourse organization, phenomena (potentially) indicative of emotion involve interruptions, intentional overlap, simultaneous speech, and—as an extreme form—shouting somebody down. On the level of topic selection and topic treatment, emotions may motivate the choice of taboo topics, or speaking the plain truth.

Emotions can be communicated not only linguistically and paralinguistically but also nonverbally. Nonverbal behavior of this type includes, first and foremost, facial expression. Contrary to popular belief, facial expression conveying a particular feeling is not universal, but culture specific.

Apart from studying verbal manifestations of emotions, linguistics also investigates the way we speak about emotions: when, how, and why humans talk about emotions and how emotions are negotiated in discourse. Emotion words and emotion concepts are the focus of semantic analysis.

Every language has an emotion lexicon, i.e. a set of words that function as labels for emotions. These are used to name and communicate about emotions. The emotion lexicon consists predominantly of nouns, e.g. *fear*, *disgust*, and *pride*, and adjectives, e.g. *sad*, *angry*, and *happy*.

Emotions can be positive, e.g. *joy*, *love*, or negative, e.g. *anxiety*, *shame*. Many emotion words, both nouns

and adjectives, form antonymous pairs, i.e. pairs of opposing emotions. Examples include *joy–sorrow*, *love–hate*, *happy–sad*. Some emotion words have more than one antonym, e.g. *joy–sorrow/grief*, and some emotion adjectives have two opposite partners, one that is related in form, e.g. *happy* vs. *unhappy*, and one that is related only in meaning, e.g. *happy* vs. *sad*. Antonyms related in form are the result of negation, i.e. of adding a negative prefix (e.g. *un-*). In this respect, the adjectival emotion lexicon displays certain asymmetries. For instance, *happy* can be negated (>*unhappy*), but *sad* cannot be negated (>**unsad*). As a rule, only positive emotion adjectives can be negated.

Emotion words form so-called lexical fields. These are subsets of the vocabulary of a language whose members are close or related in meaning. Emotion words of the same field name the same emotion or very similar emotions. For example, the word field ANGER comprises, among other words, *anger, rage, fury, wrath, ire, irritation, frustration, annoyance*, and *indignation*. The most typical representative of this field is *anger*. Less typical members include *annoyance* and *indignation*, whereas *bitterness* and *resentment* are considered only peripheral members. Some members refer to different intensities of the same emotion; e.g. *rage* is more intense than *anger*, and *fury* is even stronger than *rage*. *Annoyance*, on the other hand, is weaker than *anger*.

In the emotion lexicon, some words are considered more basic than others, because some emotions are considered more fundamental than others. This has been established empirically in both linguistics and psychology. The most basic emotions seem to be love, fear, anger, happiness, and sadness. When asked to enumerate emotions, native speakers of English are most likely to mention these five. There is a high degree of similarity concerning these emotions across languages, including not only Western European languages but also typologically distant languages. At the same time, no direct correspondence exists between the emotion vocabularies of different languages. For instance, the same lexical field may have a different number of members in different languages. For one English emotion word, there may be two or more possible translations in another language.

The way we speak about emotions reveals the way we think about them. Cognitive semantics demonstrates that we use metaphors for conceptualizing emotions. Emotion concepts are reflected in proverbs, idioms, and collocations, such as, for instance, *You make my blood boil* or *He's just letting off steam*. Such expressions illustrate that the central metaphor for anger is 'heat of fluid in a container'. Metaphorical expressions of other emotions show that the human body is generally seen as a container for emotions, as in *She was filled with love*, or *Her feelings overflowed*. To a large extent, however, emotion concepts are culture specific.

In summary, linguists examine how we communicate emotions and how we communicate about them. Emotions can be expressed linguistically, and also paralinguistically, at all levels of language. The emotive function is one of the most fundamental functions of human language. The emotion vocabulary is structured in lexical fields, involving basic vs. peripheral words as well as antonymous pairs. There is no one-to-one equivalence of emotion vocabularies across languages. Emotion concepts are reflected in culture-specific metaphorical expressions.

Empty Categories

The elements of a sentence do not always have to be pronounced. This is true in elliptical structures, in which elements have been left out for stylistic reasons or because they are easily recoverable from the context. After a statement such as *She did something weird*, a possible follow-up question would be *She did*

something weird?, but most speakers would prefer the truncated form *She did? Something weird* remains implied. Some linguists claim that sentences may also contain covert or null elements that are not the result of optional ellipsis, but always remain unpronounced. These are called *empty categories*. The reason for assuming the existence of such empty categories is that they contribute to the meaning of the sentence and that they can also play an important syntactic role. The task of the listener is to identify all these empty categories in a given sentence and to determine their proper function and interpretation. The task of the linguist goes beyond mere identification: a proper formal theory of language has to determine the specific properties of the contexts where these empty categories can appear.

In the early 1980s, Noam Chomsky proposed a classification of empty categories that are important for sentence structures. He identified several different types of empty categories and argued that they can be differentiated according to whether or not they are anaphoric and whether or not they are pronominal. Anaphoric elements refer back to elements that have been mentioned before and require an antecedent, typically in the same sentence. Pronominal elements function in a manner similar to pronouns such as *I*, *she*, or *they*, i.e. they may refer to entities that must be recoverable from the context but do not need to occur within the same sentence.

Consider first an infinitive subordinate clause, indicated by square brackets: *I want [to leave]*. Like all clauses, these must have a subject, i.e. someone who leaves. In this case, it is clear to the listener that the subject of the main clause (*I*) is also the subject of *leave*. However, it is not the case that the speaker could optionally insert *I* into the subject position of the subordinate clause; *I want I to leave* would be ungrammatical, and *I want me to leave* sounds somewhat strange. Thus, the empty subject is not the result of a stylistic type of ellipsis. Rather, Chomsky argued, this is the case of an empty subject that he called 'PRO'. The empty subject of the infinitive has to exist in the sentence structure, because it plays a part in the interpretation of the clause.

The element PRO has both pronominal and anaphoric properties. The fact that PRO is anaphoric means that, for its interpretation, it depends on another nominal phrase. In other words, PRO is 'controlled' by another nominal phrase. For example, in *John wanted [PRO to leave immediately]*, the referential properties of PRO depend on those of the controller, namely *John. John* can thus be considered the antecedent of PRO, and *PRO* is 'controlled' by *John*. There are two types of control: subject control and object control. In the first type, PRO depends for its interpretation on the subject of the main clause, as in *John promises his mother [PRO to study]*. In the second type, PRO has the same referent as the object of the main clause: *Mary forces her son [PRO to eat]*. Whether PRO is controlled by the subject or by the object depends uniquely on the properties of the main verb.

The fact that PRO is also pronominal means that the interpretation of PRO can be the same as a pronoun. In *It is better [PRO to take the car]*, PRO may have the same interpretation as *they* in *It is better [that they take the car]*. In sentences like *It is impossible [PRO to learn the secret code]*, the meaning of PRO is somewhat more vague and may be similar to *somebody* in *It is impossible [that somebody learns the secret code]*; PRO is said to have an arbitrary interpretation in such types of sentences. In its pronominal use, PRO is not controlled by an antecedent.

The second empty category is 'small' *pro*, the subject of an inflected verb. In languages such as Spanish and Italian, the pronoun subject can be left unexpressed, as in the Italian *Ha mangiato* '(He or she) has eaten'. There, the implicit subject is represented by *pro*: *pro ha mangiato*. 'Small' *pro* has to be present in such sentences because, just like large PRO, it represents the subject of the sentence and is thus crucial for its interpretation. Furthermore, it can act as an antecedent for anaphors. For example, the Italian reflexive *si* 'self/each other' in *pro si vedono spesso* '(They) often see each other' is anaphoric and has to rely on another sentence element for its interpretation. The only possible antecedent for the reflexive *si* in this sentence is the null subject of the verb.

The *pro* phenomenon is far from being unitary: sometimes *pro* acts exactly like a pronoun; it has a very specific interpretation, as in the above examples. Sometimes, however, *pro* is used nonreferentially, in contexts where the subject appears in postverbal position: *pro arriva un uomo* '(There) arrives a man'. In these cases, it acts as the nonovert counterpart of the English expletive *there*, i.e. a sentence element that is almost void of meaning. The notion of expletive *pro* has been criticized. The most important objection against this element is that it is postulated on purely theory-internal grounds, namely, the assumption that sentences require a subject *in front of* the verb. However, there is no empirical evidence to justify the existence of expletive *pro*.

Not all languages use *pro*. The languages that allow the pronominal subject to be unexpressed are called 'pro-drop languages' or 'null subject languages'. Since the 1970s, considerable work has been done to determine how *pro* is formally licensed in languages that use it. Many different hypotheses have been advanced,

but the idea present in almost every hypothesis is the 'richness of the verbal morphology'. It has often been said that *pro* appears in those languages that have a rich verbal morphology, i.e. in those languages in which the verb inflects for person, number, and gender. If the form of the verb already provides such clues about the subject, an empty subject is interpretable. Thus, in Spanish *pro hemos comido* 'we have eaten', *pro* is interpretable because the verbal inflection *-emos* clearly indicates that the subject must be first-person plural, i.e. 'we'.

The third type of empty categories depends on the assumption that the construction of certain (or all) sentences involves moving some elements around. For example, sentences like *The man has been bitten by the dog* are often claimed to involve movement of *the man* from the object position of the verb (see Figure 1).

The reasoning is that even though *the man* is in the grammatical subject position, the passive verb requires it to be interpreted as the object. Chomsky proposed that such movement leaves a 'trace', usually indicated by *t* (see Figure 2).

This type of movement trace is anaphoric, because its interpretation depends on *the man*. Because *the man* acts as the antecedent within the same clause, these traces are not pronominal: pro-

nouns do not allow an antecedent within the same clause.

Another type of trace is that left by question words, which are fronted in English (see Figure 3). *What*, here, is clearly not the subject of the sentence: *you* is the subject. Rather, *what* must be interpreted as the object of *done*.

Thus, Chomsky assumed that question formation involves moving the question word to the front of the sentence, again leaving a trace. Because *what* acts as the antecedent of the trace, the trace again cannot be pronominal. However, it cannot be anaphoric either, because it allows its antecedent to occur beyond the immediate sentence boundary, as in Figure 4.

The embedded sentence *that the famous painter will paint t* thus contains a trace without an antecedent within the same clause, something that typical anaphoric elements do not allow.

In short, there are four types of empty categories, PRO, *pro*, traces of regular noun phrase, and traces of question words. These four categories can be formally distinguished as follows: (1) PRO is anaphoric and pronominal; (2) *pro* is pronominal, but not anaphoric; (3) traces of regular noun phrases are anaphoric, but not pronominal; and (4) traces of question words are neither anaphoric nor pronominal.

Twenty years of linguistic research have thus provided a systematic classification of empty categories, and empty categories belong to the standard descriptive tools of linguists working in the Chomskyan tradition. However, one must keep in mind that competing theoretical frameworks do without empty categories or movement. Empty categories are thus theoretical metaphors that may or may not have a correspondence in the actual processing of sentences by human speakers and listeners.

Empty Morphemes

The concept of morpheme was defined by the first structuralists as the minimum linguistic unit containing signifier and meaning, that is, as a formal element with a content that cannot be divided into smaller segments that, in turn, also possess meaning: *preexistence* contains three meaningful morphemes (*pre-*, *-exist-*, and *-ence*) and cannot be divided into smaller meaningful parts.

The morphemes are recognized by their recurrence, that is to say, for their presence with the same meaning and the same form in different words: in the previous example, *pre-* also appears in *pre-history* or *pre-establish; exist* appears in *exist-ent* or *exist-ential*; and *-ence* in *prefer-ence* or *compet-ence*.

However, some linguists observed that this conception is not always sufficient, because not all the segments obtained by means of formal word analysis meet these characteristics. This can be observed in different situations:

1. The same content can be present in phonetically different segments: the regular English plurals have the forms /s/, /z/ o /iz/ (*hits* /ˈhits/, *boys* /ˈboiz/, *houses* /ˈhausiz/), depending on the circumstances.
2. A segment may not be formally divided in to smaller units, but it may seem to contain more than one meaning: in the lat. *amo*, the segment *-o* cannot be formally divided, but it contains the meanings for 'first person', 'present' and 'indicative'.
3. Some morphemes are linked to the extreme such that the boundary between them disappears, like it is the case of the Spanish *al* (*a + el*) or the French *au* (*à + le*).
4. Some morphemic contents appear in certain words, although they cannot be assigned to any part of the words: the difference between 'present' and 'past' observed in *I beat John every day* vs. *I beat John yesterday*, does not correspond to any formal segment of *beat*.
5. The formal analysis sometimes uncovers recurrent segments that are not necessarily assigned a meaning, such as the case of *-mit -* in the series formed by *remit, demit, commit…*

These problems affect the two faces that the morpheme, as a linguistic sign, possesses: it affects its signifier (problems 1–4) and meaning (problem 5). In order to try to solve them, the linguistic theory has formulated diverse ones. Among them, we are now interested in the following concepts:

On the one hand there is the established distinction between morpheme as the unit of a language, and morph, its phonetic realization. The separation of these two concepts allows to postulate that a biunivocal correspondence among them does not have to exist, in such a way that a morpheme can be represented by several morphs (called allomorphs; problem 1); a morph can comprise more than one morpheme (a phenomenon denominated syncretism; problem 2); the morphs of two morphemes can merge phonically (something usually known as amalgam or *morphs portmanteau*; problem 3); or a morphologic content may not correspond to any morph (it is said to be a zero morph; problem 4).

With respect to problem 5, which affects the meaning of the morpheme, two positions have been adopted that, although they are not always distinguished in the linguistic bibliography, is convenient to differentiate:

In the first place, some authors, adhering to the statement of Leonard Bloomfield that all production of the language is completely composed of morphemes (*principle of total accountability*), would likely affirm that elements like those that appear in the series *re-mit*, *de-mit*, *com-mit*, *trans-mit*; *re-fer*, *de-fer*, *pre-fer*, *in-fer*; *or cran-berry*, *boysen-berry*, *huckle-berry*, in spite of lacking a meaning definable in linguistic terms, they should be considered morphemes, because they appear in a recurrent way in diverse words (the prefixes *de-*, *re-*, *con-*, etc. and the roots *mit* and *fer* are present in many words of the English language) or simply because they appear linked to forms that appear in some other constructions (*cran -*, *boysen-*, and *huckle-* only appear in these three cases, but *berry* appears scattered and it combines with other morphemes in *straw-berry, blue-berry or black-berry*). Consequently, these would be morphemes lacking meaning, or *empty morphemes*.

Such an interpretation comes from Bloomfield himself, who would affirm that if a complex linguistic form contains a residual, it should necessarily be another linguistic form (as in the case of *cran-berry*), and that forms such as *remit* or *conceive* should be interpreted as complex words despite the fact that, in them, the meaning of the morphemes is impossible to

describe. This affirmation would be adopted by later linguists, as the case of Zellig Harris, Eugene Nida, Robert Robins, or Mark Aronoff.

The main consequence of this method of analyzing data is a substantial modification of the concept of morpheme. According to many modern authors, this unit can only be defined as the minimum unit of grammatical analysis, that is, a unit that appears recurrently in the words and that allows the differentiation of some words from others. A paradigmatic example of this idea is the definition by Aronoff: 'A morpheme is a phonetic string which can be connected to a linguistic entity outside that string. What is important is not its meaning, but its arbitrariness.'

Opposing this interpretation, Charles Hockett would speak of the empty morph, a term with which he designates the portion of phonic material morphologically irrelevant, that is to say, a morph that does not correspond to any morpheme of the language. For example, in the form of the Fox language *poon-i-meewa* 'he stops speaking to him', the segment *-i -* lacks semantic content; hence, it should be considered a morph that does not correspond to any morpheme of that language.

This interpretation seems identical to the previous one at first glance. In fact, it also alludes to the appearance in certain words of segments that cannot be assigned a meaning, and, as before, it also allows maintaining the principle of total accountability. However, the conceptual difference among both positions is large: the first one explicitly refuses that morphemes necessarily possess meaning; the interpretation of Hockett, on the other hand, defends the definition of the morpheme as a unit with meaning, because the segments without meaning are not morphemes, but simply, morphs.

However, not all the linguists accept these interpretations, and there are many who prefer to think of words like the ones mentioned in this article as monomorphic, since the analysis of, for example, *remit* into two morphemes can only be based on exclusively formal considerations. However, in approaches that emphasize the meaning and mechanisms that the speaker triggers when using the language, purely formal generalizations may not be of interest.

Endangered Languages

There are some 6,700 known languages in the world, and linguists estimate that 40–90% of them will disappear during this century, a situation generating alarm among linguists and the speakers of languages threatened with disappearance. There is a strong correlation between a language's vitality, or likelihood of being transmitted from generation to generation, and the number of speakers it has. In this respect, the world's languages are unevenly distributed: approximately half the world's population speaks one of just 20 languages, and eight languages (Mandarin, Spanish, English, Bengali, Hindi, Portuguese, Russian, and Japanese) have over 100 million speakers. Ninety-six percent of all languages are spoken by just 4% of the population, and approximately one fourth of all languages have less than 1,000 speakers. In North America alone, fewer than 200 languages remain, although there were certainly hundreds of distinct languages several centuries ago. Today, only a handful of these (e.g. Cree, Dakota, Ojibwa, Navajo)

have a hope of survival, and even their security is doubtful.

In a few cases language loss occurs due to the loss of the speaker population itself. Language change and loss are natural, ongoing processes. Latin, for example, was 'lost' in the sense that its various dialects evolved over time into the modern Romance languages, such as Spanish, French and Italian. Some languages disappear entirely, and it is this absolute language loss that is occurring at an unprecedented rate in modern times. The primary cause is language shift, when speakers cease to speak their own native tongue in favor of the language of what is usually the dominant culture, dominant politically, and/or economically. Such a shift from the heritage to the dominant language can occur over several generations, or even as quickly as over the course of a single generation. In many cases, the oldest generation, the grandparents, speak the heritage language as their first and primary language, the middle generation has some knowledge but uses the dominant language primarily, and the youngest generation has little to no knowledge of the heritage language, and may at most know a few words or phrases. In cases of rapid language shift, however, these changes occur across a single generation.

Language vitality is usually ranked in terms of numbers and generations of speakers. On the one end of the scale are extinct languages that are no longer spoken, and on the other end are viable languages in no current threat of endangerment. In between a number of stages can be recognized. A healthy language with strong vitality is used with a variety of functions and in a range of settings (or domains) of language use. This is true even for bilingual speakers, where one language or linguistic variety is used in personal and home life (e.g. at home, with friends, at social events, etc.) and a different language or variety is used at the workplace, or in more public or official settings. In cases of language attrition, however, the native language is used in increasingly fewer domains with fewer functions.

The causes of language attrition and loss are complex and vary with individual situations. Although significant, the size of the speaker population is not the only reliable predictor of language vitality. Languages with relatively few speakers can be more stable than languages with a larger speaker base. Navajo, a Native American language, provides an example of a language long considered to be stable because of its relatively large number of speakers. It is now considered endangered, due to rapid language shift stemming from a combination of social and economic factors. Two key factors—relative isolation and a strong sense of community identity—can help a language's vitality. The opposite influences—heavy language contact and a weakened sense of ethnic identity (and pride) can increase the likelihood of language shift.

Members of a language community often believe that knowledge of the dominant language is necessary to be successful in the dominant culture, and that knowledge of the heritage language is a hindrance to socioeconomic advancement. This is closely linked to the prestige factor: the heritage language often suffers from a general lack of prestige. There may be no conscious decision to shift from one language to another; rather, the youngest generation learns the dominant language through contact and, frequently, in the schools. Despite the fact that speakers abandon their native tongue for what they deem to be pragmatic and/or prestige factors, the majority of communities that have lost their language subsequently experience this as a deep and regrettable loss.

Native communities and linguists alike are responding to the threat of language endangerment in a number of ways. Language revitalization programs are being implemented in a number of areas; these aim to (re)educate speakers in their heritage language and promote its use. Technical support includes the development of pedagogical materials, dictionaries, the introduction of radio and television broadcasts, and the use of the Internet. Linguists are involved in the recording and documentation of endangered languages and the writing of grammatical descriptions of the endangered languages. They often play a key role in the development of alphabets and literary standards for previously unwritten languages. One crucial and often controversial issue in the development of many literary languages is the selection of the dialect or variety that will serve as the basis for the standard language. Revitalization programs face a number of obstacles, such as a lack of pedagogical materials and trained teachers, and the lack of financial resources to implement any of these.

English

In 1780, English was a language with fewer than 15 million speakers, most of whom lived in England, Ireland, Scotland, the United States of America, Canada, and the Caribbean. Yet, John Adams foresaw a world where English would play a larger role:

> English is destined to be in the next and succeeding centuries more generally the language of the world than Latin was in the last or French in the present age. The reason for this is obvious, because the increasing population in America, and their universal connection and correspondence with all nations, aided by the influence of England in the world, whether great or small, force their language into general use. (quoted from McCrum et al. 1986:239)

Today, English has an estimated 350 million native and 400 million second-language speakers on all continents. The number of foreign language users easily tops the 400 million mark and is rising as globalization and modern technologies continue to impinge on all areas of modern life worldwide. In terms of political status, English is the national language in *native*, anglophone countries (United States of America, UK, Canada, Australia, New Zealand, Republic of Ireland, Bahamas, etc.), although none of these countries has declared English as its official language. English has (co-)official status in close to 30 countries, most of which had been colonies (e.g. Ghana, Philippines, India, Western Samoa, Costa Rica). It is the dominant language in international institutions (UN, IMF, APEC, EU) and outdoes other languages in international media, companies, conferences, air and maritime traffic, publications, and the web. Sociolinguistically, the norms of English (E) no longer emanate from a single source, even British (BrE) and American English (AmE) are only two of several norm-setting epicenters in a *pluricentric* world of E. National norms also exist in many second-language countries. Foreign language contexts, too, have been claimed to develop norms. It has been said that E is best described in terms of three overlapping circles: native, second, and foreign E. A traditional view, which is adopted here, recognizes a common core across all varieties.

History

As for genetic affiliation, E belongs to the West Germanic (WGmc) branch of Indo-Aryan languages and is related to German, Dutch, and Frisian. Danish, Swedish, and Norwegian are members of the North Germanic (NGmc) family, whose linguistic distance was, at the time of the formation of E, not so large as to inhibit communication—a fact that was relevant during the Old English (OE) period. E lost many WGmc traits during the OE and Middle English (ME) periods and has become a peripheral WGmc member.

Historically, E is the result of the transplantation of the dialects of the Angles, Saxons, Jutes, and Frisians, who invaded England in AD 449, forcing the Celts to the fringes of the islands or to assimilate. The *Anglo-Saxon* or OE phase of E (to c. 1100) witnessed the formation of several kingdoms, three of which (Northumbria, Mercia, and Wessex) gained enough power to create dialects. A national form of E did not develop. The Anglo-Saxons became victims of the Viking invasions from the middle of the eighth century. King Alfred of Wessex was able to defeat them at the end of the ninth century and forced them north of a line from London to Chester (Danelaw). England was partitioned into a NGmc/WGmc north and a WGmc south. Sociolinguistically, the Viking invasions were an obstacle to the formation of a national form of E at first, but after their defeat the sociopolitical and linguistic prestige of Wessex promoted the rise of a quasi-OE standard. Christianization (from the late sixth century) and the political support it had made Latin the language of religion and writing and introduced Latin, Greek, and Hebrew loanwords into E.

The Norman Conquest (Battle of Hastings, 1066) brought about the most significant change in the history of E. For over two centuries, England was under foreign rule. E was demoted to a *low*, rural language, and French and Latin were promoted to the *high* languages in a *triglossic* situation. French gained the status of a national, public language, as well as being the native language of the French aristocracy; Latin was the language of learning, where it was dominant up to the early Modern English period (EModE). There was some bilingualism among the Norman elite and the urban English; but the shift to E occurred when the Normans, facing the loss of their French possessions in the thirteenth century, decided to stay. As E regained status, it was no longer a mere continuation of its OE form. E was a second language for a transitional period, it absorbed thousands of French and Latin expressions, and, under the congruent influence of NGmc and French, lost most inflections and became a fixed word-order language. From 1400, a written standard developed in the Chancery, the oldest national institution; an

educated spoken form developed only from the sixteenth century. Standard BrE and the Received Pronunciation (RP) gradually rose to the position they enjoy today, with the former having greater national and international prestige than the latter, while the former has never ceased to be socially controversial.

As for expansion, E included Cornwall, when Wessex conquered that region during the OE period. The Anglo-Normans founded settlements in coastal, eastern Ireland (The Pale) in the twelfth century, which were soon Gaelicized. The decisive steps forward were made during the Age of Exploration. At the beginning of the seventeenth century, the East India Company transported E to India (1600). In 1607, the foundation of the first American colony, Virginia, transplanted E to America, although some experts argue that whaling had taken E speakers to Newfoundland and Nova Scotia earlier. Slave ships brought E to West Africa and the Caribbean islands. The Bermuda settlement, for instance, was founded in 1609. As for the British Isles, Ireland came under British domination during the reign of Elizabeth I and James I. The Union with Britain in 1801 was a blow to her linguistic independence, leading to the decline of Gaelic, the shift to E, and the development of IrE, which incorporated some Gaelic features. Gaelic has survived in the west and made a recent recovery, partly due to the European Union's language policies. Scotland's southeast had been English from the OE period, but Scotland succeeded in developing a national variety, *Scots*, during ME. The Union of Crowns (1603), the Union of Parliaments (1707), and the defeat of the Highland uprising in the mid-eighteenth century intensified the E influence so much that Scotland was anglicized by the late eighteenth century. Scots declined, but revived as a literary form in the nineteenth century, Gaelic was forced to the Highlands and western islands, Norn to the Shetlands and Orkneys, where it died out in the eighteenth century.

The seventeenth century paved the way for global expansion, and the eighteenth and nineteenth centuries witenessed the most significant geographic and sociopolitical growth. The East India Company, for instance, had been no more than a commercial 'player', with *factories* (trading outposts) in coastal cities. Only by the middle of the eighteenth century did it gain political control over Bengal. It took another 100 years for the subcontinent to become a Crown Colony (1857) and for an Indian elite to emerge that was willing to accept, and later to oppose, E. Similar developments occurred elsewhere in Asia and Africa. Although Anglophone from the beginning, Australia and New Zealand were fully known only by the end of the nineteenth century. The story of the western frontier in America is too well known to require recount-

ing. Again, it was only during the nineteenth century that the United States of America assumed its current extension and it was as late as at the turn of the twentieth century that the United States of America exported their E to the Philippines, Guam (1896), and the Caribbean. AmE was coming into its own and H.L. Mencken (*The American language*, 1919) could declare it to be a 'language', separate from BrE, an allusion to the debates about a 'Federal English' in the late 1770s. The mid-twentieth century witnessed further expansion. World War II took American soldiers to the theaters of war in Asia, Africa, and Europe. Its postwar economic, technological, and cultural power, Britain's enduring role in Europe and the Commonwealth, the problems that former colonies experienced in nation building, and the collapse of communism supported the further expansion of E, which was now fed mostly by the appeal of the United States of America and, logically, AmE.

Today's position of E is, thus, not entirely due to the migratory or imperialist expansion of Great Britain and the United States of America. There was a confluence of factors and it is worth emphasizing that the econo-cultural, technological impact of E was possible only at a particular juncture, as David Crystal explains:

> [But] international language dominance is not solely the result of military might. It may take a militarily powerful nation to establish a language, but it takes an economically powerful one to maintain and expand it. This has always been the case, but it became a particularly critical factor early in the twentieth century.... Any language at the centre of such an explosion of international activity would suddenly have found itself with a global status. And English ... was in the right place at the right time. (1997:8)

Just as postcolonial nations have been willing to retain E, so has the rest of the world where it is a foreign language. Real or perceived benefits attached to E act as powerful incentives and an E language industry guarantees easy access.

The expansion did not remain without consequences for the formal system and lexis of E, norms of use, and attitudes. Up to the seventeenth century, expansion may have amounted to no more than the formation of a single and contiguous British language community. The post-Renaissance period witnessed the formation of more — and distinct — communities: first, the American one (see below), then an (Anglo-) Indian one, and then others. English absorbed *foreign* elements, norms were diluted and others recreated, and attitudes of inferiority gave way to those of pride in one's own E. This development went unnoticed for a long time; it was welcomed in the early United States of America, when the notion of a Federal (American) English was promoted. In the early twentieth century it was, however, perceived as a dangerous disintegration

of the language: 'In our study of the growth of the Empire we forget that this territorial expansion of our language sowed the seeds of disintegration.' (Lloyd James, secretary, BBC language committee 1928; quoted from Leitner 1989:12).

E was a native (ENL), second (ESL), and foreign (EFL) language in widely different contexts, and assumed pluricentric characteristics, with American, British, Australian, Indian, etc., *epicenters*. Malaysia, Singapore, Hong Kong, and other nations face an uneasy choice between condoning the facts, i.e. localization, or endorsing an ideal, i.e. foreign, model. Many countries insist on native-like E but start accepting mixed BrE–AmE forms. Endonormative countries show signs of internal pluricentricity, with national norms coexisting with those of ethnic communities, such as Afro-American E or Australia's Aboriginal E. Although localization became a powerful factor, the disintegration of E was checked by the rise of educated, British-oriented middle classes in many countries during the nineteenth and twentieth centuries. Thus, pluricentricity has not completely diluted family relationships between E varieties. And internationalization is a new unifying factor.

Structure

A formal structural survey can exploit this situation. It will be based on a *common core* and point to areas of variation. Starting with phonology, vowel and consonant systems are quite similar, variation being limited to a few phonemic contrasts between BrE and AmE and, otherwise, being confined to phonetic detail. Scottish E (ScE) and some forms of AmE still distinguish *witch* from *which*. 'Flaps', short, voiced taps of the tip of the tongue against the alveolar ridge, are realizations of /t/ and /d/, e.g. *letter*, in AmE, AusE, New Zealand E (NZE), less so in BrE. Rhoticity differentiates a southern and northern type of E. The former — exemplified by southern BrE, AusE, NZE, and Indian E (IndE) — are nonrhotic and lack postvocalic /r/ in *car*. Rhotic accents, i.e. northern EE , ScE, IrE, AmE, and CanE, retain it. In RP, /l/ has a clear and a dark articulation, cf. *leaf* and *fall*; other varieties, e.g. AusE, may have a single articulation in all positions. /l/-vocalization in postvocalic position is typical of southern EE, especially popular London, and results in a dark vowel, e.g. *school* [skuo]. Vocalization occurs in AusE and NZE. RP has an exceptionally complex and imbalanced vowel system with its 21 mono-, di-, and triphthongs. For instance, *fit/feet*, *foot/food*, *abound/purr* illustrate the only long/short vowel pairs. Words like *pot* and *port* differ qualitatively, not in length. ScE has no phonemic length, length being determined by whether a vowel occurs in open or closed syllables. ScE is, in other words, more systematic than RP. The role of phonetic context on length is worth noting: word boundaries and voiced consonants lengthen vowels (*fee/feed/feet*). Centering diphthongs, e.g. in *pair* or *tour*, mainly occur in nonrhotic accents. An interesting characteristic is that vowels maintain a constant qualitative articulatory difference between them. Thus, all of RP's short vowels are fairly open; all long vowels (and rising diphthongs) start with a rather low vowel. In AusE and NZE, in contrast, short vowels are closer; long ones and rising diphthongs have an open (or back) onset. (Some southern E accents, e.g. London's Cockney, are similar in this respect.) These properties have given rise to speculations about a Second Great Vowel shift in 'southern hemisphere' E, but some experts argue for the conservative maintenance of older features of the East Anglia accent. The reduction of unstressed vowels is another area of variation. RP and many E accents use the *bit* vowel, AusE, NZE and—more advanced RP—have a schwa. Homophony between word pairs like *boxes* and *boxers* is the result. Accents differ most perhaps in lexical phonology. Thus, *either* has /aɪ/ in RP, /i:/ in London's Cockney and genAmE; AusE may have either. From a comparative angle, one should add that E lacks front rounded vowels, which occur in WGmc languages. As for spelling, the AmE and BrE systems differ in a few areas (*center/-re*, *dialog/-ue*, *program/me*, *fueling/-lling*) and more numerously in the spellings of individual words (*check/cheque*). Other varieties follow one or the other system, or attempt to develop a system of their own, as AusE does.

E differs most from contemporary WGmc languages in its paucity of inflectional morphology. Articles lack inflection, nouns have lost most inflectional contrasts (e.g. gender), leaving behind number and the possessive case, which has an analytic variant (*the roof of the car* for *the car's roof*). The genitive can mark an NP (*A friend of y brother's favorite car*) and fulfill a syntactic, phrasal function. As for number, the OE dual has been lost except semantically in *both, either* and *neither*, irregular forms, such as *umlaut* (*goose/geese*), *-en* (*ox/oxen*; *child/children*), and zero (*sheep/sheep*) reflect OE or ME patterns. Verbs have no inflectional contrasts for voice and mood. *Were* is a peripheral remnant of the subjunctive, which is expressed by means of *should* (mainly in BrE) or the bare infinitive (mainly AmE) (e.g. *I suggest he (should) resign from office*). What remains is a third-person singular in the present tense (*he goes* vs. *I/you/they go*), a simple present and past tense (*I like/I liked*), and the progressive, which is marked by *-ing* (in combination with a form of *be*). A striking aspect is a small number of ('strong'), but frequent, irregular verbs. Some verbs have three forms (*go, went, gone*),

others two (*buy, bought*), and still others one (*put*) for the infinitive, simple past and participle, respectively. There are other 'irregularities', e.g. vowel changes (*ta<u>ke</u>, <u>took</u>, ta<u>ken</u>*), remnants of old past tense or participle endings (*tak<u>en</u>, leapt*). As for adverbs, those with initial stress and two syllables have the *-ly* suffix (e.g. *beautifully*). Others are formed analytically (e.g. *in the most friendly fashion* instead of *friendlily). Nonstandard, dialectal varieties, and speech can have unmarked adverbs (e.g. *right*).

There is more inflection in pronouns. Personal and possessive pronouns have a nominative, possessive, and objective case (e.g. *I*, *my/mine*, *me*), and natural gender (in the third-person singular). *Wh*-pronouns have a type of (natural) gender (human/nonhuman, e.g. in *who* and *which*), case (genitive *whose*, objective *whom*). A widely discussed gap is the lack of a second-person singular/plural, which is available in languages like German (*du, ihr*) or French (*tu, vous*). OE had that distinction and, moreover, a dual. Most varieties, especially the standard ones, have lost both, but some have recreated it; consider AmE (*you/you all* or *y'all*, *you guys*) or IrE (*you/youse*), where it is a calque on the Gaelic *tu:sibh* contrast.

The trade-off between inflectional morphology and syntax is a good starting point for a survey of syntax. E is essentially an SVO language; other WGmc languages permit more variation. Thus, German has two standard orders, i.e. 'verb-second' and SOV, in main and dependent clauses, respectively. 'Verb-second' means that any order (SVO, OVS, AVS/O, etc.) is correct as long as V comes second. There is less flexibility in E, but it is not entirely absent, as these examples show: *The young student I like for his sense of humor* (OSV), *Down he came* (ASV), *Here comes the train* (AVS); SOV is impossible, except in verse. Mention must be made of cleft (*It is his sense of humor I like*), pseudocleft (*What I like is his sense of humor*), and existential sentences (*There is an interesting program on TV*). Non-SVO constructions are closely related to the information structure in discourse. Interrogatives manifest subject-auxiliary inversion, which is regular in polar questions (*Can he do that? Wasn't that a great show!*). A note on so-called guided questions, a side issue, is called for, as there is a good deal of variation. They arise when a high rising intonation contour is superimposed on a declarative construction (*So, you are having an ´affair?*) and permit the inference that the proposition contained is assumed to be true. ESL varieties, in contrast, often extend this pattern to ordinary polar questions (*He came home late?*) without that inference. A different pattern has been reported from AusE, NZE, IrE, some northern E dialects, and varieties of AmE: they combine a high rising tone with declarative word order to express social meanings of empathy, friendliness, etc., without the intention of asking a question (*My name is Betty ´Smith*).

Turning to grammatical relations, E contrasts with many languages, including WGmc ones, in ruling out subjectless sentences (G *mich friert* 'I am cold'), although spoken registers like sportscasting have them, if the subject is retrievable. E, however, permits a wide range of semantic roles to occur in subject position, while some of them are more marked in other languages where, as in German, semantic roles are encoded as adverbials. Consider the following examples:

> John can certainly act wonderfully well (Agent)
> This advertising campaign will open up new markets, we hope (Instrument)
> Berlin can be a rather cold city in winter (Location: Place)
> Money is not the problem, really (Object, Theme)

Verbal syntax is another area where E has characteristics of its own. Thus, E has a causative/processual contrast with transitive and intransitive constructions, provided the object of the transitive construction is identical to the subject of the intransitive one:

> John broke the glass
> The glass broke

Ergative constructions contrast with the passive voice, which implies agency without expressing it, while the intransitive-ergative construction attributes some kind of propensity to the subject, a feature that is clearer if manner adverbs occur, as in the following examples:

> The window pane breaks easily
> The line washes well and fast in this washing machine
> Potter's latest book sold extremely well

Two characteristics, i.e. particle verbs and nominal-verbal complexes, deserve mention as very frequent and productive markers of colloquial E. As to the former, several types of such prepositional verbs (*run up* (a hill)), phrasal verbs (*run up* (a bill), (a plan) *takes off*), and phrasal–prepositional verbs (*come up with* (a good idea)) can be identified. Nominalization creates 'particle nouns', which are often marked by stress (*to take* '*off* - '*take-off*). *Take a bath*, *give a smile*, *have a chat* illustrate nominal-verbal complexes that can often be replaced by the verb they contain formally (e.g. *to bathe, to smile, to chat*). There is, one might add, substantial variation with regard to the choice of e.g. *take, have*, etc. E, in contrast to, say, German also has a dynamic *have* (*have a baby*).

Let us close with tense, aspect, and modality. The future is expressed analytically by *will* (*There will be rain in the afternoon*). But there are other ways, e.g. *the chair <u>is going to</u> dip over, be careful*; *the Foreign*

Secretary <u>is about to</u> go to Kuwait; *I'<u>m coming</u>, don't worry*, *We <u>leave for</u> London tomorrow*, which all express subtler shades of future time reference, often merged with modal meanings. A sentence like '*I will come and see you later, John*' is both a promise and a prediction. Apart from being speech act markers, modals can express three types of meaning, i.e. deontic meaning (*I must be gone* = 'I am obliged to'), epistemic meaning (*He can't be there, the light's not on* = from what I know'), and what has been described as 'ability' meaning (*I could swim when I was a small child* = 'I was able'). These meanings interact with negation and question formation in ways that cannot be detailed here (std BrE *You mustn't* (= deontic) *be too strict with the boy* vs. *He *mustn't/cannot* (= epistemic) *be at home yet*), but which suggest that there will be considerable of variation, as there is; in ScE and AusE, for instance, that sentence is grammatical.

Apart from the 'instantaneous present' in sports commentaries (*Beckenbauer kicks the goal*), etc., the simple present has to be paired with the progressive to refer to present time (**Billy goes to school* (*now*) for *Billy <u>is going</u> to school* (*now*)). On its own, it expresses habitualness, etc. The simple past refers to a definite past time, even if it is unexpressed (*Billy went to school*), while the present perfect expresses indefinite past time and notions like current relevance (*I know New York, I have been there* [= indefinite past]; *Shakespeare has written important plays* [= current relevance]. A sentence like **Shakespeare has lived in Stratford*, in contrast, calls for the simple past, as there is no conceivable current relevance. Here, too, there is a great deal of variation. AmE, for instance, has a so-called colloquial simple past; the perfect is more formal (in contrast to, say, German and French, where the opposite would apply). There are constraints on the combination of the perfect with adverbs, such as *yet*, *already*. Once again, varieties differ a great deal. Std BrE, for instance, disallows **Did John come in yet*; AmE, AusE, BrE do not.

Lexis is especially interesting from a pluricentric perspective. The quite homogeneous, original WGmc word stock has been enriched by tens of thousands of expressions that E has absorbed from languages it has been in contact with. As a result, such words have been integrated; others have been lost or specialized to new meanings, uses, or stylistic patterns. Contact with Celtic and NGmc dialects provided the first nonnative influence. NGmc introduced some frequent words like *law*, *fellow*, *they*, and *both*. Some of them became referentially distinct (*skirt–shirt*), others dialectal (*kirk*, ScE). *Brogue*, *whisk(e)y*, and *Tory* are Celtic in origin. Latin has influenced E from as early as OE, even prior to the WGmc tribes settling in England, as *street* and *kitchen* suggest. Late OE loans from Latin are *sign*,

clerk, and *demon* (the latter two of Greek origin). French has exerted a pervasive and ongoing, if decreasing, influence toward the nineteenth century. With Romance words being so frequent, they barely require illustration, except to mention that Romance (and Greek) introduced a differentiation of style. Gmc words tend to be common and/or informal, Romance ones formal and/or technical: consider *begin-commence*. Romance also increased the potential of E word-formation patterns that derived from Wgmc, e.g. *kingly*, *royal*, and *regal*, and introduced new ones, e.g. in *-ify* (*beautify*), *-ate* (*nominate*), or *describe-descriptive-description*. The latter cannot be analyzed in terms of morpheme sequencing like *king+<u>dom</u>*. As a result of borrowing, the Gmc word stock is now a low 30% and the Romance one is 50%.

We now illustrate the absorption of expressions from languages that E in its standard E (ENL) and in ESLs varieties has come in contact with during its global expansion: American-Indian (*caucus* fr. Algonquian; *hickory*), Arabic (*zero*; *assassin*), Hindi (*sari*; *bandh call* 'call for a strike'), Telugu (*bandicoot*), Australian Aboriginal languages (*boomerang*; *cooee* 'type of call'), Malaysian/Singaporean E (*la* 'emphatic particle, fr. Chinese), African languages (*baobab*), Japanese (*rickshaw*; *karaoke*), German (*angst*; *-friendly*, see 'user-friendly), Malay (*jubah* 'in Islamic culture, a kind of clothing'), Spanish (*provinciana/o* 'woman/man from provinces, considered unsophisticated', current in Philippine E). Add to this loan translations, e.g. *acupressure* [< Jap.], *walkabout* ('walk in public', < Australian Aboriginal languages), or the productive use of some patterns in e.g. *crash-friendly* (cars).

The most important feature of all is the lexical creativity of new varieties. The impact of AmE on science, technology, the media, sports, informal E, and slang is too well known to require illustration. To mention a few older words, e.g. *to trade* 'to shop'; *to ship* 'to send'; *log-rolling*; *on the fence*, some of which echo the moving frontier society. Generally speaking, AmE is more informal and its dominant form is defined as *general* AmE, in contrast to the more elitist definition of standard BrE, especially RP. Well-known expressions in AusE are *mate* 'pal, friend', *to barrack for* 'to support (e.g. a sports team)', *bushie* 'someone who lives in the bush', in IndE *carlifter* 'car thief', *handphone* in Asian E. Localized idiomatic expressions, such as *We must meet again* (AmE), *Can I leave now*, or *Have I your permission to leave, Sir* (IndE, PakE 'it's been nice talking to you'), are highly visible and invite misunderstanding, as do words like Australian AborE *women's business* 'knowledge confined to (eligible) women'. Others such as *to jump the dragon gate* in Chinese E may not be understood at all.

Many expressions remain confined to local varieties, hence the pluricentricity of E; but many have become common and have made E a lexically rich language, as the *Oxford English dictionary* and *Webster's third international dictionary* and national dictionaries in Australia, India, etc., demonstrate.

With respect to word formation, three processes will be mentioned. The first is conversion or zero derivation, the most productive pattern today, which permits words to change word class membership without a formal marker (*chair—to chair*). Often, words occur in several word classes (*right* as a preposition, noun, verb, adjective, or adverb). Similar to conversion is the derivation of noun–verb pairs by means of a stress shift, as in '*import—to im'port*, '*take-off—to take 'off*. The second is the deletion of a preposition in prepositional verbs, which results in an ordinary transitive verb. Thus, *to appeal against a decision* becomes *appeal a decision*. The inverse process inserts a preposition (*to meet with*). The third is clipping (*bod < body*) and suffixation in *-i(e)* and *-o* (*pollie/y* < 'politician', *garbo* < 'garbageman'). Phonological adaptations may be necessary, e.g. *mossies* (< *mosquitoes*) with a /z/, like *Aussies*, instead of /s/. An interesting aspect of clipping is the formation of first names to express solidarity, acquaintance, etc.; consider *Kez* (< Kerry), *Baz* (< Barry) These processes are common in E, but their application may result in words that are specific to some variety of E. ESL varieties do not seem to add processes not found in native E either. Hybridization may be more frequent (IndE *bandh call* 'call for a strike'), although it also occurs in ENL context when a borrowed word may be difficult to understand (e.g. *koala bear* in AusE).

Formation of 'Englishes'

This *tour de force* has shown that the transplantation of dialects into new *habitats*, dialect contact, and contact with local languages have been the major factors that have shaped the development, texture, and status of E. Diversification has been the predominant outcome, the loss of a variety being rare. But it has happened, as the decline of Scots shows. Centrifugal and centripetal forces have always been active. Two themes must be added to this account, viz. the dating of important BrE and AmE bipolarity and English-based contact languages, especially pidgins and creoles.

The 'great divide' between the two main 'epicenters' of E, viz. BrE and AmE, has been a slow one, although signs of separation had been seen early. With respect to phonology, the divide has been dated at around 1750. The loss of postvocalic /r/ and of secondary stress in suffixes ('*secretary* vs. AmE '*secre,tary*) have remained confined to RP; others con-sider the unrounding of the *lot*-vowel, yod-dropping in *tune*, to genAmE. The dialect divide is difficult to date, but Webster's *American dictionary of the English language* (1828) is probably as good a marker as any. It marks differences in lexis, spelling, lexico-grammar, and grammar. Apart from the national element in American debates, a strong, shared, prescriptive tradition was visible during the late eighteenth and nineteenth centuries and counteracted separation. Bishop Lowth's, Murray's, or Cobbett's grammars, etc., catered to markets on both sides of the Atlantic. Prescriptivism continued, for instance, with Henry Alford's *The Queen's English* (1864), H.W. and F.G. Fowler's *The King's English* (1906), and H.W. Fowler's *A dictionary of modern English usage* (1926). Although they explicitly denied writing for an American market, which they perceived as different, Fowlers' books were used there. Debates about *Webster's third international dictionary* and English curricula in the United States of America show the strength of prescriptivism today. It is slowly giving way to descriptive approaches. The animosity of the British against AmE, which became a public topic at the end of the eighteenth century, has survived all intellectual shifts and extended its reach to practically all varieties of E of BrE descent.

Although they are considered distinct languages, E-based pidgins and creoles must be mentioned as they show, among others, the power of the language in intercultural situations. Pidgins typically emerged in colonization scenarios in Africa (e.g. Krio), the Caribbean (e.g. Jamaican Creole), southern states of the United States of America (e.g. Gullah), Australia (e.g. Kriol), India (e.g. Butler English), and the Pacific (e.g. Tok Pisin in New Guinea). Controversies about what factors gave rise to them, the formative role of superstrate E vis-à-vis local, substrate languages, the diffusion of pidgins through maritime traffic, and the role of universal processes of language development remain unresolved. The fact remains that pidgins and creoles are similar, whether one looks at North America, Africa, or the Pacific, where genetically and typologically different languages are used. The availability of E and upward social mobility draws them into the realm of mainstream E and they tend to become the (socially) *low*, nonstandard, end of a continuum that goes *up* to (national or international) standards of E. Ethnic forms, e.g. Afro-American E or Aboriginal E, are in a middle range. Speakers can exploit the continuum for communicative purposes, but it would be wrong to assume a simple 'upward' orientation, with the highest variety having the highest prestige. The 'high' variety may be merely used in outside communication or selected domains. Contact varieties often symbolize ethnic identities and show

verbal repertoires that differ significantly from mainstream E, such as Afro-American E or Jamaican Creole. The dialect continuum may be less real, sociolinguistically, than a formal analysis suggests.

John Adams's prediction of a global role of E has come true. But it is not the E that he may have had in mind. It is not bicentric, it is pluricentric, subject to conflicting forces that emphasize local and global trends. The future is hard to predict, but it seems unlikely that it will encourage disintegration.

Epenthesis and Syncope

Syncope (from Greek 'cutting off') and epenthesis (from Greek 'insertion') are cases of the more general phenomena of the deletion and insertion of segments, respectively. Initially utilized in the description of historical phonological change, use of the terms has been extended to characterize synchronic alternations as well. Most frequently, 'syncope' refers to the dropping of a word-internal unstressed vowel, as in Latin CALIDU(M) 'hot', NOBILE 'noble', VIRIDE(M) 'green', which became Spanish *caldo*, *noble*, *verde*, respectively. Expanded usage of the term 'syncope' covers dropping of a final vowel (also called 'apocope') as in Latin BLANCU(M) 'white', MURU(M) 'wall' becoming French *blanc*, *mur*, respectively.

Further extension to sounds (both vowels and consonants) in word-initial syllables (also known as 'aphaerisis') is less common, no doubt matching the lesser frequency of the phenomenon itself given the usual salience of initial syllables. However, it does occur, as reflected in the loss of initial /k/ in such English words as *knife* and *knee*, the initial vowels in *bishop* (from Latin *episcopus*), *possum* (from Algonquian *opossum*), *special* (from Old French *especial*), or the disappearance of initial /h/ in English dialects (Cockney being the typical example).

'Epenthesis', too, designates a variety of phenomena involving the insertion of both vowels and consonants. Consonantal epenthesis (where the appropriate

conditions are created by the previous syncope of Latin E) is illustrated in (1):

(1) | Latin | Old French | |
|---|---|---|
| CIN(E)REM | *cendre* | 'cinder' |
| *ESS(E)RE | *estre* | 'to be' |
| MOL(E)RE | *moldre* | 'to grind' |
| NUM(E)RU(M) | *nombre* | 'number' |

Note that, historically, English *empty* and *thunder* show epenthetic /p/ and /d/, respectively. Moreover, the English words (French loans all) *humble* — *humility*, *cinder* — *incinerate*, *number* — *enumerate*, etc., show both the remnants of historical epenthesis at the Old French stage and a minor synchronic alternation. This Old French epenthesis underlies a synchronic alternation occurring in a number of irregular verbs in Modern French: *connaître* — *connaissons* 'to know', *coudre* — *cousons* 'to sew', *craindre* — *craignons* 'to fear', *falloir* — *faudra* 'to be necessary', *tenir* — *tiendra* 'to hold', *valoir* — *vaudra* 'to be worth', *venir* — *viendra* 'to come', among others.

Consonantal epenthesis has been investigated using both phonological considerations and phonetic approaches. In phonological (syllable structure) terms, epenthesis often reinforces the onset of the second syllable. Thus, in *cendre*, earlier /n-r/ becomes /n-dr/ where syllable-initial /dr/ provides a stronger onset. In phonetic terms, the relative timing of nasalization or fricative cessation relative to the following segment results in the insertion of a transitional or epenthetic consonant.

'Epenthesis' can also refer to the insertion of a vowel in various positions in the word. Initial vocalic epenthesis (also known as 'prothesis') is seen in Latin SCHOLA 'school', SCRIBET 'he writes', STELLA 'star' becoming Spanish *escuela*, *escribe*, *estrella*. Word-internal vocalic epenthesis (also called 'anaptyxis' or 'svarabhakti', the latter from Sanskrit where the process is common) occurs variably in such nonstandard English pronunciations as *athalete* [æθəlijt], *artheritis* [aɹθəɹajDɪs], *fillum* [fɪləm] (standard *film*), while final epenthesis, normally of a consonant and much rarer, is seen in such English forms as *amongst*, *whilst* and nonstandard *acrosst*, *heightth* (with analogical pressures from *length*, *width*, and *depth* being the obvious source in the latter case). Historically, the final stops in *pheasant* and *sound* (< Old French *fesan* and *son*, respectively) are also epenthetic. As the foregoing discussion indicates, the addition or deletion of segments can occur in a variety of positions in the word, with a correspondingly complex set of terms reflecting this behavior. Not all scholars use all terms, moreover, and their use is not always consistent. The practice

described here — syncope for loss of a word-internal unstressed vowel; epenthesis as a more general term for vowel or consonant insertion, again word-internally — seem to reflect the most widespread usage (see Lass 1984:183–8 for a thorough survey).

Both syncope and epenthesis (in either their more limited or wider senses) are interesting because of the general theoretical issues they raise. Both are linked to phonotactic considerations — the constraints on sequences of segments or on syllable structure. Consonantal epenthesis often results in the addition of syllable-initial sounds and strengthens, as a consequence, syllable onsets (cf. *cendre* above). Vocalic epenthesis has the effect of separating consonants whose proximity violates the restrictions on consonantal combinations and leads to an improved syllable structure. Thus, in *athlete (athalete)*, the rare /θl/ sequence is interrupted by the insertion of schwa and a VC.CVC syllable structure (where V = vowel and C = consonant) becomes the more acceptable V.CV.CVC. Syncope, in addition to phonotactic considerations, is also sensitive to accentual and rhythmic patterns (accented vowels and vowels in initial syllables are rarely involved). Speech rate and word frequency also play a role: deletion of vowels is fostered by rapid speech, as we see in pronunciations such as /ptéjDow/ (or even *taters*) for *potato*, and the greater frequency of *memory* (> [mɛmɹij]) vs. *mammary* facilitates deletion of the penultimate vowel in the former. Finally, if the operation of syncope were to create a prohibited sequence, it is frequently the case that deletion is blocked or delayed. Consider the Latin forms in (2) where the vowel preceding stress would normally be expected to delete:

(2) | Latin | Old French | |
|---|---|---|
| CAPRIFOLIU | chevrefeuil | 'honeysuckle' |
| *PUTRITURA | porrëure | (Mod. French *pourriture* 'rottenness') |
| QUADRIFURCU | carreforc | (Mod. French *carrefour* 'crossroads') |

In each case, the highlighted vowel in Latin is retained as schwa in Old French because deletion would have produced the unacceptable consonant clusters PRF, TRT, and DRF, respectively. (Later simplification of the consonant groups obscures the original conditions.)

Syncope and epenthesis, as characteristic of deletion and insertion in general, are directly involved with a wide variety of central phonological issues. They are relevant to considerations of syllable structure and phonotactic constraints in general, of the rhythmic properties of speech, rule naturalness, and the use of phonetic explanations in phonology, and no doubt others. As such, the two processes merit wide-ranging and detailed attention.

