It is true that all long vowels underwent some kind of change during the early Modern English period (c. 1450–1750). Nevertheless, any GVS representation ignoring the other functionally long vocalic units in ME is too restrictive. Diphthongal variants of the high vowel /iː/, /iy/, existed or arose in ME from earlier native and borrowed sequences of high vowels and following consonantal /j/ and /h/, thus ME /stiy/ 'sty', /sliy/ 'sly' from earlier <stig> /stij/, <sligh> /slij(h)/. The high back long vowel /uː/ had noncontrastive variants /uw/, as in ME /fuwl/ 'fowl', /buw(h)/ 'bough' from earlier native and borrowed <fugol> [fuɣ(ə)l], <boh> [buw(h)]. In both cases, the diphthongal and the steady-state variants merged toward a diphthongal realization. These initial diphthongs were further optimized by differentiation of their endpoints: /aɪ/ for *bind, design, wife, sty*, and /aʊ/ for *cow, crown, how, fowl*. Thus, /aɪ/ and /aʊ/ are the attested RP results of the gradual change of both 'pure' long vowels and minimal diphthongs of high vowels followed by a homorganic glide; it was the diphthongal realizations that were formative in terms of the later history of these vocalic units. Similarly, the history of the ME mid long vowels /ɛː/ (as in *steak*), /aː/ (as in *bake*), and /ɔː/ (as in *boat*) cannot be separated from the history of preexisting diphthongs as in *day, play, weigh, blow, stow, dough* from earlier /dæj, plej, wejh/, /blow, stow, dowh/. Therefore, any description of the reorganization of the vowel system of ME should take into consideration both the history of the long vowels proper and the diphthongal entities with which the long vowels merged in the course of the GVS.

(2) *Dating*. The GVS began by c. 1400, and was completed by c. 1700.

This chronological span can accommodate only some of the changes that shaped the long vowel system of Modern English. The more dramatic changes associated with the GVS, the full diphthongization of the high vowels /iː/ and /uː/ and the raising of the high mid vowels /eː/ and /oː/ in RP, were indeed arguably accomplished within this time-frame. However, the mergers of the 'pure' high vowels with preexisting diphthongs that determined the future of these vowel types were already under way in early ME, if not earlier. High-vowel diphthongization and mid-vowel raising can be traced in the spelling starting from c. 1350.

Another problem with such restrictive dating comes from the post-1700 instances of continuing shifts in non-RP varieties of English. Figure 2 shows some examples of post-GVS changes of the high vowels that are not covered by the traditional conceptualization of the shift as a single event bounded by cut-off time points. The first column represents the ME input, the second column shows the reflexes of these high vowels in RP, the third one shows the developments in London English, also Australian and New Zealand English, and the fourth column represents current realizations of these vowels in some southern US varieties of English.

The changes of the long vowels outside RP cannot be fitted within the conventional GVS picture. Regarding the GVS as a one-time coherent event, which began and ended at well-defined points of time, causes us to lose sight of the rich phonetic variation that precedes and follows it. Reference to the dating of the GVS must be accompanied by the realization that it is an artificially isolated portion of a continuum, representing the evolution of the entire phonological system of the language through time, with no starting- and no endpoints.

(3) *Mechanism*. The GVS started with the high and the high mid vowels.

(a) The high vowels /iː/ and /uː/ were diphthongized first. The raising of the high midvowels /eː/ and /oː/ was motivated by the existence of vacant slots for /iː/ and /uː/. This is the 'drag chain' theory that originates with Jespersen.

(b) The impulse for the diphthongization of the high vowels /iː/ and /uː/ came from the raising of the high mid vowels /eː/ and /oː/. This is the 'push chain' theory that originates with Luick.

The 'drag chain' position is now mostly of historical interest. Luick's observation that there was no diphthongization of /uː/ in those dialects of northern ME where /oː/ was fronted to /øː/ c. 1300, has been accepted as a good argument in favor of the causal link between the initial raising of the mid-vowels and the diphthongization of /iː/ and /uː/ in the southern dialects. In that sense, the chain linking the high and the mid high vowels is a 'push chain'.

ME	RP	Lon, Aus, NZ	Am. South	
iː~iy	aɪ	ɒi	aː	*bind, wife*
uː~uw	aʊ	æʊ	aː	*cow, crown*

Figure 2

(4) *Stages*: The GVS proceeded in two distinct unrelated stages.

Separating the developments of the long vowels into two distinct stages is a relatively recent addition to the GVS accounts. Earlier, GVS scholarship had assumed that all long vowels were proper participants in a single 'great' chain shift, yet research during the last three decades has shown that only the top two heights of the ME long vowel system were involved in chain shifting. The low mid vowels of southern ME, /ɛ:, ɔ:/ and the low vowel /a:/ began to raise and merge with preexisting /e:~ey/, /o:~ow/ only in the late sixteenth century. The merger of the vowels in e.g. *see* (ME /e:/> /i:/ c. 1550) with the vowel of *sea* (ME /ɛ:/>/e:/ c. 1650) did not begin until the end of the seventeenth century, and continued into the eighteenth century. These later developments are no longer claimed to be part of the chain shift that can properly be reconstructed for the four top vowels in southern standard British English.

In summary, the term GVS is not well defined. It has been applied as a cover term for a variety of often unrelated changes of the southern English long vowels and diphthongs that started in ME and can be shown to continue to this day. In that sense, it includes raisings, diphthongizations, mergers, and minichain shifts within the long vowel system of one language variety. A redefinition of the term GVS, suggested by Lass (1992:153), restricts it to the changes of the original high and high mid vowels [i:, u:, e:, o:] occurring in southern English in the fifteenth to sixteenth centuries. Since the remaining vowels do not participate in chain shifting in a coherent way, and only a minichain shift can be reconstructed reliably, the survival of the term Great Vowel Shift as a synonym for a comprehensive chain shift in the history of all English long vowels is in doubt.

Greek, Modern

Modern Greek is the direct descendant of Koine Greek, the language of the New Testament, which in turn was based on the Attic dialect of Ancient Greek. It is thus part of the Greek or Hellenic branch of Indo-European. The language is called *eliniká* (Hellenic) by its modern speakers. Up until about the end of the last century, the spoken language was also referred to as *roméika* (Romaic) by the common people who spoke Greek as citizens of the Ottoman Empire before 1821 and then after the successful war of independence in 1821–1832 of the Kingdom of Greece. The modern Republic of Greece has Modern Greek as its sole official language. Modern Greek is also one of the two official languages of the Republic of Cyprus (Turkish is the other one). Greek speakers are located mostly in the Republic of Greece itself, with about 10,000,000 living there, but large numbers can also be found in Cyprus (c. 600,000) and parts of the diaspora (e.g. about 1,000,000 in Australia, chiefly in Melbourne and Sydney). Historically, Greek speakers have settled all over the eastern Mediterranean, in Southern Italy, along the Black Sea coasts, in Egypt, the Levant, Cyprus, and much of Asia Minor. This geographical spread continued throughout the Hellenistic period

and on through the Byzantine and Medieval periods, and is valid to some extent even into the Modern era, although most of the Greek inhabitants of Asia Minor (present-day Turkey) were removed to Greece (and many Greek-speaking Moslems from Greece to Turkey) after the population exchanges of the early 1920s in the aftermath of World War I. Within Greece, the greatest concentration of speakers, some 3,500,000 or more, lives in the greater Athens area alone, most of them speakers of the current standard language.

Faced with the difficult problem of distinguishing between dialects of a language as opposed to separate languages, the highly divergent modern form of Greek known as Tsakonian, still spoken in the eastern Peloponnesus (in Greece), could well be considered now as a separate language from the rest of Modern Greek, and the Pontic dialects once spoken along the Black Sea coast of Asia Minor but now spoken in many parts of Greece due to the 1923 population exchanges are divergent enough to warrant consideration now as a separate language from the rest of Greek. Similarly, modern Cypriot shows significant differences on all levels (phonological, morphological, and syntactic) that invite classification as a separate language, although this judgment is perhaps a more difficult one than in the case of Tsakonian or Pontic.

Still, it is customary to treat Modern Greek as a unified language with a range of dialects, much as was the case with Ancient Greek. While the dialect complexity of Ancient Greek was largely leveled out in Hellenistic times with the emergence of the relatively unified variety of Greek known as the Koine (see the chapter on Ancient Greek), the natural forces of language change led to new dialect diversity in the Byzantine period, with the modern regional dialects emerging after about the tenth to twelfth centuries AD. The main exception to this characterization is Tsakonian (as mentioned above), which derives more or less directly from the ancient Doric dialect, although with an admixture of standard Modern Greek in recent years; in addition, the Greek of Southern Italy, still spoken, for instance, in some villages in Apulia and Calabria, seems to have ancient Doric roots. The Pontic dialects (mentioned above) may derive more directly from the Hellenistic Koine.

Stemming from the later Byzantine form of the Koine, the major modern regional dialects are (following Newton 1972) Peloponnesian-Ionian, Northern, Cretan, Old Athenian, and Southeastern (including the Greek of the Dodecanese islands and, traditionally at least, Cypriot Greek as well). Peloponnesian-Ionian has formed the basis historically for what has become the contemporary Standard language, and is the basis for the Greek of modern Athens, as by far the leading population center in Greece; the Old Athenian dialect was the Greek of Athens before the 1821 War of Independence, and is still found elsewhere in Greece due to various resettlements.

A key aspect of the development of Modern Greek pertains to its external history, namely the fact that throughout post-Classical Greek, the language and its speakers were never able to escape the important cultural influence of the Classical Greek language and Classical Greece itself. The importance of Classical Greece—in the Mediterranean, the Balkans, parts of the Middle East, and even Western and Central Europe—meant that Classical Greek was taken as the prescriptive norm against which speakers of later stages of Greek generally measured themselves. This situation led to a 'two-track system' for the language, in which a high-style consciously archaizing variety that speakers and writers modeled on Classical Greek was set against a vernacular innovative variety. After the War of Independence from the Ottoman Empire in 1821 and the founding of a new nation-state of Greece, this distinction crystallized into a significant register and stylistic difference between what has come to be known as *Katharevusa* ('Puristic', literally '(the) purifying (language)') as the high-style variety associated with official functions, i.e. those pertaining to government, education, religion, and such, and *Dimotiki* ('Demotic', literally '(the) popular (language)') as the language of the people in ordinary, day-to-day, mundane affairs. This sociolinguistic state of affairs was the basis for the formulation of the notion of *diglossia* (Ferguson 1959), and struggles between advocates of each type of Greek, carrying with them certain social attitudes and political positions, continued throughout most of the twentieth century. After a number of governmental acts and actions in 1976, *Dimotiki* became the official language, and the diglossic situation was resolved, at least from an official standpoint. Significant for understanding variation in Greek is the fact that all throughout, both the official and unofficial periods of diglossia, speakers' usage was actually somewhat mixed, with borrowing between the two varieties, especially with Puristic forms incorporated into Demotic. The present state of Demotic, what has emerged as 'Standard Modern Greek,' hereafter SG, based on the everyday Greek of the largest city and capital of Greece (Athens), reflects a number of such borrowings from *Katharevusa*, involving both grammar (morphology and syntax) and pronunciation, as well as the lexicon, as discussed below.

Also relevant along with these stylistic/register differences is the effect of orthography. There is a long tradition of written forms of Greek, with the familiar Greek alphabet being the most enduring writing system for the language; as is so often the case, written forms tend toward the conservative, especially with respect to

the representation of pronunciation. There is thus within Greek, especially regarding phonology, a basis for influence from the written language, and the potential for variation therefrom. Moreover, spelling reforms of the late 1970s and early 1980s, leading to the so-called *monotoniko* ('monotonic') system, changed certain aspects of Greek orthography, in particular doing away with several phonetically irrelevant accent marks and diacritics that reflected Ancient Greek orthography; still, the old orthography can be encountered in books published before 1981 and in private use (e.g. personal letters), so that there is variation to be found in the form of written Greek even today.

What the long-term diglossia and associated influence from a written language have meant for Greek is the emergence of dialect differences that are not just regional (geographic) in nature. Rather, there are important socially based distinctions that have been fed by diglossia and by associations between conservative social and political attitudes and conservative linguistic usage on the one hand, and progressive attitudes and innovative linguistic usage on the other. Thus, within Greek one has to reckon with mixing of varieties and borrowing among them of both a regional and stylistic/social nature.

Other types of socially based variation can be found too, although beyond the omnipresent one based on the Katharevusa vs. Dimotiki distinction. From a functional standpoint, mention should be made of the existence of certain institutionalized trade jargons, e.g. that of coppersmiths, and several varieties of 'disguised languages' (e.g. one involving switching of syllables in a word with some distortions of vowels). Especially well known in this regard is καλιαρντά/kaliar^θ da/, the dialect of the gay community that is characterized especially by a large number of Turkish loanwords and divergent meanings for SG words (see Petropoulos 1971). One might also mention here conventionalized child-language forms (e.g. with s/z for SG dental fricatives T/Δ□, and various lexical items, as for bodily functions) that all (adult) speakers know and are able to use in appropriate situations (e.g. talking with young children).

Also of importance for the issue of the mixing of varieties in Greek is the presence of other languages in Greece and in the territory surrounding Greece in the Balkans down through the ages and even into modern times. These circumstances have led to the steady entry of numerous foreign words into Greek over the years, from Balkan, Middle Eastern, and more recently Western European languages, setting the stage for variation in the use and integration of loanwords on the part of Greek speakers. In the modern era, there have been periods of reaction against the influx of loanwords, with sometimes Italian but especially Turkish words being the prime targets for purging and replacement by 'native' Greek elements. These efforts have met with varying degrees of success, but in any case there are still large numbers of Turkish words in the language today, especially at the most colloquial and everyday levels of usage.

Thus, for a number of historical reasons having to do in large part with the geographic distribution of Greek speakers and with the particular circumstances of the relationship of later Greek speakers with their cultural past and heritage, Modern Greek today shows considerable variety in its realizations. Regional differences cut across social differences, and all this has come despite the existence in most periods of various strong centralized standard forms of the language (e.g. archaizing varieties in Medieval and early modern times, the demotic standard of today, etc.) that have provided norms for prescriptive usage.

As far as the linguistic structure of SG is concerned, it would perhaps be useful to draw a quick comparison between the most widely studied Classical Greek (see entry) and its evolution into Modern Greek. In terms of its phonology, Ancient Greek voiceless aspirated stops /t^h/ (θ), /p^h/ (φ), /k^h/ (χ) and voiced unaspirated stops /d/ (δ), /b/ (β), /g/ (γ) have changed to voiceless fricatives /T/ (T), ,/f/ (φ), /x/ (χ) and voiced fricatives /Δ/ (δ), /v/ (β), and /⊗/ (γ), respectively, making SG a language with a very rich fricative inventory. Vowel length is lost and all of the Ancient Greek diphthongs have been monophthongized in the modern language (e.g. AG /ei/, /oi/ becoming SG /i/, AG /ai/ becoming SG /e/, etc.). Furthermore, many AG vowels and diphthongs (e.g. /v/, /η/, /vι/, etc.) ended up pronounced as /i/ in SG, a phenomenon sometimes referred to as iotacism. SG has also lost pitch accent, which has been replaced by lexical (dynamic) stress. Aspiration /h/ has also been lost, and voiced stops have been developed anew, usually arising from voicing of voiceless stops when found after nasals or from borrowings (e.g. AG /pente/ 'five' giving SG /pe(n)de/ or /duvari/ 'wall' from Turkish). In terms of syntax, the modern language retains the free word-order capabilities of AG since most of the morphology and the inflections have been retained. Adjectives normally precede nouns, and definite articles have to accompany proper nouns like in Ancient Greek (e.g. *o giorgos* 'the George'). The dative case has been completely replaced by genitive and accusative and many AG monolectic verbal forms have been replaced by periphrastic constructions (e.g. AG *eureka* 'I have found' has become SG *exo vri*). The infinitive form of the verb has also been lost, reflecting perhaps a Balkan pattern of language contact.

GIORGOS TSERDANELIS

Greenberg, Joseph Harold

Joseph H. Greenberg was one of the most original and influential linguists of the twentieth century. Educated at a time when there were virtually no linguistics departments, he pursued studies in classics, anthropology, Indo-European comparative linguistics, and philosophy. Greenberg also shaped the empirical scientific study of linguistics, emphasizing the examination of a broad range of languages across the world in the development of theories of language structure, language change, and language classification.

Greenberg's earliest major work was on the genetic classification of the languages of Africa. Prior to Greenberg's work, the languages of Africa had been classified into five families, but the classification used inappropriate linguistic evidence and also nonlinguistic evidence. Greenberg established three fundamental principles in classifying languages. The first is to exclude typological linguistic features. Typological features are patterns of sound only—such as the presence or absence of tones—or of meaning only—such as the presence or absence of sex gender distinctions. The most reliable evidence for genetic classification is the pairing of sound and meaning, especially in grammatical inflections and basic vocabulary. The second principle is to exclude nonlinguistic evidence, such as skin color or cultural traits. The third principle is the simultaneous comparison of the vocabulary and inflections of a large number of languages (mass comparison, later called multilateral comparison).

Greenberg used these principles to classify the languages in Africa into four families: Afroasiatic, Nilo-Saharan, Niger-Kordofanian, and Khoisan. His classification was strongly criticized by established African scholars in Europe at first, but it was ultimately accepted by virtually all African linguists.

While working on the African classification through the 1950s, Greenberg also turned his attention to language classification in Oceania, the Americas, and Eurasia. He published only preliminary results at that time, but he continued to collect evidence, and assembling that evidence took up the last 20 years of his life. In 1971, he published an article presenting evidence that the languages of Papua New Guinea that do not belong to the Austronesian family—the so-called Papuan languages—and other non-Austronesian languages spoken as far afield as the Andaman Islands and Tasmania form a single large family, Indo-Pacific, with 14 major branches and a number of languages of uncertain affiliation. The Indo-Pacific hypothesis was, however, largely ignored by specialists in the Papuan languages. Although few linguists working in the area currently believe that all Papuan languages belong to a single family, a large grouping called the Trans-New Guinea Macrophylum has been proposed by some, and a number of its branches, as well as other accepted Papuan families, correspond to branches of Greenberg's Indo-Pacific family.

In 1987, Greenberg published a book presenting evidence that all of the indigenous languages of the Americas other than the Na-Dene family in the Pacific Northwest and the Eskimo-Aleut family in the Arctic belong to a single family, Amerind, with 11 major branches. This proposal has also been strongly criticized and stimulated a lengthy debate on the methods and principles of linguistic genetic classification, to which Greenberg contributed until his death.

The central criticisms of Greenberg's methods are that a genetic family cannot be established without reconstructing the ancestral language of the family; without doing so, it is impossible to determine whether resemblances in inflections and vocabulary are due to chance or borrowing, and whether the results are affected by errors in the transcription of the data. Also, since reconstruction is progressively more difficult as time depth increases, one cannot prove genetic hypotheses for families older than about 8,000 years. The conclusion of

413

most of Greenberg's critics, therefore, has been not so much that Greenberg's hypotheses are wrong, but that they are not provable in principle.

Greenberg argued in response that one cannot reconstruct a family without a prior hypothesis as to which languages form the family, since the number of possible groupings of even a small number of languages is astronomically high; and that genetic classification is only the first step, to be followed by reconstruction. Greenberg also argued that the probability of many languages simultaneously displaying similarities in form and meaning is so high that chance resemblances (and the interference of errors) decrease in likelihood. Greenberg also argued that borrowing displays specific probabilistic patterns that can be detected, and that differences in the relative stability of basic vocabulary and grammatical inflections mean that one can identify families older than 8,000 years.

The debate is not yet resolved, in part because it requires the use of quantitative techniques not yet applied to the problem. However, one can safely say that Greenberg's work has revived a subfield of linguistics that had been dormant for several decades, and has stimulated new research in language classification, language contact, and historical linguistics. Greenberg's work has also brought linguistics into contact with anthropology and genetics. Greenberg's three-family linguistic hypothesis for the Americas found parallels in research on human dentition and genetics, and geneticists such as Luigi Luca Cavalli-Sforza have compared Greenberg's deeper linguistic classifications to genetic evidence on prehistoric human migrations.

Greenberg published evidence for a family in Eurasia consisting of seven branches: Indo-European, Uralic-Yukaghir, Altaic, Japanese-Korean-Ainu, Gilyak (Nivkh), Chukotian, and Eskimo-Aleut. This work, is as controversial as his Amerind hypothesis.

Greenberg's other major line of research, also begun in the 1950s, is in the area of typology and universals of language. Typology began as the study of the range of different structural types of languages, according to their grammar (morphology and syntax) or their sound system (phonology). Languages vary considerably in structure. Greenberg linked typology to the study of universals of language through the discovery that structural variation across languages was limited, and those limits can be described in terms of implicational universals. An implicational universal is a universal of language formulated as an if–then statement, as in 'If a relative clause precedes the noun in a language, then a demonstrative adjective also precedes'. An implicational universal describes a relationship between two structural properties of a language; but it also allows for cross-linguistic variation in language type. For example, the aforementioned universal allows for language types in which the demonstrative precedes and the relative clause follows, and for both modifiers to precede or follow; it only disallows the type in which the relative clause precedes and the demonstrative follows.

Greenberg's first major publication on language universals proposed a series of universals of word order and morphological categories. The paper used a sample of 30 languages and the proposed universals were inferred from the distribution of languages in the sample among possible structural types. Among other things, the paper introduced the language types based on the relative order of subject (S), verb (V), and object (O), such as SVO, SOV, etc. This paper is one of the most cited papers in linguistics, and Greenberg's word-order types have been used widely in all theoretical approaches to linguistic analysis.

Greenberg's method of deriving universals became the fundamental method of the typological approach to grammar, and the typological approach was often compared to the generative approach of Noam Chomsky. The typological approach to grammar is characterized by: cross-linguistic comparison of a sample of genetically and geographically diverse languages; classification of the languages into types based on their structural properties; the inductive derivation of language universals by examining attested vs. unattested (or very rare) language types in the sample; and explanation of the universals, usually by appeal to functional motivations (semantic, pragmatic, discourse-functional, or processing principles).

Greenberg's paper on word order was only one of many typological studies that he produced. Many of these studies pertained to sound structure: on the consonant–vowel dichotomy, consonant clusters, glottalized consonants, and word prosodic systems. Others were concerned with grammar: besides word order, Greenberg produced studies of numeral systems and of a typological interpretation of the concept of markedness and markedness hierarchies in inflectional categories.

In the 1960s, Greenberg became more interested in universals of language change, which he christened diachronic typology. Greenberg produced a series of seminal methodological papers in diachronic typology, and also a number of studies of universals of language change, including voiceless vowels, numeral classifier constructions, and gender marking. The last study helped begin the revival of the study of grammaticalization—the evolution of grammatical categories and constructions from independent words and syntactic patterns. Grammaticalization theory is now a central area of research in historical linguistics and typology.

Greenberg's seminal methodological and empirical papers in typology and universals, including diachronic typology, created the foundations of several major contemporary strands of linguistic research. Greenberg also made significant contributions to African linguistics,

sociolinguistics, and psycholinguistics. Although the fate of his genetic classifications is still being debated, Greenberg's legacy in the empirical, cross-linguistic study of language universals and language change is undoubtedly secure.

Biography

Joseph Harold Greenberg was born in Brooklyn, New York on May 28, 1915; he married Selma Berkowitz on November 23, 1940. He received his B.A. (1936) from Columbia University and Ph.D. (1940) for his dissertation on the influence of Islam on the Hausa, tutored by Melville Herskovits, Northwestern University. He was with the US Army Signal Intelligence Corps, 1940–1945; Assistant Professor, University of Minnesota—Minneapolis, 1946–1948; Assistant Professor, 1948–1953, Associate Professor 1953–1957, Professor, 1957–1962, Columbia University; Professor, Stanford University, 1962–1985; and Ray Lyman Wilbur Professor of social sciences in anthropology, 1971. He was also Director of African Languages and Area Center, 1967–1978 and co-editor of *Word*, 1950–1954. He was a Fellow of the National Academy of Sciences, the American Philosophical Society, and the American Academy of Arts and Sciences, and a Guggenheim Fellow in 1954–1955, 1958–1959, and 1982–1983. He was also Fellow, Center for Advanced Study in the Behavioral Sciences in 1959–1960 and 1965–1966, and Stanford Humanities Fellow in 1982–1983. He was the First Distinguished Lecturer, American Anthropological Association in 1970 and Hermann Collitz Professor, Summer Institute of the Linguistic Society of America 1987. He was President of the African Studies Association, 1964–1965; Chairman of the West African Linguistics Association, 1965–1966; and President of the Linguistic Society of America, 1977. He received the Haile Selassie Award for African Research in 1967, the New York Academy of Sciences Behavioral Sciences Award in 1980, and the National Academy of Sciences/Academy of Arts & Sciences Talcott Parsons Prize for Social Science in 1997. Greenberg died in Stanford, California on May 7, 2001.

Grice, H. Paul

In the early period of his career, H. Paul Grice participated in Oxford's ordinary language philosophy school. Some of his work is critical of particular analyses of ordinary language philosophers, such as Strawson's analysis of logical connectors (e.g. 'and', 'or', and 'if') and Austin's 'no modification without

aberration' thesis. Nonetheless, Grice retained a distinct interest in 'conceptual analysis' (i.e. the analysis of the possible uses of a linguistic expression) as a privileged, albeit not exclusive, method of philosophical analysis.

The most significant contributions of Grice to linguistics revolve around a broad attempt to reduce semantics to intentionality, via the notions of *meaning*$_{nn}$ and *implicature*. Meaning$_{nn}$ (nonnatural) is opposed to natural meaning. While natural meaning is independent of any intentionality (e.g. the presence of smoke means that there is a fire), meaning$_{nn}$ is defined specifically in terms of the speaker's intention that the hearer recognize his or her intention to mean something. The original formulation of the idea underwent several reformulations under the pressure of several counterexamples (Schiffer 1972), but the following is particularly perspicuous: the utterer (U) of an utterance *x*, meant something, if U uttered *x* intending, given an audience (A),

(1) A to produce a particular response *r*
(2) A to think (recognize) that U intends (1)
(3) A to fulfill (1) on the basis of his fulfillment of (2) (Grice 1989:92).

This M-intention (Grice 1989:105) or 'reflexive intention' (Searle 1969:47) is taken to be the defining feature of meaning$_{nn}$. A significant issue, which seems to have received very little attention (Neale 1992), is that all reformulations of the M-intention fall victim to counterexamples in which the speaker's motives are deceptive. Grice suggests (1989:302–3) blocking out 'sneaky' intentions by stipulating that one cannot mean deceptively. This provides an interesting link between the concept of meaning$_{nn}$ and the cooperative principle, specifically the maxim of Quality (see below).

The conventional nature of the speaker's reliance on meaning$_{nn}$ has been pointed out (Lewis 1969). A potentially problematic infinite regression of 'mutual knowledge' (Lewis 1969, Schiffer 1972) has also been noted. The issue revolves around the fact that the hearer knows that the speaker intended a proposition P, but the speaker must know that the hearer knows that the speaker intended P, and so on. Many have challenged the original definition of the nature of the M-intention on the basis of this alleged infinite recursion. Various solutions have been proposed to this problem. Others have challenged the exclusive reliance on intentions, without use of the conventional (literal) meaning of the utterance (Searle 1969). Grice, in fact, argues that conventional linguistic meaning can be reduced to intended speaker meaning. The meaning$_{nn}$ thesis remains controversial and has in fact been repudiated by some of its early proponents (Schiffer 1987). Others have used Grice's meaning$_{nn}$ and Lewis's con-

ventionality as the basis for a general theory of language in a behaviorist mold (Bennett 1976) or as the foundation of a cognitive theory (Sperber and Wilson 1986).

Grice's intentionalism is not limited to meaning$_{nn}$; on the contrary, he distinguishes between what is said in an utterance (roughly, literal meaning) and what is implied by it. For the latter notion, Grice introduced the neologism *implicature*. Recent work has questioned the division said/implied and introduced a third term (variously labeled *explicature/impliciture*) to denote the aspects of the meaning of an utterance that while not explicitly stated, and hence derived pragmatically, are nonetheless not part of implicature.

In its simplest form, the notion of implicature can be defined as some proposition that while not explicitly stated by the speaker is nonetheless intended by him or her and is understood by the hearer as such. Implicatures may be context-free (generalized) or context-sensitive (particularized). In the former case, they apply in any utterance of a sentence, regardless of the circumstances/context. In the latter, they are sensitive to the context. Both types of implicatures are governed by the cooperative principle (CP), arguably Grice's best-known contribution to linguistics. The CP consists of a general statement:

> make your contribution such as is required, at the stage at which it occurs, by the accepted purpose or direction of the talk exchange in which you are engaged

and of four maxims:

- The maxim of Quality

    try to make your contribution one that is true; specifically
    do not say what you believe to be false
    do not say that for which you lack adequate evidence

- The maxim of Quantity

    make your contribution as informative as is required for the current purposes of the exchange
    do not make your contribution more informative than is required

- The maxim of Relevance

    make your contribution relevant

- The maxim of Manner

    be perspicuous and specifically
    avoid obscurity
    avoid ambiguity
    be brief
    be orderly (Grice 1989:26–27).

The exact relationship between the general principle and the maxims has been the object of controversy. The generally accepted opinion is that the maxims instantiate the principle. Implicatures can be drawn on the basis of the CP by either following its rules or by deliberately and conspicuously not doing so (called *flouting*). If the speaker follows the maxims, then the hearer can assume that he or she is being truthful, relevant, etc. For example, the utterance of 'Mary won the Nobel prize' implicates that the speaker has adequate evidence that she did so. On the contrary, if the speaker is obviously not following the maxims, and makes no attempt at concealing this, then the hearer can seek an explanation. For example, as the phone rings, a speaker says 'I am not here'. Since the violation of the CP is obvious, the hearer considers the utterance relevant to the context (the incoming phone call) and therefore assumes that the speaker does not wish to talk to whoever is calling.

Reactions to Grice's CP have ranged widely. There have been total rejections based on accusations of naiveté or on the grounds that, simply put, people do not generally behave as Grice's CP would predict. These objections can be countered by the observation that Grice does not claim that people are always cooperative. Others have claimed that the CP is prescriptive (i.e. tells speakers how they *should* behave). This view is in error, as stated in the literature, but deserves reconsideration in light of Grice's views on morality. It has been claimed that the CP has been empirically falsified by anthropological evidence and that therefore its universal nature has been falsified, but these claims have been repeatedly refuted. More moderate, but still negative, reactions have embraced the general impetus of the theory but claimed that the CP and/or the maxims were too specific and/or too general and/or too vague. A related criticism is that no explicit procedure is provided to calculate the implicatures. Several authors have remarked that the CP in its original wording is limited to declarative statements and have offered rewordings that broaden its scope to nonindicative and nonassertive utterances. Considerable effort has gone into attempts at formalizing the individual maxims, especially the maxim of Relevance, within the framework of Relevance Theory, and the maxim of Quantity. The judgment on the effectiveness of these attempts is also mixed. Many have tried to determine the criteria for deriving conversational implicatures and distinguishing them from other semantically related propositions, such as presuppositions. It has been suggested to reduce the maxims to two or even one principle, often based on processing constraints, thus linking to the functionalist tradition (e.g. the principle of least effort). Conversely, there have been many proposals to augment the CP with more maxims, or even to proliferate principles. Recently, a proposal to augment the CP with a set of heuristics, based on the maxims, has been presented (Levinson 2000). These heuristics generate *generalized conversational implicatures,* which are default implicatures that hold in most contexts.

Overall, however, the critical voices have been drowned out by the sheer mass of those who have silently accepted and incorporated a more or less faithful Gricean distinction between what is said and what is implicated by an utterance. It is fair to say that the distinction has entered the realm of the basic linguistic notion that is part of the curriculum taught to beginners.

In the Californian phase of his career, Grice focused his attention toward ethics (1991). This aspect of his work is not unrelated to the research on the problems of meaning, although most linguistic applications have neglected to assess the connection between the two aspects of Grice's thought. For example, Grice attempted to provide a nonrelativistic, metaphysical foundation for value judgments, such as those of morality. This led Grice to the adoption of a substantialist view of rationality. A substantialist (i.e. noninstrumental) rationality is concerned not only with the rationality of the means to an end but also with the rationality and morality of the ends themselves. The connection with the cooperative principle is thus clear. Another example of connection between Grice's ethics and his semantics is his insistence that the reflexive intention of meaning$_{nn}$ is rational and hence evaluative (1989:283–303).

Biography

Herbert Paul Grice (1913–1988) began his career in his native England where he graduated from Oxford's Corpus Christi College in 1935 and received an M.A. in philosophy from Merton College in 1938. He became a fellow of St. John's College, where he taught from 1939 until 1967 when he moved to Berkeley, California. In 1967, Grice delivered the William James lectures (published partially in 1975 and fully published in 1989), which were widely circulated in manuscript. The widespread interest in the idea of implicature dates back to these lectures. He taught at Berkeley until his retirement in 1979. Between 1980 and 1983, he taught at the University of Washington. In 1983, Grice delivered the Carus lectures on the conception of value, published posthumously as Grice (1991). Significant parts of Grice's writing remain unpublished. The move from Europe to the United States parallels a shift of interests in his work. In the early part of his career, Grice adhered to and contributed to the development of the ordinary language philosophy of Austin, Ryle, and other Oxford

philosophers, although he always maintained a distance from this school. During this period, he worked primarily on problems of meaning. In the second phase of his work, he moved toward issues of ethics and metaphysics. Grice's influence on linguistics is largely restricted to the first phase of his work.

Grimm, Jacob

Together with his brother Wilhelm, Jacob Grimm is perhaps the most influential scholar in the field of Germanic linguistics in the nineteenth century. The sons of a lawyer, both brothers studied law in Marburg, and became interested in the history and traditions of Medieval Germany. Jacob Grimm's first publications, all of which issued from close collaboration with Wilhelm (a constant companion to his brother's life and work), were editions of Medieval texts, and the famous collection of fairy tales (*Kinder-und Hausmärchen*, published starting with 1812).

Research on ancient texts and on oral tradition finally led Jacob Grimm to develop an interest in language change, which at his time mostly meant tracing the history of particular words. Very soon, Jacob Grimm turned to grammatical description. In 1819, he published the first volume of his most important work, the *Deutsche Grammatik*. The title should not be taken as meaning 'German grammar' in a strict sense: the word *deutsch* here is used by Grimm as including all Germanic languages, at all their documented stages.

Grimm conceived of language as an ever-changing phenomenon, which can be studied only through empirical observation. Consequently, he did not only include all early stages of the Germanic languages in his grammar, but also referred to correspondences in other ancient Indo-European languages. For this reason, his work acquired primary importance for Indo-European linguistics, and he is nowadays regarded as one of the founders of Indo-European comparative studies.

Although the *Deutsche Grammatik* included four volumes (after the first, the others followed in 1826, 1831, and 1837), what earned Jacob Grimm his fame in the field of Indo-European linguistics is constituted by the first chapter of the first volume, a later addition to the 1822 second edition, devoted to sound structures. In this chapter, called in the German original text *Von den Buchstaben*, Jacob Grimm set out to provide a description of correspondences in the pronunciation of words, based on comparative research and following his conviction that pronunciation is autonomous from the rest of grammar. Grimm decided to add this important chapter after reading Rask's Icelandic grammar, in which Rask described what was later to be known as the 'first sound shift' (*erste Lautverschiebung*) or 'Grimm's Law'.

Although Rask must be credited with having been the first to understand the sound change that now bears Grimm's name, Grimm had already demonstrated his own insight into sound change in the description of particular vowel alternations (*Umlaut* and *Ablaut*) he

gave to G.F. Benecke, the editor of many Medieval texts, in 1816. Grimm observed that, much in the same way as certain Gothic consonants had undergone a one-step change away from the related Greek and Sanskrit, certain High German consonants had moved one step more in the same direction, as exemplified in the following table:

Greek became	p	b	ph	t		d	th	k	g	kh
Gothic which became	f	p	b	th	t	d		h	k	g
High German	b/v	f	p	d	z	t		g	ch	k

Hence, Grimm described consonant shift as a recurrent tendency of Germanic, and called the sound shift from Gothic to High German *zweite Lautverschiebung,* or 'second consonant shift'.

Research on the history of Germanic and other Indo-European languages did not exhaust Grimm's interest in language. Apart from further writings in the field (among which it is worth remembering the *Deutsches Wörterbuch*, started in 1854, again with the collaboration of Wilhelm, and never finished), Jacob Grimm also published an essay on the origin of language (*Über den Ursprung der Sprache*) in 1851. As habitual in the first part of the nineteenth century, Grimm conceived of language evolution as a process of decay from the 'perfect' ancient Indo-European languages with complex systems of inflection to the 'degraded' modern languages that use simpler structures with independent words instead. However, his deep empirical knowledge of language led him to understand that language change did not necessarily impoverish languages, but that, on the contrary, the loss of old categories is compensated by the creation of new ones, and that the latter are not necessarily 'worse' than the former, even if their implementation does not involve the same type of complexity. Thus, Grimm, in a very original way, and partly contradicting his own initial statements, ends up praising English as the perfect combination of Germanic and Latin elements, which make it perhaps the most powerful human language.

Jacob Grimm did not lead the life of a retired scholar: he was active in the political events of his age, and in 1848 he was, for a short time, member of the parliament of the German Republic. Especially because of his research on the history and traditions of the Germanic peoples, he was considered, already in his times, one of the fathers of German culture.

Biography

Jacob Grimm was born in Hessen (Germany) on January 4, 1785. He pursued juridical studies in Marburg under Friedrich von Savigny (1779–1861), then assistant of Savigny in Paris in 1805. After various appointments in Kassel, he returned to Paris as a representative of the Prussian diplomacy and took part in the Vienna Congress in 1815. From 1816 to 1829, he worked in Kassel as a librarian. From 1830 to 1837, his first appointment was as a professor in Göttingen. In 1837, he lost his position as a consequence of having protested against the revocation of the constitution and returned to Kassel. In 1840, he became a member of the Prussian Academy of Sciences in Berlin. He moved to Berlin in 1841. He died in Berlin on September 20, 1863.

Guaymí and Chibchan Languages

The Chibchan languages are spoken in a wide area extending from Northeastern Honduras, through the Atlantic Coast of Nicaragua, most of Costa Rica, Panama, Colombia, and the West of Venezuela. This language family constitutes the largest family in Central America and Colombia, and the best-studied family of

the linguistic area known as Intermediate. The name *Chibcha* stems from the civilization established around Bogotá (Colombia) at the time of the Spanish conquest; its language, also known as Muisca, was a member of this family. The term Chibcha has been used in many cases as a 'ragbag' for languages whose affiliation to other (larger) families is uncertain. In the past, languages as disparate as Paez (Ecuador), Tarasco (Mexico), members of other families (e.g. Carib, Aztec), and even languages from as far as Chile (Atacama) and Argentina (Allentiac) have been labeled 'Chibcha'. Recent, modern glottochronological studies, in which parallelisms between languages are used to date a potential ancestor language, have yielded a less extensive family.

The geographic distribution of the family has given rise to some controversy. The fact that only a few members are spoken in the peripheral north has given rise to two views: the Theory of North Migration and the Centrifugal Expansion Theory. The former posits Colombia as the epicenter of the Chibchan languages, from where northbound migratory movements took place in relatively late times (the name *Chibcha* applied to the whole family mirrors in this view). Glottochronological studies, however, do not seem to back up this position (which is not based on linguistic data anyway), but tend to favor the latter, according to which the original Chibchan territory was the present-day border zone between Costa Rica and Panama, at the Talamanca mountain range, which cross-cuts that border; from there, migratory movements both northbound and southbound took place. Recent anthropological research tends to back the Centrifugal Expansion Theory. The Chibchan languages are thus Central American languages.

There are 24 members in the family, eight of which are now extinct: Huetar (Costa Rica); Dorasque and Chánguena (Panama); Muisca, Duit, Atanques, Catío, and Tairona (Colombia). Others are facing imminent extinction, e.g. Paya (Honduras), Rama (Nicaragua), Guatuso, and Boruca (Costa Rica), having less than 300 speakers. The majority of the living languages have an average of 3,000 speakers and are, at least temporarily, not seriously threatened by extinction.

The living members, their geographic distribution, and the number of speakers follow (with alternative names in parentheses):

Paya (Pech)	Honduras	600
Rama	Nicaragua	24
Guatuso (Maleku)	Costa Rica	365
Bribri	Costa Rica	6,000
Cabécar	Costa Rica	2,500
Boruca (Brunca)	Costa Rica	4
Teribe (Naso)	Costa Rica, Panama	1,500
Guaymí (Ngäbére,Movere)	Costa Rica, Panama	150,000

Bocotá	Panama	2,500
Cuna	Panama, Colombia	70,000
Ika (Bíntucua, Arhuaco)	Colombia	7,000
Damana (Arsario, Malayo, Guamaca)	Colombia	1,500
Kogi (Cágaba)	Colombia	8,000
Tunebo (UwCuwa)	Colombia	1,800
Chimila	Colombia	900
Barí (Motilón)	Colombia-Venezuela	2,000

There seem to be light differences between the languages of Colombia and those of Central America in a few respects. Languages in Colombia seem to use more auxiliaries and agreement markers. Clause connectors as part of verbal morphology are absent in Central America (except in Rama), but present in Colombia. All these differences point to a more elaborate verb structure in Colombia than in Central America.

Central America is a convergence zone. Two cultural and linguistic areas meet there, that known as Mesoamerica and the so-called Intermediate Area. In general, the Mesoamerican languages (Mayan, Aztec) exhibit a verb-initial basic word order pattern of V(erb)–S(ubject)–O(bject) or VOS, they have prepositions, a possessed–possessor and an adjective–noun order; the languages of the Intermediate Area (including Chibchan), on the other hand, are SOV, they have postpositions, and possessor–possessed and noun–adjective orders.

Structural Features

Basic Word Order

The default word order in Chibchan is exceptionless: Subject–Object–Verb. The other possible orders occur under the following conditions: (a) use of pronouns, (b) subject occurring in postverbal position; and (c) implied subject. Option (a) provides the widest range of possibilities. If the verb carries agreement markers identifying both subject and object, the word order is relatively flexible: s–o–V (see (1) below), o–s–V (see (2) below), or o–V–s (see (3) below), but not s–V–o:

(1) *mu-nu-pash-ka*   DAMANA
  you-me-hit-FACTUAL
  'You hit me'

(2) *ma ni-sung-u*   RAMA
  you I-see-PAST
  'I saw you'

(3) *mi-tšua-na-rua*   IKA
  you-see-far-I
  'I saw you'

As for alternative subject position (b), in some languages it can be placed postverbally; the object

Geographic Location of the Chibchan Languages.

appears in sentence-initial position for highlighting purposes, as in Cabécar:

(4) *tkabë su-wá*   *ét-aba*   *yís të*
     snake
     see-PERFECTIVE
     one-long   I
     'A snake I saw'

The implied subject realization (c) is illustrated in (7) below.

Word Classes and Parts of Speech

There are two basic types of lexical words in Chibchan, around which most of the grammatical features and categories revolve; these are nouns and verbs. A second set of word classes is formed by adjectives and adverbs; these are second to the former in that although there are clearly identifiable adjectival (colors and basic qualities) and adverbial (time and manner) roots, their number is not that large, and most other adjectival and adverbial concepts are expressed by other means (deriving adjectives/adverbs from noun or verb roots, using phrasal expressions, etc.).

Nouns and Nominal Morphology

The most common type of determiners are numeral classifiers, forms used to categorize nouns exclusively in the context of quantification; these are found in the languages of Costa Rica and Panama. The existence of numeral classifiers in the Chibchan languages is the result of the evolution of certain classes of nouns used to form lexical compound nouns in the assumed common ancestor (proto) language; the position of the numeral form in relation to the noun (prenominal vs. postnominal) in Proto-Chibchan determined the for-

mal status of the class markers either as prefixes, as in Teribe, or as suffixes, as in Bribri, Kogi, or Cabécar. Most languages with noun classifiers have around five classes—some have more: animate, long, round, thin, human; in most languages, those classifiers are free forms, i.e. words that can stand independently. Teribe, for example, has six classes: (a) prototypically animate objects; (b) round objects; (c) wide objects; (d) long objects; (e) long and wide objects; and (f) objects that can be counted in plots. The expression of each of the classes is effected through prefixes attached to a numerical base. For example, the base for the number one is *ara*, to which the class marker prefix is added: *kl-ara* (animate), *kw-ara* (round), *k-ara* (wide), *pl-ara* (long), *kwan-na* (long-wide), and *kri-na* (plots).

The Chibchan languages use demonstrative determiners, which are free forms, to express spatial relationships. The languages can be grouped into those that have three degrees of spatial distance (Teribe, Rama, Cuna, Kogi, Damana) and those that have two degrees (Boruca, Ika, Tunebo). These languages can also be divided in terms of the determiner's position relative to the noun, as prenominal (Rama, Guatuso, Boruca, Cuna) and postnominal (Teribe, Bocotá, Bribri, Cabécar); one language, Guaymí, allows both orders.

The Chibchan personal pronouns exhibit two basic traits; (a) with the exception of Rama, the free pronoun sets are formally indistinguishable for the core cases (subject and object), and (b) free personal pronouns are generally used for emphasis. This rather limited use of personal pronouns has to do with two other pervasive features of these languages, namely the use of implied subjects/objects and, in most members, cross-referencing mechanisms.

Where the word forms do not identify subjects vs. objects, verbal affixes help to disambiguate, as in (5), where the verbal suffix marks the subject:

(5)   *lanyo kwe*   TERIBE
      *midë-**rwa** llëme*
      story DEMONSTRATIVE know-we not
      'We don't know that story'

Another strategy is to use particles identifying the subject or topic, in combination with word order:

(6a) *At **ki** ba ishd-ra*   BORUCA
      I SUBJECT YOU see-PRESENT
      'I see you'
(6b) *Ba **ki** at ishd-ra*
      you SUBJECT I see-PRESENT
      'You see me'
(6c) *At ishd-ra ba-ng*
      I see-PRESENT you-TOPIC
      'You see me'

A very conspicuous feature of Chibchan is the existence of forms expressing the status of participants as topic (what the sentence is about) or focus (new information). Such markers combine with word order to create a wealth of foregrounding structures similar in function to such mechanisms as passives or left/right dislocations in other languages. In Teribe, the topic marker is li (7); there are two focus markers, *om*, *omgo* (8a, b), and one contrast marker ra (8a):

(7)   *tlɛ) lok ga 'walë kuzong ga walë **li***'
      say PLURAL that
      'woman then that woman TOPIC
      yo-y-dë'
      appoint-we-will'
      'Then they said, 'well then, if
      it's a woman, a [this] woman
      we will appoint'
(8a) *Kone kone **om** wuë, pero kone*
      *kone **om** wuë un llëme...*
      Some FOCUS eat, but some FOCUS
      eat all not ...
      *tawa **ra om** wuë llëbo un.*
      we CONTRAST FOCUS eat thing all.
      'Some eat THEM, but some
      [others] do not eat THEM...
      WE DO eat THEM ALL'
(8b) *E tle) ga e **omgo** twa-ydë*
      DEMONSTRATIVE say CONNECTIVE
      DEMONSTRATIVE FOCUS come-will
      'He said HE is the one
      who is coming'

Verbs and Verbal Morphology

T(ENSE)A(SPECT)M(OOD) systems are abundant and in some cases highly elaborated. Some languages do not overtly distinguish tenses; tense-marking languages are Rama, Guatuso, Cuna, Kogi, and Tunebo. Some tense-marking languages also have aspectual distinctions (Rama, Kogi); others (Tunebo) have only tense.

In most Chibchan languages, the most basic TAM distinctions are expressed by bound morphology (affixes), not by free-standing auxiliaries. Auxiliaries are mainly found in the languages of Colombia, as in Kogi:

(9)   *Nac gu-ngu-cu-aini-ki,*   *yatai*
                                        na-gu-cu-a
      come do-PAST-I-and-then,   sit CERTAINTY
                                        do-I-PAST
      'I came and then I sat down'

In some Central American languages, there are positional verbs, a closed set of linking verbs specifying location and manner of the location (standing, lying), as in Bribri:

(10) *ie? dur âula a*
      he POSITION.STAND classroom in
      'He's standing in the classroom'

Teribe has seven positionals (*löng*, *shäng*, *pang*, *buk*, *sök*, *jong*, *lok*). The remarkable fact about these positionals is that sentences expressing actions and movement are often ungrammatical if they lack such a positional:

(11a) *Tawa shro-no löng na*
      we arrive-PERFECTIVE
      POSITION.BE here
      'We came here'   (ungrammatical
                                        without *löng*)
(11b) *ëng wle) -no löng e wlo*
      each other meet-PERFECTIVE
      POSITION.BE DEMONSTRATIVE
      in order to
      'for us to meet'   (ungrammatical
                                        without *löng*)

Person Markers (Agreement)

The Chibchan languages fall into three groups in terms of agreement: (a) those that have no agreement (Bribri, Cabécar, Boruca, Bocotá, Guaymí, Cuna, Tunebo); (b) those with subject agreement (Rama, Teribe); and (c) languages with both subject and object agreement (Guatuso, Ika, Kogi). A special case is Damana, which has verbal agreement markers for the indirect (dative) object in addition to agreement for the subject and the direct object.

Grammatical Relations

Seven languages have nominative–accusative case-marking, where nominative case marks the subject and accusative the (direct) object: Paya, Rama, Boruca, Teribe, Cuna, Chimila, and Barí.

Ergative Systems

Eight languages (Guatuso, Bribri, Cabécar, Guaymí, Ika, Kogi, Damana, and Tunebo) use ergative–absolutive case-marking, where the subject of an intransitive verb patterns with the direct object of a transitive one (abso-

lutive), while the subject of a transitive verb is marked with ergative case.

(12a)   *ie$^{?}$-r*   *dìwö s$\underline{a}$-w$\underline{e}$*   BRIBRI
         she-ERGATIVE   sun(ABSOLUTIVE)   see-PERFECTIVE

         'She saw the sun'

(12b)   *dìwö*   *mìchò*
         sun(ABSOLUTIVE)   go
         'The sun goes'

An important property of some of these languages is that the ergative marker may only be used when it is needed for emphasis.

Active/Nonactive Systems

One language, Bocotá, appears to follow an active/nonactive pattern. Direct marking is used to mark the active subject by *no*:

(13a)   *Cha no*   *gliá*   *gúg-le*
         I   ACTIVE   leaves   burn-PERFECTIVE
         'I burned leaves'

(13b)   *Cha*   *gugé-du*

         I   burn-PERFECTIVE
         'I burned'

(13c)   *Gliá*   *gugé-du*
         leaves   burn-PERFECTIVE
         'Leaves burned'

Gullah

Gullah, sometimes also identified as *Geechee* or *Sea Island Creole*, is an American English creole spoken in coastal South Carolina and Georgia. It is not the only variety of American English that developed from contact with another language, but it is the only one that has been singled out as a creole. It shares several structural features with Caribbean English vernaculars that have also been called creoles. Like the latter, it developed on plantations where African slaves outnumbered the European indentured servants and other colonists with whom they interacted.

Gullah differs from African American Vernacular English (AAVE, 'Black English') in the socioeconomics of its development as well as in some of its structural features (including a speech melody that is closer to that of Bahamian and Caribbean Englishes). For instance, in Gullah one can form the progressive with the preverbal marker [də] (spelled *duh* or *da* in 'eye dialect'), as in *he duh/da talk(in)* 'he is talking', but not in AAVE. Gullah developed on the coastal rice fields, where the African slaves were in the majority from the early eighteenth century to the mid-nineteenth century (the Civil War and the abolition of slavery). No such vernacular evolved on the tobacco and cotton plantations, where the Africans were generally in the minority and were not segregated from the European majority until the late nineteenth century. Geographical and social isolation from mainland America until the mid-twentieth century helped preserve Gullah to this day as quite distinct from other American offspring of English.

It took coastal South Carolina colonists 30 years or so from the foundation of the colony in 1670 to shift from the homestead type of residence, characterized by no race segregation, to a partial plantation society, in which segregation was institutionalized as early as the mid-eighteenth century. (Virginia, which was founded in 1607, had not shifted to a largely agricultural economy, with tobacco plantations, until the end of the seventeenth century, either.) It also appears that, except for coastal Georgia (which patterned its economic and social development on South Carolina), in the rest of the southeastern English ex-colonies segregation was not institutionalized on a large scale until the late nineteenth century, after the passage of the Jim Crow laws.

This difference in the timing of segregation explains partly why Gullah has developed more non-standard characteristics than AAVE. It had a separate evolution, in which African languages exercised a greater influence on the integration of English materials into the emerging dialect. With a few exceptions, the vast majority of structural peculiarities associated with AAVE are shared by other American dialects, and the most significant differences between black and white forms of American English are statistical. In contrast, few of the features associated with Gullah are attested in other North American English vernaculars, although the features have definite English origins too. In areas inland from the coast, segregation was institutionalized after over two centuries of intimate coexistence of (descendants of) Africans and low-class Europeans, after many structural features had become entrenched in both their communities' dialects. Later changes associated today with differences between them remain minimal.

The development of vacation resorts in coastal Georgia and South Carolina and the urbanization of some of the Sea Islands has fostered residential patterns similar to those that have preserved AAVE in mainland cities. The affluent in-migrants, who are predominantly white, have settled in their own parts of the Islands. They have not interacted regularly with the Gullah populations who preceded them there by two and a half centuries.

There is arguably a geographical and structural continuum in African American speech from the South Carolina and Georgia coast through the mainland Southeast. Accordingly, Gullah represents the variety that is the most different from mainland white vernaculars. After all, although their sentence melodies are clearly distinct, Gullah and AAVE share quite a few features, such as constructions without the copula *be* (e.g. *she Ø pretty* 'she [is] pretty'); use of the negative *ain(t)* not only to mean 'be not' (e.g. *he ain crazy*) but also 'have not' or 'did not' (e.g. *he ain go/gone there* 'he has not gone there', 'he did not go there'); habitual *be* (e.g. *they be havin company* 'they are/were USU-ALLY IN THE PROCESS of having company'); and emphatic PERFECT with *done* (e.g. *she done gone* 'she has/had ALREADY gone'). (This is not to say that these peculiarities definitely did not grow out of English usages; but they have clustered in a way that makes African American speech distinct from other American nonstandard vernaculars.)

The geographical continuum hypothesis does not apply to Gullah alone, but also to White Coastal Plantation English, which is distinct from American White Southern English. One could thus also argue that Southeastern American English vernaculars are basically plantation varieties. Differences among them

have resulted from the kind of plantations on which they developed and the kinds of social contacts that were obtained across race boundaries on these plantations. The coastal vernaculars are rice-field phenomena, distinct from those that developed on the tobacco and cotton plantations.

From one evolutionary point of view, Gullah is considered the most extensively restructured variety of North American English (i.e. it shows the greatest influence of its creators' ancestral languages). However, this judgment reflects a traditional bias against all colonial vernaculars that took their vocabulary from European languages and were appropriated by descendants of Africans. It also reveals how little we yet know about vernaculars such as Old Amish English and Cajun Vernacular English, which developed from appropriations of English by isolated groups of proletarian continental Europeans. The opinion is also undermined by the absence of a reliable yardstick for assessing the extent of restructuring. Every North American English variety has developed from the contact of English dialects with each other (hence they too are restructured varieties) and with other languages, especially languages from Europe.

This restructuring-through-contact puts other American English vernaculars in the same category as Gullah and AAVE. It makes the often-invoked argument of mutual intelligibility (according to which Gullah is not intelligible to most European Americans) only one-sided and largely a reflection of the fact that Gullah developed from contact with languages that happened not to be European. There is little wondering about why the varieties that developed from the contact of English with other Western European languages (before the massive nineteenth-century immigrations from Central and Eastern Europe) are to some extent mutually intelligible, even though familiarity with a particular variety is an important factor in all such claims. Contacts of typologically similar varieties in similar ethnographic settings produced similar dialects, although listeners' attitudes toward particular speakers affect their ability to understand them. Future research may very well reveal that Gullah holds the most retentions from colonial English, although not necessarily in their pristine forms. An important factor in comparing vernaculars is that their features often originated in different English varieties. Neither they nor Gullah, as systems, could be claimed to be comprehensive retentions of any particular British English dialect.

There are no records to show how distinct Gullah was from AAVE before the nineteenth century. However, there is literary documentation of undifferentiated, stereotypical black speech, with pidgin-like features, since the early eighteenth century. This sug-

gests that a distinct variety of English was spoken by some African slaves in English colonies, but it does not confirm that Gullah as a distinct ethnic variety had already developed. Advertisements concerning runaway slaves in the mid-eighteenth century reveal that English among the African slaves varied from varieties close to those spoken by white colonists to others that were quite different, which may be assumed to be the beginnings of today's Gullah. Reports of 'fluent' or 'acceptable' command of colonial English generally correlated with whether the slave was American-born, was imported young to the colony, or, if imported as an adult, had lived here long enough. The absence of literary or other records of a divergent speech of Africans in the seventeenth century can be interpreted to suggest that no singularly African American vernacular was evident then. The generally nonsegregated living conditions of the time, with the colonial populations growing more by birth than by importation, lead to this conclusion.

The lack of reports of divergent speech suggests in fact that Gullah must have followed an evolutionary path similar to those of other colonial English vernaculars, differing from them essentially in the details of the restructuring process. The differences can be correlated to the following factors: The homestead phase during which the nonnative, non-European speakers were in the minority did not last long, only about 30 years after the founding of the South Carolina colony in 1670. This is a period during which the Africans were integrated into small family farm communities and interacted regularly with Europeans. Both European American and African American children spoke the same colonial koiné as vernaculars. By 1720, the population of African descent was double the population of European descent, and on the emergent plantations on the coast, the Africans became the overwhelming majority, often at a ratio of 9 to 1 by the late eighteenth century. The early institutionalization of race segregation forced the Africans to socialize primarily among themselves. The shift to rice cultivation as the primary colonial industry brought about some demographic changes, chiefly rapid population growth by importation of new labor while the mortality rate was high. Increasingly, language was transmitted to newcomers by nonnative 'seasoned' slaves, a factor that enabled more restructuring under dominant influence from African languages. This evolution may account for why Gullah has certain grammatical characteristics not found in other American dialects, including AAVE. As noted above, the development of Gullah must have started in the eighteenth century. However, it is not clear what its actual grammatical system was like then, especially how much it diverged from other colonial English vernaculars.

The features that distinguish Gullah from AAVE are not necessarily of non-English origin. For instance, the HABITUAL marker [dəz] (spelled *duhz*) is well attested in some British nonstandard vernaculars and in Newfoundland Vernacular English. Even the fact that Gullah has the option of expressing the PROGRESSIVE with [də] before the verb, and with *a* when the verb also has the ANTERIOR marker *bin* (as in *he bina talk* 'he was talking'), does not necessarily suggest that these characteristics stem from African languages. While African languages must have exerted some influence in the selection of specific particles that occur before the verb to mark tense and aspect, the forms themselves have typically been inherited from English.

It seems very helpful indeed to make a distinction in scholarly debate between the origins of features and the influence that determined their integration into the developing dialect. This is more obvious in Gullah's sound system, where one comes across sporadic uses of [ß] as a variant of [v] and [w], as in [ßɛri ßɛl] 'very well', which also alternates with [vɛri wɛl]. Typologically, the bilabial fricative is highly unusual in the sound systems of sub-Saharan African languages. [ß] is not attested in Caribbean English creoles, where African influence would be more extensive, nor in Caribbean French creoles, which had similar influences. Its counterpart in Caribbean English creoles is [b], as in [bɛks] 'angry' < English [vɛkst]. This suggests not necessarily the absence of [v] in some African languages, but primarily the inability of those who made the creoles to reproduce [ß], which is attested in Irish English and must have occurred in colonial English. The fact that Gullah has [ß] in alternation with the English variants [v] and [w], just like the fact that it has the schwa (unlike Caribbean English creoles), reflects peculiarities of the sociohistorical conditions under which it evolved.

African influence can, on the other hand, be identified in serial verb constructions, in the associative noun plural *an dem*, as in *Easter (an) dem* 'Easter and her family/friends/associates', and in some other constructions that it shares with AAVE and other creoles. Although serial verb constructions are more diversified in Gullah, these features are also attested in other American and British nonstandard vernaculars. However, their statistical predominance and some of their usage patterns reflect the influence that must have been exerted by some African languages during the development of Gullah.

Gumperz, John Joseph

A blend of scientist, anthropologist, and linguist, John Joseph Gumperz's background is manifested both in his theoretical and applied research.

His research focused mainly on the complex nature of intercultural and interethnic communication or what came to be known as *interactional sociolinguistics*. Contrary to structuralists, who presuppose that human communication takes place in an ideal and nonproblematic context where there is almost no risk of misunderstanding, Gumperz gives substantial importance to the five elements involved in any verbal communicative event (the speaker, the listener, the context, the message, and the channel) using the macrosociological factors to interpret the microconversational effects. After his fieldwork in India, he shifted from purely dialectologist research to conversational analysis, yet without overlooking his early research interests. One of his most influential books, *Discourse strategies*, which appeared in 1982, is a product of both theoretical research in conversational analysis and his long years of fieldwork in India, Europe, and the United States, where he scrutinized both interracial and interethnic conversations. His main concern was with how the participants in a certain conversation behave according to their interpretation of the communicative intent. To answer this concern, he developed the theory of '*contextualization cues*', which he defines in *Discourse strategies* (p. 131) as 'any features of linguistic form that contributes to the signaling of contextual presuppositions'. These features may be prosodic, morphological, syntactic, lexical, or phonological. They may include other conversation behaviors such as turn-taking or code-switching. In the majority of the cases, these cues indicate how the speakers understand every part of the talk as being sequentially connected to both what has been said before and what is going to be said after. When the speakers fail to grasp and use the contextualization cues appropriately, misunderstanding could result and in some cases the communication line may break down even if the speakers shared other linguistic features. Learning another language does not guarantee effective communication unless the speakers are able to interpret the contextualization cues appropriately to keep redefining the context. Contextualization cues, then, are interpretive cues that guide the speakers in their inferential effort in any communicative event similar, in this sense, to the Gricean Maxims of conversation (Grice 1975). While the Gricean Maxims are theoretically applicable to universal communication, the contextualization cues may exist across cultures but they are still partly culture-bound and even conversation-bound.

Gumperz's interpretation of *code-switching* as a contextualization cue has been very significant in shaping later research on this complex sociolinguistic phenomenon. He claims the existence of two types of code-switching: *situational code-switching* and *metaphorical code-switching*. The first is produced when the codes used by the speakers change according to the redefinition of the situation in which they are involved. A common example is when a monolingual speaker joins a conversation already started by bilingual speakers; they would switch to his or her language so as not to exclude him or her. Metaphorical code-switching, on the other hand, is caused by the change in the topic of the conversation without changing the situation. In the following example (Gumperz 1982a:77), the switch to Hindi by speaker **B** shows the rupture with the formal conversation that he was carrying out with speaker **A**. The change in the topic of the conversation stands behind the switch and not the change in the speakers since speaker **C** was present from the beginning.

'A group of Hindi speaking graduate students are discussing the subject of Hindi–English code-switching:

A: Sometimes you get excited and then you speak in Hindi, then again you go on to English.

B: No nonsense, it depends on your control of English.

B: [shortly thereafter turning to a third participant, who has just returned from answering the doorbell] **Kɔn hai bai** (who is it)?'

One of the main explanations for the occurrence of code-switching is the *in-group* vs. *out-group* theory as elaborated by Gumperz (1972, 1982a). He refers to code-switchers as the individual speakers who, for different reasons, find themselves living in an ethnically and culturally diverse setting. This includes the case of immigrants who usually manage to keep their first language (L1) to communicate among themselves in their restricted speech communities, but who find themselves using the majority's language, generally the official language of the host country, basically at work and education. Within the boundaries of the '*in-group*', the individual speaker tends to use the '*we code*', i.e. the L1 of his or her own speech community. An example is Spanish for the Puerto Rican community in New York extensively studied by Gumperz and others. During the interaction with members of the '*out-group*', i.e. members of the majority or any other speech community, the tendency is to use the '*they code*', which is the majority language.

In some cases, the continuous switch back and forth between two codes can be an indicating strategy of the speaker's neutrality with regard to contending parties or ideologies that are associated with different codes. On the other hand, religious or political issues, among others, are often discussed in the code that is most often associated with them.

In his later book edited with S.C. Levinson, *Rethinking linguistic relativity*, Gumperz revisits his theory of contextualization cues to comment on the relationship that language has with thought and culture and the way it shapes our conception of the world. The editors signal the changes in the understanding of the Sapir-Whorf hypothesis and its implication for the theories of linguistic relativity. Here again, Gumperz manages to give equal importance both to the macrosociological and cultural factors and the very specific microconversational features in each communicative event.

Biography

Born in Germany in 1922, Gumperz moved to the United States in 1939 where he received a Bachelor of Science from the University of Cincinnati. He later earned a Ph.D. in German linguistics from the University of Michigan. In 1955, he conducted fieldwork in India. And in 1965, he was appointed as an anthropology professor at Berkeley where he is still an emeritus Professor today.

Since the appearance of his first article early in 1955 ('The phonology of North Indian Village Dialect'), Gumperz has contributed consistently to different publications (Berkeley Cognitive Science Report, The American Journal of Sociology, American Speech, etc.). In addition he has written and co-edited several other influential books including The Ethnography of Communication of (1964), Directions in Sociolinguistics (1972), and Language and Social Identity (1982).

LOTFI SAYAHI

H

Haas, Mary Rosamond

The life and growth of language: *an outline of linguistic science* (1875) by William Dwight Whitney introduced Mary Haas to linguistics, and in 1930, following her undergraduate studies at Earlham College, she set off for the University of Chicago intending to study comparative philology. A class in historical Germanic linguistics taught in German by Leonard Bloomfield did not appeal to her, but when she ventured into the anthropology department where Edward Sapir was elaborating upon the topics he had covered in his book *Language* (1921), she encountered the kind of linguistics to which she would devote much of her career.

She trained as an Americanist, a term used by anthropologists and anthropological linguists for the study of the native languages and cultures of North America. Her first fieldwork was undertaken with her then-husband Morris Swadesh. With support and direction from Sapir, the couple traveled to Vancouver Island in Canada in the summer of 1931 to collect texts and data on Nitinat. Their joint report was Mary Haas's first publication.

In Fall 1931, Sapir joined the faculty at Yale University. Haas, Swadesh, and several other graduate students followed him, becoming the nucleus of the 'Sapir School' of linguistics, focused on the collection of texts and the preparation of descriptive grammars of native American languages, with a strong concurrent interest in the extension of concepts and techniques from comparative Indo-European linguistics to the historical and comparative study of American languages.

As a graduate student, Haas worked on Tunica, a language spoken in Louisiana. 'A Grammar of the Tunica Language' became her 1935 Yale doctoral dissertation; it was later published with revisions in Franz Boas's *Handbook of American Indian languages* (1941) and remains an outstanding exemplar of Sapirian anthropological linguistics. Meanwhile, Haas spent her postdoctoral years as a fieldworker, gathering data on three Muskogean languages, Creek, Koasati, and Hichiti, as well as on Natchez. Her classic study of gender and language, 'Men's and women's speech in Koasati', appeared in 1944 in *Language*, journal of the Linguistic Society of America. Other studies drawn from the data she had collected were published later in her career; much remained unpublished.

World War II brought a new opportunity for paid work, and Haas became the first linguist supported by the Intensive Language Program of the American Council of Learned Societies (ACLS). The goal here was to develop descriptions and teaching materials for lesser known languages of Europe and Asia. She was assigned to work on Thai and when she located native speakers of the language studying at the University of Michigan, she moved there to work with them. Her article 'The linguist as a teacher of languages' (*Language* 1943) discussed how she applied her descriptive linguistic techniques to the development of materials and classroom experiences in foreign language learning. Haas went on to publish more than 20 articles and books on the Thai language, including a textbook and a reader prepared with her second husband, Heng R. Subhanka. Her analyses of various aspects of the Thai language, including its phonology, morphology, and writing system, are notable for their clarity and insight and remain valuable descriptive resources even today.

Following a brief ACLS-sponsored pilot class in Thai at the University of Michigan, Haas moved to the University of California, Berkeley as a lecturer in what was there termed Siamese. She also taught linguistics courses and was instrumental in the development of the Berkeley graduate department of linguistics. In 1953, her colleague Murray B. Emeneau obtained funding for the establishment of the Survey of California Indian Languages, and Mary Haas was appointed as director. This program provided the research center of the department, with graduate students expected to focus their long-term work on a single language, writing a descriptive grammar for a dissertation and preparing a dictionary and set of texts for publication, often in the University of California Publications in Linguistics series.

With the first half of her career devoted to the documentation of languages, Haas returned in the second half to the historical comparison of languages that had initially drawn her to the field. A lengthy 1966 article on 'Historical linguistics and the genetic relationship of languages' became *The prehistory of languages* (1969), her only book on a general linguistic topic. Here, she used her earlier fieldwork on the Muskogean language family, along with data from other native American languages, to illustrate types of language change, problems in genetic classification, and the reconstruction of protolanguages.

Throughout her career, Haas remained steadfast in her commitment to the model of Americanist linguistics developed originally by Franz Boas and then by Edward Sapir. She rejected what she felt was the rigidity of post-Bloomfieldian structuralism and was openly dismissive of some of the linguistic work of her east coast contemporaries. In the later 1950s and thereafter, Haas virtually ignored the developments in generative grammar that dominated American linguistics. She had little interest in studies drawing on English or the languages of Europe, and she believed that linguistic fieldwork was threatened by the use of their own language by generative linguists who relied on their native knowledge for linguistic insights. Haas continued on her own path, documenting the languages of native America, comparing them, and proposing genetic classifications. Toward the end of her career, she began to look back at the history of her specialization. A set of articles on the history of American Indian linguistics is reprinted in a collection of her essays (*Language culture, and history* 1978) and remains a valuable account, sometimes firsthand, of how that field developed in the United States.

Mary Haas was not interested in linguistic theory, but she was fascinated by the data of languages and she conveyed this to her students. Her most lasting legacy is the cadre of some 40 graduate students who, under her direction or with her assistance in the 1950s, 1960s, and 1970s, earned doctorates with work on American Indian languages. Not particularly effective as a classroom teacher, Haas was an inspiring mentor. Her students and their students can still be found in the linguistics departments of American and Canadian colleges and universities, many of them carrying on her Americanist tradition.

Biography

Mary Haas was born in Richmond, Indiana, on January 23, 1910. She earned the AB at Earlham College in 1930 and began her graduate study at University of Chicago in 1930–31. She carried out fieldwork on Nitinat in the summer of 1931 with Morris Swadesh. She went to Yale University in the fall of 1931, and completed her Ph.D. in 1935 with a dissertation on Tunica. She pursued postdoctoral independent research on Muskogean languages and Natchez. In 1941–1943, she pursued research, materials preparation, and pilot teaching of Thai at the University of Michigan under the Intensive Language Program of the American Council of Learned Societies. In 1943–1944 and 1946–1947, she was a lecturer in Siamese (Thai) at the University of California, Berkeley, and in 1947–1952, she was assistant professor of Siamese and linguistics. In 1952–1957, she was associate professor; in 1957–1977, professor of linguistics; department chair in 1958–1964; and director Survey of California Indian Languages (later called Survey of California and Other Indian Languages) in 1953–1977. She retired in 1977. She was visiting professor or fellow at University of Washington, Ohio State University, Barnard College and Columbia University, Australian National University, Northwestern University, University of California, San Diego, University of Georgia, University of Kansas and University of Calgary. She was also Linguistic Society of America vice president in 1956 and president in 1963. She was Guggenheim Fellow in 1964–1965 and concurrently fellow of the National Endowment for the Humanities and the Center for Advanced Studies in the Behavioral Sciences in 1967–1968; she was also elected to National Academy of Sciences in 1978. She received honorary degrees from Northwestern University in 1975, University of Chicago in 1976, and Earlham College in 1980. Haas died in Berkeley, California on May 17, 1996.

Haitian Creole

Haitian Creole is one of the many French-based Creoles that were established throughout the world during France's colonizing period. Creole languages are commonly accepted as being a language that was developed from an earlier, simpler version of that language, called a Pidgin.

Pidgins arose in situations of linguistic need (such as for trade or other economic purposes) between two or more groups of people who spoke mutually unintelligible languages. After a generation or two, the offspring of the original Pidgin speakers tended to develop a more complex language, with a wider range of expressive and social functions. These languages are referred to as Creoles, and their vocabulary is generally based on the lexicon of the colonizing group.

Although Haitian Creole is French-based, it also contains elements of African influences from Wolof, Fon, and Ewe. The basic word order is Subject, Verb, Object (SVO), but typical Creole markers appear in the use of postpositions, articles, and possessives coming after the noun (e.g. *nom-la*, 'man' 'the').

Two theories have been proposed to explain the ultimate origin of Creole languages. The claim for the monogenetic theory is that Creoles all over the world have a common origin; a Portuguese-based pidgin was created in Africa in the fifteenth century. During the establishment of the Creole, the Portuguese and native words were relexified or changed into the lexical items of the colonizing or *superstrate* language. The polygenesis theory suggests that whenever and wherever a contact situation arose between two or more languages, a pidgin was created, which subsequently led to the establishment of a Creole. This theory, however, fails to account for the amazing amount of similarity between Creole languages in widely disparate geographical areas of the world. In addition, Bickerton (1981) promotes the 'bioprogram' as the basis for the genesis of Creoles. Building on the idea of language universals and language simplification processes common to first-language acquisition, Bickerton suggested that humans are genetically programmed to acquire a specific set of linguistic structures, and that these structures are modified later in life as children are exposed to their native language. The commonality among these theories is the acceptance that the superstrate language (French, English, Spanish, etc.) provided the lexical base, while the syntactic elements were organized according to the *substrate* or original language used by Creole speakers.

For the origin of Haitian Creole French, Valdman (1997) claims that the earliest form of a French-based creole appeared first on the island of St. Kitts; this language was subsequently exported to Guadeloupe and Martinique, and then to Haiti. He extrapolates from this diffusion theory to claim that the newest, most

innovative form of a Creole language will be on those islands from which it first came—Martinique, Guadeloupe, and Haiti—and that areas that were later recipients of the language (such as Louisiana) will exhibit more conservative forms of the language.

One reason for language change (from conservation to innovation, for example) is due to the process of *decreolization*. This occurs when the use of the standard form of the superstrate is viewed as prestigious, and the use of the Creole is given low status. Because of the history of colonization and slavery often associated with Creole languages and the people who speak them, this low prestige is exacerbated, and causes a shift toward the use of the standard form of the language. This results in a continuum of varieties: the *basilect*, which is farthest from the superstrate language, the *mesolect*, an intermediate variety between the two, and the *acrolect*, the code closest to the substrate language. This *postcreole continuum* exists in Haiti, and, just as in many areas of the world where Creoles are spoken, speakers often have control over several of the varieties. When and how they use them is often dependent upon social factors such as age, gender, ethnicity, and geographical origins of the speaker and hearer. In addition, identification as Haitian often drives the use of the Creole rather than a more Standard French code. Haitians take much pride in the fact that their island was the site of the first slave revolt in modern history (1791–1804), which abolished slavery and established Haiti as the second independent nation in the Americas (Hall 1992). As a result, they have clung tenaciously to their (Creole) language, their history, and their culture.

This linguistic strength was shown in 1961 when Haitian French was granted legal and educational status in Haiti. It was accepted as the official language of the island in 1987 (along with Standard French), and has since developed a standardized written code and a growing literature. There are several dictionaries of Haitian Creole, and newspapers, articles, fiction, and poetry are being written in the language. Radio and television broadcasts are in Haitian Creole, and there was a bible printed in the language in 1985. Although economic conditions are abysmal, and political upheavals are the norm, the language appears to have been cemented in the local conscience, and therefore plays an important role in identification as Haitian.

Haitian Creole is spoken on the western portion of the island of Hispaniola; the other part of the island is the Spanish-owned Dominican Republic. There are estimated to be over five million Haitian Creole speakers at present, who represent about 90% of the island population, and constitute the largest number of Creole speakers anywhere. In addition, there are many substantial Haitian enclaves in the Bahamas, Canada, and the United States. Ninety-five percent of Haitians are of African origin, but the extremely small mulatto (mixed-race) and French population constitutes the upper class. This is also the group that has continued to use and speak standard French. Recent language attitude studies and the political climate of the island suggest that linguistic, social, and cultural mores are moving in a direction of viewing Creole as a positive force, while simultaneously rejecting or lowering the status of the standard French language and culture, which was imposed on the island so many centuries ago.

Hale, Kenneth

Like his teacher Carl Voegelin, Kenneth Hale was a prolific documenter and avid student of languages. He learnt Spanish in his youth in southern Arizona, and Navajo and O'odham (Papago). His training combined linguistics and anthropology in the Americanist tradition following Edward Sapir.

His perennial interests covered many areas of linguistics, including language typology, lexicography, syntactic theory, historical linguistics and language reconstruction, and applied linguistics in school education especially in support of minority languages.

Hale's early major work comprised several careful comparative studies of language groups based on data he collected himself, first Uto-Aztecan, then subgroups of Australian languages (Arandic, Northern Pamic). From his 1959–1960 fieldwork, Hale perceived that the phonologically aberrant languages of northern Cape York Peninsula were related by regular sound changes to other Australian languages; he further showed the implications of this for prehistory. Hale's 1961 coinage 'Pama-Nyungan' has since been generally applied to name the largest classificatory grouping of Australian languages, the outline of which appeared in 1966 (with Geoff O'Grady and the Voegelins). Hale's extensive notes, analyses, transcriptions, and sound recordings of about 70 Australian languages, archived at the Australian Institute of Aboriginal and Torres Strait Islander Studies (AIATSIS) in Canberra, are a great accomplishment, and have provided a basis for much subsequent work by others.

Hale was inspired by Noam Chomsky's *Aspects of the theory of syntax* and arranged to return to Australia and reexamine some Australian languages (Warlpiri and Lardil) with this new framework. While remaining sensitive to intricate details of complex phenomena (such as pronominal marking in clauses) at the same time Hale believed that linguistic analysis needed to 'strip away complexity' and reveal simpler principles and modules at work in combination, relating the universal and the particular. Thus, Hale was able to bridge from his Sapirian training to Chomskyan universal grammar. One of Hale's influential proposals was a later reaction (1983) to the *Aspects* model, in which he argued, on the basis of his studies of languages such as Warlpiri and O'odham (Papago), that in some languages, the mapping from (logical) argument structure to syntactic configuration works quite differently than it does in English. Such 'nonconfigurational' languages do not reserve a special syntactic position for clause subject (or object), and are expected to exhibit a contrasting cluster of syntactic properties, notably clausal word order independent of syntactic relations. This subsumed another of Hale's related influential proposals, that there are languages (such as Warlpiri) where relative clauses are not embedded (as they are in languages like English) but rather simply added (adjoined) to their host clause. For the rest of his life, he continued to explore how conceptual argument structure relates to grammar, word order, and word structure, looking at languages

as diverse as Chukchi, Dagur, English, Hopi, Miskitu, Igbo, Irish, Japanese, Navajo, O'odham, Warlpiri, and West Greenlandic, often in collaboration with native speakers of the languages.

Hale's reputation as a polyglot was well-deserved, as he commanded dozens of languages. He had an extraordinary linguistic memory: he was able to absorb intensely not only the grammar and vocabulary of a language but also the precision of pronunciation. He downplayed this ability, since he believed that full knowledge of a language also included knowing its 'phrase book' with thousands of common expressions and their appropriate use. His annual class at MIT explored the grammar of one language each year, usually with a native-speaker linguist, and included sessions of monolingual investigation. Over 30 years, the class ranged from several North American languages, to the likes of Maori, Warlpiri, Finnish, Amoy, Malayalam, Basque, Tamazight Berber, Abkhaz, Zarma, Igbo, Yoruba, Korean, and American Sign Language (ASL).

In language investigation and description, Hale drew on his anthropology training in sensitivity to various linguistic registers (appropriate to gender, age, kin relations, ceremonial situations), and to the language of songs. He did not just draw on his own abilities, but showed how the native speaker could be a collaborator, and, in particular, he demonstrated the value and multiple uses of good 'folk definitions' or 'ethnosemantic oral essays'. Many other linguists enjoyed collaborating with him; he coauthored several works with each of Geoffrey O'Grady, LaVerne Masayesva Jeanne, Paul Platero, Samuel Jay Keyser, and Maria Bittner.

Hale campaigned for action to stem the endangerment of languages. Conscious that knowledge was empowering, he sought to put the results of his linguistic and anthropological research at the disposal of the speakers of those languages. He encouraged bilingual education, coauthoring a 1974 recommendation with Geoff O'Grady on which bilingual education programs in the Northern Territory of Australia were founded. He also helped speakers of local languages obtain training in linguistics both at workshops in their communities, and at MIT, so that they could study the language themselves and get some control of its destiny. From 1986, he made several visits to work with local people to study Misumalpan languages (Miskitu, Sumu) of the Atlantic Coast of Nicaragua and Honduras. He was instrumental in the development of dictionaries, including for Warlpiri, Lardil, and Ulwa and Miskitu (two Misumalpan languages native to Nicaragua), and during his last years, he mentored the Wampanoag revival project in Massachusetts.

Under Hale's direction in the 1980s, the Lexicon Project at the Center for Cognitive Science, MIT carried out comparative lexicology (research on the nature of the lexicon) with a view to discovering general lexico-semantic themes, or principles that recur systematically in the definitions of lexical items. The languages Hale himself focused on in this project were the Central Australian language Warlpiri, Miskitu and Southern Sumu (Ulwa), and English. Later, Hale's ideas on argument structure and the nature of thematic roles were the focus of his major book (with S.J. Keyser) *Prolegomenon to a theory of argument structure*, which was brought to completion as he succumbed to cancer.

Biography

Kenneth Hale was born in Evanston, Illinois on August 15, 1934; his family moved to Canelo, Arizona by 1941. In 1952–1955, he received his B.A. (1955) in Anthropology at University of Arizona, M.A. in 1956, with a thesis on *Class II Prefixes in Navajo*, and Ph.D. in l959, with a dissertation on *A Papago Grammar*, both at Indiana University, Bloomington, Indiana under Carl Voegelin. He was part of the linguistic survey of Australian languages conducted in 1959–1960, affiliated with University of Sydney, part of CF and FM Voegelin's survey of Languages of the World. He was Assistant Professor in Anthropology and Linguistics, University of Illinois, Urbana, Illinois in 1961–1964 and University of Alberta, Edmonton, in the summer of 1964, and was also Associate Professor in Anthropology, University of Arizona, Tucson, in 1964–1966. His second stay in Australia was in 1966–1967, again supported by National Science Foundation, focusing on Warlpiri and Lardil languages. He was recruited by Morris Halle in 1966 to Massachusetts Institute of Technology, where he was Associate Professor from 1967, and was promoted to Professor in 1972, and finally became Ferrari P. Ward Professor of Modern Languages and Linguistics in 1981–1999. His visiting appointments included University of Arizona 1976–1977; Katholieke Hogeschool Tilburg, Netherlands, 1983–1984; Australian Linguistic Institute, La Trobe University, Melbourne, July 1994; Linguistic Society of America Linguistic Institutes, University of Arizona, Tucson, in the summer of 1989; and University of New Mexico, Albuquerque, in the summer of 1995.

He was active in training native speakers of indigenous and minority languages: Warlpiri (Yuendumu School, Central Australia, mid-1974); Navajo (Kin Li Chee, Arizona, summer 1975, Navajo Community College, Tsaile, Arizona, summer 1982); in Miskitu and Sumu (Programa Educativo Bilingüe-Bicultural, Puerto Cabezas, Zelaya Norte, Nicaragua, January l986 and 1994, and Bluefields, Region Autónoma Atlántico Sur, Nicaragua, January, 1988 and 1990); and Mayan languages (Proyecto Lingüístico Francisco Marroquín, Antigua Guatemala, July 1988, and CIRMA, Antigua Guatemala, August 1994.

He was a member of the Linguistic Society of America (LSA), and its President in 1994–1995. He was also a member of the American Academy of Arts and Sciences from 1989, and of the National Academy of Sciences from 1990. Hale died in Lexington, Massachusetts on October 8, 2001.

Halle, Morris

Morris Halle can be called the father of the modern study of speech sounds (i.e. phonological and phonetic theory). He was the central figure behind the development of Generative Phonology, and has had a significant impact on the study of word structure (morphology). In addition to his intellectual stature, Halle's influence as an educator is profound. He has taught and advised many of the leading figures in phonology today, including those who have proposed competing theories.

Halle began his study of structural phonology under Roman Jakobson, first at Columbia University, and later at Harvard. In his early work with Jakobson and in collaboration with Gunnar Fant, Halle started his career by questioning the idea that phonemes, i.e. sound units roughly corresponding to alphabet letters, function as the basic cognitive units in the processing of speech sounds. Jakobson et al. (1951), in the spirit of work done in the Prague School of linguistics, claimed that phonemes are themselves divisible into smaller units, so-called 'distinctive features', which capture articulatory and acoustic characteristics of speech sounds. For example, the distinction between the word *pat*, pronounced [pæt], and *bat*, pronounced [bæt], does not lie in some categorial distinction between the cognitive units /p/ and /b/, but in the fact that only the latter is pronounced with vibrating vocal cords. In later work, Halle and his students developed hierarchically organized models of feature systems to capture the fact that some features seem to be more prominent than others in the sound systems of specific languages.

While working on his dissertation, Halle began working with researchers at the Research Laboratory of Electronics (RLE) at the Massachusetts Institute of Technology. He later began teaching in the Modern Languages department there. In the mid-1950s, Halle was a driving force behind the move to develop a linguistics program at MIT. Part of building up this program included hiring Halle's collaborator and colleague Noam Chomsky. Taking a page from Chomsky's syntactic work, Halle claimed that phonological information is not merely perceptual discrimination and articulatory action, but is a cognitive system with its own set of principles. These principles form the foundation of Generative Phonology, so-called because it was assumed that all speech sounds could be *generated* on the basis of a finite set of principles or rules. The classic book of Generative Phonology is Chomsky and Halle's (1968) *The sound pattern of English* (SPE). Classical Generative Phonology assumes that there are two levels of phonological information: the underlying or base form of a word and the surface or phonetic form. The underlying form is mapped to the phonetic form by a series of ordered generative rules.

Consider, for example, the pronunciation of the plural suffix –*s* in the words *dogs* [dagz], *cats* [kæts], and *glasses* [glæsəz]. The underlying form of this plural suffix is posited to be /z/. The phonetic form of the noun–suffix combination is generated via two rules.

The first rule states that a consonant is devoiced, i.e. pronounced without vibrating vocal cords, when it follows a voiceless consonant. The second rule, called

epenthesis, inserts a schwa /ə/ sound between adjacent coronal sibalents.

The effect of these rules is seen in the following derivations of the words mentioned above:

underlying representation	/dag/ + /z/	/kæt/ + /z/	/glæs/ + /z/
epenthesis	——	——	glæsəz
devoicing	——	kæts	——
phonetic representation	[dagz]	[kæts]	[glæsəz]

It is argued that epenthesis must apply before the devoicing rule, since applying them in the other order would result in an incorrect form *[glasəs], as the final /s/ of *glass* is a voiceless sound, and the /z/ would be devoiced when adjacent to it:

underlying representation	/glæs/ + /z/
devoicing	glæss
epenthesis	glæsəs
phonetic representation	*[glæsəs]

Besides applying the theoretical framework of generative grammar to sound systems, *The Sound Pattern of English* also provides one of the most complete discussions of English phonology so far.

Metrical theory (or the study of stress) forms another important strand in Halle's research program. SPE contained the first serious description of English word stress in terms of predictable rules. Building upon the success of autosegmental phonology, in more recent years, Halle applied a notion of autosegmental structure to the study of stress. Throughout this research, Halle has not only examined stress by examining individual words, but also words in phrasal context and in verse.

In generative phonology, the sound system closely interacts with the structure of the containing words. Thus, Halle is an influential figure in the subdiscipline of morphology as well. By applying the familiar generative model to words, he developed the first explicit theory of generative morphology. This theory is a lexicalist theory of word formation (i.e. all the operations of word formation occur in the speaker's lexicon or mental dictionary). Generative morphology consisted primarily of a list of morphemes and a set of word formation rules (WFRs) which built words out of the morphemes. Work in generative morphology eventually evolved into the theory of Lexical Phonology.

In the 1990s, Halle moved away from the lexicalist position his work had previously taken, and developed the theory known as Distributed Morphology (DM), in collaboration with Alec Marantz. Distributed Morphology holds that words are not constructed in the lexicon. Instead, syntactic operations which influence morphological form can occur before the words are inserted. The theory is "distributed" because what was previously thought to occur in the lexicon is distributed into three grammatical systems: (i) a set of syntactic primitives, (ii) a list of phonological forms and the syntactic environments in which they occur and (iii) a list of sound-meaning pairs. The first system comes into play as the syntactic rules construct the sentence, the second inserts the words into the sentence and the third is the tie between the surface phonological form and the semantic structure of the word or phrase.

The influence that Morris Halle has had on the field of linguistics is extensive. He has personally trained an enormous number of today's leading scholars in phonology, phonetics, and morphology, and his vision and research have led the field to new levels of rigor and understanding.

Biography

Morris Halle was born in Liepaja, Latvia on July 23, 1923; he emigrated to the United States in 1940. He attended the City College of New York in Engineering (1941–1943), served in the United States Army in World War II (1943–1946). He received his M.A. (1948) in Linguistics from University of Chicago and did Graduate work in Slavic Languages at Columbia University (1948–1949) under the tutelage of Roman Jakobson. He did his Ph.D. (1955) on Slavic Languages, Harvard, in a dissertation entitled *the Russian Consonants: a Phonemic and Acoustical Investigation*, supervised by Roman Jakobson. He was an instructor in Russian, North Park College, Chicago, 1946–1947; Teaching Fellow in German and Russian, University of Chicago, 1947–1948; Teaching Fellow in Russian, Harvard University, 1947–1948; Assistant Professor of Modern Languages, Massachusetts Institute of Technology (MIT), 1951–1956; Associate Professor of Modern Languages, MIT, 1956–1961; Fellow, Center for Advanced Study in the Behavioral Sciences, Stanford University, 1960–1961; Founder, doctoral program in linguistics, MIT, 1961; Professor of Modern Languages, MIT, 1961–1976; Head, Department of Foreign Languages and Linguistics, MIT, 1976; Head, Department of Linguistics and Philosophy, MIT, 1976–1977; Ferrari P. Ward Professor of Modern Languages and Linguistics, MIT, 1976–1981; Institute Professor, MIT, 1981–1996; and Institute Professor Emeritus, MIT, 1996–present. He was a J.S. Guggenheim Fellow in 1960–1961 and J.R. Killian Jr. Faculty Achievement Award Lecturer at MIT in 1978–1979. He received the Science Prize from Union d'Assurances de Paris in 1991; he also received D.Sc. (hon), Brandeis University in 1988, and DHL, University of Chicago, 1992. He is a member of the

Linguistic Society of America 1951–present, and was Vice President, Linguistic Society of America in 1973; President, Linguistic Society of America in 1974; and Fellow, American Academy of Arts and Sciences 1963–present. Morris Halle is also a member of the National Academy of Sciences from 1988 to present.

Halliday, Michael Alexander Kirkwood

In his thesis ('The secret history of the Mongols') and in other research, M.A.K. Halliday mainly drew on what he had learned in China, but for his linguistic theory he drew on the work of the British teacher J.R. Firth, who had drawn from his in-depth knowledge of Indian Linguistic tradition. Firth was also influenced by the work of Polish anthropologist Bronislaw Malinowski. All these strands inform Halliday's work, which is unique in its multinational range of influence.

Halliday's work provides a theoretical base, offers descriptive illustration, and projects applied values in almost all branches of linguistics, grammar and semantics, discourse analysis and stylistics, phonology, sociolinguistics, computational linguistics, language education, and child language development.

The most distinguishing feature of Halliday's work is its *holistic character.* Halliday interprets language as a network of relationships and locates it in a sociocultural context. For him, 'language' is a resource for making meaning—a *semeogenic system.* He suggests that language is a higher-order semiotic system—one that has a lexicogrammatical level of organization (i.e. a system of wording) and one that is metafunctionally organized (i.e. organized functionally into

simultaneous strands of meaning: ideational, interpersonal, and textual). Our experience gets transformed into meaning and this is effected by grammar. Hence, Halliday says that the grammar of every natural language is a theory of human experience: 'a theory that we hold unconsciously, but that is all the more potent for that very reason.' Grammar 'construes our experience' but also 'enacts our interpersonal relationships'—sharing experiences with others, giving orders, making offers, and so on. In other words, 'grammar transforms experience into meaning' and it is this that constitutes what is called 'understanding'. 'Understanding and knowing are semiotic processes—processes of the development of meaning in the brain of every individual; and the powerhouse for such processes is the grammar.' In his special lecture on July 19, 1999 at the Central Institute of English and Foreign Languages in Hyderabad (India) — 'Language and the Reshaping of Human Experience'—Halliday said that

> Children of around four to six years old are just reaching the stage, in their language development, when they can handle meanings that are abstract: they can construe entities that have no perceptual correlate, like *worth* and *clue* and *habit* and *intend* and *price*; and this has two important consequences. First, it means that they can cope with abstract symbols, like letters or characters, and the abstract concepts that go with them (including, the critical distinction between writing and drawing); so they can now master this new medium. Secondly, it means that they can cope with abstract categories, and so are ready to explore new forms of knowledge. In other words they are ready for a reshaping of their previous experience.

Halliday's work on the internal organization of Language as a Semiotic system has also been holistic. He describes semantics, lexicogrammar, and phonology as resources for the language user, representing them as networks of options in what the user can mean. In his work 'system', comprising choices on the paradigmatic dimension, is the central organizing concept.

Systemic Functional theory has been applied with a wide range of contexts of research application. Halliday has pioneered the development of 'educational linguistics', interacting with teachers since the 1960s in the context of various projects. He has made significant contributions in other areas, including literary studies and computational linguistics. He was involved in work on machine translation already in the 1950s.

His work has been particularly influential in the development of text generation as one aspect of natural language processing—particularly through the Penman system that was launched in 1980 at the Information Sciences Institute of the University of Southern California. In the early 1990s, Halliday began to interact with researchers developing fuzzy theory and logic in Japan.

Halliday's commitment to research applications is related to his notion that linguists are socially accountable. This is also reflected in his concern, since the 1950s, with giving value to all varieties of language—showing, for example, that spoken language is highly systematic and complex in spite of the prevailing myth that it is scrappy and unorganized. The Hallidayan mode of intellection recommends developing multiple views on a phenomenon and advises engendering synthesis when faced with a choice between a thesis and its antithesis. He wants us to move in helixes, not in circles.

Biography

Michael Alexander Kirkwood Halliday was born in Leeds, Yorkshire (England) in 1925. He received his Ph.D. in Chinese Linguistics from Cambridge University in 1955.

He was earlier a student in China at Peking University and Lingnan University, where he assisted Professor Wang Li in surveying the dialects of Chinese in the Pearl River Delta. He taught at Edinburgh University, University College London, Nairobi (Kenya), Chicago, Stanford, and Essex University. In 1976, he joined the University of Sydney as the founding Professor of Linguistics. He retired in 1987 and went on to serve as Visiting Professor at NUS, Singapore and at ICU Tokyo.

Halliday has received honorary doctorates from the University of Nancy, the University of Birmingham, York University, and Macquarie University and was conferred the Honorary Fellowship of the Central Institute of English and Foreign Languages (Hyderabad, Lucknow, and Shillong), India. He has published over 150 books and articles. His seminal works are collected and edited by Jonathan J. Webster and Published by Continuum (London and New York), as a ten-volume series.

Handwriting

Despite the common use of electronic communication with keyboards, handwriting is still a major mode of written language production. The study of handwriting is concerned with the various mechanisms and processes that intervene between the intention to write a message and the movements of the body that execute the intention by instrument gestures on a writing surface. Some of the processes, such as conceptualization and formulation, are the same for spoken and written utterances. This paper will therefore concentrate on the specific movement-control aspects of handwriting: its planning, preparation, and production. Furthermore, it will be restricted to cursive Latin script by skilled right-handed adults. When fully developed, the skill enables fluent, semiautomatic writing gestures, permitting cognitive and linguistic processing to continue in parallel.

The aim of handwriting research is to arrive at a comprehensive insight into how all aspects of skill and task are acquired, represented, planned, and organized by the writer, seen as a human information-processing system, and how the eventual kinematic, or movement, sequences are physically performed. In particular, there is interest in mutual interactions, i.e. in how the act of handwriting influences linguistic production on the one hand, and in how kinematic performance measures reveal cognitive processes on the other. The latter aspect has received the most attention in recent investigations in the multidisciplinary field of quantitative and formal handwriting research, which, in contrast to the art of graphology, is known as 'graphonomics'. Contemporary research is primarily experimental and is executed in laboratories equipped with timing devices and two- and three-dimensional movement-recording instruments.

Exact timing allows an estimate of the delay (*reaction time*) between the instruction to write and the actual start of the movement; this duration reflects the intervening amount of cognitive processing, because every cognitive process takes a measurable amount of time. Under certain assumptions, it is also possible to determine the nature of the intervening processes, e.g. letter-shape selection or force implementation. Likewise, the duration of the movement itself (*movement time*) may be assessed; this is indicative of the current *mental load* on the limited-capacity information-processing system, because of the preparation and motor programming of further parts of the message.

Because of the large forces of the involved muscles relative to the little writing movements and the small implied forces, such as friction and gravitation, it seems justified to consider the *kinematics* (i.e. the movement features) in the two-dimensional writing plane as a function of time as an adequate description of the dynamics of the handwriting trajectory. The standard two-dimensional method is to let the participant in the experiment write on a graphics tablet (*digitizer*) that samples the *x* and *y* coordinates of the pen tip at a high rate (100 times per second or more). Dedicated software analyzes the writing trace, yielding relevant parameters such as size, slant, curvature, velocity, acceleration, jerk, pen pressure, and pen tilt as a function of time. Apart from reaction time and movement time, fluency measures may also reveal local or global processing load. Many laboratories now have a three-dimensional *motion-tracking* apparatus as well, to monitor the individual joints (from shoulder to fingertip) involved in writing movements. By geometric transformation, the recorded data may be represented, e.g. as a time function of the joints' *rotation*, or as the *phase relations* between several moving effector segments (e.g. hand and fingers).

The writing limb, with its multitude of segments, joints, and muscles in the arm, hand, and fingers, is capable of moving in many different ways. Technically speaking, it has a large number of *degrees of freedom*. However, this number is often reduced—although flexibly and not always in the same way—by

the coactivation of several groups of muscles acting as single functional *synergies* or *coordinative structures*. In very general terms, the shoulder and elbow take care of the global rightward progression across the page, while the hand rotating in the wrist is responsible for the small horizontal movements within and between letters, and the thumb and fingers are mainly in charge of the vertical letter strokes.

Since 1965, mechanical and computational models of handwriting have been developed. The earliest ones were concerned with the biomechanical formation of strokes and their concatenation into letters and words. Later models, since 1980, accounted for the cerebral and neural organization of handwriting and assumed information-processing stages in the cognitive-psychology tradition. Examples of these stages are the selection and ordering of the orthographically required letters (graphemes), the retrieval of a specific letter shape (allographs; see below) from long-term motor memory, and the setting of the required muscles and their force levels to execute that letter by a selected effector (e.g. hand or fingers) in the current task-space context at a specified size and speed. Recently, the models stemming from the biomechanical tradition have gained in complexity and scope. They incorporate the control of handwriting gestures at higher levels in the brain, so that, e.g. the selection of the most suitable effector combination for smooth performance is accounted for. Thus, the two types of model are increasingly covering common ground.

From a psycholinguistic viewpoint, however, the neurocognitive and *information-processing* models have made the most interesting contributions by generating testable hypotheses on the handwriting process. These models assume that handwriting involves a hierarchical procedure in which to-be-written larger units (representing the entire message, whole phrases, and words) are activated first, followed step-by-step by the activation of their even more detailed components (single allographs and individual strokes) at increasingly lower levels. *Allographs* are the (often idiosyncratic) shape variations of a grapheme with a certain letter identity (e.g. a specific cursive lowercase <r>). Different allographs are required or preferred in different contexts. Allograph representations are assumed to be stored as generalized *motor programs* in long-term memory, and—when required in the message—ready to be retrieved and executed in any size and orientation (e.g. on a large vertical blackboard).

Strokes—effectively near-vertical trace segments—are defined in the spatial domain by the upper and lower turning points of the pen-tip excursions. These turning points are characterized by sharp bends (high *curvature*), which are associated with low speed (*velocity minima*). In fluent writing, a stroke is pro-duced *ballistically*, i.e. in a single burst, with only one acceleration and one velocity peak. The normal duration of such a fluent stroke is 100 to 125 milliseconds. A continued series of loops (each considered as two strokes, one down and one up) will thus result in a repetitive digitized signal with a *frequency* of 4 to 5 hertz. An allograph may contain between two and six strokes, so that on average, two or three letters are written per second. Allographs and strokes have both been proposed as the *basic units* of handwriting processing (long-term storage, planning, and execution); more recently, it has become clear that the size of the basic unit depends on familiarity, i.e. on learning and practice.

A representative information-processing model combines *serial* with *parallel* processing. Handwriting is seen as a multicomponent task involving various independent *modules*. From high to low, these deal with semantics (meaning), syntax (sentence structure), words, speech sounds, graphemes, allographs, strokes, task space, joints, and muscles. The order given here reflects the serial processing sequence: each module transmits its processing result to the next-lower level. The parallel features of the model originate from the principle that concurrently with the lower-order written performance of an earlier part of the message, later parts will be planned and prepared by modules higher in the system. Each module requires a small amount of *processing time* (milliseconds) and *capacity* drawn from a common source. If a message contains a processing difficulty for one of these modules, this may be reflected by a delayed initiation (increased reaction time) or by a slower ongoing writing movement (increased movement time). Because of the processing priority of larger units, increased *cognitive load* at higher levels is reflected earlier in the writing trajectory than an extra load at lower levels. An unusual allograph combination will thus be 'announced' by a slight delay several letters in advance, whereas a difficult stroke will result in a slower production of the immediately preceding stroke or even of the very stroke itself.

Research over three decades has shown that linguistic factors of various kinds and levels do indeed influence the handwriting process in a modular way, as indicated here. Initiation and trajectory formation are affected by the features of units with high, medium, or low linguistic status, which are assumedly processed at corresponding levels in the proposed handwriting-movement hierarchy. As indicated, *high* levels involve words, morphemes (subword units of meaning), and syllables; *medium* levels encompass phonology (speech-sound features), orthography (spelling), and letter clusters; *low* levels imply graphemes, allographs, and strokes. In many cases, these findings are

corroborated by clinical observations involving *double dissociation* between writing disturbances: different patients seem to suffer from different exclusive writing failures, presumably mediated by specific neural structures at different levels. Application of the current insights into the neurocognitive and motor-control aspects of handwriting has resulted in advances in educational and remedial practice, in medication for motor disorders, in written-document examination, in the analysis of ancient writing, in forensic expertise, and in automatic handwriting recognition.

ARNOLD J.W.M. THOMASSEN

Harris, Zellig Sabbetai

The scientific legacy of Zellig S. Harris can be divided into five areas: (1) Northwest Semitic linguistics; (2) Structural analysis; (3) Transformational analysis; (4) Operator grammar; and (5) Politics.

While Harris was an undergraduate student at the University of Pennsylvania in 1929, epoch-making texts in Ugaritic were published and promptly deciphered. This turned his attention to new and exciting possibilities of research in Northwest Semitic, and he subsequently worked in this area with his teacher J.A. Montgomery, publishing with him a work on Ugaritic mythological texts. He already had a background in Hebrew from his family. During the 1930s, he established a solid reputation as a semitist, publishing a Phoenician grammar in 1936, and a study of Canaanite dialects in 1939. Both works have remained useful. It was here that he developed the style of writing that lasted throughout his career. It was direct and sparse, with a wealth of detail and documentation when these were called for. But he made no concessions to the reader. Harris did not pretend to be a popularizer, and one may have to struggle to follow his technical, tightly constructed argumentation.

He then moved into a more general study of language theory, even though he continued to maintain an interest in Semitic languages as material for theoretical investigations. Other semitists regretted his defection from the field, and even expressed resentment at what he was doing. The Semitics scholar J. Cantineau, in a review of Harris's book *Methods in structural linguistics,* claimed that Harris placed facts on a procrustean bed to fit his theories. He added that Harris brought nothing new or useful to linguistics, despite the specious appearance of being scientific.

Harris shook off all criticism and entered his new phase of scholarship, the cornerstone of which was the book that Cantineau reviewed unfavorably. Although he was not formally a student of Edward Sapir, he acknowledges his great debt to him. Harris stresses the importance of describing language in terms of how items fit together, and how they are distributed. While he admits that meaning is the goal of most language (poetry may sometimes be an exception), it is not susceptible to scientific quantification or description, and it, along with psychological and mentalistic notions, must be strictly avoided. He tried to isolate

the elements of a language, and the relationships that were possible between them. Harris adhered to the structuralists' credo that linguistics best studies language synchronically, and on its own terms.

Up to his time, analysis of language, whatever its theoretical basis might be, ended at the conclusion of the sentence. Harris had the ambition of setting up an analysis of texts, sentences that were strung together, and this led to his concept of Discourse Analysis, a subject on which he taught a course regularly at the university. This endeavor led him to set up normal forms of sentences, so that they could be compared within texts, and this brought him, more or less accidentally, to the notion of transformations that would connect, for example, a sentence in its active and passive form (the dog bit the man/the man was bitten by the dog). Thus evolved the idea of 'transformations', which led in turn to 'transformational grammar', which has acquired great prominence, mainly on account of the research and publications of Noam Chomsky, who was Harris's student. This gave rise to a school of thought of continuing prominence, which was subjected to obloquy similar to that meted out once to the structuralists, being described by the structuralist Charles F. Hockett (died: 2000) as 'a theory spawned by a generation of vipers'.

But Harris did not go down the same path as Chomsky. Already in the 1960s, he was teaching a course in Linguistics and Mathematical Logic, in which he was mulling over his aim to produce a mathematical model for language. It should be stressed that Harris, in moving to his new approach to language, which was distinct from the path he had previously followed, and distinct from that of Chomsky, did not thereby reject his previous work, even though he may have felt that he had taken it as far as he reasonably could. Harris did not belong to a 'God's truth' mode of looking at scientific description. Various approaches might have their own particular validity. He was remarkably unpartisan, and spent no time in engaging in public relations on behalf of himself or his views, a fact that may account for the relative obscurity of his viewpoints, and his failure to establish a school devoted to his principles.

His new approach is best understood by a simple example. If we consider the sentence *sheep eat grass,* acceptable to any English speaker, Harris observes that the word *eat* imperatively requires two other words, which do not themselves require anything else. He expresses this as O_{nn}, where O represents the operator (in this case the word *eat)* and this operator requires two arguments (here *sheep* and *grass)* which can be considered to be operators with null arguments, hence *n.* If we expand this sentence to *I know that sheep eat grass,* then *eat* now has an operator as its

first argument ('I know') and the second argument is the same, giving O_{on}. Harris recognizes that this may not give an analysis of pedagogic value by way of giving a useful order of the findings; but then he was not particularly interested in pedagogy. Like Everest climbers, he explored the claimed mathematical structure of language simply because it was there. Harris also explores the unreduced sentences of a particular language. We have no evidence of the existence now of a 'me Tarzan, you Jane' type of prehistoric language; so-called primitive languages may have richly complex syntactic structures, and are not fundamentally different in nature from other better known languages. Maybe he considered these unreduced sentences to belong to an earlier stage of language, but he does not state this expressly, even though toward the end of his life in his masterly *A theory of language and information*, he gingerly explores the nature and development of language. A simple example may be seen in *sheep eat green grass.* This is a reduced form of two sentences *sheep eat grass* and *grass is green,* i.e. *sheep eat grass which is green,* where the first two letters of *which* (*wh...*) form a link, and the remainder represents the word *grass.* An element of economy plays a part here, which has long been recognized as a possible factor in phonetic change. Harris believes that the operator-argument method is fully adequate for unreduced sentences at least. *A theory of language and information,* represents the end of his life work, which had remarkable consistency and tenacity. Thereafter, he devoted himself to a substantial political tract, published posthumously by a group of his admirers.

Biography

Zellig Sabbetai Harris was born in Balta, Ukraine, on October 12, 1909. He was brought to Philadelphia at the age of four years. His father was a *mohel* (Jewish ritual circumciser) and cantor. Harris received the degree of A.B. at the University of Pennsylvania in 1930, followed by a Ph.D. four years later, and spent his entire academic career at that institution as a student and faculty member, until his retirement at the age of 70. For much of his life he commuted between Philadelphia and Israel, where he was a member of the communal settlement Kibbutz Mishmar Haemek, near Haifa, and reportedly was known there simply as Zellig the carpenter. This kibbutz was part of the extreme left-wing *Hashomer Hatzair* ('the Young Watchman') movement. He participated in setting up an adult education program for members of such settlements. His wife Bruriah was a researcher in physics at the Weizmann Institute in Rehovot, Israel. Harris kept his academic and political interests separate, and

in his scientific work never broached his political views, which were closest to anarchism in the spirit of Kropotkin. In 1941, he took over the editorship of the *Journal of the American Oriental Society*, one of the oldest learned societies in the United States, from Norman Brown, a colleague at the University of Pennsylvania. He served in that capacity until 1948. He was president of the Linguistic Society of America in 1955. He published numerous articles in the journal *Language* until 1957; after that time, most of his books and papers were published in Europe. He died on May 22, 1992, just after publishing an uncharacteristically readable account of his views in his *A theory of language and information.*

ALAN D. CORRÉ

Haugen, Einar

Einar Haugen was one of the foremost Scandinavian linguists of his time. His parents both immigrated from central Norway to the United States, settling in Sioux City, Iowa, in 1899. Haugen grew up there, in a Norwegian neighborhood, and learned Norwegian as a native language and English in school. He in fact learned two dialects of Norwegian, the more standard dialect spoken by his schoolteacher mother and the more rural dialect spoken by his father. He spent two years in Norway as a child, from 1914 to 1916, between the ages of eight and ten, which allowed him to master his father's dialect in its natural setting. This stay reinforced his already strong ties to Norway and Norwegian; the influence of his Norwegian immigrant community and his childhood visit to Norway cannot be underestimated when analyzing his life's work.

Haugen contributed to many areas of linguistics. He was deeply concerned with the Norwegian language, writing several textbooks of Norwegian, and directing the compilation of a Norwegian–English dictionary. During World War II, he directed a project at the University of Wisconsin to teach servicemen Norwegian. He also contributed extensively to Norwegian dialectology, publishing, among other works, a two-volume survey of varieties of Norwegian spoken in the United States (*The Norwegian language in America: a study in bilingual behavior*; originally published in two volumes in 1953 and reissued as one volume in 1969) and numerous articles on the topic.

He was also interested in numerous aspects of sociolinguistics. His interest in language planning and language standardization goes back to his dissertation; he continued to work in this field, and eventually published a book dealing with language planning and Norwegian. Bilingualism, another interest stemming from his childhood experiences, was also a prominent theme in his work. *The Norwegian language in America*, as indicated by the subtitle, also dealt extensively with bilingualism, focusing largely on the adaptation of English words into American Norwegian. A later volume, *Bilingualism in the Americas: a bibliography and research guide*, was also a seminal contribution to the field. Finally, Haugen was an important contributor to the field of 'language ecology' (and in fact coined the term), the study of interactions between a language and its environment. His 1972 work,

443

The ecology of language, reprints selected essays on topics such as the relationship between language and immigration and communication difficulties between speakers of various languages.

Haugen's contributions to historical Scandinavian linguistics are critical to the field. He prepared an edition and translation of *The first grammatical treatise*, an anonymous twelfth-century Icelandic work on Old Norse phonology and orthography. His monumental work on the history of the Scandinavian languages, *The Scandinavian languages: an introduction to their history*, originally published in 1976 and translated into German in 1984, remains a standard handbook. His later monograph, *Scandinavian language structures: a comparative historical survey*, offers an accessible discussion of the development of the various components (phonology, morphology, syntax, and the lexicon) of the Scandinavian languages.

Haugen also helped shape the field of structuralist linguistics. He authored two influential articles on structuralist phonology, 'Facts and phonemics' (with W.F. Twaddell 1942) and 'Phoneme or prosodeme' (1949). Other phonological topics he dealt with included the vowel systems of Norwegian and Icelandic, tone in Norwegian, and the role of the syllable in phonology. Yet, he was never parochial in his scholarship; in his presidential address to the Linguistic Society of America (published in 1951), he urged American linguists to avoid scholarly isolationism and take developments from European scholarship into consideration.

Haugen also contributed to literary studies. He translated a number of Icelandic sagas and plays, a history of Norwegian literature, and a biography of Henrik Ibsen. He prepared word counts of a number of Scandinavian authors, and also published studies of various Icelandic sagas.

Biography

Einar Haugen was born in Sioux City, Iowa on April 19, 1906. He attended Morningside College in 1924–1927. He received his B.A. in 1928 from St. Olaf's College; M.A. in 1929, and Ph.D. for a dissertation on the development of the New-Norwegian dialect of Norwegian, University of Illinois (Urbana) in 1931. He was Assistant Professor, University of Wisconsin (Madison), 1931–1936; Associate Professor, 1936–1938; Torger Thompson Professor of Scandinavian Languages, 1938–1962; Vilas Research Professor of Scandinavian Languages, 1962–1964; Victor S. Thomas Professor of Scandinavian and Linguistics, Harvard University, 1964–1975; Cultural relations attaché, US Embassy in Oslo, 1945–1946; and President, Society for the Advancement of Scandinavian Study, 1938; Linguistic Society of America, 1950; Ninth International Congress of Linguists, 1962; American Dialect Society, 1962. He was also a member of Permanent International Committee of Linguists in 1966–1972. He was visiting lecturer (1938) and Fulbright Research Professor (1951–1952), University of Oslo; Visiting professor, University of Iceland, 1955–56; Adviser to the English Language Educational Council of Japan, 1958–1960; and Fulbright lecturer, University of Uppsala, 1976–1977. He received grants and fellowships from the Guggenheim Foundation (1942), National Endowment for the Humanities (1967), Center for Advanced Study in the Behavioral Sciences at Stanford University (1963–1964), and National Science Foundation (1967–1969). Haugen was a member of the American Academy of Arts and Sciences, the Norwegian, Icelandic, Swedish, and Danish academies of science, and the Linguistic Research Group of Pakistan. He also received the Order of St. Olaf, Norway in 1940 and Order of the North Star, Sweden in 1961. He received several honorary degrees, including University of Michigan (1953), St. Olaf College (1958), the University of Oslo (1961), and the University of Iceland (1971). He also received the Nansen Award in Oslo in 1970 and the Jancke Prize in Uppsala in 1976. Haugen died in Cambridge, Massachusetts, on June 20, 1994.

Hausa and Chadic Languages

The Chadic language family includes an estimated 140–150 languages spoken in the sub-Saharan area to the west, south, and east of Lake Chad. The best known and most widely spoken Chadic language is Hausa, with upward of 30 million first-language speakers, more than any other language in Africa south of the Sahara. The remaining languages, some of which are on the brink of extinction, probably number little more than several million speakers in total, varying in size from less than half a million to just a few dozen speakers, and new languages are still occasionally discovered. Most Chadic languages remain unwritten, and for many only brief word-lists are available, although for some, e.g. Bidiya, Guruntum, Kanakuru, Kera, Kwami, Lamang, Margi, Miya, and Mupun, good descriptive grammars now exist, and several high-quality dictionaries have appeared, e.g. Dangaléat, Lamé, Ngizim, and Tangale. Hausa has four up-to-date and comprehensive reference grammars (all produced within the last few years) and two first-class dictionaries, and these works together make it the best documented language in sub-Saharan Africa.

Chadic is a member of the Afroasiatic language superfamily, which includes Semitic (e.g. Amharic, Arabic, Hebrew), Cushitic (e.g. Oromo, Somali), Omotic (e.g. Maale, Wolaytta), Berber (e.g. Tamahaq, Tamazight), and (extinct) Ancient Egyptian/Coptic. The inclusion of Chadic within Afroasiatic was first proposed almost 150 years ago, based on specific points of resemblance between individual Chadic languages and other Afroasiatic languages. These features include an *mV-* prefix (V stands for an unspecified vowel), which occurs on nouns that refer to the agent of an action, a location, or an instrument, e.g. [Hausa] *ma-hàifii* 'parent', *ma-fakaa* 'shelter', *ma-kullii* 'key, lock'. (Transcription: *aa* = long vowel, *a* = short; *à(a)* = L(ow) tone, *â(a)* = F(alling) tone; H(igh) tone is unmarked.) Despite this, the family relationship has only been generally accepted as a fact over the last 40 years or so, following Joseph Greenberg's (1963) comprehensive reclassification of African languages.

The accepted internal classification groups Chadic languages into three major coordinate branches, West, Central (= Biu-Mandara), and East, plus an isolated Masa cluster (with sub-branches and smaller groupings) as follows:

West-A, e.g. Angas, Bole, Fyer, Galambu, Gera, Goemai, Gwandara, Hausa, Kanakuru, Karekare, Kirfi, Kulere, Kwami, Mupun, Pero, Ron, Sha, Sura, Tangale

West-B, e.g. Bade, Boghom, Duwai, Geji, Guruntum, Miya, Ngizim, Pa'a, Saya, Warji

Central-A, e.g. Bachama-Bata, Bura-Pabir, Daba, Ga'anda, Gisiga, Glavda, Gude, Guduf, Higi-Kapsiki, Kilba, Lamang, Mandara, Margi, Matakam, Mofu-Gudur, Ouldeme, Sukur, Tera

Central-B, e.g. Buduma, Kotoko, Logone, Mbara, Musgu

Central-C, e.g. Gidar

East-A, e.g. Kera, Lele, Nancere, Sarwa, Somrai, Tumak

East-B, e.g. Bidiya, Dangaléat, Jegu, Mahwa, Migama, Mogum, Mubi, Mukulu, Sokoro, Toram

Masa (isolated cluster), e.g. Lamé, Marba-Monogoy, Masa, Musey

Chadic languages have complex consonant inventories. A typical pattern is for a language to distinguish voiceless stops such as /t/ from voiced /d/, in addition to implosive stops /ɗ/ and prenasalized stops /nd/.

Vowel inventories vary from two vowels, high /ə/ and low /a/, as in Bachama and Mandara, to seven vowels /i e ɛ a ɔ o u/, as in Dangaléat, with /i (e) a ə (o) u/ a regular pattern, and the diphthongs /ai/ and /au/ are found. It is also common throughout the family to distinguish between long and short vowels, especially in word-medial position.

Chadic languages have contrastive tones (distinctive intonational pitch levels), ranging from two (e.g. Hausa) or three (e.g. Angas) level tone systems. Although tone can function in lexical discrimination, its key role is normally grammatical, e.g. [Hausa] *taa/tâa/tà zoo* 'she came/will come/should come', *zàunaa!* 'sit down!' vs. *zaunàa* 'to sit down', *nân* 'here (near me the speaker)'

445

vs. *nan* 'there (near you the hearer)'. In a number of (West) Chadic languages, phonological tone is sensitive to syllable structure in certain word categories. In Bole, for example, tone on bisyllabic verbs is predictable: if the verb is C(onsonant)V(owel).CV (light first syllable) it will be H-H tone, e.g. *tonu* 'sharpen'; if it is CVC.CV or CVV.CV (heavy first syllable) it will be L-H tone, e.g. *ràamu* 'repair', *wùndu* 'call'.

Many Chadic languages have masculine/feminine grammatical gender (an inherited Afroasiatic feature), with no distinction in the plural, and typically distinguish gender in second- and third-person singular pronouns, e.g. (independent pronouns) *kai/kee* 'you (masc./fem.)', *shii/ita* 'he/she' [Hausa], *fiy/macə* 'you (masc./fem.)', *tə/njə* 'he/she' [Miya]. Overt gender marking on nouns has also evolved in a number of West Chadic languages, e.g. [Western Bade] *mângaa-n* 'my friend (masc.)' vs. *mânga-n* 'my friend (fem.)' (*-aa* = masculine, *-a* = feminine), [Hausa] *jàakii* 'donkey' vs. *jàakaa* 'she ass' (*-ii* = masculine, *-aa* = feminine). Some also exhibit the characteristic Afroasiatic *n/t/n* (masc./fem./pl.) noun/agreement marking pattern (where the masculine and plural markers are phonologically identical), cf. [Masa] *vèt-na* 'rabbit', *vèt-ta* 'female rabbit', *vèdai-na* 'rabbits'.

Noun plural formations are varied and elaborate, and some plural suffixes can be reconstructed for the presumed ancestor language Proto-Chadic, e.g. *-Vn, *-aki, *-i,* and *-ai* (with *-Vn* and *-ai* probably even reconstructable for Proto-Afroasiatic, the superfamily ancestor language). Examples: (*-Vn*) *kùmən/kùmənən* 'mouse/mice' [Bade], *miyò/mishan* 'co-wife/co-wives' [Kanakuru], (*-aki*) *goonaa/gòonàkii* 'farm(s)' [Hausa], (*-i*) *duwimà/dùwìmi* 'guineafowl(s)' [Gera], (*-ai*) *mùtù/mutai* 'sore(s)' [Dangaléat].

Verbs in many Chadic languages preserve the lexically arbitrary Proto-Chadic distinction between final *-a* and final *-ə* verbs (where the final schwa vowel is often pronounced as [i], [ə], or [u]), cf. [Tera] *na* 'see' and *dlə* 'get', [Guruntum] *daa* 'sit' and *shi* 'eat', [Bole] *pata* 'go out' and *poru* 'say', and in many West Chadic languages final *-a(a)* stems are typically limited to bisyllabic verbs with an initial light syllable, e.g. [Bole] *kù.maa* 'hear', [Hausa] *nù.ka* 'ripen after storing'. Verbal meanings are modified by the addition of one or more suffixes. These extensions encode notions such as action 'in the direction of' (centripetal) or 'away from' (centrifugal), or action 'partially completed' or 'totally completed', e.g. (centripetal) *fit-oo* 'come out' from *fìta* 'go out' [Hausa], (totality) *sà-nyà* 'drink up' from *sà* 'drink' [Margi]. Singular imperatives are often overtly signaled with an *-i* or *-u* suffix, e.g. [Bachama] *gur-ì!* 'sing!', [Ga'anda] *còk-u!* 'break (it)!'.

In some cases, the verbal suffixes also have a syntactic function, signaling, *inter alia,* transitivization (allowing a verb to take an object), or perfectivity (indicating completed action), e.g. (transitivization) *yàw-tu* 'take down' from *yàwwu* 'go down' [Bole], (perfectivity) *pet-inà* 'he came out' [Pero]. Another characteristic feature is the formation of so-called 'pluractional' verbs, denoting an action repeated many times or affecting a plurality of subjects (if intransitive) or objects (if transitive), e.g. [Hausa] *tunàa/tun-tùnaa* 'remind/remind many people and/or often', [Bole] *dàppu/dàdàppu* 'repair', [Angas] *fwin/fwan* 'untie', [Pero] *lofò/loffò* 'beat'.

In a number of languages, intransitive verbs (verbs without objects) are followed by an 'intransitive copy pronoun', which copies the person, number, and gender features of the subject, e.g. [Kanakuru] *nà pòrò-no* 'I went out' (lit. I went out-I). Verb stems can also be overtly inflected for tense–aspect–mood by segmental and/or tone changes, e.g. (perfective/subjunctive/imperfective) *kəma/kəmì/kəmà* 'hear' [Ngizim], and grammatically-required number agreement with the subject is also found sporadically, e.g. [Karekare] *mù ngàt-ʔan kò* 'we fell' (with *-ʔan* plural suffix), cf. *nà ngàtaa kò* 'I fell'. In some Chadic languages so-called 'logophoric' pronouns are used to denote the person whose utterance is represented in reported speech, e.g. (tones not marked) *wur sat ni ɗi n nas an* 'he_i said he_i will beat me' [Mupun], where the 3rd masculine singular logophoric pronoun *ɗi* signals that the subject of the subordinate clause refers to the same person as the main clause subject. Some languages also use impersonal forms (equivalent to implied [null] subjects) with arbitrary, often human, reference, to express impersonal subjects, e.g. [Miya] *a sənà-tlən* 'one will spend the night', and impersonal constructions containing transitive verbs typically correspond to agentless passives in English, e.g. [Hausa] *an dafà àbinci* 'the food has been cooked' (lit. (some)one.perf. cook food).

Word order is normally S(ubject)-V(erb)-O(bject), e.g. [Hausa] *Audù yaa sàyi mootàa* 'Audu bought a car' (lit. Audu he.perf. buy car), although VSO order is found in a few Central Chadic/Biu-Mandara languages spoken in the Nigeria-Cameroon border area, e.g. (tones not marked) *kə bilə Musa tə bwaja* 'Musa has killed the leopard' (lit. perf. kill Musa leopard) [Gude], *daxtaatə́-l marakw* 'he/one will take the woman' (lit. take.fut.-he woman) [Lamang]. Pronominal indirect objects usually attach to the verb like an affix, whereas nominal indirect objects occur as prepositional phrases to the right of the direct object, cf. [Kanakuru] *à jòɓ-rò landài* 'he washed the robe for her' (lit. he washed-for her robe), and *à jòɓè landài gən tamno* 'he washed the robe for the woman' (lit. he washed robe for woman). (Hausa is atypical in placing both pronominal *and* nominal indirect objects immediately after the verb.)

Wh-questions, focus, and relativization often pattern together with special (focus) marking. In Hausa, the *wh*-expression, focused element, or relativized head

occur at the left periphery of the clause and focus marking appears on the preverbal inflectional element, e.g. (*wh*-fronting) *wàa kukà ganii?* 'whom did you (pl.) see?' (lit. who 2pl.focus.perf. see), (focus-fronting) *yaarònkà mukà ganii* ('it's) your boy (that) we saw' (lit. boy.your 1pl.focus.perf. see), (relativization with fronting) *yaaròn dà mukà ganii* 'the boy whom we saw' (lit. boy.the rel. 1pl.focus.perf. see). In Miya questioned and focused (preverbal) subjects remain *in situ* but require special inflectional marking, e.g. *wàa də bəsàwà?* 'who washed (it)?' (lit. who foc. washed), *tə̀ də bəsàw* '*he* washed (it)' (lit.he foc. washed).

Negation in Chadic is typically signaled with a single marker in sentence-final position, e.g. [Guruntum] *tâa kyur shau dà* 'she will not cook the food' (lit. she will cook food neg.), [Kera] *wə gùsnə̀ hàrga bà* 'he didn't buy her a goat' (lit. he bought her goat neg.), sometimes accompanied by an additional reinforcing preverbal negative marker, e.g. [Hausa] *bà tà zoo ba* 'she did not come' (lit. neg. she.perf come neg.), [Margi] *nì ndà wì mài* 'I did not run' (lit. I neg. run. perf. neg.), [Miya] *fà tà bəta zhaak-uw* 'don't untie the donkey' (lit. you (masc.) neg. untie donkey-neg.).

Cognate complement constructions are also widespread in Chadic, where the verb is repeated in a morphologically related (verbo-nominal) form, e.g. [Hausa] *taa màaree shì maarìi mài ciiwòo* 'she slapped him painfully' (lit. she.perf. slap him slapping with pain), [Miya] *mən rà-ya ràw* 'I surpass him' (lit. I surpass-him surpassing). Comparatives are normally verbal sentences using the lexical verb 'exceed, surpass, be more than', e.g. [Hausa] *Audù yaa fi Muusaa wàayoo* 'Audu is more clever than Musa' (lit. Audu he.perf. surpass Musa cleverness), [Miya] *mə̀n jiy baa də̀ rà-tlən aa wàshàshàm* 'it was I who was older than them' (lit. I it is one who perf. exceed-them for year), [Margi] *nàjà gà mdia-ɗà də dzə̀gàm* 'he is taller than me' (lit. he surpassed-me with tall).

In noun phrase syntax, the normative order for constituents is head-initial, i.e. head noun followed by definite determiners, possessives, numerals, relative clauses, adjectives, etc. The linear order in genitive constructions is possessee X (+ 'of') + possessor Y, e.g. [Hausa] *yaarò-n Muusaa* 'Musa's boy' (lit. boy-of Musa), [Margi] *tagu gə Haman* 'Haman's horse' (lit. horse of Haman). Many Chadic languages also make an overt distinction between alienable and inalienable possession, whereby inalienable possession (items that belong to someone in a deeper sense—they cannot be taken away) is expressed by direct juxtaposition (i.e. with no overt linker), cf. (inalienable) *mənda Miyim* 'Miyim's wife' (lit. wife Miyim), and alienable (items that can be taken away) *gam ma tamnoi* 'the woman's ram' (lit. ram of woman) [Kanakuru].

Some languages restrict plural marking to a narrow range of nouns (typically humans and animals), and a few languages signal plurality only by modifying the invariant noun with a demonstrative, quantifier or numeral, cf. [Pero] *landàa mijè* 'that shirt' (lit. shirt that) and *landàa mè* 'those shirts' (lit. shirt those). Reflexive pronouns ('...self') and reciprocals ('each other') are typically formed with the body-part nouns 'head' and 'body' respectively, e.g. [Hausa] *kâ-n-tà* 'herself' (lit. head-of-her), [Kwami] *kuu-nì* 'himself' (lit. head-his), [Hausa] *juuna-n-mù* 'each other (we)' (lit. body-of-our), [Miya] *tuwatùwà-tlə̀n* 'each other (they)' (lit. body-their).

Hawaiian Creole English

Hawaiian Creole English (referred to by linguists as Hawaii Creole English) is one of a number of English-lexifier pidgins and creoles. Varieties of pidgin and creole English in Hawaii are the outcome of contact between Hawaiians, Europeans (primarily English speakers, who contributed most of the vocabulary to the emerging pidgin), and the various immigrant groups (e.g. Chinese, Japanese, Portuguese, and Filipinos) brought to Hawaii to work as indentured laborers on plantations from the 1850s onward. Hawaii Pidgin English, formed between 1890 and 1910, is spoken only by a few remaining members of the oldest generation of immigrants to the plantations and is now dying out. Its descendant, Hawaii Creole English, a more complex language, emerged between 1910 and 1930. Through Hawaii Creole English, the culture, identity, and solidarity of the local working class were created. It became a badge separating locals from the tourists as well as from the resident middle class English-speaking *haoles* (Hawaiian 'foreigner'), a term referring to whites.

Varieties of Hawaii Pidgin and Creole English are locally called simply 'Pidgin', even though most of them are technically forms of creole English because they function as the native rather than the second language of most of their speakers. Hawaii Creole English is the first language of the majority of locally born children and the first language of somewhat less than half the state of Hawaii's population of just over a million. The present ethnic composition of the Hawaiian islands reflects the diversity of the different waves of foreign labor imported to work on sugar plantations. Hawaii is the only US state in which an Asian/Pacific population is the majority: 61.9% of a total population of 1.1 million. Currently, those of white ancestry account for 33.4%, Japanese for 22.3%, Filipino for 15.2%, Chinese for 6.2%, and others for 10.2%. Native Hawaiians make up another 12.5% of the population.

Like most of the world's pidgins and creoles, Hawaii Creole English has no official recognition, and its coexistence with standard English has not been peaceful. Many speakers were and still are corrected at school for speaking 'bad' or 'broken' English. Standard English was seen as a tool of assimilation to a common American culture, even before pidgin formed and spread. As the emerging middle class increasingly adopted and identified with Standard English, at least within the context of the school, the use of Hawaii Creole English began to be perceived as a liability on the job market because it indicated low social status. It was a reminder of the plantation origins that many wanted to leave behind. The campaign to eradicate Hawaii Creole English goes back at least to a federal report issued in 1920 on education in Hawaii (then a US territory). The report recommended a number of reforms, among them the 'elimination of the jargon of the plantations and 'pidgin English' of the streets'. Creole speakers were discriminated against through education in a school system that was originally set up to keep out those who could not pass an English test. In this way, it was hoped to restrict the admission of nonwhite children into the so-called English Standard schools set up in 1924 and attended mainly by white children. By institutionalizing what was essentially racial discrimination along linguistic lines, the schools managed to keep creole speakers 'in their place' and maintain a distance between them and English speakers until after World War II.

As a result of the increasing contact between creole speakers and speakers of mainland varieties of English after World War II and the political incorporation of the islands into the United States as the 50th state in 1959, the boundaries between standard English and the creole have become fuzzier than elsewhere in the Pacific, e.g. Papua New Guinea. Contact with English has decreased the autonomy of Hawaii Creole English and has created a continuum of varieties resulting from changes introduced through decreolization, a process that has made the language less creole-like and more like English in some, but not all, respects. Although adjacent varieties of the continuum are mutually intelligible, the two extreme endpoints may often not be.

ai go liv om	most creole-like
autsaid fo yu	
ai gon liv om	
autsaid fo yu	
ai going liv om	
autsaid fo yu	
aim gonna liv om	
autsaid fo yu	
ail liv om/it	least creole-like
autsaid fo yu	
I will leave it/them	most standard
outside for you	English-like

The most decreolized varieties are found on the island of Oahu, where three fourths of the state's

population is located, along with the capital, Honolulu, and the main US military base, Pearl Harbor. The outer islands of Kauai and Hawaii are the least decreolized.

Although many opponents of Hawaii Creole English believed and hoped that the language would gradually be absorbed into English through continuing decreolization, this is clearly not happening. On the contrary, Hawaii Creole English is being maintained, and even strengthened, particularly among certain groups of young people, as a symbol of local identity in the face of inundation from mainland norms. In the face of public opposition to a proposed policy of allowing teachers and students to speak and write only Standard English, in 1987, the State of Hawaii Department of Education acknowledged that Hawaii Creole English constituted a language in its own right with a structure distinct from English. However, this recognition has not resulted in any concrete action in the classroom.

Like most pidgin and creole languages, Hawaii Creole English has not been standardized. This gives rise to the popular belief that the language cannot be written or that it is not a language at all. Linguists have for some time been using a phonemic orthography (i.e. a writing system whose letters closely correspond to the actual speech sounds) developed by Carol Odo (1975). However, it has no wider recognition. Despite the lack of written norms and standardization, there are nevertheless some writers who have attempted to use the creole as a medium for poetry, short stories, and drama by adapting English spelling to represent some of the distinctive characteristics of speech varieties in Hawaii. Each writer has worked out his or her own ad hoc spelling system. This burst of literary creativity can likewise be seen partly as a manifestation of opposition to colonialism and as an affirmation of distinctive local identity in which the use of creole plays a key role.

Although most of the vocabulary of Hawaii Creole English is derived from English, a significant number of words come from Hawaiian. As many as a thousand Hawaiian words may have been in use at one time during the plantation era, of which 250 to 350 were in fairly common use colloquially among the population. Although this number is now fewer, many still persist in local English and many more in the Hawaii Creole English of older speakers. Some words, such as *hemo*, 'take off, remove', and *ho'omalimali,* 'flatter, curry favor', are not as widely known among younger people now, whereas virtually everyone resident locally would know *haole,* 'foreigner'. Because of the general decline in the knowledge of Hawaiian, many people who use a great many of these Hawaiian words every day, either in Hawaii Creole English or in other local forms of English, do not realize that commonly used words such as *akamai,* 'clever, smart', *pio,* 'to turn off, extinguish',

huhu, 'angry, annoyed', and *ono,* 'tasty', are actually Hawaiian, rather than Japanese or even English in origin. Many of these Hawaiian words are being replaced by English ones, although in some cases, the English variants are still different from mainland US English, e.g. *grinds,* 'food' (cf. *kaukau,* 'to eat/food'). The effect of Hawaiian on standard English outside Hawaii is otherwise negligible, consisting mainly of items such as *aloha*, *lei*, *hula*, *ukulele,* and a few others.

Distinctive grammatical features include the lack of the copula *be* (*now you da head man,* 'Now you are the head man'), use of *get* in both possessive and existential constructions (*get one wahine she get one daughter,* 'There is a woman who has a daughter'), use of *stay* for locatives and progressives (*Kimo stay inside da house,* 'Kimo is inside the house', *Kimo stay eating,* 'Kimo is eating'), use of *wen* or *had* as a simple past tense marker (*Charlene wen/had play with da kids,* 'Charlene played with the kids'), use of *pau* (Hawaiian 'done, finished') as a completive marker (*Come back when you pau,* 'Come back when you are finished'), preverbal negation (*Harold no mo rice,* 'Harold doesn't have any more rice'), and use of *for* as a complementizer (*She like know how fo write pidgin,* 'She wants to know how to write pidgin'). The word order is generally subject–verb–object, as in Standard English, apart from topic/comment structures such as *big, da fish,* 'The fish is big', in which the comment appears first. Formerly, there was variation in basic word order among pidgin speakers of different ethnic backgrounds, reflecting the influence of immigrant languages such as Japanese, e.g. *sometime good road get,* 'Sometimes there are good roads'.

There is considerable variation in pronunciation among local residents of different ethnic and social class backgrounds. Generally speaking, however, the phonology of Hawaii Creole English has a smaller inventory of distinctive sounds than many mainland varieties of English. The [r] after a vowel in words such as *shark* is usually absent in the most creole-like speech varieties (i.e. [shak]), and many of the diphthongs (double vowels) found in mainland varieties of English in words such as *boat* [bout] and *play* [pleI] are single vowels in the creole (i.e. [bot], [ple]). Hawaii Creole English often has full vowels where mainland varieties use reduced ones, e.g. creole [tude], 'today', vs. mainland [tədei], and creole [mauntən] 'mountain' vs. mainland [maunten]. English interdental fricatives ('th') in words such as *they* and *think* tend to become stops in the creole (i.e. [de], [tink]). The stops in consonant clusters such as [tr] in words such as *try* are affricated (i.e. [črai]), and initial [s] in clusters such as [str] in words such as *street* sounds more like 'sh' [š]. There are also some stress and intonational differences, such as the use of falling pitch for

yes/no questions, which also do not show the subject/auxiliary inversion typical of standard English, e.g. *you like go Honolulu*? 'Do you want to go to Honolulu?' The falling intonation pattern has been carried over from Hawaiian into creole. Rising pitch together with a final question particle are used as a confirmation check in utterances such as *no mo job fo you, aeh*? 'There isn't a job for you, right?'

Hebrew: Biblical

Biblical Hebrew (BH) is a Semitic language related to Arabic, Ethiopic (such as Amharic, the national language of Ethiopia), Akkadian (Assyro-Babylonian), etc. It is called 'the language of Canaan' in the Old Testament (Isaiah 19:18). It is also called *yəhūdīt*, 'the language of Judah' or 'Judean', after the dominant tribe in the southern part of the Holy Land (II Kings 18:26, 28). Hebrew is first attested more than 3,000 years ago, and the oldest BH texts date back to the twelfth century BC. In all likelihood, Hebrew became extinct as a spoken tongue in the third century AD; however, in most places it was being supplanted by its kindred language, Aramaic, in the second and first centuries BC. It has been used continuously by Jews around the world as the language of their liturgy and also for literary purposes.

Classification

More specifically, BH belongs to the Canaanite branch of the Northwest Semitic (NWS) group. Many scholars consider Ugaritic to be a member of the Canaanite family as well; however, the present author considers this cuneiform language, discovered in northern Syria in 1929, to be a distinct branch of Central Semitic in its own right (see Kaye 1991). Most authorities would agree that the Canaanite dialects consist of BH,

Phoenician, Ammonite, Edomite, and Moabite. One other language, known as Deir ʿAllā, is controversially considered by some to be Canaanite, but this author does not agree with that classification (see Kaye 1991). The Canaanite dialects are sometimes referred to as languages; however, there existed, in all probability, a high degree of mutual intelligibility among them, along the lines of, say, Egyptian Colloquial, Syrian, Palestinian, and Jordanian Arabic.

The Stages of Biblical Hebrew

Based on linguistic factors that occur in the Hebrew Bible, BH is divided into three different stages: Old BH (1100–1000 BC), Standard BH (1000–550 BC), and Late BH (550–200 BC). The standard language may be exemplified by the Pentateuch. Old BH is best represented by the archaic poetic dialect found in Judges 5 and Exodus 15 (the Song of Moses). The former, known as the Song of Deborah, appears to be Israelian, since it uses a masculine plural in *-īn* for Judahite *-īm*, and the relative particle is *ša-* for *ʾăšer*. Thus, BH definitely had regional dialects: the Judahite dialect (i.e. Jerusalem) and the (northern) Israelian dialect (e.g. Samaria and the Galilee). About four fifths of the Hebrew Old Testament is written in the Judahite dialect. Late BH shows influence from

Aramaic, the *lingua franca* of that era, and is represented by the Books of Esther, Ezra, etc.

Diglossia

BH was a diglossic language. Diglossia is a sociolinguistic situation where a high and a low variety of a language coexist (see Rendsburg 1990, Kaye 1993). Each variety is used under a different set of circumstances, viz. formal or official discourse vs. informal (the closest parallels are the diglossic cases of Arabic and Modern Greek). Examples of colloquial usage have, for a variety of reasons, entered the Biblical text, since the Old Testament should not be regarded as a compilation of speech from Biblical times, but rather as an edited collection of essays and literary versions of direct speech and oral transmissions.

Orthography

BH uses the Phoenician alphabet of 22 letters, including some polyphonous graphemes, and is written from right to left. All traditions of Ancient Hebrew agree that there are 23 consonant phonemes, including two semiconsonants that developed from a system of 29 Proto-Semitic consonants. Originally, only the consonants were represented, and the corpus had achieved its current stable state by the second century AD. As the orthography developed, a system of *matres lectionis* 'mothers of reading', or so-called vowel letters, emerged, viz., <h>, <w>, and <y> were used to indicate their respective phonetically similar corresponding vowels in final position. This system, in existence since the tenth century BC, expanded over time to include medial vowels as well (attested since the ninth century BC), while initial vowels did not need to be included, since no BH word could begin with a vowel (with the exception of /ū/, an allomorph of /wə-/ 'and'). The orthographic representations without *matres lectionis* are older spellings than those with them; <kl> 'each; every' is spelled only once as <kwl> (cf. Arabic <kl>, which is the cognate).

The Hebrew Bible's oral tradition was preserved from the sixth to the tenth century AD by a group of Jewish scholars known as the Masoretes (< Hebrew *māsōrāh* 'tradition'). These scholars established a recognized text of the Hebrew Bible called the Masoretic Text. Three different systems developed: Babylonian, Palestinian, and Tiberian. The authoritative one since about AD 1000 has been the Tiberian, the best known of which is the work of Aaron Ben-Asher (AD 915). A system of diacritics, mostly for vowels, developed, in addition to accent markings, cantillation marks for liturgical recitation, and marginal notes. Its purpose was to insure the accuracy of recording the traditional pronunciation of the Biblical text. Among the most significant of all Masoretic inventions was the dot, called *daghesh*, which was used inside some consonants to indicate a geminated or a stop version of that consonant (as opposed to a fricative, since like Aramaic, BH developed fricative allophones for /bgdkpt/, viz. [βɣðxfθ]). Consonantal gemination was phonemic in BH as it is in Arabic; however, a characteristic of the Masoretic text was that five consonants could not be geminated (probably for phonetic reasons, all being back consonants). They are: /ʾʕhḥr/. Since they do not geminate, vocalic change was commonplace with the preceding vowel via a process of compensatory lengthening.

Basic Characteristics of Biblical Hebrew

BH has two grammatical genders, masculine (*ʾīš* 'man') and feminine (*ʾiššɔ* 'woman'). It also has a dual for nouns that occur in pairs, such as for many body parts (e.g. /ˈēynayim/ 'eyes'). It has a triconsonantal root system like the other Semitic languages (see further below); e.g. the root *qdš* has to do with 'holiness' or 'sanctification'. Furthermore, it is well known for its seven major *binyanim* or verbal forms or stems (Arabic has 10!). Illustrating with the aforementioned root, they are as follows (in the perfect, third-person masculine singular, the usual or unmarked citation form for the BH verb, following Steiner 1992):

I *qal* ('simple' or basic) *qɔdaš* 'be holy'
II *nifʕal* (passive of I) *niqdaš* 'reveal oneself as holy'
III *piʕel* (intensive or causative) *qiddeš* 'sanctify; purify'
IV *puʕal* (passive of III) *quddaš*
V *hifʕīl* (causative) *hiqdīš* 'consecrate; devote'
VI *hufʕal* (passive of V) *huqdaš* 'be consecrated; devoted'
VII *hitpaʕel* (reflexive-reciprocal) *hitqaddeš* 'sanctify or purify oneself'

There are also minor stems, such as another causative *šafʕel*, which derives from a Proto-Semitic and Proto-Afroasiatic *s*-causative. The root *ktb* 'write' may serve as illustrious of nominal and verbal morphology (it occurs 203 times in the Old Testament). Among the verbal forms to be noted are *kɔtab* 'he wrote', *kɔtūb* 'written', *niktab* 'it was written', *məkatbīm* 'write constantly (masc. pl.)', and the nominal patterns *kətɔb* 'register', *kətobet* 'tattooing', *miktab* 'writing', and, possibly, *miktɔm* 'psalm of expiation' via *b* > *m*.

Further, BH has a perfect and an imperfect, which eventually came to denote the past and the present-future (see below).

Phonology

Among the most interesting of the BH phonological developments from Proto-Semitic are the changes of the interdentals to corresponding fricatives, creating mergers; e.g. */ð/ and */z/ > /z/, and */š/ and */θ/ > /š/. Also noteworthy are the following: */ṣ/, */ṣ́/, and */θ̣/ > /ṣ/, */ɣ/ and */ʿ/ > /ʿ/, and */x/ and */ħ/ > /ħ/. The best-known BH phonological fact, in all likelihood, has to do with a dialectological difference reported in the Book of Judges, where the Ephraimites were unable to pronounce *shibboleth* 'flowing stream' or 'ear of corn' correctly as in the Gileadite dialect, saying *sibboleth* instead (Judges 12:6), and this erroneous pronunciation gave away their identities. It should be pointed out that the letters *šīn* and *sīn* are written with the same grapheme and thus were polyphonous, since /ś/ merged with /š/ over time. One also notes several dialectal variants with sibilants, e.g. *śħq* and *ṣħq* 'laugh', and *zʿq* and *ṣʿq* 'shout'.

Emphatics

The exact articulation of emphatic phonemes /ṣ/, /ṭ/, and /q/ are not really known. The evidence from the cognate languages is mixed. If one compares with Arabic, the corresponding sounds are pharyngealized and velarized, except for the voiceless uvular plosive. On the other hand, if one adverts to Ethiopic and South Arabian, the sounds are glottalized (ejective). Most Semitists believe that the evidence favors the glottalization of the Proto-Semitic emphatics.

Morphology

We have already mentioned the triconsonantal root (see above). However, it is important to keep in mind that early Semitic also had many biconsonantal roots. Unquestionably, many original biconsonantal roots became triconsonantal via *Systemzwang*. Basically, the idea is that a root determinative was added to make an original biconsonantal triconsonantal. The details of this process are not fully understood, and this area is rife with controversy.

Perhaps the most controversial area in BH morphology has to do with the nature of the verbal system (see above). Many conclude that the imperfect originally expressed actions and was used to denote the durative aspect. The perfect originally expressed the stative. The preterite nature of the imperfect is preserved in the BH 'consecutive' or 'conversive' tenses. Many of the 5,280 occurrences of the root *ʾmr* 'say' are with the *wāw*-consecutive: *wayyōmɛ/ar* 'and he said'. As is the case in BH, the *wāw*-consecutive form also occurs in Ugaritic prose, not poetry.

Syntax

The adjective follows the noun and agrees with it in number, gender, and definiteness. Thus, *ʾiššɔ kūšīt* 'an Ethiopian woman' and *hɔʾiššɔ hakkūšīt* is 'the Ethiopian woman'.

The basic word order is VSO, but for emphasis other word orders are possible. There is an accusative particle *ʾet* that marks definite direct objects. Thus, Genesis 1:1 reads: *bərēšīt bɔrɔ ʾĕ/ōhīm ʾet haššɔmayim wəʾet hɔʾɔrɛṣ,* lit., 'in the beginning-created-God-Acc.-the heavens-and-ACC.-the earth'.

Loanwords

BH has borrowed vocabulary from a variety of languages, including Egyptian, Sumerian, Akkadian, Aramaic, Greek, and Persian. Two well-known examples include *barzel* 'iron' < Hittite *barzillu*, and *parʿō* 'Pharaoh' < Ancient Egyptian *pr-ʿȝ* 'the great house'. Examples of BH words that have come down into English include many proper names (Saul, David, etc.) and terms relating to religion, such as *amen* and *sabbath*, not to mention the ubiquitous *schwa*, the mid-central vowel [ə] known to all linguists.

Hebrew: Modern

Modern Hebrew (MH) is the first language for the native Jewish population in the State of Israel and the second language for the new immigrants and the native Arab population. In its current form, MH is dated back only as far as the late nineteenth century; prior to that period, Hebrew was used for liturgical and ritual purposes for about 1,700 years. The genetic affiliation of MH to the Semitic family, although not uncontroversial (Wexler 1990), is strongly manifested in its morphology and lexical stock, which were drawn from Biblical Hebrew, the language of the Old Testament. The phonology of the language, on the other hand, as well as word order, do not reflect the characteristics of Biblical Hebrew.

Verb Morphology

MH morphology is characterized by the Semitic type nonconcatenative structure, especially in the verbal system. A verb must belong to one of the five morphological classes called *binyanim* 'constructions' (singular *binyan*). Each *binyan* has a specific prosodic structure (in terms of syllables) and vocalic pattern, and some also have a prefix; for some *binyanim,* these properties must be specified for each tense. The verbs below are given in their third-person singular form; stress is final unless otherwise specified (by an acute sign). (see Table 1)

While the verbs in table 1 differ in their *binyan* (i.e. prosodic structure, vocalic pattern, and prefixes, if any), they all share a discontinuous string of consonants, traditionally called the 'consonantal root'. Verbs sharing a consonantal root often share a semantic property, and it is thus traditionally claimed (for all Semitic languages displaying this type of morphology) that the consonantal root carries the core meaning of the verb. Notice that not every root has a verb in all the *binyanim,* as can be seen from the different B2 verb in the table in table 1, which replaces the

nonexistent verb **nigdal*. It appears that there is no other language family that is claimed to have roots consisting of consonants only. For this and other reasons, the validity of the notion of the root has been challenged (Bat-El 2002). The *binyan* may contribute a syntactic property to the verb, but only in paradigmatic relations (Berman 1978). For example, B2 is the passive counterpart of B1 (*gamar* 'finish B1'—*nigmar* 'be finished B2'), B4 is the transitive counterpart of B1 (*lamad* 'learn B1'—*limed* 'teach B4'), B3 is the causative counterpart of B1 (*xatam* 'sign B1'—*hextim* 'have someone sign B3'), and B5 is the reciprocal, reflexive, or passive counterpart of B4 or B1 (*niʃek* 'kissed B4'—*hitnaʃek* 'kissed with someone B5', *raxac* 'wash B1'—*hitraxec* 'wash oneself B5', *kibel* 'receive B4'—*hitkabel* 'be received B5'). There are two passive forms, often considered to be *binyanim* as well, derived from B3 and B4 by substituting the vocalic pattern with {u, a} (B3 *higdil* 'enlarge'—*hugdal* 'be enlarged', B4 *gidel* 'raise'—*gudal* 'be raised'). These forms, although not commonly used, have no exceptions and are always contingent, structurally and semantically, upon their active counterpart.

Verbs are also accompanied by affixes indicating tense, person, number, and gender. (see Table 2)

The values of the person–number–gender properties of the verb are drawn from subject noun or pronoun with which the verb must agree (*ha-yalda gadl-a* 'the girl grew', *ha-yeladim gadl-u* 'the children grew', *ʔanaxu gadal-nu* 'we grew'). The gender properties of the noun are natural in case of animate nouns (*sus* 'horse ms.' - *susa* 'horse fm.'), but serve in a purely grammatical role in inanimate nouns (*séfer* 'book ms.', *délet* 'door fm.'). Subject–verb agreement allows phrases without a subject, but only when the subject is not the third person (*karánu séfer* '(we) read a book'). There are also phrases without a verb, but only in the present tense (*ha-séfer al ha-madaf* 'the book (is) on the shelf', *ha-yalda xaxama* 'the girl (is) smart').

TABLE 1

Binyan/Tense	Past	Participle	Future	
B1 paʔal	gadal	gadel	yigdal	'grow'
B2 nifʔal	(nigmar)	(nigmar)	(yigamer)	('be finished')
B3 hifʔil	higdil	magdil	yagdil	'enlarge'
B4 piʔel	gidel	megadel	yegadel	'raise'
B5 hitpʔael	hitgadel	mitgadel	yitgadel	'agrandize'

TABLE 2

Gender/Person	Past		Future		Participle		
	Singular	Plural	Singular	Plural		Singular	Plural
M/F - 1	gidál-ti	gidál-nu	ʔa-gadel	ne-gadel			
M - 2	gidál-ta	gidál-tem	te-gadel	te-gadl-u	M	me-gadel	me-gadl-im
M - 3	gidel	gidl-u	ye-gadel	ye-gadl-u			
F - 2	gidál-t	gidál-tem/n	te-gadl-i	te-gadl-u			
F - 3	gidl-a	gidl-u	te-gadel	ye-gadl-u	F	me-gadél-et	me-gadl-ot

Noun Morphology

Nouns, like verbs, exhibit prosodic and vocalic restrictions called *mishkal* 'weight' (plural *mishkalim*). Related nouns (and adjectives) differ in their prosodic structure and vocalic pattern, as well as affixation (*gadal* 'to grow'—*gódel* 'size', *mi-gdal* 'tower', *gadol* 'big'; *carax* 'to consume'—*córex* 'need', *ti-cróx-et* 'consumption', *carx-an* 'consumer'). Not only are there far more *mishkalim* than *binyanim*, a noun, unlike a verb, does not have to fit into a *mishkal*. Thus, while loan-verbs (or verbs derived from loan nouns) must belong to a *binyan* (*tilfen* 'to phone', *kided* 'to codify'), nouns can maintain the structure of the source word, with a few phonological modifications (*diéta* 'diet', *télefon* 'phone'). The *mishkal* system is not rigid because there is nothing in the morphology of nouns that is contingent upon the *mishkal*. In verbs, in order to be able to derive one tense from the other, it is crucial to know the *binyan*, which is identified on the basis of the prosodic structure and vocalic pattern (and prefixes, if any). Such information is not relevant for the morphology of nouns, which involves mainly suffixation: plural suffixes *-im* for masculine (*xatul-im* 'cats ms.') and *-ot* for feminine (*xatul-ot* 'cats fm.'), various feminine suffixes (*xatul-a* 'cat fm.', *rakdan-it* 'dancer fm.', *sofér-et* 'writer fm.'), a diminutive suffix (*sus-on* 'little horse'), an agent suffix (*taklit* 'record'—*taklit-an* 'DJ'), various nominal suffixes (*manhig* 'leader'—*manhig-ut* 'leadership', *mila* 'word'—*mil-on* 'dictionary', *magav* 'wiper'—*magév-et* 'towel'), and an adjectival suffix (*tarbut* 'culture'—*tarbut-i* 'cultural'). The suffixes *-a*, *-it*, *-et*, and *-ut* assign a feminine gender and all the others assign masculine gender to the base. The plural suffixes do not assign gender but rather agree with the gender of the base (with several exceptions, such as *ʃoʃana* 'rose fm', which takes the masculine plural suffix *-im*, *ʃoʃan-im*). These suffixes are not sensitive to the structure of the noun to which they are attached and one can even find borrowed nouns with a native suffix (*geográf-i* 'geographic', *dialóg-im* 'dialogs', *simétriy-ut* 'symmetry'). The participle form of the verb also functions as a noun, and its morphology is that of the noun, i.e. it has only number and gender specification (*ha-ʃomer ʃomer al ha-báyit* 'the guard guards (ms.sg.) the house', *ha-ʃomer-im ʃomer-im al ha-báyit* 'the guards guard (ms.pl.) the house').

Beyond the Word

A noun can also be formed from two nouns (and an adjective from an adjective plus a noun), where the first element determines the general meaning, thus considered the head, while the second adds specific information. For example, *beit+séfer* 'school (house+book)' is a type of a house, *naʔarat+rexov* 'street girl (girl+street)' is a type of a girl, and *ʔiver+cvaim* 'color blind (blind+colors)' refers to a type of blindness. There are two types of noun+noun structure, one called a compound and the other a construct state, where only the latter is accessible to syntactic modification (Borer 1989). In the construct state, the non-head (second) element can be modified (*gan+ʃoʃanim ʔadumot* 'a garden of red roses (garden+roses red)'), or conjoined with another noun (*gan+ʃoʃanim ve-cipornim* 'garden of roses and carnations (garden+roses and carnations)'). However, in a compound such as *gan+yeladim* 'kindergarten (garden-children)' the non-head *yeladim* is not accessible to the syntax. Despite the difference in accessibility to syntax, both the compound and the construct state display the same morphology and phonology. In both, the plural suffix, which has the special form *-ei* for masculine, is attached to the first (head) element (*gan-ei +yeladim*, *gan-ei+ʃoʃanim*), the feminine suffix *-a* takes the form *-at* (*naʔara* 'girl' - *naʔarat+rexov* 'street girl'), and, in both, the second element bears the main stress. Occasionally, speakers may disagree as to whether the noun+noun form is accessible to the syntax, i.e. whether it is a compound or a construct state.

Word order in MH is usually subject–verb–object (SVO), but permutation of this order is relatively free. Thus, the phrase *dáni raʔa ʃoʃana ʔaduma* 'Dani saw a red rose' can appear in some contexts as *ʃoʃana ʔaduma dáni raʔa* or *ʃoʃana ʔaduma raʔa dáni*. However, adjectives always follow the noun they modify (*ʃoʃana ʔaduma* 'red rose (rose red)'), and numerals, with the exception of the numeral 'one', always precede it (*ʔéser ʃoʃanim* 'ten roses', *ʃoʃana ʔaxat* 'one rose (rose one)'). Definite nouns are preceded by the definite article *ha-* 'the', which also appears in the

modifying adjective (**ha**-ʃoʃana **ha**-ʔaduma); there is no indefinite article. All other function words also appear as proclitics: prepositions appear before the phrase (**ʔal**-ha-séfer 'on the book', **me**-ha-báyit 'from the house'), the conjunctive marker ve- 'and' appears before the last element in the list (séfer, niyar **ve**-ʔet 'a book, a paper, and a pen'), and the subordination marker ʃe- 'that' appears before the subordinate clause (ha-baxur **ʃe**-xika la 'the guy that waited for her'). Question words (mi 'who', ma 'what', matay 'when', ʔeyfo 'where') appear at the beginning of the phrase (**mi** zarak kadur 'who threw a ball?') and can be preceded by a preposition (**ʔal-mi** zarákta kadur 'at whom did you throw a ball?').

Phonology

The sound system of MH consists of 20 consonants— *p, b, m, f, v, t, d, s, z, c, n, l, ʃ, y, k, g, x, r, h, and ʔ* (and in some dialects also ʕ and ħ), and five vowels; *i, u, e, o, a*. The sound *h*, is often substituted by *ʔ*, and both are deleted in casual speech.

Stress in nouns can be ultimate or penultimate (and rarely antepenultimate). When the plural suffix is added, stress shifts to the end in most nouns, whether the singular form has ultimate stress (gamád - gamadím 'dwarf sg.-pl.'), or penultimate (yéled - yeladím 'boy sg.-pl.'); in some nouns, the stress stays in the same position on the stem (salát - salátim 'salad', tíras - tírasim 'corn sg.-pl.'). In verbs, stress is always final on the stem (gadál 'he grew', gadál-nu 'we grew'), but shifts to the end when a vowel initial suffix is added (gadl-á 'she grew'). When stress shifts, the vowel in the stem final syllable is deleted when the preceding syllable is open (gadal-a —-> gadlá 'she grew'), and changes to *e* when the preceding syllable is closed (yigdal-u —-> yigdelú 'they will grow') or when flanked by identical consonants (garar-a —-> garerá 'she dragged'). Stress shift and vowel deletion/change do not affect B3 verbs (higdíl-a 'she enlarged') and

monosyllabic verbs (rác-u 'they ran'). In nouns, it is the vowel in the penultimate stem syllable that undergoes deletion, but only in a lexically marked group of nouns and adjectives (gamal - gmalim 'camel sg.-pl.' but gamad - gamadim 'dwarf sg.-pl.'). When the first consonant in the penultimate syllable is a sonorant (*m, n, l, r, y*), the vowel subject to deletion is replaced by *e* (lavan - levanim 'white sg.-pl.').

There is a stop-fricative alternation in MH (*p - f, b - v, k -x*), reminiscent of the postvocalic spirantization of Tiberain Hebrew (**k**atav 'he wrote' - yi**x**tov 'he will write'). However, this alternation is not entirely regular as there are postvocalic stops (bike ʃ 'he requested') as well as fricatives in non-post-vocalic positions (**x**ipes 'he searched'). At the current stage of the language, there is a great degree of free variation in the verb system (yixtov ~ yiktov), which may suggest a change toward a uniform verbal paradigm with respect to spirantization.

Hindi-Urdu

Hindi is a modern Indo-Aryan language spoken in South Asian countries (India, Pakistan, and Nepal) and also in countries outside Asia (Mauritius, Trinidad, Fiji, Suriname, Guyana, South Africa, and other countries). Approximately six to seven hundred million

people speak Hindi either as a first or second language. It is ranked among the two most widely spoken languages of the world. Along with English, it is the official language of India. In addition, it is the state language of Bihar, Haryana, Chattisgarh, Jharkhand,

Himachal Pradesh, Arunachal Pradesh, Madhya Pradesh, Uttar Pradesh, and Rajasthan.

Hindi, which is a descendant of the Sanskrit language, is not strictly the name of any chief dialect of the area but is an adjective, Persian in origin, meaning Indian. Historically, it was synonymous with Hindui, Hindawi, Rexta, and Rexti. The term Urdu is also used to refer to this language. All these labels denote a mixed speech spoken around areas of Delhi, North India, which gained currency during the twelfth and thirteen centuries as a contact language between Arabs, Afghans, Persian, Turks, and native residents. Hindi and Urdu have a common form known as Hindustani. This was the variety that was adopted by Mahatma Gandhi and the Indian National Congress as a symbol of national identity during the struggle for freedom from Britain.

Urdu is spoken by approximately 50 million speakers in the subcontinent of India and Pakistan. It is the national language of Pakistan and one of the 19 official languages of India. The term 'Urdu' is Turkish in origin (i.e. ordu 'camp'). As mentioned above, both Hindi and Urdu have their origins in the mixed speech spoken around Delhi. In time, this mixed speech called khari boli developed its own variety called 'Hindi' or 'Urdu'.

The first question that is immediately raised about Urdu is: How does it differ from Hindi? This is not an easy question to answer. In many respects, the two speech varieties are mutually intelligible and at another level they are quite unintelligible. Moslems often report their speech variety as Urdu, and Hindus and other non-Moslem speakers tend to report their speech variety as Hindi. Yet, one notable difference in Hindi and Urdu is script.

Hindi is written in the Devanagari script, which is ranked as the most scientific writing system among the existing writing systems of the world. The Devanagari script is written from left to right and is a descendant of the Brahmi script, which was well established in India before 500 BC. The script is phonetic in nature and there is a fairly regular correspondence between the letters and their pronunciation.

Urdu is written in the Persio-Arabic script. Like Arabic, it is written from right to left and short vowels are usually not written. It is due to Urdu that the Arabic script underwent great modification and some new symbols were added to it to represent sounds, such as retroflex consonants (produced with the tip of the tongue curled upwards), which are specific to the Indian subcontinent.

In addition to Hindi and Urdu being written in two different scripts, the two languages also differ from each other in minor ways in their grammatical systems and vocabulary. Urdu tends to borrow its vocabulary from Persio-Arabic sources, whereas Hindi borrows from indigenous Sanskrit sources. This tendency has resulted in the admission of new sounds (e.g. z, x, G) into Urdu and in the development of its distinct literary style.

The literary history of Hindi goes back to the twelfth century. Some notable literary figures of Hindi are Surdas, Tulsidas, and Mira Bai. Urdu literature flourished both in India and Pakistan. The literary history of Urdu can be traced back to approximately the thirteenth century. Its first poet was Amir Khusro (1253–1325), who termed the language *zabaan-e-Dehlvi* or Hindi. Amir Khusro included Hindi verses among his Persian poems and romances. But the greatest poet of Hindi-Urdu was Kabir, who was famous for his devotional poetry.

Urdu is particularly well known for its romantic literature. The two most famous genres of Urdu are Masnawii and Gazal, which are the gift of the mixing of the Hindu and Persian-Muslim cultures. Some notable literary figures of Hindi-Urdu literature are Inshah Alla Khan, Malik Muhammad Jayasi, Mir, Daya Shankar Nasim, Bahadur Shah Zafar, Iqbal, and Mirza Ghalib.

Hindi-Urdu has an approximately three-century-old, well-attested, and rich grammatical tradition of its own. It is a by-product of the colonial era and was born shortly after the arrival of Europeans in India.

Phonology

The two notable phonological features of the language are as follows: (1) Hindi still retains the original Indo-European (1500 BC) distinction between aspirated and unaspirated consonants, which results in a four-way contrast as shown in the following examples: *kaal* 'time', *khaal* 'skin', *gaal* 'cheek', and *ghaal* 'to put into'. (2) It has the feature of retroflexion in its consonant inventory, cf. *Taal* 'to put off' and *taal* 'pond'. The retroflex consonant is transcribed as the capital T.

The inventory of distinctive segments of standard Hindi-Urdu is shown in Table 1. Sounds that occur in Persio-Arabic words are provided in parentheses ( ).

Stress

Although stress (meaning loudness) is not a prominent feature of Hindi-Urdu, nevertheless, it seems that its existence cannot be denied. Stress can distinguish between grammatical categories such as nouns and verbs, as in

Nouns	Verbs
galaa neck	ga**laa** cause to melt
talaa sole	ta**laa** cause to fry

TABLE 1 Consonants

		Labial	Dental	Retroflex	Palatal	Velar	BackVelar
Stop	Unvoiced unaspirate	p	t	T	c	k	(q)
	Unvoiced aspirate	ph	th	Th	ch	kh	
	Voiced unaspirate	b	d	D	j	g	(G)
	Voiced aspirate	bh	dh	Dh	jh	gh	
	Nasal	m	n	N	ñ	ŋ	
Fricative	Unvoiced	(f)	s	sh		(x)	
	Voiced		(z)				
Flap	Voiced unaspirate		r	R			
	Voiced aspirate			Rh			
Lateral			l				
Semivowels			w (v)		y		

Vowels

	Front	Central	Back
High	ii		uu
	i		u
Mid	e		o
	ai	a [schwa]	au
Low		aa	

The stressed syllable is shown in bold. However, stress is not usually distinctive in Hindi-Urdu. Therefore, in general, whether one places stress on the first syllable or on the second, the meaning will not be affected. For example, the meaning of word, *sunaa* heard will remain unchanged whether one places stress on the first syllable or the second. Therefore, Hindi-Urdu is often characterized as a 'syllable-timed' language like French, where the syllables are pronounced in a steady flow, resulting in a 'machine-gun' effect.

Morphology

Word formation in Hindi-Urdu primarily uses prefixes and suffixes to define inflectional and derivational word classes. Nouns are generally inflected for number, gender, and case. There are two numbers, singular and plural; two genders, masculine and feminine; and three cases, simple, oblique, and vocative. The oblique forms occur when a noun or noun phrase is followed by a postposition, vocative case marks nouns referring to the addressee of the utterance. Nouns are inflected according to their gender and word-final sound, as exemplified by the four paradigms given in Table 2.

Adjectives are primarily of three types: (1) Simple adjective, such as *acchaa* 'good'; (2) Derived adjectives using various parts of speech such as nouns: *mardaanaa* 'masculine', adverbs: *mandaa* 'slow', and from agentive/adjectival particle *vaalaa*, e.g. *dillii vaalaa* 'from Delhi'; and (3) Participial adjectives: *caltii* 'moving', *bhaagtaa* 'running'. Adjectives can be used both attributively (immediately placed before nouns) and predicatively (immediately placed before verbs). Simple, participial, and *vaalaa* adjectives are of two types: inflected and uninflected. Inflected adjectives agree with their following noun in number, gender, and case; they end in morpheme -aa (e.g. *acchaa* 'good'), which changes to e for masculine plural and masculine oblique (*acche*), ii for feminine nouns (*acchii*). Uniflected adjectives remain unchanged.

Although the case system of pronouns is essentially the same as that of nouns, pronouns have more case forms than nouns. Case relations are essentially carried out by means of postpositions. Personal pronouns are similar to their English equivalents except that there are no gender distinctions (like *he* and *she* in English) (Table 3).

Adverbs and postpositions are invariant, except for the genitive postposition, which behaves like an inflected adjective. The postpositions mark case relations and adverbial functions.

Hindi has no articles.

Verbs

There are three tenses in Hindi: present, past, and future. The tenses are formed by the suffixation process. Verbs are inflected for number, gender, and person.

(1) vo aa-t-aa hai.
    he come-present-mas.Sg is (3sg)
    'He comes'.

(2) vo aa-yaa.
    he come-past-mas, Sg.
    'He came'.

(3) vo aa-ye-g-aa
    he come-3sg-future-mas. Sg
    'He will come'.

TABLE 2   Hindi Noun Paradigms

Case	Paradigm-I Masculine Nouns Ending in *-aa*		Paradigm-II Masculine Nouns Not Ending in *-aa*	
	Singular	Plural	Singular	Plural
Direct	*laRkaa 'boy'*	*laRke*	*aadmii 'man'*	*aadmii*
Oblique	*laRke*	*laRkõ*	*aadmii*	*aadmiõ*
Vocative	*laRke*	*laRko*	*aadmii*	*aadmio*
Case	Paradigm-III Feminine Nouns Ending in *-ii*		Paradigm-IV Feminine Nouns Not Ending in *-ii*	
	Singular	Plural	Singular	Plural
Direct	*laRkii 'girl'*	*laRkiyãã*	*maataa 'mother'*	*maataaẽ*
Oblique	*laRkii*	*laRkiyõ*	*maataa*	*maataaõ*
Vocative	*laRkii*	*laRkio*	*maataa*	*maataao*

TABLE 3   Hindi Pronoun Paradigms

	1st Person		2nd Person			3rd Person	
	Singular	Plural	Singular	Plural	Honorific	Singular	Plural
Direct	mãĩ	ham	tuu	tum	aap	vo	ve
Oblique	mujh	ham	tujh	tum	aap	us	un
Genitive	meraa	hamaaraa	teraa	tumhaaraa	aapkaa	uskaa	unkaa

In addition to simple verbs, Hindi has two categories termed 'conjunct' and 'complex' verbs. The class of conjunct verbs is usually derived adding *karnaa* 'to do' or *honaa* 'to be' to noun, adjective, pronoun, or adverb; e.g.

(4) *kaam* 'work', *kaam karnaa* 'to work',
(5) *acchaa* 'good', *acchaa honaa* 'to recover',
(6) *dhiire* 'slow', *dhiire karnaa* 'to slow down',
(7) complex verb: *likh* 'write', *lenaa* 'to take' -→
     likh lenaa 'to write' (for one's own benefit)'.

Hindi is also sensitive to stative/active and volitional/nonvolitional distinction; these four types of distinction are denoted by morphologically related verbs:

(8) *khulnaa* 'to be opened', *kholnaa* 'to open',
(9) *TuuTnaa* 'to be broken', *toRnaa* 'to break'.

Compounding is an integral and very productive process of word formation in Hindi. The noun–noun compounding involves 12 types of compounding. For example, *khaanaa* 'eating' and *piinaa* 'drinking' can be compounded into *khaan–paan*, which means 'life style'.

From the viewpoint of morphological complexity, Hindi can be classified as an agglutinating language. This means that derivation of words takes place by the addition of suffixes to simple or derived stems of major word classes. The process of prefixation is almost exclusively used with nouns and verbs; other word classes rarely participate in this process. The process of suffixation is productive equally with both nouns and verbs.

Syntax

Hindi is a Subject–Object–Verb (SOV) language with a relatively fixed word order. Interrogative or other sentence types do not introduce any changes in word order. In topicalization and focus structure, however, phrases may occur in a marked (i.e. exceptional) position, usually initial. The verb generally agrees with the subject. In transitive perfective sentences, the subject is marked with the *ne* postposition, and the verb agrees with the direct object. A rule of thumb is that the verb never agrees with any constituent that is marked with a postposition.

Any sentence can be negativized by placing the negative particle *nahii* 'not' in the preverbal position.

(10) vo   nahĩĩ   aa-ye-g-aa
     he   not   come-3sg-future-mas. Sg
     'He will come.'

Hiri Motu

Hiri Motu is a pidgin language that is of particular interest because it is one of the few well-described pidgins with a vocabulary derived from a non-Indo-European language. Its lexical source is the Motu language spoken in a dozen villages along the southern coast of the 'tail' of Papua around Port Moresby, the capital of Papua New Guinea.

Motu is a member of the huge Austronesian language family, which extends throughout Polynesia, Micronesia, much of Melanesia, most of Indonesia and Malaysia, all of the Philippines, Madagascar, and the interior of Taiwan. The Oceanic subgroup, to which Motu belongs, comprises approximately half the total number of Austronesian languages, all of which are located east of a north–south line through the Indonesian province of Papua.

Motu exhibits many of the structural features that are widely distributed in Oceanic languages. There is a set of inflectional prefixes on the verb that provide grammatical information about the subject, with the result that the subject can go unmentioned. These prefixes also mark tense and negation. Verbs that take objects are also marked by suffixes providing grammatical information about the object. Thus, *e-ita-gu* '(s)he saw me' means literally '(s)he:NONFUTURE-see-me' or *baine-ita-gu* '(s)he will see me' (literally '(s)he:FUTURE-see-me').

Although subject and object pronouns are not required in Motu, they can be present. When both subject and object are present, the subject must be followed by *ese*, as in *ia ese lau e-ita-gu* '(s)he saw me' (literally '(s)he SUBJECT me (s)he:NONFUTURE-see-me').

Motu nouns also reflect the widespread Oceanic pattern of distinguishing between inalienable and alienable possession. 'Inalienable possession' refers to an inherent relationship between the possessor and the possessed (e.g. persons and their body parts). In Motu, it is expressed with pronominal suffixes attached directly to the noun, e.g. *mata-gu* 'my eye' (literally 'eye-me'), *mata-mu* 'your eye' (literally 'eye-you'). Alienable possession, i.e. a possessive relationship that is not inherent in the nature of the items concerned, is expressed by means of pronominal suffixes attached to an independent classifying element. The alienable possession of something to be eaten involves the possessive classifier *a-*, while the alienable possession of anything else uses the possessive form *e-*, e.g. *a-gu aniani* 'my food' (literally 'foodstuff-me food'), *e-gu ruma* 'my house' (literally 'thing-me house').

Many Oceanic languages exhibit a word order of S(ubject)-O(bject)-V(erb), while others have SOV. A few languages also have VSO and VOS. Motu falls into the SOV class. SVO languages typically use prepositions to mark certain functions of a noun in the sentence, e.g. the English preposition *at* marks a location. Motu uses postpositions instead (i.e. particles that are equivalent to prepositions but occur after the noun they modify). Thus, *Guhi amo e-moru* '(S)he fell **from** the roof' (literally 'roof from (s)he:NONFUTURE-fall').

With this brief background on Motu, we can turn to Hiri Motu. Because it is a pidgin language, it would be expected to be simplified by comparison with its major source language. Pidgin languages typically eliminate (or sharply reduce) grammatical inflections. This tendency is clearly evident in Hiri Motu in that none of the inflectional prefixes, e.g. Motu's *e-* '(s)he:NONFUTURE', have been retained. Not surprisingly, the independent subject pronouns are obligatory in Hiri Motu rather than optional as in Motu. Tense and negation are marked not by prefixes but by free forms. For example, *do(hore)*, occurring before the verb, marks future tense, while *lasi* 'no' occurs after the verb to mark negation.

The object suffixes have also been lost. Pronominal objects are expressed with the same free pronouns that are found in subject position. Subject and object pronouns are thus distinguished only by word order. With pronominal subjects and objects, the word order is OSV. Thus, contrast the examples above from Motu with the following Hiri Motu equivalents: *lau ia itaia* '(s)he sees/saw me' (literally 'me (s)he see') and *lau dohore ia itaia* '(s)he will see me' (literally 'me FUTURE (s)he see').

459

With noun subjects and objects, the word order in Hiri Motu is SOV, as in Motu. For a pidgin language, this is relatively rare, and even in Pidgin Fijian, for which the lexical source is predominantly OSV, the word order is SVO.

Other features have also been simplified in Hiri Motu. The distinction between inalienable and alienable possession is lost on the grammatical level. However, the distinction is still there on the lexical level: inalienably possessed nouns such as *mata-* 'eye' include the original third-person singular suffix *-na* as part of the noun root. In the grammar, simple possession is marked by a possessive pronoun that is a combination of the independent pronouns and the original nonedible alienable possessive markers. Thus, compare the variety of Motu possessive constructions presented earlier with the following from Hiri Motu: *lauegu matana* 'my eye', *lauegu aniani* 'my food', *lauegu ruma* 'my house'.

Hiri Motu has been discussed so far as a monolithic entity, although there is in fact considerable structural variation. In particular, speakers of Austronesian languages closely related to Motu—predominantly from the coastal area around Port Moresby—incorporate more of the patterns from Motu than do Hiri Motu speakers from farther afield. These people, for example, typically maintain the distinction between inalienable and alienable possession, as well as maintaining object suffixes on transitive verbs.

Papua has long been an area of language contact, and Tom Dutton (1985) describes in detail the development of a number of contact languages from languages of this area in association with the *'hiri'* trading expeditions conducted along the Papuan coast before colonial times. As the *hiri* expeditions were abandoned, so too were the languages that arose in this context, although Dutton was able to record some information from one-time participants.

Pidgin languages based on European languages have typically evolved in language contact situations in plantation economies (whether slave-based as in the Atlantic or contract labor-based as in the Pacific). The development of Hiri Motu is significantly different, in that plantation labor played little role in its initial development. In the Port Moresby area in the 1870s and 1880s, a number of overseas visitors arrived, although, of these, only a relatively small number of Christian missionaries stayed for long periods. The missionaries set out to learn Motu, but many other people did not share the same goal, and a somewhat simplified form of Motu came to be widely used as a lingua franca (and even some of the missionaries ended up learning this simplified variety rather than the variety normally used by Motuan villagers).

In 1888, the British colony of Papua was formally proclaimed. Much of this colony was completely unknown to outsiders. The first colonial administrator immediately set out to establish a police force that would serve to spread and strengthen colonial power. Police constables from a variety of locations were appointed and trained and then posted to different parts of the colony. Some of these constables came from Fiji and the Solomon Islands, where some form of pidgin with an English-based vocabulary was already in use. These initial police trainees were then joined by Papuans from a variety of locations. While it is not known precisely how these constables communicated, it seems possible that they made use of an English-derived pidgin, along with the kind of simplified Motu that they would have acquired as a result of contact with the local Motu-speaking population (with these two varieties possibly influencing each other).

As these constables were posted to outlying areas in the late 1800s and into the 1900s, they took with them a knowledge of whatever variety of Motu they had acquired in Port Moresby, and the language was also carried to outlying areas by released prisoners (who themselves sometimes subsequently became policemen). This language spread throughout Papua as a result of the establishment of colonial authority through the police force. This is why this pidgin was initially named 'Police Motu' (instead of Pidgin Motu), a name that was shed, however, due to its colonialist connotations (see below).

Hiri Motu is currently used as a lingua franca throughout much of the former British territory of Papua, in the southern part of what is now Papua New Guinea. This is an area of immense linguistic diversity, with about 200 languages—some Austronesian, but many also highly varied non-Austronesian languages—spoken by several hundred thousand people. However, the English-derived pidgin language known as Tok Pisin is increasingly becoming the main lingua franca in areas surrounding the rapidly growing capital, Port Moresby, which is located within the traditional Hiri Motu area; it is also gaining speakers in some of the rural areas where it was not used formerly.

It is difficult to say at this stage what sort of future there is for Hiri Motu. Although it still has well over 100,000 speakers, competition with Tok Pisin is likely to slow its growth and possibly even cause its numbers to shrink. However, there has also been a degree of active resistance to the spread of Tok Pisin by some, who regard the English-based pidgin as a variety of 'broken English' imposed by the former colonial overlords. Hiri Motu, in contrast, has been seen as a genuinely 'Papuan' language, given its clearly non-English origins. This kind of political sentiment toward Hiri Motu probably peaked in the late 1970s around the

time that Papua New Guinea gained its independence from Australia (1975) with the development of the Papua Besena movement, and there has been increasing acceptance among Papuans since then of a genuinely national role for Tok Pisin.

In this political context, the original name 'Police Motu' also became quite controversial, and this name is seldom used in Papua New Guinea today. Prior to independence, the original British colony of Papua had largely been neglected, with little attention given to socioeconomic development. This contrasted sharply with the northern colony of New Guinea, which had originally been under German control (although after World War I, Australia took over). A vigorous plantation economy was established in coastal areas, and it was in this context that English-based Tok Pisin developed and spread throughout that colony.

After World War II, Papua and New Guinea were united into a single administrative entity, which was finally granted independence from Australia in 1975. However, many Papuans were uneasy about the prospect of becoming part of an independent country because they felt that they would be economically and numerically dominated by their northern neighbors, whose primary lingua franca, as it happened, was an English-based pidgin.