Eskimo-Aleut

The Eskimo-Aleut language family is spoken from the Chukotkan Peninsula on the Siberian coast in the West to Greenland in the East. It includes two major branches, Aleut and Eskimo. Eskimo consists of at least two further subgroups, Yupik and Inuit, and there is some question as to the proper classification of Sirenikski, which may be a Yupik language or may constitute a third branch of Eskimo. The terms 'Eskimo' and 'Aleut' both have unclear origins, and they are not universally in use within the respective areas. Thus, it is commonly held that 'Eskimo' was derived from a derogatory Algonquian term meaning 'eaters of raw meat'; the negative association has led to the general replacement of 'Eskimo' with *Inuit*, the native term for 'people', in most of Canada, and there are various designations for the language, including *Inuttun, Inuktitut*, and others. The term 'Aleut' was bestowed on the people native to the Aleutian Islands and their language by Russians in the eighteenth century; the native term in use today for self-designation is *Unangan* or *Unangas* for the people and *Unangam Tunuu* for the language. Because there is still no other general term to describe all of the languages and dialects encompassed by the term 'Eskimo', and for reasons of linguistic tradition, both terms are still commonly used within the field of Eskimo-Aleut linguistics.

It is generally accepted that the Eskimo and Aleut people were part of a relatively late migration from Asia across the Bering Land Bridge, sometime between 4,000 and 6,000 years ago. The development and differentiation of Eskimo-Aleut are believed to have taken place in Alaska because of the linguistic diversity found on the Alaskan side. From Alaska, there was continued migration down to the Aleutians and eastward to Greenland. The split between Aleut and Eskimo is thought to have taken place around this time, although this figure is not undisputed, and there is archeological and skeletal evidence to suggest that the divergence between Aleut and Eskimo may be at least 9,000 years old. Various attempts have been made to link Eskimo-Aleut with other language families on the Asian continent, and thus trace the history of the language family even further back in time. While there is little solid linguistic evidence of a genetic relationship between Eskimo-Aleut and other language families, there are strong suggestions of very early contact, particularly with Uralic (for a thorough discussion of possible linguistic affinities and contact, see Fortescue 1998).

Within the Eskimo branch, the split between the Yupik and Inuit branches must have taken place about 2,000 years ago, and there is good linguistic evidence (e.g. shared phonological and prosodic features between Yupik and neighboring Inuit speakers in areas now no longer predominantly Yupik) for positing the prehistoric (i.e. prior to European contact in the eighteenth century) presence of a continuum of Yupik speakers around the Bering Strait. From their original homeland in Alaska around the Seward Peninsula, Yupik speakers gradually occupied southwestern Alaska and, moving westward across the Bering Strait, reoccupied the Chukchi Peninsula in Siberia. Central Siberian Yupik and neighboring Chukchi have gradually displaced Sirenikski, and the latter is now extinct. If Sirenikski is a separate branch of Eskimo, then it may have split off about 2,500 years ago and its origins may be on the Chukchi Peninsula. About 1,000 years ago, there was another eastward migration out of Alaska; known as the Thule culture, this very rapid migration is associated with the spread of the present-day Inuit language. The present dialect differentiation is possibly as recent as the past 500 years (see Dorais 1996). There is also evidence for the spread of Inuit speakers into Yupik-speaking territory in the Seward Peninsula in the past two centuries.

There are certain features that, taken together, are particularly characteristic of the Eskimo-Aleut language family. Thus:

- All languages have three basic vowels (i, u, a), which are derived from an original four-vowel system (i, u, a, and schwa, represented by [e] in Yupik, which maintains the four-vowel

distinction; [e] will be used to represent schwa in this discussion).

- All of the languages are almost exclusively suffixing, the only exception being an anaphoric prefix *ta-* on demonstrative stems (e.g. pan-Eskimo *una*, *tauna* 'this one').

- All are polysynthetic: to a greater or lesser degree within the language family, they allow for very complex verb structures that encode meanings for which other languages need whole sentences. This is particularly developed in Canada and Greenland; e.g. Holman Island Inuinnaqtun (example from Lowe, in Tersis and Therrien 2000:167):

iqaluk-hiu-riaqtu-qati-gi-tqiktaqpak-kalua-ramiung
fish-hunt-go.to.do-partner-have-several.times-even.though-he:him
'even though he went fishing several times with him'

- All are clause-chaining: sentences typically consist of a series of dependent clauses headed by an independent clause. In the following relatively simple example from West Greenlandic, there is one indicative clause and two subordinated participial clauses; clause chains can be quite extensive (example from Fortescue 1984:39):

irn-i   *qajartur-tuq*
son-his.own   be.out.in.kayak-his

qinnguar-paa
see.through. binoculars-he:him

natsirsu-up   *sursuk-kaa*
hooded.seal attack-it/his
'he$_i$ saw his son$_j$ through his binoculars being attacked by a hooded seal while in his$_j$ kayak'

- All have SOV (subject–object–verb) word order to a more or less fixed degree (Aleut has essentially fixed word order). Note that in the previous example, the object clause *irniq qajarturtuq* precedes the verb, and the subject of each of the subordinated clauses precedes its respective verb.

- All have, or originally had, a largely ergative–absolutive case-marking system (with extreme modifications in Aleut), where the subject of intransitive verbs receives the same marking as the object of transitive verbs, namely absolutive case, while the subject of transitive verbs receives a different marking: ergative case.

The Eskimo languages are much more closely related to each other than to Aleut. In addition to the common features listed for Eskimo-Aleut, they share

- certain restrictions on syllable and other phonological structures,
- up to four or five nongrammatical cases, in addition to ergative and absolutive cases (locative, modalis, ablative, allative, vialis, and equalis),
- transitive and antipassive structures, whose choice appears to be partially determined by definiteness, as in the Central Alaskan Yup'ik examples below:

Angute-m   *neqa*   *ner-aa*
man-ERG   fish-ABS   eat-he:it
'The man eats **the** fish'

Angun   *neq-mek*   *ner'-uq*
man-ABS   fish   eat-he
'The man eats **a** fish'

In the descriptions of the languages, there are also certain features that are commonly used to differentiate the individual languages or dialects. Below, Aleut, Yupik, and Inuit are described in terms of their major languages or dialects, the major linguistic features that differentiate them from each other, and their current status and outlook.

Aleut is a language with two clearly distinct, extant dialects, and at least two other dialects historically attested. Eastern Aleut is spoken east of Amukta Island to the Alaskan Peninsula, as well as on the Pribilof Islands. Atkan, also variously called Western or Central Aleut, is today spoken on Atka Island, and a version of it is spoken on Bering Island. A third dialect, Attuan, is essentially extinct, and it had close affinities with Atkan; a mixed language known as Copper Island Aleut, consisting of Attuan stems and Russian inflection, is still spoken on Bering Island. In very early descriptions, there was apparently a separate dialect spoken on the Rat Islands in between Attu and Atka, although almost no extant information is available on this form of Aleut. Characteristic of Aleut are

- phonological features such as its lack of a [p], and its aspirated nasals,
- consonant clusters that differ from those in Eskimo in their distribution (e.g. they are permitted word-initially, as in *sngaxsix* 'to dream'), in the combinations of consonants possible (e.g. velar–uvular fricatives), and in their complexity (allowing up to three consonants, as in Eastern Aleut *ixchxingin* 'his neck'),
- use of independent pronouns, as opposed to the complex verb structures of Eskimo languages:

Aleut   *txin*   *achix-ku-qing*
              you   teach-presently-I
              'I am teaching you'

Greenlandic   *ilinniar-tip-pakkit*
learn-cause-I:you
'I am teaching you'

- its typologically unusual agreement system, in which ergative case marking is only used if a transitive object or an object of posession is not overtly expressed:

  Tayaĝu-x̂   qa-x̂   qa-ku-x̂
  man   fish   eat-presently
  'The man eats the/a fish'

  Tayaĝu-m   qa-kuu
  man-ERG   eat-presently:he:it
  'The man eats it'

Modern Aleut also has a large proportion of Russian loanwords, the result of extensive contact with Russian traders and colonizers in the eighteenth and nineteenth centuries. As a result of early decimation of the people and later suppression of the language in schools, the language is severely endangered today, with at most 150 speakers in the Aleutian Islands, the Pribilof Islands, and Anchorage, and perhaps eight to ten on Bering Island. With the exception of Atkan, the speakers are elderly.

The Yupik languages include Naukanski, spoken around East Cape on the Chukchi Peninsula; Central Siberian Yupik, also spoken on the Chukchi Peninsula as well as on St. Lawrence island; Central Alaskan Yup'ik, spoken from Norton Sound to Bristol Bay in Alaska; and Sugpiaq, also known as Sugcestun or Alutiiq, spoken around Prince William Sound, the Alaskan Peninsula, Kodiak and Afognak Islands, and the tip of the Kenai Peninsula. Yupik languages are characterized by

- their retention of a fourth vowel that presumably stems from the ancestral (proto) Eskimo language (cf. Proto-Eskimo **neqe* became Central Alaskan Yup'ik *neqa* 'food', Iñupiaq *niqi* 'food')
- more or less complex effects of intonational stress; in stressed syllables, for example, the vowel is often lengthened (for more on Yupik prosody, see Krauss 1985).

There are some nonnegligible syntactic differences between the languages, although these have not yet been well described. Siberian Yupik languages have a number of English loan words, from contact with nineteenth-century whalers, and Alaskan Yupik languages have a large number of Russian loans from eighteenth to nineteenth century Russian colonization, as well as twentieth-century English loans. Most Yupik languages are severely endangered today, with numbers of speakers ranging from 70 (Naukanski) to 1,300 (Central Siberian Yupik). The notable exception is Central Alaskan Yup'ik, with about 10,000 speakers

(and on the Kenai Peninsula these include children), and with immersion programs in the schools and active production of learning materials.

Sirenikski is considered related to the Yupik languages; however, it has also been regarded as a separate branch of Eskimo. It is seen as an important link to Proto-Eskimo because of particularly conservative features such as a retention of consonants between vowels, which were lost in all other Eskimo-Aleut languages (e.g. Proto-Eskimo **ataʀuciʀ*, Sirenikski *ateɡesegh*, Central Alaskan Yup'ik *atauciq,* Iñupiaq *atausiq* 'one'). It has, however, undergone sound changes quite different from other Eskimo languages. For example, in all nonstressed (essentially noninitial) syllables (as in the example given above) the vowel changed to schwa. Unfortunately, it was first discovered and described at the end of the nineteenth century, when it was already highly moribund; the last speaker died in the year 2000.

Inuit is generally described as a language with four distinct dialect groups, each of which have their own recognizable subdialects; these groups include Alaskan Iñupiaq, with four major subdialects spoken from the Seward Peninsula and north; Western Canadian Inuit, with four major subdialects and spoken over a vast area of Central Arctic Canada from MacKenzie Coast to Repulse Bay; Eastern Canadian Inuktitut, with six major subdialects, spoken in Baffin Island, Arctic Québec, and Labrador; and Greenlandic Kalaallisut, with three major subdialects and spoken in Greenland (there is also a sizeable population of speakers in Denmark). Characteristics of Inuit are

- lack of intonational stress as compared with Yupik (with noticeable difference in intonational patterns between the dialect groups),
- loss of the fourth vowel, with various important phonological traces,
- various degrees of consonant and vowel cluster simplifications (cf. Iñupiaq *aglaun* 'pen', Greenlandic *allaat* 'pen', in which *gl became ll* and *au turned into aa*), and
- a tendency to merge parts of the tense system most important in narration, with most extensive merging in Alaska and least in Greenland.

In Alaska and Canada, large numbers of English loans are found; in Eastern Canada, there are also a few loans from French and German through the influence of missionaries. In Greenland, on the other hand, loans are predominantly from Danish. The status and viability of the language are quite different in the different regions. In Alaska and Western Canada, the language is severely endangered, with only about 3,000 speakers, almost none of whom are children. In Eastern Canada, there are about 20,000 speakers, but there is widespread bilingualism in almost all age-groups and a growing tendency for

English to replace Inuktitut. Active efforts are under way to reverse this process, including the encouragement of Inuktitut programs in schools. In Greenland, however, over 95% of the native population of some 50,000 are speakers of Kalaallisut, and the language is thriving.

Ethnicity and Language

The words 'ethnicity' and 'ethnic' were in common use at the end of the 20th century in contexts so widely disparate that no common definition will suffice to unite the variety of meanings. We speak of 'ethnic studies', 'ethnic groups' and 'ethnic neighborhoods', 'ethnic and racial groups', of 'ethnic revivals', and 'ethnic cleansing'—a euphemism for genocide that came into use in the 1990s when certain countries tried to drive minority 'ethnicities' from their territory through terror and murder. In the 2000 census of the United States, although the Census Bureau of the United States used traditional categories of 'race' such as White, Black, Asian, or Pacific Islander, American Indian or Alaska Native, Other, and Multiracial in gathering census data, any of these might equally well be regarded as 'ethnic' classifications in today's language usage. It is unclear where ethnicity leaves off and race begins. 'Hispanic', in the 2000 census, was stipulated by the Census Bureau as 'may be of any race'—which indicates the extent to which 'race' and 'ethnicity' overlap in contemporary discourse.

Ultimately, as we use the word today, ethnicity is not a matter of strict definition. It is a matter of identity: you are what you say you are and what other people think you are. We find it convenient in certain contexts to use the phrase 'ethnic group' for a wide variety of minorities in America and other countries: Irish Americans, Italian Americans, Asian Americans, immigrant South Asians and their children, Native Americans, African Americans, Roma (Gypsies) in the many countries where they live, French Canadians in Canada and Maine, Kurds in Turkey, Basques in Spain and France. In recent years, advocates of the interests of gay and deaf communities in America have argued for the benefits of using the term 'ethnic' in referring to these groups. 'Ethnicity' in current usage is so elastic and so convenient a term of reference that it may perhaps most usefully be defined simply as the 'Other'—a member of any minority group in a country who retains or is thought to retain the distinctive characteristics of that group.

Otherness links ethnicity and language. Language always has a setting. If this setting is the majority of a country's population, then the language of that majority will be the 'language of the country'. If this setting is an ethnic minority of a country's population, then the language of that ethnicity will either be a language different from the language of the country or a dialect

of the majority language that nevertheless differs significantly from it. Language does not exist apart from ethnicity; it is a visible badge of ethnicity. A different ethnicity therefore often implies a different language, or at least a different variant of a majority language. (We sometimes refer to ethnic dialects as 'ethnolects', modeled after the pattern of 'dialect' and 'idiolect', the speech of a single individual.)

From the end of the Civil War to the end of World War I (1865–1918), the population of the United States grew rapidly through immigration. There were prejudices and laws against immigration of members of 'races' thought to be inferior or 'incompatible' with the majority population of America—against Asians and Africans for example—but for others, gaining admittance to America was not difficult. This led to massive immigration from Ireland, Germany, Italy, Poland, Russia, Scotland, Sweden, England, and other predominantly European countries. Jews, who had faced discrimination and pogroms in the old country, emigrated from eastern Europe in large numbers to America during this period.

Initially, the new immigrants tended to settle where earlier immigrants from their country and members of their family had settled before them. The Lower East Side in Manhattan became a camp of crowded tenements divided along ethnic boundaries: Italian, Jewish, Irish, German. Every great city of the northeastern United States—Philadelphia, Pittsburgh, Boston—had similar concentrations of immigrants joined by ethnicity.

In most cases, the first wave of immigrants retained the language they had brought with them—Jews Yiddish, Italians Italian, Germans German, and so on—at least until their sons and daughters, born and educated in the United States of America, grew up without fluency in the ancestral tongue. The life of the Lower East Side of Manhattan at the turn of the twentieth century was vibrant with newspapers, magazines, social clubs, and theaters in the foreign languages of the immigrants. German-language newspapers, German-medium schools, and German-language churches flourished in areas of heavy German immigration—Wisconsin and central Texas, for example—down to World War I, when war with Germany made pro-German attitudes unpopular and even dangerous. Nonetheless, even into the 1960s one could hear German spoken in America by people who had never set foot in those German-speaking countries from which their grandparents and great-grandparents had emigrated.

America is often referred to as a 'melting pot', implying that different ethnicities merge into one uniform 'American identity' after the first generation of immigrants has assimilated to American life. Most students of ethnicity now have reservations about the melting pot theory. Nathan Glazer and Daniel Patrick Moynihan, in their influential book *Beyond the melting pot* (1963), set the tone for contemporary views when they insisted that 'the point about the melting pot is that it did not happen'. Ethnic minorities have proved to be far more tenacious in clinging to aspects of their Otherness—their ethnic identities—than the melting pot theory assumed. Some minorities, the Amish, for example, or Chasidic Jews, have successfully resisted any but superficial assimilation into mainstream American life.

However, to say that the melting pot is a faulty metaphor for the realities of American assimilation is less true of language than it is of such qualities of ethnicity as religion, cuisine, marriage patterns, and social customs. Foreign languages do not normally survive in America in the second generation except in areas where a large number of immigrants are concentrated, notably Spanish- speakers from many different Spanish-speaking countries in Miami, New York City, southern Texas, and southern California. There are pockets here and there in America where foreign languages defy the rule of second-generation loss, but there are always special circumstances at play in such cases. Examples are the preservation of the Basque language among shepherds in northern California and Québec French in northern Maine. The most common complaint of immigrants who remain in the United States is that their children lose the language; they learn English and rarely have native fluency in the language of their parents.

When the first language of immigration declines, what is often left behind as a residue is an 'ethnic accent'—a pattern of speech influenced by the immigrant language and noticeably different from standard American English. Thus, the pronunciation of *Long Island*, which in standard American pronunciation is [lɔŋ ajlənd] (without a [g]), is often pronounced [lɔŋgajlənd] (with a [g]) in the 'Jewish American accent' of the northeast. This is of course, a stereotype, since by no means do all or most 'Jewish Americans' even in the northeast have this pronunciation; but to the extent that it does occur, it is a carryover from the sound patterns of the Yiddish language. Similarly, *dese* [diz] and *dose* [doz] for *these* [ðiz] and *those* [ðoz] are found in many ethnic accents in which the source language does not have the fricatives [θ] and [ð].

Not all immigrants who came to America were speakers of languages other than English. The Irish began coming to America in large numbers during the period of the Great Famine (1846–1851) when the Irish potato crop failed through disease, and going to America was often the only alternative to death by starvation. Relatively few of these immigrants were

monolingual in the Irish language, the Celtic language indigenous to Ireland (sometimes called 'Gaelic', although 'Irish' is the preferred designation). Most spoke English, but the variety of English they brought with them was 'Irish English', which is different from more 'standard' versions of British or American English.

Characteristics of Irish English pronunciation include: (1) retention of historical /r/ after vowels in words like *car* (as in standard American but not standard British pronunciation); (2) the use of 'clear' /l/ in all positions (i.e. the alveo-palatal [l] of *leaf* vs. the velar [ɫ] of *full*); (3) retention of the contrast between /w/ and /ʍ/ (so that *weather* and *whether*, *witch* and *which* differ in their initial sound); (4) monophthongs /eː oː/ in place of diphthongs [ej ow] in the vowels of words like *face*, *take* and *goat*, *soak*; (5) replacement of the fricatives /θ ð/ by stops and affricates (*thin* [θɪn] pronounced as *tin* [tɪn] or *tthin* [t^θɪn]); (6) retention of vowel distinctions before /r/ (so that the vowels in words such as *bird*, *learn*, *beard*, *turn*, in Irish English, are all different); (7) neutralization of the opposition between /ɛ/ and /ɪ/ before nasals (*pin* and *pen* are homonyms, as in much of southeastern American English). Syntactically, there is the occurrence of reflexive pronouns in sentences such as: *And it's **himself** that told me …* and *… they were paying no attention to anything at all as long as **themselves** were well*. Then, there is the curious matter of the 'after perfect': *I'm after doing it already, She understands; she's after havin' children herself*, and *They seemed pretty cool, for what they were after goin' through* (in place of standard *I've done it, She understands; she's had children herself*, and *They seemed pretty cool after all they had gone through*).

As above in the case of the stereotypical 'Jewish American accent', most Americans of Irish descent have long since accommodated their speech to General American, and none of these Irish-English traits remain in the way they talk. But some of the 'Irishness' would be apt to persist for several generations, especially in areas of big cities such as Boston, New York, and Chicago where the Irish have been resident for a long time and where in many cases the population has been steadily replenished by immigration from Ireland. To the extent that Irish-English speech patterns do persist, they make for what can be called an 'Irish ethnic accent'.

African American Vernacular English (AAVE) has been the most intensively studied ethnic dialect of English. (The terminology is not settled. What is here called AAVE is variously referred to as Black English, African American English, and Ebonics.) AAVE is the dialect of English spoken by African Americans living in the 'inner city'—the ghetto—of large urban centers

such as New York, Philadelphia, Chicago, Detroit, and Los Angeles. The sociolinguist William Labov, in pioneering research undertaken in the 1960s and 1970s, established that AAVE, far from being the 'corrupt, degenerate, ungrammatical, bad' English that linguistically naive observers had thought it to be, is as legitimate a dialect of ethnic English as any other. AAVE is rule-governed and has its own precepts of correctness and incorrectness—it is therefore a language.

Some of the major characteristics of the pronunciation of AAVE are the following: (1) deletion of /r/ except before a vowel (*dough* and *door* rhyme); (2) simplification of final consonant clusters (*he picks* is *he pick*', *she found* is *she foun*'); (3) metathesis (interchange) of consonants in words such as *ask* (*aks*); (4) neutralization of the contrast between [ɛ] and [ɪ] before nasal consonants (compare Irish English above); and (5) replacement of postvocalic [θ] and [ð] by [f] and [v] ([wɪf] for *with*, [brəvɚ] for *brother*). Syntactically, a major systematic difference between AAVE and standard American English is the presence or absence of the verb *be* to distinguish between habitual and momentary state (compare Spanish *ser* and *estar*):

Lisa be sick.	'Lisa is always sick.'
Joe sick.	'Joe is sick at the moment.'
He be late.	'He is chronically late.'
He late.	'He's late this time.'

There is scholarly dispute about the origins of AAVE. The leading opinion at present is that most of the 'nonstandard' features of AAVE can be traced back to the influence of the African languages spoken by the slaves, who were taken from many different tribes and languages of mostly western Africa and acquired English only after they were forced into slavery in America under English-speaking masters and overseers. According to this theory, AAVE arose as a pidgin language based on English in which slaves speaking different tribal languages could communicate. This pidgin language then became a creole language as the children of the slaves grew up speaking it, and from this creole AAVE of the present day has developed.

It must be emphasized that individual differences matter. African Americans, or members of any ethnic group who grow up in contact with standard American English, will speak standard American English. A blindfolded listener could not distinguish their speech from anyone else's. It is a matter of educational opportunities, mobility, and one's language contacts.

Another ethnic dialect of English is Chicano English, the language of Mexican Americans in the southwestern United States and in urban areas to which its speakers have migrated. Characteristics of Chicano

English are: (1) substitution of tense vowels for lax vowels (*sit* and *seat* are both pronounced as *seat*); (2) substitution of *ch* [tʃ] for *sh* [ʃ] (*chew* and *shoe* are both pronounced like *chew* [tʃu]) and vice-versa ([ʃɛk] for *check*); (3) consonant cluster simplification, as in *par'* for *part* and *He like' her* for *He likes her*); and (4) nonstandard patterns of stress and intonation.

A key ingredient of ethnicity is language. Language, that is to say, helps define our place in the world; it can serve either as a sign of membership in the community or as a reason for exclusion from membership in that community. In many parts of the world, ethnic unity and cultural identification are often defined by language rather than by geography or religion. This is notably true of Arabic, whose speakers—the Arabs—base their identity in large measure on the use of a common tongue. The locus of Bengali ethnic identity resides in language despite the division of the speakers of Bengali between two countries, India and Bangladesh, the number of speakers living in Bangladesh being about 100,000,000 and 68,000,000 in India. The Bengali language—a language with an ancient and much-revered literary history—is the principal basis of ethnic unity. This is clear from the name for itself taken by the new nation of eastern Bengal, formerly East Pakistan, following the 1971 war of secession from Pakistan. The noun *Bangladesh* is composed of *bangla* plus *desa*, the latter meaning 'country'. The first part of the compound does not mean the Bengali people or the territory of Bengal; the term *bangla* refers specifically to the Bengali language: *Bangladesh* = 'land of the Bengali speakers'.

The case of the French language in Québec demonstrates a particularly strong association between ethnicity and language. Six million French speakers, five million of them in Québec, compose about one-quarter of the population of Canada. The Québecois (speakers of French resident in the province of Québec) regard themselves as a distinct island in a surrounding sea of Anglophones (monolingual English speakers). They resent the English language and fear its spread in Québec; they resent the historical domination of their economy and culture by Anglophones; and they resent immigrants who want their children to be educated in both English and French. Language is intimately tied to Québecois ethnicity—to Québecois identity. Worship of the French language is the almost sacral force that fortifies and unifies the movement for an independent Québec.

Language is a major symbol of ethnicity, often the major and most tangible symbol. In this role, language has always been a force both for unity and division in the world. It has helped to unify countries—as English makes it possible for Indians from all parts and ethnicities of India to communicate—and it can be a force

for the dissolution of a country. It remains to be seen whether Québec will remain a part of Canada or secede. In Belgium, a virtual language war between French and Flemish (similar to Dutch) threatens this country with its weakly fused identity. Here, as always, ethnicity is bound up with language, economic grievances, and demands for power. The lines of guerilla warfare in Sri Lanka are drawn between Tamil Hindus and Sinhalese Buddhists—*and* between the Tamil and Sinhalese languages. The demands for independence of the Baltic states, Latvia, Lithuania, and Estonia, formerly 'republics' of the Soviet Union, were intimately bound up with fears for the future of their respective ethnicities—and languages—in a sea of Russianness.

One final aspect of the relationship between ethnicity and language deserves attention: the role of language in preserving ethnic identity, especially in diaspora settings. The world has seen countless instances of peoples forced from their homelands because of their ethnicity. In most cases, diaspora leads to loss of language and ultimately of ethnic identity. The celebrated counterexample to this is the role of the Hebrew language in the maintenance of Jewish ethnicity. Hebrew was traditionally the language of the Jewish people; however, it had become extinct as their spoken language by the beginning of the Common Era. It was maintained as the language of ritual, prayer, and disputation among rabbis. After the destruction of the Temple in 70 CE, Jews were dispersed throughout the then known world. Nevertheless, they preserved their identity, Otherness, and distinctive ethnicity. The Hebrew language, which was reborn as a spoken language in Palestine in the nineteenth century, was part of the glue that held Jewish ethnicity together through almost 2,000 years of diaspora.

To paraphrase the great linguist Edward Sapir, we should never make the mistake of confusing a language with a dictionary and a grammar. Both the effect and the affect of language go well beyond words and rules of grammar. Language touches us in the deep places of our being—in our identity, in our sense of where we belong. One of the most sensitive of these places is our ethnicity. In ethnicity begins the true study of language as a badge of identity.

Ethnography of Communication

Ethnography of communication lies at the intersection of anthropology and linguistics. Until the 1960s, anthropology and linguistics had existed largely in isolation from each other. Although they devoted much of their time to the study of mythology, folklore, and rituals, in which language clearly played an important role, few anthropologists studied language in a systematic manner. In the meantime, few linguists examined the relationship between language and culture systematically. It is against such a background that ethnography of communication came into being. The primary concern of this cross-disciplinary approach is to describe and explain the patterns of communicative behavior of people from a specific culture, across different cultures, or both. The findings of the study are used to illuminate theories of language, as well as theories of culture. Patterns of communicative behavior are regularities that occur so repeatedly that they become predictable. These patterns can be discerned in ritualized events, such as funerals and wedding ceremonies, in which people are often unwittingly compelled to repeat stereotyped expressions. In those not-so-ritualized events, patterns also exist and underlie what people say and how they interact, despite the fact that on the surface participants have every right to choose what to say.

However, patterns are not necessarily universal. Different cultures may have divergent norms governing the same communicative behavior. A typical Chinese way of greeting (e.g. *Qu na?* [literally, 'Where are you going?'] or *Chi le ma?* [literally, 'Have you eaten?']) may sound prying or impolite to an English speaker brought up in a European culture. With a view to recording and analyzing culture-sensitive patterns of communication, proponents of ethnography of communication, such as Dell Hymes, John Joseph Gumperz, Muriel Saville-Troike, and Richard Bauman and Joel Sherzer, have developed an analytic framework by using concepts like 'speech community', 'communicative situation, event, and act', and 'components of speaking'.

A speech community consists of members who not only speak a common language but also interpret the interaction in a similar way. Besides language, members of a speech community share other aspects of common ground, such as social likeness or bonds, nationality, ethnicity, religion, and personal interests. These common grounds can partly account for the fact that most speech communities are bounded geographically, although living in the same region is not a sufficient prerequisite of belonging to the same speech community. The way that speech community members share a common language or norms of interpretation is largely a matter of degree, and it is up to an individual to decide how much commonality is required. A person may simultaneously belong to several discrete or overlapping speech communities. Britain and the United States may, as a whole, be regarded as one speech community if a researcher is interested in the comparison of Western and Eastern cultures. However, when it comes to the comparison of British and American ways of speaking, they have to be treated as two different speech communities rather than as a single unit.

The second essential constituent in the ethnography of communication framework is communicative situation, event, and act. This is a hierarchical concept, with the communicative situation being the general setting (such as a dinner party) and creating the broad context of communication. A communicative situation may consist of one or several communicative events, which refer to specific activities (such as a joke). Communicative events further consist of communicative acts, the minimal unit of analysis (such as greeting).

In ethnography of communication, the key components of analysis are often subsumed under the

mnemonic code SPEAKING, in which each letter represents one aspect of a communicative event. These are the following:

- **S**etting and **S**cene: the concrete physical (e.g. location, time, and size of room) and abstract psychological (e.g. cultural definition of the occasion) circumstances in which communication takes place.
- **P**articipants: the role of each participant in the interaction, their age, sex, social background, and their relationships with one another.
- **E**nds: the purpose and expected outcome of an interaction.
- **A**ct sequence: order of actions, message form, and message content.
- **K**ey: manner and the general tone of interaction.
- **I**nstrumentalities: medium of communication (i.e. spoken or written).
- **N**orms: norms of interaction and interpretation, i.e. what communicative behaviors are regarded as appropriate by a speech community and how communicative behaviors are construed by a speech community.
- **G**enres: categories of communication, e.g. poetry, prayer, or lecture.

Among these components, norms of interaction and interpretation are the most culture specific in that people of a particular culture may share different values or assumptions from other cultures. Consequently, the norms constitute the focus of studies in ethnography of communication. Moreover, the eight components in the list do not hold equal positions in a communicative event. Some elements, such as setting, participants, and key, may determine what norms of interaction and interpretation are to be followed and what act sequence an interaction may take. However, act sequence may tell what norms of interaction and interpretation participants have adopted in conversations, because unlike other variables, norms cannot be directly observed, and their identification has to rely on act sequences, as well as language content, in a conversation.

With its unique analytic framework, ethnography of communication contributes to the understanding of the interrelationship between culture and language by highlighting the role of culture in communicative behaviors. This has important implications for other fields of study, such as psycholinguistics, second-language acquisition, and cross-cultural communication. For psycholinguistics, one of the most significant contributions made by ethnography of communication is that it draws attention to how a child develops a particular way of speaking, apart from innate linguistic knowledge, in the context of a particular culture. For second-language acquisition, the SPEAKING model identifies what a speaker needs to know to communicate appropriately within a particular communicative situation. Learning a second language involves not only acquiring general linguistic knowledge and interaction skills but also social and cultural knowledge that governs what to say to whom and when and how to say it appropriately in relation to communicative goals. For cross-cultural communication, the diversity in the norms of interaction and interpretation in different cultures, emphasized by ethnography of communication, highlights potential sources for misunderstanding and nonunderstanding in cross-cultural interaction. This is also an area that makes ethnography of communication interesting for business consultants and market researchers.

Etymology

The field of etymology studies the origin and the earliest meaning of semantic units, i.e. morphemes, words, and phrases. The source (or to use the Greek term, ety-mon) is the word at the time and in the language in which it emerged, i.e. when and where we can break it down into its constituent parts, understand its formation

and the reasons that led to the emergence of its earliest meaning, as well as understand its semantic motivation.

The word *soldier* is borrowed from Old French *soldier*, which in turn developed from Medieval Latin *solidarius* 'one serving in the army for pay'. This is its origin, as in this form the word can be explained as a derivative with the suffix *-arius*, which among other things formed terms for individuals (cf. Medieval Latin *commissarius* > English *commissary* or Medieval Latin *officarius* > (Old) French *officier* > English *officer*), of Medieval Latin *solidus* 'gold coin', which, after applying the respective historical sound change rules is preserved in French *sou* and Italian *soldo* 'wage', pl. *soldi* 'money'. The etymological explanation of the word *soldier* is thus resolved, as the mathematical product of the meanings, i.e. 'paid (military) individual', along with knowledge of the Medieval military situation, corresponds to its formal construction: *solidus* and *-arius*. It is not important for the etymological analysis of the word to indicate that *solidus* in turn is an ellipsis for the collocation *nummus solidus* 'solid coin', nor that the suffix *-arius* was originally adjectival, cf. Latin *manuarius* 'of, or belonging to the hand' from *manus* 'hand'.

The discovery process for etymological explanation of individual words (morphemes or phrases) normally consists of three parts. The first is a synchronic documentation of the word in the language in question and its philologically verifiable development, e.g. *fist* 'the hand closed tightly with the fingers bent against the palm', which is attested with the same meaning in its Old English predecessor *fȳst*. Because the word is attested in the earliest Old English texts, it can be assumed that it existed in the preliterate period, i.e. it is prehistoric. The second step in the etymological process is to establish the direction of further analysis. The question must be asked: did the word arise in a continuous linguistic development—which for English is understood as the development from the prehistoric, preliterate layers Proto-Indo-European > Proto-Germanic > Western Germanic through the historical stages of Old English to Modern English—or was it at some point borrowed from another language, a substratum, adstratum, or superstratum? In view of the fact that the appropriate source form in the languages from which the word might have been borrowed—Romance, Celtic, and Northern Germanic, from which the majority of borrowings came—is lacking, and, on the other hand, the corresponding Western Germanic cognates are attested (cf. Old High German *fūst* [> G. *Faust*], Old Frankish *fest*), it can be posited that the word arose at least in the Proto-West-Germanic period if not earlier. The comparisons at this stage can be affirmed or refuted by the comparative method, which is the fundamental tool of the etymologist. In the example presented here, the Old English phoneme *ȳ*, in light of sound changes established by the comparative method, indicates the existence at an earlier stage of the sound *i* in the second syllable, which was subsequently lost before the historical period. Thus, we can establish that 'fist' was pronounced *fūsti* in the Proto-West-Germanic period.

A word from a prehistoric period, the form and meaning of which are established through the application of the comparative method, is called a reconstruction. An asterisk before the reconstructed form indicates that it is not attested in written documents.

Despite the fact that the reconstructed *fūsti* is not found in other Germanic languages, this form is not yet the origin, as the word cannot yet be analyzed into its original morphemes and thus its original meaning cannot be established. The comparative method allows comparison between the West German reconstruction and Proto-Slavic *pęstь* 'fist', which can be reconstructed from materials in modern and historical Slavic languages, e.g. Slovene *pest*, Russian *pjast'*, Polish *pięść*, and Old Church Slavic *pęstь*. In the comparison, the following comparative-linguistic sound laws are applied: (1) Germanic *f* developed from Indo-European *p* (Grimm's Law); Proto-Slavic preserves Indo-European *p*. (2) Germanic *ū* before *h* developed from *un*, which in turn goes back to Indo-European *n̥*, which in Proto-Slavic normally develops into the nasal vowel *ę*. The development of Germanic long *ū* thus proves that the word is Proto-Germanic and that it goes back to *funhsti-*. The sound *h* in this position could have developed either from Indo-European *k* or *kʷ*, which in the position before another consonant in Proto-Slavic would have disappeared. (3) Proto-Germanic and Proto-Slavic *s* both come from Indo-European *s*. (4) Proto-Germanic and Proto-Slavic *t* both come from Indo-European *t*. (5) The fronting of Old English *ȳ* indicates an older stem ending in *-i*, which is directly affirmed by the Slavic material. The mathematical intersection of all possible reconstructions offered by the Germanic and Slavic material results in the possibilities *pn̥ksti-* and *pn̥kʷsti-*. At this point the comparative-linguistic part of the etymological process ends and the discovery of its origin and analysis into its constituent parts begins. This is done in the framework of Proto-Indo-European word-formational processes.

It turns out that the second of the possibilities mentioned above, *pn̥kʷsti-*, is more likely, as it can be derived from Indo-European *pn̥kʷ-stHi-*, which can be segmented into a compound with the first element *penkʷe* 'five' in the zero-grade and a noun derived from a verb with the root *staH-* 'to stand', also in its zero-grade variant. The etymological process is completed when it is discovered that the original form must have meant 'a standing of five (fingers)'. The explanation is all the more likely as it is typologically

paralleled by *mu-stH-i-* '(small) fist' (attested in Vedic *muṣṭí-* and Tocharian B *maśce*), in which the first element comes from Indo-European *meu̯e* 'four' (Luwian *mauwa-*), and the rest is identical to the Germanic-Slavic word for 'fist'.

Folk etymology is a change in a word or phrase, the constituent parts have become incomprehensible, and as such is reanalyzed with morphemes that are meaningful. The potential for a folk etymology arises when there is a coincidental similarity between the actual morphemes and those—usually with a minor phonological or morphological 'correction'—that speakers see in the word on the principle that 'it makes sense, therefore it must be true'. For example, the common name of a bird *wheatear* (Oenanthe oenanthe) is folk etymologized as a compound of *wheat* and *ear*. This form in turn is a singularized form of an earlier form that had been felt to be a plural, *wheatears*. In fact, the word is a compound from Old English *hwīt* (> Modern English *white*) and *arse*, a reference to the bird's prominent white rump. Folk etymology frequently occurs in borrowed words with minor 'corrections' that seem to speakers to be native derivatives, e.g. German *Abenteuer* 'adventure' is a borrowing of French *aventure*. However, it has been connected with German *Abend* 'evening', apparently on the view that adventures are as a rule evening events. Further, *sparrow grass* is found in the eastern part of the United States as a 'correction' of the unintelligible plant name *asparagus*, itself a borrowing via Latin of Greek *aspáragos*.

Euphemism

Meanings of words and phrases may be divided into denotation (the referent of the term) and connotation (the associated properties, including social import). If either the denotation or connotation of a word or phrase is offensive to social sensibilities, a 'softer', more polite form may be used. Such forms are *euphemisms*.

When the possible offense in a word lies in its connotation, a word with the same or a similar referent, but lacking this connotation, may be sought. The word 'ofay' refers to Caucasians, but carries with it connotations of opprobrium. If a speaker wishes to denote this group of people, but does not wish to insert negative 'racial' stereotypes, distancing as 'out-group', hatred or dislike, then she or he will use a euphemistic word, such as 'White' or 'Caucasian'. While a given speech community may largely share connotations and can thus count on words 'meaning' the same thing to all in-group interlocutors, connotations are not always shared among all speakers of a language. For some speakers, 'Aryan' might serve as a euphemism for 'ofay'; for others, the connotations of 'Aryan' are also negative, although the non-in-group scope of this term is larger.

While societies differ in their ascription of positive and negative values, all societies have rules of appropriateness of topics for particular groups and settings. In American society, it is generally considered bad form to discuss the body's excretory processes. It has only been in the last 30 years that 'shit' was admitted as an entry in most unabridged dictionaries. Dictionary notes on usage point out that 'shit' is considered 'vulgar'. In polite company, one is expected to refrain from using this word. Should it slip out as an exclamation or as a part of an utterance, one is expected to apologize for the breach of etiquette. In settings, such as medical interviews, where excretory processes must be discussed, euphemisms appear. Biomedical labs refer to 'stool samples'. Nurses inquire about the patient's 'bowel movements'. Euphemisms change with register shifts, as formality levels and statuses of interlocutors vary. Children who must discuss their excretions with the parents during the period of their lives euphemistically known as 'potty' training learn to use terms acceptable to their caregivers, often including 'b.m.', 'doodoo', and 'caca'.

Euphemisms are subject to pejoration. Constant use in reference to something that is itself considered dirty or vulgar pollutes the terms. As long as there is social stigma attached to the referent, some (or all) of it may transfer to the euphemistic term. In the United States, 'nigger' has long been considered a 'hate' word, not apt for polite conversation. In the early 1900s and throughout the civil rights movement in the 1950s, 'colored people' was the phrase of choice. It is preserved today

in the name 'National Association for the Advancement of Colored People', which denotes a social justice organization founded in 1909 by Ida Wells-Barnett, W.E.B. DuBois, Henry Moscowitz, Mary White Ovington, Oswald Garrison Villiard, and William English Walling. In the decade following the 1950s, cultural revitalization groups adopted the term 'black'. It spread from slogans such as 'black is beautiful' to common use as a group label. In the 1970s, Afro-American came to be used. In the next decades, the phrase African American replaced the hyphenated form.

While a society may agree that a topic is 'taboo' or socially loaded, so that reference to it must be oblique, the euphemism of choice may vary, regionally or within social strata. Euphemisms for public places where one may go to 'shit' include: the loo, the w.c., the toilet, the restroom, the washroom, the lavatory, the jensen, the john, the 'ladies', and the 'gents'.

When the discomfort with a term stems from social stresses and when those social schisms become politicized, the lexical choice is politicized as well. Thus, euphemisms are used to achieve 'politically correct' parlance. Feminism has painted the use of generic 'he' and 'man' as indicators of reactionary male hegemonic ideology, so that sentences such as 'Man nurses his young' are sexist, as well as semantically odd.

In those areas where pejoration has proliferated terms, cultural revitalization movements may seek to reclaim elements. In many Latin American countries, the term *indio* 'Indian' has been an insult for centuries; in the last 30 years, some groups in highland Mexico, Guatemala, and Peru are beginning to eschew the euphemistic *indígena* and to self-denominate as *indio*, as a marker of cultural pride. In North American, indigenous groups have been referred to by a variety of euphemistic terms: 'Indian', 'AmerInd', 'Native American', 'First Americans', and 'First Nations'. Amid this multiplicity, one person's euphemism is another's insult or effete affectation.

One can trace areas of conflict, stress, and unease within a society by mapping its euphemisms. Robin Lakoff in her 1975 book *Language and woman's place* notes that female sexuality is one such area of cultural embarrassment. The term 'woman' itself carries sexual connotations; whereas the term 'lady', being more refined, masks these connotations. Assuming that 'Jane' is a 13-year-old girl, compare the following: (a) Jane has become a young lady. (b) Jane has become a young woman. When speakers say that a woman who is a doctor is a 'lady doctor', this indicates not so much her manners, but the fact of her gender, euphemistically stated, and calls attention to it as a 'marked' case, not the cultural norm. As cultural norms shift, the references also shift.

As cultural strife is resolved, euphemisms fall out of play, or lose their sense of masking. As tensions between earlier immigrants and Irish newcomers to the United States subsided, 'Gael' and 'Irish' have fallen out of a euphemistic relation to 'Mick' and 'potato-eater'. As new stresses arise, new lexicon masks and outlines the divisions. Ageism, youth-centrism, and legislation against forced retirement are reflected in the conversion of 'old-age homes' to 'retirement villages', 'nursing homes', and 'assisted living' places for our 'senior citizens' or 'golden agers'. Language forms and is formed by society. Euphemisms are the fresh coat of paint over the stress fractures in the social structure.

European Traditional Grammar

The Greek term *grammatike* (Latin *grammatica*) meant no more at first than the understanding of letters. For the early periods of European history, philosophical works—examining virtually the whole realm of human knowledge—constituted our only sources of grammatical progress.

Plato (c. 429–347 BCE) provided a fundamental division of the Greek sentence into a nominal and a verbal

component, and this remained the primary grammatical distinction underlying sentence analysis and word classification in all subsequent European linguistic descriptions. Aristotle (384–322 BCE) maintained this distinction, but added a third syntactic component, the *syndesmoi*, a class covering what were later to be distinguished as conjunctions, articles, and pronouns.

The Stoic philosophical school, founded by Zeno (c. 315 BCE), developed new methods and doctrines in philosophy and rhetoric and gave separate treatment to grammar, with great achievements: the number of word classes was increased, and more precise definitions and additional grammatical categories were introduced to cover the word and sentence structure associated with these classes. Case in its modern usage as an inflectional category of nouns (and other words inflected like nouns) was the creation of the Stoics. Case inflection became the fundamental division between noun and verb. The Stoics also introduced the distinctions between transitive and intransitive verbs, i.e. verbs that require an object and verbs that do not.

Building on the Stoic ideas, the Greco-Roman world devised technical grammars with an effective and lasting influence on the future. The framework of technical grammar in antiquity was the *word-and-paradigm* model. A word-based grammar involves three main procedures: the identification of the word as an isolable linguistic entity, the establishment of a set of word classes to distinguish and classify the words in the language, and the working out of adequate grammatical categories to describe and analyze the structure and formation of words (morphology) entering into paradigms of associated forms.

The first piece of technical grammar in Europe was the *Tekhne Grammatike* of Dionysius Thrax (c. 100 BCE). Its first part is considered genuine; the rest is probably a later addition. The grammarian classified the consonants of Greek and distinguished eight word classes: noun, verb, participle, article, pronoun, preposition, adverb, and conjunction. The number of word classes, with one change necessitated by the absence of articles in Latin, remained constant until the end of the Middle Ages in the grammatical description of Greek and Latin, and it had a very marked influence on the grammatical analysis of several modern European languages. Each word class defined in the *Tekhne Grammatike* is followed by a statement of the categories applicable to it: gender (masculine, feminine, or neuter), type (primary or derived), form (simple or compound), number (singular, dual, or plural), and case (nominative, vocative, accusative, genitive, or dative). The classification categories introduced for the verb are mood, voice, type, form, number, person, tense, and conjugation.

The main omission of the *Tekhne* from the standpoint of modern linguistics was the absence of any sections on syntax, i.e. sentence structure. Syntax was dealt with extensively by Apollonius Dyscolus (second century CE). He sharply distinguished form and meaning, and he justified grammatical classifications by reference to meaning rather than to form. His work, however, is a case study of Greek, rather than a general theory of syntax.

Varro (first century BCE) is the first important Latin author with linguistic concerns whose work has been transmitted. In the surviving part of his *De Lingua Latina*, he distinguishes word formation processes in which the class of the word is changed (e.g. derivation of a noun from a verb via the addition of an affix, such as the noun 'runner' from the verb 'to run') and class-preserving inflections (e.g. tense markings on the verb, such as 'moved' for the past tense of 'move'). This distinction between derivational and inflectional processes was not commonly made in antiquity. Varro also proposed his own classification of Latin-inflected words by setting up a system of four contrasting classes of inflections.

Aelius Donatus was the most influential Latin grammarian of the fourth century CE and dominated grammatical doctrine in Europe at least until the twelfth century. His *Ars minor* deals with the eight parts of speech in a question-and-answer format. His *Ars maior* is more comprehensive and includes style guidelines for Latin.

Priscian's voluminous grammar (c. 500 CE) was the most important late Latin grammar. He was under the spell of Greek grammar, accepting Apollonius and his son Herodian as authorities and using the closest Latin translations for the Greek technical terms. Priscian organized the morphological description of the forms of nouns and verbs and of the other inflected words by setting up canonical, or basic, forms; from these, he derived the other forms by a series of letter changes, the letter being for him, as for the rest of Western antiquity, both the minimal graphical unit and the minimal phonological, or sound, unit.

In the first centuries after the collapse of the Western Roman Empire, grammar served mainly practical and normative purposes. Later writings took the form of commentaries and glosses, mainly based on Priscian. Donatus and Priscian shared the place of the principal grammarians of the Middle Ages as teachers' textbooks. In England, Bede and Alcuin wrote grammars of Latin in the seventh and eighth centuries, following Donatus.

Until the twelfth century, Greek and Latin were regarded as the pinnacle of culture, which explains the grammarian's exclusive attention to these languages. In the latter part of the Middle Ages, however, descriptions of other European languages appeared, serving the ends of literacy, popular literature, and educational standards. Irish grammarians showed a great deal of originality in their treatment of Irish; descriptions of

Provençal started appearing after 1240; an anonymous grammarian of the period demonstrated great insight into the description of Icelandic, especially in phonology and its graphemic representation.

The Renaissance saw the first European grammars of Hebrew and Arabic. Interest in these languages and the separate scholarly traditions in which they had been treated contributed to further loosening the strict focus on Latin and Greek. The first known native grammars of Spanish and Italian appeared in the fifteenth century, followed closely by French, Polish, and Old Church Slavonic grammars. The first printed grammar of English appeared in 1586.

The new grammars of modern languages paid great attention to the relations between spelling—now being standardized in printing—and pronunciation. Although the confusing equation of letter and spoken sound continued, phonological inadequacies of existing spelling were noted and criticized. The system of eight word classes was challenged, with systems of fewer and more classes being proposed.

English grammarians of the sixteenth, seventeenth, and eighteenth centuries usually started with the Latin system of the eight Priscianic classes. They either followed it or felt the need to express and justify their disagreements with it. The English articles, *a, an,* and *the*, having no Latin counterpart, were not given the status of a part of speech, but were merely referred to as notes or signs set before nouns to identify them as nouns. Others treated the articles as adjectives (still a subcategory of nouns), and Ben Johnson (1640) assigned them to a class of their own. The influence of the Latin tradition is seen in the retention of the adjective within the noun class, although there are fewer reasons for this theoretical choice in English than in Latin. The preoccupation of most of the grammarians with the participle, treated either (purely traditionally) as a class in its own right or as a noun adjective having particular derivational associations with the verb, is also a carryover from Latin grammar.

In the New World, the first grammar of a Native American language, Tarascan (Mexico), was published in 1558; thereafter, grammars of Quechua (Peru), Nahuatl (Mexico), and Guarani (Brazil) were published in 1560, 1571, and 1640, respectively. The seventeenth century witnessed the publication of grammars of Japanese and Persian, and the first comprehensive grammars of Chinese published in European languages appeared at the beginning of the eighteenth century. Confidence in the traditional Greco-Roman grammatical categories was weakened when it became known that Chinese generally uses independent words where Greek and Latin use affixes, whereas Native American languages often use the opposite strategy of expressing the equivalent of Greek or Latin sentences in highly complex words.

The 'discovery' of Sanskrit and the emergence of the so-called Neogrammarian theories in the nineteenth century, however, represented the most serious challenges, both to the concepts of European traditional grammar and to the idolization of Greek and Latin. The fact that Sanskrit was found to be closely related to Greek and Latin stripped them of their attributed uniqueness, and the Neogrammarian focus on the development of languages over time put them into historical perspective.

Evolution of Language 1: Overview

Although the details are disputed, it is apparent that human linguistic ability has a biological basis. That being the case, any meaningful study of the evolution of language must take into account the principles noted by Charles Darwin; they remain central tenets of evolutionary biology.

The evolutionary mechanism most often associated with Darwin is natural selection, which acts on 'any variation, however slight and from whatever cause proceeding, if it be in any degree profitable to an individual of any species, in its infinitely complex relations to other organic beings and to external nature…' (1859; *On the origin of species,* p. 61). Because human language enhances virtually all aspects of our interactions with each other and external nature, selection for the biological characteristics that make language more effective is to be expected.

Comparative studies of primates suggest that language may foster group cohesion and the formation of large social groups working cooperatively by means of seemingly useless 'gossip'. Other studies note that language allows information to be shared by many individuals, thereby fostering the solution of problems through 'collective insight'. Robust experimental data show that human speech itself is one of the keys to human linguistic ability. The process by which human speech is produced and perceived overcomes the slow information transfer rate of the human auditory system. As we talk, phonemes (speech sounds roughly equivalent to the letters of the alphabet) are melded into syllables that are transmitted below the rate at which the human auditory system would have fused individual sounds into an incomprehensible buzz. Studies of sentence comprehension reveal another role for speech. Words are silently 'rehearsed' by using the neural mechanisms that regulate overt speech, to maintain them in the neural buffer, *verbal working memory,* in which sentence comprehension takes place. Other avenues of inquiry that use computer modeling techniques suggest that the complex syntax of human language derives from limited neural memory and sentence-processing capacities.

Darwin also introduced the comparative method, which can yield reasonable inferences concerning the evolution of the 'derived' characteristics that differentiate a living species from its extinct ancestors. For example, comparative studies of living apes and humans show that upright bipedal locomotion involves certain derived anatomical features that can be traced back in time by examining the fossil record. In this light, studies of chimpanzees shed light on the evolution of human language. Although present-day chimpanzees are not members of the extinct 6- to 7-million-year-old species that was the common ancestor of humans and apes, they preserve many of the skeletal features of early hominids, including small brains and similar vocal anatomy. However, chimpanzees raised in human-like environments can acquire approximately 150 words and the ability to comprehend sentences that have a simple syntax with manual languages (American Sign Language or computer keyboards). This suggests that limited lexical and syntactic ability were present in the earliest stages of the evolution of human language and argues against theories that posit an abrupt transition that yielded human syntactic ability. Natural selection could have gradually enhanced preexisting rudimentary lexical and syntactic ability. In contrast, the fact that chimpanzees totally lack voluntary speech suggests that the speech capabilities of early hominids were limited, and this is consistent with studies of the skulls of extinct hominids. These skulls suggest a chimpanzee-like vocal anatomy incapable of producing the full range of human speech sounds.

The archeological record also preserves artifacts that hint at the cognitive and linguistic abilities of ancestral and related extinct hominid species. However, we must take into account the effects of the accelerating pace of human culture. Although we can fly through the air, our cognitive and linguistic ability is not superior to that of our ancestors during the tens of thousands of years in which horses provided the fastest means of land transportation. Moreover, genetic data must temper conclusions based on the archeological record. Although tool technologies seem to have abruptly changed 40,000 years ago in Europe, it is improbable that modern human linguistic ability first evolved at that date. Genetic studies and the fossil record show that modern human beings left Africa about 100,000 years ago and settled in most parts of the world between 60,000 and 40,000 years ago. Because any child from any region of the world can acquire any language with native proficiency, the biological capacities for language must have existed before humans left Africa.