Papuans could already see the spread of Tok Pisin into areas that had traditionally made exclusive use of Hiri Motu as a lingua franca, and some Papuan nationalists declared their separate independence (but without recognition from any other nation). Hiri Motu was felt to represent Papuan nationalist aspirations in a way that Tok Pisin never could. Because of assumed associations with the colonial past, a government committee in 1971 officially renamed the language from 'Police Motu' to 'Hiri Motu', based on the assumption—albeit an inaccurate one, as emerged from Dutton's subsequent research—that this was the language of precolonial *hiri* trading expeditions.

Historical Linguistics

Languages are constantly in the process of change. Spellings of English homophones such as *meet* and *meat* reflect vowel distinctions at an earlier stage in the history of our language, before the two vowel qualities merged. Changes take place on the level of sound structure, grammar, vocabulary, and meaning. *Historical linguistics* is the study of language change by comparison of a language at two (or more) points in time.

The field of historical linguistics developed significantly in the nineteenth century, after European scholars realized that there were systematic similarities between Sanskrit, the ancient language of India, and other well-known languages, such as classical Greek and Latin. These similarities indicated that a genetic relationship must exist; i.e. these three languages must stem from the same ancestor language.

It was already well known that the Romance languages descended from a common language, Latin. A systematic comparison of *cognates*, words in related languages known to have been derived from a single historical source, led to the observation that sound change is, in fact, systematic. For example, there is a set of words starting with *h* in Spanish, such as *hijo* 'son', *hacer* 'do/make', and *harina* 'flour', that have cognates in Portuguese that start with *f*: *filho* 'son', *fazer* 'do/make', and *farinha* 'flour'. Through comparison with the words in Latin (such as *filius* 'son'), for which written records existed, it was possible to write rules to account for the various changes that must have taken place. Written records served two purposes: in addition to confirming the validity of the methodology being developed by historical linguists, they gave important information regarding the direction of sound changes. In the above examples, the Spanish *h* developed from Latin *f* and not the contrary.

The same methodology was then applied to the comparison of other languages that were obviously closely related, even though no written records existed

for the original language, or proto-language. For example, the Germanic languages were compared and classified as to how closely they were related to each other. The same was done for the Slavic languages.

Comparison within and between such groupings led to a classification of nearly all the languages in Europe, and some beyond, as members of the Indo-European family, all descended from a hypothetical language referred to as Proto-Indo-European, for which there are no written records.

In English, as well as other Indo-European languages, there are written records of the language at various points in time, making possible a comparison of earlier stages of the language with the present-day forms. The use of written records requires interpretation of the symbols appearing in them, to discover the sound structure of a language at the time of writing. In the case of the Germanic languages, the earliest written records use a different type of script, called *runes*, which themselves changed over time.

Comparison of the sounds in cognate words from related languages led to the development of a technique for *phonological reconstruction*. Sounds are studied systematically in their various positions within a word to obtain a full picture of what the original sound system must have been like that would account for the individual differences in the various daughter languages. Returning to the examples of Spanish and Portuguese, it would have to be noted that not all words with initial *h* in Spanish begin with *f* in Portuguese; some begin with *h*, as in the cognate pair *hombre* (Spanish) and *homem* (Portuguese) 'man'. Likewise, not all words beginning with *f* in Portuguese begin with *h* in Spanish; some begin with *f*, as in *fuego* (Spanish) and *fogo* (Portuguese) 'fire'. All of these patterns have to be examined. Furthermore, the best results require that attention be given to all descendant languages; in the case of Romance languages, this would include not only the languages with many speakers (Italian, French, Rumanian, Portuguese, and Spanish) but also those with fewer speakers (Catalan, Provençal, Rheto-Romance, and Sardinian). The precedent for the rigorous detail required in the comparative method was set by Jacob Grimm, in his work relating the German consonant system to the systems of other Indo-European languages.

Another method used by historical linguists is *internal reconstruction*. This involves the observation of patterns within an individual language to arrive at hypotheses regarding an earlier stage of that language, without taking into account information from outside languages. For example, the prefix *n-* ('not') in the Wayampi language has a variant *na-,* which occurs when the prefix attaches to a consonant. However, there are restricted cases in which the *na-* variant is used before a vowel, as in *orɨ* 'he is happy', *na-orɨ-i* 'he is not happy'. Through internal reconstruction, we can account for these exceptions by hypothesizing that there must have originally been a consonant (indicated by a capital C) between the prefix and the following vowel (**na-Corɨ-i*).

The study of the loss or retention of specific vocabulary items is another method used in historical linguistics, often called *lexicostatistics*. This can be used to study the degree of change at two stages of the same language or to study the degree of relatedness of two different languages. Usually, lists of basic core vocabulary are used for this type of study.

Dialect geography is another method used by historical linguists. Details of the pronounciation of selected words are plotted on maps throughout the area where a given language is spoken to determine the details and geographical boundaries of different dialects, such as Northern and Southern American English.

When different languages come into contact with each other, some degree of *lexical borrowing* inevitably takes place. The influence of French on English after the Norman invasion of the British Isles in 1066 was a major factor affecting English vocabulary, with words of French origin, such as *arise,* joining the already existing combinations of a verb and an adverb, such as *get up*.

One principle that motivates sound change is simplification. This may involve the weakening of more complex sounds to less complex counterparts, such as a change from the affricate tʃ to a simple fricative ʃ or s. Loss of consonants at the end of syllables or words is another example of simplification. On the grammatical level, simplification may involve the elimination of certain grammatical inflections of nouns. But simplification on one level may actually increase the complexity of a language on another level and trigger additional change.

One way by which simplification is achieved, particularly on the level of word structure, is through *analogy*. The extension of use of the plural suffix *-s* in English to words that originally had other plural endings has taken place by analogy. For example, the word *hippopotamus,* which came from Latin, originally took the plural form *hippopotami*. However, *hippopotamuses,* based on the main pluralizing pattern in English, is now the more commonly used form.

Analogy is also used in the creation of new words based on an already existing pattern in the language. The development of terms such as *chairperson* took place by analogy with the words they were replacing, in this case *chairman*.

Languages may change with respect to their sound structure or grammar. The meanings of words can

change, and old vocabulary items may be lost or new ones may be added.

The change of word-initial *f* to *h* in Spanish is one example of a sound change. Another change in this language is from *o* to *ue* in all words in which *o* had intonational stress (Latin *novem* 'nine', Spanish *nueve*). This change is *conditioned*; it occurs under specific conditions, i.e. only in particular phonetic environments. If all occurrences of *o* had changed to *ue,* without reference to any phonetic environment, the change would be *unconditioned*.

One type of grammatical change consists of the change or loss of affixes. Latin had a set of case suffixes that occurred on nouns to distinguish between subject, direct object, and indirect object, as in the word for 'daughter': *fili-a, fili-am,* and *fili-ae,* respectively. In Portuguese, *filha* is used without such case distinctions; i.e. Portuguese has lost the Latin case system. Other grammatical changes may affect pronouns, as in the elimination of *thee* and *thou* from most present-day dialects of English. The relative word order of the subject, object, and verb may also undergo modifications over time.

Words may change their meaning or develop secondary meanings. For example, the word *deer,* referring to a specific animal, developed from the more generic Old English word *dēor* 'beast'. In recent years, the word *mouse* has acquired an additional meaning, referring to a computer accessory.

The acquisition of new vocabulary may take place through innovation (such as *byte*)*,* blending of already-existing vocabulary (*brunch*, from *breakfast* and *lunch*), or the use of derivational processes existing in the language (*computer* from *compute*). It may also take place through *lexical borrowing* as the result of language contact. Some examples of such borrowing into English include *canoe* (borrowed from Carib), *jaguar* (from Tupinambá), *safari* (from Swahili), and *smorgasbord* (from Swedish).

As changes take place in different geographical regions where a single language is spoken, different dialects develop. If speakers of different dialects are isolated from each other over long periods of time, the dialects may undergo so many changes that speakers from the different groups no longer understand each other. At this point in time, what were originally different dialects of the same language have become different languages, which are members of a linguistic family or possibly a subgroup within the family. For example, the Scandinavian languages (Danish, Icelandic, Norwegian, and Swedish) make up a subgroup within the Germanic language grouping. They are much more closely related to each other than they are to English, German, or Dutch, having descended from a common ancestor language referred to as Old Norse.

A detailed comparison of individual languages showing a high number of cognate words provides the information necessary for a classification and subclassification within a language family. A diagram, similar to a family tree, can then be used to show the internal *classification* of the family. This type of detailed classification was first done for Indo-European by the nineteenth-century historical linguists.

The methods of historical linguistics are now being applied to the study of many indigenous languages and language families. It is possible to recognize languages that are similar to each other, by identifying a significant number of cognates (words coming from a single source). Through a systematic comparison of the similarities and differences in the sound structure of cognates, it is possible to reconstruct what the sound system of the common ancestor, or 'proto-language', must have been like to account for the present form in the various languages. Protoforms are preceded with an asterisk to indicate that they are hypothetical. For example, in proto-Tupi-Guarani, of lowland South America, one of the reconstructed consonants is **ts,* which has reflexes of *ts, s, h*, and *0* (*zero*) in individual languages of the family.

Phonological reconstructions have been done for several indigenous language families of the Americas, as well as in other parts of the world. The quality of a reconstruction depends on the availability of adequate and accurate data of individual languages within a given family. As more data become available, the reconstructions are revised as necessary, and subclassification is possible.

The word and sentence structures of some indigenous language families, such as the Tupi-Guarani family in South America, have also been reconstructed. Grammatical reconstructions require much more data than do reconstructions of sound and are sometimes done in stages, as an increasing number of grammatical descriptions of individual languages are made available. To give an example, the set of pronouns and personal prefixes was first reconstructed for proto-Tupi-Guarani without reference to the particular grammatical contexts in which they were used. Additional data were necessary before a more complete description could be made.

Summarizing, the methods of historical linguistics, which were developed and tested in the study of Indo-European languages, are now being applied to the study of languages in other parts of the world.

History of Linguistics: Overview

The Greco-Roman World

The European tradition of linguistics begins in Classical Greece with the development of an active philosophical discourse on linguistic topics. Several of Plato's dialogs touch upon linguistic issues, with one, the *Cratylus*, devoted exclusively to the subject of the conventionality of language. The issue is discussed along the lines of a genealogy of language, with one side supporting a 'natural' origin for human communication, and another a 'conventional' basis. In the same context, onomatopoeia (sound symbolism) and the internal relation between names and their referents are discussed, with mixed conclusions. From the outset of the Greek tradition, questions about language concentrated entirely on the Greek language and were considered within the terms of the nature–convention debate and the somewhat related regularity–irregularity (analogy–anomaly) controversy. Aristotle also discussed linguistic issues in his treatises on logic and rhetoric—without dedicating any of them exclusively to the subject—with a discernible overall tendency to subscribe to conventionalist doctrine.

After Aristotle, the Stoics, with their founder Zeno (c. 315 BCE), formalized the dichotomy between form and meaning by distinguishing in language the 'signified' and the 'signifier'. They gave separate treatment to phonetics, grammar, and etymology, devoting considerable attention to the last. The Stoics accorded grammar-independent recognition within philosophical studies; it is, however, difficult to reconstruct with certainty the details of their linguistic theory.

The main aspects of linguistic study that received specific attention among early Greek scholars were etymology, phonetics, and grammar. Etymology was understood as the unfolding of words, through which their true meanings are made plain. In phonetics, some articulatory classifications of speech sounds were attempted, the syllable was introduced as a unit of description, and by the time of the Stoics there was a rudimentary understanding of speech as the effect of articulatory interference with the flow of air from the lungs. The descriptive framework for Greek phonetics was the Greek alphabet, and statements took the form of accounts of the pronunciation of the letters in it. Plato grouped together vowels in contrast to consonants and distinguished within consonants between continuants and stops, the latter being unpronounceable without an adjacent vowel sound. The Stoics distinguished three aspects of the *gramma*, thereby confirming its phonetic-orthographic unity: its phonetic value, its written shape, and the name by which it was designated. These three properties of letters continued to be distinguished throughout Antiquity and the Middle Ages, their later Latin names being *potestas*, *figura,* and *nomen*. The Greco-Roman world did its best and most influential work in the field of grammar. Dionysius Thrax's *Techne Grammatike* (most of it of debated authorship) and Apollonius Dyscolus's *Syntax* are the two most significant works in the field.

The Romans built largely on the Greek foundations. Varro—with his *De Lingua Latina*, of which only a part survives—is the first attested Latin writer on linguistic questions who is of importance. One of the main sources for the analogy–anomaly controversy, he may have misinterpreted it as a matter of permanent academic attack and counterattack, rather than as the more probable coexistence of opposing tendencies. Varro envisaged language developing from an original limited set of primal words, imposed on things so as to refer to them, and acting productively as the source of large numbers of other words through subsequent changes in letters, or in phonetic form, as civilization advanced and human life became richer. Apart from his innovative distinction between derivational and inflectional word formation, Varro also showed originality in his proposed classification of inflected words in Latin, by setting up a quadripartite system of four inflectionally contrasted classes.

Priscian's voluminous grammar (c. 500 CE) may be taken as representative of late Latin grammarians. The Greek technical terms are given fixed translations with the nearest available Latin word. Priscian draws heavily on Apollonius and his son Herodian, acknowledging both in his introductory paragraphs. He organized the description of the forms of nouns and verbs and of the other inflected words, by setting up canonical or basic forms; from these, he proceeded to the other forms by a series of letter changes, the letter being for him, as for the rest of Western Antiquity, the minimal unit of both orthography and pronunciation.

The Middle Ages

Continuing from the Classical tradition, the Middle Ages had a distinct focus on grammar as a foundation of scholarship, both as itself a liberal art and as a prerequisite for reading and writing Latin correctly. Linguistic studies, almost wholly pedagogical in their aims and largely derivative in their doctrine, were subordinate to theology, the Christian faith and Christian doctrine, and closely followed Donatus and Priscian. In the history of Medieval linguistic science, the most exciting period is from around 1100 to the end of the period (and more specifically between c. 1200 and c. 1350), when scholastic philosophy gave rise to a number of 'speculative grammars' or treatises *De modis significandi*. Scholasticism itself was the result of the integration of Aristotelian philosophy into Catholic theology. The mere description of Latin was considered inadequate, and attention was paid to the mental representations to which speech relates. The main distinction was between *significatio* (the meaning of a word) and *suppositio* (its point of reference in the real world). This basic distinction appeared repeatedly in different forms and with different interpretations, in oppositions such as meaning–reference, denotation–connotation, and intension–extension. In the modistic system, entities possess various properties (*modi essendi*). The mind apprehends these in certain modes of understanding (*modi intelligendi*). In language, the mind confers meaning on successions of sounds (*modi significandi*), which thus become words. The demand that grammatical description should be integrated into philosophical theory and represent universal principles of cognition brought about a great change in linguistic studies. Unlike all previous grammatical doctrines, the *modistae* were theory- rather than data-oriented.

The Renaissance and Modern Times

The adherence of linguistic analysis to the Greco-Roman archetype became less strict in the fifteenth and sixteenth centuries. Grammatical studies of Hebrew, Arabic, and modern European languages register a shift in the linguistic interests of Europeans and trigger creative thinking on language structure and written representation. With the invention of printing and the emergence of a need for uniform orthography within each language, pronunciation issues gain greater attention.

By the end of the sixteenth and the beginning of the seventeenth centuries, the indigenous languages of the Americas had captured the imagination of Europeans. Colonization of the Far East meant that the Chinese languages and their writing system became known to Europe and were largely admired. With very different word structures those of European languages, Chinese and Native American languages served to stretch the linguistic experience of Europeans far beyond what the Classical and Medieval world had allowed them. At the same time, the Royal Society in Britain (established 1660) and the Académie Française (established 1635) in France were both concerned with linguistic research and with literary and linguistic standards.

In the intellectual movements of the sixteenth and seventeenth centuries, both rationalist and empiricist influences may be seen at work. The notion of a universal thought possessed by mankind, basically independent of any particular language and therefore expressible in a universal language, such as that of John Wilkins, was a rationalist conception. Rationalism is also responsible for the production of philosophical grammars—especially those associated with the French Port Royal schools—which succeeded the Medieval scholastic grammars. They attempted to reveal the unity of grammar underlying the separate grammars of different languages in their role of communicating thought, itself comprising perception, judgment, and reasoning.

As part of English empiricism, work was carried out on phonetic questions under the titles of 'orthography' (right spelling) and 'orthoepy' (right pronouncing) during the same period (the term 'phonetics' is first recorded in the nineteenth century). Work by William Holder (1669) and Francis Lodwick (1686) revolutionized articulatory phonetics, and John Wilkins included in his *Essay towards a real character and a philosophical language* (1669) a sound chart that can be compared with early editions of the International Phonetic Alphabet.

In the eighteenth century, linguistic issues again became central for philosophy as part of its search for the traits of primitive society. Both Etienne Condillac and Jean-Jacques Rousseau considered that abstract vocabulary and grammatical complexity developed from an earlier individual concrete vocabulary with very few grammatical distinctions or constraints. They also regarded reliance on tonal contrasts in the

manner of Chinese as a survival of a primitive feature and considered poetry to have sprung from chanting as the earliest form of language.

In 1772, Johann Herder supported a monogenetic (common origin) theory of all languages, as of all cultures. His theory suffered from the restricted time perspective with which the eighteenth century viewed man's existence on earth, with a consequent attempt to see enduring characteristics of the early stages of language in alleged 'primitive languages' still existing in the present. Work by James Harris (1751) and Horne Tooke (1786) demonstrate the vivid interest of the time in the origin of language.

Wilhelm von Humboldt—exceptionally for his time—did not concentrate predominantly on history. He did not distinguish sharply between systemic and historical perspectives and followed Herder in asserting the individuality of each different language as a peculiar property of the nation or the group that speaks it, despite believing in the universality of speech. Humboldt is best known in linguistics for popularizing a tripartite language typology (isolating, agglutinative, and flexional) according to the predominant structure of the word as a grammatical unit.

Nineteenth Century: Comparative and Historical Linguistics

In the last quarter of the eighteenth century, linguistic science received a very productive stimulus from India. In 1786, Sir William Jones showed the historical kinship of Sanskrit, the classical language of India, with Latin, Greek, and the Germanic languages. India was not just the source of linguistic evidence but also offered an alternative linguistic tradition, dating back to the second half of the first millennium BCE, with outstanding achievements in general linguistic theory and semantics, phonetics and phonology, and descriptive grammar.

Early comparativists concentrated on Sanskrit and its relations with the other Indo-European languages (hence the term *vergleichende Grammatik* 'comparative grammar'). Rasmus Rask (1787–1832) was the first to bring order into etymological relationships by setting out systematic comparisons of word forms, matching a sound in one language with a sound in another, with such matches exemplified in a number of different words. The correspondences now known as Grimm's Law were in fact first discussed by Rask.

The historicism and nationalism of the time characterized the work of Franz Bopp and Jacob Grimm. Bopp saw as the main purpose of his *Conjugation system* the reconstruction of the original grammatical structure of the language whose gradual disintegration had produced the attested languages of the Indo-European family. Both the use of comparison as the clue to earlier history and the conception of change as degeneration from primitive integrity were common property of the scientific thought of the time. Relations between the parent language and the known Indo-European languages were set out according to the *Stammbaumtheorie* or genealogical tree model. August Schleicher, with his biological approach to language and his quest for the *Ursprache* (the original language), initiated the practice of distinguishing reconstructed forms with an asterisk (whence the later term 'starred forms'). He assigned Sanskrit a place like any other language, in the 'Arian' (Indo-Iranian) group and expressed his belief that the three current language types (isolating, agglutinating, and inflectional) represent historical stages in the growth of languages to their highest point of organization.

The Neogrammarians also strove to ground their work on comparative–historical linguistics within the natural sciences, preferring physics over biology as their model. Hermann Osthoff and Karl Brugmann set out the principles of the movement in a programmatic article (1878): all sound changes, as mechanical processes, take place according to laws that admit no exceptions (*ausnahmslose Lautgesetze*) within the same dialect and within a given period of time; the same sound in the same environment will always develop in the same way; analogical creations and reformations of specific words as lexical or grammatical entities are a universal component of linguistic change at all periods of history and prehistory. The influence of the Neogrammarians in linguistic practice has been overwhelming. It is true, however, that they were largely drawing out what had been implicit in the very practice of the subject, and distinguishing it from unnecessary and fallacious assumptions.

The critique of the Neogrammarian position came from a branch of linguistics that they had been at pains to encourage, dialectology. The temporal and geographical limits of a dialect are difficult to determine, especially when one scrutinizes the language closely. The most important opponents were Hermann Schuchardt, who included in his works an article 'On Sound Laws: Against the Neogrammarians,' and Jules Gilliéron, who put together the linguistic atlas of France.

Twentieth Century

The key figure in the change from nineteenth- to twentieth-century attitudes was the Swiss linguist Ferdinand de Saussure, who after studying in Leipzig with members of the Neogrammarian school made his first significant contribution in Indo-European comparative linguistics. Saussure's doctrine on linguistics in the early twentieth century was recorded in the *Cours de*

linguistique générale (1916; *Course in General Linguistics*), a reconstruction of his lectures from notes taken by his students, published posthumously. Saussure's contribution lies in three major areas: (1) He formalized the two fundamental dimensions of linguistic study: 'synchronic', in which languages are treated as self-contained systems of communication at any particular time; and 'diachronic', in which the changes to which languages are subject in the course of time are treated historically. (2) He distinguished the linguistic competence of the speaker as a member of a speech community from the actual phenomena or data of linguistics (utterances), as, respectively, *langue* and *parole*. (3) He showed that any *langue* must be envisaged and described synchronically as a system of interrelated elements, lexical, grammatical, and phonological, and not as an aggregate of self-sufficient entities (which he compared to a mere nomenclature). The greatest impact of structuralism was in the domain of phonology (the study of sound systems), where Nikolaj Trubetzkoy and Roman Jakobson developed the theory of 'distinctive features'.

'Structuralism' was widely preached in America and was epitomized in the historical figure of Leonard Bloomfield. American structuralism, however, differed from its European ancestor in its insistence on a data-oriented approach which originated from the urgent need to collect data on the disappearing Native American languages. This persistence remarkably limited the theoretical perspectives of American structuralism and eventually brought about its downfall.

The reaction came in the middle of the century and resulted in a profound change in the outlook of theoretical linguists worldwide. Noam Chomsky's *Syntactic structures* (1957) marks the first public appearance of a change in outlook on the study of language and the scientific status of linguistics. His theory, 'generative linguistics', is still developing and has become the dominant theory in linguistics at the end of the twentieth century. It involves the notion of a linguistic 'deep structure', whence utterances are produced through a series of 'transformations'. Transformations became less crucial in subsequent versions of the theory and the lexicon as a source attained greater importance.

In the last quarter of the twentieth century, linguistics has gained still greater status as a pioneering academic discipline. An increased diversity—stemming from the emergence of branches such as computational and applied linguistics and psycholinguistics alongside the established subdisciplines—is the most prominent and promising feature of the discipline at the turn of the millennium.

CHRISTOS G. NIFADOPOULOS

Hittite

Hittite belongs to the Anatolian branch of the Indo-European family. It was spoken in inner Anatolia during the second millennium BCE, with its written sources ranging from approximately 1650 to 1180 BCE. It is the oldest attested Indo-European language. Other Anatolian languages include Palaic and

Cuneiform Luwian (also attested in the second millennium BCE), Hieroglyphic Luwian, Lycian, Milian, Carian, and Lydian (attested in the first millennium BCE); all these languages are relatively poorly known.

Knowledge of Hittite is a recent achievement: although some Hittite texts were found much earlier, they were deciphered starting from 1916 only. Hittite is documented by several thousands of clay tablets, mostly found in the archives of the Hittite capital, Hattusa, near the modern village of Bogazkahle, about 210 km southeast of Ankara. The Hittites wrote their language in cuneiform, a syllabic system constituted by signs for CV, VC, V, and, to a limited extent, CVC syllables, also used for numerous other languages in the Ancient Near East. The cuneiform syllabary also contains a number of ideograms, conventionally rendered in transliteration with the Sumeric equivalent (in capital letters, see e.g. (1) and (2) below); ideograms were the key for the decipherment of Hittite.

Grammatical sketch

Phonology

Partly for problems connected with syllabic writing, partly on account of as yet poorly understood scribal habits, our understanding of Hittite phonology is not completely clear. Among vowels, four separate phonemes certainly existed: /a/, /e/, /i/, /u/; the existence of a phonemic /o/ is still discussed. Vowel length was probably distinctive, as shown by pairs as *uddar*, 'word', *uddār*, 'words'.

Consonants include four series of stops, bilabial, dental, velar, and labiovelar, all with a distinction between voiced and a voiceless (or lax and tense), which was apparently neutralized in the word-initial and word-final positions. Simple vs. double writing of stops and of the fricative -*h*- renders the voiced ~ voiceless contrast. The fricative /s/, liquids and nasals could be distinctively simple or geminated word-internally (Table 1).

Morphology

Hittite is an inflectional language of the fusional type. Inflectional categories of nouns include case (nominative [NOM], accusative [ACC], genitive [GEN], dative/locative [D/L], directive, ablative, instrumental, vocative) and number (singular and plural); nouns belong to two genders: common and neuter. The directive and the instrumental case are mostly limited to the ancient language (Old Hittite); later (Middle and New Hittite), they merge with the dative/locative and the ablative, respectively. Directive, ablative, and instrumental only had endings for the singular; in Old Hittite, they could never occur with animate nouns (the animate vs. inanimate distinction cross-cuts grammatical gender, inanimate nouns belonging partly to the neuter, partly to the common gender).

An original feature of Anatolian is the use of derivational suffixes to serve syntax, rather than to enrich the lexicon, a function normally assigned to inflectional morphology. Thus, in Cuneiform Luwian, there is no inflectional genitive; nouns used as modifiers of other nouns take a derivational suffix, which allows them to behave as adjectives, and agree with their heads. In Hittite, neuter nouns cannot function as subjects of transitive verbs, but must obligatorily be transposed to the common gender by means of the suffix -*ant*-: after suffixation, -*ant*- derivates take the nominative ending of the common gender and can be made the subject of transitive verbs (e.g. *tuppi*, 'clay tablet', neuter, *tuppiyanza*, same meaning, common gender).

Adjectives and pronouns inflect for case, number, and gender; attributive adjectives usually agree with their head. There is no specific morphology for comparison. Personal pronouns have stressed and unstressed forms; an unstressed nominative only exists for third-person pronouns. Besides, Old Hittite also has enclitic (i.e. unstressed, hosted by the preceding word) possessives inflected to agree with their head, which also functions as a phonological host: *attas=mas*, 'of my father' (lit.: father-GEN my-GEN; the sign = indicates enclisis); after Old Hittite, genitive forms of stressed pronouns are used instead of possessives: *ammel attas*, '(of) my father' (lit.: I-GEN, father-NOM (or GEN)).

Inflectional categories of verbs include tense (present [PRES]/future and preterit [PRET]; there is a periphrastic perfect with the auxiliaries *har(k)*-, 'have', and *es*-, 'be'), mood (indicative and imperative; other types of modality are expressed by the particle *man* and the indicative), diathesis (active and medio-passive), person, and number. Nonfinite verb forms are the infinitive, the participle, and the -*wan*- supine, only used in inchoative constructions; verbal nouns are built with the suffixes -*atar* or -*uwar/-mar: iya*-, 'to make', *iyawar*, 'the act of making'. Verbs are divided into two inflectional classes, called -*mi* and -*hi* conjugation from the ending of the first person singular. Some other verbal categories are expressed derivationally. Causatives are made with the suffix -*nu*-: *huinu*-, 'to let escape', from *huwai*-, 'to run', *huisnu*-, 'to rescue', 'to

TABLE 1 Hittite Consonants

Voiceless stops	p	t		k	kʷ
Voiced stops	b	d		g	gʷ
Voiceless fricatives		s			h
Voiced fricative					ɦ
Affricate		ts			
Nasals	m	n			
Lateral		l			
Vibrant		r			
Glides	w		j		

give life', from *huis-*, 'to live', 'to be alive' (this suffix can also derive verbs from adjectives: *daluganu-*, 'to lengthen', from *daluki-*, 'long'). The suffix *-sk-* is used for iteratives: *pai-*, 'to give', *pesk-*, 'to give habitually'.

Derivation is widely used for creating new words; derivational affixes are by the most part suffixes. (There are two verbal prefixes, *pe-* and *u-*, which mostly occur with motion verbs and express opposite deixes; verbal reduplication is not productive: often, reduplicated verbs have the same meaning as their nonreduplicated counterparts.) Composition is comparatively infrequent.

Syntax

Hittite has nominative–accusative alignment for common gender nouns. As remarked in the preceding section, neuter nouns must be transposed to common gender in order to function as the subject of transitive verbs. Since this kind of derivation has a systematic character, the derivational affix together with the common gender nominative ending functions as an ergative case. A further distinction between transitive and intransitive subjects, only involving third person, is that transitive subjects can be omitted if they are recoverable from the context, whereas intransitive subjects cannot.

Hittite has a rigid Object-Verb order, with a verb-initial variant sometimes found under specific pragmatic conditions (see e.g. (1a)). Modifiers (attributive adjectives, genitives, relative clauses) regularly precede their head, but certain determiners follow. Adpositions follow their complements (postpositions), and inflected auxiliaries follow nonfinite forms of main verbs. All enclitics, except for possessives, the focalizer *-pat*, and conjunctions used in noun phrase coordination, follow Wackernagel's Law very strictly; consequently, they are placed after the first accented word in the sentence (P2). Sentence connectives (CONN) occur in virtually every sentence after the Old Hittite period; often, it seems that they are introduced for the only purpose of hosting enclitics. The following example serves as an illustration of Hittite sentence structure:

(1 a) *sallanun=* *war= an* *kuit*
promote:1SG.PRET PTC 3SG.ACC because
ammuk
1SG.NOM

(b) *nu=* *war=an* *huwappi* DI-*esni*
CONN PTC 3SG.ACC bad:D/L tribunal:D/L
huwappi DINGIR^LIM-*ni* UL *para*
bad:D/L god:D/L NEG PREV
UL kuwapikki *tarnahhun*
never hadle:1SG.PRET

(c) *kinuna=ya=* *war=an* *karapmi*
now and PTC 3SG.ACC take:1SG.PRES

(d) *nu=* *war=an* *ANA* ^DUTU
CONN PTC 3SG.ACC to sungod
^URUTÚL-*na* *AŠŠUM*^LÚ SANGA-*UTTIM*
Arinna for priesthood
tittanumi
install:1SG.PRES
'(a) because I promoted him, (b) I never handled him over to a bad tribunal or to a bad god; (c) and now I will take him (d) and make him priest for the sun goddess of Arinna', *StBoT* 24, IV 11–15.

Note: NEG = negation; PREV = preverb; PTC = particle; SG = singular

Hypotaxis is relatively poor, the most frequent type of subordinate clause being relative clauses. Relative clauses are corelative in the great majority of occurrences: the relative clause, mostly preposed, contains its head, which may or may not be referred to by a demonstrative in the main clause. An example is given below:

(2) ^GIŠTUKUL= *ma* *kuin*
weapon PTC REL.ACC
apiya harkun *n= an*
there have-1SG.PRET CONN 3SG.ACC
halissiyanun
inlay-1SG.PRET
'the weapon that I had there I had inlaid', *StBoT* 17, obv. 46.

Note: REL = relative

Circumstantial clauses include temporal, causal, and conditional clauses; they are mostly preposed. Complement clauses are virtually nonexistent; only in New Hittite a limited number of postposed complement clauses occurs, introduced by the conjunction *kuit* (nominative/accusative neuter singular of the relative pronoun, already used in causal clauses with the meaning 'because', cf. e.g. (1a)).

Hittite is extremely rich in enclitic particles. Among P2 enclitics, one finds adversative connectives (as *-ma* in e.g. (2)), the direct speech particle *-wa(r)-* (cf. e.g. (1)), the reflexive particle *-za*, and the so-called local particles, most likely cognate to the Indo-European preverbs (the modal particle *man* can be enclitic, and occur P2, or sentence initial and host the other enclitics; enclitic personal pronouns also occur in P2, cf. the form *-an* in the examples).

Hittite and Indo-European

When Hittite was deciphered, it immediately became clear that it did not fit into the traditional reconstruction of Proto-Indo-European (PIE), mostly based on Greek and Sanskrit. The absence of a number of grammatical categories traditionally reconstructed for PIE (optative,

aorist, dual, and the three-gender system, among others) has given rise to different theories. The most well-known is the so-called 'Indo-Hittite hypothesis', put forward by Sturtevant in 1933. According to Sturtevant, Anatolian must be considered a separate branch of a language family whose other branch is constituted by all other Indo-European languages: the nonoccurrence of certain features in Anatolian can then be explained by separate developments of the Indo-European branch. Since the publication of Sturtevant's book, the understanding of Hittite has become deeper, partly thanks to the availability of newly found material; a better insight into the position of Hittite among the other Indo-European languages has been gained after cuneiform paleography has allowed a precise dating of the Hittite tablets. Many other theories have been worked out, among which was the so-called *Schwundhypothese* ('loss hypothesis'), according to which Hittite once had all the inflectional categories known from the other ancient Indo-European languages, but lost them, as a result of intensive contact with non-Indo-European languages in prehistoric times.

However, the discovery of Hittite did not only come to raise problems for the traditional reconstruction of PIE: many important findings provided evidence for theories that could scarcely be demonstrated before. The most striking confirmation was given by the reflexes of the PIE laryngeals, reconstructed on the basis of Saussure's *coefficients sonantiques* (Saussure 1878). Indirect evidence for these phonemes had been found in the other languages, but only Hittite preserves two of them as phonemes, also providing evidence for their consonantic character. It is nowadays commonly thought that the PIE phoneme inventory included three laryngeals, conventionally written as $*/h_1/$, $*/h_2/$, and $*/h_3/$. While in the other Indo-European languages laryngeals only affected the following or preceding vowel, in Hittite reflexes of $*/h_2/$ and $*/h_3/$ are found as *-h-*. Reflexes of laryngeals are found in the following examples: Hitt. *harki* 'white' (Latin *argentum*); Hitt. *hastai* 'bones' (Ancient Greek *osteon*); Hitt. *hulana* 'wool' (Sanskrit *urna*); and Hitt. *huis-* 'to live' (Latin *uiuere*). After a vowel, $*/h_2/$ is also preserved as /ḫ/: Hitt. *newahh-* 'renew', < $*neweh_2$- (Latin *nouāre*).

Another important confirmation came from the placement of enclitics in P2: Wackernagel (1892) had formulated his law on word order mostly on the basis of Ancient Greek and Sanskrit, where enclitics often occur in P2, but much less frequently than in Hittite.

The Hittite verb also preserves a number of archaic features, notably the athematic (*-mi*) conjugation; the *-hi* conjugation is a Hittite innovation, related to both the PIE perfect and the PIE middle.

Among indisputable innovations, one can list the emergence of split ergative alignment, and the constraints on omission of third-person subjects.

Hjelmslev, Louis

Among post-Saussurrean European structuralists, Louis Hjelmslev is the one who took the most extreme positions with respect to the separation between form and matter, and system and use. The son of a mathematician, he always denied any influence from his father for his interest in abstract structures: in fact, the son's attempt at

creating a system independent of experience was criticized even by the father, who studied the relation between geometry and practical experience.

In spite of his denial of the value of experience, Hjelmslev had a deep knowledge of numerous languages, in some of which he was also fluent. According to an often quoted anecdote, he used to pay his parent's maid in order to give her Italian lessons. Later on, his interest for language diversity led him to write some insightful pages on the purposes of language typology in the last chapter of his book *Sproget* (1963), and to explore the grammar of a number of exotic languages (for example in his 'La catégorie des cas', published in 1935 and reprinted in the 'Essais linguistiques').

Hjelmslev illustrated Saussure's claim that language is formed by working out a model of language based on the co-occurrence of two elements: expression and content. Each element consists of form and substance, e.g. sound is the substance of utterances, but their form is articulated in phonemes. Although for Saussure, neither form nor substance is independent of the other, and it is the conjunction of two forms, form of expression and form of content, which generates a linguistic sign, Hjelmslev's treatment clearly implies a logical priority of form over substance, contrary to Saussure's view. Note that the interdependence of form and substance reveals an Aristotelian view of matter: as Hjelmslev explained in his *Prolegomena to a theory of language*, substance can be studied only when molded by form, and beyond form it consists of an unanalyzable 'purport'.

On account of his interest being centered only on structured, Hjelmslev took a completely different path from the one taken by Saussure's own pupils, as Bailly and Séchehay, who pursued a 'linguistique de la parole', thus aiming at the description of language usage. He was also critical of the views held on phonology by members of the Prague Circle, because they paid too much attention to the phonetic substance of phonemes. His major emphasis was on the nature of a possible theory of language, which should be arbitrary and adequate, and also aim at simplicity (in the case that two available explanations yield the same results, the one that requires less complex description must be preferred).

As is often the case in the history of linguistics, Hjelmslev's thought found a fertile soil in his cultural environment, and he could develop his ideas in close collaboration with a number of other scholars, who shared his beliefs about the strictly formal and synchronic nature of languages as systems. The outcome of scientific intercourse was the creation of the Linguistic Circle of Copenhagen in 1931, on the model of the Prague Linguistic Circle, which had been founded five years before. The first result of collaboration among the Danish scholars was presented at the international conference on phonetic sciences in London in 1935, where Hjelmslev, together with P. Lier and H. Uldall, illustrated a new phonological theory, called 'phonematics'. Shortly thereafter, in December 1935, Hjelmslev and Uldall presented a unified theory of phonology and grammar, called 'glossematics', which aimed at the study of mutual relations between phonemic and grammatical systems.

In spite of the ambitious program put forth by its founders, the theory of glossematics was never fully developed. In its final shape, glossematics should have developed a metalanguage, capable of describing all existing languages in algebraic terms. Since all linguistic elements must be described only in terms of the relations holding between one another, a typology of possible relations needed to be set up prior to the study of languages. In his *Prolegomena to a theory of language*, Hjelmslev describes the possible types of relations. Crucial to the understanding of his classification is the notion of 'function'. A function is a relation between linguistic entities; since they are considered only for the sake of functions, concrete linguistic entities are called 'functives'. In the case of (superordinate) functions holding between other functions, the latter can become functives. In his *Prolegomena to a theory of language*, Hjelmslev defines three types of function: (a) interdependence, where A implies B and B implies A; (b) determination, where A implies B, but B does not imply A; and (c) constellation, where A does not imply B and B does not imply A. It is important to stress that this use of the term function differs significantly from the way in which the same term was defined by the Prague Circle, which is certainly more familiar. One of the basic tenets of the Prague Circle was that language must be investigated in its nature of 'functional system', whereby 'functional' refers to the communicating function of language, with an implication of teleology. In the theory of glossematics, on the other hand, there is no space for teleology, and no intrinsic interest toward communication.

According to the promoters of glossematics, a second stage in the development of the theory should be based on the scrutiny of the largest possible number of languages, in order to assess what types of grammatical elements can occur in language. After the metalanguage had been worked out completely, it could be applied to the description of any given language.

The theoretical foundations of glossematics, which should have been published by Hjelmslev and Uldall, never saw the light because of disagreement between the two, and the only published part, the introduction, was the work of Uldall alone (Uldall, 1957). The only

thorough description of a language following the theory of glossematics is Togeby's *Structure immanente de la langue française*. Although Hjelmslev's own focus had been primarily on phonology and morphology, Togeby's book shows that glossematics was by no means limited to these parts of grammar, and takes the text as its starting point; it also offers a discussion of syntax, consisting of a description of subordinate clauses and VP and NP structure.

Biography

Louis Hjelmslev was born in Copenhagen on October 3, 1899, as Louis Trolle Petersen (the name Hjelmslev was added in 1903 by his father, after the village where he was born). From 1917 to 1923, he studied in Copenhagen (Master of Arts), where in 1920 he received an award for work on Oscan inscriptions. He pursued further studies in Prague (1923–1924) and in Paris (1926–1927), as a pupil of Meillet and Vendryes. His first book, *Principes de grammaire générale*, was rejected as a dissertation because of its synchronic approach. He received his doctorate degree from the university of Copenhagen in 1932 with a volume of studies in Baltic linguistics. From 1934 to 1937, he was professor in Aarhus, then in Copenhagen (chair for comparative linguistics). Among the founders of the Linguistic circle of Copenhagen, he also founded the journal *Acta Linguistica* together with Viggo Brøndal. He died in Copenhagen on May 30, 1965.

Hmong and Hmong-Mien (Miao-Yao) languages

Hmong-Mien is a language family and broad cultural grouping of people primarily of China, some groups having emigrated over the last two centuries to Laos, Thailand, Vietnam, and Burma, and in the last 30–40 years as refugees to France, French Guyana, Australia, and the United States of America. There are widely differing uses of terms designating various languages, dialects and cultural groups within this broad grouping—from conflicting uses of everyday terms such as 'Blue/Green Mong', 'Flowery Miao', etc., through to the inclusion of different sets of people and/or languages under the term 'Hmong-Mien' itself, and an alternation between this term and 'Miao-Yao'. The latter term is generally preferred in China, while many Hmong outside of China reject the term 'Miao' as offensive (due to association variously with wild plants as a metaphor for barbarians, or, by an apparently orthographic route, cats). Two consequences of this are that with regard to the people, 'Hmong' is sometimes used to refer specifically to the Hmong outside of China, while in western linguistics literature, 'Hmong-Mien' is becoming the more generally accepted term for the language family as a whole.

Figure 1 shows the genealogical relationships generally accepted for the language family, together with some of the more common alternative language or dialect names. These languages or dialects are for the most part mutually unintelligible, and each subdivides further into a continuum of distinct varieties. Hmong-Mien is typically classified as a Sino-Tibetan language group by Chinese linguists, while western scholarship, debating possible affiliations rather with Austro-Asiatic, tend to leave the question as unresolved to date.

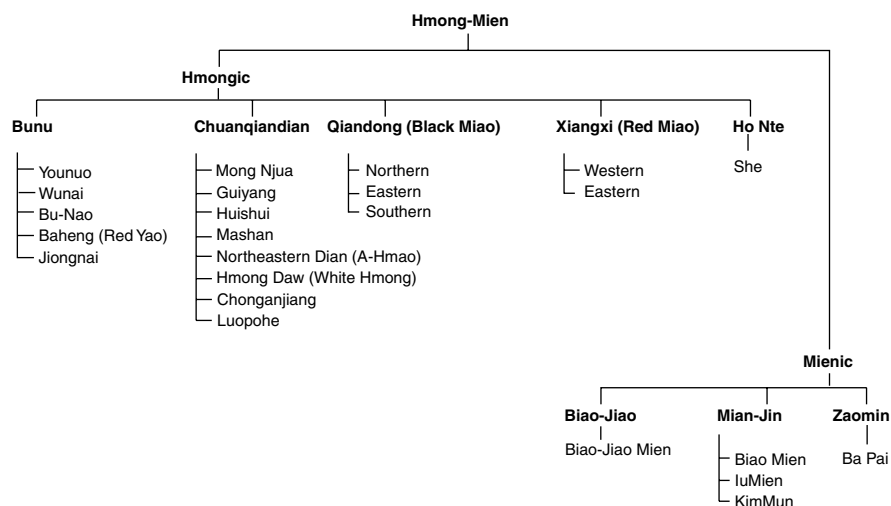
There are around 321,000 speakers of Bunu languages, predominantly Bu-Nao. Note that Bunu speakers are culturally Mien (Yao), and at least another 180,000 Bunu people speak languages other than Bunu.


Figure 1. Hmong-Mien family tree.

Qiandong speakers number around 1.4 million, mostly the Northern dialect, while the vast majority of Xiangxi's 770,000 speakers speak the Western dialect, and only a very small number of cultural She are also speakers of She. Chuanqiandian Hmong, something of a repository category for languages that do not fit easily into other subfamilies, boasts 3.6 million speakers, who constitute the bulk of Hmong living outside China. Of these, Hmong Daw and Mong Njua (with around 1.4 million speakers between them) are the primary languages of the ex-refugee diaspora in the west (well over 100,000, mostly in the United States of America). Mong Njua is the most common Chuanqiandian Hmong language in China, with around 1 million speakers, followed by Northeastern Dian with 200,000. Of the 1.7 million speakers of Mienic languages, 1.3 million speak Iu Mien.

Typological Characteristics

Hmong-Mien languages share a range of characteristics, many of which are also evident in other languages of the Southeast Asian region. The discussion below focuses primarily on Chuanqiandian Hmong languages, in particular Hmong Daw, to exemplify some of the language structures typical of this family. (Examples are from Hmong Daw except where otherwise specified. For notes on the RPA writing system used in Hmong Daw and Mong Njua examples, see the section on Writing below. Examples in slash brackets are notated in the International Phonetic Alphabet.)

Syllable Structure of C(onsonant) V(owel)
Hmong-Mien languages typically have a large assembly of initial consonants, incorporating features such as prenasalization, preglottalization, and aspiration. For instance, Baheng includes a consonant series /m mʰ mʲ mʰʲ/, while Xiangxi Hmong consonants include /t tʰ ⁿt ⁿtʰ/.

Although **CV** is the basic syllable structure, some languages also allow final nasals. In Northern Qiandong Hmong, for instance, the vowels /a/ and /o/ may be followed by a nasal /aŋ, oŋ/, while in Mong Njua, nasals always follow a long (and nasalized) vowel, as in the language name 'Mong' /mɔ̃ŋ/.

Lexical Tone
Lexical tone refers to the relative pitch or pitch contour of a given word, when it is part of how that word and its meaning are distinguished. A change in pitch signals a different word, in the same way as a change in a consonant or vowel would change the word. In Baheng, for instance, the word /ko33/ (pronounced with a mid level tone) means 'nine', while /ko22/ (mid-low level tone) means 'road'.

Hmong-Mien languages have variously developed seven, eight, or possibly as many as 13 lexical tones, all of which can be traced back to four original tones in the reconstructed ancestor language (known as Proto-Hmong-Mien). Most languages also display *tone sandhi*—that is, a change in the tone of a given word under specific circumstances, typically in response to the tones of surrounding words. Qiandong Hmong is a notable exception.

Tendency Toward a Monosyllabic Word Structure
This characteristic is necessarily associated with certain principles of grammatical structure and word formation.

Firstly, the words of Hmong-Mien languages do not accrue prefixes or suffixes to indicate meanings such as plurality, possession, case, or the comparative. Rather, where such meanings are overtly present, they are expressed by additional words in the sentence, or by word order. These two strategies, respectively, are demonstrated for the possessive in Example 1:

Example 1

Daim	*dawb*	*yog*	*kuv*	*li*
CLassifier	white	be	I	POSSessive

'The white one is mine'

Kuv tsis		*xav kom*		*kuv tus ntxhais chim*
I	NEGative	want	CAUSative	I CL daughter upset

'I don't want to upset my daughter'

Secondly, the primary strategy for word formation is compounding. This is evident both in long-established words in the languages, and in new words developed in the context of immigration to the west:

Example 2

qab	*qab*	*tsev*	*kawm*	*ntawv*
sweet	sweet	house	study	letters
'delicious'		'school'		

hnub	*chiv*	*nub*	*hli* (Mong Njua)
day	begin	day	moon
'Monday'		'Monday'	

(two of several alternatives current in the United States of America)

Noun Classifiers

This is a set of words that organize nouns into classes, such as 'round things', 'animate things', etc. Their presence or absence with a noun in a given sentence depends on the function they serve—or under certain conditions, they may stand in place of the noun. Classifier functions include clarifying the meaning of the noun, in a way analogous to the use of radicals in Chinese characters, indicating definite rather than nonspecific reference, or they may be associated with enumeration of the noun:

Example 3

Specifying meaning:
daim	*ntawv*	*tsab*	*ntawv*
CL (flat)	paper	CL (written)	paper
'piece of paper'		'letter'	

With numeral:
Thov	*ib*	*rab*	*diav*
please	one	CL (tools)	spoon
'Please could I have a spoon?'			

In place of the noun:
Puas	*muaj*	*tus*	*pab koj ua?*
QUestion	have	CL (animate)	help you do
'Is there someone to help you?'			

Two- and Four-syllable Expressives

These poetic phrases, including but by no means restricted to onomatopoeia, display a distinctive, internally repetitive form, and are scattered throughout everyday conversation, as well as in more literary styles:

Example 4

plib pleb	(of wood crackling)
dig dug	(of the ponderous bubbling of thick liquid)

kev	***noj***	***kev***	***haus***	*nyuaj*	*heev*
way	eat	way	drink	difficult	EMPHatic

'Life is very difficult'

Serial Verb Construction

Hmong-Mien languages feature strings of verbs or verb phrases, which cumulatively express a complex verbal meaning—representing, for instance, an analytic breakdown of minutely differentiated components of an action, or different simultaneous roles of participants in the event.

In the following example, the three verbs *npuav*, *nqa*, and *dua* are combined to describe the complex action of carrying something somewhere. Also note that the action of picking up the cubs must first be specified by yet another verb:

Example 5

Ob	*tus*	*dais*	*muab*	*cov*	*menyuam*
two	CL	bear	take	CL	child
npuav	*nqa*	*dua*	*nram*	*kwj-hav*	
carry	carry	pass	down	valley	
by mouth					

'The two bears picked up their cubs and carried them down into the valley'

Reliance on Context to Determine Functions Such as Tense and Plurality

A range of grammatical and pragmatic functions are not obligatorily specified in languages of this family. In the first of the following examples, the tense is implied by the aspect marker *tau* (attainment), while in the second, it can be understood only in context:

Example 6

Yuav	*tau*	*ib*	*lub*	*hnab-looj-tes*
buy	ASPect	one	CL	gloves

'I bought a pair of gloves'

Kuv	*yuav*	*lub*	*hnab-looj-tes*
I	buy	CL	gloves

'I am buying/bought/will buy some gloves'

Also note also the omission of the pronoun in the first example, and the assumed plurality of *hnab-looj-tes*.

Concluding Remarks

The above sample characteristics of Hmong-Mien languages are not a random combination. Rather, certain characteristics, such as underspecification, classifiers, and serial verb constructions, co-occur in linguistically logical and historically traceable combinations. This, in part, explains the commonality of these and other characteristics to not only this language family but also others of the region. Other aspects of Hmong-Mien languages are specific to that family—for instance, the ordering **Possessor–Possessed** illustrated in Example 1 above.

Writing

Writing and orthography are a key issue for many Hmong-Mien groups, and a good number of writing systems have been proposed and to varying extents have been implemented—either from within the communities, or by missionary linguists working with the communities, or by government organizations of the various countries of residence. The question is not only one of practical literacy in a heritage language, but is also, at least for the Hmong, embedded in cultural narratives of national identity and mythic histories, or *dab neeg*. In these *dab neeg* are encoded a Hmong history of oppression, migration, and ancient literacy, which is in turn linked to strong intragroup cohesiveness and long-cherished goals of self-determination.

Writing systems have been developed on a base of Chinese (e.g. Xiangxi and Qiandong Hmong), Thai, and Lao scripts, as well as the Roman—Vietnamese base, Pinyin base (e.g. Mien languages), and Roman Popular Alphabet (RPA—Hmong Daw and Mong Njua). In addition, there are at least four independent systems: Pollard script (Northeastern Dian), Pahawh Hmong (Hmong Daw and Mong Njua), *Ntawv Paj Ntaub* (Hmong Daw and Mong Njua, used only in a small area of California), and the *Ntawv Puaj Txwm* (an apparently ancient script).

The most widespread writing system now in use is the RPA. This is based on a featural representation of the sounds of Hmong, and utilizes consonant symbols syllable-finally to indicate tone. The word 'Hmong Daw'/m̥ɔ̃ŋ⁵⁵ daɨ⁵⁵/ is written <Hmoob Dawb>:

Example 7

hm	oo	b	d
preaspirated or voiceless nasal	long vowel (nasalised)	high level tone	alveolar stop
aw	b		
diphthong	high level tone		

(Note that the final nasal of 'Hmong' is not directly notated, being a predictable closure of the long vowel.)

Other tones are written as:

Example 8

m	low glottalized	**j**	high falling
v	mid rising	**d**	low rising, lengthened
s	mid-low falling	**g**	low breathy
(zero)	mid level		

The Pahawh Hmong, although restricted in use for the most part to small communities located throughout Australia, the United States of America and in northern Thailand, is recognized by many as a significant symbol of Hmong autonomy and, particularly for its proponents, as a realization of the millenarianist prophetic tradition threaded throughout the *dab neeg*.

The Pahawh is based on the **CV** syllable structure of Hmong, so that each syllable requires only one consonant and one vowel grapheme. A limited set of diacritics combines with each grapheme type, to (i) form a vowel-tone composite graph, or (ii) specify one of three consonants possible for a given grapheme—reducing the number of graphemes that would otherwise be needed for 59 consonants (in Hmong Daw). Example 9 is in Pahawh Version Two, as current in major Pahawh teaching organizations. (Version Three, also found in older and linguistics texts, is not fully readable on the basis of this Version.) Note that, although the writing is from left to right, the order within a word is from right to left (Vowel+tone–Consonant):

Example 9

Pahawh	ả̌	ṋ̄	ᕜ̋
RPA	*Phaj*	*hauj*	*Hmoob*
			'Pahawh Hmong'

This example demonstrates the use of zero diacritic < , >, representation of the same tone by different diacritics depending on the base vowel grapheme < ả , >, and similarly use of the same diacritic for different consonants, depending on the base consonant grapheme < , >. Many features of Pahawh writing, including word-internal ordering and the shapes of the graphemes themselves, hold symbolic significance in the tradition of its emergence.

The Hmong who have resettled in the west after the refugee period have taken advantage of the situation by embarking on a new period of accelerated language development. This includes not only orthographic development but also ongoing creation of a wealth of new words, in order to ensure the useability of the heritage language(s) in all the domains now encountered by the rising generation in the cultures of immigration. A third area of development has been a surge of publications in Hmong (Hmong Daw and Mong Njua)—language teaching and reference

materials including dictionaries and literacy primers, books on culture and history both traditional and emerging, community magazines, novels, and a rapid proliferation of websites and related communications media.

Hockett, Charles F.

Charles F. Hockett, one of the leading neo-Bloomfieldian linguists in the United States, authored more than 130 publications covering a broad spectrum: general linguistics, phonology, morphology, semantics, sound change, historical linguistics, linguistic universals, the origin of language, animal communication, Chinese, Fijian, and analyses of such American Indian languages as Potawatomi, Ojibwa, and Arapaho. As a student of Edward Sapir and Leonard Bloomfield, Hockett was trained both as a linguist and an anthropologist and never wavered from his conviction that the disciplines are inseparably intertwined. At the height of his remarkable career in the late 1950s, Hockett's behaviorist view of language and structuralist approach to linguistic analysis was eclipsed by transformational grammar, Noam Chomsky's revolutionary linguistic theory that attacked the very foundations of structuralism: behaviorism and the neglect of semantics. Hockett rejected the validity of transformational grammar and continued publishing spirited rebuttals in defense of his own views on the nature of language for two decades. As the literary executor of his mentor, Leonard Bloomfield, he devoted much time and energy publishing posthumously the bulk of Bloomfield's research material on Menomini, an American Indian language, and compiling an anthology of his most important publications.

In the 15 years between Bloomfield's death and Noam Chomsky's transformational grammar, Hockett was one of the leaders of American linguistics known especially for his role in the development of American phonological theory. As a post-Bloomfieldian structuralist, Hockett was convinced that, as he later said, linguistic analysis must be done 'from the bottom up' beginning with the sound system, progressing to the grammatical level of inflection and word formation, and only then to the syntactic level, the rules governing the arrangement of words in the sentence. Each of these levels of language was to be kept strictly separate. This meant that grammatical considerations could not be used to determine the distinctive sounds of a language, the phonemes. European phonologists of the Prague school viewed the phoneme as consisting of a set of features that could partially overlap with those of another phoneme, so that the distinction between two phonemes could be neutralized in certain positions. The phonemes /p/ and /b/ are distinguished by the feature of voicing, /p/ being voiceless, /b/ being voiced. If, as is the case in German, /b/ is

always pronounced as /p/ at the end of a word, the contrast between these two phonemes is neutralized in the word-final position. American structuralists, Hockett foremost among them, considered each phoneme to be unique and rejected partial phonemic overlap or neutralization outright. Together with the strict separation of linguistic levels, the requirement 'once a phoneme, always a phoneme' became a defining characteristic of American structuralism and a mark of its theoretical rigidity. One of Hockett's reasons for rejecting transformational grammar was the 'top-down' approach to linguistic analysis beginning with syntax and semantics rather than phonology. According to Hockett, linguistic analysis from the top-down is inappropriate because the investigator has to isolate words or morphemes before work on syntax and semantics can begin.

At the peak of his career, Hockett was perhaps best known for his textbook *A course in modern linguistics* (1958), which, as the author states in the introduction, was not written to explore frontiers and indulge in flights of fancy, but to present the generally accepted facts and principles of the field. He also included chapters on dialectology, historical linguistics, and man's place in nature. He compared animal communication systems, for example, the dance of honey bees, with human language by means of seven key properties. The property that, according to Hockett, is unique to human language is duality of patterning, a term Hockett invented to account for the fact that an infinite number of meaningful forms are built from a small number of meaningless elements.

Hockett's monograph *The state of the art* (1968) is a spirited attack on the basic principles underlying transformational grammar. As a behaviorist who insisted that only observable utterances could be the subject of linguistic analysis, he questioned Chomsky's distinction between a speaker's linguistic *competence*, the innate knowledge of the rules of his or her language, and *performance*, the speaker's actual utterance, which may be flawed by mispronunciations, inadvertent errors, repetitions, and the like. For Hockett, performance was the subject of linguistic investigation; for Chomsky, it was competence. He also disagreed with the Chomskyan premise that a speaker has access to an infinite number of sentences of infinite length and argued that there are limitations to sentence length that are part of the structure of language itself. When *the State of the Art* was published, it was already clear that transformational grammar had won the day, Hockett's spirited rearguard action notwithstanding.

Hockett's most significant and lasting contributions are, perhaps, his many publications on American Indian and Austronesian languages, and his role as Leonard Bloomfield's literary executor.

Biography

Charles Hockett was born on January 17, 1916 in Columbus, Ohio. He entered Ohio State University at 16 years of age. He received a combined B.A. and M.A. degree in ancient history in 1936. He worked as graduate student in anthropology at Yale with the anthropologist/linguist Edward Sapir and the structuralist linguist Leonard Bloomfield. Hockett received his Ph.D. in anthropology in 1939. He was drafted during Word War II and wrote an elementary Chinese text book for the War Department. Hockett joined the linguistics faculty at Cornell University in 1946 as an assistant professor and was promoted to Professor of Linguistics and Anthropology in 1956. In 1955–1956, he received a fellowship at the Center for Advanced Studies in the Behavioral Sciences at Palo Alto, California. He was president of the Linguistics Society of America, 1964–1965 and became Goldwin Smith Professor of Anthropology and Linguistics in 1970. In 1974, he was elected to the National Academy of Sciences. After retirement in 1982, he served as an adjunct professor at Rice University. He died on November 3, 2000 in Ithaca, NY.

Humboldt, Wilhelm von

The most distinguished linguistic scholar of the nineteenth century, politician, diplomat, and humanist, Karl Wilhelm Freiherr von Humboldt is generally considered to be the founder of general linguistics as a science that aims at the quest for the essence of linguistic phenomenon itself through the analysis and comparison of different languages. Together with his younger brother, Alexander von Humboldt, a natural scientist, he was given privileged education in classical studies by excellent private tutors that not only resulted in his profound and life-long interest in languages, philosophy, and humanities in general, but also motivated his later work on reforms of the Prussian educational system and the foundation of the University of Berlin. In addition to Greek and Latin, he studied Sanskrit and other Indo-European and non-Indo-European languages such as the ancient Indonesian language Kawi and Basque, while his brother Alexander, a pioneering explorer of the Americas, often sent back to him data collected from Amerindian languages with which he came into contact.

As a contemporary of German philosophers Immanuel Kant, Friedrich Hegel, and Johann Gottfried von Herder, and the Romantic writers Wolfgang Goethe and Friedrich von Schiller, Humboldt synthesized the main ideas of philosophical idealism and the Romantic emphasis on free, individual creativity and subjective meaning into his philosophy of language. He outlined his full theory in a lengthy introduction to his life work on the Jawan language Kawi, *Über die Verschiedenheit des menschlichen Sprachbaues und ihren Einfluss auf die geistige Entwicklung des Menschlichengeschlechts* (1836; *On language: the diversity of human language—structure and its influence on the mental development of mankind*). Based on the Kantian epistemological stance of cognition as activity, through which mental categories were imposed upon sensible experience, Humboldt held that language was not only a means of communication but also an a priori framework of cognition through which one formulated one's thoughts. According to Humboldt's famous dictum, language in its very essence is not a product (*ergon*) but a process and activity (*energeia*) inherent to human nature, an organ that forms the thought. Its true definition can therefore only be a genetic one, with the 'form of language' as largely programmed by the internal disposition of a genetic program. It is the 'inner form', the pattern, or structure, of grammar and meaning that is imposed on the 'outer form', the sounds from which different languages are differentiated one from another. This repeated work of the mind enables the articulated sounds to express thought, which makes an inseparable unity between language and thought and language and sounds. In accord with his theory, Humboldt holds that language acquisition does not occur through mechanical learning but is a matter of development of cognitive capacities under appropriate external conditions, just as all main human capacities develop at certain definite growth stages of life.

Postulating that reason is inseparable from language, thought is inseparable from speech, Humboldt infers, in accordance with his dynamic view of language as activity, that languages are not really means for representing already known truths but are rather instruments for discovering previously unrecognized ones. However, from his metaphysical concept of the 'inner form', he further concludes that thought does not depend only on the universal human capacity of speech but also on the different realizations of this 'inner form' in different languages. This blend of relativistic concept of the language role in intellectual processes and the idealistic, universalistic interpretation of the essence of the linguistic phenomenon by means of conceptual categories, represents the theoretical basis of Humboldt's deterministic doctrine on language as a worldview (*Weltanschauung* theory). Emphasizing the difficulties of full understanding in the process of communication and translation from one language into another, Humboldt indicates that

'each language sets certain limits to the spirit of those who speak it; it assumes a direction and, by doing so, excludes many others'. Moreover, language acts not only as an intermediary between man and the world but also between the individuals in a community and the whole humankind, so that in social terms, differences in individual linguistic worldviews lead to differences in group worldviews. Following the views of Herder, Humboldt maintains that each language and each culture reflect the world in a particular way and that the mental quality of each nation and its culture determines the language of its people, which in its turn determines the way they think and experience reality.

Analyzing a large number of world languages by a comparative method, Humboldt also made original contributions to language typology. His studies on the evolution of language and classification of languages, however, were closely related to his view on interdependency between language and the mental spirit of a nation or culture. He based his work on Friedrich Schlegel's genealogical scheme, which distinguished between the most developed 'inflectional' languages, i.e. the Indo-European languages, and those that have no inflection and are therefore called 'isolating' (e.g. Chinese) or the intermediary type of the so-called 'agglutinating' languages (as Amerindian), which put strings of forms together, but do not allow for a modification of the root. Somewhat controversially, Humboldt believed that these differences in language types reflected the developmental stages of human intellect, claiming that the highest achievement of the human mind was that of the speakers of highly inflectional Ancient Greek. Although he did not relate these types to historical progress or developmental stages of culture, he has been sometimes criticized for implying the idea of superiority of one people over another, based on the differences of language structure.

Humboldt's complex and rich ideas on dynamic language concept, 'inner form', and linguistic worldview have continuously influenced the subsequent course of linguistics in both Europe and the United States. In Europe, his legacy is evident not only in the work of his immediate successors, such as Franz Bopp, Heymann Steinthal, and the forerunner of psycholinguistics Wilhelm Wundt, and of the later group of the so-called Neo-Humboldtians, including Leo Weisgerber and Jost Trier, who advocated the majority of Humboldt's theoretical ideas, but also in some basic concepts of Ferdinand de Saussure's structural linguistics. In American linguistics, the essentials of his linguistic relativity and *Weltanschauung* theory found their clear expression in the works of the founders of linguistic anthropology Franz Boas, Edward Sapir, and Benjamin L. Whorf, while his distinction of inner and outer linguistic form represents the basic notions of generative grammar elaborated by one of the most influential modern linguists, Noam Chomsky.

Biography

Wilhelm von Humboldt was born in Potsdam, Prussia on June 22, 1767. He studied law at the University of Brandenburg in Frankfurt (Oder) in 1787, moved to Göttingen University where he also began studies in classical philology in 1788. He joined Prussian civil service as a law clerk to the Supreme Court of Berlin in 1789 and resigned from civil service in 1790. He resided on family estates in Thuringia and Jena and there he continued his studies with private tutors, devoted his interests to literature criticism and esthetics, and associated with Goethe, Schiller, and the Schlegel brothers between 1790 and 1797. He moved with his family to Paris to observe the turbulent social development in France in 1797–1799, and then to Spain where he investigated the Basque language. He rejoined the Prussian civil service and became an envoy to the Vatican in Rome in 1802–1808. He was head of the Department of Education and Arts at the Home Office in Berlin, and reformed Prussian educational system by elevating standards for teachers' training and founded the Friedrich Wilhelm University (modern Humboldt University) in Berlin, 1809. In 1809–1812, he retired to private life. He re-entered diplomatic service as the Prussian ambassador in Vienna and later London in 1812–1819. He resigned from civil service in 1819 and continued his private philological studies in the quiet atmosphere of the family manor in Tegel, investigating the Basque, Sanskrit, American, and Oriental languages and writing his most important linguistic works on the philosophy of language. He died in Tegel, Prussia on April 8, 1835.

ANITA SUJOLDZIC

Hungarian and Ugric Languages

Hungarian together with Mansi (Vogul) and Hanty (Ostyak) belongs to the Ugric group of the Finno-Ugric language family. In its turn, Ugric group is subdivided into Hungarian subgroup and Ob'-Ugrian subgroup, containing Mansi and Hanty. Hungarian is the official language of the Hungarian Republic (Magyar Nepkoztarsasag). The Hungarian language (magyar nelv) is spoken by Hungarians or Magyar, as they call themselves. In other languages, they have different names, e.g. German 'Ungarisch', Ukrainian 'Ugor'ska', Russian 'Vengerskiy', etc. A certain number of Hungarians live in the southwest of the Ukraine (Uzhgorod area), in Romania, Slovakia, Canada, and the United States of America. The total number of speakers may be estimated as 12–14 million.

Hungarians are said to have arrived to their present positions around the lake of Balaton from their original homeland in the South of Western Siberia and the Urals. Actually, Mansi and Hanty still live in the Northern Urals and Western Siberia. The Old Hungarian tribes moved to the West from the Urals and lived for about a thousand years on the Volga and Oka river basins where they had close contacts with the Permian peoples (Komi) as well as the peoples of the Volga region: Mari (Cheremis), Mordva, and the ancient Bulgars, the tribes of Turkic origin, who partly moved to the lands of modern Bulgaria, partly merged with the Tatars, Chuvash, and partly joined the ancient Hungarians. After living for some time on the Don river, the ancient Hungarian tribes moved again westward to conquer the territory of the Danube and Balaton basins from the Slavonic tribes of Slovaks in the ninth century AD. The ancient Hungarian king Arpad completed their 'settlement' (honfoglalas) by AD 896. In the fifteenth century, the flourishing period of national formation was interrupted by the Turkish invasion and then the Austrian rule. Only since 1918, after the collapse of the Austrian–Hungarian Empire, did Hungarian begin to develop without strong foreign influences. These numerous language contacts influenced modern Hungarian enormously, leading to the gap between Hungarian and Ob'-Ugrian languages (Mansi and Hanty). Now, communication between a Hungarian, Mansi, and Hanty is impossible. The oldest Hungarian literary relics are the 'Funeral oration' (Halotti Beszed, c. AD 1200) and 'Lament of Mary' (o - Maria Siralom), which is dated about a hundred years later. The greatest Hungarian poets are Sandor Petofi, Janos Arany, and Endre Ady. (In Hungarian it should be Ady Endre, because the family name comes first followed by the first name of a person.) Hungarian uses Roman alphabet without some letters (q, x, y) but with a system of diacritics for vowel length and quality. Long vowels are shown by ['] over a letter, e.g. a. Two dots over [o] and [u] like o and u shows that they are pronounced mildly, that is, like 'Umlaut' in German. The sign ['] shows long vowels with umlaut, e.g. o. Many consonant sounds are given by combinations of letters, e.g. cs [t?], dz [dz], dzs [dz], gy [d'], ly [l'], ny [n'], sz [s], ty [t'], zs [z]. Hungarian also has long consonants. The length of the consonant is denoted by doubling the letter, e.g. pp, bb, dd, mm, ll, etc. It is phonemic, i.e. they change the meaning of the word: hal 'fish' —hall 'hears'; var 'wound' —varr '(he) sews'. Long consonants built by letter combinations require doubling

only the first consonant letter, e.g. ccs, ddzs, ggy, ssz, nny, zzs. One can see that the letter 'y' is not pronounced. It shows that the preceding letter is milder, e.g. gy [d'], ny [n'], ly [l'], ty [t'].

The phonology of Hungarian is rather simple. It has no diphthongs, but it has seven long vowels denoted by ['] over the vowel. In the phonetic transcription, we use [:], e.g. a [a:]. There are 14 vowels all in all: [i, i:, u, u:, u, u:, e, e:, o, o:, o, o:, a, a:], among them eight are labialized [o, o:, u, u:, o, o:, u, u:]. According to the vertical position of the tongue, three types of vowels are defined: high vowels: [i, i:, u, u:, u, u:], middle [e:, o, o:, o, o:], and low [e, a, a:]. According to the horizontal movement of the tongue, we define two types of vowels: front [i, i:, u, u:, e, e:, o, o:] and back [a, a:, o, o:, u, u:]. The length of the vowel is phonemic, i.e. it changes the meaning of a word: lap 'page', lap 'marsh, bog', etc. Like in Turkish, Tatar, and other Turkic languages, there is vowel harmony in Hungarian. It means that in a Hungarian word, all vowels share a certain articulation pattern. They are produced with either the front or the back of the tongue, e.g. the locative suffix '-ban' is not changed when there is a back vowel in the word root:_varos 'town' - varosban - 'in town'; a haz 'the house' - a haz+ban 'in the house'; haz+hoz 'to the house'. However, the suffixes change if the root vowel is in front, e.g. a viz 'the water' - a viz+ben 'in the water'; kert+hez 'to the garden'. The stress is always on the first syllable. If the word is long, then it is also on the third syllable.

The hungarian consonantal system is rich. There are 50 consonants in Hungarian all in all. It is 3.6 times greater than the number of vowels. We can define them by the work of the active organ of speech (i.e. the place of articulation), the manner of articulation (i.e. the type of obstruction), and the work of the vocal cords. According to the work of the active organ of speech, we define the following consonants: labio-labial [p, p:, b, b:, m, m:], labio-dental [f, f:, v, v:] (for the lack of place, we shall not show the long vowels further); front (alveolar and dental) [t, d, s, z, ?, ts, dz t?, z, dz, n, l, r]; palatal (mediolingual) [t', d', j]; back (velar) [k, g, h], pharyngeal [h]. According to the manner of articulation, the following consonants are defined: sonorant [m, n, n', l, r, j]; occlusive [p, b, d, d', t, t', k, g]; affricate [ts, dz, t?, dz]; and fricative [v, s, z, ?, z, h]. According to the work of the vocal cords, we define voiced [b, v, d, d', z, dz, z, dz, g] and voiceless [p, f, t, t', s, ?, ts, t?, k]. As we can see further, the phonetical system of Hungarian is rather different from those of Mansi and Hanty.

There is no grammatical gender in Hungarian. Its morphology is of an agglutinative type, i.e. there are no prefixes before the root; the root does not change; suffixes are added ('glued') to the root, and then to

each other, e.g. haz+am 'my house'; 'haz+ad 'your house'. The plural marker '-k' is added to the consonantal stem according to the rules of vowel harmony a haz+ak 'the houses'; a kep+ek 'the pictures'. Linear addition of suffixes is characteristic of agglutinative languages (e.g. Finno-Ugric and Turkic languages). The Hungarian case system is rich. Nouns, pronouns, adjectives, and numerals are declined according to the same rules. There are 23 cases. Unlike many other languages of the world, in Hungarian, numerals are followed by a noun in the singular, kilenc haz 'nine houses'. Verbs can be transitive and intransitive in the indicative, conditional, or subjunctive [imperative moods. Definite and indefinite conjugation.

Hungarian has only 600–700 words of Finno-Ugric or Uralic origin. All the rest of the Hungarian words are borrowings. Old Hungarian borrowed a small number of words from Iranian (through Old Ossetian, e.g. tej 'milk', tehen 'cow', hid 'bridge', var 'fortress'). The first larger layer of borrowings (about 300 words) came in the fifth to ninth centuries from the Turkic languages (especially Chuvash), which belong to cattle breeding, husbandry, crafts, house building, cloth making, public and spiritual life. The second Turkic word layer entered Hungarian from the Pecheneg and Polovets languages in the tenth to thirteenth centuries. Some part of the Pecheneg and Polovets joined the Old Hungarian at that time. A great number of words (more than 500) were borrowed from the Slavonic languages, especially Slovak and Russian. They pertain to all spheres of everyday life. German also influenced Hungarian greatly giving it about 400 words concerning crafts and sciences. Religious, cultural, and school terms came from Latin. Dozens of words were borrowed from Italian, Romanian, or Spanish. So one can see that the major part of Hungarian is the words of non-Finno-Ugric origin.

The Mansi Language

Mansi belongs to the Ob'-Uric subgroup of the Ugric group of the Finno-Ugric family. Anthropologically, they are said to belong to the Mongoloid type. Some scholars believe them to have migrated to the North of Siberia from the Sayan mountains of the South of Siberia. They were called formerly Vogul, which is not correct because the people call themselves 'Man's'i'. In 1989, there were 8,474 native Mansi, but only 37.1% of them considered Mansi as their native language. May be, half of those 37.1% can actually speak Mansi. They live on the territory of the Hanty-Mansi autonomous national district in Russia, which is situated in the basins of the Ob', Sos'va, and Konda rivers and in the Northern Urals. There were four dialects in Mansi, whose speakers did not understand

each other. These dialects were so different that they could be called different languages. Actually, they were more different than German and English. Now, only some of the Northern Mansi can speak their native language, the rest of the Mansi dropped it and began to talk Russian. Two dialects of Mansi, Northern and Konda, are analyzed here to show how different they are. Russian Orthodox missionaries tried to christen Mansi in the second half of the nineteenth century; therefore, they translated the New Testament into Mansi. It was the first book in Mansi. Literary Mansi languages, based on the Northern dialect, was introduced into the mass of illiterate Mansi in the 1930s only. Then, the script was Latin, which was changed into Cyrillic in 1937. Modern Mansi borrowed many words of everyday life from the language of Siberian Tatars, who ruled Mansi before the Russians came to Siberia in the sixteenth to seventeenth centuries. Mansi has many Russian borrowings in the field of culture, sciences, arts, and education. Mansi is used in the first four forms of schooling and also on the radio and in one newspaper. The phonology of Mansi is much simpler than that of Hungarian. It has six vowels: [i, e, I, a, o, u]. Some scholars consider Mansi to have long vowel counterparts. Vowel length is not depicted in the script. This problem has not been studied by the methods of experimental phonetics therefore, one cannot state for sure that the vowel length is phonemic. It can distinguish only some words with [a] and [o]. Anyway, it needs more investigation. According to the vertical movements of the tongue three positions, thus, three vowel types are defined: high [i, u], middle [e, I, o], and low [a]. According to the horizontal movement of the tongue three positions, thus, three types of vowels are defined: front [i, e], central [I], and back [a, o, u]. Unlike Hungarian, there is no vowel harmony. The stress falls on the first, third, and fifth syllables. The stressed vowels sound longer than the unstressed ones. The number of consonantal phonemes in Mansi is not so great as in Hungarian. There are no long consonants. By the work of the active organ of speech (place of articulation), the following consonants can be defined: labio-labial [p, w, m], (no labio-dental whatsoever!); front [t, s, n, l, r]; palatal [t', s', n', l', j]; and velar [k, x, ?, ?]. By the manner of articulation, the following Mansi consonants are classified into four types: sonorant [m, w, n, n', l, r, j, ?], occlusive [p, t, t', k], (no affricates), and fricative [s, s', x, ?]. By the work of vocal cords, nonsonorant Mansi consonants are divided into two groups: voiced and voiceless. There is only one voiced [?], all the rest are voiceless [p, t, t', s, s', k, x]. In this respect, as in many others, Mansi is quite different from Hungarian. Communication between a Mansi and a Hungarian is impossible. Communication

between Northern and Konda Mansi is also impossible. Actually, Konda Mansi is quite a different language. This can be seen even from its phonemic system. Konda Mansi has 17 (short and long) vowels and 18 consonants. Nowadays, it is an extinct language. Thus, one cannot state for sure if the long vowels are phonematic. There exists a strong doubt. It may be stress that makes Konda vowels long.

According to the work of the active organ of speech, the following four groups of consonants are defined: labio-labial [p, w, m], (there are no labio-dental consonants); front [t, s, ?, l, ?, r]; palatal [t', s', n', l', j]; and velar [k, x, ?, ?]. According to the manner of articulation, the following four groups are defined: sonorant [m, n, n', l, l', ?, ?]; occlusive [p, t, t', k]; (there are no affricates); and fricative [w, s, s', ?, x, ?]. There are only two voiced nonsonorant consonants [w, ?]. One can see that the phonemic nomenclature of Konda Mansi is more similar to Northern Mansi than to Hungarian. Mansi is an agglutinative language. The suffixes are added to the root: hap 'boat'; hap+um 'my boat'; hap+ag+um+t 'in my (two) boats; nepak+ag+men 'our (two) two books'; kat+ag+um+til 'by my (two) hands'; war+s+an+en -' they (two) did these'; and jal+as+al+is 'he traveled many times', i.e. jal- 'to go', '-as' the suffix showing contiguity of action, '-al' the suffix showing the interruption of action; '-is' the suffix showing the past tense, and the lack of personal ending shows the third-person singular. Mansi nouns have no gender. The noun has number: singular, dual, and plural. The Mansi noun has seven cases, Hanty, 10. It takes possessive suffixes and is definite or indefinite. There are a small number of adjectives, but mostly nouns can serve as adjectives if they are in preposition to the other nouns, e.g. ker unsah 'iron bridge'; being in preposition to the noun, it does not agree with the noun in number or case, being a part of the predicate, it agrees with the subject in number.

There are several types of Mansi pronouns: personal, demonstrative, interrogative, negative, and indefinite. Most of them are declined. Mansi, like Hungarian, has definite and indefinite conjugations and five moods: indicative, imperative, subjunctive, conditional, and inferential. Word order is usually S(ubject)-O(bject)-V(erb) or OSV.

Hanty

Hanty together with Mansi form Ob'-Ugric subgroup of the Ugric group (plus Hungarian) of the Finno-Ugric language family. They appear more Mongoloid than Mansi. They call themselves Hanty, although in the West they are still wrongly called Ostjaks. They live in the basins of the Ob' River and Vas'ugan River.

The majority of Hanty live in the Hanty-Mansi national District (11,900 people), although some (7,300 people) live in the Jamal-Nenets national autonomous District or in Tomsk region of Russia. The Hanty language is known for its dialectal diversity; nearly every village speaks differently. Only 67.8% of Hanty consider it their native language. In the 1930s, an attempt was made to set up a literary Hanty language, but the success was even smaller than with Mansi. The Northern (Kazym) dialect was chosen to be the basis of the literary Hanty language. The first desk books were published in that dialect. However, only the Kazym Hanty could use them, while the native speakers of the other dialects could not understand them. This is why, in the 1940s they also began publishing books in the Obdor (Salehard), Ber'ozovo, and Middle Ob' (Sherkal) dialects. In the 1950s, Vach and Surgut dialects were added. Nothing has ever been published in the Southern Hanty dialects (Dem'an or Konda). Much earlier, in the 1840s, some of the Hanty folklore texts were written down by the Hungarian A. Reguly and Finn M.A. Castren. In the second half of the nineteenth century, some parts of the Holy Bible were translated by the Russian missionaries, who tried to christen the Hanty people. Since 1937, the Hanty script is Russian (Cyrillic). All the dialects mentioned here have plenty of subdialects, which can be called separate languages and whose names cannot be mentioned due to space constraints. Even the main branches are so many that none of them are mentioned. The Northern Hanty dialects (Kazym, Nizjam, Sherkal, Ber'ozovo) have a rather simple system of phonemes, if compared to the southern or eastern dialects. They have only three cases and a rather simple verb system. They have double negation. The eastern dialects (Vach, Vas'ugan, Surgut, Salym, etc.) have vowel harmony, i.e. rigid opposition between front and back vowels. They also preserve the other archaic traits, e.g. a more complicated phonemic system, paradigmatic vowel change, plenty of cases, and semiergative construction of the sentence. The southern dialects are intermediate between the northern and eastern dialects in their phonetical and grammatical characteristics. The ergative construction (as well as in the Northern dialects) is much more seldom, than in the Eastern dialects. Let us consider the similarity of the phonetical systems of two Hanty subdialects to those of Mansi. We took up Kazym (Northern) and Vach-Vas'ugan (Eastern) dialects. The vowel system of the Kazym subdialect of Hanty is very similar to that of the Northern (Sos'va) subdialect of Mansi. It has nine (long and short) vowels [i, I, e:, o, o:, u, u:, a, a:]. According to the work of the active organ of speech (place of articulation), the following four consonantal groups are defined: labio-labial [p, w, m] (no labio-dentals); front [t, s, ?, n, l, ?, r];

palatal [t', s', n', ?', j]; and velar [k, x, ?] and according to the manner of articulation: sonorant [m, w, n, n', l, ?, ?', r, j, ?], occlusive [p, t, t', k], (no affricates), and fricative [s, s', ?, x]. There are no nonsonorant voiceless consonants in the Kazym subdialect of Hanty. The vowel and consonant phonemic system of the Vach-Vas'ugan dialect are more similar to Hungarian than the rest. The following 14 vowels are defined [i, I, e, o, o, o, o, u, u, u, a, a, ?, a], and according to the work of the active organ of speech: labio-labial [p, w, m], (no labio-dental), front [t, s, ?, t?, n, l, ?, l, r], palatal [t', n', l', l', j], and velar [k, q, ?, ?]. According to the manner of articulation, the following can be defined: sonorant [m, n, n', l, l', ?, j, ?], occlusive [p, t, t', k, q], affricate [t?], fricative [w, s, ?, l, l', ?], and voiced consonants [w, l, l', ?]. Each of the described consonantal groups has its influence on the sound structure of the languages speech chain. The high frequency of sonorants may give a melodic picture of a language, while the high frequency of occlusive consonants gives a sharp and abrupt picture of it. Comparing the consonantal sound pictures of these four Ob'-Ugrian languages with the help of 'chi-squared criterion', one comes to the conclusion that the Northern (Sos'va) dialects of Mansi and Northern (Kazym) dialect of Hanty resemble each other most in terms of the distribution of certain types of consonants in their sound chains (75). The sound picture distance between Sos'va and Konda dialects of Mansi is greater (409). This distance between Kazym and the Eastern dialect of Hanty is even greater (476). The distance between Konda dialect of Mansi and Eastern dialect of Hanty is 832. Hungarian is much closer to the Eastern dialect of Hanty (151) than to the Kazym dialect of Hanty (1612) or both Mansi dialects: Sos'va (1018) or Konda (1115). One can see that these distances are much greater than the similarity of Hungarian to Mordovian (174) or Mari (226), the Finno-Ugric of the Volga region.

Hymes, Dell Hathaway

Dell H. Hymes' life and work revolve around an interest in language, a commitment to social justice, and an abiding love of folklore. The intertwining of these themes provided the fertile ground for his views: that language is embedded in culture; that the division between language and culture is a disciplinary artifact, its maintenance a result of protected disciplinary boundaries; and that the only legitimate study of language is socially constituted linguistics. Much of his writing therefore challenges current–traditional practices in anthropology, sociolinguistics, sociology, and formal linguistics. His work reflects a critical and evolutionary Marxist view of knowledge, interpreting the current dialectic as a teleological stage in the development of knowledge, leading, '... to a humanism which can deal with concrete situations, with the inequalities that actually obtain, and help to transform them through knowledge of the ways in which language is actually organized as a human problem and resource' (1996: 60).

Hymes considers the essence of humankind not as an abstraction in the individual, but an actuality entailed in specific social relations. He thus rejects giving priority to an abstract category of language or grammar, and the notion of nativism of language, both positions putting him in opposition to structuralism and Chomskyan linguistics. He met the Chomskyan challenge head on with his formulation of 'communicative competence', which deliberately creates an irony. For Noam Chomsky, competence inheres in the individual, and linguistic rules are verified by the intuitions of the ideal speaker/hearer. The idea that 'communicative' can be collocated with 'competence' turns Chomsky's notion and resulting linguistic discourse on its head. He also refutes the basic premise in linguistics that all languages are equal. Hymes claims that all languages may have equal potential, but because human beings ascribe differing attitudes to different languages and varieties, speakers of some languages and varieties have reduced opportunities.

His strongly held view that forms and meanings are part of social life has influenced both his theoretical writings and his life choices. He is probably most widely known for his formulation of the 'ethnography of speaking', first presented at a meeting of the Anthropological Society of Washington in 1962, the seed for which was germinated in a 1952 debate about the role of linguistics in anthropology, one that drew scholars from several disciplines. That ethnography would become his approach to language in society was rooted in his mixed training and later interactions with anthropologists, linguists and social scientists, at Harvard, and at Berkeley. He chose the term linguistic anthropology, making it a branch of anthropology. This approach resonates with his view of language's role in social life and by applying it to the examination of language, challenged both linguistics and anthropology. Using ethnography, anthropologists uncover the rules and symbols that hold meaning for the community being studied. Such an approach was new to linguistics, which instead considered descriptions of phonology and grammar as the principal framework. By choosing the term 'speaking', he also challenged anthropologists who, when studying cultures of a community, took speech for granted.

This paper launched a new perspective, providing the parameters for analyzing and describing speech communities—grouping members who share one or more of its 'ways of speaking'. Members who know not only the rules of speaking but also the sociocultural norms and values that guide interaction and cultural behavior within specific communities can be considered to have communicative competence. His framework for description included speech community, speech event (activities governed by rules for speaking), factors in a speech event (e.g. sender), and the functions of a speech event (e.g. persuasive).

Over the next decade, the framework was revisited as colleagues and students conducted ethnographies in different settings—nonwestern, Native American, and, increasingly, schools. In 1972, he elaborated on the factors in the speech event, devising the mnemonic SPEAKING: setting, participants, ends, act characteristics, key (tone), instrumentalities, norms, and genres. This list has been compared to Michael Halliday's field, tenor, mode, and was found to be unmotivated linguistically. Hymes, however, only ever meant SPEAKING to be a heuristic, a list of questions to ask when examining language in context. For both, the bundling of linguistic features in a community results in linguistic repertoires available to that community. Ethnography of speaking was broadened to the 'ethnography of communication', Hymes never intended to ignore written language by his use of 'speaking'; rather, he used it as a surrogate for all communication modes, including gestures and, most recently, electronic modes.

Hymes was the driving force behind a new journal, calling it *Language in Society*, not a journal of sociolinguistics, so that its concern would focus on

social/cultural life. Perhaps, his greatest source of influence was his 20 years of editing the journal, many of the articles owing much to his imaginative thinking as he dialogued with the author, sending detailed recommendations, comments, and further ideas. At the University of Pennsylvania, he moved from Anthropology to Folklore and Linguistics, because of political division within the department, even though he felt that anthropology was in a unique position for studying the sociology of language from a comparative perspective. Later still, he moved to the School of Education as Dean, a move that was not just practical (to save the School from closure) but also philosophical. He had already set a new direction for educational research with his volume coedited with Cazden and John (1972), by insisting on the need to examine actual classroom interaction in order to understand the role of language in teaching and learning. In education, his beliefs that understanding how language varies and what that variation means for speakers, especially in terms of inequality, influenced both theory and practice leading to the development of a program in educational linguistics. Education was also a platform for advocating that all human beings could benefit from an understanding of language. His most recent work has focused on analyzing oral narratives, bringing together his love of folklore, his commitment to social justice, and his insistence that language should always be examined in its social context.

Biography

Dell Hathaway Hymes was born in Portland, Oregon on June 7, 1927. He received his B.A. in 1950 from Reed College; M.A. in 1953 from Indiana University; and Ph.D. in 1955 for a dissertation that was a linguistic analysis of Kathlamet Chinook Indian texts that had been collected by Franz Boas, Indiana University. He became Instructor, then Assistant Professor, Social Relations Department, Harvard University in, 1955–1960. Also, he became Associate Professor, then Professor, Department of Anthropology, University of California, Berkeley in 1960–1965; he became Professor, Anthropology, University of Pennsylvania in 1965–1972; Professor, Folklore and Linguistics, University of Pennsylvania in 1972–1988; Professor, Sociology, University of Pennsylvania in 1974–1988; Dean of the School of Education, University of Pennsylvania in 1975–1987; Professor of Anthropology and English, University of Virginia in 1987–1990; and Commonwealth Professor of Anthropology, University

of Virginia in 1990–1998, now Emeritus. He was also Fellow of the American Association for the Advancement of Science; Life Fellow, Clare Hall, Cambridge; member of the British Academy; Fellow at the Center for Advanced Study in the Behavioral Sciences, 1957–1958; Guggenheim Fellow, 1969–1970; Senior Fellow, National Endowment for the Humanities, 1972–1973; Trustee, Center for Applied Linguistics, 1973–1978; President, American Folklore Society, 1973–1974; President, Council on Anthropology and Education, 1978; President, Council on Anthropology and Education, 1978; President, Linguistic Society of America, 1982; President, American Anthropological Association, 1983; and President, American Association for Applied Linguistics, 1986. He was also founding coeditor of *Language In Society* with William Labov and Allen Grimshaw, 1972–1992.

Iconicity

Many believe that language is arbitrary. Arbitrariness refers to a random relation between a word and its meaning. However, there are many examples of nonarbitrariness in language known as iconicity. Iconicity is the opposite of arbitrariness because iconicity refers to a resembling relation between a word and its meaning. A word is directly related to its meaning in many ways.

The form of words like *cockatoo, cuckoo, buzz, thump, crash, splash, thrash, clash, hiss, puff,* and *purr* is connected to their meanings. These words imitate the sounds created by the referents. While, '*ha, ha, ha*', captures the sarcastic laughter in English, '*he, he, he*' is commonly used after a remark intended as a joke in Malay e-mails as well as Singapore and Malaysian English e-mails. These words do not come into language by chance. The derivation of these words is based on certain comprehension based on sound. The words are sound images of the various meanings. This type of iconicity is termed imagic iconicity.

Imagic iconicity comes in the form of sound symbolism. Sound symbolism occurs if a particular sound informs a particular sense across various words. Examples in Malay, Cantonese, English, and Spanish words suggest that the vowel [o] symbolizes a negative sense across languages (Table 1).

Current bad English o-iconic words of the world are *bomb, romp,* and *storm* all of which had *brought down* lives in all four corners of the world resulting in either death or disgrace.

Another type of nonarbitrariness is diagrammatic iconicity. Diagrammatic iconicity suggests that a word is a diagram of a meaning. Linguistic signs are used to illustrate some structures of the meaning. Sign language is a form of meaning depiction. The notions of *up* and *down* in various sign languages relate closely to the vertical directions of these concepts. The resemblance between a raptor snatching a sitting-up rodent and one hand snatching at an upright finger in American Sign Language is a good example of diagrammatic-iconic gesture. However, believers of language signs must arbitrarily deny sign language as language (see Armstrong, Stokoe, and Wilcox).

Motivation is the operating force behind diagrammatic iconicity. Motivation in iconicity refers to perceived similarity between the structure of the expression and the concept represented in the expression. The need to name things results in the expansion of meaning motivated by resemblance in appearance. A schematic resemblance between a tall *crane* machine and the neck of *crane* motivates the derivation of a new meaning in the word *crane*. The creation of new words may be motivated by functional similarity, e.g. the shuttling of a *shuttlecock* and a *space shuttle* in the air.

Quantity iconicity is another type of diagrammatic iconicity. Quantity iconicity holds the basic notion that more form entails more meaning. Physical increase in quantity is captured loosely by more words in reduplication. Hence, plurals usually have more words. Simple noun reduplication in Malay exemplifies quantity iconicity (Table 2).

Diagrammatic iconicity records the flow of time from its commencement until its completion. This sequence of time and the natural order of an event unfolding in time are reflected in sentences in sequential iconicity, e.g. '*Syukri went to school on Monday*

TABLE 1

Malay	Cantonese	English	Spanish
hodoh (ugly)	*soh* (slow in thinking)	*horror*	*tonto* (stupid)
bodoh (stupid)	*lõw* (man in a rude sense)	*sorrow*	*zonzo* (stupid)
kotor (dirty)	*põr* (woman in a rude sense)	*fool*	*coco* (funny looking)
rogol (rape)	*mór* (devil)	*loon*	*memo* (silly, foolish)
bocor (leak)	*mõng* (dumb)	*moron*	*chato* (flat nose)

TABLE 2

Basic Singular Noun in Malay	Basic Plural Noun in Malay
pelajar (a student)	*pelajar-pelajar* (students)
sekolah (a school)	*sekolah-sekolah* (schools)
gunung (a mountain)	*gunung-ganang* (ranges of mountain)
sayur (a vegetable)	*sayur-mayur* (vegetables of all sort)

and left for Singapore on Tuesday in the same week,' rather than '**Syukri left for Singapore on Tuesday and went to school on Monday in the same week.'* In fact, sequential iconicity is a refection of common sense, which is imperative to sensible sentences like:

> *Jyh cooked the fish with ketchup before he ate it.*
> **Jyh ate the fish with ketchup before he cooked it.*
> *Siti knocked the vase, and consequently it broke.*
> **Siti broke the vase and consequently it knocked.*

The language of distance is iconic. The vivid sense of *near* is easier to register in the mind than the distant notion of *far*. These two senses are codified in phrases like *now and then, this and that,* and *in and out*. That *near* comes before *far* in language, just like their real-world relation illustrates syntactic iconicity. Syntactic iconicity refers to the fixed order in phrases. These phrases are known as freezes. Syntactic iconicity in *here and there* has equivalents like *ingum angum* in Tamil, *sini sana* in Malay, *li do guo do* in Cantonese, *ci dau he dau* in Hokkien, *ci gou heo gou* in Teochew, and *zhe li na li* in Mandarin.

Likewise, *above* precedes *below*, *on* precedes *under*, and *up* precedes *down* (see Landsberg). Freezes like *ups and downs, head to toe, head over heel, top-down, high and low* are common examples. Quantity decrease in freezes like *more or less*, and *big to small* are found in Mandarin and Malay. Unlike the Malay freezes *lebih kurang* (more or less), the Indonesian counterpart *kurang lebih* (less or more) does not reflect the iconicity of quantity decrease. This is due to the politeness convention that prefers a lesser or weaker meaning before a stronger one.

Freezes like *sir and madam*, *father and mother*, *papa and mama*, *Adam and Eve*, *king and queen*, *boys and girls*, *husband and wife*, *Mr. and Mrs.*, and *brothers and sisters* show that *man* syntactically precedes *woman*. That man comes before woman is based on the perception of man as the center of the universe or the *me-first* principle. This is quite true in the ancient and current real world. Contradictions like *mom and dad*, *bride and groom*, *aunts and uncles*, and *ladies and gentlemen* can be explained either by the politeness convention, the stronger phonological laws, whereby high vowels precede low vowels or the less-syllabic items precede more-syllabic items order (see Cooper and Ross).

Identity and Language

Throughout human history, language and identity have been closely linked. Political boundaries have been drawn along linguistic lines, establishing nationality as well as ethnic division. Often, a single feature of pronunciation can provide a convenient means of identification. Pronunciation, grammatical and lexical markers, naming, and discourses may all be used to establish identity. The linguistic approach that is most centrally concerned with the interrelationship between identity and language is sociolinguistics. Sociolinguistic approaches to identity and language have changed over time. At least three different strands of inquiry into identity and language can be identified: variationist, interactional, and social constructionist approaches.

Variationist sociolinguistics, which is strongly associated with the pioneering work of William Labov, is based on the premise that language reflects identity. Assuming that a person's speech reflects characteristics of that person, aspects of social identity—such as social class, sex, ethnicity, nationality, or age—were traced through forms of language. The bulk of variationist work on identity and language concerned pronunciation. Typically, certain pronunciation variables were linked to aspects of social identity. However, in recent years, work in variationist sociolinguistics has been challenged on the grounds that social identity cannot provide an explanation for language use because it is a concept that is itself in need of explanation. Critics of variationist sociolinguistics argue that instead of asking, 'How do women and men speak differently?' or 'How do Black and White Americans speak differently?' it would be more important to find out how people become gendered or racialized beings in the first place.

Interactional sociolinguistic approaches to identity and language, as pioneered by John Gumperz and used by Deborah Tannen, draw largely on social psychology. In this approach, identity is based on group membership, where the negotiation of identity in interaction is of central concern. Instead of focusing on pronunciation, interactional sociolinguists study discourse, written or spoken communication, preferring qualitative methods over quantitative in data collection and analysis. Interactional sociolinguistics assumes that identity as group-membership is negotiated, challenged, or upheld in conversation. When people come together from different backgrounds, misunderstandings are likely to occur, as they do not share the same conventions for signaling identity and role relationships. Consequently, most of the work in this tradition has been concerned with cross-cultural communication. 'Cross-cultural' has been rather loosely defined and includes interactions between people from different national backgrounds (e.g. American–Japanese business communication), between migrants and natives (e.g. South-East Asians in British job interviews), between people from different ethnic backgrounds (e.g. Black and White Americans), or between women and men. This social psychological conception of identity, however, has come under attack for at least two different reasons. In this approach, identity as group membership is seen as essentializing, meaning identity is regarded as internal and immutable. Further, this view of identity relies on the idea of a homogeneous group while, in fact, people are members of many different groups simultaneously (e.g. American, Hispanic, professor, female, heterosexual). The latter objection, that social identity is hybrid and heterogeneous, is raised by linguists who work in bi- and multilingualism studies. The language use of bilinguals clearly exemplifies that speakers do not only have one single identity but rather a repertoire of identities.

Contemporary approaches to language and identity most often build on the framework of social constructionism. Identity is now seen as relational, cultural, and contingent. It is relational because it is located in connections made between people rather than in the minds of individuals. Identity is cultural because it is based on shared understandings, and it is contingent because it is a strategic performance that may fail or misfire. Speakers are seen as strategically deploying their linguistic repertoires in order to project chosen identities. However, their acts of identity are not exclusively in their own hands as they depend (a) on the repertoires at their disposal and (b) on the ways in which their speech partners choose to view them. Identities are constructed or coconstructed depending on the power relationship that pertains between the interactants. In many societies, categories such as caste, gender, or race are imposed and coerced, leaving little or no room for individuals to perform or explore alternative identities that might deviate from prevailing ideologies. Three aspects of social identity that have played a central role in recent linguistic work will be discussed based on the following: gender, nationality, and bilingualism.

Within feminist and gender theory, identity has become the central question since, in the 1980s and 1990s, women of color and lesbian theorists started to challenge the assumption that the experience of white

heterosexual middle-class American women was universal. Consequently, language and gender researchers have begun to explore the linguistic construction of fluid, hybrid, and alternative identities. Recent research (see Bucholtz et al., 1999) explores how identity is invented (e.g. through the creation of shared experience in the coming-out stories of deaf and hearing lesbians) and how the performance and perception of identity is constrained through belief systems (e.g. through the 'woman as dessert' metaphor in English). Further foci include speakers' individual creative responses to cultural ideologies and identity constructions as 'on-line' events that may never be complete (e.g. callers on a shopping channel may position themselves simultaneously as consumers with questions about the product and experts who are familiar with consumption patterns).

Unlike gender, nationality has been seen as intricately linked to language for centuries. To the present day, many nations, particularly in Europe and North America, subscribe to a 'one nation, one language' ideology. Many states have used the reification of a standard language and the common identity that supposedly goes with a shared language as a means to naturalize political borders. In an intricate genre analysis, Wodak et al. (1999) describe how 'the same' national identity (Austrian) is performed in significantly different ways and with significantly different meanings in public and private speech (e.g. newspaper articles vs. one-to-one interviews).

For some time, researchers into multilingualism have seen language choice as meaningful and as an 'act of identity' (see Le Page and Tabouret-Keller 1985), whereby speakers proclaim their allegiance to a particular speech community. Code-switching is often seen as a means to signal changes in the role relationship that pertains between interactants. Furthermore, second-language acquisition theory has often viewed successful language learners as good assimilators. The easier they find it to shed their native identity and assimilate to the one related to the target language, the more successful their learning outcomes were thought to be. Only recently, linguists (e.g. Pavlenko et al., 2001) have come to acknowledge that bilinguals and second-language learners tend to engage in more than one community and that they may have different identities in different languages.

At present, the study of identity and language is a lively and diverse field of research, encompassing a wide array of issues and implications. Given the overall global climate of identity politics, the scope of sociolinguistic study, both theoretical and practical, is likely to increase in the future.

INGRID PILLER

Ideology and Language

Ideology's features are topics of complex debate. Often defined as matrices of ideas and images inhabiting individuals' minds, ideologies are also thought of as neither ideas nor images, but as practices that are embedded in and reproductive of specific socioeconomic structures. Ideology can empower or oppress. Furthermore, ideology is related to language in numerous ways.

An ideology may empower persons when it defines their ethnic, gender, class, or other identity, organizes a 'worldview' that gives meaning and coherence to their lives, or facilitates their entrance into social, civic, or political life. Oppressive ideologies marginalize, stigmatize, or otherwise define persons to reproduce their exploitation or subordination in a socioeconomic hierarchy.

A focus on an ideology as empowering may downplay the relations of ideology and knowledge. Sociologists comparing various cultures' ideologies may want to know the differences among ideologies rather than to judge their compliance to a normative definition of knowledge. A barrier to this unbiased evaluation is the sociologists' own assumptions about knowledge. The 'critique of ideology' exposes such mystifying errors or beliefs by which an ideology reinforces structures of oppression. Often the same ideology empowers some, oppresses others, and gains hegemony. An ideology becomes hegemonic by defining the arguments contending groups use to debate with each other; by prescribing the values to which clashing ideas must adhere to achieve legitimacy; or by projecting a totality in which diverse political actors imagine an open network of cultural, social, and economic relations to be enclosed.

Debunking an oppressive ideology's knowledge claims contests that ideology. Theorists have long debated whether ideology can be distinguished from knowledge. The European Enlightenment's attack on religious dogma claimed that ideologies are illusions that reason can dispel to foster an ideology-free society. Karl Marx defined ideology as mystification in the interest of a ruling class. Like Marx, the twentieth-century communist philosopher Louis Althusser claims that scientific knowledge is distinct from ideology. Because of ideology's role in subject formation, Althusser concludes that ideology will always exist, even in a future classless society. Contemporary 'post-Marxist' theories include ethnicity, gender, and culture as important determinants of ideology. Questioning the opposition between science and ideology, post-Marxists doubt the theorists' ability to contest oppressive ideologies effectively. Post-Marxists define political struggle as a battle for hegemony in which no participant holds the cognitive or ideological high ground.

Ideology intersects language when politics privileges one language and denigrates, restricts, or excludes others. California voters have passed a series of proposals, making English the state's 'official language', requiring that government agencies use English to the exclusion of other languages, and outlawing bilingual instruction in the state's schools, exemplifying ideology's impact on language.

Californians write and speak numerous languages, but enough Californians felt threatened by this language diversity to institutionalize an ideological monolingualism that values social unity as a function of linguistic homogeneity. The propositions' success arguably related to anxieties concerning California's growing population of Spanish speakers. These examples raise the issue of 'linguistic racism', in which prejudicial attitudes about an ethnic group extend to that group's language. Such racism often assumes that one language is inherently more beautiful or a better vehicle for thought than others. And, in the form of slurs, jokes, and ideologically coded diction, language can influence racial ideology.

Language also reflects ideologies of sexuality and gender. For example, consider the following sentence: 'A linguist, if he wants a successful career, masters contemporary linguistic research on English'. This sentence, by assuming that the typical linguist is male, betrays sexist beliefs concerning women's abilities and roles in society. Sexism in language use not only signals an ideology; sexism as a relation of power embedded in institutions reproduces itself through such uses when they are uncontested. Similarly, racism in language use reveals an ideology and contributes to the continuation of racist power relations.

Even in the study of language, ideologies present barriers to unbiased evaluation. Our sentence also assumes that English should be privileged in linguistic inquiry. The phrase 'language ideology' refers both to ideologies found in language and to ideologies about language. When power relations dictate which languages may be studied or what constitutes their legitimate study, we confront language ideology's influence on the production of linguistic knowledge.

The study of language itself reflects a language ideology that assumes languages are static entities unaffected by their ideological contexts. These contexts sometimes influence a language's pattern of sound change or even precipitate its demise. Examples of demise are the fates many indigenous peoples' languages have suffered in the wake of Europe's colonization of Asia, Africa, Australia, and the 'New World', direct victims of racist ideology. The recent trend to install Standard American English as a global lingua franca endangers ever more infrequently used languages. Language reflects ideologies, oppressive and progressive, which in turn influence the evolution of those same languages. Further, this reciprocal relationship also holds in the political arena. Language not only influences ideologies but may also be used as a tool to control groups or thought. The study of the intersection of language and ideology contributes to our understanding of the political implications of global socioeconomic realities.

ROBERT S. OVENTILE

Idiomaticity

The traditional and most widespread definition of idiomaticity maintains that it is the result of a mismatch between meaning and form: the overall meaning of an idiomatic expression is figurative and noncompositional, that is, it cannot be deduced from the literal meaning of its individual components. Idiomatic expressions are thus words, phrases, or even whole sentences that seem to function as an unanalyzable unit: *egghead, to bury the hatchet, the early bird catches the worm,* and the like.

The study of idiomaticity has advanced greatly since the 1980s because of a change in the discipline of linguistics that was characterized by an increasing interest in meaning and discourse. This universal grammatical phenomenon has begun to receive the attention it did not receive during the long period when sentence structure was the principal focus of linguistic investigation.

Although unpredictable from its form, the meaning of an idiomatic expression cannot be considered purely random; it is the direct consequence of a historical process of extension, whereby the literal, compositional meaning of that pattern, although not completely lost, is gradually replaced by a new metaphorical, noncompositional meaning that becomes widely accepted in society. Contrary to what might be expected, however, the connection between the two senses is not easily recognizable at the present time in every linguistic construction that counts as an idiom. Hence, there is a distinction between 'transparent' idiomatic expressions like *skate on thin ice,* which have a clear literal origin, and 'opaque' ones like *to pull someone's leg,* which do not display any logical relation with their source. Idiomaticity is thus the outcome of a historical process that must nonetheless be analyzed as a rather static phenomenon.

But classic theories of idiomaticity reject this distinction because, according to them, all idiomatic expressions are dead metaphors that lack any connection with their original sources. As a consequence, the relation between their form and meaning is traditionally said to be arbitrary. Recent research within the theoretical framework called 'cognitive grammar' has shown, by contrast, that the form–meaning relation underlying many idiomatic expressions is far from arbitrary—that it is motivated not only by their primitive meaning but also by conventional images and conceptual metaphors. Thus, the traditional analysis asserts that nothing explicit in *to spill the beans,* for instance, justifies its meaning 'to reveal a secret'; this new approach, however, claims that such a figurative meaning is clearly determined by the 'conduit metaphor'—that is, a metaphor that compares the mind with a container and ideas with physical entities.

Apart from shedding some light on the semantic motivation underlying idiomaticity, the afore-mentioned historical process is also noteworthy for two further reasons: (a) it is responsible for the institutionalized meaning of idiomatic expressions; (b) it explains their frequent coexistence with literal interpretations of the same expressions.

(a) Along with the nonliteralness and non-compositionality of an idiomatic expression, its sense also has to be institutionalized; that is, it must be regularly associated by the members of a speech community with a specific form. The number of people accepting such form–meaning asymmetry is considered essential in this slow process of adaptation. They can range from a small in-group to an entire linguistic community, hence, their number influences the degree of institutionalization of a specific idiomatic pattern and consequently its degree of idiomaticity: that is, the more widely used in society an idiomatic expression is, the more institutionalized and idiomatic it is, hence the contrast between those idiomatic constructions that are listed in dictionaries as approved by the entire society and those others, like slang, jargon, and familiar euphemisms that have a private meaning accessible only to small social groups. Regardless, during the institutionalization process they all acquire a national and cultural flavor that makes understanding and acquiring them highly difficult for the outsider.

(b) The institutionalization process is also significant because, although it does not imply the systematic loss of the original construction that serves as input for the idiomatic pattern, it explains the frequent coexistence of many idiomatic expressions with literal interpretations of the same expressions. The commonly suggested hypothesis that idioms are usually ambiguous between a metaphorical and a literal interpretation is thus reinforced. However, such ambiguity can no longer be considered a distinguishing property of idiomaticity, due to the following results of recent investigations based on immense collections of actual language data: (a) a vast number of idiomatic patterns, such as *rain cats and dogs* and *by and large,* lack literal interpretations, either because they would violate truth conditions or because they would be ungrammatical, (b) the literal interpretation of whatever idiomatic expressions do allow both readings is highly infrequent in actual language data, because the discourse where they occur generally favors the figurative meaning over the literal one. Even when no discourse element serves this clarifying purpose, the alleged ambiguity can still be removed via pronunciation: the idiomatic reading, in accordance with its form–meaning unity, requires shorter pauses and word durations than its literal counterpart.

Moreover, new studies have shown that idiomatic expressions are less exceptional than traditionally thought: (a) Far from being structurally frozen patterns, they present more structural variety than has been asserted. Specifically, the more semantically motivated and institutionalized the meaning of an idiomatic expression, the more structural flexibility it shows. (b) The absolute syntactic rigidity that does in fact characterize some idiomatic patterns also appears in a large number of nonidiomatic constructions: *to kick the bucket,* for instance, does not have a passive form, i.e. *the bucket was kicked (by him)* is unacceptable; however, the nonidiomatic construction *she has two sons* does not have a passive either: *two sons are had (by her)* is equally unacceptable. The traditional assumption that special rules apply to idiomatic language must thus be rejected in view of these facts.

In sum, idiomaticity is a heterogeneous and measurable linguistic phenomenon, variable in meaning, form, and discourse functions. It thus forms a continuum with different degrees of idiomaticity that cannot be straightforwardly defined according to one single parameter.

Idioms

An idiom can be defined as a set phrase, semantically opaque, whose meaning cannot be deduced from the meanings of its constituents. Although it shows an expressive and particular value, and sometimes a (lexical or syntactic) archaic structure, it behaves as a single semantic unit. Expressions such as *a night owl, a tempest in a teapot, not enough room to swing a cat, to leave no stone unturned, to knock on wood, to put the cart before the horse* are called idioms.

A set phrase is a sequence that has experienced fixation, the process by which a multiword expression whose constituents are free (or were free when the phrase was created) becomes an expression whose constituents are integral parts of it. Therefore, the elements lose their own meaning in favor of the global meaning of the expression and the phrase becomes a new lexical unit, independent, with its own new meaning.

Thus, idioms only correspond to one signified—they have a noncomplex, simple meaning. This means that they can be substituted by simple words as they are expressive alternatives to a neutral concept that already exists in the language. For example, *when hell freezes over* can be replaced by *never*. Idioms constitute a luxury of the lexicon in as much as it is possible to communicate basically without them. Therefore, understanding idioms shows that the speaker has a very good knowledge of the language in which he expresses himself (most of the time, idioms are the last aspect that speakers identify when they learn a foreign language).

Because they are fixed phrases, idioms cannot vary in their form, with the exception of some elements that enable them to adapt to the specific context. For example, when the idiom is a verbal unit, the space of the subject is free and the tense of the verb is to be chosen according to the context: Bart/My brother/The captain… *broke the ice*. The possessive can also be adapted: *I will keep* my *fingers crossed* for you.

Idioms are semantically opaque. That is to say that they cannot be understood literally, in a compositional way. They cannot be interpreted from the total of each word that constitutes it. Even if you know and understand each constituent, the meaning of the whole phrase remains confusing. For example, *white* and *lie* are words that are common and easily understood, but put together, they do not have the same meaning. The compound must be learned as if it were a new word. Thus, it is impossible to deduce the global meaning from the total of the signifieds just as it is not possible

to isolate the different matters of a chemical combination.

This can be explained by the fact that the semantic features selected are not the same ones whether the constituents are used when they are free (if they still exist outside of the phrase) or as parts of the idiom. For this reason, most of these utterances can be polysemous—they may have multiple meanings. They can be interpreted in either a literal or a figurative manner. Expressions are exocentric when the total of meanings does not enable the whole phrase to be understood. For example, an expression such as *to be in the doghouse* has two possible interpretations. When the speaker says: "*he is in the doghouse*", the expression is endocentric if the subject is a dog, and exocentric if the subject is a man (it means the man is in trouble with his wife). Thus, the endocentric utterance, whose meaning is compositional, is to be interpreted in a literal way (it is a common utterance). The exocentric statement is fixed and to be interpreted in the figurative way; it is therefore an idiom.

When the phrase is exocentric, the speaker does not conceptualize systematically the meaning of each constituent. For example, in an expression such as *to have a green thumb*, he will not imagine he has a colored finger. For a nonnative speaker (or somebody unfamiliar with the set phrase and its global meaning), his first interpretation will be literal even though the phrase must only be interpreted as a unit. Because they are set phrases, idioms are often used to create puns. One constituent replaces another, or the other meaning of the polysemous word is selected. This unexpected aspect of the new phrase or the new signification causes humor, by reverting back to the literal form. For example, using the idiom *to work for peanuts* can lead to the following play on words: 'Charlie Brown has spent his entire life working for Peanuts.'

Thus, in idioms, words are used figuratively, through two main figures of speech: metaphor and metonymy. This matter of fact gives life and richness to the language by enabling it to absorb new concepts that need to be expressed linguistically in a new way. The use of metaphors is motivated by the incapacity of the human mind to reach a complete state of abstraction. To make an abstract notion accessible and to give it more weight, the speaker compares it with a physical object he knows. He uses basic schemes in order to conceptualize his experience and the external world (even if the analogy appears a little illogical): *to bear*

one's cross, to have a monkey on one's back, to have a frog in one's throat. Thus, metaphors are based on similarity: metaphoric idioms appear in their simpler form when they are built around the adverbs 'as' or 'like': *as innocent as a lamb, as solid as a rock, like (two) peas in a pod, like a bolt out of the blue*. For its part, metonymy is based on contiguity: one word or phrase is substituted for another with which it is closely associated. But it is also an erroneous perception, which consists of confusing two different things, for example: *to put bread on the table* (bread for money), *to give a hand* (hand for help), *heads will roll* (heads for people).

Sometimes, only one interpretation is possible because the phrase appears archaic, through a form that is obsolete or belongs to an older stage of the language. Most of the time, the archaism is lexical: some words that have now disappeared as free units still exist inside some idioms. These words are called fossils. For instance, *hue* is no longer used outside of the phrase *hue and cry*; it is the same for *fro* in *to and fro* (ancient *from*), or *shrift* (confession), which never appears without *short (to give somebody/something short shrift)*.

But before becoming opaque, those expressions were motivated. The creation of idioms is influenced by two main heritages: social heritage and cultural heritage. Even if the speaker perceives the world through his language, the latter is made up of things that exist in the speaker's social environment. Animals (*blind as a bat, as the crow flies, to take a hair of the dog that bit one, to kill two birds with one stone, to play possum*), insects (*a fly in the ointment, to have a bee in one's bonnet, to get ants in one's pants*), flowers and plants (*to gild the lily, to nip something in the bud*), vegetables and fruit (*to spill the beans, the apple of someone's eye*) are very present in idiomatic imagery. In the same way, if language mirrors life, men, and society, it also arises from culture. Several idioms originate in mythology (*in seventh heaven*—the antique firmament is composed of seven vaults, seven skies that one reaches successively, *to carry the weight of the world on one's shoulders, to rise from the ashes*), in the Bible (*not to know someone from Adam, to turn the other cheek, like a lamb to the slaughter, to cast pearls before swine, to wash one's hands off (something), to separate the wheat from the chaff*), in literature (*Achilles' heel, to bite the dust, the emperor's new clothes, it's all Greek to me*), and in history (*to have an axe to grind, when the balloon goes up, to haul someone over the coals, it's like the Black Hole of Calcutta, to win one's spurs, to cross the Rubicon*).

Because idioms cannot be understood literally, they cannot be translated literally either. The translation of idioms is characterized by a double problematics, as it is necessary to express not only the meaning and the form but also the aspect of fixation of the expression used in the source language. It is not always possible to meet this requirement. If the utterance in the target language is not a set phrase, the translation cannot be satisfying. When translating idioms, three different situations arise. First, the opaque expression can be translated literally because the same idiom exists in both the source language and the target language. This occurs with languages that are similar, such as English and French: *to read between the lines/lire entre les lignes*, *to praise to the skies/porter aux nues, a drop in the ocean/une goutte d'eau dans l'océan, to burn the candle at both ends/brûler la chandelle par les deux bouts*. Second, the idiom in the source language can have an equivalent idiom in the target language, like any other simple unit with its equivalent in a dictionary: *to have other fish to fry/avoir d'autres chats à fouetter, before you could say Jack Robinson/en deux temps trois mouvements, as alike as (two) peas in a pod/comme deux gouttes d'eau, the last straw (that breaks the camel's back)/la goutte d'eau qui fait déborder le vase.* Third, the idiom can be translated by a simple word or a paraphrase if neither the same idiom nor the equivalent exists in the target language. In this case, a part of the signified will be lost.

The expression of the same ideas varies from one language to another: when *there's something in the wind* in English, there's a conger eel under the rock in French (*il y a anguille sous roche*), and something is boiling in the pot in Italian (*qualcosa bolle in pentola*). If you are *in someone's good books* in English, you are in somebody's papers in French (*être dans les papiers de quelqu'un*) or in somebody's sleeve in Italian (*essere nella manica di qualcuno*). And if you *call a spade a spade* in English, you call a cat a cat in French (*appeler un chat un chat*), and you say bread to the bread and wine to the wine in Italian (*dir pane al pane e vino al vino*). Thus, idioms have a supplementary and particular aspect that simple words do not have: because they are motivated signs, and thanks to the images that are used, they give information about conceptions of the world considered by linguistic communities.

CARINE MARRET

Igbo and Igboid Languages

Igbo (Ibo, in old orthographies) is one of the three major Nigerian languages. It is spoken by some 30 million people in present-day Imo, Abïa, Ebonyi, Enugu, Delta, Rivers, and Anambra states, and also in parts of Cross River, Akwa Ibom, Bayelsa, and Benue states of Nigeria. Igbo is now classified as belonging to the 'Benue-Congo', previously and variously to the 'Kwa', the 'Eastern Kwa'. The current Benue-Congo group includes not only Yoruba, Edo, and other smaller Nigerian languages but most of the 'Bantoid' languages of eastern, central, and southern Africa. The basis for this classification has been seriously questioned, and has been shown in many cases to be untenable. The proposition advanced by Kay Williamson (1989) that Igbo was a language of the lower Niger Delta from where it spread back north to present-day Igbo heartland has also been largely rejected by students of Igbo history and linguistics such as M. Angulu Önwüejiögwü (1980) or E. Nölue Emenanjö (2001).

Igbo is a single language, with several dialects. Following the Biafra/Nigerian war (1967–1970), there has been continuing pressure on some Igbo speakers to formally dissociate their dialects from Igbo proper. This has been particularly so with respect to Ikwere, Ahoada (Ekpeye), and Ïka. In fact, the term, 'Igboid', was coined in 1982 on an analogy with the other Benue-Congo languages (Edoid, Defoid, Platoid, etc.), in the face of an attempt to eliminate the 'Igbo' language name altogether and replace it with the nondescript term 'Lower Niger'. Still, the effect of the use of the term Igboid has been to make Igbo just one other member of a cluster of 'languages' previously understood to be dialects of Igbo—Agbo, Ekpeye, Ikwere, Izi, Ïka, Ogbah, and Ükwüanï/Enuanï. For these reasons, the term 'Igboid' is now disregarded as a strictly linguistic term since it misrepresents and understates the remarkable internal linguistic unity of Igbo among all the other languages of the Benue-Congo group.

Broadly speaking, allowing for the special dialects mentioned above, there are two major dialect zones in Igbo: Owere and Önïca, although the early missionaries proposed three: Isuama, Önïca, and 'Bonny' (Samuel Crowther 1882). In each of these zones, however, native speakers can identify sub-dialects, each marked by some distinctive detail of phonology, e.g. the glottal fricative in Ngwa; the voiced implosive /ɗ/ replacing the alveolar plosive, or the voiced glottal fricative /ɦ/ in Übakala, the ninth vowel in Izi. Other syntactical and lexical differences are also in evidence, of course; but as may be seen from the grammars of these dialect/languages (e.g. Meier and Bendor-Samuel 1975), the basic grammatical features remain the same for all Igbo dialects.

The history of Igbo language scholarship has been intimately tied up with the matter of its dialects. In its first efforts, the Church Missionary Society promoted 'Isuama Igbo' as the future national Igbo dialect, comparable to Oyo-Yoruba. The plan failed. The Roman Catholic Mission chose the Önïca dialect for its translations and other publications. This also proved unacceptable, as did 'Union Igbo', being promoted by the Colonial Education Department. A Standard Igbo (Igbo Izugbe) has now emerged, which combines generalized features of vocabulary and grammar from the Önïca and Owere dialects. This is the standard currently in use in the school system, and for most publications, although not without dissent from some eminent quarters.

The standardization of the Igbo orthography was key to this development. The first orthographies of the language were devised by repatriate Igbo missionaries of the Church Missionary Society, notably Rev. John C. Taylor, working under Bishop Samuel Crowther, who adopted Richard Lepsius's 'Standard alphabet' in a modified form for *Isuama primer* (1859, 1860), and the *Vocabulary of the Ibo language* (1882). A 'war of the orthographies', however, ensued when the Roman Catholic Mission began promoting its own system based largely on a pan-Nigeria alphabet developed by the International Institute of African Languages and Cultures (London) and recommended by the [Colonial] Education Board, Lagos in 1931. The resulting conflict between the Missions was not resolved until 1961, with the adoption of the Official (Önwü Committee) Orthography. This orthography has gained general acceptability, owing in large measure to the leadership of F.C. Ögbalü and the Society for the Promotion of Igbo Language and Culture, which also codified the basic elements of standard written Igbo. A New Standard Orthography introduced in 1998 adopts the Önwü Orthography, but replaces the subdotted vowels with their more readily available umlauted versions, as follows:

A, B, C/CH, D, E, F, G, GB, GH, GW, H, I, Ï, J, K, KP, KW, L, M, N, NW, NY, Ñ, O, Ö, P, R, S, SH, T, U, Ü, V, W, Y, Z.

Interestingly enough, although Igbo is a tone language using intonational pitch to differentiate meaning, most books (other than textbooks for teaching the language) are rarely tone-marked. The situation does not show any signs of changing any time soon.

What follows is a brief review of the phonological and syntactical features of Igbo based on Standard Igbo, with references to dialect variants as necessary.

Phonology

Igbo has eight phonemic VOWELS /a/, /i/, /ö/, /ü/; /e/, /i/, /o/, /u/. A ninth vowel (sometimes /a/, other times /ë/) is encountered in some dialects, notably Ïka, Ükwüanï, Önïca, and Izi. These vowels occur in two sets: Set (1): /e/, /i/, /o/, /u/, and Set (2) /a/, /i/, /ö/, /ü/ whose vowels, like the ninth vowel, are produced with an advanced tongue root. Igbo vowel harmony rules do not permit the co-occurrence of vowels from both sets within the same word.

The CONSONANTS include the stops (/b/, /p/, /d/, /t/, /j/, /ch/, /g/, /k/, /gw/ and /kw/); the implosives (/kp/, /gb/); the fricatives (/v/, /f/, /z/, /s/, and /sh/); the nasals (/m/, /n/, /ñ/, /ny/, and /nw/); the trill (/r/); the lateral (/l/); and the approximants (/y/, /gh/, /w/, and /h/). In some dialects, the bilabial plosives, the palatals, and labialized velars are often aspirated, the fricatives sometimes nasalized. Aspiration of the plosives has phonemic significance in certain dialects. Some fricatives and approximants are palatalized across dialects: /v/ > /f/ > /h/ > /hw/; or /h/ > /s/ > /sh/ > /r/, even /l/. Other variations include the /l/, /r/, and /n/ interchange in **ala/ana** (= earth); **ala/ara** (= breast), and the use of /nw/ for /w/, especially in Ngwa and Ikwere (e.g. **nwanyï/wanyï** = woman).

Tone System

Igbo is a two-tone (High, Low) language. The vowel bears the syllable tone. Tone is also a factor in the lexicon, morphology, and syntax. It is the only difference between **akwa** [LH] 'egg' and **akwa** [LL] 'bridge'; or between **saa** [HH] 'be wide or outspread' and **saa** [LH] 'answer; give reply to'. For nouns, the pattern of the final syllable determines their inherent tones. Most verb inflexions involve variations of tone. The primary distinction is still between verb forms with High or Low tones in their (first) root syllable. Since the infinitive prefix (**i/ï**) is always high, H-tone verbs may or may not accept low-tone inflected forms, whereas L-tone verbs remain low tone in all their inflected forms.

Downstep, a phonetic lowering of a high tone after another high tone, is a recurring feature of the language, and so also Downdrift in which there is a lowering of high tones after a high tone in a terrace-like movement over an entire word or utterance, irrespective of word boundary.

Syllabic Structure

The Igbo SYLLABLE consists of a vowel (V), a nasal consonant (/m/, /n/), or a vowel preceded by a consonant (CV). Unbound forms (other than pronouns) are either CV (as in **di** 'husband'; **ji** 'yam') or VCV (as in **ada** 'daughter'; **uru** 'grief'); or else, they are CVV (e.g. **gaa** 'go') where the final V is a marker for the imperative and is sometimes parsed as a verb stem + vowel suffix combination. Polysyllabic CVCV forms, except for initial nasal consonants (**mmanü** 'oil') and borrowings (**fada** 'priest') are invariably inflected verbs; polysyllabic VCV(V) forms are either simple nouns, or nominalizations from verbs form.

Syntax

The noun and the verb are the only significant grammatical class in Igbo, pronouns, adjectives, adverbs, and similar classes being either technically nonexistent, or having (in some instances) no more than two or three members. NOUNS and nominals (with a few exceptions) have an initial VCV syllable structure; further syllables may be added, in every case ending in a CV. General rules govern how two vowels may be adjacent to each other, and the conditions for assimilation and tone change between them. Nouns are not inflected. Polysyllabic nominals with initial nonnasal consonants (e.g. **gburugburu** 'all around; on all sides') are usually adjectivals, adverbials, or ideophones formed from base verbs. Nouns are never inflected for number or gender.

VERBS are the only inflected class of words in the language. The verb has a primary root, (usually derived from the infinitive form), and either one or more secondary roots from other bound verb forms, or from extensional suffixes. There are two verb types: (i) the regular verbs and (ii) the so-called auxiliaries (**dï, ga, ka, ma, na**) and copulas (**bü, dï, nö**, and **wü**). In compound (sometimes called complex) verbs (e.g. **dapuo** [<**daa** + **puo**] 'fall' + 'have a gap or opening', the end-verb carries the appropriate inflectional ending in affirmative imperatives.

TENSES include Present, Past, Future, or Past Perfect. The Present is actually an absolute present and only a few verbs can express it. The present tense form is the same as the verb root, without inflexional affix. The Simple Past is formed with an rV inflexional affix after the root, V being a reduplicate or copy of the verb root vowel. The Past Perfect is formed with an rV suffix attached not to the verb root, but to the affirmative imperative forms, almost always a CVV. The Future

tense is formed with an auxiliary **-ga** and a harmonizing **a/e** suffix after the verb root. The initial prefix is high, the second always low, except for verbs with HH tones in the imperative.

Aspect

ASPECT is distinguished from tense. In the present tense, aspectual inflexion may be used, for example, to reflect the duration of an action, the fact that it is ongoing, or that it is customary. Similarly, in the past tense, the harmonizing aspectual prefix **a/e** + verb root + inflexional suffix [**la/le**; **ne/na/**; **go/we**, depending on dialect] may be used to indicate fully completed (perfected) action.

Affixes, Suffixes, and Enclitics

INFLECTIONAL AFFIXES are always attached to the verb, either pre- or post-positionally, to specify tense or aspect with a harmonizing prefix **a/e**; a suffix **-we** (or dialect variants). A harmonizing rV suffix with the so-called stative verbs indicates continuing present time or the past tense. To confirm a negative status for a statement, the verb uses a harmonizing **ghï/beghï** and their dialect variants. EXTENSIONAL SUFFIXES (sometimes called lexical suffixes) are a major element in the syntax of the Igbo verb. (En)clitics are also usually affixed to verbs, but they are excluded from suffixes because they can also occur independently, as free morphemes in association sometimes with a noun phrase (NP), and other times with a verb phrase (VP).

Word Order

The basic WORD ORDER (in declarative sentences) is S(ubject)–V(erb)–O(bject)-[1]-O(bject)[2], or more exactly, N(oun)P(hrase)[1] + (VP [+ NP[2]]). The O[1] and O[2] nouns may be the direct object of the verb, or an inherent or cognate complement. Transitivity in the verb is difficult to establish because of the language's extensive use of verb complements—inherent, cognate, or otherwise.

Noun Phrases

The NOUN PHRASE, whether NP[1] or NP[2], is made up of the nominal head and the qualifiers that come after it, with the exception of the numeral, **otu** 'one', which always precedes the head. The modifier may be a word, phrase, or clause, in that order. Qualifiers come after the Igbo noun head.

Verbal Phrases

The VERB PHRASE (VP) is a complex inflected unit, marked by an initial (nonmandatory) auxiliary or a verbal prefix. This is followed by the verb stem and the required inflections (mood, tense, negation/affirmation) together with enclitics that extend the meanings of these verbs.

Situation Today

Igbo is the 'mother tongue' of some of Africa's eminent writers and artists: Chinua Achebe, Cyprian Ekwensi, Christopher Okigbo, for example. Still, original works in Igbo by these established writers are hard to come by. A kind of pan-Igbo cultural revival appears to be growing, however, and with it, a renewed effort to speak, write, and teach the language at all levels. Already several fictional works have been published for the school market and the general public. Two major dictionaries have been recently published (Echeruo 1998, Igwe 1999); others are in preparation. In addition, a major research effort is under way for the production of an archival Igbo dialect dictionary, in addition to the effort to create an Igbo metalanguage.

India

India represents an astonishing array of linguistic diversity with four language families, and more than 600 languages as well as numerous geographical, social, ethnic, religious, and rural varieties or dialects. The subcontinent competes with Papua New Guinea in terms of the sheer numeric weight of its languages and varieties, a rural–urban dichotomy, and varied social structures. For these reasons, India is often described as 'the linguistic laboratory of the World'. Consequently, one finds a complex array of linguistic situations in terms of the extent of bilingualism, ranging from diglossic bilingualism to bilingualism based on three of the five highest ranking languages in the World (Hindi, English, and Bengali) according to the number of speakers. The magnitude and scale of linguistic diversity and parameters of language usage are often beyond the comprehension of speakers who are accustomed to western-style monolingualism.

Linguistic Profile

Approximately one in every six inhabitants of the world (that is 1.0 billion people) speaks at least one of the Indian languages. Indian languages belong to four language families: Indo-European, Dravidian, Austroasiatic, and Tibeto-Burman. Indo-European, with 12 major and three minor languages, represents the most influential language family both in terms of the number of speakers and social significance.

The 12 Indo-Aryan languages of the Indo-European language family are: Hindi, Assamese, Oriya, Marathi, Konkani, Gujarati, Urdu, Punjabi, Sindhi, Bengali, Kashmiri, and Nepali. Hindi and Bengali are ranked second and fifth in the world, respectively, in terms of the number of speakers, according to the World Almanac (2002: 447). Approximately 80% of the population of India speak languages of the Indo-European stock. Kashmiri (India and Pakistan) belongs to the Dardic sub-branch of Indo-Aryan. The three minor languages are as follows: Shina, Dogri, and Bhili. The Indo-European languages not only dominate India but also all the countries of the subcontinent (i.e. Pakistan, Nepal, Sri Lanka, and Bangladesh).

The second major family are the Dravidian languages, which include four major languages: Tamil, Telugu, Malayalam, and Kannada. These four languages are spoken in South India. Tamil is spoken both in India and Sri Lanka.

Two branches of the Austroasiatic language family are also found in India: the major members of the Munda subfamily are Santhali, Mundari, and Ho, which are spoken in southern Bihar, northeastern Andhra Pradesh, and broader areas of West Bengal in India. The Mon-Khmer branch is represented by Khasi, which is spoken in Meghalaya state of India.

Tibeto-Burman is represented by many languages, spoken in the subcontinent's northeastern borderlands. While Tibetan or Bhotiya languages are spoken in India (in Laddakh and Sikkim), Bhutan, and Nepal, the major concentration of the Gurung-Tamang group is present in central to eastern Nepal.

Nineteen languages are recognized by the Indian constitution. In addition, there are numerous dialects and languages. The number of vernaculars/dialects reported ranges from 216 to over 1,500 (1,652 mother tongues self-reported in the 1961 census; 216 mother tongues with more than 10,000 speakers each reported in the 1991 census).

The linguistic situation and communication networking in India can be represented diagrammatically by a pyramid-type structure, shown in Figure 1.

Languages and Modes of Communication

Hindi and English are the two national and link languages of India. While Hindi is the language of the masses in the northwestern and north-central part of India, English is the pan-Indian language of the educated elite. Thus, English and Hindi represent the peak of the pyramid.

As noted earlier, Hindi, even without combining with Urdu, has the second largest number of speakers among the languages in the world and is the lingua franca of India and of the subcontinent. The great Moghul empire in the past, and Hindi films and the mass media in the twentieth century, have played a significant role in the spread of Hindi-Urdu, not only in India but also across the subcontinent. Hindi and Urdu are mutually intelligible but are written in two different scripts—Hindi is written in the Devanagari script and Urdu is written in Perso-Arabic script. There is also a difference in literary affiliation—Urdu is associated with Persian and Arabic literary traditions, while Hindi is tied to the Sanskrit tradition indigenous to India. In addition, Urdu borrows its technical and learned vocabulary from Persian and Arabic, whereas Hindi borrows the same kinds of terms from Sanskrit.
Figure 1. Linguistic situation in India.

'Scheduled' languages (henceforth, state languages) are spoken predominantly in their respective states: see Table 1 below. Hindi, along with English, is the only state language that is spoken in more than one state. Urdu is the official language of the state of Jammu & Kashmir. However, not all 'scheduled' languages are spoken in a particular state. Sindhi is not the official language of any Indian state. Kashmiri is spoken in the state of Jammu & Kashmir but the official language of the state is Urdu. Finally, rural dialects (mother tongues or vernaculars) are shown at the base of the pyramid.

As pointed out earlier, Modern Tamil, Telugu, Kannada, and Malayalam are Dravidian languages and are primarily spoken in the South, while Indo-Aryan languages, the descendants of the oldest documented Indo-Aryan language, Sanskrit, are primarily spoken in the North. Dravidian languages are the descendants of the proto-Dravidian languages.

Sanskrit is also recognized as an official language of India and is the language of India's cultural and intellectual tradition. English is the language of modern intellectual communication and is the official language of three states and all 'union territories'.

Before continuing with a discussion of the language situation in India, it is worthwhile discussing the sources of figures in Table 1—the census of 1991. Because the census asks for self-report of languages, it

should be noted that there are a number of problems with these figures (and other census figures as well). A claimed language may be a language or a nonlanguage—a reflection of regional, religious, caste, social, ethnic, literary and script affiliation, and even occupation. For example, it is not unusual for an ironsmith to report Lohari 'ironsmith' as his mother tongue or for a villager to report a dialect as simply the name of his village or caste. Alternatively, a language might be a speaker's perception of language/dialect on a language continuum, thus blurring language vs. dialect; or language vs. language distinction (in language contact situation).

The label 'mother tongue', which is the term used by the census, may also be ambiguous. An individual questioned may interpret this term as referring to his or her cradle language, parent tongue, language ordinarily used, or prestige language only. A prestige language such as English is often over reported, while stigmatized varieties (e.g. immigrant languages such as Saraiki from Pakistan) are underreported. An illustration of these problems is the fact that almost 50,000 speakers reported Sanskrit as their mother tongue (see Table 1). It seems extremely unlikely that Sanskrit is the cradle language of anyone. However, its prestige and daily use by some Indians have apparently led them to claim it to be their mother tongue.

TABLE 1   Scheduled Languages of India

Name	Language Family	State/spoken in	Number of Mother Tongue Speakers (1991 Census: Govt. of India)
Assamese	Indo-Aryan	Assam	13,079,696
Bengali	Indo-Aryan	Bengal	69,595,738
English[1]	Indo-European; Germanic	Meghalaya, Nagaland, Tripura	178,598
Gujarati	Indo-Aryan	Gujarat	40,673,814
Hindi	Indo-Aryan	Hindi belt: Bihar, Chattisgarh, Rajasthan, Haryana, Delhi, Himachal Pradesh, Jarkhand, Madhya Pradesh, Uttar Pradesh,	337,272,114
Kannada	Dravidian	Karnataka	32,753,676
Kashmiri	Indo-Aryan	Jammu & Kashmir[2]	56,690
Konkani	Indo-Aryan	Goa	1,760.607
Malayalam	Dravidian	Kerala	30,377,176
Manipuri	Tibeto-Burman	Manipur	1,270,216
Marathi	Indo-Aryan	Maharashtra	62,481,681
Oriya	Indo-Aryan	Orissa	28,061,313
Punjabi	Indo-Aryan	Punjab	23,378,744
Sanskrit	Indo-Aryan	No state	49,736
Sindhi	Indo-Aryan	Metro areas of western India	2,122,848
Tamil	Dravidian	Tamil	53,006,368
Telugu	Dravidian	Andhra Pradesh	66,017,615
Urdu	Indo-Aryan	Jammu and Kashmir	43,406,932

[1]The number of mother tongue speakers of English decreased in 1991! According to 1981 census, the mother tongue speakers of English were 202,000.

[2]These figures are not complete as no census was taken in J&K in 1991. Urdu and other scheduled languages are also spoken outside their respective states.

Sources and Processes of Multilingualism: Role of Sanskrit, Persian, and English

Three millennia of language contact have led to the convergence of four language families in the form of Aryanization of Dravidian languages and Dravidianization of Aryan languages. In addition, Persian, which was the official language of India during the Moghul empire, and the newest arrival, English, have added greatly to the mixed character of Indian languages, particularly Hindi. Hence, it is not uncommon for a Hindi speaker to switch between Persianized Hindi, Sanskritized Hindi, and Anglicized Hindi. In short, three contact languages have played a particularly important role in the history of India: Sanskrit, Persian, and English. Each has served as a prime vehicle for language contact and bilingualism, both historically and in the present day.

Sanskrit

It is well known that Sanskrit language is the single major force responsible for the formation of Indian languages and literatures. So great is the influence of Sanskrit on Indic languages that almost every literary and language-related activity is affected by it. As the language of the Hindu scriptures, and of the epic and classical literature, Sanskrit has traditionally constituted the medium of philosophical and technical literature throughout South Asia. A number of other factors such as past royal patronage and the promotion of Sanskrit education by the Brahmins from the sixth century BC onward have reinforced its prestige. Consequently, Sanskrit has played a leading role not only in the process of Aryanization of Dravidian and other languages but also in forming the ethos of India and other South and South East Asian countries to a varying degree.

For example, the effects of borrowings from Sanskrit on the lexical and grammatical systems of Dravidian languages have been profound. Murray Emeneau and Thomas Borrow (1962) note the tendency 'for all four of the Dravidian literary languages in the South to make literary use of the total Sanskrit lexicon indiscriminately'. So massive has the influence been that it is hard to utter more than a few sentences in these languages without using a word borrowed from Sanskrit. Over a century ago, Western scholars subscribed to the view that the Dravidian languages descended from Sanskrit, although Robert Caldwell, in his classical work, dispelled this misconception. About 20% of the noncultural part of basic vocabulary in literary Dravidian languages is loaned from Indo-Aryan mostly from Sanskrit. This proportion peaks to 50–60% in some languages due to shared cultural beliefs (e.g. Brahmanic values). This resulted not only in the replacement of content and function words but also had a substantive impact on the phonological, morphological, and syntactic structures of the Dravidian languages.

Furthermore, the study of *VyaakaraNa* (grammar) in Sanskrit was viewed as an area of the highest linguistic sophistication and a testing ground for various linguistic theories. The Sanskrit grammatical tradition resulted in grammatical works such as Panini's grammar, the *Ashtaadhyaayii,* which is still regarded as 'one of the greatest monuments of human intelligence' not only in the history of Indic grammatical tradition but also in linguisitics.

The Dravidianization of Indo-Aryan languages also took place, although the impact of Dravidian languages on Indo-Aryan languages was not nearly as extensive; nevertheless, this mutual influence (on lexicon as well as grammar) set the stage for leaky boundaries among the languages of India whether they were genetically related or not.

Not only this, Sanskrit also become a marker of caste identity, which in turn gave rise to diglossic bilingualism through Brahmin speech in Dravidian languages, particularly in Tamil. The use of Sanskrit in topical domains such as religion, philosophy, poetics, science, technology, and mathematics in Dravidian, as well as in Indo-Aryan-speaking areas, is particularly noteworthy. Hence, Sanskrit became the single most important marker of Indian culture—both in the north and in the south.

The role of Sanskrit in promoting bilingualism and language modernization inside and outside of India (e.g. in South East Asia) to this day is particularly striking. Today, the All India Radio relays news in Sanskrit and even newspapers are published in the language. Just as terms for technological innovations are created from Latin and Greek for western languages (*television*= Greek *tele-*'far', Latin *–vision* 'seeing'), Sanskrit is the source of designative cultural and technical innovations in South Asia and beyond. Consider, for example, that the technical vocabulary is drawn either from Sanskrit or English: the terms for prime minister (*pradhaan mantrii = pradhaan* 'head, principal'+*mantrii* 'minister'), president (*raashTrapati = raashTra* 'country' + *pati* 'husband'), radio (*aakaashvaaNii = aakaash* 'sky' + *vaaNii* 'voice, speech'), and TV (*duurdarshan + duur*(Hindi) 'far' + *darshan* 'sight'). The words given in the parenthesis are drawn from Sanskrit. Furthermore, Sanskrit plays an important role in the process of language modernization of South East Asian languages.

Persian

Language contact among Persian, Indo-Aryan, and Dravidian languages (Kannada and Telugu) formally began with the annexation of Punjab by the Turkish ruler Mahmud Gaznavi (twelfth century). The language contact situation with Persian was different from the Sanskritization of Indian languages. Persian was viewed as an imposed language in much of India; thus, with Moghul patronage, Persian became a marker of Islam. As a consequence, after independence in 1947 when India and Pakistan became independent nations, the influence of Persian continued to regenerate in Pakistan, a Muslim nation, while it reached a state of fossilization in India. In contrast, after independence, Sanskrit began to regenerate its original impact in India due to its association with Indian culture (particularly with Hindu religion). Just as extensive Sanskritization played an important role in the separation of Malayalam from Old Tamil, extensive Persianization together with Arabicization led to the separation of Urdu in Pakistan from Hindi-Urdu in India. Similarly, heavy Persianization and Arabicization of Hindi led Western grammarians like George Hadley (1772) and others (Schultz 1745) to claim that Persian must be the mother tongue of Hindi. Others thought that the ancestor of Hindi must be a Semitic language, perhaps Arabic or Hebrew. The concept of Indo-Aryan languages and the genetic hypothesis of languages was still a distant reality in the nineteenth century. As pointed out earlier, Hindi and Urdu in their spoken style are essentially the same language, approximately parallel to British and American English.

Persianization of Indian languages was not restricted to the lexicon (content and function words). The impact of Persian borrowing on the grammar of Indian languages was as significant as the influence of Sanskrit. The morphological processes such as reverse *compounding (sher-e-panjaab* 'the tiger of Punjab' rather than the unmarked pattern—*panjaab kaa sher* 'Punjab's tiger), inflectional morphology (plural markers), and word compounding with Persian

became part of modern Indo-Aryan languages and so did conjunct verb construction, complementation (with *ki* 'that'), and conjunction with noun phrases.

Domains such as law and regulation, sports, and business belong to Persian-mixed Hindi to this day in India. A highly Persian-Arabic style is widely used in the modern-day legal register. Also, newspaper reporting, a business section that includes a Price-index report, share market, and reports dealing with economics such as budgetary reporting, and so on, incline toward the Persianized style.

English

Although English is a newcomer in the linguistic scenes of India, it has already registered some significant results from the viewpoint of the sociology of communication, in general, and cross-linguistic communication, in particular. At present, it serves as one of the most important sources of pan-Indian bilingualism or pan-Indian communication. Consequently, it has added greatly to the already mixed character of Indian languages. What is noteworthy is that mixing with English is an important linguistic feature of India. When the introduction of English to the Indian linguistic landscape began with the dawn of the British colonial era, English began to develop roots in Indian education. A blueprint for India's educational policy was laid down in Lord Macaulay's *Minute* (Feb. 2, 1835). Macaulay's stated mission for the British Raj of creating 'a class of persons, Indian in blood and color, but English in taste, in opinions, in morals and intellect' introduced English education to India; his attitude not only toward Indian languages but also toward the languages of Southwest Asia—particularly, Arabic.

> I have no knowledge of either Sanskrit or Arabic. But I have done what I could to form a correct estimate of their value...I am quite ready to take the oriental learning at the valuation of the orientalists themselves. I have never found one amongst them who could deny that a single shelf of a good European library was worth the whole native literature of India and Arabia.

More than one and a half centuries later, English has overcome its status as merely the language of the colonial power, and has become an integral part of the Indian linguistic mosaic. Contrary to the most popular preindependence consensus that Hindi would dethrone the English language after independence, English not only continued to flourish in the educational and official network of India but also became one of the official languages of the nation and thus continues to enjoy the patronage of the Indian elite. Although the incidence of bilingualism with English is still very low, English has acquired domains such as education, law, government, media, and science and technology, which

once belonged to either Sanskrit or Persian. The uses of English, parallel to its predecessor contact languages— Sanskrit and Persian—has led to the Englishization of Indian languages. On the other hand, English has undergone significant changes locally to carry the communicative burden of Indian society. The process of nativization of Indian English continues to this day.

English has colored the phonology, morphology, and syntax of Indian languages. Hindi, for instance, has borrowed several consonant clusters such as *st-, sk-, sl-*, and phonemic segments such as /f/ and /z/ as the result of large-scale infiltration of English lexical items, such as station, school, slow , fail, etc. Even at the level of language, which is less prone to change, i.e. syntax, Indian languages have not managed to escape the influence of English. The preference for passive over active construction is attributed to the influence of English.

Turning to the first layer of the pyramid, along with English, Hindi provides a major contact language link within the communicative network. The heart of this link consists in the Hindi-Hindustani-Urdu-Punjabi core/axis. This axis forms a giant speech community with direct links to Bengali in the East, Gujarati and Marathi in the West, and Telugu and Kannada in the South. In contact with these languages and other regional varieties, Hindi has developed its own regional varieties, for example: Mumbai Hindi (Bombay Hindi, Bindi), Kalkatiya Hindi (Calcutta Hindi), Madrasi Hindi (Madras, renamed Chennai, Dakkani Hindi 'southern Hindi').

Other factors such as education, military, migration, literature (particularly devotional literature), religion (pilgrimages), popular and electronic media, and trade play an important role in societal bilingualism or multingualism in India.

Education and Government Policies

The language policies of the government of India are very conducive to the promotion of the language rights of minority languages and the advancement of linguistic diversity and pluralism. This is evident from the facts regarding languages represented in the third tier of the pyramid. The number of languages used in primary education is 47; 87 in the print media; 71 in radio and broadcasting; 13 in films; and 13 in state-level administation. In addition, the introduction of the Three Language Formula in education is yet another notable feature of national policy. This formula calls for trilingualism or quadrilingualism in education. In addition to learning of the two national languages— Hindi and English—students are expected to learn a third language apart from their native tongue. For example, in the Hindi-Urdu-Punjabi belt, students are expected to learn one of the four Dravidian languages

(Tamil, Telugu, Kannada, and Malayalam). Although the debate concerning the effectiveness of the Three Language Formula is still brewing, the underlying merit of the educational policy in the promotion of mulitilingualism is hardly questionable and best represents the multilingual character of the nation. Similarly, the National Academy of Letters (The Sahitya Akademi) of the Government of India and its regional counterparts promote literary activities at least in the 19 'scheduled' languages.

Bridging the Rural vs. Urban Divide: Literature, Popular Media, and Trade

Unchanged for centuries, rural populations constitute the heart of India. According to the 1991 census, for instance, most of the population of India (about 77–78% of the total population) lives in more than half a million (627,000) villages and speaks in numerous vernaculars (see the base of the pyramid in Figure 1). The most obvious linguistic vehicles for reaching rural India are either Hindi or the regional languages and their local vernaculars. The incidence of literacy in English is not significant in rural India. Thanks to literature in the past and popular media at present, the boundaries between rural vernaculars and Hindi have become very fluid. Historically, literature (e.g. the devotional poetry tradition—poets such as Kabir, Tulasi, Surdas, and Meera Bai) has played a major role in neutralizing such boundaries and bringing the influence of regional languages (from East to West and South to North; bidirectional) and rural varieties into Hindi. The consequence was a mixed speech, which is termed 'sadhukari bhaashaa' (the language of saadhus and saints free from any prescriptive norms). At present, the most powerful and vital force for bridging the gap between the urban vs. rural (and regional) divide is the Hindi film industry and the mass media. These sources of influence offer a unique appeal in terms of cinematic techniques, dance, drama, and music, and even constitute a viable marketing alternative to Hollywood in the world of entertainment in India and outside India. The reach of the Hindi media indeed extends well beyond one sixth of the world's population that inhabits India, reaching members of the Indian diaspora worldwide. Consequently, mutual intelligibility between regional languages and rural varieties of Hindi is growing steadily. At least this is true of spoken Hindi—caltii Hindi 'colloquial Hindi' or bazaar or Dakkini Hindi. Nevertheless, some barriers do remain.

Salient Features of Indian Multilingualism

As is self-evident from the above discussion, it is clear that linguistic diversity is a hallmark of India. India is often labeled the 'Tower of Babel', since it is remarked that India 'babbles' chaotically in 'hundreds of dialects'. Such labels or expressions reflect a lack of understanding of the complex but structured network of linguistic communication and bilingualism in India. The main focus of this section is to highlight the results of prolonged and recent bilingualism in the region.

Indian Multilingualism: A Natural Phenomenon

There is no doubt that there are linguistic rivalries and conflicts in India, even language vs. dialect conflict. Centuries-old coexistence and an ongoing process of convergence have led to an unmarked pattern of widespread naturalistic linguistic convergence, rather than separation, dominance, and disintegration. Large-scale diffusion of linguistic features across genetic and areal boundaries has resulted in mutually feeding relationships and reciprocity. Although the incidence of 'antagonistic bilingualism' of the sort witnessed in Belgium and other parts of the world cannot be ruled out, its incidence is very limited in degree and scope. In short, one of the defining features of India is one of long-term stable bilingualism and linguistic accommodation. This situation led Caldwell (1903) to propose implicitly that India as a 'linguistic area'—that is, an area in which genetically distinct languages show a remarkable level of similarity and diffusion at the level of grammar. For instance, retroflex sounds (produced with the tip of the tongue curled upward) are the integral part of the languages of India and are thus dative subject constructions:

> mujhe kitaab pasand hai
> me   book liking is.
> 'I like the book'.

Language Attitudes and Linguistic Accommodation

Why has diffusion between genetically distinct languages taken place in India to a degree rarely witnessed in other parts of the world? The answer lies not only in language-internal developments but also in linguistic attitudes that are in turn associated with the 'worldview' of Indians since ancient times. William Bright (1984) characterizes linguistic attitudes in India as an 'accepting attitude, which has brought about the assimilation of features from Dravidian, Indo-Aryan, Islamic, and even Christian and European cultures into a single system, complex, but integrated'. Thus, linguistic accommodation is another important feature of Indian bilingualism.

Stable multilingualism and multiple identities

Multilingualism is not a borderline phenomenon in India nor is it restricted to either educated or business communities. Multiple languages and multiple language identities are defining features of Indian

multilingualism that reveal the dynamics of language usage and a constant negotiation of identities. For instance, the simple act of a social encounter and associated greetings is likely to begin with the choice of one of three modes of greetings, which reveal the religious affiliation of speaker, listener, or both in addition to conveying the social ritual of greetings: *namaste* or *namaskaar* (Hindu), *aadaab* (Muslim), *sat sri akaal* (Sikh), drawn from Sanskrit, Perso-Arabic and Punjabi, respectively. Not only this, a Hindu speaker may decide to use *raam-raam* and *jai maataa dii* to express regional (rural) and ethnic affiliation, respectively, within Hinduism. Similar conditions hold true of Muslims and members of other religious and social groups.

Verbal Repertoire

Code-mixing and code-switching are natural phenomena in the life of a bilingual and are thus all-pervasive in India. Bilingual societies organize their linguistic repertoire differently from monolingual societies. No one language is viewed as suitable for all communicative occasions. This has led to the emergence of mixed languages such as Hinglish (Hindi+English). The extent of the impact of English is so great that it has caused a great deal of alarm among purist speakers of Indian languages and is seen as threatening their independent existence.

The phenomena of code alternation have brought profound changes to the formal grammar of Indian languages. Consider, for example, the case of Causatives in Hindi. Hindi Causatives are derived by the morphological process of suffixation. By adding the suffixes *-aa-* and *-waa-*, the first and the second causative verbs are formed as in: *paR* 'to study/read', *paRaa* 'to teach' (lit. 'cause to study'), and *paRwaa* 'cause x to cause y to study/read'. Mixing with English has resulted in the introduction of a new class of transitive/causative verbs of a mixed type, i.e. *study karnaa* 'to research (on a topic); lit. *study+ karnaa* 'to do study'), *teach karnaa* 'to teach', *study karwaanaa* 'to guide research', *teach karwaanaa* 'to guide teaching'. The verb *study karnaa* 'to research' is not just a paraphrase or translational equivalent of Hindi *paR* 'to study/read'; the English-based verb expresses the meaning 'to research or study a topic from the viewpoint of research' and the causative counterparts, i.e. *study karwaanaa* 'to guide research', *teach karwaanaa* 'to guide teaching' highlight the 'facilitative' (i.e. help the causee to do a particular act) while the Hindi causative marks 'compulsive' meanings.

Before the introduction of English, Hindi had two conjunct verb expressions with the meaning 'to travel': *yatraa karnaa* and *safar karnaa*. The former is Sanskrit-based and the latter is Persian-based. The former con-notes leisurely travel with religious overtones, whereas the latter marks any ordinary travel. The English-based *tour karnaa* has added yet a new semantic dimension, which expresses the concept of business travel which is contrary to what the verb *tour* conveys in English.

Freedom of choice

Linguistic diversity highlights freedom of choice of speech, which is not just a recent, twentieth-century phenomenon in India, but a centuries-old tradition. This attitude has not been seen in many parts of the world. For example, French, Chinese, and some other major languages of the world were imposed on others as part of a movement to eradicate rural and regional language varieties.

Scripts

Indic scripts constitute yet another example of 'India as a linguistic area'. Both Indo-Aryan and Dravidian languages are written in various scripts, which descend from the Brahmi script (third century AD). Indian scripts are phonetic in nature and there is a fairly regular correspondence between the letters and their pronunciation. A number of Indian languages such as Hindi, Marathi, Nepali, and Sanskrit are written in the Devanagari script, whereas it is not uncommon to write a language in different scripts. For example, Punjabi is written in at least three scripts: Gurmukhi, Devanagari, and Perso-Arabic.

Indian Ocean Creoles

In the Indian Ocean, several French-lexicon creoles are spoken by between one and two million people. They are usually divided into two mutually unintellibible and probably (largely) historically unrelated groups: (1) Réunionnais (Réu) of Réunion island, and (2) the so-called Isle de France (IdF) creoles, which emerged in Mauritius (Mau), and later (eighteenth to nineteenth centuries) spread to the Seychelles (Sey), Rodrigues, the Chagos Islands, and elsewhere.

Réu differs both historically and structurally from other creoles in several respects. Early settlement of the island was characterized by a relatively strong component of French speakers, and a rather slow influx of alloglotts. Whites made up a majority of the Réunionnais population until about 1715, i.e. half a century after the beginning of permanent settlement of the island. As late as in 1690, only one family in six did not include a native Francophone. Moreover, in search of subsistence, many members of the white proletariat were forced to take up employment in the fields alongside (former) slaves. As opposed to other plantation societies, where the economic power was always in the hands of a small white élite, a large proportion of the white population on Réunion has always been as poor as their dark-skinned compatriots. Together with a high rate of inter-racial marriages, this led to a language less distant from French than most creoles. In fact, most non-Francophone linguists see Réu as a semicreole (comparable to, e.g. Afrikaans) rather than as a creole proper, while in the French-speaking scholarly tradition, it is treated as a fully fledged creole on a par with e.g. Haitian.

As opposed to IdF, Réu maintains significant parts of French verbal morphology. Réu verbs have up to five different forms, some even having suppletives. The language, furthermore, has an attributive copula inherited from French, lacks bimorphemic interrogatives, and has very little of the incorporation into nouns of etymological articles, so characteristic of French creoles in general. The postverbal placement of the sentence negation also aligns it closely with its lexifier. Moreover, Réu retains grammatical gender, as opposed to virtually all (other) creoles. Some varieties of Réu also retain front rounded vowels.

It should be noted, however, that claims regarding the structure of Réu are difficult to make, and when made, they should be treated with some caution, for the island is dialectally very fragmented, with remarkable variation in speech from one area to another. The fact that there is a continuum between regional French and Réu among the island's almost 750,000 inhabitants also makes it impossible to give the number of speakers of either.

In contrast to Réu, the IdF varieties are typologically rather similar to Caribbean creoles. There is some evidence that a stable IdF had emerged within 50 years after the French settlement of Mauritius in 1721.

Although later slave imports were predominantly from Madagascar, and later East Africa, West Africans (speaking e.g. Wolof, Bambara, and Fon) were among the first arrivals in Mauritius, who may have contributed to making the language so similar to Caribbean creoles. Other substrate languages include Bengali and Tamil.

Occupied by the British for 150 years, English is Mauritius's official language, but the position of French (L1 of a small group) remains remarkably

strong at all levels, and it may in practice be said to be co-official. Mau, despite its lack of any official recognition whatsoever, is nowadays the home language of three fourths of the total population of 1,200,000. It is gaining ground in the Indian and Chinese languages introduced by nineteenth century immigrants whose descendants now make up the majority of the population.

The Seychelles, now with a population of about 80,000 was colonized in the 1770s, with settlers coming both from Mauritius and Réunion. Ethnolinguistically, the Seychelles differs from Mauritius mainly in having no sizable minority of Indian descent, and so far as native language is concerned, it is virtually monolingually creolophone. The Republic of the Seychelles is unusual in giving official recognition to its Creole language—the country is officially trilingual in Creole, English, and French. English is spoken as an L2 by most, and French by a sizeable minority. Media are available in all three official languages.

The IdF varieties are all mutually comprehensible without much effort. The most noticable differences between Mau and Sey are the use of the predicate marker *i* in the latter, and nasal vowels in Sey often corresponding to oral ones in Mau. In both cases, Sey is conservative vis-à-vis Mau. Lexically, Sey displays some influence from Réu in, e.g. the use of *komela* 'now' instead of *aster* as in Mau.

As mentioned above, IdF is rather similar to the better-known French creoles of the Caribbean, which may or may not have something to do with the early presence of West Africans in Mauritius. The main phonological difference is that postalveolar fricatives are depalatalized in the Indian Ocean (i.e. /ʃ, ʒ/→/s, z/). IdF also has only five oral vowels, as opposed to seven in the Caribbean creoles.

The system of preverbal tense–mood–aspect markers is particularly close to that of, e.g. Haitian, with progressive *(a)pe* (< *après*), past *ti* (< *te* < *était/été*), completive *((f)i)n* (< *finir*), and two different futures *(v)a* (< *va*) and *pu* (<*pour*).

Pluralizing (see below) and overt copular (ete < *été*) morphemes differ from those used in the Caribbean, but both appear to be postformative developments. Another such example is the verb apocope (*mãze* vs. *mãz* 'to eat'), which occurs wherever the verb governs an overt element.

Also noteworthy is the exceptionally high frequency of agglutination of French articles to nouns (e.g. *lavi* [< *la vie*] 'life', rather than specifically 'the life').

Although probably genetically unrelated, Réu and IdF do share a small number of features not found in the New World French creoles, including the depalatalization of postalveolar fricatives, the use of *zot* (< *vous/les autres*) as both 2pl and 3pl, the pluralizer *bann* (< *bande*), and possibly also the predicate marker *i*.

MIKAEL PARKVALL

Indian Traditional Grammar

It is to the Indian past that linguists of all countries and all theoretical persuasions still look for one of the crowning glories of intellect in linguistic science—to Panini's grammar of the Sanskrit language, written,

we think, some two and half millennia ago. The great grammarians of Sanskrit—Panini (phonetically, Pānini), and his followers Katyayana and Patañjali—created in their grammars of the Sanskrit language

linguistic masterpieces, as awe-inspiring in the realm of language as, in other esthetic spheres, the Mona Lisa, the works of Euclid, the Taj Mahal, or the works of Shakespeare.

Sanskrit was the language of ancient northern India and of the sacred writings of Hinduism. We believe that Indo-European (also called Indo-Aryan) invaders came into India from the northwest around 2500 BCE. The Dravidian family of languages was indigenous to India, and Sanskrit developed out of the interaction between the Dravidian substratum and the Indo-European adstratum. By about 350 BCE, Sanskrit had begun to diverge regionally, as all languages spoken over larger geographical areas do, given enough time. The Hindu grammarians broadened their interest from the Scriptures to the notion of 'correct' Sanskrit, making rules and lists of forms descriptive of the correct type of speech in every sphere: phonology, morphology, and syntax. Sanskrit was a part of every Hindu ritual, a sacred language, and it was essential that it be pronounced and inflected correctly to the last detail.

The culmination of this intense activity was the oldest treatise that has come down to us, the grammar of Panini. This grammar (the *Astadhyayi*), which dates from between 350 and 250 BCE, is one of the great monuments of human intelligence. It describes in detail every usage of its author's speech. Virtually no other language, even today, has been so completely described. Sanskrit became the official and literary language of all of Hindu India, even to the farthest reaches of the south. It ceased to be spoken as anyone's native language probably around the beginning of the Common Era, but it remained (as classical Latin remained in Europe and Hebrew in Judaism) the artificial medium for all writing on learned or religious topics, the language of the pundits.

Upper-class education in ancient India began with the acquisition, as a child, of the Sanskrit language. This was done by discussion and above all by memorizing Panini's grammar or one of the grammars based on it. Well after Sanskrit had ceased to be a widespread spoken language in India, classical Sanskrit literature was being written by men who had learned their Sanskrit from grammars and dictionaries, and teach-

ers, as we might learn Latin or Greek today. Panini was taken to be infallible: any deviations in Sanskrit compositions from the forms prescribed by Panini were errors.

One of the crowning achievements of Indian traditional grammar was phonetics. The Indian grammarians possessed a control of the technical details of phonetics that remained unmatched until well into the nineteenth century. Unlike most contemporary classifications of sounds, which use different features for vowels (high, low, back, rounded, unrounded, etc.) and consonants (voiced, voiceless, continuant, etc.), Panini's phonetic classification of the sounds of Sanskrit used a single grid for both consonants and vowels, as well as semivowels. Revised slightly and using modern phonetic terms, the phonemes of Sanskrit are as shown below:

Morphophonemics and morphology are described by means of rules, the exact nature and the interaction of which has been the subject of much debate. Typical—typical both of type and their intrinsic complexity—rules are:

a. *h* —> *ḍh,* if *h* is *saṃyogādi*, that is, if *h* is the first component of a consonant group when the suffix begins with a *jhal*-consonant (any consonant with the exception of a nasal or a semivowel). Example: *lih-dhi* —> *liḍh-dhi.*

b. A pair of rules (simultaneously ordered):
   ḍh-Deletion: ḍh —> zero / ___ ḍh
   Lengthening: i —> ī before a ḍh,
                      which is dropped

Certain aspects of Panini's treatment of morphology seem queer to us today; there is, for example, no specific recognition of the notion 'subject of a verb'. There is no case marking as such, even though Sanskrit has a richly developed case system. Perhaps the greatest accomplishment of the Indian grammarians in morphology is the notion that words are analyzable—can be broken down into roots and morphemes. Today, we think of the idea of 'root' as self-evident. It is not: Greek and Latin grammarians did not analyze words into roots and morphemes. Certain aspects of the Indian analysis of noun compounds are useful

Place of Articulation

Character of Sound	Glottal	Pharyngeal	Velar	Palatal	Labiovelar	Retroflex	Dental	Labial
Vowels		a ā		i í e ai	u ū o au	ṛ r̄	ı ī	
Stops			k kh g gh ŋ	č čhǰ ǰh ñ		ṭ ṭh d ḍh ṇ	t th d dh n	p ph b bh m
Semivowels				y		ṛ	ı	v
Continuants	h			ś				

508

today: *dvandva* = copulative (*bittersweet, flimflam, zigzag*), *bahuvrihi* ('much rice') = exocentric (*doorknob* is a kind of knob, *blackbird* is a kind of bird; these contrast with endocentric compounds such as *foul-up*, which is not a kind of *up*, or *turncoat*, which is not a kind of *coat*).

Panini's method has been summarized as follows. First, rules (*sutras*) are formalized. Second, metalinguistic elements (e.g. natural classes) are introduced for reasons of economy of description. Third, metarules (*paribhasas*), which explain how the rules work, are made explicit.

Linguistics in ancient India was the core of the intellectual and scientific tradition—it possessed an intellectual centrality and scholarly hegemony that beggar belief today. Linguistics was suffused with the light of sanctity, endowed with religious purpose. Panini and Patañjali and later Indian grammarians conceived their ministrations on behalf of the Sanskrit language as devotional. Their activity was more akin to a priesthood, a calling, than it was a profession or an academic discipline. Nevertheless, what the Indian grammarians produced over 2,000 years ago can hold its own with the best of linguistic theory today.

ROBERT D. KING

Indo-European 1: Overview

The Indo-European (IE) family is the most successful and widespread of the language families of the world. Seven out of the ten most widely spoken world languages are IE, and all of these seven belong either to its Romance, Slavic, Germanic, or Indo-Iranian branches. (These figures are taken from http://www.sil.org/ethnologue/top100.html (updated February 1999).) IE has spread over nearly all of Europe, plus large areas of Western Asia and the Indian subcontinent. Over the past few centuries, it has further spread to nearly the whole of the Americas, Australia, and New Zealand, plus most of Northern Asia, and small pockets in the Pacific and Southern Africa. This expansion has not been entirely one-sided: over the last 1,200 years, Hungarian and Turkic have gained at the expense of IE, specifically Slavic, Greek, Armenian, Iranian, and Tocharian.

IE is often considered from the point of view of its classical ancient languages (Latin, Greek, and Sanskrit), with supporting citations from Germanic and Slavic. These languages are very similar in overall structure, with nominal systems mostly distinguishing three numbers (singular, dual, plural) and three genders (masculine, feminine, and neuter), and case systems ranging from five cases (e.g. Greek, Germanic) to eight (Sanskrit), a fairly complex verbal system, characterized by distinctions of tense, voice, and mood, with some development of an aspectual system, synthesis rather than analysis, and a tendency to SOV (subject–object–verb) word order, etc. Most of the modern IE languages show greater or lesser degrees of reductions of these systems, with some languages showing remodelings. The most common reductions of these systems may be characterized by the following:

Grammatical Features

Gender: Reduction of original three-gender system to a two-gender system (mostly masculine/feminine, although sometimes common/neuter).

Number: Widespread loss of the dual.

Case system: General reduction of case, sometimes leading to the complete loss of the category, or increased syncretism.

Word order: In Europe, VSO and SVO orders have developed, with vestiges of SOV, while in Asian IE languages, SOV is still more widespread.

Most IE languages in Europe have also developed a system of definite and indefinite articles, with the definite article being more widespread than the indefinite one. They have also carried through the development of the verb 'have' more fully than the classical IE languages.

In broad outline, the following well-attested major branches are considered IE: Anatolian (the ancient languages of Asia Minor, e.g. Hittite, Luwian, Lydian, etc., attested between about 1700 BC and the fourth century BC), Indo-Iranian (e.g. Sanskrit (plus its descendants, e.g. Hindi, Bengali, Urdu, Marathi), attested from around 1000 BC; Avestan and Old Persian plus the modern Iranian languages, e.g. Persian, Kurdish, Pashto, also attested from around 1000 BC), Hellenic (Greek and its dialects, earliest attestations from 1400 BC), Italic (Latin (and its Romance descendants, e.g. French, Spanish, Italian), possibly plus other ancient languages of Italy, e.g. Oscan, Umbrian, attested from 500 BC), Celtic (e.g. extinct Continental Celtic languages, e.g. Gaulish, etc. attested in Roman times; modern Insular Celtic languages, e.g. Irish, Scottish Gaelic, Welsh, Breton attested from AD 300), Germanic (e.g. Gothic and other extinct East Germanic languages, English, German, Scandinavian languages attested from the second century AD), Baltic (e.g. Lithuanian, Latvian, attested from the sixteenth century), Slavic (e.g. Russian, Polish, Czech, Serbo-Croatian, Bulgarian, attested from the ninth century AD), Armenian (attested from the fifth century AD), Albanian (attested from the fourteenth century AD), and Tocharian (Central Asia, attested between the sixth and eighth centuries AD). Other extinct IE languages have been glimpsed in outline through early attestations, such as, e.g. Illyrian, Ligurian, Venetic, Pelasgian, Phrygian, and Thracian. In addition to the extinct IE languages noted above, the ranges of Hellenic, Baltic, Albanian, and Celtic have been severely restricted.

In this context, it should be noted that frequently family trees drawn for IE give distorted pictures, allotting nearly all the space to Germanic, Celtic, Italic, Indo-Iranian, and Balto-Slavic (nowadays sometimes also including Anatolian), while bunching Hellenic, Albanian, Armenian, and Tocharian together in a tiny slot. Despite their much smaller number of speakers, or lack thereof, it might be argued that together, the latter four groups encompass as much diversity as the former five.

The discovery of IE was a gradual process, with several stages and false trails. Thoughts by the Greeks and Romans on language were mostly confined to Greek and Latin, and later to the interrelationships between the two. For a long time, it was believed that Latin had descended from Greek, and this is reflected in the writing of authors such as Varro. This was later shown to be erroneous, although there is still a tradition of writing comparative grammars of Latin and Greek.

As the Middle Ages progressed, followed by the Renaissance, people became more aware of the linguistic interrelations within Europe, and the major families, and relationships between the coeval families, and the Classical languages. Medieval writers such as e.g. Giraldus Cambrensis and Otto of Bamberg noted several lexical items shared by Brythonic and Greek or Latin and Slavic, respectively. The general outlines of their linguistic interrelations slowly became clear during and immediately after the Renaissance. In 1599, Scaliger grouped the languages of Europe into four major and minor groupings. Scaliger's major groupings correspond to Romance, Greek, Germanic, and Slavic.

But the start of serious scholarship, and the realization that IE extended into Asia, is normally dated from Sir William Jones' famous address to the Royal Asiatic Society of Bengal in 1786, where he first conceptualized the idea of '*some common source*, which perhaps no longer exists' to explain similarities between Latin, Greek, and Sanskrit, the language of the Indian Brahmins, of which Europeans had been slowly becoming aware for about three centuries. Jones also suggested that 'both the *Gothick* (Germanic) and the *Celtick*' and the old '*Persian*' might also be derived from this 'common source'.

At first glance, Sanskrit appears even more archaic than Latin or Greek. For a while, it was even believed that Sanskrit was the ancestor of all IE languages. As the reconstruction of IE progressed, it was revealed that in some respects Sanskrit was less archaic than other IE languages (see below). Moreover, a later part of Jones' address deals with the modern languages of India, which he did not believe as descended from Sanskrit. In a lesser-known passage, he stated: 'and this analogy might induce us to believe, that the pure Hindi, whether of *Tartarian* or *Chaldean* origin, was primeval in Upper *India*, into which the Sanskrit was introduced by conquerors from other kingdoms in some very remote age...'; it was only later that it was discovered that Hindi stood in roughly the same relationship to Sanskrit as French to Latin.

Much research followed, and modifications to the theory came with time, but the basic edifice of IE remained. In the 1860s, Schleicher even felt confident enough to compose a fable in the reconstructed IE language. Schleicher's fable was later reworked by Hirt in

the 1920s, and by Lehmann in the late 1970s, but as the century progressed it became clear that IE was unamenable to this sort of analysis. The second half of the nineteenth century witnessed numerous apparent irregularities worked out. The formulations of the explanations for these irregularities were usually called 'laws', and this usage has stuck, although certain scholars were at pains to point out that they could not be equated to more universal laws, such as those of physics. These 'laws' were usually named after the scholars who formulated them.

Some of the major such 'laws', each representing a substantial step in the reconstruction of IE, and an advance in general linguistic theory, run as follows:

(1) Grimm's Law (1822) systematized the Germanic sound shift already noted by several scholars, where voiceless stops developed to voiceless fricatives, voiced stops to voiceless stops, and voiced aspirates stops to plain voiced stops (e.g. *t > th*, *tráyas/three*, *d > t*, e.g. *da a/ten*, *dh > d*, e.g. *vidhava/widow*; English forms contrasted with Sanskrit). Although many previous scholars had noted individual manifestations of this phenomenon, it is normally named Grimm's Law, as Jakob Grimm was the first to systematize it, grouping the voiceless stops (*tenues*), the voiced stops (*mediae*), and the voiced aspirates (*mediae aspiratae*) together in classes.

(2) Grassmann's Law (1863), which accounted for apparent irregularities in the distribution of voiced aspirates and voice stops, found in Greek and Sanskrit (sound changes could be spread over more than one syllable).

(3) Verner's Law (1876), which explained the role played by accent in apparent anomalies in the distribution of the reflexes of Grimm's Law (the role of accent in sound change).

(4) The Law of the Palatals (1870s), which is difficult to ascribe to any single scholar. It showed that the system of five short vowels attested in Latin and Greek (*a*, *e*, *o*, *i*, *u*) was actually more archaic than the system of three short vowels attested in Sanskrit (*a*, *i*, *u*), previously seen as the original system.

Shortly after all these laws had been formulated, the so-called Neogrammarian school emerged. They proposed that there were no exceptions to sound laws as a working hypothesis and compiled numerous comparative grammars, both of IE (Brugmann, Delbrück, Osthoff) and of individual IE languages (e.g. Leskien on Old Church Slavonic). Mainly centered in Germany, they were very influential on IE studies, and the vast compilations of their material are still consulted today, although much has been superseded. IE reconstructed at this stage in the development of the field is sometimes called 'Brugmannian IE', after one of the most prominent Neogrammarians.

Attempts were also made to delineate subgroupings within IE. The major one normally proposed, and elevated to considerable importance in the late nineteenth century, was the *centum/satem* split (from the words for 'hundred' in Latin and Avestan, respectively). In certain forms, the *centum* languages retained an original velar, while the *satem* languages developed the velars into a palatal or sibilant. Throughout most of this century, however, this postulated *centum/satem* distinction has steadily been losing importance in IE studies.

One ongoing area of IE studies is the attempt to demarcate early dialectal divisions within IE. The only universally accepted one, however, is Indo-Iranian. It was also once popularly believed that Italic and Celtic were closely related, based on a few common items of vocabulary and a few shared grammatical innovations and archaisms. Certain scholars have seen a European IE grouping of languages, mainly based on shared lexical features. There is an ongoing controversy about whether Baltic and Slavic are two separate branches of IE that have come to resemble each other through convergence, or whether an intermediate Balto-Slavic grouping may be reconstructed.

In the early years of this century, new discoveries and decipherments shed fresh light on IE, while at the same time making the picture more complicated. The first was the discovery in Western China in 1900 of manuscripts in a previously unknown IE language, Tocharian, split up into two heavily differentiated dialects, conventionally called Tocharian A and Tocharian B. The structure of Tocharian, while recognizably IE, differed in several important aspects from the Brugmannian system.

A few years later, a massive corpus of material written in cuneiform was unearthed in Anatolia. The decipherment and linguistic interpretation of the material took some time, but finally it was recognized that here was another new IE language, identified with the language of the Hittites of the Old Testament. While definitely IE, the structure of the newly interpreted language was quite unlike what had been expected: in many ways, it was closer to modern IE languages, including a fully developed verb 'have'. The verb morphology was far less complex than Greek or Sanskrit, and this caused some scholars to give serious reconsideration to the reconstruction of IE morphology. As research progressed, it was discovered that Hittite was only one member of a whole family of IE languages, normally referred to as Anatolian (see above). The most important

contribution from Anatolian, however, was its apparent confirmation of the 'laryngeal theory'. In the late 1870s, speculations about the IE vowel system had led de Saussure to postulate the existence of otherwise unattested segments, which were later reconstructed as laryngeals. These segments were actually attested in Hittite. Not all linguists accept the laryngeal theory, although the discovery and interpretation of the Hittite material have given it a tremendous accession of support.

The discovery and interpretation of Tocharian and Hittite material also caused the *centum/satem* theory some problems, as both of them showed *centum* reflexes, despite being located to the east. It has taken time for the results of research into Hittite and Tocharian to be properly integrated into mainstream IE studies, and perhaps, the process is not yet complete.

IE continues to be subject to modification and reinterpretation. It has even been quipped that 'no language has changed as much in the past fifty years as IE'. Areas where there has been much discussion recently include the glottalic theory (a reinterpretation of the nature of the IE stops), ergativity (subject–object relations), and the degree of morphological complexity of the protolanguage.

Indo-European 2: Germanic Languages

The Germanic languages are spoken by more than 450 million native speakers and display a very wide geographical distribution, partly due to the current status of English as the world's most important international language.

It is generally assumed that by the first century BCE, Germanic people speaking a fairly uniform language were living somewhere in southern Scandinavia, the Danish Isles, and northern Germany, on both sides of the North and Baltic Seas, and they started to expand rapidly during the Roman period, primarily to the detriment of Celtic languages. In time, there developed the so-called West, East, and North Germanic dialects. The West Germanic tribes settled in the lands between the Elbe and Oder rivers and to the immediate south and west of that area (about the area of modern Germany and the Benelux states), and it is here that the German language gradually evolved. The East Germanic tribes settled in the Baltic area east of the Oder River (the area of modern Poland), but their languages have long since become extinct. In Scandinavia, the North Germanic tribes spoke a language we now call Old Norse, the ancestor of the modern Scandinavian languages. In the fifth century CE, three West Germanic tribes, the Angles, Saxons, and Jutes, crossed the North Sea into Britain, bringing with them a language that would later be known as English. And in the ninth century, Old Norse was carried far westward to Iceland. These wanderings left Europe dotted with Germanic dialects.

The Germanic languages offer extensive and homogeneous documentation from a relatively early period. The oldest monuments of the Germanic languages are more than a hundred Scandinavian inscriptions in a special alphabet called Runic. They date from the third or fourth century CE and are representative of the North, or Scandinavian, group of Germanic languages.

The Germanic languages have very clear-cut and readily identifiable features distinguishing them from the other Indo-European stock. The best known is described by the so-called Grimm's Law (or the First Sound Shift), referring to a systematic shift in the Indo-European consonant system during the development of the Germanic ancestor language. Besides, the

Indo-European verbal system was simplified. The Germanic languages developed a preterite tense (called weak or regular) with a dental suffix, -d or -t (e.g. *fish, fished,* etc.). Germanic languages thus have two types of verbs: weak (regular) and strong (irregular). Strong verbs indicate tense by an internal vowel change (e.g. *ring, rang, rung*).

In terms of vocabulary, Germanic has a number of unique words that are not found in other Indo-European languages. These words may have been lost in the other Indo-European languages, borrowed from non-Indo-European languages, or perhaps coined in Germanic.

Numerous groupings of the Germanic languages have been proposed during the last centuries, beginning effectively with the grammar of Jacob Grimm in 1819. Traditionally, the Germanic languages are divided into East Germanic (with Gothic as its most important member), North, and West (sometimes 'South Germanic') subgroups.

Besides the living Germanic languages described below, there are several extinct languages such as Bastarnae, Burgundian, Frankish, Gothic, Herulian, Lombardic, Norn, Rugian, Scirian, and Vandalic.

East Germanic

The Goths were the first Germanic tribe to leave their Germanic homeland (presumably around 100 BCE) and due to this early migration their language developed differently from those of the other Germanic peoples.

Gothic offers the oldest literary record of Germanic languages: a translation of a Greek bible into Gothic by Bishop Wulfila in the fourth century CE. It is an extremely regular and consistent translation and includes a large part of the New Testament and some parts from The Old Testament.

Gothic has played an important part in the reconstruction of the Indo-European and Germanic ancestor language. Its structure is reminiscent of the other old Indo-European languages, with complex inflections of noun, verb, and adjective. It was heavily influenced by Greek in Wulfila's translation of the Bible and this influence is evident with respect to the lexicon, word order and sentence structure.

North Germanic

North Germanic is commonly divided into two subgroups gradually splitting up from the Common Scandinavian toward the end of the Viking Age (800–1050): the eastern one, including Swedish, Danish, and Gutnish (on the Baltic island of Gotland), and the western one, including Norwegian, Faroese,

and Icelandic. The oldest North Germanic language is referred to as Old Icelandic, or Old Norse, which suffered a rapid change after 700, due to the restless movements of the Viking Age. However, Old Norse is the language of an extraordinarily rich and varied literature inspired by the traditions and manners of the incomparable Viking Age.

Danish

Danish, the mother tongue of over 5 million people, is the official language of the kingdom of Denmark (including Denmark, Greenland, and the Faroe Islands). The modern language developed on the basis of the written language of Reformation influenced by the seventeenth to eighteenth centuries language of Copenhagen, the economic and cultural center of the emerging nation state. Of all Scandinavian languages, Danish has differentiated the furthest from the Common Scandinavian ancestor.

Swedish

Swedish is the official language of Sweden and it is spoken by 8.5 million Swedish and 300,000 Finlanders. It was first recorded in about 2,000 runic inscriptions from the eleventh and twelfth centuries. The modern language developed in the Mälar-Uppland region, where Stockholm and Uppsala have been raised as the main centers of government and learning since the Middle Ages.

Norwegian

Norwegian is the official language of Norway and the mother tongue of over 4 million people. It has two varieties, Neo-Norwegian (*nynorsk*) and Dano-Norwegian (*bokmål*), both official languages used by national and local officials. Nynorsk is more prevalent in rural areas, Bokmål in the cities. Bokmål is spoken by approximately 90% of the population. These two modern standards have a historical cause: during 1380–1814, Danish was the written language of Norway, while most Norwegians used their local dialects and pronounced Danish with their own Norwegian sounds. Neo-Norwegian is based on local dialects and was officially recognized in 1885. Dano-Norwegian, or 'book language', is the first language of the majority of the population.

Faroese

Faroese is spoken by 47,000 inhabitants in the Faroe Islands, where it is also the official language (together with Danish). It is a very archaic variety of North

Germanic isolated during the Viking expansion and it developed from the language of the Norwegians who colonized the islands in the early 800s. Faroese, a descendant of Old Norse, has few speakers, but a lively national literature for nearly 200 years. It has only come into relative prominence in modern times. Structurally, Faroese corresponds more to Middle Norwegian than to Icelandic.

Icelandic

Icelandic is the official language of Iceland where it has been spoken ever since the country was settled over a thousand years ago. It is the mother tongue of 250,000 people. Icelandic is the most conservative North Germanic language, due to its geographical isolation and the fierce purism of its speakers, i.e. no other Germanic language has remained so close to the ancestral form. It has never shown any real tendency to split into dialects. It has a rich literature dating from the thirteenth century.

West Germanic

West Germanic is considered to be the least unified of the three major groups. The records are relatively late and very uneven in chronology and content. Each of the individual languages is highly inconsistent and dispersed into various dialects. However, two main branches can be identified: the English group, which is usually considered with Frisian as Anglo-Frisian, and the German group, including High and Low German.

English

English is an official language of Britain, Canada, the United States, Australia, New Zealand, Ireland, the Bahamas, Jamaica, Barbados, Grenada, Trinidad and Tobago, St. Lucia, Belize, Guyana, Botswana, Cameroon, Dominica, Gambia, Ghana, Gibraltar, Lesotho, Liberia, Malawi, Nigeria, the Seychelles, Sierra Leone, Singapore, South Africa, Swaziland, Uganda, Vanuatu, Western Samoa, Zambia, and Zimbabwe; it is the associate official language of India. It is the native language of more than 300 million people and the second language of another 300 million. English is also the universal language of trade, communications, science, and transportation and the most frequently acquired second language in the world.

English is characterized by a very large vocabulary, nonphonetic spelling, an almost total lack of inflection (most plurals of nouns are indicated), a syntax almost totally dependent on word order, and a very complicated periphrastic verb system.

Frisian

Frisian is spoken in northern Holland (the province of Friesland and some adjacent islands), and also in Germany (the low coastal areas). It is one of the two official languages of the Netherlands. Of all Germanic languages, Frisian is most closely related to English. The oldest records are a series of legal documents dating from the tenth to the sixteenth centuries. Structurally, the language is very similar to Dutch.

Dutch

Dutch is the official language of the Netherlands, Suriname, and the Netherlands Antilles, and Flemish is the official language of Belgium. The language is also spoken in small parts of Germany and France, Indonesia and elsewhere in Southeast Asia. It is native to some 14 million people. The Dutch spoken in Belgium is called Flemish, although there is practically no difference from Dutch in the Netherlands. Standard Dutch is based on the dialect of the Amsterdam region after it became the capital of an independent nation.

Afrikaans

Afrikaans, sometimes considered a creole of Dutch, is an official language of South Africa and Namibia. It is spoken by 10 million people. Afrikaans developed in the seventeenth century from the Dutch brought to South Africa by the first settlers from Holland. Originally, it was a popular dialect composed of Dutch with considerable borrowings from aboriginal languages of Africa, especially Malay (spoken by the slaves in the seventeenth century).

German

German is an official language in Germany, Austria, and Switzerland; it is also spoken in eastern France (Alsace and Lorraine), Belgium, Luxembourg, Liechtenstein, pockets of the United States, parts of Eastern Europe, and in former German colonies (Namibia, Congo, Cameroon). German is also used as a second business language for Continental Europe and Scandinavia.

Following the so-called 'High German Consonant Shift', the dialects of German are divided into Low German (*Niederdeutsch, Plattdeutsch*) and High German (*Hochdeutsch*). Low German is spoken in the lowlands of northern Germany. The term 'Low German' is essentially a geographic term referring to the coastal, or lowland, area of the German region, as opposed to the High German area. Modern Standard

German developed mainly from the language of the late medieval chancery language of the court and Saxony and the East Central dialect area of Dresden.

Yiddish

Yiddish (also called Judeo-German) is a High German language spoken throughout northern continental Europe (especially Germany, Poland, Lithuania, and Russia) and North America by the Jewry. Originally, it was the language spoken by East European Jews, who migrated from Germany in the fourteenth to sixteenth centuries. There are two varieties of Yiddish: an eastern one developed under Slavic influence and developing a rich literature in a highly standardized language, and a western one developed under German influence. Yiddish literary records go back to about the thirteenth century. Like all Jewish languages, it is written in Hebrew characters read from right to left.

Pennsylvania German

Pennsylvania German, also known as 'Pennsylvania Dutch' or simply 'Dutch', is spoken by 300,000 native speakers, descendants of German colonists, mainly in the United States. It is the vehicle of a typical folk literature and its speakers are all bilingual, as the official language is English.

LAURA DANILIUC

Indo-European 3: Indo-Iranian Languages

Indo-Iranian languages are the easternmost subfamily of the I[ndo]-E[uropean]family, spoken by almost a billion people, chiefly in Iran, Afghanistan, Tajikistan, Bangladesh, India, Nepal, Pakistan, and Sri Lanka. The languages of this subfamily are among the oldest of the Indo-European group, and are well represented among the oldest records of Indo-European languages. However, there is debate about the relation of these languages to the Hittite languages of Anatolia. Some references believe them to have originated around modern Afghanistan, and some others name Turkistan. This branch consists of three groups of languages, the *Iranian*, the *Indo-Aryan* (or *Indic*), and the newly added *Dardic* (also known as *Kafir* or *Nuristani* languages), preserved in the Himalayan Mountains.

The Indo-Iranian group is remarkable, both in terms of its history and in terms of the number of its speakers. Two of the ten most widely spoken languages on earth today, Hindi and Bengali, belong to the Indic branch of Indo-Iranian. Indo-Iranian languages also have a very old history. The Indic and the Iranian languages have passed through three historical periods, namely old, middle, and new.

Iranian

The Iranian languages are mainly spoken in today's Iran, Afghanistan, Tajikistan, and some parts of Pakistan, Turkey, Iraq, and former Soviet countries. It is estimated that about 95 million people speak in these languages.

Old Iranian

Historically, the oldest Iranian languages of which there are records available are Old Persian and Avestan, both highly inflected languages. Old Persian has survived in cuneiform inscriptions from the time of the Achaemenid kings, who ruled ancient Persia during

the sixth to fourth centuries BC. Avestan is the language in which *Avesta*, or the sacred text of the Zoroastrian religion was composed. The *Avesta* probably dates from about the seventh to the fifth centuries BC, but apparently was handed down orally and was not recorded in writing until much later. Both of these languages are extinct, although Avestan is still formally in use as the religious language of the Zoroastrians.

Middle Iranian

The Middle Iranian period, dating from the third century BC to the ninth or tenth century AD, is characterized by considerable grammatical simplification, as in the reduced inflection of the noun and verb. Among the languages surviving in written records that fall within this period are Parthian, Middle Persian, Khwarazmian, Sogdian, and Saka.

New Iranian

The new Iranian languages are those languages used in the region after the emergence of Islam in the region (ninth or tenth century), and represent more phonetic and grammatical simplifications. For example, many case endings have dropped, and have been substituted by adpositions. The new Iranian languages are considerably more in number in comparison with the middle Iranian languages. What is interesting about these languages is that most of them do not have a direct and specified ancestor, and only Persian and Yaghnobi can be regarded as those having direct ancestors, Middle Persian and Sogdian, respectively.

The new Iranian languages are now divided into 'eastern' and 'western' subgroups. New west Iranian languages are basically spoken in today's Iran, and include Persian (the widest used Iranian language, with Iranian, Afghan, and Tajik variations), Kurdish, Baluchi, Mazandarani, Lori, Gilaki, Tāti, Tāleši, Lārestāni, Bashkardi, and some others. There are languages, of course, spoken beyond this border, and yet considered to be west Iranian, like Baluchi (which is also spoken in Pakistan), Zazaki (spoken in Turkey), and Kumzari (spoken in Musandam peninsula in Oman). Most of these languages do not have a writing system, and make use of Persian alphabet. Iranian Persian is also written this way, but the Tajiks make use of Cyrillic alphabet.

Middle Iranian languages have been ergative languages, and this feature has still been retained in many modern Iranian tongues. Persian, Lori, Mazandarani, and Gilaki are, of course, among the nominative-accusative Iranian languages.

The east Iranian languages are spoken in Pamir region; Afghanistan, Tajikistan, and to a much lesser extent, central Asia. They are numerous and scattered,

and some of them are greatly in danger of extinction. Some of the best-known languages of this group are Pashto, Wakhi, Ishkashmi, Yoghnobi, Yazgulami, Shughni, Parachi, Bartangi, Rushani, and Sarikoli (the easternmost Iranian language).

Indic

The Indic languages form the largest group of the Indo-Iranian subfamily. This group contains about thirty languages, some of which with numerous dialects. About 700 million people speak in these languages, of which the most widely used languages are Hindi-Urdu, Bengali, Punjabi, and Marathi (to these languages, we should add the Gypsy or Romano languages, which are scattered in various parts of Europe, as well as in the Indian subcontinent). Having voiced aspirated plosives like [bh], as well as retroflex sounds in the phonological system, are regarded as the two main characteristics of these languages. Like the Iranian languages, Indic languages have a long history, and may be studied within Old, Middle, and Modern Periods.

Old and Middle Indic

The oldest written form of the Indic group is Vedic, which is the language of the religious hymns of Veda. The Veda represents an oral tradition preserved by the ancestors of Hindu priests. Vedic has been described as the parent language of Sanskrit which by the fourth century BC had become the sacred and literary language of the Hindus of India, and its classical form was in use (at least for literature) until c. AD 1100. Sanskrit, as the most important source for all modern Indic languages, has survived to this day as a liturgical language in India. It is written in Devanagari, a development of the Brahmi script. Most Indic languages are written in some modified form of the Devanagari alphabet.

Prakrit (or 'natural' as opposed to Sanskrit 'polished'), which represents the Middle Indo-Iranian, refers to the state of the language between the third century BC and the fourth century AD. The best-known language of this era is Pali, in which the Buddhist Ašoka scriptures were originally written.

Modern Indic

Modern Indic languages have undergone extensive changes in the course of their evolution. Although the vocabulary of many Indic languages derives primarily from Sanskrit, Muslim influence over the centuries has added loan words from Arabic and Persian to some Indic languages such as Urdu and Sindhi. Besides phonemic and vocabulary changes, the simplification of the inflection of nouns and verbs is quite considerable. Cases of the nouns have been reduced from eight

to two, and are mainly represented by prepositions, rather than the earlier case markers.

Modern Indic languages are so many; thus their classification is also diverse. They can be classified as 'Northwest Indic languages' (like Punjabi and Sindhi); 'Central Indic languages' (like Hindi and Urdu); East Indic languages (like Assamese, Bengali, and Oriya); the West Indic language (Gujarati); South Indic languages (like Marathi and Singhalese); and the northern or Pahari languages.

As to the population of the speakers, Hindi, now the national language of India, stands out, and is understood by about half a billion people, mostly living in central India. Urdu is the other language, so similar to Hindi (but recorded by Persian alphabet), spoken mainly in Pakistan and India. Punjabi, spoken in Northwest India and Pakistan, is close to the Western Hindi dialect and is written in an alphabet based on the Devanagari script. Sindhi, the native language of people in Southeast Pakistan and West India, is the other language of this group, recorded in a modification of a Persian script by Muslims, although Hindus use a variety of the Devanagari alphabet as well.

Of the East Indic languages, Assamese is noteworthy. Although reminiscent of Sanskrit in vocabulary, it is allied grammatically to Bengali, the national language of Bangladesh. Oriya, the language of about 32 million persons, chiefly in the Indian state of Orissa, is closer to Sanskrit phonetically and lexically than any other modern Indic tongue. The leading West Indic language is Gujarati, spoken chiefly in the states of Gujarat and Maharashtra in India.

Of the South Indic languages, Marathi is spoken in the Indian state of Maharashtra. The other important South Indic language is Singhalese, the language spoken by people of Sri Lanka. This language is geographically separated from the other Indic languages of North and Central India by an intervening region in South India, in which the Dravidian languages are spoken. Thus, it is greatly influenced by the Dravidian languages nearby. The Pahari languages (or dialects, which are so many in number) are spoken by the people in Nepal and North India. Pahari has two main dialects, Garhwali and Kumaoni, and Western Pahari.

Dardic

There is no general agreement among the linguists on the status of Dardic group. Many references believe them to be a subgroup of the Indic, but there are firm evidences that classify them as a separate category. Dardic, or Pisacha, languages are spoken in Afghanistan. These languages share certain distinctive phonetic characteristics, feature the use of pronominal suffixes with various verb forms, and include in their vocabularies a number of words that among the languages of India are usually encountered only in Vedic Sanskrit. Kashmiri is the sole Dardic language that both has a literature and is recognized in the Indian constitution of 1950. It is written in Persian letters by Muslims, whereas Hindus use a script similar to the Devanagari alphabet.

BEHROOZ MAHMOODI-BAKHTIARI

Indo-European 4: Romance

Spoken throughout the Roman Empire, around the Mediterranean Sea, and even beyond, Latin, an Indo-European language, was the starting point of a dialectal differentiation that gave rise to Romance languages. More precisely, it was its late form by the end of the Empire (fourth century CE), which was also called 'Vulgar Latin'. It is difficult to pinpoint the moment when Romance languages first appeared, however,

since these idioms are extensions of the Latin language. Today, Romance languages in Europe extend from the Atlantic to the Black Sea. From west to east, the following national languages can be found: Portuguese, Galician, Spanish, Catalan, Occitan, French, Rhaeto-Roman, Italian, Sardinian, and Romanian, making up what is known as *Romania*. The international expansion of these languages must also be taken into account. Linguistically, they are divided into two entities: western Romania (Italo-Roman, Ibero-Roman, Gallo-Roman, Rhaeto-Roman) and eastern Romania (Daco-Roman).

Italian

Italy is the epicenter of the Italian language: 95% of its population speaks it. Dialectical segmentation, however, is very important there. Three key subgroups can be identified: in the north, Septentrional Italian with Gallo-Italic (Piemontic, Lombardic, Genoese) and Venetian, Tuscan in the center (but also in Sardinia and in Corsica), and the Central-Meridional (ranging from Roman [Rome] to Calabrian and Sicilian [Calabria, Sicily]). This fragmentation slowed the standardization of the Italian language: Venetian first played this part, but it was Tuscan (Florence) that triumphed from the nineteenth century onward, even though all the regional dialects still remain quite lively today. Italian (Venetian) also remained a vehicular language up until the end of the nineteenth century. Although it still retains traces of its past expansion in Africa (Somalia, Ethiopia, Erythrea), Italian now radiates mostly through the emigration of its speakers. There are thus large communities of Italians in America (6 million), Australia (1 million), or Europe (2 million, mainly in Belgium). Overall, this Romance language is spoken by about 66 million people, 57 million of whom are in Italy.

Sardinian

Still being used in Sardinia by 1.2 million people, Sardinian language has a conservative character compared to other Romance languages. Its lexicon is archaic, except for late borrowings from Catalan, Castilian, and Tuscan languages. There are two subgroups: Logudorian (in the north) and Campidanian (in the south). The vast majority of Sardinian speakers are bilingual Sardinian–Italian, although its recent status as an autonomous region is giving it new strength.

Spanish

The Spanish Language has three main dialects: Astur-Leonese from Asturias to Salamanca, Aragonese in the southern Pyrenees, and Castilian (ancient Castile), which, starting with Alfonso X El Sabio (thirteenth century), became dominant and the basis for modern Spanish language, even though today there are attempts to rehabilitate Aragonese. Spanish is the Romance language that has grown the most: it can be heard in Israel where there is a large Judeo-Spanish colony (about 350,000 speakers) and also almost all over Latin America since the conquest of the Aztec and Inca Empires in the sixteenth century, when it became the official language of all these countries. Its expansion continues in US States contiguous to Mexico (Arizona, New Mexico, California, Texas, etc., with at least 20 million speakers). The only noteworthy Creole that developed from contact with Spanish is that of the Dutch Antilles, *Papiamento*, which is spoken by 200,000 people and is an official language. Spanish is not widespread in Africa and only 2 million Filipinos use it in Asia. Overall, 300 million people are Hispanophones.

Portuguese

The formation of modern Portuguese comes mostly out of Gallego-Portuguese, which used to link Portuguese and Galician dialects. Political independence allowed Portuguese to become a true Romance language. It is the result of the harmonious fusion of the different dialects from the provinces that make up the country: dialects from Coimbra, Lisbon, Beira, and Estramadure. The existence of Azorean and Madeiran, however, can be noted as their differences remain somewhat stronger due to their insular character and late colonization (fifteenth century). As with Spanish, but to a lesser degree, Portuguese lexicon was influenced by Arabic. On the other hand, it has imported more words from its (former) African colonies and its (ancient) Asian trading posts. Furthermore, it can be said that the notable differences found in the Portuguese spoken in Brazil are contributing to the creation of a new Romance language: Brazilian. The differences are most obvious in the lexicon, with borrowings from indigenous languages (Tupi) and from the languages of the former African slaves (Bantu), and in its syntax, which is at times archaizing. Brazilians now make up the largest Lusophone group in the world, with 150 million speakers. Further, Portugal's former African colonies have all retained Portuguese as the official language, but only 5% of their population (i.e. 2.5 million people) use it. Native people in these countries have often modified it, giving way to Creoles, such as Capeverdean Creole (Cape Verde), which is spoken by 230,000 people. Lastly, the Portuguese Diaspora can be found in France as well as in the United States of America (Massachusetts). All in all, it can be estimated that Portuguese is now

spoken by at least 170 million people all over the world, with the great majority of speakers being from outside its country of origin.

Galician

Geographically, Galician is located within a Spanish Province. Yet, it is a dialect from the Portuguese family and can be found in northern Portugal also. Its location made it lose its contact with Portuguese very early on. In fact, it mixes both Spanish and Portuguese characteristics. It began to reappear at the beginning of the twentieth century and is today spoken by about 2.5 million people (or 90% of Galicians), but its use is strongly declining in cities. Galician has, within its Spanish Province, the status of an official language.

Catalan

Its resemblance with Occitan leads one to consider Catalan as part of the Gallo-Roman group rather than Ibero-Roman. Its mixed lexicon, however, shows that this language is more like a 'bridge' between the two groups. Its strength is that it is an international idiom, since this language can be found in Spain (Catalonia, Baleares), as well as in France (Roussillon), Andorra, or Italy (Sardinia). It does not show any strong dialectical segmentation. In Spain, it counts six million speakers and served as the official language of Catalonia between 1931 and 1939. It has regained this status since 1979. Although it has the status of official language in Andorra, it does not have any real status in France, nor in Sardinia, where less than 20,000 people use it.

French

French is the one Romance language that has evolved the most compared to the original Latin. French language is located in the northern half of today's France (except for Brittany and Alsace), as well as in southern Belgium (Wallonia). It is part of the Langue d'Oil dialects, which were thus named in opposition to the Langue d'Oc languages (Occitan). These dialects are many. Some remain in use, such as Norman (Normandy) and Gallo (west Brittany). Walloon has even been recognized as a regional language in Belgium since 1990. Others have fully disappeared, such as Champenois or Berrichon, or are hardly surviving, such as Franco-Provençal (100,000 speakers in France and Italy). Each has its own set of particularities that would be difficult to detail herewith.

The expansion of French is multiple. It first grew within the country, with the progressive eviction of all other dialects (be they Gallo-Roman or not) as early as the eleventh century; it then spread across its borders (conquest of England in particular), and beyond (Lebanon). In the eighteenth century, at a time when France excelled, Francization reached Flanders and Russia. Later, the colonization of America and Africa (Maghreb, Black Africa) gave rise to Creole languages in America (Louisiana), Caribbean (Haiti, Antilles, Guyana), and some parts of the Indian Ocean (Madagascar, Reunion, Seychelles) as well as to the Québecker dialect (the official language of Québec) and Acadian (New-Brunswick). There are 70 million francophone speakers in Europe, 72 million in African countries (Senegal-Djibouti axle), and 45 million in the Maghreb. To this, the Caribbean (750,000), the Indian Ocean (600,000), and Lebanon must be added. There are about seven million Francophones in Québec and 280,000 more across the other Canadian Provinces. The Acadians in Louisiana number about 400,000 people to which 50,000 more speakers living in the eastern part of Louisiana and in Texas must be added. Thus, French is actually spoken in at least 38 states and the total number of French speakers is estimated to be a little under 200 million, with only 30% residing in Europe.

Occitan

Occitan dialects can be found in the south along a line that splits France from Bordeaux to Briançon. There are three subgroups: Septentrional Occitan (Limousin, Auvergnat, etc.), Southern Occitan (Languedocian, west of the Rhone, and Provencal in the east), and Gascon (in Aquitaine). Occitan is characterized by different phonetic and morpho-syntatic traits. Gascon, however, through its relation to Ibero-Roman, shows originalities to the point that it could be considered a Romance language in itself. Literary and judicial language until the Albigensian Crusade (1209–1229) and the annexation of its lands by the Crown, the Occitan then experienced a decline. It would not reemerge until the nineteenth century with the Felibrige Movement and F. Mistral. Since the second half of the twentieth century, autonomist movements have claimed it as a regional language. The number of speakers who master Occitan nowadays can be reasonably estimated at about 10 million.

Rhaeto-Roman

There is no real dialectical unity in this subgroup. Its specificity is mostly historical. Linguistically, it is hinging on both Romania, based on its lexicon in particular, but globally, it is close to Gallo-Roman. It is made up of three dialects, geographically fragmented: Romansch, spoken in Switzerland (Canton of Grison),

Ladin in Italy (Tyrolean Alps, north Trentino), and the Friulan also in Italy (Province of Udine). Wedged between Bavarian and Alemannic in the north (Germanic languages), and Lombard in the south (Italian subgroup), this Romance language has frittered away as the centuries went by. Today, there are only 36,000 Romansch speakers, 30,000 Ladinophones, and about 600,000 Friulan speakers. Depending on their geographical location, most are bilingual (German in the north, Italian in the south). And even though Romansch has been one of the national languages of Switzerland since 1938, assimilation seems irreversible.

Romanian

One characteristic of the Romanian language is that it is very conservative on some points while at the same-time being very innovative on others. The influence of Slavic and Byzantine cultures explains its originalities. The Romanian lexicon is under Slavic influence, as well as under Greek, Hungarian, and even modern French influence. In the eighteenth century, Slavonic stopped being the official language. Influenced by the ideas of the French Revolution and by an awareness of the Latin origins of the language, modern Romanian appeared at the beginning of the nineteenth century. The Latin alphabet became prominent in Romania beginning in 1860, but had to be adapted. The Cyrillic alphabet, however, was still used in Moldova up to the dissolution of the USSR. Romanian language is subdivided into four groups: Daco-Romanian (found in today's Romania and official language and in Moldova), Istro-Romanian (north of Thessalia), Macedo-Romanian (or Vlach, dispersed in Greece and Macedonia), and Megleno-Romanian (south of Bulgaria and north of Thessalonica). Istro-Romanian is spoken by only about a 1,000 people and is an endangered language. Macedo-Romanian is spoken by about 100,000 people and Megleno-Romanian, the dialect of a Muslim community, by 15,000 people. The unified Romanian language (Daco-Romanian) counts overall 24 million speakers, 20 million of whom are in Romania and 3 million in Moldova. The language can also be heard in Ukraine (400,000 speakers), Macedonia, Voivodina, Albania, and Hungary. The largest Diaspora outside Europe is in the United States of America with over 200,000 speakers.

Conclusion

On the whole, 780 million people speak a Romance language, which represent about 20% of the Indo-European language speakers and 8% of humanity, as shown below.

Western Romania	Italo-Roman	Italian	66,000,000
		Sardinian	1,200,000
	Ibero-Roman	Spanish	300,000,000
		Portuguese	170,000,000
		Galician	2,500,000
	Gallo-Roman	Catalan	6,020,000
		French	200,000,000
		Occitan	10,000,000
	Rhaeto-Roman	Romansch	36,000
		Ladin	30,000
		Friulan	600,000
Eastern Romania	Daco-Roman	Romanian	24,000000
			780,386,000

Speakers of Romance languages are superior in number to that of Germanic languages (about 560 million speakers) thanks, in particular, to Latin America. Spanish is nowadays the most spoken language, followed by French and Portuguese. Still, they cannot quantitatively vie with Chinese (at least 900 million) or English, which, although officially spoken by only 450 million people, has become the international language for communication and information.

Indo-European 5: Slavic

The Slavic languages, spoken by some 288 million people, constitute one of the branches of the Indo-European family. Until approximately 500 CE, before it disintegrated into the various Slavic languages spoken today, the language of the Slavs was relatively uniform. This language, referred to as Proto-Slavic or Common Slavic, was not written down; thus, it must be reconstructed by using the evidence of later written and oral sources. The phase of the unattested Slavic language up to 500 CE is usually referred to as Proto-Slavic, and from that point to approximately the tenth century, it is referred to as Common Slavic. Its closest relative is the Baltic family, made up of modern Latvian and Lithuanian, as well as extinct Old Prussian. The modern Slavic languages are divided into three branches: West (Czech, Slovak, Upper and Lower Sorbian, Polish, and Kashubian), East (Russian, Ukrainian, and Belarusian), and South (Slovene, Croatian, Serbian, Bosnian, Macedonian, and Bulgarian). Today, the Slavic languages are spoken over a large part of Europe and parts of northern and central Asia, as well as in diaspora communities in North and South America and Australia. Most are national standard languages: Polish (Poland), Czech (Czech Republic), Slovak (Slovakia), Russian (Russia, also as a second language in many former republics of the erstwhile Soviet Union), Belarusian (Belarus), Ukrainian (Ukraine), Slovene (Slovenia), Croatian (Croatia), Bosnian (Bosnia and Herzegovina), Serbian (Serbia and Montenegro), Macedonian (Macedonia), and Bulgarian (Bulgaria). Upper and Lower Sorbian are spoken in Germany by the ethnic Sorbian minority in and around the towns of Bautzen and Cottbus, respectively. Kashubian, a divergent dialect of Polish that has gained literary status, is spoken in northern Poland in and around the city of Gdansk. Significant minority populations of Slavs exist outside the borders of the matrix nations, e.g. Russian is spoken by significant percentages of the population of Belarus, Estonia, Latvia, and Ukraine; Slovak is spoken in Hungary and Ukraine; and Slovene is spoken in Italy, Austria, and Hungary.

Slavic writing began in the late ninth century CE in connection with the conversion of the pagan Slavs to Christianity and, specifically, the mission of the Byzantine monks, Constantine and Methodius, who developed the first alphabet for the Slavs, called Glagolitic, and translated the Scriptures into Slavic. The earliest surviving texts are from the late tenth century; this means that there are no extant texts produced during the lives of Constantine and Methodius. By the eleventh century, the Glagolitic alphabet was largely replaced by a modified version of the Greek alphabet, which has come to be known as Cyrillic. This alphabet is still used in modernized forms by the East Slavs, as well as the Serbs, Macedonians, and Bulgarians. The

bulk of the earliest texts that have survived are from the eleventh century, the language of which is now referred to as Old Church Slavic (or Old Church Slavonic, which is also the British term), because of their religious content and function. However, their writing was also used for secular purposes, as evidenced by the Novgorod Birchbark Letters, which contain business records and personal correspondence. The Letters are still being excavated in and around the town of Novgorod, Russia. Latin script writing developed among the Slavs who used the Roman rite, and it continues to be used in modified, modern forms by the Czechs, Slovaks, Poles, Kashubians, Slovenes, Croats, and Bosnians. The oldest use of the Latin alphabet for a Slavic language is attested by the Freising Folia—three brief texts in the Roman rite that reflect an early eleventh-century Slavic dialect that was a precursor to modern Slovene.

The Slavic languages are most closely related to the Baltic languages, as evidenced by certain innovations that are common to the two families and absent in other Indo-European branches. For example, both Slavic and Baltic have abstract nouns formed with the component *-iba*: Old Russian *družьba* 'friendship', Latvian *draudzība* 'friendship' (the Indo-European root **dhreugh-* 'to keep together' was derived as *drug* 'friend' in Russian and other Slavic languages; it is also related to Old English *gedrēag* 'pack [of animals]'). There is some debate as to whether these common innovations arose as a consequence of a continuous common dialect emerging from Indo-European or a rapprochement resulting in intensive contact between Proto-Slavic and Proto-Baltic. Whether through common origin or contact, the close relationship of Slavic and Baltic continued up to about the fifth century BCE, a time depth at which it is very difficult to reconstruct the early forms of the language in adequate detail. Before the Balto-Slavic period, the precursor of Slavic seems to have emerged from Indo-European in conjunction with the precursors of Indo-Iranian, Armenian, Germanic, and Celtic. After the Balto-Slavic period, having migrated westward from the Indo-European homeland, Proto-Slavic crystallized as a separate ethno-linguistic entity in what is now Ukraine, in an area bounded by the rivers Bug in the west, the Dnepr in the east, and the Pripet' in the north (separating them from the Proto-Balts), although the exact location of the Proto-Slavic homeland cannot be determined.

Borrowings of words from non-Slavic languages that are attested throughout the Slavic world give evidence of the contacts that the Proto-Slavs had before their migrations. Among the earliest of these contacts were with Indo-Iranian-speaking peoples, the Alans, Scythians, and Sarmations, with whom the Proto-

Slavs apparently shared religious beliefs: *bogŭ* 'god', *rajĭ* 'heaven', *svętŭ* 'holy', *xvala* 'glory'. Germanic loanwords entered Slavic over a longer period, before, presumably during, and after the migrations. Early loans from Proto-Germanic and Gothic include *kupiti* 'to buy', *t'ud'ĭ* 'foreign', and *stĭklo* 'glass'. Later loans from Old High German, but still in the Common Slavic phase, include *kral'ĭ* 'king' (from *Karl*, referring to Charlemagne) and *penędzĭ* 'coin' (cf. German *Pfennig*). Borrowings from various Turkic languages appear throughout Slavic, although they are arguably from different sources, e.g. Russian *kolpak* 'hat' vs. Czech *klobouk*, Slovene *klobuk* (cf. Crimean Tatar *kalpak* 'cap'). Greek and Romance loanwords entered Slavic substantially through the mediation of the Church, more or less at the beginning of the historical period (i.e. from the tenth century), e.g., *dĭjavolŭ* 'devil', *psalmŭ* 'psalm', *krĭstŭ* 'cross' (Greek); *mĭša* 'Mass', *križĭ* 'cross', *židŭ* 'Jew' (Latin). Contact with varieties of Romance and other languages is responsible for many of the peculiarities of the Balkan languages. Contact with Baltic Finnic languages played a role in the formation of Russian, especially its northern dialects.

The Slavic languages present a variegated picture with respect to their sound structures. The West and East Slavic languages are characterized by complex distinctions in consonants. Russian, for example, distinguishes between plain and palatalized consonants, the latter of which are characterized by a raised tongue position, similar to that produced by English speakers when pronouncing the letter *y,* viz. *privedëš'* [prʸivʸi'dʸoʃ] 'you will bring'. However, it should be emphasized that Russians perceive this secondary articulation as a characteristic of the consonant itself, because they contrast such sounds with sequences of plain consonant plus *y,* e.g. *sel* ['sʸel] 'sat' and *s"el* ['sʸyel] 'ate'. Czech has intensified the development of palatalization so that what were formerly palatalized consonants have evolved into consonants articulated at the middle of the palate; thus, the first consonant in the word *tichý* 'quiet' is neither *t* nor *k*, but a sound in between the two; this sound contrasts with a plain *t*, as in *ty* 'you'. This intensification has resulted in the development of a trilled fricative, *ř* (*řeka* 'river', cf. Russian [rʸe'ka]), which is pronounced as the *s* in English *plea<u>s</u>ure* and simultaneously rolled/trilled as in Spanish *bu<u>rr</u>o*. In Polish, this sound existed historically, but it has merged with the nontrilled fricative, *rzeka* ['žeka] 'river'. Vocalic and accentual systems vary considerably from language to language. Czech and Slovak distinguish long and short vowels and have stress fixed on the first syllable of the word, e.g. Czech *dal* ['dal] 'he gave', *dál* ['da:l] 'further'. Slovene and Serbo-Croatian also preserve long and short vowels,

but in addition they distinguish between rising and falling intonation (pitch) in stressed syllables, e.g. Slovene *brati* [b'rá:t] 'to read' (long low or rising pitch), *brat* [b'rà:t] 'to go read' (long high or falling pitch), *bràt* [b'ràt] 'brother' (short high or falling pitch). In general, there seems to be a complementary relationship between consonantal and vocalic/accentual systems: the more complex the consonantal system, the simpler the vocalic and accentual systems, and vice versa.

As regards word structure, the Slavic languages are characterized by inflection; that is, words change to reflect grammatical relationships. For example, the Russian word *sobaka* 'dog (as a subject)' has the following forms: *sobaki* 'of the dog', *sobake* 'to the dog', *sobaku* 'dog (as an object)', *sobakoj* 'as a dog', *na sobake* 'on the dog', *sobaki* 'dogs (subject)', *sobak* 'of the dogs' or 'dogs (as an object)', *sobakam* 'to the dogs', *sobakami* 'as dogs', and *na sobakax* 'on the dogs'. This characteristic allows word order to remain flexible, which in turn permits word order to take on functions other than indicating grammatical relations, such as, for example, emphasis: *Ja ljublju sobaku* 'I love the dog' (normal word order) vs. *Sobaku ljublju ja* 'It is I who loves the dog' (emphasizes the subject). In the Balkan Slavic languages, Bulgarian, and Macedonian, most of these inflectional changes in nouns have been eliminated. Slavic verb forms mark person (the subject of the verb) and number (singular, plural, and in some Slavic languages, dual); for this reason, many Slavic languages omit the subject pronoun in neutral speech, e.g. Czech *vidím* 'I see', *vidíš* 'you see', *vidí* 's/he sees', *vidíme* 'we see', *vidíte* 'you see' (polite or plural), *vidí* 'they see'. Three genders are distinguished—masculine, feminine, and neuter—although unlike many Western European languages, these are not expressed by definite articles ('the', such as German *die, der, das* or French *la, le*), there being no articles in Slavic languages. Rather, noun endings indicate gender, e.g. Russian *žena* 'wife', *kniga* 'book' (both feminine); *čelovek* 'person', *stol* 'table' (no ending—both masculine); and *okno* 'window' (neuter), *more* 'sea'. Gender serves to coordinate sentence elements through agreement; for example, an adjective modifying a noun must agree in gender (as well as other grammatical categories) with the noun: Russian *krasivaja žena* 'beautiful wife' (feminine), *krasivoe more* 'beautiful sea' (neuter). It may also agree with the past tense of a verb, e.g. *žena stojala tam* 'the wife was standing there', *čelovek stojal tam* 'a person was standing there'. Moreover, the formation of gendered noun pairs is effected by adding a suffix to produce the feminine member of the relationship, e.g. Russian *kurd* 'Kurdish man', *kurdjanka* 'Kurdish woman'. A typical characteristic of Slavic inflection and word formation is the rich array of alternations in the shape of words; these alternations have led to a well-developed investigation into the nexus of sound systems and word structure known as morphophonemics. An example of a morphophonemic alternation is found in Russian *vižu* 'I see' vs. *vidiš* 'you see', where the basic form of the root *vid-* 'see' changes to *viž-* in the context of the first-person singular nonpast.

Verbs in Slavic languages are distinctive among European languages in that they overtly mark aspectual contrasts. That is, they distinguish completed and uncompleted actions/events, as well as express other varieties of temporal and spatial manners of organization. For example, Slovene *skočim* 'I jump (once)' (completed—perfective aspect), *skačem* 'I am jumping' or 'I jump habitually' (e.g. as a professional ski-jumper) (uncompleted—imperfective aspect). Further aspectual distinctions may be derived through suffixation and prefixation, e.g. Russian *ona brosila mjač* 'she threw the ball' (perfective), *ona brosala mjač* 'she was throwing the ball' (imperfective); *ona podbrosila mjač* 'she tossed the ball up' (perfective), and *ona podbrasyvala mjač* 'she was tossing the ball up' The arrangement of tense (time) in Slavic verbs has been considerably reorganized from the Indo-European starting point. Russian is an example of one of the more innovative tense systems. For example, the future is formed by using a perfective verb with the same formal properties as the imperfective present: *ja pojdu* 'I shall go' (the corresponding imperfective *ja idu* means 'I am going' or 'I go'). The future with the imperfective aspect is formed by adding an auxiliary verb *budu* (which goes back to an Indo-European root **bheuH-* meaning 'to grow') to the infinitive: *ja budu iti* 'I will be going.' Past tense is formed by a participle derived with the formant *-l* that agrees in gender and number with its subject, e.g. *ja pošël* 'I left.' This rather simple schema supplanted a much more complex system of past tenses that was still in place in medieval varieties of Slavic, e.g. Old Russian (twelfth to thirteenth centuries), *i vŭlny byša vyše korablä* 'and the waves were higher than the ship' (aorist, a simple past narrated event); *i reče sĭ unoša roda velika jestĭ bylŭ* 'and this youth said that he was of a great family' (perfect tense, meaning that the narrated past event is of relevance to the moment of narration). This complex system was preserved and developed further in Macedonian and Bulgarian, which have otherwise lost much of the complexity of noun and adjective inflection found elsewhere in Slavic. Parallel to the complementariness between consonants and vowels/accent, pointed out previously, such a relationship seems to hold in Slavic languages between the complexity of nominal and verbal inflection.

Indo-Pakistani Sign Language

Indo-Pakistani Sign Language (IPSL) is a visual-gestural language that uses movements of the hands, facial expressions, and head/body positions to convey linguistic messages. Dialects of IPSL are used in deaf communities in urban centers of the Indian Subcontinent. Figure 1 shows the extent of the geographic area as documented to date. It is likely that dialects of IPSL are also used in other parts of India and/or Pakistan, maybe even in neighboring countries (Sri Lanka, Nepal, Bangladesh), but this has not been fully documented.

In the deaf community, the sign language is simply called 'sign/signing/sign language', sometimes in combination with the sign for the country (as in *INDIA SIGN*). Various names are used by hearing people. In the Hindi/Urdu-speaking area, the sign language is known as *ishaaron kii zubaan* ("language of signs"). Official usage also refers to "Pakistan Sign Language (PSL)" and "Indian Sign Language (ISL)", respectively, although this usage runs contrary to the linguistic facts.

The large area covered by one and the same sign language is particularly noticeable in view of the great linguistic diversity of spoken languages in the region. IPSL is used in both the Indo-European language area (e.g. Hindi-, Nepali-, and Marathi-speaking areas) and the Dravidian language area (e.g. Telugu-speaking areas in Andhra Pradesh). All IPSL dialects have the same grammar, but lexical variation may be considerable. On average, IPSL dialects have about 75% of shared vocabulary, with about 25% of the vocabulary different across dialects.

Despite dialectal differences, IPSL users can communicate freely across a large geographic area. Many are multidialectal or become multidialectal very quickly as soon as they travel to other areas. Moreover, since IPSL is a minority language in constant contact with spoken languages, all IPSL users are to some extent bilingual in the signed and the spoken medium, the latter mostly in its written form. However, competence in spoken languages, be it English, Hindi, or one of the regional languages, is often very low among deaf people. The use of so-called 'mouthing' is also a contact phenomenon resulting from the bilingual situation. Mouthing means that sign language users accompany signs with mouth movements that correspond to words of a spoken language. For example, one may imitate the mouth movements of the Hindi word *kaam* 'work' while signing *WORK*.

The size of the language community has not been documented reliably, but IPSL users definitely number in the hundreds of thousands, possibly even over a million, thus representing one of the largest sign language communities in the world. IPSL is not known to be genetically related to any other sign language. A minor influence from British Sign Language can be seen, for example, in the use of a two-handed manual alphabet (fingerspelling) for representing English words. No manual alphabet for indigenous Indian languages is widely in use.

Word Classes and Sentence Structure

IPSL has three main word classes: verbs, multifunctional words, and particles. There are no word classes of nouns, adjectives, and adverbs. The most important

Figure 1. Geographic extent of IPSL.

subclass among the particles is a set of nine functional particles. These appear at the end of a sentence or clause and indicate sentence types such as negative sentences, questions, completed actions, commands, and existentials (equivalent to English 'there is').

The class of verbs is rather small, consisting of about 50 signs, such as the signs for 'help', 'ask', 'give', 'tell', 'teach', 'go', 'come', and the like. These are characterized by so-called 'directional movement', which means that the movement of the verb varies depending on the relationship between the persons, objects, or places involved. Figure 2 shows an example of a sign expressing a relationship between two persons.

Most signs in IPSL belong to the class of multi-functional signs, including signs as diverse as 'change', 'begin', 'difficult', 'black', 'three', 'self', 'many', 'war', 'child', and so on. One and the same multifunctional sign can function as the equivalent of both a noun and a verb/predicate in other languages. For example, one would sign *BEGIN DIFFICULT* to express 'The beginning is difficult.' (nominal function), and *WAR BEGIN COMPLETIVE-PARTICLE* to express 'The war has begun.' (verbal function).

IPSL has a subclass of signs related to pointing. Pointing with the index finger is often functionally equivalent to pronouns in spoken languages. Pronouns have the full set of IPSL number distinctions, which include a form unspecified for number that may have either singular or plural reference, a dual (for the number 'two'), and several types of plurals. Another type of pointing sign, with the index finger drawing a line between two locations in space, is used as an auxiliary. The auxiliary can express subject–object-like relationships in a general way (translatable as 'he to me', 'I to you', and so on) in combination with signs that do not have directional movement, for example: *SIGN AUXILIARY-you-me-you* 'You talk to me in sign language and I talk to you' (see Figure 3).

IPSL is a predicate-final language, the basic sentence structure being ARGUMENT – PREDICATE – FUNCTIONAL PARTICLE, as in *SCHOOL FAR NEGATIVE-PARTICLE* 'The school is not far.' A second argument will usually be a pronoun and can appear just about anywhere, e.g. *INDIA YOU LIKE EXISTEN-TIAL-PARTICLE*? 'Do you like India?' Sentences are often highly elliptic, leaving out information that can
Figure 2. 'I give someone a gift' and 'Someone gives me a gift'.
Figure 3. 'You talk to me in sign language and I talk to you'.

be recovered from the context, so that the predicate is the only obligatory constituent. Signs indicating time (such as 'tomorrow', 'before', 'in the future', etc.) always appear at the beginning of a sentence. Like most other sign languages, IPSL has no tense system. Rather, time is expressed at the level of the text, with time signs placed at the beginning of a new paragraph each time the time reference changes.

Structural Features Shared with Other Sign Languages

IPSL shares a number of aspects of its structure with other sign languages. By modifying the movement pattern of a sign, it is possible to express several aspectual meanings, such as 'do something repeatedly', 'be about to do something', or 'something happening
Figure 4. 'Develop': single opening movement; and 'develop gradually': stepwise gradual opening.

gradually'. Figure 4 shows an example, and it is obvious how the form of the sign corresponds to its meaning. Such iconicity, both in the vocabulary and in grammatical processes, is also a characteristic feature of sign languages in general and is used extensively in IPSL.

Iconicity also plays a role in some of the most productive IPSL constructions. These include a large set of signs denoting geometrical shapes, such as 'square two-dimensional', 'round three-dimensional', 'flat surface', and so on. They can be used in countless modifications and combinations to describe a wide variety of objects in terms of their visual-geometric properties. IPSL also has a subsystem known as 'classifiers' in other sign languages. However, the IPSL classifiers are fewer in number, used less frequently, and refer to people and animals only, not to other categories such as vehicles. In such a construction, one sign can express the equivalent of a whole sentence in English (see Figure 5).

IPSL and other sign languages make use of a wide range of facial expressions for both adverbial concepts (such as 'do with difficulty', 'more and more', 'unfortunately', etc.) and grammatical categories. In IPSL, the latter include facial expressions that go with yes/no-questions, questions with question words (e.g. 'what', 'how'), negative sentences, and subordinate clauses. For example, in questions with question words, the eyebrows are raised and the head is tilted backward. Such facial expressions, which are often obligatory and have to follow specific syntactic rules,
Figure 5. 'Two persons approaching each other'.

are extremely important in all sign languages documented so far.

Finally, the important grammatical role of space, for example, with directional movement, is a unique feature of sign languages that has no correlate in spoken languages. In a text, sign language users often assign particular points in space to the objects or people they are talking about and make continuous reference to these locations, for example, by pointing at them. This process is known as 'localization' and

plays an important role in IPSL grammar as well as in other sign languages.

Structural Features Different from Other Sign Languages

On the other hand, many structural features are peculiar to IPSL and differ from other sign languages. For example, many known sign languages do not have an auxiliary construction of the type described above for IPSL. In the negative, IPSL has two different functional particles for neutral negation (saying that something is not the case) and contrastive negation (rejecting something that has been said or implied before). Unlike in other sign languages, there is no particular construction for conditionals ('if-clauses'), and there are no conjunctions to link clauses. Instead, there is a general subordinating construction that is marked nonmanually by a combination of facial expression, head posture, and sign rhythm.

IPSL has few genuine compounds, but there are a number of striking types of sign combinations. Almost all signs for kinship terms are compositional, with the sign for 'man/male' or 'woman/female' preceding a sign for the family relationship, for example, *MAN+SIBLING* 'brother', *WOMAN+MARRY* 'wife' (see Figure 6). IPSL has a single question word with a general interrogative meaning (see Figure 7). To ask specific questions, the general interrogative must be combined with other signs, for example, *FACE+QUESTION-WORD* 'who', *PLACE+QUES-TION-WORD* 'where', *TIME+QUESTION-WORD* 'when'.

The use of mouthing in IPSL is also markedly different from other sign languages. Since there are so many different spoken languages in the IPSL-using area, one and the same sign may be accompanied by mouthing from different spoken languages in different areas. While in some sign languages, mouthing is functionally very important, it is much less significant in IPSL. The extent of mouthing is extremely variable; hence, signing with extensive mouthing and signing with no mouthing at all is equally possible.

Even the signing space in IPSL is structured differently from other sign languages. The upper sign space around the head and above the shoulders is particularly significant and is associated with the concepts of distance and authority. Therefore, when place names or names of institutions with authority are mentioned, an index finger pointing is added that has to be directed upward, for example, *GOVERNMENT INDEX-up, CALCUTTA INDEX-up.*

Social and Political Factors

The deaf community in India and Pakistan is a linguistic and cultural community rather than an ethnic or political entity. Focal points are the deaf schools and the deaf associations, of which there are many in all urban centers. On the other hand, the rural areas are usually cut off from the deaf community due to a lack of infrastructure, and isolated deaf people in these areas use limited ad hoc gestural communication ('home sign'). The origins of the deaf educational system date back to the late nineteenth century, when the first schools for the deaf were founded in India (c. 1882 in Mumbai, c. 1893 in Calcutta). However, this does not necessarily coincide with the age of the sign language itself. So far, there is no reliable information about when and how IPSL originated.

IPSL is not an officially recognized language in any part of the Indian Subcontinent, and there is a great deal of prejudice and misinformation about it. This
Figure 6. 'Daughter': WOMAN+BORN.
Figure 7. General question word.

may account for various recent attempts at 'developing' the sign language, for example, by inventing contrived sign systems ('Indian Sign System', 'Sign Urdu', etc.). In these systems, which are not used by deaf people among themselves, signed sentences are constructed to mirror the structure of a spoken language, disregarding IPSL structures and adding a number of newly invented signs. There have also been equally unsuccessful attempts at 'standardizing' IPSL dialects.

Deaf people themselves have often adopted the negative views on sign language held by the hearing majority. Use of the primary sign language, in particular, in the deaf educational system, is still stigmatized, although the situation is improving. Officially, most schools for the deaf follow the policy of 'oralism', with emphasis on speech training/articulation and lip reading, but day-to-day practice is often more open toward forms of manual communication. Over the last few years, the Indian government has supported the development of sign language courses and the training of qualified sign language teachers, so that attitudes toward sign language and related policies are beginning to change. However, the struggle for a genuine recognition of the linguistic human rights of the deaf community in the Indian Subcontinent still continues.

Inflection and Derivation

Inflection and derivation are terms used in morphology, the study of word structure. They distinguish the two main ways of forming words in fusional languages such as Finnish, Italian, Arabic, and—to a lesser extent—English. Isolated languages such as Mandarin, Thai, and Vietnamese tend not to use affixes; i.e. these terms do not apply very well to these languages. An affix is a morpheme attached to a word to change its grammatical function or meaning: at the start (prefix), around it (circumfix), in the middle (infix), or at the end (suffix).

Inflectional affixes signal grammatical relationships such as number, person, tense, and case, and they do not change the grammatical class of the word to which they are attached. In highly inflected languages such as Arabic, much information is conveyed very economically, as shown by the paradigm of the perfect form of *yaktub*:

katabtu	I have written
katabti	you (feminine singular) have written
katabta (masculine singular)	you have written
katabat	she has written
kataba	he has written
katabna	we have written
katabtunna	you (feminine plural) have written
katabtum	you (masculine plural) have written
katabnaa	they (feminine plural) have written
katabuu	they (masculine plural) have written
katabtumaa	you two have written
katabataa	they two (feminine) have written
katabaa	they two (masculine) have written

The appearance of inflectional suffixes in a language interacts with sentence formation. The more highly inflected the language, the less important the order of words to convey meaning. In Latin, the word order in the sentence *parvum puerum magna puella vidi* could be changed without loss of grammatical meaning because the inflectional suffixes indicate 'the tall girl saw the small boy'and not vice versa: *-a* is subject case, feminine, third-person singular, whereas *-um* is object case, masculine, third-person singular.

529

Although Old English inflected all nouns, pronouns, and adjectives, there are only eight inflectional suffixes in Modern English, only one of which can be attached to a word at a time:

-s	Third-person singular present (*wants*)
-s	Plural noun (*dogs*)
-ed	Past tense (or past participle) (*wanted*)
-'s or *-s'*	(*dog's, dogs'*) Genitive case of noun
-en	Past participle (*given*)
-ing	Progressive aspect (*giving*)
-er	Comparative adjective (*bigger*)
-est	Superlative adjective (*biggest*)

These inflections are highly 'productive' —that is, new nouns, verbs, or adjectives that enter the language will be automatically assigned these markings. 'Nonproductive' patterns lack this potential; for example, alternate plural markings such as *-en* (oxen) or *-ren* (children) would not be assigned to new nouns.

However, the limited number of inflectional affixes in English means that they are overworked and potentially ambiguous. For example, the suffix *-s* on *trains* can mark the third person of the verb *train* or the plural of the noun *train*. Similarly, *train's* can indicate possession, as in *the train's noise,* or it can be a contracted form of a noun and auxiliary, as in *the train's here.* Furthermore, *-ed*, *-ing*, and *-en* may be derivational adjectival markers (*interested*, *interesting*, *broken*), and *-er* may mark an agent of a verb (*worker*, *teacher*).

Derivational affixes are used to create new words and, unlike inflectional suffixes, they change the grammatical class of the root word to which they are attached. In most languages, derivational affixes are usually found nearest to the root, whereas inflectional affixes tend to be on the periphery of a word, usually at the beginning or at the end.

In English, most derivational affixes are suffixes, and—unlike inflectional suffixes—more than one can be added to a root. Thus, the noun *nation* combines with *-al* and *-ly* to produce an adjective and then an adverb, respectively. Derivational suffixes can also change subclasses of words: thus, the abstract noun *fatherhood* derives from the concrete noun *father*.

The rules of derivational word formation are complex, but every adult native speaker of a language knows and uses them to understand words not previously encountered. Moreover, many new words can be coined by derivational affixes. For example, a British Prime Minister gave rise to thatcherism and thatcherite, and thatcherize and thatcherizable would be fairly readily understood: these two suffixes (*-ize* and *-able*) are particularly productive. Others (for example, the prefix *im-*, as in *impossible*) are referred to as 'semiproductive' because they can be attached to fewer words. In most languages, derivational word formation is less productive than inflectional. Since the Middle Ages, most changes in English word structure have occurred by attaching derivational suffixes to Latinate roots. However, a recent tendency toward Anglicization may be noted: thus, contemporary additions to the lexicon include compound verbs such as *downgrade*, *downsize*, *outpace*, *outsource*, etc., rather than their Latin-based equivalents.

There is an interaction between affixation and sound structure. For example, in English, the pronunciation of *-s* depends on the previous consonant sound: *-s* is pronounced [s] in *cats*, because the preceding *t* is voiceless, but it is pronounced [z] in *kids*, because the preceding *d* is a voiced sound. Sometimes, the word stress shifts, for example, *photograph/photography*. In other cases, the vowel sound may alter, as in *divine/divinity*. In some cases, a feature of the final consonant changes, for example, *advice/advise*; occasionally, there are changes in both vowel and consonant quality, as in *breath/breathe*.

The previous discussion has made two assumptions. The first is that the two categories of affixation are easily distinguishable—but this is not always so. As noted previously, some inflectional affixes may have the same form as some derivational ones (e.g. *-s*: noun plural or verb third-person singular).

Second, it is also assumed that the notion of a word is itself unambiguous—but this is not the case either. The English indefinite article (*a*) and the Kivunjo expression *näikìmlyïïa* ('he is eating it for her') would each be identified by respective native speakers as a single word. Fully understanding what a word is, and therefore how it is formed through affixation, requires knowledge of sound structure, sentence grammar, and the rules of word formation.

Information Retrieval

Information retrieval (IR) is a branch of computer science (Baeza-Yates and Ribeiro-Neto 1999; Salton and McGill 1983; van Rijsbergen 1979; Jackson and Moulinier 2002) that deals with content-based searches for relevant information on very large document collections, usually composed of hundreds of thousands of documents. These documents—the IR term for all kinds of written texts—are contributed by a large variety of authors and cover a wide range of topics, genres, and writing styles, although scientific papers and newspaper articles prevail. The general goal of an IR system, in a narrow sense, is to locate all the documents in the underlying document collection that are relevant with respect to a user query expressing a specific search topic. Given these documents (or bibliographic references to them), the user of an IR system then has to access these documents, read them, and understand their contents in order to solve the problem that led him or her to formulate the specific search topic. More and more, this document-centered view of IR systems is going to be broadened to include the direct location of factual knowledge in documents and procedures for content condensation (summarization) of documents as well. Still, searches are run on unformatted textual material. This marks the borderline to fact retrieval with database systems that perform searches on prestructured, formatted data collections (e.g. relational tables). In particular, the rise of the World Wide Web and the proliferation of machine-readable texts have spurred a strong interest in IR techniques. Because documents in the WWW are often multimedia aggregates, the goal of IR also gradually expands to include the content-based search of audio, video, and graphical data as well, although the primary focus is still on textual data (and the textual description of other media).

A typical IR scenario can be described as follows: A person wants to find relevant documents on guitar players, particularly those playing jazz or rock music. Rather than submitting this search topic to an IR system in colloquial English, it must be translated into a 'formalized' query format. First, the facets of the topic under consideration are designated by search terms: GUITAR, JAZZ, ROCK MUSIC. Second, these terms have to be grouped according to their logical dependencies. The final search query then looks like this: (GUITAR *and* (JAZZ *or* ROCK MUSIC)). This query triggers a search process in the underlying document collection, which can be paraphrased as follows: 'Find me all documents in which the term GUITAR occurs and, at the same time, either the term JAZZ or ROCK MUSIC, or both, occur, too'. The IR program will then return all hits, i.e. documents that exhibit the required co-occurrences of search terms.

This is the classical Boolean approach to IR, in which search terms are combined by Boolean operators, viz. '*and*' or '*or*', sometimes also '*not*'. Such a Boolean query must exactly match with the terms in a document to be retrieved. Despite its merits as the baseline for almost all commercial IR systems, its drawbacks are evident: Boolean logic is a formal language most people are not familiar with and, even worse, Boolean queries for nontrivial search problems can become quite complex; the result set is often very large and usually unordered, all search terms are equally relevant for the query evaluation, and, finally, the search partitions the entire collection into exactly two subsets: documents that satisfy the Boolean query and documents that do not.

There are some disturbing linguistic phenomena that arise through such a surface-oriented approach, particularly concerning lexical variants due to inflection. A very simple approach for dealing with them is the use of the truncation operator '*$*'. Used as a suffix such as in 'SING$', this expression retrieves all documents in which the string 'SING' appears followed by an arbitrary string. Hence, it matches SING, SING*S*, SING*ER*, SING*ING* but also SING*ULAR*, etc. Linguistically more sophisticated alternatives are stemmers, i.e. programs that strip off suffixes based on a small set of rules without the use of dictionaries (thus preventing e.g. the reduction of SING*ULAR* to SING). In this case, the IR system takes over the initiative and the user no longer has to make ad hoc guesses about morphological regularities (as required by the proper placement of truncation operators). However, linguistically more advanced morphological analysis used to cope with the term variation problem is usually not supported by IR systems.

In the basic Boolean approach to IR, all search terms are equally important. This assumption is often inadequate and, hence, retrieval models have been proposed, which incorporate statistical methods for grading the relevance of terms for a document search. There is a very general assumption underlying the use of statistical methodology for IR, which relates the frequency of occurrence of terms to their relevance as content descriptors. This can be expressed more precisely as

follows: determine the absolute frequency of each term j, tf_{ij} (excluding irrelevant, although highly frequent stop words such as 'the', 'for', 'again', etc.) for each document $i \in [1, n]$ in the entire collection (where n gives the total amount of documents in this collection). Then, determine the corresponding relative term frequencies, documentwise and collectionwise. A term is considered relevant if its relative document frequency by far exceeds its relative collection frequency. In order to stress the specificity of a term, we may also add extra weight to those terms that have a high occurrence frequency in few documents and penalize those terms that are widespread and occur rather frequently throughout the entire collection (and, hence, do not discriminate well for searches). In essence, this is achieved by the so-called $tf*idf$ measure (term frequency—inverse document frequency). Its tf part equals tf_{ij} from above, and its idf part is constituted by $\log(\frac{n}{n_i})$, where n yields the size of the document collection and n_i specifies the number of documents in which term i occurs.

There are more advanced methods, e.g. the vector space model, in which a document is represented by an n-dimensional document-term vector, n being the number of different terms (excluding stop words) in the entire document collection. Interestingly, this approach assumes the dimensions of the vector space to be orthogonal, i.e. all terms are treated as being totally independent of each other (which sounds bizarre from a linguistic perspective). The 'similarity' (another more technical notion to express relevance) of a document and a query can then be measured by comparing the corresponding document and query vectors using well-known metrics such as the cosine measure (the higher the cosine value, i.e. the smaller the cosine of the angle of two vectors, the more similar both the items are). Accordingly, we may also determine the similarity between any two documents in the document collection based on a vector comparison between both of them. This can be exploited for the retrieval process in the following way: when a query identifies a relevant document, then another very similar document (which exhibits a high cosine value relative to the already retrieved document) should also be part of the system output. This approach to classifying documents usually requires clustering procedures, which build on the lexical vector representation of documents. In general, IR systems that apply the vector space model generate as output a list of documents, ranked by decreasing relevance in terms of how similar each document is relative to the query, given their vector representations.

A powerful extension to this single-step ranking approach is called *relevance feedback*. Based upon the results of the first retrieval round, the searcher identifies those documents among the top-ranked k documents (where k usually ranges between 20 and 50), which he or she considers relevant (all remaining ones are considered irrelevant, by convention). The terms of the relevant documents are 'added' to the vector representation of the original query, while those from the irrelevant documents are 'subtracted' from it. The entire search is then rerun with the modified query. With two or three iterations, this usually leads to improved search results within the feedback loop.

Statistical models of term association that use vector space representations and various association factors (such as the cosine measure), are a quantitative way of making sense relations explicit, although they do not distinguish between hyponyms, antonyms, or synonyms, etc. A more traditional way of accounting for lexical semantics is the use of thesauri and classification codes in document retrieval. A *thesaurus* is a lexical repository in which terms are linked to other terms via a small set of informal semantic relations, such as synonymous or quasisynonymous terms, broader or narrower terms, related terms, etc. This might be useful for document retrieval in search modes based on *query expansion*: using a broader (i.e. general) term such as INSTRUMENT explicitly linked to a thesaurus will match documents that not only contain INSTRUMENT as a term but also, say, GUITAR, DRUMS, PIANO, or TRUMPET, i.e. narrower (more specific) terms. Hence, it frees users from thinking of *conceptual* variants of search terms (synonyms, more specific or related terms) when they formulate a query.

Classification codes are another vehicle for expressing semantic relations although, usually, only along the general-specific axis. In classifications, concepts are represented by some kind of alphanumerical string (e.g. INSTRUMENT comes as MI0) and more specific concepts are represented using this string as a prefix so that, e.g. GUITAR may appear as MI01 or MI0G. *Text categorization* (*classification*) is then defined as the problem of assigning a suitable set of category codes to each document. Similarly, *indexing* denotes a process by which a document is assigned a set of index terms describing its main topics, with the index terms either being directly extracted from the source document or derived from some controlled vocabulary, e.g. a thesaurus. As far as the retrieval process is concerned, with lists of category codes or index terms being available, these document surrogates are searched rather than the full text of documents.

The above scenario assumes a person actively submitting an ad hoc query to an IR system and awaiting interactive system response. Nevertheless, the same methodologies can also be used for different information supply models. One of these focuses on *document routing* (or, *document filtering*). In this case, a query that is stable over a certain time interval (some

months, or so) is continuously evaluated in the system. When new, incoming documents match this query, they are delivered automatically to the person who set up the content router (filter). This mode helps people keep up to date with the most recent documents matching their (stable) search interests.

From a linguistic point of view, an interesting and very general conclusion can be drawn from standard IR approaches. A content-based search problem for finding relevant documents is treated as a *lexical* problem (sometimes, when noun phrases are incorporated, it is slightly extended as a phrasal problem). Relevancy, usually, is mirrored through co-occurrence patterns of nouns (as denotations of topics, issues, etc.)—either in sets of documents (Boolean retrieval) or in a vector space. Since all other kinds of text-specific information is lost (even the natural order of words in a text), this approach has been dubbed as a 'bag of words'. Although numerous attempts have been made to promote further linguistic methodologies beyond stemming (e.g. syntactic processing of phrases), their application yielded discouraging results in many experiments. By and large, linguistic methods did not outperform the much simpler statistical ones and failed to improve the performance of IR systems substantially.

While the methods discussed so far cover a traditional, fairly established view on the IR task, viz. the provision of relevant *documents*, current research tries to complement this document-centered view on IR by focusing on relevant *facts* and *data*. A corresponding *information extraction* task (Gaizauskas and Wilks 1998; and Jackson and Moulinier 2002) can then be phrased as follows: given a set of documents, extract all of the information considered relevant from these textual sources by filling a priori supplied sets of domain-specific templates (reminiscent of the knowledge representation construct of frames). Typically, these templates address names of people, locations or organizations, as well as simple relations and complex events involving these entities. In order to achieve this goal, a much more sophisticated analytic machinery than the one used for classical IR tasks has to be provided. Usually, it is based on regular expressions for named entity recognition, (cascades of) finite-state automata for partial syntactic analysis (parsing), template-filling rules which move linguistically analyzed text portions (e.g. noun or verb groups) into the canonical template structures, while template merging rules account for the final assembly of consistent and complete data about the same entity or event as captured from the entire document. Also in hybrid approaches, statistical methods play their part, although not as dominantly as in the pure IR framework.

Text mining (Hearst 1999) is slightly different from the information extraction task. Although the target is the extraction of factoid knowledge from textual sources, for text mining there are no a priori templates available, which specify the type of relevant information a system should look for. Rather, text miners try to capture 'new' and interesting (relevant) information for which no a priori conceptualization exists yet. By way of exploring textual data and interpreting it, a text miner supplies its user with unexpected and, thus, particularly valuable information. As with classical document-focused IR, the notion of relevance and the interest value is crucial for even more advanced fact-finding IR activities.

Another challenging task is concerned with factual *question answering* directly from large collections of on-line textual resources (Harabogiu and Moldovan 2003). Unlike information extraction whose scope is limited to the set of a priori available templates, text-based question answering is open-domain, i.e. not constrained to preselected topics. Successful question answering systems use pretty advanced natural language processing techniques, e.g. to capture the semantics of (*wh*) questions and to perform lexico-semantic unifications of questions and candidate answers (usually, text snippets) through the collection and assessment of evidence from multiple documents.

Recently, the field has further expanded into the area of *text summarization*, although this term is a bit of an overstatement considering the methods being used (Mani 2001). Basically, a summary is an abreviated version of a source text, which contains the most relevant information from its source, with compression ratios ranging from 5 to 25%. Single-document summarization can even be considered a special case of *multi*-document summarization where the contents of a whole set of thematically homogeneous documents has to be transformed into one comprehensive summary (redundancy and overlap determination, resolution of inconsistencies, and temporal sequence errors then become crucial issues).

Since in-depth abstraction from the source has proved to be infeasible so far, the problem has been rephrased as a sentence extraction problem. An *extract* is then formed from sentences, which are likely to contain the gist of or crucial statements of the source document. Few types of surface indicators seem to be sufficient. Given the prevailing text genres in IR (newspaper articles and technical reports), it is no surprise that cue phrases indicating the salience of a sentence (such as 'in summary', 'our experiments have shown', etc.) or the position in which a sentence occurs (e.g. lead sentences in a journal article, the first and last paragraph of a document) are really good indicators for picking up relevant sentences for an extract, while statistically relevant terms (e.g. based on some of the statistical measures mentioned for the classical

IR approach) are less reliable but still useful. Most extraction systems vary in the degree they tune the particulars of these parameters, manually or even automatically (when considered as a machine learning task).

The field of IR has a strong experimental backing. Given soft notions such as relevance, salience, importance, which are crucial for almost all IR tasks, the accomplishment of how relevant the delivered information items really are needs quantitative assessment. Among the various quality metrics discussed in the field, two particularly relevant ones have found considerable consensus, viz. precision and recall (cf. Table 1).

The f-measure (cf. Table 2) is a convenient way to combine the effects of recall and precision, allowing the designer to stress the impact of either one of these (via the weights α and β) depending on the experimental setting.

While all the above-mentioned tasks deal with *textual* data only, a real challenge to IR will be the increasing amount of *multimedia* data. This includes audio (speech, sounds, music), graphics (tables, formulae, graphs, images, animation), and video data (movies),

TABLE 1   Precision and Recall Metrics

Precision	:=	$\dfrac{\#relevant\ items\ retrieved}{\#items\ retrieved}$
Recall	:=	$\dfrac{\#relevant\ items\ retrieved}{\#relevant\ items\ in\ the\ collection}$

TABLE 2   F-Measure

F-measure := $\dfrac{(\alpha \times Recall) \times (\beta \times Precision)}{(\alpha \times Recall) + (\beta \times Precision)}$

for which only modest progress has been made so far. With the WWW becoming the prime information exchange platform for information seekers, additional linguistic challenges come up associated with the multilinguality of the Web. In this area, a distinction is made between *cross-language retrieval* (a native-language query is processed on many other languages, too, although the results are original documents in various foreign languages) and *multilingual retrieval* (in this case, hits are, usually roughly, translated to empower the searcher to assess the relevance of a document and, possibly, arrange for a detailed high-quality translation, if the document is really relevant).

Interpreting

In interpreting, a spoken message or text in the original ('source') language is converted into a spoken message or text in another ('target' or 'receptor') language. Interpreting and written translation have certain similarities, but the on-line, more directly interactive nature of most spoken text gives spoken interpreting specific features.

Three key variables in interpreting are time lag, physical/professional setting, and language direction. Looking first at time lag, the crucial difference is between consecutive and simultaneous interpreting.

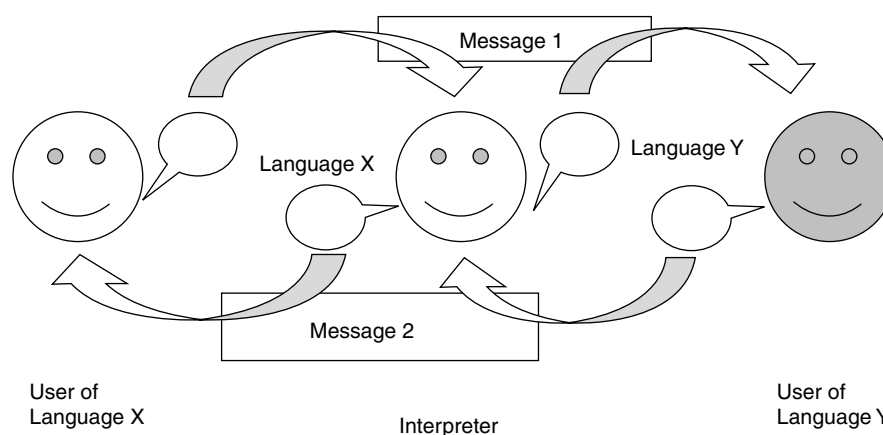
In consecutive mode, the interpreter hears the source text or a section of it (e.g. one speaker's turn, as with Message 1 in Figure 1); the source speaker then stops


Figure 1

speaking, and the interpreter delivers a translated version to the target listener. While listening, interpreters can use strategies such as note-taking and mnemonics to remember source text data, and they have time to work out the text structure (e.g. whether the first sentence contains a preamble or the main point). Good interpreters will pass on all information contained in the source message, but they are unlikely to produce a 'literal' translation. Just as 'normal' listeners, after a certain delay, remember the meaning of a message rather than exact wording or grammar, consecutive interpreters use memory of meaning to construct the target message; thus, 'places like Thailand, Malaysia, Indonesia, and Vietnam' might be translated as 'Southeast Asian countries' (see Figure 1).

In simultaneous interpreting, interpreters produce a target text while the source text is coming in: once they have received a translatable source-text segment, they pass it on in the target language while listening to the next source-text segment. The translatable segment is typically a meaning-based unit a couple of phrases long: e.g. '// the government maintains that // BSE, or 'mad cow disease', // is of no danger to the public. //' Simultaneous interpreting thus requires two closely related subskills: divided attention, i.e. the ability to pay attention to both the incoming and the outgoing message, and multitasking, i.e. the ability to perform several tasks simultaneously. The key tasks to be done simultaneously (see Figure 2) are as follows:

- Analyzing and comprehending the incoming source-language segment, fitting its information into an emerging picture of sentence and overall source-text meaning, discourse structure, speaker attitude, etc., and holding the meaning in short-term memory.
- Planning and producing the target-language segment according to the previous source-text segment and to the emerging sentence and whole-text structure.

- Monitoring (closely scrutinizing) the emerging target text and, if necessary, repairing it (correcting, e.g. inserting 'I'm sorry, that should have been X').
- Strategies can be used to make the task a little easier. For example,
- Several segments may need to come in before one has enough information to start translating (e.g. because the source and target languages have very different sentence structures, such as English and Japanese): then, when the interpreter can finally deliver a target version, he or she does so as quickly as possible to clear working memory.
- Exploit the source speaker's pauses to deliver as much target text as possible without having to process new input.

Nevertheless, simultaneous interpreting remains a specialized and taxing skill. Becoming a simultaneous interpreter requires extensive training and practice, and even experienced interpreters cannot interpret for so long at a time (typically, 20 minutes between breaks: hence, conference interpreters often operate in two-person teams). Preparation, however, is crucial in easing the difficulty of both consecutive and simultaneous interpreting: thus, before an assignment, interpreters usually ask for documentation, drafts of speeches, etc., to be given to them in advance.

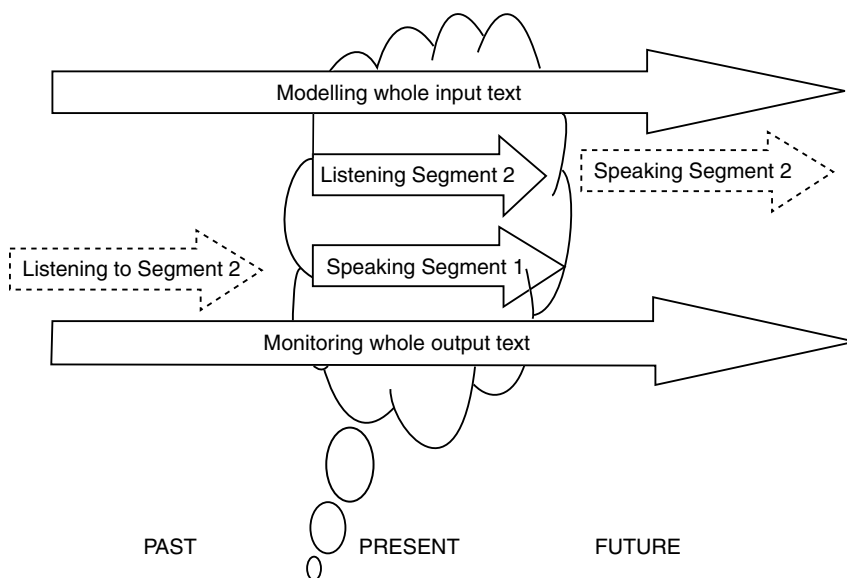
A second key variable in interpreting is the physical setting. The simultaneous interpreter is usually in a soundproofed booth, where he or she hears the source speaker through headphones and produces the target message into a microphone. Conference delegates, courtroom advocates, etc., can listen either to the interpreter through their own headphones (at conferences, switch settings may give a choice of target languages) or to the source speaker directly. With just one target-language listener, simultaneous interpreting may also


Figure 2
Figure 3

occur through *chuchotage*, where the interpreter sits close to the listener, hears the source message directly and whispers the target version into his or her ear.

In 'liaison interpreting', a consecutive interpreter enables communication between two parties—as in business or in 'community' interpreting (working with members of linguistic minorities at hospitals, with immigration authorities, etc.). The interpreter is physically present, often positioned between the two parties, and thus tends to be regarded as a fuller participant in the interaction. Usually, there is only one interpreter (see Figure 1), although sometimes—e.g. in international political talks—there may be two (one for each language direction).

In most settings—courtroom interpreting, for example—accurate rendering of source text and strict neutrality between parties are key professional ethics. In some settings (e.g. when mediating between members of different community groups, or in business negotiations), however, interpreters may see their job as facilitating communication in a wider sense. This may involve, for instance, explaining the cultural assumptions behind one party's behavior—e.g. telling a bereaved American that an Indonesian's smile indicates sympathy rather than amusement.

As for language direction, interpreters usually prefer to translate from their 'B language' (a nonnative language they know well) into their 'A language' (the language they know best—usually their native language). Research, however, indicates little difference between A→B and B→A performance with skilled interpreters (in the former, less attention is needed for source-text comprehension, and in the latter, less attention is needed for target-text production). Moreover, in some language pairs, nearly all interpreters are native speakers of one language rather than the other (e.g. most Bosnian–English interpreters are native speakers of Bosnian rather than English) and thus often find themselves having to work in both directions.

Sometimes, interpreters may not be available for a certain language pair (e.g. at a conference with English, Spanish, and Japanese as working languages, there may be no Spanish-Japanese interpreters). Then, 'relay interpreting' may take place, for

example, a Spanish speech is interpreted into English, and the English version is interpreted into Japanese; see Figure 3.

Irony

The word *irony* comes from the Greek *eironeia* ('pretense, dissimulation'), as does the history of its definition and analysis. Irony is seen as a trope (i.e. a figure of speech) in ancient rhetorics, and this analysis has remained essentially unchallenged until recently. In the traditional definition, irony is seen as saying the opposite of what one means. This definition is demonstrably incorrect, because a speaker may be ironic but not mean the opposite of what he or she says, as in 'It seems to be a little windy' (uttered in the middle of a violent storm), in which the speaker is saying less than what is meant. A recent and fruitful restatement of the irony-as-trope theory has been presented by H. Paul Grice, who sees irony as a linguistic structure with only implied meaning, which puts a significant burden on the listener, who has to decode the implication. Broadening the definition to, for example, 'saying something while meaning something else', runs the risk of obliterating the specific difference between irony and other forms of figurative or indirect speech. Despite the problems with the idea of 'oppositeness', approaches to irony as negation have been presented. Speech-act approaches to irony see it as an insincere speech act. Other approaches to irony include the 'tinge' theory, which sees irony as blending the two meanings (the stated and the implied ones) with the effect of attenuating the ironic one.

A very influential approach to irony is the mention theory (Sperber and Wilson 1981), which claims that an utterance is ironic if it is recognized as the echoic mention of another utterance by a more or less clearly identified other speaker. Furthermore, the ironic statement is critical of the echoed utterance. Similar theories based on the ideas of 'pretense' and 'reminder' have been presented as well. Criticism of the mention

theory notes that not all irony seems to be interpretable as the echo of someone else's words and that an admittedly rarer, nonnegative, praising irony exists. An example of the latter is the utterance 'Sorry to bother you' before the announcement of excellent news (e.g. winning the lottery).

All the theories of irony mentioned so far (except mention theory, which is presented as a direct access theory; see below) share the idea that the processing of irony is a two-step process in which one sense (usually assumed to be the literal meaning) of the utterance is accessed and then a second sense of the utterance is discovered (usually under contextual pressure). Thus, in a Gricean account of irony as implicature, the hearer of an utterance such as 'That was smart' (uttered as a description of clumsy behavior, such as spilling one's wine on someone's clothing) will first process the utterance as meaning literally roughly 'This behavior was consonant with how smart people behave.' This interpretation will then be discarded in favor of the implicature that the speaker means that the behavior was *not* consonant with how smart people behave. This account has been challenged recently by 'direct access' theories.

The direct access theories claim that the hearer does not process the literal meaning of an ironic utterance first and access only later the figurative (ironic) meaning. They claim instead that the literal meaning is accessed either not at all or only later. Direct access interpretations of irony are directly at odds with the traditional interpretation of irony as an implicature. Some results in psycholinguistics have been seen as supporting this view (Gibbs 1994). The mention theory of irony is a direct access theory. Other researchers have presented contrasting views that support the two-step

approach, although not always the claim that the literal meaning is processed first: claims that interpretations are accessed in order of saliency or in parallel have been put forth.

Psycholinguistic studies of irony have focused on children's acquisition of irony, progressively lowering the age at which they understand it to under 10 years. These studies focus on the neurobiology of the processing of irony, emphasizing the role of the right hemisphere alongside the left one, in which most language processing takes place, and the order of activation of the various meanings in the ironic text.

Considerable attention has been paid to the optional markers of irony, i.e. indications of the speaker's ironic intent through, primarily, intonation and body language. Although several phonological (sound) features have been considered 'markers' of irony, it seems that none is exclusively a marker of irony.

Recently, the social and situational context of irony, as well as its pragmatic ends, have begun being investigated in sociolinguistics and discourse/conversation analysis, and also in psycholinguistics. Work on the social functions of irony has found a broad range of functions, including in- and out-group definition, evaluation, aggression, politeness, verbal play, and many others. It is possible that the list may be open ended. Work on the reception of irony by its audience is also beginning to appear.

It should be noted that the term *irony* is also commonly used to describe 'situational' irony (i.e. irony of facts and things entirely dissociated from their linguistic expression), such as a fire station burning to the ground, Socratic irony, romantic irony, and even a type of religious experience (Kierkegaard). Although there may be connections between situational and verbal irony, it does not seem that literary and religious uses can be fruitfully explained in terms of linguistic irony. Other definitional problems include the purported distinction between irony and sarcasm. Although some have argued that the two can be distinguished (for example, irony can be involuntary, whereas sarcasm cannot), others maintain that no clear boundary exists. Another unresolved issue is the connection between irony and humor. It is clear that the two overlap significantly, but also that they differ: not all irony is humorous, and not all humor is ironic.

Israel

One does not ordinarily speak of 'miracles' in linguistics, and with good reason. However, if any event in linguistics and language history deserves the name 'miracle', it is the rebirth of the Hebrew language in modern Israel. Languages, once dead, do not normally rise again from the dead. This the Hebrew language did.

True, Hebrew was never completely dead; it is more accurate to speak of the 'revival' of the Hebrew language rather than its rebirth. Rabbis and learned men never ceased to use Hebrew for high purposes long after it had declined as the spoken language of the Jewish people; it was always the language of prayer

for observant Jews; it served to some extent as a lingua franca among Jews from different countries. But for over a millennium and a half until toward the end of the nineteenth century, Hebrew was virtually nobody's first language. It was a language acquired in adolescence and adulthood by at most a minority of Jewish males, by Jewish females almost never because of religious strictures. Today, it is a language like any other—that is to say, a language spoken by ordinary people going about their everyday activities and acquired in the usual way: by learning the language in infancy.

Hebrew is a member of the Semitic family of languages, to which Arabic and Amharic and extinct languages such as Aramaic and Phoenician also belong. It is written from right to left in what is essentially a consonantal script. Semitic languages are organized around the principle of the root: roots have a basic meaning expressed by means of, usually, three consonants. The Semitic root *SLM* elucidates the principle. Its basic, abstract meaning is 'peace', and from it are derived such words as Arabic *SaLaaM*—the greeting (in essence 'peace be with you', cf. Hebrew *ShaLoM*. Consider also *iSLaM* and (m)*uSLiM* and the proper names from Jewish history such as (Hebrew) *SoLoM*(*on*) and *SaLoMe* or (Arabic) *SuLeiM*(*an*). The reader of Arabic or Hebrew recognizes that the basic 'meaning' of the word or name is carried by the root structure *SLM*. The common semantic intersection of these and other words formed with the three consonants *SLM* is 'peace'.

Normally, Semitic words are written without vowels. This is possible because the context suggests the range of readings of a given word in print and because there are rules of grammar that help the reader know what vowel is to be supplied. In Hebrew, for example, the word *spr* consisting of three letters can be read /safar/ 'he counted', /siper/ 'he told', /supar/ 'it was told', /sapar/ 'barber', /sefer/ 'book', and /sfar/ 'frontier'. (In Hebrew, the same letter is used for /p/ as for /f/.) 'Full spelling', in which diacritic marks are used to indicate the vowel, can be used in Hebrew but normally is not. The reader simply has to know from context and native linguistic knowledge of the language which reading is the correct one. In Hebrew, vowel marking is used principally in pedagogical materials, children's books, Biblical texts, poetry, and dictionaries.

Israel, earlier called Palestine, has always been an area of intense historical and linguistic collisions with aftershocks extending far beyond the tiny piece of soil that the country actually encompasses. It was the birthplace of two major world religions, Judaism and Christianity, always a country pulled this way and that and culturally enriched successively by Jews, Greeks,

Romans, and Arabs, only to name the principal players who came on and off the Palestinian stage during its long history. The languages of all its occupiers contributed to a multilinguistic profusion and vibrancy that is preserved in the linguistic pluralism of present-day Israel.

Hebrew was the common language of the Jewish people—the everyday spoken language of the people of the kingdom of Judah—from around 1000 BCE and thus is at least 3,000 years old. It was the language in which most of the Jewish Bible (called in Christian usage the Old Testament) was written (the 'New Testament' of Christianity was written in Greek, not Hebrew). However, another Semitic language, Aramaic, was used for legal and official purposes by priests and officers of the court. In 800 BCE, most of the Jews of Palestine were forced into exile—the Babylonian Exile. Seventy years later, when Jews were permitted to return to their ancestral land and most did, the linguistic situation in Palestine had begun to shift dramatically. Aramaic had descended from the court to the marketplace, and it developed rapidly among both Jews and non-Jews as the major vernacular language in the Middle East, a position it maintained until well into the Common Era when Arabic took its place. Jews for the most part became bilingual in Hebrew and Aramaic, and from this time forward the days of Hebrew as the spoken language of everyday life were numbered. Jesus of Nazareth spoke Palestinian Aramaic as his native tongue.

When the Holy Land came under Greek dominion, the Jewish upper classes increasingly became 'Hellenized', meaning that they adopted Greek cultural practices and the Greek language. As Palestine passed from Greek into Roman hands, Latin also became a language that upwardly mobile Jews had to learn. Thus, by the beginning of the Common Era, bilingualism (Aramaic/Greek or Aramaic/Hebrew) was common, trilingualism (Aramaic/Greek/Hebrew or Aramaic/Greek/Latin) not uncommon, and the Jerusalem Talmud—the Talmud is the body of authoritative Jewish tradition and commentary comprising the Mishnah and Gemara—states that 'four languages are of value: Greek for song, Latin for war, Aramaic for dirges, and Hebrew for speaking'. Monolingual Hebrew speakers carried on only in remote villages in southern Judea. By the second century CE, Hebrew had become so precarious as a spoken language that we find rabbinical injunctions that fathers should speak Hebrew with their sons, a certain sign that most fathers were not speaking Hebrew with their sons.

Although Hebrew receded as spoken vernacular, it retained its significance as the language of the Bible—holy, sacred, divine—and both Aramaic and Hebrew are joined in the Hebrew designation *leshon hakodesh*,

meaning 'the language of sanctity'. To this day, Aramaic is the language in traditional Judaism of legal instruments such as a divorce decree (*get*) and the marriage contract (*ketuba*). Bilingualism in Hebrew and Aramaic is implicit in the transmission of traditional Judaism.

What is known as the Jewish Diaspora began with the destruction by the Romans of the Second Temple in 70 CE. As Jews spread out from their ancestral homeland into Europe and the lands bordering the Mediterranean, like all emigrants to foreign lands, they began to speak the language of the country in which they had settled during the early and medieval periods of our millennium. Jews in Spain spoke medieval Spanish—perhaps an identifiably Jewish variant of Spanish in some cases, but Spanish nevertheless. Jews in France spoke Old French or, again, possibly a Jewish dialect of Old French. Jews living along the Rhine and Danube rivers in Germany spoke Middle High German—the German of 1050 to 1350 CE—of one kind or another, probably always with a Jewish flavor and accent.

When the Jews were expelled from Spain in 1492 they settled for the most part around the Mediterranean Sea—in northern Africa, Italy, Greece, Turkey—but the language they carried with them was Spanish. In time, their Spanish changed and developed into the language now usually called Ladino (the usage is not settled: one also finds 'Judeo-Spanish', 'Judezmo', 'Dzhudezhmo', and 'Spaniolish'): it is Spanish with admixtures from Hebrew and the languages of the lands to which the Spanish emigrants had fled. Many of these Jews gave up their ancestral Spanish altogether and acquired the language of the country to which the winds had blown them. This branch of the Jewish people is called the *Sephardim* from the medieval Hebrew word for 'Spain'.

A different set of language choices obtained among the Jews, who had settled during the Diaspora from the Holy Land in western Europe north of the Pyrenees, primarily in Germany. These Jews are called the *Ashkenazim*, after the medieval Hebrew word for 'Germany'. Until the eleventh century CE, Jews had lived in France, Germany, and England in relative peace and security. They were technically, if often only notionally, under the protection of the Holy Roman Emperor. This changed terribly for the worse with the onset of the Crusades in 1096. What began as a war against the 'Saracens'—'Arabs', 'Turks', later 'Moors'—to reclaim the holy sites of Christianity rapidly became a war against 'unbelievers' of every stripe, and hence Jews were expropriated and massacred and expelled until finally there was nothing left for them but wholesale emigration away from the troubles. In practical terms, this meant fleeing to Poland and other countries of central and eastern Europe, where there was at the time little anti-Jewish sentiment and where Jews were welcomed for economic reasons. There was no sanctuary in the west. The language the fleeing Jews carried with them was medieval German, which on the soil of eastern Europe and in isolation from the German language in Germany, developed into the language for which the preferred designation is Yiddish (earlier 'Judeo-German').

Yiddish is written in the Hebrew alphabet, like Ladino and virtually all Jewish languages, but is some 80% German in vocabulary, 15% Hebrew, and 5% Slavic and other languages. The marginal vocabulary of Yiddish depends on where the Yiddish language is spoken—American Yiddish has borrowings from American English, French Yiddish from French. However, the basic language structure of Yiddish is Germanic through and through.

Yiddish is one of the many languages that have always suffered from inferiority complexes. Because, although it shared ancestry with German, it had developed in ways different from the standard German language, Yiddish was condemned by some as 'bad German'. Others argued, especially with the spread of Zionism in the late nineteenth and early twentieth centuries, that Jews should return to their ancient ancestral language, Hebrew, that only this ancient ancestral language could unite Jews from all parts of the world in a common quest for security and a place of their own. Still others argued for assimilation: Jews living in Poland should speak Polish, Jews living in America English, Jews living in Russia Russian, and so on.

Every place that Jews have lived they have developed 'Jewish' variants of the local language. Thus, we have Yevanic (Judeo-Greek), Dzhidi (Judeo-Persian), Judeo-Georgian, Judeo-Tat, Judeo-Tunisian Arabic, Judeo-Iraqi Arabic, and many others. In the medieval era, there was Laaz (Judeo-French) and Knaanic (Judeo-Slavic). These languages, to the extent that they still are spoken, are generally on the list of endangered languages. Ladino and Yiddish stand out among 'Jewish languages' because they are the two best known with the most extensive literatures and the largest numbers of speakers—at least until the World War II destroyed most of European Jewry. The number of speakers varies widely. In Israel today, there are estimated to be some 200,000 speakers of Yiddish, 100,000 speakers of Ladino, 250,000 speakers of Judeo-Moroccan Arabic, 60,000 speakers of Dzhidi, and 35 speakers of Yevanic. These Jewish 'legacy' languages are in addition to languages still spoken by some Israelis such as Bulgarian, French, German, Hungarian, and English. Very few people would be monolingual in one of the Jewish heritage languages,

almost all would be fluent to some degreee in Hebrew. Fluency in Hebrew has had the highest priority since the creation of modern Israel in 1948.

Hebrew remained dormant through the centuries, its use confined largely to the written form of the language, especially among the rabbinate and in the synagogue. However, it never ceased to be a written language. People whose cradle language had been anything in the world but Hebrew composed substantial works in the language, often elegantly and with originality. Every Jewish boy had to learn Hebrew in the Hebrew alphabet—well or badly, as is true today—in order to become *bar mitzvah*, signifying that he had reached his thirteenth birthday and had, therefore, attained maturity and had reached the age of religious duty and responsibility. Females did not have a coming-of-age ceremony in traditional Judaism and thus were largely illiterate in Hebrew. 'Literacy' is, of course, not nearly the same as 'fluency': to be literate simply meant that religiously observant Jewish males could read Hebrew. Jewish languages like Yiddish and Ladino, indeed virtually all Jewish variants of languages, were and are written in Hebrew characters. This goes back to the widespread literacy of Jews in Hebrew—of Jewish males at least—during the 'Dark Ages'.

The revival of Hebrew as a secular written language began during what is known as the Jewish Enlightenment (*Haskalah*) in the eighteenth century. Talented writers began to write in the language, play with it, revivify it, although they often wrote in Yiddish as well. The revival of Hebrew as a spoken language began in small steps in the late nineteenth century. One of the main reasons, ultimately, was anti-Semitism. Ill treatment of Jews—pogroms, discrimination—was on the increase in eastern Europe and Russia, and even western Europe, where since Napoleonic times the legal situation of Jews had improved considerably, was not immune. The Dreyfus Case in France, in which a Jewish officer, Alfred Dreyfus, was falsely accused of espionage and condemned to a harsh imprisonment on Devil's Island simply because he was Jewish, laid bare how thin the veneer of civility was when it came to being Jewish even in supposedly enlightened western Europe.

The darkening clouds over Jewish life in Europe led to the *Hibbat Zion* movement ('Love of Zion') and to the Zionist movement itself, founded by the Austrian Jewish journalist Theodor Herzl, which called for the creation of a Jewish homeland. Jews began to leave eastern Europe and settle in largely agricultural settlements in Palestine that they had purchased or leased from Arab or Turkish landowners. (Palestine was then part of the Ottoman Turkish Empire.)

The first wave of immigrants arrived between 1882 and 1903 (called the *First Aliyah,* or first 'homecom-

ing'). *Aliyah* brought a renewed interest in spoken Hebrew, and in the newly regained ancestral land, schoolteachers and families here and there began to use spoken Hebrew. Eliezer Ben-Yehuda (1858–1922) was one of the leaders in the movement, but it is a myth that he single-handedly brought about the revival of spoken Hebrew by refusing to speak anything else with his family. The movement was slow in the beginning. Competition from traditional Jewish Diaspora languages such as Yiddish and Ladino was stiff, not to mention French and German in the schools, and it has been estimated that by 1904 there were only about 20 Hebrew-speaking families in Palestine.

The movement accelerated with the *Second Aliyah* (1904–1906). Waves of *po'alim* 'workers' arrived, and they soon had established Hebrew-medium high schools (*gymnasia*) and teachers' seminaries to cater to the growing commitment in the Jewish population of Palestine to the resurrection of spoken Hebrew. The movement fed upon itself. To speak Hebrew was to assert that one belonged to the worldwide community of Jews and was a proud member of that small but growing band of Zionist pioneers who had returned to the ancestral home. The larger the number of Hebrew-speaking students coming out of the school system, the greater the demand for entertainment and reading material in Hebrew—plays, novels, newspapers. By 1916–1918, some 40% (34,000 of 85,000) Jews in Palestine recorded Hebrew as their first language.

The problems of bringing an ancient language up to the complexity of modern life were enormous. Words had to be invented for chicken pox, coffee, opera, electricity, idealists, billiard cure, mailman, and so on. Phrases not found in the Bible had to be devised: all right, I'll do it; make it brief; at your service. What was the correct pronunciation of Hebrew? Sephardic and Ashkenazic traditions differed, for example David vs. Dovid, Shalóm vs. Shólem 'hello'. As a rule, the Sephardic pronunciation prevailed. By the 1920s, a majority of the Jews living in Palestine spoke Hebrew, although this represented a tiny minority of the world's Jewish population, and the only ones who spoke it fluently were the *sabras*, the Israelis who had grown up with it.

After World War II had savagely reduced the world's Jewish population from some 11,000,000 to around 5,000,000, Jews emigrated in large and growing numbers to Palestine, and in 1948 the new country of Israel gained its independence from the British. The question was: what should the language of the new country be? Other things being equal, Yiddish would have been the leading candidate since most of the eastern European Jews who had survived the Holocaust and managed to get to Palestine were speakers of Yiddish. Yiddish, however, suffered from

various disabilities, one of which was that it was stigmatized as the 'language of the ghetto'. It was thought of as a victim's language. No language besides Hebrew could possibly do for the new Israel— not English, not Yiddish, not Ladino. Hebrew linked the Jewish past and the Israeli future as no other language could. Hebrew was a sublime symbol of hope, of aspiration—not only of Jewishness but of a muscular strain of Jewishness that would never allow another Holocaust to happen to its people: *Never Again*! became the rallying cry of modern Jewish pride and militancy. The Hebrew language is its symbol, its icon.

As unique an event in the annals of linguistics as the revival of the Hebrew language was, it is only part of a much larger story of linguistic legacy. If the revival of the Hebrew language in Israel was a miracle, it was part of a greater miracle: the preservation of Jewishness through centuries of discrimination, massacre, and oppression. All of the languages of Israel— Hebrew, Aramaic, Yiddish, Ladino, and all the other 'Judeo-X' variants—are part of the Jewish legacy, and all have contributed to the preservation of Jewish ethnicity from the days when Moses led his people out of Egypt into freedom in The Holy Land.

ROBERT D. KING

Italian

Italian (*Italiano*) is a Romance language spoken by more than 65 million people in Italy (including Sardinia and Sicily), Vatican, Malta and Corsica, Southern Switzerland (where it is one of the four official languages), San Marino, Istria, on the Northeastern shore of the Adriatic Sea, in the former Italian colonies of Libya, Somalia, Eritrea and Ethiopia, in Tunisia, Egypt, and Greece. It is also quite spread in the whole Mediterranean area, and is spoken by the large immigrant communities in the Americas, especially in the United States and Argentina, in Canada, North Africa, and Australia.

The earliest known written materials in Italian date from the tenth century; more precisely, a document in the Archives of Montecassino, dated year 960, contains a whole sentence, repeated four times, that is practically Italian vernacular. The first literary work of length is the *Ritmo Laurenziano* (Laurentian Rhythm), a *cantilena* in praise of a bishop by a Tuscan, of the late twelfth century.

Standard Italian is essentially based on the Tuscan dialect, which was adopted first as the literary and then as the official language for the whole Italian geographic region. The reason for this choice was that in the fourteenth century, Dante Alighieri, Francesco Petrarca, and Giovanni Boccaccio wrote their masterpieces using this Italian dialect; more precisely, the Old Florentine dialect of Tuscan, and their works became genuine models of grammar. Their impact was so strong that, even if later in the nineteenth century the dialect of Rome started gaining considerable prestige, it could never equal the Florentine's one.

Apart from the Standard Italian, there are a number of distinct dialects spread along and across the Italian-speaking territories. Some of them are very close to the national language, such as those from Tuscany, Northern Latium, and Umbria, while other dialects are more remote, such as those in the Northern and Southern Italy, as well as those in the isles.

This diversity is mainly due to the individuality of various parts of the territory, which determined that the distinctiveness of a certain region be preserved, both in the case of pre-Latin population, coming from different areas and speaking different languages, and in the case

of present-day populations living in different parts of the country. Another factor that contributed to the individualism of various geographical dialects was the barbarian invasion in the High Middle Ages, which brought new elements into the already shaped language varieties, and, of course, the fact that the political unification of Italy occurred only late in the nineteenth century.

The main groups of Italian dialects are: the Northern dialects, the Central-Southern dialects, and the Sardinian group—the last one considered by some linguists as an entirely different language. The so-called 'Spezia-Rimini line', a dividing line that runs East–West across the territory, separates the first two groups.

The Northern dialects constitute two major subgroups: the Venetian (also called Venetic) dialects, containing the Venetian proper and the Trentino dialects, and the Gallo-Italian dialects, containing the Piedmont, Liguria, Lombardy, Emilia, and Romagna dialects, all of which display a close affinity to French in their pronunciation and truncated terminations.

The Central-Southern dialect groups include the subgroup of the Tuscan dialects, consisting of the Florentine, Arezzo, Cortona, Pisa, Livorno, Lucca and Siena dialects, the subgroup of central dialects, including the Modern Roman, Lazio, Umbria, Southern Marche, Corsican, and Northern Sardinia dialects, the subgroup of the Southern dialects, further subdivided into the Neapolitan dialects and the Sicilian ones, and the subgroup of the Southern and Southeastern dialects, containing the Abruzzi, Naples, Campania, Lucania, Calabria, Otranto, and Sicily dialects.

The last group lists the most distinct dialects, i.e. Ladin, Sardinian, and Istrian. Around 60% of the population can speak the national language, but most of them usually speak a local variety. And, given the communication problems between different dialects, most of the population is now at least 'bilingual', although the proper term would be 'bidialectal'.

The Italian alphabet is: a b c d e f g h i l m n o p q r s t u v x z; j, k, w, and y are only used in foreign words, but j can also be found in some proper names in old writings.

In general, all letters are pronounced in Italian, with the exception of *h*. The letter *c* is pronounced /k/ when preceding *a*, *o*, and *u*, but /t ʃ/ when it is followed by *e* and *i*. The same rule applies to the letter *g* denoting its voiced counterpart. *G* is pronounced as /g/ before *a*, *o*, and *u*, but as /dʒ/ before *e* and *i*. The consonant cluster *gg* is also pronounced /dʒ/ before *e* and *i*. *Z* and *zz* are generally pronounced either /t ʃ/ or /dʒ/. *Sc* before *e* and *i* is pronounced /ʃ/.

The sound system of Italian is quite similar to that of Latin or Spanish. Italian has five vowels /ʌ, ɛ, ɪ, ɔ, ʊ/ and four semivowels: /j, e, o, w/, as well as 21 consonants: /p, b, m f,v, t, d, n, s, z, ts, l, r, ʃ, tʃ, dʒ, k, g, h, ɲ, ʎ/.

It is possible in Italian to have double consonants. Usually, there is an opposition between single and double consonants, as in: *eco* 'echo' vs. *ecco* 'here is', *rupe* 'rock' vs. *ruppe* 'he broke', where the double consonants are clearly pronounced.

Intonational stress in Italian generally falls on the next to last or third from last syllables, but it may range freely over the last three syllables of the word. The Italian orthography marks in writing the grave (`) and the acute (´) accents, which are usually used to distinguish otherwise similar-looking one-syllable words, e.g. *se* 'if' vs. *sè* 'oneself', *e* 'and' vs. *è* 'he is', and to indicate stress on the final vowel in polysyllabic words, e.g. *perchè* 'because', *così* 'so'. The circumflex accent (^) was reserved to poetry and it was used to mark either the ellipsis of a syllable in polysyllabic words, or the contraction of two adjacent vowels in a word.

The punctuation of Italian is rather simple. The main differences from English are that the dash (–) is commonly used to mark the exchange of dialogue, instead of inverted commas, or marks and additional comment, instead of brackets. Also, in the case of indirect questions, Italian does not use the question mark. The capitals are less used than in English. Italian does not use capitals for the names of the months, for the days of the week, for the names of the languages, for adjectives referring to a nation, or individuals belonging to a nation, e.g. *il popolo italiano* 'the Italian people', *due italiani* 'two Italians'.

As a direct offspring of the Latin language, Italian displays a Latin-based vocabulary. The greater part of the Italian vocabulary (or lexis) is formed by Latin words that are either directly or indirectly inherited from Latin, or borrowed from a certain Italian dialect. However, in the course of centuries, several foreign languages have influenced the Italian vocabulary. These languages are French, Spanish, English, German, and Arabic. The French influence is most obvious especially in the territory of the Gallo-Italian dialects, but it is not restricted to it. French have influenced the Italian language over a very long period, and the French loan words entered both the everyday language—some basic terms as *mangiare* 'to eat' and *giallo* 'yello' are borrowed from French—and the more technical jargons—*approccio* 'approach', *destriere* 'charger'. The Spanish influence imposed terms like *toreador, bolero* and, nowadays, *goleador*. The English influence was noticeable in the eighteenth and nineteenth centuries, but it was much more prominent in the twentieth century. However, given the influence of the nationalist movement in the politics during the Fascist period, many English loans have been replaced with Italian counterparts, while others changed their original meaning. Germanic exerted its influence as a result of the Teutonic conquests, predominantly in the contact area of Lombardy. The Arabic influence was most important in Sicily and Southern

Italy, and it was a result of the Saracenic invasions. Some of the most common Arabic words are *albicocco* 'apricot', *ragazzo* 'boy', and *zecca* 'mint'.

In turn, Italian has exerted its influence on the languages of Western Europe, especially on English, French, Spanish, German. Some of the English words of Italian origin are: *balcony*, *bandit*, *broccoli*, *casino*, *gondola*, *incognito*, *inferno, lava*, *macaroni*, *malaria*, *opera, spaghetti*, *studio*, *umbrella,* and *volcano*. Most of the words imposed in different languages are in the field of literature, art and, of course, music. In this respect, it must be mentioned that the contemporary musical terminology all over the world includes Italian words like *allegro*, *andante*, *aria*, *concerto*, *crescendo*, *libretto*, *maestro*, *oratorio*, *piano, quartet*, *solo*, *sonata*, *soprano*, *tempo*, and *virtuoso* almost.

The Italian grammar is similar to that of the other modern Romance languages.

The nouns have distinct inflected forms for gender and number. Most Italian nouns end in a vowel, while those ending in a consonant are usually borrowings from a foreign source, e.g. *il bar* 'pub'*, lo sport* 'sport'*, il film* 'movie'. Generally, nouns ending in *-o* are masculine, nouns ending in *-a* are feminine, while those ending in *-e* may be either masculine or feminine. The foreign borrowings ending in a consonant are generally considered to be masculine. The nouns change their vowel endings from singular to plural. The masculine nouns have a plural ending *-i,* while the feminine nouns have a plural ending either in *–i,* when their singular form ends in *–e,* or in *–e,* when their singular form ends in *–a*. A number of masculine nouns have two distinct plural forms, one for the masculine gender and one for feminine gender, each of them with its own, distinct meaning: e.g. *il membro* 'member' – *le membra* 'limbs', *i membri* 'members'; *il braccio* 'arm' – *le braccia* 'arms' (of a body), *i bracci* 'arms' (of an object). Some nouns have an irregular feminine form. In this case, it is quite common for some speakers to use only a masculine form of the nouns instead of the irregular feminine forms: *il ginocchio* 'knee' – *le ginocchia* or *i ginocchi* 'knees'.

In Italian, articles and other modifiers may accompany the noun and usually their forms agree with the form of the noun in the categories of gender and number: e.g. *il riso* 'the laughter'*, la moglie* 'the wife'.

The article forms are chosen according to the sound of the initial letters of the word it precedes. In the case of invariable nouns, the article helps to identify the categories of gender and number of the respective nouns: e.g. *il re – i re* 'the king/s', *la gru – le gru* 'the crane/s'. Also, in the case of nouns of different gender ending in the same vowel *–e*, the article reveals the gender of the noun in question: e.g. *il monte* 'mountain' (m.) vs. *la mente* 'mind' (f.). Unlike in other languages, the plural forms of the indefinite article are rarely used. The arti-

cles can be combined with some simple prepositions, resulting in contracted forms of the definite article. The combination of the definite article with a simple preposition is labeled 'the combined preposition', e.g. *il + a* : *al, gli + di* : *degli, la + con* : *colla, le + in* : *nelle.*

In Italian, there are two groups of adjectives: those ending in the vowel *–o*, e.g. *severo,* and those ending in *–e*, e.g. *grande*. The adjective also agrees in gender and number with the noun it modifies, but it does not have the same ending: e.g. *la ragazza forte – le ragazze forti* 'the strong girl/s'. *Più* 'more', *meno* 'less' and the suffix *-issimo* are used to form the comparative and the superlative degrees: e.g. *più bello* 'more beautiful', *il più bello* 'the most beautiful', *bellissimo* 'very beautiful', *meno bello* 'less beautiful', and *il meno bello* 'the least beautiful'.

The forms of the pronouns differ according to the category of case. The Personal Pronoun for the first-person singular, for example, has different forms according to the case: *io* 'I' in the Nominative (subject) changes to *me* or *mi* '(to) me' in the Dative (indirect object) and Accusative (direct object), according to whether the pronoun is stressed or unstressed. As for their use, subject pronouns are omitted in everyday speech, and they appear when needed for emphasis or contrast. The stressed form of direct object pronouns, e.g. *me* '(to) me', *te* '(to) you', *lui* '(to) him', *lei* '(to) her' is also used for emphasis or contrast; otherwise, the unstressed forms are used, e.g. *mi, ti, lo, la.*

The possessive adjectives and pronouns have different forms to distinguish whether the possessor is the first, second, or third person, e.g. *mio* 'my/mine', *tuo* 'your/yours', *suo* 'his-her/his-hers', whether the possessor is singular or plural, e.g. *mio* 'my/mine', *nostro* 'our/ours', and, moreover, whether the possessed entity is masculine, e.g. *mio,* or feminine, e.g. *mia,* singular, e.g. *mio*, or plural, e.g. *miei*. Therefore, the possessive pronoun form *vostre* 'yours', for example, displays the following information: the possessor is a second-person plural (as 'you plural'), and the possessed entities are plural and feminine (as 'things' feminine).

The verbs are traditionally classified into three classes called 'conjugations', according to their ending in the present infinitive form: the verbs ending in *–are* belong to the first conjugation, e.g. *comprare* 'to buy', those ending in *–ere* belong to the second conjugation, e.g. *credere* 'to believe', and those ending in *–ire* belong to the third conjugation, e.g. *dormire* 'to sleep'. There are seven moods in Italian, namely Indicative, Conditional, Subjunctive, Imperative, Gerund, Participle, and Infinitive, all of them having similar functions as in English. Some of these moods have additional tenses that express different time relations, such as 'past historic', which is used for completed actions that are not related to the present, and 'imperfect', which is used for

continuous action during which some other action occurs. Some of the tenses are compound, i.e. they are made up of an additional verb, called 'auxiliary', and a specific form of the verb in question (the main verb). In general, the transitive verbs (i.e. those that take a direct object) take the auxiliary *avere* 'to have', and the intransitive (i.e. those that do not take a direct object) and reflexive verbs (i.e. the verbs with a reflexive pronoun) take the auxiliary *essere* 'to be'.

The adverbs are invariable parts of speech. Most of them are formed by adding the suffix *-mente* to the feminine singular form of the corresponding adjectives, e.g. *rapidamente* 'quickly'. While the comparative form of the adverbs follows the rules of the adjectives (see above), e.g. *più gentilmente* 'kinder way', the superlative form is always formed with *molto* plus the adverb e.g. *molto gentilmente* 'very kind way'. The adverb precedes the adjective or the adverb and follows the verb it modifies, e.g. *ha finito presto* 'he finished early'.

In the case of numerals, cardinal numerals indicate the quantity; they are invariable in form and (apart for *uno* 'one') they all go with plural nouns, e.g. *cinque studentesse* 'five students'. The Italian system of writing uses points to separate thousands and commas to separate decimals. When expressing the day of the month, except for the first day, the date is indicated by cardinal numerals, e.g. *nove marzo* 'the 9th of March'. Ordinal numerals indicate a sequence; they agree in gender and number with the noun to whom they refer. The cardinal numeral *uno* 'one' is used like the indefinite article *un, una, uno* 'a/an' and agrees with the noun to whom it refers in gender.

Suffixes play an important role in the Italian vocabulary. Italian frequently uses affective suffixes, usually related to size or emotions. In order to indicate smallness or express affection, the following suffixes are used: *-ino/a/i/e,* e.g. *mamma* 'mother' – *mammina, -etto/a/i/e,* e.g. *libretto* 'little book', *-ello/a/i/e,* e.g. *paesello* 'little village', and *-uccio, -uccia, -ucci, -ucce,* e.g. *caruccio* 'quite expensive'. On the other hand, to denote largeness, the suffixes used are *-one/-ona, -oni/-*

one (plural): e.g. *librone* 'big book'. To convey the idea of a bad or ugly quality, the following suffixes are added: *-accio, -accia, -acci, -acce,* e.g. *ragazzaccio* 'rough boy'. To form collective nouns, the following suffixes are used: *-ame, -ume, -aglia,* the latter two also having a derogatory connotation, e.g. *pollame* 'poultry', *forestierume* 'foreign scum', *antiglia* 'old junk'. The suffix *–one* is used to denote specific agents, e.g. *imbroglione* 'cheat', *beone* 'drinker', while the suffix *–io* indicates repetitive tasks or actions, e.g. *lavorio* 'constant working', *mormorio* 'murmuring'. The suffix *–ardo* is used to form pejorative words, e.g. *bastardo* 'bastard', *vecchiardo* 'nasty old man'. Some of the suffixes, like *–accio* may also be used as independent words, e.g. *proprio accio* 'really bad'. Some of the suffixes also combine with each other, e.g. *–etto + -ino*: *librettino* 'little book', *-one + -ino*: *cartoncino* 'small card', *-etto + -accio*: *cagnettaccio* 'nasty little dog'. The suffixes may also be added to verbs, e.g. *lavorare* 'to work' – *lavoricchiare* 'to work a little', *dormire* 'to sleep' – *dormicchiare* 'to snooze', to adverbs, e.g. *beno* 'well' - *benino* 'quite well', *presto* 'early' – *prestino* 'quite early', and to personal names: e.g. *Gigi – Gigino, Peppe – Peppino, Simona – Simonetta.*

RADU DANILIUC

Italy

Italy, officially known as the Italian Republic (*Repubblica italiana*), is a country situated in southern Europe. It consists of the Italian Peninsula, two larger isles (Sicily and Sardinia), and quite a number of smaller ones. It has an area of 301,338 square kilome-

ters, counts 57,679,955 inhabitants and is divided into 20 regions (*regioni*).

The country's official language is Italian, which is a Romance language, i.e. a language developed from the spoken variant of Latin (other Romance languages are

French, Spanish, Portuguese, Romanian, etc.). However, the country is characterized by a large linguistic diversity. This diversity includes various dialects and minority languages. It is important to note that, in the case of Italy, the term 'dialect' is not intended in the way it usually is: it indicates a local variety that has rather little in common with the standard language and with other Italian 'dialects' (Lepschy-Lepschy). Actually, these varieties should be considered as an outcome of different developments from spoken Latin just like standard Italian, French, Spanish, and other Romance languages.

An explanation for this peculiar situation can be found in history: during centuries, the Italic Peninsula was a patchwork of different states that, politically, economically, and culturally, more or less differed one from another. On the linguistic scale, the only form of standardization consisted in that the speech of major centers was sometimes considered as a model to reach (Maiden). For quite a long time, Latin remained the language in religious, scientific, administrative, and judicial matters. In literature, however, there was a growing interest in the use of the regional language; the discussion, known as the *Questione della Lingua* ('Language question'), about the nature of a literary language for the Italian Peninsula ended up with the hegemony of the Florentine language, as used in the works of Dante Alighieri (1265–1321), Francesco Petrarca (1304–1374), and Giovanni Boccaccio (1313–1375), and described in Pietro Bembo's grammar *Prose della volgar lingua* (1525).

It was only in 1861, after the movement known as *Risorgimento* ('Resurrection'), that the country was politically unified. At that time, the writer Alessandro Manzoni (1785–1873) had already been confronted with the lack of a national language. For the third version of his famous novel *I promessi sposi* (1840, 'The Betrothed'), he had deliberately chosen the contemporary speech of the cultivated Florentine classes, since literary Florentine missed vocabulary to allow him to write about everyday life. Although Manzoni's novel aimed and obtained national spread, it was rather the literary variant that was diffused in the newly unified country (Maiden), where, around 1861, only a very small part of the literate population had a thorough command of the standard language. Despite the political unification, the linguistic unification took place rather slowly in its beginnings. However, it was boosted by a number of external factors, such as national education, the rise of mass media, general conscription, migration, and urbanization (De Mauro).

Research executed by the Italian opinion investigation institute Doxa in 1991 shows that 12.8% of the country's population claims to use 'dialect' in all or nearly all situations, while 33.6% speaks standard Italian on every occasion. However, most Italians use alternatively their proper 'dialect' and the standard language, depending on the communicative situations they are in (e.g. familiar discussion vs. formal discourse). With regard to this state of affairs, one could think of using the terms bilingualism or diglossia. It seems that, as far as Italy's standard languages and 'dialects' are concerned, the term diglossia is the most appropriate, although Ferguson's definition does not match exactly the Italian situation. Anyway, nowadays, the very large majority of Italy's inhabitants are able to express themselves in standard Italian. Apart from everyday speech, 'dialects' can also be used in literary works and for the major 'dialects', there are translating dictionaries from and to standard Italian.

As for the classification of the different 'dialects', important divisions can be made, but it should be borne in mind that on the geographical plan, the 'dialects' gradually blend into one another and that most distinct borders represent, in fact, gray zones of transition.

Traditionally, three major groups are identified:

—northern 'dialects'
—Tuscan 'dialects'
—central and southern 'dialects'.

It is considered that an imaginary line between the cities of La Spezia and Rimini delimitates the northern zone from the central and southern 'dialects', Tuscan 'dialects' (also situated below the La Spezia-Rimini line) occupying a specific position. This line roughly delimits a number of more or less general features, but it should be clear that these are abstractions and that a large variation exists within each of the 'dialect' groups. In any case, the 'dialects' closest to standard Italian are the Tuscan ones.

In addition to the so-called 'dialects', one can find, in some regions of Italy, other varieties different from standard Italian. These varieties (among which the most important are Sardinian, Friulian, and Ladin) developed from spoken Latin, just like standard Italian and Italian 'dialects'. Their status, however, has been a matter of discussion for quite a long time. Nowadays, most scholars refer to them by using the term 'languages' rather than 'dialects'.

Due to its geographical isolation, the language of the isle of Sardinia is considered as the most conservative of Romance languages, i.e. closest to Latin. Nevertheless, it should be stressed that there is no such thing as a standard Sardinian language: several varieties exist, and they are traditionally classified into four groups (speech of the Logudoro, the Campidano, the Gallura, and of Sassari). As the spread of a national language after 1861 also reached Sardinia, standard Italian is used on most formal occasions. However,

Sardinian varieties are spoken by about 1.2 million people nowadays (Klinkenberg), mostly in informal contexts. Therefore, the term bilingualism (when Sardinian is considered to be a language) and diglossia (when it is regarded as a dialect) is also used in the case of Sardinia.

Friulian and Ladin are two languages spoken in northern Italy. Friulian is spoken in parts of the autonomous region of Friuli-Venezia Giulia. The use of Ladin is limited to a number of valleys in Alto Adige (or South Tirol, part of the autonomous region of Trentino-Alto Adige, see map). Both languages are closely related to Romansh, one of Switzerland's four official languages, and have characteristics in common with northern Italian 'dialects'. Yet, like Romansh, they each represent one of a series of 'dialects'. In the case of Friulian, the variety from Udine and environs is sometimes considered as a base for a standard, but this assertion has also been criticized. Friulian is estimated to be spoken on a regular basis by approximately 430,000 people (Picco). However, it is again standard Italian that is used in formal and official contexts. One might be tempted to use the terms diglossia and bilingualism, but none of them fully accounts for the situation: *diglossia* would imply that Friulian is considered as a 'dialect' of standard Italian and the use of *bilingualism* would mean that both Friulian and Italian are used in all circumstances. Attempts to use Friulian at school and in mass media are not always successful (Francescato 1989); the lack of a Friulian standard appears to be one of the major problems.

As for Ladin, it has, like standard Italian and German, an official status in Trentino-Alto Adige and is probably spoken by about 35,000 people (official figures and estimates). There is a written standard, and Ladin can be taught and used at school. However, the Ladin language is under pressure, as it is less prestigious than standard Italian and German. In fact, these two languages are far more spoken, not only seen in a European context but also within the region itself. Moreover, German and Italian are languages that convey a widespread culture.

Like German, a number of minority languages spoken in Italy have in common that they are an official language in one or more countries or regions outside Italy. Their status within the Italian Republic, however, is not the same for all.

German is an official language in Trentino-Alto Adige, together with standard Italian and Ladin. Schools can be either in German or in Italian, but in both of them the second language is the region's other official language; there are also plurilingual schools with a fifty–fifty division of German and Italian, where Ladin is also taught (Freddi). As far as the linguistic features are concerned, the German variety spoken in Trentino-Alto Adige joins the Tyrolean and Bavarian type of speech (Mazzotta).

French is an official language in the autonomous region of Val d'Aosta, in Italy's most northwest corner. In this region, it also constitutes a compulsory subject in education. Yet another Romance language is spoken by about 90,000 people (Klinkenberg): this language, called Franco-Provençal, represents merely a group of different dialects without a standard. These dialects historically belong to a zone covering a part of France, Switzerland's French-speaking region and Val d'Aosta. In formal and official contexts, however, they are almost completely surpassed by French and Italian.

A similar situation can be found in Piedmont, where small Franco-Provençal, Occitan, and Walser minorities exist. Occitan is also a Romance language, mainly spoken in southern France, yet remaining a minority language there as well. Occitan has to cope with problems related to standardization, but like Franco-Provençal it is recognized as a minority language by national law and is promoted by various cultural associations. The same holds for the speech of the Walser, which is a variety of German spoken by a small group of people in Val d'Aosta and Piedmont.

Catalan, the official language of the region of Catalonia in Spain, is spoken by a minority of 15,000–20,000 people in the Sardinian town of Alghero, where it is also a subject in education (Klinkenberg).

Slovenian is spoken by approximately 20,000–30,000 people in Friuli-Venezia Giulia, close to the Slovenian border; there are a number of schools that provide education in Slovenian (Francescato-Ivašič Kodrič).

Serbo-Croatian is estimated to be spoken by a small comunity of 4,000–5,000 people in central Italy (Mazzotta).

Albanian and Modern Greek are spoken by scattered communities in southern Italy; it is mostly elderly people who seem to hold on to their language.

In a country where so many language varieties are used, different phenomena due to language contact can be expected. In regions where one or more languages coexist with standard Italian, these languages (French, German, etc.) may influence standard Italian. However, it is clear that the position of standard Italian as the Republic's official language remains first, as its knowledge is boosted through public education, mass media, etc.

As for the contact between standard Italian and Italian 'dialects', it is obvious that the spoken and—to a lesser extent—written use of standard Italian bears marks of 'dialectal' features, such as differences in pronunciation or in vocabulary. An example of the former is the Roman -NN- pronunciation, where standard

Italian has -ND- (*annamo* for *andiamo* 'we are going'); an example of the latter can be the use of the Venetian word *campo* for *piazza* 'square'. By the way, 'dialectal' words can be accepted in standard Italian, like the word *tortellini* ('tortellini', i.e. a type of pasta), which has its origin in Emilia (Zolli).

But the standard language also leaves its traces in 'dialectal' speech. This mainly happens in the 'dialects's' sound system and vocabulary (where a local term is abandoned in favor of an Italian one; e.g. Piedmontese ['pejla] 'pan' is replaced by [pa'dela], from standard Italian *padella*) (Sobrero 1997). The diffusion of the standard language also influences the global use of the 'dialect'. Referring to the contemporary situation, it is possible to speak of an abandonment of 'dialect', which is, however, far less frequent in rural areas than in urban zones, where several people from different origins live together and where various cultures coexist.

Recently, the term *italiano popolare* ('popular Italian') has been used to indicate a kind of substandard Italian. This substandard Italian originates from an imperfect acquisition of the standard language, possibly—but not necessarily—due to a 'dialectal' background. Some typical features of popular Italian are:

English	Standard Italian	Popular Italian
it seems to me ...	*A me* pare ... (or *Mi* pare ...)	*A me mi* pare ...
to have	*avere*	*averci* (= *avere* + *ci* 'there')
the place where we have been	il posto *dove* siamo stati	il posto *che* siamo stati ('the place *that* we have been')

Popular Italian is not a language on its own, but a whole of characteristics that differ from standard Italian. These characteristics can be widespread through the peninsula (like the examples above), but sometimes they are limited to one or more (parts of) regions.

The campaign that aimed, shortly after Italy's unification, to promote 'standard Italian' as a national language, seems to have reached its goal. Local and regional types of speech often remain lively, which leads to intense contact between the different codes.

J

Jakobson, Roman

Roman Jakobson was one of the major linguists, literary theorists, and semioticians of the twentieth century, and a leading proponent of functional structuralism.

Structural Phonology, Child Language, and Aphasia

Jakobson helped to found the Prague Linguistic Circle, the cradle of (functional) structuralism, in 1926. For the Prague School, language serves for communication and thus its internal structure has to be studied from the standpoint of the tasks it performs. Jakobson and Nikolai Trubetzkoy argued that phonological systems are structural wholes, based on their relational properties, and that language change has to be seen in terms of systems. They investigated types of phonological systems and established the study of linguistic affinities (*Sprachbünde*)—how languages that are geographically and culturally related may acquire traits in common.

Jakobson also turned his attention to the acquisition of phonology by children and its dissolution in aphasics and demonstrated that the order of acquisition goes from universal to nonuniversal, simple (optimal) structures to more complex ones. He also showed that aphasic loss follows a reverse order.

Theory of Distinctive Features and Functional View of Sound

Jakobson showed that phonemes such as /b/ and /m/ in *bat* and *mat* are not the smallest constituents of language. Rather, distinctive features are. For example,

/b/ in *bat* is differentiated from /m/ in *mat* as oral vs. nasal. He defined a small set of such features that underlie the phonological systems of all the languages of the world. He also showed the relevance of these notions for grammatical meaning, which he decomposed into semantic features.

Invariance and Relational Structure

Invariance was, for Jakobson, the dominant topic and methodological device underlying his research: any sign is defined by its invariant properties. Across languages as well, he also insisted on the importance of universal invariants (language universals), establishing the equivalence of diverse signs. Invariance for Jakobson was always invariance in relationship (equivalence), and the primary type of relation in language is that of binary opposition, phonological (e.g. nasal vs. oral), grammatical (e.g. plural vs. singular), or lexical (e.g. *near* vs. *far*), etc. Opposition is based on an asymmetry in the relationship between a marked (focused or weighted) and an unmarked (neutral) term: e.g. unmarked oral, singular, *far* vs. marked nasal, plural, *near*. For Jakobson, markedness is a fundamental way by which we organize our linguistic, semiotic, and sociocultural systems in general.

Functions of Language

For Jakobson, the *raison d'être* for language is communication and language is suited to various communicative goals, which in turn are correlated with the speech event in which language is used. He defined

six primordial functions in terms of a focus on one of the facets of the speech event: (1) emotive function (focus on the speaker)—e.g. intonation showing anger; (2) conative function (focus on the addressee)—e.g. imperatives and vocatives; (3) referential function (focus on the context)—e.g. talk about the real world; (4) poetic function (focus on the message)—e.g. poetry; (5) metalingual function (focus on the code)—e.g. definitions of words; and (6) phatic function (focus on the contact)—e.g. 'hello, do you hear me?' These functions may be dominant in a message or may be subsidiary: e.g. a referential message may also carry expressive information about the opinion of the speaker.

Metaphor and Metonymy: Similarity/Contiguity

Jakobson also analyzed the relation between communicative processes and properties of linguistic structure. First, he distinguished the two fundamental operations: selection (substitution) for encoding (production) and combination for decoding (comprehension). Then, he contrasted two types of relations: similarity (all types of equivalence) and contiguity (temporal and spatial neighborhood). Put simply, the elements in a selection set are normally associated by similarity, and those in combination by contiguity. For Jakobson, similarity/contiguity is a fundamental polarity of language, texts, culture, and human thought (cognition) in general. He proposed using it as a way of categorizing types of aphasic disturbances and also of defining the poetic function: in poetry, where focus on the message is dominant, equivalence (similarity) relations help to build the combination. Thus, rhyme, alliteration, parallelisms, metaphor, etc. help to structure the poetic text, whereas in prose contiguity is the essential constructional principle.

Grammar and Semantics

Jakobson also focused on the function of grammatical categories. For example, he worked on those elements whose general (invariant) meaning in the code can only be specified by taking into account their use in speech events, e.g. deictic pronouns designate speaker (*I*) and addressee (*you*). Thus, language encodes pragmatic factors of the context of utterance.

Grammatical categories (both morphological and syntactic), for Jakobson, are obligatory, whereas particular lexical categories (e.g. words referring to space) are optional. Thus, he provided a semantic and operational approach to the relation between language and cognition: grammatical categorizations provide the necessary patterns of thought.

Jakobson's Legacy in Linguistics

Many of Jakobson's contributions to twentieth-century thought have become a permanent part of American and European views of language. He contributed to linguistics such concepts as (distinctive) feature, binary opposition, structuralism, markedness, and universals. He also showed the importance for linguistics of child language acquisition, aphasia, poetry, the act of communication (language usage), the meaning of grammatical categories, and the systematicity of language change. He has had such a towering role in linguistics that his work has defined the field itself and many of his concepts and discoveries are now thought to be commonplace or self-evident.

Jakobson was a leading proponent of structuralism, arguably one of the most influential trends not only in linguistics but in other humanistic areas as well. His functional viewpoint has inspired functionalist approaches more generally and abetted developments such as discourse analysis, text linguistics, ethnography of communication, anthropological linguistics, sociolinguistics. Work in pragmatics has led linguists to explore the boundaries of their discipline with the neighboring fields of anthropology, sociology, mythology, philology, and philosophy in a truly Jakobsonian interdisciplinary spirit.

Jakobson stressed the need to search for general laws governing all linguistic systems and thus helped to foster the current interest in universal and law-governed, general (explanatory) properties of language. His seminal work on child language and aphasia has been signaled as the point of departure of a new era in linguistics because it showed the relation between child language and phonology, and it launched psycho- and neurolinguistics and contributed to contemporary work on the functional organization of the human brain.

The widespread movement that presently investigates universal properties of language, both universal grammar (Noam Chomsky) and language universals (Joseph Greenberg), is deeply indebted to Jakobson. Many scholars agree with Jakobson that typology is important for the study of language change, areal linguistics, and historical reconstruction. His seminal idea that changes must always be treated in view of the system that undergoes them is the essential premise for textbooks in historical linguistics.

Many linguists have claimed that the distinctive feature was Jakobson's greatest insight and, after the phoneme, the most significant step forward in modern phonology. Generative phonology recognizes Jakobson as a founding father, markedness is now widely used in linguistics and other disciplines, and componential analysis—analyzing an item into smaller properties

and representing them as a combination—has been adopted by many.

With the breadth and depth of his knowledge, his brilliant imagination, his prodigious output, the originality of his accomplishments, and his international influence on a variety of fields, Roman Jakobson has been recognized worldwide as one of the major creative minds of our century.

Biography

Roman Jakobson was born in Moscow, Russia on October 11, 1896. He was educated at Moscow University, in the Slavic section. He was awarded the Buslaev Prize in 1916 for his work on North Russian folk epics, and the master's was awarded in 1918. He helped to found the two groups known now as Russian Formalism in 1915–1916. He moved to Prague in 1920. In 1926, he was cofounder of the Prague Linguistic Circle and was its vice-president until 1939. He received his doctorate in 1930 from Prague University. In 1933, he began teaching at the T.G. Masaryk University at Brno, and assumed the chair of Russian Philology and Old Czech literature at Brno in 1937. In 1939, he fled Nazi invasion and went to Scandinavia. He was visiting lecturer in Copenhagen and Oslo until 1940, and then in Uppsala until 1941. In 1941, he took a freighter to the United States, and taught at the Ecole Libre des Hautes Etudes in New York in 1942–1946. In 1943, he was cofounder of the Linguistic Circle of New York and its vice-president until 1949. From 1943 to 1946, he was visiting professor of general linguistics at Columbia University and became T.G. Masaryk Professor of Czechoslovak Studies in 1946. In 1949, he was named Samuel Hazzard Cross Professor of Slavic Languages and Literatures at Harvard University, and in 1960 he became professor of general linguistics as well. In 1957, he was also named Institute Professor at MIT. He was President of the Linguistic Society of America in 1956, and received the International Prize for Philology and Linguistics in 1980 and the Hegel Prize in 1982. Jakobson died in Cambridge, Massachusettes on July 18, 1982.

Japanese

Japanese is the national and official language of Japan, spoken by approximately 126 million people on the Japanese islands, as well as by Japanese minorities in Hawaii, North and South America, and other parts of the world. The language is called *Kokugo*, 'language of the country' in Japan, and *Nihongo*, literally 'Japan-language', when spoken by nonnative speakers. In terms of number of speakers, Japanese ranks eighth on the list of major languages of the world.

Japanese is written with ideographic characters, called *kanji*, originally borrowed from China, and also with two syllabaries, the *hiragana* and *katakana*, developed in Japan by simplifying the Kanji Chinese characters. A *kanji* is connected to semantic content and has several different pronunciations, while *hiragana/katakana* represent syllables. Roughly, *kanji* are used for content words, e.g. 'sun' or 'read', *hiragana* for grammatical endings and grammatical function

words, e.g. *-ta* past tense or *moshi* 'if', and *katakana* for loan words, e.g. *erebeetaa* 'elevator'. Additionally, Roman script is used for abbreviations, e.g. NHK, and words cited from foreign languages. Traditionally, Japanese is written vertically and from right to left, but today horizontal left to right writing is also used, depending on text type and space.

The question of any language family membership of Japanese is still disputed. Japanese is not related to Ainu, formerly spoken on Japan's biggest northernmost island Hokkaido, the Kurile islands, and Sakhalin (an island off the northeast coast of the Asiatic continent). Nor does Japanese belong to the Sino-Tibetan language family spoken on the Asiatic continent, the most prominent representative of which is Chinese. The most widely discussed hypothesis today is an affiliation to Korean (spoken in Korea) and to Altaic languages (Turkic, Mongolian, Manchu, and Tungusic languages, spoken in continental Asia).

Japanese shares a substantial number of grammatical characteristics with both Korean and Altaic languages: word order in the sentence; suffixal inflection (with endings rather than with prefixed elements); postpositions (functioning like English prepositions, but following the noun); the existence of 'converbs' (verb forms that are used for clause linking instead of conjunctions); question formation via particles at the end of a sentence; vowel harmony (a restriction on vowels occurring together in a word, of which there are traces in Old Japanese); and the absence of a gender system, articles, and relative pronouns. Attempts to establish lexeme correspondences between Altaic languages and Japanese, and to reconstruct a common proto- (ancestral) language, however, have not led to a significant amount of convincing phonological correspondences. The absence of complex consonant clusters (e.g. tk, pl, str), and the near absence of syllable-final consonants in the Japanese sound pattern, contrasts with Altaic languages, where these uses do occur. Additionally, vowel harmony occurred only briefly in the linguistic history of Japanese, and inflectional endings on verbs for persons involved in the event being discussed are absent in Japanese.

The sound pattern, the open (vowel-final) syllables, and the basic bisyllable pattern of words in Japanese are reminiscent of a neighboring language family, the Austronesian languages (spoken in Taiwan, the Philippines, Indonesia, Oceania, and Madagascar), in which these same properties are characteristic. But again, a sufficient number of phonological correspondences between Japanese and Austronesian have not been established, and sentence structure is disparate. It is therefore assumed by some scholars that Japanese might be a hybrid language, amalgamating features of Altaic and Austronesian languages. Besides this, a

relation to Dravidian languages (spoken in the south of India) is hypothesized, as Dravidian languages also share the grammatical features listed above for Altaic languages.

The earliest Japanese writings date back to the eighth century CE. The language then developed from Old Japanese to Modern Japanese between the twelfth and sixteenth centuries. Late Old Japanese and Middle Japanese are considered today as the literary language (*bungo*). The term 'Classical Japanese' is used either to correspond to *bungo*, or may designate any stage of the language between the eighth and fourteenth centuries. This epoch produced a rich literature of lasting importance by court nobles, especially court ladies, both in prose and verse.

After Japan was politically unified in the seventh and eighth centuries, the greater Kyoto region in the west of the main island of Honshu became the political and cultural center in the eighth century, which it remained, almost without a break, for about a thousand years. The political center was then moved eastward to Tokyo at the beginning of the seventeenth century, and gained cultural authority until the end of the eighteenth century. Today, the speech of the Tokyo region, adorned by influences from the Kyoto variety and interspersed with traits of the prevailing local dialect, especially accentual features, functions as the standard national and official language.

Japanese is rich in dialectal variation. Several different classifications have been proposed, but two major dialect divisions are generally recognized: (1) between the Eastern dialect group spoken in the northeastern half of the main island of Honshu up to the northern island of Hokkaido and the Western dialect group spoken in the southwestern part of Honshu, and (2) between the Western dialects and the dialects spoken on the island of Kyushu, south of Honshu. The East–West dialect boundary runs through Central Honshu between the Niigata and Toyama prefectures in the north, along the Japanese Alps, and between the Shizuoka and Aichi prefectures in the south. The boundary is constituted by the existence and pronunciation of several sounds, by the accent pattern, and by a number of inflectional forms of the verb. Other dialects are differentiated by their sound and accent patterns, lexicon, and functionality of case markers.

A fourth linguistic area is formed by the islands of Okinawa, south of Kyushu. The language of Okinawa is sometimes considered to be another major dialect of Japanese, but it is classified by other scholars as a separate language, known as Ryukyuan or Luchuan. The latter approach is supported by the mutual unintelligibility of Japanese and Ryukyuan. Ryukyuan is estimated to have split from the Japanese stock around the beginning of the Christian era and was the language of

an independent kingdom between the fifteenth and seventeenth centuries CE, before the Ryukyu islands were incorporated into Japan. Ryukyu is divided into three larger dialects, which are mutually unintelligible both among themselves and with Japanese dialects. While Ryukyuan has a different sound pattern with fewer vowels than Japanese, sound correspondences were easily established. Morphology (word structure) and syntax (clause structure) are quite similar to Japanese, but Ryukyuan preserves the lexical, morphological, and syntactic features found in Old Japanese, having also introduced inflectional forms:

	Japanese (Tokyo)	**Ryukyuan (Naha)**
'nose'	*hana*	*hana*
'wind'	*kaze*	*kazi*
'hand'	*te*	*ti'i*
'smoke'	*kemuri*	*kibusi*
'bird'	*tori*	*tu'i*

Among the 1.3 million inhabitants of the Ryukyu islands, Ryukyuan is spoken mainly by the older generations. Those under 20 years of age speak only Japanese. Thus, Ryukyuan is a severely endangered language. Although some private broadcasting services provide news in Ryukyuan, its prospects for surviving are bad for political reasons.

Japanese grammar and lexicon present a number of phenomena that are of theoretical interest to general linguistics. Japanese has a pitch-accent pattern, which differs from both stress-accent patterns (as in English)—in which accent is marked by sound pressure or loudness—and tone languages such as Chinese—in which each syllable bears one fixed pitch out of a pool of four pitch types. In Japanese, every word has a pitch 'contour' with, at most, one pitch drop. The place of the drop from high to low pitch in a word distinguishes meaning: e.g. *hashi-ga* with the pitch pattern high–low–low (i.e. high pitch on *ha*) means 'chopsticks', while *hashi-ga* with the pitch pattern low–high–low (i.e. high pitch on *shi*) means 'bridge', and *hashi-ga* with the pitch pattern low–high–high (i.e. high pitch on *shi* and *ga*, no drop) means 'corner'.

A complex system of honorifics (expressions of respect/politeness) plays an important role in any Japanese utterance. Two kinds of honorifics are interwoven, namely, the expression of politeness toward the interlocutor, and the expression of respect toward a person one is talking about. Appropriate use of honorifics is determined by the social context of the utterance, and is socially obligatory. Politeness to the interlocutor is expressed by an inflectional ending on the verb (*-masu*); respect toward a person being mentioned is shown by the choice of special verbs or derivational forms (word formation products) of verbs and nouns. There is a neutral form for every verb (used with reference to equally ranked persons); an elevating form, which is used with reference to a socially superior person; and a humble form, which is used with reference to the speaker or the speaker's group:

	Neutral	**Elevating** 'a respected person does X'	**Humble** '(speaker) does X for/to a respected person'
'read'	*yomu*	*o-yomi-ni naru*	*o-yomi-suru* '...
'exist'	*iru*	*irassharu*	*oru*
'come'	*kuru*	*irassharu*	*mairu*
'do'	*suru*	*nasaru*	*itasu*
'eat'	*taberu*	*meshiagaru*	*itadaku*

Respect forms also exist for a number of nouns, especially kinship terms. The prefixes *o-* and *go-* are honorific:

Own thing/kin		**Respected person's thing/kin, address term**
tegami	'my letter'	*o-tegami* 'your/his/her/their letter'
hon	'my book'	*go-hon* 'your/his/her/their book'
haha	'my mother'	*o-kaasan* 'your/his/her/their mother', 'mother!'
chichi	'my father'	*o-toosan* 'your/his/her/their father', 'father!'
ane	'my elder sister'	*o-neesan* 'your/his/her/their elder sister', 'sister!'
otooto	'my younger brother'	*o-toosan* 'your/his/her/their younger brother'

An elaborate honorific system is also present in Korean.

As in Altaic languages and Korean, Japanese is rich in onomatopoetics (sound-symbolic words), which are conventionalized mimetic expressions of natural sounds, mental and emotional states, sensations, and physical states and manners. These words are usually used as adverbs. Examples are *wan-wan* (bow-wow), *patan* (with a bang), *zaa-zaa* (sound of downpour), *kossori* (stealthily), *ira-ira* (nervously), *zara-zara* (rough texture), *hara-hara* (falling down softly; fearfully), and *bara-bara* (falling of heavy objects).

Most Japanese loanwords are borrowings from Chinese and have a status comparable to Latinate words in European languages. Other loanwords come from European and other Asian languages, especially from English. Loan-word adaptation both to the Japanese sound pattern and word classes resulted in compromise forms, which introduced new sounds and syllable-final consonants into Japanese. Native words and loanwords with similar meanings may coexist and usually have specialized meanings: e.g. *torikeshi* (native), *kaiyaku* (Chinese loan), and *kyanseru* (from

English 'cancel') all mean 'cancellation', but the first example has a very general meaning, while the Chinese loan is used for formal occasions such as in contracts and the English loan for reservations or appointments.

A phenomenon of Japanese word formation of great theoretical importance occurs when from a clause construction larger than one word, the last element may undergo word formation without any other changes in the construction taking place. For example, the phrase *sake-o nomita-sa ni* (out of desire of drinking sake) is formed from the clause *sake-o nomitai* (s.o. wants to drink *(nomitai)* sake) with the help of the ending *-sa.* This is remarkable in view of the theoretical assumption that word formation is a word-level process and should not be accessible beyond the word level.

On the morphological (word structure) level, Japanese is agglutinative, i.e. various grammatical endings are chained together to form a word. Japanese has word classes of nouns, verbs, and adjectives, although the latter are a subclass not of nouns but of verbs, and they are inflected in the same way as verbs.

The function that a noun fills in a clause is signaled by elements loosely attached to the end of a noun, which are traditionally called 'postpositions'. A postposition is a word that fills the function of a preposition ('at', 'in', 'for', etc.), but follows the noun instead of preceding it. In Japanese, postpositions fill the functions of case: e.g. *Hanako-ga* 'Hanako' (nominative), *Hanako-no* 'Hanako's' (genitive), *Hanako-o* 'Hanako' (accusative), *Hanako-ni* 'to Hanako', *Hanako-to* 'with Hanako', etc. Postpositions are also characteristic of Altaic languages.

The persons involved in an action are not usually explicitly expressed, neither on the verb nor by nouns accompanying it. The bare verb constitutes a minimal sentence, and the persons involved must be deduced from the larger context: e.g. *yomu* is a complete clause that may mean, 'I read it/something', as well as 'you/he/she/it/we/you/they read it/something'. The persons involved in the action can be understood from a range of verb pairs sharing a common root (basic component). One verb of a pair signals that s.o./sth. other than the speaker or her group is acting (so-called 'intransitive'), while the other signals that the speaker is acting on s.o./sth. (so-called 'transitive'):

Nonspeaker acts		Speaker acts	
agaru	'rise'	*ageru*	'raise'
tomaru	'stop'	*tomeru*	'stop'
aku	'open'	*akeru*	'open'
okureru	'be late'	*okurasu*	'postpone'
naku	'cry'	*nakasu*	'make cry'
sakeru	'split'	*saku*	'split'

Furthermore, Japanese verbs are classified according to their behavior in tense and aspect (presentation of an event as 'bounded', having a relevant beginning and/or ending, or 'unbounded', no relevant beginning, or ending). The *-te iru* form (a kind of continuous form) of a great number of verbs refers to a continuing/continuous event, e.g. *yomu* (read), *miru* (look), *furu* (fall), and *kangaeru* (consider). For example, *yonde iru* translates as, 's.o. is reading'. With other verbs such as *shinu* (die), *sameru* (wake up), and *mitsukaru* (be found), the *-te iru* form expresses a result: *shinde iru* means, 's.o. is dead'. A third class lacks this form entirely, while for still other verbs, it is the only form that can be used to refer to present tense.

Japanese has several inflectional verb forms that cannot be used as the predicate form, i.e. the kernel, of an independent sentence, but are the predicate of a dependent clause or in connection with an auxiliary verb, such as the form ending in *-te*; these are used for clause linking. Such verb forms are known as 'converbs', which are also typical of Altaic languages.

An interesting grammatical form of a verb is the so-called passive, formed with the ending *-(r)are-*. This form is used for events that are not controlled by the person to whom they are happening, e.g. *shinobareru* (something spontaneously comes to my mind) or *ame-ni furareta*, literally 'I was fallen (on) (*furareta*) by the rain (*ame-ni*)', meaning 'I was adversely affected by the rain falling'. The 'passive' is also used for the expression of ability, such as *nerarenai* (I cannot sleep), and as an honorific form, such as *korareru* (a respected person comes).

Japanese is also a classifier language, i.e. it makes use of special elements in counting. Nouns in Japanese cannot be counted directly, as in English: 'one book', 'two books', etc. Instead, the numeral element is combined with another element that expresses the properties of the noun being counted (such as shape, kind, or function) or measures it. This classifier is then used in conjunction with the noun. Thus, the element *-ko* is used for small round objects, *-hon* for cylindrical objects, *-ri* and *-nin* for persons, *-dai* for machines, *-ken* for houses, *-sai* for age, *-hai* for cupfuls, and so forth. A counting construction takes the form *hon issatsu* (one book, literally 'book one-bound entity'), *hon nisatsu* (two books), and so forth, with *issatsu* and *nisatsu* being the classifiers for bound objects.

On the clause level, the Japanese word order is subject–object–predicate, as in *Hondasan-wa Fujiisan-o mita* (Mr./Ms. Honda saw Mr./Ms. Fujii). Modifying elements precede the word they modify, according to the patterns *kono ie* (this house), *akai ie* (red house), *watashi-no ie* (my house), *Hondasan-no ie* (Mr./Ms. Honda's house), and *Hondasan-ga mita ie* (Mr./Ms. Honda saw (*mita*) house (*ie*)), which is the equivalent of the English, 'the house that Mr./Ms. Honda saw'. Relative pronouns (such as the English 'which') do not exist. Adverbs likewise precede verbs, according to the

pattern *yukkuri-to aruku* (s.o. walks slowly, or literally slowly walks). A complicated topic discussed in the field of Japanese clause structure is configurationality, or whether or not the elements of a clause are hierarchically structured. As there are arguments both for and against Japanese being configurational, the question remains open.

An aspect of clause structure for which Japanese has become famous is the existence of two structural components of the sentence ('phrases') that are candidates for serving as the subject. These components are identifiable by the markers at their ends, *-wa* and *-ga*, respectively. They have different conditions of usage and varying functions, and they may occur simultaneously in one sentence (known as the 'double subject construction'), as in *zoo-wa hana-ga nagai* (the elephant has a long trunk), or literally, 'the elephant (*zoo-wa*, topic), the nose (*hana-ga*, subject) is long (*nagai*, predicate)'. The component marked with *-ga* is the grammatical partner of the predicate and therefore the subject; the component marked with *-wa* is the topic, i.e. the thing or person about which the speaker says something. The topic may have a looser relation to the predicate, as in *boku-wa unagi da* (eel for me), or literally 'I (*boku-wa*) it is (*da*) eel (*unagi*)'. The topic construction can be better understood if translated by the English 'as for . . . '; for example, 'as for the elephant, its trunk is long'. Japanese shares the existence of such a topic construction with Korean.

Japanese discourse, or larger bodies of spoken or written text, is thoroughly studied as well. Topics of interest in narrative discourse are the organization of a text and the elements used for signaling its structure; the way the persons involved in a story are handled linguistically to maintain a perspective; and the formal chaining of events. In the study of conversation, strategies used for turn-taking, sustaining the audience's attention, and confirming attention are studied, as well as verbal signs used in such interaction, such as absence of grammatical elements, reordering of components of a clause, sentence-final particles (small words), echoing, and affirmative sounds and gestures.

Japanese Sign Language

Japanese sign language (JSL, or NS after its Japanese name, *Nihon-Shuwa* (alternatively, *Nihon Syuwa*), literally 'Japanese hand-talk') is the dominant language of the deaf community of Japan, and to a lesser extent of the hard-of-hearing community. Owing to the establishment of deaf schools during the time of the military occupations in World War II, JSL is also cognate with the (South) Korean and Taiwanese sign languages. In the latter case, the dialects of Taipei and Tainan are said to derive from the Osaka and Tokyo dialects of JSL, respectively (see Smith 1990). JSL shares an extremely high degree of basic lexical cognates with each of the other two members of the Japanese sign language family.

Sociolinguistics

The Tokyo dialect is the socially dominant variety of Japanese sign language, owing in large part to efforts of the Japan Association of the Deaf and broadcasts of sign

language courses and sign language news on the NHK (Nihon-Housou-Kyoukai = Japanese Broadcasting Corporation, or public television) educational channel. Due to these influences, differences between dialects, although present, are declining. Lexical differences continue to be considerable in some dialects, particularly among elderly signers. Although little research has been undertaken in this area, syntactic differences also arise, affecting auxiliary verb and subject/object–verb agreement in western Japan.

As is the case with perhaps all minority languages, JSL is more or less influenced by the majority language—in this case, by spoken (and written) Japanese. The extent of influence varies according to several factors. First, JSL varies with the education of the speaker (and whether the speaker obtained his or her education in the period between the world wars and up to the early 1990s, when the Ministry of Education (Monbushou) took over control of deaf school administration and promoted a strictly oral education). Considerable difference exists, for example, between the signing of older and younger people. Significant numbers of older signers use little or no finger-spelling, and younger signers tend to allow mouthing patterns to play a much greater role in discourse. Second, JSL also varies with the speech situation (more formal situations often result in signing closer to the signed Japanese than to JSL per se), and on the judged signing proficiency (and hearing status) of the interlocutor. It would be better, therefore, to speak of a continuum from Japanese sign language to signed Japanese. Signed Japanese uses mostly JSL signs, but with Japanese word order and without most of the grammatical features of JSL (and, it should be noted, without many of the grammatical features of spoken Japanese either). Two notable (and highly noticeable) features of signed Japanese (as opposed to JSL) are the extensive use of the sign for *exist* (the inanimate form) as a copular (or linking) verb (Japanese *desu*) and the ubiquitous use of a question particle sign at the end of all questions (equivalent to Japanese *ka*); both signs have an extremely limited use with these meanings in native signing (the latter marking perhaps only a focalized question).

The differences between JSL and signed Japanese, and the limited comprehensibility of the latter to many deaf people, has a deleterious impact, especially in the fields of education and interpreting. Since almost all deaf school teachers can hear, with spoken Japanese as their primary language, and since few of those who sign have contact with JSL-signing deaf adults, the signing produced in deaf schools is almost totally signed Japanese. Also, in the field of interpreting, much interpreting is performed by volunteers, with little linguistic training or real understanding of the dif-

ferences between the two sign systems; hence, signing here is also often on the Signed Japanese end of the spectrum. In both deaf schools and interpreting situations, the reduced degree of comprehensibility of the sign system used means that much of the content is understood only partially.

Visual Cue Structure

As proposed for other sign languages such as American sign language (ASL), the structural features of JSL consist of (1) hand shape, (2) handedness (one vs. two-handed signs), (3) location of the sign in signing space (including relative to a passive base hand), (4) motion (both the hand and arm as a whole, and fingers and parts of the hand to affect hand-shape change), (5) palm and finger-tip orientation, and (6) nonmanual signals. Of all the features entering into JSL signs, the most significant studies have concentrated on hand-shape structure and nonmanual signals.

JSL comprises approximately 50 hand shapes, the vast majority of which are presumably phonemically distinctive. Of these phonemic hand shapes, perhaps half a dozen or so form the basic building blocks of the language. JSL lacks some hand shapes that are present in other sign languages (e.g. ASL /t/), and conversely possesses some that are absent elsewhere (the JSL hand shape with an extended middle finger is the prime example). In each of these cases, the given hand shape is taboo in the other (dominant as well as deaf) culture.

In contrast to the half dozen basic hand shapes, which are widespread and carry a high functional load, some hand shapes have exceedingly limited distribution, at times restricted to a single sign and a single meaning, giving them marginal status. Thus, for instance, the hand shape with all but ring finger extended (and ring finger totally bent) occurs only in the sign for *swallow* (bird). Virtually the same hand shape, but with only the proximal joint of the ring finger bent, occurs only in the sign for *medicine*. The hand shape with only the little finger bent is limited to signs with the meaning 'eight' (also '800' and '8,000'), and the same hand shape with all the extended fingers bent is limited to the meaning '80'.

Quite a few JSL hand shapes have meanings associated with them; for instance, of the single-extended-finger type of hand shape, all except the extended index finger have distinctive associated meanings. Thus, an extended thumb (with the exception of a few signs with body contact) indicates a male person (or sometimes gender-neutral person); the extended middle finger means *brother* (and, at least in some dialects, an allomorph for *son*, alternating with extended thumb); an extended little finger means *female person*, and the

extended ring finger is a dialectically limited alternate of the same sign with extended little finger.

The set of JSL hand shapes is subject to historic change. For instance, the *I love you* hand shape of ASL (with thumb, index, and little finger extended) originally existed only as a partial assimilation of the first morpheme to the second morpheme of the compound word *parents.* More recently, it has spread in the *I love you* borrowing, in *airplane* (and related lexemes, all originally and indigenously with the /Y/ hand shape), especially among the young, and at least in Tokyo among some young signers in the sign for *sparrow*, normally signed with the middle finger extended as well. Also, thumb extension, which has been said to be less prominent in JSL than in ASL, is more widely used in western Japan in variations of lexemes where it does not occur in eastern Japan, such as *Hokkaido* (Japan's northernmost island), *bridge*, and *sing* (all three 'normally' produced with just index and middle finger extended together).

Word Structure

It has been noted that JSL has no separate features distinguishing traditional parts of speech, such as noun from verb, or adjective from either. What *is* distinguishable are forms that can be made into predicates and forms that cannot. Perhaps better yet is the statement that JSL lexemes can be grouped into form classes, based on whether or not they can be modulated for agreement, aspect, etc.

JSL verbs are divided into those that can be inflected for person and/or number (agreement verbs), where inflection is shown by direction of sign motion and/or palm and finger orientation, and those that cannot (plain verbs). Other verbal inflections (for instance, aspect and tense) have been inadequately studied, but clearly exist. At the very least, a repeated form of a sign means a repeated, continuing action. Alternating motions, produced with one hand at a time, mean that the repetition is distributed over several participants. In general, inflection is used for aspect rather than tense, and the two signs *finish* and *middle*, which sometimes occur with verbs, are indicators of perfective and imperfective aspect rather than past and present (continuous) tense.

Nouns and pronouns are inflected for number and—unlike spoken Japanese—gender, but not case. Thus, number is indicated in nouns by reduplication, and in pronouns by multiple or sweeping pointing gestures; gender is indicated in nouns, pronouns, and verbs by the extended thumb for a *male person* and by the extended little finger for a *female person*.

Nonmanual signals, which play a major role at the syntactical level, also occur at the lexical level—for example, the tongue protruding in the cheek indicates 'falseness, lie', and often occurs as an independent gesture. The tongue-in-cheek can also occur simultaneously with another sign to indicate that what is being stated by the hands is in some way false (e.g. to sign *feigned absence from home*, one would co-sign *absent from home* along with a /tongue in cheek/).

Sentence Structure

JSL is primarily a topic-dominant language, with topic fronting being accompanied by certain nonmanual signals. In the absence of topic fronting, the semantically neutral sentence order is Subject–Object–Verb (SOV). Of the other five possible combinations of S, V, and O, only *VSO is not possible, given the proper context and topicalized element(s). Otherwise, generally the old information is given first, and the new information last.

Nonmanual signals (e.g. raising an eyebrow, tucking in the chin, nodding the head, blinking an eye, tilting the head, etc.) play a major role in syntax. For example, the difference between a wh-question—(*where is*) *Takashi*?—and a yes/no question—(*are you*) *Takashi*?—can potentially be indicated (e.g. in a one-word utterance) by a slight difference in such signals. Nonmanual markers are also used in the formation of topicalization, relative clauses, conditionals, negative sentences, and so forth. Individual nonmanual signal elements may occur in a variety of syntactic functions, alone or in combination with other nonmanual signal elements. One example of a multifunctional, nonmanual signal is tilting the head (or cocking the head), which is used for a range of modal meanings including noncommittal statements (possibility, allegedness); strangeness; approximation (in either number or location); and so forth. Perhaps all these meanings can be grouped in a unified way as deviation from the expected, stated, or normal. Nonmanual signals are an area where extensive research continues.

Lexicon and Borrowings

The overwhelming majority of JSL lexemes are indigenous. A certain percentage are shared with gestures of the majority hearing populace (e.g. *money*, *girl*(*friend*)). Borrowings from other sign languages have played a role in JSL, generally a small one, although in certain areas (e.g. computer technical vocabulary) the contribution of ASL stands out. Examples of nontechnical borrowings include *communication* and *analyze.* In earlier borrowings, ASL also served as the base for the finger-spelling syllabary—the vowels and the basic 'consonant + /a/' syllables unmarked by diacritics (e.g. *ka*, *sa*, *na*, *ha*, *ma*, *ra*, *ya*, *wa*) were borrowed from ASL vowels and consonants. The exception is *ta*, with the thumb tip provocatively protruding between closed index and

middle fingers, which is indigenous because the ASL form is taboo. Neologisms are sometimes literal translations of ASL words (e.g. *total-communication*, with /to/ -hand shape in place of ASL /t/), and the ASL method of initialism have been used (e.g. *kadai* 'subject, theme' from the /ka/ hand shape incorporated into the form of *mondai* 'problem, question'), although to a very limited extent.

Discourse Features

Discourse features such as selective use of signing space, index pointing, and role shift play a role in JSL discourse. JSL has a lexical (as well as nonmanual) topic marker *in-the-case-of*, but lacks a simple conjunctive ('and'), although it possesses a disjunctive *but* and *to-change-the-subject*, as well as conjunctions of causation *therefore* and *in-order-to*. To a certain extent, enumeration can play the role of conjunction, but this is largely left up to discourse-cohesive features such as topic continuity, sequential use of signing space, index-finger pointing (to the point in signing space assigned to a given referent or topic, or to a sign classifier already in place in that space), etc. Nonmanual signals also play a very important role in discourse topic tracking. Shared (extralinguistic) background knowledge and assumptions and linguistic indications of topic shift are very important in discourse flow, and repetition of the same sign or sign sequences are very important to ensure that signer and addressee are on the same page.

Javanese

Javanese is one of the Austronesian languages, belonging to the Western Malayo-Polynesian subgroup and the Sundic family. The Austronesian languages exhibit a high ratio of vowels to consonants. Most root words consist of two syllables, and from these, grammatical variants are derived by means of affixes. Austronesian languages use reduplication to indicate the plural and other grammatical concepts. All these features are manifest in Javanese. Other Sundic languages are Sundanese, Tenggerese, Osing, Madurese, and Balinese, which are all spoken on or near the island of Java. An ancestor language for Javanese, Proto-Malayo-Javanic, has been reconstructed by Nothofer (1975).

Javanese is spoken by over 40% of the people in Indonesia. It is the mother tongue of 62 million people in Java, the most populous island in Indonesia. It is spoken mainly in central and eastern Java, but is also spoken in a thin strip along the north coast of west Java, except for the area around Jakarta where a form of Malay is

spoken. The regional dialect of Solo and Yogyakarta, the historical centers of Javanese culture, is called Kejawen, and is considered the standard form of Javanese.

Javanese has a literature dating back to the eighth century and its own Indian-based script, where each symbol corresponds to a syllable consisting of a consonant and a vowel. These characters may be viewed on www.skypoint.com/~gimonca/huruf-jawa.html. Old Javanese is the language of texts written in the pre-Islamic era. Nowadays, Roman script is more commonly used, but Javanese can also be written in Arabic script. The literature of Javanese has been catalogued by Pigeaud (1967).

The Javanese vowels are *a*, *e*, *i*, *o*, and *u*, and there are open(long) and closed(short) forms of each. There is also a variant of the open *a* when it is the final syllable, pronounced half way between *o* and *a*, and a neutral (pepet) *e*, as in the English word *open*. The consonants are shown in Table 1 (Robson 1992).

Root words are typically disyllables of the form (C1) V1 (C2) V2 (C3), where (C1), (C2), and (C3) are optional consonant clusters. Allowable consonant clusters include *mb*, *nd*, *ndh*, *nj*, and *nng*, which can all occur in the initial position. There is a light stress on the second last syllable, or the final syllable when the second last syllable contains a neutral *e*. This light stress does not occur when a suffix is added.

Grammatical variants of a root word may be composed by affixation, reduplication, or combination. Affixes, which may be prefixes, suffixes, or infixes, are more common in Javanese and Tagalog than in Malay. Affixes may result in the production of either a noun or a verb. Sometimes, the surface forms of affixes that result in the formation of a noun are identical to those that result in the formation of a verb. The lists of Javanese affixes used for noun and verb formation, given by Suharno (1982), are shown in Tables 2 and 3, respectively.

Adjectives can take affixes, e.g. cukup (enough) → cukupan (more or less enough), dhuwur (high) → kedhuwuren (too high). Adjectives can also be formed from nouns with affixes, e.g. jamur (fungus) → jamuren (moldy).

TABLE 1 The Javanese Consonants

	Unvoiced	Voiced	Nasal
Labial	P	B	M
Dental	T	D	N
Retroflex	TH	DH	
Palatal	C	J	NY
Velar	K	G	NG
Liquids		R	L
Semivowels		Y	W
Sibilant		S	
Aspirant		H	

There are at least six syntactic forms of word reduplication:

Whole word reduplication without any phonological change, e.g. mangan (eat) → mangan-mangan (eat informally with other people).

Partial doubling, producing a noun from an adjective, e.g. lara (sick) → lelara (sickness), peteng (dark) → pepeteng (darkness). The reduplicated fragment is a prefix consisting of the first phoneme of the root word followed by e.

Partial doubling + an, e.g. tembung (word) → tetembungan (wording, expression). Whole word reduplication of a verb with a phonological change, e.g. bali (return) → bola-bali (to and fro), mubeng (go around) → mubang-mubeng (beat around the bush).

Lexical doubling: the root words are already doubled, since the single form does not exist.

Morphological doubling—a new meaning is formed in contrast to the nondoubled one.

Robson (1992) lists the following semantic categories created by reduplication:

Do something at leisure, e.g. mlaku (walk) → mlaku-mlaku (go for a stroll).

Do something repeatedly, e.g. njerit (shriek) → jerit-jerit (go on shrieking).

Interrogative pronouns given indefinite meaning, e.g. sapa (who) → sapa-sapa or sapaa (anyone).

Mild exasperation, e.g. mentah-mentah iya dipangan (even though it is unripe he still eats it).

Plurality with diversity for both adjectives and nouns, e.g. gedhong dhuwur-dhuwur (buildings all more or less high).

Doing something together, e.g. omong-omongan (to chat together).

To compete in, e.g. gelis-gelisan (to see who is fastest at running).

Plurality, e.g. wet–wet (trees).

An important characteristic of Javanese is the speech decorum of the language, where different levels or stylemes of speech are used depending on the relative social status of the two speakers. This system has been in existence since the sixteenth century, and is a legacy of the feudal system left behind by the old Hindu court tradition. The speech levels are not different languages, but manners of speaking that vary according to the relationship between the speaker and the addressee. Each level within the language has its own characteristic set of vocabulary.

The three main levels of modern Javanese are krama, madya, and ngoko—high, middle, and low, of which krama and ngoko are most commonly used. Someone of high status speaking to someone of low status will use ngoko, while the other will use the (more formal) krama (pronounced kromo). The basic level ngoko is used between friends and equals. Ngoko means the

TABLE 2 Javanese Affixes Used in Verb Formation

Affix	Usage	Examples
moro-, mer-	Prefix forming a verb from a simple word noun. Not productive.	Dayoh (guest) → morodayoh, merdayoh (pay a visit).
kapi-	Prefix forming a verb from a simple word noun. Not productive.	Dereng (strong wish) → kapidereng (overeager).
kami-	Prefix normally occurring in conjunction with the suffix -an to form a verb from another simple word verb. Not productive.	Seset (peel) → kamisesetan (suffer from skin peel).
kumo-	Prefix forming a verb from a simple word verb or a simple word noun. Not productive.	Wani (dare) → kumowani (recklessly dare).
a-	Prefix forming a verb from a simple word noun.	Rupo (appearance) → arupo (to have the appearance of).
ma-	Prefix forming a verb from a simple word noun. This sometimes involves a sound change: a nasal consonant must be homorganic with the initial phoneme of the root word. Also applies to *n-*.	Guru (teacher) → maguru (to learn from a teacher); sembah (respect) → manembah (pay respect to); aju (progress) → maju (move forward).
n-	Prefix forming a verb from a simple word verb or simple word noun. Nasalization is found with nearly all transitive verbs. The rules for nasalization of a root word are: initial p → m; b → mb; t → n; d → nd; th → n; dh → ndh; c → ny; j → nj; k → ng; g → ngg; r → ngr; l → ngl; s → ny; w → m or ngw.	Tules (write) → nules (write); becak (pedicab) → mbecak (ride in a pedicab); gule (stew) → nggule (make stew); inep → nginep (spend the night).
ka-, ke-	Prefix forming a verb with a passive meaning from a simple-word verb.	Junjong (lift) → kajunjong (lifted); Jupoq (take) → kejupoq (taken).
di-	Prefix forming a verb with a passive meaning from a simple-word verb.	Tandor (plant) → ditandor (planted); tuku (buy) → dituku (bought).
taq-	Prefix related to *aku (I)* forming a verb with a passive meaning from a simple word verb.	Dol (sell) → taqdol (sold by me).
koq-	Prefix related to *kowe (you)* forming a verb with a passive meaning from a simple word verb.	Gawe (make) → koqgawe (made by you).
-in-	Infix forming a verb with a passive meaning from a simple word verb.	Sawang (watch) → sinawan (seen); barong (accompany) → binarong (accompanied).
-um-	Infix forming a verb from a simple word verb or a simple word noun. Usually contracted to initial *m-*.	laku (walk, gait) → mlaku (walk); kumrisik (make a rustling sound).
-r-	Infix forming a verb from a simple word noun.	Tutol (spot) → trutol (to be spotty).
-i	Suffix forming a verb from a composed-word verb, itself formed by one of the prefixes *n-*, *di-*, *taq-*, *koq-*.	Taker (measure) → nakeri (measure repeatedly); tugel (break) → ditugeli (broken into pieces); tembong (mention) → koqtembungi (you ask for a particular thing).
-an, ka- -an	Suffix or affix combination that may form a verb from a simple word verb.	Lunggoh (sit) → lungguhan (sitting); lebu (enter) → kelebon (intruded).

Continued.

TABLE 2 Continued

Affix	Usage	Examples
-en	Suffix forming an imperative verb from a simple word verb.	Jupoq (take) → jupuqen (Take it!); pangan (eat) → panganen (Eat it!).
-o	Suffix forming an imperative verb from a single word verb, or forming a hypothetical verb from a verb formed using *di-*, *tag*, *koq-*, *-in-*.	Turu (sleep) → turuo (Sleep!); gowo (carried) → gawoo (even if carried).
-ake	Suffix, always in combination with one of *ma-*, *n-*, *ka-*, *di-*, *taq-*, *koq-*, *-in-*, forming a verb from a verb.	Maguro (learn from a teacher) → maguroqake (send someone to learn from a teacher). Njupoq (take) → njupoqake (take for someone); sinugoh (served with) → sinugohake (served to somebody).

TABLE 3 Javanese Affixes Used in Noun Formation

Affix	Usage	Examples
pi-, pang-	Prefix forming a noun from a simple word verb or noun.	Anggo (use) → panganggo (clothing); utang (debt) → piutang (credit).
ka-, ke-	Prefix forming a noun from a simple word verb. In combination with the suffix *-an* it forms a verb from a simple word noun.	Weroh (see) → kawruh (knowledge); lurah (village mayor) → kelurahan (village mayor's office).
-an	Suffix forming a noun from a simple word verb or noun. It may be used in combination with *pi-* to form a noun from a verb or a noun.	Jaran (horse) → jaranan (hobby horse); tegal (nonirrigated field) → tegalan (area of such fields); Tulung (help) → pitulungan (assistance).
-e, -ne	Suffix forming a definite noun from a simple word verb or noun.	Jaran (horse) → jarane (the horse); tuku (buy) → tukune (the purchase).
-ku	Suffix related to *aku (I)*.	Kembang (flower) → kembangku (my flower).
-mu	Suffix related to *kowe (you)*.	Omah (house) → omahmu (your house).

ngoko form of *I*, while krama means *marriage*. The madya level consists of krama containing certain words shortened and with ngoko style affixes. It is often used among strangers. There are about 900 words exclusive to krama, and also a few hundred modesty words called krama inggil (inggil means *high*). These words can be mixed into either ngoko or krama as required. Krama inggil words are used when one speaks about the person, actions, or possessions of someone to whom respect is due—either addressed or referred to. These words cannot be used of oneself. Examples of the use of the three levels of Javanese speech are given by Robson.

Ngoko (girl to her younger sister): Aku wis mangan segane (I have eaten the rice).

Krama (girl to her uncle): Kula sampun nedha sekulipun (I have eaten the rice).

Krama with krama inggil (girl to her uncle about her father: Bapak sampun dhahar sekulipun (Father has eaten the rice).

Ngoko with krama inggil (girl to her sister about her father): Bapak wis dhahar segane (Father has eaten the rice).

Madya (the old servant to the girl): Kula mpun nedha sekule (I have eaten the rice).

Another form, basongan, is only used in the kratons (Sultan's palaces) of Jogjakarta and Solo. The language of religion is called 'Jawa Halus' (refined Javanese) and many words are based on Sanskrit or Kawi, but a diminishing number of people are able to use this form of the language. The number of levels may vary according to regional dialect, and between urban and rural areas (Geertz 1960). A sample of words that differ at four different levels is shown in Table 4.

The Javanese personal pronouns are shown in Table 5.

For *we*, ngoko uses *awake dhewe*, while both ngoko and krama can use the Indonesian loanword *kita*. The second- and third-person pronouns are rarely used, and are generally replaced by kinship terms, titles, or proper names. For example, a woman may be addressed as *Bu* (literally, *mother*). A pronoun may be omitted altogether if the referent's identity is understood.

TABLE 4 Words that Differ at Four Different Levels

English	Ngoko	Krama	Madya	Krama Inggil
Allow	Kareben	Kajengipun	Kajenge	Kersanipun
Obedient	Gugu	Gega	Dhaharatur	Ngestokaken dhawun
Speak	Celathu	Wicanten	Canten	Ngendika
Wear	Enggo	Engge	Ngge	Agem
You	Kowe	Sampeyan	Samangdika	Panjenengan

TABLE 5 The Javanese Personal Pronouns

English	Ngoko	Madya	Krama	Krama Inggil
I	Aku	—	Kula	Dalem
You	Kowe	Samang	Sampeyan	Panjenengan
He, She	Dheweke	—	Piyambakipun	Panjenengane, panjenenganipun

TABLE 6 Aspect Markers in Javanese

Ngoko	Krama	Meaning
Aja	Sampun	Don't
Arep, bakal	Badhe	Will
Durung	Dereng	Not yet
Isih	Taksih	Still
Lagi	Saweg	In the process of doing
Meh	—	Almost
Meksa	—	Even so, still
Ora	Mboten	Not
Padha	Sami	Also; indicates the plurality of the subject performing the action
Sok	—	On occasion, ever
Tansah	—	Always, constantly
Wis	Sampus	Already

Verbs are not inflected to denote tenses, but instead auxiliary words are used as aspect markers preceding the verb. The list given by Robson is given in Table 6.

The normal word order within the sentence is subject–predicate. There is no copulative verb, e.g. *klambiku reget* (my shirt is dirty). No changes are found in nouns or verbs for number, case, or gender.

MICHAEL PHILIP OAKES

Jespersen, Otto

Otto Jespersen was a markedly independent scholar. He did not adopt the terminology or the viewpoints of others, he belonged to no 'school' of linguistics, and he created none, but over his long and active academic career he created an astonishing body of work in a wide variety of linguistic subfields, virtually all of which constitutes a rich and continuing source of information for later scholars and an inspiration for many.

Jespersen first became known outside his native Denmark for work in articulatory phonetics. In 1889, he developed what came to be called an antalphabetic system for describing speech sounds using letters and numbers to represent the articulating organ in the mouth (lips, tongue, etc.), the exact place of articulation in the mouth, and the degree of openness of the vocal tract in the production of a sound. The result analyzed sounds into their components in a manner more akin to modern distinctive feature analysis than to traditional phonetic transcription. For purposes of transcribing Danish and its dialects, Jespersen invented

Dania, a dialect alphabet still in use. He also published a detailed book on phonetics in Danish in 1897; it was soon translated into German, making it more widely accessible to scholars. Little was new here, but Jespersen's emphasis on first-hand observation and the scope of his examples made the texts invaluable in promoting the empirical study of speech sounds.

In a campaign to reform Danish foreign language teaching and reacting against traditional pedagogical methods that stressed rote learning, grammatical rules, and translation, Jespersen became an advocate of what he considered a more 'natural' approach, emphasizing the spoken language, the use of meaningful and interesting texts for written language, and the learning of grammar by observation and induction. *How to teach a foreign language* (1904) was influential not only in his own country but in England and particularly in North America. Indeed, Leonard Bloomfield in his most important book, *Language* (1933), presented Jespersen's 'direct' method, and elements of this later made their way into the so-called 'Army method' developed by Bloomfield and other American linguists for foreign language teaching in the years immediately preceding and then during World War II. The focus on spoken language, on meaningful material in functional context, and a more inductive approach to the acquisition of grammar all characterized both the audiolingual method used in the United States during the 1950s and 1960s and its successor, sometimes referred to as the communicative approach.

An early idea and a fundamental theme that Jespersen pursued for many years was the notion of progress in language. Based on aspects of the history of the English language, he maintained that as a language changes, original inflectional endings will disappear and be replaced by principles of fixed word order. Challenging prevailing nineteenth-century beliefs that languages decay over time, Jespersen considered such changes as progress. The modern forms, he argued, are shorter, requiring less production effort; they are fewer, requiring less memory; they are more regular morphologically and syntactically; they avoid redundancy; and their regular word order assures understanding. Jespersen admitted that his conclusions were based on information from very few languages, but nevertheless he claimed that a progressive 'tendency towards grammatical simplification is a universal fact of linguistic history' (*Language*: *its nature, development and origin,* 1921:366). Further research has supported neither the older theory of decay nor Jespersen's theory of progress.

In 1909, Jespersen began publication of what would become his most extensive study of the English language, *A modern English grammar on historical principles* (*MEG*). Contrary to an emphasis emerging at the time in both Europe and America in the work of Ferdinand de Saussure and Franz Boas, with their emphasis on synchronic study without recourse to historical information, Jespersen always maintained that the science of language was essentially historical because 'a language or a word is . . . a result of previous development and at the same time . . . the starting-point for subsequent development' (*Language*: *its nature, development and origin,* 1921:7).

The *MEG* was Jespersen's life work, his magnum opus, and he saw it as the grammatical equivalent of the *New English dictionary on historical principles*, later known as the *Oxford English dictionary* (*OED*). The volume on *Sounds and spellings* and another on *Morphology* were quite traditional and are of little interest today, but the five *Syntax* volumes remain an invaluable resource, with an abundance of citations and great insights into the nature of English syntax, cited by twentieth-century linguists as diverse as Noam Chomsky, Eugene A. Nida, and W. Nelson Francis.

In the *MEG* and in shorter books that presented similar material on syntax (e.g. *The philosophy of grammar*, 1924; *Essentials of English grammar*, 1933), Jespersen introduced the notion of ranks, a hierarchy of levels of subordination and dependency among the words of phrases (e.g. in a phrase such as *very young child*, the highest rank is held by *child*, which Jespersen would call the primary; *young* has the next highest rank, the secondary, and *very* is the lowest, the tertiary). Junction referred to subordinate constructions, nexus to predicative structures; so *the barking dog* displayed junction, *the dog is barking* nexus. Because Jespersen always held to a close connection between linguistic form and content, his grammar also made use of notional categories, universal categories of meaning.

Although work in syntax was somewhat uncommon in the linguistics of Jespersen's day, many of his ideas are precursors to aspects of modern linguistic theories. The relation of mental categories and linguistic categories is certainly central to contemporary approaches, and the ideas Jespersen sought to develop with ranks, junction, and nexus are fundamental to modern theories such as valence grammar, dependency grammar, and some types of functionalgrammar.

Jespersen's most technical work on syntax was the small book *Analytic syntax* (1937), in which he developed a notational system for representing ranks, junction, nexus, and other syntactic constructions. The system was formal and complex, and at the time, few responded to it. But as syntax and formalism became more and more a part of twentieth-century linguistics, the book was reprinted several times in the later twentieth century, a tribute to Jespersen's lifelong interest in syntax and to his lasting influence.

Unlike linguists of more modern times, Jespersen's theoretical ideas often appeared not in highly technical monographs aimed at his peers, but rather in books directed toward the educated reading public. Books such as *Language*: *its nature, development and origin* (1921), *The philosophy of grammar* (1924), and *Mankind, nature, and individual from a linguistic point of view* (1925) were described in popular journals as 'fascinating', and many members of the public came to know about linguistics by reading Otto Jespersen. The most important idea that Jespersen brought to both the public and to other linguists was the rejection of traditional grammar that set forth standards of correctness. In its place, he proposed a living grammar, based on direct observation of contemporary spoken usage, a grammar that was founded on the past but continually changing, a grammar that was systematic but not without the irregularities we should expect in anything human.

Jespersen tried to relate current usage to the users of the language. In *Language*: *its nature, development and origin*, six chapters are devoted to 'The child'. Here, Jespersen explored at length issues in the development of language in children, treating sounds, words, and grammar, as well as possible influences that children's language acquisition might have on language change. This pioneering effort to relate the nature and the universals of human language and of language change to children's language acquisition anticipated major themes in linguistics of the late twentieth and early twenty-first centuries.

The same book contained another chapter well in advance of its times, a chapter titled 'The woman', in which Jespersen presented and analyzed various accounts of differences between women's and men's speech. Modern gender studies of language use have certainly supported Jespersen's premise that women and men use language differently, often for reasons having to do with societal differences. But Jespersen's ideas were reflective of his times and place, and his chapter on 'The woman' is also a source of statements that modern scientific scholarship soundly rejects, for example, 'Men will certainly with great justice object that there is a danger of the language becoming languid and insipid if we are always to content ourselves with women's expressions . . .' (p. 247).

Jespersen's dedication to the international auxiliary language movement is sometimes treated as an odd avocation, but this interest was a rational extension of some of his most fundamental linguistic work, especially his advocacy of foreign language learning for communication, his concern with universals of language, his theories on syntax, and his principles of progress in language change. He maintained that an artificial language constructed on scientific principles should be easy to learn and efficient to use, simple in grammatical structure, the epitome of progress in language. Jespersen called his language Novial (*nov* = 'new' + *i* 'international' + *a* 'auxiliary' + *l* 'language'). But the movement was fractured and no consensus developed. Jespersen's Novial disappeared, sharing the fate of other created languages.

There is scarcely a linguistic topic of interest today that does not appear at some point in Otto Jespersen's voluminous works, which number more than 800 scholarly items in print. While some of his lines of investigation seem dated and some of his theories have been challenged by more extensive data drawn from a wider variety of languages than he used in his work, it is nevertheless often fruitful and inspiring to go back to his writings on foreign language teaching, language use, and, especially, English syntax.

Biography

Otto Jespersen was born on July 16, 1860 in Randers, Jutland, Denmark. He entered the University of Copenhagen in 1877 and studied law; in 1881, he turned to the study of languages. For seven years, while a student, he worked as a shorthand recorder in the Danish House of Parliament. He received a master's degree in 1887 with major in French, secondary concentrations in English and in Latin (the latter obligatory for language majors). He traveled for a year, meeting linguists in England (Henry Sweet, James Murray), Germany (Karl Brugmann, August Leskien, Eduard Sievers), and France (Paul Passy, Jules Gilliéron). He returned to Copenhagen, and taught English and French in private schools while working on the doctorate. He defended his doctoral dissertation 'Studies on English case' in 1891. From 1891 to 1893, he served as an unpaid Privatdocent (instructor) at the University of Copenhagen, teaching Old English and Chaucer. In 1893, he was appointed Professor of English Language and Literature, University of Copenhagen. In 1899, he was elected to membership in the Royal Danish Academy of Sciences and Letters. He visited the United States and lectured at Congress of Arts and Sciences in St. Louis in 1904, and received the French Volney Prize for *Growth and structure of the English language* in 1905. He was Dean of Faculty of Arts, University of Copenhagen from 1904 to 1906. In 1909–1910, he again visited the United States, lecturing at the University of California and Columbia University. In 1920–1921, he was Rektor (Vice Chancellor), University of Copenhagen. Jespersen retired from the University of Copenhagen in 1925, and was elected to honorary membership in the Linguistic Society of America in 1926. In 1936, he was President, Fourth International Congress of Linguists, Copenhagen. He received honorary degrees from Columbia University in

1910, St. Andrews University, Scotland in 1925, and The Sorbonne, University of Paris, in 1927. He died on April 30, 1943 in Reskilde, Denmark.