But some linguists question how human language could have evolved by means of natural selection in the brief 5-million-year period separating humans and living apes. As Darwin himself noted, natural selection can 'act only by the preservation and accumulation of infinitely small inherited modifications' (1859:95). How then could he account for major adaptations to new environments, such as the transition from aquatic to terrestrial life? Darwin's solution, often termed 'exaptation' or 'preadaptation', rested on the observation that 'an organ might be modified for some other and quite distinct purpose' (1859:190). Converging evidence suggests that preadaptation played a part in the evolution of the unique characteristics of human language, such as voluntary speech and complex syntax. The anatomy of the face and tongue was modified to allow the production of sounds that make human speech more efficient. Brain structures initially adapted for motor control may have been the starting point for neural networks that regulate syntax and cognition.

In studying the evolution of linguistic ability, general evolutionary principles, such as Von Baer's 'law',

provide another avenue of inquiry. Von Baer's law holds that the ontogenetic development, from fetal life onward, of the derived anatomical and related behavioral characteristics of a living species generally follows a sequence that mirrors their occurrence in related living and extinct species. Inferences on the evolution of the anatomy of speech production, syllable structure, vocabulary ability, and sentence structure have followed from studies of the development of children.

The exact course of the evolution of human language will probably never be known, because detailed timetables cannot be subjected to test. However, because the mark of evolution is apparent when we study the human brain and body, further insights into the evolution of human language will become apparent as our knowledge of the biological basis of human language and cognition advances.

Evolution of Language 2: Cognitive Preadaptations

A preadaptation is a change in a species which is not itself adaptive but paves the way for subsequent adaptive changes. For example, bipedalism set in train anatomical changes, which culminated in the human vocal tract. Although speech is clearly adaptive, bipedalism is not itself an adaptation for speech; it is a preadaptation. This example involves the hardware of language, the vocal tract. Many changes in our species' software, our mental capacities, were necessary before we became language-ready; these are cognitive preadaptations for language.

A human language is a system mapping combinations of speech sounds or manual signs onto meanings. The use of language is a cooperative, social activity. When humans use language, they cause inferences in a receiver's mind about states of affairs in their shared world. Preadaptations for language involved the following capacities or dispositions:

pre-phonetic capacity to produce speech sounds or manual gestures.

pre-syntactic capacity to organize longer sequences of sounds or gestures.

pre-semantic capacities to: (a) form basic concepts, (b) construct more complex concepts (e.g. propositions), and (c) carry out mental calculations over complex concepts.

pre-pragmatic capacities to: (a) infer what mental calculations others can carry out, (b) act cooperatively, (c) attend to the same external situations as others, and (d) accept symbolic action as a surrogate for real action.

311

elementary symbolic capacity to link sounds or gestures arbitrarily with basic concepts, such that perception of the action activates the concept, and attention to the concept may initiate the sound or gesture.

If some capacity is found in species distantly related to humans, this indicates that it is an ancient, primitive capacity. Conversely, if only our nearest relatives, the apes, possess some capacity, we can conclude that it is a more recent evolutionary development. Twin recurring themes in the discussion of many of these abilities are *learned*, as opposed to innate behavior, and *voluntary control* of behavior. Human languages are largely learned systems. The more ways in which a species is plastic in its behavior, the more complex are the cultural traditions, including languages, that can emerge. Our nearest relatives, the chimpanzees, are plastic in a significantly wider range of behaviors than any other nonhuman animals; their cultural traditions are correspondingly more multifaceted while falling far short of human cultural diversity and complexity. Combined with plasticity, voluntary control adds more complexity, and unpredictability, to patterns of behavior. Much of the difference between humans and other species can be attributed to greatly increased plasticity and voluntary control of these preadaptive capacities.

Prephonetic Capacity

Chimpanzees cannot speak. They typically have little voluntary breath control. To wild chimpanzees, voluntary breath control does not come naturally. On the other hand, chimpanzees have good voluntary control over their manual gestures, although they are not as capable as humans at delicate manual work. A preadaptation that was necessary for the emergence of modern spoken language was the extension of voluntary control from the hands to the vocal tract.

Learning the controlled use of physical actions entails an ability to imitate. Imitation involves an impressive 'translation' of sensory impressions into motor commands. Think of a smile. Without mirrors or language, one can have no guarantee that a certain set of muscle contractions produces the effect one perceives in another's face. Given the required voluntary control, and the anatomical hardware, imitation of speech sounds should be easier than imitation of facial gestures, because one can hear one's own voice. A capacity for imitation is found in a perplexing range of species. Some birds can imitate human speech, and many other types of sound, as well. Dolphins can be trained to imitate human movements. A capacity for imitation can evolve separately in different species, with or without the other necessary preadaptive requirements for human language. A neural basis of

imitation has been found in monkeys, in the form of 'mirror neurons', which fire both when an animal is carrying out a certain action, such as grasping, and when it observes that same action carried out by another animal. A recurrent theory in phonetics is the 'motor theory of speech perception', which claims that speech sounds are represented in the brain in terms of the motor commands required to make them.

Although they cannot speak, our ape cousins have no trouble in recognizing different spoken human words. The capacity to discriminate the kinds of sounds that constitute speech evidently preceded the arrival of speech itself.

Presyntactic Capacity

Syntax is the stringing together of independent subunits into a longer signal. The oscine birds, in which learned complex song is observed, are extremely distant relatives of humans. Many other birds, and more closely related species, including most mammals, do not, as far as we know, produce calls composed of independent subunits. Our closest relatives, the apes, do produce long calls composed of subunits. The long calls of gibbons are markers of individual identity, for advertising or defending territory. The subunit notes, used in isolation, out of the context of long calls, are used in connection with territorial aggression, and it is not clear whether the meanings of these notes can be composed by any plausible operation to yield the identity-denoting meaning of the whole signal.

Male gibbon singing performances are notable for their extreme versatility. Precise copies of songs are rarely repeated consecutively, and the song repertoires of individual males are very large. Despite this variability, rules govern the internal structure of songs. Male gibbons use a discrete number of notes to construct songs. Songs are not formed through a random assortment of notes. The use of note types varies as a function of position, and transitions between note types are nonrandom. (Mitani and Marler 1989:35)

Although it is fair to call such abilities in apes 'presyntactic', they are still far removed from the human ability to organize sequences of words into complex hierarchically organized sentences. Little is yet known about the ability of apes to learn hierarchically structured behaviors, although all researchers seem to expect apes to be less proficient at it than humans.

Presemantic Capacities

Basic Concept Formation

Many distantly related species lead simple lives, compared to humans, and even to apes, and so may not possess very many concepts, but they do nevertheless

possess them. 'Perceptual categorisation and the retention of inner descriptions of objects are intrinsic characteristics of brain function in many other animals apart from the anthropoid apes.' (Walker 1983:378). The difference between humans and other animals in terms of their inventories of concepts is quantitative. Animals have the concepts that they need, adapted to their own physiology and ecological niche. What is so surprising about humans is how many concepts they have, or are capable of acquiring, and that these concepts can go well beyond the range of what is immediately useful. Basic concrete concepts, constituting an elementary presemantic capacity, were possessed by our remote ancestors.

Something related to voluntary control is also relevant to presemantic abilities. We do not need to be stimulated by the actual presence of an object for a concept of it to be brought to mind. Some animals may have this to a limited degree. When an animal sets off on a journey to its usual foraging ground, it knows where it is going, because it can get there from many different places, and even take new routes. Hence, the animal is entertaining a concept of a place other than where it currently is. But for full human language to have taken off, a way had to evolve of mentally reviewing one's thoughts in a much more free-ranging way than animals seem to use.

Complex Concept Formation
The ability to form complex conceptual structures, composed systematically of parts, is crucial to human language. Logical predicate-argument structure underlies the messages transmitted by language. The words comprising human sentences typically correspond to elements of a conceptual/logical representation. While apes may perhaps not be capable of storing such complex structures in their heads as humans, it seems certain that they have mental representations of the predicate-argument form. Simply attending to an object is analogous to assigning a mental variable to it, which functions as the argument of any predicate expressing a judgment made by the animal. The two processes of attending to an object and forming some judgment about it are neurologically separate, involving different pathways in the brain. This is true not only for humans but also for apes and closely related monkeys as well. It seems certain that all species closely related to humans, and many species more distantly related, have at least this representational capacity. This capacity is a presemantic preadaptation for language.

Mental Calculation
Humans are not the only species capable of reasoning from experienced facts to predictions about nonexperienced states of affairs. There is a large literature on problem-solving by animals, leading to ranking of various species according to how well they perform in some task involving simple inference from recent experience. Apes and monkeys perform closest to humans in problem-solving, but their inferential ability falls short of human attainment.

Prepragmatic Capacities

Mind-reading and Manipulation
When a human hears an utterance by another person, he often has to figure out what the speaker intended; this is mind-reading. When a human speaks, he or she usually does so with some estimation of how the hearer will react; this is social manipulation. Humans have especially well-developed capacities for social manipulation and mind-reading, and these evolved from similar abilities in our ancestors, still visible in apes. Social intelligence, a well-developed ability to understand and predict the actions of fellow members of one's group, was a necessary prerequisite for the emergence of language. Recent studies amply demonstrate these manipulations and mind-reading abilities in chimpanzees.

Cooperation
People are able to understand the intended import of statements whose literal meanings are somehow inappropriate, such as 'It's cold in here', intended as a request to close the window. To explain how we cope with such indirectness, traditional logic has to be supplemented by the Cooperative Principle, which stipulates that language users always try to be helpful in various specified ways. The use of language requires this basis of cooperativeness. No such complex communication system could have evolved in the absence of assumed cooperativeness between members of the community.

Humans are near the top of the range of cooperativeness, compared with other species. The basis of cooperation in social insects is entirely innate, and the range of individual cooperative behaviors is small. In humans, building onto a general natural disposition to be cooperative, cooperation on a wide range of specific group enterprises is culturally transmitted. Children are taught to be 'team players'. No concerted instruction in cooperation exists outside humans, but there are reports of cases where an animal appears to be punished for some transgression of cooperativeness. So the basis for cooperative behavior, and for instilling such behavior in others, exists in species closely related to humans. Common Chimpanzees and bonobos, in particular, frequently engage in many different types of reconciliation and peace-making behavior. Dispositions to cooperation and maintenance of group cohesion are pragmatic cognitive preadaptations for language.

Joint Attention

Cats are hopelessly inept at following a pointing finger; dogs are somewhat better. Language is also used to point at things, both directly and indirectly. Linguists and philosophers call this 'reference'. When a speaker refers to some other person, say by using a personal pronoun, such as *he*, the intention is to get the hearer to attend to this other person. Successful use of language demands an ability to know what the other person is talking about. A mechanism for establishing joint attention is necessary. Human babies and children are especially adept at gaze- and finger-following. The fact that humans, uniquely, have whites in their eyes, probably helps us to figure out what other people are looking at.

Primates more closely related to humans are better at following the human gaze than those less closely related. Chimpanzees follow human gaze cues, while non-ape species such as macaques fail to follow human gaze cues. But experiments on rhesus macaques interacting with other rhesus macaques show that members of this species do follow the gaze of other members of their own species. Spontaneous pointing has also been observed in captive common chimpanzees (who had not received language training) and in young free-ranging orangutans. It thus appears that animals close to humans possess much of the cognitive apparatus for establishing joint attention, which is the basis of reference in language.

Ritualized Action

Short colloquial greetings such as *Hello!* and *Hi!* are just act-performing words; they do not describe anything, and they can not be said to be true or false, as a description can. We can find exactly such act-performing signals in certain ritualized actions of animals. The classic example of a ritualized action is the snarling baring of the teeth by dogs, which need not (now) precede an imminent attack, and is a sign of hostility. In order to bite, a dog must get its lips out of the way. Originally, parting the lips was only a preparatory movement before biting, but observers became aware of the baring of teeth as an index of an attack and took evasive action. Teeth-barers soon noticed that simply baring the teeth brought about the desired effect of scaring someone off. Now, baring the teeth is a ritualized signal with a meaning something like 'Beware!'. Human ritualized expressions such as *Hello* are relics of ancient animal behavior, now mostly clothed in the phonemes of the relevant language. But some human ritualized expressions, such as the alveolar click, 'tsk', indicating disapproval, are not assimilated into the phonology of their language (in this case English). The process of dissociation between the form of the signal and its meaning can be seen as the basis of the capacity to form arbitrary associations between signals and their meanings, to be discussed in the next section.

Elementary Symbolic Capacity

The sound of the word *tree*, for instance, has no iconic similarity to any property of a tree. This kind of arbitrary association is central to language. Human linguistic symbols are entirely learned. This excludes from language proper any possible universally instinctive cries, such as screams of pain or whimpers of fear. In the wild, there are many animals with limited repertoires of calls indicating the affective state of the animal. In some cases, such calls also relate systematically to constant aspects of the environment. The best-known example is the vervet monkey alarm system, in which there are distinctive calls for different classes of predator. There is no evidence that such calls are ever learned to any significant degree. Thus, no animal calls, as made in the wild, can, as yet, be taken as showing an ability to learn an arbitrary mapping from signal to message.

Trained animals, on the other hand, especially apes, have been shown to be clearly capable of acquiring arbitrary mappings between concepts and signals. The acquired vocabularies of trained apes are comparable to those of five-year-old children, with hundreds of learned items. An ape can make a mental link between an abstract symbol and some object or action, but the circumstances of wild life never nurture this ability, and it remains undeveloped.

The earliest use of arbitrary symbols in our species was perhaps to indicate personal identity. They replaced nonsymbolic indicators of status such as physical size, and involuntary indexes such as plumage displays. In gibbons, territorial calls also have features that can indicate sex, rank, and (un)mated condition.

The duetting long call behavior seen in chimpanzees and bonobos, in which one animal matches its call to that of another, indicates a degree of transferrability of the calls between individuals, and an element of learning. But it seems likely that such duetting is 'parrot-like', in that the imitating animal is in no way attempting to convey the 'meaning' (e.g. rank, identity) of the imitated call. The duetting behavior is not evidence of transfer of *symbolic* behavior from one individual to another. Probably, the duetting behavior itself has some social/pragmatic significance, perhaps similar to grooming.

In humans the ability to trade conversationally in symbols comes naturally. Even humans have some difficulty when the symbol clashes with its meaning, as, for example, if the word 'red' is printed in green. Humans are able to overcome such difficulties and get

a response to the *symbol* to take precedence over the response to the *thing*. But chimpanzees apparently cannot suppress an instinctive response to concrete stimuli in favor of response to symbols. With few exceptions, even trained apes usually only indulge in symbolic behavior to satisfy immediate desires. The circumstances of wild chimpanzee life have not led to the evolution of a species of animal with a high readiness or willingness (as with humans) to use symbols, even though the rudiments of symbolic ability are present.

Evolution of Language 3: Physical Preadaptations

We owe the concept of *preadaptation* (sometimes termed 'exaptation') to Charles Darwin (1859; *On the origin of species*: 190), who observed that 'an organ might be modified for some other and quite distinct purpose'. Preadaptation explains many seemingly unaccountable transitions in the evolutionary process. For example, the bones of the mammalian middle ear derive from the hinged jawbones of reptiles, and the retina of the eye derives from normal skin tissue. Preadaptation is responsible for many of the characteristics that differentiate human linguistic ability from the communications of closely related living species, such as chimpanzees.

In this light, studies of the communicative abilities of chimpanzees are of special interest. Approximately 98% of the genetic code is common to humans and chimpanzees; the skeletal remains of early, extinct hominids (species close to or in the line of human evolution) are similar in many ways to those of chimpanzees. Therefore, any aspect of language shared by humans and chimpanzees is most likely a 'primitive' characteristic that characterized the linguistic ability of our common ancestors some 6 to 7 million years ago. And features that differentiate humans from chimpanzees must have evolved during that period. Studies of the communications of chimpanzees in situations where they have been raised by humans and exposed to manually transmitted languages (American Sign Language or computer keyboards that code words) show that they possess the ability to acquire about 150 words and can comprehend spoken English sentences that have a simple syntax. In contrast, chimpanzees cannot talk, nor can they comprehend or produce (by using sign language) utterances that have complex syntax. We can conclude that speech production is a derived feature of human language.

Preadaptation is involved in the evolution of virtually all aspects of speech production. Speech production involves three components: (1) the lungs, which generate the expiratory airflow that is the power source; (2) the larynx, which serves for phonation, i.e. it converts alveolar airflow through vibration into a quasiperiodic series of puffs of air containing acoustic energy at audible frequencies; and (3) the airway between the larynx and lips, the supralaryngeal vocal tract (SVT), which acts as an acoustic filter, allowing maximum acoustic energy to pass through it at certain *formant* frequencies.

Speech has an overt linguistic function closely linked to syntax. The flow of air from the lungs can segment the flow of speech into sentences or into shorter clause-length segments. Human speakers can mark out the units for syntactic analysis, usually sentences, by producing each one with a single breath. A constellation of acoustic cues marks the end of each breath group. The fundamental frequency of phonation (F0), the rate at which the larynx produces puffs of air (perceived as the *pitch* of a speaker's voice), and distinctions in syllable duration and amplitude, signal the end of a breath group. These acoustic cues are the primary physical markers of sentence *intonation*. Long sentences can be linked by using two or more breath groups. The fact that speech is produced and segmented by expiratory airflow follows from the preadaptive, evolutionary history of our lungs. As Charles Darwin noted in 1859, the lungs of terrestrial animals derive from the swim bladders of fish. The elasticity of the lungs, which reflects their original function, lends itself to the production of expiratory airflow patterns that have a relatively steady air pressure. During spontaneous speech, human speakers generally anticipate the sentence that they intend to speak and execute a complex set of motor gestures to produce a breath group that has the appropriate length. The neural capacity to execute breath groups and intonation keyed to sentences may be a unique human *derived* capacity. Preliminary studies of the nerve channels of one specimen of *Homo erectus* suggest that this capacity did not exist 1 million years ago—perhaps not until the epoch of Neanderthals and modern humans.

The larynx's linguistic functions likewise show the mark of preadaptation. The original function of the larynx was to seal off the lungs of lungfish when they were underwater. In frogs and many species ultimately related to frogs (including humans), the larynx has been modified for phonation. Variations in the fundamental frequency (F0) convey emotion and affect in humans and in many other species. In many languages, systematic F0 variations alone serve to differentiate words, for example, [ma] produced with the four different *tones* of Mandarin Chinese yields four different words.

The human SVT generates the formant frequencies that differentiate vowels and consonants. The human SVT also shows the mark of preadaptation. In all primates and most mammals, including human beings older than three months, the airway above the larynx is adapted for simultaneously ingesting liquids and swallowing small chunks of solid food during breathing. In newborn primates, including humans, a relatively thin tongue is positioned almost entirely within the mouth; the larynx is positioned close to the opening to the nasal cavity and can be raised (periscope fashion), pro-

viding a sealed nose-to-lung air path during drinking. The distance between the back of the hard palate (the roof of the mouth) and vertebral column is relatively long to accommodate the raised larynx. During the first year of human life, the face moves backward relative to the rest of the skull, and the larynx descends. The larynx continues to descend until age five to six years, when the length of the mouth (the oral cavity) and the pharynx (the vertical section of the SVT) are almost equal. The pharynx and oral cavities are almost at right angles. During the course of this process, the posterior contour of the human tongue becomes almost round, forming the anterior (front) wall of the pharynx. During the production of speech, the human tongue is moved about, almost undeformed, in the right-angle space defined by the oral cavity and pharynx.

In contrast, apes follow a different growth process. As they mature, their faces restructure and project forward. They retain the high laryngeal position, long mouths, and SVTs of newborn primates. The skulls of early extinct hominids, such as Australopithecines, seem to have retained the ape-like SVTs of the common ape and human ancestral species. Examination of the skulls of juvenile and adult Neanderthal hominids, who diverged from modern human beings 500,000 years ago, show that they followed a modified nonhuman growth trajectory.

The human SVT maintains this approximately 1:1 oral/pharynx proportions throughout life. The formant frequency patterns that differentiate vowels and consonants are determined by the shape of the SVT. The formants of the vowel [i] necessitate a wide pharynx and constricted oral cavity, and those of the vowel [a] necessitate a constricted pharynx and wide oral cavity. However, the length of the SVT, which varies from person to person, results in different absolute values for the formant frequencies of the 'same' vowel or consonant produced by different individuals. Human listeners unconsciously take this into account by estimating the length of a speaker's SVT from the speech signal itself.

We, in effect, normalize formant frequencies, implicitly taking into account the anatomical constraints of speech production. The vowel [i], which cannot be produced by nonhuman SVTs that lack a 1:1 oral/pharynx proportion, is the optimal signal for this process. Because infants are able to normalize vowels between the ages of three and six months, this neural 'computation' seems to be innate. But the neural basis for normalization is another example of preadaptation; monkeys and many other animals (perhaps even alligators) seem to use formant frequencies to estimate the size of another animal. Preadaptation from this function to linguistic communication clearly occurred

and may have driven the restructuring of the human SVT to optimize the process.

The neural system of the human brain that regulates speech production is closely tied to the comprehension of language; its evolution again seems to involve preadaptation. The meaningful vocalizations of chimpanzees and monkeys often have different formant frequency patterns. However, the vocal signals of nonhuman primates are tied to specific emotions or affectual states, whereas humans produce arbitrary vocal signals that convey referential information. Humans are able to freely sequence the motor commands that generate vocal signals to form words. Although Broca's and Wernicke's areas of the cortex have been traditionally identified as the traditional language areas of the human brain, subcortical basal ganglia structures, which also sequence the motor commands necessary for walking and other aspects of motor control, are critical elements of a complex distributed neural system that confers cognitive flexibility, allowing humans to comprehend sentences with complex syntax and adapt thought processes to changing circumstances. Recent studies show that the basal ganglia perform similar sequencing operations, both in motor control and in cognitive and linguistic operations. Moreover, the neural structures that generate overt speech maintain words in short-term verbal working memory to comprehend the meaning of a sentence by the use of syntactic (arrangement of words), semantic (meaning), and pragmatic information. Because one function of the subcortical basal ganglia in humans, other mammals, and species ancestral to all mammals is to regulate adaptive motor control, preadaptation is evidently responsible for their role in the neural system that confers human linguistic ability.

Evolution of Language 4: Social Preadaptations

'Selfish gene' Darwinism differs from earlier versions of evolutionary theory in its focus on one key question: Why cooperate? The faculty of speech is an aspect of human social competence. By inference, it evolved in the context of uniquely human strategies of social cooperation.

Noam Chomsky redirected linguists' attention away from social issues, defining language as an innate competence of individuals. To study the origins of language, however, we must strike out in new directions, reconnecting linguistics with Darwinism in its modern, socially aware form. Signal evolution theory states that where social conflict exists, low-cost cryptic communication gives way to costly and elaborate display aimed at overcoming the skeptical resistance of receivers. On this basis, human speech—which is low-cost, conventional communication—can only have emerged under very different social conditions, in which listeners could afford to vest trust in one another's signaling intentions.

Communication begins not when an individual makes a sign, but when someone else interprets that action as significant. Even a purely instrumental action, after all, may be socially understood as a signal. Where this has evolutionary significance, the behavior may then undergo modification in the service

of novel, socially conferred, signaling functions. If this is accepted, syntactical structure in the case of speech may have evolved by becoming progressively elicited and then consolidated by generations of comprehending listeners. First, conceptual complexity is 'read into' signaling by the attentive mind reader; subsequently, the signaler—given such encouragement—may succeed in externalizing aspects of that complexity explicitly in the signal itself.

In keeping with this scenario, one speculative hypothesis is that speech evolved thanks to novel levels of care, solicitude, and understanding shown by human caregivers toward their offspring. Chimpanzee infants may use a characteristic 'nursing poke' as a request for the mother's nipple. To reach the nipple, the infant at first simply pushes aside its mother's arm. As mother and infant cooperatively interact, the infant saves time and effort by relying on shorthand. The abbreviated version now bears some resemblance to a linguistic sign. A distance has appeared between the gesture's underlying meaning and its surface form—suggesting the rudiments of a 'secret code'.

Among apes, however, no such code survives into adulthood. To understand why ape codes fail to survive, we must examine the social context. Whereas the human infant may anticipate long-term kin-based solicitude, benefiting from social provisioning beyond infancy, a chimp youngster must fend for itself once it has been weaned. Deprived of the prospect of caring support, it abandons not only the now irrelevant nursing poke but also most other subtle indications of need. Given the competitive exigencies of impending adulthood, the best preparatory training for the ape youngster may in fact be to *avoid* excessive reliance on cooperative understanding from others. From this perspective, elaboration of symbolic potential as young apes mature appears constrained less by cognitive deficits than by a decisive *social* one—the obvious absence, in the wild, of any unconditionally supportive or caring audience. Why bother to elucidate one's aims or interests to others who may at best show indifference—or at worst exploit such intelligence for their own ends?

When delivered in sequence, ape vocal calls emphasize a single holistic meaning. If the calls vary, they may yield at most a blended compromise between meanings. By contrast, the playful bodily gestures of ape youngsters may be rich in cognitive information and combinatorial complexity. A gesture indicating 'Let's play!', for example, may systematically reverse the significance of subsequent 'chases' or 'bites', in ways reminiscent of a grammatical marker in language. Young primates frequently engage in make-believe play, whose inventiveness may almost suggest human verbal creativity. If we are seeking an evolu-

tionary precursor for human linguistic communication, the most convincing candidate is not the vocalizations of primates but their imaginative and often humorous social play.

Conversational speech including humor in the human case extends and develops the communicative potential of immature primate play. But if this is accepted, we must ask a new question. During the course of human evolution, how did the conditions for such creativity come to be extended from infancy into adulthood? The key restriction on animals' freedom to play is reproductive competition and conflict. In many species, the onset of sexual maturity brings with it the Darwinian imperative to engage in potentially lethal sexual competition. In the primate case, this impinges upon life concurrently with sexual maturity, setting up anxieties, conflicts, and resort to defensive alliances that effectively constitute adult sociality. As competitive stresses intensify, the tendency is for play fights to give way to real ones—whereupon the play stops.

Among humans, the transition to adulthood takes a different form. Youngsters go through an extended period of childhood, during which they can rely on social as opposed to 'fend-for-yourself' provisioning. At a certain point, young hunter–gatherer adolescents become coercively incorporated into ritual coalitions. Rites of initiation—central to intergenerational cultural transmission—may be viewed as spectacular 'pretend-play' performances, drawing on hallucinatory techniques such as trance, dance, rhythm, body-painting, and so forth. Whether or not genital mutilation is involved, the declared aim is to curb individualistic pursuit of sexual advantage. Bonds of coalitionary solidarity, typically modeled on sibling solidarity, are accorded primacy over sexual bonds.

The outcome of such solidarity is a domain of institutional reality—of objective facts whose existence depends, paradoxically, on subjective belief. Within human kinship systems, for example, a woman is 'our sister' (or a man 'our brother') because the collectivity asserts it to be so. When in America today, a piece of green paper counts as a dollar bill, that too is an institutional fact, as is the belief that 'bachelor' in English means 'unmarried man'. Children engaged in games of 'let's pretend' grasp the basic principle of institutional reality when they assert, 'this rag is mummy' or 'that stick is a horse'.

During a critical transition in human evolution, the institutional realities of cultural kinship acquired supremacy over purely biological reproduction. Collective regulation of reproductive relationships substantially reduced former levels of internal, sexual, and other conflicts. The effect was to open up a new social space in which the institutional facts of language could cumulatively evolve for the first time.

Ewe and Gbe languages

The Gbe languages are spoken in an area that begins in Lower Volta in Ghana and stretches through Togo and Benin to Western Nigeria and Lower Weme. These languages belong to the Kwa family, and have been treated variously as a dialect cluster and a language cluster. Earlier, Anglophones used to refer to the whole cluster as Ewe while Francophones preferred Aja, Adja, or Adja-Tado, which are names of major dialects/languages within the cluster. The term 'Gbe' was introduced by Hounkpati Capo to refer to the whole cluster because the majority of speakers designate their speech forms by adding *-gbe* to their ethnic names. Capo divides Gbe into five major dialect clusters comprising from West to East Ewe, Gen, Aja, Phla Phera, and Fon. According to Capo, 'there is mutual intelligibility between dialects that are contiguous, e.g. Ewe and Gen, Gen and Aja, Aja and Fon, etc.; but the degree of mutual intelligibility is related to geographical distance'.

Each of Capo's dialects constitutes a dialect cluster by itself, some of which are provided in Table 1.

TABLE 1 Gbe Dialect Cluster

Ewe		Gen	Aja	Phla-Phera	Fon
Adan	Kpele	Agoi	Dogbo	Alada	Agbome

Anlo	Tonu	Gen	Sikpi	Kotafon	Kpase
Gbin	Ve	Gliji	Tado	Saxwe	Gun
Ho	Watsyi			Tofin	Maxi
Kpando	Notsie			Xwela	Weme

The Ewe dialects have been grouped into Coastal Ewe, which includes Anlo and Tonu, Central Ewe, which includes Ho and Kpedze, and Northern Ewe, which includes Anfoe and Kpando. The Central and Northern dialects are referred to as *Ewedomegbe*. While considerable variation exists within the Ewe cluster, the neighboring Gen cluster spoken in Togo and Benin is said to lack noticeable variations.

History

Oral traditions suggest that the Gbe people once lived in Ketu, a Yoruba town in present-day Republic of Benin. From there, a group moved south, and some of them settled at Tado near the Mono river. This settlement is associated with the Aja cluster. Some of those who moved south founded a settlement at Notsie (ŋɔ tsie), which is associated with Ewe. The Ewes in Ghana say their forefathers fled the tyranny of a chief called Agokoli and moved to settle in Ghana. A different group went from Ketu to settle in Adele in Togo for a while but later left to join the settlement in Notsie. Later, some of those who settled at Tado moved to found the Alada kingdom whose political nucleus was Agbome and Xɔgbonu. This settlement is associated with the Fon cluster. The Gen dialect is due to later settlement by the Fante-Aŋɛ from Elmina in Ghana who settled at Anexo, and the Ga also from Ghana who settled in the plains between Lake Gbaga and the Mono River.

Phonology

In all, 42 consonants and 16 vowels have been identified within the Gbe cluster. These are provided in Tables 2 and 3.

Not every consonant or vowel is used in every dialect. For example, Ewe is the only dialect cluster that has the voiceless and voiced bilabial fricatives, written [ƒ] and [ʋ], respectively. Some consonants also occur in complementary distribution. For instance, the nasal stops occur with nasalized vowels in Ewe while nonnasal variants occur with oral vowels, e.g. *nyɔ́* 'drip' (or *ỹɔ́* in some dialects). Also, the trill /r/ occurs only after dentals, alveolars, and palatals while the lateral occurs everywhere else, including syllable-initial position. With respect to vowels, Gɛn and Aja have merged [ɛ] and [e] into [e], while Fon and Phla Phera have retained the distinction. Within Ewe, the Coastal dialects have replaced [ɛ] with [ə].

Tone

Gbe is a tone language, i.e. intonational pitch is used to distinguish words. All the dialects use three tones namely, High, Mid, and Low. These three tones are subgrouped into High and Non-High. Consonants play an important role in the realization of these tones. Thus, a Non-High tone in a noun is realized as Mid if the noun root's consonant is a sonorant ([m, l,…]) or voiceless obstruent ([p, t, …]), as in *aŋē* 'plastic'. Where the consonant is a voiced obstruent ([b, d, g,…]), the tone is realized as Low. By contrast, a High tone in a noun is realized as High if the noun has a voiceless obstruent root consonant, and as Mid if it has a voiced obstruent. This Mid tone becomes low when the containing syllable occurs before a syllable with a high tone. In addition to these three tones that all the dialects possess, Anlo, a variant of Ewe, has an Extra High tone, and Adangbe has an Extra Low tone, which occurs on the last syllable in questions. This shows that while tone is distinctive and each lexical item possesses a basic tone, it is still highly variable in context. As such, it is not represented in the orthographic convention of the Gbe dialects. For a few words, the tones are written in Ewe to avoid confusion with other very similar words. These are the pronouns *è* 'you' vs. *e* 'he, she, it', *wò* 'you' vs. *wo* [plural marker], *nè* 'you' vs. *ne* 'if', and *lé* 'catch vs. *le* 'be located'. The combination of the three tones yields six contour tones namely, Mid–Low, High–Low, High–Mid, which are falling tones, and Low–Mid, Low–High, and Mid–High, which are falling tones.

Syllable Structure

The syllable in Gbe is predominantly open and, in the few cases where it is closed, the final consonant is always a nasal. Also, it only allows two syllable-initial consonant clusters, where the second one has to be a liquid ([l, r,…]) or an approximant ([y, w,…]), e.g. *klɔ́* 'wash', *tré* 'seal' *fiá* [fja] 'burn', and *bua* [bwa] 'pretend'.

Morphology

Nouns in Gbe can occur with the prefixes [a-], [o-], [e], [ə-], and ɛ-. While [a-] occurs in all the dialects and is obligatory for the words it occurs with, e.g. *agba* 'plate' (instead of just *gba*), the rest are optional dialectal variants (optionality indicated by parentheses). Thus, 'breast' is *(ɛ)no* 'breast' in Ho and *(ə)no* in Anlo. The Gbe dialects also have a productive reduplication process that derives different types of lexical items, including nominals, from a verbal base. Reduplication involves the copy of part of the verb root to the left. The part that is copied depends on the type of Gbe dialect. In Fon, only the initial consonant is copied, to which /i/ is added. Hence, *gba* 'build' becomes *gbigba* and *wlan* 'write' becomes *wiwlan.* In Ewe, the initial consonant together with the first vowel is copied; hence, *va* 'come' becomes *vava.* However, the second consonant in a syllable-initial cluster is not copied, e.g. *trɔ* 'turn' becomes *tɔtrɔ.*

Syntax

Gbe sentences have a basic Subject–Verb–Object word order. This order can be changed in Ewe through the focusing of an argument, e.g. *Amí kpɔ́ Kofi* 'Ami looked at Kofi' can become *Kofié Amí kpɔ́,* with *Kofi* being marked by the focus marker *-é* and moved to the sentence-initial position. The progressive and related constructions in most Gbe dialects use an auxiliary verb, e.g. *Amí le Kofi kpɔ́ḿ* 'Ami is looking at Kofi'. Note that the complement *Kofi* occurs in the preverbal position, while the progressive marker *-ḿ* is attached to the verb. In some variants, a simple high tone serves as the progressive marker. Some dialects like Aja-Dogbo and Kpesi do not allow the complement in the preverbal position.

Some verbs in Gbe are frequently mistaken for adjectives because they describe properties that are expressed by adjectives in other languages. However, they behave like other verbs in Ewe, e.g. *lolo* 'become big' takes the verbal habitual suffix *-na*. Gbe also has obligatory complement verbs (OCVs). These are verbs that cannot occur without complements. Some of the verbs are fully meaningful by themselves in the sense that they have translational equivalents in languages like English, but they must still occur with complements of generic meaning, e.g. *ɖu nú* 'lit. eat thing'. Some verbs with translational equivalents occur with complements that derive from the same root, e.g. *fi fi*

'lit. steal a steal'. A well-known type of OCV is the inherent complement verb (ICV), which is widely discussed in the literature on Kwa languages. These are verbs with indeterminate meanings that appear to be specified by their complements. The combination of an ICV and its complement usually yields concepts that are expressed by simple verbs in languages like English. An example is *fú*, which occurs with *du* 'race, course' to yield 'run', and *tsi* 'water' to yield 'swim'.

There are two types of double object verbs (DOV) in Gbe. There is the 'normal' type of DOV the only examples of which are *fíá* 'teach', and *ná* 'give', and there is the ICV type like *da* 'throw'. The complement position of the normal-type DOV is variable: either the Theme (the object transferred) or the Goal (the entity to which the transfer is effected) can occur immediately after the verb. Thus, both *fíá ha Kofi* and *fíá Kofi ha* mean 'teach Kofi a song'. The ICV-type DOV only allows the Theme to occur immediately after the verb; hence, *da kpé Kofi* 'throw a stone at Kofi'. There is a restriction on objects such that the Theme cannot be determined while the Goal is not. Thus, *Kofi ná ga lá ɖeví 'Kofi gave a child the money' is unacceptable.

Gbe also has a serial verb construction (SVC), which consists of two or more verb phrases in a clause without any syntactic marking of dependency. Additional properties of the clause include having one syntactic subject and one tense value. Also, no verb in the clause can be negated independently. An example of an SVC is *Kofi tsɔ ga lá fle agbalẽ* 'Kofi bought a book with the money.'

The Noun Phrase

The noun can occur in a clause without a determiner in which case it refers to a nondefinite entity. Thus, one can say *avu le afí má* 'lit. dog located there' to locate an animal belonging to the dog family. *Áɖé* 'a certain' is added when the speaker knows the entity. The definite article, which is *(l)á* in Ewe, is only used when the entity is known to the speaker and hearer. Gbe is also known for its logophoric pronoun. This is a pronoun used to refer to a person whose words, wishes, or thoughts are reported. The logophoric pronoun, which is *ye* in Ewe, can occur after every verb provided it occurs in a subordinate clause introduced by *bé* 'say, that', e.g. *Kofi yi be yeava kpɔ Ami* 'lit. Kofi went that he [Kofi] see Ami'.

Preposition and Postpositions

Gbe has prepositions that are derived from verbs and postpositions that are derived from nouns. The prepositions in Ewe constitute a closed class of about ten elements. They are distinguished from verbs by their inability to occur with the habitual suffix *–na*. For example, *tsó* is a verb in *Kofi tsóna le ga adé me* 'Kofi (usually) sets off at six o' clock', and a preposition in *Kofi mlɔna anyi tsó (NOT tsóna) ga ade me* 'Kofi usually sleeps from six o' clock'. Unlike Ewe, the other Gbe dialects do not have a habitual suffix and, therefore, it is difficult to determine which elements constitute a preposition without recourse to meaning. Postpositions are thus named because they occur after the noun and designate axial parts and regions of objects. Although they have mainly evolved from nouns, they are a different class of words. In Ewe, they are distinguished by their inability to take the possessive marker *ƒe*. Contrast *Kofi ƒé megbé* 'Kofi's back', where *megbé* is a nominal, with *Kofi megbé* 'behind Kofi' where it is a postposition. However, the postpositions in Gbe and other Kwa languages cannot be said to form a word class with prepositions, unlike e.g. in Japanese where the postpositions are true 'prepositions' that occur in postnominal position.

Ideophones

Finally, Gbe has ideophones — a set of words with interesting phonological and syntactic properties, e.g. *bɔhɔbɔhɔ* 'describing the heavy walk of a fat person', i.e. to dawdle. It also has utterance particles that signal the type of utterance or the attitude of the speaker, e.g. *sea* 'you hear?'

Fanakalo

Fanakalo is used in interethnic contacts in the eastern parts of South Africa. It is referred to variably as a pidgin with Zulu or Nguni vocabulary, Nguni being the Bantu subgroup to which both Zulu and Xhosa belong.

Although there is no definite consensus (there is a tendency to associate the language with the Indian emigration starting in the 1860s), it would appear that the history of Fanakalo starts with the contact between the British and speakers of Bantu languages in the Eastern Cape/Natal area from around 1840. As it proved to be a useful vehicle of interethnic communication, it soon received official encouragement—Fanakalo is rare among pidgins in that it has spread in part through formal education, as the South African Chamber of Commerce arranged courses in it in order to facilitate comprehension between miners of differing ethnic backgrounds. When European-run mining operations spread in the second half of the nineteenth century, so did Fanakalo. In the 1890s, the pidgin began to be used in Rhodesia and in the Copperbelt region of Zambia. It even ventured into the Katanga (Shaba) province of Belgian Congo, and its use has also been attested in Malawi and Namibia. In the beginning of the twentieth century, it was suggested that Fanakalo might even become *the* lingua franca of South Africa, and perhaps even of the entire southern parts of the continent.

The expansion was halted, however, and rapidly turned into a retreat. In Belgian Congo, an official decision was taken in 1918 to replace Fanakalo by Swahili as the working language, and in Zambia, the somewhat streamlined variety of Bemba known as Town Bemba gradually ousted Fanakalo. Problems gathered even on its own home turf, as Fanakalo became increasingly perceived as a means of oppressing the Black proletariat, and barring its members from learning English.

Fanakalo continues to be used in South Africa, despite explicit efforts on behalf of authorities to stamp it out. In 1995, for instance, an official reported that English ought to be used in the mines instead of Fanakalo, pretending that the latter was not an 'adequate medium of communication to ensure underground safety'. Although still known by hundreds of thousands of Africans, Fanakalo has lost much of its raison d'être, and it is most likely doomed unless the use of English in South Africa ceases to increase.

More than two thirds of the lexicon of Fanakalo is Bantu in origin—mostly Zulu, but influences from Xhosa have also been pointed out. Slightly less than a fourth of the vocabulary is derived from English, while Afrikaans has contributed the remainder. In most basic vocabulary, not unexpectedly, Zulu is dominant. On the 200-item 'Swadesh list' of basic vocabulary, only eight words are not of Zulu origin. There are some doublets in the lexicon, as in the numeral system, where English and Zulu items are in free variation.

In the segmental phonology, the most obvious departure from local Bantu languages is the substitution of plosives for clicks — at least among native speakers of nonclick languages. The implosives of Zulu have become explosive in the pidgin, but two lateral fricatives are nevertheless retained. The European component of the lexicon, on the other hand, has been largely adapted to the requirements of Bantu syllable structure. Thus, Afrikaans *sterk* 'strong' surfaces as *stelek* in the pidgin.

While Zulu is a tone language, Fanakalo does not use pitch differences to distinguish words. Also, vowel length and consonant aspiration are irrelevant. Intonational stress is on the penultimate syllable, as in Zulu. The vowel system includes five phonemes, as in the local Bantu languages.

Fanakalo is a strict S(ubject)–V(erb)–O(bject) language, as are most of those on which it is based. It is noteworthy that adjectives and numerals precede the modified nouns, as in English and Afrikaans, but contrary to Zulu and its relatives.

Although most meanings are expressed by independent words, Fanakalo does have a few bound morphemes, all of which are inherited from Zulu: past, passive, and causative are all marked by suffixes (*-ile*, *-wa*, and *-isa*, respectively).

More in line with what one would expect from a pidgin, the intricate Bantu agreement system has left few traces in Fanakalo. However, different observers disagree on the fate of the Bantu noun class system. It would seem unjustified to describe Fanakalo as a class language, although the plural prefix *ma-* has variants that distinguish whether the noun refers to animate or inanimate entities. However, Fanakalo only marginally preserves other features of the original noun class distinctions.

Different from Zulu, the future morpheme *zo* is unbound (i.e. not an affix), as is the determiner *lo*, which is perceived as shibboleth of the language to the extent that one of its aliases is *isilolo* — literally 'the lo-lo language'. The sentence negator is a free morpheme, and the bound pronominal markers of Bantu languages correspond to free morphemes in Fanakalo. These pronouns demonstrate no case distinctions, and many varieties simplify even further through the use of 2sg and 3sg plus *zonke* 'all' for the corresponding plural forms.

Clauses generally do not use a copula ('to be'), although *kona* 'to have' has a secondary use as existential copula.

Both conjunctions and subjunctions are attested, but subordination is normally replaced by coordinating strategies, often simple juxtaposition of sentences.

Several prepositions are also found, although *lapa* is semigeneralized in that it covers a wider range of uses than most prepositions in the input languages. Also common is *ga*, which — placed between the possessum and the possessor — marks genitival relationships.

Few details are known on the variation of Fanakalo. Lexical differences have been observed, however, between the different countries where pidgin is used. Not surprisingly, the Zimbabwean variety is reported to display influences from Shona, the major language of the country, in addition to having a larger English and a smaller Afrikaans component.

Farsi

Farsi is one of the three major variants of Persian, a member of the Iranian language family. The other two variants are Dari, spoken in Afghanistan, and Tajiki, spoken in Tajikistan. The Iranian languages belong to the Indo-Iranian branch of the Indo-European language family. Farsi is the official language in Iran, and is the native tongue of about half the population of this country. Other Iranian languages spoken in Iran include Gilaki, Kurdi, Lori, and Baluchi.

The evolution of Persian as the culturally dominant language of the Near East began with the political domination of the dynasties that originated in the province Pars. The name of the language, Parsi, is associated with this ancient province. After the Arab invasion in the sixth century, Parsi was utilized as *Farsi* in official documents written in Arabic due to the lack of /p/ in this language. *Farsi* is now the term used for the official language, while *Parsi* is used mostly in elevated literary writings.

Old Persian

The oldest version of Farsi is known as Old Persian, the official language of the Achæmenian Dynasty who had originated in the province Pars. Evidence of this ancient language is found in Achæmenian inscriptions, tablets, and coins. There is no document available of this language following the fall of the Achæmenian Dynasty in the third century BC.

Old Persian was structurally similar to Latin and Ancient Greek. It was a Subject–Object–Verb language with a fairly free word order in the preverbal position. The case system was rich, consisting of seven cases realized as suffixes. Here is a sample:

Nominative:	martiya 'man'
Accusative:	martiyam
Vocative:	martiyaa
Instrumental:	martiyaa
Locative:	martiyai
Genitive:	martiyahyaa
Ablative:	martiyaa

The language was basically synthetic, and the number of functional words was very limited.

Nouns and adjectives were conjugated for masculine, feminine, and neuter, and the number system consisted of singular, dual, and plural. The copula was often lacking, as illustrated by the following example:

> *Baq vazrek Ahuramazdaa*
> God great Ahuramazda
> 'The great God (is) Ahuramazda.'

Middle Persian

The oldest document available in Middle Persian, the descendent of Old Persian, belongs to the first century. That is, there is a gap of four centuries between the last documents found in Old Persian (third century BC) and the first one discovered in Middle Persian.

Middle Persian consisted of several dialects and variants. One of these variants, known as *Parti*, *Pahlavani*, or *Pahlavi*, was the language of the Ashkanian Dynasty who governed in the northeastern part of Persia from the third century BC through the third century AD. Documents related to this variant are limited to a few short inscriptions and coins attributed to this dynasty, and a few inscriptions related to the era following their fall. Another variant of Middle Persian, called *Parsik* in some documents and *Pahlavi* in some others, was the official language of the Sassanian Dynasty, a family who originated in the province Pars, and was the last dynasty before Arab invasion in the sixth century. Most scholars have this variant in mind when using the term 'Middle Persian'. The last documents detected in this language belong to the tenth century, four centuries after the fall of the Sassanian Dynasty, at a time when it had already ceased to exist as a language in use.

Although the gap between the last document found in Old Persian and the first one discovered in Middle Persian does not exceed four centuries, the morphological structure of the latter had radically changed compared to the former. The final syllables in nouns and adjectives were lost. Consequently, the rich case system had disappeared. The number system was reduced to singular and plural, and there was no sign of the three-way gender system. The plural suffix *ân* was dominantly used, and the suffix *ihâ*, the ancestor of the generic plural suffix *hâ* in Modern Farsi, was restricted to religious books such as *Bondahishn* and *Minu-ye Kherad*. Unlike Old Persian, there were many functional words present in this language. In spite of the loss of the case system, the word order was still fairly free in the preverbal position. Also, the copula continued to be absent in most cases, as in *to ki* (*hi*) (you who (are)) 'who are you'.

Modern Persian

The oldest documents written in Modern Persian can be traced to the early tenth century. Persian soon became the language of world class poetry, and has undergone some minor morphological, phonological, and syntactic changes in the last 11 centuries. Of the three variants of this language, Tajiki has preserved the syntactic properties of Middle Persian more than the other two, while spoken Farsi reveals the greatest changes with respect to word order and other syntactic properties.

Properties of Farsi

The phonological system of Farsi consisted of eight vowels in its early stages, six of them short and two long. The long vowels did not survive, and the disappearance of the feature [long] in the phonological system created a number of homophones in this language (e.g. *sheer* and *shir*, both pronounced as *shir* now, meaning 'milk' and 'lion'). All remaining vowels are tense. There are 21 consonants and one semivowel /y/ in this system. Unlike Middle Persian, Farsi does not allow initial consonant cluster, although final consonant clusters are very common in this language.

The lexicon of Farsi has been highly influenced by borrowings from Arabic. It has been estimated that 65% of the vocabulary used in modern novels and short stories is of Arabic origin. This number increases when taking into account the conservative and formal writings. The influence of modern European languages such as French, and most recently English, is also evident in the lexicon of this language.

The morphological system consists of verbal prefixes and suffixes, the generic plural suffix *hâ*, the plural suffix *ân* (only for animate nouns), and derivational affixes utilized for nouns. Verbs are inflected for person and number. There is no gender distinction, not even in the pronominal system.

One of the interesting characteristics of Farsi is its verbal constructions. Middle Persian did not have many complex verbs, and the only light verb used in verbal constructions was *kardan* 'to do'. Since the thirteenth century, complex verbs have gradually replaced simple verbs. As a result, the number of simple verbs does not exceed 115 in contemporary Farsi; many of them are not even used in the everyday application of the language. The tendency of forming complex verbs has resulted in the existence of two sets of verbs, simple and complex, for a number of verbal concepts. In many cases, the application of the simple verb is restricted to the written and elevated language (e.g. *geristan*, *gerye kardan* 'to cry'). The productivity of complex verbs is evident by the fact that its nonverbal element is not restricted to native Persian elements, nor to Arabic infinitives that entered the language centuries ago, but it also includes recent borrowings from European languages (e.g. *telefon kardan* 'to call', *tâyp kardan* 'to type'). The verbal element of complex verbs is not restricted to the verb *kardan* 'to do' as it was in Middle Persian, but it ranges over a number of simple verbs that are used as 'light verbs' in those constructions (e.g. *zadan* 'to hit', *bordan* 'to take', *dâshtan* 'to have', etc.). Another characteristic of the complex verb in Farsi is that its nonverbal element ranges over a number of categories such as nouns (*shekast dâdan* (defeat giving) 'to defeat'), adjectives (*bidâr shodan* (awake becoming) 'to wake up'), adverbs (*bâlâ bordan* (up taking) 'to promote'), and even prepositional phrases (*az yâd bordan* (of memory taking) 'to forget'). These complex verbs receive either idiomatic reading (e.g. *dast andâkhtan* (hand throwing) 'to mock') or compositional interpretation (e.g. *fekr kardan* (thought doing) 'to think').

Similar to Middle Persian, Farsi lacks a case system. The only element arguably associated with case is *râ*, a particle that marks specific direct objects for accusative case, and has evolved from Old Persian *râdi* with the meaning 'for the sake of'. The Middle Persian reflex of *râdi* is *rây*, which serves several functions such as illustrating purpose or reference, and marking the indirect object. In late Middle Persian texts, *rây* starts taking on a new function by marking the direct object as in *shaw sheerân rây be-ozan* 'Go, slay the lions'. However, even in early stages of Modern Persian the usage of this particle following specific direct objects is not widespread as in *khosro Tus be d-u dâd* 'The King gave Tus to him.' Marking specific objects for accusative case has become the dominant function of *râ* only after the fifteenth century. Lack of *râ* still persists in some unofficial dialects, such as in Jahromi, one of the Southern dialects of Persian, as in *dâr-am ketâb-et mi-khân-am* 'I am reading your book'. It has been argued that some of the Middle Persian texts were rewritten in the sixteenth and seventeenth centuries, and thus the existence of *rây* as a direct object marker in those texts might be the influence of Modern Persian, the native language of the authors. In more recent literature, the primary function of *râ* has been suggested to be marking specificity rather than accusative case. The same idea has been proposed for similar cases in regional languages, for example, *ko* in Urdu and Hindi and possibly *-I* in Turkish.

One of the major syntactic differences between Middle Persian and Farsi is the lack of ergative constructions in the latter. In Middle Persian, the transitive verb in the past tense agrees with the object, as in *man to did hi* (I you saw-2sg) 'I have seen you.' Although the verb agrees with the subject in Farsi, agreement between the nonanimate subject and the verb is optional, as in *barg-hâ sabz shod* (*and*) 'the leaves became-sg (pl) green'. However, lack of agreement is possible only in an unmarked word order in these cases. Otherwise, agreement becomes obligatory, as in *sabz shod-and / *shod barg-hâ.* Another difference between Middle Persian and Farsi is that the occurrence of the copula has become obligatory in the latter: compare *to ki* (*hi*) (who you are) in Middle Persian with *to ki *(hasti)* in Farsi.

Ezafe construction is one of the specific syntactic properties of Farsi. It is a noun phrase consisting of the head (an element with the feature [+N] such as Noun or Adjective), its modifier(s), an optional possesser, and the Ezafe particle *e* that is structurally utilized as a link between the head and its modifier, (e.g. *dokhtar-e bâhush-e dust-e mâ* 'the smart daughter of our friend'.

The basic word order is S(ubject)–O(bject)–I(ndirect) O(bject)–Verb if the direct object is followed by *râ* and receives a specific reading. The nonspecific object is semantically closer to the verb, and is syntactically adjacent to it. Thus, the basic word order is S–IO–O–V when the object is nonspecific. Farsi is a Null Subject language, and thus lacks dummy subjects comparable to *there* and *it* in English. This language has maintained the fairly free word order observed in Old and Middle Persian, and therefore is classified as a *scrambling* language. Recent studies on scrambling languages indicate that the word order in these languages is not 'free', and that the rearrangements of phrasal categories are triggered by discourse functional features such as Topic and Focus or grammatical features such as the one representing the Extended Projection Principle (EPP). The

word-order variations in these languages are subject to the general principles of Universal Grammar, and may have an effect on the semantic interpretation of the linguistic expression. Thus, the term *free word order* does not reflect the syntactic facts in Farsi and similar languages. Finally, there is no structural wh-movement in this language, although wh-phrases are subject to scrambling similar to other phrasal categories.

Feature Theory

Classical Phonetics felt the need for a classification system for speech segments to give some indication of how sounds are made and at the same time to identify relationships between them. It used the place–manner system for consonants and the high–low/front–back system for vowels. The main purpose here was clearly to enable the phonetician to specify how particular sounds were made with respect to their articulation. There was, however, an important spin-off: it became possible to use the features or parameters of the classification system to label whole sets of sounds or articulations. Thus, we might refer to 'the set of all plosives' (seven in English: *p, t, k, b, d, g*, and the *glottal stop*), 'the set of all voiced plosives' (three in English: *b, d, g*), or 'the set of all voiced alveolar plosives' (one only in English: *d*), and so on, cutting horizontally and vertically around the consonant matrix. Similarly, for vowels, 'the set of all front vowels' (English: *i, e, æ*) 'the set of all rounded vowels' (English: *u, o*), and so on.