JULIA S. FALK

Jones, Sir William

Sir William Jones, also known as 'Oriental' Jones, was a seminal linguist of the English Enlightenment, pioneering the study of comparative linguistics. Through his singular knowledge of western and oriental languages, he discovered the root relationships among them that would later be defined as the Indo-European language family. His devotion to and authoritative publications on Sanskrit and Arabic languages together with Hindu and Moslem religions and cultures made him a pioneer in introducing oriental culture to Europe. His admiration and respect for them defied and gradually began to reverse centuries of western religious and cultural ignorance and ridicule of them.

Jones studied with great success at Harrow College and Oxford University, where he held the Bennet [*sic*] fellowship. His intellectual prowess allowed him to elevate himself in society. His knowledge of the classics at Harrow so impressed Jonathan Shipley, Bishop of St. Asaph (Wales), that he recommended the young man to become the tutor in 1764 to the children of the vastly wealthy Earl of Spencer, a leading member of the independent Whig aristocrats. Tutoring financed his studies at Oxford, where he began studying the same year.

At the Spencer family seat at Althorp, he met Count Carol Revicsky, an enthusiast of Arabic and Persian, who was Polish ambassador to Great Britain and whose homeland lay in the shadow of the Ottoman Empire. Jones avidly added knowledge of these languages and cultures to the western classical ones he already knew. Arabic and Persian were of great importance in the oriental world, the first as the religious tongue of the region and the latter as its international one.

In 1770, when he was 24, Jones translated from the Persian, the *Histoire de Nader Chah*. He wrote in French, the western world's international language at the time, publishing the book in 1773 as *The history of the life of Nader Shah, King of Persia*, a tyrannical Persian ruler in India, who lived from 1688 to 1747. In 1771, Jones published *A grammar of the Persian language*, following this with pioneer translations of poetry from oriental languages.

To establish his economic and professional independence, he left the Spencer household in 1770 to study law in London at the Middle Temple. He became a lawyer and circuit magistrate in the districts of Oxford and Wales five years later and a commissioner for bankrupts. Now a noted young scholar, Jones was elected in 1773 to the Literary Club of Dr. Samuel Johnson, the renowned sage of the English language. Convening regularly at the Turk's Head Inn, club members included the historian Edward Gibbon, economist Adam Smith, painter Joshua Reynolds, and statesman Edmund Burke. A sympathizer of the movement for independence of the English colonies in America, Jones was also a friend of Benjamin Franklin, having known him from the Shipley family. Jones visited him three times in Paris after the American Declaration of Independence in 1776, where Franklin had become the young American republic's representative.

Jones's writings now advanced into the fields of law and politics. He especially concentrated on estate and commercial law, now a legal adviser to the Spencers and other aristocrats, with a work on Athenian inheritance law in 1779 and *An essay on bailments* in 1781. In addition, he wrote pamphlets and smaller works related to numerous issues regarding individual and political rights, proposing a plan for reconciliation between Britain and America based on common business interests.

To refine and deepen his oriental studies and to advance his professional position, Jones had long sought a judgeship on the bench of the English courts in India that especially oversaw operations of the East India Company. In 1783, he succeeded in being appointed an associate judge of the Supreme Court of Judicature for Bengal (now Bangladesh) in Calcutta. The same year, he was knighted by King George III, and he married Anna Maria Shipley, daughter of Bishop Shipley. They had known and been fond of each other for many years, but he vowed only to marry once he had established his financial independence. En route to the Orient, he wrote down a plan for his research, which he styled 'Objects of enquiry during my residence in Asia'. It outlined how he would survey Hindu and Moslem languages, literatures, religion, business, technology, and social and physical sciences. That he actually accomplished the study of this array of topics in the remaining 11 years of his life vaulted him to the realm of outstanding seminal scholars.

Founding the Asiatick Society in Calcutta in 1784, this association became the vehicle for propagating his voluminous research. He published *Asiatick miscellany* in 1785 and, from 1788 until his death *Asiatick researches*. He supported his research and publishing from his own financial resources. As the first president of the society, his annual presidential speeches became significant communications of his ideas and findings. The speech of 1786 (Third Anniversary Discourse) traced the common elements of western and oriental languages, the basis whereby others later identified the Indo-European family of languages. It also contributed to the development of comparative linguistics. Later discourses established the basis for establishment of comparative religious studies.

Jones also began a series of translations of epic works from oriental literature. The introduction of these classics into the English-language world and Europe would alter not only the perception of the weight and accomplishment of eastern civilizations but also influence directions and developments in modern European culture itself.

During 1784–1785 he translated nine poem-hymns to Hindu deities. In 1789, he translated *Gitagovinda* ('The song of Govinda'), a lyric poem that was one of the last Sanskrit devotional texts (*bakhti*) written. The increasing use of vernacular languages in the twelfth century began to obliterate the use of Sanskrit, somewhat as in Western Europe vernacular languages, such as Florentine Italian, began to obscure the use of Latin. In the same year, he translated the romantic verse play, the *Shakuntala* (also *Sakuntala*). This was the masterpiece of the greatest writer of classical Sanskrit, Kalidasa, a fifth-century resident of the Gupta court. In 1792, he oversaw the first printing in Sanskrit of Kalidasa's *Ritusamhara*, and translated from Arabic *Al Sirajiyyah*.

Given the vast range, quantity, and originality of the work of Sir William Jones, it seems incongruous that one can say he left his work incomplete at the time of his death in 1794. Nevertheless, he left many projects still to complete and, even more, a future promise to satisfy.

In recent decades, there has been much controversy regarding the focus and treatment of eastern cultures that Jones introduced. 'Orientalism' has been denigrated as colonialist, manipulative, and self-serving. Nevertheless, one of the central issues of modern history has been the emergence of relations between East and West as vital global concerns. It is indisputable that Sir William Jones played a key initial role in making the West aware of the East and of the need to respect the Orient's vast cultural accomplishments and to recognize the manifold characteristics that East and West share.

Biography

Sir William Jones was born in London in 1746. He was a student of Harrow College in 1753–1764, and of University College, Oxford in 1764–1768. He was private tutor to the children of the first Earl of Spencer in 1765–1770. He studied law in Middle Temple, London

in 1770–1773. Jones was elected Fellow of the Royal Society, London in 1772, and was elected as a member of the Literary Club of Samuel Johnson, London in 1773. He also practiced as a lawyer in London; as a circuit judge in Oxford and South Wales districts; and as commissioner of bankrupts in 1775–1783. Jones was knighted in 1783 and married Anna Maria Shipley the same year. He was appointed to the Supreme Court of Judicature for Bengal, Calcutta in 1783–1794. He founded the Asiatick Society of Bengal, Calcutta in 1784. Sir William Jones died as a result of liver inflammation, and was buried in Calcutta in 1794.

EDWARD A. RIEDINGER

Juba and Nubi Arabic

Juba and Nubi Arabic are two contemporary related Arabic-based Pidgins–Creoles descending from an Arabic military pidgin that developed in southern Sudan following the annexation of Sudan by the Turkish–Egyptian Government in 1820. While the northern and central parts of Sudan were already largely Arabized at the end of the eighteenth century, the southern part of Sudan laid behind the southern borders of Arabic expansion due to physical barriers. Thus, the conquest of southern Sudan between 1839 and 1841 instituted the first trade contacts between the north and the southern hinterlands. The subsequent establishment of military and trade camps and the development of a large-scale slave trade between 1854 and 1889 led to major social upheavals and to the emergence of an Arabic pidgin in this previously non-Arabic-speaking area. Many members of the local southern population (sometimes up to 25%) were captured as slaves or employed in the camps, whose population could number up to 10,000 people. In these camps, the southern population soon outnumbered the Arabic-speaking population. Coming from heterogeneous linguistic and ethnic backgrounds, this southern detribalized population quickly adopted a pidginized form of Arabic as its lingua franca. The exact origin and form of this Arabic pidgin remains unknown. Its target language seems to have been a mixture and an approximate form of Egyptian and northern/western Sudanese Colloquial Arabic. It is not certain whether a single variety spread all around southern Sudan or whether various varieties emerged simultaneously in the different camps. But the available historical and contemporary data testify to a very similar restructuring process and indicate that this Arabic-based pidgin stabilized in a very short span of time.

Following various military events at the end of the nineteenth century, the southern Sudanese Arabic pidgin first known as Bimbashi Arabic (from Osmanli, Bimbashi 'officer') developed in three further varieties: Turku in Chad, Nubi in Kenya and Uganda, and Juba Arabic in southern Sudan. Turku (from Arabic, Turuk, i.e. 'Turks') was brought from Bahr al Ghazal to Chad at the end of the nineteenth century by some Sudanese soldiers from Rabeh's army. It remained a pidgin and became one of the trade languages of Chad and neighboring countries in the first decades of the twentieth century. No present-day Turku is recorded; also, some kind of Arabic functions as interethnic lingua franca in this area. Nubi (or Ki-Nubi) was brought to Kenya–Uganda in 1888 by the retreating Sudanese

567

soldiers of Amin Pacha's army. Those Arabized and Islamized soldiers stayed and formed a new ethnic groups till locally known as Nubi and speaking an Arabic-based Creole, ki-Nubi, as their mother tongue. Cut off from further Arabic influence, Ki-Nubi developed in a dominant African/Swahili environment and is not mutually intelligible with standard Arabic (both Colloquial or Classical Arabic). Most East African Nubis are urban dwellers and are at least bilingual. In southern Sudan and more specifically in Equatoria, Bimbashi Arabic continued to develop during the first decades of the twentieth century first in the military garrisons and urban centers and then spread as the main lingua franca in the heterogeneous rural areas with minimal contact with standard Arabic. Today, it is becoming the mother tongue of a growing number of children in southern urban areas due to mixed neighboring and interethnic marriages. It thus functions both as a first and second language. It became known as Juba Arabic from Juba, the capital of Equatoria. Since 1956 and more intensively since the 1980s, Juba Arabic speakers have been more exposed to Colloquial Sudanese Arabic and Classical Arabic through mass media, schooling, urbanization, and migration to northern Sudan. Therefore, many Juba Arabic speakers can shift from a more Creolized variety to a more Colloquial one according to the setting. However, the antagonistic relationship between the North and the South fosters the identity function of Juba Arabic, which is perceived as expressing and symbolizing an 'African identity'.

Ki-Nubi and Juba Arabic are mainly spoken languages. They are not taught and have neither been standardized nor normalized through an official script. Ki-Nubi is an ethnic language for approximately 15,000 Kenyan speakers and an unknown number of Ugandans. Juba Arabic, on the other hand, is both a vehicle for the majority of the southerners and a vernacular for some urban dwellers. Its formal contexts of use include limited radio broadcastings, theatrical performances, songs, Christian religious preaching, etc. Some prayer books are written in Juba Arabic using Latin script, while individuals educated in Literary Arabic may use Arabic script. Both Nubi and Juba Arabic include regional varieties. But Nubi appeared more homogenized than Juba Arabic, which encom-

passes a wide range of individual variations. In spite of a short time of common history and a century of separate development, Nubi and Juba Arabic are structurally closed and mutually intelligible, which may indicate that their common ancestor stabilized before their split. The lexicon derives mainly from Arabic roots, but with important phonological restructuring and the addition of a number of borrowed words from African vernaculars. The morphology of Arabic has been lost (such as verbal flexions, derived verbal and nominal forms). Both languages used invariable verbal and nominal stems and independent grammatical markers for expressing grammatical categories such as tense, aspect, persons, definiteness, comparative, etc. Like for most Pidgins and Creole languages, the attention of linguists focused on the supposed origin of these linguistic features. In this respect, Arabic-based Pidgins–Creoles appear to share many similarities with other non-Arabic-based Pidgins–Creoles especially regarding the verbal system. Their restructuring has gone further than any other Arabic Colloquial varieties, including the most peripheral ones, and interferences from neighboring African languages have been pointed out at various levels. The three above-mentioned Arabic-based Pidgins–Creoles might not have been the only Arabic-based existing ones but their history testified to a radical context of emergence compared to other situations of contact. The maintenance of Nubi and Juba Arabic as specific Pidgin/Creole varieties also indicates the crucial role played by identity factors.

CATHERINE MILLER

K

Kayardild and the Tangkic Languages

The Tangkic languages are spoken in Queensland, Australia, in the Wellesley Islands and adjoining mainland. The family comprises three main languages: Lardil, Kayardild, and Yukulta. Additional and now extinct varieties are Yangkaal and Nguburindi, although the limited materials we have on these show Yangkaal to be a sister dialect of Kayardild and Nguburindi a sister dialect of Yukulta. Within Tangkic, the family bisects into 'northern Tangkic', comprising Lardil alone, and 'southern Tangkic', comprising Yukulta and Kayardild.

The Tangkic languages have no close relatives, although they are related, at a distant level, to other Australian languages and share most grammatical similarities with languages along the Roper River, well to the west.

Speakers of the Tangkic languages were traditionally hunter–gatherers, with a strong emphasis on marine resources, building stone walls around the coasts to catch fish and hunting for the abundant turtle and dugong found in the area. Apart from the Kayardild, who were relatively isolated, the other Tangkic groups were linked together in a complex network of tribal interrelationships with people to the west and south. From the 1860s for the Yukulta, the 1920s for the Lardil, and the 1940s for the Kayardild, they came into increasingly intensive contact with pastoralists on the mainland and missionaries on the islands, which disrupted many aspects of traditional life, although there has been a recent resurgence in many traditional activities. However, no Tangkic language is now spoken fluently by people below the age of 40 and none has more than a dozen speakers left: English has replaced them, albeit in a distinctive form containing many words adapted from Tangkic languages.

Apart from scanty word lists from the nineteenth and early twentieth centuries, all materials on the Tangkic languages have been recorded since the early 1960s. The practical orthographies (written language systems) used to write these languages were developed in this period. These orthographies use digraphs for a variety of sounds; e.g. *r* before a stop or nasal letter denotes retroflexion. For example, *rd* or *rn* indicates that the *d* and *n* are pronounced with the tip of the tongue curled backward. Similarly, an *h* after a stop (*th*) or nasal letter (*nh*) indicates that the blade of the tongue is placed between the teeth for the pronunciation of the relevant sounds. As far as their sound system is concerned, the Tangkic languages are typical Australian languages.

Lardil differs from the other Tangkic languages in having lost the final syllable in words greater than two syllables: cf. Kayardild *kandukandu,* 'red', but Lardil *kandukan.* Furthermore, Lardil dropped off any remaining word-final *ng*, *k, m,* or *b*: cf. Kayardild *kurkangka,* 'bulrush', but Lardil *kurka* (rather than *kurkang*). Because various grammatical suffixes 'protect' the original word stem from such truncation, Lardil has developed a systematic distinction of word forms, depending on their function and position in the sentence. The Tangkic languages are typical of Australian languages in using a rich system of case suffixes, i.e. word endings that make distinctions similar to English *the house* vs. *to the house.* This allows for great freedom of word order. Beyond this, their case systems are perhaps the most remarkable in the

world for several interrelated reasons. First—and by no means uniquely in Australia—they exhibit *double case marking,* because one noun phrase embedded in another inflects both for its own case (e.g. the possessive) and that of the main noun: cf. Kayardild *thabuju-karra,* 'brother's', and *wangal-nguni,* 'with the boomerang' (literally 'boomerang-with'), combine to *thabuju-karra-nguni wangal-nguni,* 'with brother's boomerang' (literally 'brother's-with boomerang-with'). Second, Kayardild and Lardil mark e.g. tense, not only on the verb but simultaneously via *modal case* suffixes on nouns. Thus, Ksayardild *dangka-a burldi-jarra yarbuth-ina thabuju-karra-nguni-na wangal-nguni-na,* 'the man hit the bird with brother's boomerang', shows a past-tense suffix *-jarra* on the verb *burldi,* 'hit', and also a modal case suffix *-(i)na* on the nouns *yarbuth,* 'bird', *thabuju-karra-nguni,* 'with brother's', and *wangal-nguni*, 'with the boomerang'. Third, in Kayardild, case suffixes can be used to connect sentences with each other. In this usage, the relevant suffix occurs on all words of the subordinate (dependent) clause. Much of how this strange system evolved has now been reconstructed with the help of data from Yukulta, the Tangkic language that conserves the most characteristics of the common ancestor language.

Another twist to case in the Tangkic languages is added by a further set of *verbal case* inflections, semantically and structurally part of the set of normal case inflections, but with the peculiarity that they convert their hosts from nouns into verbs. Kayardild *ngada waa-jarra wangarr-ina ngijin-maru-tharra thabuju-maru-tharra,* 'I sang a song for my brother', for example, contains *thabuju-maru-tharra,* 'for my brother', which literally means 'brother-put-(past tense)'. Thus, the *verbal dative case* suffix *-maru-* converts the noun *thabuju* into a verb, which then takes the regular verbal inflection for past tense: *-tharra.*

Like many other Australian languages, the Tangkic languages have a highly developed set of derivatives from compass terms. To locate an entity, one normally says things such as 'the east uncle' or 'the shark coming from the east'; some Kayardild examples of derivatives based on the root *ri-*, 'east', are *riinda,* 'coming from the east', *rilungka*, 'eastward', *riliida*, 'heading ever eastwards', *riyananganda*, 'to the east of', *ringurrnga*, 'east across a geographical boundary', *riyanyinda*, 'at the eastern extremity of', *rilumir-damirda,* 'sea-grass territory to the east', *rilurayaan-da,* 'from one's previous night's camp in the east', *rilijulutha,* 'move to the east', and *riinmali,* 'hey you coming from the east'.

Lardil and Yangkaal people had a special auxiliary language, known as Damin, taught to second-degree initiates, which involved substituting all roots (but not grammatical suffixes) with special forms drawn from a set of approximately 150 items with abstract meaning and a bizarre sound structure. In fact, the sound structure of Damin is unique among the world's languages in using five distinct airstream types: some sounds are produced with the usual mechanism of pressing air outward from the lungs (pulmonic egressive), others are produced with inward breath (pulmonic ingressive), and others are click sounds (velaric ingressive) and sounds produced by ejecting air via tongue movements (labiovelar lingual egressive) and by movements of the Adam's apple (glottalic egressive). Of these, the pulmonic ingressive and labiovelar lingual egressives are found nowhere else in the world's languages, at least not with a similarly prominent function. As far as meaning is concerned, Damin solves the problem of compressing the entire everyday language vocabulary into 150 terms by four methods:

- Highly abstract words, such as a single form for 'act harmfully/damagingly upon' to replace the everyday words for 'eat', 'chop', 'bite', 'shoot', and 'cut'.
- A variety of semantic extensions are used to tie together many distinct senses for the relevant word; e.g. 'stomach' is also used to mean 'large intestine' (by contiguity), 'guts, excrement' (by association), 'defecate' (product to process), and 'emerge' (by metaphor).
- The same word can be used as a noun or a verb, as shown by the extension from 'excrement' to 'defecate', above; inflectional suffixes show which is intended.
- The Damin words are supplemented by hand signs to distinguish subtypes, e.g. the abstract term for 'fish' means 'bluefish', which crunches coral with its teeth, if the speaker points to the teeth. Because these speech–sign combinations are conventionalized and taught together, Damin should probably be viewed as a mixed speech and sign language.

Khmer and Mon-Khmer Languages

The largest of the branches making up the Austroasiatic language family, the Mon-Khmer language group comprises over a hundred languages spoken throughout Southeast Asia, particularly in the countries of Kampuchea, Vietnam, and Malaysia. While primarily concentrated on the mainland of Southeast Asia, Mon-Khmer languages can be found as far west as the Republic of India and on various islands surrounding the Asian mainland. The distribution of Mon-Khmer languages throughout Southeast Asia suggests that they were among the first to be spoken in the region. Although it is hard to be certain without written evidence, some scholars have speculated that the branches of Mon-Khmer separated at approximately the same time during the second millennium BC. The most commonly accepted subgrouping of the Mon-Khmer languages proposes a classification of nine branches: Khmer, Monic, Pearic, Bahnaric, Katuic, Khmuic, Palaungic, Khasi, and Viet-Mu'o'ng.

Mon-Khmer languages possess several characteristics distinguishing them from other languages spoken in Southeast Asia. Among the most significant of these is that words in Mon-Khmer languages tend to be sesquisyllabic, i.e. a word consists of an initial unstressed syllable followed by a stressed syllable with full vocalism, in contrast to the high frequency of monosyllabic and disyllabic words in other languages in the region. Another characteristic making Mon-Khmer languages unique to the region is that they generally do not recognize tone as phonemic, i.e. creating a difference in meaning, in contrast to tonal languages in the region such as Thai, Lao, and Chinese. Mon-Khmer languages do, however, make a phonemic distinction between such vowel qualities as breathiness and creakiness, and the aspiration of consonants is recognized as phonemic as well. An additional characteristic that makes Mon-Khmer languages unique is that they possess very large, complex vowel systems. For example, the most complex vowel system among these languages is that of Bru, a member of the Katuic branch of Mon-Khmer, which has 68 vowels in its inventory. Conversely, the inventory of consonants in Mon-Khmer languages is relatively small, due in part to the absence of voiced sounds found in many other languages of the world.

Khmer

One of the oldest languages in Southeast Asia, Khmer is the official language of Kampuchea (formerly Cambodia). In addition to the six million Kampucheans who speak Khmer, political turbulence in Kampuchea, especially during the 1970s, resulted in many people fleeing the country and creating sizable populations of Khmer speakers outside Kampuchea, primarily in the neighboring countries of Thailand, Vietnam, and Laos. Khmer speakers also reside in France and the United States, bringing the total number of Khmer speakers to over seven million. Modern Standard Khmer is used throughout Kampuchea; however, regional differences are typically slight enough that there are few obstacles in cross-dialectal communication.

As a result of thousands of years of contact between various populations in Southeast Asia, many of the languages spoken in the region share much of the same vocabulary. During the Angkor period from the ninth to the fifteenth centuries CE, Khmer had a powerful influence on other languages in the region,

an influence that extended to unrelated languages such as Lao and Thai, as well as to other Mon-Khmer languages, such as those of the Pearic branch, which includes Chong and Pear, and the Bahnaric branch, which includes Phnong and Chrau. Khmer and Thai, which is primarily spoken in neighboring Thailand, share so much with respect to vocabulary that early scholars were led to believe that the two languages were genetically related. It is now assumed, however, that the similarity between the two languages is due to mutual borrowing and reborrowing between them. This borrowing has extended beyond lexical borrowing to include syntactic borrowing as well. The Khmer lexicon also includes borrowings from Vietnamese.

Khmer has also borrowed extensively from languages outside the region of Southeast Asia. During the Angkor period, Khmer borrowed much of its institutional vocabulary from Sanskrit and some of these borrowings can now be heard in colloquial speech, while others are typically only found in literary works. Since the introduction of the Buddhist religion to Kampuchea in the fifteenth century, Khmer has also borrowed heavily from Pali. During the political domination of Kampuchea by the French from the mid-nineteenth to the mid-twentieth century, Khmer borrowed many French words, some of which can still be heard, particularly in Kampuchea's urban centers. Khmer has also borrowed a small number of Chinese words. Since Khmer words are generally monosyllabic and sesquisyllabic, polysyllabicity is typically indicative of borrowings, most often from Pali, Sanskrit, or French.

Like other Mon-Khmer languages, the inventory of sounds in Khmer is interesting, mostly owing to its large vowel system. While not as vocalically rich as Bru, most standard dialects of Khmer have between 25 and 28 vowels, with a typical inventory comprising 27 vowels. The Northern Khmer dialect has a system comprising at least 31 vowels. The consonantal inventory of Khmer is somewhat smaller than its vocalic inventory, partially due to the absence of voiced sounds such as *g* and *z* that speakers of other languages would expect to find. Phonologically, consonant clusters may occur at the beginning of a Khmer word, but not at the end. Additionally, there exist several consonants never found word-finally in Khmer, including *r, s, b,* and *d.*

Like Chinese and Vietnamese, Khmer is an isolating language, which means that it tends toward a one-to-one correspondence between morpheme and word. Khmer never uses inflectional morphology, but relies on separate morphemes or context to show such things as gender, number, and tense. Although lacking inflec-

tional morphology, Khmer uses derivational morphology to create new words. With respect to affixing, Khmer does not use suffixing, but uses prefixing and infixing, particularly as a means of deriving nouns from verbs. Khmer also uses compounding extensively and reduplication is common, particularly with vowel alternation in the prefixed reduplicant to create a class of words known as iconic expressives.

The basic word order of Khmer is subject–verb–object, although topicalization, or the movement of an object to the beginning of a sentence, is a common phenomenon in Khmer. Questions retain the same word order as statements in Khmer. Adjectives and other elements dependent on the noun generally follow the nouns they modify, an exception being that numerals typically precede the noun. Negation is preverbal with an intensifier typically following the verb.

Mon

Prior to the sixteenth century CE, the Mon ruled over parts of Myanmar and Thailand, but today the Mon live primarily in small villages in Myanmar (formerly Burma) and in Thailand. In Myanmar, they generally live along the Tenasserim coast between Thaton and Tavoy, and also live in the vicinity of Pegu. Although the Mon have made many efforts to attain recognition as a state in Myanmar, these attempts have met with little success. As a result, over the past several centuries many Mon have fled to Thailand, where they live primarily in the Chao Phraya basin between Uthiathani and Bangkok. Although they do not live in the city of Bangkok itself, the Mon have established a cultural center in Thailand on the southern outskirts of the city in the town of Prapradaeng. Despite this success, the southern portion of Myanmar is still considered the homeland of the Mon.

The language of the Mon has a story parallel to the story of its speakers. A member of the Monic branch of Mon-Khmer languages, Mon was once a major language in Southeast Asia; however, it is now spoken by fewer than a million people. Although for centuries there has been pressure on the Mon in both Myanmar and Thailand to assimilate to the dominant languages and culture in the countries—Burmese and Thai, respectively—the pressure to assimilate has increased since World War II due to modernization and urbanization. In Thailand, where the Mon have been living in exile for centuries, there is intense pressure for all ethnic minorities to assimilate—the Thai government makes no distinction between ethnic groups and Thai. Additionally, the Thai language and culture are the only local language and culture recognized by the government schools. Not surprisingly, the Mon exiles

have made no attempts to gain autonomy in their adopted country of Thailand.

Khasi

The westernmost language in the Mon-Khmer group, Khasi is spoken by approximately 500,000 people living in the Khasi and Jaintia Hills of Meghalaya; as such, it is the only Mon-Khmer language found in the Republic of India. Khasi is also spoken by about 85,000 people in Bangladesh. Because of its geographical isolation from other Mon-Khmer languages, Khasi is the sole member of the Khasi branch of the Mon-Khmer group. Its status as a singular language in India, as well as its strong matrilineal society, has attracted a great deal of interest in the Khasi people, particularly among ethnographers and other scholars. As a result, the Khasi people have managed to maintain some prestige in the region.

Vietnamese

Vietnamese is the official language of Vietnam and comprises approximately 80 million speakers, primarily in Vietnam, but also in neighboring countries, as well as in France and the United States. Although Vietnamese is now generally recognized as being a member of the Mon-Khmer family, its genetic affiliation was the subject of debate among linguists for some time. The controversy arose due to the status of Vietnamese as a tonal language, a trait also possessed by Chinese and Thai, but a trait not shared by the majority of Mon-Khmer languages. Although tone is not the only characteristic that Chinese and Vietnamese share, another being the great number of lexical items the two hold in common, linguists ruled out any close genetic affiliation between the two languages long ago, instead attributing similarities, particularly with respect to vocabulary, to the long domination of the Vietnamese by the Chinese. Given the choice between Vietnamese as a Mon-Khmer language that had somehow adopted tone, or a Tai language that had borrowed much of its vocabulary from Mon-Khmer languages, many linguists adopted the latter view until the convincing argument of Haudricourt (1954). A French botanist, Haudricourt argued that the phenomenon of tonal genesis in Vietnamese was an evolutionary process in which the language acquired three tones by the sixth century through language contact with speakers and through internal changes, and doubled this number by the twelfth century to the six tones currently used in the Hanoi dialect of Vietnamese. Haudricourt went on to argue that the tones in Chinese and Thai developed in much the same way.

Despite their differences, Vietnamese and other Mon-Khmer languages share a number of characteristics. Vietnamese is an isolating language with no inflectional morphology; however, like other Mon-Khmer languages, Vietnamese uses derivational morphology as a means of creating new words. Besides prefixing, Vietnamese makes extensive use of compounding and also uses reduplication, particularly in onomatopoetic expressions.

Among the Austroasiatic languages, three have long traditions of writing: Khmer, Mon, and Vietnamese. The earliest Khmer writings in which the date is known were written in 611 CE, and other extant writings are estimated to be from the second or third centuries CE. Khmer is written in a phonologically based writing system that derives from the Pallava script, a system that was used in South India at approximately the same time and descended from the Bhrami script. Having evolved since its introduction, the script used for writing in Khmer is now called the *Khmer letters*. Mon is also written with an Indian-derived alphabet and extant texts include some dating back to the eleventh century CE. In addition, epigraphs have been found that date back to approximately 600 CE. Although Vietnamese also has a long written tradition, the history of this writing is considerably different from the histories of writing in Khmer and Mon. Written Vietnamese begins with Chinese characters, then with a writing system derived from Chinese characters, and finally a Roman script introduced by Catholic missionaries in the seventeenth century. Although scholars have speculated that the Vietnamese were using the Chinese script to record their own language as early as the eighth century CE, the earliest extant writings of Vietnamese in this script date back to the thirteenth century.

Khoisan

According to a widely accepted genetic classification by Joseph Greenberg (1963), Khoisan constitutes one of the four language phyla (or families) to be found on the African continent. Apart from two languages (Sandawe, Hadza) spoken in north-central Tanzania, all languages are found in southern Africa, mostly in Botswana and Namibia, and to a minor extent also in Angola, Zambia, and South Africa. While there must have been more than 100 Khoisan languages prior to the European conquest of southern Africa, less than 30 have survived. The total number of Khoisan speakers probably does not exceed 200,000, of whom around two thirds belong to one language community: Nama/Damara (cf. Güldemann and Vossen 2000).

Earlier work on Khoisan had assumed, largely based on nonlinguistic criteria taken from physical and cultural anthropology, that there exists a basic division between 'Hottentot' and 'Bushman' languages. The former were said to consist of the Khoekhoe branch of the Khoe family (see Table 1). The latter includes the remainder of Khoisan, with the exception of the Tanzanian languages Sandawe and Hadza, which were not associated with this general entity at that time (see e.g. Meinhof 1912). This division is reflected in the label 'Khoisan', proposed by Schultze (1928), which is composed of two lexical items from the Nama/Damara language: *khoi* (or *khoe*) 'person', standing for the 'Hottentot', and *san* 'forager', standing for the 'Bushman' languages.

Subsequent research established that there exists some kind of linguistic relationship uniting the Khoisan languages of southern Africa (cf. Köhler 1975). Greenberg (1963) was the first to argue that Khoisan forms a genetic unit, and that this unit not only includes the 'click languages' of southern Africa but also two East African languages. He proposed the following classification of Khoisan:

(1) South African Khoisan
 a. Northern
 b. Central
 c. Southern
(2) Sandawe
(3) Hatsa (= Hadza)

A number of Khoisanists are reluctant to adopt Greenberg's (1963) hypothesis that the Khoisan languages really are genetically related to one another. Greenberg's phylum hypothesis has been defended by some (e.g. Honken 1977; Ehret 1986) but rejected by others (e.g. Westphal 1971). A third group of scholars (e.g. Köhler 1981; Sands 1998; Traill 1986; Güldemann and Vossen 2000) do not explicitly reject Greenberg's hypothesis but argue that so far there has been no proof of genetic relationship; given the evidence available, this appears to be the most reasonable position to be assumed.

A substantial number of lexical and grammatical similarities across various groupings of Khoisan have been identified, but in most cases it remains unclear whether these similarities are due to genetic relationship or language contact. Only for one of the Khoisan families, Khoe, there exists a sound comparative analysis (Vossen 1997).

Table 1 gives an overview of Khoisan languages and their genetic classification (for more details and a slightly different treatment, see Güldemann and Vossen 2000). Some of the languages are presumably extinct; others form dialect clusters. The !Xun family, for example, constitutes a complex dialect cluster connected by chains of mutual intelligibility, even if many East !Xun speakers do not understand North !Xun speakers. In most cases, it remains unclear whether there is a language or a dialect boundary. For example, Kxoe, Buga, and ǁAni are treated here as different languages of Kalahari Khoe; yet, there are also reasons to consider them as dialects of one and the same language (see Table 1).

While it remains unclear whether indeed the Khoisan languages form one language family, there are a few typological characteristics that set these languages off from the neighboring Bantu languages in particular and from many other languages in general:

(1) Most Khoisan languages distinguish between at least four different types of click; languages of the !Ui-Taa and the ǂHõã families even have five. In addition to dental (ǀ), alveolar (!), palatal (ǂ), and lateral (ǁ) clicks, there is a bilabial click (ʘ) in these two families.
(2) Furthermore, there are a number of distinctions made in vowels; !Xun, for example, has distinct sets of oral, nasal, glottalized, and pharyngealized vowels.
(3) Accordingly, the number of phonemes in these languages is comparatively high; some of these languages, such as !Xõõ and !Xun, have more than one hundred distinct phonemes and thus

TABLE 1   Khoisan Languages
DC = dialect cluser, C = central, E = east, N = north, S = south, W = west, ⁺ = presumably extinct language.

Family	Branch	Group	Languages	Where Spoken	Number of Speakers
!Xun (Northern)			North !Xun (DC)	S Angola, N Namibia	Less than 5,000
			East !Xun (Juǀ'hoan; DC)	NE Namibia, NW Botswana	Less than 5,000
Khoe (Central)	Khoekhoe	North	Namara/Damara, Haiǀǀ'om, ⧺Aakhoe (DC)	Namibia	Over 120,000
		South	⁺!Ora; ⁺Cape varieties (DC)	S Namibia, South Africa	Presumably extinct
	Kalahari Khoe	West	Kxoe, Buga, ǀǀAni (DC); Naro (DC); Gǀǀana, Gǀui, ⧺Haba (DC)	NE Namibia, Botswana, SE Angola	Over 10,000
		East	Shua, Ts'ixa, Danisi, ǀXaise, ⁺Deti; Kua-Tsua (DC)	Botswana	Less than 5,000
!Ui-Taa (Southern)	!Ui		⁺ǀXam, ⁺ǀ'Auni, ⁺⧺Khomani, ⁺ǀǀXegwi, etc.	South Africa, E Namibia, W Botswana	Presumably extinct
	Taa		!Xõõ (DC)	W Botswana	A few thousand
⧺Hõã			⧺Hõã	WC Botswana	A few hundred
Kwadi			⁺Kwadi	SW Angola	Presumably extinct
Sandawe			Sandawe	C Tanzania	A few ten thousands
Hadza			Hadza	C Tanzania	A few hundred

belong to the phonetically most complex languages of the world.

(4) Although Khoisan languages have a fairly rich inventory of grammatical distinctions, their morphological structure is fairly isolating analytic.

A widespread morphological characteristic of Khoisan languages is the presence of a noun class system. There is, however, a remarkable difference between the Khoe languages on the one hand, and the !Xun and Taa languages on the other. While the latter do not make a morphological distinction based on natural sex, marking distinctions such as human vs. non-human or animate vs. inanimate instead, Khoe languages have three gender categories, which are masculine, feminine, and common. Khoe languages are further characterized by a set of portmanteau morphemes simultaneously expressing person, gender, and number (pgn-markers); since there are three categories of each person, gender, and number (singular, dual, plural), there are close to 27 different pgn-markers, as well as personal pronouns, in these languages. Sex-based gender systems are also found in Kwadi, Sandawe, and Hadza.

Widespread in the verbal system (except for Khoe) are suppletive verbs, where there are different forms for singular and plural. Suppletive verbs show number agreement with the object in the case of transitive verbs and with the subject in the case of intransitive verbs. Furthermore, a number of Khoisan languages have verbal derivational morphemes, invariably suffixes or enclitics on the verb.

Most Khoisan languages have subject–verb–object (SVO) as their basic word order, the noun precedes its modifiers, but in attributive possessive constructions the head follows its modifiers. Hadza has both verb-initial (VSO) and verb-medial (SVO) order, while all Khoe languages and Sandawe have essentially verb-final (SOV) syntax with modifiers preceding the head. While clause subordination is common in Khoe, coordination involving structures commonly found in verb-serializing languages appears to be widespread in other Khoisan languages. A syntactic characteristic of a number of Khoisan languages is the presence of a multipurpose oblique case marker used to introduce adjuncts, i.e. clausal participants that are not part of the valency of the verb (Güldemann and Vossen 2000:110).

While one language (Nama/Damara) has been described in some detail, the majority of Khoisan languages are virtually unknown, apart from a few grammatical details and/or a wordlist (see Güldemann and Vossen 2000:103). With the exception of Nama/Damara and a handful of other languages, all languages are seriously endangered, many of them on the verge of extinction.

Kinship Terms

The inventory of names for family members found in a language can tell us a great deal about the culture of the speakers of that language. How these names are used, both within and outside the family, is also closely related to culture. For these reasons, the study of kinship terms has been important to anthropological linguistics. It has also played a role in theories of word meaning. In cognitive linguistics, kinship terms can provide us with examples of 'unmarked' and 'marked' categories, that is, categories that fit neatly into a symmetrical structure as well as categories that are asymmetrical. This allows us to see the interplay between particular social structures and linguistic universals in forming systems of meanings within a language.

Kinship terminology forms a well-defined subset of vocabulary within a language, and it is a subset that tends to be more structured, symmetrically and hierarchically, than other areas of the lexicon. These characteristics make kinship terms good candidates for a type of meaning analysis known as 'componential analysis'. This type of analysis seeks to break down word meanings into their basic components, typically using a binary classification system. For example, many kinship terms designate the sex of the person referred to, so that *nephew* could be labeled as +male, while *niece* would be labeled as −male. Besides the sex of the referent, other components of kinship terminology are the sex of the speaker, generation (*x* generations older or younger), birth order (used e.g. to distinguish among older or younger siblings), whether the kinship tie is maternal or paternal, whether the relation is by blood or by marriage, and whether the relation is lineal (*father, daughter*) or collateral (*aunt, cousin*). In English, a combination of the components +2 generations, −male, and +lineal would indicate the person called *grandmother*. Different contrasts show up in different languages.

Anthropologists are interested in which contrasts are maintained and which ones are merged or overlap in different societies. In Arapaho, a man would use the term *neyóo* to refer to his brother-in-law, while a woman would use the term *neiθébi* for her brother-in-law. *Neiθébi* actually means something like 'sibling-in-law of a different sex', and it would be used by a man to refer to his sister-in-law. In the Iroquoian languages, there are different words for older and younger sisters and brothers; lineal and collateral relatives are not separated as in English: in Seneca, *noʔyéh* refers to one's mother and her sisters, and *haʔnih* refers to one's father and his brothers. In English, cousins are not distinguished by sex, but in Czech, they are.

The Omaha Indians had a system that has been described as 'skewing' and 'merging' certain categories. Generational distinctions are skewed depending on one's sex, so that a woman's brother and her father are equivalent. In other words, the brother of a female is shifted to an older generation. This leads to the merging of other relations as well: the maternal uncle would be equivalent to the grandfather, and a man's sister would

be equivalent to his daughter. It has been proposed that a system like this one can account for the facts of Proto-Indo-European kinship terminology also (cf. Latin *avus* 'grandfather' and *avunculus* 'maternal uncle').

A look at Proto-Indo-European kinship terms reveals certain features of the social organization of these ancient people. If a woman's brother takes on the status of her father, the men of the family likely held higher status positions of dominance or protection over the women within their own generation. Not only was the culture therefore patriarchal, it was also patrilocal, meaning that when a woman married, she went to live with her husband's family. This is reflected in the greater frequency and number of terms for a woman's in-laws than a man's in the Proto-Indo-European language. Thus, the kinship terms provide us with clues about the role of women in this society.

We can ask whether the categories that are important in distinguishing kinship terms affect the way in which people perceive the world. Does the lack of a particular distinction in the vocabulary of a language mean that people who speak that language are unable to mentally make that distinction? Most would reject this extreme version of linguistic relativity. That is, using the same word for both mother and mother's sisters does not mean that the speaker cannot distinguish who is his/her biological mother. It does, however, imply that one behaves in certain ways toward both the mother and her sisters, perhaps having the same obligations toward them. In this system, as found in the Arapaho language, a man would be obliged to treat his sons and his brother's sons the same way, whenever possible.

As far as behavior is concerned, the extension of kinship terms to refer to people outside the family is also symbolic of a certain expected behavior. In earlier times, African Americans would sometimes refer to any respected elders in the community as *aunt* or *uncle.* Turkish villagers, when speaking to a person of their own generation, can use either the term for mother's brother (*dayi*) to show respect or the term for father's sister's son (*aga*) to express decreased solidarity. Chinese speakers can use terms for elder uncle, younger uncle, or younger aunt to nonfamily members

to denote relative status and a person's attitude of humility toward an older addressee.

Family terms frequently extend metaphorically even into nonhuman realms. Gods and goddesses are called by the terms for father and mother. The Navajo have the same concept that some English speakers do of 'Mother Earth', which they further extend to agricultural fields and corn. Words for brother and sister have been used in various Indo-European and other languages to denote a spiritual kinship as well as a physical one. Whether our behavior toward the earth or toward our fellow human beings can ever parallel behavior expected toward our closest family members remains to be seen.

Kituba

Kituba, a.k.a. Kikongo-Kituba, is a contact-based Bantu language spoken in the western part of the Democratic Republic of Congo—from the Kwilu River all the way to the Atlantic Ocean—and in the southern part of the Republic of the Congo. It is known by several other names, including *Kikongo ya leta* 'Kikongo

of the colonial agent (*leta*)', *Kikongo ya bula-matadi* 'Kikongo of the rock-breaker' (in reference to rock-blasting during the construction of the railroad from the Atlantic coast to Kinshasa), and *Mono kutuba* 'I speak'. Outside the Bakongo area, west of Kinshasa, it is better known by the name *Kikongo*, in reference to the fact that most of its vocabulary comes from one of the Kikongo language varieties associated with the Bakongo people. In the Republic of the Congo, where some of the Bakongo people live, it is called *Ikele ve* 'it isn't', in reference to the nonnative way of negating the verb *kele* 'be'. Only an accident of history has thus favored the name *Kituba* in linguistics.

Although the emergence of Kituba is undeniably associated with the exploitation colonization of the Congo Basin by Belgium (roughly, east of the Congo River) and by France (west of the River), its roots lie in the usage of (Kikongo-) Kimanyanga as a trade language during the precolonial period. Manyanga (situated a few dozen miles west of present-day Kinshasa) was already an important trade center before the exploitation colonization of the Congo Basin—which started soon after Africa was apportioned to European colonial powers in the Berlin Treaty in 1885. During the Kongo Kingdom and its subsequent trade colonization by Europe, several caravans from long distances in the interior went through Manyanga. Kimanyanga, its Kikongo variety, served as the lingua franca. The Belgian and French colonizers adopted it to communicate not only with the Bakongo people in the territory between Kinshasa and the Atlantic coast but also with other indigenous populations farther in the interior. They took it as far east as the Kwilu River. They also brought colonial auxiliaries from West Africa and laborers from as far east as Zanzibar to build the railroad between the Atlantic coast and Kinshasa. (Labor migrations were a common phenomenon during the exploitation colonization of Africa by Europeans during the late nineteenth and early twentieth centuries.) The language contact that ensued from these population movements and contacts produced Kituba from Kimanyanga. There are at least three major dialects of Kituba to date: (1) the Western dialect, spoken in the former Kongo Kingdom south of the Congo River (i.e. in today's Democratic Republic of Congo); (2) the Northern dialect, spoken north of the Western dialect, in the Republic of the Congo; and (3) the Eastern dialect, spoken from the Kwango to the Kwilu rivers in the Democratic Republic of Congo. As explained below, they reflect specific influences of the more indigenous languages on Kituba. This has been facilitated by the fact that it is spoken as a second language in the rural areas, although more and more children have been acquiring it at school because it serves as the medium of education.

Overall, Kituba differs from Kikongo languages and other Bantu languages in the following structural respects: (1) Kituba does not use tone or pitch variations to distinguish meaning to the same extent as the other languages; (2) it has a less complex word structure; and (3) it has lost e.g. the agreement system typical of Bantu languages, in which the inflectional pattern of the subject noun matches that of the verb.

A large proportion of Kituba words have the same intonational system as Swahili. In the case of verbs, the position of the intonational stress changes, depending on whether or not it has a tense-aspect suffix. Thus, *móno kwénda* is 'I go' (in the narrative tense), but *móno kwendáka* is 'I went' (in the past tense). However, there is a significant proportion of words that seem to follow the basic high-and-low tone system of Lingala, e.g. *munoko* 'mouth' (with low tones only), *kímbambala* 'old (machine)' (with a high tone on the first syllable only), and *makilá* 'blood' (with a high tone on the last syllable only). Kituba thus incorporates both tone distinctions and pitch accent, which is not typical of Bantu languages.

Unlike in the Bantu canon, Kituba verbs do not carry pronominal or agreement prefixes, nor do they carry any other preverbal marker for tense or negation. Negation is expressed sentence-finally with an invariant marker *vé*, as in *kwísa vé* 'don't come' (literally, 'come not'). The pronouns derive from the emphatic 'independent' pronouns of Kimanyanga (viz. *móno* 'I/me', *ngé* 'you, singular', *yándi* 'he/him/she/her/it', *béto* 'we/us', *béno* 'you, plural', *báu/bô* 'they/them'), and they occupy the same positions as nouns around the verb, as in *Yándi/Pételo mon-áka ngé/María vé* 'He/She/Peter didn't see you/Mary' (literally, 'X saw Y not'). Aspect and mood are expressed by independent words, as in *yándi ké(l)e kwénda* 'he/she is going' (progressive aspect), *yándi lénda kwénda* 'he/she may/can go' (potential mood), and *yándi ata kwénda* 'he/she will go' (future aspect).

In complex noun phrases, modifiers are connected to the head noun by *na* if they are pronominal and by *ya* in other cases, as in *mukandá na móno* 'my book' (literally, 'book of me'), *mukandá ya Pételo* 'Peter's book' ('book of Peter'), *mukandá ya ngé tang-á(k)a* 'the book that you read' ('book of you read'), and *bíma ya kú-dia* 'food items' ('thing of eat').

As a nonnative lingua franca in rural areas, Kituba is often spoken with different accents that reflect its speakers' linguistic backgrounds. The 'accent' may be identified mostly in word choice (for instance, when a speaker imports a term from his or her ethnic language) and in some grammatical features. For instance, in the western dialect, the structure of the progressive construction uses the connective *na,* as in *móno kéle na kú-dia* 'I am eating' (literally 'I am LOC eat'). The

counterpart of the construction in the eastern dialect is *móno ké(l)e (kú-)dia*, without the connective. Within the eastern dialect, the pattern for commands varies. Up the Kwilu River, *kwis-éte* 'come, please' is the normal imperative, whereas elsewhere the bare imperative *kwísa* 'come' will do and will not offend the addressee. In the same variety, the connective *tí* is used in *yándi kwisáka tí bô* 'he/she came with them', whereas elsewhere in the eastern dialect the same general purpose connective *na* is used.

Whereas varieties spoken in rural areas often reflect influence from the more indigenous ethnic languages, those spoken by the educated reflect French influence. The rural varieties are looked down upon, but their educated counterparts are at best criticized by purists; they are well tolerated. The source language for the vocabulary is no longer considered as the norm from which the other varieties putatively deviate. Rural and educated varieties just deviate from the urban non-Frenchified norm. In fact, French, the official language of both the Democratic Republic of Congo and the Republic of the Congo, is not even part of the Kituba continuum, although it is the source of many lexical borrowings. Relative to Kimanyanga, the main vocabulary source, Kituba seems to have autonomized to an extent seldom reached by most creoles of the Caribbean and the Indian Ocean. Kituba speakers hardly think they speak a dialect of ethnic Kikongo, although they use the latter name in reference to their language in the eastern dialect region. It is interesting that Kituba is hardly ever included in the classification of Bantu languages, which reflects an old linguistic tradition of not including acknowledged contact-based varieties in classifications of language families. Yet Lingala, which has a similar history, is typically included among the Bantu languages.

Korean

Although the Korean language shares many characteristics with the Japanese and Altaic languages, its genetic relationship is unknown. Its syntactic structure most closely resembles Japanese, but its phonological system differs markedly. Morphologically, it displays a so-called agglutinating characteristic, i.e. words are formed from roots and affixes.

The oldest written records about Korean are in third-century Chinese, eighth-century Japanese '*Nihonshoki*' (Chronicles of Japan, 720) historical records, in which are written Korean place names, and in references to '*Samkwuk-saki*' (Chronicles of the three kingdoms, 1145) and '*Samkwuk-yusa*' (Memorabilia of the three kingdoms, 1285) of the *Goryeo* (or *Kolye* in the Yale Romanization system) dynasty. Korean is only fully recognizable in historical records after 1443, when the *Hangeul* (or *Hangŭl*, *Hankul*) writing system was created, allowing full written representation of the Korean language. Until then, the language was written mainly with Chinese characters and supplementary characters called *Gugyeol* (or *Kugyŏl*, *Kwukyel)*, but these were only able to present a partial picture of the language at the time.

With regard to the historical division of Korean, Lee (1972) calls the period before the *Goryeo* dynasty 'Old Korean', and the *Goryeo* dynasty period 'Early Middle Korean', the period from the end of the fifteenth century in the *Joseon* (or *Chosŏn*, *Yi*) dynasty and up to the Japanese invasion in the late sixteenth century 'Late Middle Korean', the period up to the late nineteenth century 'Modern Korean', and after the nineteenth century 'Contemporary Korean'. During the transition from Middle Korean to Contemporary Korean, some sound changes and various grammatical changes occurred.

Area of Use and Variants

Korean is the national language of the Democratic People's Republic of Korea in the northern part of the Korean Peninsula, and the Republic of Korea in the south. Koreans are an almost completely homogenous ethnic group. North Korea has a population of 22.27 million people, while South Korea's population is 47.27 million people. Additionally, over 1.8 million ethnic Koreans live in China and more than 400,000

reside within the borders of the former Soviet Union. As a result of Stalin's forced settlements, Koreans also inhabit Central Asian countries such as Kazakhstan and Uzbekistan. Between 1910 and 1945, Korea was in a state of annexation by Japan and forced migration to Japan occurred during this era. There are an estimated 700,000 Koreans living in Japan. Korean emigration has also extended its reach to countries like the United States and Australia. Most Korean speakers outside of the Korean Peninsula live in bilingual societies. Now, there are more than 75 million speakers of Korean worldwide.

The national languages of South Korea and North Korea are basically one and the same, but in South Korea the standard language is based on the Seoul dialect, while in North Korea the standard language is based on the Pyeongyang dialect and is called *mwunhwae* 'the language of culture'. Because of this, there are slight variations in vocabulary, pronunciation, and orthography.

Dialect

Korean dialects can be roughly divided into the following six categories. Following the Korean peninsula from north to south, they are: the northeast dialect in Hamgyeong and Ryanggang Provinces, the northwest dialect in Pyeongan and Jagang Provinces, the central dialect in Hwanghae, Gangwon, Gyeonggi and Chungcheong Provinces, the Southeast dialect of Gyeongsang Province, the southwest dialect in Jeolla Province, and Jeju dialect in Jeju Province. The Jeju dialect retains the Middle Korean vowel 'ʌ', which is now lost in Contemporary Korean, and the southwest dialect makes no distinction between the vowels 'ey' and 'ay' or between 'uy' and 'e'. Also, the fortis 'ss' is not present in the southeast dialect. In the northwest dialect, the affricate [tʃ] is pronounced [ts]. Middle Korean had a pitch accent system to distinguish word meanings, but in Contemporary Korean only the northeast and southeast dialects retain a pitch accent, while it has completely disappeared from others such as the central dialect.

Writing System

The Korean writing system, which is today called *Hankul* in South Korea and *wulikul* in North Korea, was created under the guidance of King Sejong, the fourth king of the Joseon dynasty. *Hankul* first appeared on the world stage in written form in 1446 in *Hunminjeongeum* (or *Hunminjŏngŭm*, *Hwunmincengum*), a woodblock publication containing details of the reason for its creation, construction basics, and usage examples. In other words, *Hankul* is unique in the fact that it was carved

and pressed into existence in the form of a book about *Hankul*. In *Hankul*, the written representation form of consonants is based on the forms of the point of articulation. From the following year, 1447, they were used in the publication of the official hymn of the *Joseon* dynasty 'Yongpi-echenka' and the rhyme dictionary 'Tongkwuk-cengwun', and were subsequently used in the publications of many books. Other than book publications, the official script at the time was written with Chinese characters; *Hankul* was mostly used for private communication, but at the end of the nineteenth century and the start of the modern age, *Hankul* came into general use. Today, the literacy rate in both North and South Korea is nearly 100%.

Each Korean letter represents one sound, that is, a letter of an alphabet, which are combined and arranged to form characters. Each combination of letters, or a character, represents one syllable. Therefore, Hankul simultaneously has a single sound, alphabetic characteristics like the Roman alphabet and syllabic characteristics like Chinese characters or Japanese kana:

$$k + a + m > \begin{matrix} k & a \\ & m \end{matrix}$$

ㄱ + ㅏ + ㅁ > 감

Hankul has several methods of transcription: it can be Romanized according to the McCune–Reischauer method, the Yale method, or official methods designated by the governments of North and South Korea. The Yale method is basically used in this writing. The *Hankul*, its Romanized transcriptions, and main pronunciations are shown in Table 1.

Phonetics and Phonology

Words in contemporary Korean are formed from at least one syllable. For most words, the basic vocabulary stem is one or two syllables long. Syllables generally fit this pattern: consonant + semivowel + vowel + consonant. A vowel always forms the core of the syllabic, and one consonant may come on each side of the vowel. For basic vocabulary, a relatively large number of words end with a consonant.

These are the eight vowel phonemes present in the Seoul dialect:

ㅣ i [i]   ㅡ u [ɨ]   ㅜ wu [u]
ㅔ ey [e]
ㅐ ay [ɛ]   ㅗ o [o]
　　　　ㅓ e [ɔ]
ㅏ a [a]
Of the eight vowels, the back vowel *wu* and *o* are rounded vowels, while the others are unrounded. The shape of the lips when pronouncing *i* and *u* are nearly

ㅞ	we	we	wey	we	we	we
ㅟ	wi	wi	wi	wi	wi	wi
ㅢ	ɨi	ŭi	uy	ŭi	ŭi	ui

the same. Also, in the present-day Seoul dialect, distinction of pronunciation has all but disappeared between the mid vowel *ey* and low vowel *ay*. The lack of distinction between these two vowels has even led to the disappearance of the distinction between the subjective form of the first-person pronoun *nay-ka* 'I' and the subjective form of the second-person pronoun *ney-ka* 'you'. In the present-day Seoul dialect, the first

person 'I' is pronounced *ney-ka* and the second person 'you' is pronounced *ni-ka*, or *ne-ka* by the younger generation. In addition to the above-mentioned vowels, the central vowel allophone *e* [əː] was used by members of previous generations, but it has also all but disappeared. *oy* [ø] has been diphthongized to [we]. It is believed that the disappearance of these vowels has progressed dramatically since the 1960s.

A distinction existed between long and short vowels in the first syllable of words, which were used to distinguish meaning such as [nun] (eye) and [nuːn] (snow), but this long vowel is also rapidly disappearing from the Seoul dialect, with most middle-aged and younger speakers pronouncing the long vowel as a short vowel.

There are two semivowels that form a rising diphthong: *j* and *w*. *j* comes before all vowels except *i* and *u*, and *w* comes before all vowels except *wu*, *o*, and *u*.

Consonants can be categorized based on both the point and manner of articulation, as in Table 2.

A distinguishing trait of stops and affricates is that they have three different series. /p, t, c, k/ are called lenis and are nonaspirated, /ph, th, ch, kh/ are voiceless aspirated, and /pp, tt, cc, kk/ are called fortis and are voiceless sounds with tensing of the glottis. The fricatives include the aspirated alveolar sound /s/ and the fortis sound /ss/, as well as the larynx sound /h/. At the beginning of words, /h/ becomes a fricative [h], but in the middle of words it becomes a voiced [ɦ] or is dropped. At the beginning of words, the lenis /p, t, c, k/ become the voiceless [p][t][tʃ][k], and between other voiced sounds they become voiced [b][d][dʒ][g]. The liquid sound /l/ is a flap [ɾ] at the beginning of syllables or before /h/, while after /l/ or at the final position in the syllable it becomes a lateral [l] or a retroflex lateral [ɭ].

One trait of the stops is that when they come at the end of a syllable, the labial [p], lingual [t], and velar [k], instead of being pronounced explosively, are stopped and formed implosively.

When consonants appear next to each other, various kinds of consonant assimilation can occur, such as nasalization.

Grammar

Korean has two modes of existence, as spoken or written language. The written language is not simply a mapping of the spoken language; a certain differentiation of vocabulary and grammar is allowed.

The syntactic structure of a Korean sentence is very similar to that of Japanese. The word order is S(ubject)–O(bject)–V(erb), and modifiers are located in front of the word to be modified (example provided with rough literal and free translations):

> *naˉnun ecekkey alumtawuˉn kkwumˉul kkwuˉessˉta.*
> I-topic yesterday beautiful dreamˉobject dreamˉpast.
> 'I dreamed a beautiful dream last night'.

Sentence types can be divided into predicate sentences integrated by a predicate (verb or adjective), and nonpredicate sentences that are not integrated by a predicate. As a general rule, spoken language has a higher occurrence of nonpredicate sentences than written language. Unlike languages such as English, the subject is a component of the sentence that is only present when required, and the existence of a predicate does not necessarily guarantee that a subject will also be present. Even in written language in predicate sentences such as text in novels, it is normal for there to be no subject in half the cases. Therefore, not only sentences but also clauses may be considered a complete clause if even just a predicate is present.

Predicates take various converb forms to create subordinate clauses such as manner clauses, reason clauses, conditional clauses, and opposite clauses. The elements that can be contained within a subordinate clause, such as topic words, subjects, or adverbials, are largely predetermined by their functions. Generally, the element that makes the proposition is situated in the middle of the sentence, and the modal element forms a hierarchy that surrounds it. Also, as another example of fixed hierarchy structure, whether or not a subordinate clause contains other subordinate clauses depends on its function. Multiple clause structures like the one below are possible, but one cannot switch the relationship between the clauses:

> [[[[*thipi-lul poˉmyense*] *papˉul mekˉuˉmyen*] *kenkang ey an cohˉuˉnikka*] *papˉputhe mekˉeˉla*].
> [[[[while watching TV] eating] is bad for your health] so eat first]. 'Watching TV while eating is bad for your health, so eat first'. [[[[manner clause] conditional clause] reason clause] main clause]

TABLE 2

In languages like English, the person and number of the subject dictate the predicate's form, but in Korean, the form the predicate takes is determined by what degree the speaker respects the listener—whether the listener is being treated politely or nonpolitely. This treatment level is called the speech level. For example, the verb *ha·ta* 'to do' originally took these six conjugational forms spanning four different speech levels: *ha·pnita, hay·yo*; *ha·o*; *ha·ney*; and *ha·nta, hay*. But over the past 50 years, the modern Seoul dialect has rapidly evolved to use only the polite forms *ha·pnita* and *hay·yo*, and the nonpolite form *hay*. Of the polite forms, *ha·pnita* is formal and *hay·yo* is informal, but the latter is used far more frequently in daily conversation. The nonpolite *hay* form is used when addressing children or subordinates, or in situations where the speaker is the same age or older than the listener and they have a close relationship. The *ha·o* and *ha·ney* forms are rarely used except in very limited forms of a kind of pseudospeech, such as television dramas. *Ha·nta* is used as the basic speech level form for written language in news, academic, and fiction texts. Furthermore, speech levels in spoken language can undergo dramatic level shifts, even within the same conversation with the same speakers and listeners.

In addition to the speech level paradigm, which is listener-oriented, there is the honorific/nonhonorific paradigm, which is referent-oriented. The honorific form is made by combining the verbal with the suffix *·si·*, as in *ha·nta* (nonhonorific) and *ha·si·nta* (honorific). The honorific form is always used when the speaker expresses an event in reference to an older or superior person(s); usage of the nonhonorific form would be considered rude.

Noun groups are called nominals (*cheyen* in Korean). Nouns, pronouns, and numerals belong to this group. The nominal declension system is formed by agglutinating dependent morphemes such as *salam* (person: nominative), *salam·i* (the person [did something]: subjective), *salam·uy* (person's: genitive), *salam·ul* (a person: accusative), *salam·hanthey* ([someone gave something] to a person: dative), *salam·hantheyse* (from a person: ablative), *salam·ulo* (by a person: instrumental), *salam·a* (oh, person!: vocative), and *salam·hago* (with a person: comitative). Of these, the subjective *·i/ka*, accusative *·ul/·lul*, instrumental *·ulo/·lo*, and vocative *·a/·ya* have multiple forms; the former is used with nominals that have consonant stems, while the latter is used with nominals that have vowel stems. For the subjective and dative cases, as in *sensayngnim·kkeyse* (the teacher being the subject) and *sensayngnim·kkey* (to the teacher), the honorific form differs from the nonhonorific form. Also, the dative case for animate nominals is *salam·hanthey* in spoken language but *salam·eykey* in written language, while inanimate nominals use the dative form *·ey* as in *san·ey* (to the mountain). For the inanimate form, locative·elative forms also exist: *san·eyse* (at the mountain, from the mountain). Special vocative *·iye/·ye* and comitative *·kwa/·wa* written language forms also exist. Additionally, *·uy* is a genitive, which means 'N1's N2' or 'N2 of N1' when used as 'N1·*uy* N2', but only when the genetive is specified; a rudimentary genitive meaning is also understood from the basic construction 'N1 N2' without *·uy*: *wuli nala kkoch* 'we' 'nation' 'flower' > 'our nation's flower'.

There are other markers in addition to those just mentioned, such as the topic or contrast marker *·un/·nun*, or markers that set limitations on meaning such as *·man* 'only' or *·to* 'also, as well'. These markers come after nominals. Also, it is possible to string two or more markers, as in *ku salam·hanthey·man·un* 'only to that person'.

The morphemes that present themselves with nominals are thought to be dependent words and are called particles or postpositions by some scholars, or endings or clitics by others. Regardless, these case and limitation markers are attached outside of the nominative form, and they are not independent words, but they are also different from the endings that occur within words in languages such as Russian or German.

As for word classes, in addition to verbal and nominal, there are also adverb, interjection, and adnominal. Adnominals modify nominals, such as *on* 'the whole', in *on seysang* 'the whole world' or *say* 'new', in *say sensayngnim* 'new teacher', but they themselves do not carry inflection or declension.

Vocabulary

Depending on origin, Korean vocabulary can be divided into three lexical strata: (1) native words, (2) Sino-Korean words, or (3) foreign loanwords. Native words are words considered to have their origin in the Korean language, such as *hana* 'one', *nwun* 'eye', *salam* 'person', *salang* 'love', or *ha·ta* 'to do'. Sino-Korean words are words that have their root in classical Chinese like *il* 'one', *san* 'mountain', or *chayk* 'book'. Foreign loanwords are borrowed words from English or other languages, such as *khemphyuthe* 'computer' or *khephi* 'coffee'. The Sino-Korean category also includes Japanese words made from Chinese characters, such as *chelhak* 'philosophy' or *yepse* 'postcard'. Newspapers and research papers are usually more than 50% Sino-Korean word content, while at the other end of the spectrum, literary works can have more than 70% native word content. Generally speaking, basic Korean vocabulary contains more native words than the other two types. Numerals have both native word and Sino-Korean word forms, and each is used depending on the co-occurring words.

Onomatopoeia is even more plentiful in Korean than in Japanese, with over 8,000 examples found in a typical dictionary. Also, even for a single adjective like 'red', vowel/consonant alternation results in a variety of forms like *ppalkah˘ta*, *ppelkeh˘ta*, *palkah˘ta*, and *pelkeh˘ta*, where the pronunciation shift serves to distinguish between various nuances through a well-developed system of sound symbolism. Korean also has a rich abundance of adjectives.

Krio (and West African Pidgin English)

Krio is an English-lexicon creole spoken natively by about half a million people in the Freetown area of Sierra Leone, but is used as an auxiliary language by virtually all the country's inhabitants. The foundations of the language were laid in 1787, when a settlement was founded in Sierra Leone intended to receive freed Blacks from Britain. These were later joined by two major groups of immigrants. The largest of these was a contingent of about 1,200 American ex-slaves who had fought on the British side against the Americans, and who arrived by way of Nova Scotia. A couple of years later, 550 Jamaican Maroons (slave rebels) were transported to the new colony. As the groups merged, Krio emerged as the language of the new population.

After the abolishment of the slave trade in 1807, the British navy began intercepting slave vessels bound for the Americas, landing the recaptives (in all, almost 100,000) in and around Freetown. Within a short time, they outnumbered the original settlers. Given their ethnolinguistic heterogeneity, the Recaptives also adopted Krio as their language, and by the second half of the nineteeneth century, all Freetown ethnicities had merged to one single Creole population.

Given the settlement history of the Freetown peninsula, it is not surprising that Krio shows similarities with (in this order) both Gullah and Jamaican Maroon speech, as well as with preexisting African varieties of Pidgin English. Although the question is not uncontroversial, most observers agree that Krio is in essence a New World creole.

Compared to other Atlantic English-lexicon creoles, Krio is typologically rather distant from its lexifier, something that is visible not least in its phonology.

Krio has seven oral and five nasal vowels, but it has been suggested that earlier forms of the language operated with a five-vowel system. In the consonantal system, the lack of /z/ and /h/ is noteworthy. Sporadic cases of depalatalization of /ʃ/ may suggest that this too was lacking in older Krio. Although /v/ is phonemic, it has become /b/ in the noninitial position. Furthermore, there is reason to assume that earlier forms of Krio had less liberal phonotactics than English, with a marked preference for CV syllables. On the other hand, contact with African languages has introduced coarticulated stops.

Krio is a tone language opposing high and low tones in a small number of minimal pairs.

Lexically, Krio is marked in part by its continuing contact with local languages (mainly Temne, Sherbro, and Mende), but even more by influence from the

languages of the Recaptives. Thanks to these, Krio features hundreds of items of Yoruba origin.

Characteristic features in Krio that appear to be of Transatlantic origin include the completive *dɔn*, the preposed pluralizer *dɛm*, serial comparatives involving *pas*, existential and locative copula *lib*, habitual *blant*, equative copula *na*, progressive *de*, locative copula *de*, 2pl *una*, relativizer *we*, and habitual *kin*. However, a smaller, but far from negligible, number of items can be demonstrated to represent local African developments. These include the multipurpose preposition *fɔ*, the progressive *lib fɔ*, the modal *fit* 'be able to', and the possessive construction of the type 'John his book'.

While Krio has no official status, there does exist a sizeable body of literature, consisting both of original works and translations. In particular, Sierra Leonean radio makes use of it in its news broadcasts.

The familiarity of Sierra Leoneans with western culture and their ability to speak 'English' favored their employment as middlemen in the British colonies. This was of crucial importance for the linguistic makeup of much of West Africa, where varieties (in part) derived from Krio are referred to as West African Pidgin English (WAPE).

Krio was first implanted on the island of Fernando Poo (now part of Equatorial Guinea) by the British, who founded a naval base there in the early nineteenth century. The native-speaking community is only a couple of thousand strong, but the local variety of Krio has developed into the island's lingua franca. Its position was later strengthened by massive immigration of Nigerians in the mid-twentieth century.

Sierra Leone Creoles were engaged in the British conquest of Nigeria, not only because of their being Anglophile but also because of their Recaptive ancestry having retained links with local Nigerian cultures. At least a third of the Nigerian population is now believed to know WAPE, making it (if L2 speakers are included) the most widely spoken pidgin/creole language in the world. Nativization is attested from the early 1960s, and there are a sizeable number of Nigerians speaking WAPE as their first language.

In Cameroon, WAPE was first implanted by missionaries expelled from Fernando Poo by the Spanish.

It then spread inland, until it came to be spoken in most of southwestern Cameroon. Cameroon is officially divided into an Anglophone and a Francophone zone. While the WAPE of the former is essentially an extension of Nigerian WAPE, the latter area presents some unique features due to the absence of English as a prestige variety. It is more conservative (thus closer to its Krio roots), and there is a noticeable impact of French in the lexicon. Cameroonian WAPE may be spoken by as many as 70% of the country's population, including virtually everybody in its southwestern parts. It appears to have acquired a larger proportion of native speakers than Nigerian WAPE.

In Ghana, WAPE is less widespread than elsewhere, and it does not seem to have any native speakers. It is nevertheless used emblematically in several sectors of Ghanaian society, in particular between men and in milieux such as schools, universities, and in the police corps. It was apparently imported in the late nineteenth or early twentieth century by Sierra Leoneans in British service. Related varieties have also been attested in Togo and Côte d'Ivoire, although the prestige of French has prevented its further spread in these countries.

Since the nineteenth century, finally, a variety of Krio called *Aku* is spoken by a community numbering some 6,000 in the Gambia.

Kriol (Roper River Creole)

Kriol is one of two large nontraditional indigenous languages of Australia (the other being Kep Yok (Cape York Creole), spoken in Northern Queensland and the Torres Strait Islands). Kriol is spoken by between 15,000 and 20,000 people in an area covering in excess of 350,000 square kilometers (150,000 square miles). Kriol is spoken

throughout the Kimberley region of Western Australia, in the Northern Territory as far south as the Barkly, and extensively in Western Queensland. The spread of pidgins through this area during the late nineteenth and early twentieth centuries was due to the cattle and livestock industry, but creolization occurred more recently, possibly in mission settlements. There is some evidence that these pidgins actually had their origins in the Sydney area with the earliest European settlements of the late eighteenth century. Kriol is now the primary means of communication among aboriginal people in the above-mentioned area, whose main social mobility is in the direction of broader aboriginal contacts, and not economically 'upward' into the dominant white Australian society.

While early investigations (Kaldor and Malcolm 1979; Sandefur 1979) identified Kriol as a postcreole continuum with Standard Australian English (SAE), Sandefur (1982) makes an excellent case for considering Kriol and SAE to be distinct languages. Apparent mesolects ('lighter' vs. 'heavier' creoles) are actually interlanguages, which Kriol speakers learning SAE use in their dealings with non-Aboriginal people.

Attitudes toward Kriol differ widely throughout the region. Most older speakers do not know the term 'Kriol' at all, and identify their language as either 'Pidgin' or 'English'. Of those speakers who identify it as either 'Kriol' or 'English', attitudes vary from disdain to pride. The attitude of educators had formerly been to treat Kriol as a corrupt or substandard form of English, and to attempt to eradicate it. However, most governments and education systems now recognize Kriol as a language in its own right. In some areas, bilingual Kriol–English programs exist, although these are constantly under threat from both local communities and the (ever-changing) centralized governments. Within some aboriginal communities, the recognition of Kriol is seen as a threat to the maintenance of traditional aboriginal languages, all of which are severely endangered.

Kriol is based on the grammar and vocabulary of SAE, although its phonology, morphology, and to some extent its syntax show enormous influence from traditional aboriginal languages.

Phonology

Most traditional languages lack sounds like *f, v, s, z,* and *th*, and this property is carried over into many varieties of Kriol (many varieties have *s* but not the other sounds). While most traditional languages have three-vowel (a/i/u) systems, Kriol has a five-vowel (a/e/i/o/u) system (which is found among some traditional languages in Northern Australia). Although many traditional languages distinguish long from short vowels, most dialects of Kriol do not. Initial and final consonant clusters are typically either reduced or

made polysyllabic by epenthesis. Some correspondences between SAE and Kriol include:

(1)	SAE		Kriol	
	fellow	[fɛloʊ]	bala/pela	[bala]/[pɛla]
	river	[rivə]	riba	[riba]
	that	[ðæt]	det/jat	[dɛt]/[dʒat]
	visit	[vɪzɪt]	bizit/bijit	[bɪzɪt]/[bɪdʒɪt]
	another	[ənʌðə]	naja	[nadʒa]
	been	[bi:n]	bin	[bɪn]
	all	[ɔl]	ol	[ol]
	sneak	[sni:k]	jinik	[dʒɪnɪk]

Morphology

Pronoun forms come from English morphemes, but the paradigm (given in (2)) is typical of traditional languages. There is a contrast between dual (two people) and plural (more than two), and a contrast between whether the term 'we' includes the person being spoken to or not. There is no gender contrast, and hence no distinction between 'he' and 'she'. There are no separate subject and object forms, unlike both SAE and most traditional languages.

(2)	person	singular	dual	plural
	1 addressee included	mi	yunmi	wi
	addressee excluded	-	mindubala	mibala
	2	yu	yundubala	yubala/yumob
	3	im	dubala	ol/olabat/dei

While Standard Australian English has a plethora of prepositions (e.g. *of, at, for, with*, etc.), traditional languages lack similar separate words, instead using a narrow range of suffixes to indicate these relationships. Kriol does not have such suffixes, and it does not have the broad range of prepositions either. Instead, it utilizes two prepositions, each covering many functions: *la* or *langa* are used to identify locations. *la riba* can mean 'in the river' or 'at the river'. *blanga* marks possession or association, as in *dis ngawu blanga Jingili*, meaning 'this (is the) home of the Jingili people'.

Kriol has a particle *na* that is used to indicate emphasis. *Im bin bogi-bogi* means 'she or he was swimming' (literally: 'she or he been swim-swim'; the verb *bogi* is 'reduplicated' to indicate an action in progress or a repeated action). *Im na bin bogi-bogi*, on the other hand, means 'she or he was swimming' or 'It was her who was swimming'.

If verbs take an object, they are marked with a suffix *-im* in Kriol. *-im* is derived from English 'him'. *Sili baga im bin dringk-im* means 'the silly bugger drank it' (literally 'silly bugger it been drink-it'), and *ol bin pik-im-ap manggo* means 'they picked up mangos' (literally 'they been pick-it-up mango'). Notice that the *im* 'it'

in the first sentence can be left out, since the *-im* marking on the verb already indicates that the verb is transitive, i.e. the sentence is about the fact that the silly bugger drank *something in particular*. Kriol does not make a distinction between definite 'the silly bugger' and indefinite 'a silly bugger'. The context must convey what is meant. Kriol does not distinguish between singular 'mango' and plural 'mangos' either. Here, again, the listener has to decide which interpretation is more appropriate in the situation.

Here is a brief Kriol text from Newcastle Waters in the Barkly Tableland, which illustrates many of the properties discussed above:

> *'Wel, dat dem pipul bin gu solja, wantu fait langa naja pleis, blanga naja pipul, dei bin blanga kool blad. Dey bin jinik ap an fait langa alabala waj deya wel bin fait. Sambala dei bin lusim pipul dei bin get supia tru.'*

Well, some people went off to make war [go soldiers], to fight in another country, another people's country, they went in cold blood. They snuck up and fought with all the people there and there was a battle. Some of them lost people when they got speared through.

ROB PENSALFINI

L

Labov, William

Although William Labov took many years to follow his true calling in linguistics, he made good use of the time and the life experiences that he acquired in the nonacademic world. Following ideas propagated by his mentor, Uriel Weinreich, he brought to the field of linguistics the vision that data could be naturalistically collected and empirically tested and analyzed. In the 1960s and 1970s, this was considered an extreme contrast from the ideal speaker/hearer dyad data used by Noam Chomsky and his disciples. Labov elaborated and finessed a style of linguistics that was practically unheard of at the time—sociolinguistics. Using the concepts of language variation, the linguistic variable, and the interactions of social factors with both of these, Labov literally created a new style of linguistics. Using data from Martha's Vineyard, New York City, and Philadelphia, he proved that language change can be studied and documented as it occurs.

After working as a chemist for 11 years, Labov went back to school, and created a *coup d'état* with his master's thesis work. He conducted research on the small island of Martha's Vineyard, Maine. His work on the pronunciations of the vowels of the native islanders was groundbreaking because he found that, although the variation of the vowels seemed random, it was in fact related to occupation, geography, and ethnicity. This was one of the first studies that incorporated social factors into linguistic variation, a style of investigation that began to be referred to as 'variationist' research. This study and further works by Labov are so well accepted as the linchpins of variationist research that the concepts contained in them are often simply referred to as the 'labovian framework', with no capitalization or any attribution as to the year or the research involved. Implicit in the variationist approach is the concept of the 'speech community'. A speech community traditionally referred to a group of people who were delimited solely by linguistic criteria. The definition of a speech community in the variationist approach, however, puts much less emphasis on language as a necessary and sufficient condition for group membership. Instead, it suggests that the three key requirements for membership in a linguistic/social group are the existence of a social community, that patterns of language use are shared by its members, and that norms for the social evaluation of speech are shared by community members.

This shared set of social attitudes posited for a speech community were proposed in what has come to be known as the classic variationist research, Labov's (1966) study of New York City speech. In this work, he established a range of speech styles that included word lists, minimal pairs, reading passages, interview style, and casual style. He posited that the linguistic variable that was under scrutiny (r-fulness or r-lessness, for example) would reveal *patterned* variation by speakers, which could be correlated with the independent variable of stylistic range. His hypothesis was that, since the amount of attention paid to speech is highest (more closely monitored, in Labov's terms) while reading lists of words, and the least amount of attention is paid to pronunciation in a casual setting, there would be a range of variation on going from the most 'standard-like' pronunciation in the most highly monitored speech (the word lists) to

the least 'standard-like' pronunciation in the least monitored speech (the casual style). Although the data collection methods were similar for both the Martha's Vineyard and the New York City studies, they showed diametrically different results. In Martha's Vineyard, the locals were using the 'marked' vowel pronunciation as a way of showing pride in their heritage, while in New York, the 'lower class' pronunciation (r-lessness) gave way to the more prestigious variety of the pronounced 'r' when social factors came into play.

In *Sociolinguistic patterns*, Labov (1972) set out to prove yet again that language should not be separated from the culture and society in which it finds itself. Labov was certainly not the first linguist to advocate this concept. Older works by Meillet (1921) and Fischer (1958) also recognized the fact that social factors and language use are inextricably intertwined and suggested that one could not be adequately described without accounting for the influence of the other. However, Labov carried this idea a step further by applying it not just to synchronic processes of language change, but to diachronic processes as well. He used data from a series of studies done on 'change in progress' to show that various functions of language can determine and force language change, that grammar rules can (to a certain extent) be affected by changes in society, and that linguistic evolution or change is not dysfunctional, and therefore '(not a) massive testimony to original sin' (p. 323).

Labov (1972) also examined the philosophy and views of various linguists about accepting and using social factors as one explanation of linguistic change. He suggested the following dichotomy: a 'social' group that believes that one can see change in progress, follows the 'wave model' of linguistic evolution, and believes that social factors can and do affect language, vs. an 'asocial' group that disregards the effects of linguistic diversity and contact between languages, works with a *Stammbaum* or family tree model of linguistic evolution, and does not believe that social factors can help explain linguistic change. Labov places himself squarely in the first group, and argues persuasively that social variation does have a place in not only synchronic but also diachronic description of change. These musings on philosophy and its interconnection with language are carried even further in Labov (1994), in which he compares linguistic change to geographical change, and notes that both can be either gradual or catastrophic, and that both may put linguists in a better position to correlate the social and linguistic factors and respond better to Meillet's suggestion that social change is the only possible alternative to explain linguistic change. For Labov, variation is a reflex of change in language.

It occurs both throughout time and in the present, and can be shown by studying language change in 'real time', as he did in his Martha's Vineyard study (Labov 1972), or by studying language change in 'apparent time', as he did with his study of the evolution of New York City vowels (Labov 1966, 1972).

In an attempt to quash criticism from those who claim that the variationist approach is too subjective, statistical programs that take into account and correlate social and linguistic variables have been written. This results in quantitatively analyzed data collection and analysis and allows for cross-linguistic and cross-cultural comparisons. Labov has recently written a program called Plotnik for plotting, analyzing, and comparing vowel systems. In addition, in recent years, he has also tackled the issue of forensic linguistics by giving expert testimony in court cases, promoted the cause of accepting African American Vernacular English as an accepted and normal language in and of itself, promulgated the idea that linguists should give something back to the community from which they take their data, and overseen the creation of the 'Phonological Map of North America'.

The most important concept to come out of his research was the idea of the linguistic variable. Although dialectologists have long acknowledged the fact that different people speak in different ways, no one had taken into account the fact that the same person speaks differently on different occasions. It was commonly thought that this intraspeaker variation was random, and therefore unquantifiable. With the advent of variationist sociolinguistics, it can now be seen that the variation is systematic, and is the result of the interaction between linguistic variables and social factors. Rather than variables (or linguistic elements) being in free variation (or random), they suggest that variables have been and are conditioned by certain social and cultural factors. Chambers (1995) puts this quite strongly by noting that correlating linguistic variation as the dependent variable with independent variables such as linguistic environment, style, or social categories is the primary empirical task of sociolinguistics. The linguistic fallout from this belief has resulted in an explosion of work dealing with the effects of gender on language, social class on language, race and ethnicity on language, education level on language, and geographical location on language. The interplay of these factors and their effect on speech can now be used to view language change in progress. In the past, language change had to be tediously reconstructed using ancient texts and sheer speculation. One of the most exciting facets of the variationist approach to linguistics is the fact that it can be used

as a key to the past. Language change is invariant; all languages change. The modern-day methods pioneered by Labov and others can be used as a template from which to examine previous changes that languages have undergone as well as to document the changes that speakers impose on their languages every day.

Biography

William Labor was born in Rutherford, New Jerseyon, December 4, 1927. He recived his B.A. (1948) from Harvard College; M.A. (1963) from Columbia University for a thesis on social aspects of sound change on Martha's Vineyard, tutored by Uriel Weinreich; and Ph.D. from Columbia for work on class differences in the dialects of New York City. He was Assistant Professor, Columbia University in: 1964–1970, and Associate Professor, Professor, University of Pennsylvania (1971–present). He was a Guggenheim Fellow (1970–1971 and 1987–1988), President, Linguistic Society of America (1979), and Fellow, American Association for the Advancement of Science (1997–present). He received honorary Ph.D.s form University of Uppsala (1985), University of Liege (1990), University of York (1998), and Haifa University (1999). He was Sapir Professor, Linguistic Institute in 1986, and is since 1988 to date Editor of *Language Variation and Change* (1988–present).

MEGAN E. MELANÇON

Ladefoged, Peter

Like his teacher David Abercrombie, Peter Ladefoged continues the tradition of British phonetics and linguistics, which includes the names of such scholars as Henry Sweet, Daniel Jones, and John Rupert Firth (all three of whom are featured in the photograph opposite the title page of Asher and Henderson (1981), one of the major sources in phonetic historiography, and with the exception of Firth, specifically credited for their pioneering research by Ladefoged in *A course in phonetics* (2001:ix)). Ladefoged began his career at the age of 17 studying physics, chemistry, and mathematics at Cambridge University, but after a stint in the army, he decided to study poetry. By chance, he happened to run into a man named David Abercrombie, who had just started up a Phonetics Department, and

who was himself the son of a poet, Lascelles Abercrombie. I think it is this early exposure to experimental sciences that propelled Ladefoged to concentrate on experimental phonetics. Ladefoged's student at UCLA, John J. Ohala of the University of California, Berkeley, has called the *maestro* the 'world's leading phonetician', with which I am in firm agreement. Born in England and educated in Scotland, the long-time UCLA professor of phonetics and director of the UCLA Phonetics Laboratory (currently UCLA Research Linguist and Professor of Phonetics Emeritus) is practically a household name in many linguistics departments in the United States and around the world. Countless numbers of students (including mine, ever since the first edition in 1975) have been

introduced to phonetics from the four editions of his *A course*, not to mention his numerous other books and articles (see under *References* for typical examples). Many more readers will be exposed to phonetics from another survey work of his that appeared recently, *Vowels and consonants: An introduction to the sounds of languages* (Oxford: Blackwell, 2001), which is less technical than *A course* in that it omits many detailed phonetic concepts and is couched in simpler language; however, there is, not surprisingly, some overlap between the two, such as with the vowels of English ((pp. 26-30) and *A course* (p. 29, p. 81)) and the contrasting stops in Malayalam ((p. 149)) and *A course* ((p. 141)). At first, however, it may seem more complex than *A course* since it starts with acoustic phonetics (it is Chapter 8 of 11 chapters in *A course*) — a Ladefogian specialty ever since the publication of his *The nature of vowel quality* (1962) and his *Elements of acoustic phonetics* (1962).

One of Ladefoged's most outstanding contributions to phonetic science has been the publication of his phonetic fieldwork and the insights gleaned therefrom. He has conducted field research in Africa, India, China, Papua New Guinea, Australia, etc., recording hundreds of languages over the years abroad or at the UCLA Phonetics Laboratory. These recordings, which are housed in the UCLA phonetics archives, provide the requisite data for the phonetic theory to which Ladefoged has contributed so much (see e.g. Ladefoged 1965). As a pioneer in experimental phonetics (see e.g. Ladefoged 1967), including still and cine x-ray photography (see as far back as Ladefoged 1958), palatography, spectrograms, waveforms, and aerodynamic data techniques, Ladefoged's career has been devoted to the phonetic phenomena of the world's languages (see e.g. Gordon et al. 2000), and as a result of this type of work, there now exists a scientific basis for distinguishing linguistic from nonlinguistic sounds. Thus, through the theoretical and experimental sides of his research (and that of many of his colleagues), we now know enough of the sounds of the world's languages for there to be a book with that very title (Ladefoged and Maddieson (1996)).

For Ladefoged and his student John J. Ohala, phonetics is but part of phonology, the goal of which is to understand all aspects of sound patterning in languages (see Ohala 1994:3053). It is precisely this kind of emphasis that prompts Ladefoged and Maddieson (1996:7) to assert that the typical five-vowel system for many languages is the more distinct set /i e a o u/ rather than their rounded (or more marked) counterparts /y, ø, a, ɣ, ɯ/ (/a/ is neutral and is included in both sets). Further, Ladefoged has demonstrated repeatedly that some phonological statements may be better formulated and understood by reference to the acoustic rather than articulatory properties of sounds. Also, he has shown that vowels are better described in terms of auditory rather than acoustic or articulatory parameters (Johnson et al. 1993).

In addition to his fieldwork, Ladefoged has been influential in linguistic terminology and theory. Ladefoged (1964) e.g. coined the term 'approximant', which has gained widespread acceptance in the profession as synonymous with semivowel and frictionless continuant. It is so named because one articulator *approximates* the position of another. He has demonstrated a number of interesting phonetic laws or tendencies; e.g. that there is no clear one-to-one correlation between syllables and chest-pulse movements, or that apical trills are more common than laminal trills. However, it was as the President of the International Phonetic Association that he seized the opportunity to propound the Kiel Convention of 1989, which was organized to revise the International Phonetic Alphabet (IPA). As a researcher of rare speech sounds himself, such as bilabial trills, voiceless implosives, and velar laterals, he was instrumental in making contributions to the adopted IPA revision. It is safe to report that he was the one who first noticed a flapped labial stop in an ideophonic word in Margi (a Chadic language of Nigeria). Ladefoged should also be credited for inventing new ways of looking at speech sounds. In fact, he is largely responsible for insisting that the IPA chart be regarded as a one-page theory of phonetics.

Distinctive feature theory is yet another area where Ladefoged's work has been peremptory. Critical of the features proposed in Chomsky and Halle (1968), Ladefoged (1971) proposed a new system, which recognized the importance of an auditory basis for some features. As a result of this, it is now accepted that some sounds are to be grouped together on the basis of auditory phenomena. In view of his numerous accomplishments described above, there can be little doubt that he has earned his noteworthy international reputation.

Biography

Peter Ladefoged was born in Sutton, Surrey, England on September 17 1925. He attended Haileybury College, Hertford (1938–1943). He received his M.A. (1951) and Ph.D. (1959) from the University of Edinburgh for a dissertation on the acoustics of vowel quality, with Daniel Jones, recently retired from the chair of phonetics at University College, London, serving as a consultant to the project. He was Assistant Lecturer in Phonetics, University of Edinburgh in 1953–1955 and Lecturer in Phonetics, University of Edinburgh, 1955–1959, University of Ibadan, 1959–1960, and University of Edinburgh, 1960–1961.

He was a Field Fellow in the West African Languages Survey in 1961–1962. He was also Assistant Professor of Phonetics, UCLA, 1962—1963; Associate Professor of Phonetics, UCLA, 1963–1965; and Professor of Phonetics, UCLA, 1965–1991. He: was Chair, Department. of Linguistics, UCLA in 1977–1980, and Fellow, Acoustical Society of America and American Speech and Hearing Association. He was a recepient of the Distinguished Teaching Award and Research Lecturer, UCLA, in 1972 and 1989, respectively. Ladefoged was President, Linguistic Society of America in 1978; President, International Phonetic Association in 1987–1991; Fellow of the American Academy of Arts and Sciences, 1990; and UCLA College of Letters and Science Faculty Research Lecturer in 1991. He received a Gold Medal at the XII International Congress of Phonetic Sciences in 1991. He was also Corresponding Fellow of the British Academy in 1992. He also received an honorary D. Litt. from the University of Edinburgh in 1993, and a Silver Medal from the Acoustical Society of America in 1994.

ALAN S. KAYE

Lakoff, George

George Lakoff had his first contact with Linguistics while he was an undergraduate student at MIT. There, he worked on the structure of discourse, and tried to put a narrative structure into a transformational framework. In those days, one of the basic tenets of transformational grammar was the independence of syntax from semantics. However, beginning in 1963, Lakoff started to find evidence that this central claim was not totally correct. Together with other linguists such as James D. McCawley, Paul Postal, and John Robert Ross, he developed the theory called Generative Semantics. Its main hypothesis is that there is no principled difference between syntactic and semantic processes. Along with this, there are three other main assumptions: (i) nonexistence of a purely syntactic level of 'deep structure', (ii) the universal-base hypothesis: initial representations of derivations are cross-linguistically identical logical representations, and (iii) the derivation of a sentence is a direct transformational mapping from semantics to surface structure.

Despite its initial success, Generative Semantics started to fade away in the mid-1970s. One of the main reasons was the growing body of evidence about the embodiment of mind from the fields of cognitive science and neuroscience. Work by Charles Fillmore in frame semantics, Paul Kay in color categorization, Leonard Talmy in universal spatial cognition, and Eleanor Rosch in basic categories contradicted one of the major tenets of this theory, namely the belief in formal logic and model-theoretic semantics. This new

research showed that it was not possible to define meaning in terms of reference and truth conditions, in terms of the objective structure of the external world, with no reference to the brain or mind. Therefore, formal logic could not be an adequate theory of natural language semantics, and neither could be transformational grammar of syntax. As a consequence, Lakoff stopped doing Generative Semantics and set about developing a field of Cognitive Linguistics.

Cognitive Linguistics views linguistic knowledge as part of general cognition and thinking; linguistic behavior is not separated from other general cognitive abilities that allow mental processes of reasoning, memory, attention or learning, but is understood as an integrated part of it. One of Lakoff's major contributions to the theoretical foundations of this framework is the theory of conceptual metaphor.

In the late 1970s early 1980s, Lakoff, then working in collaboration with Mark Johnson, discovered that the classical view of metaphor as a mere figure of speech based on inherent similarity to indicate a comparison was empirically false. Instead, they showed that metaphor is part of the cognitive unconscious. It is a cognitive mechanism that allows us to experientially ground conceptual systems and to reason about abstract domains (e.g. *love*) in terms of more concrete domains (e.g. *journeys*). In other words, metaphor is a cross-domain conceptual mapping. Lakoff has applied the metaphor theory to the analysis of the conceptual structure of several disparate disciplines such as poetry, visual arts, politics and social issues, philosophy, and mathematics. His work proves that a system of metaphorical mappings allows the abstract ideas of any discipline to be conceptualized in terms of embodied experience.

In the 1990s, together with other researchers such as Jerome Feldman, Lakoff founded the Neural Theory of Language, which seeks to answer the question of how the physical brain can give rise to concepts and language. The basic foundations of this research program, previously known as the L_0 Group, are drawn from many different disciplines: neurochemistry, neuroscience, neural computation, psychology, and cognitive linguistics. The result is a completely different understanding of language from that in traditional Chomskyan theories. In this framework, language is characterized as: 'embodied' —structured by our bodily and social experience of the world, as well as by the general properties of neural systems and the neural structure of systems such as vision and motor control; 'content-dependent' —physical and biological constraints; 'cognition-dependent' —other aspects of human cognition; 'evolutionary' —use of earlier evolutionary development; and 'learned' —on the basis of innate structure that is not specifically linguistic. In his career as a linguist and cognitive scientist, George Lakoff has been a founder of three different intellectual movements: Generative Semantics, Cognitive Linguistics, and the Neural Theory of Language.

Biography

George Lakoff was Born in Bayonne, New Jersey on, May 24, 1941. The graduated from MIT in 1962 in English Literature and Mathematics, and studied Linguistics with Roman Jakobson, Morris Halle, and Noam Chomsky. He received his doctorate in Linguistics in 1966 from Indiana University for his work on the irregularity in syntax and transformational grammar. He was a Research Fellow and Lecturer in Linguistics at Harvard (1965–1969). Then, he worked as associated Professor of Linguistics at the University of Michigan (1969–1972). He moved to the University of California at Berkeley, where he is Professor of Linguistics since 1972. He has been a fellow of the Institute for Advanced Study in the Behavioural Sciences at Stanford (1971–1972), and a visiting professor at the École des Hautes Études en Sciences Sociales in Paris (1995). He served on the Governing Board of the Cognitive Science Society (1990–1996), as President of the International Cognitive Linguistics Association (1990–1994), and as a member of the Science Board of the Santa Fe Institute (1995–present). Lakoff was a founding member of two recently formed political think tanks: The Rockridge Institute (1998), where he is a Senior Fellow, and the Frameworks Institute (1999), where he is a member of the Advisory Board. He was a recipient of the 2001 Hatfield Scholar Award for socially relevant research by a social scientist, Mark O. Hatfield School of Government at Portland State University.

Langacker, Ronald

Ronald Langacker had his first contact with Linguistics at the University of Illinois, where he received his training and pursued his early research in generative syntactic theory. His dissertation was a transformational description of aspects of French syntax. The first ten years of his professional career, 1966–1976, were devoted to the study of comparative grammar and historical reconstruction of the Uto-Aztecan language family of Native American languages.

In 1976, he decided that current theoretical approaches to language such as Generative linguistics no longer offered satisfying answers for understanding language. Consequently, he started developing a new linguistic framework called Cognitive Grammar, initially known as Space Grammar, which presents a radically different conceptualization of language and its structure.

In contrast to modular approaches, this new theory proposes that language is an integral part of human cognition and that grammatical structure can be characterized in terms of cognitive processing. Cognitive grammar assumes that (i) grammar is not autonomous with respect to semantics, (ii) grammar can be fully described in terms of 'symbolic units' i.e. form-meaning pairings, and (iii) grammar together with the lexicon (vocabulary), morphology (word-structure and word-formation rules), and syntax form a continuum of symbolic relationships.

This view of grammar as symbolic in nature relies on a very specific understanding of linguistic semantics. In this approach, meaning is not identified with truth conditions (as it is in classical logic), but it resides in 'conceptualization' and 'mental experience'. This includes both fixed and novel conceptions, sensory and motor experience, and a full grasping of physical, social, cultural, and linguistic context. As a consequence, the boundaries between the traditional distinction between linguistic and encyclopedic knowledge are blurred. In conceptualist semantics, the meaning of a lexical item is not restricted to the meaning of the expression designating it, but is open to all the knowledge one may have about that entity itself.

Every expression and every symbolic unit has two equally significant sides for linguistic meaning: the conceptual 'content' it evokes and the particular 'construal' imposed on that content. The content of an expression comprises a set of cognitive domains, each of which corresponds to a different aspect of the expression's semantic value. Therefore, the starting point for semantic description is not a set of semantic features or conceptual primitives, but an appropriate array of integrated conceptions organized at different levels of conceptualization. Equally important for an expression is to know how it is construed. Langacker proposed several different cognitive operations for the structuring of knowledge, different dimensions of construal that a speaker may take into account when describing a certain situation. Among the most significant, we can mention the following: (i) 'specificity', the perception of objects and situations at different levels of detail or granularity; (ii) 'scope', all the possible aspects that a given expression may evoke in its characterization; (iii) 'background' assumptions and

expectations, that is, the distinction between given and new information; (iv) 'perspective', a speaker's viewpoint on the situation, e.g. orientation, vantage point, directionality; and (v) 'prominence', which includes very influential concepts such as profile/base organization, trajector/landmark alignment.

In Cognitive Grammar, an expression's grammatical category depends on the nature of its profile. For Langacker, there are 'things' that profile nominal expressions such as nouns *(dog, table...)*, pronouns *(I, you...)*, determiners *(the, this...)* and even noun phrases *(the large table...)*, and 'relationships' that profile relational expressions; some are atemporal relations such as adjectives *(green, big...)*, adverbs *(well, quickly...)*, and prepositions *(behind, of...)*, and some others are processes or temporal relations such as verbs *(take, sleep...)*. Grammar consists of patterns that combine simpler symbolic structures with symbolic structures of greater complexity, the latter called 'grammatical constructions'.

Another important feature of this model is that it is a usage-based approach. That is to say, it is based on how speakers actually speak and understand language, which, in turn, is composed of networks of units that become conventionalized or entrenched through usage.

The first general description of Cognitive Grammar was presented in Langacker (1982), but the fundamental piece of work was published in two companion volumes: one in 1987—an introduction to the main theoretical tenets and tools—and the other in 1991a—a descriptive application mainly based on English data.

Through the years, Langacker continued to refine and further articulate this theory. Cognitive Grammar has been applied to a wider array of linguistic phenomena, for example, locatives, agreement, passive voice, tense and aspect, complementation, grammaticalization, discourse, and to a wider variety of languages and language families such as Cora, German, French, Greek, Samoan, Slavic, Spanish, just to name a few. For his work, Ronald Langacker is considered one of the leading figures in Cognitive Linguistics, a productive and influential theorist within this framework and in linguistic theory in general.

Biography

Ronald Langacker was born in Fond du Lac, Wisconsin, on December 27, 1942. He graduated from the University of Illinois in 1963 in French. He received his doctorate in Linguistics in 1966 from the same university for his work on generative syntactic theory. He moved to the University of California at San Diego in 1966, where he has been teaching ever since. Currently, he is Professor Emeritus and Research Professor. He is a member of the Program in Cognitive Science at UC San Diego (1983–2003). He is also Visiting Professor and Fellow at a number of institutions all over the world such as University of Chicago (1969), University of Illinois (1969), Belgrade University (1971), Summer Institute of Linguistics (1976), Australian National University (1991), University of New Mexico (1995), Graduate School of Linguistics, Amsterdam (1996), Graduate School in Language and Communication, Odense University (1998), Chulalongkorn University, Bangkok (2001), and University of California, Santa Barbara (Edward Sapir Professor, 2001). He served on both the Advisory Board (1989–1997) and the Governing Board (1999–present) of the International Cognitive Linguistics Association and as President of the same association (1997–1999). He is a recipient of several awards such as the National Endowment for the Humanities (senior fellowship, 1973–1974), Guggenheim Fellowship (1978–1979), the Medal of the University of Helsinki (1996), and an honorary doctorate from the University of Lodz, Poland (2003). Langacker was co-editor of the monograph series Cognitive Linguistics Research and a member of numerous editorial and advisory boards.

IRAIDE IBARRETXE-ANTUNANO

Language Change

One of the most fundamental linguistic universals is that all languages change over time. This fact is quite obvious in the case of languages having a documented history over many centuries, such as English. An English speaker attempting to learn Old English will quickly find the task equivalent to learning a foreign language. For example, in Old English the word *knight* (originally spelled *cniht*) was pronounced [kniçt]; hence, it contains both a foreign cluster (word-initial [kn]) and a foreign sound ([ç]). Old English was also very different in its word structure. The genitive plural form of *knight* (as in *the knights' horses*) was *cnihta* [kniçta], and there were specific dative forms (e.g. plural *cnihtum* [kniçtum] "to the knights") that no longer exist. There has also been semantic change, since in Old English the word *knight* meant "boy, youth, servant".

But even without historical documents, we are surrounded by various types of evidence showing that English has undergone significant change. Since spelling conventions are often maintained in spite of sound changes, written forms can reflect earlier pronunciations. We still write *knight* even though the *k* and the *gh* have not been pronounced for more than 300 years. Another type of evidence for language change is found in the comparison of English with other Germanic languages. Accordingly, the similarity of English *knight* and German *Knecht* [kneçt] can be explained by the fact that both words come from the same source; namely, an earlier West Germanic language that later split into individual dialects that eventually developed into English and German. In this case, German is more conservative than English in preserving the pronunciation of both [kn] and [ç], and the meaning of the word ("farm laborer, servant") is closer to that of Old English. Another type of evidence for language change is found in idioms and compounds, which can sometimes preserve older features of the language; e.g. *the quick and the dead* and *quicksilver,* where *quick* reflects the Old English meaning "living".

The seeds of language change are found everywhere in the form of linguistic variation. An interesting sociopolitical phenomenon is the popular reaction, almost universally negative, to linguistic variants or perceived changes. It is very often the case that reduced pronunciations are denounced as sloppy, new word formations are rejected as slang or substandard, and words being borrowed from another language are treated as a form of contamination. Such judgments have a long tradition, and no doubt when some people first began pronouncing *knight* with [n] at the start instead of the "correct" [kn], some eyebrows were raised; but over time, a linguistic community adopts one variant over another. Usually, this adoption is done at the unconscious level, but sometimes linguistic markers become prestigious or stigmatized in a fairly conscious way; e.g. whether you pronounce the first vowel in "drama" as [æ] or [ɑ], the last consonant in "garage" as [dʒ] or [ʒ], etc. While such variation might seem haphazard or random, both the variation and the resulting language change have highly systematic properties, and the same patterns of language change are found universally as a natural consequence of our common cognitive and physiological endowment.

Language change can have both external and internal motivations. External motivations involve factors independent of the language system itself, such as borrowing. Languages in contact can borrow extensively from each other, as is evident in English, where the effects of borrowing are most obvious in the case of vocabulary, but in fact all subsystems (pronunciation, grammar, meaning, etc.) can undergo change as a result of contact. Language contact is also of interest since it seems to be a catalyst of change. Languages with less contact tend to be conservative (e.g. Icelandic) and retain many archaic features. Languages with extensive contact tend to be innovative (e.g. English), i.e. they develop away from the ancestral form. Another external type of change

involves the impact of writing on pronunciation (e.g. the word *often* pronounced with a [t] is a spelling-induced pronunciation), although this impact is usually much less than people normally assume. However, even in the absence of such external factors, languages undergo change. A primary factor behind such internally motivated change is found in the language acquisition process itself. A grammar is not something that is handed down from one generation to the next, but each generation—or more correctly, each child—must construct a grammar anew. In the process, the child's grammar can differ subtly from the adult target grammar, and through the accumulation of such differences over many generations, languages can change significantly.

Explanations of particular changes are often based on reference to relative preferences relating to linguistic structure. Such an approach works particularly well in the case of change in pronunciation and word structure. For example, the elimination of word variants (*thrive/throve > thrive/thrived; old/elder > old/older*) is attributed to a preference for "one meaning, one form", and the common loss of a final consonant in syllables is motivated by the preference for syllables consisting of only a consonant and a vowel (CV). This type of explanation is strengthened in cases where the preferences find independent support in areas like language acquisition (e.g. CV syllables are the first to be acquired by children), and implicational universals (all languages have CV syllables, and some languages have only CV syllables).

From a historical perspective, it is often possible to identify drifts; that is, the tendency for a particular language or language family to display interrelated or similar changes over a long period of time. Such drifts may be attributed to the assumption that the same preferences are at work, or that a particular conditioning factor is present over an extended period; e.g. it is often claimed that the fixing of the stress accent on the root syllable in early Germanic led to the weakening and loss of unstressed syllables that is evident in all the modern Germanic languages. Accordingly, languages can drift in the same direction, even after they have become separated. For example, "umlaut" (a change in which vowels become more alike, which is the source of alternations such as *foot/feet*) occurred in both the West and North Germanic languages. Although umlaut itself cannot be attributed to Proto-Germanic, it is apparent that favorable conditioning factors were inherited in both the western and northern branches.

The study of language change is the subject of historical or diachronic linguistics. The following is a brief overview of the main subfields.

Phonological Change

Sound changes are typically triggered by a conditioning environment. A very common type of change is "regressive assimilation", where a segment becomes more similar or identical to one that follows it ([kt] > [tt] as in Latin *noctis*, Italian *notte* "night"—the arrow > indicates the direction of change). Changes can also be conditioned by properties of larger structures such as the syllable; e.g. segments are often deleted at the end of a syllable (Spanish *cabo* "end" shows the loss of [t] in syllable-final position; cf. Latin *caput*). However, some changes, such as "deaffrication" ([t^s] > [s] or [tʃ] > [ʃ]), do not necessarily require a particular conditioning environment, but rather they occur in all environments. Other changes, such as "diphthongization" (e.g. [u] > [aw], [i] > [aj]), appear to find their genesis in the phonological system itself. Vowel systems that include seven or more vowels are highly prone to diphthongization, while smaller vowel systems are not. Although most changes can be described in articulatory terms (e.g. manner or place assimilation, where fewer articulatory movements are required), some types of change show the importance of auditory factors (e.g. [x] > [f] as in *laugh*, where the *gh* was originally pronounced [x]).

Sound changes are usually regular in the sense that the particular change applies to all words displaying the necessary phonetic conditions regardless of its part of speech. However, in some cases a particular change can generalize from one word to another over time. Such "diffusion" is evident in the case of stress shifting in English nouns; e.g. stress has been shifted in *rebel* (formerly *rebél*), but not in *mistake*. Nouns such as *address* and *adult* are subject to significant variation (both *addréss* and *áddress*).

Some changes involve interrelated shifts of entire series of segments or sets of natural classes. One of the most famous sound shifts, called Grimm's Law after its nineteenth-century discoverer Jakob Grimm, involves a set of sound changes that occurred in early Proto-Germanic (the assumed common language from which the known Germanic languages developed). In its traditional formulation, Proto-Indo-European voiceless plosives shifted to voiceless fricatives, voiced plosives to voiceless plosives, and voiced aspirated plosives to voiced plosives; e.g. Latin *pater* maintains the original voiceless plosive [p], whereas the English cognate *father* with the voiceless fricative [f] shows the effects of Grimm's Law.

Morphological Change

Languages are often classified according to the type and complexity of the word structure they have.

"Analytic" languages have very simple words, while "synthetic" languages are morphologically complex—have complex words. Thus, English, a fairly analytic language, does not have a future tense marker or case inflections, whereas a synthetic language such as Latin has both. Over time, languages can lose complexity, primarily through sound change; e.g. the case system of Old English was lost in this way. At the same time, new morphological complexity can develop through morphologization or grammaticalization. "Morphologization" refers to the case where an original sound change becomes a morphological regularity; e.g. the source of irregular plurals such as *foot/feet* can be found in an earlier sound change (umlaut). In one type of "grammaticalization", an original word can become a grammatical item such as a suffix; e.g. the future tense morpheme *-ò* in Italian *finirò* "I will finish" derives from an original auxiliary verb, *habeo*, as in the Latin main verb–auxiliary construction *finire habeo*. Forms undergoing grammaticalization are typically subject to extensive phonological and semantic change.

Leveling and analogy are important kinds of morphological change. "Leveling" refers to the elimination of word variants or "allomorphs" within a paradigm. German has allomorphy in verbal paradigms of the type *ich helfe* "I help," *es hilft* "it helps" (i.e. *helf-* vs *hilf-*). Old English had the same type of allomorphy, but it was leveled out so that Modern English has only *help-* as in *I help, it helps*. "Analogy" is the extension of a regularity from one context to another, especially from members of one paradigm to those of another. For example, in earlier English there were numerous "strong" verbs of the type *drive/drove/driven, sing/sang/sung,* etc. Over time, many of the strong verbs have joined the larger *-ed* verb class through analogy. Thus, *molten,* the original past participle of *melt,* was replaced by *melted* through analogy with *-ed* verbs such as *belt/belted, work/worked,* etc. Sometimes the older forms are maintained in the language with a specialized meaning (e.g. *molten steel*) or they may be completely lost (e.g. *throve,* the original past tense of *thrive*).

"Folk etymology" is an interesting kind of morphological change involving a false or incorrect analysis. The word *bridegroom* traces back to an original compound consisting of the words *brȳd* "bride" and *guma* "man". Over time, the independent word *guma* was lost, and when the original compound was no longer understood, folk etymology occurred, and the word was reanalyzed as "bride" + "groom". Often, the result of folk etymology is semantically incoherent; e.g. the dialectal reanalysis of *asparagus* as *sparrow grass*.

Syntactic Change

Changes in sentence structure are also readily apparent in the history of English. The word order in a sentence such as *ond heo hine in þæt mynster onfeng* (literally "and she him into the monastery received") was entirely acceptable in Old English, but is not in Modern English. Indeed, a variety of evidence supports the reconstruction of the Subject–Object–Verb word order for Proto-Germanic. One of the oldest Germanic sentences, written on the Golden Horn of Gallehus about 1,700 years ago, displays Subject–Object–Verb order: *ek hlewagastiR holtijaR horna tawido* (literally "I Hlewagistir of Holt horn made") "I Hlewagistir of Holt made the horn."

Attempts to explain the shift from Old English S(ubject)–O(bject)–V(erb) to Modern English Subject–Verb–Object are usually grounded in typological studies that established two basic word order types, "dependent–head" (also called "prespecifying" or Object–Verb languages) vs. "head–dependent" ("postspecifying" or Verb–Object languages). Dependent–head languages such as Korean display the following types of orders: objects precede verbs, main verbs precede auxiliaries, relative clauses precede their nouns, and noun phrases precede their adpositions (or, in other words, dependent–head languages have postpositions). Head–dependent languages such as Maori display the opposite word order patterns (objects follow verbs, main verbs follow auxiliaries, etc.). Much syntactic work assumes the primacy of the order of the verb and the object. If the OV order changes to VO, then the head–dependent order can be generalized to the other patterns. From this perspective, it is essential to find reasons for the OV > VO shift. One very old theory that has stood the test of time is based on Wackernagel's Law, which observes that certain particles called "sentence clitics" have a tendency to be placed in clause-second position. If these clitics are verbal elements, then the clause-second position can be reinterpreted as the position of the verb, and (S)VO can result as the default order.

Semantic Change

Change of meaning also displays a systematic aspect, and patterns of change can be clearly identified. Words for "see" often take on a new meaning of "know, understand"; e.g. both *vision* (borrowed from French) and *wise* derive from the same Indo-European root. Words involving a sense of touch often take on a new meaning related to the sense of taste (e.g. *sharp*). At the same time, determining the motivations for semantic change has proved a much more elusive task than is the case for other types of change. Nevertheless, general

categories of semantic change can be determined. In semantic "broadening", the meaning of a word becomes more general or inclusive, as in the word *barn,* which derives from an Old English compound *bere* "barley" + *ærn* "house, store" that was originally used to refer to a place where barley was stored. The opposite, and more common, type of change is called "narrowing". A word such as *deer* displays narrowing, since Old English *dēor* meant "animal". The Modern German cognate *Tier* "animal" retains the older meaning. Social and technological factors can also play a role in semantic change; e.g. *write* originally meant "to scratch", since early writing involved scratching letters onto wood or other materials.

Lexical Change

Change in vocabulary primarily involves the loss or addition of words. In many societies, taboo is an important factor in lexical loss; e.g. the Indo-European word for "bear" was lost in earlier Germanic as the result of taboo. More generally, social or technological changes play an important role in motivating the creation of new words. As the need arises, new words develop either through internal sources (e.g. compounding as in *shareware*) or borrowing (*peyote*, from American Spanish).

Language: Contact—Overview

Broadly interpreted, language contact encompasses such diverse experiences as casual contact with a foreign language during travel, study of a second language as a school subject, and the acquisition of two or more languages in early childhood. Because of the power and prestige of their language, many English speakers never need learn another language and may regard monolingualism as the normal state of affairs. For the majority of the world's population, however, some degree of bilingualism (or multilingualism) is the norm; even small-scale nonliterate societies can be remarkably diverse in their linguistic composition. In the modern era, contact with other languages has increased through such phenomena as modern transportation, the Internet, mass communications, the globalization of commerce, and the growth of English as a world language. The study of language contact intersects with many areas of linguistics, and can be approached from the perspective of the society, the individual, or the language.

Early work in language contact and society looked at the typology of multilingual societies, describing each language found according to its status and function. Often in multilingual societies, different languages are used in the same way as different varieties of the same language in monolingual societies; *domain* analysis attempts to classify these functional differences by looking at the class of situations (or domain) in which each language is used. In stable contact situations, multilingualism often endures for long periods, but when contact accompanies social change, multilingualism is often transitory, as one group shifts to the language of the other. A corollary of *language shift* is *language death*, a disturbingly common phenomenon in the modern world.

Languages in contact may be seen as languages in competition, and their status must be regulated by a language policy, whether overtly formulated or residing covertly in the society's linguistic culture (Schiffman

1996). Language status planning must balance the symbolic value of a single indigenous national language against the competing interests of linguistic minorities, especially of sizeable groups that speak languages with important literary traditions. Ex-colonial countries may also have to take into account the prestige of an ex-colonial language and its value of an ex-colonial language as a link to the outside world as well as the cost of developing an indigenous language that has not been used in administrative, educational, technical, and other "higher" domains. Complementing language status policy is educational language policy, whose goal for speakers of a minority language may be to assimilate them to a dominant language or to help them maintain their language; for speakers of the dominant group, policy may aim to provide some degree of competence in another language, often a minority language of the country or an international language of wider communication, such as English.

Turning the focus to language contact and the bi- or multilingual individual immediately raises the issue of the definition of *bilingual.* How well does one have to know a second language before being considered bilingual? Certainly, the person who can use two languages with equal ease in all situations is a rarity, perhaps even an aberration. When one's time is divided between two (or more) languages, differences in competence are almost certain to arise, depending on the exposure to each. More importantly, because languages in a bi- or multilingual society are generally differentiated by domain, the normal expectation is for the individual's competence to be spread unevenly across the society's languages.

There are many paths to individual bilingualism: the languages may be learned sequentially or more or less simultaneously, in a variety of differing contexts, and with varying degrees of community support. There is a long tradition of interest in the organization of language in the bilingual brain, bilingual language acquisition, and cognitive differences between bilinguals and monolinguals. The last issue is particularly acute in relation to educational policy in bilingual societies, where the outcomes of various types of bilingual programes may be under scrutiny.

Bilinguals may alternate between languages, or *code-switch* for a wide variety of reasons: for purely linguistic reasons, such as the "triggering" effect of a loanword; for situational reasons, such as to mark transitions from one domain to another; for discourse reasons, such as to emphasize a point made, to clarify, or to mark a change in topic; and for social reasons, such as to signal a particular identity, to express solidarity or distance. Much work has been done on the structural aspects of code-switching, for example,

trying to establish constraints on where switches may occur.

In addition to purposeful code-switching, bilinguals may incorporate features of one of their languages while speaking the other. This phenomenon, known in various contexts as *borrowing, transfer,* or *interference,* may be due to incomplete mastery of one of the languages and in this way it is similar to certain interlanguage phenomena seen in second-language acquisition. However, it also takes place when speakers are fluent in both languages. Transfer may affect either language and may involve any linguistic feature: pronunciation, word structure, grammar, vocabulary, or semantics. The nature and extent of transfer are partly determined by the sociolinguistic characteristics of the contact situation (Thomason and Kaufman 1988). When transfer features become permanent fixtures of the host language, we speak of contact-induced change. Most languages have borrowed vocabulary from other languages, but the transfer of other features is now recognized to be more common than it was traditionally thought to be. In historical linguistics, a language that has influenced another during the course of language shift is known as a *substratum, superstratum,* or *adstratum* depending upon whether its speakers were socially inferior, superior, or equal to the speakers of the language to which they were shifting. If languages of different families in an entire region come to resemble one another because of contact-induced change, we speak of a *linguistic area* or *Sprachbund.*

Finally, language contact may give birth to new languages in the form of pidgins and creoles. Pidgins arise in restricted contexts for limited communication needs (such as trading in a bazaar) where contact groups have no language in common. They are not the primary language of any group, and in their initial stages they are stripped down to the barest essentials requisite for the communication of content. Over time, they may expand until they become indistinguishable from normal languages. Creoles are primary languages that arise from the nativization of pidgins or develop directly, usually in multilingual contact situations in which children acquiring the emergent language are present at an early stage and play a significant role in shaping it. Although some see creole genesis as a distinct phenomenon (e.g. Bickerton 1981), for others the structure of pidgins and creoles owes much to the structure of the contact languages. Although each context has its individual characteristics, similar transfer phenomena can be seen in stable bilingualism, language shift and death, second-language learning, pidginization, and creolization.

IAN R. SMITH

Language Death

We consider a language to be dead when it is no longer spoken. Languages may die suddenly, with the extinction of their speakers. More commonly, however, languages die gradually, as their speakers shift to another language.

In rare cases, sudden language death results from natural disasters, such as when a volcanic eruption on Sumbawa Island wiped out all the speakers of Tamboran in 1815. More often, sudden language death is the result of human intervention. For example, it is estimated that up to 90% of the indigenous population of North America was eradicated between 1600 and 1800 by diseases carried by the European settlers and their animals. The Tasmanians of Australia and the Beothuks of Newfoundland both became extinct by the nineteenth century as a result of conquest and genocide by the Europeans. In such cases, the languages of these people died with them.

Gradual language death may occur for a number of reasons. A language may fall out of daily use, becoming restricted to ceremonial and formal functions. For example, the Egyptian language Coptic is used only as a liturgical language by the Coptic Christians of Egypt, whose everyday language is Arabic. Typically, however, gradual language death takes the form of language shift, in which speakers of a minority language assimilate to a dominant language. Language shift is promoted or inhibited not by properties of the languages themselves, but rather by a number of social factors, such as the size and economic status of the minority language population and the relative prestige of the two languages. Language shift is characteristic of low-prestige languages, typically spoken by populations that are disadvantaged economically, politically, and demographically. Examples include indigenous linguistic minorities in Europe, such as Basque in France and the Celtic languages in Britain (Welsh and Scots Gaelic), and immigrant communities in North America and Western Europe.

Although multilingualism is a necessary condition for language shift, it is not sufficient, because speakers may choose to remain fully bilingual and to use both languages. Language shift results from situations of unstable multilingualism, in which speakers abandon the minority language for the dominant language, either involuntarily, through political coercion from the state, or voluntarily, to improve their economic prospects. The process of language shift takes two or three generations to complete: whereas the first generation is monolingual in the minority language or speaks the dominant language only as a second language, subsequent generations are bilingual, with the minority language gradually becoming the second language. When language shift is complete, speakers are monolingual in the dominant language.

Language shift has consequences for the structure of the dying language. (Note that many of these consequences are distinguished from normal processes of language contact and change in degree rather than in kind and in their relative rapidity.) First, there is massive and asymmetrical lexical and grammatical interference from the dominant language. For example,

more words are borrowed into the minority language than into the dominant language. Borrowings are integrated less and less into the sound system and grammar as speakers' command of the language declines, reflecting a more general pattern in the dying language, in which all linguistic systems are reduced and variation between speakers increases. Grammatical complexities are reduced, as are the sound systems, especially in sound distinctions that do not exist in the dominant language. For example, in dying varieties of Scots Gaelic, inflected pronouns such as *rium* "with me" are replaced by a form with separate particles, *ri mi.* Finally, the complexity of sentence structure decreases: word order becomes fixed, complex single-word constructions are replaced by multiword constructions, and subordinate and relative clauses are lost.

Language shift also has consequences for patterns of language use. Because minority languages tend not to be institutionally supported, the decline in usage, the increase in variation, and the changes in linguistic structure fail to elicit a puristic reaction from the educational establishment. The domains of use of the language also become progressively restricted, gradually becoming confined to the home or the local community. Because different domains are associated with different linguistic registers, or styles, this restriction leads to a loss of social norms governing the choice of styles and results in monostylistic speech. As language shift proceeds, fewer speakers know the language well and thus offer an inadequate linguistic model for younger speakers. Although these semispeakers may identify themselves as native speakers of the dying language and may in fact have excellent competence in the communicative skills of the language, they are aware that their grammatical and lexical competence is deficient.

There is some debate in the linguistics community about whether and how language shift should be halted or reversed. Although minority language speakers may voluntarily shift to the dominant language for economic reasons, subsequent generations often express regret at the loss of the dying language. Indeed, language death is a tragedy not only because every language is a unique and valuable communicative system, but also because language is so often correlated with sociocultural and ethnic identity. Language death has been halted or even reversed in a number of instances, such as the revival of Hebrew as a spoken language in Israel and the maintenance of Irish Gaelic in Ireland. Although such success stories (relatively speaking) have been aided by a combination of political and educational provisions, the major factor in preventing language death seems to be the degree to which the dying language is emblematic of a social identity that people wish to preserve.

JAMES A. WALKER

Language Planning

Language planning is the deliberate, future-oriented, systematic change of language form or use, most visibly undertaken by government, in some communities of speakers. Language planning is directed by, or leads to, the promulgation of a language policy by the government or another authoritative body or person.

A language policy is a body of ideas, laws, regulations, rules, and practices intended to achieve the intended planned language change. Language policy may be realized in very formal (overt) language planning documents and pronouncements (e.g. constitutions, legislation, and policy statements) or in informal

statements of intent (i.e. in the discourse of language, politics, and society), or it may be unstated (covert). Formal policy statements may be symbolic or substantive in their intent. Although the field differentiates between language policy (the plan) and language planning (the plan implementation), the two terms are often used interchangeably in the literature.

Language planning is an outgrowth of the positivistic economic and social science paradigms that dominated the three post-World War II decades. Initially called 'language engineering', the discipline emerged as an approach to developing programs for solving language problems in newly independent developing nations. However, by the 1970s, it was apparent that language problems were not unique to developing nations, but were widely applicable to macro (i.e. state-level) language problems and situations. In the 1990s, policy and planning principles have increasingly been applied to microlanguage situations (e.g. to language problems in companies and organizations). Language planning is a major field within applied linguistics, but it is also closely associated with disciplines such as sociolinguistics and education. Language planning subsumes literacy planning, but language planning goals, including those for literacy planning, are often undertaken on their own—not as part of some broader policy.

The practice of overt (explicit) or covert (implicit) language policy and planning may be one of four types: status planning (about society), corpus planning (about language), language-in-education (acquisition) planning (about learning), and prestige planning (about image). Each of these four types of language planning can be realized from two approaches: a policy approach, with an emphasis on form, or a cultivation approach, with an emphasis on language development and use. These eight language planning perspectives are best understood through the goals that planners set out to achieve. Status and corpus planning have been discussed extensively in the literature, with language-in-education planning often categorized as a part of status planning. Little attention has been paid to prestige planning.

Approaches	Policy Planning (on form)	Cultivation Planning (on function)
Types (overt – covert)	Goals	Goals
Status planning (about society)	Status standardization • Officialization • Nationalization • Proscription	Revival • Restoration • Revitalization • Reversal Maintenance Interlingual communication • International • Intranational Spread
Corpus planning (about language)	Corpus standardization • Graphization • Grammatication • Lexication Auxiliary code standard. • Graphization • Grammatication • Lexication	Lexical modernization Stylistic modernization Renovation • Purification • Reform • Stylistic simplification • Terminological unification Internationalization
Language-in-education (Acquisition) planning (about learning)	Access policy Personnel policy Curriculum policy Methods & materials policy Resourcing policy Community policy Evaluation policy	Reacquisition Maintenance Foreign language / Second language Shift
Prestige planning (about image)	Language promotion • Official government • Institutional • Pressure group • Individual	Intellectualization • Language of science • Language of professions • Language of high culture • Language of diplomacy

Based on Hornberger (1994)

Status Planning Goals

Status planning concerns social goals that are external to the language and that a society must make about the environment in which a language is used. Detailed status planning is a relatively neglected activity. The formal goals of status planning may include officialization, nationalization, and proscription. Functional goals may be the revival, restoration, revitalization, maintenance, and spread of languages or the promotion of interlingual communication (international or intranational).

Corpus Planning Goals

Corpus planning is directed at language and represents an attempt to codify, standardize, or modify and elaborate a language. These goals relate to the linguistic form of the languages, e.g. the standardization of the writing system, orthography, grammar, and vocabulary, or to the cultivation of linguistic functions, i.e. lexical or stylistic modernization, renovation (purification, reform, stylistic simplification, or terminological unification), and internationalization. Language renovation may involve language purification, i.e. the removal of foreign (lexical) influences or the adherence to the classical forms and lexicon of a language. Written forms of a language, by definition, are more standardized and purified than the corresponding oral forms. Although the application of technical linguistic skills is central to meeting corpus planning goals, corpus planning also involves making choices or selecting alternatives that have a social aspect and that must be resolved for such planning to be successful.

Language-in-Education (Acquisition) Planning Goals

Language-in-education planning is user related and aims to develop language education programs and teach a language for various purposes. It may relate to the form of a language-learning program, e.g. in policies concerning access, personnel, curriculum, methods and materials, and resourcing policy and/or evaluation, or to the cultivation of language teaching functions, e.g. reacquisition of a former language, maintenance of an existing one, or foreign or second-language teaching. Although language-in-education planning should co-occur with the other planning types, this often does not happen, and language-in-education planning, through schooling, can become the sole language-change agent.

Prestige Planning Goals

Prestige planning is directed at the image a language needs to develop to promote and intellectualize that language. It is conducted by individuals or groups that have or take the responsibility to create the image of the languages, e.g. in language promotion via government institutions or pressure groups. It may aim at enhancing the functional image and status of the language in key language domains, e.g. in intellectualization, the development of a language of science, a language of professions, or a language of high culture. Prestige planning represents a separate range of activities from status, corpus, and language-in-education planning. The latter are productive activities, insofar as they effect a material change. Prestige planning is receptive and influences how the three other planning activities are acted on and received. Prestige or efficiency of organizational impact levels influences the success of a language plan and the uses to which languages are put.

Language Socialization

Language socialization is the process through which new or novice speakers learn about the language and culture. Language socialization includes both socialization through language and socialization to use language.

Historically, theories of socialization have varied in the degree to which the individual is seen as active in their own socialization. Nineteenth-century theories followed Hobbes' notion of the individual as aggressive, selfish, and asocial by nature and saw socialization as the process of reshaping these natural impulses into prosocial feelings and desires. Freudian theory in the early twentieth century emphasized conflict between human nature (the id) and society (the superego). Functionalism viewed the individual as more passive and more socially directed.

A return to an active role for individuals in constructing social order was found in Mead's theory of symbolic interactionalism, which proposed that individuals and society construct one another through social interaction. This perspective influenced the work of phenomenologists, ethnomethodologists, and social interactionalists. Ethnomethodologists also incorporate close examination of the interactional procedures or methods used to construct a sense of shared context or shared realities, and social interactionalists consider socialization to be an interactional display in which a novice language learner is shown expected ways of thinking, feeling, and acting. Thus, social interactions are considered to be sociocultural environments through which language learners come to internalize and gain performance competence in socioculturally defined contexts.

Language intersects with socialization in three distinct domains: (1) language is used to instruct the learner about what to do, think, feel, etc. (e.g. 'smile'); (2) learners are taught what to say (or not) on various occasions (e.g. 'say "Thank you"'); and (3) learners are instructed in certain features of interaction that vary systematically and are correlated with individual or group variables (e.g. 'good little girls don't shout').

First, language is used to instruct the new or novice speakers about what to do, think, feel, etc. When caregivers and other native speakers use language to and in the presence of new or novice speakers, they are providing information or cues concerning what members are doing. Typically, such instruction takes the form of explicit prompting by the caregiver or an other member of a group. For example, an older person will instruct a younger child in what to say by modeling each utterance for the child to repeat. The prompting routine is marked by characteristic linguistic features. Such routines are usually, but not always, initiated by an imperative verb form meaning 'say' or 'do', followed by the utterance to be repeated. Very often, these utterances have a distinct voice quality and intonational contour, which mark them as components of the prompting activity.

Second, new or novice speakers are taught what to say (or not to say) on various occasions. Language plays a major role in the acquisition of activity/event knowledge with many formal and functional features of discourse carrying sociocultural information, including phonological and morphosyntactic constructions, the lexicon, speech-act types, conversational sequencing, genres, interruptions, overlaps, gaps, and turn length. These structures are socially organized and carry information concerning social order. They are also culturally organized and express local conceptions and theories about the world. As new or novice speakers acquire tacit knowledge and competence in the use of these cues, they acquire knowledge and competence in the social organization of activities and events. Thus, through exposure to and participation in language-mediated interactions, new or novice speakers acquire a knowledge of principles of social order and systems of belief (ethnotheories). For example, among certain social groups, some activities and events may have highly predictable discourse structures (e.g. greetings, jokes, ritual insults, teasing, begging, clarification sequences, trick-or-treat routines), whereas others may have more variable discourse organization (e.g. gossip, negotiations, giving advice, explanations, instructions).

Third, new or novice speakers are instructed in certain features of interaction that vary systematically and are correlated with individual or group variables. For example, the acquisition of sociocultural knowledge by children is influenced by their level of cognitive, social, and linguistic development. In other words, the communicative competence expected of the three-year-old child is necessarily different from that expected of a teenager or adult. Similarly, different social situations require different levels of politeness depending on the status of the speakers (e.g. higher, same, or lower than the speaker), the environment (e.g. church, home, school, etc.), or the intent of the speaker (e.g. emphasize group solidarity).

In addition, new or novice speakers are active socializers of others in their environment. Even infants and small children have a hand in socializing other members of the family into such roles as caregiver, parent, and sibling. As such, second children enter a different social environment than do first children; often, first children 'break in' adults as caregivers. As older children, they may further socialize parents into modes of acting and communicating associated with their school and peer-group experiences. This is illustrated by children's recent role as socializers of computer literacy within their respective households.

Although many theories of language acquisition assume that children develop social and cognitive skills through participating in structured cooperative interactions with more mature members of society, it is important to note that all societies do not rely on the very same set of language-socializing procedures. The cross-cultural research of researchers such as Schiefflin and Ochs (1986) has shown that although prompting a child on what to say appears widespread, expanding children's utterances, using leading questions, announcing activities/events for a child, and using a simplified lexicon and grammar to do so are cross-culturally variable. These practices are not, for example, characteristic of adult–child or child–child interactions in traditional Western Samoan households. This evidence of overt instruction is also of interest in the ongoing debate in the literature regarding the degree to which language acquisition is influenced by innate factors (e.g. Universal Grammar).

Lateralization and Handedness

The term (brain) lateralization derives from the Latin word *latus* (= side of the body) and refers to the fact that the two hemispheres of the human brain are not exactly alike. The concept of lateralization has earlier given rise to the misleading idea that one hemisphere is actually 'dominant' over the other — namely, the hemisphere in which the major capacity for language resides dominating the contralateral hemisphere. This classic concept of '*cerebral dominance'* has been replaced by the concept of '*hemispheric specialization*', with both hemispheres having different general cognitive operational modes and subserving efficient subdivision of complex functions, rather than showing any superiority of one hemisphere over the other.

The earliest known theory of brain lateralization is about 2,400 years old and stated that different hemispheres of the brain control the two functions of sensation and cognition. Although this early theory involved speculations about the two hemispheres being functionally different, up to the 1860s the majority of the scientific community maintained that the hemispheres were structurally and functionally identical. This viewpoint changed dramatically, when the clinical discoveries of Pierre Paul Broca (in 1865) and Carl Wernicke (in 1875) regarding the special role of the left hemisphere in language were made public. Broca took a firm position about the left hemispheric dominance for articulate speech, the comprehension of spoken language, reading and writing, but was careful to add that language was not the exclusive function of the left hemisphere. He further believed the right hemisphere to mediate speech in left-handed people.

It was not before the twentieth century that scientists began to wonder whether Broca might have been wrong about right-hemisphere language dominance in left-handed people. Current evidence from a number of converging sources, notably the high incidence of the language disturbance known as aphasia after left- but not right-hemisphere damage, indicates that the left hemisphere is dominant for comprehension and articulation of language in close to 99 % of adult right-handed people. Sixty-three percent of left-handed and ambidextrous people also have left-hemisphere language, 24 % have bilateral language abilities, and only 13 % of left-handed and ambidextrous people have predominantly right-hemisphere language.

Recent studies showed that some lateralization of function is already present in newborns and is thus established long before puberty. Moreover, certain anatomical asymmetries in the temporal lobe of the brain are already present in the fetus. This is in contrast to early theories, which favored the idea that the two hemispheres were equipotential at birth and for the first two years of life and that a left hemisphere superiority for linguistic functions develops with age. There is also no extensive agreement as to why functions need to be lateralized. A possible interpretation of the cause of lateralization is that it reflects the evolution of systems, which have diversified because of their functional incompatibility. One major example could be provided by linguistic and spatial skills, which are kept segregated in the human hemispheres, perhaps because optimal performance in one of them is detrimental to optimal performance of the other. Another suggestion is that the dominance of the left hemisphere over the right hand and skilled movement preceded its dominance over language.

Because parts of the unsolved problem of functional brain lateralization may stem from the nature of the method used, it is worth considering the primary methods used to study hemispheric specialization. A common approach to study functional brain lateralization is the investigation of patients with unilateral hemispheric lesions. However, the most compelling evidence of functional brain lateralization has been obtained from the results of studies on patients who have either undergone hemispherectomy (removal of the cerebral cortex of one hemisphere) or commisurotomy, a transection of the corpus callosum (the bundle of nerve fibers connecting the two hemispheres of the brain). Commisurotomy permits a direct test of each hemisphere almost working in isolation from the other in these so-called split-brain patients. Studies with these patients revealed a clear dominance of the left hemisphere for language, particularly the syntactic aspects of language and language output. However, the right hemisphere appears capable of understanding a limited amount of words and rudimentary phrases but is only able to produce speech in an extremely limited context. It is not able to recognize when one word is superordinate to another or judging antonyms and it cannot use word order to assist in deciphering meaning. However, it can indicate when a sentence ends with a semantically inappropriate word and it can make grammatical judgments. A further approach to study functional lateralization is represented by studies in normal subjects, using the simple technique of restricting sensory input initially to one or the other hemisphere. This has been done with visual (tachistoscopic presentation) and auditory (dichotic listening) linguistic material. Language lateralization has also been examined through intracarotid infusion of anesthetics (e.g. sodium amytal), which is a technique to allow one to inactivate reversibly and for a brief period one or the other hemisphere (WADA-test). A variety of neurophysiological methods that measure cortical electric or magnetic field activity (electroencephalography, EEG; magnetencephalography, MEG) or cerebral blood flow and metabolic rate (positron emission tomography, PET; functional magnetic resonance imaging, fMRI) were also applied to study hemispheric specialization. Despite the problems that each of these methods have, the best strategy for studying the functioning of the cerebral hemispheres is to use combinations of multiple methods. If the same hemisphere difference is found with multiple methods, it is unlikely to reflect methodological differences.

Efforts to characterize hemispheric differences in terms of oversimplified dichotomies such as the left hemisphere to be the analytic, verbal part of the brain and the right the perceptual, creative, or emotional part have failed. An interesting concept that has emerged from various studies is that functional lateralization is not rigidly contingent upon the stimulus itself but rather upon the way the stimulus is processed. Both hemispheres play active roles during language processing, with each side contributing in a complementary, not exclusive fashion. The left hemisphere, for instance, shows a slight advantage on recognizing detail, whereas the right hemisphere concentrates on the broad background picture. This would explain why left-hemisphere language areas are so good at a precise representation of words (phonology) and word sequences (morpho-syntax), while the right brain seems to supply a wider sense of context, prosody, pragmatics, and meaning. Moreover, the cortical areas specialized for language are not solely concerned with words. Studies of congenitally deaf individuals have shown that the brain areas devoted to sign language are the same as those that organize spoken and heard communication. Such regions are therefore specialized for symbolic representation and communication rather than for spoken language as such. Currently, the relationship between lateralization and language represents a continuing research challenge in neurolinguistics, but a great deal of research focuses on the brain's integrating rather than lateralized abilities.

SABINE WEISS

Latin

The Latin language (*Lingua latina*) is a member of the Italic subfamily of the Indo-European family of languages; it was brought into the Italian Peninsula around the tenth century BCE by a wave of immigrants from the North. As for its ties to non-Italic Indo-European languages, it is closely related to Sanskrit and Greek and to the Germanic and Celtic subfamilies. In Italy, Latin was initially the dialect of the minor district of Latium on the left bank of the lower Tiber River, and then it spread in the entire Italian Peninsula, acquiring a number of features from the indigenous languages it replaced. Latin is supposed to have originally been a member of a group of closely related dialects known as Latin-Faliscan, and its success was the consequence of the successful Roman Empire. Its name comes from *Latini*, a group of related tribes who settled in the territory of Latium.

Early Latin inscriptions exist from around the seventh century BCE. The oldest example of Latin consists of a five-word inscription on a fibula dating from the sixth century BCE. The oldest texts clearly in Roman Latin date mostly from the third century BCE, and among them there are rich texts reflecting an earlier, pastoral society. The affluence of fairly continuous and linguistically consistent material that the emerging Latin literature offers has been indispensable in the reconstruction of the ancestor language, Proto-Indo-European.

Latin underwent changes due to several foreign influences, the most important being those of the Celtic dialects in Northern Italy, the Etruscan language in central Italy, and Greek in Southern Italy, the last one being probably the most important, at least for the literary Latin language. The vocabulary from Late and Medieval Latin has been influenced by the Germanic languages in the army terminology, whereas the Arabic influence was most prolific in the case of the scientific language — e.g. *algebra*.

The history of the Latin language may be divided into four periods, similar to the periods of Latin literature. The Early Period (240–70 BCE) corresponds to the time when Latin became the dominant language in Italy. The Golden Age, or The Classical Period (70 BCE–14 CE), marks the age when the Latin language developed into an artistic medium of expression and attained its greatest richness and flexibility, when it became standardized in grammar and vocabulary. During this period, when it also became the language of the Mediterranean area, three types of Latin could be distinguished: Classical written Latin, Classical Oratorical Latin, and Colloquial, or Vernacular, Latin. The Silver Age (14–130 CE) is the period when Latin became the lingua franca of the western part of Europe. During all this time, the language follows a continuous process of development, the most noticeable changes being in the area of vocabulary and syntax. Finally, the Late Period (200–600 CE) is the time when invading barbarian tribes brought many foreign forms and idioms into the Latin language, to the extent that this new form of Latin was called the *Lingua Romana* and was distinguished from the *Lingua Latina,* the classical language of the educated people.

In the Medieval Period, Latin served as the international written medium of communication, as well as the language of science, philosophy, and theology. Approximately two thirds of all medieval European

literature was written in Latin, and the higher society used it in everyday life. Its vocabulary absorbed many words from the local languages to meet the changed intellectual and social conditions. The Medieval (or Low) Latin borrowed new words from various sources, so that new, distinct meanings emerged. In the fifteenth and sixteenth centuries, the New (or Modern) Latin emerged. The writers of the Renaissance produced a new and brilliant Latin literature that was a very close replica of that of the Latin classical writers. Latin was the diplomatic language of communication until the eighteenth century, the teaching language in the European universities until the late nineteenth century, and the language of the Roman Catholic liturgy until the twentieth century. Today, Latin is officially spoken only in Vatican. However, together with Greek, it is the main source for creating scientific terms all over the world.

The Latin (or Roman) alphabet was created in the seventh century BCE on the basis of the Etruscan alphabet. The original Latin alphabet consisted of 21 letters—A B C D E F Z H I K L M N O P Q R S T V X—, but later *Z* was replaced by *G*. The letters *Y* and *Z* were borrowed from the Greek alphabet after the conquest of Greece in the first century BCE. During the Middle Ages, *J, U,* and *W* were added. The final alphabet consisted of 26 letters, as follows: A B C D E F G H I J K L M N O P Q R S T U V W X Y Z. It must be mentioned that in antiquity, the small letter (minuscule) did not exist, although there were several types of the capital scripts, such as the *elegant book capitals*, with a rounded shape, the *lapidary capitals*, used on monuments, and the *rustic capitals*, which were less elaborate, but easier to write. The minuscules developed later through transformations of the ancient capital letters.

Classical Latin had a typically Indo-European sound system, with five long vowels, five short vowels, and plain consonants. Its major characteristic feature is the large number of diphthongs, which later disappeared from the language.

Early Latin had intonational stress on the first syllable of a word, as opposed to the Latin of the Republican and Imperial periods, when the accent fell on either the last or second to the last syllables of the word.

Latin word structure is the result of gradual simplification of the Indo-European original structure. Latin has five inflected (or variable) parts of speech: the noun, the adjective, the pronoun, the numeral, and the verb; and four uninflected (or invariable) parts of speech: the adverb, the preposition, the conjunction, and the particle.

The nouns are divided into five classes, called declensions, according to their endings. A noun can belong to only one of these declensions. The first declension consisted mostly of feminine nouns. The second declension included masculine and inanimate neuter nouns. The third declension consisted of nouns of all genders, but with similar endings. The fourth declension contained masculine and neuter nouns (with one exception), whereas the fifth declension had only a few words, all feminine. Latin nouns were inflected for gender, number, and case. Latin had six cases: the nominative (or subject case: *frater* 'brother'), the genitive (or possessive case: *fratris* 'of the brother'), the dative (or the giving case: *fratri* 'to the brother'), the accusative (or the direct object case: *fratrem* 'the brother'), the vocative case (*frater* 'brother!'), and the ablative case (or the agent case: *fratre* 'by the brother').

All Latin adjectives are in form really nouns; that is, they have approximately the same endings as nouns. They fall into two classes: the first class contains the adjectives based on the first and second nominal declensions, and the second class contains the adjectives based on the third declension. Apart from the adjectives proper, there is the class of pronominal adjectives, which follow the pronominal type of declension. The adjectives have three grades of comparison: positive (the basic form of adjective: *beatus* 'happy'), comparative (*beatior* 'happier'), and superlative (*beatissimus* 'happiest'), the last two being formed by adding specific suffixes to the stem. Adjectives agree with the noun they modify in the categories of gender, number, and case.

Pronouns in Latin are used to substitute nouns, adjectives, and numerals. The pronouns are of the following main types: the personal pronouns (e.g. *ego* 'I', *tu* 'you'), the reflexive (e.g. *se* 'self'), the possessive (e.g. *meus* 'my'), the indefinite (e.g. *aliquis* 'someone'), the relative (e.g. *qui* 'who'), the interrogative (e.g. *quis* 'who?'), and the demonstrative pronouns (e.g. *hic* 'this', *ille* 'that').

The numerals are of Indo-European origin. The cardinal numeral *unus* 'one' was declined like a first- or second-declension adjective, because it was acting in Latin as a pronominal adjective, with distinct feminine and neuter forms. Apart from 20, the numerals do not inflect after *tres* 'three', except when they are turned into regular adjectives. The cardinal numerals (e.g. *unus* 'one') are usually used with nouns in the nominative case. All ordinal numerals (e.g. *primus* 'the first') are declined like regular adjectives of the first or second declension.

Most of the adverbs are basically adjectival forms that derive from the ablative singular forms of the respective adjectives. They are used to determine a verbal action or a quality of an adjective. There are two types of adverbs: primitive and derivative. The

first type consists of proper adverbs referring to circumstances of place, time, and manner (e.g. *jam* 'already'), whereas the second type consists of adverbs that are derived from nouns or adjectives, by means of special suffixes (e.g. *longe* 'far'). Adverbs do not grammatically agree with the verb they match; i.e. they have one fixed form only.

The verbs have an entirely different set of endings from the nouns. They are divided into four classes, called conjugations. The verb conjugations express the following distinctions:

(1) Singular vs. plural: *amo* 'I love' vs. *amamus* 'we love'.

(2) First vs. second vs. third person, both in singular and plural: *amo* 'I love' vs. *amas* 'you love' vs. *amat* 's/he loves'; *amamus* 'we love' vs. *amatis* 'you love' vs. *amant* 'they love'

(3) Imperfective tense (present, imperfect, future) vs. perfective tense (perfect, pluperfect, and future-perfect): *amo* 'I love', *amabam* 'I was loving', *amabo* 'I shall love' vs. *amavi* 'I loved', *amaveram* 'I had loved', *amavero* 'I shall have loved'.

(4) Mood, which includes indicative, subjunctive, imperative, infinitive, gerund, gerundive, and participle: *amo, amem, ama, amare, amandum, amandus, amans*, respectively.

(5) Active vs. passive voice: *amo* 'I love' vs. *amor* 'I am loved'.

So-called 'inchoative' verbs denote the beginning of an action, state, or occurrence. There are three types of inchoative verbs—: primitive (e.g. *nosco* 'to get to know'), verbal (e.g. *pallesco* 'to become pale'), and nominal (e.g. *nigresco* 'to become black')— according to the way in which they are formed: inchoative verbs proper, inchoative verbs derived from other verbs, and inchoative verbs derived from nouns.

'Impersonal' verbs denote the action of an unspecified agent and are used with no expressed subject (e.g. *pluit* 'it rains'). They do not have forms for the imperative mood, and the compound tenses are formed with the participle neuter form.

Participles are adjectives with regular noun/adjective endings added to a verb stem. It must be mentioned that any Latin adjective or participle can be translated as an adjective, but if there is no convenient noun to attach itself to, it is translated as a noun. In Latin, there are three types of participles: the present participle (e.g. *amans*), the past passive participle (e.g. *amatum*), and the future active participle (e.g. *amaturus*).

The gerundive (e.g. *amandus*) is a specialized verbal adjective implying 'oughtness'; it was used either as an attribute with the noun in indirect cases or simply as an adjective of obligation, whereas the gerund is

a verbal noun in the neuter singular form, or more precisely an adjective in the neuter singular serving as an abstract noun.

Classical Latin had a free word order, in the sense that all combinations are possible. However, subject–object–verb seems to be the preferred order in Classical Latin.

In parallel with Classical Latin, Latin developed a spoken vernacular, which was spread by the Roman army throughout the empire. This *sermo plebeius* or *Lingua Romana*, i.e. Vulgar Latin, later developed into the Romance languages. However, it is quite difficult to study this variety, because almost all written materials in Latin used the Classical Latin forms, and thus there is little documentation of *Lingua romana*. One of the most useful works about Vulgar Latin is the 'Appendix of Probus', a list of correct and incorrect word forms from around the third century. One may say that Ancient Spoken Latin is mainly characterized by freedom of syntax, by the presence of numerous interjections, and by the frequent use of Greek words.

On the other hand, in the development of Latin, other characteristics of Vulgar Latin emerged. Thus, vowels lost the distinction between long and short: most of them became short in all Popular Latin dialects. Many diphthongs disappeared, as well as a large number of final vocals and consonants — sometimes all the final syllables — and in general the pronunciation experienced simplification.

The Latin noun declension was simplified over time, and the number of cases decreased. However, a new part of speech appeared: the article emerged in Popular Latin, the indefinite article from the cardinal numeral *unus*, and the definite one from the demonstrative pronouns *ille* and *iste*. The place of the definite article was before a noun in the western dialects, but it followed the nouns in Dacia. The indefinite article invariably preceded the noun. Subject–verb–object became the established word order.

During the long-lasting and wide use of Latin for scholarly and literary purposes, its influence on all the European languages has been enormous. Not only did the Romance languages assimilate the Latin vocabulary, but also all other languages that, directly or indirectly, came into contact with Latin. The legal, scientific, and technological jargons have thousands of words of Latin origin. For instance, English, a Germanic language, inherited words from Latin both directly and through other languages (especially French), so that the English vocabulary consists of almost 66% Latin words. English uses words of Latin origin, such as *cheese, cup, kitchen*, and *street* in everyday life, not to mention the technological terms, perhaps the most common one being *computer.*

RADU DANILIUC

Lehmann, Winfred Philipp

Winfred P. Lehmann has defined a role for the comparative-historical study of Indo-European languages as part of the general study of languages and language history.

With the coming of World War II, Lehmann, like many of his contemporaries, put his linguistic skills to work in the service of his country, participating in code-breaking efforts and language instruction. His work as officer in charge of the Japanese language school (1942–1946) resulted in the publication of an early practical grammar of Japanese.

Following his first academic position (Assistant Professor, Department of German, Washington University, St. Louis, 1946–1949), his move to the University of Texas at Austin (1949–), and a Fulbright Research Fellowship to Norway (1950–1951), a sudden need took the Lehmanns from a Fulbright in Egypt to Ankara and the pressing task of creating materials to teach English to Turkish speakers as Director of the Georgetown English Language Program there (1955–1956). Like his work with Japanese, this task involved the production of materials for a language very different from English. It also underlined the critical need to strengthen language teaching in America.

His move to the University of Texas at Austin soon found him building the German Department, as its Chair (1953–1964), into a department ranked first in the nation, and creating a Linguistics Department (Chair 1964–72) ranked third. He then created a new center to teach a wide range of non-European languages and brought numerous colleagues to Texas. To develop new language curricula, Lehmann took advantage of the National Defense Education Act to create programs at the University of Texas (Austin) for the study of South Asian, African, and Middle Eastern languages.

In the 1960s, the field of computational linguistics began to develop. By the mid-1960s, Lehmann was directing the Texas effort to create a German–English translation system, funded for many years by the US Air Force, and later by Siemens Corporation, which marketed a system capable of doing useful first draft translations of technical material such as that produced in quantity by the Common Market. Besides its Machine Translation (METAL) project, the University of Texas' Linguistics Research Center carried out related research on other, often ancient, languages and still does (http://www.utexas.edu/cola/depts/lrc/index.html).

The impact of Lehmann's work brought him international recognition. Among other things, he was awarded the Brothers Grimm Prize during a summer term as Professor at the University of Marburg (1974), and, in recognition of his scholarly and diplomatic abilities, he was chosen to head the linguistic delegation to China when linguists were first invited after the long diplomatic break (see Lehmann 1975). Because of his breadth and depth of contributions to the fields of linguistics, modern languages, and computational linguistics, Lehmann is unique among linguists to have served as president of three very diverse scholarly bodies: the Linguistic Society of America, the Modern Language Association, and the Association for Computational Linguistics.

Lehmann's book, *Historical linguistics* (in its several editions), has been widely translated (see Lehmann 1962, 1973, 1967, 1969, 1992). This work, originally published as a textbook, encoded the ever new directions of a rapidly changing field, as did monographs such as *Proto-Indo-European phonology, Proto-Indo-European syntax*, and *Theoretical bases of Indo-European linguistics*.

Before Lehmann's *Proto-Indo-European phonology* (1952), Indo-Europeanists reconstructed the sounds of the protolanguage as isolated sounds. Lehmann's study of Indo-European phonology as a system of

interdependent sounds underscored the need to recognize sounds as part of a larger system.

Lehmann's *Proto-Indo-European syntax* (1974), reacting to Chomsky's early syntactic work and Greenberg's work on implicational universals, suggested that general syntactic structural systems of language might limit the accumulation of structures that often resulted from comparative-historical reconstruction. When linguists were still discovering much about the range of grammatical structures in the world's languages, this also called attention to the importance of older Indo-European language data and reminded Indo-Europeanists that their data were important for more general questions of language.

His recent books, *Theoretical bases of Indo-European linguistics* (1993) and *Pre-Indo-European* (2002), further explore the relation of Indo-European to typologically diverse structures among the world's languages and go on to explore the role of linguistic paleontology in dealing with prehistory. In essence, Lehmann (2002) pushes the active language type to a period before Proto-Indo-European on the basis of structures that one might agree are only relics in Proto-Indo-European, an otherwise nominative–accusative language.

Lehmann's later work is a unique attempt to describe the language structures of prehistoric speakers whom Lehmann calls 'pre-Indo-European' as opposed to 'Proto-Indo-European'. He brings older Indo-European linguistic data here to bear on the problem of what language was like before Proto-Indo-European. Lehmann's concern with the intellectual and academic context of Indo-European is thus reflected, not only in his administrative impact on the academic institutions of which he was a part but also in the changing focus of his publications.

Lehmann's work has remained firmly rooted in the practicalities of language and culture, be they language teaching, translating, or the question of historical stages of human language. He has challenged the status quo on many fronts and impacted the course of national and international curricula.

Biography

Winfred P. Lehmann was born on June 23, 1916, in Surprise, Nebraska. Growing up in post-World War I Wisconsin, his undergraduate education at Northwestern College (Watertown, WI, B.A. 1936) reinforced his earlier focus on Greek, Latin, and German. As a graduate student at the University of Wisconsin (Madison: M.A. 1938; Ph.D. 1941), he pursued the study of older Indo-European languages such as Sanskrit and Old Irish. In his Old Irish class, taught by Professor Miles Dillon of Trinity University (Dublin), he not only learned the language of poets but also met Ruth Preston Miller, who became his wife and collaborator on Old Irish (Lehmann and Lehmann 1975).

His publications, awards, and various listings in *Who's Who's* are summarized online (http://www.utexas.edu/cola/depts/lrc/general/facultyhomes/lehmann.html).

CAROL F. JUSTUS

Leskien, August

Leskien, together with Karl Brugmann, Berthold Delbrück, and Hermann Osthoff, formed the so-called 'ursprüngliche Gruppe' (original group) of the neogrammarian movement that emerged around 1875.

In 1876, Leskien's award-winning monograph *Die Declination im Slavisch-Litauischen und Germanischen* (The Declension in Slavic-Lithuanian (i.e. Balto-Slavic) and Germanic) was published, which was to become a

fundamental contribution to the neogrammarian approach. Within this treatise, he presented a critical analysis of both August Schleicher's genealogical theory — stating that the evolution and relationship of languages could be captured in a 'family tree' model — and Johannes Schmidt's wave theory, according to which specific changes within a language spread in a similar pattern as the waves produced by a stone dropped into the water. Leskien rejected Schleicher's idea of language being comparable to a natural organism (and thus linguistics being a natural science) and criticized Schmidt's wave theory for considering the evolution of language as separate from its speakers, their history, migrations, etc. Leskien's statement that sound laws (i.e. changes in the sound system of a language) have no exception was soon considered to be the main principle of the neogrammarian movement. Analogical change (i.e. assimilation of patterns) as the second important mechanism in language change is only to be admitted as a valid explanation, after every conceivable other means was exhausted and a positive condition for analogy could be stated.

Other features still considered typical of Leskien and the other neogrammarians (although this characterization is far from being exhaustive) are the preoccupation with historical linguistics, the atomistic description of linguistic details, and the neglect of content analysis in favor of form analysis. A work of considerable influence on his own and on the linguistic conception of the neogrammarians in general was William D. Whitney's book *The life and growth of language* (1875), which Leskien translated into German (1876; Leben und Wachstum der Sprache). Whitney fully endorsed the neogrammarian position with regard to sound law and analogy, and the influence of his thinking is traceable in Leskien, when he insisted that language cannot be considered separate from its speakers. In the following years, Leskien published important works on the Baltic languages. His study *Der Ablaut der Wurzelsilben im Litauischen* (1884; The ablaut in Lithuanian root syllables) is considered to be the first monograph devoted to a special problem of Lithuanian historical phonetics. Equally important is his work *Die Bildung der Nomina im Litauischen* (1891; The formation of Lithuanian nouns), comprising valuable material for the following generations of researchers. His *Litauisches Lesebuch mit Grammatik und Wörterbuch* (1919; Lithuanian reader with grammar and dictionary) was posthumously published. Leskien is considered to be the pioneer and founder of Baltic studies in Germany. As the first chair for Slavic philology in Germany, Leskien was one of the forerunners of systematic research into Slavic linguistics. From the mid-1870s he devoted himself to the study of Old Bulgarian; his preliminary work focused on the oldest monuments of the Old Bulgarian language, especially the codices (Supraslensis, Zographensis, and Marianus). As a result of this work, Leskien published two books on Old Bulgarian (Old Church Slavonic) that are still valid today: *Handbuch der altbulgarischen (altkirchenslavischen) Sprache. Grammatik, Texte, Glossar* (1871; A Handbook of Old Bulgarian (Old Church Slavonic). Grammar, Texts, Glossary) and his *Grammatik der altbulgarischen (altkirchenslavischen) Sprache* (1909; A Grammar of Old Bulgarian (Old Church Slavonic)). He preferred the term Old Bulgarian rather than Old Church Slavonic, proving that Old Church Slavonic was mainly based on Bulgaro-Macedonian dialects. Like August Schleicher before him, Leskien thus rejected Franz von Miklosich's 'Pannonian' theory, which claimed that the oldest Slavic literary language was of pannonian-slovene origin. Leskien's reviews of Miklosich's works on 'Old Slovene' are not to be seen merely as a criticism of Miklosich's linguistic method, nevertheless, Leskien, underestimating the value of the first complete Slavic etymological dictionary, vigorously criticized Mikolsich's *Etymologisches Wörterbuch der slawischen Sprachen* (1886; Slavic etymological dictionary) and refused to review it. In his two books on Old Bulgarian, as well as in the first volume of his famous *Grammatik der serbo-kroatischen Sprache* (1914; Serbo-Croatian grammar), Leskien, following Schleicher, proposed a classification of the Slavic verb according to its present stem. Leskien contributed relatively little to syntax; although his work on syntax is documented as truly significant by his academic lectures held during the last years of his life, his two books on Old Bulgarian contain almost nothing and the manuscript of the second volume of his Serbo-Croatian grammar, which is supposed to have dealt with syntax, got lost under the bombing of Leipzig in World War II. Together with Vatroslav Jagic, Leskien in 1876 founded the journal *Archiv für slavische Philologie.* Besides his major works, Leskien published numerous articles on the phonology and morphology of the Slavic languages, as well as on graphematic questions and Old Bulgarian literature. Although Leskien devoted most of his scholarly activities to the linguistic investigation of languages, he was also deeply interested in all cultural aspects of language. His numerous publications on fairy tales, folk songs, and related literary topics (mostly dealing with Baltic, Slavic, and Balkan languages) were widely accepted as equal in quality to his linguistic works. Undoubtedly, Leskien's research laid the foundations of modern Slavic and Baltic studies and left its imprint on historical and comparative linguistics in general. Both as a scholar and as a university teacher, he influenced not only many European but also American linguists. Among those who studied under Leskien, or at

least attended his lectures, were Jan Baudouin de Courtenay, Aleksandar Belić, Leonard Bloomfield, Erich Berneker, Olaf Broch, Ben'o Conev, Filipp F. Fortunatov, Jooseppi J. Mikkola, Holger Pedersen, Ferdinand de Saussure, Aleksandur Teodorov-Balan, Lucien Tesnière, Nikolai S. Trubetzkoy, Karl Verner, Gustav Weigand, and others. Many of his works, especially his *Handbook* and his *Grammar of Old Bulgarian* as well as his *Serbo-Croatian Grammar* have become classics and are still valid and stimulating.

Biography

August Leskien was Born in Kiel, Germany on July 8, 1840. He completed high school in 1860 and began his university studies of Classical philology at Kiel University under Georg Curtius; in 1862, he followed his teacher to Leipzig, Germany, where he obtained his doctorate in 1864. In 1864–1866, he worked as a teacher of Latin and Greek at the 'Thomasschule' in Leipzig; he continued his academic studies of Comparative Indo-European Linguistics with special emphasis on Baltic and Slavic languages under August Schleicher at Jena, Germany, and received his final academic degree *venia legendi* (habilitation) in 1867. In 1867–1869, he was university lecturer of Comparative Linguistics at Göttingen, Germany, and in 1869, succeeded Schleicher at Jena as *extraordinarius* (associate professor) of Comparative Linguistics and Sanskrit. In 1870, he was appointed *extraordinarius* of Slavic Philology at Leipzig and as *ordinarius* (full professor) at Leipzig University in 1876. In 1875, he was Fellow of the Royal Saxonian Society of Sciences; a member of the Jablonowski Society of Sciences in Leipzig and Foreign Member of the Imperial St. Petersburg Academy of Sciences in 1876; a member of the Bulgarian Learned Society (since 1911 Bulgarian Academy of Sciences) in 1884; Foreign Member of the Imperial Academy of Sciences in Vienna in 1898; Foreign Member of the Prussian Academy of Sciences in 1900; a Member of the Swedish Academy of Sciences in Uppsala in 1914; and Foreign Member of the Academies in Belgrade, Munich, and Zagreb. He received an honorary Doctorate at the University of Oslo; Serbian Order 'Sava' Second Degree, Order of the Saxonian King and Title 'Geheimer Hofrat' (Court Councillor). Leskien died in Leipzig on September 20, 1916.

Lesser Antillean French Creole

Lesser Antillean French Creole is spoken in the Caribbean on the islands of Guadeloupe, Martinique, Dominica, and Saint Lucia. It has been argued to be related to other Atlantic French Creoles such as Guyanese, Haitian, and Louisianais, but such relationships being controversial, we will not take into account

these other creoles in the present study. Within this four-island cluster, at least two major distinctions differentiate the varieties spoken in Guadeloupe and Martinique from those spoken in Dominica and Saint Lucia. First, Guadeloupean and Martiniquais coexist with the French language, whereas the varieties spoken in the Commonwealth Antilles on the islands of Dominica and Saint Lucia coexist with English. Second, Lesser Antillean emerged in Guadeloupe and Martinique (where a plantation colony was developed) and was subsequently 'exported' to Dominica and Saint Lucia by migrants. Given that this article is only concerned with the study of Lesser Antillean French Creole, only the varieties spoken in Guadeloupe and Martinique will therefore be examined. In 1946, Guadeloupe and Martinique became French 'Départements d'Outre-Mer', a status that they still have today despite separatist attempts during the 1960s and 1970s.

Lesser Antillean French Creole developed in the seventeenth century at the onset of the French colonization of Guadeloupe with African slaves in 1635, the objective being the development of a plantation colony based on the cultivation of sugar cane. The influx of Black slaves lasted up to the 1860s. Geographically speaking, African slaves in the Caribbean came from Kwa-speaking areas stretching from Sierra Leone to the Ivory Coast. They also came from Togo, Benin, Nigeria, Ghana, Gabon, Congo, Zaïre, and Angola (Gadelii 1997:2). Parkvall (1999) argued that Lesser Antillean originated in present-day St.Kitts with two main substrata: Kwa and Western Bantu languages. Singler (1995) takes a similar stand, but suggests that the Bantu substratum was more important than the Kwa one based on demographic data. Lefebvre (1986) has defended that the Gbe cluster (including Ewe and Fon) in present-day Togo and Benin constitute the main substratum in the French colonies. The other languages having contributed to the genesis of Lesser Antillean French Creole are not only varieties of seventeenth-century French but also the languages of the Caribs, the indigenous group living in Guadeloupe prior to the arrival of the French colonists. While some scholars do not fully acknowledge the input of Carib languages to the genesis of Lesser Antillean due to the extermination of the tribes by the end of the seventeenth-century (Cérol 1997), others like Wittman and Fournier (1994) think otherwise. According to these authors, the language of the Karina tribe that the French colonists first encountered in the 1620s was heavily influenced by Tupi and may have given way to a French Carib pidgin (Gadelii 1997:37). They further suggested that Arawakan languages spoken by indigenous Ameridians before the Europeans arrived also influenced French-related creoles in the Caribbean.

At the phonological level, the vocalic inventory is as follows: /i/, /e/, /ɛ/, /a/, /o/, /u/ with a little variation in the acrolectal varieties. Lesser Antillean contains some consonants that do not exist in French: /h/, / N /, /tΣ/, and /dZ/. Palatalization is also quite common as in [ky], [gy], [ty], [dy], and [sy] (Gadelii 1997).

While the influence of French on the lexicon of Lesser Antillean French Creole is obvious, a number of parallelisms between Guadeloupean and African languages, documented by Cérol (1997), are worth noting at the lexical level. They fall into distinct categories:

Nouns: Kikongo *musulongo* 'the name of a bakongo group' > Guadeloupean *mousoulongo* 'savage'. Kikongo *bebele* 'piece of meat' > Guadeloupean *bébélé* 'dish made out of pieces of meat'.

African words abound in the realms of the fauna and flora: Kikongo *kyokyo* meaning 'a bird' > Guadeloupean *kyo* 'a species of bird'. Kikongo *malanga* 'yam' > Guadeloupean *malanga* 'species of yam'.

Cérol (1997) also provides numerous examples of lexical parallelisms in the domains of anatomy, food, habitat, music, and dance.

Ideophones: Kikongo*, kya-kya-kya* 'onomatopea for laughter' > *Guadeloupean kya-kya-kya* 'laughter or to laugh'.

Grammatical morphemes: Kimbudu 'for, to give' > Guadeloupean *ba* 'for, to give'.

Adverbs: Kikongo *phwele* 'crowd, a number of, a lot of ' > Guadeloupean *pwele* 'a lot of'.

Besides direct lexical inheritances from the French lexifier and the African substrates, Lesser Antillean has naturally produced many innovations of its own such as *palaviré* 'a couple of slaps', *pépa* 'cheap shoes', or *sanpalé* 'deaf'. Furthermore, the language is extremely innovative in the domain of derivational morphology, as it borrows French affixes to make up new words: *makrèl* 'indiscreet woman' + *-é* > *makrélé* 'to mind other people's business' or *pwofité* 'to abuse' +* *-asyon* > *pwofitasyon* 'abuse, tyranny' (Cérol 1997).

In the realm of morphosyntax, the definite article *la* or *a* always occurs in a postnominal position and represents one of the areas where Guadeloupean displays a behavior different from Martiniquais. In Guadeloupean, the definite marker is consistently *la* as in *vwati-la* 'the car'. In Martiniquais however, while *la* occurs after a consonant (or a semi-consonant) as in *tab-la* 'the table', its counterpart *a* must appear in a postvocalic position, as in *loto-a* 'the car' (Bernabé 1987). Damoiseau (1999: 33) further documented in Martiniquais other variants that differ according to the environment. For instance, *lan* appears after a consonant cluster as in *madanm lan* 'the woman', and *an* appears after a nasal vowel as in *pwason an* 'the fish'. From a cognitive perspective, it is

worth observing that definite nouns are prime candidates for plural marking, otherwise the marker does not appear, e.g. *Sé tab la* 'the tables' (Damoiseau 1999:34). As for the indefinite article, it is always found in a prenominal position as in *an tab* 'a table'.

In the realm of question formation, Lesser Antillean has recourse to two strategies: it may front an interrogative word as in *es ou ka travay* 'do you work' or use raising intonation '*ou ka travay*?' 'you work?' Negation is expressed by the morpheme *pa,* which always appears in a preverbal position: *Patrik **pa** lavé loto a* 'Patrick did not wash the car' (Damoiseau 1999).

As far as tense, mood, and aspect markers are concerned, just like most of its congeners, Lesser Antillean makes use of preverbal unbound markers which occur in isolation or in combination to yield diverse tense, aspect, and mood interpretations. It is important to note that the Indo-European concepts of present, past, future... are not directly applicable to the study of creole languages but are nevertheless used as useful descriptive tools. The following examples from Damoiseau (1999) stage a sample of markers that are representative of the Martiniquais variety of Lesser Antillean.

> *Iv **ka** travay* 'Yves works'. The present tense may be expressed with the marker *ka.*
> *Iv ø travay anpil* 'Yves has worked a lot.' The present perfect involves no marker.
> *Iv **té ka** travay lè nou rivé* 'Yves was working when we arrived.' The combination *té ka* expresses past progressive while *té* in isolation may express past or pluperfect.
> *Iv té ø travay isi a lè i té jenn* 'Yves worked here when he was young.'
> *Jou tala Iv té ø travay anpil*: i té las 'That day Yves had worked a lot, he was very tired.'

This last sentence shows that depending on the context, the same marker + verb combination '*té + V*' may yield different interpretations. As in a number of creoles, one can observe that adverbials like *jou tala* 'that day' have an anchoring effect on the event and are instrumental in deriving the relevant temporal and aspectual interpretation. Such areas of investigation display the true complexity of creole grammars.

MARLYSE BAPTISTA

Lévi-Strauss, Claude

One of the most original and prolific thinkers of the twentieth century, the French anthropologist Claude Lévi-Strauss is associated with the development of a school of thought in cultural anthropology known as structuralism. Challenging the dominating empirical, positivistic and functionalist tradition in social sciences, he viewed cultures as systems and elaborated the principles of the structuralist method, which sought to discover a rationalist universal theory of mind by identifying unconscious and abstract structures underlying the diversity of human cultures. He derived its method from structural linguistics, deeply convinced that 'linguistics was the only social science which could truly claim to be a science and which had achieved both the formulation of an empirical method and an understanding of the nature of the data submitted to its analysis,'

and therefore should be applied as the main model for the anthropological study of diverse cultural categories.

His famous autobiographical work *Tristes tropiques* (1955) provides an insight into early influences during his formative years of life that greatly contributed to his later conceptualization of the structuralist doctrine in anthropology. In addition to his probably innate inclination for formal logic, reinforced by academic training in philosophy, he was also fascinated by geology, Freudian psychoanalysis and Marxist ideas, which all showed him that true reality was never that which was the most manifest and that the process of understanding involved reducing one type of reality to another. Later, when he had come to New York as a refugee during World War II, he began to search for a suitable method to analyze the data on social and family life of Amerindian cultures collected during his own expeditions to central Brazil, as well as the accumulated ethnographic data on North American Indians published by the Smithsonian Institution. During this period, he met the Russian linguist, Roman Jakobson, who introduced him to the work of Ferdinand de Saussure and the basic principles of structural linguistics, thus exerting a decisive influence on his thinking.

Trying to extend the formal structural features of language described by structural linguistics to cultural categories, Lévi-Strauss began to view culture like a grammar, a formal code consisting of symbols and their logical relationships, while the job of the anthropologist was to decipher this code and to reveal the logical workings of the human mind. In search for analogies between language and cultures, he concludes that just as structural linguistics shifts from the study of conscious linguistic phenomena, observed at the level of surface structures (speech), to the study of their deep unconscious infrastructure (language), so the anthropological analysis should place priority on the underlying principles (deep structures) that lie beneath observable everyday human behavior and cultural phenomena, such as kinship rules (surface structure), in order to explain these phenomena. Structural linguistics also introduces the concept of the system of phonemic units that are put together according to certain rules. The basis of its analysis are not these units as independent entities, rather the relationships between them, based on functioning binary opposites that constitute the structure of the system. By analogy, Lévi-Strauss suggests, the true nature of social and cultural phenomena is not in these phenomena themselves, but in the relationships between them. No element has any significance in itself, but only in relation to all elements in the system, so that it is the entire system with its axes of contrasts and oppositions that defines each and every element within it. Like phonemes, kinship terms and patterns, marriage rules, similar prescribed attitudes between certain types of relatives, and other elements of culture are elements of meaning; like phonemes, they acquire meaning only if they are integrated into systems.

By extending the defining contrastive features of phonemes to the analysis of the meaning of cultural categories, Lévi-Strauss suggests that the underlying principles of human behavior and culture also take the form of oppositions, such as nature vs. culture, male vs. female, earth vs. sky, hot vs. cold, etc. However, unlike Saussure, who held that meaning was not a preexisting concept but arbitrarily attached to the form and variable across languages, Lévi-Strauss maintains that all human minds are ultimately the same, the underlying organization of all cultures is the same, generated through the universal set of semantic oppositions, the apparent differences being due simply to varying arrangement of these oppositions. Because of the absolute universality of these principles, what can be discovered by analyzing cultural categories and products in one culture is merely a formal transformation of those in completely different cultures. Accordingly, the focus of anthropological research for Lévi-Strauss is the notion of social structure, which represents a model of actual social relationships and serves to explain them. This structure or model is a system of elements, none of which can undergo change without affecting others. The model has the possibility of predicting change. For every given model, there is a system of transformations that form a set, a group of models of the same type, which make it possible to predict how the model will react if one or more of its elements are submitted to change.

In his first major work, he applied his theoretical concepts to one of the central themes of anthropology, the study of kinship. Contrary to the then prevalent view of kinship patterns as explained only by relations of blood and descent, under the influence of the French anthropologist Marcel Mauss and his exchange theory as central to social structure, Lévi-Strauss bases his theory of kinship on relationships of marital alliance and the exchange of women resulting from rules of incest avoidance. Incest taboos and marriage rules determine whom one should marry and whom one should not, implying reciprocity and the need for exchange while generating marriage structures that determine the distribution of women through marriage to different groups. The exchange of spouses, he says, is the universal basis of kinship systems in the same way the exchange of goods is the basis of the economic system and the exchange of words is the basis of the communication system. Elementary kinship structures are those in which there exists a prescribed, positive rule for marriage to someone of a particular kinship category, for example, to a cross cousin (father's sisters' and mother's brothers' children). Complex kinship structures are those that have negative marriage rules, specifying which persons one may not marry.

According to Lévi-Strauss, the elementary structures of kinship of small-scale societies consist of a system of

relationships, such as the mother's brother/sister's son relationship called avunculate, which involves relationships between mother, father, son and mother's brother characterized by consanguinity, affinity, and descent. If there is a positive relationship (+) between husband and wife, there will be a negative relationship (-) between the wife and her brother, and vice versa. If there is a positive relationship between father and son, there will be a negative relationship between that son and his mother's brother. Lévi-Strauss shows how these relationships vary in different societies depending on whether the rule of descent is patrilineal or matrilineal, using the simple formulaic expression A:B::C:D, as in mother's brother (A) : sister's son (B) :: father (C) : son (D). Proceeding in this way, he reduces diverse historical and geographical rules of kinship to only three elementary structures, constructed through only two types of exchange of women, which themselves depend on a single differential characteristic —- harmonic or disharmonic regime considered, while the whole set of prescriptions and prohibitions can be deduced from the relationship between the rule of descent and the rule of residence.

Lévi-Strauss fully illustrates the structuralist ideas in his analysis of the phenomenon of totemism, the practice of associating people and social groupings, such as clans, with animals, plants, or other objects, related to certain beliefs and rituals. Arguing against the evolutionary view on totemism as a form of primitive religion, as well as against the functionalist explanation of the phenomenon in terms of usefulness of animals, Lévi-Strauss defines totemism primarily as a system of classification of social groups based on the analogy with distinctions between species in the natural world. Totemic classifications, thus, reflect a system of oppositions based on natural objects to organize a set of cultural ones. He opposed the widespread view on presumed mental inferiority of natives and significant differences in the thought processes of so-called "primitive" or non-Western peoples and the modern scientific Western culture. He shows that traditional non-Western peoples with the *"Savage Mind"* have an inductive "science of the concrete", making generalizations from primary sensible data, which "is as rigorous as that of modern science". Close to sensory intuition, the "science of the concrete" differs from Western science in that it operates by working directly through perception and imagination, classifying things in terms of their everyday, sensible features, rather than the underlying abstract features and deductive formal principles that the Western scientist uses. In spite of these differences, Lévi-Strauss claims that the basic thought processes in terms of distinctive features and semantic oppositions remain the same in all individuals, "primitive" or "civilized". These oppositions for Lévi-Strauss are "good to think with" and they distinguish humans from animals, culture from nature.

In his most important work of four volumes of *Mythologiques* or *Introduction to the science of mythology,* he developed the line of enquiry to its climax by analyzing 813 myths taken from 200 South and North American Indians and presenting them as the purest manifestation of the *"Savage Mind"*. He stressed that myths do not have a practical function, but are aimed at solving problems as an end in itself. Comparing myth to language, he borrows from structural linguistics the concepts of syntagmatic and paradigmatic relations (paradigmatic relationships constitute a set in which one item can be substituted for another, and syntagmatic relationships are ones of contiguity and linearity) and describes the workings of myths in terms of relations of opposition, symmetry, substitution, and permutation. Myths function as systems of transformations, so that a single myth can never be understood in isolation, only in its relation to other myths. The events narrated in any single myth form a syntagmatic chain, while the personages and events can be studied as members of paradigmatic sets occurring in a corpus of myths. In his first volume of *Mythologiques, The raw and the cooked,* he begins by analyzing a myth of Bororo people and ends up examining a whole collection of myths from South America, showing as their common structure the discovery of fire and cooking, i.e. the transition from nature to culture, symbolized through invariant oppositions such as raw:cooked (the cooking of culture transforming the raw of nature), or fresh:rotten (the natural process of purification or a return to nature). Within this common structure of nature vs. culture, other analyzed myths show a series of transformations, by substituting e.g. the origin of fire with the origin of water, honey or tobacco. In this way, all the Amerindian myths studied by him are to be considered as variant versions of one another, linked together by transformations, just "as the instrumental parts of a musical work, to be studied as one studies a symphony".

The main criticisms of Lévi-Strauss's structuralism have been concerned with its too formal logic based on literal adoption of linguistic methods, with its negation of history and human initiative, as well as with overemphasis on universals of pan-human unconscious structures and on the intellectual aspect of culture on account of its emotive and practical sides. Despite these various critiques, structuralism represented a dominant intellectual framework in the1960s and 1970s, so that the impressive and voluminous work of Lévi-Strauss has influenced not only further developments in anthropology, particularly in the fields of symbolic anthropology (focused on the interpretation of meaning) and cognitive anthropology (related to mental representations of cultural practices), but also a wide range of intellectuals of varied specializations, labeled post-structuralists, such as the philosopher Jacques Derrida, the intellectual historian Michel Foucault, the psychoanalyst Jacques Lacan, and the literary critic Roland Barthes.

Biography

Claude Lévi-Strauss was born in Brussels, Belgium, on November 28 1908. He completed his B.A. in law and philosophy from the University of Paris in 1931. He held a teaching post in a provincial secondary School, 1932–1934. He moved to São Paulo, Brazil, where he taught sociology at the University of São Paulo, and made several ethnographic expeditions to central Brazil, 1935–1939. He returned to France, where he was mobilized by the French army in 1939–1940. He emigrated to New York in 1941, where he was visiting professor at the New School for Social Research, New York, 1942–1945; he was also Cultural Counsellor at the French Embassy to the United States of America, 1946–1947. He presented a doctoral thesis on 'The elementary structures of kinship' at the Sorbonne, Paris in 1948. He was Deputy Director of the Musée de l'Homme, Paris, 1949–1950; Director of Studies, École Pratique des Hautes Études, Paris, 1950–1974; and Professor and Chair in Anthropology, Collège de France, Paris, 1959–1982. He received the Prix Paul Pelliot in 1949, the Huxley Memorial Medalin 1965, and the Erasmus Prize in 1973; he was also a Member of Académie Française in 1973. After retirement in 1982, Lévi-Strauss currently resides and writes in Paris, France.

Lexical Borrowing

Lexical borrowing occurs when a language 'borrows' a word from another language and incorporates the new word into its own lexicon. The term 'borrowing' is in some ways an unfortunate metaphor, since the donor language is never asked whether it wants to lend the word or not, and the 'borrowing' language never repays the word. However, other potential metaphors such as 'giving' or 'stealing' are equally problematic, and the term 'borrowing' is so well established that we will just accept the term.

Lexical borrowing comes about when two languages are in contact with each other, and there are speakers displaying some degree of bilingualism in both borrowing and source languages. Sarah Thomason and Terrence Kaufman (1988) propose a 'borrowing scale' in which lexical borrowing occurs

with only 'casual contact', while at the upper end of the scale 'very strong cultural pressure' leads to 'heavy structural borrowing'. Lexical borrowing often occurs with only minimal contact. The English word, kangaroo, was borrowed into English from the Australian Aboriginal language Guugu Yimithirr when Captain Cook and his crew were making repairs to their ship on the northeast coast of Australia, and none of the crew ever learned to speak Guugu Yimithirr. Most probably, the word was brought into English after one of the crew pointed at an animal and was told by one of the local Aboriginals that the animal concerned was a 'kangaroo'. In fact, the Guugu Yimithirr word *gang-guru* refers specifically to the large black kangaroo.

More intensive cultural contact than occurred between Captain Cook's crew and the Guugu Yimithirr can lead to much more extensive borrowing. The Norman Conquest of England in 1066 led to English adopting literally tens of thousands of words from French, so that now almost half the words found in an average English dictionary will have their origins in French. Sometimes, the same word has been borrowed more than once, at different times and with different meanings: the English word 'chief' came from Old French *chef* meaning 'head' or 'boss'. The English word 'chef' was borrowed much later from the modern French expression *chef de cuisine* or 'head of the kitchen'.

For borrowing to occur, the borrowing language generally has to be gaining something, or it would probably make do with the words that it already has. Borrowing is often thought to occur for either reasons of necessity or reasons of prestige.

Necessity can explain the borrowing of 'kangaroo' from Guugu Yimithirr, 'banana' from Wolof, or 'kayak' from Eskimo. English has borrowed countless terms for flora, fauna, and other things that were not traditionally found in Britain.

Prestige is often involved in situations where one language is thought by its speakers to have more prestige than the other. This motivation explains all of the French words that came into English after the Norman conquest. Up until the end of World War II, French had borrowed relatively few words from English, but since then French has borrowed countless words from (American) English, referring to many aspects of pop culture and technology. Words like *sweat* 'sweatshirt', *pull* 'pullover', *jean* 'jeans' are used to refer to items of clothing popularized by Americans. Sometimes, a culture can feel threatened by the arrival of large numbers of borrowings. The *Académie Française* has fought a valiant but losing battle against all of these Americanisms, often proposing to replace them with more French equivalents. Few of their proposals have ever had any success.

Some words are more 'borrowable' than others. Basic vocabulary (including body parts, natural geographic phenomena, weather terms, small numerals, and the like) are rarely borrowed. Nouns are more borrowable than other parts of speech. Einar Haugen (1950) reports the following percentages of loans from English into American Norwegian: 75.5% nouns, 18.4% verbs, 3.4% adjectives, and only 1.2% adverbs or prepositions with 1.5% of others.

Borrowing languages can be faced with the problem of how to fit the borrowed words into their own linguistic systems. Two basic strategies are found: adaptation and adoption. Sometimes, different speakers of the same language choose different strategies, as when different speakers of English with varying degrees of familiarity with French use different pronunciations for words like 'croissant'.

Adaptation can be either phonological or grammatical. Many languages do not allow consonant clusters or final consonants, but the words they borrow from other languages may have them. Japanese generally resolves this problem by adding vowels between or after the consonants concerned, as it has with words like *besaboru* from English 'baseball'. In some instances, English homophones have created completely different Japanese words as with *seturoku,* a baseball 'strike', and *seturoki*, an industrial 'strike'.

Grammatical adaptation is required when a noun is borrowed from a language without grammatical gender, for example, into a language that has gender. Most nouns borrowed into French are made into masculine nouns, as were all the Americanisms given above. Verbs that are borrowed into French also require adaptation. The infinitive forms of French verbs all have a suffix of one of the forms -*er, -ir,* or -*re.* Virtually all borrowed verbs end up with the -*er* suffix, as, for example, *chatter* 'to chat in an internet chat room'. Sometimes, grammatical adaptation has remarkable consequences. Swahili is a language with a complex set of noun class prefixes. The prefix *ki-* marks one set of singular nouns while the prefix *vi-* marks their plural counterparts. When the English term "keep left" was borrowed as *kiplefiti*, the initial *ki-* was interpreted as the singular noun class prefix *ki-;* hence, traffic roundabouts (plural) are referred to as *viplefiti*.

Whether a language chooses to adapt or adopt often depends on the degree of familiarity its speakers have with the donor language. Taba (a minority language from eastern Indonesia) borrowed the Malay word *jadi* 'thus' replacing initial Malay /ʤ/ with the closest native equivalent /d/. In more recent times, Taba speakers have borrowed many more words (like *baju* 'shirt') with the Malay sounds preserved so that now,

/ʤ/ can actually be considered to be a native Taba phoneme.

Lexicalization

Lexicalization is a term that is used by linguists for referring to several things. The most common uses of this term are the following two: (a) When we create a word to express some meaning, we are 'lexicalizing' that meaning by means of the new term (e.g. the word *software).* (b) Another use of the term 'lexicalization' is found in historical linguistics, where it stands for a process in which a sequence of words is reduced to a single word (e.g. *nevertheless).* In both uses of the term, there is a new lexical item that is introduced to express something for which there was no single lexical item before. Thus, it is possible to find cases of lexicalization in which the word that acquires a new meaning was already available in the dictionary, although it was related to a different concept.

Semantic lexicalization has many causes. The most typical one is the extension of the meaning of existing terms by means of specialization and generalization processes, as well as through metaphor and metonymy. In a process of specialization, the word's original meaning is always narrowed down to a smaller set of special referents. An example of specialization is the English word *corn*, which was originally a term used for 'all kinds of grain'. Later, it specialized to the most typical referent in different countries, so that in the end, it acquired the meanings of 'wheat' in England, 'oats' in Scotland, and 'maize' in the United States. Something similar happened to the English word *queen*, which also went through a specialization process. Its original meaning was any 'wife or woman', but now it is restricted to only one type of wife, that of the king. As for generalization, it is the process opposite to specialization. We find generalization in the extension of meaning that took place in the senses of the word *school.* Originally, a school is 'an institution of learning'. However, this meaning has been broadened to that of 'any group of people mentally engaged upon shared activities or sharing views of style or opinions', giving as a result the senses of 'group of artists' or 'group of people sharing opinions'. Another example of generalization is the word *moon.* Originally, it referred to the Earth's satellite, but it is now applied to any kind of satellite.

Metaphor can be very productive for meaning extension. Metaphor (from Greek *metapherein,* 'carry over') is a process based on perceived similarity. We may use a word to refer to a certain notion because of their similarity of meaning, which does not need to be very close. The important point here is that the similarity should be perceived by the user, whatever it is based on. Eventually, the metaphorical sense will become lexicalized. The interpretation of a homonym such as *school* in the sense of 'group of fish' can be related to the senses of *school* as 'group of learners' and may thus be motivated by the relation of similarity that we perceive between a group of learners following a class and a group of fish swimming together and following a leader.

In metonymy, on the other hand, the extension of meaning is based on a relationship of contiguity, i.e. between the whole of something, e.g. *school* as an 'institution of learning', and a part of it, e.g. the lessons. The word *school* can metonymically stand for each of its components, i.e. the building itself, the lessons, the pupils, the staff, the headmaster, etc. The part-for-whole relationship is one of many possibilities in

metonymy, and there are also many others, such as the producer for product (*I'll have a* **Pepsi-Cola**), material for thing (*Take the* **iron**), effect for cause (*He had a* **long** *face*), etc.

All these are cases of lexicalization of new meanings using already existing words. In some other cases, new words are introduced into the language, by means of borrowing (*plateau* from French*, gestalt* from German, etc.) or creation of new terms (*telephone, software,* etc.). These processes also lexicalize meanings. In any case, both the extension of meaning and the incorporation of new words are processes that can also be examined from a diachronic (historical) point of view, because the new items enter the language at a certain moment of its history and take some time to be firmly incorporated into the system.

An interesting case in this respect is what happens when groups of words that function consistently together become only one word in the course of time. In some cases, they are still used as separate words, even though the expression has to be understood as a whole. This is what happens, for instance, with the Spanish expressions *sin embargo,* 'however', or *por lo tanto,* 'therefore', which have little to do with their components: *sin* ('without'), *embargo* ('embarrassment') would give 'without embarrassment', and *por*

('because of'), *lo* ('the') and *tanto* ('so much') would give something like 'because of (the) so much'. It is interesting to notice here that their English counterparts are also lexicalized expressions, but in this case they have become single words: *however* is made up of *how* and *ever*, and *therefore* of *there* and *fore* (*fore* no longer exists as a single word, but it has given us the present-day English word *before*). Other examples are *notwithstanding*, *nevertheless,* and *alright*. We also have lexicalized compounds among nouns, adjectives, and verbs, e.g. *blackbird, wheelchair, colour-blind, to vacuum-clean*, etc.

CARLOS INCHAURRALDE

Lexicon: Overview

A lexicon (or 'mental dictionary') contains all the words that a person knows; it is a model of how words are organized and stored in the brain. The lexicon specifies how a word is spelled, how it is pronounced, what it means, and its part of speech (e.g. noun, verb, adjective, preposition).

The lexicon figures prominently in grammatical theories, although the exact content of a 'lexical entry' (also called a *lexeme*) differs among theories. Structural theories propose that verb lexemes, for instance, include information about the types of object that a verb might take. According to this approach, the entry for *kiss* indicates that it takes a noun phrase (as in *Mary kissed the kitten*). The subject noun phrase is not specified in the lexical entry because its existence is determined by more general rules. In contrast, lexical theories assume that syntactic information is stored with individual lexical entries rather than as more general syntactic rules. Under this approach, lexemes

specify how particular nouns, verbs, and adjectives combine with arguments. For example, the verb *give* takes three arguments (e.g. the arguments for *Rod gave the cat to Jessica* are *Rod, the cat,* and *Jessica*). The verb's lexeme specifies information about semantic roles associated with the verb (e.g. the entry for *give* indicates that this verb takes an agent and a patient). The entry also indicates the mapping between semantic roles and syntax (e.g. the lexeme for *give* indicates that the agent is the subject and the patient is the object when the sentence is in the active voice).

Words often contain multiple morphemes, i.e. meaningful word parts (e.g. *walking* consists of *walk* and *-ing*, *firefly* consists of *fire* and *fly*). A debate has arisen over whether the mental lexicon contains whole words or only morphemes. Some theorists argue that each variant of a word (e.g. *brush, brushed,* and *brushing*) has its own lexeme. However, this approach is problematic for highly agglutinative languages such as

623

Finnish and Turkish because, in these languages, many prefixes and suffixes can be attached to words. Consequently, the words in these languages can have thousands of variants and would require many lexemes to represent all possible variants of each word. Therefore, some theorists have adopted an alternative approach to the one-lexeme-per-variant view. They propose that the lexicon contains solely morphemes and that variants do not have their own lexeme. Instead, words are decomposed into their morphemic parts (during recognition) or composed (during production). Which view is correct appears to depend on the kinds of morphemes that make up the word. Highly regular morphemes (called inflectional morphemes) do not significantly alter the root morpheme (e.g. the morpheme *-s* indicates plurality but otherwise does not alter the meaning of the word). However, less regular morphemes (called derivational morphemes) significantly alter the root morpheme (e.g. the morpheme *-er* changes *learn* from a verb to a noun). Multimorphemic words with derivational morphemes appear to have their own lexemes, whereas words with inflectional morphemes do not appear to be stored as whole units.

The representation of compounds in the lexicon depends on whether the meaning of the compound is 'transparent' or 'opaque'. Compounds such as *buttonhole* and *snowman* are said to be semantically transparent because their meaning can be derived from the individual morphemes. Other compounds, such as *buttercup* and *hippocampus,* are semantically opaque because their meaning is not derivable from their parts. Semantically opaque compounds (e.g. *tablespoon*) most likely have their own lexical entries in addition to entries for their morphemic constituents (e.g. *table* and *spoon*). However, semantically transparent compounds do not have their own lexical entries and instead are decomposed into their parts prior to recognition.

The lexicon is organized in a number of ways (three are described here), and this organization affects how words are accessed during active recognition or production. First, the lexicon can be divided into 'closed-class' words and 'open-class' words. Closed-class words (also called 'function' words) comprise articles, prepositions, pronouns, and conjunctions. This class of words is so called because the membership changes little over time. In contrast, new open-class words can easily be added. Open-class words comprise nouns, verbs, adjectives, and adverbs and are often thought of as the 'content' words of a language.

Second, the lexicon is organized according to syntactic category. Lexical entries contain information about their syntactic category (for example, *cat* is a noun; *pet* can be a noun or a verb). In addition, many grammarians assume that these syntactic categories can be subdivided. For example, nouns can be divided into common nouns (nouns that can be preceded by a 'determiner' such as *a* or *the*) and proper nouns (names, places, events, etc.). Common nouns can be further divided into 'count nouns' (e.g. *pebble*) and 'mass nouns' (e.g. *water*)—count nouns can be used in the plural, but mass nouns ordinarily cannot. Thus, lexical entries contain information about minor categories (such as whether the entry is a count noun) as well as major ones (such as nouns and verbs).

Third, semantic relations among open-class words play an important role in determining the structure of the lexicon. Five of the most common relations are synonymy, antonymy, incompatibility, hyponymy, and meronymy. Synonymy is traditionally defined in terms of substitution. That is, two words are said to be 'synonyms' if they can be interchanged without affecting the truth value of the statements in which they appear (e.g. *sofa* and *couch*). It should be noted that synonyms can rarely be exchanged in every possible context; thus, synonymy is also thought of as a case of extreme semantic similarity. Words are said to be 'antonyms' if they are lexical opposites (e.g. *hot* and *cold*). 'Incompatibility' refers to a relation in which two words cannot be used simultaneously (e.g. an object can be either a *circle* or a *square*, but never both). 'Hyponymy' refers to the inclusion of one class in another (e.g. *apple* is a type of *fruit*). 'Meronymy' is a semantic relation that exists between words that denote parts and wholes (e.g. a *stem* is part of an *apple*).

By measuring how quickly and accurately people can recognize or name a word, psycholinguists have identified several variables that influence access to the mental lexicon. One of the most robust findings is that high-frequency words take less time to access than low-frequency words. However, this finding appears to hold only for open-class words. A second finding is that concrete words (e.g. *apple* or *cat*) are more readily accessed than abstract words (e.g. *freedom* or *democracy*). A third finding is that the ease of accessing a word is affected by whether a semantically similar word has been recently presented in the experiment. That is, a word (e.g. *doctor*) is accessed more easily if it has been preceded by a semantically associated word (e.g. *nurse*) than if it has been preceded by an unrelated word. A fourth finding indicates that lexical access is affected by how a word sounds. Researchers have shown that when people have difficulty retrieving a word (a situation known as the 'tip-of-the-tongue phenomenon'), they tend to retrieve words with similar sounds rather than words with similar meanings. Taken together, these findings demonstrate that the organization of the lexicon is very

flexible and that grammar, meaning, and pronunciation can all play a role in retrieving a word from the lexicon.

CHRISTINA L. GAGNÉ

Lingua Franca

Although the term 'lingua franca' is best known as a common noun, meaning a language used between people who have no language in common, this entry is about the Lingua Franca in its proper noun meaning, i.e. the Italian-based contact language that was used throughout the Mediterranean area from the fifteenth to the nineteenth century. In this usage of the term, 'Franca' refers to the Franks, the word that was used for Europeans in the Arabic-speaking world of the Late Middle Ages. While 'Lingua Franca' literally means 'European language', its meaning was narrowed down to 'Romance-based pidgin'. Although Lingua Franca is sometimes referred to as Sabir, this may be confusing, since the latter is also used to refer to the French-based pidgin that came into existence (presumably on the basis of Lingua Franca) in North Africa in the late nineteenth century.

Although Lingua Franca is traditionally categorized as a pidgin language, there is some reason to qualify this classification. As was already observed by Schuchardt (1909), some of its linguistic features, such as the generalized use of the infinitive, suggest that Lingua Franca may perhaps be more accurately viewed as a form of Foreigner Talk. Other linguists (e.g. Minervini 1996) have claimed that it should rather be seen as a second-language variety of Italian. And since Italian and Spanish, the languages that formed the basis for Lingua Franca, were closely related dialects rather than separate languages five centuries ago, it might perhaps more appropriately be categorized as a koiné, i.e. the product of dialect convergence.

The Lingua Franca arose as a trade language in the context of the colonization of the Eastern Mediterranean by the Italian city-states of Venice and Genoa, whose dialects left a stamp on the language, for example, in the first and second singular pronouns *mi* and *ti*, which may well be of Venetian origin. Lingua Franca was diffused to the Western Mediterranean when the Genoese moved their commercial activities to the Iberian peninsula and North Africa, where it acquired an important role as a medium of intercultural communication in places such as Tripoli, Tunis, and, especially, Algiers. The presence of Turkish-speaking soldiers, Berber and Arabic-speaking Moors, and Christian slaves and renegades speaking a variety of European languages turned Algiers into a multilingual city *par excellence*. Due to the Spanish presence in North Africa, a number of Spanish words were incorporated, which resulted in Spanish–Italian doublets such as *fazer* (from Spanish) and *counchar* (from Italian), both meaning 'do' or 'make'. It is this presence of Spanish-derived words that forms the major difference between the western and eastern variety of Lingua Franca.

Since it is no longer spoken, all information on the language is restricted to written sources. Some of these are fictional works, such as poems and plays in which Oriental characters are depicted as speaking some sort of restructured Italian. The problem with this type of source, of course, is to decide whether they reliably reflect the language as it was actually spoken. The best known among these literary sources is Molière's (1670) *Le bourgeois gentilhomme*, which contains the famous lines *Se ti sabir, ti respondir. Se non sabir, tazir, tazir* 'If you know, answer. If you don't know, keep quiet'. Another author who has made extensive use of Lingua Franca for comical effect is the eighteenth-century Venetian playwright Carlo Goldoni. Although Schuchardt (1909) felt Goldoni's

Lingua Franca to be 'colorless', it is still worthwhile to consult Kahane and Kahane (1976) for a survey of its linguistic features.

A more reliable source of information can be found in nonfictional texts, such as historical and geographical works. The most extensive text of this type is a booklet entitled *Dictionnaire de la langue franque ou petit mauresque* (henceforth *Dict.*), published anonymously in Marseilles in 1830. It is a 112-page language primer, containing a wordlist and eight short dialogues, meant to provide the French military with a basic knowledge of the language when they embarked upon their invasion of Algiers. Another important documentary source is Haedo's (1612) *Topographia e historia general de Argel*, a geography and history of Algiers, partly based on an eyewitness account. Apart from the Lingua Franca fragments, the book also contains some acute observations on the language situation in Algiers at the turn of the sixteenth century. Haedo's remarks leave no doubt that the Lingua Franca played an important role as a medium of interethnic communication among Moors, Turks, and Europeans in that city.

As to its main linguistic features, the following may be mentioned. While the lexicon is mainly derived from Italian and Spanish, some words have been taken from Arabic, such as *taybo* 'good' and *marfuz* 'bad', and from Turkish, such as *Yoldach* 'Turk'. The morphology is more elaborate than is usually the case with pidgin languages. Agreement between the head and its modifier(s) is quite common, especially with regard to gender, as in *barbero bono* '(a) good doctor' and *bona bastonada* '(a) severe beating' (both from Haedo). Although verbal inflection is heavily reduced when compared to the lexifier languages, we find occasional use of the past participle to express past tense, as in *mi mirato iéri* 'I saw him yesterday' (lit. I seen (him) yesterday) (*Dict.*) The only other verbal form is the infinitive, sometimes combined with an adverb such as *bisognio* 'necessary' to express future or irrealis, as in *cosa bisognio counchar?* 'What shall we do?' or 'What should be done?' (lit. What necessary do?) (*Dict.*). Although reduplication is generally rare in pidgins (as opposed to creoles), it occurs quite often in the Lingua Franca, as in *mucho mucho* 'very much' (Haedo) and *siéme siéme* 'together' (*Dict.*).

The basic word order is S(ubject)-V(erb)-O(bject), although VS order is found as well, e.g. in sentences containing a focused constituent and in subordinate clauses. In contrast to many other pidgins, the copula is usually overtly expressed (by *(e)star*), as in *qouesto star véro* 'That is true' (*Dict.*). Pronominal subjects, especially third singular, often remain unexpressed, a feature that may be attributed to Italian and Spanish influence. Direct as well as indirect pronominal objects are often marked by the preposition *per*, as in *mi star contento mirar per ti* 'I'm happy to see you' (lit. I happy see PER you) (*Dict.*). Complex sentences are quite common, with the subordinate clause being attached to the matrix clause either by a conjunction, a relativizer, or a complementizer, or without any overt linking element at all. The latter occurs especially with object sentences, as in *mi pensar star meïo* 'I think it's better' (*Dict.*).

Literacy

The term literacy is most commonly interpreted as being the ability to read and write. However, focusing on decoding and encoding leads to meaningless techniques that obscure a broader understanding of this complex cultural phenomenon. Ever since the first western postwar warnings about the 'literacy crisis' and the widespread 'illiteracy' among schooled people of industrialized countries, questions have arisen that challenge the validity of this focus.

Critical debates involving social history, sociolinguistics, educational, and cultural studies have led to a specific field of research that questions the psycholinguistic view of literacy as a unified, abstract, and universal human cognitive capacity relating to the use of written materials, and describes the variety of epistemological frameworks of the current research on approaches and attitudes toward literacy.

The challenge, therefore, has been to provide a broader understanding of the nature and consequences of writing and reading as political, social, mental, physical, and linguistic actions, rather than merely individual standardized technomechanical skills.

The greatest concern in literacy studies still focuses on the fact that definitions, values, and functions ascribed to literacy are totally ambiguous unless they are viewed in specific sociohistorical contexts. The crucial question is what to consider as literacy in a given community or in a given historical epoch. From a pragmatic and ethnographic standpoint, for instance, someone who simply signs legal documents may be considered literate in rural areas, whereas someone with the skills required to decode written text, but whose ability to make sense of that text or to act upon it is not developed, is seen as illiterate in postindustrial communities. From the same viewpoint, shop floor workers who can read, follow written instructions, and write occasional short notes may be considered illiterate in a technological and computer-based work context, in which information must be fed into and taken out of computer terminals.

As these examples clearly demonstrate, recognizing and manipulating patterns in print and linking these patterns to oral language may not suffice to perform successfully in a given sociohistorical or socioprofessional context. Moreover, standardized test scores that quantify literate competence over time and across space may conceal extremely different and continually changing sociocultural realities. Hence, criteria for both literacy and illiteracy should be based on degrees in a continuum rather than on categorical distinctions and universal quantitative rates, rendering the traditional general distinctions between literacy and illiteracy, and between esthetically oriented literacy and functional or instrumental literacy useless. Any meaningful definition of literacy or illiteracy must refer to a particular sociocultural context.

A further implication of this relativistic perspective is that literacy as a subject of scientific inquiry concerns both the myriad social practices of which the activities of reading and writing are an integral part and the multitude of sociocultural concepts, values and functions of what is considered a literate performance in a given situation. The focus, therefore, is on the contextual use of language and not on abstract, context-free structures or on written products of communication. Moreover, if reading and writing are essential elements of cultural practices, i.e. cultural ways of doing things, and make sense within groups and communities, they must, perforce, be seen as deeply interconnected with and inseparable from each other.

By focusing on everyday uses of reading and writing in local communities, detailed ethnographic studies have played an important role in the investigation and description of the variety of events and communication practices that comprise the so-called 'ecology' of literacy practices. Identifying different forms of literacy in different domains of life, such as computer literacy, academic literacy, workplace literacy, etc., and developing the notion of hidden forms of literacy (in contrast to visible or dominant forms of literacy), ethnographic studies have also been the basis for insightful discussions about the strict divide traditionally drawn between oral and literate cultures and subcultures, as well as about the relationship between local forms of literacy and formal training. Some of the most telling findings of these studies concern the complementary function of oral and written forms in literate communication practices; the processes of informal learning in the acquisition of literacy practices; the discrepancy between what counts as literacy in school and in other mainstream institutions; and the pervasive role of configurations of power and social knowledge structures in shaping institutional and non-institutional literacy practices.

Another key issue in literacy studies has been the study of the consequences of literacy on language use

and on intellectual and social life. In general terms, the social view of literacy extended the notion of text and of written language usage conceived by theoretical linguistic traditions, demolishing an array of mythologies inherited from philosophical and scientific discourses about the intrinsic value of writing due to the assumed relationship between scriptural order and reason, and between literate competencies and cognitive, technoscientific, and socioeconomic development.

The link between the logic of alphabetic writing and rationality or logical reasoning was made in the 1960s and 1970s by English-speaking scholars, who integrated and extended the ideas about the cognitive and social impact of literacy. These scholars attempted to demonstrate that a 'literate mind' is cognitively distinct from a nonliterate one, since it is highly skilled in thinking and speaking abstractly, clearly, and reasonably. Accordingly, it was also asserted that a literate society possesses a distinctive form of organization and is highly skilled in technoscientific development.

Their historical, anthropological, and psychological studies about different, mainly nonindustrialized, culture has led many scholars, concerned with how the acquisition of literacy affects individuals and societies, to corroborate and reinforce some traditional assumptions about literacy as a skill-specific competence, or a cognitive condition, and about the 'great divide' between speaking and writing and between oral and literate cultures. Another implication of these assumptions is that literacy is identified as a neutral and powerful technology, which positively transforms human mental capacities and social behavior. Accordingly, its appropriation by individuals and societies is primarily a cognitive and technomethodological problem. As a result, illiteracy is identified as a cognitive handicap on both individual and collective levels, or a technomethodological insufficiency at an institutional level (for instance, the use of inappropriate equipment, sites, and pedagogical materials). Transferred to communities, therefore, these assumptions are simplistically constraining, reducing the idea of literacy by ignoring the fundamental issue of the sociopolitical regulation of access to literacy, which is associated with social inequalities of power and control.

In contrast to this perspective, and drawing on comparative socioanthropological studies, critical studies on literacy have found much evidence that different forms and levels of literacy are also shaped by social stratification and control: even nominally literate contemporary societies show institution-regulated and often pyramidal distributions of competence in basic formal and pragmatic conventions of writing. The resources of literacy to which people have access in households and communities are fundamentally unequal. Yet, as many cross-cultural and cross-historical comparisons within context-specific settings have demonstrated, what is naturalized or routinized by influential social groups is not equally acquired and used by an entire population, even with compulsory mass literacy training, which explicitly or implicitly embodies mainstream ideological and normative agendas, entailing very different consequences within particular cultures and subcultures. These studies also found that literacy practices had been historically embodied within religious, ethical, and ideological issues.

Competing perspectives of the social and cultural values and effects of literacy on the daily life of modern societies were also drawn from the prescriptive agendas of postwar western national institutions and international organizations such as UNESCO. Since the 1970s, the link between these agendas has been a strong commitment for the establishment and expansion of a standardized literate competence, as a basic human right to be achieved both in industrialized and nonindustrialized areas around the world. Following a line of reasoning and discussion that builds on commonplace literacy mythologies intertwined with arguments for competence in personal self-improvement, citizenship, and social mobility in modern nations, UNESCO's studies and campaigns, and many national educational policies inspired by them, have reinforced conventional assumptions about the 'civilizing' effects of literacy, while encouraging heated debates over the social purposes and political potential of literacy.

The studies and campaigns developed over the past few decades have been based on assumptions about the usefulness and value of universal literacy training in any social context, and have been so devised that illiteracy and the aforementioned "literacy crisis" have become a strategic governmental issue, triggering a number of local and national campaigns and massive financial investments in many nations around the world. These campaigns aimed to 'eradicate' illiteracy in the world before the year 2000. The analogy between illiteracy and disease has been a recurrent theme, widely disseminated through official texts and images.

It is generally recognized that the set of values and beliefs that underpinned institutional public discourses about literacy as a key element in the production of progressive mentalities and productive individuals for capitalist economies and modern nation-state building relates to the concepts of progress, development, and emancipation inherited from post-Enlightenment liberal social theories. Included here are beliefs in the liberating and revolutionary consequences of literacy, such as democracy and political participation.

Concomitant to such official views and guidelines, however, significant alternative viewpoints have been brought into public and educational discussions. Drawing on critical literacy studies and on a Marxist-oriented understanding of emancipative

education, many researchers have successfully demonstrated that the acquisition of literacy may entail both negative and positive aspects, and that it is necessarily associated with ideological and political issues. Accordingly, they have tried to demystify the fallacious equation of literacy with progress and social mobility, as well as the official rhetoric and current school practices that deliberately obscure the range of social, economic, and political forces that inform literacy practices and formal education. They claim that by promoting homogenizing and manipulative socialization, the acquisition of literacy has become a disempowering process (in contrast to the so-called 'empowering literacy'), which implies passivity, contributes nothing to personal improvement, and promotes social exclusion. Additionally, if literacy is often present in unequal social structures, this inequality should be the most important motivator for a reevaluation of the conceptions, functions, and uses to be ascribed to literacy within a given sociocultural context.

Having discarded a view of literacy as a context-neutral, skill-specific competence, works on literacy acquisition and language education have also challenged linguistic assumptions about the neutrality and transparency of writing as a modality of language usage. Consequently, they have also questioned school conceptions of literacy that promote the acquisition of strict instrumental skills, passive attitudes, and prescribed behavior, as well as the traditional hierarchization of literacy practices, textual genres, and linguistic modalities. In literacy training, emphasis has been placed on the social and political dimensions of the differences between different types of literacy, or different forms of literacy and, more specifically, on the whole issue of inequality between them.

In light of the different perspectives on literacy, and emphasizing the ideological dimension of any understanding of it, current research in this area focuses on the variety of written materials and communication practices of everyday life in different sociocultural networks and communities, in an attempt to throw light on the various forms of influence they may exert on the economic and political exclusion, or inclusion, of any given contemporary social group. Concomitant to this fundamental questioning is the attempt to promote a profound rethinking of the empowering properties underlying contemporary institutional and noninstitutional literacy practices. Needless to say, any and all new commitments in this field must take into account educational issues and the fact that literate competencies in postindustrial societies tend to be transformed into a set of available consumer objects like, for instance, reading training within highly structured and standardized interpretive schemata that fit in perfectly with standardized tests and performances.

Localization of Linguistic Information

The subject of localization is the relationship of function with neuronal structure. The main issues of localization are the definition of the concept of a function, the description of the anatomical structures necessary to carry out such a function in the normal brain, and the description of the duty of a certain area of the

brain. Generally, one may differentiate between the localizability of simple functions such as moving a leg and complex functions such as language processing. Simple functions have the greatest anatomical and structural correlation whereas complex functions apparently have relatively widespread cortical and subcortical localization.

Before the nineteenth century, the common theory of brain function, which was termed "holism", assumed that the brain simply was not a structure made up of discrete independent centers, each specialized for different functions, but must be looked upon as a single working unit. However, at the beginning of the nineteenth century, scientists began to assign function to certain neuronal structures and started to favor the theory of localization of function within the brain. The first localization of linguistic function to a specific region and hemisphere of the brain that became widely accepted is usually attributed to the French surgeon Pierre Paul Broca (1824–1880) and the German neurologist Carl Wernicke (1848–1905). They examined the brains of individuals who had suffered a stroke, become aphasic, and later died. Based on postmortem correlation, Broca suggested that the impaired articulation of speech was due to a lesion within the left inferior frontal gyrus of the brain (Broca's area). Wernicke correlated lesions in the left superior temporal gyrus (Wernicke's area) with disorders in language comprehension (Figure 1). Wernicke, who was neither a pure localizationist nor a pure holist, also developed an elaborate model of language processing, where he proposed that only basic perceptual and motor activities are localized to single cortical areas and interconnections between these functional sites make more complex intellectual functions possible. He stated that different components of a single behavior are processed in different regions of the brain and thus advanced the first evidence for the idea of distributed processing and connectionism. In the first part of the twentieth century, the idea of functional segregation again fell into disrepute, proposing that higher cognitive abilities depended on the function of the brain as a whole. However, at this time most neuroscientists were willing to accept some sort of cortical localization for sensory and motor function. In contrast, the situation concerning memory and language was still an active battleground for the opponents and defenders of localization. Until the 1960s, most of the information about the localization of linguistic function was based primarily on patients with brain lesions. In this case, the language deficits resulting from brain injuries have been compared to the areas of the brain which became lesioned. Even though the lesion can be accurately located, the function that is examined after injury does not reflect the simple equation of the

normal function missing, but it represents a new state of reorganization of the brain. In the 1960s the American neurologist Norman Geschwind (1926–1984) refined Wernicke's model of language processing, and this so-called Wernicke–Geschwind model still forms the basis of current investigations on normal and disturbed language function. Based on data from a large number of patients and a thorough understanding of cortical connectivity, Geschwind argued that regions of the parietal, temporal, and frontal brain lobes were critically involved in human linguistic capacities. This model holds that the comprehension and formulation of language are dependent on Wernicke's area, after which the information is transmitted over the arcuate fasciculus to Broca's area where it can be prepared for articulation.

The further expansion and improvement of this model of language processing within the brain has been made possible by the application of advanced neurophysiological methods. Electrophysiological studies using electric or magnetic stimulation and mapping techniques provided a way to delineate the language areas of the cortex prior to neurosurgical removal of brain tissue. These intraoperative mapping techniques have contributed interesting localization information, and provided evidence that a large region of the left hemisphere is clearly involved in language production and comprehension and that language localization varies from patient to patient. Modern functional neuroimaging techniques such as positron emission tomography (PET), established in the early 1980s, and functional magnetic resonance imaging (fMRI), established in the 1990s, represent a major step toward better understanding the localization of linguistic function. Both techniques are imaging procedures that visualize local changes in cerebral blood flow and metabolism that accompany language processing in normal subjects. Contemporary studies are offering new data on what brain areas might actually do and how they might contribute to a network of neuronal structures that collectively participate in language processing. The results obtained by these neurophysiological methods support the notion that besides the classical Broca's and Wernicke's areas, several additional distributed cortical and subcortical neuronal structures of both hemispheres clearly make a significant contribution to language function (see Figure 1).

Most of the areas consistently activated by linguistic processing lie within the left temporal, parietal, and frontal brain lobes (Figure 1) and partly in right hemispheric homolog areas. Extended areas in the left temporal cortex are engaged in word retrieval, naming, morphosyntactic processing, parsing, syntactic comprehension and semantic analysis and also in the articulation of speech. Moreover, several areas in the
Figure 1. Left hemispheric cortical brain areas related to auditory linguistic processing. Broca's area and parts of middle frontal gyrus (1); dorsolateral prefrontal cortex and parts of superior frontal gyrus (2); supplementary motor area (3); primary auditory cortex (4); Wernicke's area (5); parts of middle temporal gyrus (6); parts of inferotemporal gyrus (7); supramarginal gyrus (8); angular gyrus (9).

left frontal cortex including Broca's area are found to be concerned with word retrieval, verbal working memory, syntactic processing, semantic encoding and retrieval, and also articulation, comprehension, and global attentional or executive functions. Right hemispheric cortical areas that correspond to Broca's and Wernicke's areas in the left hemisphere are associated with prosodic elements that impart additional meaning to verbal communication and additional linguistic functions that have not been clearly defined up to now. Moreover, the gyrus cinguli, the cerebellum, and subcortical regions like the basal ganglia and especially the thalamus, which is presumably a lexical–semantic interface, may not only play supportive roles during linguistic processing.

The fact that there are so many new brain regions emerging in modern lesion and functional imaging studies of language suggests that the classical Wernicke–Geschwind model, although useful for so many, years has now been seen to be oversimplified. Areas all over the brain are recruited for language processing, some are involved in lexical retrieval, some in grammatical processing, some in the production of speech, and some in attention and memory. These new findings are still too fresh for any overarching theories that might explain how these areas interact. However, there is a definite need for hybrid models of language processing. Language is both localized and distributed, which means that specific language processing operations are carried out in particular brain locations organized in a distributed fashion.

SABINE WEISS

Long-Distance Dependency

The phenomenon of long-distance dependency occurs in languages such as Latin, Russian, Japanese, Korean, or Persian, in which the order of the major constituents of the clause is variable. These languages, known as 'free word order' languages, sharply contrast with languages such as English, which exhibit a relatively fixed word order. In the following German (1) and Japanese (2) examples, for instance, the direct object

may either precede or follow the subject, a possibility that is not available in English:

(1) ... weil niemand **dieses Buch** gekauft hat
... because nobody this book bought has
'... because nobody has bought this book.'
... weil **dieses Buch** niemand gekauft hat

(2) John-ga Mary-ni piza-o ageta
John-NOMINATIVE Mary-DATIVE pizza-ACCUSATIVE gave
'John gave Mary pizza.'
Piza-o John-ga Mary-ni ageta

Ross (1967, 1986) coined the term *scrambling* to refer to this variable word order and proposed a universal rule to account for it; the rule stated that two adjacent constituents can be permuted if they are constituents of the same minimal clause. It follows from Ross's definition of the scrambling rule that this phenomenon is, as in the examples above, clause-bound. However, some languages additionally exhibit so-called long-distance scrambling, which involves the movement of a constituent across a finite clause boundary. In the following Russian sentence, the noun phrase 'Petrov' has scrambled to a higher clause out of the *that*-clause between brackets:

(3) On skazal čto **Petrov**   stranno [čto ------ nam
he said that Petrovit-NOM is odd   that   us.

pomogal]
helped

It is claimed in the literature that scrambling is not a unitary phenomenon crosslinguistically. There are languages, English among them, that do not allow scrambling, languages that only have scrambling within the verb phrase (e.g. Hungarian), or clause-internally (e.g. German), and languages with a more flexible word order in which a constituent may appear outside the clause it belongs to. These free word order languages, on the other hand, also differ as regards the long-distance scrambling operations they allow, since this phenomenon is subject to language-specific restrictions. In Japanese, for example, most direct objects can undergo long-distance scrambling, but when subjects are scrambled, the sentence turns out to be ungrammatical:

(4) **Sono hon-o**   John-ga   Bill-ni [Mary-ga-----motteiru
that book-ACC John-NOM Bill-DAT Mary-NOM   have

to] itta
that said

(5) * **Sono hon-ga**   John-ga [------yoku ureteiru to]
that book-NOM John-NOM   well sell   that

omotteiru
think
* 'That book, John thinks (it) sells well.'

In contrast to Japanese, Serbo-Croatian, in which word order is much more flexible, allows both objects and subjects to be scrambled to the matrix clause:

(6) Verujem **novac** [da Petar ------daje Milanu]
I-believe money that Petar   gives to-Milan
'I believe that Peter gives money to Milan.'

(7) Verujem **Petar** [da ------novac daje Milanu]
I-believe Petar that money gives to-Milan

Crosslinguistic investigations have also shown that there are differences with respect to the syntactic positions in which scrambled elements can be located within the matrix clause. In Persian, a constituent undergoing long-distance scrambling can be placed both between the matrix subject and the verb (8) and in the clause-initial position (9). On the contrary, it seems that in Japanese this process is somehow restricted to the clause-initial position, as shown above in (4), since long-distance scrambling to the intermediate position within the matrix clause does not always result in a fully grammatical sentence (10):

(8) Ali **een ketab-ra** fekr-mikone [ke Mehry ------ be
Ali this book   think   that Mehry   to

Hassan dad]
Hassan give

'Ali thinks that Mary gave this book to Hassan.'

(9) **Een ketab-ra** Ali fekr-mikone [ke Mehry ------ be
Hassan dad]

(10) ??John-ga **sono hon-o** minna-ni [Hanako-ga ----
John-NOM thatbook-ACC everyone-DAT Hanako-NOM

yonda to] itta
read that said
?? 'John, that book, said to everyone that Hanako read.'

Another remarkable feature of long-distance scrambling is that in some languages this grammatical process can occur more than once within a single clause. The following Korean sentence, in which scrambling has been applied to both direct and indirect objects, illustrates this possibility:

(11) **Kulim-ul**$_i$ **Yenghi-eykey**$_j$ Chelswu-ka [ai-ka ------$_j$
Picture-ACC Yenghi-DAT   Chelswu-NOM child-NOM

------$_i$ cwu-ess-ta-ko] sayngkakha-n-ta
give   think

'Chelswu thought that the child gave the picture to Yenghi.'

The phenomenon of long-distance scrambling has recently received a great deal of attention. However, there is no consensus at the moment about certain descriptive and theoretical aspects concerning this

grammatical process. German, for example, is traditionally analyzed as a language that does not have long-distance scrambling. In fact, a finite clause boundary may never be crossed by a scrambled constituent in this language:

(12) *...weil Hans **den Wagen** versprochen hat [dass
because Hans the car promised has that

er ------ reparieren würde]
he repair would

'... because Hans has promised that he would repair the car.'

Nevertheless, German exhibits a structure, sometimes referred to as the 'Third Construction', which closely resembles long-distance scrambling: there are a special class of verbs—*versprochen* 'try', *versuchen* 'try', *beginnen* 'begin' or *hoffen* 'hope', among others—that allow scrambling to the matrix clause out of their infinitival complements:

(13) ... weil Hans **den Wagen** versprochen hat [------ zu reparieren]

... because Hans the car promised has to repair
'... because Hans has promised to repair the car.'

For some authors, this construction counts as an instance of long-distance scrambling and therefore they classify German together with Japanese or Russian as a long-distance scrambling language.

Turning finally to the theoretical side of this phenomenon, many recent generative approaches to scrambling assume that the alternate word order arrangements in a language are the result of a syntactic movement applied to a single basic structure. Yet there is no agreement on which kind of movement is involved: some authors argue that long-distance scrambling is a case of NP-movement—which also gives rise to passive sentences in English—while others analyze it as an instance of *wh*-movement—which forms English *wh*-questions. An alternative theory of scrambling in generative literature rejects both any type of movement and the existence of a single basic structure. Under this assumption, the alternate constituent orders are all generated as basic structures without any derivational relationship between them.

LUISA GONZÁLEZ-ROMERO

Long-Range Comparison

Long-Range Comparison (LRC) is an area of linguistics that is open to extralinguistic concerns. This has caused it to be popularized outside narrow circles of specialists. The idea that all human languages and language families might be ultimately relatable has probably been current since people started speculating about human language. There are numerous attestations of such speculations, often linked to the tale of the Tower of Babel (Genesis 11:1–9), with various refinements. LRC is an essential link in this process.

In brief detail, LRC is aimed at establishing putative relationships among or between large linguistic groupings, and pushing back the frontiers of linguistic reconstruction. Although he was not the first to note the relevant parallels, Modern LRC is often dated from Holger Pedersen's coining of the term Nostratic (from the Latin "ours"), to include Indo-European, Uralic, Altaic, and Semitic. In the 1960s Illič-Svityč compiled the first comparative dictionary of Nostratic. He added Kartvelian and Dravidian to Pedersen's grouping.

Many LRC theories apply to whole continents, groups of continents, and even the whole of the Earth (proto-World). One prominent figure in this field is Joseph Greenberg, who has a long-standing involvement in such scholarship. Greenberg's earlier work on African linguistic relationships is generally accepted by linguists, although his later work on Eurasiatic (partly, but not totally, covering the same areas as Illi -Svity's Nostratic) and Amerind (relating nearly all the languages of North and South America) has come in for much greater criticism, especially the latter; see especially Matisoff (1990), Dixon (1997), Lass (1997:160–71), and the detailed treatments in McMahon and McMahon (1995), Watkins (1997:3), Trask (1999). Another such proposal is Dene-Caucasian, combining North Caucasian, Yeniseian, Sino-Tibetan, and Na-Dene, which has also been the subject of criticism. Greenberg's disciple Merritt Ruhlen has been more daring in his proposal of reconstructing a single origin for all human languages (1994). Some scholars (e.g. Dixon 1997:43) even lament that there is a certain popular appeal to the concept of all human languages having a single ancestor ("Proto-World"). Dixon cites numerous references to areal factors, typology, etc., to set up an alternative view of linguistic development, which he dubs "punctuated equilibrium". He continues its development, and adds more criticism of LRC, in Dixon and Aikhenwald (1999).

In some cases, LRC work is hampered by the fact that many of the putative families on which the respective superfamilies are based are themselves on rather shaky ground, or their exact relationships are still being worked out. Originally, Turkic, Mongolian, and Tungus (some scholars would also include Korean and Japanese) were grouped together within the Altaic family, which often figures in various LRC theories, but recently the very status of Altaic itself has been seriously called into question. Meanwhile, Semitic has been found to be part of a much wider family conventionally dubbed Afro-Asiatic. Afro-Asiatic in turn is often compared to Indo-European; see especially the work of Bomhard (1984, 1996). The status of Afro-Asiatic within the field of LRC has also been open to some discussion: many Nostraticists would class it under Nostratic, whereas other lines of research, e.g. Greenberg's Eurasiatic theory, would group it as a family equal in status to Nostratic with a more remote level of relationship.

The existence of typological similarities between the languages and language families compared often makes LRC more difficult. Using typological parallels in genetic reconstruction is equivalent to e.g. suggesting that whales are fish based on similarities in form. One excellent example is provided by the emergence of the laryngeal theory in Indo-European studies, boosted by the discovery and interpretation of Hittite. The existence of similar segments in Semitic suggested some sort of special relationship between Indo-European and Semitic. The apparent parallels in ablaut between Indo-European and Kartvelian provide another such example. In the last century, it was believed that Uralic and Altaic formed a superfamily (still referred to as Ural-Altaic in popular literature) based primarily on typological features common to both: progressive vowel harmony and agglutination. Other examples of LRC have often been based on similarities in word order, which is often subject to rapid change.

Much of the controversy, and many of the problems, may be illustrated by citing the development of research into the history of Basque. As a language isolate, Basque is of particular interest here, as it is not included in many proposals for superfamilies which do include almost everything from Kamchatka to the Sahara. However, this has not stopped some scholars from trying. Trask (1996:358-429) provides an overview, including extensive discussion, sometimes a little harsh, on failed attempts to fit Basque into various long-range proposals.

Russian scholars, such as the late V.M. Illič-Svityč, Dolgopolsky, Shevoroshkin, and Starostin, have contributed a great deal to recent work in LRC. Much of the material is in Russian, but see Shevoroshkin and Markey (1986).

Although it often appears that LRC concentrates on lexemes, it should be noted that Illič-Svityč listed pages of useful suggestions on pronouns, affixes, morphemes, etc. Nor does more recent work on Nostratic lack a discussion of morphology; cf. Bomhard (1996:90–101) and many of the articles in Salmons and Joseph (1998). To take one example, the use of a dental stop to form some sort of preterite over wide swathes of the Nostratic area, also extending to Japanese, certainly deserves some sort of discussion, even if much LRC work appears exaggerated.

A further factor that is assuming increasing importance and shedding light on purely linguistic issues is the ongoing work on human genetics. This work is still in its early stages, but is already yielding interesting results, e.g. possible support for Greenberg's Amerind theory, see Cavalli-Sforza, et al. (1994).

ROBERT ORR

Louisiana Creole

Louisiana Creole (LC) is now a dying language, but remains spoken in the southern parts of the state. The number of native speakers of LC was estimated at somewhere between 60,000 and 80,000 in the early 1980s, but is no doubt lower today.

The first slave importations into what is today Louisiana took place in the second decade of the eighteenth century. The geographic origin of African slaves imported to French Louisiana is unusually well documented, and differs significantly from that of Caribbean slaves. In all, 64% were from Senegambia, 31% from the Bight of Benin, and 5% from Bantu-speaking areas, making Mande, West Atlantic, and Gbe languages the main substrates of LC.

It is not clear, however—and this has been subject to some debate—whether LC developed locally in Louisiana, or whether it was brought in from elsewhere, such as Africa or the Caribbean. On the one hand, the language does display similarities to West Indian French creoles, but no substantial immigration therefrom is attested until the beginning of the nineteenth century, when large numbers of refugees fleeing the revolutionary turmoil in what is today Haiti arrived. At this time, though, LC is generally believed to have already emerged.

Another migration of significance to the development of LC is the arrival from 1785 of groups of Acadians (ultimately) from Canada, who in Louisiana became known as *Cajuns*. The coexistence of LC as a minority language alongside Cajun French has had far-reaching consequences. Paradoxical though it may seem, given the obsolescence of Cajun French itself, most observers agree that LC decreolized and changed in the direction of Cajun during the twentieth century—many speakers have at the very least a passive understanding of Cajun French. Since the Cajun settlement has been limited along the Mississippi, this applies first and foremost to the prairie dialects rather than to the riverine varieties.

A final milestone, of course, in the history of LC is the transfer of the territory from French to American sovereignty in 1803. Thus began the process of complete replacement with English of French and LC as the majority language.

Although once more widespread, LC is today spoken in a couple of linguistic enclaves together constituting two main dialect areas—an eastern one along the Mississippi, and a western one around the Bayou Têche.

The best-studied riverine dialect is that of the upstream parish of Pointe Coupee, where there are perhaps 1,000 speakers of LC. Although there are speakers in New Orleans who have moved in from elsewhere in the state, the city has had an indigenous (rather Gallicized) dialect, the last few elderly speakers of which are still alive. Other varieties of the eastern

dialect are spoken in Vacherie and Kraemer (*Bayou-Bœuf*) in St. James. Another creolophone community relatively untouched by contact with Cajun or other varieties of French was found in the 1990s in St. Tammany just north of New Orleans. An offshoot of LC completely unaffected by Cajun has also been documented on the Mon Louis island in southern Alabama, but the last speaker of this variety died in the 1990s. Related varieties were spoken into the twentieth century in other localities in Mississippi, Alabama, and allegedly also in western Florida.

The nucleus of the FC-speaking area, however, is made up of the parishes of St. Martin, Lafayette, and Iberia in the Têche area. Children speaking or understanding LC may still be encountered in some communities in St. Martin, but they are becoming less and less numerous (they are no longer found in Pointe Coupee).

In addition, some few speakers are found in Lake Charles in the westernmost part of the state. Before World War II, LC could also be heard in the parishes of Natchitoches and Jefferson Davis. Outside of Louisiana, LC is also said to be spoken by emigrant communities Sacramento (California), southeastern Texas, and elsewhere.

Since most of the above-mentioned Haitian refugees and their slaves, just like the Cajuns, settled on the prairie rather than along the Mississippi, similarities with Haitian Creole are more salient in the riverine dialects than in the varieties centered around St. Martin.

It is believed that certain structural characteristics are due to the Haitian immigration, such as the possessive construction /zje a mwẽ/ 'my eyes' (alternating with presumably original /mo zje/) and the absolute possessive /mo kẽ/ 'mine' (cf. Northern Haitian /kẽ-a-m/).

As a result of the subsequent impact of Cajun, LC (even in its most basilectal forms) is—with the exception of Réunionnais—the French-lexicon Creole the least deviant from its lexifier. It is not obvious, though, that decreolization is the only factor responsible for this—it might be that a similar state of affairs was obtained even in the early days, and the structure of the Alabaman variety suggests that this is at least in part the case.

Some of the differences between the riverine Pointe Coupee variety and the more westerly Breaux Bridge (*Pont-Breaux*) dialect, which suggest a more far-reaching decreolization of the latter, include partial (re)introduction of grammatical gender, a more French-like system of adjectival comparison (using /ke/ instead of verb serialization involving /pase/ 'pass'), and changes in article usage and verbal morphology. Other comparatively recent changes in this direction include negation placement partly following French patterns, and a copula /(d)ɛt/ (< *d'être*). Some dialects also sport front rounded vowels and schwas, normally absent in French-lexicon creoles.

Other features that set LC apart from most of its relatives in the Caribbean include retention of a 2sg pronoun /to/, and preposed pronominal possessors. Contact with Cajun and English has, of course, left its mark on the LC lexicon as well, and Cajun is probably also responsible for the trilled realization of /r/ in LC.

In the communities of Vacherie and Kraemer, the white population has been heavily creolophone, although a shift to English is under way. A similar situation can be seen in villages in Pointe Coupee, St. John Baptist, St. Martin, Acadia, Lafayette, and St-Landry. In all, about a fifth of the LC-speaking population is believed to be made up of whites, but the white ethnolects have been shown to be even closer to French than their black counterparts.

MIKAEL PARKVALL

Lyons, John

John Lyons is a specialist in semantics and linguistic theory. Since the publication of his *Introduction to theoretical linguistics* in 1968, Lyons has been recognized as an outstanding linguist. His major publications include *Introduction to theoretical linguistics* (1968), *Semantics* (2 volumes, 1977), *Language, meaning and context* (1980), and *Linguistic semantics* (1995). Other publications are *Chomsky*

(first published in 1970, with two other editions in 1977 and 1991) and *Language and linguistics* (1981). Lyons' work addresses a broad range of issues of fundamental importance to linguistics. Most of his books are characterized by a clear and accessible style that appeals to a wide student readership.

Introduction to theoretical linguistics covers all major aspects of theoretical linguistics, from phonetics, semantics, and syntax to structural linguistics, universal grammar, and generative and transformational grammar. Although the book presupposes no previous knowledge, it rigorously addresses a wide range of topics, bringing the reader to an advanced level of understanding theoretical linguistics.

John Lyons' volume on *Chomsky* (1970, 1977 2nd edition, 1991 3rd edition) is a guide to Noam Chomsky's life and ideas, particularly addressing his earlier groundbreaking work. Lyons emphasizes that the short and relatively nontechnical *Syntactic Structures* "revolutionized the scientific study of language".

John Lyons is particularly known for his seminal two-volume work, *Semantics* (1977). Volume 1 is a general and comprehensive introduction to the field of semantics. It brings together the results of studies on meaning and communication from many disciplines (including logic and philosophy), placing semantics in the larger context of semiotics. It deals with language as a semiotic system, behaviorist semantics, logical semantics, structural semantics, and semantic field theory. A broad review of current semantic theories is also found in *Language, meaning and context* (1981).

Volume 2 of *Semantics*, which can be read independently, deals with the main problematic issues in the semantics of natural languages: homonymy, polysemy, conversational implicature, deixis and anaphora, tense and aspect, mood and illocutionary force. The wide range of topics analyzed in this volume and the originality of the approach make the book a standard reference work in linguistics.

Designed as an elementary textbook, *Language and linguistics. An introduction* (1981) is a general introduction to linguistics and the study of language. It covers a broader range of topics than the classic *Introduction to theoretical linguistics* and presents the main subfields of linguistics: the sounds of language, grammar, semantics, language change, psycholinguistics, language, and culture.

Linguistic Semantics: An introduction (1995) is a critical discussion introducing linguistic semantics, defined by Lyons as the study of meaning systematically encoded in the vocabulary/grammar of natural language. The book was initially planned to be a second edition of his *Language, meaning and context* (1981). However, even though the general structure of the earlier book is preserved, this volume is very different from

its predecessor in that it covers several topics that were not previously discussed and takes into account new developments in the field. Its comprehensive style brings unequivocal definitions of specific, complex notions and explains the relationship between linguistic semantics and formal and philosophical semantics and contemporary pragmatics.

Linguistic semantics: an introduction begins with an explanation of what meaning is and introduces the standard distinctions between language and speech, *langue* and *parole*, competence and performance, form and meaning, and sentences and utterances. In addition, Lyons analyzes the different techniques that can be used to define the meaning of words. The book also deals with lexical semantics: it explains Peirce's distinction between tokens and types, as well as other fundamental notions such as homonymy, polysemy, synonymy, sense, reference, extension, intension, natural kinds, and prototypes. Lyons also discusses sentence meaning in terms of meaningful and meaningless sentences, implication and negation in natural language utterances, declarative interrogative, imperative, and exclamative sentences, and the principle of compositionality. It is the last part of the book, based on J.L. Austin's theory of speech acts, and particularly the chapter on context, that has been regarded as the most remarkable. Lyons believes that a satisfactory theory of context should include findings from social sciences such as psychology, anthropology, and sociology.

John Lyons' role in the history of linguistics has often been acknowledged. In 1995, a volume of essays by distinguished scholars was published to honor Lyons' outstanding contribution to linguistics. *Grammar and meaning*, edited with an introduction by F.R. Palmer, is a collection of essays related to the major issues studied by Lyons over the years.

Biography

Born in Manchester, UK, John Lyons studied at Cambridge, taught at London (1957–1961) and Cambridge (1961–1964), then became Professor of linguistics at Edinburgh (1964–1976) and Sussex (1976–1984), and Master of Trinity Hall, Cambridge (from 1984 to September 2000). In 1987, John Lyons was knighted for his exceptional contribution to the study of linguistics.

LAURA DANILIUC

M

Machine Translation

Exhilarating goals, serious disappointments, significant successes: all have accompanied machine translation in its twentieth- and twenty-first century existence. The early goal—fully automated translation of a quality equal to that achieved by human translators—has proven elusive, and some researchers doubt that it is feasible. Nonetheless, machine translation and its sister, machine-aided human translation, must be counted a success if measured by their effectiveness in extensive use by multinational companies, governments, and the European Commission. Computer tools that aid human translators by automating some parts of the translation process, coupled with machine translation programs whose output requires final human editing, have together met a worldwide demand that is increasing faster than the supply of human translators.

The history of machine translation in modern times begins in 1947 with a memo from Warren Weaver, then director of the Natural Sciences Division of the Rockefeller Foundation, to Norbert Wiener, a well-known computer scientist (then called cyberneticist): "I have wondered if it were unthinkable to design a computer which would translate. Even if it would translate only scientific material (where the semantic difficulties are very notably less), and even if it did produce an inelegant (but intelligible) result, it would seem to be worth while" (Hutchins 1997:197).

Only two years later, in 1949, the *New York Times* reported that the computer of the United States Bureau of Standards Laboratory, which it called the 'electric brain', would be able to translate foreign languages (Hutchins 1997:197–203).

Early machine translations proceeded word for word from the original language into the target language (in those days of the Cold War often Russian to English), a process that ignores the complexity of language structure and results in an inaccurate and barely readable translation. With the development of more sophisticated tools for computerized syntactic analysis, many researchers assumed that success was near at hand. Enthusiasm for the goal of automatic, high-quality machine translation fueled generous government and private funding of research and development of translation systems through the early 1960s. Dissenting voices such as that of Yehoshua Bar-Hillel (1960) that this perfectionist goal was unrealistic were at first not heeded.

In 1966, the National Academy of Sciences Automatic Language Processing Advisory Committee (ALPAC) reported that the prospects for fully automated high-quality, general-purpose machine translation were dim, causing immediate and massive cutbacks in funding for research in the field.

By the early 1970s, interest in the field revived, but accurate and publishable translation untouched by human hands was no longer the only goal; human–machine cooperation was envisioned and the creation of automated tools for translators became a special field within machine translation research.

The appearance of interactive desktop computer workstations greatly facilitated the development of translator's aids, and sophisticated 'translator's workbenches' were engineered. Current versions of these translator's workbenches include large databases of specialized vocabulary and high-quality desktop publishing tools, as well as 'translation memory', which enables the translator to store and reuse existing translations.

Currently used machine translation systems such as Logos, Metal, Systran, and PARS can translate even complex texts in a limited and defined domain, or subject area. Nonetheless, they require the services of humans to pre-or postedit the texts. In many important ways, the quality of machine translation has not risen appreciably since the 1970s, and the need for human editing is projected to continue.

At the other end of the spectrum, uses have been discovered for the rough, often inaccurate, and largely unreadable 'rough translations' that result when context is not specified and texts are not pre- or postedited. Such rough translations have proven economical in helping users to quickly categorize large numbers of foreign texts as either not useful or deserving of thorough translation.

Inexpensive translation software for personal computers, or freeware available on the Web, is widely used for obtaining the gist of e-mail, Web pages, and on-line discussion groups. These systems, often lacking large lexicons or phrase dictionaries, provide an even less exact gist than commercial systems. An example: French: *Il fait vraiment beau*! English: *He does indeed beauteous!* Correct translation : *The weather is really nice!* (Fortune City web site) But while many users are disappointed at the poor quality of these 'quick and dirty' translations, others are satisfied to have even an approximate idea of the contents of the text.

As always, the market is driven by demand. Currently, machine translation systems into and from English are available for a very large number of the world's languages. Translation systems into and from the major European languages (French, German, Italian, and Spanish) are available for a smaller number of world languages, while dramatically smaller numbers of systems are available to translate nonmajor languages into other nonmajor languages.

Spoken language, rather than written, is the focus of much current research. The Verbmobil project of the German Ministry of Research and Technology, for example, aims to prototype an on-the-spot oral translation of business negotiations between German and Japanese speakers. The problems of speech recognition and speech generation, however, are even greater than those involved in written translation. Such projects always aim at clearly defined topic areas and types of users, rather than at unrestricted use, but even with this limitation, it is not foreseen that large systems for oral translation will be available for several decades.

Other areas of current research include the development of desktop systems for the 'interactive' composition of specialized documents (for example, business letters) in a target language by a human who does not know that language. The system generates the text by a process of asking the user more and more detailed questions about what is meant, and choosing from its inventory of phrases and structure frameworks.

Machine translation continues to be a lively field for research and development. Although completely automated high-quality translation will probably not be achieved in the near future, more user-friendly, inexpensive systems will continue to be developed, particularly those aimed at special domains and for special purposes.

RUTH H. SANDERS

Malagasy

Malagasy is one of two official languages of Madagascar (besides French). The population, estimated at 17.5 million for mid-2004, speaks either the standard language, a regional dialect, or both. Dialects also occur in Mayotte (Comoros).

History

Malagasy belongs to the Southeast Barito subgroup of the West Malayo-Polynesian subfamily of Austronesian. The language most closely related to Malagasy is Maanyan (in the southeast of Borneo).

Estimated dates of migration from Borneo range from 200 CE until the seventh century or later, based mainly on Sanskrit and Arabic loanwords exhibiting signs of borrowing via Malay. Non-Malay introductory passages in some seventh century Old Malay inscriptions have been tentatively identified as being in a precursory version of Malagasy, Maanyan, or close affiliate.

Bantu-speakers who subsequently arrived from the African mainland, adopting Malagasy, exercised substantial influence on its phonology and vocabulary. In the ninth to fifteenth centuries, contacts with Islamic traders led to considerable lexical borrowings from Swahili, Arabic, and Malay. In the fifteenth century, the Antaimoro in the southeast began writing, implementing the Arabic script soon also adopted by other dialects. In the early seventeenth century, the Menabe Sakalavas (western lowlands) gained hegemony over the west and northwest that lasted until the eighteenth century, promoting their dialect to corresponding prominence.

Around 1797, the reunited Merina in the highlands proceeded to expand, annexing the remaining highlands, the north and the east. Before the French conquest in 1895, the Merina kingdom encompassed the entire island except the south and part of the west. The Merina dialect (formerly Hova) was becoming standard in much of Madagascar, enhanced by schooling activities of British missionaries encouraged by Radama I (reigned 1810–1828). This also led to numerous English borrowings. The same missionaries introduced Latin-script spelling, made official by Radama I in 1820.

Under French rule (1896–1960), Merina remained the standard dialect of Malagasy, but the language of government, education, and the media was French. After independence, particularly after the "Malagasification" campaign launched in 1975, (Merina) Malagasy became the language of school education, and the predominant language of government and the media. But French remains the language of higher education.

This century-long bilinguality led to profuse borrowing from French.

Dialects

Malagasy has a tripartite division into East (geographical north, center, east, and southeast), West (west and southwest), and Intermediate (Betsileo, Bara, and Antanosy, sharing features of both former) groups. The following table compares Menabe Sakalava (West dialect, henceforth 'Sakalava') with Merina (East) and the reconstructed ancestor language Proto-Malagasy (P-Mlg):

P-Mlg > West/East	P-Mlg	Sakalava	Merina	English
*li- > li/di	*lime	lìme	dìmy	'five'
	*kulit	hòlitse	hòditra	'skin'
*ele > ele/eli	*kelek	hèleke	hèlika	'armpit'
*ti- > ti/tsi	*tina'i	tinày	tsinày	'intestines'
	*witik	vìtike	vìtsika	'ant'
*te > te/ti	*katen	hàte	hàtina	'itch'
-m,-n,*ŋ > -Ø/-na	*lalan	làla	làlana	'path'
*-r, *-t > -tse/-tra	*epat	èfatse	èfatra	'four'

Phonology

Merina Malagasy has 19 primary consonantal segments, spelled p, t, k, b, d, g, f, s, h, v, z, l, r, m, n, ts, j /dz/, tr /tɻ/, and dr /dɻ/ (including four affricates), and nine prenasalized consonants functioning as single segments: mp, nt, nk, mb, nd, ng /ŋg/, nts, nj, ntr, ndr. Other dialects additionally have velar ñ /ŋ/. In southern central-highlands dialects, ts is /ð/. In Betsimasaraka, s is /ʃ/. Some base-initial consonants undergo nasal sandhi with the final nasal of prefixes.

Bisegmental consonant clusters are mainly limited to loanwords and include r, l, or s as one component (artìsta 'artist', jeografia 'geography', anglìsy 'English'), also word-initially (frantsày 'French', krismàsy 'christmas'). Frequently, clusters were separated by an anaptyctic i (cf. adirèsy 'address', alikàola 'alcohol', Madagasikàra 'Madagascar') or, by vowel harmony, an o (boròsy 'brush', dokotèra 'doctor') or a (kàratra 'card'). But in casual speech, an unstressed interconsonantal vowel is sometimes dropped (fòtsiny [fùtsini] > [fùzni] 'only').

There are five simple vowels spelled *a*, *e*, *i* or *y*, *o* /u/, and *ô* /o/, and six diphthongs, *ai* or *ay* /aʸ/, *ao* /aʷ/, *ià* /iˀ/, *ià* /ʸa/, *òa* /uˀ/, and *oà* /ʷa/ (*y* stands for *i* word-finally). The *ô*, restricted to loanwords (*hôtèly* 'hotel', *tômôbìlina* 'automobile'), is often printed without diacritic, leading to ambiguity. In casual speech, the dipthongs can contract to [e] (< *ai, ià*), [i] (< *ìa*), [o] (< *ao, oà*), or [u] (< *òa*).

Malagasy does not normally have final consonants. Historical word-final coda were either dropped (*lepas > lèfa* 'liberation, escape'; *lalow > làlo* 'pass'; *apuy > àfo* 'fire') or retained as 'weak ending' with a dummy vowel spelled *a* (in some dialects *e*), pronounced as short schwa [ă] or [ɜ]: *-k, *-p > *-ka*; *-r, *-t > *-tra*; *-m, *-n, *-ŋ > *-na* (some dialects > *-ña,* and some deleted it). At suffixation, the historical situation is variedly reflected in the morphophonemics (*lèfa → fandefàsana* 'broadcast'; *làlo → lalòvina* 'passed'; *tsìdika → fitsidìhana* 'short visit'; *lèlaka → lelàfina* 'licked').

Stress (mainly indicated in dictionaries and language primers) is distinctive, cf. *tànana* 'hand' (< *taŋan) vs. *tanàna* 'town' (< *tana'-an). Words with a 'weak ending' have either stress on the antepenultimate syllable that shifts upon suffixation (*àkatra → akàrina* 'be raised') or penultimate stress that does not (*ja'it > zàitra → zàirina* 'be sewn'; *ta'an > tàna > fitànana* 'endurance'). Words without a 'weak ending' have either penultimate stress that shifts upon suffixation (*fèno → fifenòana* 'filling'; *dìa → fandiàvana* 'threshold') or ultimate stress that does not (*umei > omè → fanomèzana* 'gift'), unless an additional vowel appears (*behay > bè → fanabeàzana* 'upbringing'). When the stress shifts onto an *i/y*, this becomes *e* either when the preceding vowel is *e* (*kèly → fikelèzana* 'reduction'), or sometimes reflecting historical *e (*alem > àlina → fialèmana* 'dinner time').

Morphology

The morphology of Malagasy involves flexion (e.g. in tense alternation), affixation (voice markation, nominal derivation), alternating clitics (personal pronouns), and root alternation (deictics).

The noun is practically invariant. Number is indicated with a complex system of demonstratives that also expresses proximity: *ìo pàoma ìo* 'this apple'; *irèo pàoma irèo* 'these apples'; *irèry pàoma irèry* 'those apples'; *Marikìvy ìo* 'This one is sour.' There is also a series of locatives for 'visible' with *i-* (*ìo, ìty, ìto, ìtsy, iròa,* etc.), somewhat visible with *e-* (*èo, èty, ...*), or vague with *a-* (*ào, àty, ...*), etc. The definite articles are *ny* for nouns, and *i* for proper names.

Personal pronouns distinguish nominative (subject), oblique (object, possessive pronoun), and genitive forms (possessive adjective, actor-argument

of root-passive verbs); the latter attaches to a host word similar to a suffix:

Person and Number	Nominative	Oblique	Genitive
1st singular	*(iz)àho*	*àhy*	=*ko*/=*o*
2nd singular	*ianào*	*anào*	=*nào*/=*ào*
3rd singular	*ìzy*	*àzy*	=*ny*/=*ny*
1st plural inclusive	*isìka*	*antsìka*	=*ntsìka*/=*tsìka*
1st plural exclusive	*izahày*	*anày*	=*này*/=*ày*
2nd plural	*ianarèo*	*anarèo*	=*narèo*/=*arèo*
3rd plural	*ìzy irèo*	*àzy irèo*	=*n'ìzy irèo*/=*ny*

Authentic adjectives (*kèly* 'small', *màina* 'dry', *tsàra* 'good') are distinguished from adjectival verbs: the latter feature tense (*madìo* 'is clean', *nadìo* 'was clean', *hadìo* 'will be clean') and voice (*diòvina* 'be cleaned'). Both form degrees of comparison via combination with independent markers: *tsàra kokòa* (good more) 'better', *tsàra indrìndra* (good extremely) 'best'. In the comparative, the marker is optional: *Natsìro [kokòa] nòho ny poàra ny pàoma* (was-tasty [more] than the pear the apple) 'The apple was tastier than the pear.'

The numerals are *irày, ròa, tèlo, èfatra, dìmy, ènina, fìto, vàlo, sìvy* '1...9', *fòlo* '10', *ròapòlo* '20', *tèlopòlo* '30', etc., *zàto* '100', *ròan-jàto* '200', etc. Teens are formed by adding *ambìn'ny fòlo* after the digit (but *iràika ambìn'ny fòlo* '11'). Numerals follow numerated nouns (*òlona tèlo* 'three **persons**'), but precede units of measure (*pàoma tèlo **kilào*** 'three **kilos** of apples').

The verbs have an elaborate paradigm of forms that does not include a plural.

Tense is expressed by alternating an optional prefixal *m-* (present) with *n(o)-* (past) or *h(o)-* (future): *manadìo* 'cleanse'/*nanadìo* 'cleansed'/*hanadìo* 'will cleanse'; *mitèny* 'speak'/*nitèny*/*hitèny*; and *indràmina* 'be borrowed'/*nindràmina*/*hindràmina*. The optional *o* appears when the prefixless present-tense form has an initial consonant: *soràtana* 'be written'/ *nosoràtana*/ *hosoràtana*.

Voice is intertwined with some other categories. The active voice is formed with the prefix *maN-* (action verbs), *mi-* (action and status verbs), or *ma-* (status and adjectival verbs) to the stem (***manòratra** àho* 'I **write**'; ***Mitèhina** ny làkana àho* 'I **shove** the boat [with a pole]'; ***Matòry** àho* 'I **sleep**'; ***Mànana** tràno aho* 'I **have** a house'). Causative verbs prefix *maha-* (*fàly* 'happy' → *mifàly* 'rejoice, be merry' → *mahafàly* 'be pleasing'; *tònga* 'reach' → *mahatònga* 'cause'). The active imperative has the suffix *-a* (*manoràta* 'write!'; *mitehèna* 'shove! [with pole]'; *matorìa* 'sleep!').

Passive forms are frequently used and the most variegated. There are some 30 so-called root-passive

status verbs that topicalize the undergoer in an uninflected form (*àzo* 'received, understood'; *hèno* 'listened to', *hìta* 'seen'). A pronominal actor is in the genitive: *Hènoko ìzy* 'He is listened to by **me**.'

Passive forms of prefixed-active verbs have the suffix *-ina* or *-ana*: *Tehènina ny làkana* 'the boat **is shoved** [with a pole]'; *Totòfana tàny ny làvaka* 'the hole **is filled up** with earth'. Pronominal actors are in the genitive: *Soràtano ny taratàsy* 'The letter is written by **me**.' Active derivations of root-passive verbs have suffixed passives (*tsìnjo* 'be perceived/ noticed' → *mitsìnjo* 'observe/ watch' → *tsinjòvina* 'be observed/ watched').

For verbs with two nonactor arguments, a 'stationary' (medium, goal) and a 'mobile' one (instrument, theme), the former can be topicalized either by the above passives, or with the so-called circumstantial passive, formed by circumfixation of *aN-...-ana* or *i-...-ana* (*mandràkotra* 'cover' → *andrakòfana* 'be covered [with]'; *vìdy* 'buy' → *ividìana* 'have [something] bought [for one]'). The 'mobile' argument is then topicalized by a passive with prefix *a-* (*mandròso* 'serve [food] [to someone]' → *rosòana* 'be served [guest]'/*aròso* 'is served [food]').

The above passives all partake in the (*m*)/*n*(*o*)/h(*o*) tense alternation and form imperatives with *-o* (or *-y* when the base has *-o-*): *henòy* 'listen!'; *andràsana* 'be waited for' → *andràso* 'wait!'; *rosòy* 'serve [to someone]!'/*arosòy* 'serve [a dish]!'.

Finally, there is the resultative passive with *voa-* (*mandàza* 'say, declare' — *voalàza* 'be/get said'; *mifìdy* 'choose' — *voafìdy* 'get chosen') and the incidental resultative with *tafa-* (*mivèrina* 'return' — *tafavèrina* '[unexpectedly] be/get back'). Both have a future (with *ho-*) but no past tense, and have no imperative.

Nominalization of verbs is productive. Agent nouns derive from active verbs by inserting *-p-* after the prefixal *m-* (*mandèha* 'go' → *mpandèha* 'passenger, voyager'; *mitèny* 'speak' → *mpitèny* 'speaker'). Nouns denoting some aspect of that which is expressed by the verb can be formed by replacing prefixal *m-* by *f-* (*fandèha* 'way of walking'; *fitèny* 'manner of speaking'). Abstract nouns are formed by additional suffixation of *-(an)ana* (*fambolèna* 'cultivation'; *fidìrana* 'admission'; *fandehànana* 'departure', *fitenènana* 'conversation').

Syntax

Typically, an attribute follows the modified element—*ny tràno lehibè* 'the **big** house'—while a predicate precedes the subject—*Lehibè ny tràno* 'The house is **big**'—also demonstrating that existential clauses are formed without a 'to be' equivalent.

In possessive atribution with nominals (pronouns see above), the genitive marker *n′* is preposed to the definite article (*n′ny bòky* 'of the book', *n′i Rìta* 'Rita′s').

Names with the article *Ra-* undergo nasal sandhi (*n+r > ndr*), and a hyphen replaces the apostrophe (*ny bòkin-dRasòa* 'Rasoa's book'). Preceding adjectives merge with the genitive marker: *ny bòky vaovàon′ny mpampiànatra* 'the teacher′s **new** book'.

Malagasy sentences are mainly predicate-initial: *Vaovào ny bòky* 'The book is **new**'; *Àhy ny bòky vaovào* 'The new book is **mine**'; *Mpampiànatra àho* 'I am a **teacher**'; *Tèlo ihàny ny bòky* 'There are only **three** books'; and *Mitèny àho* 'I **speak.**' Transitive sentences are typically Verb–Object–Subject (VOS): *Mivìdy ny bòky àho* '*I buy the book*' and *Manòratra taratàsy i Rìta* 'Rita **writes** a letter.' Indirect objects precede the subject: *Mivìdy bòky ho an′ny zàza i Rìta* 'Rita buy**s** a book **for the child**.'

Subject fronting with emphasizing is achieved with the particle *no* (*Ny mpampiànatra no nivìdy ny bòky* '**The teacher** [is the one who] bought the book') that emphasizes any fronted term: *Omàly no novidìna ny bòky* 'The book was bought [precisely] **yesterday**.' Subject fronting with the particle *dìa* emphasizes the verb: *Ny mpampiànatra dìa nivìdy ny bòky* 'The teacher **bought** [didn′t steal] the book.' It also emphasizes a sentence-final subject: *Hivìdy ny bòky dìa ny mpampiànatra* '**The teacher** [noone other] will buy the book.'

The relative marker is *izày*: *ny bòky izày novidìn′i Rìta* 'the book **that** was bought by Rita.' It is often optional: *Hanòratra taratàsy ny mpampiànatra [izày] nivìdy ny bòky* 'The teacher **who** bought the book will write a letter.'

The above article still leaves out many features, particularly numerous irregularities and exceptions, but also various intricate regularities, that make Malagasy an extremely interesting object of linguistic study.

Malay-Indonesian and Malayic languages

Malayic is a subgroup of the Western Malayo-Polynesian branch of the Austronesian language family. Malayic languages are spoken throughout the Malay-Indonesian archipelago, from Sumatra in the west to New Guinea in the east, and also on mainland Southeast Asia, mostly in the Malay Peninsula and in parts of Thailand.

Malay-Indonesian is a member of the Malayic subgroup. The indigenous name for the language is *Bahasa Melayu* (literally, 'the Malay language'), but some varieties used in Indonesia are also called *Bahasa Indonesia* ('the Indonesian language', see below). Similar forms of Standard Malay-Indonesian serve as the national languages of Indonesia, Malaysia, Brunei, and Singapore; the latter three are particularly similar to each other. A large number of Malay dialects and Malay-based pidgins and creoles are also spoken throughout the region.

The number of speakers of Malay-Indonesian is estimated at over 250 million, making it by far the most widely spoken language in Southeast Asia, and a major world language. Most speakers do not use Malay-Indonesian as a native home language; the number of native speakers is difficult to estimate, but is probably over 50 million. This figure is rapidly increasing, as more and more people in Indonesia, Malaysia, and Brunei shift from their ancestral home languages to Malay-Indonesian.

Classification

While there is wide agreement about the existence of the Malayic subgroup and the Malay-Indonesian language, linguists have not been able to agree on their classification. Malayic used to be classified together with Javanese, Sundanese, Madurese, Achenese, and Lampung as in a putative 'Malayo-Javanic' branch, but strong doubts have been cast on the validity of this classification. It is now clear that Malayic is more closely related to the Chamic languages, spoken in Cambodia and Vietnam, than to any of these languages. One factor hindering classification is that many languages have borrowed heavily from Malay-Indonesian, which has served as a regional lingua franca for many centuries. This may make such languages appear to be much more closely related to Malayic than they actually are. Similarly, no clear criteria have been established for distinguishing between Malayic languages and dialects of Malay-Indonesian. Scholars in the field have therefore preferred using the neutral term 'isolect' to refer to any Malayic speech form which has a name of its own and is regarded by speakers as distinct from other varieties.

There is great variation among Malayic isolects, many of which are not mutually intelligible. They fall into several categories. Some, like Riau Malay (spoken in the Riau archipelago in Indonesia) or Kedah Malay (spoken in the Malaysian state of Kedah), are thought to be direct descendants of Proto-Malayic, a hypothetical language reconstructed on the basis of modern isolects. Other isolects, however, have had a more complex history, and owe their emergence to language contact and language shift. For example, Betawi, the language of the indigenous ethnic group of Jakarta, is based on Malay, but has incorporated lexical and grammatical elements from Balinese, Javanese, Sudanese, and Chinese, languages spoken by the ancestors of today's speakers. Some isolects have developed from pidginized forms of Malay, collectively known as Bazaar Malay, which originally served only for interethnic communication, not as a first language. Baba Malay, spoken by acculturated Chinese communities in Malacca, Penang, and Singapore, is thought to have developed from Bazaar Malay, which gradually became the speakers' first language. Most isolects spoken in eastern Indonesia are also believed to have developed from forms of

Bazaar Malay. This complex situation has also contributed to the difficulty in classifying Malayic isolects.

Standard Malay-Indonesian

History

The cradle of Malay civilization and of the Malay-Indonesian language was in south-central Sumatra. Many scholars believe, however, that its hypothetical ancestor Proto-Malayic was spoken in western Borneo. The original place name Malayu (=Malay) has been identified with the former Malay kingdom of Jambi in central Sumatra. The Chinese monk I Ching, who visited the area in the seventh century AD, reported on a place called 'Moloyu'; later Javanese inscriptions and manuscripts also refer to the area of Jambi as 'Malayu'. The *Sejarah Melayu* ('Malay Annals'), the canonical work of classical Malay literature, traces Malay origins to Palembang, a city south of Jambi, which historians and archeologists identify with the center of the ancient maritime empire of Sri Vijaya.

The earliest direct evidence of Malay comes from a handful of seventh-century AD inscriptions, found in southern Sumatra and on the nearby island of Bangka, and associated with Sri Vijaya. While not all scholars agree that the language of these inscriptions is the direct ancestor of modern standard Malay-Indonesian, it is commonly referred to as Old Malay. The inscriptions are written in a formal language that borrows heavily from Sanskrit; there is no direct evidence of the language ordinary people spoke in their everyday lives. Old Malay inscriptions dating from the ninth century were also found in areas where Malay was not indigenous, like Java and the Philippines, showing the early spread of Malay as a literary language throughout the region.

The use of Old Malay as a literary language in Java and in the Philippines did not survive long. However, in Sumatra it has continued uninterrupted. Even among peoples who speak rather different languages, like Rejang and Lampung, Malay (written in an Indian-derived script called *rencong*) continued to serve as the major literary language. The oldest extant Malay manuscript is a recently rediscovered fourteenth-century work originating from southern Sumatra. Some letters and longer works from the sixteenth century are preserved in collections in the West, and from the seventeeth century onward, Malay manuscripts become numerous. The contents of these works are varied, and range from legends, chronicles, and religious treatises, to legal documents and letters. The language of these manuscripts, while showing some variation across time, space, and style, is nevertheless remarkably uniform, and has been termed Classical Malay.

Modern Standard Malay-Indonesian came into existence in the nineteenth century, as a joint (although

sometimes uncoordinated) effort of native and Western scholars. The great Malay scholar Raja Ali Haji (c. 1809–1870) composed a grammar and a dictionary of Malay. Later, the Dutch scholar C.A. van Ophuysen (1854–1917) standardized the language for use at schools throughout the Dutch Indies. In 1928, a congress of nationalist students declared the Malay language, under the name *Bahasa Indonesia*, as the national language of the Indonesian nation. During the Japanese occupation (1942–1945), the modernization of Malay-Indonesian received an impetus, as it was widely used in the administrative and educational systems and in the mass media. Indonesia declared its independence in 1945, whereby Malay-Indonesian (under the name *Bahasa Indonesia*) became its national language. When Malaysia, Singapore, and Brunei followed suit, Malay-Indonesian (under its traditional name *Bahasa Melayu*) became their national language as well. In 1972, the spelling of Malay-Indonesian was reformed and harmonized, and a joint council (known by its acronym MABBIM) has been coordinating language planning activities in these countries ever since.

Typical Features

The sound system The sound system of Standard Malay-Indonesian is relatively simple. There are 18 primary consonants (given in their conventional orthography): *b, d, j, g, p, t, k, c, m, n, ny, ng, l, r, h, s, w, y*. Sometimes the glottal stop is also analyzed as a phoneme. (In this orthography, *c* and *j* represent palatal stops, while the digraphs *ny* and *ng* represent a single consonant each, the palatal nasal and velar nasal, respectively). The vowels are *a, e, i, o, u,* plus a mid-central vowel (confusingly written *e,* like the mid-front vowel). There are also a few loan phonemes, like *f* and *z*, which first entered the language via loanwords. In Standard Malay-Indonesian, there is no distinctive word accent.

Word formation Beyond borrowing and coining new roots, Malay-Indonesian words are formed by three principal processes: affixation, reduplication, and compounding. Affixes include prefixes (*makan* 'eat' vs. *di-makan* 'eaten'), suffixes (*kerja* 'work' vs. *kerja-kan* 'do [something]'), and circumfixes, which attach themselves simultaneously to the beginning and end of roots (*baik* 'good', *ke-baik-an* 'goodness'). Redupli-cation fills many functions. For example, *anak* means 'child', while *anak-anak* means 'a group of children'; *jalan* means 'walk' or 'road', *jalan-jalan* is 'go for a walk, go out'. Compounding combines two existing roots into one word; for example, *matahari* 'sun' is made up of the words *mata* 'eye' and *hari* 'day', and literally means 'the eye of the day'. In addition to these three processes, clipped words (made up of parts of existing words) and acronyms are very common, especially in Indonesia.

Word classes Most scholars agree that Malay-Indonesian has both function words and content words, and that content words include at least two categories: nouns and verbs. Some analyses also posit adjectives, adverbs, and other classes. Part of the discrepancy stems from different semantic, morphological, and syntactic criteria used by different scholars to classify words. Another factor has been Eurocentricity: scholars (especially in the past) tried to fit Malay-Indonesian into categories created by European scholars for European languages, which were often incompatible with the actual categories of Malay-Indonesian. In fact, it is possible that Malay-Indonesian roots are precategorial, with the category or word class determined by affixes or by the place the word fills in the sentence.

Word order The basic word order in Malay-Indonesian is, like English, Subject–Verb–Object: *Tuti makan pisang* (lit. *Tuti eat banana*) 'Tuti is eating bananas.' However, according to the circumstances and the particular emphasis desired by the speaker, these constituents can be ordered in any way. Also, unlike in English, the subject and the object can be left unsaid, if they are already understood (or deemed so by the speaker). Focusing on the object (as in English passive sentences) and not on the subject is often the normal way of expressing things in Malay-Indonesian. Thus, the usual way to say that 'someone ate the bananas' would be *pisang itu dimakan (orang)*, which literally means something like 'the bananas were eaten (by people)'. Modifiers normally follow the head, as in *rumah besar* (lit. *house big*) 'a big house' and *rumah itu* (lit. *house that*) 'that house'. Possession can be indicated by a simple juxtaposition of nouns: *rumah Tuti* (lit. *house Tuti*) 'Tuti's house', *rumah saya* (lit. *house I*) 'my house'.

An important difference between Malay-Indonesian and Indo-European languages like English is that words are not inflected, and many categories expressed by inflection in Indo-European languages are simply left unspecified in Malay-Indonesian. Thus, *rumah* can mean either 'house' or 'houses', and *makan* can mean 'eat', 'eats', 'am eating', 'have eaten', 'ate', etc., depending on the context.

Writing Systems

All early scripts that were used for writing Malay were based on Indian writing systems. The oldest Malay inscriptions were written in a slightly modified version of the Pallava script of southern India. The earliest Malay manuscript was written in the Kawi script, used for writing Old Javanese, while later Malay manuscripts from Sumatra were written in the local *rencong* script, an angular alphabet also ultimately derived from Indian writing systems.

During the first half of the second millennium AD, the Malays, who were originally animists and then Hindus and Buddhists, gradually converted to Islam. With the new religion, they also acquired the Arabic alphabet, which formed the basis for the Malay alphabet known as Jawi. The earliest example of Jawi writing is a fourteenth-century inscription from Terengganu in the Malay peninsula, and the earliest Jawi manuscripts are two letters written by the sultan of Ternate to the king of Portugal in 1520 and 1521. Since the seventeenth century, Romanized alphabets have gradually replaced Jawi, but Jawi is still used sometimes, especially in Malaysia and Brunei.

Other Malayic isolects

The number of distinct Malayic isolects probably runs into the hundreds. A few of the major ones are listed below.

Iban: The Iban people of northern Borneo were formerly known as Sea Dayaks. They speak a number of closely related isolects, mostly in the Malaysian state of Sarawak, but also in the neighboring state of Sabah and across the border in Kalimantan (Indonesian Borneo). The total number of speakers is estimated at upward of 500,000. Iban is more divergent from Malay-Indonesian than other major Malayic isolects. For this reason, it is often classified as a separate language.

Minangkabau: This important Malayic isolect is used by about 7 million people. Native to western Sumatra, it is now spoken via immigration outside its historical homeland, principally in the Indonesian province of Riau and in the Malaysian state of Negri Sembilan. Often classified as a separate language, Minangkabau has a long literary tradition, and has influenced standard Indonesian through the numerous authors of Minangkabau origin who played an important role in the creation of modern Indonesian literature.

Banjarese: Banjarese probably came into existence as a lingua franca used among the Dayaks and Malays of southern Borneo and their Javanese overlords. It is now spoken as a first language by several million people in the city of Banjarmasin and in other locations throughout the southern parts of Borneo.

Riau-Johor Malay: This dialect group is spoken in the southern part of the Malay Peninsula and in the Riau archipelago in Indonesia. Of all modern vernaculars, it bears the closest resemblance to the national standard language of Malaysia, Singapore, and Brunei.

Kelantan-Patani Malay: This group of closely related dialects is spoken by several million speakers on both sides of the Thai–Malaysian border. Kelantan-Patani Malay is characterized by radical phonological changes, which make it difficult or impossible to understand by speakers of other Malay dialects.

Ambonese Malay: This creole is spoken natively on the island of Ambon in Maluku, where it is in the process of replacing the indigenous languages. It is also widely used as a lingua franca (and increasingly as a first language) in other parts of Maluku. Ambonese Malay probably developed from a form of Bazaar Malay, which eventually became the first language of some speech communities. Closely related isolects are spoken in and around Kupang (on the island of Timor) and Larantuka (on the island of Flores).

Manado Malay: This creole originated on the island Ternate, as evidenced by its Ternate lexical component. It is spoken natively in the city of Manado in North Sulawesi, and is gradually replacing the local Minahasa languages throughout this province. Closely related varieties are spoken in northern Maluku and in many parts of northern and central Sulawesi.

Jakarta Indonesian: The urban koine of Jakarta is based on Betawi, the Malayic isolect used by the indigenous inhabitants of Jakarta, but has been influenced by Standard Indonesian. With at least 5 million native speakers and many more second-language speakers, it is one of the largest Malayic isolects. Jakarta Indonesian is becoming the language of choice for educated urban speakers throughout Indonesia.

URI TADMOR

Malkiel, Yakov

Born in Ukraine, Yakov Malkiel was formed intellectually in Germany, where he received his doctorate in Romance Linguistics. With the beginning of World War II, he moved to the United States, the country in which he combined his work as a Professor of Romance Philology in the University of Berkeley (California) with the development of most of his scientific career.

His wide cultural and linguistic knowledge, his enormous capacity of work, and his astonishing domain of several languages allowed him to produce an enormous bibliography, written in German, Italian, French, Portuguese, Spanish, and English. Although this bibliography only includes a dozen books, it contains several hundred articles and essays. In fact, Malkiel himself published his own *Autobibliography* in 1988 (*Yakov Malkiel: a tentative autobibliography*), in which more than 800 titles are registered. Such a vast scientific production comprises, as expected, very diverse topics, which makes it difficult to find a superficial description for this linguist's work lines and contributions. Nevertheless, as a guideline, it can be affirmed that the scientific work of Yakov Malkiel is related to three large thematic fields that, presented from less to more importance, are:

In the first place, it is related to the historiography of Linguistics, the field in which he published essays on the appropriate methodology of this discipline, on some of the schools and tendencies of modern Linguistics, and on some of their main figures (Leonard Bloomfield, Leo Spitzer, etc.).

It is also related to the general synchronic Linguistics, the study of (a) language(s) at a given point in time. In this sense, it is necessary to highlight his interesting studies on what he denominated *irreversible binomials*, that is, those idiomatic expressions formed by two elements whose order cannot be permuted (*odds and ends*, but **ends and odds*); on the special uses that the languages make of the letters (in the construction of acronyms, in the construction of fixed expressions, etc.); or on the relationship that exists between grammatical gender on the one hand and sex and size on the other.

But the scientific effort of Yakov Malkiel was primarily centered on diachronic (historical) linguistics, the field in which, in turn, we may distinguish two areas:

In the first place are his works on the methodology and epistemology of diachronic Linguistics and its different fields of study (etymology, forms and causes of the linguistic change, studies on phonology and historical morphology, etc.). In this area, Malkiel tried to give a new impulse to a type of linguistic investigation that was in clear decadence after the almost absolute triumph, at the beginning of the twentieth century, of the synchronic perspective defended by

Ferdinand de Saussure and his followers (the so-called structuralists) and, later, by the Generativism spawned by Noam Chomsky.

To get that revitalization of the historical studies, he established new conceptual distinctions, separating the true diachronic Linguistic, that according to him should focus on the study of specific linguistic processes, from the *Glottodynamics*, that should study the universal constants that rule linguistic change and evolution. Moreover, he substituted the proper term "diachronic Linguistics" or "historical" for that of *genetic Linguistics*, convinced that evolutionary Linguistics should not be limited to describe mere historical developments, but rather that it has to be able to discover the decisive causes of these developments. Along those lines, his theory on the *multiple causation* of linguistic change is especially remarkable, according to which most of these changes have their origin in several interrelated factors, factors that can depend on different linguistic planes (phonology, morphology, grammar, or semantics) or, even, in the extralinguistic reality.

At the same time, as he himself affirms in the foreword of one of his most important works (*From particular to general Linguistics*), he tried to harmonize genetic Linguistics with the new theoretical perspectives coming from structuralism, thus changing the atomistic type of study developed by traditional historical Linguistics for another that is more in accordance with the general lines of contemporary linguistic thought. In fact, it could be affirmed that Malkiel was, because of his way of analyzing the data and of understanding the reality of language, among the structuralist followers of Bloomfield, although he never lost his scientific individuality and maintained, with respect to the latter, important theoretical differences.

In the second place, the dedication of Malkiel to the field of historical Linguistics is reflected in the publication of countless specific studies on diachronic phonology and morphology. In those works, almost always centered on the Roman languages—and, among those, especially Spanish, Portuguese, and Italian—he tried to combine the explanation of particular facts with the formulation of general theories, something that connects these works with those described previously and that also allows his results to be extrapolated to the analysis of any other language or group of languages. From among those essays, one can cite the ones dedicated to the explanation of the evolution of certain sounds or groups of sounds in the Romance languages: those related with symbolic values of the sounds (phonosymbolism) and, above all, those focused on the study of diverse elements derivative from the Romance languages. Among the latter, those in which he argues about the possible existence of diverse types of empty morphs (morphologic elements lacking of meaning) in the Romance languages are of special importance, like the case of those that he denominated *hispanic interfixes*: morphemes without meaning that would appear between the root and the suffix of certain Spanish words (like *pan-ad-ero* 'baker', where *pan* is the root that means 'bread', *-ero* is a suffix that expresses 'agent', and *-ad-* is an intermediate element lacking any meaning).

In definitive, Yakov Malkiel can be characterized as one of the main figures of contemporary diachronic Linguistics, to which he dedicated most of his efforts and his vast knowledge, something noticeable in his numerous publications which are so filled with knowledge and data that they are quite inaccessible to the uninitiated in the particular subject matter. This dedication to a linguistic area that has been neglected over the last decades may explain that most of the main studies in the development of the modern Linguistics omit in their pages the reference to this figure, of unquestionable scientific merits and of obligated reference when someone plans to work in the field of diachronic Linguistics.

Biography

Yakov Malkiel was born in Kiev (Ukraine) in 1914, to a Jewish family. Because of the civil war, he emigrated to Germany, where he studied at the University Friedrich-Wilhems in Berlin. In 1938, he obtained his Doctorate in Linguistic Romance degree with *suma cum laude*. Because he was jewish, he was forced to emigrate again in 1940, this time to the United States. Here, he worked for a short while at the University of Wyoming, and later he moved to the University of Berkeley (California), where he successively held the positions of *Lecturer*, *Assistant Professor* of Spanish and Portuguese, *Professor* of Romance Philology and *Professor Emeritus* of Linguistics and Romance Philology. In 1946, he founded the *Romance Philology* magazine, of which he was Editor in Chief for many years. In 1952, he participated in the creation of the Department of Linguistics of the University of Berkeley, where he carried out his educational activities until his death on April 24, 1998.

The merits of his career were recognized with numerous distinctions, such as three Guggenheim Awards and an *honoris causa* doctorate from the universities of Chicago (1966), Illinois (1969), Paris (1983), Berlin (1983), Georgetown (1987), Oxford (1989), and Salamanca (1994).

Manner of Articulation

Consonants are formed by creating a constriction in the vocal tract; the *manner of articulation* describes the type of constriction, whereas the *place of articulation* indicates where the constriction takes place. Sounds can also be made with different *airstream mechanisms.*

A primary aspect of the manner of articulation is the degree of the constriction, that is, whether the air has a free passage through the mouth or whether there is an obstruction. By varying the degree of obstruction, different types of sounds can be produced. Different sounds can also be made by allowing air to pass through the nasal passage; such sounds are known as *nasal.* Also, some sounds are *lateral,* with the air passing out through the sides of the vocal tract, but not through the center.

Vowels are produced with a very open vocal tract. For consonants, we distinguish three degrees of stricture: stops, fricatives, and approximants. *Obstruents* include the oral stops, fricatives, and affricates. Nasals and approximants are nonobstruent sounds, called *sonorants.*

Stops have a complete closure in the oral cavity. *Oral stops* involve closure of both the oral and nasal cavities, with no air passing through either one. *Nasal stops* have air passing out through the nasal cavity, but not through the oral cavity. In English, [p, t, k, b, d, and g] are oral stops, and [m, n, and ŋ (as in *long*)] are nasal stops. Nasal sounds are discussed further below.

Fricatives are made with an incomplete constriction in the oral cavity, allowing air to pass through the mouth, but with the constriction close enough to cause turbulence in the airstream, producing a hissing type of noise called *frication.* The English fricatives are [f v], [θ] as in *thick,* [ð] as in *the,* [s z], [ʃ] as in *shoe,* and [ʒ] as in *garage.* The fricatives [s z ʃ ʒ] are called *sibilants.* Fricatives are also known as *spirants.*

Affricates consist of a stop immediately followed by a fricative made at the same place of articulation. English has the affricates [tʃ] as in *itch* and [ʤ] as in *badge. Approximants* have an articulatory constriction that is narrower than the vowel [i], but not close enough to cause frication. Any approximant can be turned into a fricative by narrowing the constriction until frication begins. English has the approximants [l], [ɹ] as in *Mary,* [w] as in *wine,* and [j] as in *yes.* Some dialects of English pronounce, e.g. *which* with a voiceless approximant as well, symbolized as [ʍ]. Fricatives and approximants differ only in that approximants are slightly more open than fricatives. For this reason, where no approximant symbol is given on the International Phonetic Alphabet chart, an approximant can be shown by using the "lowered" diacritic [̞] with a fricative symbol; for example, a voiced bilabial fricative would be symbolized as [β̞], indicating that it is like a fricative, but with a more open vocal tract.

Two types of *trill* are commonly found. In one, the tip of the tongue is near the front teeth; in these, the tongue tip vibrates very quickly against the roof of the mouth several times. The other trill is uvular [ʀ]; with it, the uvula strikes against the dorsum of

the tongue. Snoring often involves an uvular trill made while breathing in.

Trills are not made by consciously controlling the motion of the tongue; rather, the tongue is placed in the appropriate position and tension, air is blown through the gap, and aerodynamic forces cause the tongue to vibrate rapidly against the roof of the mouth.

Taps are often described as a trill of one vibration. The tongue is flicked quickly against the roof of the mouth. A stop, by contrast, is a more deliberate action. In North American dialects of English, the tap [ɾ] is a typical variant of /t/, occurring between vowels, as in *city*.

Laterals are made with a central constriction, but with the sides of the constriction open, allowing air to escape. English has only the one lateral [l].

Nasals are made with a velic opening allowing air to pass out through the nasal passage. If the velum is raised against the pharyngeal wall (velic closure), the nasal cavity is shut off from the rest of the vocal tract, and no air can go through the nasal cavity. If the velum is lowered (velic opening), air can pass through the nasal cavity.

The term *nasal,* used alone, means *nasal stop.* Otherwise, the type of sound must be specified, as in *nasal fricative, nasal lateral,* etc. Nasal fricatives and approximants occur, but they are usually the result of being next to a nasal stop or vowel. Nasal stops are ordinarily voiced.

Air flowing out of the body is called *egressive.* Air entering the body is called *ingressive.* Most speech is egressive, but some sounds in some languages are made with an ingressive airstream.

In addition to the direction of airflow, there are three different airstream mechanisms that are used to set the air into motion (Chart 1). Most sounds are made by pushing air out of the body by contracting the lungs. These sounds are called p*ulmonic.* Pulmonic egressive stops are called *plosives.* Pulmonic ingressive sounds are not normally used in language (see below):

Sounds can be made by making an oral closure (such as a [p]), lowering the larynx, forming a glottal stop, and then raising the larynx. These actions cause

the air pressure to rise in the pharynx and oral cavity; on release of the oral closure, air flows out with a rather hollow, popping sound. This airstream mechanism is called *glottalic*; glottalic egressive stops are called *ejectives* [p' t' k']. Many native North American languages have ejectives.

Although it is possible to make glottalic ingressive stops, they are not at all common in languages. More often, we find *implosives* [ɓ ɗ ɠ]. These are made by raising the larynx, simultaneously making a stop, and then, as the oral stop is released, lowering the larynx so that the vocal folds vibrate as they move downward.

Clicks are made by making a velar closure as in [k] and simultaneously making an oral closure further forward (e.g. [p] or [t]). Then, the tongue body is pulled back, lowering the air pressure in the oral cavity. The release of the oral closure is a click; the airstream is *velaric ingressive.* The click symbols are bilabial [ʘ], dental [ǀ], alveolar [ǃ], palatoalveolar [ǂ], and alveolar lateral [ǁ]. As ordinary consonants, clicks are found only in languages of southern Africa; however, English speakers often use the dental click [ǀ] to express mild displeasure (often written *tsk! tsk!*), and the lateral click [ǁ] is used to urge on horses. Glottalic egressive sounds are not ordinarily used in language.

Māori and the Polynesian Languages

Maori is the indigenous language of New Zealand, and since 1987, it has been an official language of the country. It was brought to New Zealand 800 to 1,000 years ago by voyagers from Central Polynesia, specifically from the Southern Cook Islands, and the area of modern French Polynesia. It is thus very closely related to the languages of these areas and less closely related to the other languages of the whole Polynesian family of languages. This language family, which forms the most easterly group within the Austronesian language family, contains some 30 languages, which are spoken by approximately 750,000 people in communities varying in size from more than 300,000 (Samoan) to just 100 or 200. The family encompasses all the indigenous languages spoken within the Polynesian Triangle, as well as many spoken within Micronesia and Melanesia. The Polynesian Triangle is a vast geographic area formed by lines joining New Zealand, Rapanui (Easter Island), and Hawaii, and the languages to be found here include Maori, Rarotongan, Tahitian, Rapanui, Hawaiian, Tongan, and Samoan. All the languages of this family are descended from Proto-Polynesian (PPN), a language spoken in the region of Tonga and Samoa some 2,500 years ago. As the Polynesian peoples dispersed and settled in the other regions of the Pacific, the language they carried with them diversified and, over time, became the modern

languages of this family. The languages named are related to one other as shown in the family tree, which shows the subgroups (subfamilies) within the family.

Through the comparative method, a great deal is known about the structure of PPN. The following table sets out examples of the data which allow the reconstruction of the sound system and vocabulary of PPN.

Tonga	Samoan	Hawaiian	Māori	PPN	English
pō	pō	pō	pō	*pō	'night'
valu	valu	walu	waru	*valu	'eight'
kai	ʻai	ʻai	kai	*kai	'eat'
tolu	tolu	kolu	toru	*tolu	'three'
fale	fale	hale	whare	*fale	'house'
fā	fala	hala	whara	*fara	'pandanus'
ʻā	ala	ala	ara	*ʔara	'awaken'
hala	sala	hala	hara	*sala	'wrong'
hala	ala	ala	ara	*hala	'way'
laʻā	lā	lā	rā	*laʔā	'sun'
ua	lua	lua	rua	*rua	'two'
fafo	fafo	waho	waho	*fafo	'outside'
fefine	fafine	wahine	wahine	*fafine	'woman'
moʻunga	mauga	mauna	maunga	*maʔuŋa	'mountain'

The asterisk indicates that the forms so marked are reconstructed by the methods of historical linguistics and not actually attested. The 'g' of Samoan and the 'ŋ' in PPN both designate the 'ng' sound of English 'sing'. The ʻ symbol in Tongan, Samoan, and

PPN

Tongan   Nuclear Polynesian

Samoan   Eastern Polynesian

Central Eastern Polynesian   Rapanui

Māori, Rarotongan, Tahitian, Hawaiian
Hawaiian, as well as the ʔ in PPN, designate the glottal stop, often called a 'catch' or 'break,' articulated in the larynx. The macron over some vowels (*ā*) indicates that these are long.

An area of the grammar of PPN and of subsequent developments in its descendants that is of particular interest to scholars studying language typology is the matter of ergativity. Ergative languages, such as Tongan, mark the subjects of clauses differently depending on whether the verb is transitive or not, whereas nonergative languages, such as Maori, treat subjects in the same way, irrespective of the nature of the verb.

Tongan:

Na'e   'alu   e   tangata
Past   go   the   man
'The man went (intransitive verb 'go')'

Na'e   kai   'e   he tangata e   ika
Past   eat   subject marker   the man   the   fish
'The man ate the fish (transitive verb 'eat')'

Māori:

I   haere   te   tangata
Past   go   the   man
'The man went (intransitive verb 'go')'

I   kai   te   tangata   i   te   ika
Past   eat   the   man   object marker   the   fish
'The man ate the fish (transitive verb 'eat')'

Given that both patterns occur in the languages of the family, the question arises as to which of these patterns predominated in PPN and by what mechanisms the descendant languages developed the patterns presently attested (see especially Chung 1978).

The study of the PPN vocabulary and of the structure of the family produces hypotheses about the settlement of the Pacific that accord well with those derived from archeology. Polynesians entered the Triangle from eastern Fiji and settled the Tonga-Samoa area before a group moved further eastward to modern French Polynesia. From there, peripheral areas such as Rapanui, Hawaii, and New Zealand were discovered and settled.

Maori itself is, in terms of its sound system, grammar, and vocabulary, typical of the family as a whole. Maori has ten consonants, p, t, k, m, n, ŋ (spelt 'ng'), r, w, h, and f (spelt 'wh'), and five vowels, a, e, i, o, and u, which may be short or long. Furthermore, syllables are restricted in shape to at most one consonant followed by up to three vowels. Thus, in Maori, consonants occur only singly and never at the end of a word. Maori has very little in the way of inflection, that is, the use of devices such as suffixes for grammatical purposes. Rather, grammatical

categories such as tense and the role that words play within sentences are indicated by means of separate particles:

I haere 'went', *kua haere* 'has gone', *ka haere* 'will go, goes', *me haere* 'must go'.

Similarly, whether nouns are subjects, objects, possessors, and so on is marked by particles: in the Maori example above, 'The man ate the fish', the fact that 'the fish' is the object of 'eat' is shown by the particle *i*.

One area of Maori grammar in which a suffix plays a role is the formation of passive verbs:

horoi 'wash', *horoia* 'be washed'; *inu* 'drink', *inumia* 'be drunk (of liquids)'; *kai* 'eat', *kainga* 'be eaten'.

There are 17 such suffixes, although many of these are very rare. However, the question of which suffix goes with which verb and how this phenomenon is best described has been a subject of some discussion within theoretical linguistics (see especially Bauer 1997:477–9).

In Maori, as in most of the languages of the Polynesian Triangle, the predicate phrase (usually a verb) occurs first in sentences in which no special emphasis is placed on any one part. It is followed by the subject and any other phrases, such as objects and adverbial phrases. The examples given above illustrate this feature for both Maori and Tongan. These languages, however, also have devices for placing particular emphasis on some part, usually by placing the phrase in the initial position:

Nā   te   tangata   te   ika   i   kai
Of   the   man   the   fish   past   eat
'It was the man who ate the fish (not someone else)'

With the exception of some eight nouns, all designating people, which lengthen the third last vowel (*wahine* 'woman', *wāhine* 'women'), nouns in Maori show no change to form plural. Rather, number is shown in the accompanying articles:

te   whare   ngā   whare
the   house   the plural   house
'the house'   'the houses'

tērā   puke   ērā   puke
that   hill   those   hill
'that hill'   'those hills'

The Maori pronoun system shows two features typical of Polynesian languages:

- Separate forms not only for singular (one person) and plural (several people) but also for dual (two people): *koe* 'you (one)', *kōrua* 'you (two)', and *koutou* 'you (several)'.
- Separate forms for 'we' depending on whether the person spoken to is included (inclusive forms)

or not (exclusive forms): *tāua* 'you (one) and me', *māua* 'him or her and me', *tātou* 'you (two or more) and me', and *mātou* 'them and me'.

The possessive constructions in most Polynesian languages, including Maori, show two parallel sets of markers. Which is appropriate depends on the relationship between the possessor and the thing possessed, in particular, whether the possessor exercises independent control over the thing possessed:

tāku	*pukapuka*	but	*tōku*	*ingoa*
my	book		my	name
'my book'			'my name'	

Nā Hēmi tēnei kai	but	*Nō Pita tēnei whare*
Of James this food		Of Peter this house
'This food is James's'		'This house is Peter's'

Spread as it is over a country of the size of New Zealand, Maori shows some dialect diversity. This is, however, mostly a matter of vocabulary and is by no means so great that mutual intelligibility is impaired.

Once the language of the entire Maori population, it has been subjected to severe pressure from English, especially during the second half of the twentieth century. Of the approximately 520,000 people (15% of the New Zealand population) who identified themselves as ethnically Maori in the 1996 census, only some 26% claimed that they could conduct a conversation on everyday matters in Maori. Other studies have shown that there has probably been some overreporting by many respondents and that there may well be only as few as about 10,000 really fluent speakers of Maori. Further, the native speakers of Maori are concentrated in the older generations, and the natural transmission of the language from parents to children within families is essentially broken. In parallel to the decrease in the population speaking Maori, there has also been a reduction in the domains where it is regularly used. In most parts of the country, Maori is regularly used only during ceremonial occasions, such as the welcoming of guests and at funerals and church services.

The awareness that the continued survival of Maori had become precarious and the strongly held feeling that the language is a central feature of Maori ethnic and cultural identity have led, since the mid-1970s, to a wide range of initiatives in language maintenance and development. In response to the recognition that the natural transmission of the language could no longer be relied on to ensure its acquisition by succeeding generations, preschools were founded in which Maori was the sole language spoken and in which instruction took place within a Maori cultural environment. Since the early 1980s, this initiative has extended into primary and secondary schooling, catering to approximately 20,000 pupils from preschool to high school levels. Maori Studies is a popular subject at all New Zealand Universities and can be pursued up to the doctoral level.

In 1987, the passage of the Maori Language Act made Maori the only de jure official language of New Zealand and founded the Maori Language Commission. This body, with its office and staff in Wellington, develops policy and promotes activities designed to give substance to the official status of the language. Part of the Commission's work has centred on the development of vocabulary. Maori is now used in official documents, in broadcasting, and in education as never before, and deliberate expansion of its vocabulary to equip it for these domains has been essential. In developing new vocabulary, the Commission and other authorities have been guided by the principle that terms should be created with the resources already found in the language. Thus, borrowing from English is ruled out, and the creation of new compounds or the specialisation of existing words are preferred strategies.

Maori is the vehicle of a considerable traditional literature. Oral traditions of a variety of genres, such as settlement histories, aetiological myths, fairy stories, songs, and poetry, were committed to writing by Maori elders themselves and are accessible partly in publications and partly in manuscripts in libraries and museums. Oratory and song are two oral genres that are still very much alive today and play central roles in Maori culture and community life. At the same time, creative writing, especially for school use, is using Maori within new literary genres, such as the short story and even the novel.

The maintenance and development of Maori is a very important strand in New Zealand's present movement toward a more equitable, multicultural, and inclusive social structure, as past wrongs and assimilationist policies are redressed.

Marshallese and Micronesian Languages

Malayo-Polynesian is one branch of the Austronesian language family, and has two sub-branches: Western Malayo-Polynesian (which includes a large number of languages, including some of the major languages of the family) and Central-Eastern. The Central-Eastern sub-branch in turn consists of two major branches: Central Malayo-Polynesian and Eastern Malayo-Polynesian. The Eastern Malayo-Polynesian in turn is subdivided into two sub-branches: South Halmahera-West New Guinea and Oceanic. The Oceanic sub-branch contains over 450 languages, or about half of the total for the Austronesian family as a whole. Most Oceanic languages have lost word-final consonants and have simplified consonant clusters. The most important sub-branch, Remote Oceanic, has a number of branches and sub-branches. The more important groups of languages belonging to Remote Oceanic are Micronesian and Central New Hebrides. The Remote Oceanic sub-branch covers most of Micronesia and all of Polynesia (including Fijian, Rotuman, Samoan, Maori, Tongan, Tahitian, Hawaiian, and Rapanui or Pascuense). However, a number of scholars question the validity of the Remote Oceanic subgroup.

The languages of most of the Micronesian islands (except the languages of Palau and the Marianas) are more closely related to those of eastern Melanesia (the Solomon Islands and Vanuatu). Linguistic analysis points toward eastern Melanesian origins for the earliest eastern Micronesian peoples. The Micronesian subgroup of the Remote Oceanic sub-branch includes all the languages of Micronesia except for Palauan, Yapese, and Chamorro (which all belong to the Western Malayo-Polynesian branch and have affinities with the western Austronesian languages of Indonesia and the Philippines) and Nukuoro and Kapingama-rangi (which are Polynesian). There are approximately 73,000 total speakers of Chamorro, of whom 60,000 are on guam and 13,500 on the Northern Mariana Islands, Micronesia. The 15,000 speakers of Palauan or Palau primarily reside in Belau, guam, and Western Carolines, Micronesia. And there are roughly 5,000 speakers of Yapese on Yap, Caroline Islands,

Micronesia. Many scholars question the position of Yapese in this group since no one has yet demonstrated that it must belong to this group. Several scholars, including Blust, have recently proposed that this language belongs to the Oceanic subgroup. The approximately 1,300 speakers of Kapingama-rangi include 700 on Kapingama-rangi and several hundred in Porakiet village on Ponape. It is somewhat intelligible with Nukuoro, with 55% lexical similarity. There are roughly 550 speakers of Nukuoro, with 125 on Ponape. The chief languages of the Remote Oceanic sub-branch include: Ikiribati (Gilbertese) with over 60,000 speakers, mainly in Kiribati; Trukese with about 45,000 speakers, including second-language speakers; and Marshallese (over 30,000 speakers).

Geographically, the Micronesian Islands lie within four major archipelagos: the Marianas, the Carolines, the Marshalls, and the Gilberts. There are 19 languages in the Micronesian subgroup including Carolinian (Saipan Carolinian), English, Kapingamarangi, Kusaie (Kosrae, Kosraean, Kusaiean), Mokil (Mokilese), Mortlock (Mortlockese), Namonuito, Ngatik, Nukuoro (Nukoro, Nuguor), Paafang, Pingelap (Pingilapese), Ponape (Pohnpeian, Ponapean), Puluwat, Satawal (Satawalese), Sonsorol, Truk (Ruk, Trukese), Ulithi, Woleain (Wolean), and Yapese. Kiribati is the language of the Kiribati (Gilbert) island chain, of neighboring Banaba (Ocean) island, Niu, and it is also spoken in the Line Islands. Kusaie is the language of 5,000 inhabitants of Kosrae State (Federated States of Micronesia), and many inhabitants also speak Ponapean. Nauruan is the traditional language of Nauru, with approximately 4,000 speakers. English has been the strongest influence on Nauruan (Australia administered the island from 1920 to 1968), and there are signs that Nauruan is being abandoned in favor of English. Ponape, with about 22,000 speakers, is the major language of Pohnpei State (Federated State of Micronesia). Ngatikese, Pingelapese, and Mokilese are counted as dialects of Pohnpeian or as closely related languages. Ponape has a 'high language' with a

partly separate vocabulary, used in speaking about people of high rank. Truk (22,000 speakers) is the major member of a dialect chain with a total of 40,000 speakers. These languages are spoken in the Caroline Islands (Federated States of Micronesia), and have numerous English and Japanese loanwords from their colonial history.

Marshallese has the largest number of speakers (about 30,000) of any Micronesian language. Marshallese is primarily spoken in the Republic of the Marshall Islands, but also on Nauru. English and Japanese have had the strongest effect on Marshallese. Japanese administration followed after World War I, and the United States took over from 1945 to 1986.

The Marshall Islands comprise 29 coral atolls and five single coral islands scattered over about 180,000 square miles of the Pacific Ocean. Kwajalein Atoll is the world's largest atoll formation, comprising 93 islets. Considering this vast area and scattered land area, the Marshallese language is amazingly homogenous, but there are two main dialects that sometimes differ in vocabulary, the choice or the pronunciation of a word, and in the vowels of words whose first two consonants are identical. These two dialects coincide with the two major chains of islands: the eastern, sunrise, or Ratak chain and the western, sunset, or Ralik chain. However, at focal centers like Majuro, or Ebeye on Kwajalein, one finds speakers of both dialects. Zewen (1977) found evidence of the two dialects merging into a kind of Marshallene 'koine' in the District Centre, as well as on Ebeye.

The Ralik dialect has obtained a higher status because the Bible was first translated into Ralik, and the early missions were located in that chain. The eastern (Ratak) dialect is more conservative. The differences between the two dialects appear in the vocabulary and the phonetic realization, rather than in the grammar. For instance, words that begin with a vowel have a different phonetic onset in the two dialects. The Ratak dialect has quite a number of words that consist of a reduplicated basic morpheme. There are also minor dialects within the major dialects: Mejit, for example, is divergent in the east, as in Ujelang in the west.

Terms associated with precolonial customs and activities such as native clothing, handicraft, and navigation are today referred to as 'Kajin Etto' (old language), although understanding of these terms varies in the present generation (Zewen 1977:4–6). In precolonial times, ritual languages were mandatory for certain activities: for instance, special words had to be used on the northern voyages, especially to Rongerik. Word taboos were associated with tattooing or particular places: for instance, on the small islands of Kwajalein Atoll, 'kako' (rooster) was taboo. Most terms of these ritual languages are metaphors or metonymies.

Students and youngsters have also developed a 'student language' or slang in Majuro and on Ebeye (Zewen 1977). It is characterized by nonstandard vocabulary, arbitrary coinages, and figures of speech that often quickly fall out of fashion or use.

Linguists have differed over the vowels of Marshallese. Certainly, Marshallese has a very high number of vowel phonemes, particularly in comparison with Ponapean (with which it has roughly 33% lexical similarity). This situation seems to be the result of vowel fusions after certain consonants have disappeared according to Marshallese sound laws. Byron Bender (1968) argues that there were three vowel phonemes (*a e I*), other vowel sounds being conditioned by surrounding consonants. The usual spelling recognizes nine. Other scholars distinguish 12 vowel phonemes, and add a distinctive feature of length, giving a total of 24. There are three groups of consonant sounds, according to their effect on neighboring vowels: the plain or light consonants, the heavy consonants, and the rounded consonants. Marshallese has lost the complex series of numeral classifiers that are found in the other Micronesian languages. 'Cilcino' (six) originates as 'cilu' (three) plus 'cilu' (three); '7' as '3 + 3 + 1'.

With respect to Marshallese phonology, there are eight basic patterns of syllables. Words, when monosyllabic, consist of one of these patterns; when polysyllabic, they consist of a sequence of these patterns. Most Marshallese words are dissyllabic.

With respect to morphology, Marshallese is not an inflected language in which word classes can be defined by the type of inflections they take. Other criteria have to be considered such as the meaning of the word, and the valence or systematic combinability with other words. For instance, nouns may be determined by demonstrative pronouns. They may be main or secondary elements of phases or may be preceded by a preposition. In clauses they may be subject, predicate, or object. With the exception of personal and nonpersonal proper nouns, they may take 'possessive suffixes' or may be constructed with possessive classifiers.

CAMILLA COCKERTON

Martinet, André

The main representative of functionalist structuralism, André Martinet is one of the most enlightening figures of twentieth-century linguistics. He spent his childhood in the peripheral Provencal region of Savoy, which endowed him with an early sensitivity for the problems of bilingualism and language social aspects, while during his brilliant classical education he acquired practical knowledge of a number of languages. His degree was in Germanic linguistics but he also acquired broad knowledge of the general European linguistic and philological tradition. During his education in Paris, Berlin, and Copenhagen, as well as later while he was teaching at Columbia University, he established direct contacts with all relevant structuralist trends in both Europe and America (developed by the Prague School, the Copenhagen School, and American structuralism), showing appreciation of all elements of other schools that could fit his own view of language. Influenced primarily by the structuralism of Ferdinand de Saussure and that of the Linguistic Circle of Prague (particularly Nikolay Trubezkoy), Martinet further developed the structuralist theoretical tenets enriching them by achievements of American linguistics and Danish glossematic theory. However, adopting a clearly functional view, he specifically emphasizes the functions of language in general, or the functions of linguistic elements as the main object of linguistic enquiry in opposition to structuralism and formalism of the majority of American structural linguists in which the system of a language is explicitly studied in abstraction from its functions. For him, language is essentially a human institution and an instrument of communication, while the method of linguistic analysis is based on the principle of communicative relevancy of linguistic units and their role in the transmission of information. Accordingly, he sees language structure only as a logical complement and manifestation of language functioning.

Within this functional perspective, Martinet clearly insists on the reliance on concrete linguistic facts and the need to study specific languages exclusively in their own functional framework, as each language corresponds to a specific organization of reality and human experience: 'What we wish to examine is the whole of man's linguistic activity, and as this activity only takes place within the framework of specific languages, our primary task is to study these languages as so many different objects.' This rational and prudent attitude, which is in sharp contrast to perhaps more attractive, bold theoretical assumptions of some other formalistic and structural linguists, has often been labeled as Martinet's 'realism'. Martinet maintains that the task of linguistic analysis is not to seek manifestations of universal categories in languages, but to discover the unique categories articulated by each language. Accordingly, in his view, theory should be always guided by analysis, not the other way around, no matter how unfamiliar the resulting theory might appear, as 'the scientific treatment of an object requires, first and foremost, that the object's integrity should not be sacrificed to methodological exigencies.'

A cornerstone of the functionalist approach and Martinet's main contribution to general linguistics is his important notion of 'double articulation' referring to two fundamental levels of language structure, that of meaningful units (primary articulation) and that of expression units (sounds) which are meaningless in themselves but serve to distinguish the meaningful elements (secondary articulation). The concept of 'double articulation' (or 'duality of patterning' as it is termed in American linguistics to avoid confusion with

the articulation of sounds) allows a small number of meaningless phonological elements to be combined to distinguish an infinite set of meaningful utterances. The minimal linguistic forms that are meaningful are monemes, corresponding roughly to what American linguists call morphemes, which Martinet further analyzes as units of grammatical meaning (morphemes) and units of lexical meaning (lexemes). Thus, the word *books* is composed of two monemes: a lexeme *book* and a morpheme *-s* denoting plurality. Moneme has both an expression and content and consists in the association between a signifier (vocal expression) and a signified (semantic content). In line with the structuralist tradition of the phonological Prague School the basic unit of the sound system is called a phoneme: it is a minimal, contrastive sound unit that distinguishes one meaningful utterance from another (e.g. *pin/bin*). Phonemes may be further analyzed in terms of a set of underlying distinctive features specifying the ways the sound is physically produced. However, Martinet rejects Roman Jakobson's phonemic theory that there is a universal inventory of these distinctive features and that they are based on binary oppositions.

Martinet made major contributions to the field of general and descriptive phonology further developing the phonemic theory of the Prague School through elaboration of such notions as phonemic frequency, functional load, neutralization, and segmentation of phonemes. His second doctoral dissertation *La phonologie du mot en danois* (1937; Phonology of Danish) was one of the first complete phonological descriptions of a language. He regards phonology as 'functional phonetics', which has to interpret real phonetic facts from the point of view of linguistic functions of sound differences and their functional effects and not as different realizations of an 'abstract system'.

Using the function of moneme in the utterance as the starting point, Martinet also developed a coherent system of general morphological and syntactic analysis focusing particularly on the sentence structure and predicate function. While rejecting logical and psychological criteria, he analyzes sentences exclusively by applying the criterion of linguistic function (revealing linguistic 'choices' of speakers by means of commutation). He establishes a hierarchical relationship between monemes, the minimal units of the first articulation according to their function in the sentence by classifying them into free monemes and bound or functional monemes. The word can consist of one nonanalyzable item or moneme, e.g. *head* and of combined items or synthemes such as *headache*. In terms of communicative relevancy, morphology is considered to be the 'presentation of the variations of the form of signifiers and of the conditioning of these variations', and syntax is 'loosely understood as the survey of all data pertaining to the combinations of significant elements'. Syntax is not completely predictable but dependent on compatibility or conventions, which one just has to know and cannot calculate in advance. Martinet, however, has been criticized for avoiding to a certain extent the problem of semantic analysis by arguing that all linguistically relevant aspects of meaning must already be manifested at the level of expression, while its other aspects easily escape objective analysis and require nonlinguistic (external) explanation and therefore should not be the subject matter of linguistics.

An important part of Martinet's work is devoted to historical linguistics and diachronic problems of language change. In his seminal work *Économie des changements phonétiques* (1955; Economy of sound changes) he formulates an original, well-grounded theory of sound change as arising, in part, from internal pressures within a phonological system. He explains that linguistic evolution is 'governed by the permanent conflict between man's communicative needs' (using as many units as possible, as different from each other as possible) and 'his tendency to reduce to a minimum his mental and physical activity' (using as few units as possible). By economy, Martinet means the principle of 'least effort' and the tendency to reconcile these two contrasting elements to attain an improved functional load and help maintain an acceptable level of communication. However, optimum economy and complete symmetry can never be reached because of physiological factors such as inertia and asymmetry of the speech organs (e.g. distinction between front and back articulation). Martinet distinguishes syntagmatic economy (contextual assimilating pressure exerted by adjacent linguistic units) from paradigmatic economy (dissimilating pressure exerted by the units in the system which might have appeared in that particular place), and determines the effect of different variable synchronic factors (such as frequency, correlative relationships, the notion of empty place in a pattern, etc.) on language development. In this way, he tried to reconcile the apparently conflicting viewpoints of synchronic and diachronic linguistics by drawing upon his findings in one field to illuminate the other. However, he has been often criticized on account of deliberate neglect of external historical and social aspects of language change. Although it is true that Martinet primarily considered the inner causes of language change, he also underlined the role of external explanation in the rate of change and its specific historical context, and in this way has convincingly succeeded in elucidating many mechanisms of sound change making his work indispensable in any serious study on language evolution.

In addition to his important theoretical achievements, Martinet also wrote about specific problems of many different languages frequently discussing methodological and practical questions of language learning and acquisition, while at the same time working on the development of international auxiliary languages. With his central position between European and American structuralist schools and explicit appreciation of positive outcomes of traditional comparative philology, Martinet was one of the rare linguists who tended to bridge the gap between different fields of linguistic study. His clearly formulated functional theory based on the empirical-deductive approach exerted an important influence on further development of European linguistics, while his method, which always remains close to the actual reality of specific languages, has been used for phonological and syntactical descriptions of more than hundred languages.

Biography

André Martinet was born in Saint-Albans-des-Villards, Savoy on April 12, 1908. He obtained degree in Germanic linguistics from Université de Sorbonne and Ecolé Pratique des Hautes Etudés, Paris (1932), and a Ph. D. for two dissertations in Germanic linguistics on consonant gemmination in Germanic languages and on phonology of Danish in 1937. He was Chair of Phonology, Ecolé Pratique des Hautes Etudés, Paris in 1938–1946. During World War II, while imprisoned in German camp, he carried out an impressive phonetic and phonological survey on contemporary French pronunciation published in 1945. He moved to New York, where he was director of interlinguistic research of International Auxiliary Language Association (IALA) 1946–1948. He was Professor at Columbia University and was an active member of the Linguistic Circle of New York 1948–1955. He was Chair of Phonology, Ecolé Pratique des Hautes Etudés and Professor of general linguistics at Sorbonne, Paris in 1955–1978; member,

Société de linguistique de Paris in 1931; President, Société européenne de linguistique, 1966–1999; honorary member, Linguistic Society of America (LSA) in 1973, Union Mundial pro Interlingua (UMI) in 1998; editor of *Word* 1946–1960; founder and editor of *La Linguistique* since1965. Martinet died in Châtenay-Malabry on July 16 1999.

ANITA SUJOLDZIC

Mass Media and Language

Broadcasting (TV, radio), print media (newspapers, magazines, books, pamphlets, posters), film, theater, and electronic products such as CDs, records, tapes, and videos are the most important instances of mass media. Telecommunications and news agencies, the two other areas of mass communications, differ from them in a number of ways, but the boundaries are being blurred by modern, especially digital, information

technologies. Important characteristics that they all share are the unidirectionality of the information flow from a source to a target and the constraints they impose on feedback. Broadcast and print media have developed response channels, which differ in kind, immediacy, and effect as a result of the technology they are based on. They are often referred to as news media since they normally carry news, current affairs, and sports. But news need not be a defining criterion as music, film, or weather channels show. Although they will be ignored, one should add that the linguistic effects of entertainment media may surpass those of the informational and educational media and may further endanger aid endangered languages.

Before turning to linguistic aspects, one must emphasize the fact that they are (sociopolitical) institutions with, as a special characteristic that emanates from their purpose, developed mechanisms for the flow, categorization and packaging of information, and a history of professionalism. In terms of communicational function, they can thus be defined as domains whose goal it is to make content public, accessible to debate. But they are better referred to as hyperdomains since all domains, e.g. politics, law, business, lifestyle, are providers of content. Their sociopolitical role, especially their relationship with sources, and their impact on audiences remain controversial. What is clear is that they are not mere transmitters of information; they may indeed have a symbiotic relationship with sources (e.g. in sport). Minimally, they should be called co-orchestrators of what is 'in the air' in the public arena.

Turning to language, co-orchestration means that the media collect, select, manipulate, shape content, and create a packaged, marketable product that is recognizable to large audiences and helps maintain a media outlet's audience share. Language is the central, but not the only, component in these processes, the others being visuals, film, sound effects, presentation, and layout. Language is crucial in the packaging of *raw* input into output and in mediating it to an audience. The inference that media language must be homogeneous, however, is unwarranted in light of the diversity of source domains, professional routines, technologies (print, radio, or TV), audience stratification and habits, and the need for outlets to create recognizable and consumable products. It is better to speak of media languages or to borrow from media sociology the term public idiom, which is better able to refer to the existence of abstract norms and professional routines that bear upon the use of language. The linguistic concept of register has been used to describe such differences as they were seen to emanate from a particular configuration of situational features or context-of-situation. Early definitions of this term highlighted lexicogrammatical features or

clusters of co-occurring features. Recent ones define it in terms of semantic potentials, the typical meanings expressed in such contents, and the typical linguistic expressions used to do that end. Expressions range from text or discourse properties to features of pronunciation. Such a wide definition is to better able to capture the diverse means of expression that are used in restricted reported domains to shape content and to express underlying ideological stances.

Focusing more narrowly on linguistics, one should begin by saying that, in view of the diversity of linguistic models, it is functional ones, pragmatics, text and discourse linguistics, socio-and psycholinguistics that have an affinity to the concerns of media studies. Four points should be emphasized. The first is that linguistics can be an ancillary discipline or an independent player. In the latter capacity, it pursues its own agenda, using media output as primary data for the descriptive study of language. In the former, it helps highlight aspects of the communicational process that are of interest to media studies. Second, media output does not occur in isolated units but as instances of higher order units, such as program formats, or as products of a medium's institutional structures, such as news and current affairs. Output is thus subject to ever more abstract norms and expectations. Third, output has a presentative and representative side. The former highlights style or, to use Hallidayan terms, the 'interpersonal' function, the latter the way reality is construed, the 'ideational' function. In other words, presentation is about the way media output targets its audience, representation about the way it (re-)constructs what it is about. Both presentation and representation are supported by ideologies and attitudes that they reaffirm. Finally, one must distinguish output as a product, the result of complex institutional processes and output as a process, the way it is experienced by an audience. Linguistics can shed light on both, including the points mentioned above, viz. the embeddedness of the public idiom inside a network of source and target domains.

Studies on sports coverage have revealed that the technology, i.e. radio, TV, or print, and the mode of communication, i.e. speech or writing, have effects on the idiom, which are independent of such factors as program formats. Radio, for instance, turned out to be more action-oriented, focusing more on detailed spatial expressions than TV and the press, even though the time constraints on radio commenting are much heavier. Combining discourse and text linguistics with Content Analysis, studies on representation have left no doubt about the existence of ideological bias in media coverage. They have revealed mechanisms whereby 'hidden meanings' are transmitted that reinforce attitudes such as racism, in the absence of an audience's direct experience with ethnic groups. Studies closer to

mainstream linguistics have looked at how language is used to recast reality into a socially coherent consensus or, less often, conflictual position. 'Critical Linguistics' or Critical Discourse Analysis, outgrowths of Hallidayan functional grammar, have thus revealed how lexical fields, grammatical systems like transitivity or modality can be used to create ideological bias. Gender analyses can be seen in this context. Text and discourse analysis have looked at macro-and microproperties of media texts. Van Dijk argues forcefully that texts express, or can be reduced to, macrosemantic propositions and are condensed in conventionalized (text-) syntactic super-structures. He exemplified his approach in a study on the international press coverage of the assassination of Lebanon's President General Gemayel, which revealed the presence of a bias in favor of 'Western' formulations of the event and the dominance of local (as against global) journalistic routines. They showed up in the shared macrostructure of media texts. From a methodological perspective, he showed how (under-lying, social) ideologies and (concrete acts of) discourse are connected through (cognitive) models that discourses such as editorials aim to activate to bring over the writer's intent. Studies on the relationship of a text's structure with news values and narrative theory have shown that news values take precedence over the chronology of events. Reports, for instance, take the form of an inverted pyramid of information structure, where the most important, often the most recent, information comes first, with background being delayed. This anticlimactic structure can be traced to the American Civil War, where the emphasis was placed on 'recency' as against 'explanatory background'. It follows that reports do not need to be read to the end. Editorials, in contrast, which argue for or against some position, have a climactic structure and require full-text reading.

A traditional concern of presentation studies has been with the choice of language (variety). Choice was seen to respond to such factors as program policy, intelligibility, and to favor standard or prestige languages. This turned out to be true only in specific situations, as when public service media enjoy a monopolistic position, when broadcasting focuses on high cultural products or on nation-building. Britain's BBC between the 1920s and 1950s is a case in point. Competitive settings as in the United States of America or federal ones as in Germany promote a wider range of varieties. It has also been shown that standard varieties reflect the tone of officialdom and of elites, and support representational bias. A strict separation between presentation and representation is thus unrealistic and generalizations about either must be tempered in light of differences between intended norms and practices, and between intended communicative effects and its actual realization.

Generally speaking, research has moved away from narrow linguistic concerns (grammatical structures, lexical choices) to broad concepts that permit the understanding of ideological bias. It is here that the audience dimension has been reintegrated, whereas older research was largely confined to comprehension and recall studies. Like all texts, media texts are assumed to contain slots for the reader, which activate in recipients shared concepts, schemata, prototypes, and the like. Mass media, thus, do not target passive recipients; they activate recipients' worldview. Although this is an attractive position, the implication is that mass media address individuals, while media sociology rightly operates with layers of recipients that reinforce or cushion off media impact. Related research has looked at linguistic details to show how texts incorporate features of the language of the audience ('audience design') to enhance their representational impact and to maintain or increase audience size.

Studies of interviews, talkback shows, etc., have revealed patterns similar to the ones in monologs. Research tends to highlight the product—messages that recipients are most directly exposed to—although they interpret findings by relating them to institutional or general social parameters. Studies of the institu-tional context of the public idiom, i.e. the formulation of communicative and language norms, reveal the institutions' internal structures, such as the contribution of advisory bodies, language guardians, or of editorial policies. To turn to linguistics as an independent player, one should note the traditional interest of descriptive and applied linguistics in media language to study the 'real', as against the 'potential', in language use. The design of reference and teaching materials have been important outcomes. Corpus linguistics has added a new methodological dimension to comparative research.

Although linguistics has important contributions to make to mass media studies, one should not forget that factors to do with ownership, legal status, business strategies in light of the globalization of communi-cation, political control, public accountability, etc., dominate research.

GERHARD LEITNER

Mathematical Linguistics

Mathematical linguistics is a branch of linguistics studying the features and properties of language from the mathematical point of view. It is usually divided into several branches: (1) quantitative or statistical linguistics, dealing with unique language entities on the phonetical, lexical, syntactical, and semantical levels; (2) algebraic linguistics; and (3) machine translation. Algebraic linguistics use qualitative mathematical methods like: algebraic methods, theory of algorithms, graph theory, topology, and mathematical logic. Mathematical linguistics develops formal apparatus for the description of natural and artificial languages. The discipline was created in the 1950s to define language phenomena logically, precisely, and exactly. Its fundamental based on the ideas that language is a functional mechanism, which can be studied through the frequency of occurrences of speech units. More often than not, under mathematical linguistics, its statistical branch is understood. Mathematical linguistics unites the study of quality and quantity in language covering such fields as phonological, lexical, grammatical, semantic, and stylistic statistics. The frequency of occurrence of linguistic units and features, their rank, order, laws of distribution, correlation, stability, and variance coefficients are studied. Considerable attention is given to the definition of the units of population, random sampling, necessary, and sufficient sample size. The forms of frequency distributions of linguistic units are studied.

Phonological statistics studies the frequency of occurrence of letters, phonemes, and phonemic groups in languages as it is and in different languages world over. One can establish the phonostatistical distances between the sound pictures of different writers or different world languages. In 1937, a Japanese linguist Masao Onishi was one of the first to compare the frequency of occurrence of groups vowels and consonants of ten languages: English, German, French, Spanish, Italian, Russian, Chinese (Cantonese), Bengali, Sechuana, and Japanese. Yuri Tambovtsev compared the frequency of the occurrence of labial, front, palatal, sonorant, occlusive, fricative, and voiced consonants in 109 world languages of different language families, e.g. Indo-European, Finno-Ugric, Samoyedic, Tungus-Manchurian, Turkic, Paleo-Asiatic, etc. He built phonostatistical distances between the languages inside each language group (e.g. Germanic, Romanic, Slavonic, Ugric, etc.) and each language family.

Lexical statistics investigates the sizes of corpus, the zones of words with high, medium, and low frequencies, the laws of their distribution, especially Zipf law. Lexical statistics gave rise to glottochronology, created by an American linguist Mooris Swadesh in the 1950s. He tried to make statistical comparisons between the rates of change within the fixed list of words of two languages to find out the time these two languages separated. The glottochronological method is based on two pivotal assumptions: (1) in every language, there exists a list of 100 core words; (2) the rate of disappearing words is constant. This method was much criticized. The main methodological fault lies in the fact that it is hard to establish the main 100 word core of a language and the false relation of the decay of carbon-14 with the disuse of words in a language. Nevertheless, if one takes the whole word stock of two languages, then one can speak about their difference, without resorting to the precise time of language separation. To establish the proximity of two languages, one should compute the correlation coefficients of their phonological, morphological, syntactical, and other categories. It is the task of statistical language typology and dialectology. Grammatical statistics researches the quantitative relationships of morphological categories and parts of speech.

Syntactic statistics determines the frequency, distribution, and relationships of sen-tence structures and types of sentences. Semantic statistics describes the quantitative properties of semantic fields of different words.

Stylistic statistics studies quantitative features of style, correlation, and disputed authorship. The application of statistical methods to problems of disputed authorship has a rather long tradition in English with respect to the works of Shakespeare, Mark Twain, Hamilton, etc. It is often called stylometry. The study of the statistics of sound or word usage helps to catch the nuances of the text. The statistical spectra of sounds or words then and now may give a history of the development and changes of a language as it is and language habits of a particular writer. The use of stylometry in authorship attribution is based on the hypothesis that there are quantifiable features of style, characteristic to a particular writer. Authorship attribution is usually performed in the following way: is the literary opus under investigation more similar to the candidate author "A" or more similar to the candidate author "B" based on the accepted computed features? Parametric and nonparametric statistical tests are used to measure similarity, e.g. t-test (or Student's-test), chi-square test (or Pearson test), Mann–Whitney, Wilcoxon, and some other tests.

Typological statistics quantifies the so-called language universals. In the 1960s, Joseph Greenberg deduced 11 typological indexes to put languages in some order, e.g. index of synthesis, i.e. the ratio of the number of morphemes to the number of words, or index of complexity of morphological structure; index of agglutination, i.e. the ratio of the number of agglutinative inner morphological links and the number of words with inner morphological links; index of derivation, i.e. the ratio of the number of roots and the number of words; index of inflation, i.e. the ratio of the number of nonreflexive morphemes and the number of words, etc. These measures were further modified and complemented by different linguists to eliminate the shortcomings.

Some linguists include corpus linguistics, a branch of linguistics concerned with the study of language use by means of large text corpora into mathematical linguistics, because they use statistical methods. For the last 30 years, natural language processing has been developing rapidly. The work that has been done in this area has resulted in a large variety of systems constructed for specific applications. Very often, this particular field is called computational linguistics, and is considered to be a separate discipline in its own right. This strand of mathematical linguistics is close to machine translation and consists in using the computer as a tool in testing theoretical linguistic models like transformational grammars, Montague grammars, generalized grammars, etc. Computational linguistics include speech synthesis, speech recognition, constructing concordances, etc. It is advisable to include in mathematical linguistics as a discipline all areas of linguistics where various statistical counts and analyses are required.

Maya and Mayan Languages

Sharer's *The Ancient Maya* (1994) begins with a clarification of the more standard uses of the terms Maya and Mayan, citing the first as both noun, as in the Maya, in reference to the Maya people, and as adjective, as in Maya writing. Mayan, on the other hand, is used with reference to the language family,

and the individual languages that make up that family, such as K'iche' Mayan, Yucatec Mayan, etc. These conventions will be adhered to in the present essay.

The Mayan language family consists of 28 extant languages and have approximately 6 million Mayan speakers covering a fairly contiguous geographical area encompassing southern Mexico, most of Guatemala, and parts of Belize, El Salvador, and Honduras. The number of speakers of individual Mayan languages ranges considerably, with speakers of K'iche', for example, spoken in southern Guatemala, numbering more than 1 million, while others, such as Itzá, spoken in the Peten of Guatemala are on the verge of extinction. The one group of Mayan speakers not geographically bound to the rest of the family, the Huastecs, migrated north some 4,000 years ago along the Gulf Coast to present-day Veracruz. It is believed that at approximately the same time, the Yucatecan branch of the Mayan family separated from the main body. This subgroup consists of four languages spoken throughout the Yucatan Peninsula, northern Guatemala, and parts of Belize. Yucatec Mayan, by far the largest of this subgroup in terms of speakers, numbering approximately 1 million, is the language of the three of the four surviving hieroglyphic books, or codices.

The main Mayan language body subsequently split into eastern and western subgroups, each with several offshoots, including, ultimately, the Cholan languages, the principal languages of Maya hieroglyphics. Much of recent inquiry and investigation into Mayan and among the Maya people has been generated by interest in the decipherment of the ancient Maya writing system, as explored thoroughly in Coe's *Breaking the Maya code* (1992).

In order to gain an appreciation of the richness of Mayan, it is important to define a few concepts and linguistic elements commonly addressed in the literature on this indigenous language family. Each will be defined and examples will be cited within the section in which they appear. The language examples cited herein, while limited to Yucatec Mayan, will serve to illustrate a number of features found cross-linguistically throughout the entire Mayan family. For more detailed explanations of a number of grammatical features in several Mayan languages, see Robertson's *The history of tense/aspect/mood/ voice in the Mayan verbal complex* (1992). The examples cited will utilize the standardized alphabet agreed to by *La Academia de la Lengua Maya de Yucatán, A.C., Mayáon, A.C.,* and others, in 1984, an important point as many recent publications and dictionaries, let alone older and colonial texts and materials, frequently do not. The topics presented in the following segments include the grammatical category aspect, the pronominal system, the concept of ergativity, the numerical system and numerical classifiers, and finally the phonological system.

Aspect

The term aspect is frequently overlooked in language teaching and learning. Comrie (1976) comments that in spite of the usage of more traditional terminology, for example, tense, with regard to the temporal relations expressed in sentences, such as *John painted the house last summer* and *John was painting the house last summer,* the distinction between these two is not one of tense, but rather of aspect. Both sentences occur in the past; thus; an additional explanation to account for the difference in meaning must be given. Aspect is the grammatical term used to describe how a situation or action is viewed. When the meaning expressed by the verb is viewed in its entirety as completed, the term perfective is used to indicate the aspectual category. When it is not viewed as completed, and makes no reference to the beginning or end of the action or state, the term imperfective is used.

Mayan languages do not have tenses, but denote temporal distinctions by means of a number of aspect markers and particles. Bricker et al. (1998) list the following aspect categories for Yucatec Mayan:

Assurative future	je'el…e'	Je'el in wilikech. I **will** see you.
Completive	t-…(-aj)	*Tin wilajech.* I saw you.
Compulsive	yaan	*Yaan in wilikech.* I must see you.
Definite future	k-…-j	*Kinj ilikech.* It is I who will see you.
Desiderative	taak	*Taak in wilikech.* I need to see you.
Durative	táan	*Táan in wilikech.* I am seeing you.
Habitual/Incomplete	k-…(-ik)	*Kin wilikech.* I see you.
Inceptive	jo'op'	*Jo'op' in wilikech.* I began seeing you.
Obligative	k'abéet	*K'abéet in wilikech.* I need to see you.
Proximate perfective	táant…e'	*Táant in wilikeche'.* I just saw you.

Additional aspect markers include constructs such as a continuous past (*laayli'…e'*), a remote future (*Bíin…*), etc. By means of these elements, Mayan speakers indicate their perceptions of the internal temporal components of a situation, without reference to external criteria needed for tense distinctions such as present, past, and future.

Pronominal System and Ergativity

The pronominal system of Mayan consists of three sets of pronouns, commonly referred to as Set A, Set B, and the Independent Set. Set A pronouns in Yucatec serve as subjects of transitive verbs, as subjects of intransitive verbs in the incompletive aspect, and as possessives. Set B pronouns serve as direct objects of transitive verbs and subjects of intransitive verbs in the completive aspect. The Independent pronouns are used for emphasis or clarification at the beginning of a sentence, with topical marker -*e'*, also at the beginning of a sentence or clause, and as indirect objects. Whereas the pronouns of Sets A and B are bound to an aspect particle or word, or to a verb, the Independent pronouns are free of such attachments, and hence the designation.

Set A pronouns

	Singular	Plural
1st person	in-	k-
2nd person	a-	a-...-e'ex
3rd person	u-	u-...o'ob

Set B pronouns

	Singular	Plural
1st person	-en	-o'on
2nd person	-ech	-e'ex
3rd person	-Ø	-o'ob

Independent pronouns

	Singular	Plural
1st person	teen	to'on
2nd person	teech	te'ex
3rd person	leti'	leti'o'ob

The uses of Set A and Set B pronouns summarized above illustrate a linguistic phenomenon common to perhaps one quarter of the world's languages, that of ergativity. Ergativity is the "term used to describe a grammatical pattern in which the subject of an intransitive clause is treated in the same way as the object of a transitive clause, and differently from transitive subject (Dixon, *Ergativity,* 1994:1)". In English, this could be rendered as *She see him* and *Him sees,* and *He sees it,* where *him* is the direct object of the transitive verb in the first example, and the subject of the intransitive in the second, complementary to the use of *He* as subject of the transitive in the third example.

The following figure shows a representation of Dixon's universal syntactic–semantic primitives, in which the letter A symbolizes the subject of transitive verbs, with S representing the subject of intransitives, and O, the object of transitives. In the nominative–accusative case marking pattern found in English, for example, the subject of transitive and intransitive verbs is treated equally, that is, they are the same; it is the object pronoun that is marked differently. In Mayan, an ergative–absolutive family of languages, the subject of intransitives and the object of transitives are marked in the same manner, and different from the subject of transitives.

$$\text{nominative} \left\{ \begin{array}{ll} A & \text{ergative} \\ S & \\ \end{array} \right.$$
$$\text{accusative} \quad\quad O \left. \begin{array}{l} \\ \end{array} \right\} \text{absolutive}$$
Many of the Mayan languages have developed a split ergative system when certain constructions follow the ergative–absolutive pattern of the ancestral Common Mayan language, and others follow a nominative–accusative pattern. This split in the usage of pronouns is aspectual in nature, with an incompletive aspect following the nominative–accusative configuration, and completive, the ergative–absolutive.

Numerical System and Numerical Classifiers

The Maya developed a vigesimal numbering system, that is, based on 20 rather than a decimal, base 10 system. Unlike English, the numbers in Maya cannot be used in isolation. For example, in response to the question *How many brothers do you have?*, you cannot say simply, *One.* The numbers are always used with a numerical classifier, denoting animacy, measure, or shape. A similar phenomenon in English can be seen with measurements and group classifications such as *a pinch of salt, a flock of geese,* and the like. A list of some of the more commonly used classifiers includes the following.

-cháach	a handful of something
-chi'náab	a measure from the thumb to the end of the forefinger
-kúuch	a load of something, typically carried on your back
-kúul	for plants
-lúub	a measure of distance of approximately four kilometers
-náab	measure from thumb to end of little finger; a handspan
-p'éel	for inanimate objects
-p'u'uk	a mouthful
-sáap	a measure of depth, equivalent to a fathom
-téen/-púul	number of times something is done
-ts'áan	a pair of things
-ts'íit	long, thin shape
-túul	for people, animals, etc.
-wáal	for flat, thin objects, such as tortillas
-xéet'	a piece of something

Phonology

Tozzer (1921), addressing issues of Mayan pronunciation from one of the earliest grammars written on Yucatec Mayan, that of Beltran de Santa Rosa dating back to 1746, says (translated):

> Because in this language you don't speak entirely like you write, nor do you pronounce many words according to the rules (and hence, some who speak it sound like foreigners or are judged as not speaking as they should; being thus, that they speak in accordance with the rules of the grammar) be advised that the use of synalepha and syncope is so necessary, that without hyperbole one may state, that all of the being and attractiveness of this language is the use of them and the main part of its grammar is their explanation.

> Syncope is no other thing than swallowing some word or some syllable, some vowel or consonant. And this figure so graces the Mayan tongue that without it it seems that her words become strange, unpleasant and in her cadence, ugly. In such a manner, that I can without recklessness say that almost one half of her words are syncoped or are syncopable.

Indeed, there are a number of phonetic changes in Mayan that clearly distinguish the written form from the spoken. Three such phenomena are syncope, the loss or suppression of one (or more) sounds in the interior of a word, synalepha, the fusion into one word from the final syllable of one word with the initial of the next, and finally, apocope, the cutting off or omitting of the last sound or syllable of a word. Occurrences of each can be seen in the following examples.

Syncope	• The transitive verb with a pronominal object may lose the **-i-** of **-ik** in the incompletive and the **-a-** of **-aj** in the completive: **Kin wilikech.** → **Kin wilkech.** • All polysyllabic transitive verbs lose the vowel of the temporal endings before the **-o'on** of the 1st person plural, **-e'ex** of the 2nd person plural and **-o'ob** of the 3rd person plural: **Tu ya'alajo'on.** → **Tu ya'aljo'on.** • In words of two syllables containing two similar vowels, the second is lost when the plural is used, a verbal pronoun is used, or a demonstrative pronoun is used: **xanab** → **xanbo'ob**
Synalepha	• Contraction of durative and A pronoun: **táan in** → **tin, táan a** → **tan** • Contraction of terminative and A pronoun: **ts'o'ok in** → **ts'in, ts'o'ok a** → **ts'a** • The negative **ma'** and the nominal pronoun: **ma' in** → **min**
Apocope	• Word final **-l** is lost in most cases: **Tun weenel** → **Tun weene.** • **j** → **Ø** optionally in many cases

An additional element of Mayan phonology of note is the predominance of stops among both consonants and vowels, a phenomenon whereby the flow of air through the oral cavity is briefly interrupted. An example of a glottal stop in English can sometimes be heard replacing the *t* sound in the word *button*, with the flow of air momentarily restricted at the vocal cords. All five of the vowels in Mayan may incorporate a glottal stop, as in *ma'*, no, and *si'*, firewood. All of the vowels may be reduplicated, in which the vowel is interrupted by the stop and then rearticulated, as in *ba'alo'ob*, things, and *tu'ux*, where.

The occurrence of stops on the consonants ch, p, and t, indicated in written form by the addition of an apostrophe, ch', p', t', is said to be phonemic in Mayan, as the articulation of these stops can serve to distinguish a word with them from another word without, as in *maak*, to cover, and *maak'*, to eat quickly, *chak*, red, and *ch'ak*, to cut with an ax.

A final distinctive phonological element common to many of the Mayan languages is that of pitch. Yucatec Mayan is a tonal language, with three distinctive tones. One is long and high, and the other is long and low, as in x*uul,* end, and x*úul,* planting stick, and *miis,* cat, and *míis,* broom. The third tone is realized on short vowels, and is considered neutral.

It is sincerely hoped that the preceding essay has provided you with a very brief but enticing introduction to the Maya and their languages, and that as a result of the planting of this infinitesimal grain of linguistic sand, your interest and enthusiasm for linguistics grows and develops into your own unique pearl.

MICHAEL VROOMAN

McCawley, James David

An enthusiastic student, James David McCawley was admitted to the University of Chicago in 1954 at age 16. He took his MS in mathematics four years later. He was awarded a Fulbright Fellowship in 1959–1960 to attend Westfälische Wilhelms University in Münster, Germany. Although the fellowship was to study mathematics, McCawley's interest began to be drawn more toward languages. He studied a variety of languages, including Dutch. After the Fulbright year, he returned to the University of Chicago, where he continued his exploration of languages, taking Japanese and falling in love with it. During this period, he read Noam Chomsky's seminal work *Syntactic structures*. Linguistics as a field of study beckoned. He applied to MIT and was accepted in their first Ph.D. class in Linguistics. In 1965, he completed his dissertation under the direction of Noam Chomsky: *The accentual system of modern standard Japanese*.

McCawley returned to the University of Chicago, where he received tenure in 1969 and became a full professor in 1970. In the summer of 1971, he met then Ph.D. candidate Noriko Akatsuka. After a whirlwind courtship, during which Dr. McCawley went to Japan to formally ask for her hand, they were married on Beethoven's birthday, December 16, 1971. Dr. Akatsuka joined Dr. McCawley at the University of Chicago.

Dr. McCawley's interests were broad-ranging. He published on elements of phonetics and phonology as well as on syntax and semantics. His early training in mathematics put him at ease with the abstract formal systems of syntactic form and semantic integration. One of his most influential works attempted to make these mysteries accessible to his colleagues and students: *Everything that linguists have always wanted to know about logic (but were ashamed to ask).* Chicago: University of Chicago Press, and Oxford: Blackwell. He was a dedicated and accessible teacher, sharing his library, notes, and insights. The courses he taught ranged from introductory linguistics courses, syntax and semantics, to 'tense and aspect', 'discourse structure', and 'speech acts' to 'tone in Bantu languages' and 'Japanese phonology'. His inventory was so extensive that rather than attempting a term-to-term rotation of classes offered, Dr. McCawley would circulate a list of topics and ask students to choose.

His stature as an internationally recognized scholar and his outstanding ability as a mentor won him a named chair at the University of Chicago. He became the Andrew MacLeish Distinguished Service Professor of Linguistics and of East Asian Languages and Civilizations.

He was widely sought after as a speaker and as a guest faculty member. He accepted visiting or temporary appointments in 17 Universities, including the University of Illinois, University of Gööteborg, Australian National University, University of Hawaii, University of New Mexico, Central Institute of English and Foreign Languages (Hyderabad, India), Guangzhou Institute of Foreign Languages, and National Tsing Hua University (Hsinchu, Taiwan).

He served the Linguistic Society of America in a number of positions: as a member of the Nominating Committee (January 1974 to December 1976; Chairman 1976); as a member of the Executive Committee (January 1978–December 1980); as Vice-President (1995); and as President (1996). He became a member of the American Academy of Arts and Sciences in 1983, and served a term as its President. Dr. McCawley was associate editor of five professional journals; consulting editor for four; and on the editorial board of another five.

Dr. James D. McCawley brought joy and enthusiasm to his study of linguistics. He regularly hosted parties to celebrate linguistics with students and colleagues. He

championed Hanggul Day, the day the Hanggul alphabet was officially adopted by Korean, as *the* linguistic holiday. He composed linguistic doggerel for the University of Chicago departmental holiday commemorating the movement of the offices from Goodspeed Hall, annually celebrated with songs and counterscholastic papers. James D. McCawley had a famous alter ego, Quang Phúc Đông, who produced fine studies in scatological linguistics. His students honored him with a festschrift in this little developed genre: *Studies out in left field: defamatory essays presented to James D. McCawley on the occasion of his 33rd or 34th birthday*.

In addition to linguistics and music, Dr. McCawley had a passion for good food. He was a gourmet and an excellent cook. A condition for guest lectures was often an eater's tour of the host city. He shared his knowledge of and pleasure in Chinese cuisine through his book: *The eater's guide to Chinese characters*.

Dr. McCawley was also a staunch Libertarian. He ran as the Libertarian candidate for the Trustee of University of Illinois in 1976, 1978, and 1980. Throughout his career, he refused to accept federal funding for his research or to review other scholar's proposals for such studies.

James D. McCawley is known for his pioneering work on the interface of syntax and semantics, for his skepticism of theory, and for his demand for rigorous treatment of data. His publication record is outstanding. A full list can be found on his web-page: http://humanities.uchicago.edu/depts/linguistics/faculty/mccawleycv.html He set the framework for studies of tonal and near-tonal systems in works such as 'Some tonal systems that come close to being pitch accent systems but don't quite make it' (1970) and 'What is a tone language?' (1978). He provided a clear critique of syntactic theory in works such as (1982) *Thirty million theories of grammar* and (1988) *The syntactic phenomena of English*. At the time of his death, Dr. McCawley had several works in progress, including two books. His students have prepared him another festschrift. His lasting contributions, both in print and through the impact of those he has trained in the field, form a modern linguistics respectful of data and meticulously formal.

Biography

James David McCawley was born James Quillan McCawley, Jr in 1938, in Glasgow, Scotland; post-World War II, he emigrated as a minor to the United States, acquired citizenship, and changed his name to James David McCawley. He earned an M.S. in mathematics from University of Chicago in 1958 and earned a Ph.D. in linguistics from Massachusetts Institute of Technology in 1965 for his thesis on 'The accentual system of modern standard Japanese'. He worked as a translator of Russain math books for University of Chicago 5–9/59, 8/60–1/61; for the mechanical translation group at MIT 1–7/62, 2–6/63; as a teaching assistant for German at MIT 9/62–1/63; and as a research linguist for IBM Watson Research Center, Yorktown Heights, NY, 6–9/64. He took up a position as Assistant Professor of linguistics, University of Chicago, 9/64 and held this position until 9/69 when he advanced to associate; then, in 9/70, he became a full professor of Linguistics. He was appointed the Currently Andrew MacLeish Distinguished Service; during his tenure at Chicago, he held visiting appointments at Tokyo Center for Advanced Studies in Language, 6–9/67; University of Illinois (Linguistic Institute), 6–8/68; Scandinavian Summer School of Linguistics, 8/69;University of Göteborg, 9–12/69; University of Michigan, 1–4/70; Fifth International Seminar on Theoretical Linguistics, Tokyo, 8/70; University of California at Santa Cruz, 6–8/71; Australian National University (Canberra), 6–8/73; University of Hawaii (Linguistic Institute), 7–8/77; University of Illinois at Chicago, 1–3/78; University of New Mexico (Linguistic Institute), 6–8/80; Central Institute of English and Foreign Languages (Hyderabad, India), 7–8/80; University of Maryland (Linguistic Institute), 7–8/82; Georgetown University (Linguistic Institute), 6–8/85; Linguistics, Institute on Transformational-Generative Grammar, University of Delhi, 8–9/85; Guangzhou Institute of Foreign Languages, 9/87; University of Arizona (Linguistic Institute), 6–8/89; and National Tsing Hua University (Hsinchu, Taiwan), 2–6/94. He served as editor for 15 journals, and was president, vice-president, and held other posts within the Linguistic Society of America; May 1983, he was appointed fellow of American Academy of Arts and Sciences. He was also three time Libertarian candidate for Trustee of the University of Illinois. In 1991, he received an honorary Ph.D. from University Göteborg, He authored 225 scholarly articles and seven books; he was also dedicatee of Zwicky, Salus, Binnick, and Vanek (eds.), Studies out in left field: defamatory essays presented to James D. McCawley on the occasion of his 33rd or 34th birthday (Edmonton: Linguistic Research, 1971; reprinted 1992, Amsterdam and Philadelphia: Benjamins), and of Brentari, Larson, and MacLeod (eds.), *The joy of grammar* (Amsterdam and Philadelphia: Benjamins, 1992); and one forthcoming. McCawley died on April 10, 1999.

JUDITH M. MAXWELL

Meaning

The linguistic study of meaning has traditionally concentrated on investigating conceptual or logical meaning, known as 'sense'. However, logical or conceptual meaning is not the only kind of meaning that sentences or utterances convey. In terms of child development, the interpersonal meanings of language are primary. And utterances might tell you who the speaker/writer is (idiosyncraey), their age or when they were speaking (age), what activity they are engaged in (occupation), where they come from (provenance), their relationship with the hearer/reader (status), and whether they are speaking or writing or combinations of these, such as reading aloud (mode) (Crystal and Davy 1969). It is clear that all these are social and interpersonal meanings, except the last, which is textual.

Semantic and Pragmatic Meaning

The distinction between interpersonal and conceptual meaning is in partial correspondence with the distinction between pragmatic and semantic meaning. Pragmatics answers the question 'What did the speaker A mean by uttering sentence X to hearer B in context C?', whereas semantics answers the much simpler question 'What does sentence X mean?' In pragmatics, meaning is a matter of what effect the speaker intends to produce in the hearer by making an utterance, which makes it interpersonal. Semantics has to do with the meanings of sentences and how these meanings can be computed by the meanings of their component parts (clauses, phrases, words, and morphemes) (Leech 1983).

Of course, we naturally encounter and learn meanings in pragmatic and social contexts, especially in our first language. Investigation of semantic meaning always involves an idealization and generalization of the meanings of the language code, abstracted from particular contexts. Such an idealization was thought necessary in order to make any progress in studying linguistic meanings scientifically and logically. However, it is apparent that semantics on its own cannot give anything like a full meaning to a sentence; in other words, semantics underdetermines meaning. One most obvious problem area is *deictic terms* (from *deixis* 'pointing'), whose meaning depends on knowing who uttered them (to whom), when they were uttered, and where they were uttered. The pronouns *I* and *you*, and the adverbs *now, yesterday,* and *here* are clear examples. But deixis is much more widespread than its occurrence in a few isolated lexical items. Most tense markers or aspectual particles are time deictics. Past, present, future, and more complex tenses refer to periods of time relative to the time of utterance. 'I saw him here yesterday' is incomplete in meaning unless we know the time of utterance so that 'saw' and 'yesterday' refer to a period of time previous to that time. In addition, we have to know where the speaker is to understand 'here', and who the speaker is to understand the referent of 'I'.

A related aspect of the pragmatic/semantic distinction is the difference between reference and sense (Frege 1892). Reference is the relationship between a phrase and the thing in the world that it identifies. The sense, however, is the concept represented by the meaning of the phrase. The versatility of language lies partly in the fact that any one sense can be used to refer to many different entities. *Woman,* whose sense is, let us say 'adult female', might be used to refer to any one of the two billion women in the world. Just as the relationship between sense and referent is one-to-many, so is the

reverse relationship between referent and sense—in other words, there are many different phrases with different senses that could be used to refer to the same individual: *The former president of the United States, the man from Arkansas, this consummate orator, the sexual partner of Monica Lewinsky.*

While reference in normally conventional, in that a particular phrase guides us quite clearly to identify the referent, this is not the case with metaphor—where the reference is unconventional. And names have no or little sense—we simply have to learn the pairing between each individual person or thing and the language form that refers to them.

Coded and Inferred Meanings

Words or lexical items can be seen as signs making up the linguistic code. These signs consist of a signifier (phonological or graphological form) and signified (meaning), like two sides of a piece of paper (Ferdinand de Saussure 1960). In general, these pairings are thought to be arbitrary; otherwise, languages would resemble each other much more (there is nothing about the form *dog* that makes it more suitable than the French *chien* to act as a signifier of 'dog'). Hence, in terms of semiotics (the study of signs), most linguistic signs are symbols (involving no resemblance between signifier and signified) rather than icons (based on resemblance) (Peirce 1940:104). This arbitrariness is not absolute, however. Some signifiers are obviously iconic, based on ono-matopoeia, e.g. *splash*, and at a more subtle level non-English speakers can guess quite reliably which word *tin* or *thunder* is most suitable as a signifier for the signified 'thunder'.

However, linguistic communication in any language is also heavily reliant on non-coded meanings, created by pragmatic inference, and some languages are perhaps more reliant on inferences from context than others. Chinese, for example, without a highly developed system of tense for time reference, leaves it to be inferred from the context.

Meaning, Social Context, and Ideology

While some inferences and interpretations might depend upon supplying general knowledge, many meanings are dependent more specifically on awareness of the context of utterance. Apart from conversation and narrative, discourse types generally occur in specific institutional contexts—lectures in an academic institution, sales reports in a business context, golf score-cards at a golf course, and so on. The concepts of register and genre are an attempt to systematically link discourse types with their institutional contexts. Each context has certain meaning potentials—likelihoods that certain meanings will occur in them.

Ideology can be seen operating directly in the meanings of words and clauses. According to Benjamin Lee Whorf (1956) and his theory of linguistic relativity, the world does not come to our consciousness in ready-made categories, but different languages dissect the continuity of our experience in different ways. Whorf's hypothesis, unfashionable for many years due to the influence of universalism in linguistics, has lately been rehabilitated to some extent (Lee 1996; Gumperz and Levinson 1996). This tradition, taken over later by Critical Discourse Analysis, emphasizes that language and its meanings are not a transparent medium through which reality is observed, but distort and construct that reality, giving us the concepts through which we think. The languages we speak hand down to us ready-made categories, which we regard as commonsense. They thereby unconsciously carry with them an ontology or ideology of which we may not be aware.

The classic case is of kinship categories. In Thai, for example, the primary criterion for categorizing siblings is by seniority rather than by sex as it is in English; elder sibling /phî:/ and younger sibling /nó:ŋ/. And this difference in ontology has ideological implications. Senior siblings in Thai culture have greater rights and responsibilities than in most Western cultures, traditionally giving orders and making demands of younger siblings, but also taking care of them and their welfare. Furthermore, Thais use these words as terms of address and second person pronouns with friends and acquaintances as well as with blood siblings, so that in a friendly conversation with a new acquaintance, when it is not obvious from appearances which of the conversational partners is the older, at some point the question has to be asked about relative age, to facilitate polite discourse and correct interpersonal behavior.

More generally, we may just not take much notice of things if we have no words for them in our language. In Chinese, there is a common word for the groove that runs between the middle of the upper lip and the nose. There is no such word in English. Presumably, this contrast reflects the unimportance of this aspect of reality to English speakers, and its importance to folk physiognomy in China.

Sometimes, of course, ideology is more obviously encoded in words and then they may become the site of ideological struggle. Was the movement of white people into Australia or Israelis into Palestine 'settlement' or 'invasion'? These words and their meanings then become contested terms. There can often be attempts to redefine the meanings of terms as

in 'property is theft'. Alternatively, one could try to replace a fashionable term with another that better suits one's ideology. For example, economic *growth* might be replaced with *cancer*, since from an ecological standpoint, growth in mature economies actually harms the environment and threatens our life-support systems. In discourse, there is often an ideological struggle to get one's meanings and metaphors accepted as the conventional ones.

Structuralism and Deconstruction

A parallel emphasis on the determination of meaning by code has been found in studies of literary meaning. Structuralism emphasized that a speaker or writer does not impart meaning to utterances, but that the code, the linguistic system underlying them, produces it. This conviction led to literary analysis aimed at revealing the underlying structures, which, rather like the grammar or morphology of the linguistic code, determine the shape of the texts that realize them (see, for example, Vladimir Propp's (1958) *Morphology of the folk tale*).

Structuralism gave way to deconstruction under the influence of Roland Barthes and Jacques Derrida. Barthes (1970) emphasized the radical ambiguity of the sign as part of the code and the play of signifiers. For him, literary meaning could and should not be constrained within the concept of unity as structuralism tried to pretend. Barthes valued literature that was less than easy to read, less than *lisible*, because it breaks with the coded conventions. In this type of writable or *scriptible* literary text, the 'code' items are echoic, intertextual, fragments of voices from other texts and from other codes. Derrida (1967) with his notion of *differance* (difference/deferring), suggested that signifiers have shifting signifieds whose meaning is never complete, because the text at hand always has reverberating connotations and each use of a text further develops its meaning. More extremely, for him, language became a play of signifiers without any signifieds—with nothing existing outside the text, and no meaning or truth independent of language (Jefferson and Robey 1982).

Reader Response, Dialogism, and Intersubjective Meaning

Less extreme than Derrida's emphasis on radical instability and subjectivity of meaning are the theories of Stanley Fish (1980) and Mikhail Bakhtin and Valentin Volosinov (1973). For Fish, meaning is 'an action made upon a reader rather than a container from which a reader gets a message'. Meaning is the experience of the process of reading in the reader's

head. He illustrates this with the sentence 'That Judas perished by hanging himself there is no certainty', which begins with the presupposition 'Judas perished by hanging himself', leading us to anticipate that the sentence will end with the word *doubt*, but reversing our expectation of certainty by ending with the word 'certainty'! However, Fish showed that it is not the subjective meanings of the individual reader that constitute either what is literature or how it should be read, but rather the inter-subjectivity of the interpretive community, into which readers are inducted by learning the conventions of how to read and make meaning.

Bakhtin too, emphasized the intersubjectivity of meaning by insisting that it only exists in dialog. Meaning is like a spark between two electric terminals (the speakers), and hence 'word is a two-sided act. It is determined by whose word it is and for whom it is meant'. Intertextually, words bear the traces of their past uses by previous speakers, and language is therefore never in one's own words but other people's words: 'the trouble with words is that you don't know whose mouth they've been in'. These uses and traces tend to be evaluative and ideological, part of social struggle. It follows from this view that 'the analysis of meaning should be based not only, and even not as much, on linguistics as on metalinguistics which studies the word not within the system of language and not in a text which is removed from dialogical intercourse, but precisely within the sphere of dialogical discourse itself'. Bakhtin's theories raise radical questions about the distinction between analytic (definitional) and synthetic (descriptive) meaning and the tension between meaning stability and meaning change.

Meaning, Metaphor, and the Experiential Hypothesis

Another alternative to subjectivity can be found in the experiential hypothesis that grew out of studies of metaphor. In its infancy, during the heyday of Chomskyan linguistics, the science of semantics attempted to marginalize metaphor as an anomaly, because nonliteral meanings posed challenges to semantic rules like selectional restrictions—the rules that stipulate what semantic pairings were allowable between phrases in a syntactic relationship. Noam Chomsky held his famous sentence 'colourless green ideas sleep furiously' to be semantically ill-formed because *sleep* should be restricted to human or animal subjects, *green* is only allowed to premodify concrete, not abstract, things, and so on. However, it is possible for an inventive reader to interpret this sentence metaphorically: 'Although ideas about protecting the

environment are boring, ignoring and suppressing them will only delay an angry social reaction.'

Besides such challenges, George Lakoff and Mark Johnson (1980) made clear that metaphor could not be ignored as it was all-pervasive, even in the language of those who try to reject it. For example, John Locke in this passage uses the metaphors 'move', 'mislead', and 'cheat'.

> But yet, if we would speak of things as they are, we must allow that ... all the artificial and figurative application of words eloquence hath invented, are for nothing else but to insinuate wrong ideas, move the passions, and thereby mislead the judgment, and so indeed are perfect cheat. [*Essay concerning human understanding* Book 3, Chapter 10, p.105]

The claims of Lakoff's conceptual metaphor theory (Lakoff 1987) are that abstract thought is fully possible only through the use of metaphor, and that these conceptual metaphors originate in our bodily infant experiences. We have certain preconceptual experiences as infants, such as body movements, our ability to move objects, to perceive them as wholes and retain images of them; and certain image schemas that recur in our everyday bodily experience, e.g. containers, paths, balance, up and down, part and whole, and front and back. The hypothesis claims that most abstract concepts arise from these preconceptual physical experiences and schemas by metaphorical projection. For example, abstract concepts like amount are conceptualized by projection from the bodily experience of up and down, producing a number of lexicalized metaphors:

> The number of books printed each year keeps on **going up**.
> My income **rose/fell** last year.
> If you're hot, turn the heat **down**.
> He is **under**age.

Many of the basic links in conceptual metaphors can be traced back to metonymic relations such as cause and effect. Hence, for example, if we have more things in a pile it will be higher than when we have less things, a possible origin of this set of lexical items. And there is a well-established set of metaphorical vocabulary in English, and other languages, which conceptualizes anger as heat. The origin of this is quite obviously one of cause and effect—when we become angry, our bodies do actually rise in temperature.

In the light of the lexical evidence for this hypothesis, Lakoff went on to develop an Experientialist philosophy, rejecting the Objectivist and Subjectivist paradigms. The problem with Objectivism is the independence assumption, namely:

> Existence and fact are independent of belief, knowledge, perception, modes of understanding, and every other aspect of human cognitive capacities. No true fact can depend on people believing it, on their knowledge of it, on their conceptualization of it, or on any other aspect of cognition. (Lakoff 1987:164)

Lakoff cannot accept this assumption, because, although there is a reality out there, we do not have unmediated access to it, as our thinking is inescapably mediated by the metaphors we use. Even scientific theories and models are basically metaphorical hypotheses that can only approximate descriptions of reality, and a new scientific model will initiate a programe of research trying to establish what features of the model do or do not apply. On the other hand, Lakoff rejects subjectivism and relativism, because infant bodily experiences are universal; hence, our conceptual metaphors are held in common. Experientialism, then, steers a middle course between objectivist philosophical traditions, which assume that truth is something we can access independent of any description of it, and subjectivism, which believes that truth is a matter of individual belief, relative to circumstances. However, unlike Critical Discourse analysts, Lakoff sees the body, not culture and ideology, as the determinant of thought and ontology.

Objectivist views of meaning disregard the idea that ideology and meaning exist intersubjectively in a dialectical relationship with each other, or that our physical experience of embodiment determines thought. According to Lakoff, the objectivist hypothesis claims that reality and fact are independent of observation or perception, or, for that matter, language. Within the objectivist paradigm of semantics, there arose a truth-conditional approach to meaning: knowing the meaning of a sentence is equivalent to knowing the conditions under which that sentence would be true. Clearly, if language constructs reality rather than merely reflecting it, the truth-conditional theory of meaning becomes circular to some extent. This is related to another problem, which is that truth–conditional semantics has tended to restrict itself to analytical statements rather than synthetic statements. A synthetic statement is one that is contingently true or untrue, such as 'Beckham transferred to Real Madrid', whereas an analytical statement is one that is necessarily true, such as 'boys are male'. It is doubtful whether theories of meaning, which exclude synthetic statements, can be useful models for the meaning of natural languages in real–world contexts.

Medicine and Language

The description of language in medical encounters is one of the oldest and most prominent topics in discourse analysis (the study of the sequences and organization of language in context). The topic is interesting for theoretical and applied reasons: Theoretically, the description of language in medical encounters contributes to our understanding of institutional interaction, symmetrical and asymmetrical roles and relationships as created and reflected by discourse, and specialized sequences within the interaction of medical encounters (Drew and Heritage). Practically, the description of language in medical encounters allows linguists to help medical professionals improve communication and to help patients and families work effectively with medical professionals.

In Western industrialized societies, the medical encounter has a recognizable event structure. One of the first articles on the medical encounter by British researchers Byrne and Long examined more than 2,000 medical encounters and identified the typical parts of an encounter: (I) relating to the patient (greetings and small talk); (II) discovering the reason for the encounter (the patient complaint); (III) conducting a verbal or physical examination, or both (the history and physical); (IV) consideration of the patient's condition (delivery of diagnostic opinion and information); (V) detailing treatment or further investigation (treatment and advice); and (VI) termination (small talk and closing). Each part of the encounter is associated with conventional discourse sequences: question and answer in the history and physical, for example, and imperatives in the delivery of treatment and advice. Byrne and Long found, however, that the discourse of the medical encounter is highly asymmetrical: it is the physician who interactionally controls most of the discourse. The physician asks the questions, controls the topics and their development, deflects or ignores patient topics or contributions that he or she deems irrelevant, provides the amount of medical information that he or she deems appropriate, and determines the amount of social talk in openings and closings. The institutional power and authority of the physician, as well as the relatively powerless institutional position of the patient, then, are created, reflected, and maintained by the asymmetrical discourse practices of the encounter.

The asymmetry of a medical encounter—the control of the physician over the discourse—was a topic of much investigation in early research on language in medicine. Some of these asymmetries were troubling because they were seemingly related to issues of gender, class, and ethnicity. For example, a number of studies described the ways physicians ignored topics mentioned by female patients, especially when those topics moved

away from the medical world and toward the patient's personal world with its complicated psychological and social conditions (Mishler; Waitzkin). Paget argued that sequences like the following show how female patients' topics can be ignored by physicians who are in control of the discourse:

(1) PT: (sigh) I dunno.
    I'm thinkin maybe it's a hormone deficiency or something.
    DR: Let me just look at the scar.
    No-no that's awright.

During the interaction of physicians and female patients, these kinds of asymmetries are found in topic control and development (Davis). Other studies noted the ways that medical care seems to be practiced differently when patients are from different social classes and ethnicities. Fisher studied encounters in two different gynecological clinics: a community clinic staffed by resident doctors-in-training and attended by mostly poor minority women and a faculty clinic staffed by university physicians and attended by mostly middle-class white women. She found that women in the community clinic received more treatment recommendations for hysterectomies than women in the faculty clinic and, in fact, were not told that options other than hysterectomy were available. In the decision-making sequences in the faculty clinic, physicians often used questioning strategies: for example, a question such as *Now did Karen explain to you the abnormal, what the abnormal Pap smear business is?* can function to give patients a chance to display their knowledge and competence as background for collaborative decision-making. Patients, too, in the faculty clinic used questioning strategies: for example, a question such as *Is that necessary?* opens up the discourse to the discussion of alternative treatment options. Physicians and patients in the community clinic, however, often did not use questioning strategies, thereby reducing the chances that the discourse of the encounter would develop into collaborative decision making. The discourse in the community clinic was more oriented to persuasional strategies justifying the physician's choice of treatment, as in the following sequences (note that there are no contributions from the patients in these sequences):

(2) DR: It (cancer) could come back…and for somebody your age, that's had your family, you're sure that you don't want children, I'd recommend a hysterectomy.
(3) DR: What you should do if you don't want any more children is have a hysterectomy. No more uterus, no more cancer, no more babies, no more birth control, and no more periods.

These persuasional sequences, with no mention of other treatment options, contrast with the presentational sequences used in the faculty clinic (note that the contribution from the patient significantly affects the course of the discourse):

(4) PT: Have a hysterectomy and that, I'm that, if there's an alternative. I'm terrified of operations.
    DR: Uh, okay, well, there certainly is an alternative, yeah, we can treat this by just freezing it here in the office and that usually will take care of it about 90% of the time.

Specific discourse practices such as questioning and the presentational or persuasional organization of information can thus have a direct effect on decision-making in the medical encounter. The troubling implication of this particular study was that the discourse of medical encounters seemed to differ on the basis of social class.

Much of this early research on the asymmetrical discourse of the medical encounter focused on question–answer sequences. Several classic studies showed how physicians control the discourse of the encounter by using questions that constrain patients to brief answers. One study looked at the discourse of ten medical encounters and found that patient-initiated questions (that is, utterances in question form that introduced new information or a new topic) comprised less than 1% of the discourse in a medical encounter (Frankel). Another study also found that physicians established question–answer discourse almost immediately after the beginning of the encounter: in this study, physicians typically interrupted the patient's account of the reason for the visit to begin asking questions after only 6 to 16 seconds (Beckman and Frankel). A third study defined questions more broadly as requests for information in any form but still found that patient questions comprised only 9% of the discourse in the 21 medical encounters that were analyzed (West).

These early studies of the language of the medical encounter were focused primarily on the ways physicians used discourse to maintain asymmetrical control of the discourse, with particular attention to the way that question–answer sequences turned the medical encounter into an interview (rather than a more symmetrical consultation or discussion). However, recent research in conversation analysis has been focused on the ways that both physicians *and* patients actively and collaboratively construct the interaction of the medical encounter as a type of institutional discourse (ten Have; Maynard). Sometimes, this construction achieves the asymmetrical discourse of the encounter as described above, with both physicians and patients working interactively to produce asymmetrical discourse. In a study of general practice encounters, for example, Heath found that patients rarely responded to

the delivery of a diagnostic opinion by a physician, not contributing an utterance at all after the delivery of diagnostic news, or offering only a minimal response:

(5) DR: Er, yes, (0.3) this one's blocked, the other one's not.
    PT: (1.2)
(6) DR: You've got, erm (0.8), bronchitis.
    PT: Er
    DR: (4.5) (doctor begins to write prescription)
        I'll give you antibiotics to take for a week.

In both sequences, the physicians offer the patients an opportunity to respond to the diagnostic news (note the pauses, with the number of seconds timed in parentheses), but the patients do not take the interactional opportunity to develop the topic. This kind of minimal response preserves the asymmetrical interactional and institutional power and role of the physician as the expert provider of diagnostic information. Patients, however, have their own interactional means of questioning or disputing a physician's diagnostic news. Although they typically remain silent or contribute only minimally to the discourse right after the delivery of diagnostic news, patients recycle the topic of diagnosis when they disagree with it. For example, a patient may repeat symptoms, emphasize their severity, or question the diagnosis during a different part of the encounter, often during the treatment recommendations or closing. In the following sequence, for example, the patient initially had not responded to the delivery of diagnostic news, but then produced an account of the severity of his symptoms after the physician had turned to the treatment activity of writing a prescription:

(7) PT: That I could understood (.) because it (.)
        it's the headaches was the thing that's
        got me, (0.4) More than anything else.
        (1.2) More than the devil in hell because
        they were getting more or less
        permanent yer know. (1.2) They were coming
        even when I was never—pain in the back of
        me neck.
        (28.00)
    DR: Right well I'll tell what we'll do Mister Tarrett.

Through their own interactional means, then, patients are able to question or challenge the physician's diagnostic opinion, even when they initially appear to have accepted it asymmetrically. A similar pattern was found in another study of the delivery of diagnostic news in a child assessment clinic: patients and families did not initially dispute the diagnostic opinion, but they found interactional ways to return to the topic if they disagreed with the diagnosis (Maynard).

Recent ethnographic research has looked at the ways that the discourse of physicians and patients reflects contextual dimensions such as power and expertise. One study looked at the ways that both physicians and patients made claims to power over the discourse of medical encounters (Ainsworth-Vaughn). In encounters in private practice between physicians and patients with long-standing relationships, the patients asked almost 40% of the questions, thereby controlling the discourse to a significant degree. An early study by Tannen and Wallat looked at the ways in which physicians construct frames for the delivery of medical information based on professional expertise. Two recent studies looked at the ways in which physicians acknowledge and utilize lay expertise in the discourse of medical encounters as well: in a children's disability clinic, families who display lay expertise about the condition of their children were able to move the discourse toward more collaborative decision-making, while families who do not display what physicians deem an appropriate lay expertise concerning their children's condition had medical encounters with a traditionally asymmetric discourse (Barton). These contextual dimensions are thus interactionally dynamic in their effect on the discourse of the medical encounter.

Analysis of the discourse of the medical encounter provides important information for the description of institutional interaction in general and physician–patient interaction in particular. This research has been used in a variety of applications. The curriculum of many medical schools now includes information about medical communication that draws on linguistic research. Community outreach programs, such as support groups, also draw on linguistic research to introduce families to ways of communicating effectively in the institutional context of medicine (e.g. asking questions about diagnostic labels, alternative treatments, and so on). Even consumer publications about medical communication have begun to draw on the research on medical discourse to advise patients and families in their efforts to work toward establishing collaborative discussion and decision-making in medical care.