For the most part, the categories or features used by Classical Phonetics reflected what phoneticians regarded as the salient parameters of articulation: place features such as bilabial, dental, alveolar, palatal, velar, pharyngeal, laryngeal, etc., and manner features such as plosive, fricative, continuant, etc. This is not an exhaustive list, but the idea was to characterize for each consonantal sound *where* in the vocal tract the sound was made and *how* it was made. In the case of vowels, the relative position of the relevant part of the tongue on the high–low and front–back axes of a two-dimensional coordinate system within the oral cavity would be sufficient, using front–back features such as front, central, and back, and high–low features such as high, mid, and low.

It was sometimes necessary to add to these basic classificatory features to reflect details of the articulation, often depending on how finely the phonetician needed to specify articulations. In the case of vowels, some additional features were necessary to expand on the two-dimensional coordinate systems: vowels could in addition be spread or round, nasal or nasalized, and long or short; and consonants could be either tense or lax. For example, in English the high front vowel [i] is said to be long, whereas the low front vowel [æ] is said to be short; [t] and [s] are tense sounds, but [b] and [v] are not tense.

As a spin-off of being able to label sets of sounds or articulations in this way, it became possible to describe the *behavior* of various sets—that is, the behavior common to members of now identifiable sets could be characterized. Thus, for example, it was possible to say that the set of voiced plosives devoice in word-final position or that all vowels lengthen before voiced plosives in the same syllable, and so on. Hence, rules no longer had to be about the contextual behavior of individual sounds, but in terms of how sets or classes of sounds behave. Phoneticians now had the ability to capture and express generalization—an important theoretical principle in linguistics: generalizations *must* be expressed whenever possible. Capturing generalizations is the basis of predictive modeling because it means that we can ask the question: What about any other segment that has these same features?—even though we may

not yet have analyzed it. Generalization leads to predictions and hypotheses, and these form a strong basis for scientific advance.

For all its potential as the basis of a truly scientific study of speech, the feature classification system afforded by Classical Phonetics, however, rested in fact on very weak theory. For example, a given sound might have its relevant features identified, but phoneticians did not yet have a way of saying why there were gaps in how features could be combined, nor was it possible to predict why certain sounds could not in fact ever occur. Why can we not have a bilabial plosive that is also a fricative? Why is it not possible to have a voiced glottal fricative? We can easily supply answers to these questions—but it is hard to construct a theory around this system that predicts all the constraints and at the same time all the possibilities in an *explanatory* way—which is ultimately what we are after. We want to know *why* things are the way they are, as well as simply being able to characterize them *as* they are.

It was not until Transformational Generative Grammar came along, though, that these generalizations became formalized in recent phonological theory. Morris Halle's *Sound pattern of Russian* (1959) was really the first influential textbook in modern phonological theory (just two years after Noam Chomsky's *Syntactic structures* (1957), the first influential textbook in modern syntactic theory). The Generative Phonologists adopted the theory of distinctive features from the earlier Prague School of Linguistics (Nikolai Trubetskoy 1958 [1939])—a much more formal representational system than that of the classical phoneticians.

Distinctive Feature Theory in Phonology

The use of distinctive features in phonology enables us to capture *natural classes*, and, by extension, to generalize regularly occurring phenomena and to formulate predictions about the behavior of class members. If we wanted to hypothesize about human processing of phonology, we would use this idea to suggest that human beings process the patterns of phonology as part of speech planning in terms of these classes rather than in terms of individual segments. The regularity of patterning in phonology is part of the evidence for this claim—but the claim is more solid when based on the evidence that when the users of a language make up new words they do so by producing utterances that obey the rules of the natural classes their sounds fall into.

There have been various sets of distinctive features proposed as the parameters of segment description and classification. The original set appeared in Jakobson et al. (1952), and consisted of around 14 features; Jakobson and Halle (1956) had 12. Chomsky and

Halle (1968) had around 45 features, explaining that they found the original set of 14 somewhat inappropriate for characterizing some subtleties in phonology.

Most modern phonologists argue for a binary system of indexing features: a segment either possesses or does not possess any one particular feature. The point here is that whereas when describing the physical world of phonetics it may be useful to have a system capable of capturing multivalued features (an *n*-ary system), in the cognitive or perceptual world of phonology the binary system is preferable. For example, although we might find that there is somewhat more coarticulation between [−nasal] vowels and surrounding [+nasal] consonants (in words like *man* or *moon*) in some US accents of English than in most British accents of English, phonologically this observation is not relevant. There are no nasal vowels in English, although we may want to note that in some accents they are nasalized in some environments, the degree of nasalization being of no consequence.

Clearly, with a binary system of indexing, the maximum number of features needed to uniquely classify the sounds of a language like English (with around 45 phonemes) would be six, giving us 2^6 or 64 segments. More would be needed to uniquely classify the sounds of all the languages of the world or indeed all possible human languages. Larger sets of features were chosen because it was felt appropriate to sacrifice mathematical simplicity or elegance in favor of a feature-labeling system that appeared to relate these phonological features with the phonetic set of Classical Phonetics. Thus, the *meaning* of the features became more transparent.

These ideas are embodied in three principles surrounding the distinctive feature set. They should be able to

(1) characterize all *contrasting segments* in human languages;
(2) capture *natural classes* in a clear fashion; and
(3) be transparent with regard to *phonetic correlates*.

A claim inherent in the *first principle* is that the feature set might somehow embody the universal humanness of features rather than any language-*specific* nature. It is predicted that if this set is correctly specified, no other features will be needed even for future languages, as long as human beings do not change how they make and handle language—that is, as long as human beings remain human.

The *second principle* refers to not just classes, but *natural* classes. The idea here is that the classes themselves reveal something of what is natural in human language behavior, once again referring to the fact that phonological processing is a human activity, and will therefore contain elements that are truly universal.

The *third principle* enables us to establish phonetic similarity—that is, to group sounds that are phonetically similar by feature. In the end, there is a very good reason for doing this: it becomes possible to explain some phonological processes in terms of the behavior of their phonetic correlates.

The distinctive feature set most usually found these days is approximately that of Halle and Clements (1983), which is based on the Chomsky and Halle (1968) set. A detailed description can be found in Gussenhoven and Jacobs (1998). Chomsky and Halle have a lengthy description of their own set.

Feature Sets

The 12 features found in Jakobson and Halle (1956) can be related to what it is they characterize articulatorily and acoustically. These are abstract, phonological features; hence, their relationship with phonetic characterizations is one of relative correlation, rather than absolute definition. The physical correlates are only approximate—there are many variants on these simple descriptions both between languages and dialects, and between different speakers (see Table 1).

The Chomsky and Halle feature set is more comprehensive. There are some 27 basic articulatory features, although each has particular acoustic correlates. One point about these features is that they can be used at an abstract phonological or perceptual level, in which case they take on binary values, or they can be used in a fairly limited way at a physical phonetic level, in which case they can be multivalued. It is important to realize, though, that the correlation is not necessarily linear or one-to-one (see Table 2).

Example Use of Distinctive Feature Theory: Redundancy

Redundancy is an important aspect of phonology that is captured by the use of distinctive features. Consider, for example, the fact that all segments in English that are [+nasal] are also [+voice]. We could say that to specify [+voice] for segments like [m] and [n] is to fail to capture this redundancy. The main distinctive feature here is the nasality—the voicing is secondary and entirely predictable: all nasal consonants are voiced—remember we are discussing abstract phonology, not phonetics.

One of the principles involved in Distinctive Feature Theory is to set up a system to capture all the segmental contrasts in the world's languages. This can be done, and we can also show where there is no contrast: there is no contrast, nor possibility of contrast, where there is redundancy. If nasals are always voiced, then there cannot be a contrast involving voiceless nasals. Two things follow from this in the way we use features in the theory:

- we need only indicate those feature markings that contribute to the contrasts in a particular language;
- we can capture the redundancies in a separate table of metarules—rules outside the Distinctive Feature specification.

TABLE 1

Feature	Opposing Feature	Articulatory Correlation	Acoustic Correlation
Vocalic	Nonvocalic	Vocal cord vibration, relatively unobstructed vocal tract	Periodic vocal cord excitation and clear formant structure
Consonantal	Non-consonantal	Partial or complete vocal tract constriction	Overall energy relatively low
Compact	Diffuse	Front 'resonance chamber' dominates	Energy focused toward the center of the spectrum
Tense	Lax	Vocal organs relatively tense or the entire tract voluntarily greatly distorted	High energy, spread throughout the spectrum
Voiced	Voiceless	Vocal cord vibration present	Periodic (laryngeal) excitation
Nasal	Oral	Nasal cavity brought into play—the velum is lowered	Additional nasal formant(s) present
Discontinuous	Continuous	Vocal tract rapidly closing and opening	Interruption of the acoustic 'flow'
Strident	Mellow	Turbulence created at the place of articulation	Temporally unstructured noise at a relatively high frequency
Checked	Unchecked	Glottalized	Abrupt energy onset/offset
Grave	Acute	Marginal within the vocal tract (not central)	Energy focused on the lower part of the spectrum
Flat	Plain	Constricted aperture (example is lip-rounding)	Upper frequencies attenuated
Sharp	Plain	Constriction of the upper oral cavity, but relative widening or the lower cavity or pharynx	Lower frequencies attenuated

This table is based on Appendix 2 of Clark and Yallop (1990)

TABLE 2

Feature	Articulatory Correlation
Major class features	
1. Sonorant	Vocal cord vibration possible and usually present
2. Vocalic (or syllabic)	Vocal cord vibration possible, but vocal tract constriction restricted to vowel positions
3. Consonantal	Significant constriction present in the vocal tract Cavity features
4. Coronal	Blade of the tongue raised
5. Anterior	Constriction in front of the palatoalveolar place
6. High	Raised tongue body
7. Low	Lowered tongue body
8. Back	Retracted tongue body
9. Rounded	Labial rounding
10. Distributed	Extended place of articulation
11. Covered	Narrow and tense pharynx or raised larynx
12. Glottal constriction	Constriction produced by the vocal cords
13. Nasal	Velar port open
14. Lateral	Tongue sides lowered
Manner of articulation features	
15. Continuant ([−continuant]=stop)	Relatively unimpeded airflow
16. Instantaneous release	Sudden release (as in plosives)
17. Velar suction	Velar closure (used in clicks, for example)
18. Implosive	Glottal closure produces inward airflow
19. Velar pressure	(Unclear)
20. Ejective	Glottal closure and increased pressure
21. Tense ([−tense]=lax)	Musculature is highly contracted
Source features	
22. Raised subglottal pressure	Increased muscular contraction to raise subglottal pressure
23. Voiced ([−voiced]=voiceless)	The vocal cords are vibrating
24. Strident	Airflow turbulence produced at point of articulation
Prosodic features	
25. Stressed	(Unclear)
26. Pitch (relative, scalar)	(Unclear)
27. Length (relative, scalar)	(Unclear)

This table is based on Appendix 2 of Clark and Yallop (1990)

Omitting feature markings where there is redundancy means literally leaving the redundant cells blank in the distinctive feature matrix formed when segments have their feature specification characterized. The fact of the redundancy is captured by separate rules that take the general form:

if X then Y
or, in our specific example,
if [+nasal] then [+voice].

But why would we want to capture this redundancy, except to show that it is a regularity in the way segmental features pattern? We want to do this because speakers of a language *know* about the redundancy. Let us look at an example: there are three nasals in English: the nasal alveolar stop [n], the bilabial nasal stop [m], and the velar nasal [ŋ]. If we ask an English speaker to *invent* a new nasal—say, a palatal nasal like the one found in the French word *angeau*—they will also automatically make it [+voice]. It is as though they know that nasals must be voiced, which is another way of stating the above rule.

A very early original important text on this point was Richard Stanley's *Redundancy rules in phonology*, published in the journal *Language* in 1967 (Vol. 43). These redundancy rules were called *segment structure rules* to contrast them with another type: *sequence structure rules*. The latter capture a speaker's knowledge of redundancy in the specification of segments themselves in patterned sequences. Thus, if we have the sequence at the beginning of a syllable in English: CCCV... (with C=consonant, V=vowel), then the first C must be [s]—a completely redundant situation, since all we need to know is that there is a consonant there, followed by two others. In fact, there are heavy constraints also, of course, on the remaining two consonants: the second one must be a plosive and the third must be a liquid ([r, l]) of some sort or a semivowel ([y, w]). Some phonologists have pointed out that the onset of a syllable strings consonants together with increasing sonority until you get to the vowel nucleus (the supreme sonorous segment), followed by a coda of consonants of decreasing sonority—although there are exceptions to this principle.

Stanley's work, which like much of the earlier work in modern phonology, adopted an essentially *linear*

approach to analysis. Segments were characterized in terms of how they behaved with respect to their neighboring segments in the surface string, which represented the underlying phonological makeup of utterances. These days it is better to reconstruct such analysis in a *nonlinear* or hierarchical way, since this is much more revealing of the underlying constraints on the sequencing of segments on the surface. Nevertheless, whatever the approach the focus is on structure in phonology and the way such structure is particularly well expressed using sets of constraints on what can and cannot happen in a phonological system.

Explanation is the ultimate goal, and for this to be fully effective it must be sourced from outside the domain of linguistics itself. Thus, for example, we could use Distinctive Feature Theory to express an observed regularity that in many languages utterance final obstruents that are [+voice] often become [−voice], and this regularity is *explained* by reference to the failure of vocal cord vibration as the transglottal airflow decreases with falling subglottal air pressure—that is, the vocal cord vibration tends to stop as we run out of breath toward the end of an utterance. The explanation for the phonological regularity captured by regularities expressed through Distinctive Feature Theory lies *outside* phonology—in the domain of aerodynamics.

Distinctive Feature Theory makes a distinction then between the use of features for characterizing the contrastive properties of phonological segments, and using them to indicate redundancy. An *incomplete* distinctive feature matrix uses blanks to indicate redundancy (and lets you know where cells are the subject of redundancy rules), whereas a *fully specified* distinctive feature matrix has all cells filled with either a + or a − to indicate exhaustively just which features are present or absent for this particular segment.

Distinctive Feature Theory has been a significant step forward in classification from the rather crude phonetically based ideas of Classical Phonetics. Remembering, however, that it is essentially a concept in abstract phonology (rather than phonetics), its principal importance lies in how it lends itself to capturing the generality of phonological processes and the principles underlying the structure of phonological segments.

Ferguson, Charles Albert

Charles Albert Ferguson is best known for his 1959 article 'Diglossia'. In it he undertook to describe a particular 'language situation' in which two closely related but substantially different varieties of a language (one designated 'High', the other 'Low') exist side by side in a single speech community in a stable and functionally complementary relationship. This article has spawned approximately 3,000 studies of the topic, with no apparent end in sight. Some view its publication as the beginning of the field of sociolinguistics.

It has been reprinted in various collections and translated into a variety of languages.

Ferguson's interests were exceptionally broad, both geographically and topically. He spent a good deal of his career focused on Arabic and with languages of South Asia, but also wrote on speech communities and topics as varied as the phonology of Philadelphia, literacy in Diyari (an Australian language), loss of agreement patterns in Swedish, and the Ethiopian educational system. His interests bridged the 'applied'

and 'theoretical' divide. During much of the first half of his career, he was professionally occupied with solving practical language problems, such as developing language training programs or assisting developing nations in matters of language planning and policy. He spent the last half of his career at Stanford University, where he was able to pursue more theoretical research (e.g. child phonology and language universals), but he remained actively involved in applied linguistics.

Over the course of his career, Ferguson pushed for a far more comprehensive theory of language than was typical of other linguists. Although trained in the American structuralist tradition, even as a student he came to see it as too narrow as he attended lectures by Roman Jakobson, a noted European linguist and key figure in the Prague School. Some time later, he began to seriously read the works of the Prague School, which deeply impressed him. This inclusiveness became a Ferguson hallmark. He never aligned himself with any particular school of linguistics nor did he found his own. His M.A. and Ph.D. advisor, Zellig Harris (whom Ferguson greatly admired but also considered overly concerned with theory building), felt that Ferguson was much like Edward Sapir. This is evident in Ferguson's interest in various types of linguistic phenomena, particularly those considered marginal by most linguists (slips of the tongue, formulaic expressions, rhymes, proverbs, baby talk, etc.).

Rather than espouse or denounce any particular theoretical persuasion, Ferguson worked to bring diverse parties together, gently pointing out gaps in their theories and opportunities for fruitful research and cooperation. He seemed to have a gift for identifying new ground that would prove fertile. As a result, he is honored as a pioneering figure in fields such as child language, sociolinguistics, modern Arabic studies, and discourse analysis. Ferguson possessed such rare vision that even much of his early work continues to be highly relevant today.

While he ranged broadly, his work is nevertheless unified by the continuous pursuit of a better understanding of the related and fundamental topics of language universals, conventionalization, and variation. With his friend and colleague, Joseph Greenberg, he pressed for studies of a broad representative sample of various languages and language situations that would illuminate the commonalities in types of language change, structure, and use. Much of language is, however, not universal and Ferguson was fascinated with the question of how the largely arbitrary code that is the language of a given speech community comes to be shared by the individual members of the community, who in fact do not all use that language precisely alike. Some of this variation is systematic, and therefore part of the conventions of the speech community (e.g. variation that correlates with an individual's social class or gender). However, some language behavior appears to be idiosyncratic. For Ferguson, an adequate theory of human language must be capable of accounting for all of this.

Methodologically, Ferguson preferred to study a manageable linguistic phenomenon, such as politeness expressions, and consider its implications for a more general understanding of human language behavior. He found comparative case studies particularly revealing. He pushed himself and others to aim for high standards of accurate observation of actual language use, to seek for insights from different perspectives, and to include data from overlooked sources. Some of this he accomplished through his own publications—including his book reviews, some of which were quite influential and have been reprinted. In addition, however, one should not overlook his considerable influence from behind the scenes as the chair of influential committees, as a mentor, as the organizer of conferences, and as the architect of a highly influential department of linguistics.

Biography

Charles Albert Ferguson was born in Philadelphia, Pennsylvania on July 6, 1921. His early curiosity led to the study of languages and linguistics at the University of Pennsylvania, where he received his B.A. (1942) in Philosophy and his M.A. (1943) and Ph.D. (1945) in Oriental Studies; in 1947 he became a founding linguist of the Foreign Service Institute of the US Department of State and founder of the Foreign Service Arabic Field School in Beirut; in 1955–1959 he taught Arabic and linguistics at Harvard University; and in 1959 he was founding director of the Center for Applied Linguistics, Washington, DC. From 1947 to 1966 he was also actively involved at Georgetown University, and in 1967 he was founding chair of the Stanford University linguistics program. In 1971, he was president, Linguistic Society of America; in 1975 he was elected to the American Academy of Arts and Sciences; and in 1986 he was Professor Emeritus of Linguistics. He passed away on September 2, 1998.

Field Methods

Language use pervades daily life. Linguistic data are ubiquitous. Nevertheless, collection of these data requires careful consideration. Methods for gathering data are tailored to the questions being investigated. The 'classic' field situation in which a linguist starts from scratch to describe a previously unknown language is increasingly rare. More often, linguists are working within communities exploring particular elements of language use: child language acquisition, gender patterning, and linguistic variation within the community.

Data Collection

In the 'classic' field situation, linguists often work with one or two principal 'informants'. The linguist records as much as possible of naturally occurring speech, but analyzes this daily for new elements and supplements these samples with elicitations designed to test for phonemic status. Once phonemes have been designated, transcription often shifts to a practical or phonemic orthography, although details that may reflect on register, style, and/or social divisions may be lost. Classical analysis proceeds to outline the basic structures of morphology and syntax, and perhaps semantics and pragmatics. In amassing vocabulary, the collection of stories, narratives, and natural conversations may be augmented by elicitation. Word lists aid in structuring such sessions; the Swadesh list (Swadesh 1952, 1955; Hymes 1960) provides 200 core vocabulary words, chosen for universality. Forms may also be generated using canonical forms for root morphemes and systematically combining these with an inventory of the derivational affixes of the language; native speakers can then note which of these potential words are actually occurring. Linguists interested in syntactic variability may not find all the structures their models predict within their corpus of natural texts; again, elicitation may check the acceptability of sentences' potentials. Insights into the pragmatics of language use often flow from 'mistakes' in the linguist's production; laughter, awkward silences, and correction provide valuable data about appropriate forms and their felicity conditions.

Sociolinguistic fieldwork requires that the researcher record the social characteristics of the speakers. Since almost any such characteristic may impact speech, most studies restrict the variables noted to some predetermined set, often including age, educational level, gender, and socioeconomic class. Dialectology requires geographic as well as social information.

Random sampling is useful for the study of variation within a community. Even when the interview

schedule is short and minimally intrusive, cooperation is often difficult to obtain. Random means of substitution for preselected interviewees should be established.

Network interviewing typically meets with less resistance. An initial contact within the community is used to explicate the study and its purpose and to enlist further contacts. Community members may serve as brokers, interviewers, and/or researchers for the project.

Some projects may be introduced from the top down. This is especially effective in 'salvage' situations, where the community feels its language is at risk or in need of development, such as bilingual education programs. The community leaders may introduce the research and the investigator, as well as provide coresearchers, interviewers, and initial contacts.

Phone interviews are possible in many countries and can be effective, where the variable to be investigated can be quickly elicited. Snail and e-mail surveys may be used to get an 'ideal' report of people's usage, if the variable is one that is transparent and non-presupposing. Such surveys do not accurately record usage of stigmatized forms. Surveys of educators have been used in language planning in many countries; such surveys can provide data on which language of several is used by children in the classroom, by their parents, and the presence of particular forms in the linguistic repertoire, although underestimation of fluency in hegemonic languages and, paradoxically, underestimation of minority language use are common.

The 'rapid and anonymous' survey is effective for documenting linguistic variables that serve as social markers. Labov's (1996) survey of department stores in New York City used a single question about the location of a store's product to elicit the answer 'fourth floor'; the presence or absence of postvocalic /r/ in the response was correlated to socioeconomic status of the store's staff.

Linguists may analyze any corpus of language use, including broadcast and print media, electronic texts, documents, and inscribed artifacts.

Equipment

Early field linguistics was done with few recording devices beyond the pen(cil) and paper, but modern electronics allows the preservation of more complete speech events. Videotaping can capture much of the context of the speech act: age and gender of the participants, part of the physical environment, kinesics. Nonetheless, for many field situations the use of a small audio recorder is more practical, as it is often considered less intrusive. Participants tend to forget the presence of the equipment after a brief time, although the technology itself can have status implications for the speakers as well as the researcher. Recordings, digital or digitized, can be fed directly into computers, which provide spectrographic analyses, time the phonations and silences, and, in some cases, provide provisional transcription. Likewise, programs can be used to facilitate phonological analyses, finding complementary and contrastive distributions, and free variation. Text processing programs designed for interlinear translation provide consistency in glossing and ease in concordancing and dictionary creation.

Transcription Techniques

How many and which details are noted in transcription correlates with the purpose of the study. In preliminary field analysis, the researcher may be limited to transcribing isolated words. Fine phonetic details such as degree of aspiration of consonants, degree of voicing, nasalization, pitch height, loudness, length, and speed may be necessary for phonological analysis. For those languages with practical orthographies, these may be used if the problem of study is above the phonological level. Researchers involved in conversational analysis find that they need to record the speaker turns, intonation units, truncations, overlaps, pauses, and laughter. Interactional analyses often require kinesic information as well: speaker gaze, body orientation, and gestures. Some writers have used 'eye-dialect' annotations to hint at the social/regional character of the interlocutors without providing actual phonetic transcription. Because 'eye-dialect' is nonsystematic and signals 'different from standard' rather than actual production, most researchers prefer to provide sociocultural information on the speakers in introductory comments, or in comment lines throughout the texts. Such comment lines can also provide background information on the topics referenced in the recorded text. Some researchers provide key codes to selected forms that they will want to extract for analysis: e.g. prefixing negative face work with -F, noticings with N, or repairs with R. Linguistic contexts are so rich that no transcription system can capture the entire event; narrowing is a necessary adjunct of 'reduction' to writing.

Ethics

A person's identity is bound up in her speech patterns. Issues of how people speak are sensitive, especially in areas where a hegemonic language or dialect is recognized as 'standard', as such codes are regularly assumed to be correct, relegating other varieties to the status of incorrect. People who are cognizant that their

speech is being monitored may alter that speech to provide a desired self-image. This may make it difficult for the linguist to elicit or record casual or natural speech. Nonetheless, clandestine recording and use of language samples without the permission of the speakers is unethical. Where the speakers are aware of the research and its goals and support these ends, the influence of overt recording can be mitigated. Familiarity with the recorders/cameras and their increasing unobstrusiveness can yield surprisingly candid language samples. Where the language being recorded is taboo, secret, or designed for use in ritual contexts only, an understanding of how/if the data will be published must be reached. When descriptive grammars are written, care should be exercised in the example sentences used to respect the cultural norms. When possible, publications and preliminary findings should be shared with the host community. Some researchers have built in evaluation by the speakers as an additional level of data collection, bearing on the attitudinal base of language use. Language data are all around us. Linguistic field methods consist of the selection, recording, and codification of these data.

Figurative Speech

Figurative speech/language is the creative manipulation of the phonological, syntactic, semantic, pragmatic structures of texts, or associations of normal language use, producing 'extra' patternings to arrive at vivid expressions and innovative ideas. It is the opposite of denotative speech/language. There are many different types of figurative speech, ranging from the repetition of a sound (alliteration) to a semantic and pragmatic contradiction in co-occurring items (oxymoron); both of these types are illustrated in the phrase 'friendly foe'.

The term 'figure' or 'figurative' comes from the Latin *figura* ('shape', 'form', or, more specifically, 'attitude', 'posture'). The concept of figures of speech is an ancient and powerful interdisciplinary one. It originated in Sicily in the fifth century $\int \chi$E as a set of conventions for speaking within a legal setting. The oratorical functions of rhetoric broadened when it was adopted in Greece. Plato attacked rhetoric; Aristotle defended it, and systematized the conventions in his *Rhetoric* (approximately 330 $\int \chi$E). The most influential Roman writer on Rhetoric was Cicero (*De Inventione,* approximately 87 $\int \chi$E). During the Renaissance, it occupied a central place in Poetics (i.e. the critical study of poetry).

The books of and on rhetoric all provide lists of terms, with definitions and examples (cf. Leech 1969; Dixon 1977). However, not all the divisions have acquired equal currency/popularity. Puttenham has classified these devices according to what sense (that of the eye, the ear, or the mind) they appeal to. A useful distinction is between 'tropes' and 'schemes'. Tropes play upon the meaning of a word/sentence. They include:

> Metaphor (referring to one thing in terms of another, e.g. He is a lion in the field. Here, the term 'lion' is used to refer to the bravery and fierceness of a human being)
>
> Metonymy (referring to something in terms of a conceptually adjacent item, e.g. *Crown* for sovereign)
>
> Synecdoche (using a part for the whole, e.g. *hand* for worker)

Simile (metaphor by explicit comparison, e.g. He is like a lion in the field)

Personification (envisaging a quality of a person, e.g. *Love* for the beloved)

Oxymoron (putting together semantically opposite terms, e.g. darkness visible)

On the other hand, schemes play upon normal sound/word order. Some of them are:

Alliteration (repetition of consonants/vowels and/or syllable within a line, e.g. the *b*reeze *b*lew)

Anaphora (repetition of the same word/phrase at the beginning of lines, e.g. the Beatitudes of the Bible that makes nine statements starting with 'Blessed are...')

Chiasmus (repetition of words or phrases in reverse order, e.g. 'If he is at Waterbath he does not care for you. If he cares for you he's not at Waterbath.')

Parison (a series of equally constructed clauses, e.g. 'It is the time of war, it is the time of care/It is the time of courage, it is the time of fear')

Zeugma (use of one word to apply to two or more words, e.g. '*Stein* her honour or her new brocade')

Another useful distinction is made linguistically, dividing the figures among phonological, orthographic, lexical, and syntactic categories. An example of a phonological figure can be alliteration, because alliteration plays with the phonemes or sound units of a language. Orthographical figures are those where the orthographical symbol, i.e. a letter/s are changed for special effects, such as 'Amerikkka' for 'America'. A metaphor is an example of a lexical figure, where a lexical item is involved in the figurative speech. A syntactic figure can be a parison, where the clauses/sentences create the figurative speech.

In addition to the examples provided above, other devices traditionally used as figures of speech include anachorism, anachronism, anticlimax, antithesis, antonomasia, apostrophe, assonance, bathos, cacophemism, climax, dysphemism, euphemism, hendiadys, hypallage/transferred epithet, hyperbaton, hyperbole, irony, litotes, meiosis/understatement, onomatopoeia, paradox, prolepsis, and pun/paronomasia (for a detailed discussion, see McArthur 1996).

It is very difficult to draw a line between figurative and literal/plain and conventional speech. The difficulty is enhanced by the fact that language itself is symbolic or figurative — we use some abstract symbols or letters to signify some real objects that we see or hear about, or some abstract ideas that we cherish.

In that sense, every word is a figurative speech. These ideas developed rapidly in the twentieth century. The classical view of figurative speech considered it to be a mere embellishment that deviates from the ordinary uses of language. This view was dominant until the end of the nineteenth century. However, the twentieth century accepted the figures to be as old as language itself.

The aim of all figurative speech is to create an impact, which may be pleasing or shocking, politically, culturally, or socially. These ends are achieved through a striking and novel imagery, through contrasts and comparisons, through juxtaposition, repetition, by evoking echoes of previous linguistic/spatial/temporal/social context(s). However, once these new concepts, associations, expressions, and comparisons are widely accepted and adopted, the figurative meaning slowly dies out or is forgotten; and the word/phrase becomes a part of the 'ordinary', 'core' language.

Figurative speech, not necessarily under that name, has remained a preoccupation in the twentieth-century literary criticism, particularly New Criticism, Stylistics, Practical Criticism, with their emphasis on micropatterns of language. Such paradigm texts as Empson's *Seven types of ambiguity* (1930) and Brooks's *The well wrought urn* (1947) are essentially reworkings of texts as structures of figurative language. Reader-oriented Criticism, like traditional rhetoric, gives focal importance to the addressee. Linguistic Stylistics, in its early days, was regarded as a modern 'descriptive rhetoric': the descriptive instruments of linguistics were deployed in the identification of rhetorical figures (Leech 1969; Fowler 1986).

There have been some plausible programs for describing and classifying figurative speech in semiotic, pragmatic, and linguistic terms (Plett 1985). The most sweeping interdisciplinary treatment of figures has been that of Jakobson (1956). He discussed metaphor and metonymy as fundamental structuring principles in such diverse fields as poetry, aphasia, and language development. Such tropes as metaphor are now widely used in analyzing how people understand and share experience (Lakoff and Johnson 1980). They have the potential to provide a promising agenda for research in Psycholinguistics and Sociolinguistics.

Fillmore, Charles John

Charles John Fillmore studied Linguistics at the University of Minnesota, in the late 1940s, followed by a brief period of anthropology studies before ending up in the US Army. After one year of training in the United States, he spent two years in Japan, with the Army Security Agency, where he spent eight hours a day listening to short-wave broadcasts from Soviet forces in and around Vladivostok. Two years later, he was discharged from the Army and attended classes at Kyoto University while earning a living teaching English at a Buddhist girls school. When he got back home in 1956, he went to the University of Michigan in Ann Arbor, at first intending more to become a Japanologist than a linguist.

As a graduate student there, Charles J. Fillmore started out mainly as a phonologist, having received most of his phonological training just at the historical point where descriptive/structuralist phonology was giving way to generative phonology. He knew Kenneth Pike's work on Phonemics very well, as well as all of the papers on phonemic analysis that could be found in the Martin Joos Reader in Linguistics. A major turning point in his thinking was a paper by Morris Halle, a review of work by a Russian linguist, Avanesov. He had been writing a paper with the phonetician Gordon Peterson (who was his teacher then) when the Halle influence came along. The Peterson–Fillmore paper was going to be a set of principles, on the basis of which it would be possible to design an automatic program for producing a phonemic analysis of any language based on purely phonetic and distributional facts. Fillmore was not able to influence Peterson to change the direction of the paper and after that he was left on his own. But, aside from a survey paper he did with Professor Peterson and a paper with Bill Wang on 'intrinsic cues for consonant perception', and a dissertation on alternative phonemic analysis of Japanese, he never did anything else in Phonetics or Phonology.

When he got his degree, he joined William Wang at Ohio State, who was invited to start a linguistics program there. Fillmore was associated with a funded research project there called Project on Linguistic Analysis, and that is where he began doing lexical work. He taught courses in the transformationalist framework, and he became sort of evangelical about this new movement. He did some work on rule ordering (a booklet on indirect object constructions and a few related papers that nobody knows about dealt with this, and his paper on 'embedding transformations', which seems to have been the first proposal for the idea of the transformational cycle, was a part of this). The interest in verbs and their complementation patterns led up to a group of papers that formulated a proposal called 'Case Grammar', which became quickly popular. This instant popularity made him suspicious. He had received relief from teaching for ten weeks to write something on Deixis, which he somehow developed interest in while at Ohio State, but he spent the time writing 'The case for case' instead.

He was invited to spend a year at the Center for Advanced Study in the Behavioral Sciences, in Palo Alto in 1970, and at that time he wrote the 'Lectures on Deixis', which was distributed in various informal ways for 30 years and finally appeared in book form in 1997. While in California, he was invited to move to Berkeley, and he accepted. Teaching in Berkeley at first tended to deal with rule ordering arguments in Syntax, Case Grammar, and General Linguistics. In later decades, he focused on Lexical Semantics, Deixis, and Pragmatics, and all this led to a strong interest in idiomaticity and fixed expressions in general. This led in a sort of natural way to Construction Grammar, his strongest interest in the last decade of active teaching. Much of this was influenced by the interdisciplinary connections fostered by the Cognitive Science program that was just getting started on the Berkeley campus. In his thinking about Construction Grammar, he has been

influenced most by Arnold Zwicky and Paul Kay. In his lexicographic work, his strongest influence has been the British lexicographer Beryl T. Sue Atkins. And his main interest since his recent retirement from the classroom has been computational lexicography, through the direction of a project called 'FrameNet' (http://www.icsi.berkeley.edu/~framenet).

With Frame Semantics, Fillmore brings into the picture the main theoretical tenets of Cognitive Linguistics: the idea that language is an integral part of cognition, which reflects the interaction of cultural, psychological, communicative, and functional considerations.

> The basic assumption of Frame Semantics [...] is that each word evokes a particular frame and possibly profiles some element or aspect of that frame. An 'evoked' frame is the structure of knowledge required for the understanding of a given lexical or phrasal item; a 'profiled' entity is the component of a frame that integrates directly into the semantic structure of the surrounding text or sentence. (Fillmore et al. 2000:2)

The frame notion is the basis for what Fillmore (1985) calls the semantics of understanding (U-semantics), which contrasts with what may be called truth conditional semantics (T-semantics). U-semantics aims to determine what it takes for a hearer to provide an interpretation of a sentence. This is not only a compositional approach, because its operation relies on a knowledge of words, phrases, and grammatical constructions for an interpretation to be construed, but also noncompositional in that the construction process is not guided by purely symbolic operations from bottom to top. In contrast, the goal of T-semantics is to determine under what conditions a sentence may be true, where truth is determined compositionally (Fillmore 1982:230–2). In fact, for him the connection between Lexical Semantics and Construction Grammar goes beyond the matter of representation. Construction Grammar views the description of grammatical patterns and the semantic and pragmatic purposes they serve as equally important and necessary. In Construction Grammar, the semantic frame associated with a lexical item provides some of the semantic information needed for the semantic interpretation of a sentence (Fillmore 1994). Thus, lexical relations as such are not as interesting as the semantic properties that words have by virtue of their participation in frames.

His latest book, *Language form, meaning and practice* (Fillmore 2001), traces questions of language form, language use, and conventions linking form, meaning, and practice. But his latest wish is to see soon a kind of lexicographic practice that recognizes the 'frame' background of sense descriptions (cf. 'FrameNet').

Biography

Charles John Fillmore, Chuck for everyone around him, was born in St. Paul, Minnesota on August 9, 1929. He received his B.A. in Linguistics at the University of Minnesota in 1951, and his M.A. (1958) and Ph.D. (1961) at the University of Michigan. The title of his dissertation was *A system for characterizing phonological theories*. The following were his honors: Institute Professor, LSA Summer Institute, Salzburg, Austria, 1979; President, Cognitive Science Society, 1980; Election to American Academy of Arts and Sciences, 1984; President, Linguistic Society of America, 1991; Festschrifts: Masayoshi Shibatani and Sandra A. Thompson (eds.), two volumes: *Grammatical constructions: their form and meaning*, Oxford 1996; *Essays in semantics and pragmatics,* Benjamins-Amsterdam 1996; and The Berkeley Citation (UCB) 1998. He was employed from 1952 to 1955 by the US Army, Army Security Agency; from 1955 to 1957 as English teacher at Kyoto Women's School, Kyoto, Japan; from 1961 to 1970 as Assistant Professor through Full Professor by The Ohio State University; 1970–1971, Fellow, Stanford Center for Advanced Study in the Behavioral Sciences; 1971–1994, Professor of Linguistics, University of California at Berkeley; Department Chairman, Department of Linguistics, 1979–1983; Acting Director, Institute of Cognitive Studies, 1985–1989; 1994–2001, Graduate School Professor at the University of California at Berkeley; Research Associate at the International Computer Science Institute, Berkeley and director of the 'FrameNet' project. He is a member of many editorial boards.

Finite-State Morphology

Finite-state morphology is a computational model of morphology that uses an abstract computing device called a *finite-state automaton* or a *finite-state machine*. Such an abstract machine is capable of defining a language and has a number of useful computational properties. Note that the term *language* is used here to mean a formal language, which is a set of sequences of symbols, and not necessarily a language spoken by humans. The following concise technical definition is included for completeness. Readers who do not require mathematical rigor may skip the formal definition and proceed to the intuitive explanation below.

Formally, a finite-state automaton is a quintuple $M = (\Sigma, S, s_0, F, \delta)$, where

- Σ is an *alphabet*,
- S is a finite set of *states*,
- s_0 is a designated *start state* within S,
- F is a subset of S called the set of *final states*, and
- δ is the *transition function* $\delta : S \times \Sigma \rightarrow S$.

Such an abstract machine is capable of defining a language through an extension of the transition function, $\delta^* : S \times \Sigma^* \rightarrow S$, that extends δ to sequences of members of Σ^*, the set of sequences of symbols taken from Σ. We define δ^* as follows:

- Let $\sigma_1 \ldots \sigma_n \in \Sigma^*$ be any sequence in Σ^*.

- Let λ denote the empty sequence consisting of no symbols. Then
  - $\delta^*(s, \lambda) = s$ and
  - $\delta^*(s, \sigma_1 \ldots \sigma_n) = \delta(\delta^*(\sigma_2 \ldots \sigma_n), \sigma_1)$ when $n > 0$.

The language $L(M)$ defined by M is the set $L(M) = \{\sigma \in \Sigma^* \mid \delta^*(s_0, \sigma) \in F\}$.

Intuitively, one can think of a finite-state automaton as a diagram where the set of states are circles and the transition function is a set of arrows connecting states as in Figure 1.

Each state has one arrow pointing out of it for each element of the alphabet. States are generally labeled for identification, and the start state and the set of final states are marked in some way. Such a diagram can be thought of as a machine by imagining a bug sitting on the start state. As the symbols of a particular sequence, σ, are called out, the bug crawls along the arrow labeled with that symbol to the next state. If, after the entire sequence has be called, the bug is sitting on a state that is a final state, then the sequence σ is in the language defined by the automaton. In the example shown in Figure 1, the language is the set of sequences of a's and b's that contain an odd number of a's. A finite state machine used in this way is called a *finite-state recognizer* since it recognizes sequences of a particular language (see Figure 1).
Figure 1. Odd number of a's (final state is shaded).

Although every state must have an arrow for each symbol of the alphabet, we generally draw the diagram with an assumed sink state that is not drawn. The sink state is one where all arrows simply point back to the same state. When an arrow is missing in the diagram, it is assumed to point to a sink state that is not in the set of final states.

If, on every arrow, we put a pair of symbols, we have what is called a finite-state transducer. Intuitively, we think of the first symbol as the input symbol and the second symbol as the output. This provides us with a kind of translator. It is finite-state transducers that are generally used for finite-state morphology.

Finite-state machines are important because they are computationally simple to implement and have a number of convenient computational properties. For example, the amount of memory required to determine if a given sequence is in the defined language is independent of the length of the sequence. Another useful property is that both finite-state recognizers and finite-state transducers can be easily combined to form the union or intersection of languages. Hence, specific morphological rules can be modeled independently by separate finite-state transducers and then combined into a single machine. Although not all languages can be defined by finite-state machines, the morphology of many human languages can be modeled quite successfully with finite-state models.

In order to use finite-state transducers for morphology, the alphabet is defined as the set of morphemes and the diagram defines the sequences of morphemes that properly define a word for a given human language. The transducer defines a 'translation' between the morphological rules that are used to construct the word and the surface realization of the word.

By far the most prevalent model for finite-state morphology is two-level morphology as proposed by Kimmo Koskenniemi, who used the model originally to describe Finnish morphology. Koskenniemi uses a set of finite-state transducers to produce a mapping between the surface graphical representation of a word and its phonological/morphological representations. In Koskenniemi's model, the multiple machines are not usually combined into a single machine, but operate in parallel, with each machine representing one morphological rule. For example, using a variant of Koskenniemi's original notation, the rule

y/i $\Leftrightarrow$ $\lozenge$[bcdfghjklmnpqrstvwxyz]~ • [e][s]

would define a rule that requires a 'y' that is preceded by a consonant and followed by the plural ending 's' being replaced by 'i' in the surface representation. The rule is essentially the rule learned in grammar school: 'To form the plural of a word that ends in a 'y' preceded by a consonant, then change the 'y' to 'i' and add es'. In the notation here, the symbol '~' denotes an instance of the left-hand side of the rule and the symbol • denotes a morphological boundary. The square brackets enclose alternative symbols so that each set of square brackets represents one symbol from among the alternatives.

Koskenniemi originally used his model for Finnish and hand translated each rule into a finite-state transducer. Later programs carry out the translation by computers. The two-level model is very powerful and can handle the morphologies of at least a large portion of the world's human languages.

Finnish and Finnic Languages

Finnic (also Fennic, Balto-Finnic) belongs to the *Finno-Ugrian languages* (also Finno-Ugric), one of the two branches of the *Uralic* languages (the other consists of Samoyed languages). In addition to Basque and the Indo-European languages, it is the only other language family represented in Europe. The concept Finno-Ugrian is based on the two dominant Finno-Ugrian languages: Finnish (Finnic) and Hungarian (Ugric). There are two theories about the original Finno-Ugrian homeland. It was situated on the western side of the Uralic mountains, at River Volga's great turn south, or is believed to have consisted of a continuum of Finno-Ugrian populations from the Uralic mountains to the Baltic sea. The latter view, which has gained increasing support, partly stems from a reevaluation of the history and development of the Finnic languages.

The Finnic languages are spoken around the Gulf of Finland. Finnish is spoken north of the Gulf, in Finland; Estonian is spoken south of it; and east of the Gulf, several minor Finnic languages are spoken: Votic (also Votian, Vote), Ingrian (also Izhorian), Karelian, Ludian, and Veps (also Vepsian). In northern Latvia, a few people still speak Livonian. Ingrian, Votic, and Livonian are likely to lack mother-tongue speakers in approximately one generation.

There have been continuous contacts in the Baltic area among early Indo-European, Baltic, Germanic, and Finno-Ugrian people since about 500–2000 BCE. Estonia has probably been inhabited by Finno-Ugrian people since 2000 BCE. Three major ancestral (proto) forms of Finnic were probably established around 300–1000 BCE. The area north of present-day St. Petersburg, the Karelian Isthmus, the area north of Lake Ladoga, and that between Ladoga and Lake Onega have housed people who later became the Karelians, the Ingrians, and possibly the Veps. By 800 CE, the Finnic languages had reached the geographical distribution that became the basis of their autonomous linguistic developments.

The early phases of the Finnic languages are not well known. The people have been known since the first century CE. The same name has, however, been used to refer to different people. The use of Fenni (by Tacitus in his *Germania*, 98 CE) was apparently used for the Saami and by others, later, for the Finns. The use of Aestii probably referred to Baltic people initially and only later became reserved for Estonians. The Saami languages are related to, but not counted as, Finnic languages. The Saami presumably shifted their language to or were extensively influenced by Proto-Finnic. The genetic origins of the Saami remain a riddle. With the expansion of the Finns in Finland, the Saami were pushed northward.

The Finnic influences have followed two main lines. There have been west–east contacts between Finnish and Karelian/Ingrian (less with Votic and Veps) and north–south contacts between Finnish and Estonian. Estonian, in turn, has been in intensive contact with Votic and Livonian. Between the periphery languages, for example, Finnish and Veps or Livonian, there are considerable linguistic differences and restricted mutual intelligibility.

The external linguistic contacts have had four main historical directions: Swedish influenced Finnish, German influenced Estonian, Russian influenced Karelian (as well as Ludian, Ingrian, Votic, and Vepsian), and Latvian influenced Livonian. Reversed local influences have also occurred, but to a lesser extent.

The Finns and Estonians were Christianized by Germanic people in the twelfth and thirteenth centuries. They remained Catholics until the Reformation. The Karelians, Votes, and Ingrians were Christianized from the south and have remained Eastern Orthodox. The Votes and Ingrians, as well as the Veps, have belonged to the political spheres of Novgorod, Moscow, and, later, Russia. A peace treaty in Pähkinäsaari in 1323 created the first national border of Finland. This border between Sweden and Finland and Novgorod and Russia has been modified many times, especially in 1617, when the Swedish conquest of the Baltic-Finnic area in the early seventeenth century caused an exodus of Orthodox Finnic people into Russia. The border has developed into a language boundary between Finns and speakers of Karelian, Ingrian, and Votic.

Finnish is spoken by approximately 5.1 million speakers in the Baltic area, including 250,000 speakers in Sweden, 10,000 in northern Norway, and 60,000 in Russia. Approximately 94% of Finland's population (5.1 million) are Finnish-speakers. Since 1919, Finnish and Swedish have been the national official languages of the Republic of Finland. Since 2000, Finnish has been an official minority language in Sweden. From time to time, Finnish has had official status in Karelia. Migrant communities can be found in the United States and Canada (100,000–150,000 speakers), Germany

(30,000), Estonia (13,000), Norway, Denmark, Australia, and elsewhere.

Finnish was codified in the sixteenth century and recodified during the nineteenth century. Up to 1540, it was called *old Finnish*. The period of *old written Finnish* continued into the 1820s. The period between 1820 and 1870 is called *early modern Finnish*. During that period, which coincided with that of the Grand Duchy of Finland (1809–1917) under the Russian Empire, a romantic, nationalistically based discussion on the origins, the future direction, and status of Finnish was largely settled. The birth of *modern Finnish* is set to around 1870, when Aleksis Kivi's novel *Seven brothers* was published. During the nineteenth century, the older, analytic Swedish-influenced language changed into the modern form of Finnish. The dialects were used as a source of relexification (renewal of the vocabulary) and grammar development.

Early Finnish writing was based on southwestern (Turku) dialects. The New Testament (1547) was translated by the cleric Michael Agricola, who lived in Turku, the political and religious center of Finland (Stockholm was the capital). The southwestern impact was weakened in the translation of the Bible (1642). Of great importance was the collection and compilation of the Kalevala epic (by Elias Lönnrot; it was completed in 1849), which had eastern origins (Savo and Karelian). The written standard formed a compromise based on older western and later eastern sources. A new spoken standard was also developed. The orthography closely matched the spoken standard: one sound largely corresponded to one sign/letter, and one letter corresponded to one way of pronouncing it. This ideal relationship does not persist today.

Finno-Ugrian studies have contributed important hypotheses about the older cultural development in the area. The contacts with Indo-European languages were established early, maybe around 2000 BCE. Among the oldest Indo-European loanwords in Finnish, one finds *nimi* 'name', *vesi* 'water', and *kesä* 'summer'. Some of the oldest Indo-European vocabulary belongs to the core vocabulary. There has also been a period of close contacts with Aryan/Iranian languages, the time of which is uncertain: *jumala* 'God', *syntyä* 'be born', and *taivas* 'heaven' stem from these contacts. Among the old loanwords are also Baltic ones: *hirvi* 'elk', *lohi* 'salmon', *heinä* 'hay', *kirves* 'ax', *seinä* 'wall', *silta* 'bridge', and *heimo* 'tribe'. The Baltic influence has been interpreted as a result of intimate contacts and interethnic marriages. Another long-term influence was Germanic: *juusto* 'cheese', *leipä* 'bread', *ranta* 'shore', *kulta* 'gold', *rauta* 'iron', *kauppa* 'shop', *raha* 'money', and *kuningas* 'king'. Slavonic influence is much more recent (600–800 CE): *lusikka* 'spoon', *ikkuna* 'win-

dow', *pappi* 'priest', *pakana* 'pagan', and *risti* 'cross'. From the twelfth century, Scandinavian/Swedish influence has been quite strong on Finnish: *katu* 'street', *laki* 'law', *helvetti* 'hell', *lasi* 'glass', and *tuoli* 'chair'. Swedish has been a mediator of western European cultural influences to Finnish throughout their common history.

Some of the older core vocabulary in Finnish, such as *kieli* 'tongue; language', *nuoli* 'arrow', *veri* 'blood', *käly* 'sister-in-law', *silmä* 'eye', *suksi* 'ski', *kala* 'fish', *päivä* 'day', *koivu* 'birch', *kaksi* 'two', *viisi* 'five', *elää* 'live', and *kuolla* 'die', probably stem from the Uralic protolanguage period (approximately 4000–5000 BCE). Several of the words reflect typical features of Finno-Ugrian languages.

Some Finnic and Finno-Ugrian languages have *vowel harmony*, for example, Finnish (Estonian lost it around the seventeenth century). Vowel harmony restricts the combination of vowels in a word and its endings according to the principle of assimilation. Front vowels (y, ö, ä) combine with each other, and back vowels (u, o, a) combine with each other. For example, *käly* 'sister-in-law' is based on front vowels, and *kuolla* 'die' is based on back vowels. The vowels /i/ and /e/ are considered neutral.

In Finnish and the Finno-Ugrian languages, words can be attached to each other in long rows (agglutination) to express the same content and grammatical relations that languages such as English express with separate words. The Finnish two-word phrase *Menisimmekö iltakävelyllemme?* corresponds to the English sentence 'shall we go for our evening walk?'

Finnish and Finnic languages lack definite and indefinite articles. The phrase *pimeässä metsässä* 'in + dark + forest' may mean 'in *a* dark forest' and also 'in *the* dark forest'. Finnish has taken steps on the way to develop a definite article during the last two centuries, *se* 'it', and an indefinite article, *yksi* 'one'.

Finnic languages lack grammatical gender. The third-person singular pronoun *hän* in Finnish is identical for 'he' and 'she'.

Finnish has two main dialect groups, the western and eastern dialects, which can be subdivided: Häme dialects, heirs of early Proto-Finnish; southwestern dialects with clear traces of Scandinavian and Estonian; Ostrobothnian dialects; Savo dialects, probably developed from Karelian; north Finnish dialects developed from trade and contacts with the north from Karelia, Häme, southwestern Finland, and, later, Savo areas; and southeastern dialects. Meänkieli, the other official minority language in northern Sweden, originates from the 'mixed' northern dialects of Finland. The Finnish dialects in Tornedalen in turn became the main source for Kven Finnish in northern Norway (seventeenth century). For Finnish dialects, few

problems of mutual intelligibility exist, except possibly between the southwestern and the eastern Savo dialects.

Capital Helsinki speech plays a central role in present-day Finnish. Helsinki has experienced several language shift periods between Swedish and Finnish since the sixteenth century. It has received many waves of speakers of different dialect backgrounds. Western dialects, especially the southern Häme dialects, have dominated. At the end of the 1800s, the influx of both Finnish-speaking and Swedish-speaking labor forces created a basis for extensive language contacts. Finally, standard spoken Finnish, which was established in the young often bilingual bourgeoisie of the late 1800s and early 1900s, has contributed to Helsinki speech. These different linguistic origins have created a mix not found elsewhere. For approximately 40–50 years, Helsinki speech has been an overt prestige model for the rest of Finland.

Estonian has two main dialects: the northern dialects (with Tallinn as the main city) and the southern dialects (main city Tartu), including the southeastern Võru dialect. The orthography is based on the northern dialects, but the southern dialects have had a writing of their own. The main dialect division may reflect the two early Finnic protolanguages south and east of the Gulf. Estonian is the third largest Finno-Ugrian language, with approximately 1 million speakers out of the 1.5 million inhabitants in Estonia. The remainder (0.4 million) mainly speaks Russian. Estonian was formally an official language, together with Russian, during the Soviet rule, but this changed after independence in 1991. In 1995, the new Language Law made Estonian the sole official language of the Republic of Estonia. Estonian communities live in northwestern Russia, Finland (10,000), and Sweden (10,000). Migrant communities live in North America and Western Europe. As a result of Russian and Soviet time deportations, Estonians also live in Siberia and the Far East.

The translation of the Catechism in 1535 by Johann Koell (in Wittenberg, Germany) introduced written Estonian. During the following centuries, Estonian books were mainly written by German speakers; hence, German had an extensive influence on written Estonian. Beginning in the nineteenth century, German influence faced a nationalistic 'purification' similar to that of Swedish in Finland. Estonians were inspired by the Finnish attempts, to the extent that a folk epic similar to Kalevala was compiled: Kalevpoeg (in 1862; by Friedrich Reinhold Kreuzwald). The 'nationalization' of Estonian brought about greater linguistic distance to Finnish, because the language activists in Estonia and Finland preferred different solutions when they created new words for Germanic loanwords. The lexical influence of Russian grew during the twentieth century, but its linguistic impact remains smaller than that of German.

Linguistic differences between Estonian and Finnish include the central high Estonian vowel /õ/, võõras, cf. Finnish vieras, 'stranger; guest'. Estonian also lost word-final vowels: Finnish silmä vs. Estonian silm 'eye', Finnish piimä 'sour milk' vs. Estonian piim 'milk', Finnish Raamattu 'Bible' vs. Estonian raamat 'book'. The last two pairs also exemplify the many shifts in meaning. Estonian lacks the Finnish diphthongs, for example: Finnish (minä) syön corresponds to Estonian ma söön, 'I eat'.