ELLEN BARTON

Meillet, Antoine

Antoine Meillet's intellectual and scientific life was organized around two fundamental axes: comparative linguistics and general linguistics. Up until 1906, his publications showed his interest in philology in the lineage of Ferdinand de Saussure, as well as his wish to describe and analyze culture in the semantic perspective of Michel Bréal. After 1906, Antoine Meillet became more familiar with the linguistic theories of the French sociologist Emile Durkheim (1858–1917). Then, he widened the fields of investigation and took an increasing interest in the definition of the general laws of linguistics.

Antoine Meillet gave a new vigor to comparative linguistics. For him, the analysis of the grammar of a language went hand in hand with the study of the history of this language. In his historical studies, he was concerned with achieving the highest degree of accuracy possible. He always maintained that linguistic forms cannot and must not be analyzed individually, but the whole encompassing systems have to be taken into account. Therefore, the exhaustive description of given languages was absolutely indispensable. These ideas are clearly formulated in his *Traité de grammaire comparée des langues classiques* (Essay on comparative grammar of classical languages). In the French edition, more than 700 pages refer not only to the linguistic relationship between Greek and Latin but also detail the development of both the Greek and the Latin linguistic system.

Ferdinand de Saussure's work *Mémoire sur le système primitif des voyelles dans les langues indo-européennes* (Report on the primitive system of vowels in Indo-European languages) (1878) made such an impression on Meillet that he used this work as a basic source and often quoted from it. He borrowed the notion of "system" from Saussure and it became the foundation of his work. The *Introduction à l'étude comparée des langues indo-européennes* (Introduction to the comparative study of the Indo-European languages), which explains and develops relationships between various Indo-European languages, is one of the most brillant illustrations of the Saussurean approach.

He also developed a theory of linguistic differentiation in order to explain how linguistic changes that occur at the point of origin of a given language family have less impact on languages in areas that are geographically remote from the point of origin. These more remote languages are thus more likely to retain archaic characteristics from their ancestor language. The impressive number of his contributions to the study of various languages (Armenian, Celtic, German,

Greek, Iranian, Latin, Polish, Slavic, etc.) shows the fruitfulness of his method and his way of thinking. His analyses were of such high quality that they still remain a model for research.

Antoine Meillet's theories on meaning have also remained influential to this day. During the first period of semantic studies, roughly from 1883 to 1931, Darwinian evolutionism gave rise to two opposing arguments. In France, Arsène Darmesteter was a defender of the organicist thesis, which maintained that languages and words must be considered as living organisms, similar to plants or animals. Thus, he argued that while the laws governing meaning may be described as fixed and timeless entities, words are born, live, change, and die according to natural selection. In *Essai de Sémantique* (Essay on semantics), published in 1897, Michel Bréal took up the opposite point of view, saying that language has no reality outside of human activity. For Bréal, the semantic laws are psychological or intellectual laws and govern language-specific patterns of words and sentences. This approach resonated with Antoine Meillet, for whom semantics always had a historical dimension. In "Comment les mots changent de sens" ("How words change meaning"), part of *Linguistique historique et linguistique générale* (Historic linguistics and general linguistics), he argued that modifications in the meaning of words depend on three interdependent sets of factors: linguistic ones (language structures), historical ones (cultural contacts), and social ones.

Throughout his career, he increasingly focused on the idea that language and the social environment are closely intertwined. In his studies on the period of bilingualism in France at the time of the Germanic invasion, he pointed out that antagonistic forces exist among communities, which must be taken into consideration in the description of the linguistic landscape. Due to these efforts, he was considered by some as the founder of a French sociological school. While this may not be completely accurate, his ideas certainly revolved around language as a social fact and he worked on topics that even today remain partly uncharted territory.

While Antoine Meillet is especially known as a comparative and general linguist, his book *Les Langues dans l'Europe nouvelle* (The tongues in New Europe), 1918, and *Les Langues du monde* (The tongues of the world), coedited with Marcel Cohen in 1924, also showed his great interest in dialect study and typology.

Famous for his publications and his personality, Antoine Meillet became a leader of a linguistic school. Many people were influenced by his theories and his works, like Émile Benveniste, Marcel Cohen, Gustave Guillaume, Louis Hjelmslev or André Martinet, and even Leonard Bloomfield in the United States admitted that his research on sentence structure were inspired by Meillet's ideas. Since Antoine Meillet's work was both innovative in its theoretical approach and rigorous in its implementation, and since it exhibited an interest in all languages, it can still be used as a stepping stone for further linguistic research.

Biography

Antoine Meillet was born in Moulins, France on November 11, 1866. He graduated at the Sorbonne in Paris, in 1885. In 1890, he conducted one year of fieldwork in the Caucasus, studying modern Armenian. Then, he became director of comparative Indo-European studies at the School of Advanced Studies in Paris. He received his Ph.D. in 1897 for his works on Old-Slavonic in *Recherches sur l'emploi du génétif-accusatif en vieux-slave* (*Researches on the Use of genitive-objective Case in Old-Slavonic*), his first thesis, and on the Indo-European root *men* in *De indo-europaea radice *men "mente agitare"* (*About the Indo-European Root *men*), his supplementary thesis in Latin. He was Professor of Armenian at the School of Advanced Studies in Paris in 1902. At the end of World War I, he contributed as an expert to the definition of linguistics groups, languages, and political boundaries. Then, he became secretary of the Société Linguistique de Paris (Paris Linguistics Society), before being elected to the Académie des Inscriptions et Belles-Lettres (French Academy of Inscriptions and Letters) in 1924. He retired in 1932. Meillet died in Châteaumeillant, France on September 21, 1936.

Metaphor

Metaphor and metonymy are two closely related concepts. They have been treated for centuries as types of figures of speech. Therefore, their study was thought to be the business of literary scholars, rather than of grammarians or linguists. Metaphor is defined from this 'classical' perspective as a figure of speech in which one word is used to indicate something different from the literal meaning, so that one thing or idea is likened to a different thing or idea. In a sentence like *He had a heart of stone*, the word *stone* is not used in its normal physical sense; rather, it conveys the idea of insensitivity, by likening this moral attitude to the hardness of stones. The classical view confines metaphor to ornate, flowery language, and assumes that the interpretation of any metaphorical use of language can be wholly reduced to literal meaning, which is its 'real' meaning (i.e. the 'real' meaning of the phrase *of stone* in this context is 'insensitive'). Conventional, automatic metaphorical expressions like *The* foot *of the mountain* are thus regarded as established literal meanings of words and cease to be metaphorical—they are called 'dead' metaphors.

Some Precognitive Modern Theories of Metaphor

The contemporary theory of metaphor that has had the strongest impact on linguistics is the cognitive theory of metaphor (see below). Among precognitive modern theories of metaphor, we can single out the 'interaction theory' and the 'pragmatist' position, which have also been followed by numerous linguists. The interaction theory, due to Max Black, claims that metaphor is the result of a semantic interaction or tension between a metaphorical term and its context. The tension between *stone* and *heart of* leads to construing the former as 'insensitivity', its 'real' meaning. The pragmatist position, due to Paul Grice and John Searle, holds that metaphor has to be reduced to the 'literal' meaning by applying a series of pragmatic principles of conversation, like conversational maxims. Some important papers representing these and other modern theories can be found in Ortony (1993).

The Cognitive Theory of Metaphor

This theory has revolutionized the scientific study of metaphor and metonymy, has dominated it for the past 20 years, and has attracted large numbers of linguists, psychologists, and other kinds of scientists to this field of research. (For the distinction and connections between metaphor and metonymy, see *Metonymy*.) The theory was first proposed in Lakoff and Johnson (1980). On empirical grounds, its authors criticized the basic assumptions of the traditional theory of metaphor and of most of the modern ones, especially the assumption that the meaning of metaphorical expressions can be reduced to 'literal' meaning, their 'real' meaning, and that metaphors had no serious conceptual import. The Cognitive Theory of Metaphor (CTM) evolved as an essential part of the approach known as Cognitive Linguistics (see *People, George Lakoff; Ronald Langacker*); a brief introduction is Ungerer and Schmid (1996). Let us now review some of the main tenets of the CTM:

(1) Metaphor makes it possible for people to understand new, complex, or abstract areas of experience ('domains') on the basis of more accessible domains, which are understood in their own terms; for instance, the abstract domain of life is often understood as a journey along a path (e.g. *He's at a crossroads* [in life]). The most basic metaphors have as input or 'source' domains universal physical notions like 'verticality', 'container', 'path', etc., known as 'image schemas' (Johnson 1987).

(2) Therefore, metaphor is not just a matter of language use but also, and fundamentally, a matter of thought, of conceptualization. Creative, conscious, unconventional metaphors are claimed to be usually extensions of automatic, unconscious, conventional metaphors.

(3) It is therefore important to distinguish between *conceptual metaphors* and *metaphorical expressions*. A given conceptual metaphor may be expressed by all kinds of linguistic and non-linguistic means (words, sentences, gestures, etc.); some of these linguistic expressions may cease to be used metaphorically but the conceptual metaphor may still motivate other expressions. For instance, in Old English *sad* originally meant 'full of food' and metaphorically 'full of sensations', the indirect source of its present sense 'sorrowful'. *Sad* stopped being a metaphorical expression when its original physical sense was lost. However, the conceptual metaphor PEOPLE ARE CONTAINERS FOR SENSATIONS, which indirectly motivated its metaphorical senses, is alive in countless other expressions (full *of joy*, *I am* fed up *with his behavior, sorrow*ful, etc.).

(4) Metaphors consist of fixed multiple simultaneous projections (or 'mappings') from the so-called 'source' domain onto the so-called 'target' domain. A sentence like *I see what you mean* is an expression of a conceptual metaphor that maps the conceptual structure of SEEING onto that of UNDERSTANDING, and which makes immediately comprehensible, without necessarily involving any pragmatic rules of interpretation, scores of other conventional expressions of the same metaphor like *Your arguments are* transparent, or *Your theory has thrown* light *on this problem*. (This is evidence against pragmatist theories.) Metaphorical mappings are fairly *systematic*, but they are only *partial* (about this, see Lakoff 1993).

(5) The mapping is always *unidirectional*: only the source is projected onto the target domain. Therefore, simultaneous *bidirectional* metaphorical projections do not exist, as the interaction theory claims. In the conceptual metaphor PEOPLE AS ANIMALS (as in *Don't* snap *at me* / *Their love* nest *has been discovered*), we project an aspect (aggressive behavior, living place) of some animals (dogs or birds) onto some aspects of people (anger, meeting point), but no aspect of people is mapped onto animals by virtue of *this* metaphor.

This would be done by a different metaphor, ANIMALS AS PEOPLE, as in *It's a* noble *dog*.

A very recent development within cognitive linguistics is the theory of 'blending' (due to Gilles Fauconnier and Mark Turner), which regards metaphor and metonymy as just two manifestations of a general mapping ability.

The CTM has been applied to the study of all aspects of language (lexicon, especially polysemy, grammar, discourse, and conversation) and to many other disciplines, from artificial intelligence to the study of literature, philosophy, anthropology, law, religion, etc.

Metathesis

'Metathesis' refers to several related processes in which the linear order of two elements is reversed, as when *ask* is pronounced *aks* in dialectal English. Although in the broadest sense metathesis is the transposition of any two linguistic units, such as syllables or words (*She will go —> Will she go?*), it most commonly denotes the transposition of two sounds: consonant with consonant, consonant with

vowel, or vowel with vowel. In some cases, not two whole sounds, but just a feature of the sounds, for example vowel length, is transposed: *basile:os* 'of a king' in Ancient Attic Greek corresponds to *basileo:s* in Ancient Ionic Greek (the colon indicates a lengthened vowel). A thorough description of metathesis must begin with the following four parameters:

(1) Synchronic ~ diachronic. Synchronic metathesis occurs within one chronological period. Diachronic metathesis takes place from one time period to another, e.g. from Middle English to Modern English.

(2) Adjacent ~ nonadjacent. Adjacent metathesis occurs when two contiguous sounds are transposed. With nonadjacent or 'long-distance' metathesis, the transposed sounds may be separated by one or more intervening sounds.

(3) Regular ~ sporadic. Regular metathesis applies consistently, to many different words. Sporadic metathesis is restricted to only a few words and occurs haphazardly.

(4) Abrupt ~ gradual. Abrupt metathesis completely transposes sounds in a single step. Gradual metathesis can best be understood as a type of chain reaction, a series of sound changes over time that eventually inverts two sounds. Gradual metathesis therefore uses one or more intermediate stages between the original order and the final transposed order.

A closer look at metathesis reveals four major types of inversion, pairing regular or sporadic with synchronic or diachronic, each one a unique combination of the above parameters with other linguistic causes and tendencies.

One type of synchronic metathesis is an abrupt regular process that applies to adjacent sounds in order to mark certain grammatical relationships between words. For example, in Rotuman, a Malayo-Polynesian language of the central Pacific, metathesis marks the distinction between definite and indefinite: /hosa/ 'the flower' vs. /hoas/ 'some (unspecified) flower'. Other languages where metathesis has a grammatical function include Clallam, Leti, Cherokee, Zoque, and Kwara'ae.

Regular synchronic metathesis is generally the product of a previous diachronic metathesis. Speaker variation between metathesized and unmetathesized forms, initially nothing more than variation in the pronunciation of a word during an earlier chronological stage of the language, is eventually sorted out over time by assigning each of the two variants to one of two options within a specific grammatical category, e.g. singular vs. plural or definite vs. indefinite.

In the absence of grammatical conditioning, synchronic metathesis is sporadic and abrupt, motivated by speech errors ('slips of the tongue') or by the influence of words related in form or meaning. For example, the English cases of *irrelevant ~ irrevelant* and *integral ~ intregal/intrical* may be due to the influence of *revelation* and *intricate*, respectively. As these examples show, sporadic cases of synchronic metathesis often occur when the inverted sounds are not adjacent to one another, and they may involve the transposition of two sounds or the relocation of one sound into another syllable.

If sporadic synchronic metathesis occurs in certain words with sufficient frequency among speakers in a given speech community, it may become a permanent diachronic sound change over time. Sporadic diachronic metathesis includes: (1) the long-distance (reciprocal) metathesis of two sounds, often *l* or *r:* e.g. Latin *parabolam* 'word' developed into Spanish *palabra;* (2) the transposition of one sound into a neighboring syllable: Latin *capra* 'goat' became dialectal Italian *crapa*; and (3) the inversion of two adjacent sounds, as with Old English *bridd* and Modern English *bird.*

A sporadic diachronic metathesis can become regular (permanently invert the same two sounds in many different words) if it fulfills a specific structural purpose. For example, a preference for syllables ending in a vowel may have caused the change from Proto-Slavic **melko* to South and West Slavic *mleko* 'milk' (the asterisk indicates that the relevant word form is not actually attested, but reconstructed on the basis of modern words). Similarly, less favored consonant sequences such as /dl/ and /nr/ are often metathesized in order to locate the more sonorant (vowel-like) sound in the syllable-final position and the less sonorant sound at the beginning of the next syllable, e.g. Latin *titulum* 'title' most likely developed first into **tidle*, which then metathesized into Old Spanish *tilde;* Latin *generum* 'brother-in-law' became **yen.ro* and then Spanish *yer.no*. In contrast to these examples, a sporadic metathesis without structural motivation, as in the *irrelevant ~ irrevelant* example*,* cannot become regular, i.e. this same process will not spread to other words with *l* and *v* in similar positions.

Regular diachronic metathesis is often the result of a series of interrelated sound changes over time, a gradual chain reaction of regular changes whose last stage creates a transposed version of the original sequence. For example, French *Breton* became **brtõ*, which then developed into Le Havre French *bertõ*. This is an example of 'pseudometathesis,' since the

two sounds *e* and *r* are not transposed directly. Rather, the *e* was first lost and then an *e* was inserted into a different position. If only the original word and the final result were compared, the modern word would seem to be the product of metathesis, when in fact it results from several nonmetathetical processes.

A gradual diachronic transposition is often the case with consonant + vowel sequences, where *i* or *u* reduces to *j* or *w*, respectively. These sounds can then merge with adjacent consonants—they become 'secondary articulations' of these consonants—and later give rise to vowel developments on the other side of the consonant. Examples of such chain processes are as follows: Ancient Greek *phéresi* > *phéresʲ* > *phérejs* 'you carry'; Latin *sapui* > **sabwi* > **sabʷi* > **sawbe* > **sowbe* > Portuguese *soube* 'I knew'. The vowels thus gradually wandered 'through' a consonant. The result, again, resembles the product of metathesis. Consonants may also reduce to secondary articulations before reappearing on the opposite side of a vowel. For example, an *h* may temporarily become a breathy-voice articulation on the neighboring vowel and then resurface as a full consonant on the other side: Cayuga /akekaha̰/ >

*agéka̰a̰ > [agékhaa̰] 'my eye'. As before, the *h* actually moved through the vowel *a* in several steps, but the result resembles a one-step metathesis.

KENNETH J. WIREBACK

Metonymy

Metaphor and metonymy are two closely related concepts. Both have been treated for centuries as figures of speech, and are as such regarded to be the business of rhetoric or literary studies rather than linguistics. The traditional theory of metonymy defines it as the 'use of the name of one thing for that of another associated with or suggested by it'. (*Webster's new twentieth century dictionary*, 2nd edition.) In *The White House issued a statement*, the phrase *the White House* is used instead of the phrase *the President*. This traditional theory treats metonymy as a matter of language use; its conceptual nature is overlooked. The meaning of metonymic expressions is also assumed to be wholly translatable into literal meaning. Metonymic expressions are considered to be necessarily referential (in the technical sense of designating an extra-linguistic entity). Most twentieth-century treatments of metonymy have essentially maintained the same views; a good illustration is Ullmann (1962).

The Cognitive Theory of Metonymy

This theory emerged alongside the cognitive theory of metaphor, but the nature of metonymy and its relevance for thought and language have only recently begun to be investigated in depth. In the standard form of the Cognitive Theory of Metonymy (CTMY), as in Lakoff and Turner (1989), metonymy is defined as a mapping with a primarily referential purpose, in which the source and the target are conceptual entities in the same domain. 'Mapping' means 'conceptual projection'. In the previous example, the concept of the White House (the 'source') is mapped onto the concept of the President (the 'target'): the President is primarily conceptualized as someone who lives in that building. This allows the phrase *the White House* to *refer to*, i.e. to designate, the person in office as the President of the United States at a given time. Finally, a place and the people or things located in it are so closely linked in experience that they can be said to be in the same 'domain' or area of experience.

Metonymy can link a part to a whole, as in *We need a couple of extra* hands *in our factory* (HANDS [BODY PART] FOR PEOPLE), a whole to a part, as in The Times *is here* (NEWSPAPER COMPANY FOR REPORTER), or a part to a part, as in *He has a good* pen (PEN [INSTRUMENT] FOR ACTION [WRITING]). This tripartite classification continues the traditional theory, except that the latter reserves the term *synecdoche* for PART-FOR-WHOLE metonymies.

In the CTMy, metonymy is a primarily conceptual phenomenon, rather than just a matter of language use, so that conceptual metonymies have to be distinguished from metonymic expressions; metonymy is systematic, as it responds to general patterns like WHOLE FOR PART or to more specific patterns like INSTRUMENT FOR ACTION. And the meaning of metonymic expressions cannot be simply reduced to literal meaning.

Some of the main areas of current debate in the CTMy are the following:

(1) Referential function. Some cognitive linguists still hold the traditional view that every metonymic noun phrase must be referential. But most cognitive linguists note that, even though referring is a very frequent function of metonymy, metonymic noun phrases are often also used nonreferentially. For instance, in *John is a good* hand *at fencing*, the predicate noun phrase does not designate an individual; it just mentions a property.

(2) The nature of the relationship between source and target. Some linguists avoid treating metonymy as a mapping process, because, unlike metaphor, metonymy apparently does not consist of systematic multiple mappings. An approach that has recently won widespread support is that of regarding the metonymic source as a 'cognitive reference point', which, in an appropriate context, can cause the mental activation of the target (see Kövecses and Radden 1998; Langacker 1999): In *The White House issued a statement*, a LOCATION causes the mental activation of the PERSON LOCATED. It also imposes a certain perspective on that person. As we saw earlier, this imposition is a type of mapping .

(3) The distinction from, and interaction with, metaphor. The key property distinguishing them, according to the standard view in the CTMy, is that metaphor is a mapping across *different* domains, whereas metonymy is a mapping within the *same* domain. Consider the metaphor LIFE IS A JOURNEY, as in *I have gone a long way* (said about one's life): life and journeys are in two different domains. In the metonymy CONTAINER FOR CONTENT, as in *He drank a* glass, the source (the glass) and the target (the contents of the glass) are in the same domain, namely, the domain of 'containment'. This criterion, however, does not always work clearly. For instance, the source and the target of PEOPLE ARE ANIMALS (*Richard is a lion*) are in the same domain, the domain of LIVING BEINGS. This and other cases have led some linguists to claim that an absolute distinction between metaphor and metonymy cannot be maintained; they are better regarded as the two ends of a continuum.

Metaphor and metonymy often interact in complex ways. One of the most intriguing of these is the fact that a great many metaphors have a metonymic basis: the metaphor MORE IS UP (*A high* number/*Prices* soared) is motivated by the metonymic activation of quantity by verticality, through their frequent experiential association (e.g. in pouring liquids into containers and watching their level rising).

The CTMy has been shown to be highly relevant for the study of cognition and reasoning, lexical semantics, grammar, and discourse. A large number of categories have been shown to have a metonymic *prototype* (a kind of model of the category); see Lakoff (1987). The CTMy provides a useful framework for the study of lexical polysemy, in which metonymy is a fundamental force. But, most importantly, the CTMy has demonstrated the pervasive metonymic motivation of a great many grammatical structures, like raising, conversion, generic sentences, etc., of certain types of pragmatic inferences like indirect speech acts and conversational implicatures, and of discourse strategies.

Mexico

The mosaic of languages in Mexico is among the richest and most complex in the Americas. It is the largest Spanish-speaking country in the world. However, Spanish has only dominated in the region that is today Mexico for the past five centuries. For millennia before, the mountain valleys and tropical forests of Middle America supported a density of population and spectrum of cultural developments that nurtured one of the richest arrays of native languages in the Americas. Mexico, therefore, concentrates the largest number of speakers of one of the most widely spoken languages in the world while preserving the largest number of speakers of the most ancient native American languages.

Demographic and Geographic Profile of Mexican Languages

There are a third of a billion speakers of Spanish in the world so that every one in 18 people in the world speaks this language. In Mexico, there are 90 million first-language speakers of Spanish, almost 90 percent of the country's population of 104 million (estimate, 2002). More than a fourth of all Spanish speakers in the world, therefore, lives in Mexico. Mexico City, the capital, concentrates a population of over 20 million, making it the fourth largest metropolis in the world. It is thereby the largest Spanish-speaking city in the world. Speakers of native languages in Mexico amount to slightly less than 10% of the population. They speak almost 300 different languages. Well over half the population of Mexico is a racial mixture of Spaniard and Amerindian, known as *mestizo*. Just under a third of the population is mainly of Amerindian descent. The speakers of the numerous languages of Mexico occupy an area of more than 750 million square miles. Mexico is four times the size of Spain, where Spanish originated. The area of present-day Mexico, however, is only half of what it was in the nineteenth century. At

that time, it lost much of its territory to what is now the southwestern region of the United States, the area from the states California to Texas. Today, this region has the largest number in the Unite States of first- and second-language speakers of Spanish.

Development and Characteristics of Mexican Spanish

Spanish came rapidly to dominate in Mexico from the earliest colonial times. This dominance resulted not just from the power of the Spanish Conquest from 1519 to 1521. Of most consequence were the devastating diseases brought to the native population by the Spanish. At the beginning of the sixteenth century, just before the Conquest, the native population of Mexico amounted to approximately 25 million. Only three decades later, well over 90% of that population had died from European diseases against which natives had no immunity. The population of Mexico did not again reach its pre-Conquest level until the middle of the twentieth century.

The Conquest had a devastating and permanent effect on the linguistic balance of Mexico. The Spanish-speaking population enjoyed robust growth, its language coming to the forefront in all the colony's commercial, cultural, military, educational, and religious activities. Native languages survived only precariously among geographically and socially isolated remnants of the original native population.

The Spaniards who came to Mexico in the early colonial period amounted to less than 100,000 people. However, they were mostly male and interbred widely with the surviving native women, producing the *mestizo* population. It was this growing population that became the main vehicle for the advancing dominance of Spanish.

Distinctions of Spanish in Mexico

The use of Spanish in Mexico has developed differences from other Hispanic countries in terms of vocabulary, pronunciation, and grammar. These distinctions have occurred based on the historical origins of the language in central and southwestern Spain and its evolution amid the dynamics of Mexican development.

The foundations of Spanish throughout Latin America originated with the language as it was spoken in central and southwestern Spain during the sixteenth and seventeenth centuries. The kingdom of Castile, in the central *mestizo* of the Iberian Peninsula, led the conquest of colonies in the Americas. In addition, soldiers, merchants, administrators, settlers, and missionaries set out from the southwestern areas of Andalusia, primarily the port of Seville, and Estramadura.

The dominance of Castile in the propagation of the language was so extensive that the Spanish language is often also referred to as *castellano* or Castilian. The base of Spanish in Mexico and throughout Latin America reflects patterns dominant in Castile and southwest Spain at the time of colonization. Variations have emerged since then from that base.

While in Spain today the "c" may have a "th" sound, in Mexico it is pronounced now only as an "s." The sound of Castilian "x" at the time of colonization was "sh" but has now evolved in Mexico to a breathed "h" sound. (Galician and Portuguese still maintain the earlier tendency.) The original pronunciation, therefore, of the first syllable of Mexico sounded like "mesh" but has now become "meh". In addition to the way in which speakers of Mexican Spanish tend to abbreviate or eliminate certain sounds and syllables, they also use a distinct musicality and intonation, raising the pitch of a phrase or sentence toward the end. Mexican Spanish is spoken more slowly, musically extending sounds. There is a tendency to emphasize consonant sounds and reduce or "swallow" unaccented vowel sounds.

As the largest Spanish-speaking country, Mexican publishers and media outlets considerably influence Spanish-language communications. This is especially true for Mexican television and radio, which massively penetrates into the Latino population of the United States. Mexican television networks, such as Univision and Telemundo, produce *novelas* (series dramas) that are broadcast around the world. Nonetheless, dominance of Spanish-language media and communications remains with Spain, and, in the Americas, is divided between Mexico and Argentina. The prominence of Mexican literature was recognized in 1990 when Octavio Paz won the Nobel Prize in literature.

The vocabulary of Spanish derives essentially from Latin. However, since the Moors occupied much of the Iberian Peninsula from the Middle Ages until the end of the fifteenth century, words of Arabic origin occur extensively in Spanish. Such is the origin of the often-used Mexican expression, *ojalá* (May it be!). Many words in Mexico beginning with "al" such as *alcalde* (mayor), *algebra* (algebra), and *algodón* (cotton) originate from Arabic.

The most distinctive source for the vocabulary of Mexican Spanish, however, derives from native languages, especially Nahuatl. This was the language of the Aztecs, who ruled the part of Mexico that the Spanish initially conquered and occupied. From the Aztec language, Mexican Spanish has received its words for *chocolate* (chocolate; from the Nahuatl word, *chocolatl*), *tomate* (tomato; from *tomatl*), and *coyote* (coyote; from *coyote*). These words have entered the vocabulary of the entire world. The strongest influence on modern vocabulary development in Mexican Spanish has been English, contributing such words as *béisbol* (baseball), *cóctel* (cocktail), and *sándwich* (sandwich).

As throughout the Spanish-speaking world, the standard, accepted version of the language in Mexico continues to adhere to rules formulated by the Spanish Royal Academy, in Madrid. (Somewhat similar to the way in which French-speaking countries follow norms established by the French Academy, in Paris.) There are, nonetheless, regional Mexican language distinctions. These occur along the border with the United States, around the industrial region of Monterey, the Caribbean coast, southern Amerindian areas, rural regions, and Mexico City. Throughout the latter part of the twentieth century, the United States has increasingly become a center for the speaking of Mexican Spanish due to the economic diaspora of millions of Mexicans to that country.

Beyond Spanish

Less than 10 million Mexicans use the several hundred native languages still surviving in the country. These languages are grouped into 11 linguistic families: Algonquin, Chiapanecan-Mangue, Chinantecan, Huave, Mayan, Mixe-Zoque, Oaxacan, Tarascan, Tlapanecan, Totonacan, and Uto-Aztecan. The major languages still have several hundred thousand to several million speakers.

Colonial missionaries established written forms for the native languages, using the Roman alphabet. Thus, writing today of native languages reflects native pronunciation as transcribed into equivalent colonial Spanish alphabetic sounds. Pre-Conquest written forms were limited to pictograms and/or ideograms. Many of these have only recently been deciphered, and often only partially. Hostility to native languages appeared throughout early Mexican history, their speaking prohibited and many documents in them burned.

The Mayan languages, which in Mexico appear along a southern belt of the country from west of the state of Chiapas then along the border with Guatemala and Belize and then into the peninsula of Yucatan, have nearly two million first- and second-language speakers. The Mayan languages spoken in Mexico are principally Chol-Chontal, Tzeltal, Tzotzil, Mocho, and Yucatecan. In the ancient language, glyphs were used for syllable sounds. The Mayan languages generally follow a syntactical sequence of verb–object–subject. The great literary epic, *Popul-Vuh*, recounting the Mayan version of the creation of the universe did not, however, originate in a Mayan language of Mexico but of Guatemala. Some publishing and radio broadcasting occurs in Mayan languages where there is a more dense concentration of such speakers.

In the southwestern part of Mexico, around the area of Oaxaca, there are half a million speakers of Zapoteco (the "cloud" people) languages. These are highly tonal (i.e. they use different levels of intonational pitch to distinguish words) and require an alphabet of 39 letters to capture their range of sounds. There are under 100,000 speakers of Mixe languages, and a quarter of million speakers of Mexteco languages. This region also has several thousand Chinanteco speakers. Oaxaca and the area around it has the greatest concentration of speakers of native languages in Mexico.

In the central part of Mexico, from Nayarit into the state of Mexico and through Puebla down to Vera Cruz, there are well over a million first- and second-language speakers of Nahuatl (Aztecan) languages. The eastern portion of the region has several hundred thousand speakers of the Totonacan languages. Unlike Mayan languages, Nahuatl does not impose a fixed word order on subject, verb, and object. Moreover, somewhat like German, it is an agglutinative language: Nahuatl strings morphemes together into words that can accumulate into more than ten syllables.

Due to extensive migration from the impoverished areas of southern Mexico into the United States, the native languages of Mexico now have hundreds of thousands of speakers in the latter country. Political and cultural consciousness has given renewed vigor to the native languages. This development is especially true in the state of Chiapas with its armed rebellion against the central government of Mexico. The growth of the *indigenista* movement throughout the twentieth century, beginning with the victory of the Mexican Revolution of 1910, supported extensive anthropologic, archeologic, and linguistic studies of the ancient native languages. Many Mexican and US universities now offer courses in the study of these languages. Publishing and media firms of varying sizes now exist in these languages.

Middle (Classical) Japanese

Middle Japanese is a historical stage in the history of the Japanese language between Old Japanese and Early Modern Japanese. The chronological span of Middle Japanese can be estimated as ninth to twelfth CE, roughly corresponding to the Heian period, although ninth century data in many respects are

transitional from Old Japanese to Middle Japanese, in pretty much the same way as thirteenth century, is transitional between Middle Japanese and Early Modern Japanese. Middle Japanese is a language predominantly based on the dialect of the upper and middle nobility in the capital Heiankyô (present day Kyôto). In contrast to Old Japanese, there is no evidence for any kind of dialectal variation, and the existing sources preserve only bits and pieces of language samples as spoken by commoners and even lesser nobility.

It is necessary to keep in mind that Old Japanese and Middle Japanese do not represent a direct continuity in time, as both of them are based on geographically close but in some respects different dialects. Nevertheless, both can be defined as belonging to the Western dialect group of Central Japanese.

Sources

The written sources of the Heian period composed completely or partially in Middle Japanese can be divided into three major groups: (1) commentaries on Buddhist and Confucian classics; (2) dictionaries; and (3) literary works. The first group of texts, the commentaries, is considerably influenced by Chinese, and mostly uses a cumbersome system of writing that only approximately represents the language. In addition, these texts contain a number of archaisms from Old Japanese, no longer essential for Middle Japanese. The second group, dictionaries, although containing valuable lexical and phonetic materials with clues on vocabulary and pronunciation, respectively, tells us next to nothing about the morphology (word structure and word formation) and syntax (sentence structure) of the language. Therefore, the present paper is based predominantly on the data found in literary texts, although dictionary data are also included for the description of Middle Japanese phonology, and the commentary texts are used for the description of the writing system.

Extant literary texts represent both poetry and prose. The Japanese written language up to the Meiji period (1868–1911 CE) was predominantly based on Middle Japanese, although starting from the Muromachi period there have been texts produced in the vernacular. For this reason, Middle Japanese is often called 'Classical Japanese'.

Writing System

Several writing systems were in use in the Heian period. Literary texts are written in a mixed system including both syllabic signs representing cursive forms of many of (but not all) earlier *man'yôgana* signs and cursive forms of Chinese characters, which roughly stand for stems of words. The syllabic system is polyphonic like *man'yogana*; one syllable can be written by more than one sign. This syllabic system of writing is a direct predecessor of modern *hiragana*, where each syllable is rendered by only one sign. The predecessor of modern *katakana* syllabary also originated in this period, although its usage was mainly limited to Buddhist texts and to indicating the reading of Old Japanese texts written in *man'yôgana*. Only in the twelfth century *katakana* gains somewhat wider usage and penetrates even some literary texts. Finally, there was another writing system with limited usage called *kunten* ('Japanese readings [rendered by] dots'), chiefly used for 'Japanicizing' the reading of texts originally written in Chinese. It was based on placing dots at certain corners or sides of a Chinese character that indicated particles or suffixes of Middle Japanese. As a matter of fact, there were several different *kunten* systems, invented by various Buddhist sects, which usually kept them secret from members of other sects.

Phonology

The sound system of Middle Japanese underwent two major radical changes as compared to the Old Japanese system. The first major change resulted in more than double of the number of consonants when certain consonants (palatalized and labiovelar) were introduced to the system due to the large influx of Chinese loanwords. The second major change was due to the weakening and subsequent loss of certain consonants between vowels that ultimately destroyed the Old Japanese requirement that no two vowels occur adjacent to each other.

Middle Japanese had the following consonants: *-p, f, f', b [^{m}b], b' [^{m}b'], t, t', d [^{n}d], d' [^{n}d'], k, k', k^w, g [^{ŋ}g], g' [^{ŋ}g'], gw [^{ŋ}g^w], m, m', n, n', -N, s, s', z [^{n}z], z [^{n}z'], w, y, r, r'*. Similar to Old Japanese, no consonant is possible in the syllable-final position; thus, only syllables of CV[V] and V structure are found in the native Middle Japanese vocabulary. In Chinese loanwords, however, nasal sonorants *-m, -n, -ŋ* and probably voiceless *-p, -t, -k* as well are possible. Consonants *b, d, g, z,* and r occur only in word-medial position in the native vocabulary. Between vowels, *-f-* shifted to *-w-* and consequently disappeared before the high vowels /i/ and /u/ or went to *-y-* before /e/. The same fate befell the original intervocalic *-w-*. In certain sets of verbs and adjectives, intervocalic *-k-* and *-s-* also disappeared before high vowels /u/ and/or /i/.

The set of Middle Japanese vowels, on the other hand, shrank compared to Old Japanese, as only five

vowels *a, i, u, e, o* are present. The vowels /e/ and /o/ are found in Middle Japanese only in post-consonantal position, that is, they never appear as a word or syllable initial.

From the Chinese–Japanese dictionary *Ruiju Myôgishô* (1081 CE), we have fairly good information on the Middle Japanese accentual system. It was a system that was based on pitch and possessed two major characteristics: register (high (H) or low (L)) and locus (location of the drop in pitch in a given word with a High–Low contour), which are also typical for the modern Kyoto dialect. Like in Modern Kyoto, nominals were characterized by both register and locus, while verbs and adjectives exhibited only register.

Lexicon

There are many loanwords from Chinese in Middle Japanese that penetrated different lexical domains, but they are most numerous among the sociopolitical and religious strata of the Middle Japanese vocabulary: *dairi* 'forbidden city', *kugyau* 'nobility', *sou* 'monk', *kyau* 'sutra'. Many Chinese loanwords have doublets in the native vocabulary, e.g. (native word is given in parentheses): *sekai (yo)* 'world', *kyau (miyako)* 'capital', *guu (miya)* 'palace', *sinwau (miko)* 'prince', *daizin (otodo)* 'minister'. There are also words coined by the Japanese from Chinese elements, e.g. *chûnagon* 'middle councilor', *dainagon* 'senior councilor'. There are also loanwords from Sanskrit borrowed via Chinese or Korean: *butu [but]* 'Buddha' < Middle Chinese *but* < Sanskrit Buddha, *fati* 'bowl for alms' < Middle Chinese *pat* or Old Korean *pati (cf. Middle Korean *pali*) 'id.' < Sanskrit *pa:tra* or *pa:tri* 'bowl'.

Morphology

Middle Japanese morphology underwent some cardinal changes as compared to Old Japanese morphology. First, a number of Old Japanese morphological markers are no longer used in Middle Japanese texts. Second, a number of new morphological markers appear in Middle Japanese that did not exist in Old Japanese, partly due to the fact that Old Japanese and Middle Japanese are based on geographically close but not identical dialects. Third, some constructions of Old Japanese consisting of clearly identifiable word elements underwent the process of reduction in Middle Japanese and conflated into single unanalyzable suffixes , e.g. the Old Japanese phrase *V-am-aku posi* 'wants to do V' became a verbal suffix *-amafosi* (morphological elements and their functions that represent new

developments in Middle Japanese that are not found in Old Japanese are indicated below in bold typeface).

Nominal Morphology

Most nominals (with the exception of some pronouns) in Middle Japanese have no formal markers, distinguishing them from other parts of speech, e.g. *yama* 'mountain', *fito* 'person', *yuki* 'snow', *midu* 'water', *fi* 'fire', *futa* '2', *towo* '10'.

Some Middle Japanese pronouns have two stems: unextended, and extended with suffix *-re*, which may be treated as a formal marker of these pronouns, distinguishing them from other parts of speech, and also from other pronouns that do not have the special stem in *-re*. It is necessary to note that Middle Japanese has a unified system of personal-reflexive pronouns (...self), which does not exist in Old Japanese.

Personal-reflexive pronouns: *wa-/ware* 1/3ps and 1/3pp (rare), **maro** 1ps (attested only once in OJ), **wa-ga mi** 1/3ps, **mi** 1ps, **midukara** 1/3ps, *wono-/wonore* 1/2/3ps and 1/2/3pp, **wono-ga mi** 1ps, **wonodukara** 1/2/3ps, **nandi** 2ps (pejorative), [mi]masi 2ps, **omafe** 2ps (honorific), **gozen** 2ps (honorific), **watakusi** 3ps. Demonstrative pronouns: proximal *ko/kore* 'this', mesial *so-/sore* 'that', distal *ka/kare* 'that over there', **a-/are**. Demonstratives *kore* and *sore* can be used as 3p pronoun 'he' or 'she'. Demonstrative pronouns indicating place or direction: proximal: *koko, konata* 'here', mesial: *soko,* **sonata** 'there', distal *kanata,* **kasiko, anata** 'over there'. Interrogative pronouns: *ta-/tare* 'who', *nani* 'what', *ika,* **ikani, ikaga, ikade** 'how', *iduku/**iduko*** 'where', *iduti* 'where to', *idure* 'which', *itu* 'when', **iku/ikuda**/*ikura* 'how many', *nado/nazo/**nadote*** 'why', **nadeu/nandeu** 'what kind', 'why'. Collective pronouns: *mina,* **subete** 'all'.

In contrast to Old Japanese, only the following native numerals are attested in Middle Japanese: *fito-* 'one', *futa-* 'two', *mi-* 'three', *yo-* 'four', *itu-* 'five', *mu-* 'six', *nana-* 'seven', *ya-* 'eight', *kokono-* 'nine', *towo* 'ten', *fatati* 'twenty', *misoti* 'thirty', *yosoti* 'forty', *musoti* 'sixty', *momo* 'hundred', *ti* 'thousand', and *yorodu* 'ten thousand'. Native numerals above ten have disappeared from the language being replaced by Chinese loanwords, e.g. *zifu iti* [ⁿzip it] 'eleven', literally 'ten' + 'one'. The numerals of Chinese origin below 'eleven' occur only with classifiers of Chinese origin and are never used independently. The system of classifiers is in its infancy, although it is already richer than the Old Japanese system. The following classifiers are well attested: *-tu* (objects used with digits), *-ti* (objects used with tens and hundreds), *-ri* (people), *-fe* (layers and folds), *-ka* (days), **-nin** (persons), **-do** (times), **-ba** (roofs), **-sudi** (long thin

objects), **-tokoro** (high-ranking persons), **-zyau** (wards).

Verbal Morphology

The verbal morphology of Middle Japanese underwent three great changes as compared to Old Japanese. First, in sharp contrast to Old Japanese, all Middle Japanese adjectives behave like verbs and not like nouns. In other words, Middle Japanese adjectives have a comparatively well-developed verb-like paradigm that differentiates between attributive and final forms, e.g. *aka-ki isi* (red-ATTR stone) 'red stone' and *isi aka-si* (stone red-FIN) 'stone is red'. Second, auxiliaries of Old Japanese that followed the infinitive form of verbs became suffixes in Middle Japanese. Third, tense marking has disappeared from the language, while 'retrospective' constructions filled the void. The last two changes can be demonstrated by a single example: old Japanese verb-*i-kyi* verb-INF-PAST became Middle Japanese verb-*iki* verb-RETR.

Middle Japanese verbs are divided into several classes: consonantal verbs, with roots ending in a consonant (*yuk-* 'go', *kir-* 'cut', *omof-* 'love, think', *nokos-* 'leave', etc.), vowel verbs, with roots ending in a vowel (including weak vowel verbs that lose the final vowel under certain conditions like *kofi-* 'love', *tasuke-* 'save', and strong vowel verbs that never lose their root vowel, like *mi-* 'see', *ke-* 'kick', etc.), and irregular verbs (*ko-* 'come', *se-* 'do', *ar-* 'exist', *sin-* 'die', *in-* 'go [away]'). In addition, there are defective verbs: *n-, to* 'be', *to* 'say' that have only a limited number of forms and are irregular as well.

Middle Japanese adjectives are traditionally divided into two classes: one with root ending in *-si* and another ending in any other syllable. The only distinction between these two classes can be seen in the final form, where *-si* adjectives do not take the final marker *-si* to avoid the doubled syllable, e.g. *aka-* 'be red' becomes *aka-si* red-FIN 'is red', but *utukusi-* 'be beautiful' becomes *utukusi* 'is beautiful'. Since very few suffixes can directly follow adjectival stems, adjectives form a special secondary conjugation type, consisting of adjectival infinitive form *-ku* plus the verb *ar-* 'exist' that contracts to *-k-ar-*, e.g.: *aka-ku ar-* be red-INF exist > *aka-k-ar-*, to which negative *-az-* can be further added: *aka-k-ar-az-u* be red-INF-exist-NEG-FIN '[it] is not red'.

Middle Japanese verbs can take both prefixes or preverbs and suffixes, but while a word is limited to only one prefix, multiple suffixes may be added. There are three verbal prefixes, **uti-, kaki-/kai-, and mote-,** with mostly unclear or poorly investigated functions, and one preverb *ye-,* which, in combination with a following negative form of the verb, conveys the lack of ability to perform an action, e.g. *ye-yom-az-u* PREV-recite-NEG-FIN '[he] cannot recite'. There is also one circumfix in Middle Japanese: *na....so,* encircling an infinitive form and making a negative imperative: *na-yak-i-so* NEG-burn-INF-IMP 'do not burn'. Verbal affixes differ in form after consonantal stems and after vowel stems (with the possible differentiation between forms found after weak and strong vowel verbs). Thus e.g. the attributive suffix has the following forms: *-u* after consonantal verbs, *-uru* after weak vowel verbs, and *-ru* after strong vowel verbs: *yuk-u* fito 'person *who goes*', *kof-uru* fito 'person *who loves*', and *mi-ru* fito It is impossible to provide a list of all verbal affixes here, so only the most important are listed: infinitive -*i*/-Ø, negative infinitive -*azu*/-*zu*, finite -*u*, attributive -*u*/-*uru*/-*ru*, imperative -*e*/-*yo*, negative -*an*-/-*az*-/-*n*-/-*z*-, tentative -*am*-/-*m*-, iterative -*af*-, passive- -*are*/-*rare*-, causative/honorific -*ase*-/-*sase*-, debitive -*ubey*-, negative debitive -*umazi*-, retrospectives -*ikyi* and -*iker*-, perfectives -*ite*-/-*it*-/-*te*-/-*t*- and -*in*-/-*n*-, perfective-progressive itar-/-*tar*-, conjectural -*umer*-, optative -*amafosi*/-*mafosi*, desiderative -*abaya*. 'person *who sees*'.

It is impossible to provide a list of all verbal affixes here, so only the most important are listed: infinitive -*i*/-Ø, negative infinitive -*azu*/-*zu*, finite -*u*, attributive -*u*/-*uru*/-*ru*, imperative -*e*/-*yo*, negative -*an*-/-*az*-/-*n*-/-*z*-, tentative -*am*-/-*m*-, iterative -*af*-, passive- **-are/-rare-**, **causative/honorific -ase-/-sase-**, debitive -*ubey*-, negative debitive **-umazi-**, **retrospectives -ikyi** and **-iker**-, perfectives **-ite-/-it-**/-*te*-/-*t*- and **-in-**/-*n*-, perfective-progressive **itar-**/-*tar*-, conjectural **-umer-**, optative **-amafosi/-mafosi**, desiderative **-abaya**.

In addition to this quite complex verbal morphology, there is also the no less complex system of auxiliary verbs that mostly follow the infinitive form of verbs. Auxiliary verbs can be subdivided into several classes (within each class, only the most frequent are listed): honorific (*tamaf-, ofas[e]-, ofos[e]-, imas-*), humble (*tatematur-, tuka[u]matur-, tamafe-, kikoye[sase]-, mawos-*), polite (*faber-, saburaf-*), assertive (*nar-*), cooperative-reciprocal (*af-*), directive (*ide-/ idas-, ire-/ir-, ko-, yuk-/ik-, age-/agar-, kudas-, yar-, watar-, yose-/yor-*), and resultative (*fate-, ok-, tuke-/tuk-, tome-*).

Middle English

Middle English is the name given to the varieties of English spoken between the Norman Conquest of 1066 and the introduction of the printing press to England by William Caxton in 1476. These historical events are simply convenient demarcation points; in reality, many of the linguistic changes characterizing Middle English started before and extended beyond these dates.

Background

In 1066, William, Duke of Normandy, also known as William the Conqueror, invaded England, defeated the English armies at Hastings, and declared himself King of England. Throughout the Middle English period, England was ruled by royals who were of French descent: the Norman line from 1066 to 1154 and the Plantagenet line from 1154 to 1485. The demographic effect of the Norman Conquest was not overwhelming, and people who spoke only French probably never exceeded 2% of the total population. The social and cultural consequences of this event, however, were substantial. The positions of power and prestige and the centers of learning and writing passed from Anglo-Saxon to Norman hands. Virtually every aspect of the history of the language during Middle English has to be described and studied both on its own terms and in the context of continuing bilingualism and imitation of Continental sources.

Early Middle English usually covers the time from the mid eleventh to the mid thirteenth centuries. Relatively few records written in English survive from that period; most of the historical documentation and literary production during the Early Middle English period was in Latin or in Anglo-Norman, the variety of French used by William the Conqueror, his successors, and their courts. For English, it was a time of rapid reduction of grammatical markers and borrowing of vocabulary from Anglo-Norman. Central Middle English stretches roughly from the mid thirteenth to the mid fourteenth centuries, up to the beginning of the Hundred Years' War (1337–1453) and the epidemic of bubonic plague known as the Black Death (1348–1350). The Central Middle English period is characterized by further attrition of inflections, vowel length adjustments, and the continuing introduction of new loanwords from French, although the use of French was already on the decline. Late Middle English is the time during and

after Chaucer's life (born c. 1340–1346, died 1400), up to the introduction of printing. (Caxton brought out the first printed edition of *The Canterbury tales* in 1478.) It was during the Late Middle English period that the pronunciation changed in a complex process commonly referred to as the *Great Vowel Shift*. Furthermore, when vowels occurred at the end of a word and were unstressed, they were completely lost in all dialects, and since word endings often had grammatical significance, the grammar changed as well. Late Middle English also marks the beginning of standardization, the complete replacement of French by English as the official, legal, and parliamentary language, and the rise in literacy.

Dialects

One consequence of the political and cultural dominance of the Anglo-Normans was that during the first three centuries of Middle English, no regional variety of the language achieved prestige and prominence comparable to that of West Saxon during the Old English period. Each geographical area had its own scribal and literary traditions. Dialects differed both in sound structure and vocabulary, as well as in word and sentence structure. The main north–south divisions of Middle English are known as Northern, Midland, and Southern Middle English. Within the south, a separate dialect, Kentish, developed in the counties of Kent and Sussex. The Midland dialect area splits further into two linguistically distinct varieties: East Midland and West Midland.

Orthography

Another consequence of the Norman Conquest was the replacement of the 'Insular' script used by the Anglo-Saxons with a Continental form of the Roman alphabet known as 'Carolingian' script. The letters <æ> and <ð> were preserved only in the earliest texts. The Old English yogh <ȝ> was used to represent both [j], as in *ȝow* 'you,' and [ç, x], as in *heiȝ (e)* 'high,' *rouȝ(h)* 'rough'; the continental <g> was adopted for [g] and [ǰ]. The letter thorn <þ> was very similar in shape to the letter <y>; hence, y^e, y^t stand for *the, that*. (y^e, y^t were retained in printers' fonts during the fifteenth and sixteenth centuries, which gave rise to pseudo-antiquarian spellings like *Ye Olde Antique Shoppe*.) New digraphs (two-letter combinations)

were introduced for the spelling of many long vowels and diphthongs: <ou, ow> for [u:], <ee> for [e:], <oo> for [o:], etc. To avoid the visual confusion of adjacent vertical strokes, the letter <u> was replaced by <o> when it was next to <m, n, u, v, w>. Thus, *sume* 'some', pronounced [sʊm(ə)], *huni* 'honey', pronounced [hʊni], and *luue* 'love', pronounced [lʊv(ə)], were respelled to *some, hon(e)y, loue*. New consonant letter combinations introduced by the Anglo-Norman scribes were: <ch, cch, tch> for [č], <gg(e)> for [ǰ], <gh> for [ç, ɣ, x], <wh, qu, quh> for earlier <hw>, and <sh, ssh, ss> for [ʃ].

Sound System

Middle English was a time of rapid change of the quality and the quantity of many vowels. The southern dialects of Late Middle English, which served as the basis of the emerging fifteenth-century standard, had five short vowels and seven long vowels:

Short vowels		Long vowels	
I	ʊ	i:	u:
		e:	o:
ɛ	ɔ	ɛ:	ɔ
	a		ɑ:

The colon marks vowel length. In dictionaries and edited manuscripts, length may be indicated by a macron (¯) over the vowel letter. Whether [ɑ:] or [ɔ:] is used in a particular word is an important dialect criterion: in the south, Old English [ɑ:] was raised and rounded to [ɔ:], while the northern dialects retained the low vowel: compare Northern Middle English *stan(e), mair* with Southern Middle English *ston(e), more*, which developed from Old English *stān* 'stone', *māra* 'more'.

Middle English inherited or developed a range of diphthongs that were to become an important component of the changes included in the *Great Vowel Shift*. The diphthongs of Late Middle English were: [ij] as in *stil(e)* 'stile', [ej] as in *weʒ* 'way', [ew] as in *newe* 'new', [iw] as in *stiward* 'steward', [uw] as in *ful* 'fowl', [ow] as in *bowe* 'bow', and [aw] as in *lawe* 'law'. Toward the end of the period, the long vowels /i:, e:, u:, o:/ had already started changing to /əj, ij, əw, uw/ in the south.

Middle English continued the Old English tendency to make vowel length dependent on its environment. A change started in the north toward the end of the twelfth century, and gradually reached the south by the end of the fourteenth, whereby stressed vowels in open syllables (syllables with no final consonant) were lengthened in words of two syllables. Examples of this development are:

Old English *talu*	[talə] 'tale'	Middle English *tale*	[ta:l(ə)]
Old English *nosu*	[nɔzə] ' nose'	Middle English *nose*	[nɔ:z(ə)]
Old English *brecan*	[brɛkən] 'break'	Middle English *brek(e)*	[brɛ:k(ə)]

The lengthening often did not take place when the second, unstressed, syllable of the word was not lost. This produces patterns of historically related words like *game ~ gammon, late ~ latter, shade ~ shadow, throat ~ throttle, nose ~ nostril*. An important spelling consequence of this change is that, in the modern language, words that contain the orthographic sequence -VC*e* (any vowel + any consonant + final -*e*) are usually interpreted as containing a long (or tense) vowel.

The opposite tendency, toward shortening, was also a continuation of Old English changes. Long vowels were shortened before two or more consonants, thus: Old English *gōdspell* 'gospel'> Middle English [gɔsp(ə)l], Old English *crēpte* [kre:pte] 'crept' > Middle English *crepte* [krɛpt(ə)]. These shortenings are responsible for Modern English patterns like *cheap ~ Chapman, dear ~ darling, five ~ fifth, wise ~ wisdom*. This change is also connected with the modern spelling convention, whereby consonants are doubled when adding suffixes only after short vowels, as in *beg ~ begged, drum ~ drummer, fat ~ fatter, sit ~ sitting, red ~ redden* (compare *fate ~ fated, site ~ siting*).

The most far-reaching single event in Middle English sound change, which profoundly affected the general shape of the language, was the loss of final unstressed vowels. In early Middle English, final unstressed vowels lost their qualitative distinctions and merged into the mid-central vowel schwa [-ə], usually spelled <-e>. By c. 1400, all final schwas, including a number of grammatical endings, had disappeared from the pronunciation; the <-e> remained in the language as a spelling convention indicating the quantity of the vowel in the preceding syllable, e.g. *bite ~ bit, cut ~ cute, mate ~ mat, mete ~ met, note ~ not*.

During Middle English, the consonantal system reached its present-day state except for the later (seventeeth century) introduction of /ʒ/ as in *measure*. Long consonants, as in *bedd* 'bed' and *sterre* 'star,' were simplified. A combination of factors, most notably the influx of French loanwords, resulted in an enriched system of consonant distinctions. The voiced fricatives, [v, ð, and z], which in Old English could appear only in the middle of a word, when flanked by vowels, became independent phonemes, allowing minimal pairs such as *fast - vast, thigh - thy*, and *seal* 'acquatic mammal' - *zeal*. The consonant /h/ remained

stable only initially before vowels. The chart below shows the consonant inventory of late Middle English:

	Labial	Dental	Alveolar	Palatal	Velar
Voiceless stops	p	t			k
Voiced stops	b	d			g
Voiceless fricatives	f	θ	s	ʃ	h, x
Voiced fricatives	v	ð	z		
Affricates			č, ǰ		
Nasals	m	n			
Liquids		l, r			
Approximants				j	w

Word and Sentence Structure

The weakening and loss of final unstressed vowels in Middle English resulted in a very significant reduction of distinctive grammatical markers. Until the twelfth century, English nouns and their determiners agreed in grammatical gender: *se dæȝ* 'the day' (masc.), *seo spræc* 'the speech' (fem.), and *þæt word* 'the word' (neuter). The Old English gender system was grammatical, because the fact that a noun was feminine or masculine did not necessarily reflect feminine or masculine traits of the object referred to. Most of the gender marking was lost during the Middle English period, and for the few elements that still show gender, such as the pronouns *he, she, it,* the gender reflects actual sex differences. While Old English inflected nouns differently depending on whether they occurred as subjects or objects, this distinction was also gradually leveled out and had disappeared completely by the end of the Middle English period. The plural and the possessive *–es* endings, used only for one subgroup of masculine and neuter nouns in Old English, spread to all nouns. The difference between singular and plural adjectives (marked by *-e* for the plurals) was abandoned after the end of the fourteenth century.

The personal pronouns in Middle English had the same distinctions as in Modern English: singular/plural, subject/object, first/second/third person, and three genders for the third-person singular. The most important innovation in the pronoun system of Middle English was the adoption of the Scandinavian pronouns *they, them, their,* which replaced Old English *hie, hem, hire.* Throughout Middle English, there were two separate second-person pronouns: *thou, thee, thine/thy* (singular) and *ye, you, your* (plural).

Verb forms in Early Middle English were marked for number, person, tense, and mood. Many of the inflections were identical, however: *-e* was the first-person singular present tense, the singular subjunctive for all persons, present and past tense, the singular imperative, etc. The phonetic loss of unstressed vowels resulted in essentially the modern system except for the survival of *-(e)st* and *-(e)th* for the second- and third-person singular, present tense. The modern third-person singular present tense suffix *-(e)s*, an inflection of obscure origin, possibly influenced by Scandinavian, was originally restricted to northern texts. It spread to the Midlands and the south during the fourteenth century and reached London by c. 1400. Many formerly 'irregular' verbs began to develop regular past tense forms ending in *-ed: cleave ~ clove ~ cleaved, help ~ holp ~ helped, leap ~ lope ~ leaped, walk ~ welk ~ walked.*

During the Middle English period, many complex verb forms and auxiliary verbs continued to develop and enrich the verbal system. Except for the passive progressive forms (*is/was being written*), all other progressive forms, the perfect, and the pluperfect forms (*has arrived, had arrived*) were in use by Late Middle English. The basic modal auxiliary verbs, *can, may, must*, were also in place, and the earlier modal auxiliaries *shall* and *will* were often used as pure future tense markers. The verb *do* was used as a tense marker, a causative verb, and a substitute verb, but not as an auxiliary verb in its modern functions. Questions were formed by simple inversion of the verb and the subject: *Seist thou hit me?* 'Are you saying it to me?' Negation in the early texts could involve attaching the particle *ne* 'not' before the verb, but gradually the negative function was taken over by the originally emphatic *naht* 'naught, not' from *nawiht* 'nothing', often positioned immediately after the verb. Multiple negation was common: *Of fule spaches hie ne mai nauht þolien.* '(Of) foul speaking they not can/may not tolerate.'

In the course of Middle English, the order of the sentence elements became essentially identical to that of Modern English, Subject–Verb–Object, in both main and subordinate clauses. Fixing the position of the subject and the object with respect to the verb is related to the loss of grammatical markers. Unlike Modern English, where only certain adverbs such as *ever, never,* and *sometimes* can intervene between an auxiliary and its main verb, Middle English allowed the object to be enclosed between the two parts of the verb: *I ne* **haue** *nowt but mi swerd* **ibrout**. 'I not-**have** nothing except my sword **brought**.'

Vocabulary and Word Formation

The most serious linguistic consequences of the Norman Conquest were in the area of vocabulary and word formation. It is estimated that approximately 10,000 words were borrowed from Anglo-Norman and

French into Middle English. Seventy-five percent of these early loanwords are still in use. Among them are (a) everyday words: *air, beast, close, dangerous, feast, flower, jealous, journey, liquor, mountain, noble, river, soil, tender, very,* etc.; (b) legal, administrative, and political terms: *army, assembly, council, defense, judge, liberty, navy, parliament, record, servant, soldier, tax;* and (c) words from the spheres of literature, art, science, and medicine: *beauty, color, grammar music, poet, physician, romance, surgeon.* New words continued to be produced by compounding: *bedtime* (c. 1250), *hangman* (c. 1393), *coal-black* (c. 1250), *to overcast* (c. 1225), and *worldly-wise* (c. 1415) are some examples, with the earliest recorded dates in parentheses. Mixed-source compounds began to appear too: *breast-plate* (1386), *freemason* (1376), and *knight erran*t (1350), combining English with French roots, while in *commonweal* (1330), *cornerstone* (1300), and *gentleman* (1275), the French root is followed by an English root. The inventory of Old English prefixes and suffixes was increased by a large number of Romance ones: *en-, mis-, re-, sub-, able-, -ance, -ess, -ment, -ous*, which could produce mixed-origin words such as *talkative, unknowable, wizard* (English roots + Romance suffixes), and *colorless, cheerful, spousehood* (Romance roots + English suffixes). Related to the fact that Middle English lost final unstressed vowels was the new tendency of freely converting words from one part of speech to another, i.e. nouns could simply be used as verbs, verbs as nouns, adjectives as verbs, etc., without any particular marking. Examples of this process are the verbs *child* 'give birth' (c. 1200), *calm* (c. 1399), *cripple* (c. 1300), *tame* (c. 1315), and *word* 'speak' (c. 1205), all formed from earlier nouns and adjectives.

Migration and Language

In some sense, probably all the world's languages are migrants. In a few cases, languages are spoken in a particular region because the ancestors of their speakers were the first people ever to live there: thus, Austronesian languages were spread across previously uninhabited Oceanic islands between about 1600 BCE and 1300 CE. Often, however, languages are carried by new settlers into a region already inhabited by speakers of different languages: hence, for instance, indigenous languages of the Americas and Australia have been largely replaced by Western European languages during the last few centuries. Such replacements may occur gradually if the migrants have techniques of food production that enable them to outreproduce the original inhabitants (*demic diffusion* or the *wave of advance* model): thus, Bantu-speaking farmers spread over much of southern Africa between about 3000 BCE and 500 CE, into territory previously

occupied by hunter–gatherers and herders speaking non-Bantu languages. Alternatively, a relatively small but highly organized group may impose a new language on an existing population through military conquest (*élite dominance*), as seems to have occurred in the Roman empire, giving rise to the Romance languages.

Migration may have a range of linguistic consequences of great theoretical interest. If it results in two languages coming into contact, one may die out because of deliberate suppression or because the speakers choose to shift to the other language on socioeconomic grounds. If both remain in existence, there may be lexical borrowing, particularly into the language perceived as having less prestige (thus, the Roman occupation of Britain resulted in extensive borrowing of vocabulary from Latin into Brittonic Celtic). In cases of long-term stable multilingualism in a community, the languages may converge in structure, as has been observed in Kupwar in India between Indo-European and Dravidian languages. Finally, a pidgin may arise when speakers of different languages have some strong need to communicate, but cannot for some reason acquire each other's languages fully, as, for instance, in trading situations or on slave plantations in the colonial era.

Another particularly significant result of migration is the creation of language families. When a speech community splits because of movement of some speakers to new areas, the language spoken by the different groups will diverge as various changes accumulate in each population (resulting from internal drift or external influence) and are unable to propagate to the other populations. Over time, this diversification produces a "family tree" of languages (the Austronesian languages seem to provide a particularly clear-cut example). However, if contact is maintained between the speech communities, changes will be able to diffuse between neighboring groups, producing a dialect continuum of related speech forms, rather than a clearly defined tree (as is still seen to some extent in Western Europe within parts of the Romance and Germanic groups).

Such language families provide the basis for comparative historical linguistics. However, their existence has also been used by several nonlinguists as evidence for prehistoric population movements. Thus, from an archeological perspective, Colin Renfrew has suggested connecting the Indo-European family with the spread of farming from Anatolia across Europe and India after approximately 6500 BCE and linking the controversial Nostratic language grouping with still earlier movements from the Fertile Crescent. Luigi Cavalli-Sforza has noted that genetic discontinuities often correspond to linguistic divisions: for instance, Rh-negative individuals are considerably more common among the Basques than other Europeans, and Basque is a linguistic isolate, unrelated to its Indo-European neighbors. He argues that the Basques may represent a pre-Indo-European people, confined to a small mountainous location by later population incursions.

Besides the mere existence of language families, other linguistic information can contribute to an understanding of early migrations. According to the *age–area hypothesis* (formalized by Isidore Dyen as *migration theory*), the location of greatest diversity within a language or family is likely to be the original homeland from which the family spread, because the deepest divisions reflect the earliest splits; moreover, this theory minimizes the number of movements required to explain the current distribution. Thus, English dialectal diversity is greater within Britain than in the more recently settled English-speaking parts of the world. Linguistic paleontology (the study of reconstructed cultural vocabulary) may also provide clues to the area of origin of a family. A third line of evidence is provided by borrowed vocabulary, revealing contact with other groups: the movements of the Gypsies from India to Iran, the Caucasus, Anatolia, and then to the Balkans have been traced by Kaufman in various sets of loanwords in Romani.

A recent strand of research relating to migration and language has considered the distribution of linguistic diversity around the world. Johanna Nichols, drawing on techniques of the population sciences, has sought to quantify structural and genetic diversity of languages in different areas and has distinguished between *residual zones* (characterized by high genetic density and structural diversity, often in mountainous regions serving as linguistic refuges: the Caucasus is an example) and *spread zones* (whose low genetic and structural variation results from the spread of a single language or family across the area: an instance is the Eurasian steppe). She has also argued that the high diversity in the Americas implies earlier and more numerous settlements than those proposed by Joseph Greenberg, whose 'Amerind' people are claimed to have entered the Americas approximately 14,000 years ago. Daniel Nettle, however, adopting Robert Dixon's evolutionary–biological model of *punctuated equilibria* for language change, has opposed her theory that languages ramify at a constant rate over time. He proposes that the initial movement of people into a large uninhabited area (such as the Americas) would promote rapid diversification as communities occupied available habitat niches, followed by gradual areal convergence or local language replacement, resulting in a decline in

linguistic and genetic diversity. A Neolithic transition in an area would provoke a faster reduction of diversity, as farming groups advanced through previous hunter-gatherer territory (as in Eurasia and Africa, where initial human settlement and development of food production were comparatively early).

Miskito and Misumalpan Languages

Miskito is the most widely spoken language of a Central American language family known as Misumalpan. John Mason coined the term Misumalpan using the first two letters of its three branches: Miskito, Sumo, and Matagalpan. Miskito and Sumo are spoken in the Mosquito Coast region of Eastern Nicaragua and Honduras by approximately 150,000 and 8,000 people, respectively. The now extinct Matagalpan languages, Matagalpa and Cacaopera, were spoken in the Central Highlands of Nicaragua and Southeastern El Salvador.

Misumalpan is a relatively small language family that in the pre-Columbian period was surrounded geographically by larger and more widespread language families from Mesoamerica (Otomanguean, Uto-Aztecan, and Mayan) and lower Central America (Chibchan). Before the ninth century, Misumalpan languages are presumed to have been spoken in all of the three major ecological zones of Nicaragua: (1) the Pacific Lowlands, (2) the Central Highlands, and (3) the Caribbean Coastal Plain. However, starting at this time, two major waves of migration from Mesoamerica resulted in Mesoamerican languages displacing Misumalpan languages to the East.

Speakers of the Otomanguean language family who originated in Soconusco, Chiapas comprised the first wave that settled in the Pacific Lowlands and the

Nicoya Peninsula of modern Costa Rica. These migrants were known by the Spanish as the Chorotega and they left behind two now extinct languages—Mangue and Subtiaba. Uto-Aztecan migration occurred slightly after the Otomanguean migration. The first Nahau-speaking people arrived in the ninth and tenth centuries and settled in what is now El Salvador and Northwestern Nicaragua. The second wave of migrants, whose languages came to be known as Pipil or Nicarao, arrived in the twelfth century and settled on the Western shore of Lake Nicaragua.

By the time of the Spanish conquest, Misumalpan languages had virtually been eliminated from the Pacific Lowlands. However, the western branch of Misumalpan languages continued to be widely spoken in the Central Highlands. Matagalpa, also known as Pantasmas, survived throughout the colonial period but by the end of the nineteenth century it had been replaced by Spanish. Nevertheless, an Indian ethnic identity and certain communal institutions and land tenure systems continue into the present in the Nicaraguan province of Matagalpa. In the Morazán province of Southeastern El Salvador, Cacaopera survived into the twentieth century but at present, it has been completely replaced by Spanish. The case of Cacaopera has puzzled linguists because it occurred well out of the Nicaraguan homeland of Misumalpan

languages. Together, Matagalpa and Cacaopera comprise Matagalpan, the name used to refer to the western branch of Misumalpan languages.

Although several distinct dialects of Miskito exist, Miskito is more homogenous than Sumo and Matagalpan and it is therefore considered an isolate within the language family. Sumo and Matagalpan are more internally differentiated and are also more closely related to one another than either is to Miskito. Therefore, they are grouped by linguists in a subfamily called Sumalpan. In turn, Sumo has two distinct branches—Northern Sumo and Southern Sumo. Three extant dialects of Northern Sumo, Tuahka, Panamahka, and Tawahka, continue to be spoken today while Southern Sumo has a single extant representative, Ulwa, and other extinct dialects such as Kukra. Tuahka, also spelled Twahka, is spoken by a few hundred people in and around the village of Wasakin along the Bambana River in the Mosquito Coast. Panamahka is the most common Sumo dialect and it is spoken by about 6,000 speakers living in the area of the Waspuk River and its tributaries in Nicaragua. Tawahka is spoken in Honduras by about 1,000 people around the Patuka River. Finally, the Southern Sumo language Ulwa is spoken in the village of Karawala on the Rio Grande de Matagalpa by about 350 people. Ulwa is in the final stages of extinction as residents of Karawala, most of whom define themselves as ethnically Ulwa, are becoming Miskito, English, and Spanish speakers, as opposed to the long-standing pattern of Miskito-Ulwa bilingualism.

Whereas Sumo and Matagalpan languages have geographically receded over the last 1,000 years, Miskito expanded during the colonial period. Believed to have originated in the Cape Gracias, a Dios region at the terminus of the Coco River that forms the eastern border between Nicaragua and Honduras, Miskito is now spoken by over 100,000 people living along the coast and major rivers between the Escondido River in Nicaragua and the Black River in Honduras. As a result of the dislocations caused by the Contra-Sandinista War, Miskito speakers now live in large numbers in Managua, Miami, and Port Arthur, Texas. In alliance with the British who became commercially and militarily active in the region starting in the 1640s, Miskito-speaking people became a strong force in the Western Caribbean allowing them to expand their area of influence and settlement well beyond their traditional boundaries. As a result, Miskito place names can be found as far as the Caribbean coastal areas of Costa Rica and Panama. Hence, the Sixaola River that divides Costa Rica comes from the Miskito 'Siksa' (Black) and 'Awala' (River).

This Miskito historical ascendance explains in part the relative homogeneity of Miskito as well as its extensive borrowing of vocabulary from English and West African languages, whose influence was brought to the region as a result of English slavery and subsequent West Indian migration to coastal Central America precipitated by banana, mining, and lumber businesses. While Miskito also borrows from Spanish, linguists have found that Sumo and Matagalpan languages demonstrated a clear preference for borrowing from Spanish, while Miskito has historically borrowed primarily from English. This undoubtedly results from the coastal and external trade orientation of the Miskito as opposed to the upriver and subsistence agricultural pattern of the Sumo, who live on the eastward-moving frontier between Spanish-speaking Western Nicaragua and the Mosquito Coast. In a volume about Mosquito Coast Creole English, Johm Holm extensively studied the influence of Mosquito Coast English and West African languages on Miskito. He concluded that Miskito grammar and phonology was not significantly influenced by African languages but lexical borrowing from among others, Fon, Twi, Bambara, Igala, Yoruba, and Kongo, is unmistakable. For example, Miskito people tell 'anansi' stories (from the Twi word for spider) and their sorcerers are known as 'sukias' (from the Fon word sukuna). Whereas the Sumo word for river mouth is 'tikipas', the Miskito word is 'bila'—derived from the Kongo 'bwiila'. Mosquito Coast English and Miskito are deeply interpenetrated. Unlike Sumo and Matagalpan languages, Miskito was able to project words into Caribbean Creole Englishes spoken in Belize, Jamaica, and elsewhere as well as British English itself. For example, the English word dory (canoe), which has an Oxford English Dictionary entry, entered British English through Miskito.

The ascendancy of Miskito people also explains in part the structural similarities between Misumalpan languages. In other words, linguists have noted the anomalous fact that based on the large degree of lexical differentiation, Misumalpan languages have clearly been separated from a common ancestor for a long time. In fact, based on the method of glottochronology, Morris Swadesh estimated that 43 minimum centuries have passed since they diverged. Yet, despite their distant point of divergence, they possess remarkably similar grammatical structures, which at first glance would suggest a more recent common origin. With regard to the similarities in grammatical structure between Miskito and Sumo, the widespread and historically deep pattern of multilingualism in the Mosquito Coast explains in part this incongruity. The majority of Sumo speakers, who have historically been in a subordinate position to

Miskito speakers, also speak Miskito as a second language.

The specific nature of multilingualism in the Mosquito Coast is directly related to the noted ethnic hierarchy and division of labor in the region that developed in the late nineteenth and early twentieth centuries when North American banana, lumber, and mining industries operated heavily in the area. During this time, English-speaking Creoles, Afro-Nicaraguans who emphasize their cultural and social connections to the West Indies, were the dominant locals who occupied the highest status occupations in the enclave economy of the region. Miskito and Spanish-speaking laborers from the Pacific occupied the next rung followed by Sumo Indians at the bottom of the hierarchy. Susan Norwood has noted a sociolinguistic landscape in which the lower status groups tend to learn higher status languages in addition to their own langauges. Hence, Miskito speakers typically learn Creole English and/or Spanish, while Sumo speakers tend to learn Miskito and Creole and/or Spanish when possible. Miskito speakers rarely learn Sumo, and English speakers often have some proficiency in Miskito but none in Sumo. Spanish speakers have by far the highest degree of monolingualism. Norwood found that some Northern Sumo speakers in the Ulwa village of Karawala spoke Panamahka, Ulwa, Miskito, English, and Spanish. Such situations of intense multilingualism and social stratification have had clear linguistic consequences, including the aforementioned structural similarities.

In 1920, German linguist Walter Lehmann convincingly demonstrated the unity of Misumalpan languages. Since then, linguists have speculated about its relationship with other language families. Until recently, linguists have commonly accepted the so-called 'Macro-Chibchan hypothesis', that postulates that Misumalpan and Chibchan languages share a common origin. This contention is based on an evaluation of the distribution of Chibchan languages in lower Central America as well as comparisons of extant Chibchan languages to Misumalpan languages. Recently, linguists such as Ken Hale, Danilo Salamanca, and Lyle Campbell have withdrawn their support from the inclusion of Mismulpan languages in Macro-Chibchan based on the inconclusiveness of the evidence.

Arguments for a Chibchan connection point to the presence of two clearly Chibchan languages both to the North and South of the Misumalpan heartland. Paya, also known as Pech, is a Chibchan language spoken by about 300 people in southern Honduras. Rama, spoken by about 25 people on Rama Cay close to Bluefields, Nicaragua, has been identified as part of the Votic branch of Chibchan that includes Costa Rica's Guatuso. Collete Craig has intensively studied and sought to preserve this language, which has now been almost completely replaced by Creole English. Adolfo Constenla Umaña, a Costa Rican scholar, has made a well-documented case for the plausibility of a shared common ancestor between Chibchan and Misumalpan. In an ambitious synthetic effort to categorize languages of the Americas, Joseph Greenberg presents 226 etymologies in his case for a high-level 'Chibchan-Paezan' family that includes Misumalpan as well as distant languages that have not been previously thought to be related such as Yanomami, Tarascan, and Chimu.

With the exception of Miskito, Misumalpan languages are in danger of becoming extinct in the near future. Despite the tireless efforts of Nicaraguan and North American linguists such as Collete Craig for Rama and Ken Hale and Tom Green for Ulwa, both these languages are not likely to last another generation. Sumo, whose Northern variant, is now sometimes called Mayangna, stands in a better position, particularly in light of recent legal victories for Sumo communities in Nicaragua.

Modern Linguistics

The discovery of Sanskrit in 1786 by Sir William Jones is a key event in the History of Linguistics because it initiates the age that extends up to the present time. The era of Modern Linguistics, as it is named, thus covers two centuries that, as will be seen, differ greatly in their linguistic methodology and orientation.

Despite being the age of Comparative and Historical Linguistics, the nineteenth century must be considered a heterogeneous era where three stages can, at least, be identified: the early, the mid-, and the late nineteenth century. The initial phase of the century is, for example, particularly important for being the period when the birth of this new linguistic tradition takes place. The resemblance of Sanskrit to classical languages such as Latin and Greek and also to several Germanic languages brings to light at the end of the eighteenth century two assumptions that, as illustrated in the works by Rasmus Rask (1787–1832), Jacob Grimm (1785–1863), and Franz Bopp (1791–1867), become the hallmark of the linguistic research initiated in the early Romantic age: (a) the existence of a common ancestor language, named Indo-European, for these apparently unconnected languages; (b) and consequently, their possible comparison, as well as, by extension, that of all languages over the world. Notice, in fact, that the first sound law intended to reconstruct the phonological system of Indo-European, known as Grimm's law, and the first linguistic typology established by Wilhelm von Humboldt (1767–1835) according to the morphological pattern the Indo-European languages exhibit, go back to this specific period.

The mid-nineteenth century is, in turn, remarkable because, transferring to the linguistic situation the growing interest of the time in history and the natural sciences, it entails the full establishment of the comparative and historical method of linguistic analysis. As a consequence, the strictly contrastive interest of the previous stage is supplemented in this intermediate phase of the Romantic age, as reflected in its most significant contributions, with an enormous desire to investigate the historical and genetic evolution of languages: August Schleicher's Genealogical Tree Model (1821–1868) is, for instance, designed in consonance with the Darwinian theory to establish the genetic relationships between Indo-European and its descendants, and Johannes Schmidt's Wave Model (1872) is alternatively devised to explain the fact that genetically unconnected languages can and, in fact, do share several linguistic phenomena.

The beliefs pervading linguistic thought up to then are altered late in the century due to the neogrammarian doctrine (1870–1900) defended by scholars such as Hermann Osthoff, Karl Brugmann, and Hermann Paul. The neogrammarians, thus, initiate a new phase in the development of Comparative and Historical Linguistics, which has to be understood, in general, as a reaction against the research carried out previously. Notice, for example, that they reject, among others, Humboldt and Schleicher's idea about the organic nature of language, and that the grammatical laws they postulate do not allow, in contrast to the earlier ones, any kind of irregularity; hence, their need to develop the concept of analogy.

The age of Comparative and Historical Linguistics comes, nevertheless, to its end at the beginning of the twentieth century with the posthumous publication of Ferdinand de Saussure's *Cours de linguistique générale* (1916), which, as deduced from its most basic contents, means a return to Descriptive Linguistics: (a) as a system of interdependent phonological, syntactic, and lexical elements, a language has form and substance; (b) the linguistic competence of a speaker is different from his real linguistic production; hence, the distinction between *langue* and *parole*; and (c) the study of language can be approached either from a diachronic or from a synchronic perspective.

The influence of this work is, in fact, quickly seen in Europe, where conferences, publications, and schools with a clear structural orientation constantly appeared during the first half of the century: among others, the Prague School with Nikolaj Trubetzkoy and Roman Jakobson, the Copenhagen School with Louis Hjelmslev and the London School with John Rupert Firth. Although also pervading the American thought up to the 1950s, the structural linguistic trend takes a slightly different course in the United States owing to the following facts: (a) the existence of unknown American-Indian languages, which arouses an anthropological interest in linguists such as Franz Boas and Edward Sapir; and (b) the influence of behaviorist psychology, which developed around the hypothesis that all kinds of analysis must be based on describable facts, excludes the semantic component of language from the structural theories of outstanding linguists such as Leonard Bloomfield.

The publication of Noam Chomsky's *Syntactic structures* in 1957 finishes, nevertheless, with the

structural theoretical framework and initiates, consequently, a new period in the History of Descriptive Linguistics. The era of Transformational-Generative Grammar, as it is called, signifies a sharp break with the linguistic tradition of the first half of the century both in Europe and America because, having as its principal objective the formulation of a finite set of basic and transformational rules that explain how the native speaker of a language can generate and comprehend all its possible grammatical sentences, it focuses mostly on syntax, and not on phonology or morphology, as structuralism does. Its situation changes, however, from the 1980s onward because, with the increasing interest in meaning awakened in this particular period, the Transformational-Generative model ceases to be the only theoretical framework of the time and instead coexists with several new approaches to the study of language, labeled as functional for regarding, in sharp contrast to the latest version of the Chomskian theory, semantics and pragmatics as the most basic levels of linguistic analysis. In any case, the last modification of Transformational-Generative Grammar nowadays continues to be the leading linguistic theory from among all the formal ones that, for their part, focus mainly on the structural components of language and show, consequently, an almost complete disregard for meaning.

In sum, the age of Modern Linguistics lasts two centuries, which, although heterogeneous in themselves, differ greatly in their linguistic interests: the nineteenth century mainly devoted to the comparison and historico-genetic evolution of languages, and the twentieth century chiefly concerned, in turn, with the description of the linguistic system.

Modification

Two properties semantically motivate the syntactic categories clause and noun phrase, respectively: predication and reference. Clauses involve a predication, that is, they make a judgment about an entity, as in *The weather was changeable*. Noun phrases exhibit the property of reference, whereby linguistic entities make reference to extralinguistic entitites, as in *the green pencil*. Fully referential noun phrases may be both determined and modified. Pronominal noun phrases do not admit either determination or modification (*****that** she* or ***outgoing** he*, for instance, are ungrammatical in Contemporary English, which is indicated by the presence of the asterisk preceding the hypothetical expression); noun phrases whose head is a name instead of a noun undergo determination and modification under certain circumstances, as in ***the big** Jack*.

Determination is a function of the noun phrase that is performed, in English, by grammatical categories (as opposed to lexical categories, which include the noun, the adjective, the verb, and the adverb): the closed classes of the article (*a* and *the*), the demonstrative (*this-these/that-those*), the quantifier (*some*, *much*, etc.; also numerals like *one-first*, etc.) and the possessive adjective. Unlike determination, modification is not exclusive of the noun phrase.

Modification is a function of the noun phrase, the adjectival phrase, the adverbial phrase, and the prepositional phrase, which is realized by the syntactic categories of phrase and clause. Instances of modification in the noun phrase, the adjectival phrase, the adverbial phrase, and the prepositional phrase are, respectively: the **sharp** edge, difficult **to handle**, **incredibly** fast, and **well** below zero. These examples illustrate the contrast between phrasal and clausal modification: the adjectival phrase sharp modifies the nominal head edge, the adverbial phrase incredibly modifies the adverbial head fast, and the adverbial phrase well modifies the prepositional below, whereas the embedded clause to handle modifies the adjectival head difficult. Phrasal and clausal modification give rise to different degrees of phrase elaboration: phrasal modification turns out simple phrases, such as the noun phrase a paltry ten pounds; whereas clausal modification produces complex phrases, as is the case with the adjectival phrase impossible to forget.

In English, the inventory of phrases as modifiers includes the noun phrase, the adjectival phrase, the adverbial phrase, and the prepositional phrase (in other words, all phrasal syntactic categories with the exception of the verb phrase). Noun phrases as modifiers of other noun phrases belong to two classes: they are either nominal compounds (lexicalized or not), as in the **picture** pen, or possesssive modifiers in the genitive, as in **Sally's** promotion. Adjectival phrases modifying nominal heads fall into the descriptive and classifying subtypes: descriptive adjectival phrases focus on a certain property of the noun that functions as a nominal head, as in the **high** wall; classifying adjectival phrases assign a label of type or class to the noun in function of nominal head, as in the **regimental headquarters**. Even though both descriptive and classifying adjectival phrases perform the function of restricting the semantic scope of the modified, descriptive adjectival modifiers in English admit intensification with very (a **very high** tower), whereas classifying adjectival phrases do not (****very** regimental headquarters*). Typically, adverbial phrases modify adjectival heads in adjectival phrases, as in **surprisingly** difficult. Adverbial phrases also function as modifiers of other adverbial phrases, as is the case with **very** deeply. Instances of adverbial phrases as modifiers of noun phrases include adverbial genitives like today's in **today's** top ten. Prepositional phrases modifying nominal heads typically involve possessive postmodification as in the branch **of the tree**. Postmodification by means of prepositional government is also present in noun phrases like the shop **with the dusty window**. An instance of a prepositional phrase modifying an adverbial head is far away **from here**. All the examples given above focus on the

recursive (i.e. repetitive) character of modification: sometimes, modifiers contain heads that are modified themselves, as in the woman with the glittering jewellery, where the prepositional phrase that modifies the nominal head woman governs a noun phrase in which the nominal head jewellery is modified by the adjectival phrase glittering.

Examples like the **sharp** edge, difficult **to handle,** and **incredibly** fast also show the difference between premodification and postmodification in English. The linear order is modifier–modified in the sharp edge and incredibly fast whereas in the adjectival phrase difficult to handle the order qualifies as a modified–modifier. The former linear order is called premodification and the latter is called postmodification. Also of structural import is the question of the syntactic (dis-) continuity of modifiers. When modifier and modified are adjacent, the linear arrangement is described as syntactically continuous, as in **a man who wore a panama hat** called in, where no constituent has been inserted between the relative clause and its antecedent. If modifier and modified are not adjacent, the linear arrangement is termed syntactically discontinuous, as in **a man** called in **who wore a panama hat**, where the verb phase separates the modified (the antecedent) and the modifier (the relative clause). Whereas relative order in the phrase and adjacency represent syntactic phenomena, the phenomenon of double (or multiple) modification is essentially semantic since the structural arrangement of the modifiers with respect to the head reflects the degree of semantic integration of the entity and the properties that are associated with it (typically, in the context of several adjectives modifying a single noun, as in a **small round green** box).

Considering clauses as modifiers, they can be either finite or nonfinite, depending on whether the verbal predicate agrees with the subject or not. Finite clauses in the function of modifier include the relative clause, the nominal modifier clause, and the adjectival modifier clause. Relevant examples of relative clauses modifying nominal heads are the man **who married my sister** (unreduced), and the woman **with the walking-stick,** the manager **promoted by the new directors,** and the girl **riding that bike** (reduced). Nominal modifier clauses can be ilustrated by means of examples like the conclusion **that the plan is feasible**. Adjectival modifier clauses contain, typically, to-infinitive—thus, nonfinite—clauses in adjectival constructions like easy **to misinterpret**.

Morphologically, modifying categories, particularly adjectives, may be either marked or unmarked, that is, variable or invariable. In Contemporary English, modifiers are morphologically unmarked or invariable (with the exception of the genitive in position of premodification -**John's** mistake- and postmodification

-a mistake of *John´s*). Consequently, the tendency is for the modified element to carry the morphological mark (the distinctive feature). In other historical stages of the English language, such as Old English, the modifying adjective showed agreement of gender, number, and case with the nominal head, thus bearing the morphological mark.

Mohawk and the Iroquoian Languages

Mohawk is a language of the Iroquoian family. The family consists of two major branches: Southern Iroquoian and Northern Iroquoian. Southern Iroquoian is represented by just one language, Cherokee, now spoken primarily in North Carolina and Oklahoma.

Northern Iroquoian has several sub-branches. The first offshoot of Northern Iroquoian developed into Nottoway, Meherrin, and Tuscarora. The Nottoway people were first encountered by Europeans near the Virginia coast in 1650. The language, which disappeared during the mid-nineteenth century, is known through just two wordlists from the early part of that century. The Meherrin people were first encountered in 1650 near the North Carolina coast, but by 1730 they had merged with the Tuscarora. All that remains of their language are two town names. The Tuscarora were first encountered in eastern North Carolina. Early in the eighteenth century, most began to move northward, where their descendants reside today in two locations: near Niagara Falls in eastern New York State and at Six Nations in southern Ontario. Few speakers remain.

The second offshoot of Northern Iroquoian was Huron. The earliest mention of the Huron people is in Champlain's account of his 1615 visit to what is now southern Ontario. The Huron Confederacy, consisting of four tribes, was decimated in 1649 by attacks from the Five Nations Iroquois. Some survivors fled toward Québec City, where their descendants live today at Lorette. The language is no longer spoken there. Others settled with other Iroquoian groups in the area. Some of these groups were subsequently defeated as well, and the survivors, a mixture of Huron, Petun, Erie, and Neutral, moved west to Sandwich, Ontario, and became known as the Wyandot. Many subsequently moved southward, ultimately ending up in Oklahoma. The Wyandot dialect of Huron was last spoken in the mid-twentieth century. French missionaries among the Huron, particularly during the seventeenth and eighteenth centuries, left rich records of the language. Wyandot texts and lexical and grammatical material were recorded in the early twentieth century. Petun, Neutral, Wenro, and Erie are known only through some names.

Five of the remaining Northern Iroquoian groups, the Seneca, Cayuga, Onondaga, Oneida, and Mohawk, formed a strong political alliance known as the League of the Five Nations Iroquois. Their territories stretched essentially from the western edge of modern New York State, where the Senecas were known as the Keepers of the Western Door, to the eastern edge, where the Mohawks were the Keepers of the Eastern Door. Another group to the north, now known as the Laurentian, was not part of the League, nor was a group to the south, the Susquehannock. The Laurentians met Jacques Cartier in 1534 at the mouth of the St. Lawrence River, but they had disappeared from the area by the time of Champlain's arrival in 1603. Vocabulary lists of their languages remain from the time of Cartier's voyage, and it is from them that we have the name *Canada*, a term that persists in the modern Five Nations languages today meaning 'settlement, town'. The Susquehannock to the south, also known as the Andaste, suffered during the

colonial period from European diseases and attacks from colonists and the other Iroquois until the last survivors were murdered in 1763. Their language is known through a wordlist recorded by a Swedish missionary in his journal published in 1696.

The Five Nations languages are all still spoken today primarily by elders, although all communities have language classes. Seneca is spoken in three communities in western New York: Cattaraugus, Allegany, and Tonawanda. Cayuga is spoken at Six Nations in southern Ontario, where many Cayugas fled after the American Revolution. Other Cayugas moved into Oklahoma, where the language was spoken until the late twentieth century. Onondaga is spoken in central New York south of Syracuse and at Six Nations. Some Oneidas remain in New York State, but most moved to southern Ontario near London, and to Wisconsin near Green Bay. There are six main Mohawk communities: Six Nations in Ontario; Tayendinaga near Deseronto in Ontario; Ahkwesahsne with territory in Ontario, Québec, and New York State; Kanehsatake at Oka to the northwest of Montreal; Kahnawake on the southern shore of the St. Lawrence across from Montreal; and Wahta at Gibson in Ontario. There are several thousand speakers of Mohawk, more than any of the other Northern languages. The ages of the youngest speakers vary from community to community, but there are immersion schools in four of them, at Six Nations (Ohsweken), Ahkwesahsne, Kanehsatake, and Kahnawake. A number of speakers of Iroquoian languages reside outside of these communities as well.

Although the languages are not mutually intelligible, their basic structures are similar. They are illustrated here with examples from Mohawk.

The consonant inventory is small: *t, k, kʷ, ts, s, n, r, y, w, h, ʔ.* There is a notable absence of labials (such as *p, b,* or *m*). The vowel inventory is similarly small: *i, e, a, o, ũ, ʌ̃.* The Mohawk communities have agreed on a practical orthography, which represents the consonants as *t, k, kw, ts, s, n, r, i, w, h, and '* (with *i* for the glide [j] and apostrophe for glottal stop). The vowels are spelled *i, e, a, o, on,* and *en,* with nasalization indicated by a following *n.* Stress originally occurred on the penultimate syllable of a word, although the pattern can be obscured by the addition of vowels within the word. The stressed syllable carries distinctive tone (pitch). An acute accent marks high or rising tone (*ó*), and a grave accent marks falling tone (*ò*). The falling tone appears where a stressed vowel immediately preceded a laryngeal (such as *h*), as in **iahratóhrok',* which became *iahatò:roke'* 'he climbed under there'. If a syllable ended in a laryngeal, the laryngeal was lost,

leaving just vowel length. Open, stressed syllables are lengthened, as in *kí:ken* 'this'. Length is marked orthographically with a colon:.

Nouns are based on a noun stem, which may be a noun root or a nominalized verb stem. Morphological nouns begin with a noun prefix. In unpossessed nouns, the prefix encodes the gender of the referent, like the Neuter *o-* in <u>*o*</u>*-tsíhkw-a'* 'fist, knot, knob, puck'. If the noun is possessed, the prefix encodes the person, number, and gender of the possessor, as in <u>*akw*</u>*-atsíhkwa'* '<u>my</u> puck'. Different sets of possessive prefixes are used for Alienable and Inalienable possession. The prefix *akw-* 'my' in 'my puck' indicates Alienable possession (meaning that the possessed is not an integral part of the possessor). The prefix *k-* 'my' in <u>*k*</u>*-atsihkwà:ke* '<u>my</u> fist' indicates Inalienable possession (meaning that the possessed is an integral part of the possessor). Inalienable possessions include most body parts, but not hair or internal organs such as the heart or stomach. Separated body parts such as eyelashes or fingernails are Alienable. Terms for most kinsmen do not describe possession, but rather the relationship, such as *rake'níha* 'my father', literally 'he is father to me', or the reciprocal *atiara'sè:'a* 'my cousin', literally 'we two are cousins to each other'.

Morphological nouns end in a noun suffix. The most common is *-a'* as in *otsíhkw-*<u>*a'*</u> 'knob'. Various grammatical endings can be added to words serving as nominals, as in *Kahnawa'kehronon'kénha'* 'former Kahnawake residents': *ka-hnaw-a'=ke=hronon'= kenha'* NEUTER - rapids - NOUN.SUFFIX = LOCATIVE = RESIDENTIAL = DECESSIVE.

Verbs are potentially the most complex words and by far the most frequent in speech. All verbs contain a pronominal prefix, a verb stem, and, apart from commands, an aspect suffix. This structure can be seen, for example, in *katerohrókha'* 'I watch': *k-aterohrok-ha'* I-watch-HABITUAL. The pronominal prefix represents the core arguments of the clause, that is, the one or two major persons or objects involved. These specify person (first, inclusive, exclusive, second, or third), number (singular, dual, or plural), and in third person, gender (masculine, neuter-zoic, or feminine-indefinite). The grammatical roles of the arguments are specified as well, but not in terms of subjects and objects, but rather as grammatical Agents (typically those performing actions and controlling situations) and grammatical Patients (typically those affected by the situation but not in control). The categories are semantically based, but they are crystallized in the lexicon and the grammar, so that speakers have no choices about degrees of agency as they speak. Verb forms are simply learned with the appropriate prefixes. The

intransitive verb *eniakwaterohrókha'* '<u>we</u>'ll go watch it' contains the Agent pronominal prefix *iakw-* 'we all'. The intransitive verb *ionkwén:ten* '<u>we</u> are poor' has the Patient pronominal prefix *ionkw-* 'we'. The Agent and Patient components of transitive pronominal prefixes are often fused. The transitive verb *shakwá:iatskwe'* '<u>we</u> called <u>him</u>' has the transitive pronominal prefix *shakwa-* 'we/him'. The transitive verb *enionkhiia'tahserón:ni'* '<u>she</u> will dress <u>us</u> up' contains the pronominal prefix *ionkhi-* 'she/us'.

The verb stem may itself be complex. This stem *aterohrok* 'watch' contains a Middle prefix *-ate-*. Verb stems may also contain an incorporated noun stem, like *-nahskw-* 'domestic animal' in *ranahskwiióhne'* 'he was a beautiful animal': *ra-<u>nahskw</u>-iio-hne'* MASCULINE.AGENT-<u>animal</u>-be.beautiful.STATIVE-PAST ('he was beautiful in the way domestic animals are'). Incorporated nouns qualify the meaning of the verb. Nouns are incorporated both to create single words for recurring concepts, as above, and to manipulate the flow of information. When speakers wish to direct special attention to an object, they generally designate it with a separate, independent noun. If the object is an established part of the scene, or incidental to the point at hand, it may be backgrounded by incorporation.

Verbs may contain various additional prefixes and suffixes. Among the prefixes are a Contrastive for unexpected situations, a Coincident for similarity or simultaneity ('the same, when'), a Partitive 'so' that appears in a variety of syntactic constructions, a Negative 'not', a Translocative 'thither', a Factual typically used for past events, a Duplicative that indicates various kinds of 'two-ness', including repetition of an event or a shift in position or state, a Future tense 'will', an Optative 'might, should, would, could', a Cislocative 'hither, there', and a Repetitive 'again, back'.

Among the suffixes are an Inchoative 'become', several Causatives ('cause'), Instrumental Applicatives ('do with …'), Benefactive Applicatives ('do for'), Reversives ('un-'), Distributives ('here and there'), and Purposives ('go in order to …'). All verbs except commands contain one of the three basic aspectual suffixes: Habitual, Punctual, or Stative. The Habitual is used for recurring events and, with some verbs, for ongoing activities. The Punctual is a Perfective, used for events viewed as wholes. The Stative is used for states. With some verbs, it is also used for activities in progress, and with some verbs it is also used as a Perfect. The Habitual and Stative may be followed by a postaspectual suffix: Past, Continuative, or Progressive.

Because all verbs contain pronominal reference to their core arguments, they can serve as complete sentences in themselves: *wa'onkwanahskwaién:ta'ne'* 'we got a pet' (*wa'-onkwa-nahskw-a-ient-a'-n'* FACTUAL-1.PLURAL.PATIENT-domestic.animal-STEM.JOINER-have-INCHOATIVE-PUNCTUAL). The same verb can be part of a larger sentence: *wa'onkwanahskwaién:ta'ne' è:rhar* 'we got a dog'. Verbs can serve other syntactic functions as well. They can function syntactically as nominals, much like nouns. Some are lexicalized as nominals, so that speakers understand them first as names for entities, such as *tewa'á:raton* 'lacrosse stick' (*te-w-a'ar-a-t-on* CISLOCATIVE-NEUTER-net-STEM.JOINER-be.in-STATIVE 'it has a net in it'). Some are used alternately as predicates or nominals, like *tahontsihkwà:'eks* 'they hit the puck, they play lacrosse' or 'lacrosse players' (*ta-hon-tsihkw-a-'ek-s* CISLOCATIVE-MASCULINE.PLURAL.AGENT-puck-STEM.JOINER-hit-HABITUAL). Full verbs are also used for many functions served by adjectives and adverbials in other languages.

Because the verb provides a full grammatical skeleton of the sentence, word order is used for purely pragmatic purposes. Nouns are strikingly rare in connected speech; sentences most often consist of just a verb and various particles. When independent nominals are present in a clause, all possible constituent orders can occur, although not all would be pragmatically felicitous. After various orienting particles, the most important elements tend to occur early in the clause, with successively more predictable and peripheral information expressed later.

Some of these structures can be seen in the excerpt below from an anecdote told by Watshenní:ne' Sawyer of Kahnawake. (Abbreviations include M for MASCULINE, N for NEUTER, PL for PLURAL, PRT for PARTITIVE, SJ for STEM JOINER, and ST for STATIVE.)

Mongolian

The language known as Mongolian, one of several languages belonging to the Mongolian subgroup of the Altaic languages, is based on the Khalkha language. It is spoken in northeastern Asia by approximately 2.5 million people in the Mongolian People's Republic, commonly known as Outer Mongolia, where it is the official language. In addition, about 2 million people in the Inner Mongolian Autonomous Region of the People's Republic of China and up to half a million people in other areas of northern China speak Khalkha Mongolian. Other languages that belong to the Mongolian subgroup of the Altaic family include Oirat in Outer Mongolia and China, Kalmyk along the lower Volga River in the Kalmykia Autonomous Soviet Socialist Republic and in parts of China, Mogul in Afghanistan, Buryat in the Buryatia Autonomous Republic and in parts of China, Dagur in Heilongjiang and the Inner Mongolian Autonomous Region of China, Santa in the Gansu region of China, and Monguor and Bao'an, both in the Qinghai region of China.

As an Altaic language, Mongolian shares several characteristics with other languages in this family. Some of these include agglutination, the use of postpositions instead of prepositions, vowel harmony, the placement of modifiers before what they modify, the absence of a relative pronoun, the absence of a verb meaning 'to have', the absence of grammatical gender, and the absence of articles. Despite these

similarities, some linguists do not accept the thesis of a common 'Altaic' origin. They claim that they may be due to sociolinguistic contact and mutual interaction over millennia, which would make the similarities typological (due to mutual contact) instead of genetic (due to a common origin). This is complicated by the obscurity of the origin of the 'Altaic' -speaking peoples, the extreme nomadism of these peoples, and, simply, linguistic change.

As an agglutinating language, Mongolian forms words by adding morphemes (meaningful elements that cannot be split into smaller meaningful elements) to a base, or root, word with each morpheme corresponding to a single lexical meaning or grammatical function. An illustration of Mongolian agglutination is the word *bari-ld-aa-tʃi-d-t* 'to the wrestlers', which is composed of the following parts: *bari-* 'to seize' + *-ld-* 'each other' + *-aa-* NOUN-FORMING SUFFIX + *-tʃi* 'an occupation' + *-d-* PLURAL + *-t* LOCATIVE. Mongolian also has a number of cases (these manifest themselves as suffixes that attach to nouns); these cases indicate the function of the word in a sentence. The following is a chart of the declension of the words *mal* 'cattle' and *ger* 'yurt'.

Case	'cattle'	'yurt'
Nominative (indicates the subject)	*mal*	*ger*
Genitive (indicates possession 'of')	*mal-iin*	*ger-iin*
Dative-Locative (indicates the indirect object or location 'in'/'at')	*mal-d*	*ger-t*
Accusative (indicates the direct object)	*mal-iig*	*ger-iig*
Ablative (indicates direction away from 'from')	*mal-aas*	*ger-ees*
Instrumental (indicates means or agency 'with'/'by')	*mal-aar*	*ger-eer*
Comitative (indicates accompaniment 'with')	*mal-taj*	*ger-tej*

As illustrated by this chart, many suffixes in Mongolian correspond to prepositions in English. For example, the Mongolian word *mal-iin* would be translated into English as 'of the cattle'. It is possible to combine more than one of the above suffixes, resulting in constructions such as *nœxœr-* 'friend' + *-iin* 'of' GENITIVE + *-d* 'at' LOCATIVE = *nœxr-iin-d* 'at my friend's house'. Mongolian also has some postpositions (these are like prepositions except that they occur after nouns), which follow nouns in the nominative, genitive, ablative, or comitative cases:

> with nominative: *dotor* 'in', e.g. *tasalgaan dotor* 'in the room';
> with genitive: *tuxay* 'about', e.g. *nom-iin tuxay* 'about the book'; etc.

One of the striking features of Mongolian (and Altaic languages in general) is vowel harmony. Vowel harmony occurs within a word, including the suffixes that have been added. When vowels harmonize, all of the vowels within a word agree—they must all either be front (/e/, /y/, /œ/) or back (/a/, /o/, /u/), with /i/ being a neutral vowel. Because of this, many suffixes have two versions: one with a front vowel and one with a back vowel. Vowel harmony is demonstrated in the ablative, instrumental, and comitative cases in the above chart; because of vowel harmony, the form **ger-aas* is ungrammatical because the suffix does not have a front vowel as the stem word. Vowel harmony rules, however, do not apply in four instances: compound words, where each member retains its own vowels (*tserendulmaa* 'Tserendulmaa' (a woman's name)); certain suffixes (*oj-gwe* 'treeless, bare of forests'); foreign names (*germaani* 'Germany'); and recent borrowings (*pjoneer* 'pioneer' (Boy Scouts)).

The basic word order of Mongolian is subject–object–verb. Modifiers (adjectives, adverbs, determiners, etc.) generally precede the word that they modify and do not show agreement, e.g. no matter what case (nominative, genitive, dative, etc.) or number (singular or plural) a noun is, the adjective will stay the same. Although Mongolian has various plural markers, e.g. *nom* 'book', *nom-uud* 'books', *zaluu* 'youth', *zaluu-tsuud* 'youths', a noun does not take a plural suffix when modified by a number, e.g. *negen nom* 'one book', *xoyor nom* 'two books', *gurav nom* 'three books'. Because the number already indicates whether there is one or more, a plural marker would be redundant. The following sentence illustrates many of the features just described.

> *bi xojor sajn mori-toj   bajn*
> I two good horse-COMITATIVE exist
> 'I have two good horses.'

The adjective *sajn* 'good' shows up before the noun *mori-toj* 'horse', which is in the comitative case, but it does not show agreement. If it were to show agreement, one would expect to find the comitative suffix added to *sajn*. Also, the noun *mori-toj* 'horse' is modified by the number *xojor* 'two', but it does not have a plural marker. The equivalent sentence with the plural marker would be

> *bi sajn mori-d-toj   bajn*
> I good horse-PLURAL-COMITATIVE exist
> 'I have good horses.'

This sentence also shows how Mongolian expresses possession without a verb 'to have': the verb meaning 'to be/to exist' is used with the possessor in the nominative case and the possessed in the comitative case. The literal translation would be 'I am with good horses.'

For comparative structures ('NOUN is ADJECTIVE-er than NOUN'), Mongolian puts the

first noun in the nominative case, the second noun ('than NOUN') in the ablative case, and then the adjective. The sentence 'Today is warmer than yesterday' would be translated *ænœædœr œtʃigdr-œœs dulaan* (today yesterday-ABLATIVE warm).

Mongolian differs from other Altaic languages in verb endings: Mongolian verbs are not marked for person. Rather, verbs only inflect for tense (past vs. nonpast) and for aspect (perfective vs. imperfective); the bare verb stem serves as an imperative (a command). There are only four basic verb endings:

	Past	Nonpast
Perfective	*-v*	*-laa*
Imperfective	*-dʒee*	*-na*

In addition to these suffixes, one can add *–aarai* to a bare stem to form a polite request: *yav* 'go!' becomes *sajn yawaarai* 'please go well!'

A verb with one of the basic verbal endings cannot be negated. The negation of a verb is achieved by attaching the negative suffix, *-gwe,* to a noun form of a verb. There are three noun-forming endings for verbs: *-san* for past tense, *-x* for nonpast, and *-dag* for customary or repeated actions. Hence, for instance, the sentences *ten ire-v* 'he came' and *bi mede-n* 'I know' would have the following negative counterparts: *ten ir-sen-gwe* 'he did not come' and *bi mede-x-gwe* 'I do not know,' not **ten ire-v-gwe* or **bi mede-n-gwe.* In English, the closest literal translation of these phrases would be 'without his having come' and 'without my knowing', respectively, both gerund structures. However, in order to negate a command, one need only add the negative word *bitgii,* as in *bitgii yav* 'Don't go.' The verb *bajn* 'to be/to exist' is also not negated like other verbs; it has its own negative counterpart, *biʃ* 'not to be/not to exist'— *ter tend biʃ* 'he is not there'.

Mongolian does not have relative pronouns. In order to form a relative clause, verbs transform into verbal nouns and are then used as attributive adjectives to modify nouns. For instance, the relative construction 'the work which we did' would be rendered *bidnii xii-sen adʒil* ('we do-PAST work'). The verb *xiix* 'to do' is turned into a noun with the addition of the past-tense morpheme *–san* (in this case, *–sen* due to vowel harmony). Then it, along with the other part(s) of the clause (in this instance, there is only a subject pronoun, *bidnii* 'we'), is placed before the noun that this modifies, *adʒil* 'work'.

The history of the Mongolian language is usually divided into three periods: the ancient period, the middle period, and the contemporary period. The ancient period lasted until about the twelfth century CE. Although texts written in ancient Mongolian have not been found, evidence exists in Chinese texts wherein a few ancient Mongolian words are attested and in modern Tungus languages, whose ancestors borrowed words from ancient Mongolian. Some characteristics of ancient Mongolian include the preservation of the consonants [p], [f], and [h] in initial position; the division of all vowels and consonants into front and back; the preservation of [γ], [g], [b], and [w] in intervocalic (between vowels) position; and the presence of grammatical categories. The middle period lasted from around the twelfth century to the sixteenth century CE. The language of this period is known as Classical Mongolian, and the Mongolian script comes into use at this time. Distinguishing traits of middle, or Classical, Mongolian include the disappearance of [γ], [g], [b] and [w] between vowels (this leads to the development of long vowels in Mongolian); the loss of [h] in initial position in some words; and the partial loss of grammatical categories. The contemporary period, which begins around the sixteenth century CE, follows middle Mongolian and continues to the present. This period is characterized by the loss of [p], [f], and [h] in initial positions; the distinction between short and long vowels; and the absence of grammatical categories.

The Mongols have used several different systems to write their language. The *Secret History of the Mongols,* a major literary work that dates from 1240 CE and marks the beginning of the Middle Mongolian period, was written in Chinese characters. The classical Mongolian script was in use by the thirteenth century. Most scholars believe that the Mongols borrowed this alphabet from the Uigurs who had adopted it from a version of the Syriac alphabet. The letters of this Mongolian alphabet have initial, medial, and final forms (the shape of the letter changes depending on whether it is the first letter, a middle letter, or the final letter of a word), and it was originally written horizontally from right to left. Later, this changed to a vertical, left-to-right format, perhaps under the influence of Chinese. The Mongolian script was used in the Mongolian People's Republic until 1941 when a new Cyrillic-based alphabet was adopted. There were two reasons stated in official documents for this adoption: first, a big gap between the written language (using the traditional Mongolian script) and the spoken language had developed; and second, the Mongolian script was not suitable for assimilating foreign words. Despite this adoption, the Mongolian script continues to be used by Mongolian speakers in China and in private correspondences by older people in Outer Mongolia.

Montague, Richard

Richard Montague is one of the most influential philosophers of the past century and can be deservedly considered the founder of contemporary formal semantics. As an undergraduate at the University of California at Berkeley (1948–1950), he was attracted to a number of disciplines, but particularly to mathematics, philosophy, and Semitic languages, all of which he pursued very rapidly to an advanced level. The most important single influence on the direction of his work was the logician Alfred Tarski. While still a graduate student at Berkeley, Montague had already acquired considerable national and even international reputation. Between 1954 and his formal dissertation defense in 1957, he authored six, and coauthored another four, significant papers in mathematical logic, including researches on Boolean algebras, proof theory, model theory, and axiomatic set theory. In 1955, he joined the faculty of the University of California at Los Angeles and expanded his interests into other areas in the field of logic such as abstract recursion theory, predicate logic, and the model theory of higher-order logics. In the early 1960s, he increasingly focused on the application of sophisticated logical methods to traditional problem areas in philosophy: determinism (in "Deterministic theories," published in 1962); the concept of scientific explanation; the so-called hangman or surprise examination paradox ("A paradox regained," 1960, with David Kaplan); conditional or derived obligation; events ("On the nature of certain philosophical entities," 1960); and indirect discourse ("That," 1959, with Donald Kalish).

From the mid-1960s until his untimely death, Montague embarked on an ambitious program to apply some of the precise tools of mathematical logic and model theory to the analysis of natural language. This was a concern that started to emerge in his introductory logic text, *Logic: techniques of formal reasoning* (1954, with Donald Kalish). The main advantage of this mathematical approach was achieving an accurate, adequate, and philosophically satisfactory scientific account of natural language. The initial words of "Universal grammar" (1970a) mark a clear declaration of intentions:

> "There is in my opinion no important theoretical difference between natural languages and the artificial languages of logicians; indeed I consider it possible to comprehend the syntax and semantics of both kinds of languages within a single natural and mathematically precise theory."

In this paper, he states that a grammar consists of a syntactic algebra and a semantic algebra that are subject to a homomorphism condition: there is a homomorphism mapping elements of the syntactic algebra onto elements of the semantic algebra. This requirement elegantly captures Frege's Compositionality Principle in a formal setting: the meaning of a complex expression will be a function of the meaning of its parts and the operation or operations combining them.

Montague also introduced the method of fragments. Unlike in generative grammar, where structural descriptions and rules are proposed for a single construction or constructions but the rest of the grammar is left undefined (or assumed to be generated by standard mechanisms), Montague presented a formal and precise treatment of several "fragments" or subsets of expressions of English. The monostratal syntactic formalism he proposed also departed from the standard multistratal proposals preferred within generative-transformational approaches. In the latter, syntactic derivations are based on a set of base rules and additional transformations that change the linear arrangements of terminals, respectively deriving deep and surface structure representations. Montague's syntax is modeled on the recursive bottom-up rules preferred by logicians and categorial grammarians. These rules derive well-formed expressions of different categories, which in turn are assigned an interpretation.

There are two possible methods for providing a semantic interpretation for a fragment of English. The first one, illustrated in "English as a formal language" (1970b), is the method of direct interpretation. Expressions of a language are directly assigned denotations in a model. The second method (the indirect method) is developed in "The proper treatment of quantification in ordinary English" (1973). It consists of translating the expressions of English into a formalized logical language (the language of typed intensional higher-order logic) on a first step and providing an interpretation for this language. Although from a technical point of view, this intermediate step should be dispensable, in practice using a formalized representation language has several advantages. First, it makes possible a systematic analysis of semantic ambiguity. One or more disambiguated formulae are assigned to each ambiguous English sentence. Second, translating English into a rigidified uniform language increases perspicuity and the ability to represent the logical properties of natural language in different realms (tense, modality, quantification) using well-known precise formal devices. Finally, Montague always maintained a nonpsychological objectivistic stance, and considered the syntax, semantics, and pragmatics of natural languages as branches of mathematics on par with geometry or number theory. Nevertheless, in the following decades several connections have been drawn with some of the psychological concerns of linguistic theories, mostly in that the intermediate semantic representation language can be viewed as a characterization of the speakers' semantic competence (or at least of some of its properties).

Numerous innovative semantic proposals by Montague have become standards in the field. First, he treated noun phrases as uniformly denoting (generalized) quantifiers, against the received view in logic that considers proper names as constants and existential, and universals as quantifiers. Second, Montague used lambda-abstraction and the lambda-operator to represent the compositional combination of expressions as functions and arguments. Finally, he generalized the Frege/Carnap distinction between sense/intension and reference/extension to a full intensional semantics. The intension of an expression is a function from possible worlds to its extension. Intensionality is pervasive in natural language, not only in opaque contexts such as the complements of verbs like *believe* but also in the transitive complements of verbs such as *seek*, or in modifiers such as *presumed*, *alleged,* or *former*.

Montague's most significant articles with applications in linguistics and philosophy were posthumously compiled by Richmond Thomason in the volume *Formal philosophy* (Yale University Press,

1974). The groundbreaking nature of Montague's approach can only be properly understood in the context of a comparison between the linguistic landscape of that time and the field of formal semantics nowadays. This discipline has undergone radical changes that are almost entirely attributed to Montague's legacy, namely to the combination of the ideas and analysis contained in his most influential papers and the developments by his disciples and followers, within the enterprise commonly known as Montague Grammar.

Biography

Richard Montague was born in Stockton, California, on September 20, 1930. He received his B.A. from University of California, Berkeley in 1950 and Ph.D. for a dissertation on mathematical logic, tutored by Alfred Tarski, (University of California, Berkeley) in 1957. During his graduate years, he also worked with Professors W.J. Fischel in Arabic, and Paul Marhenke and Benson Mates in philosophy; between 1950 and 1953, he held the Howison Fellowship in Philosophy, and for two succeeding years he was a teaching assistant in mathematics. In the spring semester of 1955, he joined the faculty of the University of California, Los Angeles, as Acting Instructor in Philosophy, and in the following years he advanced very quickly through the academic ranks. He served as a member of the United States National Committee for the International Union of the History and Philosophy of Science and, for the years 1966 and 1967, as Chairman of the national Subcommittee for Logic, Methodology, and Philosophy of Science. He also served as Secretary of the Association for Symbolic Logic from 1966 until his death and as a consulting editor for the *Journal of Symbolic Logic* since 1958. He died on March 7, 1971, in his home in Los Angeles, at the hands of persons still unknown at the time of writing

Mood

The grammatical meaning of *mood* (often also referred to as *modality* or by the adjective *modal*) is a complex one, but one that we can break down into two main characteristics. In its narrow meaning, it denotes a particular aspect of verbal morphology, usually indicated by an inflectional marking on a verb form, tied in closely with tense and aspect relations. But in the larger context of sentences ("form") and meaning ("function"), it refers to the grammatical category expressing the type of sentence. To make matters more complicated, both types are sensitive to the specific modal function of individual elements, in addition to both the narrow and wider understanding of mood.

In traditional grammar, mood expressed in verbal morphology commonly distinguishes the indicative (*John plays soccer.*), the subjunctive (*John would play soccer.*), the imperative (*Play soccer, John!*), and (in Classical Greek or Hungarian) the optative (roughly, *I wish John played soccer.*). These distinctions can be found in many European languages. Other languages express the same moods by the use of particles (e.g. Ngiyambaa, a language from Australia or Jacaltec from Guatemala), and also clitics (such as Luiseño from California). This state of affairs warrants a wider conception of mood already than simply referring to verbal paradigms. Moreover, even those languages that express mood with verbs can be further differentiated. The classical languages (Classical Greek, Latin) and the modern Romance languages beyond French (e.g. Spanish, Italian) have particular verbal paradigms, i.e. inflectional endings on the main verb. The North European languages (such as French, English, or German) use modal verbs, but German and French, for example, can also express moods through verbal inflection, namely the subjunctive.

From a European point of view, the modal verbs are the clearest example of the narrow conception of mood. The traditional modal verbs of English are *may, can, must, ought (to), will*, *shall*, and to some extent *need* and *dare* (including *might, could, would, should*). These have counterparts in German (e.g. *mögen* 'may', *wollen* 'want'*, könn, 'can*') and in French (such as *pouvoir* 'can', *devoir* 'must', *vouloir* 'want'). In this sense, there is an obvious interplay of mood with *tense*, the grammatical distinctions of time made, and *aspect*, relating to the internal temporal structure of a situation (see also the paragraph on epistemic vs. deontic modality).

It must be said, however, that from a typological perspective, this characterization of mood is less than clear: not all mood forms are used equally in all languages—neither with respect to type of expression (e.g. verbal morphology vs. separate expressions) nor variety of expression; one extreme in the latter category is Tuyuca, a language spoken in Brazil and Colombia, where every sentence is modal: Tuyuca has five evidential modals (see below) that characterize even every declarative sentence in a specific modal form. The English sentence *He played soccer*, for example, can be rendered by *díiga apé-wi* 'He played soccer (I saw him play)', *díiga apé-ti* 'I heard the game and him, but I didn't see it or him', or *díiga apé-yi* 'I have seen evidence that he played: his distinctive shoe print on the playing fields. But I didn't see him play', for example.

And comparing German and English, for a moment, we can see another factor of the interplay of different types of modality. The German equivalent of the English sentence *He should have come home* is *Er hätte nach Hause kommen sollen*, where the first boldfaced word is the subjunctive form of the verb 'to have', while the second one is the modal form for 'should', both expressed by one modal form in English (see also the paragraph on epistemic vs. deontic modality below). On the other hand, languages like French use the subjunctive often for purely morphosyntactic reasons, rather than semantic ones, namely when embedded under particular verbs.

Apart from verbal mood classes, mood also expresses the speaker's attitude. Among the classifications of mood distinctions that have been proposed in the literature, the one between *epistemic* and *deontic* use is the most common one. Epistemic modality is the area of mood concerned with knowledge and belief (incl. 'possibility', 'probability', 'certainty'), and it may also express the speaker's degree of commitment to what he says (see also evidential mood below). The deontic use of mood or modality expresses 'permission', 'obligation', and 'prohibition'. For example, *John may play soccer tomorrow* is ambiguous between the possibility of John playing soccer the next day (the epistemic meaning viz. 'possibility') and the 'permission' given to John to play soccer (by the speaker or someone else; the deontic use).

Another proposal considers a three-way distinction of mood between *illocutionary force* (the 'communicative intention of an utterance'; see below), *status* ('degree or kind of reality'), and *modality* (in the sense of declarative, interrogative, etc.). *Evidential* and *evaluative* distinctions are also sometimes regarded as mood distinctions. We have already seen an instance of the former above, indicating the kind of evidence a speaker has for what he says (e.g. direct vs. indirect evidence). Evaluatives, on the other hand, can be defined as attitudes toward known facts, such as Hixkaryana (a Carib language spoken in Northern Brazil), where *nomokyaha hampɨnɨ* 'He's coming—be warned!' vs. *nomokyatxow hampe* 'They are coming! I don't believe it!'.

The larger picture that mood or modality expresses is the *illocutionary force* of an utterance, which may be that of a request for action or information, or an order, a warning, a promise, etc. Here, a strict characterization is even more difficult than with the narrower meanings of mood, because the illocutionary force of an utterance is in general independent of its grammatical form, or *sentence type*. In this connection, we often speak of sentence type referring to the form of a sentence (the above-mentioned moods 'declarative', 'interrogative', etc.), where it is clear that not every interrogative asks for information, for example (viz. *Could you pass the salt, please?*, which requests an action, akin to an imperative or order).

In sum, mood in its narrow sense denotes a particular distinction in the (often verbal) paradigm of languages, either by encoding inflectional morphology, modal verbs, particles or clitics expressing a particular mood. In the broader context, modality relates to the speaker's attitude (e.g. epistemic vs. deontic modality) and the function of a sentence uttered (viz. illocutionary force). There is a rich literature that can be found on each of these topics, both from the point of view of a single language as well as typologically, and ongoing research keeps providing new insights.

Moore and the Gur Languages

The Gur languages (sometimes called Voltaic/ Voltaique languages, especially by French-speaking scholars), a family in the immense Niger-Congo phylum, are spoken in interior West Africa, in Burkina Faso, Mali, Niger, and the northern parts of Côte d'Ivoire, Ghana, Togo, Benin, and Nigeria. The Gur

language family comprises subgroups including Oti-Volta and Grusi. Most of the Gur languages belong to these two subgroups; Oti-Volta in turn includes Gurma and Mabia (Western Oti-Volta). Since the most prominent languages of the Gur family are in the Mabia subgroup, this subgroup is the focus of this brief survey (see Figure 1).

The Mabia languages can be divided into five main groups; the languages within most of these groups are more or less mutually intelligible. Major languages within each group are written in capitals in the diagram. Western Mabia, which includes Dagaare, Waale, Birifor, and Safaliba, is located in northwestern Ghana and adjacent Burkina Faso. Northern Mabia, which includes just Moore and its dialectal forms, is found mostly in Burkina Faso. Central Mabia is located approximately in the middle of the Gur area. There is one overall name for this group, Gurenne, which includes Frafra, Nankani, and Nabit. A subdivision of this group is Mid-Central Mabia. The two languages in this subgroup, Buli and Konni, although geographically close to Gurenne, are linguistically slightly distinct from Gurenne and some of the other Mabia languages; in fact, there is some controversy as to whether this group belongs in Mabia or in Grusi. Here, it is included in Mabia because it has more similarities in vocabulary with Mabia than with Grusi. Southern Mabia, comprising Dagbane,

Mampruli, and Nanuni, is at the south of the Gur area. Southern Mabia too has a subdivision, Mid-Southern Mabia (Hanga-Kamara). Hanga and Kamara, although also found in the south, are quite different from, for instance, Dagbane. The fifth group, Eastern Mabia, is composed of Kusaal and Talni.

This attempt at classifying the Mabia languages does not mean to suggest that there are clear boundaries. Most of the languages, in fact, form a continuum (speakers of adjacent languages can usually understand each other), and variation between the languages is rather gradual. For instance, it is sometimes difficult to say whether Mampruli is more closely related to Dagbane or to Kusaal. A similar situation has been observed for Birifor, Waale, and Dagaare.

Gur languages display some rather interesting typological features. Within typological studies, linguists try to outline the characteristics of sound systems and word and sentence structures in natural languages and then find out how a particular language or group of languages may be classified according to these types of grammatical features.

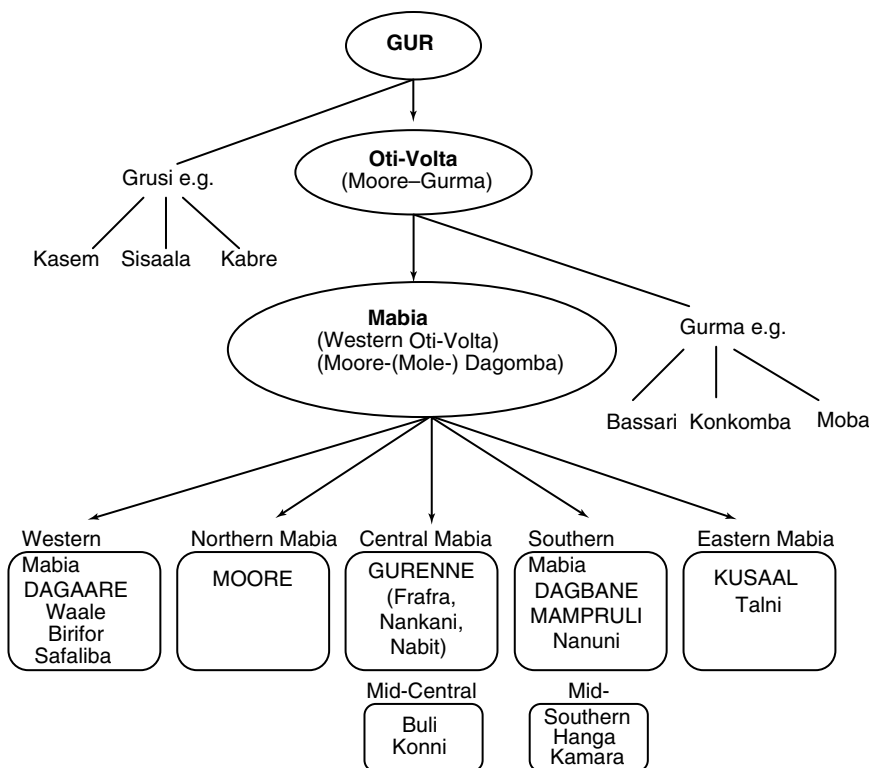
The Gur languages are marked by a preponderance of consonants and a scarcity of vowels when compared to Indo-European languages like English and French, and they have some consonants with complex articulation that is rare in Indo-European languages.


Figure 1

An example would be labio-velar stops, i.e. consonants for which the lips are pressed together as in [b] and the tongue is simultaneously pressed against the back of the roof of the mouth as in [g]. This is actually a common African language feature, even though it is conspicuously absent in languages such as Akan.

With respect to vowels, there is the typological feature of vowel harmony, i.e. the vowels within a word tend to be alike in certain respects and according to specific rules. Not only does this feature distinguish between some of these languages and Indo-European languages it also divides these languages, into harmonizing and nonharmonizing languages. For instance, one difference between Western Mabia languages like Dagaare and Waale and the rest of the group is that these exhibit vowel harmony while the other members of the group do not seem to. It may, however, be possible that vowel harmony existed in the ancestor form of all these languages.

Gur languages are tone languages, i.e. pitch differences within a word can alone change the meaning. Most Gur languages use only two tone levels, i.e. they distinguish between high and low tones. The former are indicated by an acute accent (*á*), while a grave accent (*à*) indicates the latter. These tones serve to express both lexical and grammatical oppositions as in the Dagaare verbs *dá* "push", *dà* "buy".

An important typological feature for these languages is the system of noun classes—nouns belonging to different classes are inflected differently (the masculine and feminine genders of many European languages are examples of noun classes). The manifestation of noun classes is common in Niger-Congo languages but, while these languages usually mark noun classes with prefixes, most Gur languages use suffixes.

Moore

Moore, the language of the Mossi, is the most prominent Gur language in terms of the number of speakers and political importance. It is spoken by about 5 million people in Burkina Faso, where it is the de facto national language, and about 1 million more in Côte d'Ivoire, Ghana, Togo, and elsewhere. Moore shows typical Gur language characteristics. It has two tones, it exhibits vowel harmony, it has a system of noun classes where suffixes indicate the class a noun belongs to, and it has Subject–Verb–Object order. The three sentences below illustrate this structure:

M rîgdá ráágà wá
I going market the
"I am going to the market."

Bòè lá fó mààndà
What that you doing
"What are you doing?"

À yáá tónd tèngá nààbá
(S)he saw our village chief
"He saw the chief of our village."

The language as spoken in Burkina Faso comprises four main dialects with focal points around the towns of Ouagadougou (the capital), Koudougou, Koupela, and Ouahigouya, which are all major provincial centers. Glottochronological studies, which attempt to determine how long ago two or more languages split by comparing the number of very common words they have presumably retained from their ancestral language, indicate centuries of divergence within this language group. They show that Moore, including all its dialects, is more closely related to Dagara, a variant of the Dagaare language, with only two centuries of divergence between them.

Dagbane

Dagbane, including Nanuni, is spoken by about 1.5 million people in Ghana. It is a trade language in and around Tamale, the fourth largest town in Ghana. It is a major language of education and literacy in Dagbon, home of the Dagomba. It is taught in various undergraduate programs at universities in Ghana. Dagbane and Mampruli are mutually intelligible.

Dagaare

Dagaare, including Waale and Birifor, is spoken in northwestern Ghana around towns including Wa, Tuna, Jirapa, Lawra, and Nandom, and in Burkina Faso around towns including Dano and Dissin. Native speakers of Dagaare number up to 2 million. It benefited from early missionary activities and has one of the most extensive arrays of literature in the region. It is taught in primary and secondary schools in Dagao, homeland of the Dagaaba, and in various undergraduate programs at universities in Ghana and Burkina Faso.

Gurenne

Gurenne (Frafra, Nankanne, and Nabit) also has a large number of native speakers, numbering about 1 million. It is the language of Bolgatanga, one of the cosmopolitan towns in northern Ghana. It is fast becoming a lingua franca in northeastern Ghana, where speakers of different languages, such as Kusaal,

Kasem, Mampruli, and Talni, use it in the Bolgatanga metropolitan area.

Kusaal

Kusaal, language of the Kusaasi, is spoken by about 250,000 people in the extreme northeast of Ghana around towns including Bawku. It is an important language of communication in the area. Glottochronological studies show that it is most closely related to Mampruli, with only two centuries of divergence between them.

Mampruli

Mampruli, language of the Mamprussi, is spoken by about 100,000 people around towns including Gambaga, Nalerigu, and Walewale. Mampruli is very closely related to Kusaal and Dagbane, having diverged from them only two centuries ago. Indeed, both languages are quite intelligible to its speakers.

Buli

Buli, the language of the Bulsa, with about 65,000 speakers in and around Sandema, also has some literacy programs. It is closely related to the much smaller language Konni but quite distinct from all the other major Gur languages.

Kasem

Kasem, language of the Kasena, belongs to the Grusi subgroup along with languages including Sisaali, Chakali, Tampulma, Kabre, Vagla, and Mo. It is spoken around towns including Navrongo in Ghana and in adjacent settlements in Burkina Faso. It is spoken by approximately 300,000 people. Kasem, like Dagaare, was one of the first literary languages of northern Ghana, having benefited from early missionary activities.

Sisaali

Sisaali, or Isaaleng, language of the Sisaala, is spoken around the towns of Tumu, Gwellu, and Lambussie in Ghana and in adjoining areas of Burkina Faso. It is spoken by about 200,000 people. Sisaali is scarcely intelligible with the other Gur languages, but many speakers of Sisaali speak Dagaare as a second language.

Konkomba

Konkomba, belonging to the Gurma group along with languages including Moba and Bassari, is also called Likpakpalnli. It is spoken by about 500,000 people. Many of its speakers use Dagbane as a second language in their homeland around Saboba and Zabzugu. The language is taught in primary schools, and there are many literacy programs involving Konkomba.

To sum up, most of the Gur languages are in use for educational purposes in their communities. Some of them serve communities beyond their traditional areas. There are some mass communication programs on radio and TV in these languages in Ghana, Burkina Faso, and other countries. The unrelated Chadic language, Hausa, is often thought to be an effective lingua franca in the Gur-speaking area, but this is hardly a fact. It may have been so some time ago, but currently some of the Gur languages, including Moore, Dagbane, and Dagaare, are fast replacing it as lingua francas in their respective areas of influence. There are serious attempts at functional literacy and mass communication in all these indigenous languages. Awareness is gradually being raised regarding the importance of mother tongues as major languages of mass communication for socioeconomic development in this part of West Africa.

Morpheme

The word *uncountable* is made up of three units: *un-, count,* and *-able*. Each of these units recurs elsewhere in English, for example, in the words *unkind, count-down,* and *acceptable,* respectively. When they recur, they have the same meaning (*un-* means, approximately, 'not' in both *uncountable* and *unkind*) and the same form or a closely related one (in the examples cited so far, the form is identical). Moreover, we cannot subdivide these units into smaller units with these same properties. It is true that we can see two different letters standing for two different sounds in *un-,* /ʌ/ and /n/, but although these have the same form in other words, such as *sun,* they do not have a meaning there: *sun* does not mean 's not.' Lastly, the units *un-, count,* and *-able* between them exhaustively analyze the word *uncountable*: they account for every bit of form; there are no unexplained bits left over.

Let us define units that have all of these properties as 'morphs', although we shall see below that not all scholars require every one of these properties.

When a morph can stand alone as a word, such as *count,* it is called a (potentially) free morph. When, like *un-,* it is found only attached to something else, it is called an (obligatorily) bound morph.

Uncountable is related to the word *uncountability*. Again, we can divide this into morphs as *un·count·abil·ity,* where the *-ity* bit recurs in words like *probability* and *sensitivity,* with a meaning something like 'quality of being'. However, a close comparison with *uncountable* will show that *-able* /əbl/ has changed to *-abil-* /əbɪl/. When the second syllable of *–able* is stressed, as it is whenever *-ity* is added, we find *-abil-* instead of *-able*. The meaning is the same, and the form is still very closely related (it still contains the sounds /ə/, /b/, and /l/), but *-able* and *-abil-* occur in different environments. They are in complementary distribution: where you find one, you cannot find the other. We call morphs that are in complementary distribution in this way 'allomorphs' of the same morpheme. The terminology is entirely parallel to the terminology used in the theoretical descriptions of speech sounds, where one speaks of 'allophones' of the same 'phoneme'. Where there are not several different allomorphs of the same morpheme, as with *count,* whose form is always *count,* we can still say that the single morph *count* instantiates the morpheme {count}, where the braces show that we are treating this as a morpheme.

There are many problems with this notion of a morpheme, and the linguistic community has responded by overtly or covertly modifying the definition of morpheme in several different ways, to such an extent that there are probably few who would adopt the characterization that has been provided here, although they might allow the definition of a morpheme as the minimal unit of grammatical analysis.

Consider the plural markers *in cats, oxen, mice,* and *tempi*. The regular marker on the end of *cats* is not a problem and can be dealt with easily: the word can be analyzed into two morphs, a root *cat* and a suffix *-s,* each of which represents a morpheme. The morpheme for the suffix has three allomorphs, one of which is the /s/ found on the end of *cats*. The first question is: is the same morpheme present in *oxen*? According to the characterization given above, it is not, because there is no form in common between /s/ and /ən/; rather, these are two synonymous morphemes. An alternative view gives more weight to the meaning side of the equation, along with the fact that both are members of the same paradigm of number, and allows /ən/ as an allomorph of {plural} determined by the lexeme (vocabulary unit) *ox*. In *mice,* it is not clear that there are two morphs at all, although some scholars have tried to argue that the root of the word is the discontinuous morph /m—s/ and the plural marker is the diphthong /aɪ/. However, if there is just one morpheme {plural}, then perhaps that morpheme is present in *mice,* even if it cannot be segmented out. The term 'portmanteau morph' is used for a morph that represents more than one morpheme, although some scholars restrict it to instances in which morphemes that are usually represented as independent words are merged, as in French *du,* 'of the (masculine)', which can be seen as a conflation of *de,* 'of ', and *le,* 'the (masculine)'. In the case of *tempi,* there is an alternative plural *tempos,* hence, the *-i* marker and the *-s* marker are not in complementary distribution. However, the fact that they do not contrast is usually accepted as sufficient for them to belong to the same morpheme.

Yet other scholars do not even insist on a constant meaning for the morpheme. Mark Aronoff (1976) argues that because *permit, emit,* and similar words all have irregular nominalizations in *-mission,* the consistent change from *mit* to *mis* is sufficient to establish *-mit* as a morpheme, despite the fact that it cannot be assigned a constant meaning in modern English. For other scholars, this is a matter of etymology (historical development) rather than a

matter of morphology. Joachim Mugdan (1986) provides a survey of definitions of the morpheme.

The problems with the concept of the morpheme are so great that some linguists have given up on the notion entirely. Stephen Anderson (1992) introduces the notion of a-morphous morphology, where the structure of words is determined by the construction of a sound structure on the basis of roots and syntactico-semantic structure, without any recognition of an intermediate level at which there are morphs or morphemes. However, such a stance is still controversial (although it is becoming more generally accepted), and the morpheme is still recognized as one of the fundamental units of linguistic analysis.

Morphological Typology

Morphological typology is the study of differences among the world's languages relating to the ways in which words are formed from smaller meaningful units referred to as 'morphemes'.

If we examine the formation of plurals in English, then regular plurals like *cats* as the plural of *cat* show the following relation between word and morphemes. *Cats* is a single word, as indicated by the fact that it is a minimal free form, i.e. it is not possible to pronounce *cats* with a pause within the word. In terms of its morphological structure, however, it clearly consists of two meaningful elements, the lexical root *cat* and the plural suffix *-s*. The single word *cats* thus consists of two morphemes and can readily be divided into those two morphemes (*cat + s*). Not all plurals, however, follow this pattern. Thus, the plural of *tooth* is *teeth*, with the plural being marked not by attaching a suffix to the root, but rather by changing the vowel of the root. And occasionally in English, one forms the plural by means of a separate word, as in the nonstandard plural of *who* as *who all*, for instance in *Who all are coming to dinner tonight?*

The different ways of forming plurals in English correspond to the three major morphological types that have been identified by considering many languages around the world. 'Isolating' or 'analytic' morphology refers to a system in which each word consists of only a single morpheme. Vietnamese is a language that comes close to being an ideal isolating language, as can be seen from the following example:

Khi	tôi	đến	nhà	**bạn**	tôi,
when	I	come	house	friend	I

chúng	tôi	**bắt**	đâu	làm	bài.
PLURAL	I	begin		do	lesson

'When I came to my friend's house, we began to do lessons.'

None of these Vietnamese words shows any of the morphological changes that are found in the English translation, such as *come ~ came, begin ~ began,* or *I ~ my;* indeed, even the plural pronoun 'we' is expressed by combining a separate word indicating plurality, *chúng,* with the pronoun *tôi* 'I.' The only exception to strict isolating structure is the verb *bắt đâu* 'begin,' which is a compound word, i.e. a single word made up of two components, literally 'seize' and 'head.' (Note that Vietnamese orthography leaves a space between syllables, and not only between words; the Vietnamese for 'Bolivia' is *Bô li vi a*.)

In contrast to isolating languages, we find 'synthetic' languages, which permit more than one morpheme to combine to form a word. In one type of synthetic language, namely 'agglutinating' languages, the boundaries between the individual morphemes are clear-cut. The classic example of an agglutinating language is Turkish. If we look at the way in which a Turkish noun changes its form to show different numbers (singular vs. plural) and cases (e.g. nominative or dative), we can always easily identify which sequence of sounds is the root, which sequence indicates number, and which sequence indicates case. Thus, the dative plural of *adam* 'man' is *adamlara* 'to the men', which can be broken down into the morphemes *adam + lar + a;* the root is *adam,* and we find this in the nominative singular *adam*

'man' (both singular number and nominative case take no suffix); the plural suffix is *-lar,* and we find this in the nominative plural *adamlar* (*adam* + *lar*) 'men'; the dative suffix is *-a,* and we find this in the dative singular *adama* (*adam* + *a*) 'to the man'. (Note that Turkish has no definite article corresponding to 'the'.) Knowing that the ablative suffix is *-dan,* we can readily form the ablative singular *adamdan* (*adam* + *dan*) 'from the man' and the ablative plural *adamlardan* (*adam* + *lar* + *dan*) 'from the men'. Incidentally, Turkish can in this way string together quite long sequences of suffixes, as in *avrupalılaştırılamıyanlardansınız* 'you are one of those who cannot be Europeanized.' From the noun *Avrupa,* the suffix *-lı* forms the adjective 'European'; from this, the suffix *-laş* forms a verb meaning 'become European'; the suffix *-tır* adds the meaning 'cause to', i.e. 'cause to become European' or 'Europeanize'; *-ıl* makes this passive, i.e. 'be Europeanized'; then *-amı* adds the element of inability, i.e. 'unable to be Europeanized'; *-yan* turns this into a participle, i.e. 'being unable to be Europeanized, one who is unable to be Europeanized'; *-lar* makes this plural and *-dan* adds ablative case, i.e. 'from those who are unable to be Europeanized'; and finally *-sınız* adds the element 'you'.

A second kind of synthetic language is a 'fusional' language, in which the various morphemes fuse together to give a single, unsegmentable whole. We have already encountered an example of fusional morphology in the irregular English plural *teeth,* in its relation to *tooth,* since in this plural the elements root and plural are not segmentable as they are in a regular plural like *cats.* Certain Indo-European languages such as Latin, Greek, and Russian provide good examples of fusional morphology. Whereas in Turkish the markers of case and number are always separable from one another, in Russian the two are inextricably fused. In the nominative, we have the singular *stol* 'table' and the plural *stoly* 'tables'. In the genitive, the singular is *stola* 'of the table' and the plural *stolov* 'of the tables'; it is already clear that the genitive plural suffix *-ov* cannot be segmented into a component that we could identify with nominative plural *-y* and another that we could identify with genitive singular *-a.* The picture is only further compounded as we examine other cases, e.g. dative singular *stolu* 'to the table' vs. plural *stolam* 'to the tables'.

A fourth morphological type is sometimes, but by no means always, recognized, namely 'polysynthetic'. Characteristic of polysynthetic languages is that typically a large number of morphemes are combined in a word, i.e. these languages are, as one might suspect from their name, very synthetic. An example is provided by the Chukchi language spoken on the Chukotka peninsula at the eastern tip of Asiatic Russia, where one finds the single-word sentence *tə-mejŋə-lewtə-pəɣt-*

ərkən 'I have a fierce headache,' whose components are the first-person singular prefix *t-* 'I', the root *mejŋ-* 'big, great', the root *lewt-* 'head', the root *pəɣt-* 'ache', and the imperfective aspect suffix *-rkən* here indicating an ongoing state. (The other instances of ə are inserted to break up consonant clusters.) The possibility of having a single word corresponding to a sentence of several words in most other languages of the world is also often cited as a characteristic of polysynthetic languages. However, it is not really clear whether polysynthetic should be recognized as a distinct type. In the Chukchi example just given, the basic morphological technique is agglutination, and the only unusual feature is the extent to which such agglutination is carried out, combining both lexical morphemes like 'big', 'head,' and 'ache' and grammatical morphemes like first-person singular and imperfective aspect. Polysynthesis is thus arguably just agglutination (sometimes with elements of fusion) carried to an extreme.

Although some languages come close to one of the three ideal types, isolating, agglutinating, and fusional, such as Vietnamese, most languages combine elements of all three types to different degrees. For instance, English is generally an isolating language, and it is quite possible to produce quite long sentences that involve no word consisting of more than one morpheme, e.g. *Every day I see the cat on the wall near the tree.* Agglutinating morphology in English is limited to compounding (e.g. *birthday,* i.e. *birth* + *day*), to the genitive and plural forms of nouns (*cat's, cats*), and to a handful of verb forms (third-person singular present tense *walks,* past tense *walked,* past participle *walked,* present participle *walking*—note that some verbs do have distinct past tense and past participle, e.g. *ate, eaten*). Fusional morphology is limited to a handful of irregular noun plurals (like *tooth ~ teeth*) and a limited number of irregular verbs in the past tense and past participle (e.g. *drink ~ drank ~ drunk*).

The major morphological types can be given a systematic explication in terms of two indices. The 'index of synthesis' indicates how many morphemes are combined into a single word. The 'index of fusion', relevant only if the index of fusion is above 1, indicates how many morphemes are fused together into a single form. By calculating these indices for representative texts in a language, one can assess that language's index of synthesis and index of fusion, thus capturing the intuition that all languages combine the different types to different degrees.

Historically, agglutination can often be shown to result from separate words becoming affixes, as when the Modern English suffix *-hood,* as in *childhood,* derives from an Old English word *hād* meaning 'quality, condition'. Likewise, fusion can often be

shown to have developed from the effect of a lost affix; e.g. a plural suffix *-i*, long since lost, caused the vowel change in nouns like *tooth ~ teeth*.

Morphology

The central focus of those who study morphology is how language users understand complex words and how they create new ones. Compare the two English words *secure* and *insecurity*. The word *secure* cannot be broken down further into meaningful parts. It is morphologically simple. By contrast, *insecurity* is morphologically complex because it consists of three unanalyzable meaningful components (i.e. in + secure + ity), which linguists call morphemes. The study of the patterning of morphemes within a word and how morphemes combine to form new complex words falls within the domain of morphology. Morphemes are meaningful elements and must be distinguished from units of sound, because a simple morpheme may be complex in its sound structure: the simple morpheme *secure* is complex in terms of sound, consisting of two syllables and six phonemes. The study of the sound structure in language processing is well established. Only relatively recently, however, have psycholinguists begun to examine morphology as a window on how we process words.

The first morpheme in *insecurity* is the prefix (in-), which means approximately 'not'; the second or stem is the adjective *secure*; the third and word final morpheme is the suffix (-ity), which serves to form a noun from the adjective *secure*. The meaning of *insecurity* (viz. 'the state of not being secure') is fully predictable from the meaning of its components. It is semantically transparent. The same prefix occurs in many other words, as does its suffix (e.g. *inactivity*, *impartiality*). Note, however, that not all adjective stems can combine with morphemes such as *in* or *ity*. For example, the stem *abashed* combines with the affixes *un* and *ness* to form the noun *unabashedness* while *continue* combines with *dis* and *ity* to form the adjective *discontinuity*. The fact that nouns like **incontinueness* or **disambiguosity* are impossible

also tells us that there are restrictions on how morphemes combine. At the same time, we can understand novel forms such as *unfaxable*. It is the morphologist's job to discover the general principles that underlie our ability to form and understand some complex forms but not others.

Affixes are morphemes that appear before or after the stem morpheme (viz. prefixes and suffixes, respectively). Affixes may vary quite widely in their productivity, the likelihood that they will appear in new words. Compare the three English suffixes *-ory, -ive,* and *-able*, all of which form adjectives from verbs. The first suffix is almost completely unproductive in Modern English; very few new words with this suffix have been added to the language in centuries. The second occurs in such recent words as *adaptive* and *adoptive*. The third is highly productive: innovations such as *unfaxable* are common. Productivity is usually defined with respect to the extent to which a morpheme is expected to appear in novel forms. For example, if we search a large database for new words (words that do not appear in a large standard dictionary) containing the two morphemes *in-* and *-ity* that we introduced at the beginning of this article, we find very few new words with in- (actual examples include *ineliminable* and *inegalitarian*), but many more with *-ity* (actual examples include *avuncularity* and *deviosity*). We therefore say that *-ity* is more productive than *in-*. However, sometimes researchers define productivity with respect to the total number of words in which a morpheme appears. Again, we find that the affix *able* appears in many more than does the affix *ive*. Analogous to affixes, stem morphemes can differ with respect to their family size, that is, the number of words formed from a particular morpheme stem. For example, many more words are formed from the stem *sist* (i.e. consist, persist, desist, insist, and

approximately 31 derivations) than from the stem *flect* (i.e. inflect, deflect, reflect, and approximately seven derivations).

Depending on whether or not they can stand alone, morphemes are classified into two basic types: free (e.g. *secure*) and bound e.g. *in*, *ity*, *fect*). Affixes are bound because they cannot appear in isolation, but must combine with (be bound to) another morpheme to form a word. Repeated additions of bound morphemes allow for the formation of more complex words as affixes pile one onto another. The word *inconclusiveness* contains three bound morphemes as well as a free stem [conclude] and has been built up in stages from *conclude* by first adding the suffix *-ive* to the verbal stem (with a sound change from d to s), so as to produce *conclusive*, then the prefix *-in* so as to form *conclusive*, and finally the suffix *-ness*, resulting in [[in[[conclude]$_V$ ive]$_A$]$_A$ ness]$_N$. Note that *in* cannot combine with *conclude* but it can combine with *conclusive*. This reflects the strict ordering of stages when complex words are formed. Sometimes, two morphemes can be added to a stem in two different orders, yielding two different meanings. Consider the word *unbalanced*. It can mean either 'not balanced' or 'deranged'. The first meaning results from adding the suffix *-ed to balance* and then adding the prefix *un-,* which, when attached to adjectives means 'not'. The second meaning results from first adding the prefix *un-* to the verb balance, giving us the verb *unbalance*, which means 'derange'. When the suffix *-ed* is added to this complex verb, it creates the adjective meaning, hence 'deranged'.

Finally, among bound morphemes, linguists distinguish inflectional from derivational morphemes. Derivational morphology deals with how distinct words are related to one another; inflectional morphology focuses on the different forms that a word may take, depending on its role in a sentence. English is quite sparse inflectionally, as compared with many other languages (e.g. Classical Greek and most Slavic languages), where each noun, verb, and adjective will have a large number of inflected forms.

The way in which morphemes combine to form complex words also varies across languages. Some languages (e.g. Chinese) have little in the way of combining morphology. Others (e.g. Turkish) are distinctive for the manner in which multiple morphemes occur within a single word. Rules for combining morphemes also vary across languages. In English, morphemes are linked linearly as in words such as *inconclusiveness.* In Hebrew, by contrast, morphemes can be interleaved with one another (e.g. R-G-L combines with -e-e to form ReGeL meaning 'leg' and with m-a-e?- to form mragel? meaning 'spy'). The relation between 'legs' and 'spies' may

seem obscure until one realizes that in biblical times one could only spy by walking around.

Knowledge about words is represented in the mental lexicon. A major research question for psycholinguists is how the mental lexicon represents morphological knowledge. One issue is whether regular forms and irregular are represented differently in the mental lexicon. If regularity is defined with respect to form, we can ask whether words with stems that undergo a change in spelling (and sometimes pronunciation) are represented differently from words whose stem is always regular. That is, are forms such as *run* and *ran* represented differently from forms such as *turn* and *turn*ed? Derivation tends to be semantically somewhat unpredictable: *walker* can mean either 'one who walks' or 'a special support that helps one to walk'. If regularity is defined with respect to meaning, a second issue is whether inflected forms such as *concluded* and derived forms such as *conclusive* are represented in the same manner. Similarly, we can ask whether semantically opaque (or ambiguous) forms (e.g. *walker*) as well as semantically transparent morphological relatives (e.g. *talker*) are represented in a like manner in the lexicon. Within the mental lexicon, some theorists express morphological relatedness in terms of representations that are decomposed and share a constituent morpheme. Other theorists express morphological relatedness in terms of a principle of similarity among full forms.

In the psycholinguistic literature, the classic task for exploring morphological knowledge is the lexical decision task. Letter strings are presented visually. Readers must decide whether each is a real word, and reaction time to decide is measured. Words are usually presented in pairs, a prime and then a target. Typically, prime and target occur in immediate succession. When both prime and target are fully visible, decision latencies to the target are faster when it is preceded by a prime that is morphologically related (e.g. *turned-turn*) than by a prime that is similar in form (e.g. *turnip-turn*) or meaning (e.g. *rotate-turn*) but not morphologically related. Reduced decision latencies following a morphologically related prime as compared to an unrelated prime is termed morphological facilitation and many psycholinguists interpret the effect as evidence that the same base morpheme or stem was activated by the prime and by the target. Typically, morphological facilitation arises both when morphological relatives of the target are regular (e.g. *turned-turn*) and when they are irregular (e.g. *ran-run*), however. Nonetheless, the magnitude of morphological facilitation in lexical decision as well as in other experimental tasks tends to be attenuated when the prime is irregular and involves either reduced form or reduced semantic similarity

with its target. Finally, morphological facilitation has been documented in a variety of languages including those where morphemes are not generally appended linearly (viz., nonconcatenative) such as American Sign, and Hebrew, as well as in many where morphemes are concatenated such as Bulgarian, Dutch, English, French, German, Greek, Serbian, and Spanish. Dimensions of morphological relatedness that can alter the magnitude of morphological facilitation in variants of the lexical decision task include inflection vs. derivation, semantic transparency or opacity (or ambiguousness), and orthographic regularity vs. irregularity.

Murrinh-Patha and the Daly Languages

Murrinh-patha is an Australian Aboriginal language spoken on the country's far northern coast, in an area several hundred kilometers to the southwest of Darwin. The language, which now has no significant dialectal variations, is spoken by some 2,000 people, predominantly in the township of Wadeye (formerly Port Keats) and the numerous satellite out-stations and dry season camps that it supplies. With this number of speakers, Murrinh-patha stands out as being one of the few Australian languages not under immediate threat of extinction. Indeed, the Murrinh-patha speech community has been growing rather than diminishing in size over the last few decades, with an expanding population of Murrinh-patha children continuing to learn it as a first language, and with Marringarr-, Mati Ge-, and Marrisyefin- speaking groups from the neighboring regions showing generational shift to Murrinh-patha as they become increasingly integrated into a greater Wadeye community. The language is further supported through a bilingual program in the Wadeye School and language maintenance programs undertaken by the community Language Centre.

Classification

For many years, Murrinh-patha was regarded as something of an Australian isolate, accepted as a member of the Australian language family, but held to belong to no lower level subgroup. In particular, Murrinh-patha was thought to have no close genetic link with any of the dozen or so languages of the Daly River region to its north and east, these being presented by Tryon (1974) as together constituting the 'Daly Family'. The cornerstone to this view of Murrinh-patha's genetic status was the lexical data; Murrinh-patha has at most an 11% shared vocabulary density with any other language against which it has been tested.

Present research is, however, overturning these long-held assumptions. Green (2003) has now made out a compelling case for considering Murrinh-patha as making up a genetic subgroup with the Ngan'gi languages (Ngan'gikurunggurr and Ngen'giwumirri), formerly claimed to constitute a branch of the Daly family. The case is based primarily on formal

correspondences in the core morphological sequences of finite verbs, which Green argues are too matching in their complexities and irregularities to have plausibly come about through anything other than a shared genetic legacy, and which he demonstrates through reconstruction of finite verb paradigms as being systematically derivable from an innovative common parent.

At the same time, Tryon's construction of an overall Daly Family is now also seen as problematic. Green has suggested that in place of the single family proposed by Tryon, the formal evidence establishes five separate Australian subgroups in the region. These are given in Table 1. (Identifiable branches of each subgroup are listed on separate lines.) Green claims that the five subgroups cannot convincingly be related together as a single genetic unit, and argues that the similarities that Tryon considered to be diagnostic of membership in the Daly Family are better accounted for either diffusionally or as genetically inherited features shared with a wide range of northern Australian languages.

TABLE 1 Genetic Subgroups in the Daly River Region

Subgroup	Principal Language Varieties
Anson Bay	Batjamalh (aka Wadjiginy), Kendjerramalh (aka PunguPungu)
Northern Daly	MalakMalak, Tyeraty, Kuwema
Eastern Daly	Matngele, Kamu
Western Daly	Marrithiyel, Marrisyefin (aka Marri Tjebin), Marri Ammu, Marringarr, Mati Ge (aka Magati Ge) Marramaninydyi, Marranunggu (aka Merranunggu and Warrgat), Emmi-Menhdhe
Southern Daly	Murrinh-patha, Ngan'gikurunggurr, Ngen'giwumirri

Areal Features

Like the majority of languages spoken in Australia's central far north, Murrinh-patha and the Daly languages are of the 'polysynthetic' structural type, and are categorized within Australianist typology as belonging in the 'non-Pama-Nyungan' and 'prefixing' groups. They possess complex verbal structures built up through the addition of strings of prefixes and suffixes to the lexical roots. Many of the affixes are suppletive in form and portmanteau in nature, simultaneously encoding a number of grammatical categories. Equally, it is not uncommon for grammatical categories, such as person, number, and tense, to be marked discontinuously via different affixes at different points in the verb, as illustrated in example 1.

Example 1. Murrinh-patha (Walsh 1993a,b)
ma-nanku-ma-purl-nu-ngintha-nga-ni
1sgS.Hands.Fut-2dlO-hand-wash-Fut.   Positive-2dl.non-male.mixed sub-section-1sgS.Fut-Sit
I will keep on washing the hands of you two (who are not siblings and one or both of whom are female).

Pronominal Indexing

Verbs obligatorily index core participants such as 'subject' (I saw you) and 'object' (I saw you) by bound pronominal prefixes. Most languages additionally allow for the verbal cross-referencing of other kinds of participants, such as 'goals' (I said it to her), 'benefactives' (I did it for her), and 'adversatives' (My wife ran away on me). Pronominal indexing is shown in example 2, from Ngen'giwumirri (< Southern Daly), where subject, object, and adversative are indexed on the one verb. Observe that the subject pronoun also encodes a tense category, in this case the perfective. Variation of the subject pronoun for tense is found in all languages, typically as the historical result of fusion with a formerly discrete tense affix.

Example 2. Ngen'giwumirri
Danginy-nyi-fime-ngidde-wurru
3sgS.Poke.Perf-2sgO-give-1sgAdv-bad
She gave it away to you against my wishes.

Verbal Classification

Many languages of Australia's central far north share the further characteristic of forming their verbs with not one, but rather two, root-like elements. This two-part structure typically involves the pairing of a relatively inert root (or 'co-verb'), the element that provides the main lexical information for the verb, with a root that hosts the core grammatical affixes. The lexical roots form an open class, while the 'grammatical' roots belong to a closed class, normally numbering less than 50. The two-part verbal structure is thought to be an ancient diffusional feature. And while in some other parts of Australia's north the grammatical root has synchronically no clear semantic value, in the Southern and Western Daly subgroups, it functions as a classifier of the verbal action. The Southern Daly languages all have more than 30 of these classifiers, while the Western Daly varieties have around 20 or so. Verbal classification may simply involve specifying the relative orientation of the subject, as with the intransitive classifiers in examples 3 and 4.

Example 3. Marrithiyel
ga-wu-fifi-nysyen-a
3sgS.Realis-stand-smoke-then-Past
He was standing up smoking then.

Example 4. Marrithiyel
ga-fulh-fifi-nysjen-a
3sgS.Realis-lie-smoke-then-Past
He was lying down smoking then.

Verbal classification may also be relatively abstract in nature, as illustrated by the transitive classifiers in examples 5 and 6 below. In example 5, the grammatical verb root functions to conceptualize the action as performed at the end of an elongated instrument. Contrast this with example 6, in which the replacement of the grammatical verb-root achieves a different schematic conceptualization, this time of the action as performed along the shaft, rather than the end, of an elongated instrument.

Example 5. Marrithiyel
sjendi-gin gu-mun-git-a
spear-Instrumental 3sgS.Realis-jab-sever-Past
He cut it with a spear (that is, by jabbing at it with the end of the spear).

Example 6. Marrithiyel
sjendi-gin gi-ny-git-a
spear-Instrumental 3sgS.Realis-swing-sever-Past
He cut it with a spear (that is, by swinging at it with the shaft of the spear).

These rich classificatory systems are not, however, found right across the Daly region. The Northern and Eastern Daly languages, for example, have much smaller and simpler systems, with just a single productive transitive classifier combining with a few intransitives, while the Anson Bay subgroup shows only recent and rudimentary developments in this direction.

When compared to the other languages of the Daly, and to northern Australia generally, the classifying verb structures of the Southern and Western Daly languages reveal two aberrant features. Firstly, they exhibit a tight morpho-phonological binding between co-verb and the inflected grammatical root. Secondly, they show an innovative ordering, placing the co-verb after the inflected grammatical root rather than preposed to it. Reid (2003) argues that these shared features result from recent diffusion rather than a shared genetic legacy, demonstrating how the Southern Daly languages Ngan'gikurunggurr and Ngen'giwumirri have acquired them only within the last hundred years.

Free pronouns

The Daly languages have freeform pronoun systems that are interesting for several reasons. Firstly, they tend to be complex by virtue of grammaticizing multiple nonsingular number categories. Some languages have singular/dual/trial/plural systems, while others have singular/dual/paucal/plural systems. Secondly, some have developed systems of pronouns where the categories of number and person have become integrated with other categories of information. For example, in Murrinh-patha features of the subsection system, and a gender categorization that hinges on the minimal inclusion of at least one female within a group determine pronominal choice. As can be seen from Table 2 (from Walsh 1976), this type of complexity results in nine Murrinh-patha pronouns corresponding to English 'we'.

Nominal Classification

All the Daly languages have at least a few generic nouns, such as 'meat', 'vegetable food', and 'fire', which are regularly placed in front of specific nouns to encode salient cultural categories. In Murrinh-patha, this has become extended into a system in which the category membership of all entities is obligatorily encoded by one of around a dozen NP initial generic nouns.

In an adjacent bloc of Daly languages, encompassing Ngan'gikurunggurr, Ngen'giwumirri, and all but the northernmost Western Daly varieties, the systems have the same number of categories, but have become more grammaticized, displaying agreement phenomena and reduction of the independent generic. Sometimes, agreement is marked by bound forms attached to nouns as well as modifiers such as adjectives or demonstratives. In other cases, noun class assignment is marked by freeform generics that precede specific nouns and also precede the modifiers. Both these possibilities are demonstrated in the Marrithiyel examples below.

Example 9. Marrithiyel
a-madi a-ngelfu
animal-barramundi animal-many
many barramundi fish

Example 10. Marrithiyel
Wadi meri wadi gutlik wadi gan
Male man male blind man this
This blind man

Noun class phenomena in Daly languages have proved theoretically interesting by providing a perspective on the historical development of bound class from freeform to proclitic to prefix. They have also contributed to theorizing about the process by which agreement phenomena develop (Reid 1997) and to considerations of the nature of the distinction between noun class and noun-classifying systems (Green 1997).

TABLE 2   Murrinh-Patha Freeform Pronouns

	1st Inclusive	1st Exclusive	2nd Person	3rd Person	
Singular		ngayi	nyinyi	nukunu	Male
				nigunu	Female
Dual	neki	ngankuninda	nankuninda	peninda	All male, mixed subsections
		ngankunginda	nankunginda	peninginda	At least one female, mixed subsections
		nganku	nanku	piguna	All same sub section
Paucal	nekineme	ngankuneme	nankuneme	peneme	All male, mixed subsections
	nekingime	ngankungime	nankungime	peningime	At least one female, mixed sub sections
Plural	nganki		nanki	pigunu	All same subsection

TABLE 3   Ngen'giwumirri Phonemic Inventory

	Bilabial	Alveolar	Palatal	Velar
Voiceless stop	p	t	ty	k
Voiced stop	b	d		
Fricative	f	s	sy	g
Nasal	m	n	ny	ng
Lateral		l		
Rhotics		r (approximant) rr (trill)		
Glide	w		y	

Phonology

Australian languages generally lack phonemic fricatives, and have just the single series of stop. The Daly region shows a significant departure from this pattern. With the exception of Anson Bay, all the subgroups show at least some phonemic voicing contrast. In addition, in Ngan'gikurunggurr, Ngen'giwumirri, and the Western Daly varieties, there are phonemic fricatives, with a resultant three-way voiced stop, voiceless stop, and fricative contrast in the bilabials, alveolars, and (in some languages) palatals. The phonemes of Ngen'giwumirri, showing the atypical obstruent set in an otherwise standard Australian inventory, are given in Table 3 in their practical orthography.

Nahuatl and Uto-Aztecan Languages

The Uto-Aztecan (also spelled Uto-Aztekan) language family is comprised of eight branches, spread across the Great Basin, into the northwest, California, the southwest of the United State, and through Mesoamerica. The major groups are Numic, Tübatulabal, Hopi, Takic, Pimic, Taracahitic, Corachol, and Aztecan.

Pre-European contact Numic peoples ranged through the western portion of the United States into Alberta and Saskatchewan; postcontact, their range contracted. Today, groups live in Wyoming, Idaho, Oregon, Utah, California, Colorado, Nevada, Arizona, and New Mexico. Numic languages include Comanche and Shoshoni (also written Shoshone), Kawaiisu, Ute, Northern and Southern Paiute, and Mono. Although covering a wide area, languages of this group remain quite similar in lexicon and morphology, suggesting a relatively recent dispersal. Miller (1983) follows Lamb (1958) and Fowler (1972) in surmising that the initial communities inhabited the southwestern part of the Great Basin, which began to separate into northern and southern groups about 2,000 years ago, moving out to their greatest extension around 1,000 years thereafter. Today, Paiute and Shoshoni remain vigorous languages. The Yerington band dialect of Paiute is expanding its forms and domains of usage. Most other Numic-speaking communities are shifting to English as a first or dominant language; this shift is complete for Mono and Kawaiisu.

The Tübatulabal branch consisted of a single family. It became extinct at the end of the twentieth century.

Hopi remains a viable language, spoken in northeast Arizona, Utah, and New Mexico. Eighty percent of ethnically ascribed Hopi speak their language. The Hopilavayi Project of the Hopi Cultural Preservation Office has designed materials to help communities teach the language within the homes, villages, and schools.

Benjamin Whorf relied heavily on his study of Hopi in developing his theory of linguistic determinism. Ekkehart Malotki, working closely with Michael Lomatuway'ma, has published seven collections of Hopi tales, presented in bilingual format. He has also explored the encoding of time in the Hopi language, the basis for much of Whorf's speculation.

The Takic branch, situated in Southern California, consists of Cahuilla, Cupeño, Luiseño, and Serrano. Each of these languages has fewer than 50 speakers; only one speaker was reported for Serrano in 1994. Although California has had a mentor-language-learning system, which pairs young Native Americans with fluent speakers of their languages for total immersion, some elders prefer not teaching the language to teaching one that they must fill with neologisms.

The Pimic branch (also called Tepiman) includes Pima, Papago, and Tepehuan. Papago-Pima is also known as O'odham, O'othham, Nevome, Nebome, and Upper Piman. The term O'odham means 'We, the People'. The Pimas of the Gila River area call themselves *ʔakimel ʔoʔodham* 'river people', while the Papago to the south are *Tohono ʔoʔodham* 'desert people'. Through the early 1900s, Pima elders continued to record their life histories on calendar sticks. The writing system appears to have been a mixture of personal symbols and ideographs. Most of these records were destroyed upon the authors' deaths. The languages are now recorded in the roman alphabet. The

Tohono O'odham have K-12 bilingual education. Two Piman languages, both referred to as Pima Bajo, are spoken in Mexico, Chihuahua, and Sonora. Speakers are just becoming bilingual in Spanish. Tepehuan, divided into three major dialects, is spoken in Durango, Chihuahua, and, until recently, in northwestern Jalisco, and has approximately 35,000 speakers. Tubar, once spoken in Chihuahua, is now extinct.

Taracahitic consists of Guarijio, c. 5,000 speakers in the western Sierra Madre; Tarahumara, in Chihuahua, with around 72,000 speakers; and the Cahitic languages: Mayo, in southern Sonora and northern Sinaloa; Ópata in the Districto Federal and the state of México; and Yaqui, with speakers in Sonora and in Arizona. While Ópata is moribund, Mayo and Yaqui continue to be highly used, and are similar in structure and lexicon. Yaqui is tonal, while Mayo is not.

Corachol is made up of Cora, spoken in Nayarit and in a pocket of western Colorado, and Huichol in northwestern Jalisco. All the languages of this group are tonal.

The Nahuatl branch, also called Aztec, Mexicano, and Nahua, is robust, with around 1.9 million speakers. Precontact Nahuatl-speaking communities were scattered from the southern Sonoran desert through Salvador and Honduras. The Spanish crown made Nahuatl an official language for legal proceedings. Many non-Nahuatl communities retained Nahuatl scribes to file their land claims, wills, and petitions. Spanish priests wrote excellent dictionaries and grammars of the language; a Nahuatl speaker trained by the Jesuit priest/linguist Horacio Carochi composed a series of 'dialogues' meant to serve the priests as a model for polite discourse (Karttunen and Lockhart 1987). In addition, many Nahuatl town scribes recorded local histories in annals; although postcontact and written in the roman alphabet, many of these annals record earlier events. That of Quauauhtitlan covers 635–1519 CE; that of the Chichimecs spans 1116–1544 CE. Some or all of these documents may have been based on earlier nonalphabetically recorded texts. Precontact Nahuatl writings are predominatly picto- and logographic. There is evidence that some signs in late texts were being used for their phonetic value, rather than as illustrations of the words or concepts they represented, perhaps indicating a shift toward a more syllabic or phonetic writing system. Surviving precontact writings are dynastic histories, annals, maps, divinatory guides, or combinations of these.

Nahuatl schools for noble youths were often taken over by priests, postcontact. Early texts produced by young men trained in these schools occasionally retained logograph-like illustrations or marginalia. Fray Bernardino de Sahagún, working with a cadre of Nahuatl scholars, produced a compendium of cultural exegeses, which he entitled *General history of the Things of New Spain*. Treatises cover precontact religious practices, sacred songs, origin tales, divination, philosophy, astronomy, political structure, occupations, plants and animals, and the Spanish invasion. Nahuatl intellectuals in the early colonial period, among them Chimalpahin and Tezozomoc, wrote political and historical essays, and composed poetry and songs. Major tropes include parallelism (morphological, syntactic, and semantic), metaphor, couplets-for-class (naming a class by two prime examplars, as *cuāuhtli, ōcēlōtl* 'eagle, jaguar', the two major warrior societies standing for 'warriors'; *tōchtli, mazātl* 'rabbit, deer', two prime wild animals, standing for the 'wild'), and inversion. Parallelism is a common feature in indigenous literatures of the Americas, as are the couplets-for-class. Inversion is more particular to colonial Nahuatl canons. In inversion, a word or phrase is used to refer to its 'inverse' or antonym. Thus, *cuāuhtli, ōcēlōtl* 'eagle, jaguar' may be used to refer to a commoner, a farmer, rather than to the elite warriors; *pilli* 'child' is also the term for a person of the nobility.

Legal and ecclesiastical records were still kept in Nahuatl through the eighteenth century. In the mid-twentieth century, Mexican intellectuals began a Nahuatl revitalization, publishing poetry and prose again in Nahuatl. UNAM publishes a journal *Tlalocan*, primarily dedicated to Nahuatl studies. The Mexican Ministry of Education sponsors bilingual education in Nahuatl communities. A full range of teaching materials is available for K-12. Mexican-Americans have also taken up Nahuatl as a symbol of identity. Nahuatl words, written and spoken, are used emblematically by populations in California and, to a lesser extent, Arizona.

Pipil is the Nahuatl variety spoken in El Salvador. Official estimates have long placed this language close to extinction. However, a 1979–1980 survey by the Universidad Centroamericana José Simeón Cañas revealed that there were still viable populations of speakers in the three northernmost departments. With the resolution of the civil war, a bilingual education project was established. Materials and teachers from sister communities in central Mexico helped jumpstart the schools in Pipil-speaking communities.

Proto-Uto-Aztecan had a relatively simple consonant inventory: p, t, č, k, kw, ʔ, s, h, m, n, w, y, and five vowels. Classical Nahuatl had long and short i, e, a, and a back vowel [o~u]. Some modern languages within the family are tonal, but tone appears to have been developed from glottal stops and consonantal sandhi. Most languages of the group have fixed stress.

Morphologically, languages of this group tend to share the use of an absolute suffix, although they

vary with respect to its ubiquity. Some languages have only vestiges of this affix in citation forms. In others, such as modern spoken Nahuatl, the affix appears when noun stems are neither possessed nor initial elements of compounds. Compounding is a productive mechanism for word formation, as are cliticization and affixation. In Cora, the verb word may be quite long, as habitual objects, goals, and instruments may be incorporated into the verb word. Verb–verb, verb–adverb compounds are also common. Huichol has productive compounds; Mayo has relatively shorter words, and Classical Nahuatl combined compounding, with elaborate affixation. A verb word in Classical Nahuatl could contain a negator, an incorporated adverbial, an antecessive marker, additional time adverbs, subject pronouns, object pronouns, movement markers, reflexives, incorporated noun objects/goals, reduplication (for intensity or distribution), incorporated indefinite objectmaker, further reduplication, a verb root, a series of derivations affecting transitivity, a connective, one or more auxilliary verbs, aspect marker, and a number marker. Nouns, although less complex, could be elaborate as well, containing reduplication, one or two roots, derivational affixes, and either an initial possessive or a final absolutive maker. Common postpositions marked both positive and negative affect, location, abundance, position, or manner.

Modern Nahuatl retains most of these possibilities, although the extended alternation of transitivizing and intransitivizing verbal suffixes found in courtly colonial Nahuatl writings does not appear in modern honorific usage. The compounding potential of Nahuatl has made the formation of neologisms relatively easy. This potential is open to the other languages of this family.

Classifiers for nouns or for counting are relatively undeveloped within Uto-Aztecan. Most languages have a few. Classical Nahuatl had seven. Modern spoken Nahuatl varieties seldom use more than three. This may be related to the use of Spanish number expressions for most counting.

Proto-Uto-Aztecan appears to have placed verbs following the complement or direct object (SOV). Many modern languages have experienced some reordering in main clauses, while retaining the early order in subordinate clauses. Most languages in this family have postpositions and, at least, allow Subject–Object–Verb order today. Preposing an argument or clause is used for emphasis. Relative clauses may occur without a relative pronoun. Subordination is often by juxtaposition. In Proto-Uto-Aztecan, subject noun phrases of subordinate clauses were inflected as objects. Most languages of the family retain this trait. Nouns and adjectives may serve as predicates, with a 'zero' copula. Generic action may be shown

with indefinite actor pronoun affixes on the verbs. Number can be marked in several ways in Uto-Aztecan languages, including use of numerals, inflection on nouns and pronouns, on verb forms, and on pronominal verb affixes. Languages within the family differ with respect to the obligatoriness of number marking and agreement. Classical Nahuatl did not require number agreement between pronominal affixes and coreferent noun phrases, although increasing animacy brought increasing agreement. Modern spoken varieties of Nahuatl more consistently mark plural on nouns, both animate and inanimate. There is also more agreement between pronominal verb affixes and their coreferent noun phrases. Classical Nahuatl had a variety of mechanisms for inflecting for plural, including reduplication. Modern Nahuatl retains examples of earlier plural classes in fossilized forms. The productive morphemes are now restricted to a few forms for general pluralization, diminuitives, and vocatives. Hopi may mark the plurality on nouns by reduplication. Nouns and verbs in Hopi may also carry plural suffixes. Some Hopi verbs have suppletive stems for the plural. Hopi also makes a distinction between singular, dual, and plural for subjects. Some speakers retain a separate dual noun suffix; others do not, but the singular, dual, plural distinction is shown by agreement on the verb. A singular noun phrase with singular verb agreement is interpreted as singular. A plural noun phrase with a plural verb is plural, while a plural noun phrase with singular agreement is dual.

The Uto-Aztecan family is large and diverse; member languages are spoken from the Canadian border to El Salvador. The family retains many typological and structural features, with enough shared lexicon to allow fairly strong reconstructions. Suárez (1983: 28) gives a glottochronological estimate of 5,100 years of separation.

Naming

Names have always been seen as a very special class of linguistic signs, and naming as a very special linguistic process. Many cultures and societies associate names and naming with magic and taboo. A famous example is the tale of Rumpelstiltskin:

> The goblin Rumpelstiltskin helps a poor maid to become queen but demands her first child in return. When she gives birth and refuses to give up her child, she can only break the goblin's power over her by discovering his secret name. When she finally does, Rumpelstiltskin explodes with anger and rage and his power is broken forever.

The relationship between person and name is so close that in many cultures saying the name of a person is believed to result in serious harm. Some Australian Aboriginal groups bestow two names on each person: one that is commonly used, and one that is only known to the fully initiated and is only uttered on the most solemn occasions and even then only in a whisper (for further examples of magic and taboo associated with names, see Frazer 1993). This essay provides an overview of onomastics (as the academic discipline of name study is called) by reviewing the status of names as linguistic signs, describing the uses of naming, and discussing three categories of names in more detail, namely personal names, place names, and brand names.

At first glance, the difference between names or 'proper nouns' and common nouns seems straightforward enough: the former have unique reference and denote individuals, while the latter have generic (or 'common') reference and denote classes of entities. This means that all referents of a common noun such as *house* have something in common (walls, windows, roofs, etc.), and a sentence such as *Houses are important for humans to live in* makes sense. However, this is not true for proper nouns, and therefore they normally do not allow for plurals. It is true that names such as *John* or *Newcastle* may have many different referents (John Smith, John Baker, John Howard, etc.; Newcastle, UK; Newcastle, Australia; etc.). But even if a name refers to more than one single extralinguistic referent, those referents do not have anything in common. Therefore, sentences such as *Johns make good lovers* or *Newcastles are good places to live in* do not make sense. This seemingly clear-cut difference between proper nouns and common nouns on the basis of unique and common reference can be attacked on a number of grounds, however. First, on closer inspection the various referents of *John* and *Newcastle* do have some things in common: Johns will be male; will have been born into an English-speaking environment; and, given that most personal names are subject to fashion, one can even make an educated guess about the age of many Johns. Second, there are a number of common nouns whose reference is also unique: *sun, moon, hell,* etc., all refer to a unique extralinguistic referent, although they are not usually considered names.

Other criteria that have been suggested for distinguishing between proper nouns and common nouns are related to sentence structure, translation, and context. The syntactic criterion that defines names (in English) is the absence of a determiner: while common nouns take determiners (*a/the house*), proper nouns do not (*a/the John, a/the Newcastle* are ungrammatical expressions). However, not all common nouns can take the full range of determiners: *a music,* for example, is not a possible expression in English. At the same time, some proper nouns require a determiner (e.g. *The Hague, the Buddha, the Potomac*). With brand names, the distinction is lost completely, as the determiner contrast can be used here to distinguish between the name of a company and the name of a product, as in *Onassis bought Ford* vs. *Onassis bought a Ford.*

With respect to meaning and sentence structure, proper and common nouns clearly form a gradient, with prototypical cases at either end and many fuzzy ones in between. Some scholars have argued that translatability (of common nouns) and nontranslatability (of proper nouns) can provide the only clear distinction. However, counterexamples are easy to find, even if they are rather rare: e.g. *New York* can be translated into German as *Neu York* and into Spanish as *Nueva Yorca*, or German *Schwarzwald* becomes *Black Forest* in English. Ultimately, the intention and perception of language users is the only way to distinguish between common nouns and proper nouns. However, this distinction is no longer systematic and inherent in the language, but determined by context: whether any given noun is considered a name or not would thus shift from context to context. The shifting use of words as proper and common nouns is best exemplified with brand names: from the producers' perspective, brand names have to be unique and distinctive. At the same time, they refer to classes of items that are more identical than any two *houses* are ever likely to be. Indeed, with the widespread practice of *badge-engineering* (diversifying your product range by selling the same item under different names), the name may even be the only difference that exists across different classes of items. With respect to context, there are two important uses to which names can be put. First, they can be used to identify and individualize their referents. It might be argued that this purpose could be more rationally achieved through numerical coding, but names are more memorable and much richer in connotation. Second, personal names are used to address people. Together with terms of address, names allow for rich combinatorial possibilities of expressing the social relationship between speaker and addressee (e.g. Carrie, Carol, Carol Walker, Ms. Carol Walker, Ms. Walker, Dr. Walker, Aunt Carol). Only personal names are normally used in forms of address, and these will now be described in some more detail, followed by place names and brand names.

Personal names are names used for people, but names for pets are also sometimes included in this category. In many parts of the world, personal names consist of a 'given' part and a 'family' part, which tend to be fundamentally different in that given names are usually a matter of choice while the surname runs in the family. The surname is largely conventionalized in that it is usually the father's family name in many parts of the world (although recent societal changes have led to an increase in the mother's name or a combination of parental family names also being used). Research questions concerning these two categories of personal names differ significantly. Questions about first names include the following: (1) How are they formed? Female first names, for instance, often follow a pattern of ending in

-a, as in *Lydia*, *Moira,* or *Sonya*. (2) Where do first names come from? In English-speaking societies, a significant source of first names has traditionally been the Bible (e.g. *Mark, Michael, Peter*). (3) What patterns of sex-specific names are there? For instance, the pool of boys' names has tended to be much more stable over the years than the pool of girls' names. In recent years, there is also an increasing trend toward gender-neutral names such as *Ashley*, *Taylor*, or *Madison*. (4) How has first name choice developed historically and what naming fashions are there? Less than a century ago, the pool of first names was much more limited than it is today, now that parents wish to express their child's individuality as uniquely as possible. (5) How and why do people choose particular names? Reasons include family tradition, 'hero worship' (e.g. naming a child after a celebrity), expressing a wish for the child's future or its personality (e.g. *Victoria, Rose*), or sound appeal. (6) Is there a link between name and personality? Such links undoubtedly exist but it is almost impossible to say whether people live up (or down) to their names or whether they are perceived in particular ways because of the names they carry.

Interest in family names, on the other hand, is often genealogical, and records of family names are used to trace the settlement history of an area or the migratory history of people. Other concerns include the etymology of family names, the pattern of their transmission, and laws regarding naming. Further areas of inquiry into personal names are the use of pseudonyms, naming in literature, name change, nicknames, and their use in functions that are not directly related to naming. These include generic forms such as *Jane Doe* or *John Doe*, metaphoric uses (e.g. *John Bull, Uncle Sam*), use in idioms and proverbs (e.g. *jack-in-the-box, all work and no play makes Jack a dull boy*), and metonymic uses, which are most often found in various specialized registers (e.g. *Mercedes, Creutzfeldt-Jakob disease*).

Place names include names for settlements, rural areas, rivers, and streets. The study of place names is relevant to the work of dialectologists, archeologists, and historians because place names can provide valuable clues to the settlement history of an area, in addition to or in the absence of other linguistic and material records. Britain's Celtic (e.g. *Thames*), Anglo-Saxon (e.g. *Winston*), Latin (e.g. *Chester*), Viking (e.g. *Derby*), and French (e.g. *Bellevue*) names reflect the successive waves of conquest that have shaped the history of the island. Consequently, the main research interest is in the etymologies of place names. However, the formation of place names and their meanings are also of interest. Place names typically refer to the form of a place (e.g. *Hillsdale*), its geological quality (e.g. *Rocky Mountains*), its situation in relation to water (e.g. *Tennant's Creek*), its position (e.g. *West Ryde*), its flora

(e.g. *French Forest*), or its fauna (e.g. *Emu Plains*). Furthermore, place names often refer to human uses to which the land was put (e.g. *Hyde Park*), they commemorate events (e.g. *Breakfast Creek*), or they are named after deities or people (e.g. *San Francisco*).

Brand names have often been excluded from onomastic research on the grounds that they are closer to common nouns than to personal and place names. However, brand names are fascinating, both in form and in meaning, because they are more consciously created than any other words. In addition, there often exist good records of the creators' motivation in choosing a particular brand name. As a matter of fact, some of the most creative minds are engaged in brand name creation. Brand names have to fulfill a number of legal and commercial requirements. The legal constraints are the various copyright and trademark laws, which tend to exclude offensive words as well as words of public interest (e.g. *federal*, *national*) and disallow words that are similar to brand names already in use. From a commercial point of view, brand names have to be distinctive and memorable: they have to aid the advertising of a product and encapsulate the brand's image. Creating a name that fulfills all these functions may prove to be very difficult, particularly in today's global marketplace, where a name should ideally accomplish that goal in a number of languages. Despite the extensive market research that goes into brand name creation (in the late 1990s, the creation of an international brand name cost around $60,000), grotesque multilingual failures are not unheard of. The Mitsubishi *Pajero,* for instance, failed in Spanish-speaking markets because *pajero* means 'masturbator' there. Similarly, the Chevrolet *Nova* did not sell well in Spanish-speaking markets because *no va* translates as 'does not move'—obviously a poor omen for a car.

There can be no doubt that the relationship between a name and its referent has more psychological reality for language users than that pertaining between any other linguistic signs and their referents. This observation has excited philosophers for centuries, as is evidenced in Plato's *Cratylus*. Modern linguistics, philosophy, and onomastics, however, have tended to dismiss this widely held assumption as 'primitive' or 'superstitious'. This stance has led to an ever-widening chasm between limited academic interest in names and naming (as evidenced e.g. in the small number of academic programs in onomastics) and widespread popular interest (as evidenced e.g. in the innumerable internet sites devoted to names and naming). It seems that Juliet's question remains as enigmatic as ever: 'What's in a name?'

Natural Classes

The notion of natural class is widely used in phonological theory for the categorization of segments or phonemes, our focus here, although the notion can also be applied to other domains—for example, a group of morphemes may constitute a natural class. As we will see, this notion is useful for descriptive

purposes, but plays no direct role in grammatical theory. Given this derivative status, we begin with an informal example, instead of choosing one of the various formalizations of the notion that are implicitly or explicitly used in the literature.

Informally, the featural representation [voiceless stop] defines a natural class of English phonology, which includes the sounds [p, t, k] and no others. The other sounds of English are either voiced (e.g. [a, m, g]) or not stops (e.g. [f s]). Because natural classes are defined in terms of a conjunction of shared properties, it is generally the case that using *more* features, yielding a more specific (richer) specification, will define a class with *fewer* members: the class defined by [voiceless stop] has fewer members than the class defined by [stop], since the latter includes voiced and voiceless stops. Several issues arise when discussing natural classes: (i) language specificity, (ii) organization of the feature inventory, (iii) underspecification, (iv) relation to substantive (e.g. phonetic) categories, (v) level of analysis (UR, SR), and (vi) status in grammatical theory. We briefly consider each of these.

(i) *Language specificity*: It is crucial to note that natural classes can only be defined with respect to a given language. For example, in English, [t, n] do not form a natural class of sounds: using binary valued features, their representations both contain the set of features [−continuant, + coronal]. However, this set of features is also contained in the representation of [d], which also occurs in English. Any description of [t,n] that merely conjoins features cannot include [t, n] but excludes [d]. However, in a language where there is no [d], where say [t] and [n] are the only noncontinuant coronal consonants, [t, n] would constitute a natural class of sounds.

(ii) *Organization of feature inventory*: If phonological representations are assumed to consist not merely of unordered sets of features, then natural classes cannot be defined in simple set theoretical terms—members of a set are not organized in any way. For example, in theories of *Feature geometry,* which impose hierarchical groupings of features, the more complex notion of subsumption must be used.

(iii) *Underspecification*: Another formal problem arises with the use of certain kinds of underspecified representations. If, at a given grammatical level, two representations *A* and *B* differ in that *A* contains a subset of the information contained in *B*, then it is not possible to distinguish the representation of the natural class containing both *A* and *B* from the representation of just *A*. In other words, *A* and *B* are not distinct in the sense of Chomsky and Halle (1968:328). This issue arises in models that treat certain segments as defaults. If [t] is treated as a default stop, with no features for place of articulation, then the representation

of [t] ([− voiced, −continuant]) will be a subset of the representation of [p] ([− voiced, −continuant, + labial]) or [k] ([− voiced, −continuant, + velar]). In such a system, the representation of [t] is identical to the representation of the class [p,t,k].

(iv) *Relation to substantive categories*: Does every formally definable natural class constitute a natural phonetic (acoustic or articulatory) grouping of sounds? Clearly, there is a fairly straightforward match between a natural class such as the voiceless fricatives [−voiced, + continuant] of English and a cluster of phonetic properties. However, it is less clear that a definable natural class such as [−lateral], which would potentially include all the sounds of English except for the lateral [l], forms a phonetically identifiable grouping. There are several approaches to take. First, it may not be the case that [−lateral] describes all the sounds of English besides [l]. Perhaps the vowels are completely unspecified for the feature [lateral]; perhaps the feature [lateral] is only present on the non-nasal sonorants [l] and [r], the first being [+ lateral] and the second [−lateral]. Second, just because a natural class is definable formally, it does not follow that it must play a role in the phonology of every language, or even of any language.

The natural classes that can be defined depend upon the set of features available to the language faculty; thus, the set of natural classes is theory dependent. For example, given a set of features that distinguishes the vowels [i, I, e, E] on the basis of height alone, there is no way to group [i, e] or [I, E] into natural classes by themselves. However, if the feature system represents the former pair as [+ tense] and the latter as [−tense], we can represent the relevant classes. Phonetic factors ([+ tense] vowels share articulatory properties) and phonological factors such as the existence of harmony systems that treat [i, e] uniformly as opposed to [I, E] support the existence of the relevant feature.

This brings us to an apparent circularity of reasoning: rules or processes are *defined* as applying to natural classes of sounds, and natural classes are defined on the basis of features that are posited when a set of sounds is treated uniformly by rules. For example, in Lamba, there is a process that palatalizes [s] to [S] before [i]. There is also a palatalization of [k] to [C] before [i]. It is tempting to collapse these processes into a single rule; however, there is no feature system that will treat [s, k] as a natural class to the exclusion of [t], which is also found in the language and which does not undergo palatalization. Should we take the Lamba data as evidence of a new feature [F], such that [s, k] are [+ F] and [t] is [−F]? There are several reasons not to do so. First, our identification of the two processes may be somewhat superficial—palatalization' is a descriptive term that does not obviously rep-

resent a single process. It covers a wide range of synchronic and diachronic phenomena. Second, we can restrict the distinctive feature theory by requiring that every featural distinction be transducible from the acoustic signal. There is no possible acoustic parameter that is shared by [s, k] to the exclusion of [t]. In other words, we can take a phonetic parameter to be a necessary (but not sufficient) correlate of a distinctive feature.

(v) *Level of analysis*: It will have been noted that allophonic variation was not taken into account in the discussion above. For example, it was stated that [p, t, k] constitute the natural class of voiceless stops in English, without acknowledging the existence of aspirated stops [pʰ, tʰ, kʰ]. Should natural classes be defined at the level of Underlying Representation, the level of Surface Representation, or at both these levels? Since, as the following paragraph will argue, the notion of natural class is a mere descriptive convenience, natural classes can be referred to wherever it is convenient to do so, as their existence is epiphenomenal.

(vi) *Status in linguistic theory*: Given the dubious status of the phoneme in generative phonology, and the equally difficult notion of segment, the question arises of the status of the notion natural class. Is the notion useless, a useful descriptive device without real theoretical content, or an actual element of linguistic theory? The best view is probably the second—a natural class is just a convenient way to refer to the set of representations a rule applies to, but speakers' knowledge of phonology need not contain the notion. Natural classes of segments are affected by rules since the Structural Description of the target of a rule may contain a subset of the information found in any particular token of a representation that the rule affects. For example, if a grammar contains a rule

$$[-\text{sonorant}] > [-\text{voiced}] / \_\_ [-\text{voiced}]$$

then any representation that is [−sonorant] will undergo the rule in the right context, but this set of representations need not be identified within the grammar as constituting a natural class, independently of this rule.

Navajo and Athabaskan-Eyak Language

The Navajo language is one of several Southern Athabaskan languages, more commonly known as Apachean languages, spoken in the Southwest. The Athabaskan languages, along with Tlingit and Eyak, make up the larger Na Dene language family. There are three major geographical groupings of Athabaskan languages:

(1) Northern Athabaskan—including about 25 languages spoken in Alaska and Canada, including Koyukon, Holikachuk, Tanacross, Ahtna, Dena'ina, Deg Hit'an, Tanana, Upper Kuskokwim in Alaska, Han and Gwitch'in in Alaska and Canada, Tagish, Tutchone, and Tahltan at the Yukon headwater, Tahltahn, Sekani, Tsetsaut, Babine, Carrier, and Chilcotin in the far west of Canada, and Hare, Bearlake, Mountain, Kaska, Dogrib, Slave, Beaver, Chipewyan, and Sarcee across the rest of western Canada. It is important to note that, rather than discrete groups, the Alaskan and Canadian Athabaskan languages constitute a language and dialect continuum, i.e. neighboring languages/dialects may be mutually intelligible.

(2) Pacific Coast Athabaskan (and extinct Kwalhioqua-Tlatskanai)—including Hupa and Tolowa in California, and Tututni in Oregon.

(3) Navajo and Apache—including seven Apachean languages divided into two main groups: (1) the Western group, including Navajo in one branch and a second branch divided into the San Carlos group (San Carlos, White Mountain, Cibecue, etc.) and the Mescalero-Chiricahua group, and (2) the Eastern group, divided into a branch containing Jicarilla and Lipan and a second branch containing Plains Apache.

Of the Athabaskan languages, all but Navajo are moribund, with little if any intergenerational transmission. Even Navajo, with approximately 125,000 speakers, is threatened: while more than 95% of children entering bilingual education programs were fluent in Navajo in the mid-1970s, today fewer than 50% of

kindergartners are fluent. Of the Apachean languages, Navajo is by far the best documented, and indeed may be the best documented of any Native American language. This is due in large measure to the pioneering work of Robert Young and William Morgan. Their grammars and dictionaries of Navajo over the past half century (e.g. 1987, 1992) have set the standard for work both in Apachean and in Athabaskan more generally.

Phonology

The distinctive sounds (phonemes) of Athabaskan include obstruents, sonorants, and vowels. The ancestor language—Proto Athabaskan—likely contained the following stop obstruents:

T   TL   TS   CH   K^y CH^w Q

The modern languages show a range of shifts among the Proto-Athabaskan stops. The following list shows the modern reflexes of the Proto-Athabaskan word *-tsi'* 'head':

Tanaina	*-tsi'*
Tanana, Han	*-tthì'*
Koyukon	*-tli'*
Gwitch'in (AK)	*-kì'*
Gwitch'in (Can.)	*-chì'*
Hare	*-pfí', fí'*
Bearlake	*-kwí', kfí'*
Navajo	*-tsi:'*

The sonorants of Proto Athabaskan were *w* and *y*, *m, n*, and a palato-velar nasal. Proto Athabaskan vowels are reconstructed as *i, e, a, u* plus three reduced vowels (mid, low, and back). All of the modern Athabaskan languages have both oral and nasal vowels. Some of the languages have short and long vowels; others have full and reduced vowels.

The phonemes of Navajo include plain, aspirated, and glottalized stops and affricates (*d, dl, dz, j,* and *g* are the symbols used for the plain stops), fricatives (*s, z, sh, zh, h, gh*), and liquids and sonorants (*l, ł, y, w, n, m*). Navajo has plain and nasalized short and long vowels, and high vs. low tone (distinctive pitch).

Morphology and Verb Structure

The Verb Complex

The Athabaskan verb is a complex polysynthetic structure made up of a stem plus prefixes. The stem is composed of a root plus suffixes (or other modification) indicating mode and aspect. Prefixes indicate subject and objects, mode and aspect, and adverbials. The prefix complex can be analyzed as a template comprised of basic positions or zones preceding the stem. The prefix chart in Figure 1 gives a general idea of the ordering of prefixes. Note that the stem is in position zero and subject prefixes are in positions 2 and 5, with tense, aspect, and mode in 3, and direct object in 6.

Some of the prefixes noted above are obligatory in the sense that the particular position they occupy must be filled by one of the possible variants of that prefix class in every derivative of the verb. These obligatory prefixes are the person, tense, aspect, mode, and voice/valence (also called the 'classifier') prefixes. Other, derivational, prefixes, e.g. adverbial, iterative, are optional—he positions these prefixes occupy may or may not be filled depending on the meaning of the derivative. Sometimes, prefixes are thematic—they encode a situational participant—and they are lexicalized, which means that they are present in every derivation of a particular verb. These thematic prefixes in combination with the voice/valence prefix and the root of the verb are referred to as the VERB THEME.

The Athabaskan theme is the underlying skeleton or verb construction to which prefixes and suffixal elements are added in producing an utterance. The theme itself has a meaning and is the basic unit of the Athabaskan verbal lexicon. Verb forms derived from themes have, in addition to the stem (i.e. the aspectually suffixed root) and theme prefixes, inflectional prefixes (person, number, etc.) and derivational prefixes (aspect, adverbials, etc.). These prefixes are arranged in relatively fixed positions preceding the stem as shown in Figure 1.

In Navajo, the THEME consists of the valence prefix (position 1) plus the stem (position 0). The VERB BASE consists of the mode—conjugation prefixes (position 3) plus the subject pronoun (position 2) plus the verb theme. Examples of verb themes in Navajo, with verb words derived from them, are shown below:

Theme:	*na + θ + né*	'play'
Example verb:	*naashné*	'I'm playing'
Analysis:	*na + θ + sh + né*	
	Thematic + imperf + 1st person subject + stem	
Theme:	**ha # O + ł + géésh**	'cut O (object) out'

10	9	8	7	# #	6	5	4	3	2	1	0
post positions	derivational/ thematic	reflexive reversionary semiliterative iterative	distrib./pl	disjunct boundary	DO	Subj. (3rd)	derivational/ thematic	mode/ conjugation	Subj. (1st & 2nd sg & pl)	voice/valence	stem

Figure 1. Navajo prefix chart.

Example verb: ***hadeiilgéésh*** 'we're cutting it out'
Analysis: ***ha # da # θ + θ + sh + ł + géésh***
Thematic # distributive plural # 3rd person direct obj. + imperf. + 1st person subj. + valence + stem

The Aspectual System

Aspect in Athabaskan is expressed by a complex, multidimensional system. There are two major categories that combine in expressing the temporal contour of the state or activity described by the verb. The convention in Athabaskan linguistics is to call one of these two categories MODE and the other ASPECT (although some researchers refer to these categories as 'aspect' and 'aktionsart', respectively). Both of these categories are obligatory—every verb must be marked for both mode and aspect. This morphological marking is an intersecting one, i.e. mode and aspect are marked by prefixal and suffixal elements, which encode both categories.

There are seven modes in Navajo, describing activity as incomplete, complete, ongoing, future, potential, customary, or recurrent. Examples of verbs in the imperfective and perfective modes are:

Imperfective: ***yáshti'*** 'I'm talking'
Perfective: ***yáłáti'*** 'I talked

The second basic temporal category is aspect, which describes the manner in which an activity or event is carried out over time—whether it happens once, or repeatedly, or at length. There are 12 aspects in Navajo and they allow the expression of such distinctions in meaning as: 'I am red' vs. "I turned red' and 'I am chewing it' vs. 'I bit it'. For example:

Durative: **yáshti'** 'I'm talking'
Momentaneous: **'ayániishtééh** 'I'm starting to talk"
Repetitive: **yádíshtih** 'I'm chattering'

Classificatory Verbs

Athabaskan verbs in general show a wide range of classificatory functions. Some verb stems are specialized according to whether the subject of the action is singular (or dual) or plural. Others are specialized for singular vs. plural objects. Still other actions are referred to by different stems depending on the physical characteristics of the subject or object involved. These stems are the classificatory verb stems. The Athabaskan classificatory verbs categorize the material, shape, consistency, size, animacy, arrangement, quanta, and containment of the subjects of intransitive verbs of position and location, and the objects of transitive verbs of handling.

The 11 Navajo classificatory verbs delineate (1) solid, round, or compact objects, (2) slender, flexible, or paired objects, (3) slender, rigid, or stick-like objects, (4) animate objects, (5) plural separable objects, (6) plural objects in profusion, (7) noncompact matter, (8) objects in open containers, (9) flat, flexible, or cloth-like objects, (10) mushy wet objects, and (11) heavy, large, or bulky objects.

Word Order

The word order of the Navajo sentence is Subject–Object–Verb (SOV).

Łééchaa'í mósí yinoołchééł
Dog   cat   it's chasing it
S   O   V

Most transitive Navajo sentences do not name both the subject and object in noun phrases. When only one is mentioned as a noun phrase, it is usually the direct object, that is, the new information. In this case, the direct object has an agreement prefix on the verb, which is ***yi-***. However, when the topic, or old information, is mentioned in a noun phrase, this unusual case is marked by a different object agreement prefix, ***bi-***. For example:

Mary hayííłtî 'He carried Mary up'
Mary habííltî 'Mary carried him up'

The Future of Athabaskan Languages

Work on language revitalization is under way in many Athabaskan-speaking communities, and efforts in the Navajo community are perhaps the most robust. There are language programs in many schools across the Reservation, and at the two branches of Diné College. The language is also taught at the state universities of New Mexico and Arizona. The Rock Point School on the Navajo reservation is a model bilingual education program. At Rock Point, children come expecting that they will succeed and they do—the Navajo program gives students pride in being Navajo, in their language, and in their culture. This effective program includes lessons in Navajo by community elders on Navajo cultural matters and a strong involvement of parents and so family both in conferences and in activities such as Language Fairs and book-making nights.

MELISSA AXELROD

Neurolinguistics

Neurolinguistics is a relatively new discipline that comprises both clinical and basic research into the functional relationship between language and the brain. The research topics of neurolinguistics require a multidisciplinary approach and share parts of traditional disciplines such as linguistics, medicine, psychology, and computer science, and more precisely, parts of the fields of psycholinguistics, aphasiology, neurology, brain imaging, neuropsychology, and neuroinformatics. Due to the combination of theories and methods, all these fields contribute to a new discipline in life sciences, called cognitive neurosciences. As for linguistics, this leads to an innovative research area providing empirical and neurophysiological methods for testing aspects of linguistic theories and models.

Looking back on the first emergence of common research methods in the history of linguistics, five main stages can be observed until now: (1) language philosophy, using introspection with an over 2000-year-old tradition; (2) first empirical studies on genealogy and roots of languages, using comparative approaches in typology for more than 200 years; (3) empirical behavioral studies of psycholinguistics, using e.g. reaction time experiments, with an almost 50-year-old tradition; (4) computer-aided simulation of language processes in computerlinguistics, using e.g. neural networks, for more than 30 years; (5) brain imaging of language processing and higher brain function in cognitive neurosciences during the last 20 years.

Therefore, neurolinguistics is one of the newest, but also one of the most rapidly growing fields in contemporary linguistics. At present, neurolinguistics can be divided into three major branches, depending on the research domain (see Figure 1).

Clinical Neurolinguistics or Clinical Linguistics

This field, formerly also called patholinguistics or aphasiology, mainly deals with clinical aspects of brain-related language disorders (aphasia). Aphasia is an acquired language disorder caused by brain damage, which may induce severe impairment in both language comprehension and production, as well as in reading and writing. Reasons for brain damage are mainly strokes, due to an interruption of the blood flow that causes the death of nerve cells in the respective area. Possible reasons for the interruption may be a blocked vessel (arteriosclerosis), a blood clot (thrombosis), or a burst blood vessel accompanied by bleeding, e.g. caused by a ballooning expansion of a weak vessel wall (aneurysm). Moreover, traumatic head injuries and brain tumors in certain areas may cause such language deficits. Types of aphasic language disorders range from minor difficulties, which concern only naming, to major difficulties such as a complete loss of language. The strength of the impairment depends on the location and extent of the brain damage. Currently, aphasia affects more than 1,000,000 individuals (stroke survivors) in the United States. By combining linguistic theory and neurological knowledge on aphasia, clinical neurolinguists typically work in stroke units and rehabilitation clinics, providing mainly three occupations: (1) Diagnosis: In order to test aphasic patients on the extent and the special type of language deficit in standardized examinations, several neurolinguistic test batteries are used: e.g. the *Boston Diagnostic Aphasia Examination*
Figure 1

(BDAE), *Porch Index of Communicative Ability* (PICA), or the *Western Aphasia Battery* (WAB). (2) Speech therapy: This represents the main activity of the clinical neurolinguists, who have to perform adapted speech therapy programs with the patients for several weeks or months. (3) Clinical research: This part of their occupation covers the linguistic aspects of aphasia research in hospitals and universities and results in the optimization of treatment efficacy and effectiveness of therapy programs.

Experimental Neurolinguistics

In contrast to clinical neurolinguistics, this field mainly covers basic research on the neurobiology of language of healthy probands. Experimental neurolinguists try to understand the nature of representation and physiological processes that contribute to normal language by investigating underlying neural mechanisms in general. Their main goal is to study the neurophysiological phenomena in the brain during language comprehension and production. Combining state-of-the-art neurophysiological noninvasive techniques with linguistic, neurobiological, and neuropsychological findings, experimental neurolinguists investigate certain aspects of language processing under laboratory conditions. Since this work requires high-tech equipment and a broad expertise in several disciplines, this kind of research involves typical teamwork, often represented by more than one laboratory.

Common noninvasive techniques for the study of language processes in healthy participants are the following techniques, which represent the most frequently used empirical methods in neurolinguistics. Some invasive techniques, only used during preoperative diagnostics of patients, are described later.

(1) Electroencephalography. By using scalp disc-electrodes, which are attached on to the head skin by an electrolyte conductive gel, human electroencephalography (EEG) is a real noninvasive technique, first described in 1929 by Hans Berger. This technique gained its current importance in neurolinguistics after powerful computers became available. Recording the electrical activities of the underlying neural substrate (at least several 10,000 neurons), the EEG signal provides information on the time course of certain cognitive processes. Since the EEG measures the brain's activity directly, it has a very high time resolution below 1 millisecond and this allows assessing 'when' a certain event is processed in the brain. Analyzing the brain waves elicited of a certain event (e.g. onset of a given word), the amplitude and time course of the wave can be interpreted (= event-related potential, ERP). Analyzing the coherence changes within certain frequency bands, the correlated activity of different brain areas during a task can be measured (= coherence analysis). This latter analysis allows to monitor the cooperation of different neuronal networks during cognitive tasks such as language processing.

(2) Magnetoencephalography. Like EEG, magnetoencephalography (MEG) is the second real noninvasive technique, and provides the same advantages of direct measurement of brain processes. In contrast to EEG, MEG measures the magnetic component of electrical activity. By using superconducting quantum interference devices (SQUIDs), which are contactlessly positioned around the head in a so-called Dewar, MEG records the very low magnetic fields accompanying the neural activity. Like the EEG technique, ERP- and coherence analysis of the MEG signal allows investigating language processes in the time and frequency domain.

(3) Positron emission tomography. Even though the positron emission tomography (PET) technique is not based on invasion of the skull, it is a 'small'-invasive technique, since radioisotopes are injected or inhaled. In clinical use since the late 1970s, PET scanners visualize differences in metabolic processes of the brains during a stimulus task (e.g. listening to words) and during a control task (e.g. listening to noise). Short-lived radioactive isotopes are intravenously injected and can be tracked from outside the head with a tomographic scintillation counter after their radioactive decay. While passing the brain tissue, the emitted positron of the former isotope collides after 2 to 8 mm with a body's electron, producing two gamma rays. By detecting and analyzing such coincident gamma rays, the spatial position of the former isotope can be determined. The spatial distribution of the isotopes in the brain allows an insight into the extent of the metabolic processes, and thus the brain's activity during a time window of several seconds. After the computational visualization of the data, false color pictures indicate the brain areas of higher or lower neural activity during a certain language task compared with a control task.

(4) Magnetic resonance tomography (MRT) or *magnetic resonance imaging* (MRI) are synonymously used for a powerful technique, which allows three-dimensional high-resolution brain imaging. After the head is exposed to the strong magnetic field of a cylindrical superconducting magnet, the spin axes of every hydrogen atom of the head brought into alignment. Then, short radio waves of the hydrogen resonance frequency (125 MHz) are sent to the tissue and by absorbing the energy the spin axes of the atoms are disordered for a short moment. After this radio wave stimulation, the hydrogen spin axes return to their

original, randomized state and emit energy in the form of a very weak radio wave. These remitted radio waves deliver the information on the head's structure. After being analyzed and visualized by computer, cross-sectional images of the brain with a resolution of less than 1 millimeter can be made. Outside of clinical use, MRI scanners of up to 11 Tesla are used.

This technique provides high-resolution information on the anatomy of the brain and can be combined with electrophysiological findings of EEG or MEG. In order to monitor cognitive processes in terms of metabolic changes, functional MRI must also be performed. Functional magnetic resonance imaging (fMRI) maps changes in oxygen concentration that correspond to nerve cell activity. By overlaying a map of oxygen concentration changes on the anatomical data, those brain areas that show increasing activity correlated to a given stimulus can be defined. Even though the time resolution is not excellent, the spatial resolution is in the range of several millimeters, which makes fMRI one of the most powerful techniques in neurolinguistic research.

(5) Invasive techniques. During preoperative diagnostics, e.g. prior to epilepsy surgery, electrode arrays are implanted and monitored for several days to identify the focus of abnormal electrical activity. Such intracranial electrodes, placed directly onto the cortex, allow the recording of underlying cortical activity during cognitive tasks, e.g. object naming, speaking, reading, etc. Furthermore, the underlying cortex area can be electrically stimulated by short pulse trains of weak currents. If the stimulated cortex area contributes to language, speech arrest or another aphasiological symptom will occur. In other words, by electrical stimulation, temporary lesions of the brain can be made in order to test the possible role of a given cortex region in the language process. This test is required prior to the performance of a neurosurgical epilepsy operation to assess where certain cerebral functions are centered such as memory and speech.

Another invasive technique applied for the same clinical reasons as mentioned above is the Wada test or *Intracarotid Sodium Amytal Test* (first described by Juhn A. Wada). After the injection of an anesthetic (e.g. sodium amytal) into the right or left internal carotid artery, the respective hemisphere is anesthetized for a few minutes. The type and extent of cerebral dominance of a patient can be assessed during the following behavioral test of language comprehension, production, object naming, and memory abilities. In a healthy, typical right-handed volunteer, suspension of the left (language-dominant) hemisphere leads to a Wernicke aphasia with a neologistic jargon, whereas suspension of the right hemisphere leads to a dysprosody.

Simulative Neurolinguistics

In simulative neurolinguistics, the knowledge of theoretical linguistics, clinical linguistics, neuropsychological case studies, and results of experimental neurolinguistics are used as input for a computer simulation with special software environments. By using computational techniques of computerlinguistics and neuroinformatics (e.g. connectionist neural networks), previously observed real language processes can be used for a computer simulation. During simulation, each condition can be modified step by step, and the results can be obtained immediately. The time required depends only on the computing power of the hardware used. The advantage of this technique is the enormous flexibility of the simulated paradigm. Contrary to real-life processes, where investigators have to wait for patients with certain impairments, virtual impairment can be created and tested within seconds. On the other hand, the reliability of the predictions of such simulations depends on the implemented processes, models, and constraints. However, even though simulative neurolinguistics seem to have an enormous potential for future research, it did not have a remarkable influence on neurolinguistics or cognitive neuroscience until now.

Based on the large progress in brain imaging and computerized analysis of brain data during the last few years, it can be expected that neurolinguistics will strongly contribute to linguistic theory and modeling during the next decades. For a few years now, brain processes during language can be investigated with a resolution in time of less than 1 millisecond and in space of less than 1 millimeter. Thus, a powerful new tool is available for linguists in the at least 2000-year-old attempt to understand human language. All methods developed and used in linguistics (see above) form an emergent instrument for the very different topics, questions, and approaches in studying language within the different fields of linguistics. For most of them, an integration of neurophysiological techniques would be valuable. For example, neurolinguistic studies indicate how and when language is learned as first or second language in a mono- or bilingual child, how different languages are learned by a juvenile or adolescent, and how it is represented in the brain as well as how learning can be facilitated or disturbed. In addition, the contemporary theories and models of language may be improved by neurolinguistic findings. The enormous impact of the behavioral data of psycholinguistics on linguistic modeling since the 1950s did show the necessity and usefulness of empirical evaluation. Neurolinguistic research offers an even stronger and more direct observation of cognitive phenomena and language processes in the brain.

New Guinea

New Guinea, the second largest island in the world, lies roughly 100 miles north of Australia. It contains more than 1,000 languages, about one sixth of the world's total (or one language in every 900 square kilometers), making it linguistically one of the most dense and complex regions of the world. The name was given to the island by the Spanish navigator Ortiz de Retes, possibly because he saw some resemblance between the indigenous population and the inhabitants of the Guinea coast of Africa. Politically, the island is divided between two countries: Papua New Guinea, occupying the eastern half of the island, and some 600 associated islands, the largest of which are New Britain, New Ireland, and Bougainville, and Irian Jaya (West Irian), a former Dutch colony until 1963, now the easternmost province of Indonesia. An independent nation since 1975, Papua New Guinea is historically an amalgamation of what were two separate colonies: Kaiserwilhelmsland, occupying the northeastern half of the mainland and islands under German rule from 1884 until 1914, and subsequently mandated by the United Nations to Australian administration under the name 'New Guinea'; and Papua, the southern half of the mainland, formerly British New Guinea, which was proclaimed the Australian territory of Papua in 1906. Papua New Guinea has the highest population (5.2 million) and land mass of the Pacific island nations, with 64% of its population and 84% of its land mass. Irian Jaya has a population between 1.8 and 4 million and occupies a land mass approximately the size of California.

New Guinea was originally peopled by many different waves of migrants, whose prehistory is largely unknown. Although human habitation of the island extends back some 40,000 years, recorded history is very recent and in some cases goes back only a few decades. It was the last major land area in the world to be colonized by European powers; almost all regions have a history of contact of less than a century. The terrain is extremely rugged, with mountains reaching altitudes of more than 15,000 feet, dense tropical rain forests, and fast-flowing rivers, which have long cut the interior of the country off from outsiders. Many villages have no road or river links with other centers, and some can be reached only by walking for up to two weeks.

The peoples of New Guinea are mainly settled villagers living in a subsistence economy. Their productive activities vary according to the zone they inhabit on the island's extraordinary vertical ecology. The extreme highlands have an alpine climate, with widespread frost. There, an intensive agriculture based on the sweet potato has developed over the last few hundred years. This highly productive system has given rise to a local population boom, and the highlands support large, dense groups with large languages. The ten largest indigenous languages of Papua New Guinea belong to the large groups of the interior Highlands; they have from 30,000 to 100,000 speakers. Between them, they account for nearly one third of the population. Perhaps 80% of the languages have fewer than 5,000 speakers, and as many as one third

have fewer than 500. These languages are found mainly in the coastal lowlands and the intermediate areas known as the highland fringe, consisting of pockets of rain forest, swamps, and grassland, where the population is low and thinly spread.

Linguists generally recognize two major language groupings in New Guinea: Austronesian and non-Austronesian (or Papuan). The Austronesian languages clearly constitute a family with a common ancestor, Proto-Austronesian, and comprise some 450 descendant languages in the Pacific basin and another 600 to 700 outside it, making it the largest language family. About one quarter of New Guinea languages are of Austronesian origin, and most of them (with the exception of the languages of western Irian Jaya) belong to the Oceanic subgroup established by the German linguist Otto Dempwolff. The relationships among the non-Austronesian (Papuan) languages are less clear, and the label is best seen as a cover term for a number, perhaps as many as 60, of distinct families.

Figure 1 shows the distribution of the Austronesian and Papuan languages. Most linguists agree that the coastal distribution of most of the Austronesian languages indicates the later arrival of their speakers. The immediate ancestors of the Proto-Oceanic speakers migrated from eastern Indonesia through eastern Irian Jaya into the Bismarck Archipelago. The interior of New Guinea, where the majority of Papua languages are spoken, experienced no European contact until shortly before (and even in some cases some time after) World War II, and hence most of the languages were unknown to the outside world until quite recently. A number are classified as isolates, i.e. languages that seem to have no known relatives. The Indo-Pacific hypothesis, which attempts to link Papuan languages

with those of Tasmania (but not mainland Australia) and the Andaman Islands in the Indian Ocean, has not been generally accepted, nor has the suggestion of a link between Australian languages and the languages of the Eastern Highlands of Papua New Guinea. It is possible that Australia was settled from New Guinea because they were one continent until around 8,000 years ago. Only after the last Ice Age did sea levels rise to separate them.

New Guinea languages are typologically diverse, displaying many interesting and unusual linguistic features. There are languages with SVO (subject–verb–object), SOV, VSO, VOS, and OSV word orders; OVS is the only unattested word order, and this order is quite rare across the world. Most Papuan languages, however, tend to be verb final. In addition, there are examples of noun classifier systems, such as in the Papuan language Nasioi, with a set of more than 100 suffixes added to nouns, adjectives, numerals, and derived nominals to classify the entity being referred to. Both Papuan and Oceanic languages, however, tend to have relatively simple sound systems, with sound inventories smaller than that of English. Consonant clusters are absent or rare in Austronesian, but they are present in many Papuan languages.

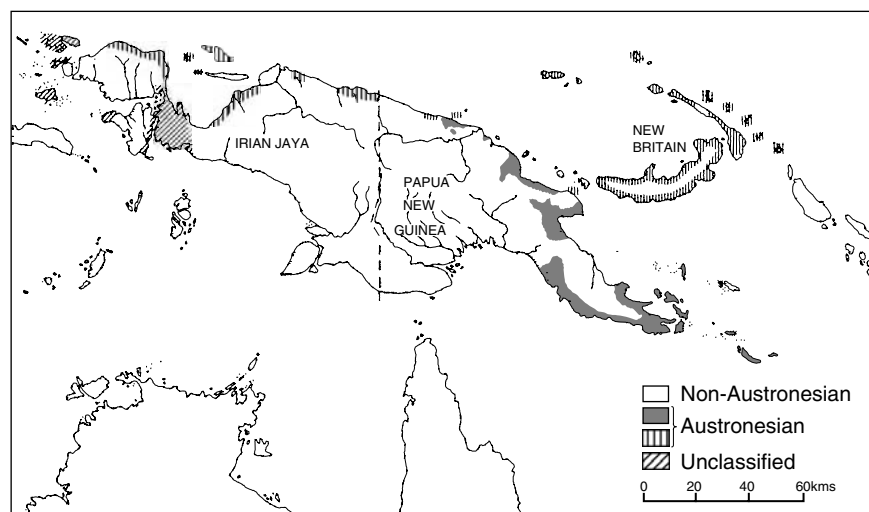
Almost all Oceanic languages distinguish between inclusive (referring to the speaker and addressee or addressees, 'I + you') and exclusive first-person pronouns (referring to the speaker and some other person or persons, 'I + he/she/it/they'), as well as a three-way distinction in number between singular (one), dual (only two), and plural, or paucal (more than two). Some languages have a trial, referring to only three. Very few Oceanic languages mark gender in pronouns, and most have a three-way distinction in their


Figure 1. Map of New Guinea showing New Britain and the distribution of Austronesian and non-Austronesian languages.

demonstratives between proximate ('this' near the speaker), intermediate ('that' near the addressee), and distant ('that' away from both speaker and addressee). Most Oceanic languages also distinguish two types of possessive marking, with all nouns being classified into alienable and inalienable. Alienable nouns refer to objects that belong to the speaker, where the speaker typically has control over the possession and may reject it (e.g. food, clothes, etc.). Inalienable nouns refer to items inseparably connected to the speaker, such as relatives or body parts. Inalienable nouns are marked with suffixes that vary in a minor way from language to language.

Only a small number of Oceanic languages have a contrast between active and passive. Grammatical distinctions, such as tense, are mostly expressed by independent particles rather than affixes:

Tuna yau ga   gire
     'I'   PAST see
     'I saw it'.

Papuan languages, however, often have a rich and strongly developed affixal word structure:

Yimas   ama-wa-t
     'I' go PERFECT
     'I went'

Pronoun systems vary widely in Papuan languages but are generally not as complex as in the Oceanic languages. Very few Papuan languages distinguish inclusive and exclusive first-person pronouns, although a number of them distinguish gender in pronouns. Articles are virtually nonexistent, and possessive constructions are less complex than in Oceanic languages. A number of languages have more than one existential ('be') verb, such as Anggor in the Sepik region of Papua New Guinea, which has 18. The different verb forms depend on the shape of the object, its location, and posture. In Enga, 'there are men' is expressed as 'the man stands', whereas 'there are women' is expressed as 'the woman sits'.

Switch reference, although generally rare in the Pacific, is typical of complex sentences in Papuan languages. When two or more clauses join to form a complex sentence, the last verb in the clause retains the subject-tense marking of the first verb, but the other (medial) verbs do not. Instead, they incorporate a suffix indicating whether the subject of the verb is the same as or different from the subject of the following verb.

Nasioi   kad-o-ma   nan-ant-in
     talk-'I'-SAME ACTOR   go-'I'-IMMEDIATE PAST
     'While talking, I went.'

     da? po-ko   nan-amp-e-ain
     you come-DIFFERENT ACTOR   go-'we'-FUTURE
     'When you come, we two will go.'

Much less research has been done on the approximately 250 languages in Irian Jaya, only four of which are spoken by 40,000 people or more, and somewhat more on the roughly 860 languages in Papua New Guinea. In many cases, missionaries undertook the first studies of languages in New Guinea, and missionary linguist work continues today, particularly in Papua New Guinea, through the Summer Institute of Linguistics.

Contacts between speakers of Papuan and Austronesian languages have led to rapid change and diversification to the point where languages such as Magori and Maisin in Papua New Guinea are difficult to classify as Austronesian or Papuan. The Motu language spoken along the southern coast of Papua New Guinea has the grammatical particle system typical of Austronesian languages, but it has the typical SOV word order of Papuan languages.

tau ese au-na   imea bogarai-na-I vada   e   hado
man a tree-the garden middle-its-at PERFECT he/she/it plant
'The man planted a tree in the middle of the garden.'

The small size of many Melanesian societies has also permitted change to spread more rapidly than in larger societies. Significant changes have affected the basic vocabulary and grammar of the Austronesian language Muyuw, spoken on Woodlark Island in Milne Bay Province of Papua New Guinea, in just a 50-year period. Local vernaculars are seen as a unique badge of identity and distinctiveness. Villagers in one community decided at a meeting that they would be different from other Selepet-speaking villages by adopting a new word (*bunge*) for 'no' to replace their usual word (*bia*) shared by all Selepet speakers.

Multilingualism is widespread, and because people marry outside of their community, husbands and wives often speak different languages. Many people, especially men, know the languages of one or two neighboring communities, or perhaps a language with wider currency around their valley or coastline. Where language groups were large, as in the highlands, only those in the border areas would be multilingual. Where groups were small, everyone was effectively in a border area, and knowledge of multiple languages was universal. In the lowland village of Gapun, whose language Taiap is an isolate spoken by about 80 people, the average number of languages understood by men over 40 was five: the vernacular, a lingua franca, and three or so of the other local languages.

In addition to the indigenous languages, there are a number of pidgins and creoles, as well as languages of the metropolitan powers, particularly English (and formerly also German) in Papua New Guinea and Bahasa Indonesia (and formerly also Dutch) in Irian Jaya. Among the pidgins and creoles are those based on

indigenous languages such as Pidgin Yimas, based on the Papuan language Yimas and spoken in Papua New Guinea's Sepik region, and Hiri Motu ('trade Motu'), based on the Austronesian language Motu, spoken by a quarter of a million people and one of Papua New Guinea's three national languages, along with English and Tok Pisin, an English-based pidgin and creole. Papua New Guinea's most widespread language, Tok Pisin, with over 2 million speakers, is the largest pidgin/creole language in the Pacific. In many parts of Papua New Guinea, children grow up speaking Tok Pisin and no longer acquire their local village language. In Gapun, parents began speaking mainly Tok Pisin to their children, and now children over the age of ten no longer use Taiap. The vernacular languages have very little place in the national life of either Papua New Guinea or Irian Jaya. In the former, English is the main language of government and education, and in the latter, Bahasa Indonesia.

SUZANNE ROMAINE

Nida, Eugene Albert

Eugene Nida's research in linguistics and cultural anthropology spans a period of 60 years, during which he has continuously developed and refined his perception of languages and cultures. His initial studies of classical Greek and the New Testament as well as his early books on morphology and the structure of English were ideal qualifications for dealing with Bible translations, a task that he was asked to fulfill by the American Bible Society. A large part of Nida's works and efforts were indeed devoted to showing translators how to better understand the Bible in order to make it understandable, in their turn, to receptors speaking highly different languages and belonging to most diverse cultures. This activity brought him into contact with over 200 languages and cultures in Asia, Australia, Africa, and the Americas. His views on the way in which languages function are thus based on extensive field surveys.

In his description of the word and sentence structure of languages, Nida has resorted to the concepts of American structural linguistics, placing, however, the meaning at the center of his investigations and replacing formal with referential classes. In his works, he has amply demonstrated that, despite formal similarities, words may develop different semantic relations between themselves and the use of strictly formal criteria of analysis can be misleading. Moreover, meaning cannot be located in words, which have 'fuzzy boundaries', but rather on a 'molecular' level, in their combinations with other words. Context thus becomes a fundamental factor in Nida's analysis of meaning, and he follows Martin Joos (1972) in maximizing its role in lexical combinations.

From word and syntax levels, Nida's research has encompassed, in an increasingly detailed manner, the structures of discourse as well as textual organization, texts being regarded as the basic and ultimate carriers of meaning. Still, his investigation of contexts goes beyond strictly linguistic scrutiny. Like Edward Sapir and Bronislav Malinovski, Nida has constantly emphasized the crucial role of cultures in describing and explaining languages. Moreover, his adoption of a sociosemiotic stance has allowed him to explore the social aspects of language as well as the ways in which

language signs relate to other sign systems and to the real world of referents.

Eugene Nida has made a fundamental contribution to the development of translation theory and practice, and his impact on Bible translators, translation scholars, and translation schools has been outstanding. He has brought rigor and scientific objectivity to the subject by incorporating concepts, methods, and classifications from linguistics, pragmatics, semantics, and discourse analysis as well as necessary data from cultural anthropology, linking languages to cultures and broader contexts of communication. The concept of dynamic/functional equivalence that he has introduced in the translational discourse has shifted the emphasis in translation theory from the faithful reproduction of source messages to the creation of translated texts with a strong communicative impact, focusing on the receivers' needs for clarity as well as on their linguistic and cultural expectations. This receptor orientation gives priority to the content of texts and may entail, in some cases, a more radical formal restructuring of the source text without, however, altering its meaning.

In *The theory and practice of translation* (co-authored with Charles Taber, 1969) and in subsequent books, Nida provides a model for describing the translating process and analyzing meaning in more detail. In his view, the translating process involves analysis, transfer, and restructuring. Analysis consists in a reduction of surface structures to kernels (i.e. substructures), making use of the functional classes of objects, events, abstracts, and relations. At the kernel level, languages are found to 'agree far more than on the level of more elaborate structures' (1969:39), and it is at this level that the transfer into the receptor language occurs. The transformation into a new surface structure through restructuring takes place according to the deemed expectations of the receivers. The model draws on principles used in transformational-generative grammar, although the influence of this linguistic direction on Nida's work has often been overemphasized. For one thing, Nida reverses Noam Chomsky's model by starting from surface structures and moving to kernels and not the other way round. Secondly, Nida is interested in language-in-use (Ferdinand de Saussure's *parole* or Chomsky's performance), and not in the abstract level of Chomsky's deep structures. Thirdly, Nida rejects the idea that languages are strictly rule-governed, as this would leave no space for their creative use. It is nevertheless true that transformational-generative grammar offered him a theoretical perspective for explaining processes of decoding and encoding texts. From a similar stance, he could also account for the similarities between languages on a conceptual and even on a formal level, in keeping with his conviction that effective interlingual communication is always possible, although there is no such thing as absolute communication.

In more recent publications in linguistics and translation theory, Nida undertakes detailed analyses at all language levels, broadening the area of interlingual investigations. The author includes a high number of case studies of Bible translations, of scientific and technical texts, of various literary genres, and of European Union texts, and a multitude of experience-based examples from different languages and cultures illustrating his translation principles.

Debates around Nida's works were mainly generated by ideological and religious speculations on his receptor-oriented position in translation as well as by the principle of 'equivalence of effect', on which dynamic/functional equivalence is based. Although the American scholar has suggested a series of tests for checking and comparing the source to target text receivers' understanding and response, "effect" has been regarded as too vague a notion to serve as a criterion for translation evaluation.

Eugene Nida's approach to linguistics and translation is avowedly eclectic. This encyclopedic perspective enables him to cover all major aspects of languages and their translation. He combines insights from structural linguistics, pragmatics, sociolinguistics, discourse analysis, functional grammar, transformational-generative grammar, semiotics, psycholinguistics, rhetoric, stylistics, information theory, etc. Nida openly declares his mistrust of the holistic systems that 'can stifle creativity and lock minds shut to new evidence' (2003:140). His books have aroused considerable interest among linguists, theologians, and translation scholars, and they have certainly been of great help to all those dealing with intralingual, interlingual, and intercultural communication, be it religious or secular.

Biography

Eugene Albert Nida was born in Oklahoma City, Oklahoma on November 11, 1914. He received his B.A. in Greek and Linguistics from the University of California at Los Angeles an 1936, and an M.A. in Patristics from the University of Southern California in 1939. He taught at the Summer Institute of Linguistics in 1937–1952. He did his Ph.D. on English Syntactic Structures under the supervision of Charles C. Fries, Professor of English and Linguistics at the University of Michigan, in 1943. He was consultant for the American Bible Society and the United Bible Societies, 1943–1981; President of the Linguistic Society of America, 1968: and Translations Research Coordinator for the United Bible Societies, 1970–1980. He has studied languages and cultures, counseling on Bible

translating in more than 90 countries, and has lectured in more than 100 universities, also actively participating in other scientific and academic reunions worldwide. He also received five honorary Ph.D.s. He is author and co-author of more than 40 books and 250 articles. Nida has lived in Brussels since 1995, consulting with Bible societies and translators from the European Union.

RODICA DIMITRIU

Niger-Congo

The Niger-Congo language family, previously labeled *Nigritic*, or *western Nigritic*, is one of the four main language families in Africa. The other language families are Khoisan, Nilo-Saharan, and Afro-Asiatic. Niger-Congo languages are spoken in the basins of the Niger and Congo rivers and in the Nuba Mountains in the Sudan. Joseph Greenberg's (1955) original classification viewed the Niger-Congo family as a sister language of the Kordofanian family. He named the ancestor language from which the two emerged as Niger-Kordofanian. However, Kay Williamson (1989a,b) notes that the Kordofanian family falls within the Niger-Congo family; hence, she uses the label Niger-Congo in place of Niger-Kordofanian for the whole family. The Niger-Congo group of languages is spoken by well over 80% of the population of Africa. Geographically, they are spoken in areas stretching from Senegal (West Africa) to Kenya (East Africa). They also stretch from Sudan (North Africa) to the south in the Republic of South Africa. Niger-Congo has ten daughter languages, namely Adamawa-Ubangi (formerly Adamawa Eastern), Atlantic (formerly West Atlantic), Benue-Congo, Dogon, Gur, Ijoid, Kordofanian, Kru, Kwa, and Mande.

Adamawa-Ubangi

Adamawa-Ubanji, previously called Adamawa-Eastern, is spoken in parts of Central African Republic, eastern Nigeria, northern Cameroon, and southwestern Chad. It has languages like Gbaya, Banda, and Zande. The Adamawa-Ubangi family has two daughter languages: Adamawa and Ubangi. Adamawa has languages like Leko, Duru, Jen, Nimbari, Mbum, Bua, Kim, Day, Waja, Daka, and Fali. Ubangi languages are spoken in the area stretching from northern Cameroon across the Central Africa Republic to parts of southern Sudan and northern Democratic Republic of Congo (formerly Zaire). Ubangi languages include Banda, Gbaya, Ngbaka (Sere, Mba), Sango, and Zande. Sango is a lingua franca of the Central African Republic.

While Adamawa allows words to end in consonants, none of the Ubanji languages, with the exception of Gbaya, allows final consonants. Whereas other language families may have nasal sounds, Adamawa-Ubanji has nasal morphemes (root words). Word order is Subject–Verb–Object, and verb reduplication (doubling of verbs in certain grammatical constructions) is common to all the languages in the subfamily. The

languages have between two and four tonal phonemes, i.e. pitch patterns that may alone distinguish meaning.

Atlantic

Atlantic languages, also called West Atlantic languages, are spoken in West Africa in the area stretching from the Senegal river down into Liberia. Most languages in this family are spoken in Senegal, The Gambia, Guinea, Guinea-Bissau, Liberia, and Sierra Leone. Atlantic has about 45 languages and over 30 million speakers. Languages in this family with large numbers of speakers include Fula, Wolof, Diola, Serer, Manjaku, Balanta, Basari, Limba, Kisi, Sua, and Temne. Important linguistic features include consonant mutation/alternation (specific consonants may change into another in particular sound patterns), noun class, and concord systems in which the choice of specific parts of speech (especially nouns) requires other elements (verbs, adjectives, adverbs, etc.) of the sentence to occur with particular affixes, depending on the grammatical construction.

(New) Benue-Congo

The Benue-Congo language family is the largest sub-family of the Niger-Congo group. It is spoken in the areas in and around the Benue and Congo river basins. It is made up of the former Eastern Kwa—Yoruba, Edo, Nupe, Idoma, Igbo—and Bantoid (subclassified into non-Bantu and Wide Bantu). The New Benue-Congo language family is subclassified into eight sub-families: Defoid (Yoruba, Akoko), Edoid (Edo), Nupoid (Nupe, Ebira, Asu, and Gbagyi), Idomoid (Idoma), Igboid (Igbo), Kainji and Platoid (Kainji, Eloyi, Kagoma, Jukun), Cross River (Obolo, Ogoni, Legbo, Ogbia), and Bantoid (Tiv, Swahili, Kikuyu, Kirundi, Kinyarwanda, Shona, Zulu, and Xhosa). The Bantoid group is by far the largest group in the Benue Congo subfamily. Important linguistic characteristics of this large subfamily include cross-height harmony (where either only tense or only lax vowels occur in words) and vowel coalescence (where two or more vowels merge to become one). Syllable structure ranges from CV (consonant–vowel) to CCV and CVC. Consonant types include such uncommon sounds as breathy voiced plosives /bh dh/ and labio velar sounds /kp gb/. Other important features include noun class and concord systems and an SVO word order. Some of the Bantu languages have a fixed stress pattern—words in Swahili, for example, are always stressed on the penultimate (last but one) syllable.

Dogon

Dogon, which is spoken on the mountains of Mali, was classified as a Gur language until 1989. However, it may also be classified as an independent member of the Volta Congo group. Dogon has six major dialects: Donnɔ Sɔɔ, Tombɔ Sɔɔ, Torɔ Sɔɔ, Jamsay, Togo Kan, and TomO Kan. Important linguistic features include independent nasalized vowels (phonemic nasalization of vowels), vowel harmony (co-occurrence restrictions in the distribution of vowels), a two-tone system, and Subject–Object–Verb word order. In Dogon noun phrases, the noun always comes first.

Gur

Geographically, the Gur group of languages is distributed over a wide area stretching from the Ivory Coast, through Ghana, Togo, Benin to Burkina Faso. Gur languages are also spoken on the fringes of Niger, Benin, and Mali. The Gur phylum subdivides into Oti-Volta, Bwamu, Kurumfe, Grusi, Kirma, Dyan, Gan, Dogoso, among others. There are nearly a hundred languages in the Gur family. Some of the languages in this group include Moore (spoken in Burkina Faso by nearly seven million people), Grusi, Gurenne, Wali (Dagaari), Dagbani, Buli, Kabre, Kotokoli, Kasem, Konni, Tayiri, Kusaal, Bassari, Ntrobo, Sisaala, Waali, Mampruli, and Nafaanra. Over twenty million people speak the Gur languages. Some of the phonological features found in Gur languages are tone, vowel harmony, uncommon consonants such as implosives, coarticulated sounds (e.g. /kp/ /gb/), and a syllable-timed rhythm.

Ijoid

Ijo, the smallest branch of the Niger-Congo language family, is spoken by the Ijo of Nigeria and covers both Ijo and Defaka (Afakani). It is spoken in the Niger River delta region and adjacent riverine areas within the Rivers, Bendel, and Ondo states of Nigeria (Jenewari 1989). The Ijo language family is made up of seven languages: Biseni (Amegi), Okodia, Oruma, Nkoroo, Eastern Ijo (which comprises Kalabari, Okrika, and Ibani), Brass Ijo (Nember-Akassa), and Izon (Bumo, Kolokuma, Mein, and Arogbo). Speakers of Ijo are a little over one million. The Ijo were among the first West Africans to have contact with Europeans, and the Kalabari, an Ijo language, is believed to be one of the first Nigerian languages to be written. An important unique structural feature is a consonant harmony also called 'implosive harmony' (which requires that any given word either contains implosives or plosives, but never both), and a noun class system drawing grammatical distinctions based on animateness and biological gender. The basic word order is Subject–Object–Verb, although different word orders are possible (Object–Subject–Verb and Subject– Verb–Object) if object or subject need to be marked as the topic of conversation.

Kordofanian

The Kordofanian language family is located in the Nuba Mountains of Sudan. Its status in the Niger-Congo family has been widely debated. As mentioned earlier, it was first viewed as a sister family of Niger-Congo in a larger grouping called Niger-Kordofanian, but later it came to be seen as a sub-branch of Niger-Congo. Kordofanian has over half a million speakers and consists of about 20 languages. Moro, Mudo, Talla, Miri, Krongo, Talasa (Tumtum), Tiro, Utoro, Rere, Ngile, Tocho, Goy, Gom (Tegali), and Kalak are some of the languages of this subfamily. Kordofanian languages have dental /d, ð, t/ (tongue touches teeth) and retroflex consonants /ṭ, ḍ/ (tongue curls back). Plosives like /t/ occurring between vowels change to fricatives such as /s/, and the noun class system is reminiscent of those found in other Niger-Congo.

Kru

The Kru language family is spoken in southwestern Ivory Coast and southern Liberia. There are 24 languages in this subfamily and the total number of speakers ranges between three and four million. Some of the Kru languages include Grebo, Klao, Dida, Godie, Bete, Nyabwa, Konobo, Bassa, Gbii, Bakwe, Kuwaa, Aizi, Wobe, Dewoin, SEmE, Guere (Krahn, Wɛɛ), Tepo, Chedepo, and Neyo. Most Kru languages have eight vowel phonemes and a vowel harmony where only vowels from a particular set may occur in any given morpheme. Kru syllables tend to end in a vowel. Central vowels such as /i, u, a,/ are found in some of the Kru languages. Uncommon consonant sounds such as implosives, double articulated sounds, and velar fricatives are found in the Kru languages. Kru languages have subject–verb–object word order with indirect objects preceding direct objects. When there is an auxiliary, then both the direct and indirect objects precede the verb. Sentences may be negated with the help of an auxiliary or a particle as well as changes in tone pattern.

Kwa

Kwa has undergone tremendous reclassification with several languages and language groups such as Ijo, Kru, Yoruba, and others moved to other major language families. The New Kwa, as it is now called, is spoken in Côte d'Ivoire, Ghana, Togo, Benin, and Nigeria by about 30 million people. It subdivides into two main subfamilies, namely Nyo and Left bank. Important subfamilies under Nyo include Avikam-Alladian, Agnéby, Potou-Tano, and Ga-Dangme. Gbe, Avatime-Nyangbo, Kposo, and Keby-Animere are identified as members of the Left Bank subfamily. Important New Kwa languages include Akan, Ewe (and other Gbe languages), Ga, Dangme, Gwa, Avikam, Anyi, Baule, Chakosi, Nzema, Santrokofi, Likpe, Adele, Logba, and Kposo. Important linguistic features associated with some of the New Kwa languages are the occurrence of voiceless and voiced labial and velar fricatives, double articulated sounds (single sounds with two different places of articulations e.g. /kp, tp, gb/), vowel harmony, and tone terracing, where pitch is lowered toward the word end.

Mande

The Mande group of languages is spoken in West African countries: Senegal, The Gambia, Mali, the Ivory Coast, Guinea, Sierra Leone, Liberia, Guinea Bissau, Burkina Faso, Mauritania, Benin, Niger, Nigeria, and Ghana. Bambara, Dyula, Susu, Mende, Kpelle, Vai, Lorma, Loko, Soninke, Kweni, Dan, Maninka, Kpelle, Busa, Bisa, Ligbi, Togo and Bobo are Mande languages. Over 40 languages are found in this family. The Mande languages are spoken by a little over 20 million people. Phonologically, many Mande languages have between seven and nine vowel phonemes, labiovelar stops, consonant mutation, two tones, and tone sandhi (adjacent tones influence one another). Unlike most African languages, Mande languages do not have serial verb constructions. Word order is Subject–Object–Verb. In noun phrase constructions, definite determiners, articles, and plurals tend to follow the noun. However, possessive pronouns precede nouns. Some of the languages such as Vai, Mende, Loma, and Kpelle in this group have combinations of Arabic script, Latin writing systems, and unique African writing systems.

Nigeria

The Federal Republic of Nigeria is the most populous country in Africa. This 'giant of Africa' gained independence from the British on October 1, 1960. Nigeria is located in West Africa. In the south, it is washed by the Atlantic Ocean. Its four neighbors are Nigér Republic in the north, Chad in the northeast, Cameroon in the east, and Benin Republic in the west. Presently, it has a presidential form of government. The centrally located city of Abuja is Nigeria's new capital. The Niger river and its tributary, the Benue, divide Nigeria into three parts: the northern region or Hausaland, the southwestern region or Yorubaland, and the southeastern region or I(g)boland. The names of these regions mirror the linguistic basis of their nomenclature; Hausa is the primary language of Hausaland, Yoruba is the main language of Yorubaland, and Igbo (or Ibo) is the primary language of Igboland. The importance of River Niger is evident in the name of the country, which is exemplary of a creative linguistic process, which combines the words 'Niger' and 'area'. 'Nig- area', spelled NIG-ER-IA, literally refers to the area around the River Niger.

Nigeria has the largest number of languages found in any African nation, accounting for over one quarter of Africa's languages. Nigeria's linguistic landscape is as variable as its vegetation, which ranges from swampland on the southern coast, to lush tropical rainforests, and a continuum of savannah land—guinea savannah, through sudan savannah, sahel savannah, and finally desert, studded with the mighty baobab. The flora and fauna are distinctive to the region; many plants and trees are not known to the western world; hence, they have become part of the lexicon of Nigerian English. Prime examples are *kola (nut), cam wood,* the *udala* tree, *bitter leaf* (from which *bitter leaf soup* is made), and the *acacia* tree. In *Things fall apart*, a classic bestseller that has sold over two million copies and has been translated into over 50 languages, Achebe utilizes Nigerian English, which echoes the oral tradition the text celebrates. The text is rich in proverbs, metaphor, simile, and folklore, as exemplified by the following excerpts:

a. 'Okoye said the next half a dozen sentences in proverbs. Among the Ibo, the art of conversation is regarded very highly, and proverbs are the palmoil with which words are eaten' (7).
b. 'A clan was like a lizard; if it lost its tail, it soon grew another' (171)

Stories of Igboland are recounted and significant beliefs are celebrated, such as the Week of Peace, the New Yam Festival, and the precolonial conception of time in relation to market weeks and the position of the moon.

In Nigeria, English serves multifarious functions—in administration, education, commerce, and more. The national anthem and the national pledge, the two most widely recited verses of patriotism, are both in English, and illustrate how Nigeria is conceptualized as both a fatherland and a motherland. As a result of the dynamics of English usage in different strata of Nigerian society, at least three varieties of English are discernable: the acrolect, the mesolect, and the basilect (see Bamiro 1991; Pandey 1997). Many Nigerians now use Americanisms.

Multilingualism, with its accompanying problems as regards the selection of a national language, has 'forced' English—a neutral code—to function, in many ways, as the quasinational language (Emenyonu 1989:83). English is now a permanent resident in Nigeria, a primary Nigerian language in all senses of the term. In Achebe's words, 'It has been bent and twisted to bear the burden of the African experience' (1975). It is a Nigerian brand of English (Ubahakwe 1979; Akere 1982; Bamgbose 1982; Odumuh 1987), with a distinctive local flavor. As Akere (1982) puts it,

What has happened here in Nigeria… is that the resources of a second language are superimposed on an intricate system of social and kinship relationships, and on a completely different pattern of cultural outlook and social expectations. …The English forms of address and greetings have become modified to suit local communicative needs. (97)

The educated Nigerian generally has access to the largest language repertoire and even initiates switches to the stigmatized Nigerian Pidgin (English) in conversations with peers and lesser-educated Nigerians. This is a marked difference between the 'Outer Circle' (see Kachru 1982) to which Nigeria belongs on account of the variety of English it has grown, and the 'Inner circle', where it is rather unusual to find college-educated individuals being the most multilingual and multidialectal citizens who readily and willingly switch to nonstandard varieties in exchanges with lesser-educated citizens (see Pandey 1999). Not surprisingly, code-mixing, code-switching, and speech accommodation are frequently used conversational strategies, even by Nigerian creative writers whose language use mirrors the conversational realities of Nigerian society (see Pandey 1997).

Occupying approximately three fifths of Nigeria's land area, the Niger-Benue river basin is a major source of sustenance. Its waters have also nourished and transported a variety of water-borne languages, namely, Pidgins and Creoles, and specifically Nigerian Pidgin English (NPE hereafter), the nation's linguistic lifeline or primary lingua franca. NPE still bears linguistic evidence of the earliest European contact in Nigeria. The Portuguese are known to have arrived on the coast of West Africa in the fifteenth century. Exemplary Portuguese words that constitute part an parcel of the core vocabulary of this linguistic medley (NPE) include *sabi* (comprehend, understand), *pickin* (child or children), *palava* (trouble), and *dash* (a gift or bribe, including the act of giving). The excerpt that follows, an Efik Chief's diary entry, provides some of the earliest evidence of the development of a pidginized interlanguage in Calabar: 'about 6 am in aqua Landing with small Rain morning so I walk up to see Esim and Egbo Young so I see Jimmy Henshaw come to see wee and wee tell him for go on bord …' (Forde 1956). Around Lokoja, a confluence town, different varieties of pidgin are spoken in a relatively small area. The same has been recorded for the Delta and Rivers regions, where several varieties of NPE have been documented (Marchese and Shnukal 1982; Faraclas 1985). Opinions differ regarding the conjectured expansion of NPE into a Creole in some parts of Nigeria (Donwa-Ifode 1983).

Even though English is Nigeria's official language, NPE is the preferred lingua franca; hence, it should come as no surprise that NPE is the most widely spoken pidgin in the world, with over 40 million estimated speakers, not all of whom are Nigerians (Faraclas 1996:1). Some speakers are from neighboring Cameroon and Ghana—both of which witnessed a 'brain drain' (the Nigerian English term for intellectual loss) or an exodus of immigrants to Nigeria—during Nigeria's oil boom. For the most part, these and other expatriates have acquired NPE. In the absence of a standard orthography, NPE is written the way it sounds (to the speaker). Faraclas (1996) observes that the name NPE is actually a misnomer, as it has developed trilectal varieties: a pidginized basilectal variant often referred to as 'Pidgin Propa' (i.e. 'Pidgin Proper' or PP) and frequently used by less educated or uneducated Nigerians; a creolized 'mesolect'; and a decreolized variant that is often used by educated Nigerians. Eze (1980) refers to this variety as 'Hyperanglised Pidgin' (HPP) and notes that it differs extensively from 'Pidgin Propa' in its more-Standard-English-oriented use of prepositions, as opposed to the use of 'for' to represent all prepositional functions in 'Pidgin Propa'. There are, of course, other differences, such as the more economical lexicon of 'Pidgin Proper'. Examples include:

(1) a. Im mother been come meet am <u>in</u> the office (HPP)
b. Im moda been come see am <u>for</u> (im) office (PP)

[Gloss: His/Her mother came to meet or see him/her in the office OR His/Her mother DID (indeed) come and meet him/her at the/his/her office]

(2) a. 'The thing pained me bad bad because I wanted to be big man like lawyer or doctor riding car and talking big big English' (HPP, excerpted from Saro-Wiwa's *Sozaboy*, p. 2)

[Gloss: The thing/It hurt me very badly because I wanted to be an accomplished and successful person, like a doctor or a lawyer, driving a nice car and impressing people with my command of the English language]

b. E/De ting vex me bad bad. I wan be big man like lawya or docto wey get car and tok big big English (PP)
(3) 'Everyting scatta' (from 'Zombie') [Gloss: Everything is scattered/is in disarray]
(4) 'I look the D.O. well well. Then I tell am say no be tallness go fight the war…' (from Saro-Wiwa's *Sozaboy*, p. 27)

[Gloss: I looked at/stared at the D.O. for a long time. Then I told him that when it came to fighting the war, it didn't matter how tall you were]

(5) *E get one pikin, I/Ai get four (pikin*) [Gloss: She/he has one child; I have four (children)]

(6) 'If you neva ready to carry the load, O', why put am for another person head?… Dis kain life, na so so wahala' (lyrics excerpted from 'Wait for Me' composed by King Sunny Ade and Shina Peters) [Gloss: If you aren't ready to shoulder your responsibility, why burden others with it? That approach is full of troubles]

(7) 'No money, woman no go follow you, even if you fine fine pass everybody' (from Saro-Wiwa's *Sozaboy*, p. 21)

[Gloss: If you have no money, women won't come after you, even if you are the most handsome man in the world]

(8) Wettin you de talk? (What are you talking about? OR What *thing* are you referring to?)

Nonetheless, some core features that different varieties of NPE share include an anglicized vocabulary: African grammatical and discourse structures, the nonuse of tense markers, as in (3) and (4), the zero copula and zero distinctions in gender and number (see (1b)), zero genitive forms (see (6)), reduplication—a feature of many African languages (see (4) and (7)), and multiple meanings associated with a single word (e.g. the word *chop*, which means *consume(d), eat(en), ate, digest(ed), food, a snack,* and *a bribe).* Other similarities include a mixed vocabulary that contains many words from Nigerian languages, reduced or zero articles, and demonstratives; communicative contractions such as 'tori' for 'story', 'gree' for 'agree', and 'kain' for 'kind"; communicatively expressive compounds like 'sofahead' (a creative term used to refer to one who worries too much), and coalesced creations, such as 'likam' (like him/her, likes him/her), 'wey' (who, whose, where), and 'wettin', a combination of 'what' and 'thing', as in (8).

Like Nigerian English, NPE is particularly creative, and echoes the rich Nigerian oral tradition (over 2,000 years old). Proverbs are a vital ingredient and color this code in a refreshing manner. Examples include: *Who go dash monkey banana?* (Gloss: Who gives monkeys bananas out of sheer goodwill?/There are no free lunches) and *Kaki no be leda* (Gloss: Khaki is not leather; in short, it's like comparing apples and oranges). Sayings in NPE enable their speakers to succinctly communicate a whole lot. In a culture where economy, metaphor, and wit are prized in conversation, this code is valuable. Because of its function as the language of the people, many Nigerian literary artists utilize NPE in their works (Lindfors 1974). In fact, for a long time, NPE served as a safe outlet for political expression, particularly during military regimes (Eka 1999). Exemplary works include *Sozaboy: A novel in*

rotten English written by the recently hanged Nigerian writer Ken Saro-Wiwa, who, although not a linguist, made the following sociolinguistic observation:

Both 'High Life' and *Sozaboy* are the result of my fascination with the adaptability of the English Language and of my closely observing the speech and writings of a certain segment of Nigerian society. For, as Platt, Weber, and Ho accurately observe in their book *The new Englishes* (1984), 'In some nations … the New Englishes have developed a noticeable range of different varieties. … ' Sozaboy's language is what I call 'rotten English', a mixture of Nigerian pidgin English, broken English, and occasional flashes of good, even idiomatic English. This language is disordered and disorderly. … It thrives on lawlessness, and is part of the dislocated and discordant society in which Sozaboy must live, move, and have not his being ('Author's Note').

Works by other Nigerian artists that are entirely or predominantly in NPE include 'Zombie', lyrics by Fela Kuti, one of Africa's foremost musicians, and *No longer at ease* in which the characters' use of NPE both mirrors and intensifies the neocolonial discord Achebe depicts through his artful use of varieties of Nigerian English. Some of Africa's best-known writers, playwrights, and musicians come from Nigeria, and their works have been instrumental in the development of Nigerian English. Several are world-renowned and have contributed substantially to both African literature and world literature. In 1986, Wole Soyinka became the first African to receive the Nobel Prize in literature. Chinua Achebe was awarded the Nigerian National Merit Award, Nigeria's highest award for intellectual achievement. *Arrow of God* won the New Statesman-Jock Campbell Award, and *Anthills of the Savannah* was the finalist for the 1987 Booker Prize.

Nigerian artists such as Chinua Achebe, Wole Soyinka, Ola Rotimi, Amos Tutuola, John Pepper Clark, Segun Oyewole, Tunde Fatunde, Christopher Okigbo, Gabriel Okara, and Femi Osofisan have been known to utilize NPE for literary effect—to color their characters or the plot (e.g. Amos Tutuola's *The Palm-Wine Drinkard),* to add humor (e.g. Soyinka's *Jero's Plays,* Segun Oyewole's *Katakata for Sofahead*), sarcasm, local flavor, or to give the text a linguistic facelift (see Pandey 1997). NPE is also frequently used in Onitsha Market literature, including well-known plays like Ogali Ogali's *Veronica my daughter* that has sold over 250,000 copies since 1956, and short stories written by a host of Nigerian pamphleteers (Sander 1980). Ogali uses NPE or 'uncooked English', as Veronica calls it, to portray her traditional father (Chief Jombo) and Chief Bassey, and Standard English to portray the other characters. Bomber Billy speaks a bombastic variety of English, and is ridiculed by the writer and by

one of the characters in his play, Paulina. She describes him as 'a negligible pocket radio that utters useless words'. In Sander's (1980) opinion,

> Ogali is making fun of those people in Nigerian society who, eager to demonstrate their mastery of the English language, go to any extremes in the use of polysyllabic words or the creation of new words. … Through the use of various levels of English, Ogali manipulates the response of the audience (x).

In short, NPE is frequently utilized in Nigerian literature, and its continued use contributes to its popularity. As far back as 1979, NPE was observed to have replaced Efik as the lingua franca of the Cross River area (Dunstan 1969:35).

Being a West African pidgin, NPE is of vital importance to the study of creolistics, because of its historical role in the development of anglophone pidgins and creoles. In the words of Nicholas Faraclas (1996), 'Nigerian Pidgin can be considered to be one link in a chain of English-lexifier pidgins and creoles spoken along the coast of West Africa and in African diaspora communities throughout the Atlantic Basin' (1). Advocates of the Afrogenesis hypothesis, which traces the roots of pidgins and creoles to Africa, look to West African pidgins and creoles for answers (Romaine 1994; Dalphinis 1985). According to one view, 'Created in West Africa, … work pidgins were transported across oceans where they took on new roles as lingua francas among the enslaved. …' (McWhorter 1984:240). In the case of NPE, as well as Nigerian English, many of the ingredients are African. These include the names of food (*akara balls,* fried bean cakes; *moimoi,* steamed bean cakes; *dodo,* fried plantains; *gari,* powdered cassava; *Jollof rice,* rice flavored with Nigerian peppers; *masa;* millet cakes eaten in Hausaland; *pounded yam, egusi soup,* etc.); clothing (*agbada,* the flowing robes that Yoruba men wear; *buba and wrapper*, the women's traditional outfit); local customs and festivals (*naming ceremonies* for newborns); regional celebrations (e.g. Masquerade Day, a tribute to the ancestors in the Ekiti region); and expressions of linguistic pride such as *ajibotta*, the well-known derogative Yoruba word for a butter eater or westernized Nigerian (the Nigerian English equivalent is *been-to).* Exemplary Yoruba words in NPE include *Oga* (a respectful term, roughly equivalent to 'Sir'), *katakata* (major disturbance or problem), and the honorific *O'.* Some Hausa words that have entered NPE include *wahala* (trouble) and *haba* (Goodness! or Listen up!). Igbo words in NPE include *sef* (a discourse marker), *yanga* (boasting or boastfulness), and *na* (a particle with multiple meanings, such as 'it is', and the attention-getter *Na wa, O'!*, a popular expression of shock).

The vast majority of Nigeria's languages—including Yoruba and Igbo, two of the three major languages—belong to the Niger-Congo family. Estimates vary regarding the exact number of indigenous languages thriving in Nigeria. While Bamgbose (1991:2) and McArthur (1992) put the number at 400, Katzner (1995) estimates that there are 'about 250' (352). While we cannot rule out the threat of language endangerment arising from the central place that English occupies in Nigeria's linguistic horizon, the discrepancy in estimates has a lot to do with differences in opinions regarding what constitutes a language and what constitutes a dialect. For instance, Ibibio, Efik, and Annang, being mutually intelligible, are viewed by many Nigerians as one and the same language (Dunstan 1969:35), namely Efik/Calabar (or Ibibio to some Nigerians), which has acquired the status of a Standard dialect, on account of its use in broadcasts and textbooks. Some Nigerians do, however, regard them as separate languages. According to some, Ikwer(r)e/Ikwerri has 12 dialects. Many non-Ibibio speakers regard Qua, Oron, Eket, Okobo, and Ibuno as dialects of Ibibio, while others view them as lesser-used languages. While some view Kolokuma and Ijo as dialects of the same language, others might not, as Nigerian codes of communication have distinct names. Most have several names. Isoko, for instance, is also called Biotu, Sobo, and Igaba; yet, some consider the last two names to be offensive.

To most Nigerians, dialects tend to coincide with geographical boundaries or specific urban locations. Chief dialects identified for Eksako, for instance, are said to be those of Auchi, Aviele, Ekperi, South Ibie, Uzairue, and Weppe Wano—names of towns and cities, and of specific 'clans' (Dunstan 1969:47). The three main dialects of Fula/Fulani found in Nigeria also coincide with the names of major cities or geographical terrains, namely *Sokoto, Adamawa,* and the *central dialect* of Kano, Bauchi, Gombe, Katagum Division, and Jos (Dunstan 1969:57).

Most educated Nigerians speak at least three languages, English (the official language), one or more of the major regional languages, a local language, and NPE, not to mention the other dialect(s) they might switch to in the middle of a conversation. For most Qua speakers, for instance, Efik is a second language, Igbo the third, NPE the fourth, and (Nigerian) English the fifth.

In Nigeria, ethnicity and linguistic identities are inextricably intertwined. McArthur (1992) recognizes eight major ethnic groups, namely 21% Hausa, 21% Yoruba, 18% Igbo, 10% Fulani, 6% Tiv, 5% Kanuri, 5% Ibibio, 4% Edo, and 10% minorities. Because of the close ties between the Hausa and the Fulani, it is not unusual to find these groups conjoined under one

label, namely, the Hausa-Fulani. The minority ethnic groups would include, among others, the Ogoni, Isoko, Izon, Kwale, Degema, Itsekiri, Ibuno, Izi, Ewe, Andoni, Amo, Angas, Birom, Chip, Chella, Efik, Mada, Nabor, Nembe, Tera, Yergam, Gwari, and Gonja peoples of Nigeria. The names of their languages tend to coincide with their ethnic descriptors, further emphasizing the linguistic basis of ethnic identity in Nigeria. Each ethnic group has its own unique customs and language, making for a diverse group of Nigerians; yet, the minor languages tend not to be as carefully studied. Some (Fula, Tiv, Igala, Efik, and Edo) enjoy a more functional status than others, because of their use in the media. The nation's linguistic and cultural diversity has a lot to do with its historical location at the heart of transcontinental migration routes. The greatest concentration of languages and ethnic groups is found in Central Nigeria. One has only to travel to Kwara State or Illorin to get a feel for the linguistic diversity.

The most widely spoken indigenous language is Hausa (Katzner 1985; McArthur 1992). This is followed closely by Yoruba (18% of the population or some 20 million speakers), then Igbo (11% or some 15 million speakers), Fulani (approximately 8 million speakers), Kanuri (3 million), Efik and Ibibio (3 million), Tiv (spoken around Gboko by some 2 million), Ijo or Ijaw (2 million), Edo (one million), Urhobo (half a million), Nupe (in the Gur subfamily of Niger-Congo languages, with roughly 500,000 speakers), Idoma (some 250,000 speakers), and Eksako (also spelled Esako and Etsako(r), an Edo language with some 120,000 speakers). These numbers are more estimates than up-to-date survey findings of 'native speakers' of these languages, as representative language surveys are hard to administer in this complex multilingual environment, and such surveys have rarely been administered (see Bamgbose 1995:34).

Hausa, a Chadic language that contains many words borrowed from Arabic, is spoken by roughly 27% of the population or some 40 million Nigerians. It is the primary language or mother tongue of at least 25 million Nigerians (Katzner 1985:288). The Kano dialect is regarded as the Standard variety. The number of Hausa speakers has clearly grown; in 1979, an estimated 12 million Nigerians were native Hausa speakers (Dunstan 1969:73). Hausa is the lingua franca for the bulk of northern Nigeria and also plays the role of a regional language in West Africa. It is, in fact, the most widely spoken African language in West Africa, with speakers found in neighboring countries, including Nigér (as many as five million speakers), Ghana, Togo, Benin, Mali, and Senegal. The Hausa Language Board, established in 1955, has assisted in the standardization of the language. Prior to independence, Hausa enjoyed official language status alongside English in what was then the Northern Region. At that time, Hausa was written in the Arabic script known as Ajami, but now the Roman script is used.

Yoruba, a paradigm Kwa language and a subgroup of the Niger-Congo family, is spoken in southwestern Nigerian, from Illorin (Kwara State) down to Akure, Ado-Ekiti, and Igede-Ekiti (Ekiti State), Ibadan (Oyo State), and Lagos. It is Nigeria's second major language. This language and the rich mythology (of Sango and Ogun) constitute seminal ingredients in many of Wole Soyinka's works. The mythology is also resonant in the Afro-Caribbean beliefs transported to the Caribbean (see Burnett 1986). Some 20 dialects of Yoruba can be heard in Nigeria, and one, 'based largely on the Oyo dialect' (Dunstan 1969:80), is the Standard. Yoruba is also spoken in some other West African nations, including parts of Ghana, Togo, and Benin. Tonality is mirrored in its orthography. Three letters and their corresponding sounds are noteworthy: o, pronounced as in 'sought' (e.g. oba); é pronouced as in 'let' (e.g. *éjé* which means blood); and s, pronounced /sh/ as in 'ekuse' (i.e. Well done!). In orthography, the acute and grave accents indicate tone (not stress).

Igbo, another Kwa language like Yoruba and Ewe, is Nigeria's third major language. It is spoken in southeastern Nigeria, in Port Harcourt, Enugu, Calabar, Onitsha, Owerri, and surrounding areas. The three main dialects that are recognized are the Central, Owerri, and Umuahia dialects. Prior to 1961, its orthography was disputed (Dunstan 1969:85). The official orthography, adopted by the Onwu Committtee, is now compulsory in the School Certificate Igbo examination. Igbo features regularly in the works of Chinua Achebe. In *Things fall apart*, some 37 Ibo words and phrases are woven into the fabric of the text. Many have no translation equivalents, including *chi* (personal god), *ogbanje* (which Achebe describes as a 'changeling' that will keep dying until its 'iyi-uwa' is first dug up and destroyed), *uri* (a betrothal day, after the bride-price has been paid), *Nne* (mother, including one's nonbiological mothers in a polygamous household), *umunna* (kinsmen), and *ndichie* (one's elders). These indigenous words bring the richness of precolonial Igbo society to life. From a sociolinguistic standpoint, they constitute prime examples of the Sapir–Whorfian hypothesis, which illustrates how specific cultural concepts are embodied in words.

Fula(ni) is generally termed Fulfulde in Nigeria. This Niger-Congo language (the West Atlantic branch) of the Fulani/Fulbe people is of great historical significance, as the Fulani are 'a people of great antiquity' (Katzner 1995:289) and have heavily influenced the sociolinguistics of northern Nigeria, where over eight

million of the estimated 15 million Fulani people reside. Many are cattle-herders, and follow the nomadic and seminomadic lifestyle they are accustomed to. Areas in which Fulani is spoken in Nigeria include Sokoto, Kano, Kaduna, Plateau, Bauchi, and Kwara States. In Mauritania, Gambia, Benin, Ghana, Mali, Burkina Faso, Chad, Nigér, and Cameroon, where it is also spoken, it is called Fula. In Senegal, it is called by its other name, Pulaar, and in Guinea-Bissau, it is termed Pulle. The root morpheme in all these names is {Ful-} or {Pul-} from which the Germanic name Fula(ni) and the Frenchified 'Peul' originated. Its regional spread makes it a frequently used lingua franca in West Africa.

The national language question has received quite a bit of attention since the mid-1970s. In *Language and the nation,* Ayo Bamgbose observes that:

> The language question in Sub-Saharan Africa arises from the fact that not only are most of the countries multilingual, the colonial experience has led to the importation of foreign official languages which have taken on the roles of national communication, unification, administration and medium of education from early or late primary to university level. Thus, the existing multilingual situation is compounded by the addition of imported languages whose strength does not lie in numbers of speakers, but rather in the superior roles assigned to them (1).

During the colonial period, western education was restricted to only a small segment of the population that played a role in the 'indirect rule' in place; hence, even today, only the elite uses Standard English. British administrative policy in Nigeria relied on empowered Nigerians—primarily Chiefs and Emirs—to serve as intermediary rulers. English usage and English-medium western education were most widespread in parts of the country where Christian missions were established (Ajayi and Crowder 1985:68). Islam (roughly 47% of the population) and Christianity are the two primary religions, with an estimated 19% of the populace being 'traditionalists' (McArthur 1992). As Christianity was resisted in Islamic northern Nigeria, where the Jihad or Holy War led by Uthman dan Fodio in the early nineteenth century had left its religious mark, the discrepancy in English usage between northern and southern Nigeria has persisted to this day. So pronounced were the differences on the eve of independence that there was even a fear that those with an English-based Western education 'would dominate the economic and political life' (Ajayi and Crowder 1985:68) of the new nation. The establishment of major regional universities can be attributed, in part, to this regional-linguistic competition. As the University of Ibadan, Nigeria's oldest institution, was garnering a lot of (inter) national attention, many Nigerians saw the need for a university in Igboland and another in Hausaland. At the wake of

independence, then, several universities were established in Nigeria, most notable among them The University of Nigeria in Nssuka, eastern Nigeria, Ahmadu Bello University, located at the heart of Hausaland, and the University of Ile-Ife, located in Ife, a very important city in Yorubaland, and home of the Oba of Ife, one of the most highly regarded Chiefs in the Yoruba chieftaincy. Ahmadu Bello University (better known as ABU) was named after (Sir) Ahmadu Bello who was northern Nigeria's first Premier. A resident of Hausaland, and a well-known political figure, northerners (called 'Gambaris' by some southerners) named the University after him, as a tribute to his accomplishments. The University is located in Zaria, a famous northern city that played a pivotal role in the intricate emirate system that was in place prior to the colonial period.

English and NPE usage declines steadily as one moves north of the town of Illorin. Instead, one tends to hear more Hausa and Fulani in everyday conversations and even in service-counter exchanges. Koranic schools and after-school Arabic classes are commonplace in the north, where Arabic is a language of great (religious) importance, although rarely used in conversations. In contrast, in the open markets in the Yoruba-speaking Ekiti area or in Onitsha, which is famous for its market, NPE is the preferred transactional code, ideal for bargaining. So important is NPE in the markets of Yorubaland and Igboland that mastery of NPE gives buyers a competitive advantage over non-NPE speakers, as haggling is a culturally acceptable and expected discourse practice. One who does not speak the language of the seller is usually at a disadvantage. Some vendors can be heard speaking what is called 'Broken English' in Nigeria, and mainly in their limited-but-meaningful exchanges (e.g. 'Oga, buy tomato! Good Good!') with the Oyĩbo(s), the Yoruba term used to identify outsiders or non-Nigerians. Some traders and children use the compound term 'Oyĩbo man'. This term literally means 'white man' or 'white person', but its use is not limited to Europeans alone. Also, it is not intended as an insult, particularly when it is followed by the respect marker 'O(h)', although it could easily be misconstrued as such, particularly when one is surrounded by a crowd chorusing 'Oyĩbo O''. The term should be interpreted as more of a congregational announcement of the presence of a visitor whom one would like to honor by acknowledging. 'O'' is an honorific term in Yoruba, which means roughly 'respectful Sir or Ma'am', and has been adopted by NPE. The equivalent term for expatriates in Hausa is 'Baturé' (masculine) or 'Baturiya' (feminine).

It would be a mistake to view Nigeria as an ESL environment, because it is an English-as-an-indigenized-language context (Bamgbose 1995). Even

though English is the medium of instruction from third grade onward, most Nigerians speak Nigerian English, which differs from Standard British or American English. In the past 10 years, a matter of grave concern to Nigerian educators has been the 'mass failure syndrome' (Bamgbose 1995:130–52) or the increasing number of failing grades in English obtained in the main college-entry examinations, namely, the WAEC or the West African School Certificate Examination, and the JAMB or the Joint Admissions and Matriculation Board Examination. These examinations are patterned along the colonial, British variety, yet the students hear and learn a Nigerian variety. Many of the idioms that students are tested on are, in fact, foreign to the culture and environment. Examples include the following italicized items: a finger in every *pie,* comparing *apples* and oranges, looking for a needle in a *haystack,* over the *grape vine,* and *penny* wise, *pound* foolish. Students are often tested on noncount nouns like *information,* even though most Nigerians pluralize these. The end result is a mismatch between the variety of English that is learned, spoken, heard, and taught, on the one hand, and what is tested. Admission into college is contingent upon a credit pass in English, and yet a curricular change is unlikely, as administrators do not recognize Nigerian English.

In a report submitted to the Federal Ministry of Information, the Nigerian Public Service Review Commission drew attention to the need for a national language:

> An overriding problem, which affects the public service as it does all aspects of society, is that of language. Nigeria shares with many developing, and some developed nations, the lack of an indigenous *lingua franca.* What this means for efficiency in the conduct of government business is rarely even thought about perhaps because there seems to be no immediate answer. But it is perfectly clear to the careful observer that below the top-most levels in the various sectors of society, people are conducting their business in a language which, in varying degrees, they have not in fact mastered (6).

Since that time, some of the major motions that have been tabled include the idea of a trilectal national language policy, a rotational language policy (which also draws on the three regional languages, one by one), and the creation of a single conglomerate language, like Esperanto, which would be called WAZOBIA, and which would combine elements of Hausa, Yoruba, and Igbo. Another idea that has received considerable attention is the pan-Africanist idea of adopting the most widely spoken African language, namely, Swahili. This proposal has been led by Wole Soyinka. In the last few years, French has been added to the list of contested languages. In general, Nigerians in favor

of a national language have advanced the idea of an indigenous national language.

Special programs have been designed to reduce tribalism and foster national unity. One such measure is the Nigerian Youth Corp Service, better known as the NYSC, which is a year-long commitment required of all graduates. It requires them to serve in a region that is linguistically different from their own, so that they learn to be more tolerant of other ethnic and linguistic groups. This year of service almost always ensures a process of assimilation. Most 'youth corpers' end up acquiring yet another language—usually a major regional language—during their NYSC year. The prop on which this program rests is essentially sociolinguistic. Another multilingual measure is the attempt to revive the local languages, particularly the three major languages that constitute the cornerstones of Nigeria's linguistic 'stool' (a symbol of the seat of government in the precolonial Chieftaincy era). This includes making them instructionally viable (Rufa'i 1991; Arohunmolase 1998, 1999) through the development of textbooks, teacher preparation, and so on. The WAEC now offers certification examinations in some Nigerian languages.

Nilo-Saharan Languages

The idea of a Nilo-Saharan (NiSa) phylum among African languages alongside Afro-Asiatic, Niger-Congo, and Khoisan was brought into existence by Joseph H. Greenberg (1963). On the basis of 161 lexical and 29 grammatical sound–meaning similarities, he suggested genetic unity among 82 languages, which had been treated as 22 separate language units before by Tucker and Bryan (1956, 1966) and for some of which genetic unity had never been suggested (Table 1).

On the level of language units as presented in Tucker and Bryan (1956), Greenberg proposed some significant changes, most of which have been accepted since and partly also substantiated in detailed studies:

(a) The inclusion of Mimi into the Maban group.
(b) The combination of Tucker and Bryan's 'Nilotic' and 'Nilo-Hamitic' into one group with three branches: Western, Eastern, and Southern Nilotic.
(c) The combination of Moru-Mangbetu and Bongo-Bagirmi into a Central Sudanic group.

Greenberg's fusion of Gule and Koma into one group, however, has been revised. Bender (1996) suggests again two units although differently subdivided, i.e.

TABLE 1 Language Groups of Tucker and Bryan (1956) and Greenberg (1963)

Tucker and Bryan (1956)	Greenberg (1963)		
	1. <u>Songhai</u>		
2. Eastern Sudanic	2. <u>Saharan</u>: (a) Kanuri, Kanembu; (b) Teda, Daza; (c) Zaghawa [today also: Beria], Berti		
10. Mimi 11. Maba group	3. <u>Maban</u>: Maba, Runga, Mimi (of Nachtigal), Mime (of Gaudefroy-Demombynes)		
13. Fur	4. <u>Fur</u>		
20. Nubian group			1. Nubian group
27. Didinga-Murle group			2. Murle, Logarim, etc. [today: Surmic]
21.Barea	5. <u>Chari-Nile</u>		3. Barea [today: Nara ~ Nera]
24. Tabi		A.	4. Ingassana (Tabi) [today also: Gaam/Jebel]
15. Nyimang group		Eastern	5. Nyima, Afitti
16. Temein group		Sudanic	6. Temein, Teis-um-Danab
12. Tama group			7. Merarit, Tama, Sungor
14. Daju group			8. Daju group
30. Nilotic			9. Nilotic
31. Nilo-Hamitic			
29. Teuso			10. Nyangiya, Teuso [today: Kuliak]
1. Moru-Mangbetu		B. Central Sudanic	
2. Bongo-Bagirimi			
23. Berta		C. Berta	
22. Kunama		D. Kunama	
25. 'Gule' [extinct] 26. Koma group	6. <u>Coman</u>: Koma, Ganza, Uduk, Gule, Gumuz, Mao		

I. Koman: T'wampa (Uduk), Gule, Komo, Kwama and Opo (Shita) and

J. Gumuz (dialect cluster).

Several morphological sound–meaning similarities used by Greenberg (1963) to define Nilo-Saharan are still major arguments regarding Nilo-Saharan unity, among them:

—independent subject pronouns, especially in the singular, show the vowels *a* (1st person), *i* or *u* (2nd person) and *e* (3rd person),

—*ma* and *ko* as relative and adjective formant,

—*n/k* singular–plural alternation,

—*t/k* singular–plural alternation,

—nominal derivational prefix *k-* ('movable' *k-*),

—verbal dative affix *-kV-*,

—causative in *t*

Several morphological sound–meaning correspondences proposed by Greenberg to support Nilo-Saharan unity, however, are also found in neighboring Afro-Asiatic (e.g. negation in *b* or *m*) or in Niger-Congo languages, thus weakening the argument and pointing to the general difficulty of separating areal from genetic features.

Most recently, only two comprehensive studies on the genetic classification of Nilo-Saharan since Greenberg's have been published, i.e. Bender (1996) and Ehret (2001). The comparison of the results presented in these studies highlight significant features of the current state of discussion in the field of Nilo-Saharan genetic studies:

—The idea of a Nilo-Saharan phylum remains widely accepted, although the external boundaries of Nilo-Saharan as well as significant parts of its internal subdivision remain highly controversial.

—Greenberg's proposal of a Chari-Nile group has been rejected as a valid genetic unit, while the genetic unity of Eastern Sudanic and of Central Sudanic remains unchallenged.

—The lower-level units (Tucker and Bryan's language units as revised by Greenberg) are also largely uncontroversial.

—The most substantial progress since Greenberg has been made regarding language documentation, genetic classification, and reconstruction within these lower-level units.

External boundaries

Discussions regarding the external boundaries of Nilo-Saharan relate particularly to the following topics:

Songhay cluster: Its geographic distance from the other Nilo-Saharan languages and long-standing contact with Mande (Niger-Congo) and Berber (Afroasiatic) languages continue to cast doubt on the Nilo-Saharan affiliation suggested by Greenberg (1963) and supported

by Bender (1996) and Ehret (2001). Nicolai (1990) reconstructs it as a post-Creole with a Berber base, while some other scholars follow an old argument by Delafosse and discuss Mande affiliation.

Kadugli-Krongo (Kadu): This group appears in Greenberg (1963) under the name of Tumtum as one of five Kordofanian branches despite divergent properties. Following suggestions made by Dimmendaal (1987) among others and supported by the fact that this group shows several of the typical Nilo-Saharan features (1sg pronoun *a'a*, 2sg pronoun *ʊ'ʊ*, movable *k*, *n/k* plural formation, etc.), Bender (1996) includes Kadugli-Krongo in his Core of Nilo-Saharan, while Ehret (2001) rejects any Nilo-Saharan affiliation.

Shabo (formerly: Mikeyir): The genetic position of this rudimentarily documented language of SW Ethiopia remains unclear. Bender proposes a Nilo-Saharan affiliation, which Ehret rejects.

Meroitic: The extinct language of the ancient Meroitic Empire (Sudan) preserved by a number of written records has been linked to various genetic groups and phyla, among them Afro-Asiatic, Tokharian, Saharan, and Eastern Sudanic. This latter affiliation was also supported by Greenberg, and has most recently again been substantiated by Claude Rilly, among others.

Relation to Niger-Congo: Due to a number of lexical and morphological similarities between Nilo-Saharan and Niger-Congo languages, Gregersen (1972) proposed to combine these two phyla into a single one, i.e. Kongo-Saharan. His line of argument has been taken up by Roger Blench in recent years, who attempts to establish Niger-Congo as a branch of Nilo-Saharan.

Internal subgrouping

General disagreement also characterizes higher-level units within Nilo-Saharan. Greenberg's subgrouping (Table 1) has only partly been accepted. The reason for this derives not so much from the still highly fragmentary documentation of numerous Nilo-Saharan languages, but from their generally great internal lexical and grammatical heterogeneity. This feature may point to a history of thousands of years for the whole phylum. Detailed studies of lower-level language units, however, also reveal continuous episodes of heavy language contact, thus complicating lexical and morphological reconstruction and hence higher-level grouping considerably.

Based on morphological as well as on lexical comparison, Bender (1996) proposes four branches of Nilo-Saharan: (A) Songhay, (B) Saharan, (K) Kuliak, called 'Outliers', and the rest, called 'Satellite–Core', which he further subdivides as indicated in Table 2.

Ehret's (2001:88f, 70f) alternative genetic classification of Nilo-Saharan uses phonological and lexical isoglosses derived from an extensive comparative lexical database, but also considers grammatical and derivational morphemes as far as they are accessible through language descriptions. His result is presented in a mainly bilaterally branching tree, with one specific small language group or language branching off at each level and set against the rest, which receives novel geography-based labels. In the following condensed representation of his result, previously known group and language labels are underlined (see graph).

The extreme lexical heterogeneity of Nilo-Saharan languages, even in the most basic vocabulary, is paralleled by a large grammatical diversity, and hardly any of these grammatical features is specific to the phylum.

Nilo-Saharan languages are tone languages with two to four underlying level tones, which are used for grammatical as well as lexical purposes. The number of tones and their main functional domain correlate to a considerable degree with the morphological type of the respective language. Five-vowel systems with

advanced tongue root (ATR) vowel harmony, often with contrastive length, are frequently synchronically or diachronically reconstructable. The consonant systems show either four or five (e.g. Gaam, Berta, Koma, Western Nilotic) places of articulation, which partly also extends to the nasal. Ehret (2001:16) claims five places of articulation for Proto-Nilo-Saharan in the case of plosives and four in the case of nasals. He also suggests a complex set of plosives for Proto-Nilo-Saharan, with voiced implosives and explosives, voiceless aspirated and unaspirated as well as glottalized plosives. Although all of these sets do occur in Nilo-Saharan languages synchronically, only Twampa (Uduk) comes close to such a system.

The morphological type of Nilo-Saharan languages ranges from largely isolating (e.g. Central Sudanic languages), to agglutinative (e.g. Southern Nilotic) and highly fusional (e.g. Kanuri, partly Western Nilotic). Languages of the same genetic unit often belong to different morphological types, which possibly has to be interpreted as an outcome of substantial language contact. Nonisolating Nilo-Saharan languages are mostly characterized by complex verbal derivational morphology, while isolating Nilo-Saharan languages tend to make use of serial verb construction for derivational and morphosyntactic purposes. Nominal morphology is equally heterogeneous, with some languages having gender (e.g. Eastern Nilotic), others not. A morphologically tripartite number system, in which either a singular/singulative or a plural form or both are morphologically derived from a nominal root, is widespread in Nilo-Saharan and may even be a potential isogloss.

TABLE 3 Nilo-Saharan Languages: Languages and Speakers Per Country

Country	No. of NiSa Languages	No. of NiSa Speakers	% of Population
Kenya	~ 6	7.5 Mio.	**29.2**
Sudan	**~ 64**	7.2 Mio.	**29**
Uganda	**~ 20**	5.6 Mio.	**25.5**
Nigeria	6	3.5 Mio.	3.5
DR Congo	**22**	3.0 Mio.	7
Chad	**~ 33**	2.6 Mio	**40.6**
Niger	~ 7	2.7 Mio.	**32.5**
Tanzania	~ 4	858 000	0.3
Mali	1	640 000	6
Ethiopia	**16**	376 000	0.7
CAR	13	223 000	6.6
Eritrea	2	210 000	5.7
Cameroon	2	150 000	1.2
Burkina Faso	2	125 000	0.8
Egypt	1	100 000	0.1
Benin	2	50 000	0.9
Libya	2	9 000	0.1

Syntactically, all the common basic word orders with its concomitant features occur, namely SOV (e.g. Kanuri, Nubian), VSO (e.g. East and South Nilotic, Kuliak, partly Kadugli-Krongo), and SVO. Morphological and partly also syntactic ergativity has been reported for Jur-Luwo, Anywa, Päri, Shilluk (Western Nilotic), and Toposa (Eastern Nilotic).

Demography

Numbers given for Nilo-Saharan languages range from 80–90 (lumpers) up to 199 (splitters). The area in which they are spoken stretches from the river Nile in the

TABLE 4 Numerically Dominant Nilo-Saharan Languages

Speakers	Language	Sub-division	Country
3–4 Mio.	Songhai	Songhay	Niger, Mali, Nigeria, Burkina, Faso, Benin
	Kanuri	Saharan	Nigeria, Niger, Cameroon, Chad, Sudan
	Dholuo	Western Nilotic	Kenya, Tanzania
	Dinka	Western Nilotic	Sudan
> 2 Mio.	Lwo (Acholi + Lango)	Western Nilotic	Uganda, Sudan
	Kalenjin	Southern Nilotic	Kenya
> 1 Mio.	Lugbara	Central Sudanic	DR Congo, Uganda
	Alur	Western Nilotic	DR Congo, Uganda
	Teso	Eastern Nilotic	Uganda, Kenya
	Maa	Eastern Nilotic	Kenya, Tanzania
	Nuer	Western Nilotic	Sudan, Ethiopia
> 500,000	Ngambay	Central Sudanic	Chad, Cameroon, Nigeria
	Lendu	Badha/Lendu	DR Congo, Uganda
	Mangbetu	Mangbetu-Balese	DR Congo
	Fur	Fur	Sudan, Chad
> 250,000	Maba	Maban	Chad
	Teda-Daza	Saharan	Chad, Niger, Libyen
	Masalit	Maban	Chad, Sudan
	Bari	Eastern Nilotic	Sudan, Uganda, DR Congo
	Karimojong	Eastern Nilotic	Uganda
	Nile Nubian (Nobiin)	Nubian	Sudan, Egypt

northeast up to Lake Chad and—in the case of Kanuri and Songhay—further west to northeastern Nigeria and to the Mali-Niger-Burkina Faso border area, respectively. Nilo-Saharan languages are spoken as a first language in 17 African countries by over 30 Mio. speakers (Table 3).

The highest number of speakers are found in Kenya (7.5 Mio.), Sudan (7.2 Mio.), Uganda (5.6 Mio.), Nigeria (3.5 Mio.), DR Kongo (3.0 Mio.), Niger (2.7 Mio.), Chad (2.6 Mio.), but these speakers represent significant portions of the population only in four countries, namely Chad (41%), Niger (32%), Sudan (29%), Kenya (29%), and Uganda (25%). With respect to the number of Nilo-Saharan languages per country, Sudan comes first (~64), followed by Chad, DR Congo, Uganda and—despite the overall low number of NiSa speakers—Ethiopia (16) and Central African Republic (13).

Table 4 presents major Nilo-Saharan languages in terms of number of speakers and geographic distribution. As indicated, most of them are cross-border languages, thus making language-planning activities comparatively difficult.

MECHTHILD REH

Nootka and Wakashan Languages

Wakashan is one of a dozen or so language families indigenous to North America's Pacific Northwest, a lush and mountainous region of tremendous linguistic diversity. The term is a variation of 'Wakashian', which Captain James Cook proposed to call the people he visited in Nootka Sound in 1778:

> The word *wakash* ... was frequently in their mouths. It seemed to express applause, approbation, and friendship. For when they appeared to be satisfied, or well pleased with anything they saw, or any incident that happened, they would, with one voice, call out *wakash! wakash!*

The study of Wakashan languages has contributed significantly to the development of linguistics. For instance, the lasting and profound influence of such famous linguists as Franz Boas, Edward Sapir, Morris Swadesh, and Mary Haas is due in large part to their seminal work on these languages. Besides refuting the popular misconception that native languages are somehow primitive, their pioneering work spawned valuable research in linguistic affiliation relating to the ethnohistory of North America, and it also uncovered important structural and semantic phenomena that had not been found in more widely studied languages. Well-known contemporary linguists such as Emmon Bach and Stephen Anderson also credit their fieldwork on Wakashan languages for improving their understanding of language.

Wakashan languages fall neatly into two branches, each comprising three languages. The southern branch ('Nootkan') includes Nootka (Nuu-chah-nulth) and Nitinat (Ditidaht) spoken along the west coast of Vancouver Island, as well as Makah spoken on Washington's Olympic Peninsula. The northern branch ('Kwakiutlan') consists of Haisla-Henaksiala and Heiltsuk-Oowekyala spoken on the north and central coasts of British Columbia, and Kwakw'ala spoken on northern Vancouver Island and the adjacent mainland coast. The genetic relation between the two branches was discovered by Franz Boas in 1889. Their kinship is most clearly evidenced by the locational lexical suffixes (*-ił* 'indoors', *-as* 'outdoors on the ground', *-is* 'on the beach', *-a* 'on a rock', etc.), which are of great frequency in all Wakashan languages.

Edward Sapir and Morris Swadesh hypothesized that Wakashan belongs with Salish, Chimakuan, and Kutenai under a larger 'stock' called Mosan, and with Algic under a still larger 'phylum' called Algonkin-Wakashan (or Almosan). At present, these primeval affiliations are not widely accepted by specialists, most of whom have chosen to recoil from such large-scale classification until the histories of the smaller groupings are better understood. The lexical differences between Nootkan and Kwakiutlan alone are such that Swadesh estimated the two to have separated around three millenia ago, a time depth that is considered plausible by some (e.g. Jacobsen 1979) but too brief by others (e.g. Embleton 1985). For both branches, dialectal differentiation is greatest on Vancouver Island, which is therefore assumed to be the original home of the ancient Wakashans. The specialized proto-Wakashan vocabulary on local maritime culture also suggests that the Wakashan Urheimat lies in its present area.

Historically, the Wakashans were vigorous peoples. For instance, they used giant cedar trees to construct expansive houses for their extended families, to carve beautiful totem poles, and to build huge canoes which they used to fish for halibut and to hunt sea mammals —including colossal humpback and gray whales. But they were almost decimated by the arrival of the Europeans. Epidemics (especially smallpox), alcohol, and firearms used in intertribal wars reduced their population from tens of thousands before contact (the 1700s) to a few thousand in 1929. Fortunately, Wakashan peoples are now recovering rapidly from these historical disasters; for instance, at present, the Nootka (Nuu-chah-nulth) and the descendants of Kwakw'ala-speaking tribes (Kwakw<u>a</u>ka'wakw) number almost 8,000 and 6,000, respectively.

Unfortunately, Wakashan languages remain in a grave state of decline. The Canadian government not only prohibited Wakashan peoples' main social events ('potlatches') from 1884 to 1951 but also relocated their children to church-run residential schools from 1888 to 1983. These measures, which were taken deliberately to break down the transmission of culture and language, were all too effective. More passively, too, Wakashan languages have become obsolete under the influence of English, which has become the primary language at school and at home in every community thanks in part to the influence of the mass media. Thus, currently there are little more than a couple hundred speakers each of Nootka (Nuu-chah-nulth), Kwakw'ala, Haisla-Henaksiala, and Heiltsuk-Oowekyala. Makah has just 20 to 30 speakers, while Nitinat (Ditidaht) has less than ten. Recently, however, communities have sought to counteract the loss of their ancestral languages by integrating them in schools. To this end, they have adopted standardized orthographies, compiled dictionaries, and developed multimedia materials on their languages. The long-term effect of these efforts on the survival of Wakashan languages is unknown but hopeful.

Let us now focus on *Nootka*. This term is actually an error dating to Cook's visit. On one popular account, the legendary captain mistook it as the name of the natives who told him *nootka* ('circle about!') to come to their village on the other side of an island. The term continues to be used widely in linguistics, but nowadays the people themselves prefer to be called *Nuu-chah-nulth* ('along the mountains'). There are a dozen distinct Nuu-chah-nulth tribes, with many different dialects. Grammars exist for three of these: the southern Tseshaht, the central Ahousaht, and the northern <u>K</u>a:'yu:k't'h' (formerly Kyuquot). The following is a

brief survey of some structural characteristics of Nootka that the reader might find strikingly different and interesting.

Nootka shares 12 consonant phonemes with English, and has at least 27 others. Fifteen of these involve various kinds of glottalization. For instance, the above-mentioned dialect name *Tseshaht* is pronounced with a postglottalized 'ejective' consonant and a glottal stop [t͡s'iʃaːʔatħ], while Nuu-chah-nulth is pronounced with a preglottalized 'creaky' consonant [nuːt͡ʃaːʔnuɬ]. Nootka consonants draw on all known places of articulation except dental. For example, the dialect names <u>K</u>a:'yu:k't'h' and *Ahousaht* involve uvular, pharyngeal, and epiglottal consonants: [qaːʔjuːk'atħ, ʔaːħuːsʔatħ]. Nootka's consonantal inventory would have been even larger had it not historically abandoned the lateral approximants [l ʔl] and the voiced obstruents [b d d͡z d͡ʒ g gʷ ɢ ɢʷ], which are still in use in other Wakashan languages. In contrast to its manifold use of consonants, Nootka has just three basic vowels, in long [iː aː uː] and short [i a u] varieties, plus two marginal vowels [ɛː, ɔː] found mainly in foreign borrowings. Nootka lacks schwa [ə], which is widely used in Kwakiutlan.

Nootka phonemes are implicated in many active phonological processes, including lenition, glottalization, assimilation, shortening, and deletion. For instance, all these processes are involved in the following utterance (Tseshaht): /hiɬ-ʔaħs-uk-ʔap-maːħ/ → [hiʔjaħsukʷ'amaħ] 'I put mine in a container' (LOC-'in vessel'-POSS-CAUS-LS). Every Nootka syllable consists of a vowel obligatorily preceded by a single consonant, and optionally followed by up to three consonants, as in [.ʔintħ.tin.ʔi.] 'the one made of snot'. However, in the <u>K</u>a:'yu:k't'h dialect, vowels are regularly dropped inside and at the ends of words, such that any number of consonants is possible in sequence; for example, [t͡ɬ'uːt͡ɬ'uʃinkʷʃtɬħt͡ɬs'] (…-inuk 'at hands' + -ʃitɬ mom. + -ħts'iː 'at fire') 'he was drying his hands at the fire'. Incidentally, an extreme form of consonant sequencing occurs in Oowekyala: this Kwakiutlan dialect is remarkable in permitting consonant-only words such as [t'xt'kʷ's] 'fish hawk' and even consonant-only utterances such as [t͡ɬχspstɬkts] 'this (not visible) will be a nice thwart'. Words in Nootka show regular stress patterns (e.g. [haˈjaˌʔakˌʃiʔatɬ] 'did not know now'), as in other Wakashan languages (but not all; Haisla has a pitch accent system and Heiltsuk is tonal).

Nootka morphology is also very complex. On the one hand, it is polysynthetic in that hundreds of lexical suffixes can combine with well over a thousand roots to form large stems with composite meanings. For example, a verbal suffix like -*naːk* 'to have' can be added to a nominal root as in *t͡ʃ'apat͡s-nak* (canoe-have) 'to have a canoe', to an adjectival root as in *ʔiːħ-*

nak t͡ʃ'apat͡s (big-have canoe) 'to have a big canoe', or to a 'dummy' root as in *ʔu-naːk ʔiːħ t͡ʃ'apat͡s* (it-have big canoe) 'to have a big canoe'. It can also combine with other lexical suffixes as in *tupk-naːk-maʔiqtɬ* (black-have-want) 'to want to have a black one'. On the other hand, much of Nootka morphology is nonconcatenative in that many lexical and aspectual distinctions are expressed by reduplicating the root or by lenghtening its vowel(s). For instance, from the verb form *mitx-ʃitɬ* 'to make a turn', we get the ITERATIVE *mitxmitx-ʃitɬ* 'to start in on turns at intervals', the GRADUATIVE *miːtx-ʃitɬ* 'making a turn', the REPETITIVE *miːtxmiːtx-ʃitɬ* 'to start turning around and around', and (tenuously) the DISTRIBUTIVE REPETITIVE *mimiːtxmitx-ʃitɬ* 'to start turning around and around here and there'. In sum, the Nootka word consists of a root, which itself may be modified by reduplication or lengthening, and to which may be added a large number of suffixes with various lexical and grammatical meanings.

Turning to syntax, it is often obscured in Nootka by the complex morphology that allows words to convey sentences, as in <u>K</u>a:'yu:k't'h' *ʔu-kʷiːɬ-t͡ʃip-'it͡ʃ-is-im* (it-make-for-IMPV-you(PL)-me-will) 'you'll make it for me!', *ʔu-suːp-intiʃ* (it-kill-PST.IND) 'he killed it', and *muk-suːp-intiʃ* (deer-kill-PST.IND) 'he killed the deer'. When individual words are used instead of affixes, the following basic order is apparent: predicate–subject–object, as in *qaħsaːp-intiʃ t͡ʃakup muwit͡ʃ* (kill-PST.IND man deer) 'a man killed a deer'. Interestingly, any category of word can be a predicate in Nootka, including adverbs as in *ʔaħti-intiʃ qaħsaːp muwit͡ʃ* (nightly-PST.IND kill deer) 'it was at night he killed the deer', nouns as in *t͡ʃakup-intiʃ qaħsaːp muwit͡ʃ* (man-PST.IND kill deer) 'it was a man that killed the deer', and demonstratives as in *ʔuħ-intiʃ t͡ʃakupi qaħsaːp muwit͡ʃ* (that-PST.IND man kill deer) 'it was that man that killed the deer'. Of particular interest in this context is the oft-repeated claim that Nootka lacks category distinctions. This claim is controversial, but most linguists agree that this kind of distinction is weak in Nootkan syntax. For example, in Tseshaht *quːʔas* 'man' and *mamuːk* 'work' act as noun and verb, respectively, in *mamuːk-ma quːʔas-ʔi* 'the man is working' (work-he man-the), but these grammatical categories appear to be reversed in *quːʔas-ma mamuːk-ʔi* 'the working one is a man' (man-he work-the).

DARIN HOWE

Northwest Caucasian Languages

The languages of the Northwest Caucasian family—Abaza, Abkhaz, Adyghe, Kabardian, and Ubykh—were originally spoken in a contiguous region stretching from Abkhazia on the Black Sea in the south to the Kuban River in the north. As a result of the relocations following the Russo-Caucasian War (1817–1864), substantial communities of each now exist in Turkey, as well as smaller enclaves in Syria, Jordan, Israel, former Yugoslavia, Western Europe, and New Jersey. The languages of this family fall into three groups: Abkhaz/Abaza, Ubykh, and Circassian, the latter containing the languages Adyghe and Kabardian.

In 1850, there were approximately one million speakers of Northwest Caucasian languages, most of them Circassians. The Russo-Caucasian war and the Russian colonization of the Caucasus drastically changed this situation: many Abkhaz and Circassians were forced to flee westward to the Ottoman Empire, and the Ubykh and Sadz Abkhaz were entirely displaced from their homelands near the Kwydypsta River just north of present-day Abkhazia. At present, some 800,000 Northwest Caucasians still reside in the Caucasus, most of whom retain their ancestral languages, as well as Russian. In addition, more than a million Northwest Caucasians now live in the diaspora, primarily in Turkey. Current estimates of the number of North Caucasians in Turkey range from one to six million, depending on the sources used. It is difficult to generate reliable figures, because many Northwest Caucasians now have complicated ethnic identities resulting from cultural and linguistic assimilation and intermarriage. In the Northwest Caucasus

proper, the different ethnic groups have generally preserved their own languages, although for some Russian has become the dominant language.

Many Caucasian linguists believe that the Northwest Caucasian family is genetically related to the neighboring Northeast Caucasian family, but the linguistic arguments presented in support of this connection are not convincing, resting on typological similarity rather than the comparative method. All of the Northwest Caucasian languages have literary forms, with the exception of Ubykh, which is now extinct. Their current orthographic forms are based on the Cyrillic script, although there is currently movement to develop a new orthography based on the Roman script (most likely its Turkish manifestation). Abkhaz and Abaza are quite similar to one another and are considered by some scholars to be dialects of the same language; the same holds for Adyghe with respect to Kabardian. Ubykh is linguistically intermediate between these two groups.

The Northwest Caucasian languages are most famous for pairing unusually rich consonant inventories (containing as many as 83 consonants, in Ubykh) with unusually small vowel inventories, typically consisting (in native words) of only a low vowel /a/ and a non-low vowel /ɨ/. The richness of the consonant system derives for the most part from the addition of labial and palatal secondary articulations. It appears that the enormity and smallness of the consonantal and vocalic systems, respectively, are related: the ancestral (proto) language most likely had more conventional vowel and consonant systems, and subsequently reinterpreted the [back] and [round] features of the vowels

as resulting from secondary7 articulations on neighboring consonants. (Turkish, Arabic, and Persian but not Russian loans underwent this reanalysis as well: cf. Turkish dükkân 'store'→Abkhaz /a-dʷɨk'yan/ [ádˌbukʼʲán].) One can see in this example that what are now phonologically consonantal secondary articulations still surface on the vowels in most contexts. All of the Northwest Caucasian languages distinguish three types of laryngeal consonants, opposing plain voiced, voiceless aspirated, and ejective stops. Many also possess extremely complicated intonational stress systems, most famously Abkhaz.

The system of agreement marking in Northwest Caucasian verbs is also uncommonly intricate. Abkhaz, for example, overtly marks verbal agreement with subjects, direct objects, indirect objects, and various other oblique arguments, as in the following Abzhuy example from George Hewitt (transcribed in the IPA):

saɾá	ɑ-pħʸɨs	ɑ-sɑpʼɨn
I	the-woman	the-soap

s-χaɾpʰ (∅-)ɑ-lɑ-l sɨ-ɾ-dʒʸɨdʒʸá-(∅-)jtʼ
my-shirt (it-)it-by her-I-cause-wash-(PAST-)FINITE
'I got the woman to wash my shirt with (the) soap'

It is possible to string together as many as nine overt morphemes in a row in a sequence of verbal prefixes.

The nominal morphology, on the other hand, is relatively simple, containing only two cases (direct object and oblique or adverbial). Possession is expressed via prefixes, as in Abkhaz sɨ-napʼ-kʷá 'my hands' (I-hand-nonhuman.plural). Abkhaz (and Abaza) distinguish human vs. nonhuman in certain morphological classes, as can be seen in the plural in this example. All of the Northwest Caucasian languages distinguish two genders, two numbers, and three persons in their system of agreement markers.

Finding lexical items shared by all of the Northwest Caucasian languages is difficult, but not impossible:

Proto-Northwest Caucasian	Common Circassian	Ubykh	Common Abkhaz
*pxʲa 'back'	pxa	pšʲa	*(p)χʲa
*bza 'tongue'	*bza	bzʲa	*bzə
*zʷʲa 'cook, boil'	*zʷʲa	zʷʲa	*zʷʲə
*gʷʲə 'heart'	*gʷə	gʲə	*gʷə

The Northwest Caucasian numeral system is interesting in that it preserves vestiges of an original vigesimal system in the numbers 30–99. For instance, Abkhaz (Cwyzhy dialect) eцχʷejцχʷɑbɑ 'thirty' is literally 'twenty (eцχʷɑ) and (-j) ten (zʷɑ-)'; цɨneцχʷɑ 'forty' is 'two twenties', and so on.

Turning to the individual languages, Abaza had 34,800 speakers in the Karachay-Cherkess autonomous region of Russia at the time of the 1989 census; as of 1995, there were 10,000 more in Turkey, 80 (out of 150 members of the ethnic group) in Germany, and about 15 in the United States. There are three main dialects: Tapanta, Ashkhar, and Bezshagh. The literary language is based on the Tapanta dialect. Abaza is reported to be mutual with Abkhaz.

Abkhaz had 101,000 speakers in Abkhazia in 1993, as well as 4,000 speakers out of approximately 15–30,000 ethnic Abkhaz in Turkey, and smaller numbers scattered in other countries. Abkhazia was under Georgian rule during the Soviet period, but seceded shortly after the dissolution of the Soviet Union in the mid-1990s. The continued refusal by foreign nations to recognize Abkhazia's sovereign status, together with the forced immigration into Abkhazia of Slavs, Armenians, and Mingrelians during the 1930s, and Georgia's continuing attempts to eliminate its ethnic minorities, have placed the Abkhaz language in danger of disappearing. The assignment of literary status to Abkhaz (including TV broadcasts since 1978) has helped counteract this tendency within Abkhazia, but few members of the younger generation are learning the language in the diaspora. There are three main dialect groups: Bzyp (north of Sukhumi), Abzhui, the literary dialect (south of Sukhumi), and Sadz (now spoken only by a handful of Abkhaz in Turkey).

The Circassians live in the Adyghe, Kabardino-Balkar, and Karachay-Cherkess republics in the Russian Federation. The Circassians have two main languages, Adyghe (West Circassian) and Kabardian (East Circassian), the former of which has four main dialects (Shapsugh, Bzhedug, Temirgoy (the literary dialect), and Abzakh) and the latter of which has six (Besleney, Malka, Bakhsan, Terek, Mozdok, and Lesser Kabardian). As of 1993, there were some 125,000 Adyghe and 46,000 Kabardians in Russia, 100,000 Adyghe and 202,000 Kabardians in Turkey, and a total of approximately 750,000 Circassians in the world as a whole. Both languages have literary status and are taught in the schools in their respective republics, but their survival in the diaspora is less secure following the closing of the Circassian school in Turkey by Atatürk in 1920 and the outlawing of publication in minority languages in Turkey in 1983.

The Ubykh community originally lived on the Black Sea just north of Abkhazia, but all 50,000 of its members were deported to the Ottoman Empire following the Russian conquest of the Caucasus, ending up in Hacı Osman, a town near Istanbul. Although the community retains a distinct identity, its language is now extinct. Isolated individuals can still be found who know pieces of the grammar and vocabulary, but

most of the remaining Ubykhs speak Adyghe and/or Turkish.

BERT VAUX

Noun Incorporation

The term Noun Incorporation refers to the linguistic phenomenon according to which a noun and a verb may combine into a single word. The two elements form one morphological unit that is often described as a complex verb (or as a compound). Usually, the incorporated noun is interpreted as the object of the verb.

For example, in Onondaga, an American Indian language of the Iroquian language family, the noun (stem) *hwist* 'money', which is in **bold** below, may appear as part of the verb (stem) *ahtu* 'lose'. In particular, the noun (stem) immediately precedes the verb (stem), as we can see in the following example:

(a). Pet   wa?-ha-**hwist**-ahtu-?t-a?
     Pat   he-**money**-lost
     'Pat lost money'

In this case, the noun (stem) and the verb (stem) form a single word, namely the complex verb *wa?-ha-hwist-ahtu-?t-a?* 'he-**money**-lost'. The incorporated noun (stem) *hwist* 'money' is interpreted as the object of the verb *ahtu* 'lose'.

In the same language, the object of the verb can be an independent word in the sentence. In this case, the object is one word: *ne?o-hwist-a?* 'the money', while the verb is another word, namely, *wa?-ha-htu-?t-a?* 'he-lost'. The noun now follows the verb, as illustrated below:

(b)   Pet   wa?-ha-htu-?t-a?   ne?o-**hwist**-a?
      Pat   he-lost   the-money
      'Pat lost the money'

(Examples (a) and (b) are taken from Baker 1988:76.)

Incorporating languages thus have two ways of expressing the verb and its object: either the two elements are realized as a single word after incorporation of the noun into the verb, as shown in example (a), or they appear as two separate words. In the latter case, the noun does not incorporate into the verb, but it follows the verb, as shown in example (b). The two constructions may differ slightly in their interpretation. For example, Incorporation sometimes has the function of narrowing the semantic range of the verb. This implies that the speakers of incorporating languages chose between the nonanalytic configuration (where the object is incorporated into the verb) and the analytic configuration (where the object is not incorporated into the verb) on the basis of the particulars of the information they want to communicate.

Noun Incorporation is a productive process mainly in non-Indo-European languages. It is attested in some North American languages (Athapaskan, Caddoan, Chimariko, Iroquian, Siouan, Kiowa-Tanoan, Natchez, Takelma, Uto-Aztecan, Yana, Zuni), in Australian languages (Rembarnga), in Paleo-Siberian languages (Chukchee), in Oceanic languages, in Turkish, and in other languages.

There has been a long debate in the literature of Generative Grammar regarding Noun Incorporation. The debate concerns the locus where these complex words are formed. On the one hand, it has been argued

that Noun Incorporation is an instance of compounding in the Lexicon (Mithun 1984; Di Sciullo and Williams 1987; Rosen 1989). Compounding refers to the combination of two (or more) stems or words into one single word. For example, the English word *bedroom* is a compound consisting of two elements: *bed* and *room*. Hence, it has been argued that Noun Incorporation is a case of a noun and a verb that are put together in the same way that *bed* and *room* are combined into *bedroom*. According to this view, the noun–verb complex is not related structurally to its analytic counterpart. That is, there is no association between the noun–verb compound and the structure that involves the verb and its object, despite the fact that the two configurations may have very similar interpretation. The noun and the verb are put together morphologically and behave as one syntactic unit. This hypothesis is usually known as the lexicalist hypothesis.

Baker (1988), on the other hand, was the first to argue that Noun Incorporation is a syntactic phenomenon. His main idea is that Noun Incorporation is a syntactic process that derives complex verbs from sentences where the verb takes a noun as its object. Specifically, Baker argues that the incorporated noun starts out as an independent word, in a position following the verb. It ends up in a position preceding the verb after an operation of syntactic movement. That is, syntactic movement changes the position of the noun and places it within the verbal complex. An empty slot is left behind, in the original postverbal position of the noun, which is called the trace of the moved element.

Baker provides a straightforward explanation of the fact that the incorporated noun is interpreted as the object of the verb. It starts out as the complement of the verb, i.e. the two elements are adjacent and in a specific order: the noun follows the verb. This is considered as the structural position where the internal theta-role of the verb is assigned (following Baker's Universal Theta-role Assignment Hypothesis—the UTAH—according to which each thematic role of the verb is assigned in a specific syntactic configuration). That is, any element that is base-generated in that particular syntactic position is interpreted as the direct object of the verb, namely as the theme (i.e. the argument that is affected by the action described by the verb). Hence, if the incorporated noun starts out as the complement of the verb, it is assigned the internal theta-role of the verb and is thus interpreted as the object of the verb, even after incorporating (by syntactic movement) into the verb. Incorporation is predicted to be possible with any noun that starts out from the verbal complement position. This is actually true: Noun Incorporation is a productive process in incorporating languages.

In nonincorporating languages, like English, the object cannot form a single word with the verb. Words like *truck drive* are not in use. This means that the noun

truck, which is the object of the verb, cannot become part of the verb *drive*, but rather the two elements have to remain two separate words. The noun *truck* can be combined with the noun *driver,* giving rise to a complex noun: *truck driver*. However, it can be argued that these cases are different from genuine instances of Noun Incorporation in that the derived word is a noun rather than a verb. There are some complex words in English that resemble cases of Noun Incorporation. It could be argued that the formation of verbs like *baby sit* possibly involves an operation of syntactic movement. However, such examples lack a parallel analytic configuration. That is, *to sit a baby* cannot be considered as the parallel analytic configuration of the complex verb to *baby sit*. The latter has a very unexpected meaning. It expresses the notion 'to look after a baby'. If *baby sit* is not an instance of Noun Incorporation, it could be viewed as an instance of compounding. This would mean that the verb *baby sit* is derived by a lexical or a morphological process and not by a syntactic process.

Lastly, it has been argued that Incorporation is a widely spread phenomenon that is not necessarily restricted to nouns. It is a process that allows any two elements to combine into a single word. One of the two parts of the derived word is usually a verb. It has been proposed, for example, that certain kinds of pronouns incorporate into the verb. These are called clitic pronouns and are set apart from other pronouns by certain special characteristics. While ordinary pronouns do not appear as parts of the verb, clitic pronouns may do so. This process is often named cliticization. The process of cliticization can be distinguished, though, from Noun Incorporation in that the former possibly involves incorporation of a functional element (a clitic pronoun) whereas the latter involves incorporation of a lexical element (a noun).

Number Marking

Number is the morphological category that expresses contrasts involving countable quantities. The most widespread number opposition is likely that between singular (one) and plural (more than one). Several languages, however, make further distinctions. Some of them (e.g. Greek or Sanskrit) exhibit dual forms that apply to two individuals, and a few languages (e.g. some Southwest Pacific languages) additionally distinguish a trial form that refers to three individuals. In some systems, there are also paucal forms for indicating a small number, as in Arabic.

Although number implies a basic linguistic contrast, languages deal with this category in different ways. Most languages mark number in nouns; yet, there are languages (e.g. Maori, a Polynesian language) in which it is signaled by determiners, and others that lack number distinctions (e.g. Nancowry, spoken in India's Nicobarese Islands). The explicit expression of number, on the other hand, may be obligatory, as in most English nouns; limited to certain nominal categories, as in most Algonquian languages (spoken by American Indians); or optional, as in Halkomelen (another American Indian language).

Number marking differs greatly among languages, depending on the morphological system they display. In languages traditionally classified as analytic, such as Chinese, words consist of only one syllable and are invariable. Thus, plural nouns do not exhibit any formal marker and the notion of plurality must be inferred from the context. Only when this information is not contextually available or the idea of plurality is to be emphasized, separate words are added: *ki* 'some', *šu* 'number'. Synthetic languages, on the contrary, rely on inflection, i.e. the modification of a word's form, to express number distinctions. Modifications of words may equally result in derivation, which involves the creation of new words with new meanings. In traditional morphological theory, which has its origins in American structuralism, the analysis of word structure was based on the morpheme—the smallest meaningful unit of language. Morphemes are, however, abstract elements that are physically realized by morphs. The word *houses*, for example, consists of two morphs: *house* and *-s*. It is very frequent that a particular morpheme is represented by different morphs in different environments. For instance, the plural morpheme in the English noun *oxen* is not realized by the regular morph *-s*, but by the irregular *-en*. These alternants are called allomorphs.

Both inflection and derivation are traditionally explained exclusively in terms of affixation. As regards inflection, affixation consists in the addition of an inflectional affix (an obligatorily bound morph that contains grammatical information) to another morph with lexical content, as in *house-s*. This approach to inflection, however, is said to face important difficulties. One of them is illustrated by irregular English plurals such as *men,* in which plurality is marked not by the addition of an allomorph, but rather by means of a process that causes a vocalic change. The so-called portmanteau morphs (morphs that realize more than one morpheme, as the ending *-us* in the Latin noun *annus* 'year', which indicates simultaneously singular number and nominative case) are also problematic, since this approach assumes a one-to-one correspondence between form and meaning. In view of such shortcomings, recent morphological theories of inflection have abandoned this classical treatment and have adopted a model in which words are modified by means of different morphological processes that apply to the word itself, which is considered the base or stem.

The most simple device to express number is, as in traditional accounts, affixation. Affixes can be divided into three main classes: prefixes, which attach to the front of the stem; suffixes, which come after the stem; and infixes, which occur within the stem. Most Indo-European languages make use of suffixes, such as the English or Spanish regular plural ending *-s*, to express number contrasts. Number marking by means of prefixation can be found in Bantu languages such as Kikuyu (*mũ-rũ ũ thi* 'lion', pl. *mĩ-rũ ũ thi*), whereas the Uto-Aztecan language Oaxaca Chontal illustrates the use of infixes to distinguish number (*kwepoʔ* 'lizard', pl. *kwe-ł-poʔ*).

Other processes by which number oppositions may be expressed involve the modification of the stem. This shift may affect the quantity or quality of the internal vowel, as in the English pair *foot/feet*. Vowel change is generally referred to as 'ablaut', although, because of its historical origin, the alternation just mentioned receives the distinct name 'umlaut'. Not only vowels but also consonants may be modified to mark number. In the West African language, Fula, the plural of the word *yiite* 'fire', is formed by changing the initial consonant, *giite*. Such consonant alternations are frequently the result of a phonological change induced by an affix, which is then lost.

In many languages, information about number is conveyed by means of modifications of the suprasegmental features tone and stress. In Somali (an East African language), for example, number is indicated by a change in the tone pattern: the singular form *èy* 'dog' takes a falling tone, whereas the plural *éy* takes a high tone. Russian illustrates the use of stress shift to distinguish singular from plural: in a particular group of neuter nouns, the singular is ending-stressed, while the plural is stem-stressed: *oknó* 'window' (nominative singular), *ókna* (nominative plural).

Another common morphological process in certain languages is reduplication, which consists in the copying of the whole stem—total reduplication—or only of a part of it—partial reduplication, typically the leftmost portion. Reduplication is said to be frequently used iconally, i.e. the form of the word reflects its meaning. For this reason, reduplication is a common marker of plurality. Total reduplication to form the plural is found in Indonesian (*babi* 'pig', pl. *babibabi*), whereas partial reduplication is used in Motu, a language of Papua New Guinea (*tau* 'man', pl. *tatau*).

The last morphological operation associated with number marking is suppletion. This process replaces one form by a phonologically unrelated form. A clear example of this phenomenon is the use of *went* as the past tense of *go*. Suppletion appears in many Western North American languages as a number marking device: in Navajo, the form for 'one is standing' is different from that for 'several are standing'.

Official Language Selection

Official language selection may be simply defined as the political choice of which language, or languages, to use in the legislative, executive, and judicial business of government. Given that all nations in the twenty-first century comprise populations speaking different languages, the selection of official languages is much more complex than the definition. This is because granting official status to a particular language will enhance its prestige, extend its use to educational and nonofficial domains, privilege its speakers, and impinge on the linguistic rights of speakers of other languages within the community. Both newly independent and well-established countries face difficulties when selecting official languages, although the contributing factors differ. Examples of each will now be considered.

Countries that are colonized or subjected to imperialism in one form or another usually have the language of the colonial state imposed on them. Upon reaching independence, the selection of the official language is a matter of considerable importance—and controversy—because there are often several contending languages. One of them may be the first language of a majority of, or dominant group within, the population, and this would seem the obvious choice for nation building. This was the case with the nations that re emerged after the demise of the Soviet Union in the 1990s (Ukraine, Latvia, Belarus, and so on). However, in such cases, speakers of other indigenous languages may feel that they are regarded as second-class citizens for whom access to public services is restricted, if not denied completely, by the lack of official recognition of their mother tongue. This situation arose in Pakistan, where Urdu was declared the official language on independence from Britain in 1947. However, because Urdu was not an indigenous language of East Pakistan, the overwhelmingly Bengali-speaking majority there felt marginalized; the unrequited demand for language rights led to civil war, after which Bangladesh achieved independence from Pakistan in 1971. Therefore, some newly independent nations select the language of the previous imperial power; this was the pattern among most ex-colonies of Britain in the 1960s and 1970s, such as Ghana, Nigeria, and Kenya. Although this choice means that a new nation may relatively easily build on the existing communications infrastructure, the choice may be inappropriate. There is often a residue of ill-feeling toward the culture and language of the erstwhile rulers; such a decision may also leave in positions of influence those who collaborated with the colonial power and who may be out of sympathy with a new regime. Because of this, some countries adopt another international language. The example of East Timor, which became independent in 2000, is a case in point. None of the indigenous languages was considered appropriate as the official language. The language of the erstwhile dominant power—Indonesia—was considered unacceptable on political and cultural grounds. Portuguese—the language of the earlier colonizer—was eventually chosen because it was widely understood and was used both within East Timor and internationally. Since 1994, South Africa has presented a very different example of language policy—one of national pluralism. At the national level, 11 indigenous languages have official status, and each provincial

legislature can determine which of the languages will be used for internal official purposes.

Longer established nations may also have difficulty in selecting official languages, as examples from major English-speaking countries illustrate. For many years, the francophone population of Canada struggled for legal recognition of their language until eventually the 1969 Official Languages Act declared that English and French had equality of status with equal rights and privileges. The case of the United Kingdom is different because although English is the national language, it has no official status: the only legally recognized official language in Great Britain is, since 1967, Welsh. Similarly, since 1987, the only official language throughout New Zealand is Maori. The reason for this apparent legal anomaly is that the indigenous speakers of those two minority ethnic groups campaigned to have their languages officially sanctioned for use in public services such as the legal system and education, health, and social services. With regard to English, there was no need to formalize such rights because they existed in fact, although not in law. Some English-speaking people in these countries opposed the granting of prestige and rights to these minority languages; they also opposed the allocation of public resources for their development and diffusion. None of these countries has an explicit overall national policy on languages, and there is considerable scope for uncertainty and even anxiety regarding the language rights of speakers of nonofficial languages:for example, immigrants and minority ethnic communities in all three countries and the indigenous First Nation peoples of Canada. By contrast, Australia has been developing a comprehensive National Languages Policy since 1987; although this now declares that English is the official language of Australia, it recognizes the aboriginal languages and also specifies the provision of services in languages other than English. The United States has never selected an official language, despite the large number of indigenous, colonial, and immigrant language communities. Recent attempts to change the federal constitution to adopt English as the official language throughout the United States have been unsuccessful, although since the 1980s many state legislatures have passed laws proclaiming, with varying degrees of specificity, English as the official language within their own borders.

Language is not merely a means of communication: it is the most important cultural symbol of a community. For many countries—Japan, Somalia, Malta, and many others—the national language is a core value that bonds the people together and indeed defines that very community. Increasingly, however, all nation states are host to diverse linguistic minority communities in their midst, whether this is caused by temporary business activity, permanent migration, urgent asylum-seeking, or the revitalization of indigenous languages. It is, therefore, necessary for national policy-makers to consider the extent to which multilingualism (and multiculturalism) presents either a threat or a resource to their communities, and thereafter to select official languages and frame national language policies in the light of this understanding.

Ojibwe and Algonquian Languages

Ojibwe (sometimes Ojibwa, Chippewa) is a Native American language and belongs to the Algonquian family, one of the largest of precontact North America. Although widely dispersed, these languages share many of the same grammatical features. Other members in this group include Blackfoot, Cheyenne and

Arapaho, Cree, Potawotami, Menominee, Fox, Illinois, Shawnee, Micmac, Passamaquoddy, and Abenaki.

Algonquian speakers have inhabited North America for thousands of years. Their homeland was suggested to be somewhere in the region of Lake Huron or Georgian Bay, but given the ease of movement throughout the eastern woodlands area, most researchers are noncommittal in this regard. At the time of European contact, Algonquian languages were spoken along the eastern seaboard north of Virginia, as well as to the east of the lower Mississippi River. Today they can be found from the Atlantic Ocean to the Rocky Mountains along what is now the United States/Canadian border. Place names such as Connecticut, Manitoba, Massachusetts, Michigan, Minnesota, Mississippi, Ontario, Saskatchewan, and Wisconsin are all Algonquian in origin, as are the words *moose*, *chipmunk,* and *toboggan.*

Linguists often speak of Algonquian in terms of regional subdivisions, but only Eastern Algonquian constitutes a family in the true sense; i.e. it can be shown that these languages have a common ancestor. Members of this group include Abenaki (spoken in Québec and Maine), Passamaquoddy-Maliseet (Maine, New Brunswick), and Micmac (Nova Scotia, New Brunswick). Arapaho, Cheyenne (Wyoming), and Blackfoot (Montana, Alberta) fall into the western group. 'Central Algonquian'—of which Ojibwe is a member—is spoken around the area of the Great Lakes. Ottawa (Odawa), Algonquin, and Salteaux (all spoken in Canada) are essentially the same as Ojibwe; Cree, Fox, and Shawnee are close relatives. Divisions along geographical lines are not completely arbitrary: members of each region share certain sounds, vocabulary, and sentence patterns not found in others. The differences between one language and the next shift gradually from west to east, with western languages being the oldest.

Algonquian was one of the first language families to be reconstructed by using methods developed in the nineteenth century for Indo-European. By comparing words in various languages, the American structuralist Leonard Bloomfield was able to determine the forms of 'proto' Algonquian, at the same time making significant contributions to our understanding of linguistic change itself. Since then, many other researchers have followed in Bloomfield's footsteps, to the point where Algonquian is often looked on as a textbook case of structuralist analysis. Outside of taxonomy and analyses of sound change, not much systematic work has been done on Algonquian. Compared with other languages, our understanding of word and sentence structure is incomplete, and research on meaning and discourse is still in its infancy.

As a spoken language, Ojibwe is fairly robust, whereas several other Algonquian languages have declined or died out altogether. Most speakers live on reservations in Minnesota, Wisconsin, and Michigan (United States), as well as in the province of Ontario (Canada). One recent estimate puts the total number of Ojibwe speakers at 51,000, but most other estimates are lower. In any case, only a small percentage represents unilingual Ojibwe speakers. Many efforts are under way to preserve and/or revive the language. These usually take the form of bilingual education programs in the schools, language centers for adults, or the establishment of institutional or personal websites. Recently published word lists and dictionaries abound, and Ojibwe has received a relatively good deal of attention from linguists. Otherwise, the model of loss is similar to endangered languages worldwide: younger speakers are heavily influenced by the dominant culture (in this case, Anglo-America) and use their first language primarily in family or tribal situations. Borrowed speech habits continually erode native sound and sentence patterns until only the elders speak the language fluently.

The sounds of Ojibwe are typical of other Algonquian languages. There are five vowels of different quality, and vowel length (indicated by a colon) distinguishes meaning. The vowels are [i, e, (schwa), i:, a:, and o:]. The consonants are [p, b, g, k, m, n, ch, j, w, y ,h, and ʔ]. Note the absence of [t, d].

Ojibwe (henceforth Algonquian) is a polysynthetic language, a term that carries with it many implications: single, complex words typically express the meaning of whole sentences, pronouns are 'understood' rather than overt, and expressions such as 'all' or 'every' may be separated from the nouns they modify by other words. In addition, polysynthetic languages are rich in agreement: subjects, direct objects, and even indirect objects cause the verb to inflect for person, number, and gender—and sometimes case. Noun phrases, meanwhile, do not appear in fixed positions within the sentence, as in English; instead they are considered 'appositional' (add-ons), only loosely linked to the verbs. Many meanings that are conveyed in full phrases in other languages are expressed via particles that attach to the verb.

Verbs in Ojibwe (and all Algonquian languages) agree with subjects as well as direct objects, sometimes in very intricate ways. In the sentence *[ni-ki:-wa:pem-a:-n] kene:peko:n* '[I saw] the snake', the prefix *ni-* indicates that the subject is first person, whereas the absence of a plural marker ensures that it is singular. The third-person feature of *kene:peko:n* 'snake' is encoded by the suffix *-a:,* whereas *-n* signals that the (singular) object is different from the subject (cf. obviation below). Because of such rich agreement, there is no need for separate pronouns other than

emphatic ones. In the absence of an object, this sentence would simply mean 'I saw him/her/it.' When plural morphemes are added to the verb, agreement is 'skewed', yielding the order

person prefix -	person -	number -	number
(verb stem)	suffix	suffix	suffix
SUBJECT	OBJECT	SUBJECT	OBJECT

In other words, subject as well as object agreement is split between two nonadjacent positions. Various linguistic theories have attempted to deal with facts like these, but so far very few have succeeded in providing a natural account. Finally, nouns inflect for person, number, and obviation too, as in *ni-gwis-ag* [first person-son-plural] 'my sons'. Note that often the same affixes involved in verbal agreement also show up in this context.

A large class of elements called preverbs appear in fixed positions before the verb stem. These typically modify the state or action denoted by verb, much like modifier phrases do in English. Examples from Ojibwe are *ojaanimi* 'busy, noisy', *wani* 'mistakenly', and *aano* 'in vain, without result'. Some preverbs are themselves verbal in character, such as *giizhii* 'finish, get through doing', *gwiinawii* 'don't know, not able to', and *goji* 'try, attempt'. Still others pertain to the way that a speaker perceives an event: *bi* 'here, toward the speaker', *madwe* 'audible from a distance, can be heard', *ani/ni* 'going away from the speaker, approaching the time of doing something'. In short, preverbs have different functions that parallel phrasal expressions in nonpolysynthetic languages. Although it is possible for several preverbs to appear in a string, their order is not random.

One of the characteristics of a polysynthetic language is the richness of word formation processes. In Ojibwe/Algonquian, many words are made up of multiple roots, not unlike English compounds, e.g. 'killdeer' (a kind of bird), 'snow removal', etc. Roots can be divided into initials, medials, and finals, depending on their position within the word. Initials carry most of the meaning, often describing processes or resulting states. Medials are usually nounlike, denoting body parts or instruments, and finals typically indicate simple states or actions. The complex Passamaquoddy stem *napici koli-hqeh-mon* 'She or he sticks it onto something' could be translated as 'onto stuck-surface-make' [preverb initial-medial-final]. Final roots in Ojibwe/Algonquian also specify the gender class of intransitive subjects and transitive objects (cf. the discussion of gender below). A common pitfall in understanding polysynthetic languages has been to ascribe variations in word form to the speaker's viewpoint of the world, when in fact they probably result from regular grammatical processes.

The seemingly many names for snow in Eskimo (*Yup'ik, Inuktitut*) is a classic example. Similarly, Algonquian languages (like French) seem to contain an inordinate number of verbal paradigms. The difference, for example, between 'if he comes' and 'when he comes' depends on the change or deletion of a single vowel. The third major order in Algonquian is the imperative. The important thing to realize is that speakers do not memorize these myriad forms, but rather freely produce and understand them by internalizing a finite set of rules.

Nouns in Ojibwe (Algonquian) are classified on the basis of animacy, roughly 'being like a conscious living thing'. As one might expect, humans and animals are [+animate], whereas rocks and similar types of objects are [−animate]. The division is not always based on clear-cut properties, however. For example, trees are [+animate], along with containers used for liquid (cups, spoons, pens, etc.). In Passamaquoddy (Eastern Algonquian), the words for rope, milk, and fallen snow are all [+animate], as are those for fingernail and knee. Other body parts (heart, tongue) are [−animate], however. The animacy of a given noun is overtly indicated by the verb-stem final, but only under certain grammatical conditions.

Ojibwe speakers have a complex system of referring to things or people in a sentence or discourse. English normally uses pronouns like 'he' or phrases like 'that guy' to refer to someone after first introducing him by name. In Ojibwe, however, pronouns are not expressed overtly: one usually infers their presence through subject/object agreement on the verb or possessor agreement on the noun. The 'obviation' system guarantees that certain noun phrases (inaudible pronouns as well as audible noun phrases) are not confused with others. Within a complex noun phrase like *niw wday-an* 'his dog', for example, the possessive pronoun 'his' (which is only implied) would not be indicated by inflection, whereas *niw* 'dog' is marked as obviative (the suffix -*an*). This ensures that 'his' and 'dog' do not refer to the same entity. The second domain of obviation is the clause. This can be seen in *uki:-necci:we'a:-n [eniw kwi:wesse:ns-an]* 'He scolded [that boy]', where the subject is unmarked and the object triggers obviation (underlined) on the verb as well as the noun phrase. As in possessed noun phrases, obviation within a clause is obligatory. In the third domain of obviation, subjects of main clauses are unmarked, but those in subordinate clauses are obviative (underlined):

gii-boonii-w dash maa dVdibew [mitigoonsikaa-<u>ini</u>-g]
'Then she landed on the shore [where there were bushes]'

Further restrictions determine whether subjects and objects are overtly expressed or implied. Although it is possible to say 'I wrote them' or 'You hurt me', for

instance, the opposite 'They wrote me' or 'I hurt you' cannot be expressed without changing the affixes of the verb. In the first two sentences, a 'direct' morpheme is attached to the verb stem, and in the latter two an 'inverse' one. The choice of direct or inverse is determined by a 'participant hierarchy' that ranks noun phrases according to person and obviation. In direct sentences, subjects outrank objects on the scale: 2 > 1 > 3 > 3′—that is, second persons ('you') are ranked higher than first persons ('I/we'), which in turn are higher than third persons ('she or he'). Nonobviative third persons (3) are ranked higher than obviative (3′) ones. In inverse sentences, exactly the opposite holds: objects must outrank subjects on the same scale. Strikingly, subjects in the inverse appear as objects in the direct, and vice versa:

Direct	Inverse
ni-wa:pam-a:-k	ni-wa:pam-ik-o:k
1-see-third person/direct-pl	1-see-third person/inverse-pl
'I see them'	'They see me'

Hierarchical effects such as those exhibited by Ojibwe/Algonquian pose a challenge to linguists attempting to explain them.

Okanagan and Salishan Languages

Okanagan is one of four languages that belong to the Southern Interior branch of the Salishan linguistic family of North America. All but two languages of the family occupy contiguous territory that extends longitudinally from about 123°W to about 113°W, and latitudinally from about 52°N to about 45°N. In contrast to early speculations that the Salishan languages had spread from an inland location (Boas 1905), recently scholars have proposed that speakers of the original language occupied a maritime area, and migrated outward from there, following routes to the interior along such major rivers as the Fraser and Thompson (Suttles

and Elmendorf 1963; Suttles 1987). The linguistic evidence adduced focuses on terms of flora and fauna (Kinkade 1991).

Subgroupings: The family divides into five branches, the result of migrations. A single group is thought to have headed northwest and settled in the area where Bella Coola is now found, surrounded by non-Salishan languages, Wakashan seaside, and Athapascan inlandside. Another group is thought to have settled along the coast, and then spread further, one subgroup going southward to where Tillamook, now extinct, was spoken, and formed the third branch of the linguistic family. This language, too, is surrounded by non-Salishan languages, clockwise from the north: Chinookan, Athapascan, Takelman, and Maidu. A fourth group, forming the Tsamosan branch, also moved southward, and a fifth group, forming the Interior branch, moved eastward (see Figure 1). One now extinct Athapascan language, Nicola, was spoken in the approximate geographic center of the Salish area.

The area where Okanagan is spoken by perhaps as many as 1,000 speakers of mostly mature age spans along the north–south expanse of the Okanagan valley from what is now Enderby to the south of Okanogan,

Washington, and westward in the Similkameen and Methow valleys; and along the north–south expanses of the Sanpoil and Kettle rivers, and the area west of the Columbia river as far as the bend around Wilbur, Washington. Dialectal differences are minor but remain to be described. (Figure 1 here)

Phonology: In spite of the size of the family, and the number of different languages represented, it is possible to provide a generalized phonology of Salish (see Figure 2).

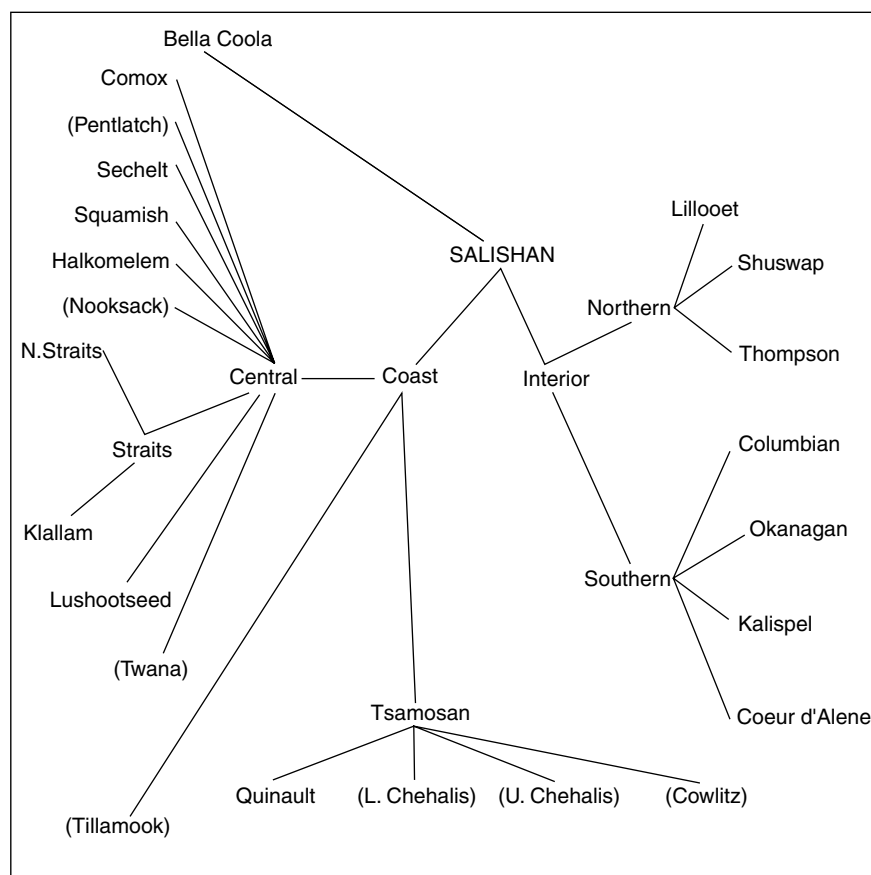
The angled brackets notation should be read as either/or: with few exceptions, a Salishan language has one or the other series, the velar being the conservative one. Okanagan has the velar series. The northern dialects of Okanagan include voiced postpalatal resonants (ɣ', ɣ) that correspond to y' y in the other dialects. In the same northern dialects, the labialized pharyngeals have merged with their unrounded counterparts. Voiced stops are rare in Salishan languages, but occur in Coeur d'Alene, Twana, Lushootseed, and Comox, where they do not derive historically from proto-stops. Pharyngeals are found only in the Salish languages of the Interior; and no language, except Comox, has a phonemic nonejective lateral affricate.


Figure 1

p'	t'	c'	λ'	<tʃ'>	<k'>	kʼʷ	q'	qʼʷ	
p	t	c		<tʃ>	<k>	kʷ	q	qʷ	ʔ
	s	ɬ		<ʃ>	<x>	xʷ	χ	χʷ	h
m'	n'	r'	l'		y'		w'	ʕ'	ʕʼʷ
m	n	r	l		y		w	ʕ	ʕʷ

Figure 2. Generalized Salish consonant inventory.

Okanagan has a symmetric three -vowel system, /i u a/, while the vowel systems of Salishan languages often include four vowels, sometimes five, with some asymmetries, notably the occasional absence of a high back vowel. Schwas are for the most part epenthetic. Salishan languages are wellknown for their propensity for consonant clusters; Bella Coola for several lexical items that consist entirely of voiceless obstruents.

Morphosyntax: Salish languages have large numbers of affixes, predominantly suffixes. All Salish languages have developed lexical affixes, bound forms with lexical content, with a function that resembles that of incorporated nouns, and all Salish languages have several reduplicative patterns that mark primarily augmentative, diminutive, and inchoative forms. A nominalizer with the shape *s-* is nearly universally found, but homophonous aspectual prefixes also occur, notably in Coeur d'Alene and Okanagan.

Person marking: Six Interior languages have different sets of person markers for transitive, intransitive, and subordinate predicates; the paradigms are less differentiated in Lillooet, closest to the languages of the coast, and in the noninterior languages. Possessive paradigms include prefixes and suffixes in all the languages. Okanagan has four main sets of person reference markers: the kn̲ set (intransitive), the i(n)- set (possessive), the -(í)n set (transitive subject), and the (transitive) object set.

The kn̲ set consists of clitics (marked with the ligature) and a suffix:

kn̲	1sg	kʷu̲	1pl
kʷ̲	2sg	p	2pl
Ø	3sg	Ø ...-lx	3pl

These markers accompany stems that in English translate as intransitive verbs, nouns, and adjectives.

kn̲ ʔitx. *I slept.*
kʷ̲sqilxʷ. *You are an Indian/a person.*
ʔayχʷt (axáʔ). *This one is tired.*

A subset of these markers, identical in all persons except for 1sg kʷu̲, co-occurs with the possessive set of person markers, and is reserved for double possessives and verb nominalizations.

The possessive set, used with nouns, psych verbs, and verb nominalizations, consists of these markers

(prefixes and suffixes; parentheses abbreviate variants):

i(n)-	1sg	-tt	1pl
a(n)-	2sg	-mp	2pl
-s/-c	3sg	-s-lx / -c-lx	3pl

which yield such forms as

an-lʔíw *your father*
in-χmínk *I like/want it*

which, in turn, may combine with members of the kn̲ set (kʷu̲ subset) to yield forms such as

kʷu̲ an-lʔíw *I am your father.*
kʷ̲ in-χmínk *I like/want you (you are my wanting).*
kʷ̲ i-ks-ʔam-ɬt-ím an-lʔíw *I am going to feed your father.*

The last is the nominalization of a future (ks-) possessor applicative (-ɬt) verb form (root ʔam, *feed*), in which the suffix -(i)m, sometimes referred to as the antipassive, is required.

The transitive subject set, often called the ergative set, consists of the following suffixes (parentheses abbreviate stressed and unstressed variants):

-(í)n	1sg	-(í)m /-t	1pl
-(í)xʷ	2sg	-(í)p	2pl
-(í)s	3sg	-(í)s-lx	3pl

These markers follow the object markers, which, in turn, follow one of several obligatory transitive markers (see below).

The (transitive) object set consists of the following markers (one proclitic and suffixes):

kʷu̲	1sg	kʷu̲...-m	1pl
-s / -m	2sg	-ɬ(úl)m	2pl
-Ø	3sg	-Ø... -lx	3pl

Because third -person object markers and thirdperson intransitive subject markers are Ø, Salishan languages are often characterized as split ergative systems. The allomorphy of the second singular object is transitivizer dependent. The disambiguation of number in the first-person object is accomplished by the suffix -m and such forms are interpreted as 3rd indef subject - 1pl object:

kʷu̲ sp'-nt-is *He whipped me (-nt transitivizer).*
kʷu̲ sp'-nt-im *They whipped us/We were whipped.*

-(í)m occurs also with Ø, and the interpretation of these forms can be indefinite subject, or passive:

| sp'-nt-is | *3rd person whipped 3rd person.* |
| sp'-nt-im | *3rd person indef whipped 3rd person/3rd person was whipped.* |

Word classes: Aspectual criteria can be established to distinguish word classes, and, as expected, these may derive forms of other classes—nouns can derive verbs and verbs can be nominalized (for example, N. Mattina as reported in Kroeber 1999). A prototypical noun like **kʷilstn** *sweat lodge*, culturally relevant and categorially marked (**-tn** instrumental), derives a verb with **-m**:

kn̓ kʷilstn-m. *I sweat bathed.*

Similarly, **qʷacqn** *hat* derives **qʷacqn-m** *wear a hat* (intransitive); **ntχʷχʷin** *noon* derives **ntχʷχʷin-m** *do lunch* (intransitive).

Analogously, **qiʔs** *dream* (intransitive) derives **s-qiʔs** *dream*, and the latter form can be inflected with possessive markers and interpreted as a possessive noun form, or as a nominalized verb form.

Most Okanagan stems can also be transitivized (see below).

Nominal and pronominal arguments: Scholars have argued that Salishan languages are pronominal argument languages: a form like **wik-nt-xʷ** *You saw it* is a full sentence with a third-person object (Ø) and second-person subject (-xʷ). In this interpretation, any object expressed in nominal form is an adjunct, not a (nominal) argument. The claim is countered with the suggestion that in applicative sentences like

kʷu̓tq-ɬt-is in-kílx. *He touched my hand*

the noun phrase in-kílx *my hand* functions as one of the arguments of the possessor applicative verb form kʷu̓tq-ɬt-is *He touched my ...* and this argument is not, and cannot be, referenced in pronominal form on the verb.

Intransitive forms are also analyzed as fully predicative.

kn̓ xʷuy	*I went.*
kʷ̓ilmíxʷm	*You are a boss.*
kʷ̓ χast	*You are fine.*

In these sentences, the clitics kn̓ and kʷ̓ are the subjects, and the word to which the clitics are attached are the predicates. Third-person forms have Ø subject person marking, and forms like **sql'tmixʷ** have been analyzed as full predications that should be translated as something like 'He is a man' or 'It's a man.' In the stream of discourse, such words can function as predicative elements. The normal way to express either of the isolated propositions 'He's a man' and 'It's a man' is with utterances like **ixíʔ sql'tmixʷ** *That's a man*, or

sql'tmixʷ yaʔχís *That one over there is a man*; that is, by juxtaposing (in either order) the stem **sql'tmixʷ** and a deictic stem (ixíʔ, yaʔχís). In traditional terms, these sentences would be analyzed as exocentric equational constructions consisting of a subject and a predicate. The participant persons kn̓ and kʷ̓ are pronominal subjects; third-person forms can be analyzed as having a nominal subject of the classes mentioned, which, in context, can be deleted. Another complication for the interpretation of all full words as predicative is presented by the different markings for morphological and syntactic plurals: the morphological plural of **citxʷ** *house* is the reduplicated form **ct-citxʷ** *houses*, while the syntactic plural of the same form is **citxʷ-lx** (ixíʔ) *(Those) are houses*.

In recent times, when scholars are preferring to view all constructions to have heads (or centers, in the old terminology), the question is raised as to what constitutes the head of such a sentence as kn̓ sql'tmíxʷ. Most common is the hypothesis that the verb is the head of the sentence (here it would be the predicate nominal), but because the identification of *head* with *lexical head* can be dispensed with, just as abstract features within the Inflection or Agreement nodes have been proposed to head sentences, and just as the determiner has been proposed to head Determiner Phrases, so can kn̓ be proposed to head the sentence kn̓ sql'tmíxʷ. An utterance like **xʷuy** *He went*, then, can be viewed as the abbreviation of **xʷuy ixíʔ** *That one went*, and analyzed either as having a null subject, or as requiring a third-person nominal subject which undergoes deletion in the appropriate circumstances.

Intransitive, possessive, and transitive paradigms: Beside the intransitive constructions already discussed, Okanagan uses kn̓ inflection in a number of forms derived by means of prefixes, suffixes, and circumfixes. Among these forms are: To-Be nouns (kn̓ kɬ-noun). **kɬ-ilmíxʷm** snk'lip *Coyote will be chief/is chief-to-be;* kɬ- *have* forms (kn̓ kɬ-noun). kn̓ **kɬ-qʷacqn** *I have a hat;* inchoatives (kn̓ verb+-ʔ- before stressed vowel). kn̓ **c'ʔax** *I got ashamed.* (root c'ax); patient forms (kn̓ verb+VC₂). kn̓ **t'k'ʷ-ak'ʷ** *I fell.* (cf. t'k'ʷ-nt *put something down*); get patient forms (kn̓ c+verb). uɬ ilíʔ kn̓ **c-lak'** *I was in jail* a long time (cf. lk'-nt *tie something*); habitual/durative forms (kn̓ c+verb). ilíʔ kn̓ **c-wix** *I live there;* imperfective forms (kn̓ s-c+verb-(mi)x *I have been X-ing*); inceptive forms (kn̓ ks+verb-(mí)xaʔx *I am about to X*); and past perfect forms (kn̓ ksc+verb). kn̓ ksc-nik' *I have cut some, I have some cut*.

Beside the possessive, double possessive, and psych forms discussed, other forms, some intransitive and others transitive (the latter always marked by the suffix -m), take possessive inflection: durative/intent forms (i+s+verb) s-q'sápiʔ-s ilíʔ **i-s-ilíʔ** *I lived there* a long

time (root ilíʔ *there*, lit. long-time there I-there); perfective forms (i+sc+verb). in-χást **i-sc-ʔítx** *I slept well* (my-good my-having-slept); future forms (i+ks+verb) lut a-**ks-xʷúy** *Don't go*; kʷ i-**ks-(s)íw-m** *I'll ask you*; future imperative forms (i+kc+verb) lut a-**kc-náqʼʷ** *You will not steal*. χast a-**kc-kʼʷúlʼ-m** *You will work well*; and future applicative forms (a-ks-verb-t-m) kw̰ i-**ks-mayʼ-xít-m** *... I am going to tell you ...*

Finally, all transitive forms take transitive person markers. Okanagan has two transitivizers, -nt and -st; a *causative* -st; three applicatives -ɬt, -x(í)t, -túɬt; and three suffixes that prepare stems for transitivization: -nun, -min, -xix. Customary transitive forms are marked with the circumfix c-...-st, as in c-wik-st-n *I always see it*.

ANTHONY MATTINA

Old Chinese

Old Chinese may be subperiodized into Early Old Chinese, Middle Old Chinese, and Late Old Chinese. It is generally thought that most Early Old Chinese polysyllabic words became monosyllabic by or during the Middle Old Chinese period, so the Late Old Chinese language was overwhelmingly monosyllabic.

Proto-Chinese, the ancestor of Old Chinese, is practically unknown. Although many scholars believe it to be related to the Tibeto-Burman family of languages in a 'Sino-Tibetan' genetic family, the theory remains controversial due to the lack of regular correspondences in phonology (sound structure), morphology (word structure), and syntax (sentence structure) between Chinese and Tibeto-Burman. Moreover, from Early Old Chinese times to the present, the Chinese language has spread into territory inhabited by peoples who originally spoke other languages, and for centuries it has been spoken by far more people than any other language in the world. Without a thorough comparative study of loanwords in languages known to have bordered on the Chinese-speaking area in Antiquity, the affiliations of Chinese must be considered uncertain and the relationship with Tibeto-Burman likely to be due to convergence. Even if the Sino-Tibetan theory is correct, Proto-Chinese and the Tibeto-Burman languages must have diverged long before the Oracle Bone Inscriptions, the first documents written in Old Chinese. These texts appear in the mid-second millenium BCE and already contain distinctively Chinese phonological and syntactic characteristics that had developed in Proto-Chinese, before the language was first written down. For example, only one negative particle, *ma, is reconstructable for Proto-Tibeto-Burman, but the Oracle Bone Inscriptions have two negative roots, *pa- and *ma-. This distinction is preserved in all later forms of Chinese, including modern Mandarin, where it is still found in numerous bound forms and in the free negative forms 不 *bù* [pu] and 沒 *méi* [mej].

The Old Chinese writing system contains important information for the reconstruction of the language.

Although it includes many characters with no phonetic elements, such as 龜 *guî* 'tortoise, turtle' (originally a pictograph), some characters are phonetically 'borrowed'. (N.B.: Pronunciation of characters is given in Mandarin unless otherwise noted.) For example, the originally pictographic character used to write the word for 'wheat' was borrowed to write the then homonymous word 來 *lái* 'to come'. Most characters are actually constructed of two or more parts, of which one part is a 'phonetic' element and another is an often simplified semantic or 'significant' element usually called the 'radical', such as 隹 *zhuî* 'short-tailed bird' (originally a pictograph) and 萑 **zhuî* (now usually pronounced, irregularly, *huán*) 'grass used for making mats', written with the 'grass' radical as the significant and 隹 *zhuî* as the phonetic. Although other examples—such as 魯 *lǔ* 'blunt, stupid; Lu, the home state of Confucius' and its phonetic 魚 *yú* 'fish'—have differences that are important for reconstruction (see below), the phonetic information contained in the script is not by itself sufficient to allow reconstruction of Old Chinese phonological structure. In fact, Chinese is not well attested phonetically until the seventh century CE, when Middle Chinese forms begin to be recorded in Old Tibetan alphabetic script. The phonology of Old Chinese can therefore only be recovered through reconstruction.

Modern reconstructions of Old Chinese nearly all belong to a tradition that may be called Historic Sinological Reconstruction. It derives ultimately from the early Chinese grammarians, on whose work the pioneering Sinologist Bernhard Karlgren based his system of reconstruction. Although the appearance of most Old Chinese reconstructions has changed radically since the publication of Karlgren's etymological dictionary *Grammata Serica recensa* (1957; A Chinese Grammar, Revised), Historic Sinological Reconstruction is still based on the method pioneered by Karlgren.

The most important sources used in the traditional Historic Sinological Reconstruction approach to Old Chinese phonology are: the phonological information derivable from analysis of the characters themselves (mostly mid-second millenium BCE to second century BCE) and their variants or substitutions; the rhymes of the *Shijing* (late first millenium BCE; Book of Songs); Chinese transcriptions of known foreign words (c. first century CE onward); books by Chinese grammarians on dialects and rhymes (first century BCE onward), especially the lost Middle Chinese *Qieyun* (601 CE; Cut Rhymes); the rhyme books, particularly the *Guangyun* (Extensive Rhymes) and *Jiyun* (Collected Rhymes), both from the eleventh century CE; and, above all, the rhyme tables, especially the *Yunjing* (Mirror of Rhymes), from the twelfth century CE. The latter three works, although compiled much later, are based ulti-

mately on the *Qieyun*. However, unlike earlier works, the *Yunjing* organizes the material in tabular form. Historic Sinological Reconstruction of Old Chinese depends heavily on the projection back in time of the categories established by the tables in the *Yunjing*, adjusted according to the rhyme categories implied by the *Shijing* poems and to phonological information derivable from the characters themselves. Change in one part of the system necessarily entails change in many other parts in order to maintain consistent correspondences between the categories of the tables and the phonological categories of Middle Chinese and the modern Chinese dialects, hence the reconstructions of one scholar's system often look radically different from those of another. Unfortunately, Historic Sinological Reconstruction does not allow subperiodization of Old Chinese—contemporary proponents of the method explicitly claim that they are not actually trying to reconstruct a real language spoken by real people in different places and at different times but only a theoretical construct from which all later forms of Chinese can be derived—so it is impossible to systematically use contemporaneous data to check the reconstructions themselves. This results in a tendency to ignore attested data in favor of the system. For example, Sergei Starostin (1989) reconstructs 女 'woman; you (in the latter sense also written 汝)' as Old Chinese **nraʔ* even though overwhelming Oracle Bone Inscription and other evidence indicates that the word initial must have been a bilabial in Early Old Chinese and apparently well into the Middle Old Chinese period. Another result is the production of many unlikely forms, such as Old Chinese **fisrjɨʔ(s)*, the reconstruction of 事 'affair, matter' by William Baxter (1992). Although scholars working in this tradition have made progress toward the reconstruction of Old Chinese, recently their method has been challenged. Reconstructions have been proposed that are not based on the categories of the rhyme tables but on contemporaneous data, emphasizing Old Chinese character variations, loanwords found in neighboring languages, and Middle Chinese reconstructions grounded in foreign transcriptions and the earliest attested text of the *Qieyun* (706 CE).

Early Old Chinese (called by some scholars 'pre-Archaic Chinese'), the language of the Yin, or late Shang dynasty period (fourteenth to eleventh centuries BCE), is preserved mainly in the Oracle Bone Inscriptions, which are divination texts inscribed on bones and turtle shells. These texts have been found in great numbers in the area of the lower Yellow River valley. The syntax of Early Old Chinese, although slightly different from that of the earliest classical texts from a millenium later in the late Middle Old Chinese and Late Old Chinese periods, is already SVO (Subject–Verb–Object) in basic sentence word-order,

as in modern Chinese. Several scholars have argued that Early Old Chinese must have had many disyllabic words or roots. Reconstructable examples include 女 Early Old Chinese *Cwena (where 'C' stands for an unknown consonant) 'woman; you', and 苦 Early Old Chinese *kara 'bitter'. However, Early Old Chinese phonology has yet to be studied in depth.

Middle Old Chinese is essentially the language of the post-Shang bronze and stone inscriptions and the earliest transmitted Classical texts. The inscriptions on bronze vessels are often dated, and cover the period from the early Zhou dynasty (c. 1145 BCE onward) into the Warring States period (475–221 BCE). Some of them contain rhymed passages and variant characters from which phonological information can be derived. The Middle Old Chinese period may be divided into three subperiods: the early Middle Old Chinese of the Western Zhou dynasty, when the capital was located in the area of present-day Shaanxi Province and the prestige language was influenced by the local dialect; the middle Middle Old Chinese of the Eastern Zhou, when the capital moved eastward into another dialect area; and late Middle Old Chinese, the language of the earliest transmitted 'Confucian' classical texts, including the *Shijing*. These periods are marked by phonological changes, partly motivated by prestige-dialect shift when the capital moved to a new dialect region, and partly due to change over time. One example must suffice here. The usual first person singular pronoun ('I') in early Middle Old Chinese is 余 (also written 予) *yú,* but in middle Middle Old Chinese (beginning with the Stone Drum inscriptions, c. fifth to sixth centuries BCE) this word is replaced by 吾 *wú,* which by Late Old Chinese displaces 余 *yú* except in deliberately archaizing texts. The character 吾 *wú* 'I' has as its phonetic element the character 五 *wǔ* 'five', while in other middle Middle Old Chinese texts it is generally written instead with 魚 *yú* 'fish' as its phonetic. Because the Old Tibetan numerals are known to be cognate with (derived from the same historical source as) Chinese, Old Tibetan *lŋa* 'five' is cognate with the Chinese word for 'five'. (Whether the Tibetan numerals are borrowed from Chinese or inherited from a common 'Sino-Tibetan' ancestor is irrelevant for present purposes.) Since 魚 *yú* (from Middle Chinese *ŋɨɔ[1]) 'fish' is also the phonetic in the character 魯 *lǔ* (from Middle Chinese *lɔ[2]) 'Lu', it is clear that not only must the Middle Old Chinese form of the word for 'five' have been close to *lŋâ, but it and the word for 'fish', the first person pronoun, 'Lu', and other words, such as 語 *yǔ* 'speak, speech', were pronounced the same in one or more of the Middle Old Chinese dialects. Because the character used to write the earlier first person pronoun 余 *yú* is also used as a phonetic in other characters, it is reconstructable as *lâ, which derives from an earlier *laCa. It is clear that these

synonyms must be related. Since 吾 *lŋâ, one dialect form of the Middle Old Chinese first person pronoun, may be reconstructed as *laŋa, the other dialect form, 余 *lâ, may be reconstructed as *laɣa, both deriving from an Early Old Chinese *laga or *lege. This word is evidently related in turn to another early first person pronoun, 我 Early Old Chinese *aga or *ege.

During the Middle Old Chinese period, most previously disyllabic morphemes became monosyllabic. This change produced many homonyms by late Middle Old Chinese—such as *lŋâ 'first person pronoun' ~ 'five' ~ 'fish' ~ 'speak'—and resulted in other drastic phonological changes, including widespread metathesis (segments changing place) in one or more dialects. For example, middle Middle Old Chinese *lŋâ 'fish' (from Proto-Chinese *laka) became late Middle Old Chinese *ŋlâ or *ŋrâ. The development of monosyllabism was also probably a major motivation for the eventual development of phonemic tone (intonational pitch distinguishing meanings). The shift to a monosyllabic morpheme structure was largely complete by the time the *Shijing* was recorded.

Late Old Chinese is characterized by a number of phonological changes, including that of the Middle Old Chinese syllable-initial *l to either *y [j] or *d, of Middle Old Chinese medial *l or *r to *ɨ, and of the Middle Old Chinese syllable-final *r to *n or *y [j]. (The rules for these changes are still unclear.) The change of final *r to *n took place in the ancient central dialect and is found in all modern Chinese dialects, but it was not completed in some peripheral dialects, notably in the northeast, where ancient final *r was retained as a syllable coda at least into the Middle Chinese period. Another significant change includes the beginning of what has been called the Great Chinese Vowel Shift, in which the Middle Old Chinese vowel *â (or [aː]) became Middle Chinese *ɔ and Mandarin *u*. Thus, late Middle Old Chinese *ŋlâ (or *ŋrâ) 'fish' became Late Old Chinese *ŋɨâ, Middle Chinese *ŋɨɔ[1], Late Middle Chinese *ŋü[1], and Mandarin *yú* [ü]. Some traces of Late Old Chinese forms are found in the modern Southern Min dialect. (Chinese is otherwise internally reconstructable only back to Middle Chinese.) The written Late Old Chinese of the Former Han dynasty (206 BCE to 9 CE) became the standard Classical Chinese literary language, which continued in use into the twentieth century and is still used for some purposes even today.

Old Church Slavonic

Old Church Slav(on)ic (OCS) is the language of a group of Slavic texts containing copies of religious works, almost all originally translated from Greek. The corpus includes eight parchment manuscripts having 100 or more folia, and an approximately equal number of fragments. A half-dozen inscriptions survive from the same period and area. No manuscript bears an explicit date or locale, but paleographic and linguistic features indicate that most of the surviving manuscripts were copied in the eleventh century CE, with a very small number possibly from the late tenth. The original translations are generally assumed to go back to the second half of the ninth or early tenth centuries, and were connected with the mission of Cyril and Methodius to the Slavs and the activities of their pupils in Bulgaria following the death of Methodius in 885 CE. Every manuscript deviates in some ways from normalized Old Church Slavonic, but as a group they show an Eastern South Slavic dialect which has often been called Old Bulgarian, and it is in fact very close to the reconstructed Late Common Slavic (LCS), which is usually considered to have lasted until around the end of the first millennium CE. With the passage of time, this liturgical and literary language took on certain local characteristics in each area where it remained in use, producing Russian/Bulgarian/ Serbian, etc. recensions of Church Slav(on)ic, which remained mutually comprehensible and collectively served as a common literary language for the Orthodox Slavs and some other peoples, such as the Romanians.

Old Church Slavonic was written in two alphabets: Glagolitic, invented (or, less likely, edited and brought into its final form) by St. Cyril, perhaps with the participation of his brother Methodius, for their mission to the Slavs in the 860s, and Cyrillic, invented later, probably in Eastern Bulgaria, and named in honor of Cyril. Cyrillic was based upon the Greek uncial letters; Glagolitic has no immediately obvious resemblance to any other alphabet, although some features compare suggestively to the Greek cursive of the time. Glagolitic was used in some parts of Croatia until the early twentieth century, but elsewhere (Kievan Rus', Bulgaria, Serbia, etc.) was quickly displaced by Cyrillic, which has remained in use among the Orthodox Slavs until the present day.

Late Common Slavic introduced far-reaching changes to the sound system of late Indo-European (IE). As in some other dialects of IE, *o and *a conflated to *å, with the long vowel giving Slavic a and the short vowel giving Slavic o. IE *ē became LCS *ě (in OCS, a low front vowel [æ]), and IE *ĕ went to LCS *e. IE *ī gave LCS *i, IE *ĭ gave LCS *ь, a high short (lax) front vowel. IE *ū eventually became *y, a high unrounded nonfront vowel (*sūnus > *synъ 'son'), and IE *ŭ became LCS *ъ, a high short (lax) back vowel.

This gave a vowel system with binary oppositions in height, fronting, and length (long/short):

	front	nonfront
high	ī / ĭ	ū / ŭ
nonhigh	ē / ĕ	ā / ă

realized as OCS

	front	nonfront
high	i / ь	y / ъ
nonhigh	ě / e	a / o

plus diphthongs. Those diphthongs in *w and *y were converted to monophthongs: *ow > *u; *ew > *ju; *oy > *ě or *i; *ey > *i. Diphthongs in *r and *l were transposed (*gord- > *grad- 'enclosed area,' *xold- > xlad- 'cold', and diphthongs in *m or *n became nasal vowels (*ronka > *rǫka 'hand,' *sēmen > *sěmę 'seed').

As a result, the vowel system of OCS contained i, ь, ě, e, a, o, y, ъ, u, ę, ǫ, with oppositions based upon front(i, ь, ě, e, ę)/back, high(i, ь, y, ъ, u)/low, rounded(ъ,u, o, ǫ)/unrounded, tense/lax, and oral/nasal.

Slavic is a *satem* language, as shown by such OCS words as *sъto* 'hundred' and *zlato* 'gold.' The consonant system shows only a two-way contrast, between voiced and voiceless, with a division into labial, dental, palatal (*not* palatalized), and velar. Stops were *p b t d k g*, continuants included *s z š ž x*, and the affricates were *c (ts)*, ʒ *(dz)*, č, and in some dialects, ǯ. Sonorants were *m n l r* ń *(=nj)*, ļ *(=lj)*, ŗ *(=rj)*, glides contained *w* and *j*.

LCS syllable structure had undergone a number of significant changes. Syllables in LCS were always 'open' Syllable-closing consonants were dropped: *sup-nos* > *sъnъ* (*sŭnŭ*). The basic syllable formula was *strV*, where *s* stands for *s* or *z*, *t* for almost any consonant, and *r* for a sonorant, although the details are quite complex. The consonant clusters that actually occur can be quite formidable: OCS *umrъštvļǫ* 'I will kill.'

Syllables also showed a type of 'synharmony', where consonants and vowels were subject to mutual accommodation, such as fronting of vowels after *j* or palatal consonants, the 'palatalization' of the velars *k g x* to *č ž š* or *c ʒ s* before a front vowel, or 'jotization' of combinations of consonants with *j*: *sj > š, kj > č*, etc. This produced paired endings and consonant alternations in several instances. For examples of the changes, see the *o/jo* and *a/ja* declensions given below, including the forms of *vlьkъ* and *rǫka* given in the same tables.

Inflected words in OCS may be divided into nominal and verbal groups, with the nominals subdivided into nouns, adjectives, and pronouns. Numerals pattern with nouns or pronouns; 'one' through 'four' and their compounds also show gender agreement.

Both verbs and nouns show number (singular, plural, and dual). Nouns distinguish up to seven grammatical cases marking subject (nominative), direct object (accusative), possession (genitive), location (locative), indirect object (dative), instruments/means (instrumental), and also a form of address(*vocative*). Nouns have inherent gender (masculine, feminine, and neuter). Verbs distinguish six tenses, and have indicative, imperative, and conditional forms; they can be active or passive and indicate completed vs. incompleted actions.

Noun markings in OCS fall into five patterns (declensions); in Indo-European terms they are *o/jo, a/ja,* ĭ, ŭ, and consonant stems. The difference between the *o* and *jo* stems and between the *a* and *ja* stems are due largely to the intrasyllabic changes referred to above as 'synharmony'. The *o* and the ŭ stem endings have intermixed so much by the time the OCS texts were copied that one can no longer really set up ŭ-stems as a separate declension. Consonant stems come in several varieties, e.g. *r*-stems such as *mati*, gen. sg. *matere* 'mother'; *s*-stems such as *nebo*, gen. sg. *nebese* 'heaven'; *en*-stems such as *vrěmę*, gen. sg. *vrěmene* 'time' and *kamy*, gen. sg. *kamene* 'stone'. The productive declensions are the *o/jo, a/ja,* and ĭ-stems. Some of the ŭ-stem endings occur frequently and even become productive in the *o/jo* declension.

Sample Declensions

See Table 1.

Adjectives are inflected and show agreement in gender, number, and case. Masculine and neuter adjectives decline in principle like *o/jo*-stem nouns, while feminine adjectival forms are essentially like those of the *a/ja*-stem nouns. Adjectives also distinguish between definite and indefinite*;* definite adjectives are made from indefinite adjectives by appending pronominal suffixes to the indefinite forms; thus, *nova rěka* means 'a new river,' but *novaja rěka* means 'the new river'; *novo selo* means 'a new village' and *novoje selo* (*o > e* after *j* by 'synharmony') means 'the new village.' The comparative (more...) is formed by suffixation; the superlative (most ...) is made syntactically from the comparative.

Although no single OCS verb is attested in all possible forms, the conjugation of *ved-* 'lead' must have been as shown in Table 2.

Word order in OCS is most often S(ubject) V(erb) O(bject), but can be quite free. It is often quite difficult to know when OCS word order is following that of the Greek from which the text was originally translated and when it represents truly Slavic usage. All grammatical cases except the nominative occur with prepositions, but all, including the locative, occur without prepositions. Under the influence of Greek, OCS syntax often becomes rather convoluted.