Estonian has resisted the dominance of both German and Russian. The great social distance between the German speakers and Estonians may have been one reason, because Estonians experienced a harsh serfdom under Balto-German landlords up to the nineteenth century. Another reason may be that Peter the Great created an administrative and cultural center east of Estonia when he founded St. Petersburg, his window to the west at the Baltic Sea. Other Finnic languages in that area were submersed by Russian dominance. For example, Votic and Ingrian today rely on some dozens of speakers. The area around St. Petersburg has also been a battlefield during several wars between Sweden/Finland and Russia and between Russia and Germany. Genocide of Finnic people (especially Ingrians) during some of the Soviet regimes and Russification of all citizens of the Soviet Union have contributed to the language death of the Finnic neighbors of Estonian.

Karelian is the third largest of the Finnic languages. It is believed to have developed more independently from the ninth to eleventh century CE. Proto-Karelian made up the basis for Ingrian, but Karelian itself has developed in close contact with Veps. Karelian consists of four major dialects, which are partly an effect of different language contacts. North Karelian dialects are close to the eastern Finnish dialects. South Karelian is spoken west and north of Lake Ladoga. Aunus is spoken southeast of south Karelian, in and around the town of Aunus. Ludian is spoken west of Petrozavodsk. Ludian is sometimes described as a contact language of Karelian and Veps. As a result of the exodus into Russia in the seventeenth century, some Karelian 'islands' developed close to Kalinin. These so-called Tver-Karelians still speak Karelian.

During the 1930s, three attempts were made to create a standard Karelian orthography. Karelian is a minority language within its own autonomous Karelian Republic (approximately 10% of the 800,000 inhabitants speak Karelian). Their distribution is uneven, however: Karelian has been better maintained in rural areas. The dialect split has made the choice of

one variety and one writing system difficult. Speakers of the northern dialects and the notable group of Finnish speakers in Karelia have preferred standard Finnish orthography. The fact that all Karelians know Russian, and the strong Orthodox faith, are other factors complicating the introduction of a Latinized Karelian writing.

Veps is often described as an archaic Finnic language. In historical time, it remained in contact with the eastern Finno-Ugrian languages. It is spoken south of Ludian and west and south of Lake Onega and Lake Valgjärvi. The number of speakers of Veps is estimated at 10,000 to 12,000. Three of four main dialects have survived: North, Central, and South Veps. The number of speakers of Veps and its area have diminished continuously. The post-Soviet society has made it possible to support and study Veps (also for western Finno-Ugrists). In-depth studies of Veps would cast additional light on the contacts among the Indo-European, Baltic, Finnic, and other Finno-Ugrian people. They could also add new aspects to the study of the potential development of a Baltic Sprachbund. The study of and support to Veps are urgent tasks because of its ongoing language shift.

Firth, John Rupert

The British linguist John Rupert Firth (1890–1960) has traditionally been associated with two quite different approaches in linguistics. The first approach relates to a sociological linguistic theory called the *Theory of the context of situation*, influenced by the works of the anthropologist Bronislaw Malinowski. The second is a technique of phonological analysis developed by the so-called London School. However, a detailed study of Firth's work and teaching (mainly from 1930 to 1957) forces us to describe his influence in linguistics in somewhat different terms. Throughout his works, Firth developed a linguistic theory of his own that places special theoretical emphasis on two levels of analysis: the social level (equivalent to the *pragmatic* level, in modern terms) and the phonological one.

Firth explained his theory on language in *Speech* (1930) and *The tongues of men* (1937). Both works present functionalist and relativist thinking in the study of language, which Firth called 'descriptive linguistics'. Firth developed a theory for language in action, not a universal theory of human linguistic ability. These books are a presentation of his thinking similar to Sapir's *Language* (1921) and Bloomfield's *Language* (1933), but Firth did not expound a method of linguistic analysis. Rather, he wrote for the general public and showed a multidisciplinary theoretical approach, which he maintained throughout his works. Thus, these books develop a study of language from the biological, historical, sociological, and linguistic point of view. The rest of Firth's work—its greatest part—is published as highly specialized theoretical articles or collections of articles. Firth's style has been described as obscure, mainly because he rarely focused on one topic throughout any given article. His essays are usually an amalgam of theoretical knowledge, readings, and opinions.

Firth understood language as a system of signs that we use to do things; that is to say, language works in different ways in different contexts. For Firth, language is somewhat magical, and this linguistic power is what we learn from the day we are born. All the events in a speaker's life (society, culture, roles, personalities, etc.) dictate the form of this person's language. Some critics detect here a behaviorist attitude in Firth's writing, inherited from Malinowski's works and teaching. However, one could point out that this may be just one of the many functionalist aspects of his thinking, and that there is a relationship between Malinowski (and later Firth) and the American prag-matism in the works of G.H. Mead, J. Dewey, and G. de Laguna.

Descriptive linguistics identifies the social component of language as a critical aspect of language, and Firth introduced a linguistic category encompassing the elements that usually occur in a communicative situation. He labeled this category *Context of situation*, and its elements are:

(1) The participants: persons, personalities, and relevant features of these.

    (a) The verbal action of the participants.
    (b) The nonverbal action of the participants.

(2) The relevant objects and nonverbal and nonpersonal events.
(3) The effect of the verbal action.

Firth used a recurring metaphor—the dispersion of light into a spectrum—to explain another important part of his theory: levels of analysis. He described linguistics as the prism through which light (the language) passes. The result of this division—or dispersion—are the different modes of meaning that we can find in the linguistic analysis of an utterance. These modes of meaning must be described by their own linguistic categories, which establish different levels of analysis (e.g. phonetics vs. phonology vs. morphology, etc.). The different meanings must be revealed and analyzed by the linguist, keeping in mind a very important premise in firthian theory: that Meaning is Function (cf. Wittgenstein's *Philosophical investigations*, 1954).

Thus, descriptive linguistics studies different meanings on the different levels of analysis, but not necessarily in a hierarchical way (from phonetics to semantics or vice versa). Apart from the context of situation level, Firth posits the lexical, grammatical (syntactical and morphological level), phonological, and phonetic levels, but he is committed to a specific number of levels.

Two theoretical concepts developed by Firth now form part of the technical vocabulary of linguistics: collocation and colligation. The first is used at the lexical level and refers to a word that acquires part of its meaning by the company of the words it usually keeps. The second term is colligation, very similar to agreement, which is used at the grammatical level to refer to the syntactical relationship that an element maintains within a construction with others.

The theoretical points of view that Firth maintained in his works are very peculiar. Since the publication of De Saussure's *Cours de linguistique générale* (1916), language has been divided into systems and structures with their respective paradigmatic and syntagmatic relationships. One concept, however, separates Firth (and later the London School) from the rest of the linguistic paradigms: polisystemicity. Polisystemic means 'several systems', and this concept is applied to different aspects of linguistic analysis. For example, a language can contain several phonetic systems: a native system with its own phonetic patterns, and systems of foreign phonetic patterns borrowed from other languages. At the same time, a language can contain several subsystems within its structures: a consonant–vowel–consonant pattern (CVC) is a structure that contains a system for initial consonants C-, a system for medial vowels -V-, and a system for final consonants -C. This polisystemic approach is opposed to the monosystemic approach (typical of structuralism), where only one system is posited for the whole language (a good example is the hypothesis of a 'phonological system' of a language containing a closed set of phonemes).

Firth criticized this monosystemic and paradigmatic approach because it provides only an incomplete analysis of a language. His polisystemic approach, in contrast, studies not only the paradigmatic relationships but also the syntagmatic ones. These are the theoretical underpinnings of the main categories that Firth established at the phonological level: phonematic unit and prosody. These two categories form the conceptual basis of Firth's phonology, and later of the Prosodic Analysis developed by the London School.

Phonematic unit is a phonological category, applied at the phonological level. Sound structures are represented using the phonematic units 'C' for consonants and 'V' for vowels. Each one of these units is, at the same time, the representation of a system given at that place in the structure where some potential elements appear. Phonematic unit is thus the expression of a paradigmatic or vertical relationship. On the other hand, prosody, far from classical definitions (related to poetry, metrics, or suprasegmentals), is a syntagmatic or horizontal relationship given in a structure, i.e. something that happens at the same time in the structure as a whole and characterizes it. In fact, a prosody is usually the guide for setting up a structure. These concepts are implicit in Firth's early works but are most clearly developed in his 1948 article 'Sounds and prosodies'. This article is known as the foundation of the *Prosodic analysis* (later *Firthian prosodic analysis*, FPA), a technique of phonological analysis almost solely used by the London School. The most important work of this school was done during the 1950s and 1960s by authors such as E. Henderson, J. Carnochan, K. Sprigg, F.R. Palmer, and R.H. Robins. Although some bibliographies claim that FPA failed, it is still being developed (with some theoretical changes due to recent phonological studies) in some parts of the United Kingdom.

Thus, Firth developed a linguistic theory that found different applications on different levels of analysis. Firth's influence, although important, is not well known. While his name is mainly associated with the London School and *Firthian prosodic analysis, systemic-functional grammar*, which is associated with the work of M.A.K. Halliday, he is also known as *Neo-Firthian*. More complete works on Firth and FPA are currently becoming available, which, in some sense, is a vindication of his theoretical contribution to linguistics.

Biography

John Rupert Firth was born in Leeds, England, Great Britain, on June 17, 1890. He did his B.A. (1911) and M.A. (1913), both in history. He was a lecturer in History at the City of Leeds Training College in 1913, and that year joined the Indian Education Service. He was Professor of English at the University of the Punjab, Lahore (now Pakistan) (1920–1928), and Senior Lecturer in the Department of Phonetics at University College, London (1928–1938), holding meanwhile a number of part-time appointments. He had an Assistantship in Sociology of Languages at the London School of Economics (1928), where he worked with Bronislaw Malinowsky, was Senior Lecturer in the School of Oriental and African Studies in 1938, and Reader in Linguistics and Indian Phonetics in 1940.

Firth held the first chair of General Linguistics in Great Britain (1944) at the University College, London. He was also Head of the Department of Phonetics and Linguistics since 1941. Although he retired in 1955, he continued attending the Philological Society meetings, of which he was a member since 1933, President from 1954 to 1957, and Vice-President in 1959. He died on December 14, 1960.

Fishman, Joshua A.

With his prolific research work spanning almost four decades, Joshua Fishman has been recognized as a leading sociolinguist/sociologist of language. He has been influential in scholarly studies of the relationship between language and society—at the macro level (i.e. the broad societal level) as against micro (i.e. the individual level). His major theoretical contribution is the concept of 'domains' (i.e. a larger unit than situation, e.g. that of family, work) of language use and the extension of the concept of 'diglossia' (i.e. the existence of two or more varieties of the same dialect/language) to include bilingualism. The fact that three volumes of scholarly articles were brought out on his 65th birthday indicates the extent of his academic influence.

Fishman's first scholarly article appeared in *Yidishe Shprakh* in 1947. It was an outcome of his ardent interest in the study of his mother tongue, Yiddish. In 1949, he received a prize from the Yiddish Scientific Institute for an unpublished monograph on bilingualism. An extended study of minority languages and bilingualism started in response to a routine questionnaire circulated by the US Census Bureau for the national census of 1960, for which he suggested a revision of the language questions. This initiated his campaign to establish the importance of collecting data on the status of non-English languages in the United States. Eventually, it led to the publication of the book *Language loyalty in the United States* (1966), the major reference work in the preparation of the Bilingual Education Act (Senate Bill 428). It also established a new area of research in Sociolinguistics: language maintenance and shift as a field of study.

Broad perspectives on the issues involved in language planning typify Fishman's work—he has probed into interrelated topics such as the relationship of language, ethnicity, nationality, and state (see Fishman 1972); language maintenance and shift (1964); bilingualism and diglossia (1967); languages of wider communication (1989); the stages involved in adequate language planning (1974); and issues of corpus planning such as the development of vocabulary in Israel (Fellman and Fishman 1977). His edited book, *Handbook of language and ethnic identity*, is a collection of 28 unpublished papers that provide a kaleidoscopic vision of a variety of social issues—including Economics, History, Political Science, Ethnography, Sociology, Sociolinguistics, Psychology, and Religion.

A macrosociological and quantitative (i.e. statistical data collection) approach is the distinguishing feature of Fishman's work. His work is characterized by meticulous analysis of large bodies of data collected in major surveys using methods of sociology and more recently, in collaboration with Gella Fishman, it has also incorporated the exhaustive elucidation and interpretation of archival material.

Fishman's concept of 'domain' has been particularly influential in promoting research into bilingualism and diglossia and related issues. For example, Parasher (1980) has applied it to the Indian bilingual cum diglossic situation. Similarly, Rubin (1968) applied it to the national bilingual situation in Paraguay.

Fishman has been criticized for having a European bias, and for threatening the fundamental assumptions of nation building. There is an internally consistent

response in Fishman's work to these criticisms: the preservation and promotion of the minority groups and their languages do not necessarily constitute a challenge to the larger societal groups. In fact, with planning awareness and appreciation of the potential contribution of all the elements, a rich and ultimately stronger social organization can be achieved.

Biography

Joshua A. Fishman was born in Philadelphia, PA, on July 18, 1926. He received B.S. and M.S. degrees from the University of Pennsylvania (1944–1948). He studied Yiddish, his mother tongue, at UCLA. He did his Ph.D. in social psychology from Colombia University (1953), and served as Educational Psychologist for the Jewish Education Committee of New York in 1951–1954. He directed research for the College Entrance Examination Board, while teaching sociology of language at City College (CUNY), in 1955–1958. He was Associate Professor of Human Relations and Psychology at the University of Pennsylvania (1958–1960); Professor of psychology and sociology at Yeshiva University, New York (1960); Dean of the Ferkauf Graduate School of Social Sciences (1966); served as academic vice president (1973–1975); and became professor emeritus in 1988. He held visiting appointments at ten major universities in the United States of America, Israel, and the Philippines, and fellowships at the Center for Advanced Study in the Behavioural Sciences (Stanford, CA), the East–West Center (Honlulu), the Institute for Advanced Study (Princeton, NJ), the Netherlands Institute for Advanced Study (Wassenar), and the Israel Institute for Advanced Study (Jerusalem). He has been editor of the *International Journal of the Sociology of Language* since its inception in 1973.

Focality

The terms focus, focal, and focality are used in two different domains: phonetics and syntax/semantics.

In phonetics, focus is understood as a specific stress or pitch; in a narrow sense, focal stress means the (typically falling, or rising–falling) sentence stress, placed in the unmarked (normal) case at the end of the sentence, and is distinguished from contrastive (typically rising) pitch that is often used at the beginning of a sentence: in the following examples, the latter is written in italics, the former in capital letters (with examples of typical preceding co-text segments closed in parentheses):

(1) (Mary visited us last week.) *Paul* was here YESTERDAY.

(2) (As a Christmas present, Jim got a picture from me.) *For Martin* his mother has brought a new BOOK.

(3) (Last Saturday I went to an exhibition with Jane.) *On Monday* we visited an old CASTLE.

(4) (Jerry and Marilyn were there too.) *Him* she SAW (, but she did not recognize Marilyn).

The contrastive pitch has to be distinguished from the presence of a focus in a marked position, which is the case in (1′):

(1′) (Who was visiting you yesterday?) PAUL was here yesterday.

In the analysis of the sentence and its information structure, focus is understood as that part of the sentence referring to 'new' information, rather than to the 'given' information (corresponding to the topic of the sentence). Phonetic focus is carried by a part of the informational focus; cf. the following examples, in which normal intonation is assumed (with the stress at the end of the sentence) and the sign '/' marks the boundary between topic and focus):

(5) (When did your friends visit you?) Some of them were present/at our party last Friday.

(6) Many men/read few books. —Few books are read/by many men.

(7) Mary was writing her dissertation/on the weekends. —On the weekends, Mary was writing her dissertation.

As the last two examples show, the articulation of the sentence in its topic and focus is semantically relevant. The passivization may be understood as triggering a word-order variation, for which otherwise English allows only in specific syntactic contexts, such as:

(8) They moved/from a village to a large industrial center. —They moved to a large industrial center/from a village.

(9) We went/by car to a lake. —We went to a lake/by car.

In many other languages (Latin, German, Czech, and most other Slavic languages), the word order is much freer than in English, so that e.g. an object belonging to the topic can precede the subject:

(10) Das Buch hat mir mein Vater gegeben (lit.: the book has me my father given—'My father gave me the book').

While a definite noun group included in the topic prototypically triggers a presupposition of the existence of an entity that it refers to (more precisely, to the communicative availability of the referent), noun groups contained in the focus are not connected with such a presupposition (a presupposition is an assertion, the truth of which follows not only from the sentence triggering it but also from its negative counterpart), cf.:

(11) Mike's sister has visited that exhibition (presupposition: *Mike has a sister*).

(12) That exhibition was visited by Mike's sister (no such presupposition, the existence of Mike's sister follows only from the positive sentence, but not from its negative counterpart).

It is more exact not to work only with the dichotomy of topic and focus, but to describe the information structure of the sentence on the basis of an opposition of contextually bound and nonbound items. This allows for a more subtle classification, cf. the following examples, in which the indices b and n are used for contextually bound and nonbound items, respectively.

(13) (A young pair was present there.) I_b recognized$_n$ only$_n$ him$_n$.

(14) (I prefer fiction written by a not much known lady from Edinburgh.) This$_b$ author's$_b$ books$_b$ have$_n$ a specific$_n$ flavour$_n$ for me$_b$.

In the unmarked case, nonbound items belong to the focus of the sentence and bound ones are included in its topic; exceptions concern bound items embedded in the focus (such as *for me*, if understood as a modifier of *flavour* in (14)) and nonbound items in the topic.

Note that the opposition of contextual boundness is understood as a pair of grammatical values, which corresponds to the cognitive notions of 'given' and 'new' information in the prototypical case, but not always; e.g. *Him* in (13) as a stressed pronoun belongs to the focus of the sentence and is nonbound, although its pronominal (anaphoric) character is connected with the fact that it refers to an entity known to the speaker (at least in some sense) and that is assumed to be known also to the hearer.

Forensic Linguistics

Forensic linguistics is the scientific study of language as applied to forensic purposes and contexts—the application of linguistic knowledge to legal problems. It is a new area of linguistics and a rapidly growing area of modern applied linguistics.

Recent research demonstrates increased interest and research in forensic linguistics. Overviews of language, law, and the legal process have been elaborated by many scholars, e.g. Levi (1994b). Work has continued on the language of the courtroom and on analysis of discourse in the language used in legal settings (Shuy 1993, 1998). Many specific studies and collections relating to linguistic applications to the law have been written or edited, one of the first and most significant being that of Levi and Graffam Walker (1990). Documentation of advances in forensic linguistics appears in the research of individual forensic linguists and in the bibliographic work of Levi (1994a) and of the University of Birmingham.

Recent milestones in forensic linguistics include the following: Judith Levi and Anne Graffam Walker organized and coordinated the 1985 Georgetown University conference on Language in the Judicial Process. In 1995, Bethany Dumas started *Language in the judicial process*, an electronic newsletter aimed at disseminating information on bibliography, organizations, courses and programs, and legal cases. During the 1990s, university courses on language and law were developed and presented around the world. The most important advances in the study of forensic linguistics were the University of Birmingham's initiation of *Forensic Linguistics: The International Journal of Speech, Language and the Law* in 1994 and their founding of the International Association of Forensic Linguistics, which have since provided serious venues for the presentation of research that are more regular, unified, and formal than ever before.

The classification of areas in forensic linguistics is evolving as the field develops, usually following those of the structure and function of language. The research and casework of forensic linguists presently define the field in a taxonomy that includes the following areas: auditory and acoustic phonetics, semantics, discourse and pragmatics, stylistics, language of the law and of the courtroom, and interpretation and translation.

Auditory phonetics is the study of speech sounds based on what is heard and interpreted by the human listener (the aural–perceptual characteristics of language),

although studies in forensic phonetics often use both auditory and acoustic methods of analysis. The primary areas of auditory research in forensic phonetics are speaker discrimination and identification by victims and witnesses; voice perception, discrimination, imitation, and disguise; and identification of group characteristics of speakers, including first-language interference, regional or social accent and dialect, and speaker age. An introduction to the use of auditory (and acoustic) phonetics in forensic examinations is French (1994).

Acoustic phonetics is the study of the physical characteristics of speech sounds as they leave the speaker, move into the air, and gradually dissipate. The acoustic analysis of speech sounds requires laboratory observation with instruments and specialized computer analysis.

Vowels and consonants are presented as waveforms having three features: amplitude, corresponding to loudness; frequency of complete repetitions, corresponding to high/low pitch; and complexity, corresponding to the periodic waves of a simple sound, or to a mixture of waves from a complex sound, like a vowel sound. The waveforms are presented visually as a spectrogram. See Hollien (1990) for the forensic application of acoustic phonetics.

The primary area of acoustic analysis in forensic phonetics is speaker identification, but many studies have also been carried out to identify group characteristics of speakers, including their physical height and weight; regional, social, or language group; voice and accent disguise; effect of intoxication on speech; and technical aspects of speech samples and recordings.

Semantics is the study of meaning as expressed in words, phrases, sentences, or texts. The focus of semantic analysis in forensic contexts is on the comprehensibility and interpretation of language that is difficult to understand. Some studies combine semantic and pragmatic approaches to meaning interpretation. A thorough introduction to this area can be found in Solan (1999). The point of view that expert linguists have no role to play in helping judges interpret statutes is presented by Murphy (1998).

Primary areas of research in forensic semantics are: interpretation of words, phrases, sentences, and texts; ambiguity in texts and laws; and interpretation of meaning in spoken discourse, such as reading of rights and police warnings, police interviews, and jury instructions.

Analysis of discourse is the study of units of language that are larger than the sentence, such as narratives and conversations. Discourse in spoken and written language can take many forms, especially in conversations tied to specific social contexts. Analysis of a speaker's intended meaning in actual language use is the study of pragmatics. Pragmatics is important for forensic purposes because speakers and writers do not always directly match the words they use with the meaning they intend to convey. This leaves the speaker's intended meaning more open to interpretation by the listener, sometimes resulting in miscommunication.

The linguist most closely associated with developing forensic discourse analysis for a broad range of cases is Roger Shuy. Some of his cases are documented in *Language crimes: the use and abuse of language evidence in the courtroom* (Shuy 1993) and in *The language of confessions, interrogation and deception* (Shuy 1998).

Primary areas of research in forensic discourse and pragmatics include: analysis of spoken and written language; study of the discourse of specific contexts, such as dictation, conversations, and hearings; the language of the courtroom, i.e. of lawyers, clients, questioning, and jury instructions; and the language of specific speech acts, such as threats, promises, and warnings.

The focus of forensic stylistics is author identification of questioned writings. While the methods were developed mainly for literary purposes, applications of stylistic analysis to forensic authorship problems have become very common. In criminal and civil cases with questioned writings, there is often a need to determine whether one author wrote all the writings in a questioned set, whether one of a number of possible authors authored the questioned writing, or whether a single suspect-author can be eliminated or identified as the writer.

Linguistic stylistics uses two approaches to authorship identification: qualitative and quantitative. The work is qualitative when features of writing are identified and then described as being characteristic of an author. The work is quantitative when certain indicators are identified and then measured in some way, e.g. their relative frequency of occurrence in a given set of writings. Certain quantitative methods are referred to as stylometry. Qualitative and quantitative methods complement one another and are often used together to identify, describe, and measure the presence or absence of style markers in questioned and known writings.

Examples of descriptive (qualitative) style markers from two separate cases appear in Figure 1.

Another recent development in forensic authorship identification is the application of stylistic analysis to computer programming. Researchers (Krsul 1994) and security analysts, working on proprietary issues and virus sources, have identified various style indicators as indicative of authorship in programming code, e.g. variable names, layout, upper/lowercase letters, placement of comments, debugging symbols, line length, and ratio of white lines to code lines.

Linguistic Unit	In QUESTIONED Writing	In KNOWN writing
Same-Author Case A: *confidentiality*	confidentuality	-Confidentuality
Same-Author Case A: *I'll see you.*	A SEEYOU	a See you later
Different-Author Case B: Spanish *hice*	_ise	hice
Different-Author Case B: Spanish *estaba*	_estaba.	ESTAVA

Primary areas of research in forensic stylistics relate to the descriptive and quantitative methods of authorship identification, dialect evidenced in written language, the questioned time and occasion of writing, stylometry, statistical methods of analysis, use of corpus linguistics in forensic analysis, and computer programs for the analysis of style. A relatively complete survey of forensic stylistics can be found in McMenamin (2002).

Perhaps the most important development in the language of the law was that begun by David Melinkoff in his 1963 book, *Language of the law*. Melinkoff pressed for clarity and brevity in the law, which extended to a later movement to simplify the language of laws, insurance policies, and consumer literature. Systematic analysis of legal language is carried on today with, for example, Tiersma's (1999) emphasis on plain legal language, language rights, and the pragmatics of written legal language as well as of courtroom language.

The courtroom personae who speak are witnesses, lawyers, and judges. Research related especially to the discourse and pragmatic use of courtroom language has made this one area of forensic linguistics that can significantly affect case outcomes. Studies of courtroom language are analyses of the language of all the players: the language of witnesses (witness examination, victims, children, men vs. women); the language of lawyers (trial language, legal debate, closing arguments); and the language of judges (trial participation, jury instructions).

Interpreting is a complex skill and especially difficult in forensic contexts. Interpretation studies such as those in Cooke et al. (1999) focus on interpretation tasks specific to questions and answers in testimony, the perceived role of the interpreter, interpreter education, the right to interpretation, etc. Forensic and academic scholars are giving more and more attention to the theory and practice of interpretation and translation, especially in these areas, and in others such as pretrial interpreting, courtroom interpretation, interpretation with cultural and dialect differences, questioning in interpreted testimony, and the absence of interpretation.

Translating in the legal context requires much more than a literal, word-for-word matchup of two languages. Good translations are constrained by the intended meaning of the writer, the new text created by the translator, and the meaning given the translated text by the reader.

Areas associated with forensic linguistics include document examination and aspects of psycholinguistics. The examination of questioned documents relies on the scientific study of the physical evidence of a document. Forensic document examiners look to the writing instrument, the writing surface, and the writer for physical traces that assist in uncovering the history of a document. The document examiner observes features of handwriting (letter size, formation, and relative proportions; letter slant, spacing, pressure, line quality, connecting strokes, etc.) and of typing (typeface or font style, spacing between letters and lines, association of a document with a particular machine or type of typewriter, printer, or copier).

Previous studies indicate that examination for authorship determination includes numerous characteristics of writing style (punctuation, spelling, abbreviations, forms of dates, etc.), but newer studies are drawing a sharper line between forensic document examination and the elements of writing style studied in linguistic stylistics.

Psycholinguistics is the academic discipline that integrates the study of psychology, linguistics, and cognitive science. The acquisition, comprehension, and production of language are studied in various related ways: cognitively, neurologically, and conceptually. However, this is not what has been referred to as 'psycholinguistics' in forensic contexts. The late Murray S. Miron developed the so-called 'psycholinguistic approach', which examines written or spoken language to profile the origins, background, and psychology of the originator, especially in the context of threats. It is difficult for a nonpsychologist (e.g. a judge or jury) to understand and evaluate the nexus made between a written-language threat and the diagnostic profile of the writer, and the practice of 'psycholinguistics' can be risky and may lead to mistakes. This kind of 'psycholinguistics' is not commonly regarded as a subdiscipline of forensic linguistics.

France

This article deals with the linguistic situation of France, and with the French language in its international context. Since 1992 the French constitution has stated that the language of the republic is French. As a major western European state (population 59 million) and former imperial power, France has a long history of standardizing and promoting French, although there are other languages within its borders.

The French Language

French is classified as a Gallo-Romance language. The Romans who colonized Gaul in the first century BC had a profound and lasting influence on the institutions, culture and language of the country that we know as France. Of the period prior to Roman domination, only a few traces remain of the Gaullish (Celtic) substratum—everyday words e.g. for trees *if* 'yew tree', or place names, e.g. the *dun* ('fort') ending found in *Verdun*. The Romans spread their language (or languages, from classical written Latin, to a later more popular and largely spoken form) so successfully that when Germanic tribes invaded in the fifth century AD, their languages influenced the Latinate language in use (e.g. in vocabulary items such as *guerre* from *werra*) but did not supplant it. Evidence for the emergence of a recognizably distinct French language (or set of dialects) is found in the bilingual Strasbourg Oaths (842 AD). The dialects of the north, the *langues d'oïl*, showed more Germanic influence, as against the Romance *langues d'oc* in the south. (This division is still reflected today in the existence of three main linguistic zones, the north being divided from the south by a line running east from Poitiers, with an intermediate *franco-provençal* triangle fanning out from the region of the Alps.) Among the major dialects of the north with a written form, it was the language of the Ile de France (around Paris) which was set to become the high prestige variety. So-called 'Old French' of the twelfth and thirteenth centuries had a wide range of vocalic sounds and had reduced to two the Latin system of cases. During the fourteenth century case endings disappear, with a corresponding reliance on determiners, the vocalic system is simplified and we find that the final consonants have been dropped. Through the Edict of Villers-Cotterêts of 1539, French replaced Latin as the official language for administrative and legal documents. Ten years later the writer Joachim du Bellay in his *Défense et illustration de la langue française* advocated the use of French in literature; du Bellay and other writers contributed greatly to the enrichment of the French language, although the Renaissance also brought in its wake an influx of Italian loan words. The seventeenth century saw the codification of the 'standard' language, with the *Académie Française* being set up in

1635. Nevertheless, there were still significant numbers of speakers of other languages by the mid-eighteenth century when the revolutionaires tried to ensure the development of a unified state. A report by the Abbé Grégoire estimated that no more than three million (about a fifth of the population) mastered standard French. From the late nineteenth century onwards, standard (Parisian) French was further promoted by free, universal schooling (from 1880 on by Jules Ferry), conscription in World War 1 and the mobility of civil servants. Today, facilitated also by the media, standard French dominates across the whole of France, sometimes alongside a regional form of French and sometimes alongside a regional language or dialect. Even apart from dialectal variation, there is a good deal of sociostylistic (register) variation. While the efforts of bodies such as the *Académie* to conserve the language have applied mainly to a formal, usually written, register, the spoken language demonstrates certain syntactic differences (e.g. deviation from canonic Subject–Word–Object word-order, dropping of pre-verbal negative particle *ne*) and characteristic lexical features (a rich range of colloquial vocabulary for everyday items (*bouquin-livre* 'book') with many abbrieviated forms (*apéro-apéritif* 'before-dinner drink'). So-called *français jeune* refers to the French spoken by some young people, characterized by a mix of colloquial French, 'slang' vocabulary such as *le verlan* based on the inversion of syllables with subsequent modifications (thus *laisse béton—laisse tomber* 'leave it', *meuf —femme* 'woman') and borrowings from various languages. Borrowings from English are plentiful in all registers of contemporary French, hence recent attempts to legislate in favor of the protection of French, from the Bas-Lauriol law of 1975 to the controversial *loi Toubon* passed in 1994. A debate that had rumbled on for years about orthographic reform was finally settled in 1991 with a compromise solution, with a small number of spelling rationalizations being recommended but not imposed. Apart from the *Académie* which still pronounces (usually prescriptively) on language matters, there are currently various commissions devoted to protecting French, such as the *Conseil supérieur de la langue française* which promotes 'good usage', and the *Délégation générale à la langue française et aux langues de France* part of whose job is to liaise between the terminological commissions set up by each government ministry to stem the influx of English words, as well as to promote French world-wide.

The Other Languages of France

The regional languages that the revolutionaries and educationists had tried to suppress began to fight back in the mid twentieth century. Their modest revival was eventually made possible by the place won for them within the French education system, and by a shift in government thinking initiated by the socialist president Mitterand's recognition of the 'right to difference' in 1981. The *loi Falloux* of 1851 had stipulated that French was the only language to be used in schools, but 100 years later the *loi Deixonne* allowed schools to give a few hours optional teaching a week in those regional languages that were not the language of a foreign power (Corsican, considered a dialect of Italian, was only added in 1974). Since 1981 government policy has become gradually less hostile to the regional languages, which have been boosted by the *écoles associatives* in which they can be the medium of instruction. Today, the following are recognized as 'regional languages': three Romance languages, Occitan, Corsican (close to Italian) and Catalan (an official language of Catalonia in Spain); two Germanic languages (Alsatian in Alsace and part of Lorraine) and Flemish for a small number of speakers near the Belgian border; and one Celtic language (Breton) and the non-Indo-European language Basque (also spoken on the Spanish side of the border). It is difficult to get an objective estimate of the numbers of speakers, or even of the health of these languages (but see Judge 2000, Sanders 1993 and the publications of the European Union on the Lesser Used Languages of Europe EBLUL).

Basque (approximately 80,000 speakers) has been boosted by the *ikastolak* (*Basque language schools*), which have received state funding for primary and secondary levels since 1994. The first school opened its doors in 1969 to five pupils and by 1997 there were 1630 pupils receiving nursery, primary or secondary education through the medium of Basque. There are four dialects of **Breton** and probably about 500,000 speakers. In 1997, 1,751 pupils sat for the French school-leaving exam (*baccaulauréat*) having followed a complete cursus through the *diwan* (Breton schools) created 20 years earlier, and had the possibility of taking some courses in Breton e.g. at the University of Rennes. There are an estimated 100,000 speakers of **Catalan** in the Languedoc-Roussillon area of France, who are at once encouraged and overshadowed by the support given to the language by the provincial government of Catalonia on the Spanish side of the Pyrenees. Catalan schools started in 1976 and it is now possible to go up to doctoral level at the University of Perpignan. The future of **Corsican** (approximately 200,000 speakers) is linked to on-going discussions about the status of the island, including the possibility of a regional assembly and of the increased use of Corsican in schools, many inhabitants being bilingual in French and

Corsican. In a 1982 survey by the French agency INSEE, 96% of Corsicans on the island understood the language and about 86% claimed to speak. It is possible to study Corsican up to postgraduate level (University of Corti), and there has been a strong literary revival. In some respects the Germanic languages of north-east France fare less well in the education system (and in the media) than other regional languages. As **Flemish** and **Alsatian** were classified as official languages of a neighbouring state, no support was given under the terms of the *loi Deixonne*. A current estimate of 80,000 speakers of Flemish may be optimistic. Alsatian is treated as a spoken dialect for which the written form is German, and the high number of those represented as studying this 'regional language' is misleading, as it includes pupils taking German, and for Alsatian itself there are no schools, only *classes associatives*. **Occitan** should be the giant of the regional languages, covering as it does 31 *départments* in the southern half of France. However, various factors such as migration to and from the area, and dialectal differences between Gascon and Northern and Southern Occitan (the latter dividing further into Provençal and Langdocien), mean that the survival of this language group, with its rich medieval literary heritage, cannot be taken for granted. The orthography proposed by the nineteenth century poet Mistral and his association, the *Félibrige*, was not necessarily suitable for Occitan in the twentieth century and a compromise form has now been reached. A flowering of theatre and song in the second half of the twentieth century was accompanied by a degree of political activism. There are now over 30 *calendretas* (schools), and 12,532 children were taught Occitan in the school year 1997–8. Overall, there may be up to 10 million people who understand the *langues d'oc*, and two million who practise them. The **langues d'oïl**, the dialects of northern French, were treated as 'patois' and given little consideration for many years, but a number of studies have recently demonstrated the tenacity of *picard* or the *chtimi* dialect of the Lille area.

Beside the indigenous languages of metropolitan France, there are other languages that are worthy of mention. A report by Bernard Cerquiglini in 1999 identified 75 languages in 'greater' France. Firstly, the other languages of the overseas departments of France (e.g. the Polynesian and Melanesian languages of the French Pacific territories) are technically 'languages of France'. Secondly, so are the non-territorial languages (Romany languages, Yiddish) and the immigrant languages of metropolitan France. The latter are the result of successive waves of migration—Polish, Italian, Spanish, Portuguese, Chinese, and speakers of sub-Saharan African languages, to mention only a few.

The largest groups currently originate from North Africa: thus, there are estimated to be approximately 1.5 million speakers of Arabic and 0.5 million Berber speakers in France. There have been some attempts to provide instruction for Arabic heritage pupils, but so far these have partly foundered on such issues as which dialect to teach (classical, Algerian, etc.). To sum up, levels of educational provision vary from language to language, as do levels of competence. As for most languages with no official backing, the regional languages have suffered from dialect fragmentation, and the norm adopted has not pleased all activists. Those now being educated in the *écoles associatives* may be in a position of having parents who do not speak the language and grand-parents who speak a different dialect of it; few will have the chance to speak the language in the work-place. Within the European Union, French is one of the two major working languages, although constantly under pressure from English. After some delay France became a signatory to the European Union's Charter for Regional or Minority Languages but did not ratify it, on the grounds that it is incompatible with the constitution which, holding all citizens to be equal, does not recognize minorities. However, the title of the *Délégation générale à la langue française* has been amended to include the 'languages of France' which may be a hopeful sign for the regional languages.

The French-Speaking World (la Francophonie)

France's first wave of colonial expansion in the sixteenth century took the French language to the Americas, and its second during the nineteenth and the twentieth centuries to North and sub-Saharan Africa, the Pacific and parts of Asia. Today a reminder of this imperial past remains in the use of French in France's former territories (Québec) as well as in her overseas departments (such as the French Antilles) or territories (e.g. French Polynesia). Depending on the country or area, French may be the only official language (as in Québec), one of two or more official languages (cf. French and English in New Brunswick or the same two languages in Cameroun), one of several official languages of a multi-lingual state (Belgium or Switzerland), or it may be a major language of education and business without being an official language (e.g. Morocco or Madagascar). It is sometimes claimed that the future of French lies with its use outside France and that will be, for example, more speakers of French in Africa than in France. However, this depends on the definition of a 'French-speaker', not all of those who use French as a vehicular language being fluent speakers, and such varieties as *le français*

populaire d'Abijan differing substantially from standard metropolitan French. What follows is an attempt to estimate the numbers of French-speakers in illustrative situations from around the world.

Europe To the 59 million citizens of metropolitan France must be added about 6.5 million speakers of French in Belgium, Switzerland, Monaco, Luxembourg, Andorra and small pockets such as the *Val d'Aosta* in Italy. 4.5 million of these are in Belgium where French is one of three official languages, the other two being Flemish (i.e. Dutch) and German. The original superior status accorded to French when Belgium became a nation in 1830 gave rise to a succession of protests, which eventually led to the establishment of a trilingual state, with parallel organizations for the French and (now majority) Flemish speaking populations. Thus, apart from the small German-speaking community near the German border, the country is divided into three linguistic entities: the French-speaking community (which includes Belgian French and the Romance *wallon* dialect), the Flemish-speaking community, and Brussels, accorded special bilingual status. Educated Belgian and Parisian French are very close, with some particular features characterizing Belgian French such as the use of the numerals *septante, octante* etc. for standard French *soixante-dix* ('sixty') and *quatre-vingts* (eighty).

The Americas French and English are the official languages of federal Canada, though each province determines its linguistic status. The majority of French-speakers are in Québec (population 6.5 million) where French is the only official language, but there are also French speakers elsewhere, notably in the Maritime provinces, Ontario, Manitoba and Saskatchewa. *Québécois* French retains traces of the sixteenth-century regional speech of the original migrants, as in the characteristic pronunciation of /mwe/ for *moi* ('me/I'). The linguistic range extends from educated *québécois* French, which may show certain differences, largely in pronunciation and lexis, from metropolitan French, to a variety of rural and urban dialects—in the latter case most notably the urban working-class *joual* of Montreal. In the last half century, French in Quebec has benefited from strenuous provincial government efforts to promote its use through linguistic legislation and the setting up of bodies such as the *Office de la langue française*.

French-speaking emigrants deported by the English from the Arcadian area of the Maritimes took their language to New England and to Louisiana where French was further bolstered by French Canadian economic migrants (in New England) and by French and Creole-speaking migrants from the Caribbean (in the case of Louisiana). In the Caribbean, both French and French-based Creole are spoken in independent Haiti and in the French departments of Guadeloupe, Martinique and Guyane, but only French is recognized as the official language in the latter.

Africa French is widely used as a vehicular language in the former French colonies in sub-Saharan Africa. The situation is fluid, but currently the following are among the countries in which French is an official language but co-exists in daily use with African languages: Burkina Faso, Congo, Guinea, Ivory Coast, Mali, Niger, Senegal. In North Africa (Tunisia, Algeria, Morocco), there has been a policy of 'arabization', but French is still widely used. In the Indian Ocean, French is used in education in Mauritius (official language: English) and Madagascar (official language: Malagasy) and Réunion (a department of France, where Creole co-exists with the official language French).

Since some speakers have French as a second or third language, estimating the number of speakers worldwide is not easy, but the estimate of 80–100 million with French as a mother-tongue is sometimes given. A great strength of French is that it is present on every continent, and another is that educated speakers from around the world speak a mutually comprehensible form of French which approximates to the Parisian norm. An international 'francophone summit' meets every two years to promote cooperation among French-speaking countries. In addition to France, certain other countries now play an important role in promoting French worldwide. In certain areas e.g. terminology banks, or the 'feminizing' of the language (particularly for job titles), Francophone countries such as Canada have acted more effectively than has France herself. French is indubitably the vehicle for a vibrant *francophone* culture, in literature, cinema and media in many countries.

French Language

French is one of the major languages of Europe, spoken as a first language not only in France (where it originated) but also in parts of Belgium, Switzerland, Luxembourg, and a small region of Italy (the Aosta Valley). In addition, as a result of colonization, French is spoken in many other parts of the world. In Africa, it is the official language of 18 countries, which occupy a good half of the land area of Africa, from Mauritania in the west to the Central African Republic to Chad, Mali, and Senegal in the east to Congo, Zaire, Rwanda, and Burundi in the south. It is also spoken and understood by a considerable section of the population in the three Arab countries of North Africa that constitute what is called the Maghreb (Morocco, Algeria, and Tunisia). Across the Atlantic, in North America, it is one of the two official languages of Canada and is the first language for many Canadians in Québec and other provinces of Eastern Canada. There are vestiges of French in the United States as well, particularly in Louisiana, Missouri, and parts of New England, and in the Caribbean islands of Martinique and Guadeloupe (which are still dependencies of France), as well as the Republic of Haiti. On the continent of Asia, it was spoken by many in former French Indo-China and still retains its prestige in Laos and Kampuchea (former Cambodia), but is much less used in Vietnam than formerly. There are many islands in the Indian Ocean and Oceania where French is still spoken: Madagascar and smaller islands nearby, and New Caledonia, French Polynesia (including Tahiti), New Hebrides, and various smaller islands. In all, there are about 88 million francophones (speakers of French) in the world. After English, it is the second international language, used by institutions such as the United Nations and UNESCO (United Nations Educational, Scientific, and Cultural Organization).

Although French is the official language of France and, since the beginning of the twentieth century the media have been accessible everywhere, not everyone in France speaks French. First of all, there are still other languages spoken in France: e.g. Basque in the southeast (on the border with Spain), Breton in the west, Flemish in the north (on the border with Belgium), and Alsatian and Lorrain in the east (on the border with Germany). In addition, there is Occitan (including Provençal) in the south, Franco-Provençal (spoken in France, Switzerland, and Italy), as well as many small local languages spoken all through France. All these have their effect on French. In Southern French (Occitan area), for example, mute (written) *e*'s tend to be sounded, while they are silent in Standard French. Alsatian French shares many features of pronunciation with the Germanic dialect spoken in the region.

The same is true of French spoken outside France. The French spoken in the rest of Europe tends to differ from the French of France most notably in pronunciation and somewhat in vocabulary. The numbers 70, 80, and 90, for example, have different names in Belgium and Switzerland than in France. But it is the French outside of Europe that shows the most diversity—e.g. québécois in Canada, Cajun in Louisiana, the various types of French in former Indo-China, the Indian Ocean, French Polynesia, and Africa all have developed their own specific traits of the language. As one example, in Canadian French, stress placement (word accent), intonation (inflection of the voice), and the vowel system are not the same as in Standard French, nor is the vocabulary. As for French creoles (found in Louisiana, French Guyana, the Caribbean, and the Indian Ocean), they are not intelligible to speakers of French. Their vocabulary is based on that of French, but they are entirely new languages with their own particular morphology and syntax.

French has a variety of roles in the linguistic repertoire of its users. It can be a native language (for example, in France, Belgium, Canada, Luxembourg, and Switzerland). In many countries, it is an (or even the) official language used for governmental and other purposes (in the nations just mentioned; also in Haiti, the Comoros, and in many former French and Belgian colonies in sub-Saharan Africa). In still others, it functions as a *lingua franca* (a language of communication by those whose own languages are very different from each other), for example, in sub-Saharan Africa and in New Caledonia. For many people, it is their second or third language in contexts where there may be many other languages around; in such cases, it is highly prestigious to speak French and thus only the well-educated elite do (in French Polynesia and in Creole-speaking areas such as Haiti, French Guyana, Mauritius, some of the Caribbean Islands, and the Seychelles). It is also, for some, a language of culture (in Lebanon and the Maghreb). In many countries outside *Francophonie* (those countries where French is recognized as a means of communication), French remains—after English—a preferred foreign language learned at school.

History of French: Old and Middle French

French is a descendant of the Vulgar Latin (common spoken language) brought by Roman settlers to the area occupied by modern-day France in the last century BC, after it was conquered by Julius Caesar in the Gallic Wars. It became the spoken language of Gaul, as the region was then known, and remained so even after the fifth-century invasions by Germanic tribes. But this Gallo-Romance way of speaking diverged increasingly from Latin, as recognized by the Council of Tours (813), which recommended not using Latin in preaching because the common people could not understand it. Moreover, by the end of the ninth century, the northern dialects were most influenced by the Germanic speech of the dominant Franks, and the southern dialects remained closer to Latin. This resulted in the emergence of two separate languages: *langue d'oïl* in the north and *langue d'oc* in the south (*oïl* and *oc* were the words used for 'yes' in the two languages). Modern French is a descendant of *langue d'oïl*. The oldest document in *langue d'oïl* is the *Strasbourg oaths* (843), which marks the beginning of the Old French period (ninth to fourteenth centuries). Latin being virtually the only written medium of the early middle ages, documents in Old French are rare. Literary texts appear first in *langue d'oc*, the language of the *troubadours*, at the end of the eleventh century, a hundred years before their counterparts in Old French.

In the tenth century, French kings made their court in Paris and, as the royal domain increased, so too did the prestige of the dialect they spoke (called *francien*). In the twelfth century, Parisian speech was already a model to be emulated; by the end of the Old French period, the King's French was in the process of becoming the written norm in France.

In the Middle French period (fourteenth to sixteenth centuries), the use of French continued to expand. In 1539, a royal edict banned Latin from court proceedings and legal deeds and replaced it with the French spoken at the time. French was also promoted as a vehicle of learning and culture at the expense of other dialects, which were relegated to the status of *patois* (local vernaculars).

In 1549, Joachim Du Bellay's *Defense and illustration of the French language* maintained that French was not inferior to the classical languages (Latin and Greek) and should be used for literary works. During this period, the King's dialect began to be codified and, with the advent of printing, attempts were made to simplify and regularize the orthography.

Classical French

The Classical French period (seventeenth to eighteenth centuries) witnessed further efforts to standardize the language. In 1635, the French Academy was founded to give 'firm rules' to the language, to make it 'pure and eloquent', and to compose a grammar and a dictionary. Claude Vaugelas, in his *Remarks about the French language* (1647), established that the linguistic norm should be based on 'good usage', i.e. the French spoken at the Court and used by the best writers. During the Classical period, French acquired great prestige abroad. It was the international language used in European courts and became the medium of diplomacy. Such was the fame of French that competitions were held to extol its virtues. In 1784, Antoine Rivarol won first prize from the Academy of Berlin for his 'Discourse on the universality of the French language'. Great writers also contributed to the preeminence of French and the development of the literary language.

Modern French

By the time of the French Revolution in 1789, French had spread to the bourgeoisie (middle class) in urban areas; but outside the Paris region, the *patois* were still very much the vernacular of the people. In 1790, Abbé Grégoire conducted the first survey about the use of French and found that 45% of the population of France were not able to speak French. The Revolutionaries held that linguistic uniformity was essential to the cohesion of the nation and equated the *patois* with backwardness and antirepublican sentiments. They wanted, therefore, to exterminate the *patois* and to have French taught at school to every citizen. These ideas were not implemented until almost a century later, during the Third Republic. Through laws devised by Jules Ferry and passed in 1881–1886, primary school education was made free, secular, and compulsory. The teaching of French was central to the curriculum, and the use of any other language at school, inside or outside of the classroom, was banned and punished. In addition, railways, roads and cities, military service, mass media (newspapers, radio, television)—all contributed to impose French as the only language of the nation in the twentieth century. In 1992, an amendment to the Constitution officially proclaimed French to be 'the language of the Republic'. At the same time, there has been a more tolerant attitude toward regional languages and regional differences. In 1951, the educational policy was relaxed to allow some regional languages, e.g. Basque, Occitan, and Breton, to be taught in French schools (the Deixonne law). By then, however, there were hardly any school-age native speakers of *patois* left and the demise of these languages is all but irreversible.

Protecting the French Language

With the rise of Anglo-American influence in the years following World War II in international commerce,

science, technology, and especially popular culture, a strong view has emerged in some French government and intellectual circles that French is under serious threat from English. While the proportion of English borrowings in everyday speech is in fact very low, concern for maintaining the purity of French has in recent times led to the creation of the General Delegation for the French Language (1989) and various ministerial committees charged with developing French vocabulary in economic and technical domains. The Bas-Lauriol (1975) and Toubon (1994) laws were passed to limit the use of foreign languages in the spheres of trade, employment, and services. Similar actions were taken in Québec where Anglo-American influence is overwhelming. The Charter of the French Language (1977) makes French the only official language in Québec and gives precedence to French in all areas of public life (education, work, economy).

Francophonie

In the 1960s, the notion of a francophone identity for users of French around the world became prevalent. African leaders suggested a new type of association, culturally and linguistically based, called *Francophonie*, which would replace the old colonial ties. The francophone movement was enthusiastically supported by France, Québec, and French-speaking Belgium. In France, the Supreme Council for Francophonie (founded in 1984) has contributed actively to the promotion of French outside of France. And since 1986, *Francophonie* summits have been organized every other year with about 40 participating countries.

Romance Languages

French is a Romance language because it has descended from the language spoken by Roman settlers as they went out to conquer neighboring lands and founded the Roman empire. The other Romance languages include Spanish, Catalan, Portuguese, Occitan, Italian, Rhaeto-Romance (spoken mostly in Switzerland), Dalmatian (spoken on the Dalmatian coast, in former Yugoslavia), Rumanian, and Sardinian. As descendants from Latin, the Romance languages have much in common, in particular their vocabulary. They also share other traits that they inherited from Vulgar Latin. Noun morphology was simplified in most of the Romance languages, so that there are two genders (masculine and feminine) instead of three (neuter), and the case system (by which grammatical relations in the sentence are indicated by various endings) also disappeared. They also share the fact that the adjective

typically comes after the noun it modifies, and it agrees with that noun in gender and number (singular or plural). The noun is often used with a definite article (*le, la, les* in French) and an indefinite article (*un, une, des* in French), both of which are placed before the noun. The informality/formality of situations is also characteristically reflected by the choice of pronouns of address, *tu/vous* 'you' in French.

During the course of time, French has lost or acquired features that did not exist in Latin and many of which are not found in the other Romance languages. Some of its most characteristic sounds are innovations: pharyngeal (guttural) R, nasal vowels as in *vin* 'wine' and *bon* 'good', and rounded front vowels as in *rue* 'street' or *peu* 'little'. It is true that adjectives agree with the nouns they modify in gender and number, but the gender of the noun is often not overtly given and simply has to be memorized, and for both adjectives and nouns the plural found in writing (with 's') is typically not sounded in the spoken language. Unlike Latin, French still has a rich verb morphology, but it has been greatly restructured since Latin times. The imperfect and simple past of Latin were augmented by a conditional and a new future tense, as well as a series of compound tenses (present perfect, pluperfect, future perfect, etc.) and other tenses with some sort of auxiliary verb (e.g. future with *aller* 'go'). French also has a subjunctive, although its use is often predictable: it is most often used in subordinate clauses after certain kinds of verbs in the main clause or after certain kinds of conjunctions. Modern French syntax is characterized by a fixed subject–verb–object word order; adjectives typically are placed after the noun they modify, as are relative clauses. Questions are asked by placing the subject after the verb, especially in formal usage, or by using the expression *est-ce que* 'is it that'. In the spoken language, questions are also often asked through a rising inflection (intonation).

Where French differs most is in how the verb is formed: the other Romance languages typically have suffixes that give the person (1st, 2nd, or 3rd) and number (singular, plural) of the subject of the verb, but French has lost most (but not all) of its verb suffixes. As a result, it has had to rely on nouns or pronouns (that come before the verb) to give that information; and typically, if no noun is present, then a pronoun has to be used. In most of the other Romance languages, the use of a subject pronoun is optional. Compare French *je chante* with Latin/Spanish/Italian *canto* 'I sing' (where *cant-* means sing and *-o* means 'I', and the use of the pronoun *ego/yo/io* is optional).

The vocabulary of French has also evolved over time. The lexical stock is essentially of Latin origin, but many learnèd words from Greek were added in the

Renaissance period, as were words borrowed from Latin. There are borrowings from numerous other languages (Germanic, Spanish, Arabic, Italian, and English), which reflect the history of contacts that the French people have had with other cultures.

Current Changes in Spoken French

Social background, sex, and age affect the way in which French is spoken. Young people from the outer suburbs of large French cities (many of whom are poor and/or from immigrant families) use more nonstandard features of the language, as well as *verlan*, a back-to-front slang, and borrowings from English and Arabic. The forms of language that are used are also influenced by the kind of linguistic situations in which speakers are involved. In the written language, the simple past is a marker of formal registers and in other usages is replaced by the present perfect form.

But what is perhaps most notable right now is the fact that the ordinary spoken language used by educated speakers is moving further and further away from the written language and the standard French spoken only 50 to 10 years ago. For example, subject pronouns like *je*, *tu*, and *il* are becoming prefixes, attached to the front of the verb, along with object pronouns like *me*, *te*, and *le*. The pronoun for 'we' is no longer *nous*, inherited from Latin, but *on*, which used to mean 'one'. The negative marker *ne* is also just about gone. In other words, twenty-first century French is evolving further and further away from its origins in Vulgar Latin and from the other Romance languages.

Fromkin, Victoria Alexandra

Victoria Fromkin described herself as a 'professional radical revolutionary' in her youth (quoted in Cheng and Sybesma, 'Interview with Victoria Fromkin', *Glot International* 2:5.1(1996)), and the qualities of intellectual independence that sustained her in that work later came to characterize her career in linguistics.

She began the study of linguistics as a graduate student in 1961, when the American linguistic world was enmeshed in challenges posed by Noam Chomsky and generative grammar to the uniquely American form of structuralism developed in the 1940s and 1950s by followers of Leonard Bloomfield. Her first teachers at the University of California, Los Angeles (UCLA) were not part of the generative movement, but at an institute on machine translation in Venice, Italy, she met Yehoshua Bar-Hillel, a philosopher and colleague of Chomsky. Talking with Bar-Hillel, Fromkin's understanding of linguistics and the goals of linguistic theory were clarified. Chomsky's distinction between linguistic competence and linguistic performance and his conception of linguistic theory as an attempt to understand the nature of language and the human mind were considered revolutionary at the time, and that, of course, appealed to Fromkin.

Fromkin's doctoral dissertation was written under the direction of the linguist and phonetician Peter Ladefoged, and for some years thereafter she worked on the physical nature of speech sounds and the properties of a universal phonetic theory. Some linguists at the time rejected phonetics as part of the discipline, arguing that it dealt merely with physical phenomena, not with the structure of language. Fromkin's view of linguistics was more generous:

> The question of the boundaries of phonetics and linguistics, or whether such boundaries should be drawn, is an important one. . . . When I first came into the field I was interested in electromyographic registrations of linguistic units, and there were people who said: 'That is

not linguistics', and I said: 'But linguistics is whatever tells us more about the nature of human language and how language is realized in speech and in perception'. (*Phonetica* 37. 22–3, 1980)

It was just this ability to see beyond the constraints that some would impose upon the discipline that enabled Fromkin to expand her own work, and that of the field, in ways that led eventually to the cross-disciplinary specialization of neurolinguistics. For Fromkin, the research began with slips of the tongue. Her interest lay not in merely describing, categorizing, or even explaining slips and other speech errors, but rather in determining what such errors might imply about issues of language structure and language processing that were relevant to linguistic theory. In her landmark paper on speech errors published in 1971, she demonstrated that slips of the tongue involve discrete units of a language (for example, sounds, syllables, words) in accord with the rules of that language. That is, speech errors are not random. They are structured in the same way that language is structured, and studying such errors may provide insights into the way in which language is organized in the brain.

In her studies of lexical substitutions, for example (saying 'Take the milk out of the oven' when a speaker intended 'Take the milk out of the refrigerator'), Fromkin argued that such substitutions suggest that in our mental dictionary, words are specified with their semantic features. Other errors point to specification of phonetic, phonological, morphological, and syntactic features, as well as orthographic (spelling) properties. The vocabulary in our brain is not a mere alphabetical listing, but a complex set of independent and interconnected subsystems of linguistic information.

Fromkin's work on speech errors and their implications for linguistic theory was highly regarded and very influential. She edited two books of contributions by scholars from around the world, the first in 1973 (*Speech errors as linguistic evidence*), the second the result of a symposium she led at the 12th International Congress of Linguists in Vienna, Austria in 1977 (*Errors in linguistic performance: slips of the tongue, ear, pen, and hand*, 1980). In 1988, she contributed the state-of-the-art article on speech errors to *Linguistics: the Cambridge survey*. As her friends and colleagues were well aware, she always carried a notebook in which to record any speech errors she heard. The compilation eventually reached more than 12,000 examples.

In her later work, Fromkin investigated language use and loss in people with aphasia, dyslexia, and Parkinson's disease, and she promoted the study of sign languages and of language acquisition in children who had been denied language input by illness or neglect. In these studies, she explored evidence revealing the linguistic capacities of the human brain and the modularity of language.

Modularity—the theory that there is a unique language 'organ' distinct from other cognitive systems and abilities—was central to much of Fromkin's work, and her support for the theory of a genetically determined language faculty placed her within the general scope of Chomskyan generative linguistics. However, her work was often on the bridge between linguistics and other disciplines (aphasia studies, neurobiology, psychology), and so, except for debates over modularity, she was not a core figure in controversies of theoretical linguistics.

Partly because of this, and partly because of her strong administrative skills, she played a significant leadership role in national and international linguistic organizations, serving as president of the Linguistic Society of America (1985), as secretary and then chair of Linguistics Section Z of the American Association for the Advancement of Science (1993–1996, 1997–1998), and as an executive board member of the Permanent International Committee of Linguists. Her accomplishments were recognized by her election to the National Academy of Sciences.

In both her academic and her administrative work, Fromkin was always concerned with building bridges between linguistics and other disciplines: 'You can't do work on language without linguistics' (quoted by Cheng and Sybesma, 'Interview with Victoria Fromkin', *Glot International* 2:5.23 (1996)). She encouraged linguists to contribute their understanding of language to other fields, and she searched those fields for evidence that might support claims that linguists made about language and its organization in the brain.

Fromkin also took seriously the responsibility of bringing linguistics and its findings to the public and to the undergraduate population of colleges and universities. At UCLA, she taught the Introduction to Language class for more than 30 years, and it was from that class that she developed, with co-author Robert Rodman, her book *Introduction to language*, without doubt the most widely read of all introductory linguistics textbooks in the second half of the twentieth century.

Biography

Victoria Fromkin was born in Passaic, New Jersey, on May 16, 1923. She did her B.A. in economics from the University of California, Berkeley (1944). She married in 1948 and had one child. She returned to school in 1961, University of California, Los Angeles; and received her M. A. (1963) and Ph.D. with dissertation on phonetics guided by Peter Ladefoged (1965). She

was Assistant Professor, English, California State University, Los Angeles, spring 1965; joined the University of California, Los Angeles faculty in 1966 in Speech; in 1967 transferred to Linguistics and remained affiliated there throughout her career; in 1966 she was Assistant Professor, 1969 Associate Professor, 1972 Professor, Chair of Department of Linguistics 1970–1971 and 1973–1977, Dean of the Graduate Division 1979–1989, Vice-Chancellor of Graduate Programs 1980–1989, and she retired in 1991. She served on the faculty of the Linguistic Institutes of the Linguistic Society of America in 1966, 1976, 1977, and 1983; taught in the summer program in linguistics at the University of California, Santa Cruz 1971, 1972, 1973; and was visiting professor at University of Stockholm 1977, Cambridge University 1977, Wolfson College at Oxford University 1983 and 1987. She was President of the Linguistic Society of America 1985; President of Association of Graduate Schools 1988; Chair, Board of Governors of Academy of Aphasia 1991–1993; secretary 1993–1996 and then chair 1997–1998 of Linguistics Section Z of the American Association for the Advancement of Science; fellow of the Acoustical Society of America, the New York Academy of Sciences, the American Association for the Advancement of Science, and the American Psychological Society; executive board member of the Permanent International Committee of Linguists; elected member National Academy of Sciences, American Academy of Arts and Sciences, Aphasia Research Group of the World Federation of Neurology. She died in Los Angeles on January 19, 2000.

Function Words

Words are divided into two basic classes: (1) lexical, or open class words and (2) function, or closed class words. Lexical words refer to nouns (e.g. *dog, house*), verbs (e.g. *to go, to see*), and adjectives (e.g. *green, nice*), and supply the bulk of the meaning in a sentence. This class is called 'open' because speakers can freely add new words. Function words, on the other hand, as seen in these English examples, include determiners, such as *the* and *a(n);* auxiliary verbs (or simply 'auxiliaries'), such as *might, have,* and *be;* conjunctions, such as *and, that,* and *whether;* and degree adverbs, such as *very* and *too.* These words are

called 'functional' or 'grammatical' because they carry little meaning (have no synonyms) and typically 'help' another word. For instance, determiners add grammatical information about specificity and definiteness (*the dog* vs. *a dog*), but do not essentially alter the meaning of the phrase. They are also called 'closed class words', since speakers do not easily add new words to the set.

Lexical words typically carry intonational emphasis or stress, while function words are generally unstressed. Therefore, function words are prone to contraction—for example, the auxiliary *have* in *I've seen it*.

The distinction between function and lexical words has been very fruitful for linguistic description. So-called analytical languages, such as Chinese, use a large number of function words. In contrast, function words are typically lacking in the speech of young children, certain kinds of aphasia, and telegraphic speech. It is also widely confirmed that languages rarely borrow function words from other languages or invent new ones (hence their status as a 'closed' class). Most of the recent innovations in the English vocabulary, such as *pizza, angst, fax, E-mail, phat, AIDS, website, browser, screenager, to surf, Nethead,* and *technobabble,* are lexical rather than functional in nature.

Function words primarily add grammatical information, which means that they are defined above all by their syntactic behavior. Most traditional grammarians assumed (and their descendants continue to assume) that the structure of sentences and phrases is influenced mainly by lexical words. Function words were regarded as mere additions to lexical phrases. Thus, the sentence, '*The rabbit will see the fox*' was analyzed as a noun phrase *the rabbit*, followed by a verb phrase *will see the fox*. The determiner *the* was thus simply an addition to the noun phrase, and the auxiliary verb *will* was added to the verb phrase.

A shift in this thinking came in the 1980s within the framework of generative grammar. From then on, auxiliaries were seen as providing their own, independent, contribution to sentence structure. Nevertheless, function words still did not play a part in determining the category in which a phrase was placed—for example, a phrase such as *the rabbit* continued to be regarded as a noun phrase that happened to contain a determiner.

This view changed radically by the mid-1980s, when function words were increasingly treated as the key factor when deciding which sentence elements should be placed in which category. To use the technical terminology, function words were 'projecting to a phrase' or 'heading a phrase'. Determiners, for example, now came to be regarded as the head of determiner phrases—that is, *the rabbit* was now interpreted as a determiner phrase *the . . .* containing the noun phrase *rabbit,* instead of a noun phrase that happens to con-

tain a determiner. 'Functional projections' were thus assigned a structure and importance similar to 'lexical phrases'.

Research in the late 1980s and 1990s revolved around the question of exactly which functional projections a sentence may contain. Each function word that had a grammatical function was soon regarded as the main structural building block of a sentence. The increasing importance of function words in linguistic theories went hand in hand with an increasingly abstract description of sentence structure. This shift provided many empirical and theoretical advantages.

First, sentence structure could now be divided into three function domains: (1) a lexical domain around the verb, which establishes semantic relations between the main sentence elements; (2) a grammatical domain around the auxiliary, which establishes grammatical relations such as agreement (the auxiliary agrees in number and person with the subject: *I am/She is/They are leaving*); and (3) a discourse domain around the complementizer *that,* which links an embedded clause to a main clause (*I know **that** this is true* or *I wonder **whether** this is true*).

Second, differences between languages could be explained by how the function words, and the domains they define, were used. For instance, so-called verb-second languages, such as German, Middle English, Dutch, and Swedish, move the verb to the complementizer domain, whereas languages such as English refrain from doing so. For example, the word order in the English sentence, '*Yesterday the rabbit saw the fox*' would be, in German, '*Yesterday **saw** the rabbit the fox*'. Differences even between unrelated languages were thus reduced to very basic principles.

Function words and lexical words are not sharply distinct categories, but rather form a continuum. Certain classes of words can thus share features with both prototypical lexical words and prototypical function words. The English preposition is a case in point: some prepositions have lexical meaning, such as location (*behind*) and direction (*toward*), while others have little meaning (*of* or *to*). Many prepositions are used to introduce sentences (*after, for, like*) and are therefore similar to prototypical function words, namely, complementizers.

Grammatical meaning can be expressed in different ways. English uses independent auxiliaries to express present or past tense (*I am* thinking vs. *I was* thinking), but also inflects the verb for the same purpose (*I think* vs. *I thought*). Languages exhibit great variation along these lines: some languages express all grammatical meaning via independent function words, and such languages are called 'analytic'. In contrast, so-called 'synthetic' languages use inflection and other markings on lexical words throughout.

This distinction between analytic and synthetic languages also represents a continuum, and languages change in this respect over time. Old English made extensive use of grammatical markings on lexical words. Modern English has lost much of this capability and instead uses auxiliaries to fill the gap. In fact, the auxiliary verb *will* used to be a lexical verb in Old English, but its meaning ('to want') changed when it was recruited to express future tense. In modern theoretical approaches, such as the Minimalist Program, which tend to focus more on underlying differences than on surface variation, the distinction between analytic and synthetic languages becomes negligible.

Function words have little lexical meaning and usually carry no stress. In traditional grammars, they do not carry the function of governing an independent projection or phrase, whereas in some modern approaches they do. Function words are quite similar (and are historically related) to grammatical markers on lexical words.

Functional Approaches

Functional linguistics appeared as a reaction to formal approaches to grammar, especially generative and transformational approaches. One of its basic assumptions is that language is a symbolic system with a certain purpose or purposes, mainly communication, although there are other possibilities too, such as the use of language as an instrument of thought.

Apart from structures and form, any linguistic system also has functions. Functional approaches to language assume that there is a correspondence between form and function, and this correspondence is always motivated. However, a very subtle theoretical matter is what kind of function we are referring to. Apart from the most general functions of communication and organization of thought, it is possible to refer to functions at more atomic levels (i.e. functions of linguistic elements or functions of linguistic constituents, considered in different levels of linguistic analysis such as phonetics, morphology, semantics, syntax, etc.). At the most general level, however, there are several typologies with different functions that try to provide different functional alternatives, like the ones proposed by authors such as Karl Bühler (cognitive, expressive and conative/instrumental), M.A.K. Halliday (ideational, interpersonal and textual), or Roman Jakobson.

Today, there are two main approaches that claim to be 'functional'. These are M.A.K. Halliday's systemic functional linguistics, and Simon Dik's functional grammar, both discussed below.

Michael Halliday's systemic grammar follows the tradition of the London school and, more concretely, the work of John Rupert Firth, who developed his own theory studying language as part of a social system. According to Firth, language was used with a specific purpose in situational contexts, which, in turn, reflected cultural contexts. Other minor influences on Halliday's work are the linguistic theories of the Prague school around Nikolay Trubetskoy, Louis Hjelmslev's glossematics, and the ideas of the American linguist Benjamin Lee Whorf.

In 1961, Halliday, one of Firth's disciples, developed from Firth's ideas a theory that dealt with different scales and categories. He used the categories of structure, system, unit, and class, as well as three scales (rank, delicacy, and exponency) that connected the categories with one another and with the data. This grammar received criticism, especially concerning the categories of class and structure, the scale of rank, and the taxonomic nature of the theory, as mentioned by Christopher Butler (1985:29–38; 1995:529). Later, this grammar evolved toward what was first called

systemic grammar (Halliday 1967/1968), and some years later, systemic functional grammar (Halliday 1973, 1985), which is the current form of the theory.

Systemic grammar is based on a distinction between three main meta-functions of language: (1) the ideational function, which deals with the expression of content and with the experience of the speaker within the real world; here, it is possible to distinguish two subfunctions: experiential and logical; (2) the interpersonal function, which is used for establishing and maintaining social relations; and (3) the textual function, which deals with the creation of texts and the relations that are established within them. These meta-functions occur simultaneously in language. This simultaneity can be applied to two axes for the organization of the theory: the systemic (paradigmatic) and the structural (syntagmatic) axes. Each of these meta-functions involves different systems that can be organized according to the different units of the scale of rank (clause, phrase, group, word, informative unit). In fact, these three descriptive dimensions of the theory eventually become even more complicated, because Halliday also talks of a stratification in phonology, lexicogrammar, semantics, and context. The use of many axes for the organization of this theory makes systemic grammar a complicated one that tries to gather the complexity of language into many dimensions. In this respect, it does not have among its priorities the criteria of parsimony and elegance that appear in other theories. Additionally, systemic grammar is characterized by its being a theory that is sociologically oriented: that is, it classifies different contextual parameters of a social nature into dialectal and diatypical (based on different registers), and the latter into: field, which is the type of social activity in which language is inserted; tenor, which concerns the role relationships of roles among those who interact; and mode, which refers to the medium of communication. These types of parameters are related to the meta-functions of language: field to the ideational function, tenor to the interpersonal function, and mode to the textual function. Halliday's theory encompasses all usage domains of language, and in that respect it can be rightly considered a functional theory.

Simon Dik's Functional grammar presents a different approach. It claims to be a functional theory, since language is conceived mainly as an instrument of social interaction, and this characteristic is incorporated into the model. Despite this claim, the results, both in this first version of the theory (1978) and in the second (1989), are not as satisfactory as Halliday's proposal. Dik's grammar was influenced by the work of many previous authors, like Joseph Greenberg, James Fillmore, David Perlmutter and Paul Postal, Emmon Bach, H. Paul Grice, Herbert Clark, and Susan Haviland, among others. The architecture of its

model receives ideas already put forward by William Foley and Robert Van Valin in 1980 in their *Role and reference grammar*, but their proposal is original and different.

Dik (1989) proposes adequacy standards for his grammar, such as psychological adequacy, typological adequacy, and pragmatic adequacy, without which it would not be possible to account for language as an instrument of social interaction, and therefore the grammar would no longer be a functional grammar. However, the proposed model presents a high degree of formalization that is characterized by having an internal architecture with different levels that appear included one within another. The resulting embedding could be represented as: $[_{Level\,4}\,[_{Level\,3}\,[_{Level\,2}\,[_{Level\,1}$ Nuclear Predicate$]]]]$. Any clause has this basic configuration, to which the rules of expression can be applied in order to produce the concrete form of the sentence in English. In a posterior elaboration of the model by Kees Hengeveld (2004), the mentioned scheme constitutes the representational level, but this level is produced from information in the interpersonal level, and it is determined as much by the cognitive context as by a *cognitive component*.

In this new formulation of Dik's functional grammar, the roles of the interpersonal factor and the communicative context appear more clearly, which characterize this model as even more functional.

Gender and Language

One meaning of the term *gender,* in the phrase 'Gender and language', is gender *as a characteristic of language as an abstract system.* In this sense, *gender* refers to a *grammatical* category. A second meaning of *gender* refers broadly to the 'human' and necessarily social concepts of femininity and masculinity.

Gender as Grammatical Category

Traditionally, languages have been described as having either 'natural' or 'grammatical' gender. A language with natural gender requires that the gender of an animate noun or pronoun corresponds to the biological sex of the person or animal to which that noun refers. In this way, *woman* and *girl* in present-day English are feminine nouns and *she* and *her* are feminine pronouns. Similarly, *bull* is a masculine noun and *vixen* is a feminine noun. Nouns like *computer* and *marmalade* are neither feminine nor masculine, but rather 'neuter'. Despite a very few odd but well-known exceptions (like a ship being sometimes referred to as *she*), the English language is usually seen as having natural gender.

Grammatical gender, in contrast, is 'formal'. In languages with grammatical gender, all nouns have a gender, although whether this is masculine, feminine, or neuter is unlikely to be evident from the noun itself. In French, for example, *chaise* (*chair*) is feminine and *pain* (*bread*) is masculine. The determiner (in these cases, the definite article) indicates the gender (*la chaise, le pain*).

Some masculine nouns and pronouns in English and other languages supposedly have the potential to be 'generic' or 'sex-indefinite', i.e. to have the capacity to include both males and females. Examples include *man* (and its compounds) and *he* (as well as some animal names such as *dog* and *lion*). Thus, in principle, it is grammatically correct to say to a class of male and female students: 'Everyone will get his homework back tomorrow.' But since *his* here is intended to include females, this illustrates that gender in English is in fact in part grammatical.

The genericity of those masculine forms in English that can in principle additionally refer to 'humans' has however been seriously challenged—one reason being that phrases like 'Man breastfeeds his young' sound odd; another that what may be intended as generic may not be so interpreted (by either sex), and accordingly that women and girls may be effectively excluded or rendered relatively invisible by the use of these 'generics'. The 'generics' *man* and *he* have thus been seen by feminists as one form of 'sexist language' (other forms being those that define, stereotype, trivialize, and/or degrade women, e.g. *Miss/Mrs* (*vis à vis Mr*), *usherette, air hostess, 'she's a blonde', dumb blonde*). (see Lakoff (1975) for an influential—although, in retrospect, problematic—pioneer account of such language.)

The masculine 'generics' as well as other 'sexist language' items now have a somewhat old-fashioned ring to them, and are often substituted for by alternatives (although not replacements) such as *people, he or she, s/he,* 'singular *they*' (especially in spoken English, e.g. 'Everyone will get their homework back tomorrow'), *flight attendant*, and *Ms*. These alternatives are now included in grammars and dictionaries, and

'inclusive language' is required by many journals and institutional Codes of Practice. Other nonsexist alternatives have been adopted for languages other than English (Pauwels 1998).

The vociferous and in many ways effective campaign against sexist language (see Lakoff (1975) for an influential—although, in retrospect, problematic—pioneer account of such language) was loosely based on a 'structuralist' view of language—one form, one meaning. Several limitations of this have now been identified, in particular that (a) word meanings change, (b) the meaning of a word will vary with context, (c) people will *interpret* a given word in a whole range of ways, and, perhaps most importantly, (d) sexist *discourse* can very easily occur without a single 'sexist language item' (for example, *people* can be used in a sexist way if it actually refers only to males; a text can still be degrading to women without using any 'sexist language'). Partly because of the evident limitations of 'nonsexist language', feminist critique has shifted to *discourse*, in the sense of 'ways of structuring knowledge and social practice' (Fairclough 1992), or of 'ways of seeing the world'. Gendered discourses *represent* men and women in particular ways, e.g. in contemporary childcare texts, 'Father as baby entertainer' (see Sunderland 2004). Other contemporary sexist discourses can be seen as (a) 'universal heterosexuality', i.e. the apparent assumption that every adult is either with a partner of the opposite sex or seeking one, (b) 'vive la diffrénce', i.e. that apparently essential differences between women and men are enjoyed by both and should/need not be problematized, (c) 'the battle of the sexes', i.e. that women's gains represent losses for men, (d) 'how to get your man and keep him' (Hollway 1984), a discourse *sine qua non* of many women's magazines, and (e) 'male sex drive' (Hollway 1984) (or 'men can't help their sexually aggressive behavior'). Masculinity and femininity, as well as individual women and men, and indeed gender relations, can be represented in particular ways in discourse in a whole range of written and spoken texts (Mills 1995). But representation can only ever be part of the story—it says nothing about how a text will be responded to by a reader.

Gender as Social Concept

The second, social use of the term *gender* in the context of gender and language study has witnessed considerable changes in meaning. Feminist linguistics in the 1970s largely bought into the traditional, sociolinguistic, variationist paradigm, in which gender was broadly mapped onto the biological category of *sex*. Although the feminist view of gender was always that it was primarily social or cultural rather than biological,

the overriding research question was whether and how women and men used language differently.

This project was characterized by two different approaches. The first was the 'dominance' paradigm, i.e. a concern with mixed-sex talk and whether men actually dominated women linguistically, making their use of language a form of 'doing power' (Kramarae 1981; Thorne et al. 1983). A British pioneer was Dale Spender, who in the 1980s popularized what were then new and important findings about male dominance in classrooms, in terms of boys being the recipients of most teacher talk, and the producers of most classroom talk (Spender 1982).

The other, slightly later approach was the more liberal '(cultural) difference' paradigm, exemplified in its most extreme form by Deborah Tannen (1990), in a less extreme form by Jennifer Coates (1998). Coates' work concerns particularly single-sex (women's) talk. In this approach, in which dominance was much less of an issue, men and women were seen as speaking differently as a result of having grown up in different linguistic subcultures.

However, these apparently different approaches also had a great deal in common. Focusing variously on women's disadvantages ('dominance') and women's strengths ('cultural difference') in their concerns with identification of gender *differences* in talk, they played down *similarities*, and underemphasized differences 'within' men as a group and women as a group. With exceptions, they both tended to generalize (women do this, men do that), to underplay the importance of context and local meanings, and to stress the importance of gender over other identities (see below). More profoundly, they implicitly shared a model of gender as broadly 'fixed', and somehow shaping or even *determining* talk, and accordingly linguistic gender differences—rather than of gender as itself being shaped *by* language use.

A combination of impatience with difference/dominance, and developments in cultural studies and feminist theory, led feminist linguists to turn the previous conception of the language/gender relationship on its head, i.e. from 'How does gender shape language?' (or 'How is language a reflection of gender'?) to 'How does language (or discourse) shape gender?' (especially over the last 20 years) Accordingly, one of the major ways in which the language and gender field (particularly that with a sociolinguistic orientation) has changed (especially over the last 10 or 15 years) is the growing recognition of the *problematic* nature of a model of gender as fixed (established at the age of 16 or 18 or whatever), and the newer understanding of gender as changing all the time.

Corresponding to this is a recognition that if gender is not fixed, the binary, 'gender differences' approach

to language use (which underpinned both the 'dominance' and the '(cultural) difference' paradigms) is also problematic (see Cameron (1992) for a useful critique). Gender and language study now acknowledges the further complexity of gender since it can be seen as coexisting with considerations of, inter alia, class, ethnicity, and sexuality.

One response to the question of *how* language shapes gender is 'through discourse, which is both shaped by *and shapes identity*'. To see gender (masculinity, femininity) as identity excludes neither shaping by social forces nor an individual's own agency (Bucholtz et al. 1999; Norton 2000). Neither does it entail fixity. Johnson for example sees masculinity and femininity as 'on-going social processes dependent upon systematic restatement' (1997:22).

If identity is further conceptualized as *multiple*, gender can be seen as one of several *identities* (e.g. masculinity/femininity, ethnicity, sexual identity)—although one identity may be foregrounded at any given time. Hence, while, say, ethnic identity might be experienced as most salient for some individuals in some contexts (for themselves and/or for others), this cannot be seen as separate from gender. Each identity will mediate and be mediated by the others.

Masculinity, already referred to in passing, is one recent concern of gender and language study (see Johnson and Meinhof 1997; Coates 2003). Masculinity can be manifested and constructed linguistically in a range of ways, as can femininity. Many of these are likely to be forms of what has been referred to as hegemonic (crucially, heterosexual) masculinity. The study of gender identities, both masculinities and femininities, from gay as well as the previous heterosexual perspectives has thus paved the way for 'Queer Theory', which rather than advocating inclusion and equal opportunities, entails problematizing all sexual identities, and thus advocates continual enquiry as regards heterosexual and other 'hegemonic' identities as well as more marginalized ones (Butler 1999; Nelson 1999).

Gender and language study does not however conceptualize gender only as identity. It can also be seen as *performance*—of doing rather than of being (Butler 1999). Butler does not deny identity—rather, she sees gender identity as coming from, rather than preexisting, performance. For Butler, people perform an identity—linguistically, in discourse, and in other ways. To illustrate this, looking at the talk of gay males, it is possible to distinguish between 'Gayspeak', the identifiable talk of gay men (a form of talk whose existence has been challenged)—and the idea of gay men deliberately speaking in a stereotypically camp way in order to signal their sexual identity. This 'performance' may however bear no relation to the way in which gay men speak when they are not interested in signaling their sexual identity.

Thus, it is now possible to see the previous 'two prongs' of gender and language research as having dovetailed into *discourse*, and discourse *as social practice* as a shaper of identity. The relationship between language/discourse and gender is now explored across a range of genres and settings (see e.g. Sunderland 2000, 2004). However, one particular recent and influential context-related concept for feminist linguistics is that of 'Community of Practice' (Holmes and Meyerhoff 1999). A 'Community of Practice' can be defined both by its membership *and* its practice. The 'practice', both nonlinguistic and linguistic, will include heterogeneity as well as homogeneity in the ways things are done, and the way they are talked about. It can be, and normally is, both gendered and gendering.

To conclude, gender and language study is now characterized by considerations of (i) gender as *identity*, and this identity as both multiple and fluid ('becoming' rather than 'being'), (ii) *representation*, in a range of written and spoken texts and text types, (iii) the ongoing social and linguistic *construction* of gender, (iv) individual agency, (v) the possibility of seeing gender as 'performance', (vi) discursive practices and discourse(s) as *social practice* (Fairclough 1992), and (vii) gendering through a 'Community of Practice' (see Bergvall et al. 1995; Hall and Bucholtz 1995; Bucholtz et al. 1999).

Gender: Class Marking

Nouns can be marked according to number, but there is also the possibility of marking nouns according to their belonging to certain classes. These classes were originally based on semantic criteria, which may still be present in many nouns, but it is customary to find nouns that do not match the criteria in their own class. In English and Indo-European languages in general, we normally refer to class marking as 'gender', and the original semantic basis for the marking is sex. Since sex applies to most animate beings, it is easy and straightforward to distinguish between male and female, which are marked grammatically as masculine and feminine, respectively. Inanimate beings, on the other hand, cannot be either male or female, and that is why in some Indo-European languages there is still a third class, the neuter, which marks grammatically those nouns denoting entities that have no sex. The picture becomes complicated by the fact that many nouns are classified within the different gender classes regardless of semantic considerations. Some examples follow.

In German, there are three genders, which reflect the semantic distinction in terms of sex in nouns like *Mann,* 'man', which is masculine, or *Frau,* 'woman', which is feminine. However, there are also cases in which there is no correlation with the semantic notion of sex, as can be seen in nouns like *Mädchen,* 'girl', which is neuter. In Spanish, there is no neuter, but there is a neat distinction between masculine and feminine, which closely follows the sex notion in nouns like *hombre,* 'man', and *mujer,* 'woman', but which is arbitrarily assigned in many other cases. In these two languages, gender is marked by special endings and the required agreement with certain forms of the article and demonstratives. Gender is also present as a grammatical distinction that requires different forms for personal pronouns. In English, there are no distinctive endings for nouns according to gender (although nouns sometimes have special forms that reflect gender, e.g. *heroine* is a feminine noun and *hero* is a masculine noun). In addition to this, there are no gender endings for articles and demonstratives. The only word class that should be clearly marked at all times according to gender is the class of personal pronouns, following these criteria: male humans (or animate beings in some situations) are masculine (*John came, but **he** left early*), female humans are feminine (*Mary didn't come. **She** stayed at home*), animals and plants in general are neuter (*I saw a cat yesterday. **It** was black*), and inanimate beings are neuter (*I like this bicycle because **it** does not weigh much*). There are some special cases that do not follow these rules (e.g. *Isn't **she** a beautiful BMW?* refers to a car, which is an inanimate being).

Class marking can be more complex than what gender alone suggests. In Bemba, a Bantu language, we find 16 different classes, which are marked morphologically in combination with number, corresponding to the original semantic values of humans, plants, fruits, mass/liquid, small objects or inanimates, animates, inanimate elongated objects, and paired body parts. The marking is carried out by means of prefixes (e.g. in *umu-ana*, 'child', the morpheme marking class-inclusion is *umu*). Swahili, another Bantu language,

has 11 classes, with the following prefixes for nouns, adjectives (which agree with the noun they accompany), and pronouns:

Class	Nominal Prefix	Adjectival Prefix	Pronominal Prefix
1	*m-*	*m-*	*a-/m-; yu-; w-; ye-*
2	*wa-*	*wa-*	*wa-*
3	*m-*	*m-*	*u-*
4	*mi-*	*mi-*	*i-*
5	*zero or ji-*	*zero or ji-*	*li-*
6	*ma-*	*ma-*	*ya-*
7	*ki-*	*ki-*	*ki-*
8	*vi-*	*vi-*	*vi-*
9	*zero or n-*	*zero or n-*	*i-*
10	*zero or n-*	*zero or n-*	*zi-*
11	*u-*	*m-*	*u-*

Swahili's classes can be grouped according to semantic criteria (similar to those of Bemba), but there can be many inconsistencies in the groupings. A classification proposal that takes into account all the nouns that do not fit into the system divides the noun classes into two subsets: a 'derived' set of classes, in which there is a fit between meaning and form (this is also called 'fixed' gender), and an 'inherent' set of classes, with arbitrary membership ('free' gender). There is overlap between these two sets formally, but the distinction helps in making the system consistent, because we can tell which nouns are classified according to semantic criteria and which are not.

As for the linguistic form used, Swahili and Bemba mark class membership by means of prefixes; but, as we have seen, there are other means. In Indo-European languages, such as Spanish, German, or Russian, class marking is in the ending. That is, classes are marked by means of information conveyed by suffixes. In Spanish, *-a* is normally the ending of feminine singular nouns, whereas *-o* is normally the ending of masculine singular nouns. However, this is not always so, because there are some nouns that end in *-a* which are masculine (e.g. *poeta*, the Spanish word for 'poet'). In this language, gender information is combined with number, so that all plurals add *-s* to the singular form, and we can find in general the following pattern:

	Masculine	Feminine
Singular	-o	-a
Plural	-os	-as

However, there are numerous exceptions to this rule, and there are also other endings, which are difficult to assign to one of the two classes. In German or

Russian, it is even more difficult to establish correspondences between suffixes and gender, since the endings also reflect grammatical case. The forms that can be used in German for the nouns Tisch 'table', Körper 'body', Mensch 'man' (masculine), and Jahr 'year', System 'system' (neuter) in the singular are the following:

	Masculine		Neuter	
Nominative	*-/-/-*	*(Tisch, Körper, Mensch)*	*-/-*	*(Jahr, System)*
Accusative	*-/-/-en*	*(Tisch, Körper, Menschen)*	*-/-*	*(Jahr, System)*
Genitive	*-es/-s/-en*	*(Tisches, Körpers, Menschen)*	*-es/-s*	*(Jahres, Systems)*
Dative	*-/-/-en*	*(Tisch, Körper, Menschen)*	*-e/-*	*(Jahre, System)*

The feminine and plural forms are simpler than these, since they are in most cases invariable; but it may be impossible to find out gender simply by looking at the ending (e.g. *Jahre* is the nominative plural and the dative singular of *Jahr,* 'year', which is neuter, whereas *Frage,* 'question', is the nominative singular of a feminine word; all these forms end in *-e*).

Articles and adjectives normally agree in gender with nouns in Indo-European languages (English is one of the exceptions), which means that they have full-ending paradigms for masculine, feminine, and, in some cases, neuter. Pronouns also use different ending paradigms according to gender, so that they can agree with the gender and number of the noun that corresponds to the entity to which they refer.

Generation

Generation is the process by which thought is rendered into language. Within computational linguistics, it is referred to as 'natural language generation' (NLG) to help distinguish it from Chomsky's generative grammar and to contrast with natural language understanding. It is the study of how actual speakers, people or computers, construct utterances in actual contexts—the situations that motivate them to speak. As such, NLG is part of the larger field of Cognitive Science, where it is also referred to as 'production', particularly by psycholinguists.

The first NLG systems were developed in the 1950s as part of machine translation systems. The field gained maturity in the 1980s, with its own series of workshops and conferences and its own unique problems. As gauged by membership in the special interest group SIGGEN, there are several hundred people today actively pursuing research on generation.

NLG takes its methodology from Artificial Intelligence. To study a cognitive capability, you design and implement computer programs that attempt to replicate it: in this instance to produce fluent utterances for a purpose. To do this, the program ('generator') starts with a body of data or information. This might be the daily movement of a stock market index (Kukich 1988) or numerical data about temperature and wind patterns (Goldberg et al. 1994). In cases like these, the first thing the generator must do is analyze the data to determine both what information it contains (e.g. what is particularly salient: have winds increased or diminished) and what concepts—ultimately what words or phrases—could be used to communicate that information.

There is a consensus among NLG researchers that generation involves three broad-brush components: (1) determining and organizing the information content to be expressed; (2) 'microplanning', where the sentential and referential structures are determined; and (3) 'surface realization', where the text plan is processed by a grammar to construct the sequence of syntactically and morphologically appropriate word forms, which are then rendered on some output medium, typically formatted text displays or web pages. (For details of alternative NLG architectures, see McDonald (2000) or Reiter and Dale (2000).)

Surface realization is the most advanced of these three components since it draws on the well-established knowledge of grammar in linguistics and computational linguistics as a whole. Virtually every kind of grammar that linguists have developed has been applied to NLG including some that are relatively unknown in the wider community such as Melcuk's Meaning-Text Theory and Halliday's Systemic Functional Grammar (SFL). Interest in these theories of grammar stems from the need to reason about the alternative choices that are available, the functions they perform, and their consequences for other choices later on. For example, saying '*the house is red*' vs. '*the red house*' will express the same fact about the house, but with differences in emphasis and in what parts of the sentence they leave open for other information to fill. Surface realization is also the only component within the architecture of NLG systems that is sufficiently mature for 'plug and play' reusable components to have emerged, notably KPML (Bateman 1997) and FUF/SURGE (Elhadad and Robin 2001) both of which use SFL.

The state of the art in NLG is measured by a combination of the fluency of the texts it is possible to produce and comparative difficulty of adapting to new subjects or genres. Consider this example, an automatically generated recipe for butter bean soup (Dale 1992: 14).

> Soak, drain and rinse the butter beans. Peel and chop the onion. Peel and chop the potato. Scrape and chop the carrots. Slice the celery. Melt the butter. Add the vegetables. Sauté them. Add the butter beans, the stock and the milk. Simmer. Liquidize the soup. Stir in the cream. Add the seasonings. Reheat.

Notice how this text is tailored to its genre. All the sentences are imperatives; objects can be omitted when they are obvious ('*Reheat __*'), and the sentences are simple and short. One of the problems in microplanning is how to formulate this 'tactical' knowledge about a genre's preferred constructions in such a way that it can be deployed by other NLG systems producing texts about a different subject, especially when they use different processing methodologies. We know how to do this with grammars, but not with the knowledge of how to balance the consequences of alternatives when a text is composed.

This class of problems, unique to generation, is further illustrated with the example below, which was produced by Robin's STREAK system (1993). It is an example of the best that can be done today as it is indistinguishable from what a human sports journalist would produce as a capsule summary of a basketball game.

Dallas, TX—Charles Barkley matched his season record with 42 points Friday night as the Phoenix Suns routed the Dallas Mavericks 123–97.

STREAK uses an architecture based on revisions to an initial draft, where it continually looks for opportunities to incorporate historical knowledge into a skeleton of reported facts. In this instance, for example, there is the fact that the Mavericks are on a long losing streak. It is not possible to add the number of losses to the sentence, given its present structure; however, this generator has extensive tactical knowledge about the choices available to it and knows that if it uses an alternative way of phrasing the fact that the Suns lost, one that reifies the loss as a noun, it can then incorporate the number of losses by modifying the noun with the count. Underlines indicate the text that has changed:

. . . the Phoenix Suns <u>handed</u> the Dallas Mavericks <u>their 27th defeat in a row at home</u> 123–97.

The focus of ongoing research is in text planning problems such as this illustrates; in the extension of established capabilities to larger texts (as this is written, the limit is multiple page, individually tailored instruction, or advice pamphlets), and in integration with other modalities such as real-time graphics and the production of speech with appropriate prosodics.

Generative Grammar

Generative grammar is a conceptual model whose central tenet is that language is a property for which human beings are biologically prewired. While all models of language assume some role for both biology and environment, they differ with respect to the emphasis that they place on each: empiricist models attribute a greater role to the environment, and focus on differences across speakers' grammars (for instance, how the particular input that children receive influences the development of their grammar). Nativist models, in contrast, attribute a greater role to the biological component, and focus on commonalities across speakers' grammars. While all nativist models assume language to be biologically determined, they differ with respect to the nature of such knowledge: The emergentist approach, favored largely by psychol-ogists, attributes knowledge of language to general-purpose learning mechanisms, and thus assumes this ability to be no different from any other cognitive capability; the generative approach, in contrast, subscribed to by many linguists, views linguistic knowledge as being unique and specialized, and stemming from brain structures devoted specifically to the processing of language.

The generative framework had its origins in the 1950s with the publication of Noam Chomsky's 1957 book *Syntactic structures,* which built on the work of his teacher Zellig Harris. Chomsky's approach was a reaction to the behaviorist theory of language prevalent at the time, championed by the psychologist Skinner. Under a behaviorist model, the brain is considered a blank slate with regard to linguistic knowledge;

children must thus be explicitly taught their language by the adults around them in a stimulus–response manner, their behavior being rewarded when they imitate the adults' language correctly. Chomsky instead advocated a view subscribed to in the previous century (to which behaviorism had been a reaction) that some brain activities are unconscious and reflexive, just as is the case for many physical processes. Much of human beings' linguistic knowledge, Chomsky argued, is abstract and unconscious, but can be brought to conscious awareness by examining speakers' usage of such linguistic knowledge (known as the competence/performance dichotomy).

Under a generative approach, human beings are assumed to be prewired for language, beginning life not with a blank slate but rather with a linguistic template or blueprint that they flesh out upon exposure to specific linguistic data. Instead of learning language by imitating those around them, children create their own grammars. One reason for assuming this is that they make errors that adults do not (e.g. 'I hurted myself') and generate novel forms, neither of which should occur if they learned solely by imitating. In addition, most children are not given explicit instruction in their language or corrected on errors, necessary in an imitative model, yet all manage to acquire language. Furthermore, although the environments in which children acquire their language vary, they all go through similar stages in acquiring a language and during the same general time frame (for instance, forming sentences with content words such as nouns and verbs around 18 to 24 months, and function words like 'will' and 'my' between 24 and 30 months). Moreover, although children do not hear examples of every possible structural pattern, they nonetheless attain a grammar capable of generating all the possible sentences in their language (known as the poverty of the stimulus argument). And, although each is exposed to different data and in a different order, they all end up with the same basic grammar for their language, which would be unexpected under an imitative account.

The name 'generative grammar' is used to refer to this model since speakers are assumed to possess a grammar capable of generating all the possible sentences in their language (while excluding all the impossible ones). The grammar consists of a finite number of rules, yet is capable of generating an infinite number of sentences from such rules due to their ability to refer back to each other repeatedly (known as recursion). For instance, one can continue to embed sentences within one another as in the example 'John thought that Mary said that Fred believed that Cindy suspected that the student had read the book,' each further embedding resulting in a new sentence. Another central feature of such a grammar is that it is highly constrained. For instance, all syntactic rules make reference to the internal structure of the sentence (known as structure dependency). Thus, yes–no questions in English are formed by moving the auxiliary to the front of the sentence ('Will the student read the book?'), such a rule being framed in terms of an internal grammatical unit (the auxiliary 'will'). No language has rules that are structure independent, such as moving the third word to the front of the sentence to form a question, which refer instead to surface properties such as linear position. That the latter formulation will not work can be seen when the subject is replaced with a pronoun: while the structure-dependent rule will generate the correct question since it always moves the auxiliary ('Will he read the book?'), the structure-independent formulation will not, as the auxiliary is no longer the third word ('Read he will the book?'). Constraints such as structure dependency support the idea of speakers possessing unconscious, abstract linguistic knowledge, as there is no overt evidence of the syntactic groupings of words in the input that they hear. And, the fact that speakers were never taught such constraints, let alone being aware that they exist, coupled with the fact that these hold across all languages, supports the idea of there being a wired-in universal component to language.

While the idea of an innate, prewired blueprint has remained constant in generative grammar, the conceptual details have varied across the decades. In the 1960s, the emphasis was on the distinction between a deep structure, which conveyed the semantic properties of a sentence, and a surface structure, which supplied its pronunciation. Thus, the passive sentence 'The book was read by the student' was assumed to come from the same deep or underlying structure as its active counterpart, 'The student read the book', as both have the same meaning. In the 1970s, the emphasis shifted to finding the set of transformations used to derive the various syntactic patterns of each language. The list included transformations for passives, yes–no questions, and wh-questions ('Which book did the student read?'). While the number of sentences in a language is potentially infinite, it was assumed that the number of transformations could be reduced to a finite set. However, it soon became clear that there were many more transformations than it was possible to enumerate. Emphasis then shifted to narrowing down the transformations by type. Two general types were established: noun phrase (NP) movement, which moved a phrase within a sentence, as in passives, and wh-movement, which moved a phrase outside a sentence to

a presentential landing site, as in wh-questions. Eventually, these two transformations were collapsed into one general transformation, move alpha, which allowed movement of any constituent anywhere, subject to certain constraints.

In the 1980s, the model was flipped on its head. Rather than looking for the possible structures in a language, the emphasis instead shifted to determining the impossible structures. This represented a significant evolution in the conceptual model: whereas the number of patterns possible in a language is potentially infinite, the number of constraints is thought to be very small. In addition, it also made it possible to shift the emphasis to universal aspects of language, rather than simply to those properties that an individual language possessed. The grammar was now taken to consist, not of a set of rules, but rather of a set of autonomous modules that interacted with each other; one conception of such a model became known as government-binding theory, named after two of the modules, while alternative models were also proposed such as lexical-functional grammar. The overall conceptual model became known as the principles-and-parameters model since it considered language to consist of a set of wired-in principles that all languages shared, along with a set of parameters that they also shared, but whose values varied cross-linguistically and needed to be set upon exposure to language-particular data (such innate knowledge being referred to as Universal Grammar). An example of a principle would be a movement constraint known as subjacency, which prohibits movement of a phrase out of more than one clause or noun phrase in a single step (the name 'subjacency' referring to the fact that movement can occur to an adjacent clause, but not a subadjacent one). Thus, one cannot say 'Which book do you know the student who read?' since 'which book' has been moved from within the relative clause ('the student who read which book') and the upper sentence ('you know the student who read which book'). While such a constraint is thought to be universal, the constituents out of which the element may move (the bounding nodes) vary cross-linguistically. English is freer in its movement allowances than Russian, but less so than Italian or Swedish; a language like Japanese, in contrast, allows no overt syntactic movement. Thus, a parametric difference linked to this principle would dictate what the bounding nodes for a given language are.

In the 1990s, the emphasis turned to making the model even simpler conceptually. The new approach, called minimalism, assumed a much more limited role for the syntactic component. It now was seen as a computational device that simply checked that sentences were formed correctly. All morphology was assumed to be attached directly in the lexicon; the syntactic component then checked to see that features on the words matched. If so, the derivation was said to converge, otherwise, it crashed. Thus, the sentence 'The student enjoys the book' would be acceptable since 'student' and 'enjoys' are both third-person singular, whereas 'The student enjoy the book' would be ungrammatical as the number agreement on the noun and verb do not match. The formation of sentences was now assumed to occur by means of a few basic operations such as merge, used to generate basic declarative sentences, and move, used to derive patterns such as passives and questions. Another conceptual model that developed during this decade was optimality theory, which attributed variation among languages to their different rankings of a set of universal constraints.

Since any model proposed for a grammar must be one that is learnable by the child, language acquisition research has helped to shape development of the generative framework, and much first- and second-language research today is solidly grounded in such a framework. First-language researchers are interested in questions such as whether the principles of language are all present at birth or instead come online gradually as the child develops cognitively (the continuity/ maturation debate). Second-language researchers are interested in determining whether second-language learners have full access to the language faculty as first-language learners do, partial access only (properties that are the same transferring, but new ones not being acquirable), or no access at all. And, a central question for both first- and second-language acquisition is whether there is a critical time period during which language must be acquired, as is true for other biologically determined properties.

While the conceptual details of the generative grammar model have changed greatly over half a century, the basic underlying tenet, that language is a species-specific property for which human beings come prewired, has remained constant. Future research will undoubtedly yield new insights into the specific shape of the grammar, while remaining true to the model's belief in a wired-in blueprint.

Genericity

Much of our knowledge about the world is expressed in sentences such as

(1) *A raven is black.*
(2) *Birds lay eggs.*
(3) *The tiger has stripes.*
(4) *Mary smokes.*

These are examples of generics.

Generics can occur in many syntactic forms: (1) involves the indefinite singular noun phrase *a raven*, (2) contains the bare plural noun *birds*, and the subject of (3) is the definite singular noun phrase *the tiger*, whereas that of (4) is the name *Mary*. All these forms can have nongeneric uses as well. Indeed, there does not seem to be any sentence *form* that is unique to generics; what characterizes them is their *meaning*. Intuitively, the above sentences seem to express some sort of generalization, about ravens, birds, tigers, and Mary. Yet, it is far from clear exactly what generics mean. What does it mean to say that some generalization holds?

Possibly the first hypothesis that comes to mind is that generics express some sort of quantification. *A raven is black*, for example, could be taken to mean that a certain number of ravens are black. But how many? What is the generic quantifier? It cannot be *every,* because *A raven is black* is true despite the existence of albino ravens. It cannot be *most*, since *Birds lay eggs* is true despite the fact that fewer than half of all birds lay eggs (adult females only). The problem is even harder with *Mary smokes*, because it is quite unclear how often Mary has to smoke in order for the sentence to be true.

Faced with the diversity of interpretations of generics, researchers have taken two general approaches. The first attempts to define the quantifier in such a way that its nature, possibly in conjunction with context, intonation, and world knowledge, may account for all the interpretations of generics. For example, one could still maintain that the generic quantifier is *most*, and propose that to determine the truth or falsity of *Birds lay eggs*, only female birds need to be considered. Since most female birds lay eggs, the sentence is true.

An alternative approach denies that there is any quantification involved. Rather, generics are evaluated with respect to rules and regulations. For example, *A raven is black* is true not because of the properties of individual ravens, but because there is a (biological) rule stating that ravens are black.

Perhaps one of the difficulties in determining whether generics are quantificational is that generics are *lawlike*; they cannot express accidental generalizations. For example, even if it turned out that all Supreme Court judges had an even Social Security number, the generic *Supreme Court judges have an even Social Security number* would be odd. Contrast this with *Supreme Court judges are appointed by the President*, which is fine. Intuitively, this is because there is a law stating that Supreme Court judges must be appointed by the President, but no law governs their Social Security number.

To account for lawlikeness, some researchers treat it as a form of necessity. According to standard accounts of necessity, a necessary statement is not merely true in the actual world, but in all *possible worlds*. That is to say, there are any number of ways the world could have been different from the way it actually is; but in all such hypothetical situations, a necessary statement would still be true. The idea is, then, that a lawlike statement is true in 'sufficiently many' possible worlds.

Indeed, it seems that the truth or falsity of a generic does not depend on specific events in the actual world. In the sentence *A computer computes the daily weather forecast*, for example, *the daily weather forecast* cannot be taken to refer to the current weather forecast. For example, if we know that today's forecast predicts a blizzard and is the main news item, we still cannot change the above sentence to *A computer computes the main news item*. Yet, if *the daily weather forecast* did refer to the current weather forecast, this last statement should be true.

However, although generics do not seem to depend on specific events in the actual world, their interpretation nevertheless depends on real-world circumstances.

Suppose the weather report is Mary's favorite newspaper column. Although the world could well have been such that Mary would have no interest in the weather forecast, we may still truthfully say that *A computer computes Mary's favorite newspaper column.*

Thus, the truth or falsity of the generic statement *A computer computes the daily weather forecast* depends on the actual world, rather than what may be the case in hypothetical circumstances, but the interpretation apparently cannot be tied to a specific point in time.

To account for this aspect of genericity, some theories propose to restrict the possible worlds applicable to interpretation only to those that are *normal*, or those that are close to the actual world in terms of its essential properties. Such theories have to face the problem of defining normality or essence in such a way that a world in which, say, Mary is not interested in the weather is not included in this definition.

Alternatively, it has been proposed that generics are evaluated with respect to a variety of possible futures (e.g. that tomorrow the weather forecast may not be the main news item) but not with respect to alternatives to the world as it actually is (e.g. that Mary might not ever have been interested in the weather forecast).

It is probably evident from this discussion that, despite much progress, generics remain a puzzling and deeply contested phenomenon, with many questions and few widely accepted answers. In fact, one of the interesting and, so far, unanswered questions is this: if it is so difficult to define what generics actually mean, why do we use them so often?

Genetic Relationship

If we look at the word for 'brother' in a handful of European languages, we can see some striking resemblances: for example, between English *brother*, German *Bruder*, Polish *brat*, Welsh *brawd*, Irish *brathair*, Swedish *broder*, Dutch *broer*, and Czech *bratr.* Clearly, there is some kind of relationship between these languages, but how exactly do we account for these similarities? And why is it that differences also exist?

The most salient way in which languages come to be related is through a genetic relationship. This means that, at some point in their history, the several languages in question were actually the same language (normally known as the protolanguage) and underwent a period of common development from which their similarities arise. This is the case, for example, with the major modern Romance languages (i.e. Italian, Spanish, Portuguese, French, and Romanian), which all have their origins in the Latin language spoken throughout the ancient Roman empire. As time progresses, however, divergence occurs, mostly as a result of population migrations or through loss of a central unifying standard: certain groups of speakers of the protolanguage are split off from one another and, subsequently, their now separated language varieties pursue their own courses of development, from which the differences between them arise.

This model of language relationship is usually known as the family tree model, and was proposed by August Schleicher in 1871. However, in its purest form, the family tree model gives rise to a number of problems. Firstly, it assumes that there are clear dividing lines between languages (both temporally and geographically), so that there is a point at which we can make a distinction between, say, late vulgar Latin as a protolanguage and early Spanish as a separate development from it; however, it is very difficult to draw these lines clearly. Secondly, the pure family tree model assumes that no further interaction takes place between the separated languages and the protolanguage after a split has occurred; however, this is again often not so, as Romance demonstrates—the protolanguage (Latin) continued to be used quite extensively alongside the modern Romance languages, for example, by the church and the universities. Similarly, the model also does not allow for a later convergence between languages that resulted from an earlier split. For example, it is estimated that roughly a third of the English vocabulary is of French origin. However, the ancestors of English and French split off from one another at a very early date, and this shared vocabulary does not stem from that more distant genetic relationship between English and French; rather, it is a result of large-scale later borrowing into English, especially in the years following the Norman conquest of England in 1066 CE. This example is salutary, because it shows that a large degree of similarity (e.g. in vocabulary) does not necessarily result directly from a genetic relationship.

Clearly, therefore, although genetic relationship is often a very important determining factor in language similarity, as with the Romance languages, the purest form of the family tree model must be considered an idealization of reality.

There are, in fact, broadly three other reasons (apart from genetic heritage) that can lead to a close interrelationship between languages. Probably the next most important, which has already been alluded to, is borrowing from one language into another. Although small numbers of loans are very common, large-scale borrowing that leads to a substantial overlap in vocabulary and/or grammar normally arises either in a context where many speakers are bilingual or in a situation where two languages are in close geographical proximity to one another. To account for this, another model of language relation was proposed by Johannes Schmidt in 1872. This is known as the wave model and it is based on the principles of dialectology. The wave model rejects the notion that precise geographical borders exist between different languages. Instead, it assumes that the spatial extent of individual linguistic features (be they sound patterns,

words, or grammatical features) is marked by equally individual borders (known as isoglosses). These isoglosses may well form relatively strong borders between languages when they bundle closely together, but they are by no means necessarily located in the same places. The wave theory proposes that individual features spread from one place to another by means of diffusion. In other words, the extent of a feature's isogloss spreads as it gradually moves from one location to the next, rather like passing a message along a chain of people; and, as more features spread out, the more similar the language spoken in the different places along the chain becomes. Because it does not assume that shared features are always the result of a single period of shared historical development, this model is able to accommodate later convergence between languages. Similarly, it also allows for the influence of non-genetically-related languages in these contexts, for example, the influence of the Semitic Arabic language on the Indo-European Urdu language.