OCS vocabulary is primarily of Indo-European, or at least Balto-Slavic origin, although it also contains borrowings from several other sources, including Iranian (e.g. *bogъ* 'god,' *rajь* 'paradise') and Germanic (e.g. *xlěbъ* 'bread,' *kupiti* 'buy'). As one would expect, most of the religious terminology and an overwhelming majority of the abstract, legal, philosophical, administrative, and didactic vocabulary is either direct borrowings or loan translations (calques) from Greek.

CHARLES GRIBBLE

Old English

Old English (OE) is the collective name given to the varieties of Germanic brought to Britain by the Jutes, Saxons, and Angles in the fifth and sixth centuries. The event separating Old from Middle English is the Norman Conquest of 1066. The root *Engl-* in the names *Engl-ish* and *England < Engla-land* 'land of the Angles' represents a form of the Latin and Common Germanic name of the tribe *Angli*. The OE language is also sometimes referred to as Anglo-Saxon (AS), although more frequently a distinction is made between the OE language and AS history, law, literature, culture, etc. The closest linguistic relative of OE is Old Frisian. OE and Old Frisian belong to the West Germanic subgroup of the Germanic branch of Indo-European.

The date usually associated with the beginning of OE is 449 CE, when Germanic-speaking warriors, led by the legendary brothers Hengist and Horsa, sailed to Britain to fight against the Picts at the invitation of the Celtic king Vortigern. From the middle of the fifth century onward, Germanic settlers arrived in Britain in considerable numbers. The Jutes remained mostly in Kent, parts of Hampshire, and the Isle of Wight, and the Saxons occupied the lands south of the Thames, as well as Middlesex and Essex. The Angles spread westward and as far north as the Scottish Lowlands. The Germanic invasions and settlements resulted in the partial displacement of the indigenous Celtic-speaking populations from central England to the more southern, western, and northern parts of the country. The most common periodization of OE is into early OE, from the beginnings to c. 800 CE, classical OE, c. 800–950, and late OE, c. 950–1100.

Two notable historical events that had a profound effect on AS culture and the vocabulary of OE are the conversion to Christianity, initiated by the arrival of St. Augustine in Kent in 597, and the Viking invasions and settlements. The Vikings, who were Scandinavian seafaring warriors, began their raids on Northumbria in the late eighth century. In the ninth century, their attacks culminated in the establishment of a separate administrative unit, the Danelaw (< Dena lagu 'law of the Danes'), which included large parts of the northern, central, and eastern regions of England, roughly northeast of a line linking London and Chester. The treaty which established the Danelaw, negotiated by the West Saxon king Alfred the Great, who ruled from 871 to 889, provided for a relatively peaceful period during the tenth century. At the beginning of the eleventh century, the balance of political power shifted again toward Scandinavia: between 1016 and 1042, England was ruled by the Danish king Cnut and his sons.

Orthography

The earliest OE written records are runic inscriptions dated c. 650–700 CE. They were either records of individual names, or brief decorative messages. The runic alphabet, originally linked to Germanic pagan rituals, was abandoned after the adoption and spread of Christianity during the sixth and seventh centuries. The alphabet used subsequently was a modified form of the Roman alphabet, known as the *Insular hand* in which the letter <s> was written in its long form <ʃ>, and <g> appeared as <ȝ>, known as 'yogh'. The three specifically OE letters, not used in the Roman alphabet, are <æ> 'ash', for the vowel [æ], and <þ> 'thorn' and <ð> 'eth' (or 'ðæt'), used interchangeably for the consonant sounds [ð], as in *that*, or [θ], as in *thump*. Consonant letter combinations specific to OE writing are: <sc>, which represented [sk] for most of the period, but probably also [ʃ] after c. 1000, and <cȝ>, which stood for [ǰ].

Dialects

The three original groups of settlers, the Jutes, the Saxons, and the Angles, maintained their dialect differences throughout the AS period. The main dialects of Old English are Kentish, West Saxon, East Saxon, Mercian, and Northumbrian. Mercian and Northumbrian were two varieties of Anglian, spoken to the south and north of the river Humber. Prior to the Scandinavian invasions, Northumbrian was a dialect of great prestige due to the religious, artistic, and intellectual achievements of the Northumbrian kingdom. After the end of the ninth century, the kingdom of Wessex unified and dominated the rest of the country, and the new political and cultural situation led to the spread of the West Saxon literary norms to the neighboring dialects. West Saxon is the tenth century literary *koiné* of Anglo-Saxon England. Classical West Saxon is the variety of OE described in the standard reference works, and it is also the dialect on which the following descriptions are based.

Phonology

The system of OE stressed vowels consisted of seven short vowels, seven long vowels, and two diphthongs. The colon sign in parentheses is the phonetic symbol for vowel length. Vowel length was not marked in the

OE manuscripts, although many modern printings use the convention of a macron (ˉ) over a vowel letter to indicate that it is long.

Simple vowels   Diphthongs

i(:)   y(:)   u(:)   eo or eə
    e(:)   o(:)   æa or æə
        æ(:)   ɑ(:)

The most important phonological change, which occurred prior to the first OE written records and changed the quality of many vowels in some positions, was *I-Mutation*, also known as *I-Umlaut*. This is a right-to-left (regressive) vowel harmony phenomenon: back vowels became front and low front vowels were raised before /i, j/ in the same word. (The dashed line indicates the direction of the sound change from early OE to late OE and ME.)

i(:)<------ y(:) <——————   u(:)
↑
e(:) <------ ø(:) <——————   o(:)   . . . before /i,j/
↑
æ(:) <————————————   ɑ(:)
The change created stem alternations, depending on whether the stem was used by itself or whether it was followed by an affix containing /i,j/. I-Mutation is responsible for the different vowels in pairs such as *full-fill* (OE full - fyllan < *fulljan 'to fill'), *foot-feet* (OE fōt – fēt < *fōtiz 'feet', pl.), *man-men* (OE mann – menn < *manni- 'men', pl.).

An important quantitative change during the OE period was the lengthening of short vowels before some consonant groups, most notably *-ld, -mb, -nd*. This development, which started during the ninth century, accounts for the historically long vowels in words such as *child, comb, hound, kind*. A third consonant prevented the lengthening; this is the reason for the survival of the short vowels in words such as *children, hundred, kindred*.

Only short vowels could appear in fully unstressed syllables. The most frequent spellings of unstressed vowels are <e>, <o>, or <a>. In late OE, the spelling distinctions for unstressed vowels were disappearing, suggesting that by the end of the period most of the unstressed vowels were neutralized to [ə].

Classical OE had the following consonants:

	Labial	Dental	Alveolar	Palatal	Velar
Voiceless stops	p	t			k
Voiced stops	b	d			g
Fricatives	f/v	θ/ð	s/z	(ʃ)	x,ɣ
Affricates			(č),ǰ		
Nasals	m	n			
Liquids		l, r			
Approximants				j	w

The palatal fricative ʃ and the affricate č are in parentheses because their existence as independent units before the end of the OE period has not been proven. The voiced fricatives v, ð, and z could appear only word-medially when flanked by vowels or nasals and liquids. In all other positions, the fricatives were voiceless. The distribution of these sounds in OE is responsible for present-day alternations of the type *leaf-leaves* (OE *leaf*, sg.-*leafa* gen. pl, *leafum*, dat. pl. 'leaves'), *bath-bathe* (OE *bæþ*, n.-*bæþian* 'to bathe'), *glass-glaze* (OE *glæs*,n.-*glæsen*, adj. 'made of glass, vitreous, glazed'). All OE consonants except the approximants could be doubled in the word-medial position.

Word stress in OE was regularly placed on the first syllable of the root. This correlates with verse composition in OE, where alliteration on the first stressed syllable in each half-line is one of the basic structural characteristics of the line. The most frequent prefixes, *ge-* and *be-*, were never stressed, but some noun and adjective prefixes that retained their lexical meaning could be accented: *óferfyllo*, n. 'repletion' but *oferfýllan*, v. 'feed to excess', *andswárian*, v. 'answer', *ándswaru*, n. 'answer'. In compounds, both roots were stressed on the first syllable, with the first stress stronger than the second: *níed-fàru* 'enforced journey, death', *túngol-wìtega* 'astrologer', *scéarp-ècged* 'sharp edged'.

Morphosyntax

OE was a predominantly synthetic language, which means that the grammatical relations between the words in the clause were expressed by means of inflexional affixes. The nouns had special markings for the following categories:

(a) Number: singular, plural, e.g. *stan* 'stone', sg. *stan-**as*** 'stones', pl.

(b) Case: nominative (for the subject), accusative (for the direct object), genitive (noun modifiers, possessives), dative (indirect and prepositional objects), e.g. *stan-**es***, 'of stone, stone's', gen, *stan -**um*** 'with stones', dat. pl.

(c) Gender: masculine, feminine, neuter. The grammatical gender of a noun was determined by agreement with the demonstrative pronouns and adjectives accompanying it, not by reference to biological sex, e.g. *se stan* 'this stone', masculine, *þæt wif* 'this wife', neuter, and *seo rod* 'this cross', feminine.

The adjectives in OE had separate markings for the same categories as the nouns they modified (number, case, gender). They also varied according to their syntactic placement. The *strong,* or *definite* declension

was used for adjectives which were part of a definite noun group (*se brada sæ* 'this broad sea'), and the *weak*, or *indefinite* declension was selected when the adjective was used predicatively (*wæs þæt rice brad* 'that kingdom was broad'). Like modern adjectives, OE adjectives could be marked for degrees of comparison: comparative (*brad -re* 'broader') and superlative (*brad-ost* 'broadest').

The personal pronouns of OE were: *ic* 'I', *þu* 'thou, you, sg.', *heo* 'she', *he* 'he', *hit* 'it', *we* 'we', *ʒe* 'you, pl'., *hie/hy* 'they'. They agree with the main verb in person (first, second, third) and number (singular, plural). In addition to the familiar singular–plural number distinction, OE had two special 'dual 'pronouns: *wit* 'the two of us' and *ʒit* 'the two of you'. Like the nouns, the pronouns had case forms depending on their syntactic function. Personal pronouns and demonstratives also had three genders: feminine, masculine, and neuter. There were no gender distinctions in the plural.

The OE verbs had inflexions for the following grammatical categories:

(a) Tense: present and preterit, e.g. *fylle- fylde* '(I) fill-filled'; *riseþ-ras* '(she) rises-rose'.
(b) Person: first, second, third, e.g. *fylle-fyllest-fylleþ* '(I) fill-(you) fill-(he) fills'.
(c) Number: singular and plural, e.g. *fylle -fyllaþ* '(I)fill-(we) fill'.
(d) Mood: indicative, imperative, subjunctive, e.g. *fyllest-fyll(a)-fylle* '(you) fill-fill!-(should, would) fill'.

OE had two types of verbs. The 'weak' verbs used a dental suffix: *-de, -te, -ed, -od,* etc., to form the preterit and the past participle; *fylde* 'filled', *(Ʒe)-fylled* 'filled'. Strong verbs changed their root vowel, depending on tense and number: *rise, ras, rison* 'rise-(it) rose-(they) rose'. Modern English survivals of this group are called 'irregular' verbs. Verbs like *bind, choose, drink, eat, ride, run, see* belong here.

Unlike Modern English, which has a very elaborate set of complex verb forms, OE used such forms very sparingly. The verbs *willan* 'want' and *scullan* 'must' were used to express the future tense only occasionally, and the verbs *have* and *be* had not developed their auxiliary functions, as in *we have arrived, we had been traveling.* The predecessors of the Modern English modal verbs, e.g. *cunnan* 'know, be able', *magan* 'be able', *motan,* p.t. *moste* 'be allowed to', were more like the rest of the verbs in the language in that they had tense, person, number, and mood inflexions.

In terms of word-order, OE was, to a large extent, a 'verb-second' language: typically, the inflected verb in main clauses appeared in the second constituent position. The first position could be filled by the subject, by one or more adverbs, and even by an object, although noun objects normally followed the verb; statistically the order V–O was dominant. The subject could precede or follow the verb, depending on whether the first constituent position in the clause was filled and on whether the subject was a full noun or a pronoun.

> On þam twelftan dæge cristes acennednysse *comon* þa þry tungelwitegan…

> On the twelfth day of Christ's birth *came* the three astrologers…

With complex verb forms, the first verb occupied the second position, while the second part of the verb, an infinitive or a past participle, appeared at the end of the clause. Thus, the two parts of the verb formed a 'brace' enclosing all but the very first clause constituent.

> We *sceolon…* mid halgum mægnum þone eard *ofgan…*
> We *must…*with holy virtues this country *obtain…*

In subordinate clauses, the normal position of the inflected verb was at the end:

> Ac heo weron synfulle, þeah þe heo swa ne *wendon…*
> But they were sinful, though they so (did) not think.

The verb *do* was not used as an auxiliary verb in OE. Negative sentences were formed by attaching the particle *ne* 'not' to the left of the verb, and questions required inversion of the verb and the subject. Multiple negation was the norm in OE.

> *Ne* genealæceþ him *nænig* yldo ne sorh ne sar ne deaþ.
> Not approaches him no old age, nor sorrow, nor pain, nor death

Vocabulary and Word Formation

The recorded vocabulary of OE is estimated at approximately 30,000 words. Only about 3% of these were of non-Germanic origin. The number of Celtic borrowings such as *binn* 'bin', *torr* 'rock', is limited. The influence of Latin is most noticeable in religious and learned texts; *abbod* 'abbot', *cantere* 'cantor', *fers* 'verse', and *Læden* 'Latin' are some examples. The most significant outside addition to the OE vocabulary comes from Scandinavian. Although many Scandinavian loanwords were not recorded until after the Norman Conquest, OE is arguably the period during which about 1,000 words were borrowed from Scandinavian. This component of the vocabulary includes everyday words: Modern English words such as *bank, call, fellow, guess, law, leg, loan, score, skill, sky, skin, take* belong in this group. Scandinavian is the source of the pronouns *they, them, their,* and the function words *till* and *though.* There are also about

1,400 Scandinavian place names in the northern and eastern parts of England. These are place names ending in -*by* 'settlement' (*Carnaby, Rugby, Thirtleby*), -*thorpe* 'hamlet' (*Barleythorpe, Grimsthorpe, Fridaythorpe*), -*thwaite* 'clearing' (*Hampsthwaite, Hunderthwaite, Husthwaite*).

OE was extremely resourceful in enriching its vocabulary through derivation and compounding. New items could be derived by prefixation as in *a-sendan* 'send away, dispatch', *in-genga* 'invader', *un-wisdom* 'stupidity'. Frequently used OE suffixes are: -*ere*, as in *fisc-ere* 'fisher', -*estre*, as in *spinn-estre* 'female spinner', -*ing*, as in *cyn-ing* 'head of the kin, king'. Other highly productive OE suffixes were: -*dom, -had, -scipe, -nes(s)* for nouns, and -*ig, -isc, -sum, -en, -fæst, -lic, -leas, -ful* for adjectives. Compounding was another prominent vocabulary enrichment strategy. Some examples are: *heafod-mann* 'head-man, leader', *eorð-cræft* 'earth-craft, geography', *wid-sæ* 'wide-sea, ocean', *mild-heort* 'mild-hearted, merciful'. Metaphoric compounds, or *kennings*, are characteristic of the OE poetic tradition, e.g. *ban-cofa* 'chamber for bones, body', *gar-berend* 'sword carrier, warrior', *guðwudu* 'battle wooden piece, spear'.

Old French

'Old French' refers to the set of dialects spoken in northern and central France from the ninth to the fourteenth centuries. The term is most commonly identified, especially in the later stages, with *francien*, the speech of the Île-de-France region surrounding Paris, because of that variety's central geographic position and its association with the royal court and the burgeoning political, economic, and cultural importance of the capital.

The birth of Old French (henceforth OF) is traditionally linked with the *Serments de Strasbourg* (AD 842), a document containing oaths sworn by the troops of two of Charlemagne's grandsons concerning the partition of his empire. This document contains structures (particularly a new future form) sufficiently different from Classical Latin (henceforth CL) to allow the conclusion that a new language has emerged (although any firm date is clearly artificial—the changes had to have been in effect for some time prior to their appearance in the *Serments*). The early OF period extends from the ninth to the early twelfth century, and constitutes a period of rapid linguistic change and considerable regional diversity. The later OF period (mid-twelfth to fourteenth century) sees the establishment of the University of Paris and the law courts, the flourishing of literary works (by no means limited to the dialect of the Ile-de-France), and the increasing prestige and expansion of *francien*.

How might one characterize linguistically this new language? (We must bear in mind that any summary of five centuries of evolution is inevitably far from complete—we concentrate here on one representation of

the 'classic' forms of the twelfth century and on the major differences leading from Latin through to Modern French [MF].) In its pronunciation, OF lost the distinction between long and short vowels characteristic of Latin; often modified stressed vowels (BREVIS /brĕwis/ > OF *brief* /brjɛf/ > MF *bref*[1] 'brief', HORA /hoRa/ > OF *eure* /ewrə/ > MF *heure* 'hour'); deleted many unstressed or final vowels (except /a/ and those vowels following a final group of consonants [final /a/ becomes /ə/]: MALUM > *mal* 'bad', ARBOREM > *arbre* 'tree', GUTTA > *goute* 'drop'); introduced the affricates [tʃ dʒ ts dz] through palatalization, as in OF *ch*a*lt* 'hot', *jorn* 'day', *cent* 'hundred', *onze* 'eleven', respectively; began a long-term process of vowel nasalization culminating in forms such as MF *un* [œ̃] 'one' < UNUM, *chien* [ʃjɛ̃] 'dog' < CANEM, *pont* [põ] 'bridge' < PONTEM; and deleted or weakened consonants between vowels, as in VITA > *vie* 'life', SAPONEM > *savon* 'soap'.

In word structure, the changes were no less dramatic. The loss of final vowels had profound effects on many grammatically relevant suffixes. Among the nouns and adjectives, the original CL system used suffixes to distinguish five separate classes of nouns, three genders (masculine, feminine, and neuter), two numbers (singular and plural), and six cases (nominative, genitive, dative, accusative, vocative, ablative, each with various syntactic roles indicating, among other things, subject [nominative case], direct object [accusative] and indirect object [dative], possession [genitive], terms of address [vocative], and so on). These were reduced in OF to three classes of nouns, two genders, two numbers, and two cases. With the disappearance of the final vowels, the suffixes disappeared in large part, so that the syntactic distinctions originally indicated by these suffixes were also directly affected. As a result, we see compensating developments in the increased use of prepositions (e.g. *le livre de Cicéron* 'the book **of** Cicero = Cicero's book' rather than LIBER CICERONIS), and OF word order patterns become more constrained than in CL (where, because suffixes indicated the words' function, words could appear in virtually any order depending on stylistic factors [CANEM ['dog–accusative'] HOMO [man—nominative] VIDET > *l'homme voit le chien* 'The man sees the dog']). The determiner system also underwent radical change, with great increases in the use of demonstratives (e.g. OF *cest* 'this', *cel* 'that') and particularly articles (e.g. OF *li, le, la, les* 'the (sg. and pl.)', *uns, un, une* 'a (masc. and fem.)').

Declensional classes for nouns are illustrated below for *murs* 'wall', *rose* 'rose', *ber* 'baron', and *none* 'nun', respectively.

OF declensional classes (major types only, including definite articles; imparisyllabic forms have a different number of syllables in the nominative singular as compared to the remaining forms; 'oblique' refers to an amalgam of all nonnominative cases):

	Masculine	Feminine	Double (Imparisyllabic)	Stems
Nominative singular	li murs	la rose	li ber	la none
Nominative plural	le mur	la rose	le baron	la nonain
Oblique singular	li mur	les roses	li baron	les nonains
Oblique plural	les murs	les roses	les barons	les nonains

(Thus, *La none li baron veit.* 'The nun sees the baron.')

In the verb system, equally striking losses occurred. Many distinctions (passive forms, for example) disappeared completely. A new future tense arose, built with the infinitive and suffixes based on HABERE 'to have': CANTABO (the older form) > CANTARE HABEO 'I have to/will sing' > OF *chanterai* 'I will sing.' Verb endings also eroded, so that person/number distinctions (I, you, he/she/it [sg.]; we, you, they [pl.]), formerly indicated by suffixes, were also threatened. As a result, pronoun use gradually increased, especially in the singular as a way of preserving the former differences.

The form of OF words was significantly more variable than in the modern language. The effects of earlier sound change often resulted in different forms of noun and verb stems that were regularized subsequent to the OF period (OF *truef—trovons* > MF *trouve—trouvons* 'find' [1 sg.—1 pl.]; *serf—sers* > MF *serfs—serfs* 'serf' [sg.—pl.]; OF *larc—large* [masc.—fem.] > MF *large* 'wide'). Fusion of unstressed forms is also widespread: *a le > au* 'to + the (sg.)', *en les > es* 'in + the (pl.)', *je le > jel* 'I + him/it', *ne les > nes* 'neg + them', *qui me > quim* 'who + me', *si me > sim* 'if + me', and numerous others.

In its sentence structure, OF still permitted relatively free word order compared to the modern language, but certain patterns, particularly those where the verb is in the second position in the sentence, began to predominate: subject–verb–object: *Li vilains apele son fil.* 'The peasant calls his son.' [*Fabliaux* 3, l. 39]; the frequent object–verb–subject (– X): *Ses barons fist li rois venir.* 'The king had his barons come.' [*Le roman de Renart*, l. 1807]; *De venoison ont grant plente.* 'They

---

[1] The symbol '>' indicates the direction of development: Latin BREVIS becomes (>) OF *brief*. Conversely, '<' indicates the source: OF *chien* comes from (<) Latin CANEM.

have a lot of venison.' [*Tristran*, l. 1773]; and subject–object–verb: *Li rois Tristran menace.* 'The king threatens Tristran.' [*Tristran*, l. 770]. Given the disappearance of the CL passive verb forms, it is not surprising that replacements of these CL constructions appeared based on *estre* 'to be' plus the past participle (*La pucele fut donc pendue.* 'They hanged the young girl' [*Vie de sainte Marguerite*, l. 1]); on the increased use of pronouns such as *on/l'en* (*On me desrobe en vostre terre.* 'I am being robbed in your land.' [*Fabliaux* 11, l. 191–2]); or on the expansion of constructions with the reflexive pronoun *se* (*Carles se dort.* 'Charles falls asleep.' [*Chanson de Roland*, l. 724]). OF sentence patterns, in other words, remind us much more of the modern language than of CL.

In vocabuary, the Latin origins of OF are clear —the great majority of lexical items descend directly from Latin, although often from informal or popular rather than classical speech. In addition to popular items, which have become the norm (TESTA 'jug' > OF *teste* 'head'; CABALLUS 'nag, packhorse' > OF *cheval* 'horse'; GENUS 'knee' — GENUCULUM [vernacular diminutive form] > OF *genoil* [Modern French *genou*] 'knee'), we see innovative use of many suffixes (e.g. OF *-age* used to indicate taxes of various types: *abeillage, arivage, cheminage, melage* [on bees, docking, roads and apples, respectively]; Germanic loans from the early Frankish conquerors (*biere* 'coffin', *helme* 'helmet', *honte* 'shame'); learned words entering from religious or legal texts (*avaricieux* 'avaricious', *crestiien* 'Christian', *testimonie* 'testimo-

ny'); and importations from a variety of other sources (Celtic *chemin* 'road', *if* 'yew tree'; Arabic *alchimie* 'alchemy'; Greek *eglise* 'church'; Occitan *amour* 'love' [notably via the influence of the Troubadour poets], and many others). Nonetheless, the unmistakably major lexical source is Latin.

But despite this parentage, OF is clearly French, no longer a 'corrupted' Latin, and has distanced itself from its origins much more than such well-known Romance relatives as Italian, Occitan, Catalan, or Spanish. While not easily comprehensible to modern readers, it leaves a stong impression of familiarity, and should inspire us as a source of great cultural and linguistic richness.

Old High German

The German language is estimated to be about 1,500 years old based on the earliest written sources, though as a spoken language it is almost surely older. Old High German is the traditional designation of the German language in its earliest stage, roughly between the years 750 and 1050 CE (some scholars use the period 600–1100).

German is a member of the Germanic subfamily of the 'centum' branch of the Indo-European language family. The linguistic features that set Germanic off against other Indo-European languages are several, principal among which are the First Sound Shift (also called the Germanic Sound Shift, the First or Germanic Consonant Shift, or Grimm's Law), Verner's Law, the

fixing of main intonational stress on the initial syllable of the word, and a variety of vowel changes.

The origins of the Germanic peoples—the speakers of the ancestor language Proto-Germanic—are cloaked in mystery, as indeed are the origins of the Indo-Europeans. We are relatively certain that sometime prior to 1000 BCE Germanic-speaking people occupied their primeval home (*Urheimat*) in what is today the area comprising southern Sweden and Norway, Denmark, and northern Germany. Between 1000 BCE and 500 BCE, at least some of the Germanic tribes began to move away from their original home, migrating farther north or striking out to the south and the east. The reason for this migration was doubtless due in

part to inundation of the *Urheimat*, much of which is covered today by the relatively shallow North Sea.

Out of this *Völkerwanderung* ('migration of peoples') arose the traditional classification of the Germanic languages into East, North, and West Germanic. German belongs to the latter group, as do English, Dutch, Frisian, and Low German. We know nothing for certain about the people who occupied this territory before the Germanic tribes arrived. We know nothing about the early contacts between the Germanic intruders and the autochthonous inhabitants of the *Urheimat*, nor do we know what language(s) the latter spoke. The general rule of thumb in historical linguistics is that the greater the degree of contact between languages, the greater the amount of language change. The changes in pronunciation and vocabulary that Germanic languages underwent (the First Sound Shift and others) were extensive compared with more conservative Indo-European languages. Moreover, approximately one-third of the vocabulary of the Germanic languages is from other than Indo-European stock. Therefore, we assume that contacts with the autochthonous inhabitants were deep and extensive—and that the languages of these speakers had many fricative consonants (the source of English *f, th, s, sh*).

While there are competing representations for illustrating the relationships among the Germanic family depending on which criteria are given priority, the most widely used and traditional genetic classification of the Germanic languages is a tripartite one into East, North, and West. The family tree (stammbaum) of Proto-Germanic can be represented (and simplified) as follows. (The terms 'Ingvaeonic' and 'Istvaeonic' refer to the names of Germanic tribes; 'North Sea Germanic' and 'Weser-Rhine Germanic' are used almost interchangeably with 'Ingvaeonic' and 'Istvaeonic'. Old Low Franconian gave us Dutch, and Old Saxon was the ancestral language of modern Low German, which is spoken today in northern Germany.) (See Figure 1.)

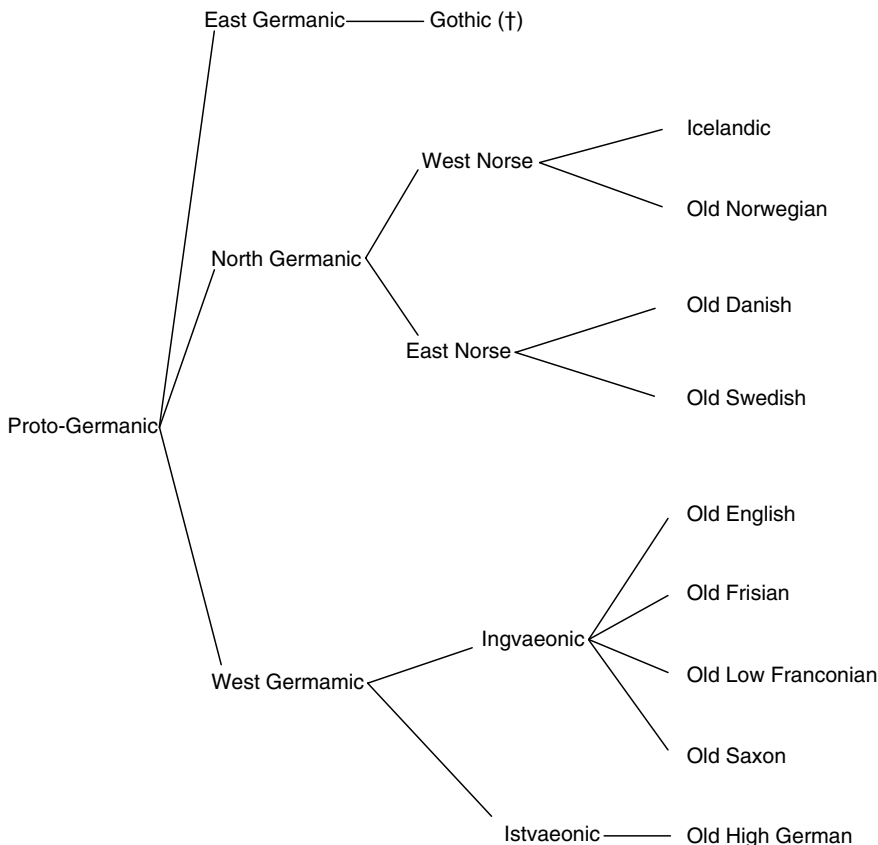
The principal linguistic change that set Old High German apart from its other West Germanic sibling languages was the Old High German Consonant Shift, also called the Second Consonant Shift or the Second Sound Shift. This, along with the First Sound Shift differentiating Germanic from Indo-European, is one of the most illustrious sound changes in Germanic linguistics. It affected the voiceless stops /p t k/, changing them according to the phonetic environment into affricates /pf ts kx/ or fricatives /f s x/, the latter of which could occur as both long (geminated) /ff ss xx/


Figure 1

and short /f s x/. In general outlines, the Old High German Consonant Shift went as follows:

Pre-Old High German		Old High German	Phonetic Environment
p t k	>	pf ts kx	Word-initially and following m, n, l, r
	>	ff ss xx	Medially following a short vowel
	>	f s x	Medially following a long vowel and word-finally

We can see the effects of the Old High German Consonant Shift from a comparison of modern German words with their English cognates:

Modern German	English
Pfund	pound
Pfeffer	pepper
Wasser	water
machen	make
Zeit	tide
helfen	help
auf	up
kochen	cook

An additional sound change of Pre-Old High German *d* to Old High German *t* is considered by some linguists to be part of the Old High German Consonant Shift. Its effects are seen in cognates such as English *do, day, ride* vs. German *tun, Tag, reiten.*

The designation 'High' has two meanings in the context of High vs. Low German. On the one hand, it is a purely linguistic designation for those dialects of West Germanic that underwent any part of the Old High German Consonant Shift. Its original meaning in this context, however, referred to altitude: those dialects of German that did not undergo the Old High German Consonant Shift are located in northern Germany on the flatlands bordering the North and Baltic Seas—'low lying'in other words, hence 'Low' German—and the dialects of German that did undergo the Old High German Consonant Shift are located in the higher regions of southern and central Germany, Switzerland, and Austria, thus 'High German'. One occasionally encounters the use of 'High' to mean 'good, correct, elevated, superior, grammatical' and 'Low' to mean the opposite, linguistically, of those qualities. One does not encourage this usage.

Old High German is divided into Central German and Upper German dialects. Upper German consists of those dialects spoken in southern Germany, Switzerland, and Austria. The principal Upper German dialects of Old High German are Alemannic, spoken in present-day Switzerland, and Bavarian, spoken today in the German state of Bavaria and in Austria. Central German dialects are spoken in an east–west band lying between Low German in the north and Upper German in the south. The principal Central German dialects are Franconian (Middle Franconian, Rhine Franconian, East Franconian) and East Central German, which overlaps with Thuringian, Upper Saxon, and Silesian.

Upper German dialects are characterized by greater completeness in the effects of the Old High German Consonant Shift. It is assumed therefore that the Old High German Consonant Shift began in the far south and spread toward the north: the underlying idea is that sound change goes further toward completion in the area it has been around in longest. Most Upper German dialects have all of the changes stated above as comprising the Old High German consonant shift. Central German dialects show more mixed results. Central German dialects are most consistent in the shift of *k* to *x* and less consistent in the shifts of *t* to *s* and *p* to *f.* Thus, where Upper German dialects will consistently have fricatives in **ich** 'I', *dorf* 'village', and *das* 'that', Central German dialects can be found with **ich**, *dorf, dat* and **ich**, *dorp, dat.*

The distinctive sounds of Old High German are:

Vowels

Short		Long		Diphthongs	
i	u	ī	ū	ei	ou
e	o	ē	ō	ie	uo
a		ā			

Consonants

		Labial	Dental	Palatal	Velar	Glottal
Stops	vl.	p	t		k	
	vd.	b	d		g	
Fricatives	vl.	f	s̲	ṣ	x	
Affricates	vl.	p^f	t^s		k^x	
Nasals		m	n			
Liquids			l		r	
Semivowels		w		y		h

([s̲] and [ṣ] are respectively dorsal—formed with the blade of the tongue against the alveolar ridge—and apical—formed with the tip of the tongue against the alveolar ridge. They have different historical sources: [s̲] is created by the shift of *t* to *s* in the Old High German Consonant Shift; [ṣ] continues Indo-European *s*).

The back vowels [u o a ū ō ā] had front variants [ü ö æ ǖ ȫ ǣ] before syllables containing a high front vowel or semivowel [i ī y], thus *gesti* 'guests', *skôni* 'beautiful', and *ubil* 'evil' were phonetically [gesti skoni übil]. These are the so-called 'umlaut' sounds of German (*Gäste, schön, übel*).

The German language is traditionally divided into four periods: Old High German (750–1050); Middle High German (1050–1350); Early New High German

(1350–1650); and New High German (1650–present). The division between Old High German and Middle High German is dated from the reduction of the unstressed vowels [i e a o u] into a single sound schwa [ə]. Since this did not occur in a single day, the transition from Old High German to Middle High German is variously placed between 1050 and 1100, at which time the reduction of unstressed vowels to schwa was complete except in remote and isolated dialects. From the beginning of the Common Era, Old High German was in contact with Romans during the expansionist phase of the Roman Empire. Lexical borrowings were heavy, and their semantic domains reveal much about the nature of these early contacts: 'wine' (Old High German *wîn*, Latin *vinum*), 'arrow' (Old High German *pfîl*, Latin *pilum*).

The earliest written records of the Old High German language are words and fragments written in runes. Somewhat later, after the Germanic tribes had been Christianized, we find Old High German glosses interspersed in Latin texts. In the *Vocabularius Scti Galli*, slightly later than 765 CE, we find *sapiens wizzo* (in normalized Old High German spelling), *scitus wiser, fortis stark*. Lengthier texts are found beginning in the ninth century, many of them translations into Old High German of religious writings originally in Latin: Isidor's diatribe *Contra Judaeos*, the *Weissenburg Catechism*, the gospel harmonies *Tatian* and *Otfrid*, and the translation of Boethius made by Notker, an especially talented monk from the monastery of Saint Gall in Switzerland.

Typical of the genre of most early Old High German writing is the Lord's Prayer from St. Gall:

> Fater unsêr, dû bist in himile, wîhi namun dînan, kweme rîhhi dîn, werde willo dîn, sô in himile sôsa in erdu. brôd unsêr emezzihig gib uns hiutu, oblâz uns skuldi unsêro, sô wir oblâzêm uns skuldîgêm, enti ni unsih firleiti in khorunka, ûzzer lôsi unsih fona ubile.

Typical too were 'How to say it in Old High German' booklets such as the 'Conversations from Paris', written presumably for monks literate in Latin for traveling in Germany (the unnormalized spelling of Old High German points clearly and amusingly to the French background of the monk who wrote the thing):

> Gueliche lande cumen ger? (de qua patria?) 'What land do you come from?'
> Guer is tin erro? (ubi est senior tuus?) 'Where is your master?'
> Ne guez. (nescio.) 'I don't know.'
> Gimer min ros. (da mihi meum equum.) 'Give me my horse.'

Of particular cultural and historical interest are the 'Oaths of Strassburg', which date from 843. These are oaths of allegiance intended to end a fratricidal rivalry between the kings Louis and Charles of the Franks, sons of Charlemagne. Because the eastern Franks spoke Old Low German and the western Franks Old French, the oaths were composed in both languages, thus giving us linguistic information as useful for a student of the history of the French language as for a student of the history of German.

There is in Old High German a certain amount of original composition not derived from Latin translations and more substantial than 'give me my horse'. The *Muspilli* is a religious poem of some length that is strikingly original, what we have of it, and in the later Old High German period there are *Memento Mori* and *The song of Ezzo*.

It must be admitted that Old High German literature is inferior in comparison with the contemporaneous literature of Old English (*Beowulf*) or even its close relative, Old Saxon (*Heliand*). It is vastly inferior to the rich medieval literature of Middle High German with its courtly epics, its *Nibelungenlied*, its poetry. Old High German literature is not equal to the slightly later literature of Old Icelandic. There is very little original in Old High German literature, much that is derivative.

However, its literary deficiencies should not detract from its linguistic importance. It was the language of the Second Sound Shift, the Old High German Consonant Shift, which along with the First Sound Shift (Grimm's Law) and Verner's Law is one of the great defining phonological events in the Germanic family of languages. The Old High German Consonant Shift—its causality, its spread, how it happened—has provided and continues to provide historical linguistics with grist for its theoretical mill. The importance of a language must never be judged by its literature alone.

Old Irish

Old Irish is a now extinct Indo-European language belonging to the Insular Celtic branch of the Celtic language family. Insular Celtic is that branch of Celtic that is (relatively speaking) indigenous to the British Isles. Old Irish is the direct ancestor of present-day Irish, as well as of Scots Gaelic and Manx.

Within earlier Insular Celtic, it is possible to distinguish two major dialects, known respectively as Q-Celtic (sometimes called Goidelic or Gaelic) and P-Celtic (sometimes called Brythonic or Britannic). These labels have been retained by linguists to classify the later distinct Celtic languages. Q-Celtic is so called because it shows /k/ as the descendent of an original Indo-European /*kʷ/. (The name 'Q-', rather than 'K-', Celtic originates in Latin spelling.) In contrast, P-Celtic shows /p/ as the descendent of /*kʷ/. Irish, along with Scots Gaelic and Manx, belongs to the Q-Celtic group, while the P-Celtic group contains Welsh and Cornish, as well as Breton. We may contrast the development of the inherited word for 'four', which in Old Irish became _cethair_ but in Old Welsh became _petguar_.

The earliest surviving evidence for Q-Celtic comes from inscriptions written in the native Ogham alphabet, which date from the fourth to seventh centuries CE. These consist primarily of proper names, and so the amount of grammatical information that they can provide is limited; however, they do provide information about the sound system and word structure of Q-Celtic in the immediately pre-Old-Irish period.

The Old Irish period proper is normally considered to fall between 600 and 900 CE, and it is from this period that the earliest literary evidence for Irish comes. Within the Old Irish period are sometimes further distinguished an Archaic Old Irish period (prior to the 700s CE) and a Later (or Classical) Old Irish period (the 700s and 800s CE). Ogham writing, incidentally, continued to be taught until around the seventeenth century, but its role after the inscriptional period of Q-Celtic was greatly restricted and most Old Irish material is thus written using a form of the Roman alphabet.

The corpus of contemporary texts that represents Old Irish is relatively limited in both size and genre. The most important texts, dating from the Classical Old Irish period, consist of marginal notes (or 'glosses') on Latin manuscripts. Of these, the most important are the Würzburg glosses, dated mainly to around 750 CE, the Milan glosses, normally considered to date from sometime before 825 CE, and the St. Gall glosses, dating in manuscript from around 845 CE but containing copies of earlier material. To these texts can be added a number of further sources consisting of additional glosses as well as a small number of continuous texts such as poems. In addition to the Classical Old Irish texts, there also exist a small number of older texts from the 600s CE.

It is generally agreed that further Old Irish material is also preserved in later manuscripts, and, indeed, it has been argued that some of this material illustrates a period of Old Irish that pre-dates the earliest contemporary manuscripts. Certainly, some of these texts do show differences in comparison with other texts of the same date, notably in word order. However, this is a disputed area, and it has been argued convincingly that at least some of this variation may be due more to genre than to date. The texts may also have come under the influence of Latin models, and some of their distinctive characteristics may in part reflect interference from Latin. Thus, the contemporary Old Irish manuscripts still form the main, and safest, basis for the linguistic description of Old Irish, although scholars vary as to how far they will admit evidence from the later manuscripts.

The Old Irish texts that have come down to us are linguistically very homogeneous and show rather little evidence of dialect variation. The classical view has been that what variation does exist is due to differences in date, although it has been tentatively suggested that these differences do, in fact, reflect dialectal variation. Certainly, the relative homogeneity of the Old Irish sources should not be taken to indicate that some degree of dialect variation did not exist within Old Irish; indeed, it would be unusual if this were the case, since the language was spoken in the whole of Ireland and in a large part of Scotland. We do not know how small or substantial these dialect differences may have been in the spoken language. As regards the homogeneity of the literary sources, it should be remembered that they were written by scholars in monastic communities, and some degree of dialect mixing, and possibly informal standardization, will undoubtedly have taken place.

The vocabulary of Old Irish is predominantly of Q-Celtic origin, but also contains substantial loan material, primarily from P-Celtic and from Latin. Some of the Latin loans have undergone sound changes that suggest they were borrowed indirectly via P-Celtic, while others seem to have been borrowed directly.

In structural terms, Old Irish has a number of features that are interesting from a historical and comparative perspective.

On the one hand, the evolution of Old Irish to modern Irish shows trends toward the breakdown of complex systems of functional endings (inflexions), simplification, and the atomization of meaning-carrying elements that are paralleled in other language groups—for instance, in the development from Latin to modern Romance languages such as Italian and French.

In the noun, for instance, Old Irish maintained a complex set of inflexions: for example, it had special dual forms for pairs of things, as well as a set of five case endings indicating grammatical relations such as subject, object, and possession. The same was also true of the adjective, which agreed with the noun that it modified. Although already largely obsolete in Old Irish, owing to the emergence of a fairly fixed word order, this system of endings was to be retained well into the modern Irish period (up to the 1600s CE). However, it has since broken down substantially, and must already have been breaking down at an earlier date in the spoken language. Some modern Irish dialects have practically abandoned noun inflexion, and even the more conservative standard written language uses a reduced set of endings.

The Old Irish verb, too, was exceptionally complex, and has consequently received much attention from linguists. The basic distinction was between simple verbs and complex verbs, that is, those that were formed from simple verbs by the addition of various preverbal elements. For instance, from *beirid* ('bear') could be derived compound verbs such as *do·beir* ('give'), *for·beir* ('grow'), *as·beir* ('say'), and *tremi·beir* ('transfer'). In addition to these compounding preverbal elements, other preverbal affixes existed: for example, *ro* was used to distinguish, among other things, between the perfect and simple past (contrast English 'I have run' and 'I ran'). Each of the two classes of verb had, in turn, two full sets of personal endings, which were used in parallel to one another, depending on the grammatical context: in the simple verb, they were known as absolute and conjunct endings, and in the compound verb as prototonic and deuterotonic endings. In addition, there were special endings in the simple verb to indicate a verb's participation in a relative clause. Furthermore, as with other languages such as Latin, pronoun subjects were not expressed, and the meaning was carried by endings (contrast the unchanging *bear* in English 'I bear' and 'you bear' with Old Irish *biru* ['I bear'] and *biri* ['you bear']). One of the main changes distinguishing Old Irish from later periods of Irish is the breakdown, and consequent simplification, of this complex verbal system, notably the disappearance of the two sets of absolute and conjunct endings and the near disappearance of the prototonic and deuterotonic distinction.

On the other hand, Old Irish also has features that are characteristic of itself and of the wider Celtic language family, in contrast with other Indo-European languages.

In common with the other Celtic languages, Old Irish has Verb–Subject–Object as its basic word order. The Celtic languages are the only Indo-European languages to have this as their basic word order. There has been some discussion about the emergence of this word order in Old Irish. One suggestion has been that it is the consequence of generalizing the order that resulted from suffixed pronouns (see below).

In Old Irish, as in other Celtic languages, the boundaries between the different language levels of sentence structure, word structure, and sound structure are not discrete. For instance, the initial sounds of Old Irish words can change in certain contexts (so-called 'mutations'). These changes were originally triggered by the final sound in the preceding word, but a number of these sounds later disappeared and the pattern of mutation was also extended by analogy to other contexts. Some mutations thus came to be used to mark grammatical relationships, rather than being the result of local phonetic influence. This is the case, for example, in certain kinds of relative clause, where the main verb of the relative clause undergoes mutation. Thus, sentence function triggers a change in wordform, which was originally phonetically motivated.

A further peculiarity of Old Irish is the frequency with which certain grammatically interrelated words within a sentence or clause are fused into a single word unit, where, in contrast, other languages (such as English) would normally use two or more free-standing words. One example of this is the situation where the object of a verb is a pronoun. In Old Irish, pronoun objects were often suffixed to the verb, rather than standing on their own as separate words–for example, *beirthi̱* ('bears it') or *iurru̱s* ('will wound them'). Following one of the preverbal elements referred to earlier, a pronoun could actually become infixed within the verb—for example, *ro·m̱·gab* ('has taken me'). In contrast to this Old Irish tendency, pronouns in modern Irish may also be free-standing, and the use of this option is becoming increasingly frequent, at the expense of the suffixed pronoun construction. A related phenomenon, which modern Irish has retained, is the case of the so-called 'conjugated prepositions', in which forms of the pronoun are also suffixed to prepositions, resulting in 'one-word' expressions such as *lat* ('with you', from *la* = with and *-t* = you).

Aside from its importance as a crucial chapter in the history of modern Irish and the other Q-Celtic languages, Old Irish is linguistically important more

generally for two main reasons. Firstly, from a historical perspective, it provides further evidence for the universality of certain principles of language change. Secondly, it is interesting typologically, in that it exhibits a number of features not normally found in Indo-European languages outside the Celtic language family.

Old Japanese

Old Japanese is the oldest attested representative of the Japonic (Japanese-Ryukyuan) language family. There are two major varieties of Old Japanese: (1) Western Old Japanese (seventh to eighth century CE), a language based on the dialect of Asuka and Nara regions (roughly corresponding to modern Nara prefecture); and (2) Eastern Old Japanese (eighth century CE), a dialectal continuum located roughly in the southern part of the modern Chûbu and Kantô regions. Western Old Japanese was the basis of the literary language of the time, and consequently there are many more extant Western Old Japanese texts than Eastern Old Japanese texts. Furthermore, it is quite apparent that the westernmost dialects in the Eastern Old Japanese dialect continuum were considerably influenced by the Western Old Japanese standard, and this influence gradually diminishes from west to east. There is a widespread but mistaken opinion that Western Old Japanese is practically identical to Middle (Classical) Japanese. On the contrary, both languages are very different, with a number of important distinctions found in pronunciation, vocabulary, and grammar. Furthermore, Western Old Japanese is not even a direct predecessor of Middle Japanese: both are based on geographically close but not identical dialects.

Sources: All Eastern Old Japanese and most Western Old Japanese texts are poetry, although Western Old Japanese also has two texts that are written in prose. The major noninscriptional texts are: poetry from the 'Kojiki (Records of Ancient Matters)'

(712 CE), the 'Nihonshoki (Annals of Japan)' (720 CE), and the 'Fudoki (Gazeteers)' (713–737 CE); poetic anthology 'Man'yôshû (Collection of myriad leaves [of words])' (c. 759 CE), prose texts 'Senmyô (Imperial Edicts)' (seventh to eighth century), and 'Norito (Liturgies)' (seventh to ninth century). There are several important inscriptions as well, the largest of them being a poetic one: 'Bussoku seki uta (Songs of the Buddha's footprint)' (c. 755 CE).

Writing system: Western Old Japanese uses the writing system known as 'man'yôgana' (the 'Man'yôshû' writing). Man'yôgana is a syllabic system of writing, where Chinese characters are used phonetically (to represent syllables), although they can also be used logographically (to represent words or concepts). When Chinese characters are used both phonetically and logographically, there is a clear tendency to write roots or stems logographically and suffixes and particles phonetically; however, due to the syllabic nature of writing, the exact boundaries between stems (especially verbal stems) and suffixes may not be reflected in writing. Man'yôgana can be subdivided into two major types according to the historic stage of the underlying Chinese pronunciation of the characters on which man'yôgana is based. The later type is based on the Late Middle Chinese character readings of the eighth century, and it is used exclusively in the Nihonshoki. The earlier type is based on the Early Middle Chinese character readings of the sixth to seventh century; most likely it was not coined

directly in Japan on the basis of these readings, but was borrowed from Korea. All other Western Old Japanese texts use this earlier type of the man'yôgana. Eastern Old Japanese also uses this type of Western Old Japanese writing system, and it is necessary to note that all Eastern Old Japanese texts are essentially written in Western Old Japanese orthography.

Phonology: Western Old Japanese has the following consonants: *p, b [ᵐb], t, d [ⁿd], k, g [ᵑg], m, n, s, z [ⁿz], w, y, r*. No consonant is possible in the syllable-final position; thus, only syllables of C(onsonant)V(owel) and V structure are found in the language. Consonants *b, d, g, z,* and *r* occur only in word-medial position in native vocabulary. There are no sequences *wu and *yi in Western Old Japanese, but the rare exceptions to the general syllable template of [C]VCVCV…, like *kai* 'oar', suggest that at least the sequence *yi existed once at the pre-Western Old Japanese stage. The Eastern Old Japanese consonant system seems to be identical to Western Old Japanese.

Western Old Japanese vowels include the following vowels (Yale notation is given with the most likely phonetic values in brackets): *a [a], yi [i], u [u], iy [ï], ye [e], o [ə], wo [o]*, and one diphthong *ey [əy],* which was previously considered to be a unit vowel *[ɛ]*. The contrast between vowels *yi/iy, ye/ey*, and *o/wo* that later merged as /i/, /e/, and /o/ is not found in every possible position even in Western Old Japanese. Thus, there is no contrast in initial position for any of the three pairs; there is no contrast between *yi/iy* and *ye/ey* after coronal consonants (such as *t, d, s, z*), and a suggested contrast between *po* and *pwo* is questioned by some linguists, although it is likely that there is some supportive evidence for it in the earliest texts. In all cases where there is no contrast, it is customary to write just *i, e, o*.

The set of Eastern Old Japanese vowels is markedly different: it includes only five vowels: *a, i, u, e, o*, although there is the possibility that one or two additional vowels can be hidden behind the Western Old Japanese spelling system. In any case, vocalic correspondences between Western Old Japanese and Eastern Old Japanese are not straightforward, indicating that a parent language of both used to have a system somewhat different from its descendants.

Data on Western Old Japanese accent system are controversial: it has been suggested that in the 'Nihonshoki', Chinese characters with level tone were used to transcribe Western Old Japanese low pitch and Chinese characters with other tones to transcribe Western Old Japanese high pitch, but it appears to be true only statistically.

Lexicon: Japanese poetic texts did not use words that, at the time, were obvious loanwords until quite late, so poetic texts contain only native vocabulary and nativized loanwords, such as e.g. *uma* 'horse', *umey* 'plum blossom' (both from Old Chinese *mra and *mɨ), and *tera* 'Buddhist temple' (from Old Korean *tyerV). A few loanwords can be seen in prose texts, most from Chinese or Sanskrit (via Chinese intermediary).

Morphology: The description of word structure and word formation in the present article is based on Western Old Japanese, because of its prestigious nature and due to the less complete data from Eastern Old Japanese. Both Western Old Japanese nominal and verbal morphology are significantly different from any later stages of the language, including Middle Japanese (morphological elements and their functions typical only for Western Old Japanese and not found in later stages of the language are indicated in bold typeface).

Nominal morphology: Most nominals (with the exception of some pronouns) in Western Old Japanese have no formal markers, distinguishing them from other parts of speech, e.g. *yama* 'mountain', *pyito* 'person', *yukyi* 'snow', *myidu* 'water', *piy* 'fire', *puta* '2', *towo* '10'.

The following is the list of the most frequent WOJ affixes. Nominal prefixes: honorific *myi-,* intensive *ma-,* dimunitive *wo-* and *kwo-,* locative **sa-.** Plural suffixes: *-ra* (**neutral** plural marker), *-domo, -tati,* **-na.** Case markers: active-**i**, possessive *-ga,* genitive *-no,* genitive-locative **-tu,** dative-locatives *-ni* and **-ra,** accusative-**absolutive** *-wo*, comitative *-to*, ablative **-ywo/-ywori/-yu/-yuri,** directives **-gari** and *pye,* comparative **-no/-ni/nasu/-nosu,** and terminative *-made*. Dimunitive suffixes: **-ra, rø -kwo.**

Some Western Old Japanese pronouns have two stems: unextended, and extended with suffix *-re*, which may be treated as a formal marker of these pronouns, distinguishing them from other parts of speech, and also from other pronouns that do not have the special stem in *-re*. Personal pronouns: *wa-/ware* 1ps and 1pp (rare), **a-/are** 1ps, **na** 1ps, **na-/nare** 2ps and 2pp (rare), [myi]masi 2ps, **si/so-** 3ps. Reflexive pronoun: *ono-/onore*. It is necessary to note that Middle Japanese has a unified system of personal reflexive pronouns (...self), which does not exist in Western Old Japanese or Eastern Old Japanese. Demonstrative pronouns: proximal *ko/kore* 'this', mesial *so/sore* 'that', distal *ka/kare* 'that over there'. Demonstrative pronouns indicating place or direction: proximal: *koko, koti, konata* 'here'; mesial: *soko* 'there'; distal: *kanata* 'over there'. The distal forms in Western Old Japanese and Eastern Old Japanese may be an innovation, as they are rather rare. In Western Old Japanese there is another distal demonstrative pronoun **woti/woto/wote** that is used more frequently than *ka/kare*, but its usage is predominantly limited to indicating distal place or

time. Interrogative pronouns: *ta-/tare* 'who', *nani* 'what', *ika* 'how', **idu/iduku** 'where', *iduti* 'where to', *idure* 'which', *itu* 'when', **iku/ikuda/ikura** 'how many', *nado/nazo* 'why'. Collective pronouns: *miyna*, **mor̯o** 'all'.

The numerical system of Western Old Japanese sharply contrasts with later stages of the language; numerals of Chinese origin are not yet used, or at least they are not present in the texts. The main problem with attestation of numerals is that they are frequently written logographically, and the phonetic attestations are lacking. The following cardinal numerals are attested phonetically: *pyit̯o* '1', *puta* '2', *myi* '3', *y̯o* '4', *itu* '5', *mu* '6', *nana* '7', *ya* '8', *k̯ok̯on̯o* '9', *t̯owo* '10'. After *t̯owo* '10', attested tens include *pata* '20', *myi-swo* '30', *y̯o-swo* '40', and *ya-swo* '80'. There is only one phonetic attestation of a numeral including both tens and digits: *myiswo-ti amar-i puta-tu* '32' (30-class exceedinf 2-class) that, alongside later glosses to numerals written logographically in Western Old Japanese texts, provides us with the way in which the digits were added to tens: tens + classifier + infinitive of the verb *amar-* 'to exceed' + digit + classifier. Among higher numerals, only the following are attested phonetically: *mwomwo* '100', **i-pwo** '500', **ya-pwo** '800', *ti* '1,000', *y̯or̯odu* '10,000'. The system of classifiers is in its infancy, and only the following classifiers are attested: *-tu* (objects used with digits), *-ti* (objects used with tens and hundreds), *-ri* (people), **-mot̯o** (grassy plants), *-pye* (layers and folds), *-ka* (days).

Verbal morphology: One of the greatest differences between Western Old Japanese and all later stages of the language is that quality verbs like modern Japanese *siro-i* 'white' or Middle Japanese *siro-ki* 'id' are still in the process of formation. This is because in Western Old Japanese stems of quality verbs can still behave as regular adjectives: e.g. <u>*sira* namyi</u> '<u>white</u> waves', <u>*opo* kapa</u> '<u>big</u> river', cf. Middle Japanese <u>*siro-ki* nami</u> 'white waves' and <u>*opo-ki* kafa</u> 'big river' with the obligatory attributive suffix *-ki*, which is not obligatory in Western Old Japanese. Therefore, Western Old Japanese adjectives are in transition from nominals to verbs.

Western Old Japanese verbs are divided into several classes: consonantal verbs, with roots ending in a consonant (*yuk-* 'go', *kyir-* 'cut', *omop-* 'love, think', *n̯ok̯os-* 'leave', etc.), vowel verbs, with roots ending in a vowel (*kwopiy-* 'love', *tasukey-* 'save', *myi-* 'see', *miy-* 'turn', etc.), and irregular verbs (*k̯o-* 'come', *se-* 'do', *ar-* 'exist', *sin-* 'die', *in-* 'go [away]'). In addition, there are defective verbs—*n-*, *t̯o* 'be', *t̯o* 'say'— that have only a limited number of forms and are irregular as well.

Western Old Japanese verbs can take both prefixes and suffixes. The prefixal position is limited to one slot, whereas suffixal positions are multiple. There are a sizeable number of verbal prefixes, most of which occur only in Old Japanese—*i-, ka-, ari-, ta-*, etc.— with mostly unclear or poorly investigated functions. Verbal suffixes can be divided into word-final and word-nonfinal, the main difference between these two groups being that the second group cannot conclude the verbal form and is always followed by another suffix. The rules governing the combination of verbal roots and suffixes are quite complex. However, a general rule of thumb is that suffixes with initial vowel keep the vowel after consonantal roots, and lose it after vowel roots, while consonant-initial suffixes keep initial consonant after vowel roots, but lose it after consonantal roots. Since some vowel-initial suffixes do not lose their initial vowels after vowel roots, but rather cause the last vowel of the verbal root to be dropped, it is convenient to subdivide vowel verbs into strong vowel verbs (that never lose their final vowels) and weak vowel verbs (that lose their final vowels before certain suffixes). Due to these complexities, it is necessary to list verbal affixes in two forms: after consonantal stems and after vowel stems (with the possible differentiation between forms found after weak and strong vowel verbs). Thus, for example the attributive suffix has the following forms: *-u* (<*-uru) after consonantal verb, *-uru* after weak vowel verb, and *-ru* after strong vowel verb: *yuk-u* pyit̯o 'person *who goes*', *kwop-uru* pyit̯o 'person *who loves*', and *myi-ru* pyit̯o "person *who sees*".

It is impossible to provide a list of all verbal affixes here, so only the most important are listed: infinitive *-i/-Ø*, negative infinitive *-azu/-zu,* finite *-u,* attributive *-u/-uru/-ru,* imperative *-ye/-y̯o,* negative *-an-/-az-/-n-/-z-,* tentative *-am-/-m-,* volunative **-ana/-na,** iterative **-ap,** passive **-ye-/?-raye-,** causative **-asimey-/-simey-,** debitive *-ubey-,* negative debitive **-umasizi-,** nominalizer **-aku,** honorific **-as-.**

Besides suffixation, Western Old Japanese widely uses some auxiliaries after the infinitives: **past tense** *-kyi,* retrospective *-kyer-,* perfectives *-te-/-t-* and *-n-,* perfective-progressive *-tar-.* In the later stages of language, these grammaticalized auxiliaries became inseparable from the infinitive marker *-i,* and thus formed new secondary suffixes.

Syntax. Old Japanese syntax remains the most poorly studied area of Old Japanese grammar. Nevertheless, it appears that there were some significant differences with later periods of the language, particularly concerning embedded clauses.

Old Norse

Old Norse (ON), in the widest sense of the term, refers to the varieties of the North Germanic family used in Scandinavia and its colonies from the breakup of its parent Germanic until around the fourteenth century. A narrower usage would restrict ON to Old Norwegian (ONo) and Old Icelandic (OIc) between the seventh and fifteenth centuries; still more restrictively, Classical ON (ClON) refers to the literary language of Iceland from around 1150 to 1350, a period well attested in saga literature, and it is this variety from which examples will generally be drawn.

As a member of the Germanic branch of the Indo-European family, ON preserves a number of archaic features, which make it useful for comparison with other early Indo-European languages. For nouns, two numbers, three genders, and four cases are distinguished; around 14 declension patterns occur, based on original stem type. Adjectives and pronouns agree with nouns in number, gender, and case. Many verbs retain the ancient vowel ablaut to mark tense, e.g. bita—beit—bitinn 'to bite—bit (sg.)—bitten' (compare Greek leipo—leloipa—elipon). From the Proto-Germanic (PrGmc) period, evidence of the Grimm's Law consonantal shift remains, e.g. fiskr 'fish', kinn 'cheek' (compare Latin piscis, gena), and more indirectly, of Verner's Law, e.g. finna—fundu 'to find—they found', vas—varu 'was—were'. New dual first and second person pronouns, a double declension of adjectives, and a past tense suffix containing a dental consonant are also PrGmc innovations retained in ON.

The earliest period of Norse history covers the gradual separation of the language from PrGmc, approximately between the first and sixth centuries CE. This era is often termed urnordische/urnordisk (Proto-Norse/Ancient Scandinavian, etc.), although since many changes were still shared with WGmc (ancestor of Old High German (OHG), Old English (OE), Old Saxon (OS), etc.) but not with EGmc (i.e. Gothic (Got)),

it might be regarded as Proto-North-West Germanic rather than specifically Norse. Thus, PrGmc *ae became NGmc and WGmc *a but EGmc *e e.g. ON mani OS mano vs. Got mena 'moon'; likewise, PrGmc *z developed into NGmc and WGmc *r (in NGmc, perhaps via some kind of palatalized fricative, usually represented as R) but remained in EGmc (or was devoiced,) e.g. ON eyra OHG ora vs. Got auso 'ear'. However, some have regarded parallels between NGmc and EGmc as more significant for grouping the languages, e.g. PrGmc *ww gave NGmc and EGmc *ggw but WGmc *uw (then becoming a diphthong), e.g. ON tryggr (acc. tryggvan) Got triggws vs. OE triewe 'true'.

The 'Norse' of this period is attested in a number of inscriptions in the runic alphabet (the older futhark, containing 24 runes), some of which predate the fourth-century Gothic biblical translation, and are thus the earliest direct evidence for Germanic. They are found mainly in Denmark and southern Norway and Sweden, and reflect a time when the phonology and morphology of PrGmc were still well preserved. Thus, the Gallehus horn inscription from Denmark from around 400 CE reads ek hlewagastiR holtijaR horna tawido—'I, Hlegest son of Holti, made (the) horn', which would produce the shorter ClON equivalent ek Hlegestr Holtir horn tadha.

Between roughly the sixth and tenth centuries, various important changes further distinguished Norse from the rest of Germanic, while internal distinctions were minimal. This period might be termed Common or Viking Norse, since from around 800 to 1000 viking expansions carried Norse speakers outside Scandinavia itself, sometimes resulting in lasting settlements: from Norway, west to Scotland, Ireland, the Faroes, Iceland, and Greenland; from Denmark, to England, northern France, and eastern Prussia; from Sweden, east to Gotland and Russia. The language is still mainly known from runic inscriptions, largely in the younger 16-rune futhark, although much poetry preserved in

later manuscripts, in the court (skaldic) and heroic (eddaic) traditions, was composed orally in this period.

During Common Norse (CN), unstressed vowels were reduced to only three qualities, ceased to distinguish length, and were completely lost in many phonetic environments. This caused the loss of a number of morphological markers and hence several mergers and analogical reformations in the nominal system. However, many distinctions were retained through a shift of information from (often lost) final vowels to stressed root vowels: by the process of mutation or umlaut, root vowels underwent partial assimilation to following sounds, and these new pronunciations were then phonologized, expanding the stressed vowel inventory. Thus, through palatal mutation, a following unstressed [i] (or [j]) changed [a] to [E] (later written <ae> or <e>), [o] to [o] (written <oe> when long) and [u] to [y] (i.e. fronting/raising), while labial mutation (by [u] and [w]) rounded [a] to [o] (written <o>), [i] to [y], and new [E] to [oe] (written <o>), i.e. five new vowel qualities were created. A following unstressed [a] also caused lowering of preceding high vowels, and breaking/diphthongization of preceding [e] to [ia]. Morphological alternations such as fotr—foetr (from *fotiR) 'foot—feet', land—lond (from *landu) 'land—lands', and geldr—gjalda (from *geldan) 'pays—to pay' were thus established.

An apparent irregularity in the operation of i-mutation has attracted considerable interest among Norse researchers. The vowel of a short syllable does not seem to have been mutated by lost [i], e.g. katlar (from *katiloR) 'kettles' as opposed to the mutated singular ketill (from *katilaR). The traditional theory of Axel Kock explains this as the result of i-mutation having taken place in two different periods: first, only long syllables were affected, and the following [i] was then lost; later [i] was generally lost after short syllables; finally, all instances of remaining [i] caused mutation. However, this model does not appear entirely satisfactory, and a range of other explanations have been presented.

Several notable grammatical developments also occurred during CN. A new set of verbal forms with reflexive/medio-passive significance arose from the suffixation of the reflexive pronoun sik to the verb, e.g. berja 'to beat, strike' vs. berjask 'to fight'. The combination of 'to have' with the neuter past participle produced new perfect and pluperfect constructions, e.g. fadhir hans hafdhi haldit skottum fyrir Hakoni 'his father had withheld taxes from Hakon'. A definite article was developed from the demonstrative hinn, which could be suffixed to nouns, e.g. medh ollum farminum 'with all the cargo'; in arma jotna systir 'the wretched giants' sister'. A pitch accent distinguishing monosyllables and bisyllables may also have come into existence at this time, although it was not shown in writing.

From the tenth century onward, dialectal differences began to develop between West Norse (WN), spoken in Norway and its colonies (chiefly Iceland), and East Norse (EN), spoken in Sweden, Denmark and their colonies (although Gutnish might be regarded as intermediate between WN and EN). A notable distinction was the EN monophthongization of CN [Ei] > [e:] and [ou], [Ey] > [o:], e.g. Old Danish (ODa) enn 'one', dothaer 'dead' vs. Old Icelandic (OIc) einn, daudhr. Mutation by [i] and [u] was carried out more completely in WN than EN, and palatal mutation was also caused by -R and by [g]/[k] before high front vowels in WN, e.g. OIc nofnum 'names (dat.)', thaer 'they (fem.)' vs. Old Swedish (OSw) nafnum, thar. By contrast, breaking occurred more widely in EN.

During the late tenth and early eleventh centuries, the Scandinavian countries were converted to Christianity, and Norse began to be written in a modified form of the Roman alphabet (borrowing the rune thorn <th> and the letter eth <dh> from Old English usage in some regions to represent the dental fricatives, and adding diacritics to some vowels). The oldest surviving manuscripts in Norse are, however, from the late twelfth century. From this era until around 1350 (when the Middle periods of the Scandinavian languages might be said to begin), dialectal distinctions within EN and WN became increasingly marked, and one can refer to OIc, ONo, etc.

EN, and in particular ODa, was generally more innovative than WN. ODa merged the unstressed vowels as schwa (written <ae> or <e>), e.g. ODa brothaer 'brother', dottaerson 'daughter's son' vs. OIc brodhir, dottur-son. Intervocalic consonants underwent lenition, with voiceless stops being voiced, voiced stops sometimes becoming fricatives, and voiced fricatives becoming semivowels or being lost, e.g. ODa nogaer 'some, a certain', sauthe 'said' vs. OIc nokkurr, sagdhi. The case system was substantially reduced, and there was leveling among the personal endings of verbs. The pitch accent distinguishing original monosyllables from bisyllables was changed into a reduced glottal stop, termed the stod, in stressed syllables with long vowels or final voiced consonants; this accent became lexically distinctive where old monosyllables became bisyllabic through the insertion of epenthetic vowels to break up consonant clusters, or through suffixation of the definite article.

OSw underwent many of the same developments as ODa, but to a lesser degree, and later. A phenomenon of vowel balance affected unstressed vowels: after long syllables, they were pronounced more weakly, being written as <ae e o> in some manuscripts, and eventually merged and underwent apocope; after short syllables, however, they retained their qualities longer, being written as <a i u>, and were more resistant to reduction and loss, e.g. mother 'mother' vs. fathir 'father', gangae 'to go, walk' vs. fara 'to go, travel'.

ONo, while generally similar to OIc, shared some developments with EN, e.g. initial clusters of [hl] and [hr] were simplified to [l] and [r]: ONo lut 'share (acc.)', ratt 'pushed' vs. OIc hlut, hratt. Some parts of ONo exhibited vowel harmony of unstressed vowels: following nonhigh vowels, [i u] were lowered to [e o], e.g. honom 'him (dat.)' vs. sinum 'their (dat.)', kononge 'king (dat.)' vs. bili 'moment (dat.)'.

OIc (i.e. ClON) was generally a very conservative variety; however, it innovated in some ways. Around the start of the literary OIc period, the language had a seven-vowel basic 'triangle': three front vowels [i e E] and four back vowels [u o o a], with two front rounded vowels [y o] that resulted from the CN mutations; all could be either long or short, and nasalized long vowels were also contrastive. There were three falling diphthongs: [Ei ou Ey]. This system is described in the remarkable twelfth-century native work known as the First Grammatical Treatise. During the literary period, the low–mid vowels underwent mergers: [E] merged with [e], [E:] with [o:], [o] with [o] (later written <o>), and [o:] with [a:], e.g. OIc segidh 'say!', fell 'fell' vs. ONo saeghit, fell. Nasalization was also lost; [y] merged with [i]; [e:] diphthongized to [jE] and [o:] to [ai].

The consonantal system of ClON underwent limited change from CN. Before [l], [r] and most rounded vowels, [w] was lost; it survived as [v] in some environments, e.g. OIc reka 'to drive', ordhinn 'having become', vidh 'against' vs. OSw vraekae, wordhin, Old Gutnish withr. Velar stops palatalized before front vowels and [j] during the literary period, and consonant clusters ending in sonorants were broken up with epenthetic [u], e.g. Modern Icelandic madhur 'man' vs. OIc madhr. If a tonal accent existed in CN, it was lost in Icelandic.

Grammatically, the morphology of CN was very well preserved in ClON. There were a number of loanwords from Latin, English, or German associated with the new Church, e.g. kirkja 'church', paskar 'Easter', biskup 'bishop'. Word order was fairly free, although with a tendency to subject–verb–object, in prose at least. A notable feature of narrative style was the frequent use of the historical present, with tense often switching casually within sentences, e.g. Sidhan logdhu their saman flotann; teksk thar in grimmasta orrosta ok fell mart af hvarumtveggjum… 'Then they brought the fleets together; the fiercest battle begins there and many fell on both (sides)…'.

ON is worthy of study not only for its intrinsic linguistic interest, but also for the access it gives to a wealth of literature, reflecting a time when pagan and Christian worlds met, when explorers and conquerors expanded out of their original homelands, and when the modern nations of Scandinavia were born.

Old Tibetan

Old Tibetan is the ancestor of all modern Tibetan dialects. This language is attested from the seventh century onward. It was originally spoken in a relatively tiny area (if we compare with historical Tibet's huge size). The origin of the Tibetan people was most probably the Lhoka in southern Tibet, where remain the Yum-bung

bla-sgang, the oldest fortress in Tibet, and the royal tombs in 'Phyong-rgyas. From Emperor Srong-btsan sGam-po at the beginning of the seventh century up to the middle of the ninth century, the Tibetan Empire became one of the major powers in Central Asia. After this brief period of expansion, the Tibetan-speaking area has not changed much up to now.

Old Tibetan should not be confused with Classical Tibetan, which is still the standard written language for most Tibetans. Classical Tibetan is an old dialect that is not the direct ancestor of all modern dialects, but it is the basis for the orthography of Modern Literary Tibetan, also called 'Written Tibetan'. We consider only texts older than the tenth century as genuine 'Old Tibetan'.

The Buddhist conversion of Tibet entailed the coinage of new terms, and the creation of a dictionary, the Mahatvutpatti (*bye brag rtog ched*) at the beginning of the eighth century. Besides, the orthography underwent several reforms by the end of the Imperial Period. Few documents exist in genuine Old Tibetan. There are the famous Sino-Tibetan bilingual treaties inscribed on pillars (*rdo ring*), the extensive Dunhuang documents that have been partially translated into French, English, and Chinese, and only two transmitted texts that preserve the most archaic features: *the bKa-chems ka-khol-ma* (testament of Srong-btsan sGam-po) and the *sBa-bzhed* (chronicle of bSam-yas). Many texts from the Buddhist canonical scriptures (*bKa-'gyur* and *bsTan-'gyur*) date from the Imperial Period, but they were rewritten so many times that most archaic features have been weeded out. No grammar of Old Tibetan exists yet and the extent of the difference between the Classical and the Old language is not fully understood.

Language Classification

Tibetan is usually classified as a Bodic language. The Tamang-Gurung-Thakali languages of Nepal are generally considered its closest relatives. However, no reconstruction of the ancestor language Proto-Tibetan based on the comparison with these languages has been undertaken so far; hence, our knowledge of the prehistory of Tibetan is mostly based on internal reconstruction and on comparison with more remote cousins like Archaic Chinese and Burmese. Some scholars have proposed that Tibetan is especially close to Chinese within the Tibeto-Burman family, but further investigations are needed.

Vocabulary

Tibetan has few loanwords from either Sanskrit or Chinese. Indic words are limited to animals and plants not found in Tibet (*seng-ge* 'lion', *pad-ma* 'lotus', *ping kyur ma* 'a kind of bird'). Loanwords from Middle Chinese are restricted to cultural vocabulary (*lcog tse* 'table', *dong tse* 'coin'). The loanwords from Archaic Chinese have never been studied yet, as it is difficult to tell apart loanwords from words with the same ancestry (cognates) (one such example is *lcags* 'iron' : it must be a loanword, since iron appeared only in the fifth century BC in China). Besides, Tibetan absorbed many non-Tibetan languages during the expansion of the empire, and these have certainly influenced its vocabulary. This might be one cause for the existence of redundantly duplicated words with similar meaning, such as *rmi* and *rmang* 'dream'.

Tibetan has several striking lexical innovations, such as *bdun* 'seven' (Burmese *khu hnac*), *khyed* 'you' (Burmese *nang*), *khrag* 'blood' (Burmese *sweh*), not found in any other language of the family.

Clear traces of the derivational morphology inherited from Proto-Sino-Tibetan are found in Tibetan. However, it probably was not in active use anymore even by the time of the first Buddhist translations, since new means were created to coin new terms: instead of using the -s suffix deriving an action noun from a verb (*za* 'to eat' *zas* 'food'), translators chose to add the verb *byed* 'to do' in its future form *bya* after a verb to translate the Sanskrit past participle.

Writing System and Phonology

The phonology of Old Tibetan is obscured by the irregularities in spellings found in most Dunhuang documents, which often make the translation quite difficult if not impossible. The exact pronunciation of Tibetan in the imperial period is mostly uncontroversial, except for a few letters. The prefixed '-, incorrectly called 'a chung' even by Tibetan specialists ('a chung designates in fact the little 'a used to indicate vowel length in Sanskrit words), has been the object of some debate, as it seems to have three distinct functions in Tibetan orthography: when used as an initial, it represents a voiced glottal fricative (as in *'od* 'light'). This sound is still heard in some dialects. As a preinitial, it indicates prenasalization (as in *'khor* 'to turn', most likely pronounced as *ηkhor*). Finally, since the vowel a is not written by any special symbol in the indic alphabet, this letter also serves to disambiguate some combinations of letters (*mda'* 'arrow', written M D ' as opposed to *mad* 'under' written M D).

The final stops -b -d -g are written with the symbols for voiced consonants, although these were most probably pronounced as unreleased stops as in most languages in the area.

Old Tibetan boasts of a great quantity of complex consonant clusters that are preserved in modern orthography but only partially in dialects. These clusters are extremely interesting typologically, since

some of them are highly unusual: clusters such as *rt-* are permitted, but not the cross-linguistically much more common *tr-*.

Tibetan admits up to four initial consonants (*brgyad* 'eight'), but no more than two finals (*dmangs* 'people'). One of the most conspicuous differences between Old and Classical Tibetan is the *da drag*: while in Classical only -s can stand as a second final, in Old Tibetan some clusters exist with -d as a second final, such as in *mnard* 'he oppressed' (Classical *mnar*).

In the Tibetan writing system, there are three series of initial consonants : voiced, aspirated, and plain unvoiced. The former can appear in all contexts, but the latter two seem to be variants of a single type in Classical Tibetan: except for some rare exceptions, only aspirated consonants can begin a word or stand after nasal preinitials (m- and '-), while when preceded by any other preinitial (stop, liquid or s-), only plain voiceless stops are permitted. This reminds one of English stops (p is aspirated in *pit* and nonaspirated in *spit*). In Old Tibetan, the distribution of these graphemes is much less predictable (*gchig* systematically for Classical *gcig* 'one', for instance), but it is not probable that these two series are truly distinctive in Old Tibetan.

Finally, there is a vowel in Old Tibetan never found in the Classical language: the inverted I, transliterated as *ï*. This sign does not seem to represent a phoneme distinct from *i*, though. The rules governing their distribution are still unknown.

Verbal System

Like modern Tibetan dialects, Old Tibetan was an ergative language, which means that the object of a transitive verb bears the same mark as the subject of an intransitive verb (in Old Tibetan, this case has no overt marking), while the subject of a transitive verb is marked with ergative case (variously marked as 'is, kyis, gyis, or gis).

klu-gong glo-ba nye'o (Zhol inscription, South:20)
Klu-gong (no suffix)—intention—near—finite verb ending
Klu-gong was loyal.

gzhan '**is** **bdag** bsad **sha** zos dka' myi dka' (Pelliot Tibétain 126: 20)

other—ergative suffix—**yourself** (no
suffix)—kill—**flesh** (no
suffix)—eat—hard—not—hard
If others killed you and ate (your) flesh, wouldn't it be hard?

The ergative suffix, however, serves as an intrumental case and can mark emphasis.

Unlike Kiranti or rGyalrongic languages, Tibetan has no trace of agreement between verb and e.g. the subject. Transitive verbs have four forms (present, past, future, and imperative), and intransitive verbs have two forms. In most cases, one form is not sufficient to derive the four forms, so that the verbal conjugation is far from simple. Here are examples of verbal patterns found in Old Tibetan (for some forms unattested in Old Tibetan, we provide Classical Tibetan in italics):

Present	Past	Future	Imperative	
byed	byas	bya	byos	
'dzin / zin	bzung	gzung	*zung*	to take
'dogs	btags	gdags	*thogs*	to tie
za	zos	bza	zos	to eat
sbyor	sbyard / spyard	sbyar	*sbyor*	to join

Some elements of the verbal conjugation are quite old: the past tense -s suffix is also found in rGyalrong, Qiang, and Kachin, and the change of a to o in the imperative is related to the imperative -o suffix found in Tamang. However, many peculiarities of the verbal system (the change a to o in the present tense of some verbs, the past tense b- prefix) do not seem to be relatable to anything in other Tibeto-Burman languages.

An interesting irregularity in conjugation that is common to Tibetan and Kiranti languages is the conjugation of the verb 'to eat'. In Tibetan, it presents an exceptional vowel alternation in the past tense a à o unrelated to the more common alternations found in the present and imperative. In Hayu, 'to eat' is one of the four verbs with a -o stem alternation: *dza-ng* (I eat it), *dzo* (You eat it). The same irregularity is found in a dialect of Limbu. This must be an archaism going back far in the prehistory of the language.

Onomatopoeia

Onomatopoeia is better understood as a semantic phenomenon if language is likened as a diagram. A referent is codified through the phonetic-symbolic means of language into a word, i.e. the linguistic depiction of its representation. All languages show some kind of imitative linguistic codification known as onomatopoeia. Onomatopoeia represents a referent based on a diagrammatic sound–meaning identification. This direct sound–meaning relationship is nonarbitrary or isomorphic. Examples are easily found in many languages, especially the use of animal sounds like the Malay *kokok* 'the crow of a rooster', *embek* 'the bleat of a goat', the Mandarin *gaga* 'the quack of a duck', and *miao miao* 'the meow of a cat'. Onomatopoeia as a universal language feature can be divided into three types: sound imitation, secondary sound symbolism, and echo.

Onomatopoeia of the first type occurs when linguistic sound imitates sounds of the real world. Each linguistic imitation is taken as the diagrammatic sign of the signified referent. Many terms are derived from sound imitation, for example, *cuckoo, cockatoo, boom, buzz, rumble, twang, chirp, slam, thump, clap, flap,* and *rattle*. More common onomatopoeic words like *ha ha ha* that signifies laughter in English and Cantonese opera is used as a sarcastic tag as in 'How funny, ha ha ha' in specific contexts of communication.

Onomatopoeic words are salient in Malay vocabulary as illustrated in Table 1.

Sound symbolism occurs when there is a recurrence of sound–meaning correlation. An example would be the high front unrounded vowel taken to symbolize a sense of small, insignificant, slight, or weak. The vowel contrast in *pinch* vs. *punch*, *gripe* vs. *grope*, and *sip* vs. *suck* points to this sound–meaning symbolism in /i/. Research shows that the distribution of sounds in men's and women's names is not random. It is common for Caucasian women's names to end with /i/ and men's with consonants like fricative, i.e. /s, f/, and stop, i.e. /t, k/. The psychology experiment concludes that the gendered sound difference in personal names is best understood as reflecting emotional differences. Men's names are associated with active, cheerful, nasty, and unpleasant emotions while women's names are associated with passive, sad, soft, and pleasant emotions (see Whissell 2001). If language is diagrammatic, personal names are depictions of human beings whose respective names become the aspirations intended for them.

Secondary sound symbolism in the onomatopoeia context is a linguistic sound taken to connote another meaning based on phonetic similarity. Mandarin and Cantonese speakers believe that the sound of 8, i.e. *ba,* is sound symbolic to *fa* 'prosper'. As such, car registration numbers that contain many 8's are more expensive in Malaysia and Singapore. Since 4 *sì* is sound symbolically related to *sì* 'die' in these languages, karaokes in Singapore and Malaysia will add lucky phrases to tags with the number 4 before offering this queue number to customers. One can imagine how confident a typical Chinese needs to be in order to drive in a car with 4444 as the registration number.

Secondary sound symbolism plays an important role in Chinese speech communities when one chooses a name for a child. *Lóng* 'dragon', a symbol of divinity and good fortune, is a favourite character used for boys. An excellent example would be *Chen Long* (Jackie Chan), who became the dragon of Chinese cinematography. Bruce Lee's middle name is also the character of a dragon. Other favorite characters used as Chinese personal names are *fa* 'prosperous' as in *Chow Yuen Fatt*, *an* 'safe' as in Ang Lee, and *kuang* 'bright' the first name of the former Singapore Prime Minister. Onomatopoeia in the form of secondary sound symbolism is culturally significant as it influences one's belief.

TABLE 1

Onomatopoeic Lexicon	Meaning
Debuk	The sound of slapping or boxing
Debum	The sound of heavy things falling
Debung	The sound of drumming
Debur	The sound of waves breaking on the shore
Debus	The sound of flapping of wings
Debut	The sound of squeezing out of a small hole
Debak	The sound of boxing each other
Debar	The sound of heart pounding
Debik	The sound of hitting with one's palm
Degar	The sound of blowing with a stick
Deguk	The sound of gulping water
Dekah	The sound of hearty laughter
Deham	The sound of a little cough
Dengkung	The wailing of a dog
Dengung	The sound of a plane
Dengkur	Snoring
Dentang	The sound of hitting the iron
Denting	The sound of falling coins
Dentung	The sound of thunder
Dering	The ringing of the phone

TABLE 2

Semantic Criterion	Examples
Motion	huff-puff, flip-flap, flipperty-flopperty
Tumult	rumble-jumble, hubble-shubble, wringle-wrangle
Inferiority	shally-wally, phoney-baloney, whimsy-whamsy
Trickery	hooky-crooky, hanky-panky, cuddle-muddle
Mental instability	randy-dandy, shilly-shally, hazy-dazy
Mutuality	equal-aqual, hob-nob, tiggle-taggle
High degree	tip-top, wee-jee, itsy-bitsy
Hypocoristic	mousey-pousey, tootsy-wootsy, lovey-dovey

Echo is a form of reduplication that occurs in the form of freezes, binomials, echo formation, and other forms of bipartites. Echoic morphology is language universal. Table 2 illustrates some English echos.

Malay echoic reduplications like *gunung-ganang* 'ranges of moutain', *batu-batan* 'rocks', *sayur-mayur* 'all kinds of vegetables', *bengkang-bengkok* 'very crooked', and *cucu-cicit* 'descendants' are commonly used in daily conversation. Malay partial reduplication is important in word fomation, especially in naming things: *tikus* 'mouse' > *tetikus* 'computer mouse', *kunci* 'key' > *papan kekunci* 'keyboard', and *pejal* 'solid (adjective)' > *pepejal* 'solid (noun)'. South Asian echos, on the other hand, are loaded with pragmatic functions. Bhojpuri echos like *deslai-oslai* 'matchbox etc.' is used as an indirect request for cigarettes by youngsters or subordinates because smoking in the presence of parents or elderly persons is bad manners. In Tamil, *vendu* 'come' is echoed as *vendu gindu* 'come etc.'. The echo is used for the addressee to come (and run an errand for him). Cantonese echos like *yùhn lūk lūk* 'rounded', *chī lahp lahp* 'sticky/goey', *dung bīng bīng* 'freezing cold', and *baahk syūt syūt* 'snow-white' come in tripartites. These echos illustrate more intense

meaning, i.e. quantity iconicity where more forms entail more meaning.

Despite the skepticism about the relevance of onomatopoeia, it remains resilient in language. The fact that onomatopoeia exists through time and manifests creatively in various forms testifies to the significance of this component either as pragmatic tool, cultural routine, or semantic paradigm that prevails in language use.

Oto-Manguean Languages

Oto-Manguean languages are distributed throughout Mesoamerica and form the language stock with the deepest time depth in the Americas. The emergence of its eight linguistic families patterns geographically with the ecological zones of the domestication of maize, chili, squash, and beans, which emerged as primary

agricultural products among the peoples of Archaic Mexico beginning about 4400 BCE. In this account, early Oto-Manguean diversified on a landscape where smaller, more mobile bands came to rely increasingly on domesticated plants and center their production in villages on the mesas and highland valleys of the

Central Altiplano, the Mixteca Alta, the Valley of Oaxaca, and the Tehuacán Valley. These regions help define four branches of Oto-Manguean, with Otopamean-Chinantecan and Tlapanecan-Manguean forming the Western division and Amuzgo-Mixtecan and Popolocan-Zapotecan the Eastern division.

Most of the language families of West Oto-Manguean are centered in the highlands and watersheds from the Central Altiplano to the Pacific in Guerrero, and East Oto-Manguean families in highlands and watersheds from the Mixteca Alta to the Pacific in Oaxaca. Some consonant differences between the separate reconstructions of the ancestor languages for East and West suggest that the oldest accessible form of Oto-Manguean may already show dialect differentiation, possibly resulting from dispersal among these watersheds. The connections between the Chiapanecan and Manguean languages in the far east of Mesoamerica and Tlapaneco of West Oto-Manguean are accounted for as the result of population migrations in prehistory.

West Oto-Manguean includes the two branches of Oto-Pamean-Chinantecan and Tlapanecan-Manguean. Northern Oto-Pamean consists of Chichimeco of Guanajuato and the Pame languages of San Luis Potosí. Southern Oto-Pamean consists of Matlatzinca and Ocuilteco around the Valley of Toluca, and an Otomian group comprising the Mazahua language and six branches of Otomí in the states of Mexico, Tlaxcala, and Michoacan. The Chinanteco language family represents the extension of the stock east of the Sierra Madre and contains at least six languages. The Tlapanecan-Manguean branch consists of Tlapanecan-Subtiaban and Chiapanecan-Manguean. Tlapaneco is spoken in several varieties in the state of Guerrero, and Subtiaba was historically spoken near the Pacific coast of Nicaragua. Chiapanecan-Manguean consisted of Chiapaneco in Chiapas and Mangue in coastal Honduras and Nicaragua.

East Oto-Manguean includes the Popolocan-Zapotecan and Amuzgo-Mixtecan branches. Popolocan comprises four Mazateco languages of Oaxaca, Puebla, and Veracruz; four Chocho-Popolocan languages of Oaxaca and Puebla; and Ixcateco of Oaxaca. Zapotecan includes three Chatino languages in southwestern Oaxaca and five branches of Zapoteco in the mountains of southern, western, southwestern, and northern Oaxaca, and in the Valley of Oaxaca east to the Isthmus of Tehuantepec. Each branch of Zapoteco further divides into several distinct languages. Amuzgo-Mixtecan is made up of Amuzgo in Guerrero, two Trique languages in Oaxaca, and Mixteco-Cuicateco, which itself includes the Cuicateco language of Oaxaca and several divergent Mixtecan language areas in Guerrero, Puebla, and Oaxaca.

Over 100 years of Oto-Manguean scholarship provides us with evidence for several statements about the grammatical structure of Proto-Oto-Manguean, the assumed ancestor language. Simple words typically had only one syllable, and complex words could be formed by compounding simple word roots or by attaching prefixes. The language most likely had tone distinctions; i.e. melodic pitch differences between otherwise identical words could alone indicate a meaning difference. The vocalic system included minimally *i, *e, *a, *u, several diphthongs, the semivowels *w and *y, and the consonants *t, *ts, *k, *kʷ, *s, *x, *xʷ, *l, *n, *m (the asterisks indicate that these sounds have been reconstructed on the basis of documented languages).

While parts of the Oto-Manguean family as presented here were separately grouped by researchers of the nineteenth and early twentieth centuries, it was Edward Sapir's 1929 classification that was the first to include the earlier groupings of Mixtecan-Zapotecan, Otomian, Chiapanecan-Manguean, and Chinantecan in a single group. From the 1940s until the mid-1960s, Oto-Manguean research had a blossoming period during which several dedicated scholars worked out the relations of diversity within the Oto-Manguean branches. A student of Sapir, Morris Swadesh, compiled the first comparative study of the sound correspondences of the Zapotecan languages. In the 1950s, Sarah Gudschinsky worked on the internal diversity of Popolocan and supported a larger grouping that included the East Oto-Manguean families of Mixtecan and Popolocan, which she called 'Proto-Popotecan'. Eric Hamp refined and revised both Gudschinsky's earlier subgrouping of Proto-Popolocan and the analysis of the sound system of Chiapanecan-Manguean. María Teresa Fernández de Miranda also worked intensively with the Popolocan language family and the Manguean family and was working out a reconstruction of Proto-Zapotecan before her untimely death. Robert Longacre's extensive work on the internal relationships of Amuzgo-Mixtecan also began with publications in the 1950s. In the same decade, our knowledge of West Oto-Manguean developed with Stanley Newman and Robert Weitlaner's Proto-Otomí reconstructions. In the 1960s, Doris Bartholomew contributed work on Oto-Pamean and revised the Proto-Otomí reconstructions. Along with Michael Piper, she prepared Fernández de Miranda's unfinished Proto-Zapoteco reconstructions for publication.

A virtual dearth of publications spans over a decade before the publication of the most influential work on Proto-Oto-Manguean. Calvin Rensch began systematic work on Proto-Oto-Manguean in the early 1960s. A brief period of new interest developed after the 1976 publication of Rensch's 1966 thesis, *Comparative Oto-*

Manguean phonology, in which he focuses on reconstructing the tone-carrying syllables of words in Proto-Mixtecan. Based largely on Rensch (1976), J. Kathryn Josserand, Marcus Winter, and Nicholas Hopkins's (1984) *Essays in Oto-Manguean culture history* treated the unique opportunity that Mesoamerica provides for integrating historical linguistic and archeological approaches to culture history. In the 1980s, a student of Eric Hamp, Terrence Kaufman, critically assessed the word and sound correspondences contained in the work of Rensch, Longacre, and other historical sources, and in 1994 presented the classification adopted here.

The work of the handful of scholars mentioned above only begins to point to the interest of this language stock for linguistic and historical linguistic theory. The bulk of the above works focus mostly on the sound system and the vocabulary. However, the languages of Oto-Manguean also present challenges for research in intonation, sentence grammar, word structure, and meaning, for which the literature is almost entirely lacking.

The Oto-Manguean sound system exhibits some unique characteristics. For example, many of the languages lack [p] and [b], and most consonants are voiceless, i.e. they are produced, like [t, k, s], without vocal cord vibration. Voiced consonants such as [d, g, z], on the other hand, are rare.

Oto-Manguean is the world's oldest language stock that provides sufficient evidence for tone distinctions in the ancestor language. The complicated tone systems distinguish between two and six pitch levels; i.e. in the most complex scenario, one could theoretically have six different one-syllable words differing only in the pitch or the pitch pattern of the vowel.

'Whistled speech' has been reported in Mazateco, Mixteco, and Zapoteco. This is a form of speech that is basically stripped of individual segments and consists almost exclusively of melody. It provides speakers with the ability to communicate a wide range of utterances across a distance.

The grammar of Oto-Manguean languages makes heavy use of particles. In Oto-Manguean languages, they can carry meanings associated with intonational patterns in languages like English or the Romance languages. For example, yes/no questions, topicalization, exclamation, and emphasis are indicated by particles. However, at this time, very little work has been done on Oto-Manguean sentence structure.

Oto-Manguean continues to have great import in the development of historical linguistic theory. It is a family with an internal complexity comparable to that of Indo-European but has diversified within a restricted cultural-ecological zone associated with highland agriculture. Thus, Oto-Manguean languages provide a natural testing ground for addressing the interaction of language-internal changes and regionally defined patterns of linguistic diffusion. From Archaic through Post-Classic Mesoamerica, webs of political and economic interaction mediated the divergence of related languages as villages allied themselves to larger centers emerging with the origins of the states of Pre-Columbian Mexico.

Oto-Manguean language history also involves contacts with languages outside the family but within a greater Mesoamerican culture area. Such relations include speakers of Huave, Totonac, Mixe-Zoque, Maya, and later arriving Uto-Aztecan speakers including the Aztecs. Loanwords and structural similarities shared among many of the languages of Mesoamerica support a view that networks of contact have been most important in shaping the patterns of linguistic features in this culture area. The Spanish Conquest brought a common language of the empire that must also be counted in the histories of the divergence of Oto-Manguean languages as well as in shaping our knowledge of those that were chronicled in Colonial and Post-Colonial Mesoamerica but are no longer spoken at the present time.

Today the status of Oto-Manguean languages varies from village to village. Some families have well over 100,000 speakers, but the languages of that family may range from villages of several thousand, where all the children learn an Oto-Manguean language as a first language, to villages where less than a dozen elders have any memory of their language. In most communities, bilingualism is the norm, with Spanish being learned either at home or in school. Many villages that once spoke an Oto-Manguean language have entirely shifted to Spanish. This trend is occurring in some regions at an alarming rate. Several key languages and language families are already extinct. Chiapaneco and all of Manguean have long since passed. While the documents on Manguean are sufficient to demonstrate its membership in the Oto-Manguean stock, the data were not recorded with attention to tone and other complex issues of pronunciation. Most of the Tlapanecan-Manguean languages have not been adequately documented at all. For Oto-Manguean overall, there are very few dictionaries and grammars, and few practical orthographies have been developed. The next couple of generations will decide whether Oto-Manguean voices will still be heard in Mexico's future.

P

Pacific

The area covered by the Pacific ocean occupies about a third of the Earth's surface and is by far the world's largest geographic region. It contains more than 1,000 indigenous languages, Asian mainland languages, half a dozen European languages, and a number of pidgins and creoles. Geographically, it includes the island nations and territories of Micronesia, Polynesia, and Melanesia, collectively known as Oceania. The islands occupy just less than 500,000 square miles of land area. New Guinea, the second largest island in the world after Greenland, represents 64% of this total, and New Zealand represents another 20%. The remaining 10% is divided among more than 10,000 scattered islands. Micronesia comprises the island groups east of the Philippines and north of the equator, including, for instance, the Mariana, Marshall, Caroline, and Gilbert islands. Melanesia encompasses the island groups in the southwestern Pacific extending southeastward from the Admiralty islands to Fiji, including such nations as Papua New Guinea, Solomon Islands, Vanuatu, and New Caledonia. Polynesia consists of a group of islands extending from New Zealand north to Hawaii and east to Easter Island.

Politically, the status of the islands ranges from those that are independent (e.g. Papua New Guinea, Fiji, Kiribati, Palau, Samoa—formerly Western Samoa, Tuvalu, and Tonga), those that are quasi-colonies or territories (e.g. New Caledonia, French Polynesia, and Wallis and Futuna—French overseas territories; Guam and American Samoa—United States territories; Norfolk Island—an Australian territory; Rapa Nui/Easter Island—a dependency of Chile; and Northern Marianas—a Commonwealth of the United States), those that are self-governing in free association with other countries (e.g. Cook Islands, Tokelau, and Niue in relation to New Zealand, and the Federated States of Micronesia, Chuuk, Pohnpei, Yap, and Kosrae, in relation to the United States), and those that are colonies (e.g. Pitcairn Island—a British colony), to those that have been incorporated into other nations (e.g. Hawaii—formerly a territory of the United States, now the fiftieth state).

The Pacific islands were peopled by influxes from both mainland and island Southeast Asia, with the earliest migrations to Melanesia. From Melanesia, generations of voyagers headed northward into eastern Micronesia and eastward into Polynesia. European exploration of the Pacific began with the voyages of Ferdinand Magellan in the 1520s, which inaugurated a period of Spanish and Portuguese influence, followed by Dutch, English, French, and German influences. Most of the major island groups were annexed by Britain, the United States, France, and Germany in the nineteenth century. Many Micronesian territories changed hands a number of times, beginning with Spanish colonial administration that was followed by German, Japanese, and American regimes.

The historical partition of the islands among the various European colonizers has left the islands' populations divided primarily into a Francophone and Anglophone set of nations, each with different political, economic, linguistic, and cultural orientations. More recently, however, notions of a Pacific islander identity

have begun to emerge, fueled partially by recognition of a common history of colonization, as well as by demands from nonindependent territories and nations for increased political autonomy.

The indigenous languages of the Pacific belong to two language families: Austronesian and non-Austronesian (Papuan). The Austronesian language family is the largest and most widespread family in the world. The Oceanic or easternmost subgroup of the Austronesian family is the largest and best defined of all subgroups, containing all Polynesian languages, all Micronesian languages (except Palauan and Chamorro), and all Austronesian languages of Melanesia east of the Mamberamo River in Irian Jaya (the western half of the island of New Guinea, Indonesia's easternmost province).

The Polynesian languages are a subgroup of Oceanic containing approximately 30 languages organized into two major subgroupings: Tongic (including Tongan and Niuean) and Nuclear Polynesian (all the rest). The latter is divided into two further groups: Samoic Outlier (consisting of Samoan and Tuvaluan) and Eastern Polynesian (consisting of Hawaiian, Tahitian, Maori, Rapa Nui, and Marquesan). Speakers number fewer than a million people spread across a large area of the Pacific, ranging from Hawaii in the north to New Zealand in the south and Easter Island. This so-called Polynesian Triangle encloses an area approximately twice the size of the continental United States. Despite their great geographic spread, the Polynesian languages show a relative homogeneity, which indicates that they have dispersed only in the last 2,500 years from an original center in the Tonga-Samoa area. In addition, there are some 18 further Polynesian-speaking communities known as 'Polynesian Outliers' in Micronesia (e.g. Kapingamarangi and Nukuoro, two atolls in the southwestern portion of Pohnpei state) and Melanesia (e.g. Ontong Java atoll and Rennell island in the Solomon Islands). Although some Polynesian languages have a relatively large number of speakers, such as Samoan with about 200,000, many others have very few, and some, such as Maori and Hawaiian, face possible extinction as their speakers have shifted to English.

Most of the Oceanic Micronesian languages (with the exception of Nauruan, which has not been sufficiently studied) form a closely related subgroup called Nuclear Micronesian. Palauan and Chamorro, however, appear to be the result of distinct migrations from Indonesia or the Philippines. Although Yapese is probably Oceanic, it does not appear closely related to any of the other Micronesian languages, because of its complex history of borrowing. It is also the only

Austronesian language containing glottalized consonants, (i.e. pronounced with simultaneous contraction of the vocal folds). Most of the Micronesian languages have relatively small numbers of speakers, with a few, such as Sonsorolese on Sonsoral island in Palau, having only several hundred speakers.

Historical relationships among the Papuan languages, found primarily in the New Guinea interior, an area of immense linguistic complexity, are less clear than in the much better studied Austronesian language family, and the label is best seen as a cover term for many, perhaps as many as 60, distinct families. The Papuan-speaking peoples were the earliest people in the region, occupying the Sahul continent (which later partially submerged to become the island of New Guinea) at least 40,000 years ago. By 30,000 years ago, the Bismarck Archipelago east of New Guinea was occupied by speakers of Papuan languages. Speakers of Austronesian languages, who arrived much later, established coastal communities in New Guinea, the southeastern Solomons, Vanuatu, New Caledonia, and Fiji. Contacts between speakers of Papuan and Austronesian languages have made it difficult to classify some languages as Austronesian or Papuan, such as Maisin in Papua New Guinea, which displays features typical of both language families.

The European languages spoken in the Pacific region are primarily those of the former colonizers and still have official status in most areas. Although French is important, no European language has had the impact that English has had. In addition to the standard variety of British or American English that serves as the official language in Anglophone territories, English exists in a number of locally distinct varieties in New Zealand and Hawaii, and it also exists in the form of numerous pidgins and creoles. French has left its legacy in the form of a number of local varieties of colonial French spoken, for example, in New Caledonia and Tahiti, as well as in a French creole, Tayo, in New Caledonia. Standard French still has official status in French territories of the Pacific, as well as in independent Vanuatu, formerly a condominium ruled jointly by Britain and France, where it shares co-official status with English. Because Germany lost most of its colonies after World War I, German never had a chance to spread as widely as other colonial languages. The language left some remnants, nonetheless, in the form of a German creole, Unserdeutsch, as well as borrowings, both into forms of pidgin English, such as Tok Pisin in Papua New Guinea, as well as into indigenous languages. Spanish has only a limited presence in the Pacific as the official language of Rapa Nui/Easter Island.

In addition to European languages, other languages were introduced as a result of colonization, such as Japanese, Korean, varieties of Chinese (for example, in Papua New Guinea, Nauru, Tahiti, and elsewhere), and Vietnamese in New Caledonia. Varieties of Southeast Asian languages, such as Hindi, were introduced into Fiji, and Javanese was introduced into New Caledonia. Philippine languages such as Tagalog, Ilocano, and Visayan were introduced into Hawaii through the importation of migrant labor and indentured plantation workers.

The Pacific pidgins and creoles originated primarily in the late eighteenth and early nineteenth centuries. By the latter part of the nineteenth century, trade contacts between English speakers and Pacific islanders had led to the formation of English-based pidgins spoken in various forms and with differing degrees of stability in almost the entire Pacific basin from New Guinea to Pitcairn island, from the Marshall Islands and Hawaii to New Caledonia and New Zealand. Not all of these have survived. In Micronesia and most of Polynesia (with the exception of Hawaii), forms of pidgin English disappeared because their role in internal communication was quite limited. Chinese Pidgin English, the oldest form of Pidgin English in the Pacific, which developed around the port of Canton in 1700, has subsequently died out, although a mixed form of Melanesian-Chinese Pidgin English is still used on Nauru in a variety of commercial contexts, including Chinese trade stores and restaurants, and in the phosphate mining industry, which began in 1906.

In addition, there are a number of pidgins and creoles based on indigenous languages such as Hiri Motu in Papua New Guinea, one of the three official languages of Papua New Guinea (along with English and Tok Pisin). A number of indigenous pidgins such as Pidgin Maori, Pidgin Fijian, and Pidgin Hawaiian are no longer in use.

Pidgin and creole languages based on English are more numerous than those related to any other language, attesting to the greater spread of English than any other metropolitan language. Because the French and Germans were relative latecomers to the Pacific, they found varieties of Pidgin English well established in many areas. Melanesian Pidgin English emerged on plantations in Queensland, Australia, to which workers from all over Melanesia were recruited, and later evolved into a number of distinctly named varieties, including Tok Pisin, spoken in Papua New Guinea; Bislama, spoken in Vanuatu; and Pijin, spoken in the Solomon Islands. In these highly multilingual countries, these languages are the normal everyday medium of communication for millions of people. Tok Pisin is the largest language in the South Pacific today, with as many as 2 million speakers. Most business in the House of Assembly, the country's main legislative body, is conducted in Tok Pisin, which is the most widely shared language among the members. In Hawaii, a creole English developed on plantations and is still in use, primarily among working-class speakers. There is some dispute over the status of the variety of English spoken on Pitcairn and Norfolk Islands, spoken by descendants of the British mutineers from HMS *Bounty*.

Only Tok Pisin and Bislama have received some official recognition. Tok Pisin is a de facto official language in Papua New Guinea and is spoken by more than half the population; however, English is the official medium of education. Although Bislama is recognized by the constitution of Vanuatu as the national language of the country, it is forbidden in the schools. English and French, the languages of the former colonial powers, are still the official languages of education.

The only example of a German creole is Rabaul Creole German, called Unserdeutsch, 'our German', which arose at the turn of the century as a lingua franca of the Catholic mixed-race community in Vunapope near Rabaul in what is now East New Britain Province of Papua New Guinea. This was formerly part of the German colony Kaiserwilhelmsland from 1884 to 1914. This language was apparently used by children at a mission boarding school and creolized in one generation. It is now extinct.

The only example of a French creole is Tayo, spoken in the southern part of New Caledonia around St. Louis, the site of a Catholic mission and plantation, where linguistic diversity among the surrounding tribes led to the emergence of a creolized French as a lingua franca.

Pama-Nyungan

The term Pama-Nyungan, coined by Ken Hale in the early 1960s after the words for 'man' in the northeastern and southwestern extremities of Australia, refers to a group of 160 or so languages spoken over about seven eighths of the continent (shown in gray on the map). This group was initially proposed on the basis of lexicostatistical comparisons of 100 basic words, and was believed to represent a single family of genetically related languages. The remaining eighth of the continent is considerably more diverse, and the languages were assigned to some 28 additional families, referred to collectively as non-Pama-Nyungan. It was considered that almost all Australian languages, Pama-Nyungan and non-Pama-Nyungan, are ultimately genetically related.

The lexicostatistical classification correlates well with a typological classification (the essence of which was proposed in 1940 by Arthur Capell). Most Pama-Nyungan languages are 'suffixing' (by definition, have only suffixes, and no prefixes) and dependent marking (grammatical relations signalled on noun phrases), while non-Pama-Nyungan languages are overwhelmingly 'prefixing' (by definition, have both prefixes and suffixes) and head marking (grammatical relations signaled on the verb, and sometimes also on noun phrases). There are a few exceptions: the Tangkic languages are suffixing and dependent marking but non-Pama-Nyungan; Yanyuwa is Pama-Nyungan but prefixing and head marking. The classification has been the subject of considerable controversy in recent years. There is, however, no widely accepted alternative, and most Australianists accept it in broad outline.

Current State of the Languages

Most Australian languages (Pama-Nyungan and non-Pama-Nyungan) are endangered or moribund. Many languages of the east and southeast, where conflict with Europeans was particularly intense and violent, are no longer used as vehicles of everyday communication, and are effectively dead; some disappeared before adequate records could be made of them. On the other hand, some of the most viable languages, with the best chance of future survival, are Pama-Nyungan. These include the Western Desert language, with some 4,000–5,000 speakers; Arrernte and Warlpiri, with some 3,000 speakers each; Yolngu varieties with some 2,000; and Kala Lagaw Ya (Torres Strait Islands) with some 3,000–4,000 speakers.

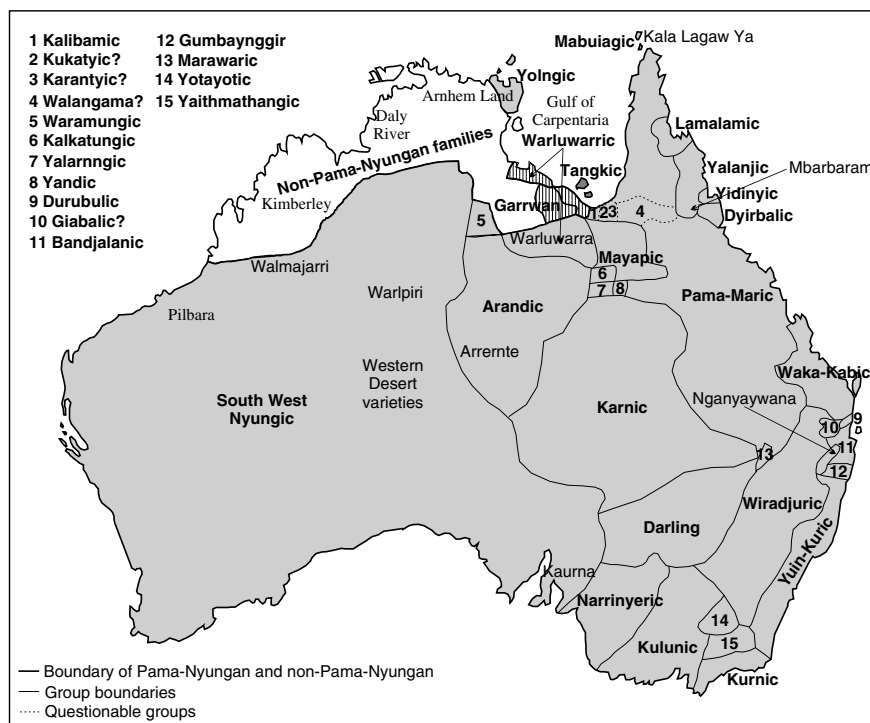
Boundary of Pama-Nyungan and non-Pama-Nyungan
Group boundaries
Questionable groups


Efforts are being made by speakers and their descendants to reintroduce some dead Pama-Nyungan languages (e.g. Kaurna in the Adelaide region), and to strengthen some weakening languages (e.g. Walmajarri in the northwest). But few such efforts have achieved appreciable results, and considerably more needs to be done before the process of attrition can be considered to have been arrested generally, or for any language.

Status of Pama-Nyungan and Relation to non-Pama-Nyungan

The notion of a Pama-Nyungan family is widely accepted by Australianists; most believe that a genetic family of roughly the size shown on the map will ultimately prove valid, although we are a long way from providing convincing arguments. It has not been established as a family by rigorous application of the comparative method: little of (ancestral) proto-Pama-Nyungan phonology, lexicon, or grammar has been reconstructed, and few subgroupings have been argued on the evidence of shared innovations. One reason for this situation is that investigators have assumed the genetic relatedness of Australian languages, and have focused on the search for shared innovations, rather than attempting to reconstruct proto-Pama-Nyungan.

With improved descriptions of more languages, and use of the comparative method, the membership and scope of Pama-Nyungan have been refined somewhat since the 1960s, as have details of the subclassification. Thus, Mbabaram (Queensland rain forest region) and Nganyaywana (northeast New South Wales), originally excluded from the Australian superfamily, were shown by Robert Dixon and Terry Crowley, respectively, in the 1970s to be closely related to their neighbors; both had undergone radical sound changes that obscured cognates (related words).

Perhaps the major revision was proposed in the late 1980s by Barry Blake (1988) and Nicholas Evans (1988). They reclassified the Tangkic languages, previously considered to be Pama-Nyungan (largely on typological grounds, since these languages show low vocabulary sharing with Pama-Nyungan) as non-Pama-Nyungan, and Yanyuwa, previously taken to be a non-Pama-Nyungan isolate, as Pama-Nyungan. They assigned Yanyuwa to a subgroup with Warluwarra, spoken to the south and separated from Yanyuwa by the Garrwan languages (whose classification has also proved problematic). (These are indicated by vertical hatching on the map.) Their evidence mainly concerned forms of pronominals and case-markers.

Blake (1988) reconstructed a pronominal system for proto-Pama-Nyungan, and a different one for proto-non-Pama-Nyungan. Evans (1988) proposed further that Pama-Nyungan could be identified as a subgroup (within Australian) on the basis of specific phonetic and grammatical characteristics, for example, the wide occurrence of the variants -lu ~ -nggu as a marker for ergative case.

Dixon has always been a virulent critic of the notion that Pama-Nyungan languages constitute a genetic family of their own, lambasting the idea on methodological and other grounds. Dixon has made some valid criticisms of lexicostatistical methodology. However, the lexicostatistical classification was always regarded as a tentative means of providing a preliminary genetic classification, one that must be refined and supported by the comparative method. Most Australianists who accept the classification do so tentatively (an imperfect or faulty classification is preferable to none, provided that its provisional status is borne in mind).

Dixon also argues against Pama-Nyungan on the grounds that the putative innovations in the pronominal and case-marking systems—e.g. the first-person dual inclusive *ngali* 'we two (including you)' and the ergative variants -lu ~ -nggu—are not present in all Pama-Nyungan languages. Dixon avers that areal diffusion rather than common ancestry provides the simplest explanation for the distribution of these features. He suggests that the -nggu allomorph was independently innovated (via natural phonological conditioning) in four different places, and subsequently diffused areally. Others consider that the distribution of -nggu is better explained as a retention from a proto-language that was lost in some modern languages or groups. And as Evans (2003) pertinently observes, although instances of diffusion of specific morpheme variants are well attested in Australia, diffusion of variant sets (with complex conditioning factors) such as -lu ~ -nggu are not. In a similar way, many Australianists consider it to be probable that the absence of the first-person dual inclusive *ngali* in a few Pama-Nyungan languages represents loss of the form in these languages, rather than incomplete diffusion over the Pama-Nyungan region.

Both Barry Alpher (e.g. 1990) and Harold Koch (e.g. 2003) argue the advantages, indeed necessity, of taking inflectional paradigms into account in reconstructing proto-Pama-Nyungan, and not merely the forms of roots and affixes separately. Both show that sets of paradigmatic forms—verb inflection paradigms by Alpher (1990), and case-paradigms for singular free pronominals and interrogative particles by Koch (2003)—can be identified in a diverse selection of Pama-Nyungan languages that permit reconstruction of inflectional paradigms, and thus support the genetic unity of Pama-Nyungan.

Subgrouping

The map gives an approximate idea of the groups within Pama-Nyungan. Some 30 groups are identified, which are further divided into almost seventy subgroups. The groups and subgroups differ considerably in distribution and size. One group, the Nyungic group, takes up nearly half of the Pama-Nyungan region, and is divided into about a dozen subgroups. On the other hand, Warumingic, Kalkatungic, and Yandic consist of single languages.

The establishment of the groups and subgroups of Pama-Nyungan is in a very preliminary state, and there are doubts about the status of many. Various changes to the group and subgroup structure have been proposed since 1966. Attempts have also been made to motivate groups or subgroups by more reliable means than the original lexicostatistical criteria. In a number of cases, however, the genetic relatedness of a set of languages has been established, although not subgroup status by identification of shared innovations.

In a careful study of the Pilbara situation, Alan Dench (2001) has pointed out a variety of difficulties in determining whether shared morphological and syntactic features are innovations indicative of common inheritance or the result of diffusion. He concludes that although the languages are probably genetically related, there is no evidence that they form a subgroup of any larger group; the languages form, in his view, a linguistic area within which much lexical and grammatical diffusion has occurred. Although Dench takes the extreme position that diffusional explanations should be privileged over genetic retention, he correctly observes the difficulties inherent in distinguishing genetically inherited features from areally diffused features.

Dixon's current position (2002) is that the putative Pama-Nyungan family is made up of some 30 low-level genetic 'subgroups', which are effectively small language families on their own (the prefix 'sub-', he explains, does not imply that there is necessarily any higher order containing group, only that there may be).

Dixon further proposes that some of the accepted groups within Pama-Nyungan are areal groups, not genetic subgroups. These include the Arandic and adjacent Karnic groups of Central Australia. However, Koch (2004) and Claire Bowern (2001) provide carefully argued cases for their subgroup status on the basis of shared innovations, at least some of which (e.g. paradigmatic irregularities) are more likely to be retentions from an earlier proto-language than resulting from diffusion. Examples of such shared innovations peculiar to the Arandic languages are phonological changes (including complete loss of all initial consonants, centralization of vowels in unstressed syllables, and stress shift to the second syllable of words), and innovations in personal pronouns, nominal inflections, and interrogatives. In Karnic languages, they include lexical and morphological innovations.

Origin and Dispersal of Pama-Nyungan Languages

The uneven distribution of language families across Australia, and of groups within the Pama-Nyungan region is striking, and invites explanation. Some proposals have been put forward. These accept that proto-Pama-Nyungan was originally spoken in a much smaller homeland region, and that the continent as a whole once showed linguistic diversity comparable to that of the non-Pama-Nyungan region today. Around 3,000–5,000 years ago (the dating is a guess, based on the apparent diversity within the family), it began spreading out to ultimately cover the large region it occupies today.

Stephen Wurm (1972) suggests a link with the emergence of an advanced technology (ground axes and hafted stone tools) that also appears on the archeological horizon some 5,000 years ago. He proposes that users of this technology, speakers of proto-Pama-Nyungan, expanded out into areas formerly occupied by speakers of different languages, their advanced technology presumably giving them an edge over the local inhabitants.

A more elaborate model is suggested by Nicolas Evans and Rhys Jones (1997). These authors propose (on the basis of the diversity of subgroups of Pama-Nyungan and the number of potential sister families) a homeland region in the vicinity of the Gulf of Carpenteria. In contrast to Wurm, they do not link the spread of Pama-Nyungan to major migrations and conquests by the wielders of a new technology, but to a cluster of social changes, including the spread of ceremonial activity associated with the new highly valued technology, and the exploitation of new vegetable foods that could support large intergroup ceremonial activities. They suggest that initiation into the rituals associated with the new technology might attract payment in the form of wives for the sons of the initiators, thus giving rise to larger networks of exogamous social interactions than had existed previously. In such circumstances, proto-Pama-Nyungan could well have been a high-status language, and its usage a sign of the status of performers of the new ceremony. Thus, Pama-Nyungan could have spread out with relatively minor (though still discernible) demographic changes.

Both models are of course speculative. Nevertheless they are noteworthy in that they attempt to forge links between linguistic, anthropological, and archeological evidence. They also make potentially testable predictions concerning the distribution of bio-genetic

markers and substrate influences on modern Pama-Nyungan languages.

WILLIAM B. MCGREGOR

Pāṇini

Virtually nothing is known about the life of the great Indian grammarian Pāṇini, except for the fact that he was a native of Śalātura, in northwestern India (Gandhāra); from his matronymic, we learn that his mother's name was Dākṣī. None of the numerous commentators say anything about the time in which he lived, but, based on the variety of Sanskrit he describes, he is now thought to have lived in the fourth (or maybe fifth) century BCE. His grammatical treatise, the *Aṣṭādhyāyī* ('Eight chapters'), is the most important grammatical description of Sanskrit, and a large part of the Indian grammatical tradition after Pāṇini consists of commentaries on his work.

The style of the *Aṣṭādhyāyī* appears quite striking if considered from the point of view of Western grammatical tradition: it is constituted by 3,996 *sūtra*, or aphoristic rules, by which Pāṇini not only describes grammatical rules but also defines the way in which grammatical terms and constructions are used in his metalanguage. Pāṇini's terminology constitutes his own achievement only in part: grammatical description already relied on a rather conspicuous tradition,

judging from the fact that Pāṇini mentions the names of ten of his predecessors.

The language described by Pāṇini is a variety of Sanskrit that does not correspond exactly to the language of any known text. This fact has aroused suspicion, especially among Western scholars in the nineteenth century, leading some to blame Pāṇini of describing an invented variety. A further complication is given by the fact that even the earliest commentators are at variance with Pāṇini on some points: most likely, different varieties of Sanskrit underlie their descriptions. The philological tradition of Pāṇini's text is not without problems either, as some minor parts probably belong to later commentaries (notably to Patañjali's *Mahābhāṣya* see below).

It is noteworthy that Pāṇini occasionally mentions differences between the variety he describes and earlier varieties, notably Vedic Sanskrit. This has led some scholars to state that Pāṇini had a historical view of grammar: however, in view of the existence of earlier grammarians, who had mostly described Vedic, it seems more likely that Pāṇini only wanted to mention

variants found in other treatises, without historical intentions.

Among the most important commentators of Pāṇini are Kātyāyana, who, according to tradition, lived in the third century BCE and annotated about a third of Pāṇini's work, and Patañjali, author of the *Mahābhāṣya* ('Great commentary', around 150 BCE). Patañjali's commentary, which takes as a starting point Kātyāyana's notes (which, in fact, we only know through the *Mahābhāṣya*), and adds comments, partly to the notes, and partly to Pāṇini's text, also contains in the introduction some general statements about the *Vedas* and about grammar.

Pāṇini's grammar became known to Western scholars at the end of the eighteenth century, with the beginning of Indological studies; since then, its fortune in the West has undergone quite dramatic changes. During the nineteenth century, the striking differences between the frameworks in which grammatical description was organized by Pāṇini and by the Greco-Roman tradition, together with the increasing conviction that insights into language could be gained only by means of historical investigation, progressively led to a negative evaluation of Pāṇini's work. Perhaps the worst opinions about Pāṇini were held by the American indologist Withney, who not only thought, as many of his contemporaries, that the Indian grammarian described an invented language but also dismissed his grammatical terminology as crude and philosophically not well founded.

In spite of this and other severe judgments, Indian grammatical tradition influenced Indo-European linguistics in its early development, partly providing a basis for the terminology, partly because the Indian use of listing roots helped to develop the concept of morpheme.

The twentieth century brought a complete reevaluation of Pāṇini's methods, in some cases with enthusiastic appraisals. The systematic character of Pāṇini's treatment of grammar, and the formulation of the *sūtra* as grammatical rule appealed to scholars working within various frameworks; Pāṇini was hailed as a predecessor of both structuralism and generativism. It became apparent that Pāṇini had a much more thorough understanding of phonology than his Greek contemporaries, and his description of vocalic *sandhi* was even said to presuppose a theory similar to (early) generative phonology.

Perhaps the field in which Pāṇini has enjoyed most admiration lately is case theory. In the late 1960s, after the outburst of Fillmorean Case Grammar, it was pointed out that Pāṇini's notion of *kāraka* corresponded to what Fillmore called 'deep cases', or, to state it in more modern terminology, semantic roles. Thus, there is *kāraka* of the agent, which can be expressed in the nominative or instrumental, the use of the latter ending being demonstrated by means of passive constructions.

In fact, when describing the use of 'affixes' (meaning both verbal and nominal affixes), Pāṇini I mostly has a semantically based approach, rather than an approach based on forms, as was usual within the Greco-Roman tradition. Some later grammarians gave sematically finer definitions: for example, within the philosophical school of Nyāya the *kāraka* of the agent was conceived as implying intentionality, so that only animate entities could be regarded as agents. On the contrary, Pāṇini and his followers (Pāṇinīyas) called agents all subjects of action verbs, including inanimate entities (in examples such as 'the cart goes to the village').

Papiamento

Papiamento (Papiamentu) is a language spoken north of Venezuela on the Leeward Islands of the Netherlands, Antilles, Curaçao, and Bonaire, and on the island of Aruba, otherwise known as the ABC islands. It is estimated that Papiamento is spoken natively by about a quarter of a million people, mostly in the Caribbean, and by some 40,000 people living in the Netherlands. Although the official language on the ABC islands is Dutch, Papiamento pervades all levels of society, including the educational system and

government. Papiamento also has a rich literary tradition, an established presence in electronic and digital media, and several newspapers and magazines are also published in the language. The name is derived from the verb *papia* meaning 'to speak' and the suffix, -mento. Thus, Papiamento can be literally interpreted as '(the act of) speaking'.

Papiamento is a creole language, which emerged during the second half of the seventeenth century around the period of European colonization of the Caribbean islands. Like other creole languages, Papiamento inherited structural characteristics from a mixture of West-African languages (the substrate languages). Approximately two thirds of its vocabulary comes from Iberian languages (the superstrate languages), about a quarter from Dutch, and the rest from other languages including French and English. The language also has traces of Amerindian and West African vocabulary as well.

The history of the ABC islands provides some insight into the social and linguistic context in which Papiamento developed: originally populated by Amerindians speaking an Arawakan language, Curaçao was settled by the Spanish in 1527. After a century of Spanish occupation, the Dutch conquered Curaçao in 1634 at which time most of the Amerindians and the Spanish were driven from the island. Shortly thereafter, it became a depot for the slave-trading practices of the Dutch West-India Company. Not long after the fall of the Dutch Brazilian Empire in 1654, a substantial population of Portuguese Jews (and non-Jewish settlers as well) arrived on the island. Despite the diverse linguistic backgrounds of the island's inhabitants, Papiamentu is believed to have stabilized as a creole on Curaçao around 1700 and spread to Bonaire and Aruba by the end of the century.

Although this brief account of the islands' history demonstrates the importance of Dutch and Portuguese in the incipience of the language, Papiamento clearly exhibits Spanish elements and in fact, a diary belonging to a Jesuit missionary on Curaçao dating from 1704, first referred to the language on the island as 'broken Spanish'. This has caused some controversy surrounding the origins of the language with respect to whether it is actually a Portuguese- or Spanish-based creole. Some scholars argue that the Portuguese contribution to the language has been obscured by its continual contact with Spanish. Consequently, the earliest forms of Papiamento are thought to have exhibited the Portuguese contribution more so than the Spanish; however, the earliest written attestation of the language, a letter dating from 1776 written by a Portuguese Jew to his wife, shows a remarkable resemblance to the language spoken on the islands today, replete with elements of the Spanish language thought to be less prominent in the earlier stages of Papiamento. Thus, questions concerning the precise origins of Papiamento continue and as it is not directly related to any other Portuguese- or Spanish-based creole, scholars can only continue to piece together linguistic and historical evidence to help shed light on the genesis and subsequent evolution of the language.

Papiamento has existed in tandem with Dutch on the islands for centuries; however, the Dutch influence in the language is far less obvious than the Iberian influences, in both historical and contemporary contexts. In spite of the fact that Dutch is the official language of the regions where Papiamento is spoken natively, it is quickly becoming far less common even in the areas of government administration, education, and the judiciary system, realms of society in which it was traditionally used, testifying to the high level of social prestige affiliated with Papiamento—a fact that makes it somewhat unique among creole languages. Papiamento's social currency is also demonstrated by the fact that it has an official orthographic system, differing slightly on the islands of Curaçao and Bonaire than on the island of Aruba. These spelling differences can be seen in the name of the language itself, while the former islands prefer Papiamentu as opposed to Papiamento, its Aruban counterpart. Additionally, after careful language planning efforts, in 1987, Papiamento was officially integrated into the educational system of the ABC islands.

The phonemes (sounds) of Papiamento include almost all the consonants and vowels found in American Spanish, as well as some Dutch vowels. A linguistic trait of Papiamento not found in either the Iberian languages or Dutch, and which is rare in creole languages in general, is the use of high (´) and low (`) tones to distinguish between pairs of words (eg. *párà* 'bird', *pàrá* 'to stand, to stop'; *wárdà* 'guard service', *wàrdá* 'to wait'). This feature of the language is attributed to the West African, or substratal influences. West African structural influences typical of creole languages can be noticed in serial-verb constructions such as *Ela **kore bai** su kas* or 'She or He ran (go) home,' or focus particles found in sentence-initial positions like ***Ta** e buki m'a dunabu* or '(Focus) I gave you the book.' Below are some Papiamento words that illustrate the Iberian and Dutch contributions to the language:

Portuguese: *bai* 'to go'; *preto* 'black'; *bringa* 'to fight' (derived from brigar)

Spanish: *Dios* 'God'; *salida* 'departure'; *ruman* 'brother' (derived from hermano)

Dutch: *wikent* 'weekend'; *spiel* 'mirror' (derived from spiegel), and *wak* 'to see' (derived from waken).

Paralanguage

The term paralanguage refers to a wide variety of nonverbal behaviors relevant to communication. Vocal paralanguage includes voice quality, intonation, and voice dynamics such as loudness, pitch range, and rate of speech. Bodily paralanguage incorporates facial expression, hand gestures, posture, touch, and physical proximity to others. These behaviors, all of which may co-occur with verbal communication, differ from language per se in that they do not form part of a hierarchically structured, coded system in which a discrete symbol is arbitrarily associated with a particular meaning.

While paralanguage does not convey meaning in the same way as language, it plays important functions in communication. Paralinguistic behavior conveys the emotional state of speakers and listeners, expresses semantic nuances that could not be inferred from language alone, helps regulate the flow of interaction, and provides cues regarding the sex, age, culture, and socioeconomic status of speakers.

The study of paralanguage has grown significantly over the past 30 years. Technological advances such as audio and videorecording, and more recently, the widespread availability of computers and specialized software analysis packages, have facilitated a more systematic approach to the study of paralanguage. The sections below describe some key paralinguistic channels: voice quality, intonation, and hand gestures (see Siegman and Feldstein (1987) and Feldman and Rime (1991) for an overview of these and other paralinguistic channels).

Voice Quality

Voice quality may be defined as a quasipermanent setting of the vocal tract that characterizes the speech of an individual, or a cultural, social, or linguistic group (see Laver (1980) for a thorough introduction to this subject; and Kent and Ball (2000) for an overview of recent research).

Voice quality settings may be roughly divided into two categories: laryngeal and supralaryngeal. Laryngeal settings (also known as 'phonation types') involve different patterns of vocal fold vibration. These settings include modal voice, breathy voice, creaky voice, harsh voice, falsetto voice, whisper, and the various possible combinations of these phonation types (e.g. harsh whispery voice). Modal voice involves quasiperiodic vibration of the vocal folds, in that the vocal folds are open and closed for approximately equal periods of time, lending the voice a smooth, even quality. Other laryngeal configurations may be thought of as departures from this 'neutral' setting. For example, for a breathy voice, the vocal folds are open longer than they are closed, producing audible friction. By contrast, for a harsh voice, the vocal folds are closed longer than they are open, and the vibration is irregular, producing a rasping, uneven quality that is often enhanced by the vibration of the ventricular or 'false folds'. For a whisper, the vocal folds do not vibrate at all: the vocal folds are closed along most of their length, and a triangular opening is left at the posterior part of the vocal folds, generating strong friction as air passes through. Some laryngeal settings are readily identifiable by their pitch, as, for instance, the very high pitch of falsetto voice, involving the vibration of a small portion of the vocal folds, and the very low pitch of creaky voice, in which the listener can hear each separate vibration of the vocal folds.

Supralaryngeal settings involve different configurations of the larynx, pharynx, soft palate, tongue, lips, and jaw, all of which affect the resonance of the voice.

The larynx may be raised or lowered, the pharynx widened or constricted, the soft palate raised or lowered, the tongue and lips protruded or retracted, and the jaw lowered or raised—all of which, separately or in combination, have distinct acoustic and auditory effects. For example, a speaker with a habitually lowered soft palate will have a nasal voice. A speaker with a lowered larynx will have a deeper sounding voice than he or she would with a neutral or raised larynx, by virtue of having produced a longer vocal tract with correspondingly lower formant frequencies.

The combination of various laryngeal and supralaryngeal settings contributes to the characteristic 'tone of voice' or 'accent' that listeners come to associate with different individuals and regional or social groups. For example, North American females are more likely than their male counterparts to speak in a habitually breathy voice—a habit that some women may deliberately alter in order to sound more professional in a particular work or social setting. Certain regional accents of English may be distinguished by a particular voice quality setting, such as, for instance, the nasal quality characteristic of speakers in the southern United States of America. Some foreign accents are stereotypically associated with a particular voice quality setting, such as the quasi-permanent retraction of the tongue tip (or 'retroflexion') that often characterizes an East Indian accent.

In addition to suggesting social, cultural, and linguistic characteristics of speakers, voice quality settings can be deliberately exploited by a single individual in different communicative settings to convey paralinguistic meaning—whether to signal the speaker's actual emotional state or attitude toward what he or she is saying. For example, in English-speaking countries, a whisper is often used to signal secrecy, while a breathy voice may be used to convey intimacy or sexual attractiveness. A creaky voice may sometimes be used to suggest sadness or boredom, while lowered larynx voice may be used by speakers who wish to sound serious or authoritative.

Intonation

Intonation refers to the variations in pitch or fundamental frequency that occur in speech, creating its characteristic melodies. In intonational analysis, these melodies are broken down into 'tone units' or 'intonation groups'. Tone units usually consist of five or six words, often constituting a grammatical constituent such as a sentence, clause, or phrase, but sometimes consisting of a single word, or even a single syllable. The major characteristic of a tone unit, independent of its length or grammatical status, is that it contains one major pitch movement, realized primarily on the most prominent, or 'accented' syllable in the tone group. Within the British system of intonation analysis, there are five major nuclear tones: falls, rises, levels, fall–rises, and rise–falls. Within the predominantly American autosegmental metrical system, (for example, the ToBI, or 'Tone and Break Index' system), these and other contours are expressed as different patterns of high and low tones ('H' and 'L'). (See Cruttenden (1997) for a thorough overview of intonation in the British and American traditions.)

Intonation may have linguistic or paralinguistic meaning. For instance, in English, an utterance produced with falling intonation is associated with a statement or declarative sentence, while a rising intonation is often used for questions. Such uses of intonation are often considered linguistic. However, there are many intonational variations that carry paralinguistic meaning. For instance, some speakers use rising intonation for declarative sentences as a way of checking whether or not the listener understands what they are saying, to suggest openness to an alternative point of view, or, possibly, to convey a lack of confidence in what they are saying. This particular usage is more common among young North American females than their male counterparts. The word 'yes', spoken slowly with a rising then falling pitch, may suggest doubt or hesitation on the speaker's part, even though the word itself conveys agreement. The same word, spoken slightly more quickly, with a falling then rising pitch, may suggest impatience or irritation on the part of the speaker. These are but a few of many possible examples of the paralinguistic use of intonation.

Intonation, in combination with voice quality, and other features of voice dynamics, such as variations in pitch range (wide vs. narrow), intensity (loud vs. soft), and rate of speech (fast vs. slow), provide the listener with significant cues regarding the speaker's attitude and/or emotional state. For example, a wide pitch range is often characteristic of a happy mood, and a more restricted pitch range is characteristic of a more depressed state. Anger is often associated in a loud, high-pitched voice, while fear may be expressed with a quieter, high-pitched voice, sometimes combined with a whispery quality. In a state of excitement, people often speak more quickly than when they are calm. The qualities associated with a particular mood may be characteristic of a speaker's habitual use of the voice, possibly suggesting more permanent personality traits.

Gestures

While speaking, people can often be seen moving their hands up and down, pointing, or drawing pictures in the air, in ways that appear connected to what they are saying. These movements, as opposed to other hand

movements that they might happen to make while speaking, such as smoothing their hair or removing lint from their pants (the latter are called "self-adaptors"), are considered communicative gestures.

Adam Kendon—a pioneer in the research on gestures—has characterized hand gestures as existing along a continuum, ranging from completely nonlinguistic gestures to the fully linguistic hand movements that comprise actual sign languages (see McNeill (1992:37) for a fuller description of Kendon's continuum). In the middle of this continuum are the semilinguistic hand gestures known as 'emblems'. Emblems have a fixed form that is associated with a particular meaning, and may in this sense, be considered to be quasilexical. Emblems vary considerably from culture to culture. For example, the 'thumbs-up' gesture often used in English-speaking countries to signal a victory or a generally positive attitude toward a particular situation, has an obscene connotation in Iran. Some cultures—Neopolitan Italian culture, for example—have elaborate sets of emblems that are extensively used in day-to-day conversation. Because of their quasilexical nature, emblematic gestures can often be used instead of words in face-to-face interaction for communicative effect.

However, the majority of communicative hand gestures are nonlinguistic, and co-occur with speech. Nonlinguistic gestures have been categorized in a variety of ways over the past 50 years; but the categories developed by McNeill (1992) are those most commonly used in the current literature on gestures. Nonlinguistic gestures may be classified as iconic, metaphoric, deictic, or beats. Iconic gestures illustrate concrete entities in the world, while metaphoric gestures depict abstract concepts. Iconic and metaphoric gestures have no fixed form, and are spontaneously invented by speakers to physically represent some aspect of what they are saying. For example, while saying 'and the guy just grabbed her purse', a speaker might physically depict this action in an iconic gesture—thereby often conveying information not fully expressed in words, such as the precise movement involved in the grabbing. Deictic gestures involve pointing, either to a location within the speaker's environment, or to an area in space that symbolizes a location referred to in the accompanying speech. Beats are short, rhythmic movements of the hands, often physically oriented toward the listener (e.g. involving an open palm facing the listener) and do not represent anything in the accompanying speech. Rather, they are used to emphasize the delivery of information, help structure discourse, and help regulate aspects of interaction, for instance, turn-taking routines.

As noted above, nonlinguistic gestures are closely synchronized with speech. Gestures may be divided into three phases: a preparatory or onset phase, in which the hands rise from a position of rest; a stroke phase, the most 'energetic' portion of the gesture, or the point at which the gesture appears to have reached its 'destination'; and a recovery or offset phase, the point at which the hands return to a position of rest. The stroke of a gesture almost always co-occurs with the word or phrase with which it is meaningfully connected. Moreover, the stroke often co-occurs with the most prominent, or accented syllable in a tone unit, suggesting that the planning of gesture is closely linked with the planning of speech.

In recent years, there has been a surge of interest in the study of gesture and other paralinguistic phenomena, such as facial expression, voice quality, and intonation. Traditionally, these features have often been considered to reflect the emotional state of speakers. While this approach continues to form a significant part of research on paralanguage, recent research has also highlighted the important semantic information conveyed through paralinguistic channels (see, for example, McNeill 1992, 2000). Moreover, there is a growing interest in the complex ways in which linguistic and paralinguistic channels interact. This line of research is leading to an enriched understanding of communication as integrated, multimodal behavior— and perhaps challenging the traditional distinction between language and paralanguage.

Parsing

A recognizer is an algorithm that takes a string as input and either accepts or rejects it, depending on whether or not the string is a sentence of a particular grammar (Grosz et al. 1986). A parser is a recognizer that also shows all the ways in which the string can be derived, in the form of the invoked grammar rules arranged in trees or nested square brackets.

The most common way to represent a grammar is as a set of production rules, which are also called rewrite rules. Phrase structure grammars are sets of production rules that specify the various ways in which a sentence can be decomposed into its constituent syntactic units, which themselves can be decomposed into smaller units, and finally into individual words. The production rule S → VP NP shows that a sentence can consist of a noun phrase followed by a verb phrase, and the rule ADJ → small|red|new shows that an adjective can consist of one of the following individual words: small, red, or new.

Symbols that are themselves further expanded by rules are called nonterminal symbols, which generally correspond to syntactic classes. Symbols that correspond to individual word strings that must be found in the input sentence are called terminal symbols (Rich and Knight 1991). The nonterminal symbol S, which stands for the input sentence in its entirety, is called the root of the grammar. An example of a simple grammar which derives the sentence 'John ate the cat' is given by Allen (1995:42).

(1) S → NP VP
(2) VP → V NP
(3) NP → NAME
(4) NP → ART N
(5) NAME → John
(6) V → ate
(7) ART → the
(8) N → cat

The parse tree corresponding to this parse is shown in Figure 1.
Figure 1. A tree representation of John *ate the cat*.

Context-Free Parsers

The term context free (CF) was introduced by Chomsky in 1956. CF grammars consist of rules with a single symbol on the left-hand side. Such rules are always applicable, since they are in no way dependent on the nature of constituents elsewhere in the input text. Most of the CF parsing algorithms were developed in the 1960s for use with computer language compilers, but pure CF grammars are not effective for describing natural languages. Grammars that are not CF are said to be context sensitive, where the rules have been augmented with additional conditions, meaning that they only apply if certain things are found elsewhere in the input text.

Top-Down and Bottom-Up Parsing

A top-down parsing strategy starts with the start symbol S and then searches through different ways to rewrite the symbols until either the input sentence is reproduced or all different ways to rewrite the symbols have been tried. A top-down parse using the simple grammar above to derive the sentence 'John ate the cat' would proceed as follows:

S

➜ NP VP (rewriting S)
➜ NAME VP (rewriting NP)
➜ John VP (rewriting NAME)
➜ John V NP (rewriting VP)
➜ John ate NP (rewriting V)
➜ John ate ART N (rewriting NP)
➜ John ate the N (rewriting ART)
➜ John ate the cat (rewriting N).

The bottom-up parsing strategy, on the other hand, starts with the actual words of the sentence and uses the rewrite rules in reverse until either the S symbol alone is generated or all combinations of the rewrite rules have been tried. A bottom-up parse of 'John ate the cat' might proceed as follows:

John ate the cat

➜ NAME ate the cat (rewriting John)
➜ NAME V the cat (rewriting ate)
➜ NAME V ART cat (rewriting the)
➜ NAME V ART N (rewriting cat)
➜ NP V ART N (rewriting NAME)
➜ NP V NP (rewriting ART N)
➜ NP VP (rewriting V NP)
➜ S (rewriting NP VP)

LR parsers read their input from left to right and produce a rightmost derivation, i.e. expand the rightmost non-terminals of the production rules first.

Chart Parsers

In a standard parser, if an early segment can be analyzed in more than one way, each step in the recognition of subsequent phrases in the sentence will be repeated once for each earlier analysis. Chart parsers (Winograd 1983) provide a means of eliminating such redundant computation. Kay described the chart as 'a kind of well formed substring table'. It allows the parser to store the partial results of the matching it has done so far so that this work need not be duplicated.

First, we will consider the bottom-up chart parser. Each word in the input sentence is considered in turn. The current input word is called the key. For each new key, we look for rules that match a word sequence involving the key—either a rule that begins with the key, or a rule that has already been started by earlier keys, which can either be extended or completed by the current key. Allen presents the following example of a grammar:

(1) S → NP VP
(2) NP → ART ADJ N
(3) NP → ART N
(4) NP → ADJ N
(5) VP → AUX VP
(6) VP → V NP

If we are parsing a sentence that begins with ART, ART becomes the first key, and rules (2) and (3) are matched since their right-hand sides both begin with ART. The following notation is used to show that rules (2) and (3) can be continued from the point of the ART (denoted by 'o') onwards. The partially matched rules are stored in the chart, along with their locus (starting position in the sentence) and position of the last word to match so far:

(2′) NP → ART o ADJ N (1,2)
(3′) NP → ART o N (1,2)

If the next key is ADJ, then rule 4 can be started, and rule 2′ can be extended:

(2′) NP → ART ADJ o N (1,3)
(4′) NP → ADJ o N (2,3)

The chart keeps the record of all the rules found so far which have been matched partially by the previous keys. These partially matched rules are called active arcs.

Active arcs are never removed from the chart; hence, their original and extended forms are simultaneously present. The chart also records the completely matched syntactic constituents (as defined by the grammar rules) found so far in the parse.

Completed constituents are placed on a list called the agenda. The algorithm proceeds by selecting a completed constituent from the agenda. For each matching rule in the grammar, an active arc is combined with the completed constituent in the agenda. Whenever the agenda is empty, all possible syntactic interpretations of the next word in the sentence are added. The parse ends when an active arc and a completed constituent combine to produce an entire sentence S. If all possible parses of a sentence are required, the process continues until the agenda is empty. The top-down chart parser is called the Earley parser (Earley, 1970).

Augmented Transition Networks

An early model for natural language grammars was a transition graph called the finite state machine. This consists of a network of nodes (states) and directed arcs or transitions, marked by arrowheads pointing away from the previous state and toward the next state. Each arc has a symbol, representing terminal symbols (individual words such as 'red' or syntactic classes such as 'adjective') which may appear in an input sentence. There may be more than one arc arriving at each state or leaving each state.

There is one distinguished state called the start state (with no inward arcs), and a number of distinguished states called final states (with no outward arcs). Starting at the start state, the words of the sentence to be parsed are read off in turn. If the first word read off matches the symbol on one of the arcs leaving the start state, the next state is the one found by following that arc. The second word is read in, and if that word matches an arc leaving the second state, the arc is followed to the third state. This process continues, and if we have arrived at one of the final states as a result of reading in the last word, the sentence has been accepted by the augmented transition network (ATN) grammar. Sometimes an arc can return to the very same state that it left, to show that optional additional words of the type specified by the arc's symbol are permitted at that point in the sentence.

ATN are finite state machines augmented by allowing not only terminal symbols on the arcs, but nonterminal symbols representing entire phrases (Woods 1970). These phrases are themselves represented by ATNs. For example, an ATN designed to recognize a prepositional phrase is shown in Figure 2.

Figure 2. A simple augmented transition network.

To make the transition from S2 to finish, there must be a noun phrase (NP) in the input sentence. In an operation called a 'push', processing is suspended at the point the NP is requested, and a new ATN is entered, which accepts subsequent words from the input sentence. This is analogous to a subroutine call in a computer program. When the final state of the new ATN is reached (showing that the sequence of input words since entering the new ATN was indeed an NP), an operation called a 'pop' takes place and processing of the input sentence resumes at the point in the original ATN from where it left off. A called ATN may itself call other ATNs, and an ATN may call itself (recursion). The record of the sequence in which the ATNs have called each other is called a 'stack', analogous to a stack of plates, each plate representing an ATN, which may be 'pushed' onto or 'popped' off the stack. The most recently called ATN is at the top of the stack, but it cannot be 'popped' off until any ATNs it calls itself are completed. Advantages of ATNs are their generative power, efficiency of representation, and their ability to capture regularities in language.

Probabilistic Parsing

A deterministic parser consists of a set of rules, each with equal a priori likelihood. It either generates just one parse according to the ordering of the rules, or all possible parses of a sentence, but does not mention whether any one of these parses is any likelier than the others. A probabilistic parser, on the other hand, may offer alternative rules for the decomposition of the constituents of a sentence, each with an associated probability value, e.g. VP → V NP 0.6, VP → V PP 0.4. The overall probability of a parse is found by multiplying together the probabilities of all the rules that were called upon in the derivation of that parse. The likeliest parse among many possible parses is found by the Viterbi algorithm. The strategy of exploring the paths with high probability constituents first is called Best First Parsing.

The Penn Treebank contains over two million words of American English parsed manually. It has proved useful as a reference corpus for the comparison of different parsing algorithms, such as in the PARSE-VAL evaluations (Black et al. 1991). In 1994, Magerman was able to derive rules automatically for a probabilistic parser through an analysis of the Penn Treebank. The simplest approach is to count the number of times each rule is used in the treebank and normalize this to estimate the probability of each rule.

For certain grammars, the most probable parse cannot be found easily using the Viterbi algorithm. In such cases, a most probable parse may be found using Monte Carlo simulation techniques. Many parse trees for the same sentence are randomly generated. The likelihood of each rule being used in a particular random parse depends on its probability. When the sample is large enough, the most frequently occurring output parse tree over all the random tests is assumed to be the most probable parse.

Tagging

Tagging is marking items in a text with additional information, related to their linguistic properties. This information is attached to the text items in the form of codes called tags. Here, we will mainly discuss the automatic assignment of part of speech (POS) category tags to words in a text; but tagging can also involve the assignment of semantic categories as a by-product of word sense disambiguation.

The Brill (1995) tagger operates as follows. An initial guess is made as to the POS of each word in the text by an initial state annotator. Simple methods of doing this include (a) labeling all words with their most frequent tag as found in the training corpus and (b) assuming all unknown words are nouns. The output of the initial state annotator is then compared with the manually annotated Penn Treebank, and a list of transformations is learned that can be applied to the output of the initial state annotator, according to the nature of words in the vicinity of each tagged word. The transformations have two components, a rewrite rule (such as 'change the tag from modal to singular noun') and a triggering environment (such as 'if the preceding word is a determiner'). Using this transformation, if the word 'can' has been given an incorrect initial tag as in 'the_DT can_MD rusted_VBD', the modal (MD) tag is replaced by a singular noun (NN) tag, because the previous word has a determiner (DT) tag. Other transformations are 'change an infinitive verb to a singular noun if one of the previous two tags is a determiner', and 'change a singular noun to a verb infinitive if the previous word is 'to'.

The CLAWS probabilistic tagger (Garside et al. 1987) takes an input sentence such as 'Henry likes stews'. and compares it word by word against the CLAWS lexicon, which shows that 'Henry' must be tagged as a proper noun (NP); 'likes' and 'stews' could either be tagged as plural nouns or verbs (NNS or VBZ), and the full stop always has its own tag (.). For each of the four possible tag sequences spanning this region of ambiguity, a value is generated by calculating the product of the frequencies per thousand for successive tag adjacencies as found in the Brown corpus, as shown below. The number 17 shows that in the Brown corpus, the tag NP is followed by the tag NNS 17 times per 1,000, while 983 times out of 1,000 it is followed by something else.

Value(NP-NNS-NNS-.) = $17 \times 5 \times 135 = 11{,}475$
Value(NP-NNS-VBZ-.) = $17 \times 1 \times 37 = 629$
Value(NP-VBZ-NNS-.) = $7 \times 28 \times 135 = 26{,}460$
Value(NP-VBZ-VBZ-.) = $7 \times 0 \times 37 = 0$

Thus, the tag sequence 'Henry_NP likes_VBZ stews_NNS ._' is found to be the likeliest. Since there are generally too many possible sequences to find a value for them all, the Viterbi algorithm (Forney 1973) is used, which means that only the most promising sequences are tested. The CLAWS tagger relies on bigram (pairs of adjacent tags) frequencies, while in 1988, Church described a tagger based on trigram (sequences of three adjacent tags) frequencies.

Affix Stripping

Affix stripping and morphological parsing are parsing at the subword level. Instead of analyzing a sentence in terms of its constituent words, a word is analyzed in terms of its constituent morphemes. Klavans and Chodorow (1991) used an instructional morphological parser to teach morphological theory. Several sets of rules exist for the automatic removal and replacement of common suffixes (stemming), including those produced by Paice (1990), Lovins, and Porter. Recognizing suffixes automatically can help in POS identification, where, for example, any word ending in 'ation' must be a noun. The simplest form of stemming is the reduction of all regular nouns and verbs to their inflectional root, which is the singular form for nouns and the infinitive form for verbs.

The rule sets for the removal and replacement of common suffixes are in the form of production rules, in the form 'old suffix → new suffix', meaning that if a word ends in the old suffix, this must be removed and replaced by the new suffix. The new suffix may be null, meaning that the old suffix is removed and is not replaced with anything. The rules must be presented in a fixed order. Four of the rules given by Paice are as follows:

(1) ING → NULL
(2) E → NULL
(3) ION → NULL
(4) OLV → OLUT

Imagine that the word 'resolving' is given to each rule in turn. Rule (1) removes the suffix 'ing' and replaces it with nothing; hence, we are left with 'resolv'. This does not end in 'e' or 'ion', hence, rules (2) and (3) have no effect. However, rule (4) states that the current suffix 'olv' must be removed and replaced by 'olut', leaving the string 'resolut'. The words 'resolve' and 'resolution' will also be reduced to 'resolut', rendering all three words equivalent. Prefix removal may be less useful than suffix removal, as the removal of a prefix may radically alter the meaning of a word: consider the group 'bisect', 'dissect', 'insect', 'sect'.

Semantic Parsing

A semantic grammar, like a syntactic grammar, consists of production rules, but instead of specifying only the syntactic constituents that may be present in a sentence, may also specify domain-specific semantic categories. Allen (1995) gives an example in the domain of airline bookings, of a semantic grammar that should cater for such input phrases as 'flight 457 to Chicago'. This would include such rules as 'FLIGHT-NP → FLIGHT-N NUMB' (A noun phrase referring to a flight consists of a noun referring to a flight and a number) and 'FLIGHT-NP → FLIGHT-N to CITY-NP' (A noun phrase referring to a flight consists of a noun meaning 'flight', followed by 'to', then a noun phrase which is the name of a city). Different algorithms for semantic parsing vary according to whether it is necessary to produce a syntactic parse first, or whether one should proceed directly with the semantic parse.

Paul, Hermann

Hermann Paul was one of the most influential linguists of the late nineteenth and early twentieth centuries. Paul was a neogrammarian (Germ. *Junggrammatiker*), a school of linguistics that flourished in his time and had an immense influence on linguistics thereafter, as discussed further below. His interest in languages and linguistics dates back to his schooldays, when he developed a taste for medieval German literature and Middle High German (superseding an earlier interest in mathematics).

In a brief autobiographical essay published just after his death, Paul suggested that his work could be divided into two general categories: literary interpretations and textual criticism, with a focus on Middle High German, and the phonology and morphology of the Germanic languages. While Paul was certainly an important contributor to these fields, this self-classification is something of an oversimplification, as he made significant contributions to a number of other fields of linguistics and German studies.

Paul was certainly an influential figure in literary studies and textual criticism. His dissertation and *Habilitionsschrift* both dealt with questions of Middle High German literature. He authored a variety of articles on literary topics, ranging from the life of Hartman von Aue, an important Middle High German poet, to the question of whether a Middle High German literary language ever really existed. As to textual criticism, he was the founding editor of the *Altdeutsche Textbibliothek* [*Early German text library*], and edited three of the volumes of the series, all Middle High German texts. His *Mittelhochdeutsche Grammatik* [*Middle High German grammar*], first published in 1881 and republished many times (11 editions appeared in Paul's lifetime), remains a standard handbook in the field.

Paul's contributions to the study of Germanic phonology and morphology were also immense. He published a monograph-length article entitled 'Zur geschichte des germanischen vocalismus' ('On the history of germanic vocalism'), as well as articles on the vowels of the inflectional and derivational syllables in the oldest Germanic dialects and the ablative case in Germanic, among others. His most important work in this area is the five-volume *Deutsche Grammatik* (*German grammar*), described in his obituary as 'die einzige vollendete wissenschaftliche Grammatik der deutschen Sprache' ('the only completed scientific grammar of the German language').

Other areas of linguistics Paul contributed to include lexicography, syntax, word formation, and language pedagogy. He compiled a German dictionary, the *Deutsches Wörterbuch* (*German dictionary*), which remains in print today. Paul was also interested in the theoretical aspects of lexicography, publishing various essays on lexicographic topics (although the titles of these essays indicate that his main concern was with his German dictionary). As for syntax, Paul recognized its importance early on; his Middle High German grammar was one of the first such handbooks to include a section on syntax (although it must be admitted that this section was not in the first edition of the book; it was added to the 2nd edition, published in 1884). His work in word formation was generally an offshoot of his lexicographical work; he published an important article on word formation, 'Zur Wortbildungslehre' ('On the doctrine of word formation'), in 1896. Finally, a volume on language pedagogy, *Über Sprachunterricht* (*On language teaching*), was published posthumously in 1922.

Probably Paul's most significant contribution to linguistics was his work *Prinzipien der Sprachgeschichte* (*Principles of the history of language*), originally published in 1880. This volume rapidly became a standard handbook (five editions of the text were published during Paul's lifetime, along with an English translation of the second German edition), and proved to have a lasting influence on the field. It is notable not only for its incisive statements of many Neogrammarian ideas but also for its innovativeness, and is rewarding reading even today.

Finally, Paul's activities as an editor cannot be underestimated. Together with his friend and former fellow student Wilhelm Braune, Paul founded a journal, the *Beiträge zur Geschichte der deutschen Sprache und Literatur* [*Contributions on the history of the German language and [its] literature*], which is still generally referred to as the 'PBB', for *Paul-Braune Beiträge*. Paul served as coeditor of this journal for nearly 20 years, from 1874–1891, and was a consulting editor for 30 years after that. Paul was also the general editor of the *Grundriss der germanischen Philologie* (*Outline of Germanic philology*). Furthermore, as noted above, he was the founding editor of the *Altdeutsche Textbibliothek* (*Early German text library*), and edited three of the volumes of the series (listed above).

Despite his many contributions to the field, Paul is too often dismissed as 'merely' a historical linguist.

This viewpoint is entirely natural, since most of his work was on historical linguistics, and because of statements like the following, found in his *Prinzipien*: 'Es ist eingewendet, dass es noch eine wissenschaftliche Betrachtung der Sprache gäbe, als die geschichtliche. Ich muss das in Abrede stellen'. ['It has been claimed that there is another way to view language than the historical. I must object to this.'] On the other hand, it has also been claimed that Paul was much more than 'merely' a historical linguist. It has been argued that Paul was a forerunner of Structuralism; more specifically, that certain concepts found in the work of Ferdinand de Saussure, the well-known Swiss linguist who is generally viewed as the intellectual father of Structuralism (especially the distinctions between *synchrony* and *diachrony* and between *langue* and *parole*), were inspired by Paul's work (e.g. by his differentiation between individual linguistic acts and more general language use). The first of these viewpoints must be rejected; a closer reading of Paul's *Prinzipien* readily indicates that he was also interested in synchronic topics. The second of these viewpoints is probably also an overstatement. It is clear that de Saussure codified a number of ideas that were current linguistic theory at his time, but to trace the critical distinction between *synchrony* and *diachrony* to Paul, as some have, for example, is probably an exaggeration.

Regardless of these ideas, it is clear that Paul was an immensely important figure in linguistics. Paul played an extremely important role in the development of the Neogrammarian school of linguistics; he has been described by one historian of linguistics of the period as the Neogrammarians' 'most fertile and formidable theoretician', and his *Prinzipien* codified many aspects of Neogrammarian thought. More specifically, this same historian of linguistics (Kurt Jankowsky; the relevant work is cited under 'Further Reading' below) has argued that Paul's influence on his contemporaries can be traced by examining five major aspects of his work. First, Paul rejected the equation of linguistics to the natural sciences, suggesting that the term 'sound law' should not be understood as a 'law' is understood in physics and chemistry. Second, Paul distinguished between historical and comparative linguistics. Third, Paul was interested not only in *how* languages change, but *why* they do so. Fourth, Paul emphasized individual psychology over group psychology in his psychological approach to language. Fifth, Paul was deeply interested in linguistic geography, recognizing early on that a standard language is a convenient abstract fiction, made up of a variety of dialects and idiolects. A discussion of the place of the Neogrammarians in the history of linguistics is clearly beyond the scope of this entry, but their influence on linguistics, especially historical linguistics, was considerable. Numerous prominent linguists, in America and abroad, ranging from Leonard Bloomfield, the dean of American linguistics in the 1930s and 1940s, to William Labov, a prominent sociolinguist of today, were deeply influenced by Neogrammarian thought. Given the importance of the Neogrammarians, and Paul's importance within the group, his place in the history of linguistics seems assured.

Biography

Paul Hermann was born in Salbkempierc bei Magdeburg, Germany on, August 7, 1846. He attended the University of Berlin 1866–1867. He received a Doctorate (1870) for his dissertation on Freidank, Habilition (1872) for work on Gottfried's *Tristan*, University of Leipzig. He was Privatdozent in Leipzig in 1872–1874. He was also Professor of German, University of Freiburg im Breisgau, 1874–1893; Professor of German, University of Munich, 1893–1916; and Rektor, University of Munich, 1909–1910. He was a corresponding member of the Wissenschaftliche Akademie in Vienna in 1919–1921. Hermann died in Munich, Germany, on December 29, 1921.

Peirce, Charles Sanders

Charles Sanders Peirce was a most original and highly versatile American philosopher, logician, and scientist—by all standards, a veritable polymath. Son of Benjamin Peirce, a distinguished Harvard mathematician, Charles was born in 1839 and grew up in a family milieu that was most conducive to a promising career in academia. Yet, except for a brief period as a lecturer in logic at the Johns Hopkins University (1879–1884), Peirce never did any systematic teaching. He was a difficult person to get along with and the university refrained from renewing his contract on charges of personal misconduct. His most sustained employment was with the U.S. Coast Survey, where he worked for 31 years and made a successful career as a geodesist, until the termination of his appointment in 1891. Thereafter, he set up a private practice as a chemical engineer and, thanks to the intervention of his friend and admirer William James, was invited to give occasional series of lectures at Harvard. His last years were spent in penury and failing health.

Peirce is widely known as the founding father of Pragmatism, a distinctively American philosophical movement whose central tenet is that belief guides action. Our ordinary beliefs as well as more sophisticated doctrines are nothing but dispositions to act in certain ways and are to be judged by taking into account their practical consequences. Peirce therefore rejected much of metaphysics—i.e. claims about the ultimate reality of what there is—since no practical consequences necessarily follow from alternative metaphysical conceptions. He was averse to the sort of intuitive rationalism as advocated by Descartes and foundationalism as encapsulated in the Cartesian quest for first principles, as well as his celebrated 'Method of Doubt'. As he famously put it in an essay published in 1878 titled 'How to make our ideas clear,' truth is simply that opinion which is destined to be agreed to by everyone who is disposed to finding it and so-called reality is made up of the objects represented in that opinion.

The idea of truth as resulting from a convergence of opinion was interpreted by many of his followers to mean that there is no more to it than a matter of mere consensus. William James for one regarded truth as 'whatever proves to be good in the way of belief'. But it is clear from Peirce's later writings that he subscribed to an objectivist conception of reality—the idea that there is a reality out there that is independent of what anyone believed about it. As for his epistemology, Peirce rejected the Cartesian attempt to use self-knowledge as the doorway to knowledge about the world, arguing instead that all knowledge is fallible, although continuous inquiry makes it self-corrective. He also contended that the ultimate reality is mental, matter being nothing but 'effete mind', and that science provides us with the best method of arriving at it.

Along with the Swiss linguist Ferdinand de Saussure, Peirce is also widely looked upon as a founding father of semiotics (or 'semeiotic', as he himself preferred to spell it). Unlike Saussure who claimed the sign relation to be dyadic—involving a sign (signifier) and a referent (signified) Peirce insisted that it was irreducibly triadic and involved, in addition to the object and the sign, an interpretant (the interpreting thought or meaning). The sign, in Peirce's conception, mediates between its object and its interpretant, which are therefore its correlatives. Central to Peirce's thinking is the idea that language does not simply and unproblematically refer to a reality external to it; it does so by *representing* it. This means, he claimed, all of cognition is necessarily mediated by the process of sign interpretation or semiosis. Peirce also viewed semiotics as fundamentally a classificatory science, like chemistry and biology. Furthermore, signs are not restricted to the activity of the human mind but are of the order of nature itself and, in this too, he differed from Saussure, for whom 'semiology' was part of social psychology. Unlike Saussure too, Peirce saw semiotics as teleological, tending toward the truth of things as they really are.

Peirce was a meticulous system-builder and his mind worked typically by positing trichotomies. Building on his own triadic characterization of sign relation, Peirce initially distinguished three divisions of signs: based on the nature of the sign itself, the relation between the sign and its object, and the role of the interpretant in representing the object. In their turn, these three divisions harked back to three ontological categories: quality (firstness), relation (secondness), and representation (thirdness). The first division, the one based on the nature of the sign itself, yielded a three-way distinction among 'qualisign' (appearance), 'sinsign' (token), and 'legisign' (type). Under the second division, the one obtained by taking into account the relation of the sign to its object,

Peirce distinguished icons (that bear a certain resemblance to the object), indices (that signify by direct causal interaction with the object in question), and symbols (that are associated with their object via convention). Finally, under the third division, the one where the interpretant enters the picture, yet another triad was postulated: rhemes (predicative signs), prepositional signs, and arguments. The arguments were further divided into the three categories—abduction (hypothesis/diagnosis), deduction (tautological reasoning), and induction (generalization)—the first two leading to qualitative or conceptual understanding and the last providing important quantitative details to it.

Toward the end of his life, Peirce grew increasingly impatient with the way the word 'pragmatism' was being used (and, in his view, abused) by other writers including William James and John Dewey and, in 1905, in a paper called 'What pragmatism is' published *The Monist*, pleaded that the word 'pragmaticism' be used instead to refer to his own doctrine, and distinguished it from that of the others, adding that the neologism was 'ugly enough to be safe from kidnappers'. There followed two other papers (forming a trilogy): 'Issues of pragmaticism' (1905) and 'Prologomena to an apology for pragmaticism' (1906).

Peirce died in 1914, an almost forgotten man. Early commentators often described him as 'a wasp in the bottle', someone who constantly came up against formidable odds and did everything but avail himself of the only way out of his troubles. Starting with the last quarter of the twentieth century or so, however, there has been a resurgence of interest in Peirce's work and a widespread recognition of the importance of his views to such areas as epistemology, linguistics, anthropology, psychology, and cognitive science.

Biography

Charles Sanders Peirce was born on September 10, 1839 in Cambridge, Massachusetts (USA). In 1855, he entered Harvard College, graduating in 1859 and continuing as a 'resident graduate' for one year. The same year, he began his career as a field aid at the Coast Survey, specializing in geodesy and working his way up until being appointed an Assistant. He entered Lawrence Scientific School at Harvard in 1861 and two years later obtained a graduate degree in Chemistry. He delivered Harvard lectures on 'The Logic of Science,' in the spring of 1865 and Lowell Institute lectures on 'The Logic of Science; or Induction and Hypothesis,' October 24,–December 1, 1866. He was elected to the American Academy of Arts and Sciences on January 30, 1867. He was Assistant at Harvard Observatory, October 1869–December 1872 and was elected to the National Academy of Sciences on April 20, 1877. He was appointed lecturer in Logic at Johns Hopkins in 1879 and was dismissed on charges of misconduct in 1884. He was elected to the American Association for the Advancement of Science in August 1880. He purchased a farm near Milford, Pennsylvania on May 10, 1888; over the next two years, he reconstructed the existing farmhouse and bought more land, and named the estate 'Arisbe'. The manuscript of 'How to reason' was rejected by both Macmillan and Ginn Co (1894) and that of 'New elements of mathematics' was rejected by Open Court (1895). In 1902, a grant application for 'Proposed memoirs on minute logic' was rejected by Carnegie Institution. He gave lectures on 'Pragmatism' at Harvard March 26–May 17, 1903 and Lowell lectures on 'Some topics of logic' November 23–December, 17, 1903. He was invited to deliver the Harvard Philosophy Club lectures on 'Logical methodeutic' April 8–13, 1907. Peirce died at Arisbe on April 19, 1914, of cancer.

Personality and Language

Personality and language are two terms that suggest some promising interconnections, such as the likely effect of personality pathologies on speech, the effect of personality traits on the use of certain linguistic—especially discursive—patterns, or the influence of individual learner differences on the acquisition of a second language. The effect of language on the configuration of personality is apparent if we think of the lexical terms used in a given culture to refer to personality phenomena. The ways in which people describe their own or others' personalities and the fundamental influence of a person's speech style on others' perception of his or her personality are examples of the interrelationship of the two. Additionally, personality may be seen as a key factor in the construction of language and of the speech style of each individual.

Notwithstanding these areas of inquiry, we are still far from claiming any conclusive direct effect of one over the other. Not surprisingly, it is speech (i.e. the oral performance of language by a given speaker) that has been the primary focus of researchers interested in the links between language and personality. These researchers have generally avoided claiming strong connections between personality and language as a system and have instead claimed a relationship between speech style and personality features, either self-assigned by the speaker or attributed by listeners.

Psychological research on personality has not been extremely consistent in providing a clear model against which to test any possible mutual influences of language and personality. Existing models range from viewing the structure of personality as composed of one or two dimensions, to the three or five factors that are currently the most widely accepted models. In the 1990s, the so-called Five Factor Model gained popularity within the research community. This model was first proposed in the 1960s, but it started receiving wide attention and empirical support three decades later. However, it still has to be confirmed in studies involving non-Western societies, where a different categorization of personality traits may be more accurate. In Western societies, the model seems to provide a good account of personality structure with the following five factors: extraversion, agreeableness, conscientiousness, emotional stability, and openness (also referred to as intellect).

The existence of a predominant model may eventually clarify research questions on the interplay between language and personality, and significant advances in this area may be seen in the near future. So far, the most intensive attempts to explore the common ground between the two areas of research have been conducted by social psychologists and—to a lesser extent—second-language researchers. Research has been primarily focused on two issues.

The first issue is the effects of linguistic differences on the attribution of personality features by listeners, whose evaluation is based solely on speech. These studies started with the seminal work of Wallace Lambert and his associates. They found that listeners in Montreal rated the personality of a given speaker differently when he spoke in two distinct languages (i.e. French and English) and also that French-speaking listeners tended to assign personality traits to the speaker quite differently from English-speaking listeners. Other speech evaluation studies of evaluations assigned to Spanish and English speakers in the United States followed. Howard Giles and his associates explored the effect of different regional and social speech varieties on personality ratings. Their research uncovered stereotypes linked to speech differences, and it was very valuable precisely in demonstrating that laypeople's connections between language and personality are the result of previously existing stereotypes. In all cases, two factors were identified: a competence factor, which had to do with efficiency and high status in society; and a solidarity factor, which involved a high affective empathy with the speaker. A common result of most studies conducted so far has been that language varieties that enjoy high prestige and can be regarded as the varieties of the most powerful people tend to be not so well valued in terms of personal empathy, and vice versa. More recently, some attempts have also been made to connect personality ratings and nonnative proficiency, with provisional outcomes that also point at the important role that language variation may play in listeners' perceptions of a speaker's personality, with all the major subsequent consequences for interpersonal relations. This method of study is less subjective than self-reports or self-accounts of personality traits, which tend to be heavily mediated by the idea of what one would like to be like rather than what one really is or seems to be. Another positive aspect of attributions of personality by listeners is the fact that they are closely related to social stereotyping. Thus, the study of the influence of

speech style on personality evaluation leads to the uncovering of social stereotypes.

The second area of research that links language and personality is second language acquisition, particularly the role of different personality traits in the ultimate achievement of second language proficiency. Surveys conducted among second language teachers and students show that personality is considered to be a primary factor in second language achievement. Empirical studies have mainly focused on a single personality factor: extraversion. Extroverted people seem to be more successful in acquiring basic communicative abilities because of their willingness to interact with other people and search for communication opportunities. Introverts are less engaged in communicative interactions but may benefit from an increased attention to the formal aspects of language. On the whole, research has not found one type of learner to be inherently better than another, but personality profiles seem to affect the preferred path to learning and, therefore, the final outcome of the process.

Personality and language should be viewed as two uniquely human characteristics that are bound to interact; however, at this point, there is a need for much more research to investigate the relationship between the two.

Philippine Spanish Creoles

The Spanish-based Creoles in the Philippines developed after the Spanish conquest in the sixteenth century and are commonly known as Chabacano. Despite its despicable original meaning ('tasteless', 'vulgar'), this name is used by the speech-community as a self-designation. Alongside Papiamento and Palenquero in the Americas, Chabacano is one of the three Spanish-based Creoles worldwide. It shares interesting features with other European-based Creoles in Asia, a fact differentiating it from the Atlantic creoles. Further, unlike the latter, Chabacano has been acquiring a mixed character; especially from the twentieth century onward.

The total number of Chabacano speakers can be estimated at no more than 500,000. Geolinguistically, Chabacano can be divided into two main varieties: Manila Bay Creole and Southern Mindanao Creole. Dialects of the former are found on the northern island of Luzon and are spoken by relatively small communities in the towns of Cavite and Ternate, but the dialect of Ermita, a district of Manila, can now be regarded as extinct. Southern Mindanao Creole is spoken on the island Mindanao in the south of the archipelago. The highest degree of vitality of Southern Mindanao Creole, and of Chabacano generally, can be observed in the city of Zamboanga and the surrounding area in the extreme western part of Mindanao (approximately 300,000 speakers). Creole is also used here as a lingua franca by diverse ethnolinguistic groups. It is codified for public and private purposes with a hispanic orthography; there are bible translations, literary writings, and until recently press. Public oral use has recently been increasing, there is broadcasting in the language, and it is used in church and partially in school. A subvariety of Zamboangueño is

also spoken in the town of Cotabato; however, little is known about the vitality of the subvariety of Southern Mindanao Creole found in Davao.

The genesis and history of Chabacano, especially Zamboangueño, is somewhat complex due to different contact situations in time and space. Keith Whinnom (1956) suggested that Chabacano grew out of the Portuguese creole of the Indonesian island of Ternate, which had been transported to the Philippines in the seventeenth century. He considered Zamboangueño a layer of Manila Bay Creole. This theory was contested principally by John Lipski (1992), who affirmed a typical creolization of a Spanish-based pidgin with Tagalog influences for Manila Bay Creole. For the special case of Zamboangueño, he proposes a development of different stages from the eighteenth century onward: it arose in the garrison, absorbing elements from Manila Bay Creole later on. During the nineteenth century, Hiligaynon elements were introduced through contact from ships coming from Manila having made a stop in Central Philippines. Afterward, it was re-hispanicized by native speakers from Europe and Mexico who came to Zamboanga. It was also influenced by Cebuano, like Hiligaynon, a Visayan language, which was brought by large-scale immigration. From the 1930s onward, the influence of English and, after World War II, that of the national language Pilipino have been increasing, especially affecting the lexicon. Consequently, Zamboangueño does not fit into the classification of plantation, fort, and maritime Creoles; nor can the dichotomy of exogene and endogene Creoles adequately describe the situation of Zamboangueño. In contrast to the Atlantic creoles, slavery played a marginal role. Whatever the different theories on the origin of Chabacano, first documented in Hugo Schuchardt's *Kreolische Studien* (1883; Creole studies), in the beginning there was a pidginized form of Spanish used for intercommunication by different ethnic groups, namely, European Spaniards, Mexicans, West-Austronesian speaking groups, and Chinese immigrants. A pidgin created by the latter is still spoken by shopkeepers in Davao ('Bamboo Spanish').

The current structure of the language, especially concerning the vocabulary and word structure, is heavily influenced by Philippine languages. The sound system shows Philippine features like the merging of [o]/[u] and [e]/[i] in nonaccented syllables and the occurrence of the glottal stop. Some of the productive morphemes for word formation in Zamboangueño originally come from Spanish, and many are from Hiligaynon or Cebuano (e.g. the verbalizing prefix *man-*: *kwénto* 'story' → *man-kwénto* 'to tell' or the adjectivizing prefix *ma-*: *pwérte* 'strength' → *ma-pwérte* 'strong'). Their form is often identical to those of the source languages, but in many cases they have different functions. The word-formation system seems to be unusually complex for a Creole. The plural of nouns is marked with the particle *maga* (*el maga péhro* 'the dog*s*'). In Zamboangueño, first-person plural pronouns have a Philippine form encoding inclusion or exclusion of the addressee. The basic word order of V(erb)-S(ubject)-O(bject) stems from Austronesian contact, e.g. *man-čángge yo* 'I'm going shopping'. This is exceptional compared to other European-based creoles that are typically SVO. As in Philippine languages, human proper names in subject function are marked with *si* (*ta-kantá si Maria* 'Maria is singing'). Human and definite objects are obligatorily marked with *kon*, perhaps a merger of an Austronesian element and Spanish *con* 'with', (*konosé-le kon ese muhér* 'he knows that women'). There are many discourse particles of Philippine origin (e.g. *daw* for reported information). However, Chabacano also has features typical of Atlantic creoles, e.g. serial verb constructions (*pwéde asé salé* 'to be able to make to go out'), no syntactic passive construction, lack of an equative copula (*soltéro el hénte* 'the man is a bachelor'), identity of 'have' and 'there is' (both *tyéne*), and preverbal markers for tense, mood, and aspect (e.g. *ya-andá yo na Samboanga* 'I went to Zamboanga', *ta-kusiná le* '(s)he is cooking' and *ay-kantá silá* 'they will sing'). The lexicon principally consists of Spanish vocabulary (83%), with some Philippine (c. 15%) and English (2.5%) words. It can be assumed that, more recently, the influence of English has increased and that of Spanish has diminished. Very few words are of Portuguese origin (e.g. *gumitá* < port. *gomitar* 'to vomit'). The importance of Mexican input is shown by words like *čangge* 'market' < *tiangue* (a Mexican word of Nahuatl origin). Despite the close geographical contact with Zamboanga, the local languages, Tausug, Subanon, and Yakan have nearly no influence on the lexicon.

Philology

Etymologically, philology is the love of words (or, perhaps, the study of love). In the broadest sense, it covers everything having to do with the study of language—grammar, texts, history, civilization. Indeed, until a century or so ago, what is now called linguistics was simply part of philology, and even today, the term 'comparative philology' can still be found as a synonym for 'historical linguistics', especially within Indo-European studies. But here we should look at those branches of philology that have not been co-opted by (descriptive, historical, or theoretical) linguistics.

Thus narrowed, philology can be considered to be the study of texts, with all that implies: first, determining exactly what the author of a text actually wrote; then, determining what the author said; then, determining what the author meant. Correspondingly, a typical edition—whether of a book of the Bible, a play by Shakespeare, a novel by Joyce, or an inscription from an Indian temple—will contain the text itself, notes on every detail, and an interpretative commentary. Traditionally, the interpretative work of philology relies on the prior accomplishments of four subdisciplines: epigraphy, paleography, diplomatics, and textual criticism.

Epigraphy

Epigraphy is the study of inscriptions on hard material, such as stone and metal. People have been carving important texts into walls for as long as they have been writing—in Egypt, Mesopotamia, China, Anatolia, Greece, Arabia, Rome, Iran, India, Inner Asia, and Mesoamerica, in rough chronological order—and often such inscriptions are the only surviving written evidence of past civilizations. Sometimes they are official decrees, and by reading between the lines we can learn much about the societies that prompted them. Sometimes, as is almost exclusively the case with

Etruscan, they are funerary commemorations, from which we learn only of family relationships.

The task of the epigrapher is to record inscriptions accurately (and photography can rarely substitute for the sharp eye and steady hand of the draftsman), to publish them first promptly and then systematically, and to provide such tools as charts of letter forms that will assist in the interpretation of newly discovered inscriptions. A separate branch of epigraphy is numismatics, the study of coins and their inscriptions.

Paleography

Paleography is the study of manuscripts, written with pen or brush and ink on flexible material, namely papyrus, skin, or paper; textiles, wood, or leaves. These are perishable materials, so only rarely have they survived from more than a few centuries ago. The exceptions are due to extremely dry climates, as near the Nile and Jordan Rivers, areas where thousands of Egyptian papyri and the Dead Sea Scrolls have been found. In extremely rare cases, careful curatorial attention has preserved precious documents for a thousand years or more, but our knowledge of ancient texts results far more from a continual tradition of copying than from ancient attestations. (The tradition was fairly quickly superseded by printing beginning c. 1450.)

The paleographer's job is primarily to study the development of handwriting over generations of copyists, using dated manuscripts to anchor changes in stylistic trends and exercising judgment in assigning undated ones to this or that range of dates—although it must be recalled that any individual scribe's hand will not change much over their professional career, so a date based strictly on paleographical grounds cannot be more precise than within a generation or so. There are as many fields of paleography as there are scripts with manuscript traditions—cuneiform, Egyptian, Chinese,

Greek, Latin, Indian, Southeast Asian, etc. (there are no general surveys of world paleography outside histories of writing like Diringer (1968) and Jensen (1969); Urry (1974) considers only Greek and Latin).

Diplomatics

Diplomatics is the study of the form of documents. Its principal concern is detecting forgeries, so it deals principally with the physical properties of manuscripts and is the aspect of philology farthest removed from linguistics.

Textual Criticism

Textual criticism is the study of the history of the content of texts. Whenever a scribe makes a copy of a manuscript by hand, however carefully, mistakes are introduced. If a work was popular, many copies would be produced, and copies of copies, and so on, every one of them differing very slightly from all the others. By noting the correspondences among the differences in different copies, the chain of transmission can be reconstructed, and even if the author's original manuscript has not survived, it may be possible to reconstruct the author's original text with considerable certainty, with successive changes being removed.

Different scribal traditions handle the problem of scribal error in different ways. The rabbis who codified the text of the Hebrew Bible, known as Masoretes, did things like counting the number of words and even letters in each book. Scribes in the Islamic tradition included elaborate COLOPHONS in their manuscripts, naming not only the scribe and the date and circumstances of copying (as is often found elsewhere) but also a full list of all intervening scholar/copyists back to the original author. And Chinese scribes sometimes bypassed the problem by making copies of major works by printing them off woodblocks or even stone inscriptions of the texts, thus coming full circle in the fields of philology.

An interesting offshoot of textual criticism is that it is often possible to determine that a given text has been translated from another language, and that other language identified with considerable certainty. Thus, R.H. Charles was able to say of the Book of Enoch, which was known in full only in Ge'ez, with fragments surviving in Greek and Latin, that portions—chapters 1–5 and 37–104—were originally written in Hebrew, and chapters 6–36 were originally written in Aramaic (1912:lvii–lxx). Decades later, fragments of the Aramaic original were identified among the Dead Sea Scrolls.

Decipherment

The philological task most relevant to linguistics is the decipherment of disused scripts. Usually, these are brought to light by archeological excavations. Rarely, the unfamiliar inscription is accompanied by an inscription in a familiar script and language, and it can be assumed that the texts are at least roughly equivalent. This state of affairs is known as a BILINGUAL, and both the first decipherment, of the Aramaic language Palmyrene by Jean-Jacques Barthélemy in 1754, and the best known, of Egyptian hieroglyphics by Jean-François Champollion in 1822, involved bilinguals, although these two accomplishments were vastly different in difficulties. Pope (1999) includes detailed descriptions.

When no bilingual is available, the ingenuity of the philologist is required to discover a VIRTUAL BILINGUAL. The most challenging, and for its impact on our understanding of human history the most important, decipherment was of CUNEIFORM. Late-eighteenth-century travelers brought back to Europe drawings of inscriptions they found at the ruins of the capital of the Persian Empire, Persepolis, which was destroyed by Alexander in 330 BCE. Each inscription was in three different scripts, which were assumed to represent the same content in three languages (hence, they are called TRILINGUALS), but none of the scripts was familiar. The characters in all of them were composed of incised wedges (*cuneus* in Latin), whence the name.

The first success in interpreting cuneiform came in 1802. A German high school teacher, Georg Friedrich Grotefend, surmised that because the simplest of the three scripts always appeared in the most prominent position among the three, it probably wrote the ancient Persian language of the Empire. A few years earlier, the Frenchman Antoine Isaac Sylvestre de Sacy had deciphered royal inscriptions of a successor Iranian empire, the Sassanian, finding that they usually began with a genealogy in the form 'X, great king, son of Y, great king ….' Grotefend knew the names of the kings—Darius, Xerxes, and so on—from the Greek *Histories* of Herodotus and sought similar formulas at Persepolis. He soon found the expected recurring patterns in the inscriptions, and although he himself was not an Iranian philologist, his breakthrough discovery made it possible for specialists like the Danes Christian Lassen and Rasmus Rask to determine the basics of Old Persian. Edward Hincks, a Church of Ireland (Anglican) clergyman, showed that each of the 36 characters of Old Persian script represented a Consonant–Vowel (CV) syllable.