The two other causes of language similarity are (1) chance similarity and (2) the operation of universal linguistic processes, which lead to similar developments after languages have split off from one another. As an example of the latter, we can consider the development of the definite articles (= 'the') in two of the Romance languages—French and Italian. These are descended in both languages from the Latin pronoun *ille* and its variants. In both French and Italian, the feminine singular forms are the same (*la*) and both also lose their /a/ vowel before another vowel (French *l'allumette*; Italian *l'amica*). However, this does not mean that the word *la* came either directly from Latin or was borrowed from Italian into French (or vice versa); rather, universal phonetic principles (loss of an unstressed vowel and the merging of adjacent vowel sounds) have operated on the original Latin word (*illa*) with the same end results.

Genre

'Genre' stems from Latin *genus* and French *genre*, words meaning 'kind'. Hence, the popular meaning of genre in *Do you have some shoes in the same genre*? is close to its etymological roots. Historically, however, and largely as an inheritance from Aristotle, 'genre' was defined normatively as a given category of literature, with the choices originally restricted to 'dramas' and 'novels'. With Romanticism, 'poetry' came to be included as well. Hence, at the end of the nineteenth century, under the influence of literary criticism and mass-produced literature, subgenres and mixtures of the three classic forms were accepted as genres and a comprehensive system of defined kinds of literary writing was established.

This normative understanding prevailed until the late 1960s, when it was challenged from within literary theory and by other disciplines, such as anthropology, pragmatics, and text theory. 'Genre' as an exclusive literary concept was rejected. Genres were simply text types and were approached descriptively. However, different forms of opera, film, video, music, dance, professional and everyday practice—in brief, *any kind of cultural communication*—were soon considered genres as well. Genre had returned to its origin, 'kind'.

Genre had traditionally often been defined one-sidedly by proceeding from one of the three main aspects of text: form, content, or use. For instance, formal (or syntactic) orientations would argue that genres such as limericks and death notices could be recognized from certain textual structures. Contentual (or semantic) views would focus on typicality in content, seeing patents and psalms, for instance, as particular kinds of descriptions. Finally, focusing on use (or function), genres were primarily seen as (social) action, such as commands and recipes.

As long as linguistics focused mainly on pronunciation, grammar, and meaning at the sentence level or below, higher levels, such as text and context, were of less interest. However, once linguistic pragmatics started focusing on the use of language, perceptions of genres went through a paradigmatic change. Genres were now seen as function-oriented tools for social action. This created a tension between a functionalist/pragmatic and a semantic/syntactic approach. In the 1980s, there was successful advocacy for a syntactic–semantic approach to genre within the field of film/media, with both form and content defining genre. In other words, the relationship between the main communicational aspects of genre was unresolved.

More recently, however, language and communication are increasingly viewed as multimodal and systemic. Hence, genres are often perceived as the interactive interplay of form, content, and use. Consequently, discourse and hence genres interrelate three major aspects of the lifeworld: 'uttering selves', 'referred worlds', and 'acting societies'. This triadic perspective considers genre as a recognizable balance of aesthetics (form), epistemology (content), and ethics (use). However, this multidimensional view raises new questions: Should genres be defined by their degree of stability? Can they be understood and analyzed one by one in isolation? Where are they really located? Can genres be defined properly?

To address the questions in order, genres are certainly not just given or static. Studying forms of communication historically and sociologically makes it clear that genres come into being, live, change, and fade out. Genres have to mix cultural stability and change. Hence, genres are now more often seen as relatively stable and flexible, some more stable than others, the variation motivated by social needs for openness and closeness. Further, it is clear that genres are inherited and create system-like connections. Narratives, from short jokes to 'endless' television series, for instance, share some aspects but differ in others. Genres are thus systemic, i.e. no aspect of a particular genre can be analyzed without defining its relationships with others.

Whether a verbal genre is *in* a text is disputed. The understanding of language as a describably closed system is often combined with the view that genres are repetitive, fixed macropatterns of communication located *in* texts. Approaches seeing genres as flexible and open phenomena, however, perceive them more as a set of potential forms, meanings, and uses. Metaphorically, genres can be seen as nine tenths of an iceberg, where the visible part (the utterance) only symptomatically hints or directs communicators to a potential intended meaning framed by a possible genre. Hence, even a verbal genre is a growing, immanent potential of mind and body, not just a kind of text; and, by the same token, a text is not *in* a verbal genre.

The relation between the two planes is regulated by a mechanism called, in text theory, theme/rheme, which balances the given (or the expected in relation to the genre, the context, or the situation) and the new: *Once upon a time there was* (theme/given in the genre 'fairy tale') *a big troll* (rheme/new). The relationship

between utterance/text and genre/context is dialogical in the sense that the genre influences the utterance. However, once an utterance is uttered, it contributes in principle to changing the genre. Over time, genres are changed by utterances.

The unpredictable and growing hidden and immanent potential makes it hard, if not impossible, to describe the 'true' nature of genres. Hence, a dilemma for applied linguistics is that focusing on stability may yield a more trustworthy and precise scientific discipline, but its value for application and practical understanding will be reduced. Some academic disciplines favor precise definitions to obtain valid operationalization in research. This has led either to a rejection of the concept of genre or to a predisposition for searching only for fixed aspects and hence to a self-fulfilling hypothesis of genre as fixed.

Thus, when the concept of genre has at the same time become more general in daily life as well as in the perception of several academic professions, a trustworthy and overall usable definition of the concept is endangered. However, while the acceptance of too much openness may lead to an increased understanding of the dynamics of text and context, it may reduce its scientific validity. Thus, genre urges analysts to decide whether the purpose of definitions and explanation is proof or understanding, precision or likelihood, description or application.

Georgian and Caucasian Languages

The Caucasus is a range of mountains that run from the northwest near the Sea of Azov at the top of the Black Sea in southern Russia in a nearly straight line southwestward to the Caspian Sea coast where they end in the Apsheron Peninsula near Baku in Azerbaijan. Known as the Mountain of Tongues, the Caucasus Mountains harbor roughly 50 languages, at least 37 of which are indigenous to the region.

Georgian

Among the best known of the native languages is Georgian. Georgian belongs to the Kartvelian or South Caucasian language family, to which Mingrelian and Laz also belong, often grouped together as Zan or Chan, and the distantly related Svan in the mountains themselves. The family is located, as one of its names

suggests, on the southern slopes of the Caucasus massif, extending down toward the lowlands along the eastern Black Sea coast and well into eastern Turkey. Georgia is a republic and has roughly 3.5 million inhabitants who speak Georgian or a related language. The 1989 Turkish census listed 8.6 million people of 'Georgian' ancestry, most in the eastern regions. A few immigrant communities exist in North America and Europe, as well as in Russia.

Georgian itself is a literary language that dates back to the fifth century CE, and has an older (khutsuri or clerical) script and a later modern one (mkhedruli or knightly). Old Georgian exists as a bible and in other older church writing. The modern language is a vehicle for a whole culture and has an extensive literature, which may be dated to the 12th century.

Georgian is a language of bewildering complexity, not merely for reasons of its grammatical richness, but also because of a high degree of irregularity exhibited by that grammar. The sound system has many features typical of a Caucasian language generally, with the addition of two features that make it typically Kartvelian. First, the system shows a three way contrast in the stop consonant series and a two-way contrast in the fricative series, taking the dental stops and affricates as examples: stops /t, d, t'/, affricates /c, ʒ, c'/, fricatives /s, z/. It also has a series of ejective consonants. Georgian stands apart from other Caucasian languages, as do other members of its family, in lacking lateral fricatives and affricates, and in lacking pharyngeal fricatives. Georgian also exhibits the peculiar "harmonic clusters" of Kartvelian. These are two series coronal stops and affricates that are made with simultaneous velar or uvular closure. Thus Georgian has the coronals in (1).

Velarized and uvularized coronals
a. /tkeši/ pouring rain /txa/, /tqa/ goat
b. /dgoma/ to stand /dɣe/ day
c. /t'k'bili/ sweet /t'q'e/ forest
d. /ckera/ to look /cxeni/, /cqeni/ horse
e. /ʒgera/ beat, pulse /ʒɣola/ to lead
f. /c'k'riala/ clear, cheerful /c'q'ali/ water
g. /čkmeta/ to pinch /čxiri/, /čqiri/ rod, stick
h. /ǯgup'i/ group /ǯɣabna/ to scribble
i. /č'k'ua/ mind, intellect /č'q'ap'i/ slush

If the harmonic (rounded) clusters are treated as unitary complex segments, then the syllable onsets of Georgian become relatively straightforward: C(onsonant)V(owel), CCV, CSV, and SCV, where S stands for any sonorant (consonants with acoustic properties similar to vowels, e.g. r, l, y, w, m, n). One can have great strings of consonants, such as /wprckwnd-i/ = [fp'rc' °k' °ndi] 1-peel-past-1.past, 'I peeled it,' (coll.),

which is CCSCCSCVC. In fact Georgian is typologically highly unusual in allowing such strings, but also admitting strings of vowels, as in /aairebadi/ 'transient, volatile, volatility,' or /da-a-aprak'-d-a/ direction-active-warp-past-3, "It warped it," with each /a/ given a slight pulse of energy. Georgian has the canonical pure vowels /a, e, i, o, u/, with only Svan showing vowel length. Georgian has a light percussive intonational stress, which is highly unusual in that it is variable, falling sometimes on the penultimate and at other times on the antepenultimate syllable, for example /tbilísi/, /tbílisi/. Despite its consonantism Georgian is mellifluous.

Georgian has very complex word forms and word formation processes. Derivational processes changing the class of a word, e.g. from verb to noun, generally proceeds by means of suffixation:

a. /tavisupal/ 'free'   vs.   /tavisupl-eba/ 'freedom' (with syncope)

b. /bawšw/ 'child'   vs.   /bawšw-oba/ 'childhood.'

Circumfixes, i.e. combinations of prefixal and suffixal elements that are used simultaneously, are also widely used:

a. /or/ 'two'   vs.   /me-or-e/ 'second'
b. /xšir/ 'frequent'   vs.   /si-xšir-e/ 'frequency'
c. /kartwel/ 'Georgian'   vs.   /sa-kartwel-o/ 'Georgia'
d. /ɣrma/ 'deep'   vs.   /u-ɣrm-es-i/ 'very/the most old'

Georgian nouns and pronouns do not distinguish gender, but are marked for seven grammatical cases. These encode grammatical relations (ergative, absolutive, dative), address (vocative), possession (genitive), means (instrumental) and manner (adverbial).

Most Georgian morphology takes place in the complex verb, which can consist of up to ten morphemes, with many irregularities. Georgian verbs can express highly complex meanings for which other languages need whole sentences, as the following examples show – each given with a rough literal translation and a possible free translation:

a. ga-v- c'itl-d-e-t
   surface- I- blush- start- maybe- plural
   '…(that) we might blush'
b. ga-mo-gw-e-č'ri-a surface-
   toward.speaker-us-medial-wound-was
   'We wounded him.'
c. mo-m-k'lav-en
   toward speaker me kill they
   'They will kill me.'

d. s- daraʒob-s
   him watch he(subject)
   'He was watching him'

Georgian shows ergative – absolutive case markings for subject and direct object with verbs of completed action, absolutive – dative markings for verbs of incomplete or future action, and dative – absolutive for perfect tense verbs. Determining how this rich system of case marking interacts with more conventional aspects of syntax is a central problem in the study of Georgian.

Nakh-Daghestanian Languages

To the east of the Kartvelian family lies the Nakh-Daghestian or Northeast Caucasian family. This consists of roughly thirty-two languages. See the table, where * denotes literary languages, all written in modified Cyrillic and, with the exception of scant material, all dating from the Soviet period. They extend from the center of the northern Caucasus down to Azerbaijan, where they trail off into isolated villages. Hinukh may be the smallest speech community on earth.

Nakh-Daghestanian languages (approximate population)

1. Vai Nakh *Chechen (792,000), *Ingush (197,000), Batsbi (Kisti) (3,000)
2. Avaro-Andi-Tsez
   a. *Avar (7 dialects) (501,000)
   b. Andic – Andi (9,000), Karata (5,000), Chamalal (4,000), Bagwalal (4,000), Akhwakh (5,000), Botlikh (3,000), Godoberi (2,500), Tindi (5,000), Udi (formerly 6,000),
   c. Tsezic - Tsez (Dido) (7,000), Hinukh (200), Hunzib (400), Khwarshi (1,000), Bezhta (Kapuchis) (3,000), Inkhokwari (unknown)
   d. Lakk-Dargwa - *Lakk (92,000), *Dargwa (282,000), Kubachi (3,000), Khaidaq (28,000),
   e. Lezghian - *Lezgi (367,000), *Aghul (14,000), *Tabasaran (78,000), *Rutul (15,000). Archi (1,000), *Tsakhur (19,000), Budukh (1,000), Khinalug (2,000)
3. Kryz (6,000)

These languages contrast plain stops with "intense" ones (marked with full colon). The numerous lateral affricates are velar in their articulation. Contrasts occur among velar, uvular, pharyngeal, and laryngeal consonants. Some, such as Archi and Aghul, add pharyngealized uvulars as well. In many languages the presence of a pharyngeal or pharyngealized sound element in a word triggers the spread of pharyngealization across the word. The Richa dialect of Aghul is the only language known to contrast pharyngealized uvulars, true pharyngeals, "adytals" (sounds made with the epiglottis covering the adytus, the opening of the larynx), and laryngeals.

Richa Aghul contrasts
a. uvular /xǎw/ 'house' /ɣad/ 'hammer'
b. pharyngealized uvular /x̄ǎw/ 'nut' /ɣ̄ǎb/ 'stack'
c. pharyngeal /ḥ̣aw/ 'udder' /ʕ̣an/ 'belly'
d. adytal /ḥač/ 'apple' /ʕak°/ 'light'

The vowel systems are also rich. While the Lezghian and Lakk-Dargwa languages lack /o/, the others can have any number of vocalic contrasts, including front rounded and high back unrounded vowels. The vowels can also come nasalized, long, and adytalized, the last having a harsh quality. Dargwa shows an opposition between truly pharyngealized vowels and adytalized ones, the only language on earth to show this in its vowels. Godoberi (an Andic language) has "stiff" vowels, made with great articulatory force. Vocalic sequences are prohibited.

The morphology of these languages is characterized by a grammatical class system, ranging from the familiar gender system of male, female, neuter, and plural, to systems (in Vai Nakh) with six classifications, both in singular and in plural, or with fifteen in Godoberi, with masculine, feminine, and neuter singulars, and with human and neuter plurals, each with three distinct sub-types. The Lezghian languages tend to lack any grammatical class. A few nouns will exhibit these markers, for example Avar /w-ac:/ masculine(masc)-sibling, 'brother', /y-ac:/ feminine(fem)-sibling, 'sister', /b-ac:/ animal-sibling, 'littermate of an animal'. Generally, however, such markers occur as prefixes or suffixes on pronouns, adjectives, associated adverbs, and verbs, which reflect the class of the noun in the absolutive, as for example with Avar /hán-iw do-w ha-w-ize/ here-adverb masc 3rd-masc be.born-masc-infinitve, '(for) him to be born here'.

The languages tend to have a rigidly S(ubject)-O(bject)-V(erb) word order, with adjectives and relative clauses preceding the word they modify. Only in Vai Nakh do OVS and VSO orders occur in certain discourse environments. Embedded clauses generally precede the main clause. Some examples from Avar:

a. /w-as w-ekér-ula/
   masc-child masc-run-he.now
   'The boy runs.'
b. /čí t'axá-l r-ós-ul-e-w w-úgo/
   man book-plural plural-buy-now-masc masc-is
   'The man is buying the books.'
c. /ḥinč'.-a-ƛ·u-l mac'· b-úgo du-r, k'aƛa-l-é-ƛ·u-l/
   bird-its-animal voice animal-is you-of,

speak-now-of 'When you speak you sound like a bird.' Literally, 'Bird's voice is yours, while (you are) speaking.'

Northwest Caucasian Languages

The Northwest Caucasian family lies to the west of Kartvelian, where Abkhaz adjoins Mingrelian, and extends up along the Black Sea coast to the Sea of Azov, thence eastward toward the center of the North Caucasus. Perhaps half a million speakers still live in this homeland, but ten times that number reside in a diaspora that has communities in Turkey, the Middle East, Europe, and North America. The languages are Circassian, in western (Adyghean) and eastern (Kabardian) forms, with the moribund Ubykh transitional to Abkhaz and Abaza (on the northern side of the massif from Abkhaz). Apart from some tales recorded in the 19th century, and perhaps some ancient monuments in cuneiform or in runes, the literary languages come from the Soviet period. All are written in modified Cyrillic except for Ubykh texts, which are written in Latin script. These languages are famed for the complexity of their consonantal systems and the simplicity of their vocalic one. Ubykh, for example, has 81 consonants and only two vowels. These languages can show aspirated and ejective fricatives, as well as pharyngealized labials and uvulars, palatalized uvulars, and labialized dentals, [pt], etc. Consontatal clusters abound, but vocalic sequences are absent.

Derivational morphology proceeds by suffixation and compounding. What is striking is the limited number of basic roots, only several hundred. Most of the vocabulary is made of compounds, often for terms that would seem basic. Some forms are extremely elaborate, as with Bzhedukh West Circassian /śha-a-nə-ɣˠə-pč a-y-a-šˁʸ-a-a-ƛ'-a/ head-/a/-purpose-door-direction-to-lead-in-/a/-near-to, 'shutter for a window.' In some cases the semantic machinery at work is clearly visible.

Progressively abstract compounds (Bzhedukh West Circassian)
a. /pqə/ 'bone, frame, strut'
b. /śḥa-pq/ head-bone, 'skull'
c. /ʔa-pq+ƛa-pq/ arm-frame+leg-frame, 'body' (as a structure)
d. /wəna-pq/ house-frame, 'framework of a house'
e. /waradə-pq/ song-frame, 'melody'

It is the verb in these languages that is one of the wonders of morphology. It can bear morphemes expressing (roughly from start to end) the absolutive noun, the speaker's interest in the action or incredulity, as well as the syntactic function of the complex (subordinated, adverbial, gerundive), any deictic setting for the action, benefactives and adversatives, other adjuncts, all the arguments of a sentence and their number, capability or inability, the geometry of the scene of action, details of motion to or from or around that scene, any incorporated nouns that modify the sense of the verb, causative agent(s), valence of the root, reiteration of a state or action, adverbs, tense, mood, number of the absolutive noun, adverbial and modal suffixes, and subordinating complementizers at the very end. It is more a phrase than a simple lexical unit. Discourse often consists of strings of verbs with only the occasional noun:

Bzhedukh West Circassian verbal morphology
a. /sa sə-qə-z-a-tˤ-y-a-y-ə-ɣa-wəćˁə-žʸə-žʸə-ɣa/
I me-change.of.state-self-dative-surface-direction-to-3-past-let-stop-again-finally-past
'He let me stop again at last.'
b. /ø-qə-z-fə-w-śˀˁə-z-a-tⁿ-y-a-wəćˁə-śˀə-aḥe-ɣa-gˠara-r/
3-change.of.state-what-for-you-despite-self-dative-surface-direction-to-stop-able-around-past-definite.gerund-absolutive
'why he was able to stop all around despite you/your efforts'
c. /sa a-r ø-qə-s-ʔa+čˀʸə-w-fa-s-wəčˀʸə-na/
I 3-absolutive 3-interest-my-arm+instrumental-you-for-I-kill-immediate.future
'I shall kill him with my own hands for your sake.'

Syntax is ergative with SOV order. Modifiers follow and embeddings precede heads.

German

German is one of the main cultural languages of the Western world, spoken by approximately 100 million people around the world. It is the supraregional standard of a connected language area in Central Europe and the national language of both Germany (77 million) and Austria (8 million), and it is one of the four official languages of Switzerland, spoken by three fourths of the population (4.5 million speakers). Additionally, it is spoken in Alsace-Lorraine in eastern France, in the region of Alto Adige in Italy, and also in eastern Belgium, Luxembourg, and Liechtenstein. German forms a continuum from Switzerland north to the sea; a local dialect can be understood by speakers of nearby dialects, but not necessarily by speakers of far-away dialects.

Reliable statistics are not available concerning the number of German-speaking persons who inhabit those regions of Eastern Europe from which the Germans were expelled at the end of World War II: regions of the former Soviet Union (especially Ukraine), Hungary, the Czech Republic, Slovakia, Poland, and Romania (all of them former regions of the Austro-Hungarian Empire). Outside Europe, the largest number of people using German as their mother tongue live in the United States (1.5 million). An important group of German-speaking people in the United States speak the so-called Pennsylvania Dutch. German is also spoken in Australia, Canada, Argentina, Brazil, Chile, and in former German colonies (Namibia, Congo, Cameroon). German is important as a cultural and commercial second language for millions of people in Central, Northern, and Eastern Europe and in North and South America.

History of the German Language

German is a member of the Western Germanic family. A descendant of the Old High German language, German is a mixture of dialects that, following the so-called 'High German Consonant Shift' (sixth to eleventh centuries) that affected the southern areas, were divided into Low German (*Niederdeutsch, Plattdeutsch*), spoken in the lowlands of the North of Germany, and High German (*Hochdeutsch*), spoken in the highlands of the South of Germany and Austria. The term 'Low German' is essentially a geographic one, referring to the coastal, or lowland, area of the German region, as opposed to the High German area. The usually cited dividing line, south of which High German is spoken, runs eastward from Aachen, south of Düsseldorf, Kassel, Magdeburg, and Berlin, to Frankfurt-an-der-Oder. Although dialectal differences within both the High German and Low German regions remain, a trend toward uniformity in the direction of the written standard is expected partly as a result of widespread broadcasting, diminishing isolation, and increased socioeconomic mobility.

High German is the standard written language, even in the regions where Low German is more commonly spoken; High German is also the standard used in the schools of Austria and Germany, taught to foreigners, and used in the worlds of business and communications. High German is divided into Upper German, in Switzerland, Austria, Liechtenstein, and southern Germany, and Middle German, across Luxembourg and the middle of Germany.

Historically speaking, German falls into three main periods: Old German (750 CE–1050 CE), Middle German (1050–1500), and Modern German (1500 up to the present). The earliest existing records in German date back to about 750 CE. At that time, the language was developing in the Kingdom of Franks, especially in its eastern parts where the population was formed mainly of Germanic tribes. Dialects of this region formed a single language around the eighth century. Old German is characterized by the use of local dialects in writing and by the absence of a standard language. During the Middle German period, a relatively uniform written language developed in the government: during the reign of Louis IV (1314–1347), the Holy Roman emperor, German was adopted as the language of official court documents, instead of the Latin that until then was dominating official writings. Middle German had additional syllable vowels and a more analytic syntax. Besides, it was the first common language of the people that was the language of chivalric poetry. Between 1480 and 1500, it was introduced for official use in many municipalities and in the courts of Saxony and Meissen and was also adopted by the universities of Leipzig and Wittenberg. By 1500, German had generally been accepted as the official language in all parts of Saxony and Thuringia. It was this German that Martin Luther, often referred to as 'the creator of New High German', adapted for his translation of the Bible in 1523. His translation had such a wide distribution and acceptance that the East Middle German dialect in which it had been written came to serve as the authoritative exemplification of

modern High German. In addition, the publication of books in German developed in the East Middle German towns of Wittenberg, Erfurt, and Leipzig, as well as in such western and southwestern cities as Mainz, Strassburg, Basel, Nuremberg, and Augsburg. These developments helped reduce regional differences and standardize the literary language.

Standard written German emerged during the first quarter of the sixteenth century in the eastern midland area of Erfurt, Meissen, Dresden, and Leipzig, where the inhabitants, originally from regions farther west and southwest, spoke a dialect based on the Middle and Upper German dialects of High German. Despite the progress made in the sixteenth and seventeenth centuries to develop and maintain a *Nationalsprache* (national language), French still continued to be a considerable influence on the German language because it was the language of the German courts. During the reign of France's 'sun king', Louis XIV (1643–1715), it seemed that French was very much in fashion with the upper and middle classes. Not surprisingly, nevertheless, several societies began to develop a tendency against the influence of foreign languages on German, more particularly dedicated to the preservation and purification of the German language.

By the eighteenth century, German-speaking lands had generally adopted a written language, even though common spoken language continued to be marked by local and regional variations.

As for Low German, its history started in the thirteenth century as the heir of Old Saxon (Old Low German). Formerly a flourishing language, spoken in the rich cities of Hansa, it later suffered the strengthening influence of High German. Nowadays, it is used mostly in rural areas, although some revival has been taking place for the last 50 years in the universities of Northern Germany. The Low German vocabulary has generally remained much more archaic. In the last two centuries, there have been considerable loanwords of High German origin, especially in the field of culture and industry.

The history of the German language was affected by several systematic shifts of certain consonants. The so-called Germanic consonant shift distinguished the ancient Proto-Germanic language from other Indo-European members. In this shift, described by Grimm's Law, Indo-European *p, t, k* changed to Germanic *f, th, h,* respectively; Indo-European *b, d, g* to Germanic *p, t, k*; and similarly Indo-European *bh, dh, gh* to Germanic *b, d, g.* After Western Germanic had developed its own distinctive traits, the High German sound shift occurred (500–700 CE): the Germanic *p* became *pf* under certain conditions (High German *Pflanze,* Low German *Plante,* 'plant'); when used medially or finally after vowels it became *ff* or *f*

(High German *hoffen,* Low German *hopen,* 'to hope'). Another consequence is the transformation of the Germanic *t* in *z* (*Pflanze*) or *ss* (High German *essen,* Low German *eten,* 'to eat'). After vowels, *k* became *ch* (High German *machen,* Low German *maken,* 'to make'); in all other cases, *k* remained unchanged except in the extreme south of Germany, where it first became *kch,* and later *ch.* A later change, also found in Low German, is that of the Germanic *th* to *d* (High German *das,* Low German *dat,* 'that').

Characteristics of German

Another characteristic of German, as well as of all the Germanic languages, is that the principal accent falls regularly upon the first syllable of a word; in verbal combinations, however, the root syllable, not the prefix, is stressed (see examples below).

The German language makes extensive use of inflectional endings, both for nouns and verbs. However, Old High German was much more inflected than Modern German. Before the tenth century, its speakers used numerous endings: the noun could vary in gender (three genders), case (five cases), and number. Over time, this complex system of inflections was simplified.

Modern German nouns are inflected for case and number, but not for gender. Of 43 nominal inflections that existed in Old High German, only nine survived in the modern language. Still, the German language remains much more inflective than its relatives English or Dutch.

German nouns are classified according to three genders (masculine, feminine, and neuter). The gender is most easily identified by the noun's definite article in the nominative case: *der* (masculine), *die* (feminine and plural), and *das* (neuter). Sometimes, the grammatical gender of a noun has little to do with biological gender: *die Sonne* 'the sun' is feminine, but *der Mond* 'the moon' is masculine. There is a gender distinction for German nouns in the singular, but there is no gender distinction in the plural. All plural nouns (in the nominative and accusative) take the definite article *die*.

Nouns can appear in four cases: nominative (indicating the subject of the sentence), accusative (the object), dative (the indirect object), and genitive (the possessor of any other noun). The last three cases are also used after prepositions, according to very specific German grammar rules. This case system allows for a freer word order, so that subject, object, and indirect object can be placed in any order in the sentence. This flexibility of word order also allows for word play and greater poetic license.

The function of a noun in a German sentence determines its case, which, together with its gender, determines the article, and the endings on modifiers and

adjectives preceding the noun (or on the noun itself): e.g. *Der junge Mann sitzt hier.* 'The young man is sitting here.' (nominative); *Kennen Sie den jungen Mann?* 'Do you know the young man?' (accusative); *Ich gebe es dem jungen Mann.* 'I give it to the young man.' (dative); *Wie ist der Name des jungen Mannes?* 'What is the young man's name?' (genitive).

There are seven types of pronouns in German: personal pronouns (e.g. *ich* 'I', *wir* 'we', etc.), reflexive pronouns (e.g. *Sie wäscht <u>sich</u>.* 'She washes herself'), demonstrative pronouns (with the same form as the definite articles), indefinite pronouns (e.g. *viele* 'many', *etwas* 'something', etc.), relative pronouns and interrogative pronouns (e.g. *wer* 'who', *wen* 'whom', *wessen* 'whose', etc.), and intensive pronouns.

The proper German personal pronoun for the second person depends upon the closeness to the person one is addressing: i.e. *Sie* and its related forms are used when addressing one or several persons whom you would normally call by the last name, while *du* and its related forms are used when addressing one person (*ihr* more than one person) whom you would normally call by the first name: e.g. *Herr Schmidt, kennen Sie meine Frau?* 'Mr. Schmidt, do you know my wife?', *Robert, hast du meinen Hut?* 'Robert, do you have my hat?', *Kinder, ihr seid zu laut!* 'Children, you are too loud!' Depending upon its context, the personal pronoun *sie* can have various meanings. When it is capitalized and does not begin a sentence, it always means 'you' (singular or plural in a formal way): e.g. *Was meinen Sie dazu?* 'What do you think of that? When it is not capitalized and appears as the subject of a singular verb, it means 'she' or 'it' if it refers to an object of feminine grammatical gender: e.g. *Was meint sie dazu?* 'What does she think of that?' When it is not capitalized and appears as the subject of a plural verb, it means 'they'. When it is used as the direct object of a verb, it can mean 'her' or 'it' (if it refers to an object of feminine grammatical gender), or 'them': e.g. *Ich fahre sie durch die Stadt.* 'I drive her (or them) through the town.'

There were several changes during the history of the German verbal system. During the Old High German period, the verb could take many different forms. Nowadays, the number of main forms of the verb is reduced to three: *helfen - half - geholfen* 'help - helped - helped' instead of Middle High German *helfen -half - hulfen -geholfen.*

There are four types of verb in German: *Hilfsverben* (auxiliary verbs), *Modalverben* (modal auxiliary verbs), regelmäßige Verben (regular verbs), and unregelmäßige Verben (irregular verbs). There are 173 irregular verbs in Modern German, but this class is decreasing in number. However, it still contains many verbs belonging to the basic vocabulary.

The only tenses the German verb can form by itself are *Präsens* (present tense), *Präterium* (past tense), *Konjunktiv* I (subjunctive I), and *Konjunktiv* II (subjunctive II). In all other tenses, one of the verbs *haben* (to have), *sein* (to be), *werden* (to become, to get) is used as an auxiliary verb, in conjunction with the *Partizip* II (past participle) or the *Infinitiv* (infinitive) form of the principal verb. Generally, German uses the verb *werden* 'to become' to form the future tense, the verbs *haben* 'to have', and *sein* 'to be' to form the perfect tenses. The verb *haben* is generally used with transitive verbs and *sein* with certain intransitive verbs. Nearly all of the verbs conjugated with *sein* are strong verbs or irregular.

There are six modal auxiliary verbs in German: *dürfen* 'to be permitted, may', *müssen* 'to have to, must', *können* 'to be able, can', *mögen* 'to like to', *wollen* 'to want to', and *sollen* 'to suppose to, ought to'.

German has a large number of phrasal verbs made up of a verb (e.g. *kommen* 'come') and one or two particles or prefixes (e.g. *an* 'at'). These particles and their verbs have the force of single-word verbs (e.g. *ankommen* 'arrive'). Many of these particles attached to verbs are also ordinary prepositions: *ab* 'away from', *ein* 'into', *vor* 'before', etc. They provide additional (or sometimes changed) meaning to the verb. Occasionally, some of these prefixes become separated from the verb in clauses. In a simple sentence, these prefixes are separated from the verb at the end of the clause: *Sie kommen nun an.* 'They are arriving now.' They join the verb in the past tense: *Wir sind angekommen.* 'We have arrived.' When an infinitive is used or if the verb appears at the end of a subordinate clause, the prefix remains attached: *Wir werden ankommen.* 'We will arrive.'

Certain verbs have inseparable prefixes that are not used alone, have no fixed meaning alone, and are never separated from the verbs they are accompanying. An example would be *be* in *bekommen* 'get.' Separable prefixes have intonational stress, as in <u>an</u>kommen, but prefixes are never stressed, as in be<u>kommen</u>.

Adjectives and adverbs have the same form in German. The context in which they are used indicates how to interpret them: *Dieser Käsekuchen ist sehr gut.* 'This cheesecake is very good' vs. *Sie bäckt den Kuchen sehr gut.* 'She bakes the cake very well.'

The major word classes are interconnected by a complex network of word-formation rules. A distinctive feature of German is its extensive use of lengthy compound words. For example, the German counterpart of the English 'history of antiquity' is *Altertumswissenschaft.*

Traditionally, German was written in a Gothic or Black Letter style of the Roman alphabet, known in

German as *Fraktur* (meaning 'fractured'), which dates from the twelfth century. In the period following World War II, however, *Fraktur* was largely superseded by the Roman characters exclusively used throughout the rest of Western Europe. The Roman script contains the symbol ß or double s, which is used only in the lower case and represents a voiceless *s* (as in English *mouse*), and the umlauted vowels *ä, ö,* and *ü*. German is the only language in which all nouns are capitalized, common as well as proper (as they were in English several hundred years ago). This makes the nouns easy to spot when reading a sentence. Verbs and adjectives functioning as nouns are also capitalized.

Pennsylvania German

Pennsylvania German, also known as 'Pennsylvania Dutch' or simply 'Dutch', is spoken by 300,000 native speakers, descendants of German colonists, who left the Palatinate region of Germany during the late seventeenth and eighteenth centuries and settled in the southeastern part of Pennsylvania in the United States. They speak the Rhine-Franconian dialect with relatively few admixtures of English. It is the vehicle of a typical folk literature and its speakers are all bilingual, as the official language is English.

Germany

Germany, or more accurately the Federal Republic of Germany (*Bundesrepublik Deutschland*), consists of 16 states (*Bundesländer*), five of which constituted the German Democratic Republic (East Germany) until reunification in 1990. Germany is situated in Central Europe, with the Baltic Sea, the North Sea, and Denmark to the north, Poland and the Czech Republic to the east, Austria and Switzerland to the south, and France, Luxembourg, Belgium, and the Netherlands to the west. It has an area of 357,020 square kilometers and a total population of 82,536,700 (as of December 2002).

The official language of the country is German Standard German (as opposed to e.g. Austrian Standard German). The development of this supraregional written norm is a relatively recent phenomenon and a good example of language planning, i.e. the use of deliberate, often official, measures relating to the status and/or form of a language. At the end of the Middle High German period (c. 1050–c. 1350), the written standard was still Latin, and the orthography, grammar, and vocabulary of the German texts of that time were not standardized but rather were strongly influenced by substantially different regional spoken language forms. Such regional variation was a result of the High German Sound Shift (also termed the Second Sound Shift), which had taken place to differing degrees in different parts of the German-speaking community from the sixth to eighth centuries CE. In this sound shift, the voiceless stops /p/, /t/, /k/ changed to voiceless fricatives /f/, /s/, /x/ and affricates /pf/, /ts/, /kx/, and the voiced stops /b/, /d/, /g/ to voiceless stops /p/, /t/, /k/. The dialects in the south of Germany, termed Upper German (*Oberdeutsch*) in keeping with the topography of the area, were affected first and most completely. Gradually, the shift moved northward. It became weaker as it did so, however, and the dialects in the center of Germany (Central German, *Mitteldeutsch*) were only partially affected, while those in the north (Low German, *Niederdeutsch*) remained unaffected.

During the Early New High German (Early Modern) period (c. 1350–c. 1750), however, the functional motivation for a standard increased, because of the development of towns and cities, the increase in

secular education, the invention of the printing press, and, in particular, because of Martin Luther's translation of the Bible into a variety of German intended to be understood by all speakers of German (1522–1534). Aside from these influences, a conscious drive was made by grammarians and lexicographers in the sixteenth century toward standardization, so that this process is thought to have been largely complete by the mid-eighteenth century. The variety of German that ultimately served as the basis for the development of written Standard German (High German, *Hochdeutsch*) was based on East Central German. Without doubt, the adoption of the standard was gradual, so that Charles Ferguson's concept of 'diglossia', i.e. a situation in which two varieties have mutually exclusive functions within a particular speech community, was relevant in the period following the introduction of the standard: speakers at that time would have used their local dialect (the Low variety) in the private domain of home and friends and the standard variety (the High variety) in the public domain.

The strict regulation of German orthography dates back to the mid-nineteenth century. Prior to this, there existed no unified spelling. Indeed, until a decree in 1862 ruled otherwise, various spellings could even be taught in a single school. The first significant attempts to standardize German orthography took place after the establishment of the German Reich (1871) at the *Verhandlungen der zur Herstellung größerer Einigung in der deutschen Rechtschreibung berufenen Konferenz* (Conference on the Establishment of Greater Standardization of German Orthography) in Berlin in 1876. The proposals of this conference, however, were never enforced. The process nevertheless continued, and at the second national orthography conference, held in Berlin in 1901–1902, a set of orthographic rules was developed on a trial basis for use in Germany. These were also adopted by Austria and Switzerland. The seventh edition of Konrad Duden's orthographic dictionary (*Orthographisches Wörterbuch der deutschen Sprache*, Orthographic dictionary of the German language), produced in 1902, incorporated these rules, and in December 1955, the education and arts ministers of the states of the Federal Republic of Germany awarded the Duden legal status, declaring it the orthographic norm for German. The rules of the second national orthography conference served as the orthographic norm for German until August 1998, when a spelling reform was instituted. The central motive for the reform process, which aimed at standardization and simplification, was educational, since it was argued that the time devoted to teaching spelling to children could be better spent otherwise and also that the complex spelling rules discriminated against working-class children whose exposure to written

German is generally less than that of middle-class children.

Adherence to the 'stem principle' is one of the rules introduced with the recent reform. Unlike in the old spelling, all consonants are to be maintained in the spelling of compound words, even in cases where three identical consonants may come together. The word for 'ballet dancer', a compound of *Ballett* 'ballet' and *Tänzer* 'dancer', thus becomes *Balletttänzer* with three *t*s rather than the former form, *Ballettänzer,* with two *t*s. Also, the decision as to whether to spell words apart or together was regularized. Rather than writing *radfahren* 'to ride a bicycle' but *Auto fahren* 'to drive a car', for example, both are now written apart, as *Rad fahren* and *Auto fahren.*

The reform process, which began in the 1950s, was a lengthy and complex one, clearly exemplifying the difficulties of language planning. Not only was inter-state and international consensus concerning the orthographic norm difficult to reach, but public support was also weak. It was not until several attempts at reform had been rejected that a list of recommendations (drawn up by a group of representatives from Germany, Austria, and Switzerland as well as Belgium, France (Alsace), Hungary, Italy (South Tyrol), Liechtenstein, and Romania) was accepted in July 1996 at an orthography conference in Vienna. These new spelling rules have represented the official norm since August 1, 1998. Their implementation and review is the task of the Institut für deutsche Sprache in Mannheim. The initial grace period during which both the old and new spelling may be used ends on July 31, 2005.

In public opinion, the spelling reform met with general rejection. Indeed, the state of Schleswig-Holstein, in a referendum on September 27, 1998, voted not to accept the reform. The reasons for the lack of public support were varied, although many involved emotion, laziness, or ignorance. Many individuals were reluctant to change since they identified with the old spelling, were not prepared to learn the new rules, or mistakenly equated language with spelling, believing that such planning would disturb the natural progression of a natural language. Other reasons involved the belief that the costs of the reform were not justified since the reform did not go far enough, representing a mere tidying-up process.

As for the standardization of German pronunciation, it was not until 1898 that the norm, codified by Theodor Siebs and based on the pronunciation of German Standard German in the north of Germany, was established (Stage German, *Bühnendeutsch*). However, although radio announcers from different parts of Germany may sound the same even today, regional pronunciations of the standard variety based

on the accents of the local nonstandard German dialects reign, since *Bühnendeutsch* was never completely adopted. Indeed, it is not only in pronunciation that German Standard German presently shows regional variation; German Standard German is colored with regional variation on every level of language, except the strictly regulated orthographic level. On the level of vocabulary, for example, the word *Samstag* is commonly used in the south and west of the country for 'Saturday', whereas *Sonnabend* is generally used in the north and east. Indeed, in recent years, the trend toward regionalism has become increasingly evident.

Despite standardization, the dialects of German are many and reflect the uneven effect of the aforementioned Second Sound Shift in various parts of Germany. The 'Benrath line' is an isogloss (i.e. a line drawn on a linguistic map to locate the outer limits of some characteristic feature) that runs from Aachen in the west through Benrath, a suburb of Düsseldorf, to Frankfurt an der Oder in the east, dividing the country into two regions. To the north are found Low German dialects not affected by the sound shift, and to the south, High German dialects affected by the shift. Dialects from the very north and very south of this divide are virtually mutually incomprehensible. In the transition zone in the middle (Central German), partial traces of the shift are found. Within the divide into Low, Central, and Upper German, further divisions are made based on particular linguistic criteria. The accompanying map provides a sketch of some of the principal differentiations. It must be pointed out, however, that none of these dialect areas are as homogeneous or as strictly defined as they appear (see Figure 1).

Standardization has led to an overall decline in the use of local dialects, and not all are equally healthy, despite a general trend toward regionalism. In the south, in Bavaria, Baden-Württemberg, and to a lesser degree in Hesse and parts of the Rhineland, dialects function as markers of regional identity to a substantial extent and are therefore relatively healthy, being used fairly far up the social ladder. In the north, however, their use is more socially stigmatized. Not surprisingly, therefore, German Standard German has already replaced many of the Lower German dialects of the north. Diglossia is rare in Germany, except in the case of elderly people living in rural parts of the Upper German dialect region and in remote rural areas in the Low German and Central German regions. Instead, most speakers today commonly shift their choice of variety along a continuum between the poles of dialect and standard, with most everyday spoken German being of a colloquial nature (*Umgangssprache*), a relatively new level of language that has developed in urban areas due primarily to the presence of a standard written variety. Colloquial German itself can be situated near or far from the standard, depending on the region and the specific situational constellations. In the north of the country, for example, colloquial speech is closer to the standard than in the south.

Germany is a multilingual country, and although German is the principal language, many other languages are also spoken in the Federal Republic. While many of these, such as Frisian, Sorbian, and Danish, are long-established minority languages, others, such as Arabic, Greek, Turkish, Hindi, Italian, and Spanish, were only introduced in the late 1950s via the immigration of guest workers (*Gastarbeiter*). In more recent years, there has also been immigration of individuals of German descent (*Aussiedler*) from Eastern countries. In 1999, 7.2% of the population were not of German nationality.

Frisian is the West Germanic language most closely related to English. Today, two mutually unintelligible main varieties are spoken in Germany: North Frisian and East Frisian. East Frisian, or more specifically Saterland Frisian, is still spoken in the Saterland, west of Oldenburg in East Frisia in the north of Germany (fewer than 1,000 speakers). It is being displaced by German. The same is also true of North Frisian (approx. 8,000–9,000 speakers), which itself includes nine very different, partially mutually incomprehensible, dialects spoken on the west coast of Schleswig-Holstein north of Husum and on the offshore islands of Föhr, Amrum, Sylt, Nordstrand, Pellworm, the ten islands of the Halligen group, and Heligoland. Reasons for the dwindling numbers of Frisian speakers are improved communication, the centralization of the education system, the large number of dialects of the language, and the fact that no standard written or spoken form exists. A form of colloquial language close to German Standard German is thus favored. Efforts to save the Frisian language from extinction have generally been rather insignificant. While the people of the tourist island of Sylt manage to nurture their identity and speak Frisian, speakers in other areas on the mainland have a more difficult task since they do not form an isolated group. In addition, many speakers wish to discard the 'socially backward and poor' image commonly associated with speakers of Frisian. Since the late 1980s, political engagement for the Frisian language has increased; money has been made available to teach Frisian on a voluntary basis in schools, for example. While such efforts may serve to delay the extinction of Frisian, it is doubtful whether they will prevent it.

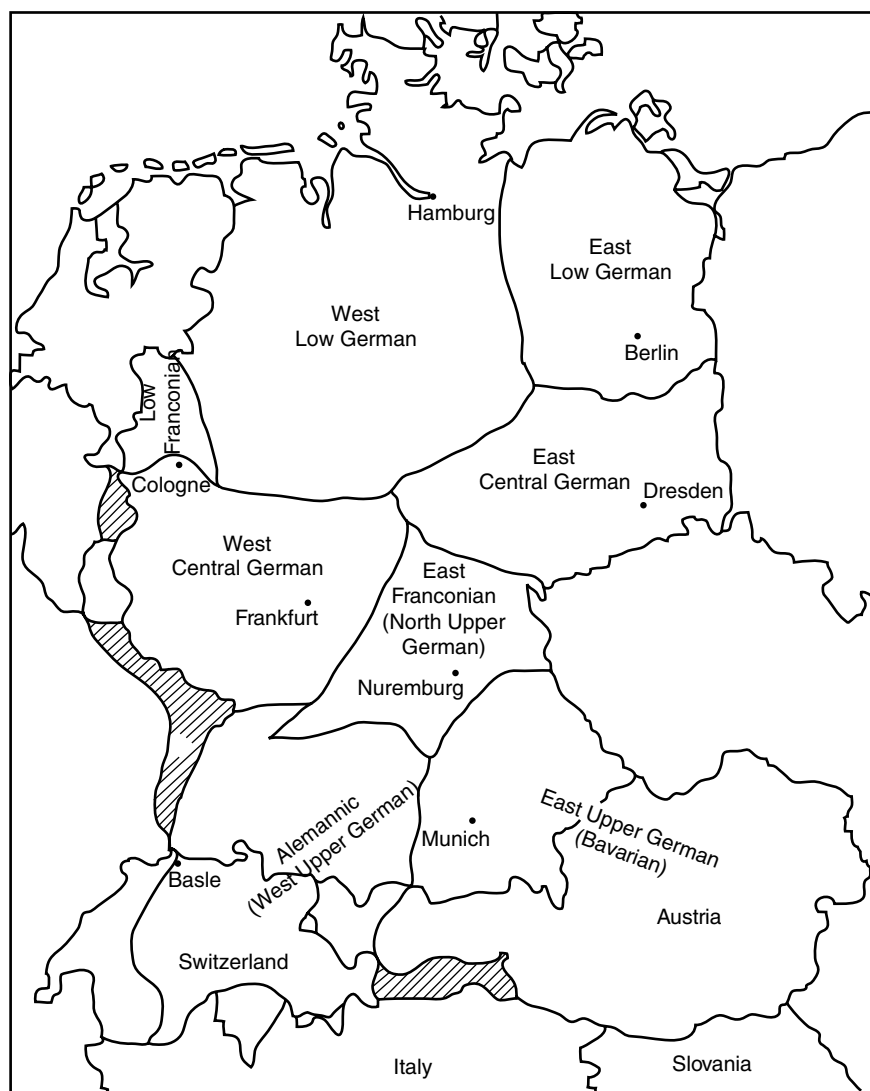
Standard Danish is spoken by a recognized minority in southern Schleswig. Despite the existence of schools there in which Danish is spoken, the future for the language in this area is also rather pessimistic.


Figure 1. German Dialects.

Since the seventh century, the Slavic language Sorbian (approx. 67,000 speakers) has been spoken in Lusatia (Lausitz), a relatively vaguely defined area in former East Germany bordering on Poland and the Czech Republic and belonging administratively to the German states of Brandenburg and Saxony. Two varieties, Lower Sorbian and Upper Sorbian, are differentiated. Lower Sorbian is spoken in the area around Cottbus (*Chośebuz*) in Lower Lusatia and Upper Sorbian in the area around Bautzen (*Budyšin*) in Upper Lusatia. The Sorbians themselves never formed their own state but have remained under German rule. After a period of repression during the Nazi era, Sorbian was promoted in the German Democratic Republic. Its use in local government was authorized and children had the right to learn it in schools, although in reality it was often not possible to practice such rights. German reunification brought generous support for the language and culture of the Sorbian minority. In 1991, for

example, a foundation was established for the Sorbian people (*Stiftung für das sorbische Volk*) with the task of promoting the language and culture. However, despite such efforts, the survival of the Sorbian language, although the least endangered of the established minority languages in Germany, is uncertain since all speakers are bilingual in German, the tight bonds that existed between Sorbians in former times have dissolved in the meantime, and many young Sorbians living in German-speaking areas do not identify with their language.

As for foreign language teaching in German schools, not surprisingly, English, given its international status, is primary.

Gastarbeiter 'guest workers', also and more appropriately termed migrants, immigrants, work immigrants, and foreign workers, came to the Federal Republic primarily from countries such as Greece, Italy, Turkey, and the former Yugoslavia from the late

1950s onward, following a policy decision designed to ameliorate the acute labor shortage in West Germany at the time. They settled mostly in urban areas such as Munich, Stuttgart, and Frankfurt am Main, often in concentrated ethnic groups (e.g. Turks in West Berlin (Kreuzberg), Greeks in Munich, Yugoslavs in Stuttgart). The early 1970s witnessed an end to this policy, and immigration laws became stricter. With changing economic circumstances, these 'guest' workers were encouraged to return to their home countries from the early 1980s onward. But many have remained, settled down, and brought relatives to Germany. Unfortunately, this group leads a marginal existence in Germany, being denied dual citizenship, for example, on the basis of policy assumptions that this workforce was in Germany temporarily and that Germany is not an immigrant country.

Most first-generation foreign workers are not proficient in German despite having lived in the country for a number of decades. The majority of them had not enjoyed any instruction in German prior to their arrival and, since integration was not foreseen, few have ever been taught German systematically. With the exception of much of the Turkish population, though, many second-generation immigrants are bilingual, with German as the dominant language.

The linguistic study of the German spoken by the migrant workers has provided a number of insights into the process of uninstructed second-language acquisition. It has been demonstrated, for instance, that although speakers do transfer features from their native language to their second language, the German of speakers of languages as different as Spanish and Italian (Romance languages) and Croatian and Slovenian (Slavic languages) is characterized by similar simplifying measures, such as deletion and reduction. A typical example of the former is the utterance *Ich fahre zwei Wochen Irland* 'I'm going two weeks Ireland', in which two prepositions have been deleted—the utterance should read *Ich fahre **in/ für** zwei Wochen **nach** Irland* 'I'm going **to** Ireland **in/for** two weeks'. An example of reduction is the use of the informal '*du*' whatever the formality of the situation. Given such similarities between speakers of different native languages, it is possible to speak of the existence of Guest Worker German (*Gastarbeiterdeutsch*). Considerable variation is also present, though. An order of acquisition of grammatical structures has also been established based on the analysis of Guest Worker German. How far a particular individual progresses along the path of acquisition has been found to depend on a number of factors, the most important being the degree and intensity of contact with Germans, age on arrival, level of education acquired in home country, years of schooling, period of residence

in Germany, and the subjective social and psychological distance between the individual and native speakers of German.

Guest Worker German is also of interest to researchers of pidgins, i.e. languages without native speakers that arise out of a basic need to find a lingua franca (a common system of communication), since it shares many features of pidgins, even though it arises as a result of communication between migrant workers and German native speakers rather than between migrant workers of various cultures, the usual occasion for the development of a pidgin.

Finally, individuals of German descent (*Aussiedler*) from Eastern Europe, primarily from Romania, Poland, and the former Soviet Union, have been immigrating to Germany since the 1950s. However, such immigration, particularly from the former Soviet Union, increased dramatically between the fall of the Iron Curtain and 1995; since then, numbers have been steadily decreasing. While some of those from the former Soviet Union and Romania speak a variety of German, others from Russia speak an archaic dialect of German and can understand but not speak German Standard German. Those from Poland, on the other hand, have little or no competence in German. The German of these speakers shares many similarities with Guest Worker German.

In sum, the study of the linguistic situation in the Federal Republic of Germany is a rewarding endeavor. The study of the standardization of German Standard German sheds light on the difficult process of language planning, and the study of minority languages highlights the possible consequences of language contact, the issue of language shift, and, in the case of the immigrant languages, aspects of uninstructed second-language acquisition.

Givón, Talmy

Talmy Givón's outstanding contribution to the study of language in a wide scientific setting cannot be understood without the influence of two leading figures of North-American linguistics: Dwight Bolinger and Joseph Greenberg. Like his teacher Bolinger, Givón has followed the central claim of the functional tradition of linguistics, which ultimately can be traced back to the Prague School of Linguistics and European functionalism, namely that language cannot be studied independently of its context. Like Greenberg, Givón has been concerned with describing cross-linguistic phenomena and finding functional explanations for them.

It is significant that among the many influences that Givón acknowledges in his works, which include fellow functionalists like Wallace Chafe, Bernard Comrie, Robert Dixon, John Haiman, Bernd Heine, Paul Hopper, and Sandra Thompson as well as Noam Chomsky, two teachers of Givón´s are mentioned with particular warmth and respect. The first is Bolinger, to whom Givón attributes an insistence that the form of language cannot be studied in isolation from its meaning, that grammar is a set of meaningful devices, and that the aim of the forms of language is to express thought. The other—rather unexpected—is a high school teacher of humanities who eventually became a reputed Egyptologist, Sarah Groll. Since Givón considers Groll´s teachings a formative experience that has lasted him a lifetime, it does not seem out of place to put down the interest in cultural and linguistic diversity shown by this author to the influence of Groll.

Along with these influences, three main principles could be said to characterize Givón´s work: the principle of antimodularity, the principle of cognitive plausibility, and the principle of linguistic relativity.

Considering antimodularity in the first place, it must be borne in mind that generative grammars, including formal approaches like Chomskian Transformational Grammar and functional approaches like Simon Dik and Kees Hengeveld´s Functional Grammar, consider grammar as a set of descriptive devices in such a way that several components or modules turn out different aspects of the final linguistic expression. The output of each module constitutes the input to the next module: typically, the lexicon turns out lexical items, the component of predication-formation fills in the semantic-syntactic slots of the clause with lexical items, thus turning out a sentence, and a morphophonological component gives the sentence its final (pronounced) form.

Cognitive plausibility implies that it is not enough to propose descriptive devices such as rules or operations, or even explanatory devices like specific or general principles. Much more than that, it is necessary to consider the plausibility of grammatical devices in the light of human abilities of memory and processing. For example, sentence elements or constituents bearing contrastive information, which typically occupy a clause-initial position in English, can be inserted into the correct slot by a rule that places contrastive focus constituents in the clause-initial position; or as a result of the application of a functional principle that stipulates that more important information is more likely to be placed earlier in the clause. For Givón, the cognitive basis of this functional principle is that the earlier a chunk of information is placed within its relevant unit, the more attention it attracts. Moreover, the information that attracts more attention is memorized, stored, and retrieved more efficiently. Another point of interest related to cognitive plausibility is Givón´s epistemology: for him, Western Philosophy cannot be reduced to

Plato and Aristotle. Kant, Peirce, and Wittgenstein also shed light on the social and communicative dimensions of language and, more importantly, on language categorization, which is not discrete but continuous, that is, based on the notion of prototype of a category.

Givón follows in Franz Boas and Edward Sapir´s footsteps in the question of linguistic relativity, advocating the study of each language on its own terms. The ideological basis of linguistic relativity is even more obvious in Givón than in the work of his predecessors: in order to avoid Eurocentrism (the scientific hegemony of Indo-European languages over languages belonging to other families), the conclusions reached after the study of English cannot be automatically generalized to all languages independently of their typological characteristics, and English cannot be the recurrent term of comparison for any linguistic topic. For this reason, Givón prefers a formally unconstrained grammar, which consists of functionally oriented principles, rather than a formally constrained grammar involving language-specific rules whose typological validity is, at least, questionable. Functionally oriented principles are based on explanatory devices like iconicity (or resemblance between the linguistic code and the extra-linguistic reality) and markedness (or asymmetry between two members of a pair or one of the members of a cluster and the rest of the members of such a cluster).

Givón has been a source of refreshing and thought-provoking inspiration; without him, some recent developments in functionalism would not be easy to explain.

Biography

Talmy Givón was born in Afula, Palestine on June 22, 1936. He received his B.S. in Agriculture in 1959; M.S. in Horticulture in 1962; M.A. in Linguistics in 1966; and Ph.D. in Linguistics in 1969. He taught at the UCLA Linguistics Department (1968–1981) and the University of Oregon Linguistics Department (1981–2002). Gothic

Gothic, the only documented member of the Eastern Germanic branch of the Indo-European family, is an extinct language once spoken by the Goths. The Gothic historian Jordanes (AD 551) says that his people came originally from Scandinavia; place names, including the island of Gotland, show their presence there around the first millennium BC. The Goths then moved from Scandinavia, through the Baltic islands, and to the Black Sea, where they divided into two major groups around AD 270.

The West Goths—the Visigoths—invaded the territory of the Roman Empire during the reign of Marcus Aurelius (AD 270–275) and settled in the province of Dacia (modern-day Romania) near the lower Danube

and then migrated to Gaul and Spain, where they established a powerful kingdom that lasted for over three to four centuries. Around AD 490 in Constantinople, the East Goths—the Ostrogoths—under the leadership of Theordoric established an Ostrogothic kingdom in Italy that was subsequently destroyed by the Byzantines in the middle of the sixth century. By the eighth century, both groups were assimilated into the larger populations who surrounded them.

Proto-Gothic, the direct predecessor of Gothic and one of the descendants of Proto-Germanic, can only be studied through probable reconstructions of Proto-Gothic words. However, early Gothic literary records that provide language samples for linguistic study are available and date from the fourth century, predating records of any of the other Germanic languages. Gothic is the cornerstone of Germanic linguistics because it provides the oldest extensive collection of written samples in the Germanic group of languages, except for a few brief Norse runic inscriptions. Comparable specimens of other Germanic language, like English, Frisian, High German, and Norse, do not appear until four to nine centuries later. Very little is known about the other Eastern Germanic languages of Burgundian, Gepidic, Rugian, and Vandalic.

Gothic had two main dialects: Ostrogothic was the language of the Ostrogoths in eastern Europe and Italy, and Visigothic was the language of the Visigoths of east central Europe, Gaul, and Spain. Some scholars believe that the Ostrogothic dialect became extinct after the fall of the Ostrogoth kingdom in Italy in the sixth century; however, Ogier Ghislain de Busbecq, a Flemish ambassador who served in Constantinople between 1560 and 1562, found traces of Gothic in the words and phrases of the area. Even though his scholarship and transcription were less than ideal, this variety is thought to be a dialect of Ostrogothic and is now known as *Krimgotisch* (Crimean Gothic). The Visigothic dialect is believed to have become extinct around the time of the Arab conquest of Spain in 711.

The earliest Gothic literary work and the cornerstone to all Germanic linguistics is the translation of the Bible by Wulfila (311–383), a Visigothic bishop from Moesia (modern Bulgaria). Wulfila's original translation of the Bible from Greek has not survived; however, several reproductions of his work from the fifth and sixth centuries still exist. The *Codex Argenteus*, written in the first half of the sixth century by Ostrogothic scribes in northern Italy, consists of translations of the gospels and epistles, providing about three-quarters of the New Testament. A bound volume of manuscripts, the *Codex Argenteus,* the most studied of the Wulfila reproductions, is written in gold and silver on purple velum. Discovered in the sixteenth century, it is now in the care of Uppsala University in Sweden.

Other Gothic texts are limited, but include the *Skeireins* (eight unconnected pages of a commentary on the Gospel of St. John), some deeds of sale, a fragment of a calendar of martyrs, the five *Codices Ambrosiani*, and bilingual manuscripts like the Gothic-Latin *Codex Carolinus*. However, the *Codex Argenteus* is the earliest literary remains in any Germanic language; the only earlier records are limited to a few Norse runic inscriptions and some loanwords preserved in a few non-Germanic languages.

Historians generally agree that Wulfila created the Gothic alphabet (which should not be confused with the Gothic script also known as Black Letter that is used by printers) with the sole purpose of translating the Bible. The Gothic alphabet has 27 letters; the majority of the letters were derived from Greek, but five or six of the letters came from Latin, and two were borrowed from runic script. In general, though, the Gothic alphabet resembles Latin and Greek scripts with some differences in the order and sounds of the letters. Gothic is written from left to right with only very rare spacing between letters. What we know about the pronunciation of Gothic is based on how the Greek and Latin foreign words and names in the Gothic Bible were transcribed.

Gothic, separated from other Germanic languages early on, does not exhibit many of the linguistic developments that appear in other Germanic languages in later periods. Therefore, the phenomena that are unique to Gothic are considered important to all Germanic linguistics.

One way in which Gothic can be distinguished from other members of the Germanic family is by its use of the long [ê] sound (as in *mênoþ* 'month'), a sound that is assumed to have been in Proto-Germanic and that disappeared in all other Germanic languages. Another Gothic singularity is how it preserved the original Proto-Germanic [z] sound (as in *huzd* 'hoard') that changed to [r] in all other Germanic languages.

Gothic nouns and pronouns had five Germanic cases: nominative, vocative, genitive, dative, and accusative; however, some of the pronouns and adjectives also retained the instrumental case that was lost in other Germanic languages. Gothic nouns, pronouns, and adjectives had three genders (masculine, feminine, and neuter) and three numbers (singular, dual, and plural). The dual number (a plural form expressing two persons or things) is an archaic feature that does not appear in later varieties of other Germanic languages. Gothic also had a reflexive pronoun (*seina, sis, sik* 'self') that can be traced back to Proto-Indo-European.

Some verb features specific to Gothic occur seldom, if at all, in the other Germanic languages that appear in later written samples. Germanic verbs, in general, can be divided into strong (regular) and weak (irregular) verbs, and each of these can also be divided into subclasses. The seventh class of Gothic strong verbs is distinguished from other Germanic languages in that it uses the process of reduplication (repetition of syllables) to form the verbs. For example, the past tense of the verb *háitan* 'to call' is formed by repeating the first consonant of the verb stem and attaching it after the vowel *ái*, resulting in a form that attaches as a prefix to the basic stem to form *haíháit* 'called'. Another verb feature unique to Gothic are the retained passive inflectional suffixes for verbs; all other Germanic languages use the periphrastic construction of auxiliary plus verb plus past participle (as in 'is called' in English). Gothic uses passive inflectional suffixes, as seen in the use of *-ada* to form the passive *háitada* 'is called' from the verb *háitan* 'to call'.

A sample Gothic sentence reads as *Þanuh þan in menoþ saihstin insandiþs was aggilus Gabriel fram guþa* ('then-then-in-month-sixth-sent-was-angel-Gabriel-from-God'), yielding the English translation 'Then in the sixth month was sent the angel Gabriel from God.'

Grammar, Traditional

Traditional grammar refers to the type of grammar study done prior to the beginnings of modern linguistics. Grammar, in this traditional sense, is the study of the structure and formation of words and sentences, usually without much reference to sound and meaning. In the more modern linguistic sense, grammar is the study of the entire interrelated system of structures— sounds, words, meanings, sentences—within a language.

Traditional grammar can be traced back over 2,000 years and includes grammars from the classical period of Greece, India, and Rome; the Middle Ages; the Renaissance; the eighteenth and nineteenth century; and more modern times. The grammars created in this tradition reflect the prescriptive view that one dialect or variety of a language is to be valued more highly than others and should be the norm for all speakers of the language. Traditional grammars include prescriptive rules that are to be followed and proscriptive rules of usage to be avoided. 'When describing an emotion, use of an English word descended from Latin is preferred over an Anglo-Saxon word' is an example of a prescriptive rule, and 'Never split an infinitive' is an example of a proscriptive rule.

The analytical study of language began around 500 BC in Greece and India. The work of Greek scholar Dionysius Thrax is the model for all grammars of European languages that follow. His *Hē grammátikē tékhnē* (c. 100 BC; The Art of Letters) was the first widely recognized text to provide a curriculum for learning proper Greek. His lessons included an introduction to the alphabet, lessons on how to join syllables together properly, and instruction in the appreciation of word arrangement (syntax). To Thrax, grammar was the technical knowledge necessary to produce the prestige language of poets, orators, and writers.

Around the same time, the Roman scholar Marcus Terentius Varro produced the 25 volumes of his *De lingua latina* (c. 100, About the Latin Language). Varro contrasted Latin with Greek, changed Greek grammatical terms into Latin, and formed his grammar of Latin by adapting Greek rules.

Other Latin grammars, influenced by the works of Thrax and Varro, were produced in the Middle Ages. Aelius Donatus published *Ars Grammatica* (c. fourth century, Art of Letters), and Donat Priscianus Caesariensis (Priscian) wrote *Institutiones grammaticae*

(c. sixth century, Grammatical Foundations), which is the only complete surviving Latin grammar.

As printing became more widely available in the Renaissance, European grammarians began the mass production of grammars of their languages by mirroring the Latin grammars of Varro, Donatus, and Priscian. These traditional grammarians presumed that the grammatical descriptions of Latin could be routinely applied to their own languages; this perception, however, was not accurate and resulted in many artificial prescriptive and proscriptive rules. Many of these false assumptions still carry over to attitudes about English today.

Continuing with this tradition, grammarians in the eighteenth century studied English, along with many other European languages, by using the prescriptive approach in traditional grammar; during this time alone, over 270 grammars of English were published. During most of the eighteenth and nineteenth centuries, grammar was viewed as the art or science of correct language in both speech and writing. By pointing out common mistakes in usage, these early grammarians created grammars and dictionaries to help settle usage arguments and to encourage the improvement of English.

One of the most influential grammars of the eighteenth century was Lindley Murray's *English grammar* (1794), which was updated in new editions for decades. Murray's rules were taught for many years throughout school systems in England and the United States and helped to create modern attitudes about the existence of a correct or standard variety of English. Murray's grammar represents a practice that continued to develop throughout the nineteenth century and was still dominant in the 1960s when linguistics began to focus more on generative and transformational grammar due to Noam Chomsky's groundbreaking and influential ideas.

Even though linguists today view traditional grammar as an unscientific way to study language and grammar, many of the basic Latin-based notions of grammar can still be found in all levels of the classroom and in textbooks and usage guides available to educators and the public. Traditional grammar books usually provide lists of grammatical terms, definitions of those terms, and advice on using so-called 'standard' grammar, including suggested correct usage of punctuation, spelling, and word choice. This advice is usually based on the prescriptive rules of prestige varieties of English, varieties often only able to be used by those in power either economically or politically.

Linguists, along with many English faculty, would rather have students study language with a descriptive approach that includes the analysis of real samples of a mixture of English dialect varieties, not just the prescribed, and sometimes inconsistent, prestige forms. Linguists or teachers using a descriptive approach say that it allows students to investigate language on a deeper level, enabling students to see the system at work, instead of teaching them isolated prescriptive and proscriptive rules based on Latin, a dead language no longer in flux as English constantly is.

Linguists also believe that the rules of traditional grammar are inadequate because many of the rules are oversimplified, inconsistent, or not consistently conformed to. The grammars of classical Greece and Rome were based on the best orators or poets of the day. However, the best poets or speakers of our day are lauded for their poetic use of language that breaks prescriptive rules. For example, a traditional grammar rule of modern English, often found in usage guides and student handbooks, forbids the use of fragment sentences like 'The train running up the hill.' However, e.e. cummings or Maya Angelou could use this sentence for poetic effect without question.

Many teachers themselves want to be trained in traditional grammar, even though its inconsistencies may not help them when they have to explain grammatical points to their students. The National Council for Accreditation of Teacher Education (NCATE) requires that teachers in training take linguistics or language courses to teach them to examine the differences between traditional grammar and more modern grammars. However, many English teachers view traditional grammar as necessary and newer grammars as little help to them. And even though more modern types of grammatical analysis exist, many students, future teachers, and the general public still believe grammar means the traditional Latin-based grammar of old.

Grammar, Theories

Grammar theories have several overlapping main purposes in linguistics: to

- provide a model that clarifies our understanding of a particular language,
- model language in general,
- provide a convenient way of working with language, particularly with computers,
- describe the fundamental structures of language, and
- model human communication.

Noam Chomsky's transformational grammar has, in recent decades, been by far the most prevalent theory.

Phrase-Structure Grammar

Phrase-structure grammar was introduced by Noam Chomsky as a grammatical production system that categorized grammars and languages into a hierarchy of four types. A very similar notational scheme to describe one of those types (context free) was developed independently by John Backus for the purpose of describing programming languages. Phrase-structure grammar describes a language literally in terms of the structure of its phrases. The basic idea is that a sentence of a language is defined in terms of its phrase structure. The definition typically includes constituents that have their own phrase structure and hence require their own definitions. For example, in the sentence 'The big black dog chased the car', the phrase 'The big black dog' serves as the entity that is doing the chasing while the phrase 'the car' is the entity being chased. We could define the structure of a simple sentence as follows:

(1) S → NP VP
(2) NP → ART ADJ-SEQ NOUN
(3) VP → Verb | Verb NP
(4) ART → a | the
(5) ADJ-SEQ → ADJ | ADJ ADJ-SEQ
(6) ADJ → big | little | black | white | good | bad
(7) NOUN → boy | girl | dog | cat | car | truck
(8) Verb → chased | followed | saw

Each rule defines the phrase structure of one type of constituent (the arrow is read as 'is defined as'). The first rule defines a sentence (called an S) as a sequence of an NP followed by a VP. An NP is defined in rule (2) as being a sequence of three components, each of which requires further definitions. The first component,

which we have called ART, is defined by rule (4) and is either the word 'a' or the word 'the' (the vertical bar is read as a logical 'or'). The third rule requires a bit more explanation. The constituent ADJ-SEQ is defined, in part, in terms of itself. Such a definition is called a recursive definition. Using 'The big black dog' as an example, the ADJ-SEQ would be defined as an ADJ (the adjective 'big') followed by another ADJ-SEQ that consists only of an ADJ, which is the adjective 'black'. The process of matching of the actual words and phrases to the constituents defined by the grammar is called parsing, and the result of that matching is called a parse. Since, when one diagrams the matching, the result is a tree-like hierarchical structure, the result is often referred to as a parse tree.

Certain constituents, such as ART, ADJ, and NOUN, clearly indicate particular word classes. Generally, we assume a lexicon of the words of the language so that the grammar rules would assume a specific set of word classes:

(1) S → NP VP
(2) NP → article ADJ-SEQ noun
(3) VP → verb | verb NP
(4) ART → a | the
(5) ADJ-SEQ → adjective | adjective ADJ-SEQ

In such a characterization, an 'article' is any entry in the lexicon that is identified as belonging to the word class 'article'. Nouns, adjectives, verbs, and other classes are similarly defined.

Although the example is greatly oversimplified, it will be adequate to illustrate many of the major issues addressed by various grammatical models. Several points should be noted by this first simple example:

(1) Each rule defines a constituent, regardless of the context of that constituent, and is therefore called a context-free grammar. There are various ways to extend context-free grammars to account for context and some of those extensions are included in the grammatical models discussed below. Note also that phrase-structure grammars are not necessarily context free. In Chomsky's hierarchy, context-free grammars are in the second lowest (in terms of expressive power) level of the hierarchy. Generally, context-free grammars are highly desirable because of the relative ease in reading and understanding them. Greater expressive power may be achieved by allowing the left-hand side of a rule to contain more than one symbol, but such models are seldom used. Generally, other kinds of extensions are used.

(2) We omit discussions here of whether morphological rules are accounted for by the lexicon or the grammar. Hence, the word 'chased' may be in the lexicon explicitly, or there may be a morphological component that identifies 'chased' as being the past tense of the lexicon entry 'chase'. Although that is not relevant for our example, it is certainly relevant in general when evaluating grammatical theories. Some languages (e.g. Turkish, Hungarian, Finnish, or Mohawk) have morphological complexities that would make the positing of a lexicon that holds all morphological forms untenable.

(3) The discussion so far has addressed only the syntax of the language. It has not addressed semantic, pragmatic, or other issues.

(4) The example deals only with defining a sentence, but generally any model that attempts to deal with meaning must address larger units of language in order to account for context.

Categorial Grammars

The term categorial grammar was introduced by Yehoshua Bar-Hillel and combined some of Bar-Hillel's own work with earlier work of some Polish logicians, most notably Kazimierz Adjukiewicz. Categorial grammars in their original form are equivalent in expressive power to context-free phrase-structure grammars, but are based much more on words and their influence on adjacent or nearby words than are phrase-structure grammars. Each word class is a 'category'. Categories are either basic categories or derived categories. Derived categories have one or more operators in them that allow them to be combined with adjacent words in a manner much like multiplication. In the following example, the only basic category is C. Hence, a phrase 'the boy' would have the categories (NP/C)C. Treating the slash much as one would division, we can 'multiply' (NP/C) by C, arriving at NP. Hence, the phrase 'The boy' will be an NP. Similarly, the phrase 'The big boy' would have the category sequence (NP/C)(C/C)C, which, when 'multiplied' out, gives NP.

A categorial grammar equivalent to the phrase-structure grammar given above would have only one rule and a lexicon as follows:

Grammar Rule	Lexicon
(Ci/Cj)Cj → Ci	a:(NP/C)
	big: (C/C)
	black(C/C)
	boy:C
	cat:C
	dog:C
	girl:C
	little(C/C)
	the: (NP/C)
	white(C/C)

The example of categorial grammar has only one grammar rule. The rest of the language structure is in the lexicon. Although categorial grammars generally have more than one rule, the number of rules is always small (often two) with the structure primarily being handled by the lexicon. The underlying principle of categorial grammars is that each word is a functor, an object that operates as a function that maps one or more adjacent words into a new object, generally a new function.

Relational Grammar

Relational grammar is a direct descendant of transformational grammars that was developed primarily by David Perlmutter and Paul Postal in the early 1970s. One important characteristic of relational grammars is their cross-language generality. Early transformational grammars dealt almost entirely with English, but relational grammars were developed using a large variety of languages. Relational grammars view syntactic structures as a hierarchy of relations that are taken to be uninstantiated primitives. For example, the subject is level 1, the direct object is level 2, and the indirect object is level 3. Clausal structure is represented by a hierarchical diagram, called a stratal diagram, of the clause's terms.

One of the main motivations for the creation of relational grammars was to correct a perceived weakness of transformational grammars. Perlmutter and Postal argued that logical sentence components such as the subject are defined directly in terms of the sentence structure, which did not provide for a general characterization of relationships such as that between active and passive voice. As a simple example, 'The dog chased the boy' and 'The boy was chased by the dog' have different syntactic subjects, but the same logical 'subject'. That is, the dog does the chasing in both sentences. Hence, a model that defines the term 'subject' strictly in terms of constituent structure will have difficultly accounting for the similarity of the two sentences.

Case Grammar

Another descendant of transformational grammar is case grammar as introduced by Charles Fillmore in the early 1970s. Case grammar is based, according to Fillmore, on two principles: (1) the centrality of syntax and (2) covert categories. The former implies that the sentence's syntactic structure is primary (as opposed to, say, morphology) and the latter refers to the dominance of the meaning underlying the use of words and constituents. For example, in the sentence 'The boy hit the dog with a stick', syntactically, 'the boy' is the subject, 'the dog' is the direct object, and 'a stick' is the object of a preposition. A model consistent with case grammar would view the sentence as requiring the covert categories 'actor', 'affected', and 'instrument'. In the example, 'the boy'

would be the actor, 'the dog' would be the affected, and 'a stick' would be the instrument.

One place where we can see a more illustrative example is in the analysis of coordination. For example, given that Tom is cooking and Susan is cooking, it is reasonable to assert that Tom and Susan are cooking. However, given that Tom is cooking and the omelet is cooking, we would not say that Tom and the omelet are cooking (except, perhaps, to be humorous.) The point here is that although the sentence clauses 'Susan is cooking' and 'the omelet is cooking' appear to be syntactically similar sentences, the role that 'Susan' fills in the sentence is quite different from the role filled by 'the omelet'. In this example, the respective roles would be difficult to distinguish via purely syntactic means. Of course, sometimes the roles cannot be determined by syntactic means but depend on semantics and the context of the situation. For example, in a cartoon, Susan and a chicken could be cooking in the sense that both are in the act of preparing a meal, or both could be in the other role in a context involving cannibals.

Dependency Grammar

An alternative to describing the syntax of a language via its phrase structure is to describe the dependencies that exist among the words, phrases, and clauses. The idea is a very old one, but the modern characterization is based largely on the work of Lucien Tesnière in the late 1950s. The dependency approach to syntactic structure was overwhelmed by Noam Chomsky's transformational grammar approach and was thus largely ignored by the modern linguistic community. In recent years, more interest has been shown in the dependency approach as well as other alternatives to phrase-structure representations for syntactic structures.

Dependency grammars take the head and modifier approach to constituent structure. For example, in a phrase-structure approach, one might analyze the sentence 'cars burn gas' by focusing on the verb, 'burn'. Cars are the things doing the burning and gas is the stuff being burned. An alternative approach would be to consider cars as the head of the sentence and the burning of gas as an attribute of cars. Basically, the 'head' of a sentence, clause, or phrase is where we focus our attention. The dependencies are generally determined via the semantics of the sentence. An easy thumb rule is to imagine that you are recording the information of the sentence in, say, some kind of encyclopedia. The head of the phrase is then the entry under which the information is stored. In the case of 'cars burn gas' it is likely that storing the information under 'car' rather than 'burn' would ultimately prove to be more useful. Dependency grammars have often been used in information retrieval systems, particularly early systems.

Lexical-Functional Grammar

Lexical-functional grammar was developed in the early 1970s by Joan Bresnan and Ron Kaplan to provide a model that could serve as the basis of both a computationally feasible and psychologically realistic model of human language. Like relational grammar, it deviated from the transformation model by including nonstructural factors in the syntactic component of language. Also, like relational grammar, it gives a distinguished status to the notion of 'subject' and 'object'. The 'lexical' in the title is due to its emphasis on the role of the lexicon.

In a lexical-functional description of a sentence, there are two components: a constituent structure and a functional structure. The constituent structure is strictly structural and is based on a context-free phrase-structure grammar. The functional structure is by additional computations, expressed as equations, associated with the context-free rules. The computational aspects of lexical-functional are quite similar to a different formalism, developed in the late 1960s by Donald Knuth, called an attribute grammar. The basic idea is that each constituent of the language has a set of attributes. For example, the 'number' attribute of the NP 'the big black dog' could be ultimately assigned as 'singular' since the words 'the' and 'dog' are both marked as singular by the lexicon. Note that if their number attributes had been different, the noun phrase would not have been well formed.

Lexical–functional grammar is similar to case grammar in that the attributes constitute a set of named slots that are filled by the computational rules. Note also that attributes and their associated computational rules need not be confined to syntactic properties. Semantic features with complex values, including values that are actually active computational agents such as automata or computer programs, fit naturally into the model.

Generalized Phrase-Structure Grammar

Unlike lexical–functional grammar, generalized phrase-structure grammar (GPS) does not posit a separate, distinct functional component. The model presented here was introduced by Gerald Gazdar, in the late 1970s, but the formal mechanisms are very similar to W-grammar as developed by A. Van Vijngaarden in the late 1960s. The basic idea is to use phrase-structure grammar, but to allow more powerful *metarules* that define additional rules rather than syntactic constituents. This seemingly small change in the formalism changes the expressive power of the grammar substantially and allows the specification of complex syntactic rules such as matching a sentence in the active voice to its corresponding passive sentence. In particular, it allows GPS to dispense with the transformations of transformational grammar.

In Gazdar's model, grammatical constituents included components called derived categories, which were denoted using notation similar to the derived categories in categorial grammar. However, in GPS the derived category X/Y (where X and Y stand for grammatical constituents) represents a constituent X that is missing the constituent Y, that would normally be included as a component of X. This ability to define constituents with 'holes' allows a relatively straightforward treatment of sentences such as 'Which book is that article on Gazdar in?' In this example, the verb phrase of the sentence is missing a noun phrase ('which book'), and hence requires a noun phrase elsewhere in the sentence that can 'fill in the hole'.

Cognitive Grammar

Cognitive grammar was developed in the mid-1970s by Ronald Langacker. It was originally called space grammar and was considered by its creator to be fundamentally at odds with current linguistic trends of the time in that it claimed the inseparability of syntax and semantics, rejected the primacy of formal logic as the foundation of grammar, and argued for integration rather than specialization of theories for separate linguistic components.

Cognitive grammar, as its name implies, considers language as an integral part of human cognition and therefore knowledge of language cannot be wholly independent of knowledge of human cognition. Langacker argues that a separate processing unit that deals with reason and cognition has not been firmly established and may not exist. His model is intended to be valid whether such a separate module exists or not.

There are exactly three kinds of grammatical structures in cognitive grammar: semantic, phonological, and symbolic. Symbolic structures are not distinct from the other two, but combine them. Cognitive grammar attempts to characterize the mapping and providing the correspondence of the sounds we hear to the thoughts we associate with those sounds.

Cognitive grammar is based on several underlying principles. First, formal logic is not suitable for modeling the meaning of a sentence, since meaning is not based on truth values, but rather individual experiences. Second, the meaning of a particular word is defined by the universe of experience of the speaker (or listener) and not by a constrained formula such as is implied by a dictionary entry. Finally, like words, linguistic categories are not simple structures, but generally complex networks of linked structures.

Definite Clause Grammar

Definite clause grammar was first proposed by Alain Colmerauer in the late 1970s and developed further by Fernando Pereira and David Warren. Definite clause grammar is primarily a computational model that is based directly on logical formulas. For example, the phrase structure rule of the first example, S → NP VP, could be written as the logical formula:

For all sequences of words x, y, and z, if x is an NP and y is a VP and the concatenation of x and y is z, then z is an S.

All of the rules of any Phrase-structure grammar could be written according to such a logical formula. The purpose of stating a rule in that fashion is that it allows for direct implementation of a parser on a computer. Definite clause grammar was originally created as a natural way to write parsers in the programming language Prolog. Like GPS, definite clause grammar does not posit a separate distinct functional component, but simply adds additional components to the logical formula. For example:

For all sequences of words x, y, and z, if the concatenation of x and y is z and either (1) x is a singular NP and y is a singular VP, or (2) x is a plural NP and y is a plural VP, then z is an S.

This is a logical formula that would include number agreement between the noun phrase and the verb phrase. The logical formulas can be translated directly into computer code that provides a parser.

Grammatical Function

The concept of 'grammatical function' or 'grammatical relation' comes from traditional grammars, which differentiate four grammatical functions. For example, in a sentence like *John gave this book to Peter at school*, it can be said that *John* functions as a 'subject' of the verb *to give*; *this book* is the verb's 'direct object' and *to Peter* plays the role of its 'indirect object'; finally, the locative *at school* is 'oblique'. These labels underlie a network of relations between the verb and its arguments.

In early studies of natural language, a sentence was identified with the logical proposition, which has two essential components: the substance (subject) and its property (predicate). The subject is supposed to be known to both speaker and hearer, while the predicate adds something new about the subject. Therefore, subjects usually have a definite reference, and precede the predicative part of an utterance (the verb with its objects). To put it differently, grammatical subjects ensure the coherence of a discourse that leads from old to new information. This perspective was developed by Prague School linguists of the 1920s and is followed by modern functional approaches to grammar.

From a semantic point of view, grammatical functions are usually associated with different situational roles, known as 'thematic roles'. For example, the subject is usually associated with the role of Agent (or Actor) (***John** writes …*), while such roles as Theme (*to give **a book***) and Goal (*to give it **to John***) are related to direct and indirect objects, respectively. Oblique arguments can express Instrumental and Locative thematic roles (*to be loved **by Mary**, to live **in London***). However, with psychological verbs the direct correspondence between thematic roles and grammatical functions is problematic. For example, the verb *to fear* assigns the Experiencer role to the subject and the Theme role to the object (*John* (subject) *fears this story* (object)), while the synonymous verb *to frighten* assigns the same roles, but in inverse order (*This story* (subject) *frightens John* (object)).

With respect to relevant word forms, the subject, rather than the object, induces verbal agreement in a finite clause. In ***He** knows them*, for example, the verb is marked with a final -*s* indicating third-person singular. Thus, the verb is said to 'agree' with the subject *he,* which is a third-person singular pronoun. Moreover, in so-called accusative languages, case-marking on nouns and pronouns can serve as an indicator of grammatical functions. Thus, in English we observe different pronominal forms for subject and object, as in *He saw him,* where *he* is the form for nominative case (subject) and *him* is accusative (object). Nevertheless, the correspondence between case-marking and grammatical functions is different in so-called ergative languages (including Inuit, Georgian, Basque, Hindi, and many others). In these languages, the subject of an intransitive verb (***I** run*) has the same marking as the object of a transitive verb—that is, the equivalent of the English sentence *The teacher has seen **me*** would be something like *The teacher **I** has seen* in Burushaski (a language isolate spoken in northern Pakistan).

Finally, some more complex grammatical properties also differentiate the subject from the object. For example, subjects (but not objects) can 'control' a missing element in a subordinate clause: thus, in *Paul helps Mary without asking for money,* it is Paul (subject), not Mary (object), who does not ask for money, i.e. the complete sentence would be *Paul helps Mary without Paul asking for money.* The subject of the subordinate clause can only be left out if it is identical to the subject of the main clause. Notice that in *Paul helps Mary without Mary asking for money* the subject of the subordinate clause cannot be left out. Moreover, in some languages (e.g. Latin, Russian, Norwegian, Icelandic) there are reflexive pronouns whose antecedant must be the subject (so-called 'subject-oriented reflexives'). Accordingly, in the Icelandic sentence *Pall gaf barninu bók sín* (literally *Paul gave child book self's*), the book is construed as belonging to Paul (subject), not to the child (object).

In languages with rich noun inflection, a noun may behave syntactically as a subject but be marked as an object (so-called 'grammatical function-splitting'). Icelandic, for instance, has such constructions as *Mér likuði konan sín* (literally *Me likes wife self's*), *I like my wife*. Here, *mér* does not have the word form normally

associated with the subject, since it is dative (not nominative) and does not trigger verbal agreement. However, *mér* is the subject from the syntactic point of view, since it can refer to the same entity as a subject-oriented possessive *sín*. In the literature, such cases are known as the 'quirky subject' phenomenon.

Many linguists (following Noam Chomsky) maintain that objects are more closely related to the verb, and consequently more likely to form idioms than subjects (*John is **pulling my leg**, this house **catches the eye***, etc.). This asymmetry is said to be due to the fact that verbs and objects form the predicative unit, while the subject is a more independent entity. From this point of view, the notions of 'subject' and 'object' can be defined on structural grounds.

However, nonconfigurational languages, in which word order is free (e.g. the Australian language Warlpiri), have been used to argue against a purely structural interpretation of grammatical functions. Since the mid-1970s, some new theoretical approaches have been created on the basis of grammatical functions being autonomous categories. For example, grammatical functions may be regarded as syntactic primitives forming the following hierarchy: subject > direct object > indirect object > oblique. This is the stance taken by the framework of 'relational grammar'. It is argued that certain sentence structures may be described in terms of 'grammatical function-changing processes' . For example, the formation of passives, such as ***John has broken the glass—The glass has been broken (by John)***, is characterized as follows: the object is 'promoted' (in hierarchy) to the subject, while the subject is 'demoted' to the oblique (the presence of the latter is optional). Dative shift in English (e.g. *I gave my favorite book **to Mary*** and *I gave **Mary** my favorite book*) also represents 'grammatical function-changing', here the promotion of the indirect object to the direct object.

Another possibility is to conceive of grammatical functions as categories that relate thematic roles (Agent, Patient, Experiencer, etc.) to the concrete means of expression in a given language. For instance, the English lexicon has the verb *to invite,* whose Agent role is mapped to the subject, while its Patient role is mapped to the object, as in *John* (subject-Agent) ***invited** the president* (object-Patient). The passive counterpart of this verb is formed by remapping Patient to the subject and Agent to the oblique, as in *John* (subject-Patient) *is **invited** by the president* (oblique-Agent). This is the view elaborated in the framework of 'lexical-functional grammar.'

Summing up, the traditional notion of grammatical function is controversial in modern linguistics. The core grammatical functions, subject and object, cannot be defined absolutely, since they are differentiated on the basis of several possibly independent properties. From the semantic point of view, they represent the two main participants in the event denoted by the verb. Grammatical functions may be useful descriptively, since they make it possible to abstract away from language-specific properties and to generalize over certain syntactic phenomena.

Grammaticalization

Grammaticalization is defined as the development from words with full meaning to forms with only grammatical function, and from grammatical to even more grammatical forms. Since the development of grammatical forms is not independent of the grammatical constructions to which they belong, the study of grammaticalization is also concerned with constructions, and with even larger discourse segments. The primary goal of grammaticalization theory is to describe how grammatical forms and constructions

arise and develop through space and time, and to explain why they are structured the way they are.

In the history of grammaticalization studies, three main phases can be distinguished. The first phase is associated with the work of eighteenth-century French and British philosophers who argued that grammatical complexity and abstract vocabulary derive historically from concrete words. In the nineteenth century, it was mostly German linguists, especially Franz Bopp and Georg von der Gabelentz, who used findings of grammaticalization to understand grammatical change and language structure. The third phase started in the 1970s and was shaped by scholars using functionalist frameworks of linguistic analysis, most of all Talmy Givón. His slogan 'Today's morphology is yesterday's syntax' opened a new perspective for understanding grammar, and he proposed the following unidirectional cycle (where the endpoint marks the beginning of a new cycle again leading from Discourse to Zero; see Givón 1971, 1979):

Discourse > Syntax > Morphology > Morphophonemics > Zero.

While earlier work dealt mostly with the study of individual words and grammatical items, modern work is more concerned with the use of linguistic forms in constructions and larger discourse units.

The following are the main assumptions underlying grammaticalization theory. First, it is argued that language is a historical product and has to be accounted for, first of all, with reference to the historical forces that are responsible for its present structure. Accordingly, it is claimed that this theory offers more powerful explanations of language structure than any approach that is confined to the analysis of a language at a particular point in time.

Second, the development of grammatical forms is unidirectional, being the result of a process whereby forms for concrete meanings are used to express more abstract (grammatical) meanings as well, e.g. when a form used for a visible object (e.g. the body part *back*) is also used to refer to a nonvisible item (the spatial notion *behind*), or a form used for an action (*go to*) is used to also refer to a grammatical notion (FUTURE TENSE). But equally common are processes whereby items that are already part of the inventory of grammatical forms give rise to more strongly grammaticalized and more abstract items. A number of examples contradicting the unidirectionality principle have been found, but as acknowledged by most scholars who have identified exceptional cases, such examples are few compared to the large number of cases that conform to the principle (see especially Newmeyer 1998).

On account of its specific directionality, grammaticalization has been described in terms of metaphorical transfer, leading from the domain of concrete objects to that of space, from space to time, from ('real-world') space to discourse space, and so on.

There is wide agreement that grammaticalization involves three interrelated mechanisms: (1) 'desemanticization' (or 'semantic bleaching'), loss of meaning content; (2) 'decategorialization', loss of morphosyntactic properties (e.g. inflection) characteristic of lexical or other less grammaticalized forms; and (3) 'erosion' (or 'phonetic reduction'), loss of phonetic substance. Desemanticization results from the use of forms for concrete meanings that are reinterpreted in specific contexts as more abstract, grammatical meanings. Having acquired grammatical meanings, these forms tend to become increasingly divergent from their old uses: they lose categorial properties characteristic of their old uses, hence undergo decategorialization, and they tend to be used more frequently, become more predictable in their occurrence and, consequently, tend to lose sounds. While all three mechanisms involve a loss of properties, there are also gains. In the same way as linguistic items undergoing grammaticalization lose in semantic, morphosyntactic, and phonetic substance, they also gain properties characteristic of their uses in new contexts. Grammaticalization requires specific contexts to take place, and it can be, and has been, described as a product of context-induced reinterpretation or inferencing.

Grammaticalization thus begins with concrete, lexical forms and constructions, and ideally ends in zero, that is, grammatical forms increasingly lose semantic and phonetic content and, in the end, they may be replaced by altogether new forms; grammaticalization has therefore been described as a cyclical process. Cyclicity is a frequent but not a necessary property of grammaticalization processes. Furthermore, grammaticalization has been described by some as a process that involves the reanalysis of grammatical forms and/or constructions, while other authors argue that there is no necessary relationship between grammaticalization and reanalysis.

Great Britain

Great Britain, or more properly the United Kingdom of Great Britain and Northern Ireland, includes England, Scotland, and Wales and Northern Ireland. The total area of the current United Kingdom is 244,820 square kilometers with a total population of 59,511,464 (2000 est.).

Wales was politically integrated with England in 1536, Scotland officially joined England and Wales in 1707 with the Act of Union, and Ireland was added in 1801 to create the political union of the United Kingdom of Great Britain and Ireland. The union with Ireland was in effect until the Irish Free State was formed in 1921. The six counties of Northern Ireland, with a predominantly Protestant population, remained in the union, and the official name was changed to the United Kingdom of Great Britain and Northern Ireland in 1927. Now known as the Republic of Ireland (Eire), the Irish Free State became a separate republic in 1949.

The approximate historical periods of English within Great Britain are recognized as Old English from 450 to 1100, Middle English from 1100 to 1500, early modern English from 1500 to 1700, and modern English from 1700 to the present.

Many languages have existed in Great Britain; however, English has been the dominant language since the sixteenth century, with various other languages and dialects existing throughout the area. Languages that were once in Great Britain but are now extinct include Anglo-Danish, Anglo-Latin, Anglo-Saxon (Old English), Brythonic, Cornish, Manx Gaelic, Norman French, Norn, and Pictish.

Indigenous languages currently found in Great Britain include English, Irish Gaelic, Scots, Scottish Gaelic, and Welsh. Various other immigrant languages (including Caribbean English Creole, Hindi, Urdu, Punjabi, and Cantonese) are now spoken in cities like Birmingham, Cardiff, Glasgow, Leeds, and London.

England

England, which gets its name from the Old English *Englaland* (the land of the Angles), is in the southern part of the island of Britain and is the original home of English, a Germanic language that came with the Angles and Saxons to England from modern-day northern Germany, starting in the fifth century. The Celts, the earlier inhabitants, intermarried with the Anglo-Saxons or migrated to the outer parts of the British Isles. Even though the Anglo-Saxons lost their power in 1066 with the Norman Conquest, English and England remained strong, and by the sixteenth century, English was the official language of England.

Various minority groups live in England, using languages other than English as their only language or as a bilingual partner to English. The Irish are the largest minority group, and there are also groups of Europeans (Italians, Greeks, Turkish Cypriots, and Poles), Asians, Africans, Arabs, West Indians, Pakistanis, and Indians. In addition, Welsh and Cornish are also still spoken. Cornish, a Celtic language, has been revived and is now taught in some Cornwall schools, and some speakers of Welsh in places like London maintain their language.

English

English is the official language and is sometimes referred to as Anglo-English, England English, English English, and British English. The term 'British English' is often used when trying to compare the dialects of England with dialects around the world.

Many social and regional English dialects exist. Even though some people from different dialect groups may sometimes have difficulty understanding each other, the media has helped spread standardized words and pronunciations.

Standard English and Received Pronunciation

Standard English (SE) and Received Pronunciation (RP) are prestige social forms of English. SE, in its linguistics sense, relates to mostly the standardized grammar and vocabulary of English, and RP to the pronunciation of the educated upper-middle and upper class. However, the terms are often used interchangeably by those outside of linguistics. Even though it is assumed that SE includes RP, various accents are part of SE use. Most people write SE with slight variations in grammar and spelling; many also speak SE with some variation in regional vocabulary. Some speakers use two dialects—a social or regional one for friends and family and a version of SE for formal use, and most urban and rural areas have a variety of spoken English that has been influenced in some way by social or regional factors.

Cockney

Another social dialect at the opposite end of the social spectrum from RP is Cockney, the speech of about 7 million working-class Londoners. Although often stigmatized, Cockney has a long history and makes up the most prominent and widely spoken urban dialect in Great Britain.

Regional Dialects

Different regional dialects of English can be traced back in England to the eighth century when the Germanic tribes, who had settled in different areas of England in the preceding three centuries, had *Englisc* as their common language. The Angles settled in the Midlands and along the eastern coast, and their dialects included Mercian and Northumbrian. The Jutes settled around Kent and spoke the Kentish dialect. The Saxons settled in Essex, Middlesex, Sussex, and Wessex. Under the leadership of Alfred the Great, the West Saxon dialect of Wessex became the dominant dialect and served as the prestige and literary dialect of the Middle Ages.

Eleventh-century dialects included Northern, West Midland, East Midland, Southern, and Kentish. After the Norman Conquest, the East Midland dialect from the London and East Anglian region became the new standard with the help of William Caxton, the first major British printer, who used East Midland as the printing standard. Regional speech came to be considered as substandard but was used well into the eighteenth century by the middle and upper classes.

Today, regional varieties of English dialects are still strong, especially in large cities and rural areas. Regional dialects include South-East English around the London area, South-West English around the Cornwall area, West Midlands English around the Birmingham area, East Midlands English around the East Anglian region, North-West English around Liverpool and Manchester, and North-East English around Leeds, York, and the Yorkshire countryside.

Wales

Wales, in the southwest corner of the island of Britain, gets its name from the Old English word *Wealas* (foreigners). Celts from northwestern Europe originally settled in this area and were subsequently invaded by Romans. When Anglo-Saxons took control of England in the fifth century, Wales was the only Celtic region left in southern Britain, and the Welsh fought off the English, Irish, Scandinavians, and Normans from the fifth to eleventh centuries. In the thirteenth century, the last native Welsh prince was killed during an English invasion, and from 1301 on, the Prince of Wales has been British. In 1536, Wales was officially united with England, and English became the official language.

Welsh English

Close to 100% of the Wales population speaks English. Welsh English represents a spectrum of varieties and includes the social dialects of bilingual Welsh/English speakers, the English of the working class, SE speakers with a Welsh accent, and SE speakers with an RP accent. Welsh has a strong influence on the northern, mid, and southern regional dialects of Wales, with a very strong influence in the northern counties, where English/Welsh bilingualism is common.

There is little or no stigma attached to the use of Welsh English in Wales; however, many believe that education should be bilingual and hence all Welsh people have access to Welsh as the national language. Others, especially non-Welsh speakers, do not believe that speaking Welsh is a necessary part of being Welsh. Tensions are high, however, concerning the use of the Welsh language, since many believe that education should be bilingual so all Welsh people have access to Welsh as their national language.

Welsh

Welsh, the Celtic language of Wales, is known as *Cymraeg* to its speakers and was the main language of Wales for many centuries. However, Welsh use has been diminishing since the fifteenth century. An eighteenth- and nineteenth-century revival led to Welsh being taught in all schools; in some schools, it is even the language of instruction. Currently, about 26% of the population is bilingual (with Welsh and English); however, only a few monolingual Welsh speakers exist. Even so, Welsh is relatively stable; a

Welsh-only television channel and bilingual road signs show that its steady decline might be slowing. Welsh has several dialects that differ mostly in pronunciation; the vocabulary has mostly been standardized by education and the media.

Scotland

Scotland, a part of Great Britain since 1707, gets its name from the Old English 'land of the Scots' and includes the mainland, which is divided into three main regions (the Highlands, the Lowlands, and the Southern Uplands), and the outlying islands, which include the Western Isles (also known as the Hebrides) and the Northern Isles (the islands of Orkney and Shetland).

When the Romans invaded Britain in the first century, they called the area now known as modern Scotland by the name *Caledonia* and called its inhabitants the Picts (from Latin *picius* 'painted') because of the Pict tradition of painting their bodies. In the fifth century, after the Romans withdrew from England, and Germanic tribes began their invasions into England, Christian Celtic immigrants from Ireland began to settle the area of modern Scotland, converted the Picts to Christianity during the sixth century, and added the Pictish kingdom to the Scots kingdom by the ninth century.

By the tenth century, this area was known as Scotland. After the Norman Conquest, many Anglo-Saxons settled in the Lowlands of Scotland, bringing English customs and the English language. England and Scotland were joined formally together in the Act of Union of 1707 in which both parliaments were merged, thus creating the Kingdom of Great Britain.

Scotland's language history is complex. In the Middle Ages, six languages were in regular use: Cumbric, Gaelic, Inglis, Norn, Norman French, and Latin. Modern Scotland has two or three (depending on who does the analysis) languages: Scottish Gaelic, English (Scottish and RP), and Scots. Up to the fifteenth century, Scots was the term applied only to Gaelic and its speakers; now this variety is most commonly referred to as Gaelic, Scots Gaelic, or Scottish Gaelic. From the late fifteenth century, the term Scots has referred to Scots English, the language of the Lowlands. Scottish English refers to the other varieties of English used in Scotland and, depending on the analysis and the discussion, can include or exclude Scots English.

Scottish Gaelic
Gaelic is the English name for the Celtic language of Ireland, Scotland, and the Isle of Man. In Scotland, it was formerly called *Erse* or *Irish,* but speakers today often refer to it as *the Gaelic*.

Until the eighteenth century, Gaelic was the principal language of Ireland; however, with the increased influence and pressure of Northern English, the use and prestige of Gaelic have declined since the twelfth century. Since the late twentieth century, Gaelic has been a first language for very few people (usually in the Hebrides) but has regained some of its prestige through efforts to encourage bilingual policies, and has made Gaelic a part of the educational system. According to the 1981 census, approximately 80,000 people speak Gaelic, but most of these are bilingual English/Gaelic speakers.

Scottish Gaelic has a strong literary tradition, and there is a resurging twentieth-century Gaelic literature encouraged by *An Comunn Gaidhealach* (The Highland Association) and *Comunn na Gàidhlig* (The Gaelic Association), two organizations that support and promote the Gaelic culture and language.

Scottish Gaelic has influenced Scots English and other varieties of Scottish English in pronunciation, syntax, and vocabulary, and this influence runs both ways.

Scots
Some language scholars consider Scots (or Scots English) a language and others consider it a dialect of English. Whatever way it is defined, since the beginning of the eighteenth century, scholars have specialized in studying it in its different periods: Old English (to 1100), Early Scots (1100–1450), Middle Scots (1450–1700), and Modern Scots (1700 onward).

Scots is first recorded in the seventh century in southern Scotland as a variant of the Old English of Northern England. By the fourteenth century, this variety known as *Inglis* had replaced Gaelic as the language of the Lowlands. By the mid-sixteenth century, Scots began to be heavily influenced by the English of southern England. In the eighteenth century, Scots was considered substandard, but a revival of vernacular literature in Scots in the nineteenth century encouraged the middle and upper classes to become more interested in the Scots language. In the twentieth century, there have been more attempts to revive Scots as the national language; even so, English and Scottish English are still the dialects of power and prestige, and there has been a steady decline of native Scots speakers.

The dialects of Scots fall into four main regional dialect areas: the Northern Isles Scots of Orkney and Shetland, the Northern Scots of northern Scotland, the Southern Scots near the English border, and the Central Scots of middle Scotland, including the working-class dialects of Edinburgh and Glasgow, which are often referred to pejoratively as Gutter Scots.

Scottish English

If Scots is a language, then Scottish English includes all other varieties of English in Scotland, including the Highland English of the Highlands and Islands, the Scottish standard English of the past three centuries, and the RP dialect of the upper middle and upper class. Scottish English has many similarities with the English of England but also has many features of Scots, and many modern speakers of Scottish English acquired Scots as their first language in their childhood.

Northern Ireland

Northern Ireland, a part of the United Kingdom, includes six of the nine counties that originally made up the early Celtic kingdom of Ulster: Antrim, Armagh, Derry or Londonderry, Down, Fermanagh, and Tyrone. The Celt leaders, who were Druids, lost their power in the fifth century after St. Patrick introduced Christianity. After many centuries of Celtic challenges to both Christianity and the power of England, the Celt leaders fled Northern Ireland in the early seventeenth century, and about two thirds of the current Northern Ireland population are descendants of Protestant English and Scottish settlers who came to Ulster in the same century. The other third are Irish in origin and Catholic. By the mid-nineteenth century, English was the language of power and prestige. In modern Northern Ireland, an omnipresent tension exists between Protestants and Catholics, and even though the right to free language choice is part of this tension, both sides of the argument are likely to use some variety of English now.

Irish Gaelic

Irish Gaelic, or Irish, is a Celtic language that remained the main language of Ireland until the eighteenth century when the British passed and enforced laws that made Irish the language of the powerless. The school system was restructured with new National Schools, in which English was the only language of instruction. Gaelic was also negatively impacted by the Irish famine of the mid-nineteenth century, which resulted in the mass emigration of Gaelic first-language speakers.

By the end of the nineteenth century, there was a revival of interest in the Irish language, literature, and history of Northern Ireland and the Republic of Ireland. This new national attitude helped slow the steady decline of Irish Gaelic but only after English had already gained enormous power and Irish had died out as a spoken language except in isolated rural areas of Northern Ireland.

Northern Irish English

Northern Irish English refers to the English used in Northern Ireland; however, there are four distinct varieties: Ulster Scots, Anglo-Irish, Hiberno-English, and Belfast English.

Ulster Scots

Ulster Scots, also known as Scotch-Irish, was brought to Ireland in the seventeenth century by about 200,000 migrating Lowland Scots and is mainly found in parts of Antrim, Derry, and Down counties in Northern Island. Ulster Scots is usually identified as the dialect of the working class and is found throughout Northern Ireland and the Irish Republic.

Anglo-Irish

Anglo-Irish, or Ulster English, is a variety of English spoken over most of Northern Ireland and the Irish Republic, except for the most northern counties. Like Ulster Scots, the beginnings of Anglo-Irish came to Ireland in the seventeenth century, but with English settlers and not Scottish. There are regional and social varieties that are heavily influenced by the education of the speaker. RP is usually part of the Anglo-Irish of the middle class, but less educated speakers usually have other distinct pronunciations. As time goes by, a standardized variety of Anglo-Irish is becoming more common.

Hiberno-English

Hiberno-English is another variety of English in Ireland, used mainly by less educated speakers. Mostly found in rural counties (Armagh, Fermanagh, and Tyrone) in Northern Ireland, it is heavily influenced by Irish Gaelic.

Belfast English

Belfast English, another variety of English in Northern Ireland, varies with the level of education of the speaker. It is normally described as rapid informal speech that has the vocabulary of Ulster Scots with some nonstandard grammatical features of Anglo-Irish.

Great Vowel Shift

English is unique among the European languages using the Roman alphabet in that it has a special set of 'names' for the vowel letters <i, e, a, o>. The names reflect the pronounciation of these letters when they represent long or tense vowels, as in *mine, cede, fame, grove*. Until the fourteenth century the value of these letters was close enough to their Latin pronounciation so that Chaucer (d. 1400) could rhyme *A* with *omnia*:

> On which was first i-write a crowned A,

> And after, *Amor vincit omnia. Prol.* 161

The long vowels acquired their English names subsequent to a set of changes known collectively as *The Great Vowel Shift* (GVS). The GVS is one of the main reasons for the apparent anomalies of English spelling today. The changes covered by this label are universally acknowledged as the most dramatic readjustment of the system of long vowels in the recorded history of English. The phenomena subsumed under the general designation of GVS have been the focus of extensive scholarly inquiry during the last 150 years, and the debate is ongoing.

The research history of the GVS encapsulates the history of phonological research in general, and the history of English historical language studies: from atomistic description, to structuralist and generative generalizations, and, more recently, increased attention to surface phonetic facts in the context of regional and social variation. Nineteenth-century philologists described the changes in great detail, focusing on the results in southern standard British English, or, more specifically, on Received Pronounciation (RP). The latter is the supraregional variety of British English based on nineteenth-century southern pronounciations, and fostered until at least the 1960s as the standard in the media and the 'correct' pronounciation in (British) English instruction around the world. The vowel correspondences reconstructed for the changes between late Middle English (ME), c. 1350–1400, and twentieth-century RP are as follows (see Figure 1).

The last century has witnessed both the 'making' and the 'undoing' of the GVS. Starting with Karl Luick (1898) and Otto Jespersen (1909), the changes shown above have been treated as a unified set of phonological events, where each new value is supposed to be the result and the trigger of a chain-like shift of all ME pure long vowels. In most cases, the phonemic contrasts between the original entities were preserved, although their phonetic realizations were changed. This position is well represented by Jespersen's summary statement (1909:231): 'The great vowel-shift consists in a general raising of all long vowels with the exception of the two high vowels /i:/ and /u:/, which could not be raised further without becoming consonants and which were diphthongized into …[ai, au].' The presumed structural connectedness among the changes is represented in the chart below:

aɪ ← i: u: → aʊ

      e: o:

The all-encompassing, chain-shift view of the GVS dominated the scholarship throughout the early parts of the twentieth century. Hypotheses addressing the initiation, causation, and propagation of the putative massive chain shift have been proposed in terms of numerous phonological theories, including structuralism, generative phonology, lexical phonology, dependency phonology, particle phonology, lexical diffusion, and optimality theory. With rare exceptions, a representation of the changes from Middle to Modern English, with each long vowel linked to an arrow pointing upward or outward, is still repeated in textbook accounts of the history of English phonology. The characteristics associated with the position that the GVS was a comprehensive and coherent chain shift of the ME
